### **Phase III KATHERINE Clinical Trial Crossed Early Reporting Boundary and Met its Primary Endpoint**

*Adjuvant T-DM1 improved invasive disease-free survival (IDFS) in patients with HER2-positive early breast cancer with residual invasive disease at surgery following neoadjuvant chemotherapy and trastuzumab*

SAN ANTONIO — Substituting trastuzumab emtansine (T-DM1, Kadcyla) for adjuvant trastuzumab (Herceptin) in patients who had residual disease after receiving neoadjuvant chemotherapy and trastuzumab reduced the risk of developing an invasive recurrence of HER2-positive early-stage breast cancer by 50 percent, according to data from the phase III clinical trial [KATHERINE](#) presented at the 2018 [San Antonio Breast Cancer Symposium](#), held Dec. 4–8.

“HER2-positive breast cancers account for about 15 percent of all breast cancers, and patients presenting with larger tumors or tumors that have spread to axillary lymph nodes are generally treated with chemotherapy and HER-targeted therapy with trastuzumab, more recently combined with pertuzumab (Perjeta) as well. Patients found to have no residual cancer at subsequent surgery have a favorable prognosis with relatively low risk for recurrence,” said [Charles E. Geyer, Jr., MD](#), professor of medicine at Virginia Commonwealth University School of Medicine; associate director for clinical research and Harrigan, Haw, Luck Families Chair in Cancer Research at Massey Cancer Center in Richmond, Virginia. “However, patients with residual invasive cancer in the surgical specimen have a substantially less favorable prognosis with a higher risk for recurrence, and are in need of more effective therapies.”

The goal of the KATHERINE trial was to determine if treating patients at higher risk for recurrence following neoadjuvant therapy (based on the finding of persisting invasive breast cancer at surgery) with the antibody-drug conjugate T-DM1 instead of the standard therapy of trastuzumab would reduce the risk of recurrence without an unacceptable increase in toxicities, Geyer said.

“We found that T-DM1 reduced the risk of developing an invasive recurrence of the breast cancer or death by 50 percent, corresponding to an absolute improvement of three-year invasive disease-free survival (IDFS) rate by 11.3 percentage points (77 percent with trastuzumab and 88.3 percent with T-DM1),” Geyer noted.

“The large benefit was seen consistently across all of the important subgroups of patients including those with both hormone receptor-positive and -negative tumors, the amount of residual disease at surgery, patients with disease-negative lymph nodes and minimal amounts of cancer remaining in their breast, single or dual HER2-targeted therapy in the neoadjuvant regimen, and baseline patient characteristics such as age, menopausal status, and racial groups,” Geyer said.

“I believe these results will be practice-changing,” Geyer said. “The results should form the foundation of a new standard of care in patients with residual invasive breast cancer following neoadjuvant therapy. KATHERINE demonstrates that neoadjuvant therapy can be used to identify patients at increased risk for recurrence based on less than optimal response to standard neoadjuvant therapies who can benefit by switching to T-DM1.”

T-DM1 is currently approved by the U.S. Food and Drug Administration to treat patients with metastatic HER2-positive breast cancer following previous treatment with trastuzumab and a taxane type of chemotherapy.

KATHERINE is an open-label study of 1,486 patients with HER2-positive early-stage breast cancer who received neoadjuvant chemotherapy plus HER2-targeted therapy that included a taxane and trastuzumab, followed by surgery. All patients had residual invasive disease in the breast or axillary lymph nodes. Within 12 weeks of surgery, patients were randomly assigned 1:1 to T-DM1 (3.6 mg/kg IV every three weeks) or trastuzumab (6 mg/kg IV every three weeks), for 14 cycles. The primary endpoint was IDFS.

IDFS events (events of disease recurrence or death without recurrence) occurred in 12.2 percent of patients in the T-DM1 arm, compared with 22.2 percent in the trastuzumab arm. Secondary efficacy endpoints of disease-free survival and distant recurrence-free interval also demonstrated clinically meaningful reduction in events with T-DM1 relative to trastuzumab. Additional follow-up will be needed to determine the effect of adjuvant T-DM1 on survival.

The side effects in KATHERINE were similar to what occurs when T-DM1 is used for treating patients with metastatic disease, Geyer noted. Side effects included drops in platelet count, sensory neuropathy, and elevations in liver enzymes, with the majority of these toxicities being grade 1 or 2, and resolved following reduction of the dose of T-DM1 or discontinuation.

A potential limitation of KATHERINE was the decision to preferentially perform central confirmation of positive HER2-status on the pretreatment core biopsy of the primary tumor rather than the residual tumor, Geyer said. “Paired specimens from over two-thirds of KATHERINE patients have been collected and further analyses to define the rate of HER2-loss in the post-surgical specimens and the activity of T-DM1 in these patients are planned,” he added. “The paired specimens will also facilitate further analyses to define potential resistance mechanisms to neoadjuvant chemotherapy and trastuzumab, as well as adjuvant T-DM1.”

This study was supported by F. Hoffmann La Roche/Genentech. Geyer serves (uncompensated) on breast cancer advisory boards for F. Hoffmann La Roche/Genentech and receives travel reimbursement.

**About SABCS**

Since 1977 the San Antonio Breast Cancer Symposium® (SABCS®) has been the leading scientific conference for basic scientists, physician-scientists, clinical investigators and breast care providers, and advocates seeking an exchange of new information in experimental biology, etiology, prevention, diagnosis, and therapy of premalignant breast disease and breast cancer. Founded, owned, and operated by UT Health San Antonio, the symposium has grown to a five-day event attended by an international audience of academic investigators and private physicians from over 80 countries to attain information through abstract presentations, panel discussions, research findings, and state-of-the-art educational sessions. UT Health San Antonio, with co-sponsors the Dan L Duncan Comprehensive Cancer Center at Baylor College of Medicine and the American Association for Cancer Research, supports SABCS, which provides education and accessibility to the latest information regarding the prevention, diagnosis, and treatment of premalignant breast cancer and breast disease.
