The stromal compartment plays a pivotal role in tumor progression. This is best illustrated in breast cancer bone metastases, where the stromal compartment supports tumor growth, albeit through poorly defined mechanisms. p38MAPK α is frequently expressed in tumor cells and surrounding stromal cells and its expression levels correlate with poor prognosis. Using clinically relevant breast cancer metastasis models, we show that orally administered, small-molecule inhibitors of p38MAPK α or its downstream kinase, MK2, each limited outgrowth of metastatic breast cancer cells in the bone and visceral organs. Further we found that this effect is mediated by inhibition of the p38MAPK α pathway within the stromal compartment. Beyond effectively limiting metastatic tumor growth, we also found that these inhibitors reduced tumor-associated and chemotherapy-induced bone loss, which is a devastating comorbidity for cancer patients that drastically impacts their quality of life. Mechanistic studies revealed that p38MAPK α 's ability to limit tumor growth within the bone is dependent on CD4 T cells and macrophages. To determine which cell types within the bone contribute to tumor growth and bone loss, we carried out single cell RNA-sequencing of stromal cells located within the bone metastatic lesion and cells outside the lesion. We found numerous differences that could explain how the stromal compartment contributes to tumor progression and bone loss and how inhibition of p38MAPK α or MK2 contribute. These data underscore the vital role stromal-derived factors play in tumor progression and identify the p38MAPK-MK2 pathway as a promising therapeutic target for metastatic disease and prevention of tumor-induced bone loss.

Drug tolerant Persister cells in cancer

Joan S. Brugge

Despite favorable initial response to therapy, many cancer patients develop recurrent disease and succumb to it within five years of diagnosis. While there has been much progress in characterizing the pathways that contribute to stable genetic drug resistance, non-genetic mechanisms have recently emerged as important drivers of therapy failure in cancer. In my presentation, I will discuss different types of non-genetic, reversible mechanisms that confer therapy resistance, those involving immediate adaptive responses to stresses associated with therapies, and the other states associated with longer term persistence. I will include a discussion of strategies to target the vulnerabilities associated with each of these adaptive responses.

An understanding of how and why somatic mutations accumulate is required to shed light on cancer evolution. DNA replication during each cell cycle is an essential and highly regulated process that ensures the correct duplication of the entire genome. The timing of DNA replication has been indirectly linked to mutation acquisition and genome instability. However, the extent and the importance of altered replication timing (ART) from normal to cancer cells, and whether this process directly influences mutation acquisition during cancer evolution, have not been explored. Here we evaluated the impact of ART by analysing data from 1271 whole-genome sequenced lung (100,000 Genomes Project ¹) and breast (560 breast cancer genomes from Nik-Zainal et al. ²) tumours, together with replication-timing sequencing data of multiple cancer and normal cell lines. We find that 6%-18% of the genome is subject to ART in cancer cells. Genomic regions subject to a shift from early to late replication in cancer cells exhibit an increased mutation rate in tumours and are associated with distinct mutational signatures compared to unaltered early replicated regions. In particular, we identify APOBEC3-mediated mutation clusters (omikli events) in unaltered early and late-to-early ART regions, associated with the acquisition of driver mutations. We demonstrate that ART is a relatively early event during the evolution of breast cancer and lung adenocarcinomas. Finally, genes replicated early in cancer but late in normal cells exhibit an up-regulated expression in tumour samples. The incorporation of single-cell DNA sequencing further enables accurate identification of proliferation rates. Taken together, replication timing alterations during malignant transformation are prevalent in cancer and significantly impact the genomic and transcriptomic landscape during tumour evolution.

How to measure and improve drug adherence in clinical trials

Presenting Author(s) and Co-Author(s):

Dawn Hershman, MD, MS, FASCO - *Columbia University*

City: New York, NY

Country: United States

The past decade has seen a dramatic increase in the number of Food and Drug Administration approval of oral anti-cancer drugs (OACDs). In 2018 alone, OACDs comprised ten of the sixteen newly approved oncology therapeutics in the United States. Despite the clinical benefits and convenience of OACDs, these new oral options present potential challenges, including polypharmacy, and can result in increased toxicities, drug–drug interactions (DDIs), inappropriate consumption of medications, and medication non-adherence. Adverse drug events have the potential to affect quality of life, healthcare utilization, treatment response, and survival.

For the treatment of breast cancer, Endocrine therapies have remained a critical component of care for early stage and advance disease. Despite the proven efficacy adherence to therapy is suboptimal. Issues related to non-adherence are increasingly important, as analyses from prospective randomized trials show compliance to endocrine therapy is associated with improved disease-free survival. The reasons for non-adherence to hormonal therapy are multifactorial. Barriers to compliance include patient, physician, medication and system related variables and poor compliance is usually associated with a combination of these factors. Characteristics associated with non-adherence include very high and low age, minority race, being single, increased number of comorbidities, lack of knowledge about efficacy of AI therapy, history of non-adherence to other chronic medications, limited insurance status, and higher out of pocket costs. Side effects from hormonal therapy is the most common reason for early discontinuation. An understanding of factors that contribute to non-adherence and interventions that have been tested to improve adherence will be discussed.

Medication compliance has become a more salient issue in cancer care with the increased availability of oral antineoplastic therapies for breast cancer. The treatment of BC now routinely encompasses targeted therapies such as oral poly(ADP-ribose) polymerase (PARP) inhibitors and cyclin-dependent kinase 4 (CDK4) and CDK6 inhibitors, PI3 Kinase(PI3K) Inhibitors, in addition to traditional ET. Furthermore, as advances in BC treatment have improved long-term prognosis, the management of other chronic conditions has become an essential component of BC survivorship care. It remains unclear how this increased oral medication burden on BC survivors affects compliance with both ET and other chronic medications. Issues related to adherence measurement will be discussed.

This education session will review early palliative care in oncology and applications in patients with metastatic breast cancer. This presentation provides an overview of the field of research in early palliative care for patients with advanced solid tumors and discusses considerations specific to breast cancer. The speaker will present current challenges that we face in integrating palliative care into our practice and future areas for clinical innovation and research in palliative care. The speaker will present practical tips for how breast oncologists can deliver early palliative care to patients. The speaker will present guiding principles on when to consider referral to interdisciplinary, specialty palliative care.

Support for patients with MBC

Presenting Author(s) and Co-Author(s):

Abbey Kaler, MS, APRN, FNP-C - *UT MD Anderson Cancer Center*

City: Houston

State: TX

Country: United States

Over the last decade we have witnessed rapid advances in the treatment of patients with metastatic breast cancer (MBC) with seminal discoveries in cancer biology, correlative biomarkers and clinical trials leading to multiple new drug approvals. While these milestones have improved survival, the science of survivorship in this population is just beginning. The diagnosis of MBC is life-changing and requires individualized and multidisciplinary support. The NCI defined the areas of epidemiology and surveillance, symptom management, psychosocial research, health-care delivery, and health behaviors as necessary fields to advance the state of the science in advanced cancer survivors. A multifaceted program addressing these domains is needed to assess MBC patients and their unique and ever-changing needs. With input from patients and providers, program components should include: therapeutic clinical trials, multidisciplinary specialty care, individualized patient navigation, peer support, continuing education, and patient reported outcome (PRO) collection to support patients living with MBC. Input for a program for MBC patients can be guided by a multidisciplinary steering committee in which patient advocates are a major voice. Patients can provide insight into what works for them, and what they are facing may be very different from the experience of an early-stage breast cancer patient.

Clinical trials designed to advance the current scientific knowledge of breast cancer treatment are essential to patients living longer, more fulfilled lives with MBC. Clinical trials may include systemic therapy, local therapies such as surgery and radiation for MBC patients, side-effect management and quality of life (may put elsewhere). A comprehensive systemic therapy portfolio should include all biological subtypes as well as recommended treatment options (hormonal therapy, targeted therapy, chemotherapy, and immunotherapy).

Multidisciplinary care is necessary to diagnose and treat any condition the MBC patient may encounter and is essential in providing quality care. Comorbidities and debilitating side effects arising from cancer treatment are known to be associated with inferior outcomes. MBC patients may experience lack of familiarity of some providers with novel MBC cancer treatment, side effects, and interactions of their cancer treatment with non-cancer conditions and treatment. With the increasing life expectancy of MBC patients, it is important to manage the medical comorbidities in coordination with the MBC patient's cancer treatment. Integrative Medicine helps support the quality of life of patients through providing clinical modalities such as stress management, yoga, meditation, acupuncture, massage and lifestyle counseling. Supportive care helps support cancer related fatigue and sleep challenges, geriatrics and hospice and palliative care for advanced cancer patients.

The role of navigation for MBC patients is unique and should be designed to support the patient's many individual needs. Navigation requires assessment of individual knowledge deficit, coordination of care challenges, internal resource utilization, cultural requests, and emotional health. Navigation should also address the patient's financial and disability questions, medication assistance, symptom management, advanced care planning and goals of care

discussions. Additional items to be discussed during navigation visits include primary care provider utilization, COVID-19 vaccination, illness and medication questions, and other patient questions as they arise.

A comprehensive registry of MBC patient's medical records and histories will assist researchers in designing future therapeutic and quality of life clinical trials. The categories of patient demographics, clinical variables, pathological variables, treatment variables, outcomes of MBC, and PROs will create a robust registry. A comprehensive patient registry can create a rich database which can guide and inspire future innovative research.

Peer support through support groups and peer-to-peer matching is pivotal to MBC patients finding and utilizing their patient voice, emotionally supporting each other and learning from other's similar experiences. Connection between patients and the creation of a community of survivors can empower patients to positively impact their care through self-advocacy and self-efficacy.

Continuing patient education is also essential to providing quality cancer care. The format of a weekly virtual education webinars are helpful in creating an engaged patient community and a platform to disseminate educational resources in a reoccurring digestible format. Frequent educational webinars covering a wide variety of topics can positively influence patient interactions with their healthcare providers and influence how patients living with MBC view their own cancer experience. Educational webinars provide opportunities for patients to connect with subject matter experts, other patients like themselves, and share information with their family and friends. Informed patients can discuss and ask questions more confidently with their health care providers about information and services presented during the educational webinars.

The symptom profile of patients living with MBC are impacted by numerous variables such as disease burden, treatment plan, comorbidities, supportive regimen etc.. The collection of PROs has been shown to improve patient satisfaction with his/her care, improve quality of life, decrease emergency room visits and hospitalizations, and increased overall survival. The routine measurement and management of MBC patients' symptoms has been found to be integral in providing comprehensive cancer treatment. The collection of PROs improves patient and provider communication and elicits the outcome to symptoms that matter most to each patient.

Patients diagnosed with MBC are living longer because of the recent advancements in therapeutic treatments. A multifaceted and comprehensive program consisting of therapeutic clinical trials, multidisciplinary specialty care, individualized patient navigation, peer support, continuing education, and PROs collection is integral to fully support patients living with MBC.

Financial toxicity

Presenting Author(s) and Co-Author(s):

Fumiko Chino, MD - *Memorial Sloan Kettering Cancer Center*

City: New York

State: New York

Country: United States

People with cancer spend more out of pocket for medical care than others with chronic diseases, a pattern that persists years after initial cancer diagnosis and treatment. Patients and their families are at risk for financial toxicity including problems paying medical bills, increased stress and/or symptom burden, and delaying or forgoing care due to costs. In this talk, Dr. Fumiko Chino provides an overview of financial toxicity in cancer care and its real-life impact on people with cancer. Factors contributing to financial toxicity are addressed as well potential solutions.

1. Define financial toxicity as a negative consequence of cancer diagnosis/treatment
2. Describe effects of financial toxicity on quality of life, adherence, and outcomes
3. Name potential solutions to financial toxicity on a health system, provider, and patient level

Contralateral mastectomy in patients with germline mutations

Presenting Author(s) and Co-Author(s):

Katharine Yao, MD - *Northshore Medical Group*

City: Evanston

State: IL

Country: United States

The educational session titled "Contralateral mastectomy in patients with germline mutations" will cover contralateral mastectomy in affected gene carriers. The session will first cover trends in contralateral mastectomy in germline mutation carriers and the impact of genetic testing on contralateral mastectomy utilization. Second, the session will review guidelines on contralateral mastectomy for gene carriers. Literature on potential beneficial impacts of contralateral mastectomy for gene carriers will be reviewed. Impact to contralateral risk, survival outcomes and patient quality of life will be examined. Lastly, the session will review new surgical approaches for prophylactic mastectomy and protocols to reduce pain and enhance recovery after mastectomy.

RT: How short can it be

Presenting Author(s) and Co-Author(s):

David Krug, Dr Med - *Universitätsklinikum Schleswig-Holstein*

City: Kiel

Country: Germany

Adjuvant whole-breast radiotherapy for breast cancer has traditionally been delivered over the course of 5 weeks. In the past decades, there has been a paradigm shift towards moderate hypofractionation with 15-16 fractions over 3 weeks based on randomized controlled trials demonstrating comparable oncological safety, decreased acute toxicity and similar long-term toxicity compared to conventional fractionation. More recently, ultra-hypofractionated whole-breast radiotherapy delivered with 5 fractions over 1 week or 5 weeks has been introduced into the clinic. Furthermore, the increasing use of partial-breast irradiation with a de-escalation of the target volume to the region of the lumpectomy cavity has further allowed acceleration of radiotherapy delivery for patients with breast cancer. This lecture will summarize recent advances and data on hypofractionation for breast cancer.

11:20 AM - 12:00 PM

How to reconcile novel reconstructive techniques with the need to radiate

Presenting Author(s) and Co-Author(s):

Christine Solbach, MD, PhD - *University Hospital Frankfurt*

City: Frankfurt

Country: Germany

The indication for postmastectomy radiotherapy (PMRT) is mainly based on tumor stage and the extent of lymph node involvement. The results of EBCTCG meta-analysis (EBCTCG Lancet, 2014) support the need of radiation therapy (RT) for patients with one to three axillary metastatic lymph nodes (LN), as well as for patients with > 3 affected LN.

In nearly 40% of patients with mastectomy (ME) RT is required. According to the plastic surgery statistics report 2020 approximately 80% of patients seeking breast reconstruction in the USA receive an implant-based breast reconstruction (IBBR), while 18% undergo autologous reconstruction (ASoPS 2020). PMRT, regardless of reconstructive method, has been found to have a detrimental effect on outcomes with increased postoperative complications and decreased patient satisfaction. Nevertheless, even in this cohort the number of breast reconstruction (BR) is increasing over time. Surgical techniques for ME and BR are advancing constantly. With the increasing use of skin-sparing ME (SPM) techniques, particularly nipple-sparing ME (NSM), one stage IBBR (single-stage direct-to-implant, DTI) become more popular. With the availability of supportive materials such as synthetic/biological mesh or acellular dermal matrix (ADM) there has been a significant improvement in pre-pectoral implant reconstruction. The impact of PMRT on the outcomes of pre-pectoral IBRR has been recently summarized in a systemic review and meta-analysis by Awadeen (Aesth Plast Surg, 2022). Wound infection, capsular contraction and implant loss were significantly more frequent in the irradiated than in the non-irradiated breasts. Several studies describe the delayed/2-stage IBBR in the setting of PMRT as more promising and discuss different timings of exchange from expanders to implant. In one systematic review, PMRT to permanent implants reduced the rate of reconstructive failure compared to TE (J Surg Oncol,2015). After prosthetic-based BR and RT, conversion to autologous reconstruction can always be considered. Recommendations for immediate autologous reconstruction vary when PMRT is required. PMRT can result in wound complications, fat necrosis and volume loss, but overall cosmetic results are better than with IBBR and PMRT. When undergoing delayed reconstruction after PMRT, the optimal time from PMRT to reconstruction is unknown. In patients with a history of RT, NCCN-guidelines (V.4.2022) recommend autologous reconstruction as the preferred reconstruction option. Fat grafting, which can optimize tissue perfusion and wound healing, is playing an emerging role in breast surgery. Lipofilling can be used to improve the thickness of the mastectomy flap and to recontour breast defects after PMRT. There is an increasing awareness for better understanding of the different reconstruction types to define target volumes depending on the varying risk for residual tissue and potential recurrences. The ESTRO-ACROP guidelines discuss adapted dose distribution in accordance with the different locations of the implant (pre- or sub-pectoral) (Radiotherapy and Oncology, 2019).

The risks and benefits of immediate versus delayed as well as implant-based versus autologous reconstruction must be considered for each individual patient and should be planned in a multidisciplinary setting, especially when PMRT is required.

Pol-theta inhibitors in HRD tumors

Alan D. D'Andrea, M.D.

Center for DNA Damage and Repair, Dana-Farber Cancer Institute, Boston, MA, USA.

Susan F. Smith Center for Women's Cancers, Dana-Farber Cancer Institute, Boston, MA, USA.

Deficiency of homologous recombination (HR)-mediated DNA repair occurs through genetic or epigenetic inactivation of the BRCA1 and BRCA2 (BRCA1/2) genes, and it plays a role in the initiation and progression of many tumor types. HR-deficiency also provides unique opportunities for targeted therapy, as exemplified by the extreme sensitivity of BRCA1/2-mutated tumors to poly (ADP-ribose) polymerase inhibitors (PARPi). In the last decade, several PARP inhibitors have been approved for clinical use. At first, PARPi were solely used in combination with chemotherapeutics, and platinum sensitivity was used as a surrogate marker of HR-deficiency for enrolling patients for treatment. The promising clinical response of patients with germline BRCA1/2-mutations prompted the use of PARPi for patients with somatic BRCA1/2 mutations as well. In addition, it also opened the possibility for extended use of PARPi for the treatment of various types of ovarian, breast, pancreatic and prostate tumors with HR defects. PARPi efficacy is currently being evaluated in different clinical settings such as first line chemotherapy, neoadjuvant therapy, and combination therapy with chemo- or immuno-therapies.

Despite initial sensitivity to PARPi, resistance to these drugs is emerging as the major obstacle to its clinical effectiveness in patients with HR-deficient tumors. PARPi resistance can result from several independent mechanisms, often leading to the restoration of Homologous Recombination and/or Replication Fork stabilization. In addition, resistance to PARPi often correlates with platinum resistance, which remains the backbone therapy for most BRCA1/2-mutated tumors. The absence of alternative therapeutic options for patients with tumors with innate or acquired resistance underlines the urgency to develop additional therapeutics. While several mechanisms of PARPi resistance have been described, an effective method for overcoming such resistance is still lacking.

DNA polymerase theta (POL θ or POLQ) recently emerged as a new promising drug target for the treatment of HR-deficient tumors. POL θ expression is particularly high in subtypes of breast and ovarian tumors with defects in HR, where it mediates backup DNA double-strand breaks (DSBs) repair, thus compensating for the loss of HR. As a result, POL θ is synthetic lethal with HR, and POL θ inhibition in HR-deficient tumors induces cell death. In addition, POL θ inhibition synergizes with PARPi in the killing of HR-deficient tumors.

Synthetic lethality between HR-deficiency and POL θ inhibition hinges on several functions of POL θ . The enzyme maintains genomic stability and prevents tumorigenesis. It is a crucial enzyme in the mutagenic microhomology-mediated end joining (MMEJ) repair of DSBs, a pathway that plays critical role in genomic stability. Inhibiting PARP1, a key enzyme in MMEJ, prevents POL θ recruitment to sites of laser micro-irradiation. Since POL θ inhibition and PARPi have additive effects on HR-deficient cells, these data suggest that POL θ also functions outside the PARP-mediated MMEJ pathway and in pathways that are critical to the survival of HR-deficient cells.

POL θ is a large protein that contains 3 domains and is structurally and functionally distinct from other polymerases. The N-term contains a helicase-like ATPase domain that can unwind several types of DNA structures, while the central domain binds RAD51, displaces RPA proteins from resected DSBs, and antagonizes HR repair in an ATP-hydrolysis dependent manner. Finally, the C-term contains a nuclease domain which trims DNA ends and a polymerase domain that fills in nucleotides during MMEJ. Both the ATPase and polymerase domains are required for MMEJ repair.

POL θ has several functions that preserve genomic stability, and POL θ -mediated MMEJ repair can compensate for the loss of HR. It remains unclear which of the many functions of POL θ underlies the synthetic lethality with HR. Nevertheless, POL θ exhibits unique features of druggability, providing a strong rationale for developing POL θ inhibitors.

We have recently performed a small-molecule screen for inhibitors of POL θ ATPase activity and identified the antibiotic novobiocin (NVB) as a specific and potent inhibitor of human POL θ . NVB binds to purified POL θ protein, prevents its recruitment to DNA damage, and inhibits MMEJ repair. Importantly, we have shown that NVB selectively kills HR-deficient (BRCA1- and BRCA2-deficient) cells over wild-type cells and potentiates the cytotoxic effect of PARPi in HR-deficient tumor cells *in vitro* and *in vivo*. Moreover, NVB kills HR-deficient, PARPi-resistant tumor cells. These results suggest that NVB can be used alone or in combination with PARPi for treating HR-deficient tumors, even after they have acquired PARPi resistance. Accordingly, clinical trials have now been initiated for the use of NVB in the management of these tumors.

Mechanisms of sensitivity and resistance to HRD targeting agents in breast cancer – PARPi and beyond

Presenting Author(s) and Co-Author(s):

Christopher Lord, MD - *Institute of Cancer Research*

City: London

Country: United Kingdom

Although PARP inhibitors (PARPi) deliver significant and sustained anti-tumour responses in those with HR defective cancers, PARPi resistance is a common clinical phenomenon and limits the overall effectiveness of these agents. I will discuss how reversion mutations in BRCA1 and BRCA2 cause PARPi resistance and how the emergence of reversions might be targeted by immune responses against the neopeptides caused by reversion mutations. I will also discuss how other mechanisms of PARPi resistance such as 53BP1/Shieldin complex dysfunction could be targeted by evolutionary “double binds” using drugs such as Pol-theta inhibitors that exploit new vulnerabilities put in place by emerging PARPi resistance mechanisms

12/6/2022

ATR inhibitors and PARP1 selective PARP inhibitors

Presenting Author(s) and Co-Author(s):

Andrew Tutt, MB ChB, MRCP, FRCR, PhD - *Institute of Cancer Research*

City: London

Country: United Kingdom

“ATR inhibitors and PARP1 selective PARP inhibitors”

The targeting of Homologous Recombination deficient (HRD) malignancy using a synthetic lethal strategy based on the inhibition and trapping of PARP1 on DNA in manner that leads to tumour selective effects via dependency on the function of HR gene products such as BRCA1, BRCA2 and PALB2 for DNA replication fitness is now well established. However, there is a need to improve both the frequency and duration of response in the licensed indications and to explore combination PARP inhibitor (PARPi) strategies that may be effective a broader range of breast cancers with functional deficiencies in HR and the wider DNA damage response. ATR inhibitors exacerbate replication stress that is toxic to HR deficient cells. Combinations of an ATR inhibition (ATRi) and PARPi have been shown to be synergistic and to be active in PARPi resistant pre-clinical model contexts. The development of combination strategies of these agents and of platinum and ATRi have been limited by combinatorial toxicity but have recently reported results in breast cancer. PARP1 is part of a family of PARP enzymes and currently licensed PARPi inhibit several family members that underpin some of their toxicity. New PARP1 selective agents have recently reported results in early phase trials. I will review some of the mechanistic rationale, preclinical data and relevant clinical trial data in my lecture.

Hormone receptor positive breast cancer

Presenting Author(s) and Co-Author(s):

Cynthia Ma, MD, PhD - *Washington University in St. Louis*

City: St. Louis

State: MO

Country: United States

Estrogen receptor (ER) positive breast cancer is a heterogeneous group of diseases. While the major goal of neoadjuvant treatment in patients with locally advanced disease is to downstage the cancer to facilitate resectability and breast-conserving surgery, there is increasing evidence that response in the neoadjuvant setting has prognostic implications in predicting long term relapse outcomes. However, questions remain as to strategies that optimize neoadjuvant treatment selection of endocrine therapy versus chemotherapy, and whether adjuvant therapy could be tailored based on treatment response in the neoadjuvant setting. In this lecture, we will discuss evolving data regarding pathologic and molecular characteristics of ER positive breast cancer that assist with treatment selection in the neoadjuvant setting and the potential role of pathologic and biomarker response to neoadjuvant endocrine therapy in tailoring adjuvant chemotherapy decisions.

“Clinical relevance and value of neoadjuvant therapy of HER2+ early breast cancer at individual and at trial level”

Luca Gianni, MD - *Fondazione Michelangelo*, Milan Italy

Giampaolo Bianchini, MD - *Medical Oncology*, San Raffaele Hospital, Milan, Italy

Neoadjuvant therapy of HER2+ breast cancer has been groundbreaking. It showed the superior results in terms of pathologic complete response (pCR) and event free survival (EFS) of adding trastuzumab to chemotherapy in women with locally advanced breast cancer (NOAH trial) that led to the first regulatory approval of a neoadjuvant approach in the field of breast cancer. In addition, neoadjuvant studies (NeoSphere, neoALLTO) clearly showed the improved antitumor activity of dual blockade of the HER2 receptor, paved the way to the Aphinity adjuvant study and justified the current worldwide use of dual block of HER2 in high/moderate risk HER2+ early breast cancer.

In the above scenario the design and results of the Katherine study were a landmark achievement. By proving the clinical value of shifting treatment from trastuzumab to trastuzumab-DM1 in women with residual disease after neoadjuvant therapy the study provided firm clinical evidence that residual disease can be used as a surrogate of relative resistance that per se justifies the adoption of alternative non cross resistant regimens/therapies at the individual level.

The clinical success of neoadjuvant trials in HER2+ early breast cancer went hand-to-hand with translational studies that are identifying markers predicting for pCR and EFS that are and will be used to fine tuning a more individually tailored approach to treatment, and eventually effective and safe de-escalation strategies.

The rich collection of neoadjuvant studies that shaped the modern approach to treatment of women with early HER2+ breast cancer will be enriched of studies with new drugs, trastuzumab deruxtecan and tucatinib to name some of the front runners. All current and future treatments will greatly depend on the neoadjuvant approach as a tool for a quick assessment of the clinical value of new therapies. Such approach has so far been used as basis or supporting evidence for regulatory approvals worldwide, based on the concept that pCR can be viewed as surrogate of long-term benefit. Individual trials and meta-analyses are challenging the dependability of pCR to predict EFS at trial level. However, the benefits of tumor eradication (pCR) at individual level continue to support the simple clinical concept that more pCR is better and that regimens leading to it deserve full credit.

Introduction:

Racial disparities in breast cancer (BC) outcomes continues to be a major health care challenge. The 21-gene recurrence score (RS) is an important tool to guide treatment (tx) decisions among women with early-stage BC. We report an analysis of clinical characteristics,

survival outcomes and race in association with RS in participants (pts) in the RxPONDER trial.

Methods:

We analyzed clinical outcomes with respect to race and ethnicity. Unreported race excluded 18.7% of the pts, with most due to privacy rules. The primary outcome was invasive disease-free survival (IDFS). Distant relapse-free survival (DRFS) was also evaluated. Analyses adjusted for assigned tx arm, RS, and grade were performed. There were too few events to include Native American/Pacific Islander (NAPI) women in the survival analyses.

Results:

A total of 4,048 trial women with Hormone Receptor positive, HER2 negative (HR+/HER2-) BC, 1-3 involved axillary lymph nodes (LNs), RS \leq 25 and known race/ethnicity were included in this analysis including the following: 2,833 non-Hispanic (NH) White pts (70%), 248 NH Black pts (6.1%), 610 Hispanic pts (15.1%), 324 Asian pts (8.0%), and 33 NAPI pts (0.8%). Asian and Hispanic women were younger than NH Whites (by 7.1 and 2.4 years, respectively) but NH Blacks did not differ in age. RS distribution did not differ among all racial subgroups ($p=0.49$). There were also no significant differences in tumor size ($p=0.10$) or number of positive LNs ($p=0.26$) across all racial groups. However, tumor grade was found to be significantly different with grade 3 tumors higher for NH Blacks (18.0%), NH NAPI (21.1%), and Hispanics (14.5%) vs. NH Whites (10.4%) and Asians (6.5%) ($p < 0.001$). Overall five-year IDFS was lower for NH Blacks (87.0%) compared to that for Asians (93.9%), NH Whites (91.5%), and Hispanics (91.4%) (Table 1). A multivariable Cox model adjusting for RS and tx arm showed worse IDFS for NH Blacks compared to NH Whites (HR=1.38; 95% CI 1.00-1.90; $p=0.048$), although Asian pts had better IDFS than NH Whites (HR=0.65; 95% CI 0.44-0.97; $p=0.034$). In a separate analysis by menopausal status the magnitude of the IDFS hazard ratios (HRs) for NH Blacks was similar, although no longer statistically significant (premenopausal HR=1.37; 95% CI 0.69-2.72; postmenopausal HR=1.38; 95% CI 0.96-1.98). While there was no statistically significant interaction between NH Blacks vs. NH Whites and tx arm for either premenopausal ($p=0.99$) or postmenopausal women ($p=0.44$), adjusting for RS, the small number of events in the NH Black cohort, particularly in premenopausal women ($n = 9$ IDFS events), limit power and inference about differences in chemotherapy benefit. Among postmenopausal women, NH Blacks had worse DRFS compared to NH Whites (HR=1.69; 95% CI 1.12-2.53; $p=0.01$), adjusting for tx and RS. A similar trend was seen among premenopausal women (HR=1.74; 95% CI 0.79-3.82; $p=0.17$), although not statistically significant. Data on tx adherence over 5 years was not mature, although NH Blacks were more likely to accept tx assignment compared to NH Whites at randomization (93% vs. 86%, $p=0.004$).

Conclusion:

Black women with HR+/HER2- BC, 1-3 involved LNs and RS \leq 25 have worse outcomes compared to White women despite similar RS results. There was no significant interaction between NH Blacks vs. NH Whites and tx arm, although this analysis was limited due to sample size. There remains an important need for novel approaches to improve clinical outcomes particularly for NH Black Women.

Table 1. IDFS by Race and Ethnicity

Table 1. IDFS by Race and Ethnicity

Race/ethnicity	N	IDFS Events	5-year IDFS, %	Adjusted HR (95% CI)
NH Whites	2,833	353	91.5%	1.00 (referent)
Asians	324	27	93.9%	0.65 (0.44-0.97)
Hispanics	610	72	91.4%	0.91 (0.70-1.17)
NH Blacks	248	42	87.0%	1.38 (1.00-1.90)

Background: Black, compared to White women with localized breast cancer have higher mortality and worse distant recurrence free survival (DRFS). This has been attributed to social determinants of health and higher prevalence of triple negative breast cancer (TNBC) in Black compared to White women. Recent studies indicate that racial disparity in outcome is present in patients with estrogen receptor-positive (ER+), but not ER- disease, in particular in patients with residual disease after neoadjuvant chemotherapy (NAC). It has been shown that in some patients NAC may induce pro-metastatic changes in tumor microenvironment, such as increased density of tumor associated macrophages and portals for cancer cell dissemination to distant sites called TMEM doorways (TMEM score). TMEM score correlates with metastasis in patients with ER+/HER2- breast cancer. We hypothesized that racial disparity in DRFS in patients with residual ER+/HER2- disease is due to enhanced pro-metastatic components (macrophage and TMEM doorway density) in the tumor microenvironment post-chemotherapy in Black compared to White women.

Methods: We performed a retrospective, multi-institutional study of TMEM score and macrophage density in the residual disease after NAC from 196 patients diagnosed with unilateral invasive ductal cancer of breast between 2004 and 2014. 99 patients self-identified as Black and 97 as White. TMEM doorways were visualized by triple immunohistochemistry for macrophages (CD68), tumor cells (panMena), and endothelial cells (CD31). The evaluation of TMEM score and macrophage density was done using automated image analysis. Tumor characteristics and patient survival were compared between Black and White patients. The relationship between TMEM score, macrophage density and DRFS was examined by log-rank test and multivariate Cox regression model. The covariates in Cox model included TMEM score, age (continuous), race (Black vs White), surgery type (mastectomy vs lumpectomy), tumor stage (T3 vs T1; T2 vs T1), lymph node status (positive vs negative), and tumor subtype (triple negative [TN] vs ER+/HER2-; other vs ER+/HER2-).

Results: Black compared to White women were more likely to develop distant recurrence (49.5% vs 34%, $p=0.04$), receive mastectomy (69.7% vs 51.5%, $p=0.014$), and have higher grade ($p=0.001$). Tumors from Black patients had more macrophages and a higher TMEM score in the entire cohort ($p=0.004$; $p=0.001$ respectively) and in the ER+/HER2- subset ($p=0.008$; $p=0.008$ respectively), but not in the TNBC subset. High TMEM score was associated with worse DRFS in all patients ($p=0.004$) and in the ER+/HER2- ($p=0.03$), but not in TNBC. In multivariate Cox model, TMEM score was an independent prognostic factor in the entire cohort (HR, 1.92; 95%CI, 1.15-3.22; $p=0.01$) and trended towards significance in ER+/HER2- disease (HR, 2.13; 95%CI, 0.96-4.71; $p=0.06$). TN, compared to ER+/HER2- cancers had higher TMEM

score ($p=0.01$), and macrophage density ($p=0.001$).

Conclusion: Racial disparity in outcome in patients with localized breast cancer may be due to a more pronounced pro-metastatic response to chemotherapy in Black, compared to White patients with ER+/HER2- disease. Thus, higher prevalence of TNBC in Black patients may not be the controlling factor in racial disparity.

Introduction: Breast cancer treatment is associated with cancer-related cognitive impairment (CRCI). However, the differential effect of endocrine therapy (ET) vs chemotherapy followed by endocrine therapy (CET), including the impact of menopausal status, on CRCI is not well understood.

Methods: Participants (pts) with hormone receptor positive, HER2 negative breast cancer with 1-3 positive lymph nodes and an Oncotype DX recurrence score of 0-25 enrolled in the RxPONDER trial were randomly assigned to ET alone versus CET. Until the health-related quality of life (HRQoL) accrual goal was reached, English speaking pts in the US were invited to complete HRQoL questionnaires including the 8-item PROMIS Perceived Cognitive Function Concerns (PCF) Short Form questionnaire shortly after randomization (baseline), as well as 6, 12, and 36 months after baseline. Analysis of measures of anxiety and fatigue is presented separately. Standardized T scores (mean 50; SD 10) for PCF were computed with higher scores indicating less cognitive impairment. The primary endpoint of this exploratory analysis was to compare mean PCF T scores by treatment arm and menopausal status. Separately by

menopausal status, a generalized estimating equations (GEE) model was fit to the three timepoints adjusting for baseline to estimate the difference between treatment arms and whether there was a time trend over the three follow-up measures.

Results: The HRQoL accrual exceeded the goal of 500 patients, with 74% of pts participating voluntarily until the QOL invitation was removed from the protocol (Dec 1, 2012). A total of 139 pre and 429 postmenopausal pts completed the questionnaires at baseline. T scores were similar between ET and CET arms at baseline [Table]. In the ET arm, T scores decreased from baseline to 6 and 12 months but recovered to baseline at 36 months. In the CET arm, T scores decreased from baseline to 6 months and 12 months but did not return to baseline at 36 months. The mean score difference between CET and ET over time was -3.02 (p=0.01) and -2.36 (p=0.003) for pre and postmenopausal pts, respectively. Adjusting for baseline, there was no significant time trend over the three follow-up periods for either premenopausal (p=0.12) or postmenopausal (p=0.49) pts. Dropoff occurred over time with 79%, 76%, 60% of pts at baseline participating at 6, 12, and 36 months. Complete endocrine treatment adherence data are not yet available at each timepoint.

Conclusion: Chemoendocrine therapy has a greater negative effect on patient-reported CRCI compared to ET alone in both pre- and post-menopausal pts and it is sustained over 36 months. Interventions to prevent or treat CRCI are needed to improve the long-term quality of life of patients treated with CET.

Comparisons of mean Cognitive Function score by treatment arm and menopausal status

Table. Comparisons of mean Cognitive Function score by treatment arm and menopausal status

Menopausal status	Treatment Arm	Timepoint				CET vs. ET difference
		Randomization	6 months	12 months	36 months	
Premenopausal	CET	52.84	49.27	47.95	48.80	-3.02 (p=0.01)
	ET	53.53	51.49	51.35	53.50	
Postmenopausal	CET	50.65	48.32	47.30	48.43	-2.36 (p<0.003)
	ET	51.73	51.35	51.30	51.89

Background: Late recurrence of breast cancer after 5 years accounts for about 50% of recurrences in hormone receptor (HR)-positive early breast cancer (EBC). TAILORx established non-inferiority of adjuvant endocrine therapy (ET) given for at least 5 years to chemotherapy plus ET (CET) in EBC and a 21-gene recurrence score (RS) of 11-25, although there was some chemotherapy benefit in women

Methods: Eligibility criteria included women 18-75 years with HR-positive, HER2-negative, T1b-T2N0 EBC who agreed to have CT assigned or randomized based on the RS assay. The primary endpoint was invasive disease-free survival (iDFS) in the RS 11-25 group. The “primary analysis” refers to the original prespecified analysis for the primary IDFS endpoint (836 IDFS events at full information in the RS 11-25 group) after a median of 7.5 years. The “updated analysis” was performed after a median followup of 11.0 and 10.4 years in the randomized and overall populations, respectively.

Results: 10,253 eligible women enrolled between 4/7/06-10/6/10. The updated analysis includes substantially more events than the primary analysis, including IDFS events (1819 vs. 1210), distant recurrences (561 vs. 384), locoregional +/- distant recurrences (764 vs. 543), and deaths (910 vs. 499). The table provides 5 and 12-year event rates (and standard errors) for all arms, and comparisons of the randomized arms. The primary trial conclusions remain unchanged: ET was non-inferior to CET in the randomized group with a RS 11-25. Although recurrence occurred in < 10% by 12 years for a RS 0-25, late recurrence events beyond 5 years exceeded earlier recurrence. Non-recurrence events occurred in about 13% at 12 years (~1%/year), contributing substantially to the IDFS rates. For women
Conclusions: The current updated analysis confirms findings from the original primary analysis that ET is non-inferior to CET in HR-positive, HER2-negative, node-negative EBC and a RS 11-

25. As in the original primary analysis, the subgroup of women

Event Rate	Arm A RS <11 ET (n=1619)	Arm B RS 11-25 ET (n=3399)	Arm C RS 11-25 CET (n=3312)	Arm D RS >25 CET (n=1389)		Hazard Ratio: Arm B vs. C (95% C.I.)
5-year	94.0% (0.6)	92.8% (0.5)	93.1% (0.5)	87.6% (1.0)	IDFS	Primary analysis: 1.08 (0.94, 1.24, p=0.26)
12-year	75.9% (1.3)	76.8% (0.9)	77.4% (0.9)	65.9% (2.9)		Updated analysis: 1.08 (0.96, 1.20)

Background:

The landmark Suppression of Ovarian Function Trial (SOFT) in premenopausal breast cancer patients revealed that the addition of ovarian function suppression (OFS) to adjuvant endocrine therapy with either tamoxifen (T+OFS) or exemestane (E+OFS) reduces the risk of recurrence compared with adjuvant tamoxifen alone. The benefit from the addition of OFS was most clinically meaningful for patients at higher clinico-pathologic risk of recurrence. There are no biomarkers to aid decision-making about intensification of endocrine therapy with OFS and its resultant toxicities. The Breast Cancer Index (BCI) is a gene expression-based signature that stratifies patients based on the risk of overall (0-10 years) and late (post-5 years) distant recurrence (DR) and predicts the likelihood of benefit from extended endocrine therapy in early stage HR+ breast cancer. The purpose of this study is to assess BCI's prognostic and predictive ability in premenopausal women randomly assigned to 5-years treatment with E+OFS or T+OFS vs T alone in the SOFT trial.

Methods:

All available FFPE tumor samples from the SOFT trial (n=1718 of 3047) were included in the study. BCI testing was performed blinded to clinical characteristics, treatment and outcome. Median follow-up was 13 years. Primary endpoint was breast cancer-free interval (BCFI). Secondary endpoints were distant recurrence-free interval (DRFI) and disease-free survival (DFS). Kaplan-Meier analysis and Cox proportional hazards regression models, stratified by prior chemotherapy and lymph node status, were used to evaluate the predictive performance of BCI (H/I) status (High vs Low), and secondarily H/I as a continuous score. Hypothesis testing for interaction was performed by stratified log-rank tests.

Results:

Tumor samples from 1687 (98%) patients (30.4% < 40 years, 64.1% T1, 50.1% G2, 65.8% N0, 85.5% HER2-, 53.3% received prior chemotherapy) were successful in BCI testing and included in the final analysis. Patient characteristics in the translational cohort are representative of the parent SOFT trial. 42.4% of patients' tumors had H/I-High status. Prognostic and predictive analyses are ongoing and will be presented at the meeting.

BACKGROUND: Abnormalities of the PI3kinase/AKT/mTOR signaling network are common in breast cancer (BC) and are associated with endocrine resistance. Everolimus, an mTOR-

inhibitor increased PFS when combined with endocrine therapy (ET) in the metastatic setting and is thought to revert endocrine resistance. S1207 is a phase III randomized, placebo-controlled trial evaluating the role of everolimus in combination with ET in the adjuvant setting among patients with high-risk hormone receptor-positive, HER2-negative BC (NCT01674140). METHODS: Eligible patients were >18 years of age with histologically confirmed invasive hormone receptor-positive and HER2-negative high-risk BC. Four risk groups were defined as: 1) > 2cm node-negative disease (or pN1mi), and either an Oncotype DX® Recurrence Score (RS) > 25 or MammaPrint® high-risk category (MP high); 2) 1-3 positive nodes and either RS >25, MP high or a pathological grade 3 tumor; 3) >4 positive lymph nodes. Patients treated with neoadjuvant chemotherapy were eligible if: 4) after surgery had >1 lymph node involvement. Patients were randomized 1:1 to physician's choice adjuvant ET in combination with one year of everolimus (10 mg PO daily) or ET plus placebo stratified by risk group. The primary endpoint was invasive disease-free survival (IDFS) evaluated by a stratified log-rank test. Secondary endpoints included overall survival (OS) and safety. The hazard ratio (HR) for treatment efficacy was estimated using Cox regression with stratification by risk groups. Subset analyses included preplanned evaluation within risk group and exploratory analyses of menopausal status and age. RESULTS: 1,939 patients were randomized between September 2013 and May 2019, of them 1,792 were eligible and included in the analysis (896 per arm). Primary reason for ineligibility was timing after chemotherapy/radiation or not high risk. Median age was 54 years (22-85) and 32% were premenopausal. With a median follow-up of 50.5 months, there were 389 IDFS events as of May 2022 (data cutoff). 5-year IDFS was 74.8% among patients treated with everolimus and 73.9% among patients treated with placebo, HR=0.93 (95% CI 0.76-1.14). However, the proportional hazards assumption was violated (p=0.02) suggesting differential treatment effect over time. The HR during the one year of treatment was 0.72 (95% CI 0.47-1.10) while after one year it was 1.00 (95% CI 0.80-1.26). The 5-year OS was 87.6% in the everolimus arm and 85.5% in the placebo arm, HR=0.98 (95% CI 0.75-1.28). Analysis by risk group did not show higher everolimus benefit as risk increased. No difference in IDFS or OS was seen among postmenopausal patients (IDFS HR=1.08 [95% CI 0.85-1.36], OS HR=1.19 [95% CI 0.87-1.61]). Among premenopausal patients, everolimus was associated with improved IDFS (HR=0.63 [95% CI 0.43-0.93]) and OS (HR=0.48 [95% CI 0.26-0.88]). Treatment completion of randomized therapy was lower in the everolimus arm compared to placebo (47.9% v 72.7%). Grade 3 and 4 toxicities were noted in 6.5% and 0.5% of patients in the placebo arm and in 31.2% and 3.7% in the everolimus arm respectively. CONCLUSIONS: Addition of one year of adjuvant everolimus to standard adjuvant ET did not improve IDFS or OS and was associated with low completion rate and increased AEs. Among premenopausal patients there was a benefit in IDFS and OS that is hypothesis generating. Future translational studies will evaluate potential predictors of everolimus benefit and drug toxicity.

Background Adjuvant abemaciclib (a CDK4 and 6 inhibitor) combined with ET resulted in significant and clinically meaningful improvement in invasive disease-free survival (IDFS) and distant relapse-free survival (DRFS) in patients (pts) with HR+, HER2-, node-positive, high risk EBC in the monarchE trial, and is an approved adjuvant therapy for these patients. Here we present efficacy results from a pre-specified overall survival interim analysis (OS IA2) which was planned to occur 2 years (yrs) after the primary outcome analysis. Methods Pts were

randomized (1:1) to receive ET for up to 10 yrs +/- abemaciclib for 2 yrs (study treatment period). High-risk EBC was defined as either ≥ 4 positive axillary lymph nodes (ALN), or 1-3 ALN with either Grade 3 disease and/or tumor ≥ 5 cm (Cohort 1). While the proliferation biomarker Ki-67 was centrally assessed in all pts with available tissue sample, an additional smaller group of pts with 1-3+ ALN and central Ki-67 $\geq 20\%$ as the only high-risk feature were included (Cohort 2). The intent-to-treat (ITT) population consisted of both Cohort 1 (5120 pts) and Cohort 2 (517 pts). Hazard ratios (HR) were estimated using Cox proportional hazard model. Results At a median follow-up of 42 months, all pts were off abemaciclib. IDFS and DRFS data illustrate a sustained benefit beyond the treatment period. In the ITT population, the HR for IDFS was 0.664 (95% CI: 0.578, 0.762) and DRFS was 0.659 (95% CI: 0.567, 0.767). At 4 yrs, this reflected an improvement in IDFS rates from 79.4% to 85.8% (absolute difference 6.4%), and in DRFS rates from 82.5% to 88.4% (absolute difference 5.9%). The continued separation of the curves was associated with an increase in absolute benefit in IDFS 4-year rates compared to 2- and 3-year IDFS rates (absolute difference 2.8% and 4.8% respectively). While OS remained immature, there was a lower number of deaths observed in the abemaciclib plus ET arm compared to the ET alone arm (157 [5.6%] vs 173 [6.1%], HR 0.929 [95% CI: 0.748, 1.153], $p = 0.503$), suggesting that the robust benefit in IDFS and DRFS began to translate into a numerically favorable OS HR. As previously described, within Cohort 1, a Ki-67 index of $\geq 20\%$ was associated with a worse prognosis, but similar abemaciclib treatment effects were observed regardless of Ki-67 index. No new safety signals were observed. Conclusion The clinically meaningful benefit of adjuvant abemaciclib added to ET in HR+, HER2-, node-positive, high-risk EBC persists beyond completion of abemaciclib therapy, yielding an increase in absolute IDFS and DRFS benefit at 4 yrs. While OS remains immature at this time, the lower number of deaths in the abemaciclib arm compared to the ET arm suggest that a survival signal favoring abemaciclib is emerging.

Background: Combination chemotherapy (CT) remains a standard of care in advanced breast cancer (ABC) with aggressive disease features (rapidly progressing or highly symptomatic disease, including life-threatening visceral crisis). To date, no data have been published on a head-to-head comparison of CDK4/6 inhibitor (CDK4/6i) + endocrine therapy (ET) vs combination CT in this patient (pt) population. RIGHT Choice, a randomized, open-label, multi-national, Phase II trial, investigated the efficacy and safety of first-line ribociclib (RIB) + ET vs

combination CT in pre/perimenopausal pts with HR+/HER2- ABC with aggressive disease (where combination CT is clinically indicated by physician's judgment). Here we report the results of the primary endpoint of progression-free survival (PFS) and key secondary endpoints from this study.

Methods: Pre/perimenopausal pts with HR+/HER2- ABC (>10% estrogen receptor-positive [ER+]) and no prior systemic therapy for ABC were randomized 1:1 to receive either RIB (600 mg daily, 3 weeks on/1 week off) with letrozole/anastrozole + goserelin or investigator's choice of CT (docetaxel + capecitabine, paclitaxel + gemcitabine, or capecitabine + vinorelbine). Randomization was stratified by presence of liver metastases and whether the disease-free interval (duration from date of complete tumor resection for primary breast cancer lesion to the date of documented disease recurrence) was less than two years. Pts included in the trial had ABC not amenable to curative therapy for which combination CT was clinically indicated by physician's judgment (i.e., symptomatic visceral metastases, rapid progression of disease or impending visceral compromise, or markedly symptomatic non-visceral disease). Median PFS (mPFS) and median time to treatment failure (mTTF) were evaluated by Kaplan-Meier methods. Overall response rate (ORR) was also analyzed, with quality of life and biomarker analyses planned. RIGHT Choice is registered at ClinicalTrials.gov (NCT03839823).

Results: A total of 222 pts (112 RIB + ET; 110 CT) were enrolled from Feb 2019 to Nov 2021. Pts with symptomatic visceral metastases (n=150; 67.6%), rapid disease progression (n=41; 18.5%), and markedly symptomatic non-visceral metastases (n=31; 14.0%) were included. Overall, 116 pts (52.3%) had visceral crisis based on guideline definitions. A majority of pts (n=190; 85.6%) had tumors that were ≥50% ER+. At data cutoff (Apr 12, 2022), median follow-up was 24.1 mo; 45.5% and 23.6% of pts remained on treatment in the RIB + ET arm and combination CT arm, respectively. The primary endpoint was met, with a statistically significant PFS benefit of ≈1 year for RIB + ET vs combination CT (mPFS, 24.0 vs 12.3 mo; hazard ratio, 0.54; 95% CI, 0.36-0.79; P=.0007). OS data were immature at data cutoff. The mTTF was ≈10 mo longer for RIB + ET vs CT (18.6 vs 8.5 mo; hazard ratio, 0.45; 95% CI, 0.32-0.63). The ORR was similar for RIB + ET vs CT (65.2% vs 60.0%). No new safety signals were observed in pts on RIB. Lower rates of treatment-related serious adverse events (AEs; 1.8% vs 8.0%) and lower rates of discontinuation due to treatment-related AEs (7.1% vs 23.0%) were seen with RIB + ET vs CT, respectively. AEs observed with combination CT were consistent with the published data.

Conclusions: This analysis demonstrated a statistically significant and clinically meaningful PFS benefit with RIB + ET over combination CT in the first-line pre/perimenopausal pt population with aggressive HR+/HER2- ABC disease. This is the first study comparing a CDK4/6i + ET vs combination CT and demonstrating the superiority of RIB + ET in aggressive HR+/HER2- ABC. This evidence supports RIB+ ET use as a preferred option for this pt population.

Background: HR+/HER2- mBC, the most common subset of breast cancer, is treated with sequential endocrine therapy + targeted agents followed by sequential single-agent chemotherapy (CT), with increasingly shorter benefit duration with each subsequent treatment. High Trop-2 expression is observed in breast cancer regardless of subtype. SG is a Trop-2-directed antibody-drug conjugate approved for pre-treated metastatic triple-negative breast cancer. In the phase 3 TROPiCS-02 study, SG showed both significant progression-free survival (PFS) benefit (HR, 0.66; $P < 0.001$; median 5.5 vs 4.0 mo; JCO 2022) at the primary analysis and overall survival (OS) benefit (median 14.4 vs 11.2 mo; HR, 0.79; $P = 0.02$; ESMO 2022) at the 2nd planned interim OS analysis vs TPC in pretreated HR+/HER2- mBC. Here we compare efficacy outcomes for SG and TPC by Trop-2 expression. Methods: Eligible pts had HR+/HER2- locally recurrent inoperable or mBC; received ≥ 1 prior taxane, endocrine therapy, a CDK4/6 inhibitor; and received 2-4 prior CT regimens for mBC. Pts were randomized 1:1 to receive SG (10 mg/kg IV on d 1 and 8, every 21 d) or TPC (eribulin, gemcitabine, capecitabine, or vinorelbine) until disease progression or unacceptable toxicity. The primary endpoint was PFS by independent review per RECIST v1.1; OS and objective response rate (ORR) were key secondary endpoints. ORR was assessed by blinded independent central review per RECIST v1.1. Membrane Trop-2 expression on archival tumor tissue was assessed by immunohistochemistry and expressed as a histochemical score (H-score; range, 0-300); efficacy outcomes were assessed in H-score < 100 and ≥ 100 groups. The H-score < 100 group was further divided into H-score ≤ 10 and > 10 - < 100 subgroups to assess the activity of SG in pts with very low Trop-2 expression. Results: Data cut-off was January 3, 2022 for PFS (median follow-up, 10.2 mo) and July 1, 2022 for OS (median follow-up, 12.5 mo). In total, 543 pts were randomized to receive SG (n=272) vs TPC (n=271). Pts had a median of 3 prior CT regimens for mBC; 95% had visceral metastases. There were 238 (88%) vs 224 (83%) Trop-2-evaluable pts in the SG vs TPC groups, respectively; of these, 95% had tumors with Trop-2 H-score > 0 . Of Trop-2-evaluable pts, 192 (42%) and 270 (58%) had H-scores < 100 and ≥ 100 , respectively. Demographics and baseline characteristics were generally consistent across H-score groups. PFS and OS benefit was observed for SG vs TPC across both Trop-2 groups (Table). Median PFS was 5.3 vs 4.0 mo (HR, 0.77; 95% CI, 0.54-1.09) and 6.4 vs 4.1 mo (HR, 0.60; 95% CI, 0.44-0.81) in the H-score < 100 and ≥ 100 groups; median OS was 14.6 vs 11.3 mo (HR, 0.75; 95% CI, 0.54-1.04) and 14.4 vs 11.2 mo (HR, 0.83; 95% CI, 0.62-1.11), respectively. Disease response was observed in the 34 pts with H-score ≤ 10 who received SG. In pts who received SG, those with H-score ≤ 10 , > 10 - < 100 , and ≥ 100 had ORRs of 24%, 18%, and 23%, respectively. The safety profile for SG by Trop-2 H-score was consistent with previous reports. Conclusions: In this TROPiCS-02 post-hoc analysis, improved efficacy with SG vs TPC was observed regardless of Trop-2 expression, and there was no clear level of

Trop-2 expression at which a better treatment effect for SG was observed. These results support SG as an effective novel treatment option for patients with pretreated, endocrine-resistant HR+/HER2- mBC, and reinforce that Trop-2 testing is not required for SG treatment.

Table

	n (SG/TPC)	Median PFS (SG vs TPC), mo	PFS HR (95%CI)	Median OS (SG vs TPC), mo	OS HR (95%CI)
Trop-2 expression, H-score					
<100	96/96	5.3 vs 4.0	0.77 (0.54-1.09)	14.6 vs 11.3	0.75 (0.54-1.04)
≥100	142/128	6.4 vs 4.1	0.60 (0.44-0.81)	14.4 vs 11.2	0.83 (0.62-1.11)
≤10	34/45	5.5 vs 4.3	0.89 (0.51-1.57)	17.6 vs 12.3	0.61 (0.34-1.08)
>10-<100	62/51	5.0 vs 3.5	0.67 (0.42-1.07)	13.7 vs 11.0	0.81 (0.54-1.23)
>10	204/179	5.6 vs 4.0	0.62 (0.48-0.80)	14.1 vs 11.1	0.82 (0.65-1.04)

H-score, histochemical score; OS, overall survival; PFS, progression-free survival; SG, sacituzumab govitecan; TPC, treatment of physician's choice.

Background: Most patients with early stage oestrogen receptor positive (ER+) and HER2 negative breast cancer will be cured of their cancer. However, up to 20% of patients may experience disease recurrence in the first 10 years. Molecular relapse of ER+ breast cancer can be detected with circulating tumour DNA (ctDNA) before clinical relapse occurs. Palbociclib, a CDK4/6 inhibitor, plus fulvestrant, a selective oestrogen receptor degrader, is a standard first line therapy for patients with ER+ breast cancer who have relapsed on standard endocrine therapy. We designed TRAK-ER to establish a surveillance system for ctDNA detection and then to assess whether treating patients, who have ctDNA detected molecular relapse, with palbociclib and fulvestrant may defer or prevent relapse. Design: TRAK-ER is a phase 2 multi-centre, randomised, open-label parallel superiority trial in patients with ER+ early breast cancer, recruiting at centres in the UK and France. In the surveillance phase patients will be monitored for molecular recurrence with ctDNA testing. To be eligible for the surveillance phase patients must be aged 18 or over, have ER+ ($\geq 10\%$ or Allred score 6/8 or greater) and HER2 negative breast cancer and have completed their primary surgery, chemotherapy and radiotherapy. Standard endocrine therapy (GnRH analogues, aromatase inhibitors and tamoxifen) must have been received for a minimum of 6 months and a maximum of 7 years and be planned to continue for at least another 3 years. Inclusion criteria in patients who did not receive neoadjuvant chemotherapy are at least one of: (a) four or more involved axillary or positive supraclavicular lymph node; (b) tumour size $>5\text{cm}$; (c) one to three involved axillary lymph nodes together with at least one of: tumour size $>3\text{cm}$, grade 3 or a high genomic risk score. Patients who received neoadjuvant chemotherapy require at least one lymph node positive or a tumour size $>3\text{cm}$ after chemotherapy. Invitae Personalized Cancer Monitoring (PCM TM) will be used for ctDNA analysis, a pan-cancer, tumour-informed liquid biopsy test that uses next-generation sequencing to detect minimal or molecular residual disease (MRD) in solid tumours. ctDNA analysis will be every 3 months for up to 3 years. Detection of ctDNA will trigger staging imaging. If no overt metastatic disease is identified, patients will be able to enter the treatment phase of the study, and be 1:1 randomised using minimisation to either remain on standard endocrine therapy or switch to palbociclib plus fulvestrant. Those who are allocated to remain on endocrine therapy are allowed to continue on the same therapy or change standard endocrine therapy. Duration of palbociclib and fulvestrant will be 2 years, or until relapse. Up to

1300 patients will enrol for tissue screening to allow 1100 patients to enter into ctDNA surveillance. 132 patients will enter the treatment part of the study. The primary endpoint of the surveillance phase is ctDNA detection rate. The primary endpoint of the treatment phase is relapse free survival (RFS). RFS will be calculated in the intention to treat population using Kaplan Meier methods from the date of randomisation to the date of recurrence or death from any cause. Secondary endpoints include relapse free interval, invasive disease free survival, distant recurrence free survival, overall survival and ctDNA clearance. (NCT04985266)

Background: Adjuvant ET has been the standard of care for patients with estrogen receptor-positive (ER+), human epidermal growth factor receptor 2-negative (HER2-) EBC. A significant proportion of patients with increased risk still experience disease relapse despite available ET and more optimum ET is needed to prevent patients developing incurable metastatic cancer. Distant recurrence risk ranges from 20% to 40% after 5 years of adjuvant ET, depending on clinicopathological (clin-path) features at diagnosis. Consequently, there is a need to further optimize adjuvant treatment, particularly in those patients who are at increased risk of recurrence. Imlunestrant is an orally bioavailable selective estrogen receptor degrader (SERD) with pure antagonistic properties and the potential to overcome ET resistance. In early phase trials, imlunestrant monotherapy showed favorable safety with pharmacokinetic (PK) exposures exceeding fulvestrant and preliminary efficacy in ER+, HER2- advanced breast cancer patients (EMBER, Jhaveri 2022) along with robust biological/pharmacodynamic activity and tolerability in EBC (EMBER-2, Neven). Trial Design: EMBER-4 is a randomized, open-label, global phase 3 study comparing imlunestrant versus physicians' choice of ET, in patients who are at an increased risk of recurrence based on clin-path features and who have received 2 to 5 years of standard adjuvant ET. Approximately 6,000 patients will be randomized 1:1 to receive imlunestrant (400 mg daily) for 5 years or physicians' choice of adjuvant ET (tamoxifen or an aromatase inhibitor, AI, dosed per label). Study treatment duration is 5 years. Males and pre-/peri-menopausal women will receive concomitant treatment with a GnRH agonist if receiving imlunestrant or an AI. Stratification factors include time from initial adjuvant ET, use of prior adjuvant cyclin dependent kinase 4/6 inhibitors, nodal status, menopausal status, and geographic region. Eligibility criteria: Eligible patients are adult males and females (pre-, peri- or postmenopausal) with ER+, HER2- EBC who have completed definitive locoregional therapy and have received 2 to 5 years of prior adjuvant ET without disease recurrence, but who are at increased risk of recurrence based on clin-path features at diagnosis. Prior (neo) adjuvant chemotherapy and/or targeted therapy with a CDK4/6- or PARP- inhibitor is permitted. Study endpoints: The primary endpoint is invasive disease-free survival (IDFS), excluding second non-breast primary invasive cancers. Key secondary endpoints include distant relapse-free survival, overall survival, IDFS including second non-breast primary invasive cancers, safety, PK and patient reported outcomes. Recruitment for EMBER-4 begins globally in Q4 2022.

Abstract: Trials in progress **Authors:** Dr Rachel Dear, A/Prof Christine Chaffer, Dr Beatriz Perez San Juan **Title:** 4CAST: A Phase 1b dose exploration and dose expansion, open-label study evaluating the safety and efficacy of INO-464 in combination with Chemotherapy in patients with metASTatic breast cancer. **Problem statement:** Metastatic triple negative breast cancer (mTNBC) has poor outcomes, with rapid progression and a median overall survival of 16 months. Standard treatment includes chemotherapy, with a possible role for immunotherapy. The antibody-drug conjugate sacituzumab govitecan was been granted recent approval. The development of new targeted treatments remains an unmet need. The androgen receptor is a mediator of chemotherapy-resistance in triple-negative breast cancer. Taxane and platinum-based chemotherapy induces cell plasticity and the emergence of chemotherapy-resistance. The androgen receptor (AR) antagonist, INO-464, but not abiraterone or enzalutamide, blocks chemotherapy induced cell plasticity to inhibit and primary and metastatic tumour growth. Three early-phase prospective clinical studies investigating anti-androgen therapy have demonstrated clinical benefit of single-agent AR-targeted agents in women with metastatic AR positive TNBC. The 450 mg daily start dose of INO-464 was well-tolerated and declared the recommended phase 2 dose. Preliminary laboratory data demonstrates an increase in survival and suppression of metastatic TNBC when INO-464 is used in combination with docetaxel. **Methods:** To determine the feasibility, safety and efficacy of INO-464 in combination with chemotherapy for the treatment of metastatic breast cancer. In Part 1 (dose exploration) of the trial we aim to establish the tolerability and safety and determine the recommended phase 2 dose of INO-464 when used in combination with docetaxel. Part 1 will recruit 6-18 females or males with locally advanced or metastatic breast cancer ie hormone receptor positive, HER2-positive or triple-negative breast cancer. In Part 2 (dose expansion) the clinical activity INO-464 and docetaxel in participants with metastatic triple negative breast cancer will be assessed. **Results:** Ethics approval for Part 1 of the trial was granted in May 2021. The trial received governance approval from St Vincent's Hospital governance in June 2022. Recruitment commenced on the 1 July 2022. The trial has received 40 enquiries, of which three patients

were eligible and one patient has consented to the trial and will be ready to start in the next two weeks. Conclusion: This investigator-initiated trial is an example of a collaborative effort between the Garvan Institute of Medical Research and the Kinghorn Cancer Centre at St Vincent's Hospital. If the combination of INO-464 and docetaxel is shown to be safe we look forward to recruiting to the part 2 dose expansion phase across multiple Australian sites. This study is registered with ClinicalTrials.gov NCT04947189. Disclosure of interests: A/Prof Christine Chaffer is the Managing Director of Kembi Therapeutics that is providing the investigational product for the clinical trial.

There is growing interest in targeting the androgen receptor (AR) in advanced/metastatic breast cancer. It has been recently demonstrated preclinically that AR activation, rather than AR suppression, exerts potent antitumor activity across a number of ER+ /AR+ breast tumors, including those resistant to standard-of-care endocrine therapy and CDK4/6 inhibitors (Hickey et al, *Nature Medicine* 2021 27: 310-320). Mechanistically, agonist activation of AR altered the genomic distribution of ER and essential co-activators resulting in repression of ER-regulated cell cycle genes and upregulation of AR target genes, including known tumor suppressors. EP0062 is an oral, non-steroidal, SARM currently being developed for the treatment of AR+/HER2-/ER+ advanced breast cancer. The efficacy and safety of EP0062 has previously been investigated in a Phase 1 clinical trial of AR+/HER2-/ER+ advanced breast cancer, and demonstrated that EP0062 has acceptable tolerability with evidence of clinical efficacy (LoRusso et al. *Clinical Breast Cancer* 2022 22;1 67-77). This new study is designed to further extend the evaluation of EP0062 as a potential therapy for AR+/HER2-/ER+ advanced breast cancer. The primary aim of the study is to assess tolerability and identify an optimal RP2D dose. The study will also explore the relationship between efficacy of EP0062 and AR expression, to establish a threshold for future patient selection, and undertake an initial evaluation of the safety and efficacy of EP0062 in combination with established standard of care therapies. The study will recruit up to 128 patients with AR+/HER2-/ER+ advanced breast cancer. Module A is a dose finding cohort to investigate safety, tolerability, PK and PD and to define the maximum tolerated dose (MTD) and/or Recommended Phase II Dose (RP2D). Dose finding will be based on a 3+3 design and is expected to recruit up to 32 patients. Once

potential recommended doses are identified, approximately 60 evaluable patients will be randomised to two different dose cohorts in Module B in order to further optimise the RP2D dose, by further evaluation of safety and tolerability, as well as prospectively evaluate the relationship between efficacy and AR expression. In Module C, EP0062 will be combined with select standard of care targeted therapies in patients with relapsed AR+/HER2-/ER+ advanced breast cancer to confirm safety and explore efficacy. This will include approximately 36 patients across a number of single arm expansion cohorts. The key inclusion criteria are as follows: • Post-menopausal women, ≥18 years • ECOG performance status of 0 to 1 • Locally advanced or metastatic breast cancer • ER+, HER2- as per ASCO CAP guidelines • AR+, as defined as ≥ 10% AR nuclei staining by IHC • Endocrine-sensitive defined as greater than 3 years endocrine treatment prior to recurrence if recurrence occurred in the adjuvant setting, or ≥ 6 months treatment and response if recurrence occurred from primary treatment in the advanced setting • Relapsed, defined as clear and documented evidence of disease progression following ≥ 1 lines and ≤2 prior lines of previous endocrine therapy and ≤ 2 lines of chemotherapy in the advanced/metastatic setting • Measurable disease defined by RECIST version 1.1, or measurable bone-only disease EP0062 will be dosed to progression. Endpoints include incidence of DLTs during Cycle 1 of EP0062 treatment (28 days), MTD, RP2D (Module A), incidence and severity of AEs and SAEs, plasma PK parameters, Clinical Benefit Rate (complete response, partial response, or stable disease) at 24 weeks, ORR, duration of response, PFS, OS and quality of life. Clinic follow-up will be at 2 and 4 weeks, then every 4 weeks until disease progression. Recruitment is scheduled to initiate in Q4 2022.

Background: Breast cancer (BC) is the most commonly diagnosed cancer and one of the leading causes of cancer death in women. Despite significant therapeutic advances, the

majority of patients with unresectable or recurrent/metastatic disease eventually develop resistance to available standard of care (SOC) therapies. B7-H4 is a poor prognostic factor and is overexpressed in several cancers including endometrial, ovarian, and breast. As a member of the CD28/B7 family of cell surface proteins, it promotes tumorigenesis by suppressing anti-tumor immunity. XMT-1660 is a B7-H4-targeted Dolasynthen antibody drug conjugate with a precise, optimized drug-to-antibody ratio and a DolaLock microtubule inhibitor payload with controlled bystander effect. In the preclinical setting, XMT-1660 has demonstrated anti-tumor activity in TNBC and ER+/HER2- patient-derived xenograft mouse models, which included tumors from heavily pre-treated patients (Collins et al, AACR 2022). Increased anti-tumor activity tended to be more frequent in models with higher B7-H4 expression, providing rationale for a Ph1 clinical trial. Methods: The Ph1 trial includes a first-in-human open-label dose escalation (DES) portion followed by dose expansion (EXP) evaluating XMT-1660 in patients with BC, EC, and OC following progression on SOC as applicable (i.e., CDK4/6i + ET; platinum-based chemotherapy). In the DES, Bayesian Optimal Interval (BOIN) design will be used to determine the MTD. Patients will receive XMT-1660 IV Q3 weeks. Primary endpoints in DES are to assess safety and determine a recommended phase 2 dose (RP2D) and assessment of preliminary efficacy as a secondary endpoint. In the EXP portion, cohorts enrolling TNBC, ER+/HER2- BC, EC/OC are planned and additional patients may be enrolled based on emerging data. The primary endpoint of EXP is to assess safety and tolerability, overall response rate, disease control rate, and duration of response. Secondary endpoints include pharmacokinetic analysis and antidrug antibodies. Patients are not selected by B7-H4 status, but baseline tumors samples are collected for retrospective tumor tissue evaluation. The trial is currently enrolling patients. NCT05377996

Background: The therapeutic options for patients (pts) with previously treated metastatic TNBC are limited compared with other breast cancer subtypes. SKB264 is an antibody drug conjugate (ADC) composed of an anti-TROP2 antibody coupled to the cytotoxic belotecan-derivative via a novel linker. Here, we present results from a Phase 2 expansion cohort for pts with mTNBC (NCT04152499). Methods: Pts with previously treated mTNBC were enrolled to receive SKB264 4 mg/kg Q2W or 5 mg/kg Q2W in a non-randomized fashion until disease progression/unacceptable toxicity. The assessment for tumor response was performed every 8 weeks per RECIST v1.1 assessed by investigator. The TROP2 expression was scored using the semi-quantitative H-score method, and cut off point was set to 200. TROP2 expression and its association with anti-tumor activity was retrospectively analyzed. Results: At data cut-off date (May 15, 2022), 59 pts were enrolled (23 in 4 mg/kg, 36 in 5 mg/kg), 88% of them (52 pts) had received ≥ 3 prior therapies for metastatic disease. Among 53 patients with tissue available for TROP2 testing, 29 patients (55%) had TROP2 high (H-score $>200-300$) tumors. The median follow up was 9.6 months. Of 55 pts (21 in 4 mg/kg and 34 in 5 mg/kg) evaluable for response assessment (≥ 1 on-study scan), the confirmed ORR (cORR) was 40% (22/55) and disease control rate (PR+CR+SD) was 80% (44/55). The cORR was 55% (16/29) in the subset of patients with high TROP2 expression. The median duration of response (DoR) was not reached with range from 1.0+ to 11.0+ months and the 6-month DoR rate was 82%. Median PFS was 5.7 months (95% CI: 3.9, 7.6). Treatment-related adverse events (TRAEs) of \geq Grade 3 were reported in 55.9% (33/59) of pts. The most common \geq Grade 3 TRAEs ($\geq 10\%$) were neutrophil count decreased (23.7%), anemia (20.3%) and platelet count decreased (16.9%). TRAEs led to dose reduction in 15.2% (9/59) of pts and to discontinuation in 6.8% (4/59) of pts. No treatment-related AEs leading to death or interstitial lung disease (ILD) were reported. Safety and anti-tumor activities of SKB264 by dose level will be presented. Conclusions: SKB264 demonstrates a manageable safety profile and promising antitumor activity in pts with heavily pretreated mTNBC. SKB264 toxicity was mainly hematologic. A Phase 3 study of SKB264 vs investigator selected chemo alone in pts with locally advanced inoperable or metastatic TNBC was initiated (NCT05347134).

Background LIV-1 is a highly expressed transmembrane protein in breast cancer cells. Ladiratumab vedotin (LV) is an investigational antibody–drug conjugate directed to LIV-1 via a humanized IgG1 monoclonal antibody conjugated to monomethyl auristatin E (MMAE) by a protease-cleavable linker. LV is internalized when it binds LIV-1 on cell surfaces and MMAE is released, which binds tubulin and induces apoptosis. We established that weekly doses of LV up to 1.5 mg/kg were clinically active and generally well tolerated in patients with second-line metastatic triple-negative breast cancer (mTNBC) (Tsai 2021). Based on pharmacokinetic and pharmacodynamic (PK/PD) modeling and simulation analysis, we are evaluating an intermittent LV dosing schedule to improve antitumor activity while maintaining a manageable safety profile. There is currently an unmet medical need for front-line novel therapies in patients with programmed death ligand 1 (PD-L1) low or negative mTNBC, where response rates to standard of care chemotherapy are poor. Part F of this study focuses on this patient population. Methods SGNLVA-001 (NCT01969643) is an ongoing phase 1 study assessing the safety, tolerability, and preliminary efficacy of LV. Part F will enroll ~30 patients with first-line unresectable locally advanced (LA)/mTNBC. Eligible patients must not have received prior cytotoxic therapy in the unresectable LA/mTNBC setting and have tumors with a PD-L1 combined positive score < 10. Patients must also have at least 1 measurable lesion per RECIST v1.1, adequate organ function, and an ECOG status of ≤ 1 . Patients with Grade ≥ 2 peripheral neuropathy and prior therapy with LV or MMAE-containing agents are not eligible. Tumor LIV-1 expression is not required for enrollment. Patients in Part F will receive LV 1.5 mg/kg by intravenous infusion on Days 1 and 8 every 3 weeks, until progression or unacceptable toxicity. Tumor assessments will be conducted every 6 weeks (± 1 week) for the first 10 cycles and every 12 weeks thereafter. All patients will be followed for safety. The primary safety endpoint is the incidence of adverse events. Key efficacy endpoints include confirmed overall response rate, duration of response, progression-free survival, and overall survival. PK and markers of PD will be assessed. Safety, PK, and efficacy measures will be summarized using descriptive statistics. Enrollment for Part F is ongoing in the US.

Background: Chemotherapy is the main treatment in patients with pre-treated endocrine-resistant HR+/HER2– metastatic breast cancer, but has limited efficacy and substantial toxicities. The antibody-drug conjugate Dato-DXd consists of a humanized IgG1 mAb targeting TROP2 attached via a stable cleavable linker to a topoisomerase I (TopI) inhibitor payload. Heavily pre-treated patients with metastatic triple-negative breast cancer in the TROPION-PanTumor01 (NCT03401385) study of Dato-DXd showed a manageable safety profile and highly encouraging objective response rates (ORR by blinded independent central review [BICR]: 34% in all patients; 52% in patients treatment-naïve to TopI inhibitor-based therapies). The metastatic HR+/HER2– breast cancer cohort of TROPION-PanTumor01 has completed enrollment (n=41); data are currently maturing. Trial design: TROPION-Breast01 (NCT05104866) is an ongoing, global, phase 3, open-label, randomized trial evaluating efficacy and safety of Dato-DXd vs investigators' choice of chemotherapy (ICC) in patients with inoperable or metastatic HR+/HER2– breast cancer. Patients (n≈700) are randomized 1:1 to Dato-DXd 6 mg/kg IV Q3W or ICC (eribulin, capecitabine, vinorelbine, or gemcitabine) until progression. Adults with an ECOG performance status of 0–1, who experienced progression on or are unsuitable for endocrine therapy, and received 1–2 prior lines of standard-of-care chemotherapy in the inoperable or metastatic setting are eligible. Monotherapy treatment with inhibitors of mTOR, PD-[L]1, CDK4/6 and PARP do not count as prior chemotherapy lines. Patients must have ≥1 measurable lesion per RECIST 1.1 and an archival or fresh formalin-fixed and paraffin-embedded tumor sample. Clinically inactive brain metastases are permitted. Dual primary endpoints are progression-free survival (PFS) by BICR, and overall survival. Secondary endpoints include PFS per investigator, ORR, disease control rate, patient-reported outcomes, and Dato-DXd pharmacokinetics and immunogenicity. Exploratory endpoints include TROP2 expression and exposure–efficacy relationship. Patients are stratified by number of prior chemotherapy lines, prior CDK4/6 inhibitor use, and region. At the time of writing 236 patients have been enrolled across 19 countries.

Introduction: Despite recent treatment advances, the prognosis for patients diagnosed with locally recurrent inoperable or metastatic triple-negative breast cancer (TNBC) remains poor. Single-agent chemotherapy has been the mainstay of treatment for metastatic TNBC for many years, with very limited treatment options for patients who are not candidates for anti-PD-1/PD-L1 therapy; consequently, there remains an urgent unmet need. Trophoblast cell surface protein 2 (TROP2) is a type I transmembrane glycoprotein highly expressed on various solid tumors, including breast. Datopotamab deruxtecan (Dato-DXd) is an antibody-drug conjugate (ADC) composed of a humanized anti-TROP2 IgG1 monoclonal antibody covalently linked to an exatecan derivative (DXd) – a highly potent topoisomerase I inhibitor payload – via a stable, tumor-selective, tetrapeptide-based cleavable linker. Dato-DXd has previously been evaluated in TROPION-PanTumor01 (NCT03401385) – an ongoing Phase I clinical trial across multiple advanced solid tumors, including heavily-pretreated, metastatic TNBC. As of the July 30, 2021 cut-off date, the objective response rate (ORR) by blinded independent central review (BICR) was 34% (15/44) in all patients with TNBC and 52% (14/27) in those patients treatment-naïve to topoisomerase I inhibitor-based ADC therapies, with measurable disease (per RECIST 1.1) at baseline. Furthermore, a manageable safety profile was reported, with no new safety signals identified; low grade nausea and stomatitis were most frequent, with neutropenia and diarrhea being uncommon. The aim of the phase 3 TROPION-Breast02 trial is to evaluate the efficacy and safety of Dato-DXd versus investigator's choice of chemotherapy (ICC) in patients with TNBC who are not candidates for PD-1/PD-L1 inhibitor therapy. Methods: TROPION-Breast02 (NCT05374512) is an ongoing Phase 3, open-label, randomized study of Dato-DXd versus ICC in first-line treatment of patients with locally recurrent inoperable or metastatic TNBC. Approximately 600 patients will be randomized 1:1 to receive either Dato-DXd 6 mg/kg IV every three weeks or ICC (paclitaxel, nab-paclitaxel, carboplatin, capecitabine, or eribulin mesylate). Patients ≥18 years with histologically/cytologically confirmed TNBC who have not received prior chemotherapy or targeted systemic therapy for metastatic or locally recurrent inoperable disease are eligible for inclusion. Patients are also required to have an ECOG PS of 0 or 1 and be eligible for treatment with one of the ICC options per investigator assessment. Patients must have ≥1 measurable lesion per RECIST v1.1 not previously irradiated, along with a formalin-fixed and paraffin-embedded tumor sample available. Those with a previously treated neoplastic spinal cord compression or clinically inactive brain metastases can be included. Key exclusion criteria are history of another primary malignancy; persistent toxicity from previous anti-cancer treatments; uncontrolled infections; current/prior interstitial lung disease/pneumonitis or clinically severe pulmonary function compromise; clinically significant corneal disease; and prior treatment with topoisomerase I inhibitors, TROP2-targeted therapy, or the same chemotherapy agent chosen for on-study ICC. The dual primary endpoints are progression free survival (PFS) per RECIST 1.1 by BICR, and OS. Secondary endpoints include ORR, duration of response, PFS by investigator assessment, time to deterioration for patient-reported outcomes, time to first subsequent therapy, time to second subsequent therapy, time to second progression or death, pharmacokinetics and immunogenicity of Dato-DXd, and safety. Recruitment for this study is ongoing as of June 2022.

Background Patients with metastatic triple-negative breast cancer (mTNBC) have a poor prognosis. Treatment combinations of anti-programmed death protein 1 (anti-PD-1) agents with chemotherapy have shown promise in mTNBC. Ladiratuzumab vedotin (LV) is an investigational antibody-drug conjugate directed to LIV-1, a protein highly expressed on breast cancer cells, via a humanized IgG1 monoclonal antibody conjugated to approximately 4 molecules of monomethyl auristatin E (MMAE) by a protease-cleavable linker. LIV-1-mediated delivery of MMAE disrupts microtubules and induces cell cycle arrest and apoptosis. LV has also been shown to drive immunogenic cell death (ICD) to elicit an immune response. LV + pembrolizumab may result in synergistic activity through LV-induced ICD, creating a microenvironment favorable for enhanced anti-PD-1 activity. Interim results from an ongoing, multi-part, open-label study investigating the safety and efficacy of LV in patients with metastatic breast cancer (SGNLVA-001, NCT01969643), showed weekly LV monotherapy at doses up to 1.5 mg/kg were clinically active and generally well tolerated (Tsai 2021). Based on pharmacokinetic and pharmacodynamic modeling and simulation analysis, an intermittent LV + pembrolizumab dosing regimen is being evaluated to further enhance efficacy and improve the tolerability profile. Due to an unmet medical need for patients with unresectable locally advanced (LA)/mTNBC who are programmed death ligand 1 (PD-L1) low or negative, Part D will focus on this patient population. Trial Design SGNLVA-002 (NCT03310957) is an ongoing global single-arm, open-label phase 1b/2 study of LV + pembrolizumab as 1L therapy for patients with unresectable LA/mTNBC. Part D is currently enrolling ~40 patients. Eligible patients must have advanced disease with no prior cytotoxic/anti-PD-1 treatment, PD-L1 combined positive score < 10, measurable disease per RECIST v1.1, and an ECOG performance status ≤1. Patients with Grade ≥2 pre-existing neuropathy or active central nervous system metastases are not permitted. Patients will receive LV at 1.5 mg/kg on Days 1 and 8 every 21 days plus pembrolizumab 200 mg on Day 1 q3w. The primary objectives are to evaluate the safety/tolerability and objective response rate of LV + pembrolizumab. Secondary objectives include duration of response, disease control rate, progression-free survival, and overall survival. Safety and efficacy endpoints will be summarized with descriptive statistics. Global enrollment is ongoing in the US, EU, and Asia.

Background: About 30% of patients (pts) with hormone receptor (HR)-positive early breast cancer (EBC) on adjuvant aromatase inhibitor (AI) therapy discontinue due to toxicity with 22% of pts discontinuing during the first year (Henry et al. JCO 2012). For these patients who struggle with adjuvant AIs, there are limited alternatives including switch to a different AI which may have similar side effects, tamoxifen, or observation. This paucity of effective and tolerable options may contribute to poor adherence and/or early discontinuation of adjuvant endocrine therapy, which is associated with worse outcomes. Amcenestrant (SAR439859) is an optimized oral selective estrogen receptor degrader (SERD) with potent dual activity which antagonizes and degrades the estrogen receptor (ER), resulting in inhibition of the ER signaling pathway. In the phase 1/2 AMEERA-1 first-in-human trial (SABCS 2020 PD8-08), amcenestrant showed strong antitumor activity and favorable safety profile in the treatment of HR+ metastatic breast cancer. The phase 2 window-of-opportunity study AMEERA-4 evaluating two doses of amcenestrant demonstrated robust Ki67 reductions, strong engagement of the ER target, and

continued to show a favorable safety profile in an early breast cancer population. Based on pharmacodynamic activity, safety, and emerging results from other ongoing amcenestrant trials, the 200 mg daily dose of amcenestrant was selected for the AMEERA-6 study. Trial Design: This is a prospective, randomized, international, double-blind, double-dummy, phase 3 superiority study of amcenestrant versus tamoxifen. Eligible pts are men and women with any menopausal status with HR+ stage IIB/III breast cancer, irrespective of human epidermal growth factor receptor 2 (HER2) status. If neoadjuvant systemic therapy was administered, pts must have residual nodal disease after definitive breast surgery (ypN1-3). Pts will be centrally assessed to have ER-positive and/or progesterone receptor-positive ($\geq 10\%$ positive stained cells) status by immunohistochemistry assay. Pts must have received at least 6 months of adjuvant AIs (≥ 3 months in the adjuvant setting if they received prior neoadjuvant AI) and discontinued within 30 months of initiation due to AI-related toxicity. Pts may have been treated with more than one AI. All adjuvant therapies including chemotherapy, anti-HER2 treatment, cyclin-dependent kinase (CDK) 4/6 inhibitor, and/or poly (ADP-ribose) polymerase (PARP) inhibitors must be completed or stopped prior to randomization. 3738 pts will be randomized 1:1 to receive either amcenestrant 200 mg daily or tamoxifen 20 mg daily for 5 years and will be followed for 10 years from randomization. Men and pre/peri-menopausal women will also receive a GnRH analog. Extended adjuvant endocrine therapy upon completion of study treatment is allowed per investigator discretion. Stratification factors include duration of prior AI therapy, HER2 status and prior chemotherapy, prior CDK4/6 inhibitors, geographic region, and menopausal status. The primary endpoint is invasive breast cancer-free survival (IBCFS) based on STEEP criteria version 2.0 defined as occurrence of first recurrence of the disease: ipsilateral or regional invasive, distant recurrence, contralateral invasive breast cancer and death. Key secondary endpoint is invasive disease-free survival (IDFS) and other secondary endpoints include overall survival, safety, patient reported outcomes, and pharmacokinetics of amcenestrant. Adherence to treatment and biomarkers are exploratory endpoints. AMEERA-6 recruited the first patient in March 2022 and is being conducted in partnership with AFT, BIG, EORTC, and Sanofi. Clinical trial information: NCT05128773

Introduction: We performed matched case-control studies utilizing cohorts of postmenopausal women with ER+ breast cancer receiving adjuvant aromatase inhibitors (AI) on MA.27 [anastrozole, exemestane] or PreFace [letrozole] to assess the association between estrogen suppression after 6 months of treatment and an early breast cancer (EBC) event within 5 years of AI initiation (Clin Cancer Res 2020;26:2986-98). We found a significant 3.0-fold increase in risk of an EBC event for those taking anastrozole with levels of estrone (E1) ≥ 1.3 pg/mL and estradiol (E2) ≥ 0.5 pg/mL, but not for exemestane or letrozole. Given these findings we designed a prospective pharmacodynamic (PD) study to evaluate the impact of anastrozole (1 mg/day: ANA1) on E1 and E2 levels, and among those with inadequate estrogen suppression (IES: E1 ≥ 1.3 pg/mL and E2 ≥ 0.5 pg/mL), to evaluate the safety and PD efficacy of high-dose anastrozole (10 mg/day: ANA10), which has been found to be safe in prior clinical trials (Cancer 1998;83:1142-52). Methods: Post-menopausal women with stage I-III, ER $\geq 1\%$ positive/HER2-negative breast cancer who were candidates for anastrozole were eligible after completion of locoregional therapy and chemotherapy, as clinically indicated. Women who were pre-menopausal at diagnosis were not eligible. All patients received 8-10 weeks of ANA1, after which those with adequate estrogen suppression (AES: E1 < 1.3 pg/mL or E2 < 0.5 pg/mL) came off study. Those with IES went on to receive ANA10 for 8-10 weeks, followed by letrozole (2.5 mg/day: LET) for 8-10 weeks. All patients were managed at their treating oncologist's discretion following study discontinuation. E1 and E2 blood levels were measured pre-treatment

and after completion of each treatment cycle by a CLIA-approved liquid chromatography with tandem mass spectrometry in the Immunochemical Core Laboratory at Mayo Clinic. With a sample size of 29 patients with IES after ANA1, a one-sided binomial test of proportions with a significance level of 0.05 will have an 87% chance of rejecting the proportion with AES after ANA10 is at most 25% (H_0) when the true proportion is at least 50%. Specifically, the null hypothesis is rejected if the number of women with AES after ANA10 is 12 or more. Data lock was July 6, 2022. Results: Of the 161 women enrolled from April 2020 through May 2022, 3 withdrew consent prior to start of ANA1 and 2 were ineligible; thus, 156 women comprised the study cohort. Median patient age was 64 years (range 44-86), 10% of patients were of Hispanic ethnicity and/or non-white race, and 15% received chemotherapy. Six patients remain on ANA1, and 10 discontinued ANA1 due to refusal (7), adverse event (AE) (2), or COVID-19 (1). Forty-one of the remaining 140 patients (29.3%; 95%CI: 21.9-37.6%) had IES with ANA1. Nine of these 41 patients did not go on to ANA10 due to refusal (6) or AE (3). Of the 32 patients who started ANA10, 8 remain on treatment, 5 discontinued due to refusal (3) or AE (1-grade 2 urinary tract infection; 1-grade 1 palpitations), and 19 had a blood draw 45 days or more after starting ANA10. No grade 3-5 AEs or grade 2 hot flashes or arthralgias were reported. Of these 19 patients, 14 achieved AES with ANA10 (73.7%; 95%CI: 48.8-90.9%). All 19 patients switched to LET of which 3 remain on treatment, 1 is missing E1/E2 data, and 15 had a blood draw 45 days or more after starting LET. Of these 15 patients, 10 maintained AES, 2 acquired AES with LET, and 3 no longer had AES. Anastrozole and letrozole drug levels will be reported at the meeting. Conclusions: Approximately 29% of postmenopausal women with ER+/HER2-BC receiving adjuvant anastrozole 1 mg/daily had IES. A majority of these patients achieved AES with dose escalation to ANA10 without tolerability issues. E1 and E2 levels are logical biomarkers given the mechanism of action of anastrozole, and further study utilizing them to determine the optimal dose of anastrozole for a given patient should be performed.

Background : Anti-PD-1 antibody combined with antiangiogenic drugs have demonstrated antitumor activity in advanced triple negative breast cancer (TNBC). Anlotinib, an oral multi-targeted tyrosine kinase inhibitor (TKI), has synergistic effect with anti-PD-1 antibody. Preclinical studies showed that metronomic chemotherapy inhibited angiogenesis and enhanced immunotherapy efficacy in TNBC via modulation of tumor immune microenvironment. We hereby conducted a single-arm, multicenter, phase II trial to investigate the efficacy and safety of sintilimab (anti-PD-1 antibody) in combination with anlotinib plus metronomic chemotherapy as a potential novel therapeutic strategy in advanced TNBC and explore potential biomarkers. Methods : Forty-three cases were planning to be included in this trial. The eligible patients who had received no more than two lines of chemotherapy for metastatic disease were enrolled and received sintilimab (200 mg iv q3w) in combination with anlotinib (12

mg po d1-14 q3w) plus capecitabine (500 mg po, tid) or vinorelbine (40 mg po, tiw) until disease progression or intolerable toxicity. The primary endpoint is objective response rate (ORR) and secondary endpoints are disease control rate (DCR), progression free survival (PFS), and overall survival (OS). The safety profile has also been assessed. Blood samples collected at different time points of the baseline, first and second cycle post-treatment, and disease progression were used for next-generation sequencing of ctDNA containing 654 tumor-related genes. Results: As of July 2022, a total of 32 patients were enrolled, and 29 patients were evaluable for efficacy. 2 patients (6.9%) achieved complete response (CR). 6 patients (20.7%) achieved partial response (PR). The ORR is 27.6% (8/29) and DCR is 79.3% (23/29). The median PFS was not reached. The most common grade 1 or 2 adverse events (AEs) include elevated thyroid stimulating hormone (37.0%, 10/27), hand-foot syndrome (18.5%, 5/27), elevated aspartate aminotransferase (14.8%, 4/27), elevated bilirubin (11.1%, 3/27) and hypertension (11.1%, 3/27). Grade 3 AEs include elevated bilirubin (3.7%, 1/27) and hypertension (3.7%, 1/27). No grade 4 or 5 AEs occurred. By analyzing ctDNA mutations of blood samples in 10 patients at baseline, we found that genes with high mutation frequency were HLA-DRB5 (8/10, 80%), TP53 (7/10, 70%), HLA-DRB1 (5/10, 50%) and PIK3CA (4/10, 40%). Among these 10 patients, 2, 3 and 5 patients achieved PR, SD and PD, respectively. The number of gene mutations in patients with PD was higher than that in patients with PR or SD at baseline. This indicate that mutations in ctDNA may be associated with poor efficacy in advanced TNBC. But this still needs further verification. Dynamic analysis of gene mutations at different time points showed that the amplification of HLA-DRB5 or the elimination of KMT2D, RELN and TP53 occurred in patients with PR and SD, but not in patients with PD. Conclusions: Sintilimab in combination with anlotinib plus metronomic chemotherapy has shown favorable efficacy and acceptable safety profile in patients with advanced TNBC. The clinical significance of ctDNA dynamic monitoring needs further validation. Clinical trial information: ChiCTR2100044725

Introduction: Axillary lymph node dissection (ALND) has always been part of breast cancer (BC) treatment. However, during the past 25 years, the surgical management of the axilla has shifted towards a more conservative approach. Until now, ALND has remained the standard surgical technique when the sentinel lymph node (SLN) is macrometastatic. However, ALND may now be considered overtreatment for early-stage BC. The SINODAR-ONE trial is a prospective non-inferiority multicenter randomized study aimed at assessing the role of ALND in patients undergoing either breast-conserving surgery (BCS) or mastectomy for T1-2 BC presenting 1-2 macrometastatic SLNs. Objectives: The primary endpoint was to evaluate whether sentinel lymph node biopsy (SLNB) only was associated with clinically relevant worsening of the prognosis compared with ALND in terms of overall survival (OS). The secondary endpoint was to evaluate whether there was increased regional (lymph node recurrence) or distant recurrence in terms of recurrence-free survival (RFS) in patients with macrometastatic SLN who did not undergo ALND. Methods: Patients were randomly assigned (1:1 ratio) to either removal of ≥ 10 axillary level I/II non-SLNs followed by adjuvant therapy (standard arm) or no further axillary treatment (experimental arm). Results: The trial started in April 2015 and ceased in April 2020, involving 889 patients. The majority of the patients (75.2%) underwent BCS; 328 of 439 patients (74.7%) in the standard treatment arm, and 333 of 440 patients (75.7%) in the experimental treatment arm. 218 patients (24.8%) underwent mastectomy. SLN status at randomization was comparable between the two groups of treatment, with a median number of two SLNs removed and a median number of one positive SLN in both arms. The median number of non-SLNs identified at definitive histopathological evaluation was 16 (interquartile range [IQR] 12–21) in the ALND group. Overall, 193 of 439 patients (44.0%) in the standard treatment arm had additional macrometastases in the removed axillary lymph nodes. However, the median number of positive non SLNs was 0 (IQR 0–1) in the ALND group. Median follow-up was 34.0 months. There were eight deaths (ALND, 4; SNLB only, 4), with a 5-year cumulative mortality of 5.8% and 2.1% in the standard and experimental arm, respectively ($p = 0.984$). There were 26 recurrences (ALND 11; SNLB only, 15), with a 5-year cumulative incidence of recurrence of 6.9% and 3.3% in the standard and experimental arm, respectively ($p = 0.444$). Only one axillary lymph node recurrence was observed in each arm. The 5-year OS rates were 98.9% and 98.8%, in the ALND and SNLB only arm, respectively ($p = 0.936$). Conclusion: The 3-year survival and relapse rates of T1-2 BC patients with 1-2 macrometastatic SLNs treated with SLNB only, and adjuvant therapy, were not inferior to those of patients treated with ALND. These results do not support the use of routine ALND in patients undergoing BCS. However, given the low number of patients treated with mastectomy, there is no certainty that ALND omission can be extended also to this sub-group. In order to collect further evidence regarding the safety of the experimental treatment in patients candidates for mastectomy, the reopening of the enrollment of these patients as part of a single-arm experimental study started in June 2022.

Background: Currently, axillary surgery for breast cancer is considered a staging procedure that does not seem to influence breast cancer mortality since the risk of developing metastasis depends mainly on the biological behavior of the primary (seed-and-soil model). Based on this, postsurgical therapy should be considered based on biological tumor characteristics. Retrospective data of cancer registry trials showed a strong correlation between breast pathologic complete response (pCR) and nodal pCR depending on intrinsic subtypes. Improvements in systemic treatments for breast cancer have increased the rates of pCR in patients receiving neoadjuvant systemic therapy (NAST), offering the opportunity to decrease, and perhaps eliminate, surgery in patients who have a pCR. Trial design: The EUBREAST network designed a clinical trial (NCT04101851) in which only patients with the highest likelihood of having a pCR after NAST (triple-negative or HER2-positive breast cancer) will be included, and type of surgery will be defined according to the response to NAST rather than on the classical T and N status at presentation. In the ongoing trial, axillary surgery will be eliminated (no axillary sentinel lymph node biopsy [SLNB]) for initially clinical node-negative (cN0) patients with radiologic complete remission (rCR) and a breast pCR (ypT0/ypTis) as determined in the lumpectomy specimen. The trial design is a multicenter single-arm study with a limited number of patients (N=440 as the screening population with an expected 80% pCR-rate) which might give practice-changing results in a short period, sparing the time and the costs of a randomized comparison. Patients will be recruited in European countries (Austria, Germany, Italy, and Spain) over 36 months. Inclusion criteria: -Written informed consent - Histologically confirmed unilateral primary invasive carcinoma of the breast (core biopsy). Multifocal or multicentric tumors are allowed if breast-conserving surgery (BCS) is planned. - Age at diagnosis at least 18 years -imaging techniques with estimated tumor stage between cT1-T3 before NAST -triple-negative (TNBC) or HER2-positive invasive breast cancer -TNBC is defined by: ER-negative (< 10% positive cells in IHC) and PgR-negative (< 10% positive cells in IHC), HER2-negative -clinically and sonographically tumor-free axilla before core biopsy (cN0/iN0) -in cases with cN0 and iN+, a negative core biopsy or fine-needle aspiration biopsy of the sonographically suspected lymph node is required -no evidence for distant metastasis (M0) -standard NAST with rCR -planned BCS with postoperative external whole-breast irradiation (conventional fractionation or hypofractionation) Primary objective: 3-year rate of axillary recurrence-free survival (ARFS) after BCS Statistics: The calculated total case number for per-protocol analysis is N=350, and the expected total number of screened patients is N=440. The assumption for acceptable 3-year ARFS $\geq 98.5\%$ in the experimental arm is based on previous study findings. Timelines: -First patient in: January 2021 -Last patient in: December 2023 - Primary outcome analysis: Q1/2027 Current accrual: In June 2022, 150 patients were recruited in Germany and Italy. AXSANA – EUBREAST3: An international prospective multicenter cohort study to evaluate different surgical methods of axillary staging in clinically node-positive breast cancer patients treated with neoadjuvant chemotherapy

Presenting Author(s) and Co-Author(s):

Thorsten Kühn, MD, PhD, *Head of Clinic for Gynecology and Obstetrics - Department of Gynecology, Hospital Esslingen, Esslingen, Germany*

Country: United States

Background The optimal surgical staging procedure of the axilla in patients who convert from a clinically positive (cN+) to a clinically negative node status (ycN0) through neoadjuvant chemotherapy is still controversial. Widely diverse techniques such as full Axillary Lymph Node Dissection (ALND), Targeted Axillary Dissection (TAD), Targeted Lymph Node Biopsy (TLNB) and Sentinel Lymph Node Biopsy (SLNB) alone are given preference in different international guidelines. So far, no comparative data on the oncological outcome or the morbidity of the different procedures are available. Further research is needed to safely de-escalate the extent of axillary surgery in this patient group. **Trial design** The AXSANA study is an international prospective cohort study including cN+ patients converting to ycN0 status and treated with different axillary staging techniques according to the standard at their treating institution. The study was initiated by the EUBREAST network. The trial includes patients with cT1-4c tumors, who present initially with clinically axillary lymph node involvement metastasis scheduled for neoadjuvant chemotherapy. According to an amendment in 2020 the inclusion of patients with highly suspicious nodes without confirmation using a minimally invasive biopsy is allowed. All patients converting to ycN0 status undergo follow-up for 5 years irrespectively of the ypN status. **Primary endpoints:** Invasive disease-free survival, axillary recurrence rate and health-related quality of life (HRQoL). HRQoL are evaluated using four standardized questionnaires (EORTC QLQ-C 30, EORTC QLQ-BR23, Lymph-ICF and SOC 13) at baseline and after 1, 3 and 5 years after surgery. **Secondary endpoints** are the feasibility and performance of different axillary staging techniques (detection rate, number of removed lymph nodes and association with complications, arm morbidity and quality of life, operating time and use of clinical and economic resources); impact of learning curve, and the detailed mapping of surgical and oncological treatment standards in different countries. The impact on different regional treatment strategies (radiotherapy, ALND) in patients with ypN0(i+), ypN1(mi) and ypN1 is assessed. **Current status of the study:** 2347 patients from 247 study sites and 23 countries were enrolled in the study between June 2020 and June 2022. Among 1804 patients with a defined surgical concept 758 women were scheduled for ALND, 722 for TAD, 232 for SLNB, 16 for TLNB and 19 for other procedures. A target lymph node was marked in 1215 patients, most frequently using clips/coils (982, 82.0%), followed by magnetic seeds (100, 8.4%), carbon ink (99, 8.3%), radar marker (21, 1.8%), radioactive seeds (5, 0.4%), and other techniques (8, 0.7%).

Background : In breast cancer patients, neoadjuvant chemotherapy (NAC) allows to obtain pathological complete response (pCR). In case of initially involved node before NAC, pCR after NAC could make it possible to avoid axillary surgery. The aim of our study was to address parameters to build a tool able to accurately select patients at a high probability of axillary pCR after NAC. Method : GANEA 3 was a French prospective multi institutional cohorts of breast cancer patients with a proven axillary involved node treated with NAC (NCT03630913). Initially involved node was clipped before treatment. Each patient received, before and after NAC, a bilateral mammography, a Magnetic Resonance Imaging (MRI), an axillary sonography. After NAC breast, conservative or radical, and axillary surgery, were performed. Breast surgery allowed to measure breast tumor residual and to perform a Sataloff classification. Targeted axillary detection (TAD) was defined as the combination of the resection of the clipped node and SLN dissection. Axillary clipped node, sentinel lymph node (SLN) and axillary lymph node dissection (ALND) were always performed. ALND allowed to assess the false negative rate (FNR) of axillary clipped node and SLN dissection. A total of 500 included patients is planned to close this still ongoing trial. Results : From January 2019 to March 2022, 405 patients were included from 18 institutions. We present here the results of the 260 first patients, who experienced a complete treatment with NAC courses and post NAC breast and axillary surgery. Among these patients, SBR grade was III in 52%, OR and PR were positive in 59% and 46% respectively, HER2 was overexpressed in 40%, 26% were triple negative and pCR was present in 28%. FNR of the SLN detection was 21.1%, 9% for the clipped node alone and 6% for the TAD. Histopronostic grading, progesteron receptors, HER2 expression, MRI results and Sataloff grading of breast residual tumor were indepently linked with global pCR (breast and axilla) in multivariate analysis. The Area Under the Curve (AUC) model was 0.91 with 82% correctly patients classified. The false negative rate of no pCR classified patients was 14%. Conclusion : Intermediate results of Ganea 3 trial showed that operable breast cancer patients with an initially involved axillary node treated with NAC, showed that TAD allows to reduce the FNR of axillary surgery. Patients with histopronostic grade 3, negative progesteron receptors, HER2 overexpression, a normal MRI after NAC and a breast Sataloff A, have a low risk of axillary tumour residual burden and could be safely spare from any axillary surgery. Large prospective trials are needed to confirm the safety of this surgical de-escalation.

Background: For patients who are node positive at presentation and are found to have a complete nodal tumour response (ypN0) post-neoadjuvant chemotherapy (NACT), we do not yet know whether local axillary therapy can be modified based on the response to NACT. ATNEC addresses whether axillary treatment can be de-escalated, post-surgery, in T1-3N1M0 breast cancer patients who have no residual nodal disease post-NACT. Methods: Design: ATNEC is a phase III, randomized (1:1), multi-centre trial, with embedded economic evaluation. Patients with proven axillary node metastases on needle biopsy receive NACT followed by sentinel node biopsy (SNB). If the sentinel nodes have converted to ypN0, ATNEC randomizes patients to axillary treatment (nodal radiotherapy [ART] or axillary nodal clearance [ANC]) vs. no further axillary treatment. Stratification: Institution, type of surgery (breast conserving surgery vs mastectomy), receptor status (triple negative vs HER2 positive vs ER positive and/or PR positive and HER2 negative). Inclusion criteria: • Age \geq 18 • Male or female • T1-3N1M0 breast cancer at diagnosis (pre-NACT) • FNA or core biopsy confirmed axillary nodal metastases at presentation • ER and HER2 status evaluated on primary tumour • Received standard NACT as per local guidelines • Imaging of the axilla to assess response to NACT • Dual tracer SNB post-NACT and at least 3 nodes removed (sentinel nodes and marked node).
o If a single tracer is used, the patient is eligible if the involved node is marked pre-NACT and at least 3 nodes removed (including the marked node)
o If axillary node sampling is performed following failed localization of sentinel nodes, patient is eligible if at least 3 nodes removed (including the marked node).
o If node is not marked, or marked node is not removed, patient is eligible if the histology report shows evidence of down-staging with complete pathological response in at least one node of the 3 removed nodes. • No evidence of nodal metastases post-NACT (ypN0) Exclusion criteria: • Bilateral invasive breast cancer • SNB prior to NACT • Previous ipsilateral axillary nodal surgery • Previous cancer within last 5 years or concomitant malignancy Aims: To assess whether omitting further axillary treatment (ART or ANC) for patients with early stage breast cancer and axillary nodal metastases on needle biopsy - who post NACT have no residual nodal disease on SNB (ypN0) - is non-inferior to axillary treatment in terms of disease-free survival, and whether lymphoedema is reduced at 5 years. Statistical methods: All analyses will be carried out on an intention-to-treat basis to preserve randomization, avoid bias from exclusions and preserve statistical power. Radiotherapy Quality Assurance: ATNEC has in-built radiotherapy QA coordinated by National Radiotherapy Trials QA (RTTQA) group. The RTQA monitors trial protocol compliance ensuring clinical outcomes reflect differences in randomization schedules rather than departures from the protocol. ATNEC is the only trial in the UK that offers QA for IMC radiotherapy. Screening Data: ATNEC collects screening data to monitor acceptance rates and reasons why patients decline the trial to identify ways to improve recruitment. Screening data until 30-Jun-22 shows that 69% of eligible patients were approached (244/354) and, of those approached, 45% were consented (109/244). For the 81 patients who declined, the most common reasons were; preference for axillary treatment (31%), preference for no axillary treatment (10%), no reason documented (23%) and ineligibility (21%). ClinicalTrials.gov: NCT04109079 Target accrual: 1900 Target sites: 100 Trial Status: Recruiting. As of 30-Jun-22: 52 sites open, 158 patients enrolled, 54 randomised. ATNEC is open to new sites and international collaboration.

Treatment with Tucatinib in addition to Pertuzumab and Trastuzumab in patients with HER2-positive metastatic breast cancer (HER2+ MBC) after local therapy of isolated brain progression: InTTercePT, a UCBG/GINECO study. Background HER2+ MBC patient on first line treatment with pertuzumab and trastuzumab have a 13% risk of developing brain metastasis (BM) as the first site of progression. For such patient with isolated brain progression, guidelines recommend to use central nervous system (CNS) directed therapy whenever possible (stereotactic radiosurgery or surgery or both). These patients will have a higher risk of subsequent brain and systemic progression after local treatment. Therefore, whether systemic treatment should be continued or changed remains an open question. The tyrosine kinase inhibitor tucatinib is an orally bioavailable HER2 inhibitor with validated antineoplastic activity and the ability to cross the blood brain barrier. The randomized HER2CLIMB study, demonstrated that adding tucatinib to trastuzumab/capecitabine improved both progression-free survival (PFS) and overall survival (OS) among HER2+ MBC patients previously treated with trastuzumab, pertuzumab and T-DM1. Particularly, this regimen demonstrated improved antitumor activity in patients with BM, in terms of CNS-PFS and OS. Exploratory analysis of HER2CLIMB and in a phase 1b study, showed patients who continued systemic treatment with tucatinib (in combination either with trastuzumab/capecitabine or TDM-1) after CNS-directed treatment had a better outcome compared with those that discontinued systemic tucatinib-based treatment. These results suggest that for patient in the first line metastatic setting who experience isolated brain progression, adding tucatinib to the trastuzumab/pertuzumab regimen could help control BM, improve PFS, OS and patients' quality of life. Trial design InTTercePT is an open-label, single-arm, national, multicentric, phase II trial assessing the combination of tucatinib, pertuzumab and trastuzumab. Tucatinib will be administered orally twice daily at 300 mg. Pertuzumab and trastuzumab will be administered at the initial dose of 840 mg and 8 mg/kg respectively following by a maintenance dose of 420 mg and 6mg/kg respectively, 3-weekly. If indicated, hormone therapy is allowed in combination with HER2-directed therapy. Eligibility criteria include HER2+ MBC with isolated brain progression (new or progressive BM with stable or responding systemic disease) under pertuzumab/trastuzumab treatment (\pm taxane) after complete local treatment (surgery and/or radiation therapy). There is no limit to the number and size of BM. Specific aims To evaluate the efficacy, in terms of PFS rate (RECIST v1.1) of tucatinib in combination with pertuzumab/trastuzumab. Secondary endpoints include OS, brain PFS (RECIST v1.1) and BM response in patient not in complete remission at the brain level after local treatment and safety (NCI-CTCAE v5.0). Statistical methods Given the lack of safety data from this association, two interim safety analysis are planned: after 10 and 20 patients having received at least one dose of the treatments combination during at least one cycle. The number of patients to be included was calculated using Fleming's single-stage procedure for phase II trials. The sample size calculation was based on a minimum success (non-progression rate at 6 months) considered of interest of $p_1 = 75\%$ and an uninteresting rate of $p_0 = 60\%$. Assuming a unilateral type I error alpha of 10% and a power of 85%, 52 patients are needed. Considering 5% of the patients may be non-evaluable, 55 patients will be included. At the time of analysis, if at least 37 successes are observed, the treatment will be considered as interesting for further investigation. The study is recruiting. By July 1, 2022, 10 patients have been screened and 8 treated (NCT05041842). Funding SeaGen Contact information thomas.bachelot@lyon.unicancer.fr

Background: Development of brain metastasis (BM) portends poor prognosis in patients (pts) with metastatic breast cancer (MBC) mainly due to lack of systemic therapy with strong activity in CNS. While survival in HER2+ BC BMs has improved due to development of various HER2 therapies with activity against BM, outcome for HER2- BC BMs remains dismal. A novel assay (CELsignia) which measures underlying HER2 signal (HS) of live cancer cells in response to HER2 agonists & antagonists showed that about 25% of BC deemed HER2- by standard methods have underlying abnormal HS. Preclinical data showed various HER2 therapies inhibit tumor growth of such HER2- BC with abnormal HS. Among tested HER2 inhibitors with known CNS activity, neratinib had the lowest IC50. We propose a trial which identifies HER2- BC BM pts with abnormal HS & assesses activity of neratinib based therapy. Design: This is a phase II single arm study with 2 steps- step 0 (biopsy) & step 1 (treatment). Pts eligible for Step 0 will be registered as "Immediate Treatment (IT)" (intent to register to Step 1 immediately) or "Future Treatment" [registration can be delayed up to 28 weeks (wks)] & undergo biopsy of most accessible extra CNS (eCNS) tumor. Tumor will be sent for CELsignia testing (2 wks turn around). Additional biopsies may be obtained for standard of care (SOC). IT pts can be treated

with a brief course of capecitabine 1gm/m² BID for 1 wk followed by 1 wk off while waiting for CELSigia result. Pts with BC having abnormal HS will be screened & registered to step 1. Enrolled pts will receive neratinib 240mg daily (with SOC anti-diarrheal prophylaxis) + capecitabine 750mg/m² BID for 2 wks in every 3 wks cycle (C). Tumor assessments will be done prior to C3, 5 & 7 then every 12 wks with MRI brain, CT chest abdomen pelvis & bone scan using RECIST1.1 (eCNS disease) and a modified BM RANO criteria (>5mm, measurable disease, CNS). In isolated CNS progression, investigators have option of treatment beyond progression after SOC local treatment of progressing BMs. Key Eligibility Criteria: Step 0: Inclusion Criteria (IC): histologically confirmed HER2- BC (primary or metastatic); has radiological evidence of BM; prior treatment with CDK4/6 inhibitor + endocrine therapy required for hormone receptor+ BC, no prior specific treatment required for triple negative BC; radiological evidence of eCNS measurable disease (RECIST1.1) accessible for biopsy. Exclusion Criteria (EC): prior use of capecitabine in metastatic setting; known/suspected leptomeningeal disease. Step 1: IC: Abnormal HS; New or progressing BM that is measurable (>5mm); minimum washout periods in wks: last chemotherapy 2, hormonal therapy 1 except fulvestrant 4, targeted therapies 3, eCNS radiation 1, any investigational treatment 4. ECOG performance status 0-2; adequate end organ functions. EC: whole brain radiation in last 3 months (m). Endpoints: Co-primary: Overall survival (OS) and CNS progression free survival (CNS PFS). Key Secondary: Objective response rate, clinical benefit rate and duration of response (CNS using BM RANO, eCNS using RECIST1.1), eCNS PFS, various feasibility endpoints. Safety. Statistical methods: To detect 70% improvement in this trial in CNS PFS and OS compared to historical control (BEACON trial BM subset) 2.7m vs. 4.6m and 4.8m vs. 8.2 m with 80% power and 1-sided 5% significance level, a sample size of 22 is required. About 88 patients will undergo biopsy to enroll 22 pts in step 1. One fertility assessment is planned when the first 12 pts have been treated for at least 6 wks or have failed (died or progressed) prior to 6 wks. If 9 or more in the first 12 have died or progressed by 6 wks of treatment, the study will close for fertility. PFS and OS will be analyzed using Kaplan-Meier survival functions. Background: PARP inhibitors are currently approved for the treatment of germline BRCA1/2 mutant metastatic breast cancer (MBC), which accounts for 5-10% of breast cancer. We hypothesize that a PARP inhibitor may also have efficacy in somatic BRCA1/2 mutant MBC, expanding the potential clinical applicability of PARP inhibitors. We previously demonstrated that somatic BRCA1/2 mutations can be identified by both cell-free DNA and tumor tissue genotyping in a subset of patients with MBC who are not germline BRCA1/2 carriers. Furthermore, a PARP inhibitor was demonstrated to induce cell growth inhibition in a circulating tumor cell culture model generated from a patient with pathogenic somatic BRCA1 mutant MBC (Vidula, Dubash, CCR, 2020). In this trial, we are evaluating the efficacy of a PARP inhibitor in somatic BRCA1/2 mutant MBC. Trial Design: This phase II investigator-initiated clinical trial is enrolling 30 patients with somatic BRCA1/2 mutant MBC identified via cell-free DNA or tumor tissue genotyping. Patients are treated with talazoparib, a PARP inhibitor, until disease progression. At baseline and every 3 months, patients undergo CT chest, abdomen, and pelvis, and a bone scan for disease assessment. Patients undergo blood collection at baseline for the Cancer Risk B (CR-B) assay, a novel flow variant assay to assess double-strand break repair mutations in circulating blood cells (Syeda, 2017) and monthly blood collection for cell-free DNA analysis to evaluate changes in the genomic environment. Eligibility Criteria: Patients with MBC with a pathogenic somatic BRCA1/2 mutation identified by cell-free DNA or tumor tissue genotyping are eligible. Both patients with triple-negative breast cancer (≥ 1 prior chemotherapy) or hormone receptor positive/HER2- MBC (≥ 1 prior hormone therapy) are eligible. Patients should not be known germline BRCA1/2 carriers. There is no limit on prior therapies including receipt of a prior platinum (in the absence of disease progression on prior platinum). A prior PARP inhibitor is not allowed. Adequate performance status and organ function are needed. Specific Aims: Primary aim is progression-free survival (PFS) assessed by RECIST 1.1. Secondary aims include objective response rate and toxicity assessed by NCI CTCAE v 5.0. Exploratory aims include assessing impact of BRCA1/2 reversion mutations in cell-free DNA, studying serial changes in BRCA1/2 mutant allelic frequency in cell-free DNA, comparing pre- and post-treatment cell-free DNA results to identify changes in the genomic environment, assessing the CR-B assay positivity rate, and correlating these biomarker analyses with patient response. Statistical Methods: This study uses a two-stage design with 80% power to demonstrate that talazoparib is associated with "success" (PFS > 12 weeks) in 53% patients (4% alpha). Accrual: This study (NCT03990896) is open at Massachusetts General Hospital, MD Anderson, University of California San Francisco, and Emory, with pending activation at Northwestern, Cornell, and Vanderbilt. Five patients are enrolled as of 7/2022. Funding: This study is supported by a Pfizer ASPIRE award and Conquer Cancer Foundation of ASCO–Breast Cancer Research Foundation- Career Development Award. BACKGROUND: Approximately 50% of newly diagnosed breast cancers are stage 1, with the majority being ER/PR-positive, HER2-negative. Genomic assays such as Oncotype DX® have identified pts with reduced distant metastasis and without benefit from chemotherapy, freeing patients from excess toxicity. Also, these genomic assays are prognostic of local-regional recurrence (LRR). The de-escalation of therapy is of interest to pts, providers, and payers. Low risk, as identified by Oncotype and MammaPrint®, is associated with low LRR after BCS and breast radiotherapy (RT). **METHODS:** We hypothesize that BCS alone is non-inferior to BCS plus RT for ipsilateral breast recurrence (IBR) and breast preservation in women intending appropriate endocrine therapy (ET) for stage 1 (ER and/or PR positive, HER2-negative, with an Oncotype DX Recurrence Score [RS] of ≤18) breast cancer. Stratification is by age (< 60; ≥60), tumor size (≤1 cm; >1-2cm), and RS (< 11; 11-18). Pts are randomized post-BCS to Arm 1 with breast RT using standard methods (hypo- or conventional-fractionated whole breast RT with or without boost, APBI) plus 5 years of ET (tamoxifen or AI) or Arm 2 with 5 years of ET (tamoxifen or AI) alone. The specific regimen of ET in both arms is at the treating physician's discretion. Eligible pts are stage 1: pT1 (≤2 cm), pN0, age ≥50 to < 70 years, s/p BCS with

negative margins (no ink on tumor), s/p axillary nodal staging (SNB or ALND), ER and/or PR positive (ASCO/CAP), HER2-negative (ASCO/CAP), and have an Oncotype DX RS of ≤ 18 (diagnostic core biopsy or resected specimen). Primary endpoint is IBR. Secondary endpoints are breast conservation rate, invasive in-breast recurrence, recurrence-free interval, distant disease-free survival, overall survival, patient-reported breast pain, patient-reported worry about recurrence, and adherence to ET. We assume a clinically acceptable difference in IBR of 4% at 10 years to judge omission of RT as non-inferior (10-year event-free survival for RT group is 95.6% versus 91.6% for the omission-of-RT group). The study is designed to be able to detect non-inferiority with 80% power and a one-sided $\alpha=0.025$, and assuming that there would be a ramp-up in accrual in the first two years of the study (leveling off in Years 3-5), 1,670 (835 per arm) patients are required to be randomized. Conservative loss to follow-up is 1% per year. Some of the T1a pts screened will have Oncotype DX scores >18 , making them ineligible for the study. In the accrual process, pts will be required to register (1,714 patients) to ensure that our final randomized cohort is 1,670 pts. Accrual as of 6-30-2022 is 169 screened and 147 randomized. Background: Breast conserving surgery (BCS) is typically followed by adjuvant radiotherapy (RT) based on several landmark trials demonstrating improvements in disease control and survival. Since completion of these historical trials, the advent of molecular subtyping has revealed that breast cancer is not a single disease entity, but rather a class of cancers with differential risk profiles. We evaluated whether RT could be safely omitted following BCS for patients with the most favorable subtype as defined by the Prosigna PAM50 assay. Methods: We conducted a multicenter prospective single-arm cohort study with IRB approval and an FDA investigational device exemption (IDE). Eligible patients were women 50 to 75 years of age (inclusive) who had undergone BCS revealing tumors ≤ 2 cm in size, that were estrogen or progesterone receptor positive (HR+), HER2 negative, grade 1-2, node negative (N0), with negative excision margins (no ink on tumor). Intent to take endocrine therapy was required. Upon registration, tumors were submitted for central Prosigna testing and those with Risk of Recurrence (ROR) score ≤ 40 were deemed eligible for the investigational omission of RT. The primary endpoint was the 5-year locoregional recurrence rate (LRR). Anticipating a total of 345 RT-omitting patients to enroll over 3.5 years, the study was designed with 90% power to exclude a 5-year LRR of 5% using a one-sample exponential test with one-sided type I error of 0.025. Results: From 2016 to 2020, 671 patients were registered from 13 centers, inclusive of affiliated regional network sites. Of these, 382 patients had a ROR Score ≤ 40 and opted to forego RT, comprising the main intention-to-treat (ITT) study population. Median age was 65 years (range 50 to 75), and median tumor size was 0.9 cm (range 0.1 to 2.0 cm). At a median follow-up of 26.9 months, 12 events were observed: 4 patients had ipsilateral in-breast recurrences, 7 had contralateral breast cancers, and 1 developed an unrelated melanoma. There were no regional-nodal or distant recurrences. The 2-year cumulative rate of LRR was 0.3% (95% CI: 0 – 1.0%). Of the 4 ipsilateral breast recurrences, 2 were in the same quadrant as the original primary tumor. Conclusion: In this preliminary report of the PRECISION trial, patients 50-75 years of age undergoing BCS and endocrine therapy for pT1N0 HR+ HER2-negative breast cancer with ROR score ≤ 40 had exceedingly low rates of LRR in the absence of adjuvant RT at a median follow-up of 26.9 months. Additional follow-up is required to determine whether these favorable results are durable.

Introduction: Precision breast conserving surgery (PBCS) requires doctors to precisely remove the tumor while preserving as much normal tissue as possible. The aims of this study were to determine whether wire-guided localization (WGL) combined with multidetector CT (MDCT) guided 3D reconstruction could guide PBCS.

Methods: From 2020 to 2022, 31 patients with unifocal breast cancer were enrolled for PBCS guided by WGL combined with MDCT guided 3D reconstruction. Surrounding WGL was performed under local anesthesia, followed by an immediate contrast enhanced MDCT scan. PBCS guided by MDCT guided 3D reconstruction was performed one day after the localization. Women who underwent palpation guided BCS were included as control, and logistic regression analysis was applied.

Results: PBCS were performed in 31 patients. The mean tumor size in US was 19.48±5.86mm (9-32mm). Compare with control group, a smaller specimen diameter was observed in PBCS group (P=0.005), and the rate of the largest margin greater than or equal to 20mm were significantly lower (P=0.004). The operation time of PBCS was shortened (P=0.046). Moreover, PBCS does not affect the reoperation rate (P=0.514) or the rate of positive margins (P=0.660). Conclusion: For patients with unifocal breast cancer, WGL combined with MDCT guided 3D reconstruction could guide PBCS without affecting the safety.

Table 1 Baseline characteristics of patients in PBCS_group and control group.

Background Re-operation for involved margins in breast conserving surgery is associated with worse cosmetic outcome, increased medical costs, and patient anxiety. Therefore, obtaining negative margins during primary BCS is essential. In our prior non-interventional study, published in October 2021 (Thill M et al., J Surg Oncol 2021) the re-operation rate would have been reduced by 83% for invasive carcinoma, from 10% to 2%, and 50% for DCIS, from 30% to 15% re-operations, if results had not been blinded for the surgeon. The results suggested a potential reduction of the re-operation rate by up to 80% for patients undergoing BCS. Aim of the study Aim of our current study is to evaluate the interventional performance of the ClearCoast™ system (ClearCut Medical, Ltd.) in assessing surgical margins for IBC in breast conserving surgery (BCS) and reducing the re-excision rates. Material and Methods The ClearCoast™ system utilizes a diffusion-weighted-imaging (DWI) protocol to create 2D surface maps showing T2*, a MR parameter related to the tissue's apparent diffusion coefficient (ADC), with a depth penetration of 1mm. ADC is a highly accurate differentiator for irregular versus normal tissue. From May 2021 till to date a prospective, non- blinded post marketing study (N=93), evaluating the performance of the ClearCoast™ system is currently ongoing in the Breast Centre at the AGAPLESION MARKUS KRANKENHAUS, Frankfurt, Germany. After standard evaluation with ultrasound and/or X-ray with or without wire or clip marking, the specimens are intraoperatively scanned with the ClearCoast™ system, and positive margins will lead to a direct re-resection by decision of the surgeon applying a simple T2* threshold to

flag irregular tissue. The final histopathology results will be compared with the scan results on a margin per margin bases. In addition, the rates of recurrent surgery of the interventional group will be compared with those of a historical group on the bases of matched pairs. Primary endpoint of the study is the re-excision rates in both the interventional and the historical standard of care group. To date, 64 patients are enrolled in the trial, therefore, results of the trial may be presented at the SABCS 2022.

Research question: Is it feasible to conduct a multicentre randomised controlled trial (RCT) to test the long-term efficacy and safety of biological matrices compared with synthetic meshes in women undergoing one-stage mesh and implant breast reconstruction as standard care. Background: The use of biological and synthetic meshes in implant-based breast reconstruction has become standard care and is the most widely used procedure in the UK. However, there is limited evidence on patient outcomes and how safe each type of mesh is in the long-term to guide patient choices and surgeon decision-making. Aims: To assess patient and clinician acceptance, recruitment rate, and compliance with randomly allocated intervention. We will evaluate completeness of data on proposed future main study outcomes. The standard deviation (SD) of patient reported 'satisfaction with breasts' score on Breast Q will inform sample size calculations for the main study. To inform economic evaluation of main study, we will evaluate completeness of EQ-5D-5L and recommendation of an alternative preference-based QoL measure to be used in a definitive trial. Methods: Design: Pragmatic, feasibility, randomised controlled trial. Target population: Women undergoing mastectomy for breast cancer or risk reduction and immediate one-stage breast reconstruction using implant and mesh as standard care. Randomisation: Women will be randomised to biological matrix or synthetic mesh in a 1:1 ratio. Measurement of outcomes Complications: such as infection, wound breakdown, readmission, reoperation, unplanned surgery, skin flap necrosis, implant loss, seroma, pain, capsular contracture and haematoma will be recorded at 3- and 6-months post-surgery. Patient reported outcomes: Women will complete Breast Q and EQ-5D-5L questionnaires at randomisation, 3- and 6-months post-surgery. Sample size: By recruiting 60 (out of 120) we will be able to estimate a participation rate of 50% of women offered the trial to within a 95% confidence interval of +/-9% and a completion rate of 90% (54 of 60) within a 95% confidence interval of (80%, 95%). Additionally, 60 participants will be enough to estimate the SD for sample size calculation for the main study. Timelines for delivery: Recruitment start date:

01 September 2022. Anticipated Impact and Dissemination: The BIOSYM research question has been identified as a key research gap by Association of Breast Surgery (UK). If we can demonstrate feasibility, the definitive trial will provide high quality long-term data on patient outcomes and safety of each type of mesh. Results will be published in peer-reviewed high impact journals and, with PPI partners we will produce patient-facing summaries for a lay audience. The results will inform specialist and NICE guidelines.

Endocrine therapy is the main treatment for premenopausal women with HR+/HER2- breast cancer. Palbociclib is an oral CDK4/6 inhibitor which preclinical evidence that ER+ and HER2-amplified breast cancer cell lines are most sensitive to CDK4/6 inhibition of proliferation and is used in vitro in combination with endocrine therapy showed better tumor suppressive effect. To evaluate the efficacy and safety of palbociclib in patients with locally advanced or metastatic breast cancer, we enrolled females with hormone receptor-positive breast cancer who treat with Palbociclib from July 2018 to March 2022. The study has so far included 267 patients in 4 centers. 32.83% patients were treated in first-line, 31.32% and 38.85% patients in second and third lines. 30.34% patients had hepatic metastasis. 35.47% patients were sensitive to previous endocrine therapy; 18.23% patients had primary resistance to endocrine therapy, while 46.31% patients had secondary resistance to endocrine therapy. The median PFS was 12.67 months (95% CI 11.51-13.92), and Median overall survival (OS) was not reached. Among all patients, the overall response rate (ORR) was 25.84%, and the disease control rate (DCR) was 78.62%. The main adverse events related to treatment were neutropenia (91.38%), white blood cell decreased (90.09%), anemia (43.78%), and thrombocytopenia (37.93%). The most common grade 3/4 adverse event was neutropenia (55.61%). 11.99% of patients had dose reductions. More patients still needed for further analyze.

Background: Despite evidence of substantial breast cancer risk reduction, few high-risk women adopt chemopreventive medications such as selective estrogen receptor modulators (SERMs) or aromatase inhibitors (AIs). Women with benign breast disease, such as atypical hyperplasia (AH) or lobular carcinoma in situ (LCIS), have an increased risk of developing breast cancer and derive a greater benefit from antiestrogens compared to other high-risk women. Reasons for low uptake of chemoprevention include insufficient patient and clinician knowledge about antiestrogens, time constraints during the clinical encounter, and concerns about side effects. To address these barriers, we have developed patient and provider web-based decision support tools to improve informed choice about breast cancer chemoprevention among women with AH or LCIS. Study design: We are conducting a cluster-randomized controlled trial of clinical decision support to improve chemoprevention informed choice among women with AH or LCIS and their treating providers. Twenty-six U.S. sites through the SWOG Cancer Research Network were randomly assigned 1:1 to standard educational materials alone or in combination with the patient-centered decision aid (RealRisks) and provider decision support tool (BNAV). A total of 415 patients and 200 healthcare providers will be recruited from these sites. RealRisks consists of interactive modules to calculate personalized breast cancer risk and elicit preferences on chemoprevention. The modules are available in English and Spanish. BNAV is

comprised of self-directed case-based learning modules on breast cancer risk assessment and chemoprevention. Patients complete questionnaires at baseline, 6 and 12 months. Providers complete surveys at baseline and after their enrolled patient's 6-month clinical encounter. The primary endpoint is chemoprevention informed choice at 6 months, using a measure combining knowledge, attitude, and intention scales. Secondary endpoints include perceived breast cancer risk/worry, chemoprevention knowledge/intention, decision conflict/regret, shared decision-making, and chemoprevention uptake. For patients who begin chemoprevention, adherence and reasons for discontinuation are assessed annually for up to 5 years. Barriers and facilitators to implementing RealRisks and BNAV into clinic workflow will be assessed by conducting patient and provider interviews at baseline and mid-implementation. Eligibility criteria: Eligible patients include women, age 35-74 years, with AH or LCIS, no history of breast cancer, no prior use of SERMs or AIs, no bilateral mastectomies, English or Spanish-speaking, and access to the internet. Eligible providers include breast surgeons, medical oncologists, primary care providers, and physician extenders who see patients with AH or LCIS. Statistical methods: We have 90% power to detect a 15% increase in the frequency of chemoprevention informed choice with a 1-sided 0.025 level test, assuming an intraclass correlation (ICC) of 0.02 to account for clustering, roughly equal accrual at each site, 10% loss to follow-up, and ≤10% event rate in the control arm. Current/target accrual: The trial was activated on 9/1/2020. As of 7/7/2022, all 26 sites have been randomized, 157/200 providers and 184/415 patients have been enrolled. Discussion: Our hybrid effectiveness/implementation study seeks to evaluate the effectiveness of a multi-level intervention in promoting informed decision-making about breast cancer chemoprevention. Study results will provide valuable insights on how the decision support tools are integrated in diverse clinical settings.

Introduction: Cancer-related fatigue (CRF) is a common symptom in patients with metastatic breast cancer (MBC), who receive taxane-based chemotherapy, and is associated with poor outcomes. Current guidelines recommend regular screening for fatigue from the time of cancer diagnosis, during treatment, and after treatment is completed to identify CRF early, lessen its negative impact on quality of life, and prevent potential treatment interruptions. Fatigue is a subjective symptom and is assessed through patient questionnaires such as the FACIT-Fatigue (Functional Assessment of Chronic Illness Therapy-Fatigue) survey. However, there is currently no gold standard or recommended survey to assess CRF. **Methods:** A prospective, non-interventional, multicenter trial is ongoing to validate the FACIT-Fatigue scale in patients with locally advanced or metastatic breast cancer who are eligible to receive taxane-based chemotherapy. Adult patients who have documented locally advanced or metastatic breast cancer (not amenable to surgical resection), and mild-to-moderate CRF indicated by a score of 1 to 6 on a scale from 0 to 10 (10 being most severe), who are candidates to receive cycle one of taxane chemotherapy will be included. Patients who are unable to take oral medications, have other cancer-related causes of fatigue, are using oral morphine ≥ 60 mg/day, or are participating in another clinical trial will be excluded. The primary objective is to evaluate the change in FACIT-Fatigue scores at baseline and at the end of the study (16 weeks). Secondary endpoints include evaluation of quality-of-life outcomes. A subgroup of patients will participate in a phone-based cognitive interview at the end of study visit or within 2 weeks of this visit to explore fatigue factors deemed important to patients. **Results:** The total planned sample size is estimated to be 60 patients to allow for a minimum clinically important difference (MCID) with a minimum precision of 1.9 points, and standard deviation of 3 points. The qualitative assessment will be conducted as part of a substudy inclusive of data from 30 patients. **Conclusions:** This study is currently ongoing to determine the MCID in FACIT-Fatigue scores in patients with locally advanced or MBC receiving treatment with taxane-based chemotherapy. Contact usmedinfo@dompe.com for information related to clinical trial sites and this study.

Background Chemotherapy induced peripheral neuropathy (CIPN) is one of the most common dose-limiting side effects seen among patients with early stage breast cancer and received taxane-containing regimens. The primary clinical manifestation of CIPN is sensory neuropathy such as numbness, tingling and pain in hands and feet, which negatively affect the patient's

quality of life (QoL). Although in most patients, CIPN improves over time, in a subset of patients, it remains a substantial debilitating problem, significantly affecting QoL. To date, there are no effective prevention strategies- or sufficient treatment due to the limited understanding of CIPN pre-disposing factors or pathophysiology. We hypothesize that a multimodal integration of biomarkers with CIPN progression analysis will be required to understand the pathophysiology and to consistently predict patient susceptibility. Further, we hypothesize that this multimodal approach may be leveraged to identify targets for CIPN treatment and/or prevention. This abstract describes the study protocol used to explore this hypothesis. Objective This study is designed to 1) identify genetic, transcriptional, epigenetic, metabolic, inflammatory biomarkers predictive of CIPN development among patients with early stage breast cancer receiving a taxane containing therapy; 2) With these biomarkers, develop an algorithm to identify patients who are at risk of developing CIPN before or during taxane therapy. Methods This is a longitudinal, multicenter, observational study. Patients with early-stage breast cancer who are receiving a taxane-containing (paclitaxel, docetaxel or nab-paclitaxel) treatment regimen, without preexisting peripheral neuropathy are eligible. Estimated enrollment is 400 patients. Demographic and clinical data are collected after patients consent to participate. Molecular data and patient reported outcomes (PRO) are collected prior to initiation of taxane therapy, the 4th, 8th, and 12th week of taxane therapy, and at 3, 6, and 9 months after completion of taxane therapy. Blood samples are collected for molecular data which include genetic, transcriptional, epigenetic (DNA-methylation), and metabolic data. . PRO are assessed using (i) the European Organization for Research and Treatment of Cancer CIPN20 questionnaire, (ii) the Brief Pain Inventory, (iii) the Pain Catastrophizing Scale, and (iv) the PRO Measurement System for anxiety, depression and pain interference. Initial data analysis will characterize the association of biomarkers in each modality (e.g., genetic, epigenetic, etc.) with the presence or absence of CIPN, and machine learning will be used to build candidate biomarker signatures to predict CIPN before and during taxane treatment. Two distinct multi-modal prediction models will be constructed: 1) a pre-treatment model to predict risk of developing CIPN , and 2) an on-treatment model to predict the onset of CIPN. The goal is to develop a parsimonious, clinically translatable model for robust and accurate predictions of taxane-induced CIPN. Trial Status: Active, 135 subjects enrolled. Trial Centers: 1) Cleveland Clinic Foundation (8 regional sites in Ohio and 1 in Florida); 2) Huntsman Cancer Institute, University of Utah Research Funding: National Institute of Neurological Disorder and Stroke. Grant No.: 1R61NS113258-01A1

OBJECTIVE: To compare skin sensitivity in patients diagnosed with breast cancer undergoing cycles of chemotherapy with taxanes, applied three different techniques, acupuncture needles, acupuncture with silicon tablets (Stiper) and kinesiotherapy. **DESIGN:** Randomized, controlled, open, parallel clinical trial. **Inclusion criteria:** women undergoing chemotherapy with taxanes from the 1st cycle onwards both neoadjuvant and adjuvant with stages I to III. **Excluded** were women with pre-existing diseases such as cancer in locoregional or distant activity, previous joint pain, rheumatologic diseases, and not undergoing chemotherapy containing Anthracyclines and/or Cisplatin, and those who had acupuncture in another service in the last three. **METHODS:** This study was carried out at the Oncomastology, Outpatient Clinic of the Mastology Discipline of the Gynecology Department of the Federal University of São Paulo (UNIFESP). 102 patients diagnosed with breast cancer. Excluded 39 patients, 63 volunteers were selected and randomized, allocated to three groups (Group S: Stiper n=26, Group A Acupuncture n=18: and Group C: Kinesiotherapy n=19) to undergo treatment once a week for ten consecutive weeks. Signed the Informed Consent Form and agreed to participate in the project (ICF). **INTERVENTION:** Division of the groups, GS - non-invasive acupuncture technique (silicon pads covered with acrylic blanket) are used for stimulation of acupuncture points on the meridians. GA: acupuncture applied the technique with sterile, disposable systemic needles, (measuring 0.25mm x 30mm) for stimulation of the acupuncture points on the meridians. GC Kinesiotherapy, a physiotherapy technique consisting of upper and lower limb exercises and lower limb proprioception training and sensitivity improvement with vibration. GS, GA, performed acupuncture on the acupoints (B11Dazhu, SI14 Jianwaishu, CV12 Zhongwan, GB34 Yanglingquan, SP6 Sanyinjiao, LR3 Taichong), frequency of 1 time per week, for 10 consecutive weeks, duration of 30 minutes per session. To evaluate Sensitivity, the

esthesiometer was used, consisting of microfilaments thickness and the force (in grams) needed to bend the filaments, the colors and values are: green (0.05 g), blue (0.2 g), violet (2.0 g), dark red (4.0 g), orange (10.0 g) and magenta red (300 g). The evaluation of quality of life FACT/GOG-Ntx before and after treatment. RESULTS: The qualitative demographic characteristics of patients at the chemotherapy. Neoadjuvant Chemotherapy was predominantly in the three groups: GS(88.5%), GA(83.3%) and GC(89.5%), $p=0.83$. Cancer type CINE (Non-special Invasive Carcinoma), GS(92.6%), GA (93.8%) and GC (94.4%), $p=0.58$. Diabetes Mellitus GS(84.6%), GA(77.8%) and GC(79.8%), $p=0.82$ and Systemic Hypertension GS(72%), GA(72.2%) and GC(52.6%), $p=0.32$. The C6D upper limb skin sensitivity assessment ($p < 0.04$ intergroup GS, GA and GC). T1D ($p < 0.03$ intergroup GS, GA and GC), corresponds to the forearm region. FACT/GOG-Ntx quality of life questionnaire in the domains (PWB, FWB and TaxS), Taxane Trial Outcome Index (TOI) comparing 1st session with 10th session $p < 0.02$, TaxS (Evaluates Symptoms of Chemotherapy Induced Peripheral Neuropathy) comparing 1st session with 10th session $p < 0.03$. Taxane total score) comparing 1st session with 10th session, $p < 0.03$. CONCLUSION: The C6 right hand and T1 right forearm sensitivity changes showed improvement in skin sensitivity after the intragroup intervention. FACT/GOG-Ntx questionnaire showed worsening of symptoms, physical, functional and peripheral neuropathy symptoms induced by chemotherapy compared to before and after. The cutaneous sensitivity of hands and feet remained stable and improved in the upper limbs, but chemotherapy had a negative impact on the quality of life, requiring further studies to evaluate the neuropathy of these patients. Background: Local tumor destruction with cryoablation (cryo) induces inflammation and releases antigens that can activate tumor-specific immune responses. Pre-clinically, cryo with immune checkpoint inhibition (ICI)-augmented tumor-specific immune responses and prevented recurrence. Clinically, we established that peri-operative (peri-op) cryo with ipilimumab (ipi) +/- nivolumab (nivo) was not only safe in patients (pts) with operable, early stage breast cancer (ESBC) but also generated robust intra-tumoral and systemic immune responses. In this phase 2 study, we evaluate the disease specific impact of peri-op ICI in women with residual triple negative breast cancer (TNBC) after neoadjuvant chemotherapy (NAC), a subset at high risk of early relapse. Methods: Eligible pts are ≥ 18 y, with ER < 10%, PR < 10%, HER2 negative (per ASCO/CAP definition), ≥ 1.0 cm, residual operable disease after taxane-based NAC. Approximately 80 pts will be enrolled and treated with ipi/nivo/cryo followed by breast surgery and adjuvant nivo across multiple institutions. Pts undergo percutaneous, image-guided cryo with concurrent research core biopsy 7-10 days prior to surgery and will receive ipi (1mg/kg IV) with nivo (240mg IV) 1 to 5 days prior to cryo. After surgery, pts will receive 3 additional doses of nivo at 240mg IV Q2 weeks. Adjuvant capecitabine is recommended for all patients per local standard-of-care. Patients will be stratified by NAC platinum administration, NAC anthracycline administration, and clinical nodal status (positive versus negative). The primary endpoint is 3-year Event Free Survival (EFS). Secondary endpoints include Invasive Disease-Free Survival (IDFS), Distant Disease-Free Survival (DDFS), overall survival (OS) and safety. Exploratory correlative studies will be performed on tumor and serum to characterize the immunologic impact of the intervention and to explore predictors of efficacy and toxicity. Background Approximately 15-30% of women with a preoperative diagnosis of ductal carcinoma in situ (DCIS) will be diagnosed with invasive cancer (IBC) on specimen pathology. Risk of upgrade, and impairment of lymphatic outflow after breast surgery, mainly mastectomy, are drivers for upfront sentinel lymph node dissection (SLND). In the SentiNot feasibility study, marking the SLN by superparamagnetic iron oxide nanoparticles (SPIO) injection during primary surgery minimized unnecessary SLNDs, allowing for delayed SLND (d-SLND) only in those with IBC up to 50 days after primary surgery. This policy resulted in that 78.3% study participants avoided upfront SLND. In the d-SLND setting, SPIO detection outperformed the isotope (98.5 vs 60.6%), regardless of type of breast procedure. Incremental healthcare costs were reduced by 8.5% (485 USD per patient) for the entire trial population (ref 1). Prospective Clinical Trial Design SentiNot 2.0 (ClinicalTrials.gov Identifier: NCT04722692), is currently

accruing data, powered to examine the detection rate of SPIO over isotope±blue dye during d-SLND. Trial candidates are: patients with a diagnosis of high-risk DCIS/pLCIS (mass-lesions, microinvasion, grade 3, grade 2 >20mm) regardless of type of breast surgery, and patients with planned breast surgery that precludes safe and accurate axillary mapping at a d-SLND (extensive oncoplastic breast conservation, tumors of the axillary tail and mastectomy). In d-SLND, study patients receive isotope±blue dye and within-patient-randomization is performed for which detection method to start with (SPIO-first vs. isotope-first). The trial is stratified for mastectomy and breast conservation. Secondary outcomes are nodal concordance (SPIO vs. isotope) at d-SLND, quality-of-life and health-economy outcomes. Present and Planned Accrual Total target accrual is 500 d-SLNDs. Insofar, 360 women have been included at six different sites in Sweden, Hong Kong, and the USA. Currently, data accrual and institution recruitment is active and expanding. For more information about the trial please refer to ClinicalTrials.gov Identifier: NCT04722692. For discussion regarding potential participation contact dr Andreas Karakatsanis (andreas.karakatsanis@surgsci.uu.se) .

Background: High-grade DCIS with immune infiltrates may represent lesions that are able to be kept in check by the immune system, but still are at risk for progression to invasive disease. We and others have demonstrated that the presence of T cells, and in particular the spatial proximity of CD8+/PD-1+ T cells and PD-L1+ cells predicts response to chemotherapy and PD-1 inhibitors in the setting of invasive triple negative breast cancer. DCIS with high-risk features (e.g. large, palpable, high grade, HR-, or HER2+) often have T cell infiltrates. We hypothesized that it might be possible to potentiate the immune response in high-risk DCIS with immune checkpoint blockade. Since mortality for DCIS is extremely low, we proposed an intralesional pembrolizumab (pembro) treatment approach to avoid systemic adverse effects. In a phase 1

dose escalation study of single agent pembrolizumab we found 2 doses of 8 mg, administered intralesionally 2-3 wks apart, was tolerable, induced immunological changes within the DCIS lesions, but had little clinical benefit. Herein, we expanded the number of injections to 4 and also tested a combination with mRNA-2752 (Moderna), an mRNA-based therapeutic encoding a T cell co-stimulator OX40L, and pro-inflammatory cytokines IL-23 and IL-36 gamma, to determine if we could find a dose that was both tolerable and elicited anti-tumor responses.

Methods Women eligible for this study had DCIS with at least 2 of the following high-risk features: age < 45; high grade, extensive comedonecrosis; palpable mass; hormone receptor negative [HR-]; HER2+; size >5 cm, or microinvasion. A dose expansion cohort was performed using 4 doses of 8 mg pembro, 2-3 wks apart (n=5). We then combined pembro with mRNA-2752 (n=8 cases), initially at 8 and 4 mg, respectively. Dose reductions were implemented based on AEs. Patients received an MRI before and after 2 injections, spaced 2-3 wks apart. A total of 4 injections were allowed. Core biopsy or surgery was conducted after the last MRI.

Results We observed an increase in T cell density in the dose expansion cohort (pembro only), except when there was a paucity of T cells in the pre-treatment biopsy. However, only 1 patient in this cohort demonstrated a reduction in lesion size (clinically and on MRI). As of 22SEP22, 8 patients have received the combination of pembro and mRNA-2752; 7 are evaluable. Two patients with minimal T cell infiltrates at baseline (both HR+) failed to respond, based on imaging or pathology. 4/5 patients with moderate to high T cell infiltrates at baseline had partial (2) or complete responses (2) based on imaging (surgery pending), one of whom had absence of DCIS on post-therapy core biopsy and a clear MRI 4 months later. Correlative studies (immune cell densities, spatial proximities) will be presented at the meeting along with complete data (including post-treatment pathology) on the first 8 patients. Side effects were independent of response and included Gr1/2 fever, myalgias, and fatigue starting within 12 hours of injection (3-4 days), enlargement of regional nodes by day 2, and Gr 1/2 erythema and induration of the breast starting at 4 days and lasting 4-20 days. Earlier onset and persistence of symptoms with subsequent exposure required dose reductions for the majority of patients to maintain tolerability (avoid fevers over 39.4°C, intense erythema and swelling of the breast lasting > 4 days). No AEs were higher than grade 2.

Conclusion: The combination of intralesional pembro and mRNA-2752 demonstrated modulation of the tumor immune microenvironment and robust antitumor activity in high-risk DCIS (typically HR- or HER2+) with existing T cell infiltrates. This is an ongoing study; the optimal Phase 2 dose for the combination will be based on the totality of evolving safety and translational data.

Background Five to eight percent of breast cancer (BC) patients present with distant metastasis at diagnosis, known as 'de Novo' metastatic breast cancer (dnMBC). Recent data showed that approximately 40% of dnMBC patients undergo locoregional treatment (LRT). LRT treatment modalities for metastasis and primary tumor benefit a subset of patients with oligometastatic disease. Our study group has recently demonstrated two prospective studies regarding this topic with favorable outcomes. MF07-01 IMET study, one of the first clinical randomized trials, showed that the patients with the diagnosis of dnMBC undergoing LRT followed by systemic therapy had an additional 14% OS benefit by the end of the 10-year follow-up when compared with others who received only systemic therapy. A prospective multicenter registry study MF14-

01 BOMET also presented LRT prolonged survival and decreased locoregional recurrence in a prospective registry study with a median follow-up of 3 years. Timing of primary breast surgery either at diagnosis or after systemic treatment provided a survival benefit similar to systemic therapy alone in bone-only dnMBC patients. Although, the optimal timing of concurrent endocrine therapy, radiotherapy, and/or sequential surgery remains unclear. Hypothesis We hypothesize that in the era of modern radiotherapy and endocrine therapy, concurrent radiation and endocrine therapy will be non-inferior to sequential treatment modalities in terms of locoregional and systemic disease control in dnMBC. ER/PR (+), Her2 neu (-) oligometastatic dnMBC patients are potentially curable with multimodality treatments. Objectives The primary objective is to perform a Phase I study to evaluate the feasibility of this curative intent treatment approach for patients with oligometastatic disease. Secondary objectives are to present the treatment response evaluating with CTC and/or ctDNA, and IHC and marker changes with multimodality treatments Methods Postmenopausal ER/PR (+) and Her2 neu (-), oligometastatic dnMBC patients will be enrolled in the study. Inclusion criteria: Primary breast tumor amenable for complete surgical resection, patients in good physical condition for receiving protocol-driven locoregional and systemic treatments and radiotherapy; Bone-only oligometastatic disease (5 or less metastasis); Primary tumor biopsy, metastatic site biopsy (ER/PR, Her2, Ki67). Exclusion criteria: Primary tumor not amenable for complete resection; primary tumor with extended infection, bleeding, or necrosis; patients with poor physical condition which prevents the patient from receiving protocol-driven locoregional and systemic treatment; synchronous primary cancer at the contralateral breast; clinically involved contralateral axillary nodes; patients not suitable for adequate follow-up, and failure to give informed consent. Study Design: • RT to the primary tumor (Hypo fractionated) + AI concurrent, Collect CTC and/or ctDNA • Add CDK4/6i to AI 2-4 weeks after RT + (6 months) • RT to bone metastasis (if still visible), Collect CTC and/or ctDNA + (12 months) • Primary Breast Surgery, Collect CTC and/or ctDNA, ER/PR/Her 2 in the final specimen + • CDK4/6i +AI until progression and/or unmanageable toxicity Conclusion We hypothesize that in the era of modern radiotherapy and endocrine therapy, concurrent radiation and endocrine therapy will be non-inferior to sequential treatment modalities in terms of locoregional and systemic disease control in dnMBC. ER/PR (+), Her2 neu (-) oligometastatic dnMBC patients are potentially curable with multimodality treatments.

Background: A previous study on 22 metastatic breast cancer (mBC) patients (Allegretti et al. Mol Cancer 2021) has associated drug resistance to Ado-trastuzumab emtansine (T-DM1) with two sets of genomic events: a) reversal of HER2 amplification, b) 'oncogenic replacement' of HER2 by alternative cancer drivers. To expand on this, we designed GIM21 (Gruppo Italiano Mammella) study. Materials and Methods: GIM21 is a multicentre, prospective study; tumor and

circulating total nucleic acids (tTNA and ctTNA) were obtained from primary and metastatic lesions (n=36 altogether), as well as plasma samples (n=501), the latter serially collected coincident with medical imaging re-evaluations. tCNAs/ctTNAs were sequenced by ultra-deep, largely overlapping 50-gene panels on Ion Torrent Gene Studio S5. Orthogonal dPCR validation was by dPCR (Quant Studio 3D). ctTNAs were correlated with clinical readouts and patient outcomes. Results: from September 2018 to January 2022, 50 HER2+ mBC patients receiving T-DM1 as second-line treatment. Median time to progression was 6.5 months (range 2.0-27.2). As previously shown, only a minority of patients (9/50 – 18%) retained residual HER2 amplification in blood at baseline, likely due to HER2 counterselection during previous therapy lines; all of them (9/9) underwent further neutralization during T-DM1 treatment, but an HER2-neutral blood status was reached in only 5 patients. In contrast, 2 HER2-neutral patients acquired HER2 amplification, suggesting either insufficient T-DM1 pressure or an unprecedented clonal escape mechanism. Overall, the circulating HER2 status did not correlate with progression free survival (PFS), further highlighting a loss of clinically relevant HER2 oncogenic dependence. At baseline, 24 circulating mutations were detected in 29/50 (58%) patients, 9 of which did not overlap with tissue mutations. Of note, carrying a given aberration in either blood or tissue resulted in outcome trends (p=0.16), but no clear association with therapeutic response. Rather, it was serial monitoring (appearance of any aberration in the blood) that predicted a dismal clinical outcome in 16/41 (39%) patients, with a median time to progression of 2.8 months (2.2-3.9). Unfortunately, liquid biopsy (LB) was confirmed to miss most patients developing brain (3/3 patients) or skin (2/3 patients) metastases. Most circulating alterations present at progression (40/60) were actionable (OncoKB level < 3B) in 34/41 (82.9%) patients, suggesting that LB may guide therapeutic strategies in post-T-DM1 settings. Conclusions: GIM21 trial showed that LB accurately predicts clinical outcome and reveals actionable drivers of T-DM1 escape. The final analysis are ongoing.

Background: The detection of breast lesions through self-examination or during screening tests is a frequent finding. Breast biopsy is required in case of radiologically suspect lesions, bestowing a high burden on both patients and national healthcare system, since only one every four biopsies is breast cancer (BC). To date, the assessment of circulating biomarkers failed to demonstrate clinical utility in the early diagnosis of BC, for its suboptimal accuracy and difficult transferability to clinical practice. The combination of novel cutting-edge methods for the assessment of circulating analytes in an integrated multiomic classifier may overcome such limitations, possibly allowing liquid biopsy to become a novel noninvasive procedure for the differential diagnosis of BC. Design: In the RENOVATE trial (NCT04781062), women with suspect (BI-RADS-4/5) breast lesions ≤ 2 cm (cT1) are asked, before biopsy, to donate ~ 35 mL of blood collected in four dedicated tubes and ~ 50 mL of urine at the Diagnostic Senology Unit of Ospedale Policlinico San Martino (Genoa, IT). Plasma cell-free DNA methylation and copy number alterations are assessed in a cohort of patients diagnosed with early BC and a matched set of patients with histologically proven benign lesions through cell-free methylated DNA immunoprecipitation and high throughput sequencing (cfMeDIPseq), as well as ultra-low

pass whole genome sequencing (ULP-WGS). Thanks to the volume and quality of our sample set, other experimental techniques will be tested as well. Results from cfMeDIP-seq and ULP-WGS, possibly in combination with other findings, will be integrated in a unique classifier for the noninvasive differential diagnosis of suspect breast lesions. Eligibility criteria: Patients with radiologically suspect breast lesions ≤ 2 cm (i.e. BIRADS 4/5) are eligible. Patients with previous history of cancer, or diagnosed with autoimmune or active allergic diseases, acute or chronic hepatic, renal, or cardiac diseases, or acute or chronic infectious diseases are excluded from the present trial. Specific aims: The primary aim of the present trial is to develop a noninvasive classifier for the differential diagnosis of suspect breast lesions detected through mammography and/or ultrasound. For such purpose we will assess the performance of plasma cfMeDIPseq, ULP-WGS, and other promising techniques for the differential diagnosis of BC. Such techniques will be integrated in a unique classifier in order to reach the maximum possible accuracy. Statistical methods: Sample size was calculated with a semi-parametric simulation-based approach from beta-distributions of PBMC datasets: assuming to test 20,000 CpG regions, with 300 differentially methylated target CpGs, a target maximal difference in DNA methylation of 0.2 between groups and an FDR of 0.05, $1 - \beta \sim 0.90$ would be achieved with an overall sample size of 150 samples split in a 1:2 ratio. Target accrual and present accrual: Minimum target accrual is set at 49 patients with BC and 98 patients with benign lesions. To date, we have collected plasma samples from 74 eligible patients with BC and 115 eligible patients with benign lesions. A validation cohort accounting for $\sim 30\%$ of our sample set will be recruited at Istituto Nazionale dei Tumori (Milan, IT). Contact information: For further information, please contact Gabriele Zoppoli at gabriele.zoppoli@unige.it.

Purpose: There is little evidence determining whether elderly patients (from 70 to 90 years old) with triple-negative breast cancer (TNBC) could benefit from adjuvant chemotherapy (AC). The objective of this study was to explore the effect of AC in these population following surgery. **Methods:** A total of 4610 patients were identified in the Surveillance, Epidemiology, and End Results database (2010-2018). Inverse probability of treatment weighting (IPTW) was used to reduce the selection bias. IPTW-adjusted Kaplan-Meiers survival analysis and Cox proportional hazards models were performed to compare breast cancer specific survival (BCSS) and overall survival (OS) in the two different treatment groups. **Results:** All eligible patients were divided into two groups, the chemotherapy (n=1989) and the observation (n=2621) groups. The percentage of patients receiving AC versus observation increased significantly from 2010 to 2018 (estimated annual percentage change, 1.49%; 95%CI, 0.75-2.16%, p=0.002). The 5-year IPTW-adjusted rates of BCSS and OS in AC group were better than that in observation group (BCSS: 82.32% vs. 78.42%, p=0.010; OS: 75.54% vs. 64.65%, p< 0.001). In IPTW-adjusted Cox proportional hazards regression analysis, elderly patients could benefit from AC (BCSS: HR, 0.77, 95%CI, 0.62-0.94, p=0.012; OS: HR, 0.66, 95%CI, 0.57-0.78, p< 0.001). AC was associated with a significant outcome benefit across year at diagnosis, marital status, stage,

lymph node, surgery and radiation subgroups (all $p < 0.05$). Patients with T1ab could not benefit from AC. Conclusions: We show a BCSS and OS benefit from AC in old patients with TNBC. AC may remain a reasonable treatment approach in these specific patients. For the patients with T1ab, de-escalated treatment should be administered with caution. It requires further randomized controlled trial to ensure the AC effectiveness for elderly TNBC patients.

Background

The RxPONDER trial showed that in premenopausal breast cancer (BC) subjects who were hormone receptor positive (HR+), N1 lymph node status and had an OncotypeDx (RS) score \leq 25, the use of adjuvant chemotherapy (AC) along with endocrine therapy (ET) had better disease free and distant relapse free survival than ET alone. Using a large national database, we wanted to see if adding AC improved overall survival in a similar cohort of node positive BC patients.

Methods

The 2004-2018 National Cancer Database was used to include female BC patients aged 18-50 years. Inclusion criteria were N1-N3 lymph node status, M0 patients with any T stage, RS \leq 25, HR+ and HER2-. Patients who received neoadjuvant chemotherapy were excluded. Logistic regression was used to evaluate AC utility trends. Kaplan-Meier (KM) and multivariate (MV) propensity score (PS) weighted Cox model were used to compare survival between patients with and without AC use.

Results

8628 women were included of which only 3519 (40.8%) received AC (AC+). 5109 (59.2%) did not receive AC (AC-). AC+ had the following age distribution: (18-40 years: 23.73%, 41-50 years: 76.27%), while AC- had the following: (18-40 years: 15.15%, 41-50 years: 84.85%). RS score distribution are as follows: AC+(0-11: 17.56%, 12-25: 82.44%), AC-(0-11: 35.49%, 12-25: 64.51%). Most of the cohort received ET (AC+: 94.74%, AC-: 93.25%) and majority were N1 (AC+: 92.61%, AC-: 98.9%). Factors associated with AC use includes caucasian race [african american vs caucasian: 0.777(0.647,0.934), $p=0.0072$], higher stage [II vs I: 1.825(1.598,2.084), $p<0.0001$, III vs I: 3.199(1.593,6.426), $p=0.0011$] and higher grade [G3 vs G1: 2.261(1.886,2.711), G2 vs G1: 1.467(1.301,1.655), $p<0.0001$], radiation (RT) use [1.758(1.544,2.002), $p<0.0001$], younger age [40-50 vs 18-40: 0.684(0.542,0.863), $p=0.0013$], higher RS [12-25 vs 0-11: 2.325(2.065,2.618), $p<0.0001$], mastectomy [vs partial surgery:

1.668(1.469,1.894), $p < 0.0001$] and N2N3 nodal stage [N2N3 vs N1: 2.688(1.423,5.079), $p=0.0023$].

KM curves showed that AC+ had better survival at 10 years (93% vs 91%) (Table). Hazard Ratio (HR) comparison between the 2 groups favored AC+ [0.602(0.482,0.751), $p < 0.0001$] (Table). Subgroup analysis for overall mortality benefits from AC+, using MV adjusted HR showed favorable results in caucasian race [0.512(0.348,0.752)], both age groups of 18-40 years [0.429(0.217,0.847) and 40-50 years [0.585(0.394,0.869)], both poorly differentiated [0.404(0.186,0.874)] and well-differentiated [0.386(0.165, 0.903] grades and RS 12-25 [0.549(0.379,0.795)]. RS 0-11 did not reach significance [0.555(0.216,1.423)].

Discussion

Based on our analysis, AC use was noted in 40.8% of young, lymph node and HR+ BC patients with an RS score of 0-25. This group of patients had an overall survival advantage of around 40% with AC use, further supporting the findings of the RxPONDER trial. This benefit is of particular significance in patients with a RS of 12-25. The survival advantage was present in all patients less than 50 years, regardless of the age subgroup used in our analysis. Possible mechanisms leading to these outcomes include direct cytotoxic effects and menopausal induction with AC use. Limitations of our study include the use of non-population-based data and the possibility of confounding despite the use of PS matching. Moving forward, AC use along with hormone therapy may become standard practice in young HR + BC patients with lymph node involvement, regardless of the RS score.

Table. Survival difference between AC+ and AC-.

Survival Rate % at 10 years from KM estimate		
	AC+	AC-
Overall	93.0(89.8,95.2)	91.0(87.9,93.4)
18-40 years	86.0(72.6,93.1)	82.8(70.0,90.5)
41-50 years	94.7(91.9,96.5)	92.2(88.9,94.6)
HR estimates AC+ vs AC-		
MV cox model	0.543(0.388,0.759)	0.0004
PS weighted Cox model	0.602(0.482,0.751)	<0.0001

KM-Kaplan-Meier, AC-Adjuvant Chemotherapy, HR-Hazard Ratio, MV-Multivariate, PS-propensity score.

Introduction In the South African Breast Cancer and HIV Outcomes (SABCHO) study, early-stage breast cancer patients living with HIV, compared to their HIV-negative counterparts, demonstrated higher overall mortality and lower rates of pathologic complete response if treated with neoadjuvant chemotherapy. We aimed to determine if comorbid HIV also impacted receipt of timely and complete neoadjuvant and adjuvant chemotherapy. Methods We retrospectively identified Black, stage I-III SABCHO participants diagnosed with breast cancer from June 2015 to July 2019 and who received at least 2 doses of neoadjuvant or adjuvant chemotherapy at either Charlotte Maxeke Johannesburg Academic Hospital (Gauteng) or Grey's Hospital (KwaZulu-Natal). Data on the originally prescribed chemotherapy regimen and the dose and timing of all received chemotherapy was extracted from patients' medical records, as well as values from all complete blood counts and metabolic panels performed during treatment. Relative dose intensity (RDI) was calculated for each agent in the prescribed regimen with the mean RDI of all agents representing the RDI of the full regimen. We assessed

for associations between full regimen RDI and HIV status using a multivariable linear regression model that included demographic and clinical covariates also shown to impact RDI. We also compared rates of myelosuppression, alkaline phosphatase elevation, and creatinine elevation using linear regression. Using previously collected survival data, we compared overall mortality based on overall RDI above or below 0.85. Results We analyzed data from 325 eligible subjects, 166 of whom were living with HIV. No differences based on HIV status were appreciated in the prescribed chemotherapy regimens. For women without HIV median RDI was 0.87 (interquartile range (IQR) 0.77-0.94) and, in those living with HIV, it was 0.89 (IQR 0.77-0.95). HIV status showed no significant association with RDI on multivariable analysis, and the only patient characteristics associated with RDI were estrogen/progesterone receptor (ER/PR) and HER2 status. Patients living with HIV experienced more CTCAE v5.0 grade 3+ anemia and leukopenia than those without HIV (anemia: 10.8% vs 1.9%, $p=0.001$; leukopenia: 8.4% vs 1.9%, $p=0.008$) and were more likely to receive at least one dose of filgrastim (24.7% vs 10.7%, $p=0.001$). Receipt of RDI greater or less than 0.85 did not predict overall mortality in the full cohort or HIV status subgroups. A trend towards improved survival with RDI greater than 0.85 was seen among the 69 participants with ER/PR negative disease (hazard ratio: 0.60, 95% confidence interval: 0.30-1.21, $p = 0.15$). Conclusions Neoadjuvant and adjuvant chemotherapy RDI did not differ by HIV status among women in the SABCHO study, although women living with HIV experienced more myelotoxicity during treatment. Efforts to reduce chemotherapy dose reduction and delays should target all South African breast cancer patients.

Comparing the Effects of TC and Anthracycline-based Chemotherapy in Women with Breast Cancer HER2 Negative Treated in the Adjuvant Setting – An individual Patient Meta-Analysis

Presenting Author(s) and Co-Author(s):

Danilo Giffoni M. M. Mata, MD. MSc., *Medical Oncologist - Sunnybrook Health Sciences Centre*
Country: Canada

Mary Smowton, RN, *Registered Nurse Emergency Department - Michael Garron Hospital*
Country: United States

Background: Among women, breast cancer is the most common diagnosis of non-skin cancer and the fifth cause of oncological-related death worldwide. Adjuvant chemotherapy has been shown to extend overall survival (OS) and disease-free survival (DFS). Anthracyclines are cytotoxic regimens largely used in breast cancer, mainly in patients with risk factors or high burden of disease. The docetaxel and cyclophosphamide (TC) regimen is a Taxane-based treatment, and is an alternative option when anthracyclines are not indicated. However, anthracyclines have a myriad of adverse effects including alopecia, cardiac-related side effects and myelotoxicity. The question that remains is in which breast cancer population anthracycline chemotherapy should be omitted. Methods: A literature search was performed in Embase, Medline, and the Cochrane Libraries up to February 28 2022. We conducted an individual patient-level meta-analysis of 11,902 participants of 7 randomised controlled trials. The target population was adult women, with a histologically confirmed HER2 negative, stage I-III breast cancer who were treated with TC versus anthracycline-based chemotherapy in adjuvant setting under randomised-controlled trials. To analyse OS and DFS, we utilized the generic inverse variance method for time-to-event outcomes using hazard ratio (HR). A sensitivity analysis of risk of bias (ROB) was undertaken to examine the effects of high/moderate risk studies on each study endpoint. The assessment of certainty of evidence was conducted based on the Grading of Recommendations Assessment, Development and Evaluation (GRADE) criteria. Results: With a median follow up of 60 months, the pooled analysis from 7 studies with available data on OS, and from 6 studies on DFS. From a total of 11,778 there was a total of 288 and 281 events of death in the TC and in the anthracycline-based chemotherapy groups, respectively. The analysis of OS revealed HR 1.01, 95% CI (0.86 – 1.19), $p = 0.88$; high certainty of evidence. From a total of 11,902 participants, there were 639 and 595 recurrence events in the TC and in the anthracycline-based chemotherapy groups, respectively. The analysis of DFS revealed HR 1.07, 95% CI 0.95-1.22, $p=0.26$; moderate certainty of evidence. No relevant absolute risk of death or recurrence events were found between the two treatments. In the quality of evidence assessment, the heterogeneity across all the studies is likely not more than what is due to chance ($i^2 < 14\%$). The risk of bias was not a serious concern, and the publication bias was undetected for the endpoints OS and DFS. Conclusion: In this study population, TC chemotherapy likely results little to no difference in OS or DFS compared to anthracyclines-based chemotherapies. Despite the large number of participants and minimum heterogeneity across all the studies, there was no evidence of significant benefit or harm between the treatments. Overall, there is a high to moderate quality of evidence that adjuvant TC chemotherapy does not increase OS or DFS when compared to anthracycline-based chemotherapy in patients with breast cancer HER2-negative. Albeit the choice between the two chemotherapies would need to be balanced considering the specific side-effects that each treatment is likely to cause.

Background: The Phase III POTENT trial demonstrated an improvement in invasive disease-free survival (IDFS) by the addition of S-1, an oral fluoropyrimidine, to adjuvant endocrine therapy in patients with ER-positive/HER2-negative early breast cancer. Because the trial was terminated at the interim analysis as the primary endpoint was met, the result of the overall survival (OS) remains immature. **Methods:** This multicenter observational study aimed to investigate the survival outcomes of patients who participated in the POTENT trial, in which patients with stage I to IIIB ER-positive, HER2-negative breast cancer without protocol-defined low-risk features received adjuvant endocrine therapy alone or with S-1 for 1 year. Of the full analysis set (FAS) of the POTENT trial (N=1930), patients who withdrew the consent or whose institutions terminated the contract were excluded from this study. The primary endpoint was OS. Secondary endpoints were IDFS and distant recurrence-free survival (DRFS). **Results:** A total of 337 patients (17%) in the POTENT study were excluded from this analysis (eight patients withdrew consent and 329 patients for institutions whose contract had been terminated). A total of 1593 patients were included in this study (803 in the endocrine therapy alone group and 790 in the endocrine therapy plus S-1 group). The median follow-up was 77.5 months (IQR: 68.8–86.0). The median duration of endocrine therapy was 71 and 69 months in the endocrine therapy alone and endocrine therapy plus S-1 groups, respectively. The patient characteristics were well balanced between the treatment groups, except for the number of lymph nodes involved. The endocrine therapy alone group included more patients with four or more positive nodes than the endocrine therapy plus S-1 group (12% vs. 9%, P=0.01). 58 (7%) patients in the endocrine therapy alone group and 51 (6%) in the endocrine therapy plus S-1 group died (HR 0.89, 95%CI: 0.61–1.30, P=0.54). The 5-year overall survival estimate was 94.7% (95%CI: 92.9–96.1%) in the endocrine therapy alone group and 95.6% (95%CI: 93.8–96.8%) in the endocrine therapy plus S-1 group. IDFS events were observed in 166 patients (21%) in the endocrine therapy alone group and in 135 patients (17%) in the endocrine therapy plus S-1 group (HR 0.80, 95%CI: 0.64–1.01). DRFS events occurred in 123 patients (15%) in the endocrine therapy alone group and in 91 patients (12%) in the endocrine therapy plus S-1 group (HR 0.74, 95%CI: 0.56–0.97). **Conclusions:** In this observational study, data from 337 patients (17%) were missing from the FAS of the POTENT trial. Both the endocrine therapy alone group and endocrine therapy plus S-1 groups showed favorable OS, and OS was similar between the treatment groups. The benefit of IDFS and DRFS by the addition of S-1 to endocrine therapy were maintained.

Background:

Breast cancer treatment includes neoadjuvant chemotherapy (NAC), offered to patients with locally advanced breast cancer and who may benefit from down-staging before conservation therapy. NAC allows for evaluation of treatment response with pathologic complete response (pCR) acting as a marker of survival. Black women receive NAC more frequently as they often present with more advanced stage tumors and the triple negative subtype. Furthermore, Black women without pCR following NAC are at greater risk of mortality. Obesity is a prognostic factor for breast cancer. Non-Hispanic Black women have the greatest prevalence of obesity in most states. Patients with higher Body Mass Index (BMI) have previously been shown to have lower rates of chemotherapy response. Data on racial and ethnic differences in pCR rates are limited and whether obesity is a confounding factor requires investigation.

Methods:

Retrospective review of patients diagnosed with non-metastatic breast cancer who completed NAC and had surgery at Ohio State University James Comprehensive Cancer Center between January 1, 2005, and December 31, 2019, were analyzed. Clinical stage was calculated based on tumor size and nodal status. Operative treatment received was recorded to determine pathologic stage and chemotherapy response. The study endpoint, pCR, was assessed after definitive surgery. BMI categories were based on World Health Organization classification and obese defined as $\geq 30\text{kg/m}^2$. For the data analysis, we included self-reported Black and White women, excluding patients classified as "Other" race. Preliminary analyses included the distribution of sample descriptive characteristics. Differences by race and demographic characteristics were compared using Pearson's chi-square test for categorical variables and t-test or Wilcoxon rank-sum test for continuous variables. Univariate analysis and multivariable logistic regression for pCR by age, race, BMI, menopausal status, insurance status and employment status were performed.

Results:

A final sample of 882 met criteria (11.7% Black and 88.3% white women, 1% Hispanic ethnicity). Median age of diagnosis is 51, with median 147.4 months of follow-up. 64% of the sample had clinical stage 2 disease, 22% were triple negative, 62% Her-2 positive subtypes. For tumor characteristics 67% of Black women and 59% white women had high grade tumor. Black women also had more triple negative disease (30% vs. 21%), more advanced stage at presentation (27% vs. 21%). More white women were employed and had private insurance compared to Black women, who predominantly had public insurance. The median BMI was higher among Black women (31.5) than white women (28.6). 52% of white women vs. 47% Black had mastectomy over lumpectomy. 67% of white women had radiation vs. 61% of Black women. Overall, 33% of Black and white women had pCR, with 67% having no pCR. Race and BMI were not significant predictors of PCR rates on univariate or multivariable analysis. Age < 40 is the only variable associated with pCR (OR 1.645, [95 CI 1.117-2.420] p-value: 0.012).

Conclusions:

BMI was not a significant predictor of pCR in this limited retrospective review. However, further exploration with a larger sample evaluating differences in pCR by BMI can lead to a better understanding of the association between obesity and pCR. Though race was not significant in predicting pCR, there is also room for further research considering socioeconomic disparities and obesity rates by race.

Table 1. Predictors for pCR

Table 1. Multivariable logistic regression for pCR adjusted by age, race, BMI, menopause status, insurance status, employment status

Effect	Odds Ratio Estimates			P-values
	Point Estimate	95% Wald Confidence Limits		
Age: Age <40 vs Age >40	1.645	1.117	2.420	0.012
BMI: BMI <30 vs BMI >30	1.099	0.823	1.469	0.522
Race: White vs Black	1.024	0.644	1.628	0.921
Menopause: Postmenopausal vs Premenopausal	1.101	0.795	1.523	0.563
Insurance: Public vs Private	0.990	0.695	1.411	0.956
Insurance: Uninsured vs Private	1.354	0.656	2.798	0.413
Employment: Employed vs Unemployed	1.268	0.864	1.862	0.225

Univariate analysis for predictors of pCR performed for race and BMI.

Background: The prevalence of breast cancer in older adults (>65 years) is increasing, and these patients are often under-represented in clinical trials¹. It has been demonstrated that older patients are more likely to require dose alterations due to treatment-related toxicities². Increasing evidence suggests that with new-generation chemotherapy regimens, these patients can better tolerate optimal dose intensities^{3,4}. Here, we aim to assess the tolerability and toxicity of adjuvant and neoadjuvant chemotherapy in older patients diagnosed with early or locally advanced breast cancer at a UK tertiary cancer centre. Methods: Patients aged 65 years or over who were diagnosed with early or locally advanced breast cancer and received neoadjuvant or adjuvant chemotherapy between 2016 and 2021 at Royal Free Hospital NHS Trust in London, UK, were included in the analysis. Data was collected from the local patient database including patient demographics, performance status as defined by the Eastern Cooperative Oncology group, pathologic characteristics, chemotherapy and surgical treatment and disease progression and mortality. Statistical analysis was carried out using Pearson's chi-squared test to compare the underlying factors causing changes in dose intensities and treatment-related toxicities. Results: A total of 130 patients with early or locally advanced breast cancer met the inclusion criteria for analysis - 96 patients (mean age 74.5 years, range 68-86 years) and 34 patients (mean age 73.1 years, range 68-85 years) received adjuvant and neoadjuvant chemotherapy, respectively. In the adjuvant chemotherapy setting, 34.0% had ER+ breast cancer, 40.2% HER2+ and 25.8% triple negative (TNBC). Epirubicin/cyclophosphamide/paclitaxel (ECT) was the most frequently delivered chemotherapy regimen (42.7%), followed by paclitaxel plus trastuzumab (32.3%). 77.1% of patients had a dose alteration – 6.3% required a dose delay, 40.6% a dose reduction and 30.2% early discontinuation. Treatment-related toxicity (51.3%, $p=0.017$, $n=39$) was a significant factor leading to dose reduction, of which peripheral neuropathy was the major complaint (50.0%, $p=0.001$), as well as consideration of older age at the start of treatment (35.9%, $p=0.782$). Early

discontinuation of treatment was required in 30.2% (n=29), due to treatment-related toxicity (48.3%, p = 0.0001). Peripheral neuropathy was also the predominant toxicity within this cohort (57.1%, p=0.006). Other reasons for discontinuation were hospital admission (10.3%), adverse reaction to chemotherapy (13.8%) and acute infection (13.8%). Four patients (4.2%) had disease progression and there were no treatment-related deaths. In the neoadjuvant setting, 14.7% were ER+, 52.9% HER2+ and 32.4% TNBC.

Epirubicin/paclitaxel/cyclophosphamide/trastuzumab/pertuzumab (35.0%) and ECT (32.0%) were the most frequent chemotherapy regimens. Dose intensity was altered in 88.0% of patients – 6.0% dose delay, 50.0% dose reduction and 32.0% early discontinuation. Reasons for a dose reduction included toxicity (64.7%, p=0.0002), consideration of older age at the start of treatment (11.8%, p=0.208) and hospital admission (5.9%, p=0.069). Reported toxicities (n=11) were neutropenia (54.5%, p=0.02), peripheral neuropathy (18.2%), fatigue (9.1%) and mucositis (2.0%). Early discontinuation in chemotherapy (32.0%, n=11) occurred due to toxicity (90.9%, p=0.007) and hospital admission (9.1%). Partial pathological response to treatment was 70.6%, whilst 29.4% had a complete pathological response. Disease progression was seen in four patients (11.8%); however, no treatment-related deaths were observed.

Conclusion: This study shows that a large proportion of older patients with breast cancer require changes to their initial chemotherapy dose intensity, with neutropenia and peripheral neuropathy being significant toxicities in neoadjuvant and adjuvant treatment respectively.

Background: Five years of adjuvant endocrine therapy (ET) including aromatase inhibitors (AIs) and tamoxifen (TAM) is considered the standard of care in hormone receptor–positive, human epidermal growth factor–negative (HR+/HER2–) early breast cancer (eBC). Clinical practice guidelines recommend the use of an AI or TAM depending on menopausal status and clinical risk stratification. Although TAM is generally recommended and more commonly used in premenopausal women, there is mixed evidence for different clinical outcomes. Patient-level meta-analyses conducted by the Early Breast Cancer Trialists' Collaborative Group (EBCTCG) showed significantly lower rates of BC recurrence with AIs vs TAM. However, this was not specific to patients with HR+/HER2– eBC. This trial-level meta-analysis was conducted to compare AIs ± ovarian function suppression (OFS) vs TAM ± OFS in HR+/HER2–, pre- and postmenopausal patients with eBC. **Methods:** A systematic literature review (SLR) was conducted using key literature databases, ie, Embase, PubMed, and MEDLINE In-Process (from database inception to March 2022) and key conferences (2019-2021). Studies selected for the SLR were those that included either ≥80% of patients with HR+/HER2– eBC in the mixed patient population or subgroup data provided specifically for patients with HR+/HER2– eBC. Of these, randomized controlled trials (RCTs) investigating AI ± OFS vs TAM ± OFS and assessing disease-free survival (DFS) were included in the trial-level meta-analysis. This meta-analysis was conducted using the generic invariance method to obtain a pooled effect estimate (hazard ratio [HR]) together with its CI for DFS. This pooled estimate was calculated as a weighted average of the intervention effects estimated in the individual trials. Both fixed- and random-effect models (FEM, REM) were used to estimate the effect size. A base-case analysis was performed including all eligible trials. Three other scenario analyses were conducted: trials investigating only nonsteroidal AIs (NSAIs), assessing only premenopausal women, and assessing only postmenopausal women. Heterogeneity across the trials was assessed using I² statistic. **Results:** A total of 5 RCTs comparing AI ± OFS vs TAM ± OFS were eligible for the meta-analysis (SOFT, HOBOE, BIG 1-98, N-SAS BC 03, Li 2019; additional information on rationale for exclusion of specific trials will be reported). Two studies assessing NSAI vs TAM included postmenopausal women, while 3 studies assessing AIs + OFS vs TAM ± OFS included premenopausal women. A total of 6623 patients were followed up for 34-97.2 months across these five trials. Heterogeneity was found to be low (I² < 40%) across all scenarios. The base-case results (including all studies) using FEM significantly favored AIs ± OFS over TAM ± OFS, with a 29% reduction in risk of recurrence or death (pooled HR, 0.71 [95%CI, 0.64-0.80]). Similar results were observed with NSAIs ± OFS vs TAM ± OFS (HR, 0.73 [95% CI, 0.64-0.83]). Among premenopausal patients, the pooled HR for AIs + OFS vs TAM ± OFS was 0.66 (95% CI, 0.54-0.79). For postmenopausal women, the HR was 0.75 (95% CI, 0.65-0.87), favoring AIs over TAM. The findings for the base-case and different scenarios remained consistent when REM was used. **Conclusions:** This trial-level meta-analysis suggests significantly greater benefit with AIs than with TAM for HR+/HER2– eBC. Notably, AIs in combination with OFS are associated with a 34% reduction in risk of recurrence or death vs TAM ± OFS in premenopausal women; these results are aligned with the patient-level data findings of the EBCTCG. The findings indicate that AIs ± OFS are associated with a better DFS in the HR+/HER2– population, especially premenopausal women, than TAM ± OFS.

Background: Approximately 10% of breast cancers (BC) are hormone receptor positive (HR+) and HER2 positive (HER2+). Despite treatment advances in the modern era of HER2 targeted therapies for early-stage disease, there remains a risk for late relapses. However, the role of adjuvant endocrine therapy (ET) to reduce recurrence in this BC subtype is unclear. Oncologists employ clinical judgment given lack of consensus, resulting in differences in treatment patterns. The ideal endocrine agent including the role of adding ovarian suppression (OS) in premenopausal women is unknown. These patients are largely underrepresented in clinical trials such as the phase III SOFT and TEXT studies. Additionally, these trials were initiated prior to the widespread use of trastuzumab with chemotherapy, which is now standard of care for HER2+ disease. We aimed to describe real world patterns surrounding choice of adjuvant ET and clinicopathologic features which predicted treatment with OS in premenopausal women with HR+/HER2+ BC.

Methods: We performed a multi-institutional retrospective analysis of premenopausal women with non-metastatic HR+/HER2+ BC in the American Society of Clinical Oncology CancerlinQ® Discovery database from January 2010 to May 2020. Electronic health record data was obtained from 74 participating academic and community oncology sites. We collected clinical data on women less than 50 years who received chemotherapy, anti-HER2 therapy (trastuzumab with or without pertuzumab), and ET. Adjuvant OS was defined as receipt of at least 6 months of goserelin or leuprolide or surgical bilateral oophorectomy. Demographics, clinical characteristics, and treatment history was collected. Patients were categorized into 1 of 4 groups based on type of adjuvant ET prescribed at treatment initiation: aromatase inhibitor (AI) + OS, OS, tamoxifen + OS, or tamoxifen. Multivariable logistic regression was conducted to assess the association between clinicopathologic features and OS use.

Results: Out of 360,540 patients with invasive breast cancer in the database, 937 met inclusion criteria. Mean age was 41.7 (SD 5.9) years; 83% had stage 1 or 2 BC and 78% had node positive disease. The majority (n=818, 87%) were prescribed tamoxifen whereas only 4 (0.4%), 50 (5.3%), and 65 (6.9%) received OS, tamoxifen + OS, and AI + OS, respectively. Table 1 includes demographic and clinical characteristics of the cohort. No clinicopathologic features predicted OS use apart from age; patients ≥ 35 years were less likely to receive OS compared with those < 35 ($p < 0.001$) (table 2).

Conclusion: To our knowledge, this is the first real world study evaluating OS treatment in HR+/HER2+ BC. The use of OS was uncommon; this suggests a perception of its limited benefit when added to HER2-targeted therapy. Most patients received tamoxifen as the ET of choice. Age was the only factor to predict OS treatment; high risk features including node

positivity and higher stage was not associated with its use. This highlights the wide variability in real world practice surrounding the clinical indications for OS. Further investigation is warranted to characterize the utility of ET including addition of OS to prevent recurrence in premenopausal HR+/HER2+ BC. This will better inform a personalized approach to tailor therapy for optimal outcomes in this distinct BC subtype.

Background The Regan Composite Risk Score (RCRS) is a web-based prognostic and predictive calculator to guide the use of adjuvant exemestane plus ovarian function suppression (AI + OFS) versus tamoxifen plus ovarian function suppression (TAM + OFS) or tamoxifen alone (TAM) for premenopausal women with hormone receptor-positive HER2-negative early breast cancer (HR+/HER2- EBC). We compared our adjuvant endocrine therapy policy based on the tumor board with the treatment guided by the RCRS during 2 time periods, one before and one after the acquaintance of the Tamoxifen and Exemestane Trial (TEXT) and Suppression and Ovarian Function Trial (SOFT) data. This allowed us to see a possible evolution in therapy policy. **Methods** A retrospective cohort study of 563 premenopausal patients with HR+/HER2- and HER2+ EBC diagnosed at the University Hospital of Leuven during 2 periods, 2010-2012 (cohort 1) and 2015-2017 (cohort 2), was conducted. For each patient with HER2- EBC, the RCRS was calculated by entering the requested characteristics in the online available tool. The primary outcome was to investigate how frequent our therapy differed from the therapy guided by the RCRS based on the estimated 8-yr distant relapse free interval (DRFI) with an arbitrary cut-off set at 3 %. If the received therapy was ≥ 3 % less efficient in 8-year DRFI compared to the optimal therapy according to RCRS, the patient was considered undertreated. If the received therapy differed by less than 3 % in 8-year DRFI compared to the optimal therapy according to RCRS and yet the most intensive therapy (AI + OFS > TAM + OFS > TAM) was administered, the patient was considered overtreated. In the other cases, the patient was considered to have been treated concordant with the RCRS. **Secondarily**, nonadherence of the HER2- and HER2+ patients towards the endocrine treatments leading to therapy switch because of intolerance was recorded at 6, 12, 24 and 36 months. Analyses were performed using SAS software and the comparison of both cohorts was performed by the chi-squared test for categorical variables. **Results** According to the RCRS, 43.2 % (89/206) of the HER2-negative patients of cohort 1 were undertreated compared to 22.1 % (43/194) in cohort 2 (chi-squared test, p-value < 0.001). The number of overtreated patients also differed significantly between the two cohorts (chi-squared test, p-value = 0.003) with 2.9 % (6/206) in the first cohort and 10.3 % (20/194) in the second cohort. Finally, the number of patients treated concordant with the guidance derived from the RCRS was 53.9 % (111/206) in cohort 1 and 67.5 % (131/194) in cohort 2 (chi-squared test, p-value = 0.005). Treatment intolerance and switch was observed in 34.8 %, 16.7 % and 12.4 % of the patients receiving AI + OFS, TAM + OFS or TAM as initial therapy respectively; this was numerically higher for all treatments in cohort 2 vs cohort 1, although the observed difference was only significant for TAM. **Conclusion** In our center, a recent cohort of premenopausal women was more likely to be

treated with the adjuvant endocrine treatment concordant with the guidance derived from the RCRS when using an arbitrary cut-off of 3 % to define a relevant improvement in outcome.

Background: The microbiome consists of the totality of microorganisms (bacteria, fungi, protist, viruses, and phages) that live on and within the body. Studies implicate the gut bacterial microbiome as a risk factor for estrogen receptor-positive (ER+) breast cancer. While diet is the main contributor to the gut microbiome, medications also shift the bacterial microbiome. We currently do not know whether oral endocrine targeting therapies, such as aromatase inhibitors or tamoxifen shift the gut microbiome. Furthermore, we do not know whether gut microbiome populations can influence drug efficacy. Methods: Fecal samples from human donors were placed into ex-vivo colonic bioreactors for stabilization (n=3). Bioreactors were untreated or treated with letrozole or tamoxifen citrate for 48 hours. Samples were collected, DNA isolated, and metagenomic sequencing performed to determine direct drug-bug interactions. C57BL/6 mice were placed on a healthy control (HC; 21% kcal from fat derived from olive oil and fish oil) or a Western diet (45% kcal from fat derived from corn oil, lard, and milkfat) for 6 weeks. Mice within dietary patterns were randomized and administered control, tamoxifen (TAM; 37 ppm tamoxifen citrate), or an aromatase inhibitor (AI; 5 ppm letrozole) for 16 weeks. Metagenomics sequencing were performed on fecal DNA samples at study endpoint. Female BALB/c mice fed a HC or Western diet were injected with bone metastatic 4T1.2ER+ breast cancer cells. Mice were administered tamoxifen citrate, oral probiotics, or a combination of TAM + probiotics for 3-weeks. Tumor volume, tumor weight, and lung weight were recorded at the end of the study. Hindlimbs were analyzed for metastatic lesions. Results: Metagenomic sequencing from the ex-vivo colonic bioreactors treated with aromatase inhibitors or tamoxifen display differential shifts

in several β -glucuronidase-expressing and obesity-associated bacterial species suggesting AI and selective estrogen receptor modulators have varying effects in the gut microbiome that may influence estrogen bioavailability and metabolic parameters. C57BL/6 mice on HC or Western diet treated with AI or TAM also display differences in the microbiota and phage populations with TAM elevating *Lactobacillus johnsonii* and letrozole increasing *Lactococcus lactis* bacterial proportional abundance. In the tumor-bearing model, combination of oral *Lactobacillus* probiotics and TAM significantly reduced tumor weight when compared with the tumor weight in control, TAM, or probiotic treated mice fed a Western diet. Combination of probiotics and TAM also prevented the development of ER+ bone metastatic lesions. Conclusions: Our study indicates oral endocrine therapies differentially affect the gut microbiome and these drug-bug interactions are sensitive to dietary-influenced baseline microbiota populations, which may influence drug efficacy and metabolic outcomes. Furthermore, our preclinical studies suggest oral probiotic supplements may enhance tamoxifen efficacy to reduce tumor growth and metastatic development. Further clinical studies are needed on this topic.

Background: Poor survival outcome in young women with hormone-sensitive breast cancer was reported. And previous studies have demonstrated that the addition of ovarian function suppression (OFS) significantly improved disease-free survival (DFS) in patients with premenopausal hormone receptor-positive breast cancer. In this study, we examined whether

ovarian function suppression treatment in premenopausal women is effective in survival comparable to postmenopausal status.

Methods: We evaluated 1,298 breast cancer patients included in the post-trial follow-up of the Addition of Ovarian Suppression to Tamoxifen in Young Women With Hormone-Sensitive Breast Cancer Who Remain Premenopausal or Regain Vaginal Bleeding After Chemotherapy (ASTRRA) trial who received either tamoxifen (TAM) only (n=647) or TAM + OFS (n=635), randomly assigned in a 1:1 ratio and postmenopausal patients in AMC (Asan Medical Center; Seoul, Korea) treated with aromatase inhibitor (AI) (n=603). All patients analyzed in this study underwent surgery between March 2009 and November 2011. The primary endpoint was disease-free survival (DFS) and the secondary endpoint was overall survival (OS). We use propensity-score matching by lymph node status, tumor size, tumor grade, histologic type of cancer, human epidermal growth factor receptor-2 (HER2) status, chemotherapy regimen, surgical modality, and radiotherapy in the overall cohort and in separate subgroups according to anti-hormonal therapy regimens.

Results: In the overall matched cohort, there was a significant difference between the postmenopausal AI group and premenopausal Tam only group in DFS (hazard ratio for the postmenopausal AI group, 0.654; 95% CI, 0.432 to 0.991) and OS was not significantly different between the premenopausal Tam only group and postmenopausal AI group (p=0.061). On the other hand, there was no significant difference between the postmenopausal AI group and premenopausal Tam+OFS group in disease free survival (hazard ratio for the postmenopausal AI group, 1.156; 95% confidence interval [CI], 0.735 to 1.820) or the overall survival (hazard ratio for the postmenopausal AI group, 1.04; 95% CI, 0.553 to 1.956).

Conclusion: This study's findings suggest that the poor prognosis of young women with hormone-sensitive breast cancer is improved by adding OFS to Tam and the effect is not inferior to that of using AI in post-menopausal women.

Outcomes in a Cohort of Patients Matched for Propensity Scores

	Propensity score matched set 1				Propensity score matched set 2			
	postmeno AI vs premeno Tam+OFS(Ref)				postmeno AI vs premeno Tam(Ref)			
	Hazard Ratio	95% CI	P value	Hazard Ratio	95% CI	P value		
Disease free survival (DFS)	1.156	0.735	1.820	0.530	0.654	0.432	0.991	0.045
Overall survival (OS)	1.040	0.553	1.956	0.902	0.489	0.231	1.033	0.061
Distant meta free survival (DMFS)	0.816	0.493	1.351	0.430	0.433	0.265	0.709	0.001
Free from distant meta	0.732	0.430	1.246	0.250	0.424	0.252	0.713	0.001
Recurrence free interval (RFI)	0.861	0.531	1.399	0.546	0.493	0.309	0.786	0.003
Loco-regional free survival (LRFS)	1.090	0.619	1.921	0.765	0.447	0.252	0.794	0.006

postmeno AI, postmenopausal patients who treated with aromatase inhibitor in Asan Medical Center; premeno Tam+OFS, premenopausal ASTRRA participants who treated with tamoxifen and ovarian function suppression; premeno Tam, premenopausal ASTRRA participants who treated with tamoxifen only

Background Tamoxifen is frequently used in the adjuvant treatment of hormone sensitive breast cancer. Unfortunately, tamoxifen can lead to bothersome side effects resulting in non-adherence in 40% of patients. Patients searching for relief from these side effects are increasingly turning to cannabinoids such as CBD. However, since tamoxifen is mainly metabolised by CYP2D6, and CBD is suggested to be an inhibitor of CYP2D6, the use of CBD might affect tamoxifen pharmacokinetics (PK). Since the effect of CBD on both tamoxifen PK as tamoxifen-related side effects has never been investigated, the aims of this study were to determine the pharmacokinetic interaction between CBD and tamoxifen, and to subsequently investigate whether there is a beneficial influence of CBD on tamoxifen-related side effects.

Methods Patients had to be treated with tamoxifen for at least 3 months, have steady-state endoxifen levels >16 nM (conservative threshold) and experience tamoxifen-related side effects. PK sampling was done at initiation of CBD-oil and 28 days thereafter. Bio-equivalence could be concluded if the 90% confidence interval (CI) for the difference in endoxifen area under the curve (AUC) fell within the [-20%; +25%] interval (n = 15, two-sided α 0.05, β 0.20). In addition, endoxifen PK was analyzed for each CYP2D6 phenotype separately. The effect of CBD on side effects was evaluated with the FACT-ES questionnaire (n = 25, two-sided α 0.05, β 0.20). An improvement > 0.5 times standard deviation (SD) of baseline score was considered clinically relevant. Last, potential side effects of CBD were assessed. Results In this study 15 patients were included for PK analysis and 24 patients for side effect analysis. Endoxifen AUC decreased after CBD by 12.6% (90% CI -18.7%, -6,1%) but remained within bio-equivalence boundaries. The decrease seemed more pronounced in patients with intermediate (IM) CYP2D6 phenotype (-20.8%, 90% CI -26.4%, -14.8%, n = 8) compared to normal CYP2D6 phenotype (-2.2%, 90% CI -11.1%, 7.6%, n = 7). There was no difference in tamoxifen AUC (with or without CBD). On average, the endocrine sub-scale of the FACT-ES improved with a clinically relevant improvement of 8.3 points (95% CI 4.9 – 11.7) after using CBD (baseline SD = 12.8). CBD itself has a mild toxicity profile with few side effects in 10 of 24 patients. Side effects were headache (n=2), dry mouth (n=3), fatigue (n=3), gastroesophageal reflux (n=1), abdominal pain (n=1) and nausea (n=1) and all graded CTCAE 1. Conclusions As endoxifen levels with or without CBD remained within bio-equivalence boundaries and CBD-oil might have a positive effect on tamoxifen-related side effects, it could be considered in case of treatment-related side effects. However, caution is needed in patients with IM or poor metabolizer CYP2D6 phenotypes.

Background Eribulin is a chemotherapeutic drug that prolongs overall survival (OS) in patients with HER2-negative metastatic breast cancer (MBC), mainly in third-line or later chemotherapy (ChT) [1]. However, health-related quality of life (HRQOL) and efficacy in patients who receive eribulin as first- or second-line therapy is not well known. In contrast, S-1, an oral 5-fluorouracil derivative, shows similar OS to taxanes as first-line ChT and better HRQOL, based on a large phase III trial conducted in Japan [2]. Here, we compared the effect on HRQOL and efficacy of eribulin and S-1 in MBC patients in a first- or second-line ChT setting. Methods We planned an open-label, multicenter, randomized controlled phase III study at 50 hospitals in Japan. We enrolled patients with HER2-negative MBC who had no or one previous ChT for MBC regardless of prior administration of anthracyclines and taxanes. Patients were randomly assigned (1:1) to either eribulin (1.4 mg/m² administered on days 1 and 8 of a 21-day) or S-1 (40–60 mg twice daily for 14 consecutive days, followed by a 7-day break). Randomization was stratified by institution, age, treatment line, hormone receptor status, and time from surgery to recurrence. HRQOL assessment was conducted using the European Organisation for Research and Treatment of Cancer (EORTC) Quality of Life Questionnaire-Core 30 questions (QLQ-C30) every six weeks until week 24, and then every nine weeks until week 42 after baseline assessment. The primary outcome measure was the global health status (GHS) score of EORTC QLQ-C30, with a prespecified non-inferiority margin of 10% for a difference in the proportion of patients experiencing deterioration at one year. Clinically meaningful deterioration was defined as a ≥ 10 -point decrease from baseline GHS score or death. Secondary outcomes were OS, progression-free survival (PFS), and adverse events. We estimated that the study needed 330 patients to obtain 80% power for non-inferiority. This trial was registered with the University Hospital Medical Information Network, Japan (protocol ID 000021398). Results Between June 2016 and October 2019, 302 patients were enrolled, with 152 assigned to eribulin and 148 to S-1. The full analysis set for HRQOL assessment included 134 and 136 patients, while that for efficacy consisted of 141 and 144 patients, respectively. Overall compliance with the questionnaire was 85.6%. Among the full analysis set for efficacy, 28 (19.9%) and 31 (21.5%) cases were triple negative, respectively. Eribulin and S-1 were administered as first-line ChT in 99 (70.2%) and 101 (70.1%) patients, respectively. Risk difference of GHS deterioration through one year for the eribulin versus S1 group was -0.66% (95% CI -12.47 to 11.16; P non-inferiority =0.077). Median time to first deterioration in GHS score was 5.64 months (95% CI 3.51–8.00) and 5.28 months (95% CI 3.28-7.80) (HR 1.07 [95% CI 0.79–1.45]; P =0.667); median OS was 35.0 months (95% CI 27.2-41.0) and 27.8 months (95% CI 24.6-33.5) (HR 0.69 [95% CI 0.50-0.95]; P=0.023); and median PFS was 6.07 months (95% CI 5.48-7.80) and 6.66 months (95% CI 5.48-7.77), respectively (HR 0.90 [95%

CI 0.68-1.18]; P=0.427). No previously unrecognized adverse events were observed. Conclusions We found a marginal non-inferiority in HRQOL for eribulin, albeit that the difference was not statistically significant owing to the smaller than planned sample size. Time to first clinically meaningful deterioration was almost identical between the two arms, whereas OS was significantly extended with eribulin. These findings indicate that eribulin in first- or second-line ChT is acceptable as a standard regimen in this patient population. [1] Lancet 2011; 377: 914–23 [2] Lancet Oncol 2016; 17: 90–98

Background: Breast cancer (BC) with low-level HER2 expression (HER2-low) is defined by an immunohistochemistry (IHC) score of 1+ or 2+ without HER2 gene amplification or excess HER2 gene copy number, as measured by in situ hybridization (ISH). This represents approximately half of patients with BC overall (estimated as 55% for hormone-receptor positive [HR+] BC and 38% for triple-negative breast cancer [TNBC]; Scott, ASCO, 2021). Some data suggest that patients with HER2-low BC may respond differently to treatment than those whose BC has no HER2 expression (HER2-0). In this post hoc unplanned analysis, we analyzed data from two pivotal phase 3 studies (Studies 305 and 301) comparing eribulin with other chemotherapeutic agents (treatment of physician's choice and capecitabine, respectively ["control"]) in patients with both HER2-low and HER2-0 MBC. Methods: Patients with MBC, 2–5 (Study 305) or < 2 (Study 301) prior lines of chemotherapy for advanced/metastatic disease, and who had received an anthracycline and a taxane, were analyzed. HER2-expression status was determined by IHC and/or ISH assays. Median progression-free survival (PFS) and overall survival (OS) were calculated using the Kaplan–Meier method adjusted by study; comparisons of PFS and OS between treatment groups were performed using stratified (by prior

capecitabine use, geographic region, and study) log-rank tests. Hazard ratios were estimated by a stratified Cox model. For each study, median PFS and OS were also calculated for HR+ and TNBC subgroups. Results: Baseline characteristics were generally balanced between treatment groups among patients with HER2-low (n=427) and HER2-0 (n=824) BC. Patients with HER2-low or HER2-0 BC showed trends toward benefit with eribulin treatment. In patients with HER2-low and HER2-0 BC, median OS was longer with eribulin vs control (15.1 vs 12.0 months and 15.2 vs 12.5 months, respectively); median PFS by independent imaging review (IIR) was also longer with eribulin vs control (4.0 vs 3.1 months and 3.9 vs 3.1 months, respectively). Objective response rate (ORR) by IIR was also higher with eribulin vs control in patients with HER2-low and HER2-0 BC (13.7% vs 9.2% and 10.2% vs 7.4%, respectively). In a separate analysis, median OS was longer with eribulin vs capecitabine in patients with TNBC and HER2-low and HER2-0 (15.4 vs 10.3 months and 14.4 vs 8.9 months, respectively). Conclusions: In this post hoc analysis, treatment with eribulin demonstrated trends toward improved OS, PFS, and ORR compared with chemotherapy controls in patients with HER2-low or HER2-0 MBC. Funding source: This trial was sponsored by Eisai Inc., Nutley, NJ, USA. Medical writing support was provided by Oxford PharmaGenesis Inc., Newtown, PA, USA, and was funded by Eisai Inc., Nutley, NJ, USA.

Real-World Treatment Patterns and Clinical Outcomes in Patients Treated with Eribulin After Prior PI3K Inhibitor Therapy for Metastatic Breast Cancer

Presenting Author(s) and Co-Author(s):

Ravi K. Goyal, MS, BPharm, *Senior Director, Health Economics - RTI Health Solutions*
Country: United States

Jingchuan Zhang, PhD, *Associate Director, Worldwide RWE - Eisai Inc.*

Country: United States

Background: Eribulin has been used in the treatment of metastatic breast cancer (MBC) following approval in 2010 in the United States (US). Recently, several new therapeutic classes have been approved for patients with MBC, including the phosphoinositide 3-kinase (PI3K) inhibitor alpelisib. This study aimed to assess the treatment patterns and clinical outcomes in patients with MBC treated with eribulin following alpelisib in US clinical practice. Methods: A retrospective, noninterventional medical chart review study was performed to obtain de-identified patient data via participating oncologists. Study population included adult female patients with a diagnosis of MBC who initiated eribulin therapy between March 1, 2019, and September 30, 2020, following prior therapy with alpelisib. Eribulin treatment parameters and patient characteristics were captured. Progression-free survival (PFS) and overall survival (OS) since eribulin initiation was assessed using Kaplan-Meier methods. Results: This interim analysis included 47 eligible patients (median age 62 years at eribulin initiation; 77% Caucasian). The majority (91.5%) of this cohort had HR+/HER2- MBC; 72.3% had a known PIK3CA mutation. Eribulin was classified as 2nd line, 3rd line, and 4th line or later in 34%, 47%, and 19% of patients, respectively, in regard to the line of therapy in the metastatic setting. At last follow-up, eribulin treatment was ongoing for 34% of patients. The median treatment duration was 5.2 months (q1, q3: 3.9, 7.1) among those who had discontinued eribulin, and 11.3 months (q1, q3: 10.0, 13.7) among those who were still on treatment. At last follow-up, 72.3% of patients were alive. The estimated PFS rate at 12 months was 57.1% (95% CI: 40.0-70.9). Median was not reached for OS after initiation of eribulin; the estimated OS rates at 12 and 24 months were 80.2% (95% CI: 65.3-89.2) and 61.8% (95% CI: 37.2-79.2), respectively. Conclusion: Among patients with MBC who initiated eribulin following prior treatment with a PI3K inhibitor, over 60% were estimated to survive for at least 2 years. Future studies to confirm these results are warranted.

Background Obesity has previously been correlated with poorer survival in both early and metastatic breast cancer. Adipose tissues release proangiogenic factors such as Insulin-like Growth Factor and Vascular Endothelial Growth Factor that may ultimately promote tumor growth. CTscan can be used to measure the visceral fat area (VFA) and the subcutaneous fat area (SFA) on the same section. High VFA has been shown to independently predict poorer outcome in patients given first-line bevacizumab-based treatment for metastatic colorectal cancer and metastatic renal cell carcinoma. The prospective multicenter COMET trial included metastatic HER2 negative breast cancer patients receiving bevacizumab and paclitaxel as first-line chemotherapy. This study was designed to identify and validate reliable factors to predict benefit of bevacizumab and allow for a more personalized use of this antiangiogenic agent. Our aim was to evaluate the prognostic value of BMI (Body Mass Index), VFA and SFA in the COMET cohort and their impact on the quality of life. Patients and Methods Out of the 510 patients included in the COMET trial from 9/2012 to 3/2016, 480 received bevacizumab and paclitaxel as first-line treatment and 360 had available CTscan data. VFA and SFA were measured retrospectively on the CTscans performed before chemotherapy initiation, at the level of the umbilicus with the patient in the supine position. ImageJ software was used to measure pixels with densities in the -190 HU to -30 HU range in order to delineate the subcutaneous and visceral compartments and to compute the cross-sectional area of each in cm². These measurements were performed by a radiologist blinded to patients' characteristics and outcomes. For VFA and SFA, we used a threshold at the median value. VFA and SFA levels were tested for their association with progression-free survival (PFS) and overall survival (OS). The impact on quality of life was based on the Global Health Status, the Physical functioning, the Emotional functioning, Fatigue and Pain scores. Results The mean age at inclusion was 57 years (range: 28-83). At initial diagnosis, the main histological type was invasive ductal carcinoma (n = 247, 80.7%). Most patients had received prior neoadjuvant/adjuvant chemotherapy (n = 245, 68.1%) and a large majority (95.4%) had less than 3 metastatic sites. One hundred and forty patients (46.7%) had histological grade II and 41% had grade III tumors. The majority of the patients had positive hormone receptor tumor (n = 238, 79.3 %) and 62 (20.7%) had triple-negative tumor subtype. The median BMI was 24.7

(range : 17-46). After a median follow-up of 60.6 months (95%CI, 60-61.3), median PFS was 9.5 months (95CI, 8.6-10.3). There was no significant correlation between BMI ($p = 0.69$), VFA ($p = 0.24$) or SFA ($p = 0.58$) and PFS in the univariate analysis. The median OS was 29.6 months (95CI, 25.9-32.4). BMI, VFA and SFA were not correlated with OS. Out of the 360 patients, 328 had available data regarding the quality of life. There was no impact of the VFA or the SFA on the different quality of life scores. Conclusions In our prospective cohort of 360 patients with metastatic breast cancer receiving bevacizumab and paclitaxel as first-line treatment, high VFA or high SFA were not associated with a poorer survival. VFA and SFA had no impact on quality of life.

Background: Management of metastatic breast cancer (mBC) in elderly patients (pts) faces some challenges since some pts are frail or have functionality impairment, with higher risk of severe adverse events from oncologic therapy. We aimed to assess the treatment patterns for elderly pts with MBC and evaluate factors associated with outcomes in this population. **Methods:** This retrospective study evaluated pts 70 years and older with mBC treated in a tertiary cancer center from 2009 to 2022. Charlson index (ChI) was used to measure comorbidities. Endpoints were proportion and type of first-line systemic therapy, rates of treatment discontinuation due to toxicities, overall survival (OS) and prognostic factors. The Kaplan-Meier method was used for survival analyses. Hazard ratio (HR) and 95% confidence interval (95% CI) were calculated using Cox regression. **Results:** 460 pts with mBC were evaluated. Median age was 78 years (IQR 70-96). Most pts (n=331; 72%) had hormone receptor-positive HER2-negative (HR+HER2-) BC, while 11% (n=50) had HER2-positive (HER2+) BC and 14% (n=64) triple-negative (TN) BC. Most pts has de novo metastatic disease (n=316; 69%); ECOG-PS 3-4 (n=313, 68%), and ChI ≤ 7 (n=354; 77%). Forty-five pts (10%) did not receive systemic therapy for metastatic BC; this proportion was higher among TNBC (34%) than other subtypes (HR+HER2-: 5%; HER2+: 6%) ($P < 0.001$). The proportion not receiving systemic therapy was also higher among pts with ECOG-PS 3-4 (13%, $P < 0.001$), older than 90 years (19%; $P = 0.069$), and with ChI > 7 (15%; $P = 0.088$). Among 165 pts who received first-line endocrine therapy, 2% discontinued due to toxicity. Ninety pts received first-line chemotherapy and 18% discontinued due to toxicity. Breast cancer was the main cause of death (94%) in the cohort. Factors associated with increased risk of death were HER2+BC (HR 1.48, 95% CI 1.04 – 2.09; $P = 0.027$), TNBC (HR 1.52, 95% CI 1.05 – 2.20; $P = 0.025$), age group 80-90 years (HR 1.30, 95% CI 1.02-1.64; $P = 0.028$), ECOG-PS 3-4 (HR 2.34, 95% CI 1.73-3.15, $P < 0.001$), and not receiving systemic therapy (HR 4.48, 95% CI 2.88-6.98, $P < 0.001$). Median OS was 29 months for pts treated with systemic therapy, and 2.3 months for those who did not receive it ($P < 0.001$). **Conclusions:** Many factors influence the prognosis and the treatment decision for elderly pts with mBC. The rates of pts who do not receive systemic therapy are higher among TNBC, which points to the need for better tolerated therapies for this group.

Background: Dual HER2 blockade with trastuzumab and pertuzumab combined with docetaxel (DHP) is the standard first-line treatment option for patients with HER2-positive metastatic breast cancer. However, HER2 positivity alone often fails to predict treatment outcome of HER2 targeted therapy. The magnitude of HER2 immunohistochemical staining (IHC) and HER2/CEP17 ratio from in situ hybridization (ISH) is a well-known predictive biomarker for HER2 targeted therapy. In the neo-adjuvant setting, patients with HER2 IHC 3+ have higher pathologic complete response (pCR) rate compared to HER2 IHC < 3+ with HER2 ISH positive. In addition, higher HER2/CEP17 ratio is associated with higher pCR rate in HER2-positive breast cancer patients treated with dual HER2 blockade regimens. However, there is no data whether there is an association between HER2/CEP17 ratio and treatment outcome of DHP regimen in patients with advanced of metastatic breast cancer especially among those with HER2 IHC 3+.

Methods: We performed a retrospective cohort study with patients with locally advanced or metastatic HER2-positive breast cancer who were treated with first-line palliative DHP regimen between August 2008 and January 2021 at Seoul National University Hospital. In the clinical setting, HER2 IHC 3+ is defined as HER2 positive and no further ISH testing is required. Additional ISH was performed in patients with HER2 IHC 3+ without archival HER2 ISH results. The association between HER2/CEP17 ratio and treatment outcome was assessed.

Results: In total, 165 patients were included with a median follow-up duration of 28.0 months. Among the 165 patients, 35 patients had archival ISH result and additional ISH was performed in 53 patients. The correlation between HER2/CEP17 ratio and treatment outcome was assessed in 88 patients. Cox proportional hazard analysis revealed that HER2/CEP17 ratio is correlated with PFS (HR 0.23, 95% CI 0.11-0.49, $p < 0.001$). When dichotomized by the median

HER2/CEP17 ratio of 4.17, patients with higher HER2/CEP17 ratio had significantly longer PFS (37.5 vs. 17.4 months, $p = 0.003$) and numerically higher ORR (54.5% vs. 34.1%, $p = 0.085$). Multivariate analysis revealed that HER2/CEP17 ratio is an independent prognostic factor for PFS (HR 0.72, $p = 0.001$). Of 88 patients with ISH results, 25 had HER2 IHC 1+ or 2+ and 63 had HER2 IHC 3+. HER2/CEP17 ratio was associated with PFS in both HER2 IHC 1+/2+ patients (HR 0.12, 95% CI 0.02-0.88, $p = 0.037$) and HER2 IHC 3+ patients (HR 0.18, 95% CI 0.07-0.49, $p = 0.001$). Patients with higher HER2/CEP17 ratio had longer PFS in both HER2 IHC 1+/2+ patients (28.6 vs. 12.9 months, $p = 0.003$) and HER2 IHC 3+ patients (Not reached vs. 18.3 months, $p = 0.005$) when dichotomized by the median HER2/CEP17 of 2.95 and 4.75, respectively.

Conclusion: This is the first study to report that higher HER2/CEP17 ratio is associated with longer PFS in HER2-positive advanced breast cancer patients treated with palliative first-line DHP. The strength of this study is that we identified prognostic role of ISH even in patients with HER2 IHC 3+. It would be helpful to perform ISH not only in patients whose HER2 IHC is ambiguous, but also in patients with HER2 IHC 3+ to make better prediction of treatment outcome.

Table 1. Patient characteristics

	Number of patients (%) (N = 165)
Female sex	165 (100.0%)
Age	
Median	52
Range	22 – 79
Disease status	
De novo metastatic disease	76 (46.1%)
Recurrence	89 (53.9%)
Metastatic site	
Locally advanced	23 (13.9%)
Bone only	27 (16.4%)
Visceral metastasis	115 (69.7%)
Specific metastatic sites

Background: Greater gut microbiome diversity is observed in patients with a clinical response to immune checkpoint inhibitor (ICI) therapy in solid tumors and in preclinical models targeting the gut microbiome is a promising strategy to improve ICI efficacy. The investigation of the immunomodulatory effects of the gut microbiome and tumor biology is in its infancy and whether interindividual microbiome variations correlate with tumor biology in breast cancer is unknown. Here we report a correlative analysis of gut microbiome diversity with tumor biomarkers: PD-L1, tumor immune cell density, tumor infiltrating lymphocytes (TILs), MutSig3, and interferon (IFN) gene signatures in a cohort of mTNBC patients treated with olaparib and durvalumab of the Adaptive Multi-Drug Treatment of Evolving Cancers (AMTEC) trial (NCT03801369). Methods: AMTEC participants undergo a baseline biopsy (bx) and fecal sample collection, then start olaparib monotherapy on a 28-day cycle. Following the first cycle, an on-treatment (on-tx) bx and fecal sample are collected, then as part of enrollment to Arm 1, durvalumab is added to the treatment regimen. Ten patients with stool collections and tissue biopsies were used in this analysis, eight had paired pre- and on-tx collections. At interim-analysis, participants were categorized as responders (PR/SD) or non-responders (PD). Gut microbiome composition in fecal samples collected pre- and on-olaparib monotherapy was

assessed by 16S rRNA sequencing and alpha diversity was quantified by observed diversity, Fisher, Inverse Simpson, Pielou, and Shannon indices. Response, PDL1 expression (Positive CPS >1), multiplex immunohistochemistry (mIHC) immune cell density and immune cell signature, TILs, RNA signatures including interferon (INF) family signatures, and mutational significance (MutSig3) were correlated to alpha diversity by T-test. Results: Average baseline alpha diversity of the fecal microbiome did not vary based on response (6 non-responses and 4 responses). However, in the on-tx samples, Fisher (CB: mean = 21.81, std. dev. = 3.6; PD: mean = 17.04, std. dev. = 2.3; p=0.048) and Observed alpha diversity (CB: mean = 260, std. dev. = 38.8; PD: mean = 209, std. dev. = 25.8; p = 0.049) were higher in responders. Average baseline alpha diversity of the gut microbiome as measured across all examined indices was significantly lower in participants with PD-L1 expressing tumors ($p < 0.05$ for each, T-test). Among on-tx samples, there was a trend toward lower alpha diversity in PD-L1 expressing tumors, but PD-L1 expression did not correlate with clinical response. There was a notable trend toward greater alpha diversity in on-tx bx and high TILs. Alpha diversity did not differ by immune cell densities by mIHC (CD8+ T cell, B cell, and regulatory T cells), hypo-inflamed/pro-inflammatory signature, IFN gene signature, nor MutSig3 score. Conclusion: Our preliminary data reveal that higher alpha diversity following olaparib monotherapy correlated with response to therapy with combination olaparib and durvalumab and correlated with tumor PD-L1 status. Whether gut microbiome features represent a meaningful biomarker for ICI treatment of mTNBC warrants further study. Enrollment to stage 2 of AMTEC Arm 1 is ongoing.

Introduction Triple negative breast cancer (TNBC) is a heterogeneous breast cancer subtype which continues to portend a particularly poor prognosis compared to other breast cancer subtypes. Immune checkpoint inhibitor (ICI) therapies have emerged as promising options for locally advanced and metastatic TNBC. However, clinical trials have demonstrated mixed

results with respect to ICI response. Given varied outcomes and the potential for immune-related adverse events associated with ICIs, there is critical need for identification of accurate biomarkers of response and improved strategies to counteract ICI resistance and/or toxicity. Methods Advanced immunoprofiling of peripheral blood mononuclear cells (PBMCs) and plasma from 7 metastatic TNBC patients with variable responses to anti-PD1 or anti-PDL1 therapy was performed. Samples were analyzed from blood draws obtained: (i) prior to first administration, (ii) while receiving ICI treatment, and (iii) at the time of conformed clinical progression or response to therapy. Response was determined by standard radiological assessment. Immunoprofiling included high parameter flow cytometry, single cell transcriptomics (10x genomics) and secretome analysis (Isoplexis). Single cell RNA profiles from 63,984 cells were analyzed. Results High parameter flow cytometry identified higher circulating levels of a subpopulation of activated CD4+ T cells with a phenotype of CXCR3low CD62Llow CD45RAhigh and CD57high expression in responders versus non-responders. Higher effector function of CD4+ T cells was corroborated by significantly elevated plasma concentrations of IL-2 ($p=0.02$) and IL-5 ($p < 0.0001$) among responders. Single cell transcriptomic analysis revealed clusters of B and T cells with distinct activation patterns that were associated with radiographic response. Strikingly, genes involved in B cell activation and T cell-B cell conjugation such as CD81 were found to be highly upregulated among CD4+ T cells from responders. Conclusions Our results are consistent with previous reports describing an association of increased B cell activity in TNBC with improved overall survival. We identified a subpopulation of CD4+ T cells with effector functions consistent with type 2 helper T cells that may not only target cancer cells by direct cytotoxic function, but also promote increased B cell anti-tumor activity. Our study provides insight into specific mechanisms of immune cell interplay that may drive response to ICI therapy. These cell populations and their associated pathways may represent potential biomarkers of response and/or targets for resistance reversal.

Background: HER2DX is a 27-gene prognostic (risk-score) and predictive (pathological complete response [pCR]-score) assay in early-stage HER2+ breast cancer (BC) based on clinical data and the expression of 4 gene signatures (immune, proliferation, luminal differentiation, and HER2 amplicon). Here we aim to evaluate, for the first time, the ability of HER2DX to predict pCR following neoadjuvant THP in HER2+ BC.

Methods: Standardized HER2DX was evaluated centrally on baseline pre-treatment FFPE

tumor biopsies from the DAPHNe phase II trial (Waks et al. NPJ Breast 2022; NCT03716180), in which patients (pts) with newly diagnosed stage II-III HER2+ BC were treated with neoadjuvant weekly paclitaxel x12 and HP every 3 weeks x4. Primary aim was to test the ability of HER2DX pCR-score to predict pCR (ypT0/isN0). Secondary objectives were to test the ability of HER2DX pCR-score to predict pCR independent of clinical-pathological variables and PAM50 subtype (HER2-enriched vs not) and to evaluate the association of HER2DX pCR-score with HER2DX risk-score. Five patients who received additional neoadjuvant chemotherapy after THP were excluded from this analysis. Logistic regression and receiver-operator curve (ROC) analysis were assessed. Statistical analyses were performed in R code 4.0.5.

Results: HER2DX was evaluated in 80 of 97 pts (82.5%) enrolled in the DAPHNe trial who received study treatment. Clinical T2-4 disease represented 81.3% of cases (n=65), clinical node-negative disease (cN0) represented 65.0% of cases (n=52), and 70.0% of tumors (n=56) were hormone receptor-positive. The overall pCR rate was 60.0% (95% confidence interval [CI] 49.3-70.7): 87.0% (95% CI 79.6-94.4) in hormone receptor-negative disease and 48.2% (95% CI 37.2-59.1) in hormone receptor-positive disease. The proportion of HER2DX low-, medium- and high-pCR groups was 38.8%, 27.5% and 33.7%, respectively. HER2DX pCR-score (as a continuous variable from 0 to 100) was significantly associated with pCR (odds ratio [OR]=1.05, p< 0.0001). In the overall population, the pCR rates in HER2DX pCR-high, pCR-med and pCR-low groups were 92.6%, 63.6% and 29.0% (pCR-high vs pCR-low OR=30.6, p< 0.0001), respectively. The AUC ROC of HER2DX pCR score (as a continuous variable) and pCR status was 0.835. In the ER-negative population, the pCR rates in HER2DX pCR-high, pCR-med and pCR-low groups were 94.7%, 66.7%, and 0%, respectively (Table 1). HER2DX pCR-score was significantly associated with pCR independent of hormone receptor status, HER2 immunohistochemistry (IHC) score, clinical stage, and PAM50 HER2-enriched subtype. The correlation between HER2DX pCR-score and HER2DX risk-score was weak (Pearson coefficient=-0.12), as previously described (Prat et al. EBiomedicine 2022). 51.3% of patients were categorized as HER2DX low-risk.

Conclusion: The 27-gene HER2DX genomic test predicts pCR following neoadjuvant THP in newly diagnosed stage II-III HER2+ BC. Patients with HER2DX pCR-low score and HER2DX high-risk score, representing 22.5% of pts, warrant further attention in order to optimize therapeutic strategies in this subset. The combination of HER2DX pCR-score and risk-score might guide therapeutic decisions by identifying patients who are ideal candidates for de-escalated or escalated systemic and locoregional treatments.

Table 1

HER2DX pCR score group / ER IHC status	N	%	pCR rate	HER2DX pCR score group / HER2DX risk of relapse group	N	%	pCR rate
High/ER+	8	10.0	87.50%	High/High	14	17.5	92.90%
High/ER-	19	23.7	94.70%	High/Low	13	16.3	92.30%
Med/ER+	16	20.0	62.50%	Med/High	7	8.7	57.10%
Med/ER-	6	7.5	66.70%	Med/Low	15	18.8	66.70%
Low/ER+	30	37.6	30.00%	Low/High	18	22.5	27.80%
Low/ER-	1	1.2	0.00%	Low/Low	13	16.2	30.80%

Background: HER2-positive versus HER2-negative ductal carcinoma in situ (DCIS) of the breast has been associated with an increased risk of local recurrence after breast-conserving surgery (BCS) and radiotherapy (RT). In recognition of this, the NASBP-B43 trial was designed to determine if two doses of trastuzumab would improve local control with BCS plus RT in HER2-positive DCIS. The trial demonstrated a non-statistically significant advantage with the addition of trastuzumab in reducing ipsilateral breast recurrence (IBR). The predictive 7-gene DCIS biosignature, DCISionRT with Residual Risk Subtype (PreludeDx™, Laguna Hills, CA) has been shown to classify DCIS patients into two distinct groups of patients with substantially different rates of IBR following BCS plus RT. Based upon these differences in outcome, we assessed the IBR rate in patients with HER2(+) DCIS treated with BCS and RT who were or were not in the Residual Risk Subtype group defined using DCISionRT, while accounting for the varying clinicopathologic profile of the patients.

Materials & Methods: DCISionRT was evaluated in a subset of 178 women with HER2(+) DCIS treated with BCS and RT as part of a multinational cohort of 926 patients from the United States, Sweden, and Australia, who were used in the validation studies for DCISionRT. Central pathology review and biosignature testing were performed at a CLIA-certified lab (Laguna Hills, CA). HER2(+) DCIS was defined as patients with a HER2(3+) immunohistochemistry >10% per ASCO/CAP guidelines. The IBR rate was calculated for the overall group of HER2(+) patients and those in the Residual Risk group. Individual patient outcome and biosignature results were analyzed using Kaplan Meier and Cox Proportional Hazard analyses.

Results: The biosignature classified 113 of the 178 (63%) HER2(+) women into the Residual Risk group (DS>2.8 with RRt). Patients in the Residual Risk group had a significantly greater IBR (HR=8.3; 95%CI: 1.1,50, p=.012) over 10-years, with a corresponding 10-year total IBR rate of 16.2% (95%CI: 9.7%, 26.5%) versus 1.6% (95%CI: 0.2%, 10.9%) for all other HER2(+) patients.

In univariate analysis, younger patients tended to have higher IBR rate after BCS plus RT, but only Residual Risk was significantly associated with IBR rate after BCS plus RT. Moreover, multivariable analysis demonstrated that the Residual Risk group was eight times more likely to recur after BCS and RT, while clinicopathologic factors (age, grade, tumor size) were not associated with higher IBR rates.

Conclusion: The DCISionRT Residual Risk group was predictive for 10-year IBR risk after BCS plus RT in women with HER2(+) DCIS. Approximately 40% of patients with HER2(+) DCIS

would be expected to achieve low rates of recurrence with BCS and RT, while about 60% of these women (classified in the Residual Risk group) would have higher recurrence rates and may benefit from further therapy, such as HER2-directed therapies. These findings suggest that if the results of the B43 trial were re-analyzed using the predictive 7-gene biosignature (DCISionRT with Residual Risk Subtype), better clarity could be gained on the true impact of trastuzumab on IBR rates in patients with HER2(+) DCIS and the patients most likely to benefit from this additional therapy.

Table 1: Univariate and Multivariable Cox Proportional Hazards Analyses

Factors	Multivariable		Univariate	
	HR 95% CI	p value	HR 95% CI	p value
Biosignature Residual Risk group (vs Low and Elevated Risk groups)	7.9 (1.0, 63)	.048	8.5 (1.1, 67)	.038
Extent >10 mm (vs ≤ 10 mm)	2.4 (0.8, 7.1)	.17	2.8 (0.7, 5.8)	.16
Grade 3 (vs Grade 1 and 2)	1.0 (0.2, 4.7)	.98	1.8 (0.4, 8.1)	.42
Age<50 (vs ≥age 50)	2.6 (0.9, 7.5)	.07	2.4 (0.9, 6.7)	.09

Background: A gap in personalized medicine exists in the absence of a test to assess the probability of pathological complete response (pCR) for early-stage breast cancer patients. We have previously shown that our TumorScope platform, which utilizes pretreatment standard-of-care (SOC) diagnostic data to model in-vivo biologic interactions, can reliably predict a binary outcome of pCR for a given patient with any physician-chosen SOC neoadjuvant chemotherapeutic (NAC) regimen. To drive further utility, we now investigate a pCR score as a continuous outcome (0-100) to establish a prognostic system that evaluates the predictive probability that a patient will achieve pCR with any SOC NAC regimen. Furthermore, we sought to establish thresholds (low, low-mid, high-mid, high) and corroborate the score's utility in the context of 5-year EFS. Methods: The total cohort consisted of 1050 patients from seven institutions. The pCR Score was calibrated with a training cohort consisting of 665 patients of all breast cancer subtypes. We used a logistic regression model to calculate the probability of pCR for each individual patient based on NAC regimen, clinical and multiscale simulation predictors. For all breast cancer subtypes, the baseline model included the following clinical variables: age, race, grade, T stage, N stage. For hormone receptor-positive (HR+) and HER2+ subtypes, ER, PR and HER2 status were included. The TumorScope model included the clinical variables and simulation derived features including modeled tumor volume at start (V_s) and end (V_e) of therapy ($V_s + V_e$). We compared the TumorScope model (clinical variables + simulation variables) to the model consisting solely of clinical variables. We then calculated the prognostic ability of the pCR score to corroborate EFS in an independent testing cohort of 385 patients. Patients were stratified according to the likelihood of pCR into high, high-mid, low-mid or low probability and correlated to the 5-year event-free survival (EFS) for all patients and per breast cancer subtype. Results: TumorScope showed superiority in predicting pCR probability in all breast cancer subtypes calculated as the number of times that TumorScope outperformed the clinical model: HR+/HER2- (70% of 233 cases, $p=6 \times 10^{-8}$), HR+/HER2+ (79.6% of 162 cases, $p=8 \times 10^{-13}$), HR-/HER2+ (72.2% of 115 cases, $p=2 \times 10^{-6}$) and TNBC (96.4% of 253 cases, $p=3 \times 10^{-12}$). In the overall analysis, patient EFS at 5-year follow-up according to pCR score was as follows: low pCR score ($n=76$) 61% EFS, low-mid pCR score ($n=126$) 75% EFS, high-

mid pCR score (n=86) 82% EFS, and high pCR score (n=97) EFS 96%. EFS was also calculated for each breast cancer subtype stratified into high or low pCR score; high pCR score correlated with the best 5-year EFS and low score correlated with poor 5-year EFS in alignment with empiric expectations. Of the different subtypes, HR+/HER2+ with high pCR score had the best 5-year EFS (~85-90%) and TBNC with low pCR score had the worst EFS (55-60%). Conclusion: The TumorScope pCR (continuous) score system offers an enriched test output to further refine prognostic capability beyond a conventional binary (yes/no) result and permits risk-stratification of patients into predictive categories. Here, we validate the TumorScope pCR score as a reliable metric using a large, multicenter cohort. The TumorScope pCR score can be correlated with 5-year EFS in an easy-to-understand format, concurrent with currently available prognostic tests in the market. As the TumorScope model uses pre-treatment information for predictions, it may be a valuable tool to inform treatment-related outcomes in patients receiving NAC.

Background: As pathologic complete response (pCR) is correlated with higher rates of event free survival, accurately forecasting pCR advances our collective endeavors in precision oncology to discern and translate individual patient-specific data into risk stratification. We developed the TumorScope engine, a software platform that utilizes pretreatment diagnostic data to build a computational tumor model that simulates in vivo tumor characteristics and interactions, incorporating morphology, metabolism, vascularity, and nutrient and drug delivery. This non-invasive approach enables accurate forecasting of a patient's response to physician-chosen neoadjuvant chemotherapy-based treatment (NAC). Here we validate the prognostic capacity of this technology at a single site cancer center.

Methods: A blinded, prospective trial using retrospective data was conducted at UNC. The study cohort included patients aged 18 years or older diagnosed with any subtype of breast cancer who were treated with a NAC regimen and had a pre-treatment T1-weighted dynamic contrast enhanced (DCE) MRI available. Pre-treatment diagnostic and planned treatment data (demographics, drug regimen, receptor status (ER/PR/HER2), DCE MRI, and pathology) were input into the TumorScope engine to simulate predicted final tumor volumes (V_t) for each tumor and predict pCR or residual disease (RD); pCR predictions were compared to post-surgery pathologic assessments defined as ypT0/is/N0. Predicted pCR was set at pre-defined threshold of predicted V_t less than 0.01 cm^3 , or at least a 99.9% V_t reduction.

Results: One hundred and fifty subjects with 157 tumors were enrolled in the study. After excluding missing data (absent DCE-MRI), a total of 143 cases in 136 patients were included. The majority of patients self-identified as Caucasian (63%) or African American (23%). TumorScope had a pCR overall prediction accuracy of 92.3% (95% CI: 86.7 - 96.1%) with a sensitivity of 90.9 % (95% CI: 75.7 - 98.1 %) and specificity of 92.7% (95% CI: 86.2 – 96.8%). Based on our subgroup analysis, predictive accuracy remained reliable for HR+/HER2- (n=65; 95.4%), HR+/HER2+ (n=20; 85.0%), HR-/HER2+ (n=21; 85.7%) and TNBC (n=37; 94.6%) subtypes. Predictive performance remained stable across ethnic subtypes and tumor grade (see Table 1).

Conclusion: The TumorScope noninvasive method that incorporates imaging, pathologic, demographic and planned treatment data appears to accurately predict an individual patient's probability of pCR across clinical subtypes.

Table 1. TumorScope prediction performance.

	Overall n=143 (95% CI)	TNBC n=37 pCR rate=48% (95% CI)	HR-/HER2+ n=21 pCR rate=45% (95% CI)	HR+/HER2- n=65 pCR rate=3% (95% CI)	HR+/HER2+ n=20 pCR rate=20% (95% CI)

Background: The 21-gene Recurrence Score (Oncotype DX) is a genomic assay that provides prognostic information for distant recurrence risk and is predictive of adjuvant chemotherapy benefit in hormone receptor (HR)-positive, HER-2 negative early-stage breast cancer (EBC). The Breast Cancer Index (BCI) is another molecular gene expression-based assay that evaluates the utility of extending adjuvant endocrine therapy (ET) from 5 to 10 years and

predicts risk of distant recurrence. In January 2021, the National Comprehensive Cancer Network (NCCN) Guidelines added BCI to guide duration of adjuvant ET as a category 2A recommendation. The goal of this study was to evaluate the association between BCI and RS in terms of their predicted benefit for adjuvant therapy and risk of distant recurrence. We also assessed the association of various anatomic and biologic tumor features with BCI. Methods: We performed a retrospective chart review of all patients with HR-positive EBC who had a BCI and Oncotype DX performed between 2007-2021. Demographics, tumor characteristics and BCI and RS results were extracted from the electronic medical record. Patients were categorized by BCI predictive of extended ET (formerly BCI high) versus not (formerly BCI low) and RS of low (0-10), intermediate (11-25) and high (26-100). Numerical values for distant recurrence risk were recorded for both BCI and Oncotype DX tests. Multivariable regression models were used to assess the relationship between BCI and Oncotype DX as well as factors associated with each. Results: We identified 153 women with HR-positive EBC with both RS and BCI performed. The median age of the population was 57 years and 25% were premenopausal. 32% (n=49) had a BCI result predictive of benefit from extended adjuvant ET. When comparing patients with BCI predictive of extended ET versus those with BCI not predictive of extended ET, there was no association between BCI and RS based on multivariate logistic regression models, $p=0.7$. A similar distribution of RS was observed between patients who had a BCI result predictive of benefit from extended ET versus not predictive. Among 49 patients with a BCI predictive of extended ET, 35% had high RS, 63% intermediate RS and 2% low RS. Among 104 patients with a BCI not predictive of extended ET, 24%, 73% and 3% had high, intermediate, and low RS, respectively. Multivariate regression models revealed an association between poorly differentiated tumors and BCI result predictive of extended ET, $p=0.002$. No associations were observed between BCI and menopausal status, ER%, PR%, tumor size or lymph node positivity. Regarding risk of recurrence, there was an association between BCI and Oncotype DX in terms of their predicted numerical risk of recurrence, $p<0.001$. Higher percentage of PR positivity, poorly differentiated tumors, and lymph node positivity were associated with a higher risk of recurrence on the BCI. Conclusions: In our patient population selected to have Oncotype DX and BCI performed, we found no association between the two genomic assays in terms of their predictive benefit. However, there was an association between Oncotype DX and BCI in terms of their prognostic ability. Given the increased use of BCI since its inclusion in national guidelines, it is important to understand its relationship with other genomic assays especially when used to guide clinical decisions and estimate prognosis.

Background: The primary aim of the NRG Oncology/NSABP B-52 clinical trial was to test if estrogen deprivation (ED) administered concomitantly with neoadjuvant docetaxel, carboplatin, trastuzumab, and pertuzumab (TCHP), would improve the pCR rate in patients with HER2+/ER+ early breast cancer. A numerical increase in the pCR rate was observed with ED (46.1% v 40.9%), but the difference was not statistically significant. The purposes of this study were to assess the association of sTILs in pretreatment biopsies with pCR in the total population and within the molecular subtypes of breast cancer and to assess changes in sTILs between pre- and on-treatment biopsies. The secondary endpoints of recurrence-free interval (RFI) and overall survival (OS) are currently being analyzed and will be presented along with association of these endpoints with sTILs in pretreatment biopsies in the total cohort and within molecular subtypes. Methods: Scoring of sTILs on routine H&E slides from pre-treatment biopsies with sufficient tumor from 249 of the 315 patients (79%) entered in B-52 were performed by one of two pathologists (SKM, RSM). Both pathologists scored sTILs on a subset of 64 patients to document concordance. Wilcoxon two-sided test, box and whisker plots, and forest plots were used to assess associations with pCR. Molecular subtypes were determined utilizing RNA-seq data and AIMS subtyping method. On-treatment biopsies were available in 46 patients and were scored and compared to paired baseline samples. Results: Good concordance between pathologists was established with an inter-pathologist difference of <20% difference between scores in 92% of cases. sTILs in pre-treatment samples were associated with pCR across both arms of the trial (p=0.0074) and in the TCHP+ED arm (p=0.033), but not in the TCHP arm (p=0.093). The distribution of intrinsic subtypes was 34% luminal B, 29% luminal A, 28% HER2E, 5.8% normal, and 2.7% basal, with no significant differences between the arms. Presence of sTILs showed a trend for association with pCR in HER2E pre-treatment samples (p=0.054) but not in non-HER2E (p=0.75). Similarly, sTILs were associated with pCR in non-luminal tumors (p=0.055) but not in luminal tumors (p=0.44). Stratification by treatment

arm and menopausal status suggested sTILs are associated with pCR in premenopausal women treated with TCHP (OR: 1.04, 95% CI=1.00-1.09). Interestingly, decreases in the sTIL scores with treatment were associated with pCR in the TCHP+ED arm (p=0.01) but not in the TCHP arm. Analysis of RFI and OS on B-52 is ongoing and will be presented along with associations of sTILs with intrinsic subtypes for RFI and OS. Conclusions: Although a positive correlation between sTILs and pCR was observed, the clinical utility appears limited because of the extensive overlap in the TIL scores between pCR and non-pCR tumors. Significance for a positive association of sTILs with pCR was detected in HER2E but not in luminal tumors. This may be due to the molecular differences of the subtypes, or the make-up of the TILs, or both. The association of a decrease in sTILs with TCHP+ED treatment needs further investigation. The small number of samples is a limitation of the study; however, the B-52 protocol specified that the collection of the B-52 samples was for the purpose of exploratory analysis. Our results highlight the molecular heterogeneity of the HER+/ER+ patient population and suggests that different treatment strategies may be required in future treatment regimens for this patient population. Support: NSABP Foundation; BCRF; 3U10CA180868-03S2, -180822; UG1CA189867; Genentech.

Rationale Human Epidermal Growth Factor Receptor 2 (HER2)-positive breast cancer (BC) represents a distinct subgroup of patients (pts) that derives significant benefits from anti-HER2 therapy. More recently, patients with metastatic BC that were previously considered HER2-Negative but with low positivity by immunohistochemistry (IHC) and a negative in situ hybridization (ISH) (HER2 1+, or 2+ with negative ISH) derived benefit from treatment with trastuzumab-deruxtecan (T-Dxd), an antibody-drug conjugate that targets HER2 receptor. This novel subgroup, termed HER2-Low (H-Low), represents nearly 60% of BCs. Tumor infiltrating-lymphocytes (TILs) are a biomarker that can be easily analyzed without additional stains, and that tend to be higher in tumors with more aggressive features. High levels of TILs can predict better outcomes in triple-negative (TN) and HER2-Positive (H-Pos) tumors. To date, there is no information about TILs levels in H-Low tumors. Objectives This work aims to determine TILs levels in HER2-Low tumors and their correlation with clinicopathologic features. Methods We retrospectively analyzed tissue from breast surgical products in a tertiary hospital in Sao Paulo, Brazil, from January 2021 to March 2022. Inclusion criteria were stage I to III invasive BC and available data for TILs, HER2, estrogen receptor (ER), progesterone receptor (PR) by IHC, and ISH, when applicable. Exclusion criteria was neoadjuvant therapy. We extracted clinical, histopathologic, and IHC parameters. HER2 subtypes were defined as follows: HER2-Negative (H-Neg) when HER2 0+ in IHC; H-Low when IHC 1+, or 2+ with ISH negative; and H-Pos when IHC 3+ or 2+ with ISH positive. TILs were defined as absent (0), low (1 to 9%), intermediate (10 to 39%) and high (>40%). Ki-67 levels were divided as low (up to 19%) and high ($\geq 20\%$). Results We included 202 eligible pts. 128 were H-Neg, 51 were H-Low (35 IHC 1+ and 16 IHC 2+ with ISH negative), and 23 were H-Pos. Four pts were TN in H-Neg and none in H-Low group. The mean ages for H-Neg, H-Low and H-Pos were 57, 51, and 57 years, respectively. ER and PR were negative in 3.1% and 11.7% of H-Neg, 0 and 7.8% of H-Low, and 52.4% and 56.5% of H-Pos. Ki-67 levels were high in 27.3% of H-Neg, 31.4% of H-Low and 82.6% of H-Pos. Nodal stages and multifocality were similar. Ductal histology had 89 (69.5%), 45 (88.2%), and 21 (91.3%) cases for H-Neg, H-Low, and H-Pos. Lobular carcinoma was found in 30 (23.4%) in H-Neg, 4 (7.8%) in H-Low, and none in the H-Pos group. Nuclear grade (NG) 2 was seen in 64.8% of H-Neg and 62% of H-Low. Nuclear grade 3 seen was in 82.6% of H-Pos. Histologic grade 1 was present in H-Neg and H-Low, with 29.7% and 25.5%; grade 2 was seen in 56.3% and 56.9%, respectively. In H-Pos grade 3 was found in 47.8%. Angiolymphatic invasion and perineural invasion were present in 26.6%, 35.3%, and 17.4%; and 26.6%, 35.3%,

and 13% of H-Neg, H-Low and H-Pos respectively. TILs in H-Neg, H-Low, and H-Pos were, respectively, absent in 16.4%, 17.6%, and 8.7%; low in 69.5%, 52.9% and 34.8%; intermediate in 11.7%, 25.5% and 47.8%; and high in 2.3%, 3.9% and 8.7%. We divided samples into TILs levels to look at the distribution of HER2 subtypes. Absent, low, intermediate, and high TILs had respectively 32, 124, 39, and 7 cases. There were more H-Neg in low TILs and H-Pos in high TILs, with, respectively, 65.6% and 6.3% of absent; 71.8% and 6.5% of low; 38.5% and 28.2% of intermediate; and 42.9% and 28.6% of high TILs. Conversely, H-Low showed stability among the groups, with 28.1%, 21.8%, 33.3%, and 28.6% in absent, low, intermediate, and high TILs, respectively. Complete data and statistical analysis will be presented at the meeting. Conclusion TILs in H-Low are similar to H-Neg. Both had lower TILs compared to H-Pos pts. In our study, only 25% were defined as H-Low, which demonstrates that a better comprehension about prevalence or pathology concordance between HER2 IHC 0 and 1+ is warranted. TILs may not play a role as a biomarker in H-Low tumors.

Background Peripheral blood cells and secreted products are important regulators of the systemic immune response. Circulating cytokines have been shown to predict severity of immune-related toxicity in melanoma patients that received combination anti-PD-1-based immunotherapy. In this study, we evaluated 38 serum cytokines and the peripheral blood t cell receptor (TCR) immune repertoire of 66 patients with TNBC for associations with pCR, treatment phase (PRE; POST), and immune related treatment emergent adverse events (TEAEs). Methods Serum and peripheral blood buffy coats were collected at pre-treatment (week 0) and at post-treatment (~ week 24). MILLIPLEX MAP Human Cytokine/Chemokine Magnetic Bead Panel was run in duplicate and read on the Luminex platform. Genomic DNA was isolated using QIAGEN Kits per manufacturer's instructions. TCR immune repertoire profiling was performed using the Immunoseq at Adaptive Biotechnologies. Statistical analysis was performed in R. P-values < 0.05 for serum cytokines and P-values < 0.05 for TCR were considered significant. Results Pielou's diversity index showed no difference between patient groups for TCR (P>0.319). Baseline samples had increased sCD40L, EGF, and IL-10 in patients with RD compared to pCR (P< 0.05). Baseline samples had decreased FGF2 and IFN gamma in patients with immune related TEAEs compared to those with no immune related TEAEs (P< 0.05). Comparison of Pre- vs Post-treatment revealed that EGF, MIP1 alpha, IL-1 alpha, IL-8, and MDC were increased in patients with pCR compared to those with RD. Comparison of Pre- vs. Post- also revealed increased levels of cytokines (EGF, IL-7, IFN gamma, GM-CSF) in samples in patients with immune related TEAEs (P< 0.05) compared to those patients without immune-related TEAEs. It also revealed that there was an increase in a subset of cytokines (IL-7, IL-4, MCP3, and IL-1 alpha) in patients that presented with serious immune related TEAEs (P< 0.05) compared to those patients without serious immune-related TEAEs. Conclusions There are subsets of circulating inflammatory cytokines that may be associated with treatment emergent adverse events in patients with TNBC treated with Durvalumab concomitant with standard of care chemotherapy.

Background: Patients with metastatic triple negative breast cancer (mTNBC) have a poor prognosis with median survival of 18 months or less. While the combination of immune checkpoint inhibitors (ICIs) and chemotherapy has shown promise in mTNBC, biomarkers beyond PDL-1 are needed to better predict which individuals will benefit from this treatment approach. In this study, we assessed the ability of spatial characteristics in predicting clinical best response in patients with PDL-1 positive mTNBC treated with an ICI and chemotherapy. Methods: Women with advanced unresectable or mTNBC treated with an ICI plus chemotherapy at Emory University between 2019 and 2021 with available biopsy specimens were retrospectively evaluated. Different cell types (tumor, stroma, immune cells) were identified by morphology on H&E staining. A cellular network was created by connecting each cell centroid to its adjacent centroids within a 30- μ m distance. The resulting spatial neighborhood network was used to assess tumor density and quantify immune infiltration. The immune infiltration score was defined as the number of immune to tumor cell neighbors divided by the total number of immune cell neighbors in a region of 75- μ m. A final immunoscore was calculated for each patient by averaging the immune infiltration scores in regions with high tumor cell density. Tumor infiltrating lymphocytes (TILs) were manually quantified. Responders were defined as those with a complete response (CR), partial response (PR), or stable disease (SD), while those with progressive disease (PD) were categorized as non-responders. A continuous response score was developed from tumor measurements of a target lesion on

serial imaging. Pearson's correlation coefficients were used to assess the relationship between continuous response scores and tumor characteristics. Responders and non-responders were compared using Mann-Whitney U tests. Results: Fifteen women with PDL-1 positive mTNBC treated with ICI plus chemotherapy and available tissue were included. All patients had relapsed disease, and 10 patients (67%) received an ICI and chemotherapy as first line treatment for mTNBC. Eight patients (53%) received atezolizumab and nab-paclitaxel while the remaining 7 (47%) patients received pembrolizumab with an approved chemotherapeutic agent. Seven patients (47%) experienced a PR, 3 (20%) with a CR, and 1 (7%) had SD. Four patients (27%) had PD with no clinical benefit. Higher immunoscores (-0.17, $p=0.6$) and TILs (-0.21, $p=0.5$) were numerically associated with continuous response scores. However, there were no significant differences in immunoscores (0.28 vs 0.26, $p=0.6$) or TIL counts (2 vs 5, $p=0.6$) between responders (N=11) and non-responders (N=4). Interestingly, patients with response to treatment had lower tumor densities compared to non-responders (7.5 vs 17.3, $p=0.02$). Conclusions: Spatial analysis of tumor density and immune infiltration, including immunoscore shows evidence of correlation with response. Tumor density was the only parameter significantly associated with response. The study identified novel tumor characteristics that need to be considered in the prediction of response to ICIs plus chemotherapy in mTNBC. The current findings are hypothesis generating and need validation in additional tissue samples to determine the role of tumor density as a predictor of response to ICI.

The 21-gene breast-cancer assay (Oncotype DX) has become widely available since 2011 and it is incorporated in treatment guidelines for early hormone-receptor–positive, human epidermal growth factor receptor 2 (HER2)–negative breast cancer. The Rxponder trial shows the role of adjuvant chemotherapy in node positive patients with a RS score less than 25, but in patients under 50 years of age benefit from adjuvant chemotherapy treatment regardless of the Oncotype. We analyzed our results of the Oncotype Dx in 317 node positive hormone-receptor–positive, HER2-negative early breast cancer patients, performed as a clinical practice since 2015 to 2020. The aims to current study are to examine the clinical significance of the oncotype Dx results in this specific population. The median age was 59 years with 102 patients (32%) less than 50 years. Median Oncotype DX score was 18 (1–68), RS< 25 in 247 (78%) and RS>25 in 70 (22%) patients. Median initial tumor size was 20 mm and the expression of classical biological variables was: median estrogen and progesterone receptors by immunohistochemistry 276 and 139 respectively and median Ki67 index was 23%. 145 patients received chemotherapy treatment (45,7%), (RS < 25:32%, RS>25: 94%) with a 63% of the

patients in the group less than 50 years of age in contrast to 36% in patients with more than 50 years. Patients with more than 50 years have less RS score (median 18) than patients less than 50 years (median 21). With a median of follow up of 45 month with achieved a total of 29 recurrence (9,1%), RS< 25: 8% and RS>25 13%. The estimated median disease free survival of patients with RS< 25 was 111 in contrast to 97 in patients with RS>25 (log rangk : p:0,035) and without differences according with age of the patients. In axillary node positive patients, Oncotype Dx could avoided chemotherapy in 55% of patients, with a index of recurrence of 9%. Patients with a RS score greater than 25 have a higher rate of recurrence (13%) despite the fact that the majority (94%) received treatment with chemotherapy. Improve adjuvant treatment is needed in patients with a score greater than 25.

A nomogram based on clinicopathologic factors and pretreatment systemic inflammation response index to predict pathological complete response of neoadjuvant systemic therapy in HER2-positive breast cancer: A dual-center study

Presenting Author(s) and Co-Author(s):

Hong Yu Wu, M.D., *Chief Resident - Kaohsiung Veterans General Hospital*
Country: United States

Yen-Dun Tzeng, M.D., *Attending surgeon - Kaohsiung Veterans General Hospital*

Country: United States

Purpose:

Multiple pretreatment systemic inflammatory markers (SIMs) have been reported as predictors of pathological complete response (pCR) after neoadjuvant systemic therapy (NST) in patients with breast cancer (BC). However, the most significant SIM remains to be conclusively identified, and variations among different molecular subtypes remain unknown. The objective of the study was to identify the most significant SIM in patients with human epidermal growth factor receptor 2 (HER2) positive BC, and to construct a pCR-predictive nomogram combining it with other clinicopathological factors.

Methods:

We retrospectively reviewed the findings for 240 patients with stage I–III HER2-positive BC who underwent NST and subsequent surgery at Kaohsiung and Taichung Veterans General Hospital from 2011 to 2021. Clinicopathological factors were analyzed by stepwise logistic regression with forward selection. The data were used to construct a nomogram plot for determining the probability of pCR.

Results:

Among the pretreatment SIMs, only SIRI was significantly related to pCR, with an optimal cutoff value of $1.27 \times 10^9/L$. Stepwise logistic analyses indicated that clinical N stage, HER2 immunohistochemistry (IHC) score, hormone receptor status, targeted therapy regimen, and SIRI were independent predictors of pCR, with an area under the curve (AUC) of 0.722. The Hosmer–Lemeshow test and calibration curve revealed that the predictive ability was a good fit to actual observations. A nomogram was constructed based on the logistic model.

Conclusions:

Pretreatment SIRI < 1.27 is predictive of pCR in HER2-positive BC. Our nomogram could efficiently predict pCR and facilitate clinical decision-making before neoadjuvant treatment.

Background: HER2 is a tyrosine kinase receptor belonging to the human epidermal receptor family and is considered an important proto-oncogene in the biology of breast carcinoma. HER2 overexpression is determined by a +3 score on the immunohistochemistry (IHC) assay. In addition, tumors with IHC results of +1 or +2 with ISH negative were defined as HER2-low. Recent studies have shown that the clinicopathological characteristics of HER2-low tumors, pointing out potential differences regarding hormone receptor status and new treatment possibilities in this patients. Objective: To assess the frequency and clinicopathological differences between cancer subtypes, as well as the survival of these patients. Methods: All patients with breast cancer diagnosed between 1987 and 2021 included in the Pérola Byington Hospital database were eligible. Patients were excluded if they had bilateral disease, had participated in clinical studies, or had incomplete data. The primary endpoint was overall survival stratified by cancer subtype, secondary endpoints were clinicopathological differences between cancer subtypes and death probability. Both the t-test and the chi-square test were used to analyze the association of each variable between the groups. Multivariate analysis was used to calculate odds ratios (OR) and 95% confidence intervals (CI) for the death outcome. Cox regression was used for survival analysis, with the Log-rank method and the results were presented in a survival graph using the Kaplan-Meier method. The R software version 4.1.1 was used to perform all analyzes, with a p-value < 0.05 being considered statistically significant. Results: 11,234 patients were included: 4,541 (40.42%) had Luminal cancer subtype, 2,955 (26.30%) HER2 Low, 2,242 (19.96%) triple negative, and 1,496 (13.32%) HER2 overexpression. Age, self-reported ethnicity, BMI, presence of comorbidities, clinical stage, nuclear grade, histological grade, family history, radiotherapy, chemotherapy, surgery, local, and systemic recurrence, and death showed statistically significant differences between cancer subtypes (table 1). In the multivariate regression (adjusted for the other evaluated

characteristics), patients with HER2 overexpression cancer subtype showed a 44.8% greater probability of death than patients with HER2 Low (OR 1.448, 95%CI 1.046-2.004, p=0.026), while the patient with triple-negative cancer had a 26.1% lower probability of evolving to death when compared to the HER2 Low patient (OR 0.739, 95%CI 0.562-0.969, p=0.0229). The luminal subtype showed no statistically significant difference when compared to the patient with HER2 Low. Overall survival showed a statistically significant difference between cancer subtypes, with a median of 12 years for Luminal HR 0.816 (0.73-0.913), 15 years for HER2 overexpression HR 1.154 (1.003-, 327), and no statistical difference for triple negative HR 0.978 (0.859-1.114) compared to 12 years for HER2 Low. Conclusion: This study in breast cancer patients demonstrates significant differences between cancer subtypes, with a higher probability of progression to death for patients with HER2 overexpression, while patients with Luminal subtype had a lower probability, when compared with HER2 Low. More studies are needed to clarify the impact of these differences between cancer subtypes on response to therapy.

Association between cancer subtype and other variables (n=11,234).

INTRODUCTION Human Epidermal Growth Factor Receptor (HER2) is overexpressed and/or amplified in 15-20% of breast cancer at time of first diagnosis and is associated with an aggressive clinical progression disease. Management of HER2+ early breast cancer, include a combination of sequential chemotherapy and HER2-targeted therapy, which is currently the gold standard of care. Achieving pathological complete response (pCR) to after neoadjuvant

therapy has been proposed as a prognostic marker for the prediction of disease-free survival (DFS). Although there are different criteria to define pCR, in general pathological complete response is the absence of residual disease in breast and lymph nodes in the pathology analysis of the surgical piece resection (ypTo/is ypN0). However, there is a compelling need to identify molecular biomarkers that will help determine which patients will benefit from neoadjuvant therapy. Considering that the UGT2B family plays an important role in drug metabolism, our aim is to analyze its role as potential predictive biomarkers of pCR to neoadjuvant therapy in breast cancer. **METHODS** We included 18 female patients diagnosed as early breast cancer HER2+ at the time of neoadjuvant treatment. Tissue samples were obtained from the surgical resection performed at Virgen del Rocío Hospital (Seville, Spain) and were formalin-fixed paraffin-embedded (FFPE) to subsequently carry out the pertinent analyses of the study. All patients were treated with chemotherapy plus anti-HER2-targeted therapy and were stratified according to response to neoadjuvant treatment. We defined two groups: responder (R; RCB-0; n=14) and non-responder (NR; RCB-II/III; n=4). Total RNA from FFPE tissue was extracted using the RecoverAll Total Nucleic Acid Isolation commercial kit (Ambion, Austin, TX, USA) following the manufacturer's instructions. RNA concentration was measured using the NanoDrop ND-1000 spectrophotometer (Nanodrop Tech, DE, USA). A total of 18 samples were labeled and hybridized with a Clariom D pico Array microarray (Affymetrix, Santa Clara, CA, USA) following the manufacturer's instructions. Differences in expressed genes according to response were identified using the Mann-Whitney U test where p-values < 0.05 were considered significant and ROC curve was used to determine predictor value of complete response for each member of UGT2 family. Differential expression between the two groups was analyzed using the statistical packages SPSS version 28 and R 4.1.1.1. Statistical significance was established for p-values < 0.05 and fold change ≥ 2 **RESULTS** We found 954 differentially expressed transcripts: 311 downregulated transcripts (lower expression in R) and 643 upregulated transcripts (higher expression in R). Our data showed a significant upregulation in 5 genes of the UGT2B family in non-responder patients (p-value < 0.05). 3 genes of the UGT2b family showed an acceptable ability to discriminate responders and non-responders to neoadjuvant treatment of HER2-positive in the ROC (receiver operating characteristic curve) analysis. **CONCLUSIONS** We identified a set of transcript differentially expressed (FC > 2; adjusted p-value < 0.05) in patients with residual disease (nR) when compared with tissue samples in patients that achieve pCR (R). UGT2B family genes are consistently upregulated in non-responder patients. UGT2B genes encode enzymes involved in glucuronidation. They are phase II drug-metabolizing enzymes with steroids removal capabilities in the liver and various steroid target tissues. An increased rate of glucuronidation is been associated with a loss of potency for the target drugs. These genes would be used as predictive biomarkers of pCR to neoadjuvant therapy in breast cancer.

Background: For breast cancer patients, prolonged time from core needle biopsy to initiation of treatment is associated with an incremental decrease in overall survival. This overall survival reduction disproportionately affects patients with stage I and II breast cancer (hazard ratio: 1.09-1.16, $p < 0.001$), the subgroup of breast cancer patients for which a survival reduction would be least expected due to its early stage and least accepted due to its large population size and potential increased cost of healthcare. Materials and Methods: We conducted an IRB-approved quality improvement initiative among patients with Medicare Advantage at a large integrated healthcare organization in Nevada to assess the ability of an innovative digital health platform to reduce the time interval between positive core needle biopsy to initiation of breast cancer treatment compared to a historical cohort of Medicare Advantage patients diagnosed and treated at the same facility over the preceding 6-month period. The study was restricted to women evaluated at a single contracted breast imaging center for inconclusive (BI-RADS 0) and suspicious (BI-RADS 4 & 5) mammograms, ultrasound, and/or breast MRI. Time to treatment (TTT) calculations were limited to the subset of patients diagnosed with in situ and invasive breast cancer by core needle biopsy. The primary goal was to reduce the historical TTT by greater than 50%. A secondary goal was to reduce TTT to < 30 days, well below the interval where overall survival would be adversely affected. Results: Between September 2021 and April 2022, 552 patients with BI-RADS 0, 4, and 5 breast imaging were enrolled in the quality improvement initiative and managed on the XpediteMD digital health platform. 208 patients were designated as BI-RADS 4 or 5 (i.e., suspicious imaging findings), all of whom ultimately underwent a diagnostic core needle biopsy. Of these, 75 patients were found to have invasive or in situ breast cancer and were subsequently referred to surgery or medical oncology where treatment was initiated. Among these patients, average TTT was 32 days with use of the digital health platform compared to 74 days in the historical cohort, a statistically significant 57% reduction in TTT, exceeding the 50% TTT goal. Although the study did not meet the target goal of average TTT < 30 days from needle biopsy to initiation of treatment, failure to achieve this goal was largely attributable to 3 patients who elected to delay cancer therapy for personal or health reasons. Excluding these 3 patients would have yielded an average TTT of 28.75 days, which is within our < 30 -day goal. Conclusions: This quality improvement initiative demonstrated the successful deployment of a novel digital health platform which achieved a 57% reduction in the time interval from a positive core needle biopsy to performance of breast cancer surgery or initiation of systemic therapy. By reducing TTT to 32 days, the initiative

eliminated any delay in initiation of cancer therapy that could have compromised patients' overall survival.

Introduction: Mammography is the cornerstone of breast cancer screening, diagnosis, and surveillance. After definitive treatment for breast cancer, mammograms are continued for surveillance. The current recommendations regarding surveillance after definitive treatment (surgery and radiation) lack consensus amongst various societies. There are no clear guidelines in regards to the type of mammogram recommended: diagnostic or screening mammogram or if a diagnostic mammogram is used, when to return to routine screening protocols. Current practice patterns are driven by physician's preference. We conducted a survey to evaluate physicians' preferences in ordering breast imaging post- breast cancer diagnosis and treatment. Methods: This survey was approved by University of Arizona institutional review board. This survey was conducted through American Society of Clinical Oncology (ASCO) voluntary opt-in Research Survey Pool (RSP). ASCO sent out this survey to 1000 randomly selected members between 10/19/2021-11/22/2021. Weekly reminders to participate were sent through the ASCO RSP for 5 weeks. Participants clicked the link to the survey platform where upon consent they completed the survey. Results: The survey was completed by 244 healthcare professionals through the ASCO RSP. Most respondents were physicians (n=228), primarily medical oncologists (n=174) and practiced in an academic environment in the United States (n=132). After definitive treatment, majority (58%) ordered first

imaging at 6 months post-surgery/radiation, and it was primarily a diagnostic mammogram (68%). Interestingly, for patients at age 80 or above, screening mammogram was used for surveillance after definitive treatment by most respondents (59%). After first post-surgery/radiation mammogram there is an almost even split (50%) on continuing with diagnostic versus screening mammograms for follow up. Of those who order diagnostic mammograms, majority (38%) do it for 3-5 years with an additional 30% continuing it beyond 5 years. Almost 65% of respondents reported they do not stop screening mammograms at any age for patients with a history of early-stage breast cancer as long as they are healthy. Conclusions: The practice patterns of healthcare professionals as it relates to the type and frequency of breast imaging varies significantly. Despite having the same imaging quality there is a significant difference in the cost of screening and diagnostic mammograms. In addition, in clinical practice, most routine screening care is covered by insurances without co-pays or out of pocket costs for patients. Diagnostic imaging does not fall under routine screening care and frequently requires out of pocket expenses for patients. As insurance companies start to decline certain imaging modalities used for cancer detection due to lack of data supporting the use of these expensive studies, specific imaging guidelines for follow up in post-treatment setting for patients with breast cancer are needed.

Although the categorization of ultrasound using the Breast Imaging Reporting and Data System (BI-RADS) has become widespread worldwide, the problem of inter-observer variability remains. To maintain uniformity in diagnostic accuracy, we have developed a novel artificial intelligence (AI) system in which AI can distinguish whether a static image obtained using a breast ultrasound represents BI-RADS3 or lower, or BI-RADS4a or higher, to determine the medical management that should be performed on a patient whose breast ultrasound shows abnormalities. To establish and validate the AI system, a training dataset consisting of 4,028 images containing 5,014 lesions and a test dataset consisting of 3,166 images containing 3,656 lesions were collected and annotated. We selected a setting that maximized the area under the curve (AUC) and minimized the difference in sensitivity and specificity by adjusting the internal parameters of the AI system, achieving an AUC, sensitivity, and specificity of 0.95, 90.0%, and 88.5%, respectively. Furthermore, based on 30 images extracted from the test data, the

diagnostic accuracy of 20 clinicians and the AI system was compared, and the AI system was found to be significantly superior to the clinicians (McNemar test, $p < 0.001$). Then, we conducted a trial to introduce the system for use in clinical practice. Physicians reviewed the images and determined whether they were BI-RADS3 or lower, or BI-RADS4a or higher. Next, the classification was performed again for the same images concerning the AI diagnosis. At this time, the initial judgment was allowed to be overturned. We checked whether there was any difference in the diagnostic accuracy, sensitivity, and specificity before and after reviewing to the AI diagnosis. Reviews by 24 physicians were evaluated: 4 Japanese Breast Cancer Society breast specialists, 5 non-specialists and physicians with experience treating more than 40 cases of breast cancer, and 15 non-specialists and physicians with no experience treating more than 40 cases of breast cancer. The average rate of accuracy before confirming the AI diagnosis increased to 73.1% after confirming the AI diagnosis ($p=0.00548$), compared to 69.3% on average before the AI diagnosis. Compared to practice experience, the accuracy increased from an average of 77.1% to 79.6% for the 9 physicians who were breast specialists or who had treated 40 or more cases of breast cancer. For the 15 physicians with less than 40 breast cancer cases, the average rate of accuracy increased from 64.7% to 69.2%. Furthermore, sensitivity increased significantly to an average of 99.7% after reviewing of the AI diagnosis from an average of 88.8% prior to reviewing the AI-diagnosis. ($p < 0.01$). Specificity increased from an average of 62.4% to 63.8% ($p=0.433$) after reviewing AI diagnosis. We showed that our AI system, when applied to clinical practice and used by physicians, contributes to the improvement of diagnostic accuracy. Our results indicated that our AI diagnostic system was sufficiently accurate to be used in the clinical practice.

Mohammad Muhsin Chisti, MD, *Associate Professor of Hematology and Medical Oncology - Oakland University William Beaumont School of Medicine*

Country: United States

Background:

Circulating tumor DNA (ctDNA) are short DNA sequences shed by tumor cells into the systemic circulation. Studies have shown potential utility of the test to predict relapse or recurrence following treatment in solid tumors, but sensitivity and specificity have varied widely, ranging from 19-100% and 80-100% respectively, in breast cancer specifically. Moreover, literature describing the utility of monitoring dynamic changes in ctDNA trends is limited. We aim to evaluate the correlation between ctDNA test, both single test as well as dynamic trends in value over time, with imaging findings.

Methods:

We retrospectively analyzed the medical records of all adult patients diagnosed with breast cancer who underwent ctDNA testing at the hematology-oncology clinic at William Beaumont - Royal Oak and Troy Hospitals, Michigan, from August 2017 to June 2022. Patients who had ctDNA testing done but did not have imaging to correlate it with were excluded from the study. We calculated the sensitivity and specificity of a single positive ctDNA test to detect disease progression or residual disease on imaging. In patients with multiple ctDNA tests, we calculated the sensitivity and specificity of dynamic trends in ctDNA values to detect progression, regression, or absence of disease on imaging. Moreover, we calculated the lead time for positive ctDNA results to detect disease progression compared to imaging.

Results:

Nineteen patients were included in the study, with 34 total ctDNA test results, each utilized as a separate data point to compare with corresponding imaging findings (Table 1). Ten out of the 19 patients had multiple(≥ 2) ctDNA test results reported, with a total of 15 pairs of ctDNA values and each pair was analyzed separately as up trending (N=7), down trending (N=4), or persistent negative (N=4) to compare with a corresponding pair of imaging findings (Table 2). The median age at diagnosis was 55 years, and 94.7% were female. At diagnosis, majority of

patients (68.4%) had either stage III or IV disease. Our primary endpoint, the correlation of single positive ctDNA result with imaging showing either progression or residual disease, showed a sensitivity and specificity of 100% and 93.3%, respectively. Secondly, serial ctDNA trend analysis in ten patients revealed both sensitivity and specificity of 100% for up-trending ctDNA values to detect progression, down-trending to detect regression, and persistent negative results to detect absence of disease on imaging, respectively. The positive ctDNA results detected disease progression with a median lead time of 44.5 days compared to imaging.

Conclusion:

Given the high sensitivity and specificity to detect disease progression and regression in breast cancer patients by single ctDNA results and dynamic ctDNA trends in our study, we conclude that this may be a valid way to reliably monitor for changes in disease status before they become evident in imaging studies. Further clinical studies are required to prove the utility of ctDNA to detect changes in disease status and to guide therapeutic interventions in breast cancer.

Correlation of single ctDNA result with imaging findings

Table 1: Correlation of single ctDNA result with imaging finding

CtDNA result	Imaging finding		
	Progression/residual disease	No progression/residual disease	Total
Positive	19	1	20
Negative	0	14	14
Total	19	15	34

Correlation of dynamic trends in ctDNA values with imaging findings

Table 2: Correlation of dynamic trends of serial ctDNA values with imaging finding

CtDNA values	Imaging/biopsy finding			
	Progression	Regression	Absence of disease	Total
Up-trending	7	0	0	7
Down-trending	0	4	0	4
Persistent negative	0	0	4	4
Total	7	4	4	15

Introduction: Women 30 years-old or older that present with a breast complaint typically receive a standard work-up, which includes a diagnostic mammogram □ ultrasound. Because women under 30 years-old have extremely dense breast tissue, the initial imaging work-up begins with ultrasound. The American College of Radiology Breast Imaging Reporting and Data System (BI-RADS) describes and categorizes imaging findings using a standardized language to convey to non-radiologist physicians and patients the risk associated with a described breast lesion. Interpretation of the results can be problematic in young women (< 18 y.o) that may undergo imaging at a pediatric facility, often without on-site breast imaging specialists and standard breast imaging protocols in place, including the usage of the BI-RADS lexicon. Appropriateness of biopsy and surgical management require careful consideration especially in a setting where the pathology is often benign. We describe our 5-year experience of 482 young women undergoing breast imaging at a single institution to identify key features characteristic of young women with malignant lesions.

Methods: A retrospective cohort study was conducted on all patients between the ages of 9-29 years old that presented to a breast imaging center for evaluation of a breast complaint from January 2017 through December 2021. Patients were identified via an Epic SlicerDicer query based on age and breast imaging procedure. A retrospective chart review was conducted on this cohort to capture demographic information (Table 1), medical history and family history. Information related to radiographic evaluation, biopsy procedures, and post-operative pathology

was also recorded.

Results: Four hundred-eight two patients with mean age of 23.8 ± 3.7 years were seen for a breast complaint at the imaging center, of which 462 underwent breast ultrasound (96.7%). A BI-RADS classification was assigned in 418 reports (87%). Fifty-eight patients (12%) had imaging at an outside facility before coming to our dedicated breast imaging center. The mean maximal dimension at presentation was 1.3 ± 1.6 cm. A BI-RADS classification of ≥4 was assigned to 46 patients (9.6%). A core needle biopsy (CNB) was performed in 63 patients (13.1%). Seventy-seven patients (16%) underwent surgery. Of the patients undergoing surgery, 38 (49.4%) had a CNB prior to surgery and the mean pre-operative maximal dimension on ultrasound was 3.1 ± 1.6. Reason for excision included: mass size (30.3%), symptoms (27.6%), biopsy result (21.1%) and growth (19.7%). Eight patients (12.7%) were found to have a malignancy on CNB. Fibroadenoma (64.5%) was the most common pathology after surgery. A phyllodes tumor was identified in 8 patients, of which 6 were benign (7.9%) and 2 were classified as borderline (2.6%); there were no malignant phyllodes in the cohort. The mean size for phyllodes lesions were 3.8 ± 1.8 cm. Six of 8 patients had a malignant lesion on final surgical pathology (7.9%); the other 2 patients achieved a pathologic complete response (pCR). Details regarding malignant lesions can be found in Table 2.

Conclusions:

While the American College of Radiology helps provide guidance for appropriate imaging evaluation in young women, there are no treatment algorithms that address the appropriateness of surgical treatment in this age group where the diagnosis is often benign. Radiologist and surgeons that specialize in breast disease may be asked to provide guidance on management decisions for a population they may rarely see (patients < 18 years-old), just as pediatrician or pediatric surgeons may feel pressure to making management plans for complaints they rarely encounter (breast). The value of using standardized imaging and treatment protocols with dedicated breast radiologist and surgeons may offer the best comprehensive approach to this unique subset of patients and deserves further evaluation.

Breast cancers, both early and advanced, are heterogeneous causing differential responses to targeted therapy. Explosion in targeted treatment choices requires real time assessment of tumor characteristics in patients initially and over time. A dynamic detection system, not a static pathology specimen, is required for continuous profiling while treatment changes; hence, the interest in circulating tumor cells (CTCs). Our novel QCDx br™ system analyzes all nucleated cells from a blood sample aliquot, morphologically intact and immobilized in hydrogel, after multiplex, immunofluorescent (IF) staining. We characterize increased numbers of CTCs (nucleated, CD45-negative cells) as single cells, in clusters and in connection with circulating inflammatory cells, stained with two, separate IF marker cocktails, denoting (1) epithelial (EpCAM, Cytokeratin CK), mesenchymal (Vimentin VIM) phenotypes and (2) therapeutic HER2, ER and TROP2 targets which are the basis for targeted therapy in breast cancer. In the ongoing, prospective CLINBREAC trial, we enrolled to date 9 neoadjuvant (early stage, ES) and 21 metastatic (late stage, LS) breast cancer patients, collecting 7.5 ml of blood at 3-month intervals or at change of therapy. We are now out over 2 years with the earliest ES and LS patients showing changes in CTCs with disease progression and in response to treatment, often pre-dating changes seen in follow up biopsies. Detection of HER2+ CTCs was of particular interest in patients with HER2 low cancers (1+ or 2+). Results presented here, contain the more complete datasets from 8 ES and 11 LS patients. QCDx br™ detected CTCs in all 19 Stage I-IV patients that could exceed 100 CTCs/2500 nucleated cells in LS and 50 CTCs/2500 nucleated cells in ES patients. The table shows count averages of CTCs/2500 nucleated cells detected by different IF markers. Of note, CTCs showed combinations of IF markers (hybrid cells). For example, CTCs expressed both VIM and CK indicating epithelial to

mesenchymal transition (EMT) phenotype, which may signify higher metastatic potential. ER+ CTC were seen in LS, not ES patients. All ES patients including those with HER2 low tumors, showed HER2+ CTCs. Of note, not included in the table are two, triple-positive patients with oligo-metastatic disease now 4 and 10 years out from diagnosis without evidence of disease and on maintenance HER2 and ER-directed therapy. No CTCs are seen at their first data point. We were unable to detect CTCs in 13 healthy volunteers. In ES patients, CTC numbers did not associate with tumor size, nodal involvement, ER or HER2 status. For example, one TNBC patient with a T3 tumor and positive nodes had some of the lowest numbers of CTCs. The more complete quantification of the LS patients is in process. As development of QCDx br™ continues, multiplex IF staining of 12+ markers per CTC and identification of single CTC mutational changes is expected. This powerful technology enables targeted treatment decisions with specific drugs resulting in maximal responses.

Average CTC counts/2500 nucleated cells detected by phenotypic and therapeutic IF cocktails

Patients	Phenotypic Panel				Therapeutic Panel			
	CTC	EpCAM	VIM	CK	CTC	HER2	ER	TROP2
Early	27	7	14	15	14	8	1	7
Late	85	17	52	42	81	34	18	38

Referral pathways for breast cancer diagnosis and treatment in Mexico: a physicians' survey

Presenting Author(s) and Co-Author(s):

Daniela Vazquez-Juarez, n/a, *Medical Oncologist - Breast Cancer Center, Hospital Zambrano Hellion TecSalud*

Country: United States

Raul Andrade-Moreno, n/a, *Medical Oncologist - Breast Cancer Center, Hospital Zambrano Hellion TecSalud*

Country: United States

Cynthia Villareal Garza, MD, DSc - *Tecnológico de Monterrey*

City: Monterrey

Country: Mexico

Background: Clinical stage at diagnosis is one of the most relevant prognostic factors for breast cancer (BC). In Mexico, more than half of BC patients are diagnosed at stage III-IV due to delays in referral, diagnosis, and treatment. The median time between symptom presentation and treatment initiation is 7 months; with the longest delay occurring between the first consultation and treatment start. The cause of this delay is not well defined. Our objective is to investigate if physicians in Mexico are aware of referral pathways in their respective institutions for patients with clinical suspicion and confirmation of BC.

Methods: Physicians were asked to answer an anonymous and voluntary survey that included 20 questions aimed at collecting general sociodemographic data, their plan of action when BC is suspected or diagnosed, and the perception of delays and barriers in breast cancer care. The survey was promoted on exclusive social networks of Mexican health professionals.

Results: In total, 802 surveys were collected. Of these, 98% were physicians, with the highest proportion (50%) being gynecologists, family, and general practitioners. The average age was 41 years, and 36% reported practicing in the public sector, 35% in the private sector, and 29% in both sectors. When faced with clinical signs and symptoms suggestive of BC, 41% of physicians in the public sector would request a breast imaging study and refer to another specialist. In contrast, 39% of specialists in the private sector preferred to request a breast imaging study and reevaluate the results.

Specialties to which physicians refer patients when suspicious in public and private sectors were gynecology 41% and 29%, surgical oncology 24% and 36%, and medical oncology 17% and 19%, respectively. In the case of a confirmed BC diagnosis, physicians preferred to refer patients to oncologic surgery in 40% and 45%, medical oncology in 40% and 32%, and gynecology in 9% and 10%, respectively. Of the healthcare professionals that were surveyed, 36% in the public sector and 67% in the private sector ignored the existence of referral pathways for BC clinical suspicion and confirmation in their institution.

Regarding the time interval from the onset of symptoms to treatment initiation, 64% of the private practice physicians estimated a waiting time of < 30 days. In contrast, only 22% considered this time interval in the public sector, 30% answered between 31-90 days, and 17% replied > 90 days.

Most respondents from the private sector considered factors associated with the patient as the main cause for this delay. Respondents from the public sector added to this opinion that factors related to the public health services were a contributor to the delays (Table1). Lack of knowledge about the referral pathways was significantly associated with perceiving greater

delays in care ($p < 0.001$).

Conclusion: The results of this study indicate that there is no consensus among healthcare professionals in Mexico about an action plan when breast cancer is suspected or diagnosed. Although a proportion of the respondents acknowledge the presence of established referral pathways, long waiting times and delays persist between the first evaluation and the start of treatment. Associated factors include the saturation and limited resources of public health services. The development of a universal program and its promotion among all health professionals is imperative to improve BC care in Mexico.

Table 1. Factors associated of delay in the care of clinical suspicion and confirmation of BC

Table 1. Factors associated of delay in the care of clinical suspicion and confirmation of BC		
	Public sector (%)	Private sector (%)
Absence of a defined diagnostic algorithm	62 (12.1)	52 (10.4)
Factors associated with the patient (fear, apathy, lack of knowledge, financial, difficulty of transportation, etc.)	217 (42.5)	323 (64.9)
Lack of medical specialists in several areas (pathology, oncologists, radio-oncologists)	174 (34.1)	25 (5.0)
Lack of well-established referral paths	108 (21.1)	62 (12.4)
Saturation of services to establish a diagnosis (outpatient clinic, laboratory, imaging)	322 (63.1)	39 (6.4)
Saturation to start treatment (delayed surgery times or insufficient chemotherapy infusion centers)	209 (40.9)	32 (6.4)

Background Breast cancer is one of the most common cancers worldwide with the highest incidence among females in 2020 [1]. The application of breast ultrasound benefits the diagnosis of breast cancer at the early stage, but also leads to over-diagnosis. Patients with breast nodules detected by ultrasound at BI-RADS 4a or higher are usually advised to have a fine needle biopsy or surgery, although the PPVs of BI-RADS 4a and 4b categories are low (6% and 25%, respectively) [2]. Methods In this study, AnchorIRIS™ assay was used for analyzing the methylated status of cfDNA. Target enrichment was performed using an AnchorDx breast cancer-specific methylation panel consisting of 129,794 methylated markers. One hundred and twelve pairs of breast tissue and plasma samples (Malignant: Benign= 56: 56) and 40 leukocyte samples (Malignant: Benign = 20: 20) were used to identify reliable breast cancer-specific methylation markers with low noise background. Finally, a methylation model trained on 307 plasma samples (train set: test set = 214: 93) was selected for differentiating benign from malignant nodules, which was validated by two independent sets (Validation-1: Malignant: Benign = 42:46; Validation-2: Malignant: Benign = 62: 46). Results This methylation model exhibited a powerful performance on differentiating benign from malignant nodules with an AUC of 0.837 (95% CI: 0.757-0.918) in the test set, and maintained a stable predictive power with AUCs of 0.820 and 0.801 in two independent validation sets, respectively. In addition, this

methylation model can reflect the difference in methylation signals between metastatic and non-metastatic cancers three years in advance. In contrast to ultrasound, the prediction rate of breast cancer is more accurate across the different age groups using the methylation model, especially for younger women less than 40 years old. Under the ultrasound BI-RADS 4 category, the accuracy (ACC) of the methylation model (IndVal-1, 73.02%; IndVal-2, 78.31%) is on average 22% higher than ultrasound (IndVal-1, 55.56%; IndVal-2, 51.81%). In both of the independent validation sets, the overall accuracy (78.7%) and specificity (SP) (58.7%) at the sensitivities above 95% of the combined model is greater than applying either ultrasound (ACC: 65%; SP: 26.1%) or the methylation model (ACC: 70.6%; SP: 52.2%) alone. Conclusion This methylation model has great potential for the diagnosis of early-stage breast cancer. It improves the diagnostic accuracy of the indeterminate breast nodules, which may assist in decreasing the unnecessary biopsies or surgeries of patients with benign lesions. The methylation model also has the potential in predicting metastatic and non-metastatic breast cancers that is valuable for patient surveillance and risk prediction. References: [1]. Country: United States

Aglia Schiza, *n/a, MD, PhD - Uppsala University Hospital*

Country: Sweden

Background: Cancer antigen 15-3 (CA 15-3) is the most commonly used tumor marker in patients with breast cancer (BC). However, the usefulness of CA 15-3 is still controversial and there is lack of evidence for its role in metastatic BC. We performed a retrospective analysis of the value of CA 15-3 for monitoring and diagnosis in subgroups of metastatic BC. Method: This retrospective study included three cohorts of a total of 196 patients with advanced or metastatic BC treated during the years 2015-2020. Patients' data, such as subtype, hormone receptor status, and CA 15-3 values, were retrieved from a treatment database to find out how well the CA 15-3 levels followed the disease progression or remission over time. An increase or decrease of CA 15-3 less than 10% indicated stable disease and changes larger than 10% indicated progress or response of therapy. The patients were then categorized into one of six groups based on the proportion of correct CA 15-3 values in each patient during the course of the disease. A proportion of correct values of 95% or higher placed the patient in category 5, between 90% and 95% category 4, 75% to 90% were category 3, 50% to 75% category 2, and below 50% category 1. Patients without any elevated CA 15-3 values and with no evidence of association with a trend of CA 15-3 and disease progression were categorized as 0. Patients in categories 3, 4, and 5 were classified with approved CA 15-3 conformity and categories 4 and 5 with excellent conformity. Results: The median number of samples per patient was 27 (range 5-102) and at diagnosis of metastatic disease, 79%, 66% and 60% of patients had elevated CA 15-3 in the luminal, HER2-positive, and TNBC groups, respectively. Overall, 72.4%, 95% confidence intervals (CI) (66.2-78.7) of the patients had an approved conformity of CA 15-3 to monitor the course of the disease. The benefit of CA 15-3 differed significantly between the subtypes, luminal BC had an approved conformity for 94%, 95% CI (88.6-99.1) of the patients, HER2 BC 63%, 95% CI (52.1-73.5) and for TNBC 46% (95% CI 29.9-62.0) of patients. In patients with Luminal A, the conformity was excellent in 84% of patients compared to 60% of patients with Luminal B. Estrogen receptor status (ER) was the single most important factor for the value of CA 15-3, with an approved conformity of 91%, 95% CI (85.6-95.7) of ER-positive patients and 37%, 95% CI (25.3-48.2) of all ER-negative patients. Elevated baseline levels of CA 15-3 in the diagnosis of metastatic BC increased the benefit of the marker to approved levels in 62.5% of the ER-negative patients, but ER-positive patients mostly had approved conformity, despite negative CA 15-3 at baseline. Visceral or bone metastases further improved

the utility of CA 15-3 and soft tissue or solitary CNS metastases decreased it. Conclusion: The benefit of serum marker CA 15-3 in monitoring patients with metastatic BC depends mainly on whether the tumor expresses ER or not. ER-positive patients were excellently monitored in most cases and elevated CA 15-3 values at baseline indicated potential utility in ER-negative patients.

Background: Routine imaging can be inaccurate, especially in metastatic breast cancer (MBC) with bone-only disease or mainly bone disease. This analysis investigates how the use of whole-body magnetic resonance imaging (WB-MRI), in addition to routine computed tomography (CT) and bone scintigraphy (BS), can influence treatment decisions in patients with known MBC. Methods: In a prospective observational study, in our Institute, we performed WB-MRI as baseline and follow-up examination in addition to routine imaging (CT, BS) in luminal/HER2-negative BC patients with prevalence of bone disease potentially candidate to CDK 4/6 inhibitors. All examinations were interpreted by two experienced radiology specialists. Using the results of the examination, a multidisciplinary oncology committee (MOC) reported on the treatment strategy. A positive impact on clinical management was considered if the examination determined a modification in the treatment strategy compared to the MOC decision before WB-MRI. Results: Thirty consecutive luminal breast cancer patients in a metastatic setting at standard imaging were recruited. All these patients underwent CT and BS followed by WB-MRI study. At standard imaging, fourteen patients (46.7%) presented with bone-only disease, while eight patients (26.6%) did not show bone lesions. In 18 of 30 cases (60%) WB-MRI led to a modification of the therapeutic approach. Due to the detection of new metastatic lesions or progression of known metastatic sites, reported on WB-MRI alone, the therapeutic decision changed in 6 (20%) and 3 (10%) patients, respectively. In one patient (3%) the therapeutic decision changed because of both findings. Nine patients (30%) started a new therapeutic line due to evidence of progressive disease on WB-MRI, while 4 patients (13.3%) underwent radiotherapy and 1 patient received orthopaedic counselling for high risk WB-MRI-assessed bone lesions. In 8 patients (26.6%) the disease was re-classified as early breast cancer based on WB-MRI assessment. Conclusions: WB-MRI could play a role in the clinical assessment of luminal MBC. Further studies are needed to better address the potential use of WB-MRI in the assessment and monitoring of bone only/bone predominant luminal MBC and/or in equivocal cases.

The potential of cell-free tumor DNA (ctDNA) for early tumor detection in asymptomatic patients is yet to be established. In the case of pregnancy associated breast cancer (BC), early detection is of special interest, since it is an entity of special aggressiveness due to a delay in diagnosis, along with the negative effect of mammary gland involution when BC is diagnosed during the postpartum period (PPBC). Indeed, PPBC has double metastatic risk and worst prognosis. With a potential applicability for cancer screening during breastfeeding, here we explored the presence of ctDNA in breast milk (BM) from women with BC associated to pregnancy. Matched samples from breast tumor, plasma and BM from a cohort of 14 women diagnosed during pregnancy or breastfeeding were analysed by droplet digital PCR and a targeted next generation sequencing panel (NGS). Thirteen patients had early-stage disease (11% Stage I, 61% Stage II and 28% Stage III) whilst one was diagnosed at advanced stage. BM harboured ctDNA, since mutations present in the tumor tissue were detected in 86% of the cases by ddPCR and in 71,4% by NGS (difference owing to technique sensitivity). Matched plasma samples had detectable ctDNA levels in only 8% of the cases. In one of the patients, a BM sample collected 18 months prior to BC diagnosis revealed the presence of a pathogenic PIK3CA mutation later detected in the surgically removed tumor. With the ultimate goal of applying the NGS in BM as a technique for early detection of BC in the postpartum period, we have collected samples from healthy volunteers and patients at high risk of developing BC (defined as women becoming pregnant at >40 years or carriers of germ-line pathogenic variants associated with BC -ie: BRCA1, BRCA2, PALB2, RAD51C/D). The application of NGS in BM as a technique for early detection of BC in the postpartum period, identified in a high-risk woman (criteria of enrolment was the age, 46yo) an AKT1 pathogenic mutation in the right-sided BM anticipating by 6 months the radiological diagnosis of a Luminal A tumor, stage pT1bN0M0. In summary, our data provides evidence that ctDNA in BM is highly prevalent even at initial tumor stages, and could be exploited for early breast cancer screening during breastfeeding.

PURPOSE

Triple-negative breast cancer (TNBC) is a heterogeneous disease with variable response to neoadjuvant therapy (NAT). Pathologic complete response (pCR) has become a prognostic marker for overall and disease-free survival. The aim of this study was to determine if dynamic contrast-enhanced (DCE)-MRI after 2 and/or 4 cycles of NAT can identify patients with a high likelihood of achieving pCR, triaging them to standard of care (SOC), or, when appropriate, to de-escalation trials. Conversely, we aimed to identify chemoresistant tumors that are unlikely to achieve pCR and may benefit from escalated targeted trials.

METHOD AND MATERIALS

309 patients with stage I-III TNBC underwent DCE-MRI (temporal resolution: 9-12 sec) at baseline (BL), 2 cycles (C2), and 4 cycles (C4) of SOC doxorubicin/cyclophosphamide (AC) NAT as part of a prospective IRB-approved study (NCT02276443). Tumor volumes of the index lesion were calculated using 3 axis measurements during the early phase of the DCE-MRI (60s). Percent tumor volume reduction (TVR) between BL, C2, and C4 was calculated. Patients were randomly assigned to a training or a validation cohort in a 1:1 ratio. pCR was assessed at surgery after completion of SOC NAT. Correlation between pCR and TVR was evaluated using

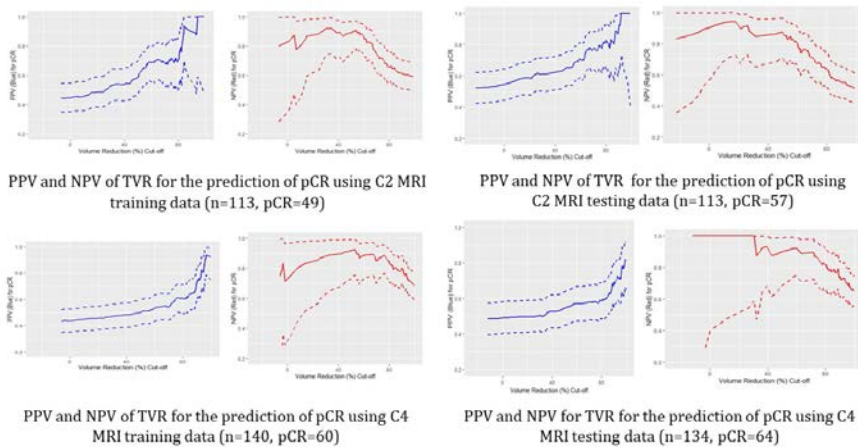

ROC analysis.

RESULTS

Of 309 TNBC patients, 136 (44%) achieved pCR. Following 2 cycles of NAT, TVR >80% was predictive of pCR (chemosensitivity), while TVR ≤ 55% was predictive of non-pCR (chemoresistance) with PPV 80%, NPV 89%, AUC 0.811 (0.73~0.893, p< 0.0001) in the training cohort, and PPV 82% , NPV 85%, AUC 0.815 (CI:0.736~0.894, p< 0.0001) in the validation cohort. Following 4 cycles of NAT, TVR >90% was predictive of pCR, while TVR ≤80% was predictive of non-pCR with PPV 80%, NPV 84%, AUC 0.827 (0.756~0.898, p< 0.0001) in the training cohort and with PPV 73%, NPV 82%, AUC 0.785 (CI:0.709~0.862, p< 0.001) in the validation cohort. Using this model, the pCR status was correctly classified in 50% of TNBC patients using C2 DCE-MRI in the training cohort, and 54% in the validation cohort. Only 8% were misclassified in the training cohort, and 10% in the validation cohort. Using C4 DCE-MRI, the pCR status of 61% and 57% of TNBC was correctly classified in the validation and the testing cohorts, respectively. 12% were misclassified in the validation cohort, and 21% in the testing cohort.

CONCLUSION

DCE-MRI after 2 and 4 cycles of AC-based NAT correctly predicted the pCR status of 54% and 57% of TNBC patients, respectively, as either excellent responders or nonresponders with high AUC 0.811 and 0.827. This may allow patients to be triaged to SOC NAT with option of de-escalation or early targeted therapies for non-responders.

Bioimpedance Spectroscopy Monitoring Reduces Long-term Clinical Lymphedema Risk

Presenting Author(s) and Co-Author(s):

Country: United States

Background: A prospective surveillance model (PSM) of care can reduce the risk of breast cancer related lymphedema (BCRL). Bioimpedance spectroscopy (BIS) devices can identify sub-clinical BCRL (sBCRL). A recent randomized controlled trial (RCT) demonstrated the benefit of a PSM model of care using BIS over tape measure (TM) but it did not look at the long-term risk following intervention. This work reports the actuarial risk of clinical lymphedema for those who have triggered an intervention for sBCRL by either BIS or TM. **Materials and Methods:** 879 women with breast cancer were randomized to lymphedema screening with either BIS (n=442) or TM (n=437). Following consent, patients underwent baseline pre-surgical measurements with BIS (L-Dex U400, ImpediMed) and volume (circumference) measurements (Gulick II tape) and randomized after surgery. Both the TM and BIS arms underwent planned post-operative assessments at 3, 6, 12, 18, 24, 30, and 36 months as well at the end of any intervention. Patients with a BIS change from baseline of ≥ 6.5 L-Dex units or TM volume change ≥ 5 and $< 10\%$ above pre-surgical baselines "triggered" for sBCRL form the basis of this study. Triggered patients underwent 4-weeks of wearing a class two (23–32 mmHg) compression sleeve and gauntlet for 12 hours per day. TM volume change $\geq 10\%$ was considered clinical BCRL (cBCRL) for all patients who triggered by either BIS or TM. The cumulative incidence of cBCRL was calculated via the Kaplan-Meier method and compared by the Log-rank test. **Results:** 209 (23.8%) women triggered an intervention and completed treatment for sBCRL (BIS: 89 (20.1%), TM: 120 (27.5%)). The median follow up for the women who triggered was 32.2 months (IQR 17.0 – 33.9) with 30 women (14.4%) women developing cBCRL (BIS: 7 (7.9%), TM: 23 (19.2%)). There was a significant difference in risk between the groups over the follow up interval (log rank test $p = 0.021$) with the cumulative risk in the BIS group being lower compared to the TM group (Hazard Ratio = 0.38, 95%CI 0.19 – 0.79). The 2-year actuarial risk of cBCRL for triggered patients undergoing lymphedema screening by BIS was 5.0% versus 15.7% for TM screening ($p = 0.021$, HR = 0.30). The corresponding 3-year rates of cBCRL were 10.3% and 21.2%, ($p = 0.031$, HR = 0.40) respectively. **Conclusions:** BIS monitoring for sBCRL with subsequent intervention provides significantly lower risks of cBCRL. The lower triggering rates with BIS highlight its better discrimination of true sBCRL compared to TM and support its use for post-treatment surveillance to detect sBCRL and initiate early intervention. These data suggest that monitoring for sBCRL with BIS and subsequent intervention does not just delay the inevitable progression to cBCRL, but rather prevents it over the duration of the study.

Radiomic models based on dynamic contrast-enhanced magnetic resonance imaging predict the immunophenotype reflecting spatial distribution of CD8+ tumor-infiltrating lymphocytes in breast cancer

Presenting Author(s) and Co-Author(s):

Yu Jin Lim, *n/a, Assistant Professor - Kyung Hee University*
Country: Republic of Korea

Purpose: This study aimed to develop noninvasive magnetic resonance imaging (MRI)-based radiomic models to predict immunophenotypes of breast cancer. Methods: A total of 182 breast cancer patients who underwent upfront surgery were analyzed, divided into training (n = 137) and validation (n = 45) cohorts. Dynamic contrast-enhanced (DCE)-MRI was acquired, and immunophenotype was determined on the surgical tumor sections: immune-inflamed (high degree of CD8+ T cells infiltrated), -excluded (CD8+ T cells accumulated at invasive margin but not efficiently infiltrated in tumor bed), and -desert (CD8+ T cells absent within tumor and at margins). Based on 833 radiomic features extracted after manual delineation, the least absolute shrinkage and selection operator method was used to build radiomic models. Results: Our radiomic models from the whole tumor sections showed moderate performance in predicting the immune-inflamed versus non-inflamed tumors, showing the highest AUC values, of 0.659 and 0.671 for training and validation cohorts, respectively. Combining the models, much improved predictability was observed, with AUC values of 0.973 and 0.985 for training and validation cohorts, respectively. Other radiomic features from tumor periphery data discriminated immune-excluded versus immune-desert status, with AUC values of 0.993 and 0.984 for training and validation cohorts, respectively. The combined models were also applicable to predicting immunophenotype for different molecular subtypes, with AUC values \geq 0.867. Conclusions: By integrating the immunohistochemistry profiles, we established MRI-derived radiomic models to predict the detailed immunophenotype of breast cancer. This study suggests the feasibility of noninvasive assessment of tumor immune status in real-world clinics.

Background

Early detection of breast cancer is crucial for optimal patient outcomes but cannot always be accomplished based on symptoms or screening mammography. Biomarker-based screening could aid early detection of breast cancer by improving sensitivity and specificity. Exai Bio has developed a novel liquid biopsy technology that detects and analyzes small non-coding RNAs that are cancer specific, termed orphan non-coding RNAs (oncRNAs). Previous work in patients with diagnosed breast cancer demonstrated that changes in oncRNAs in serum reflected treatment response and event-free survival. In this study, we developed an assay that measures oncRNAs in serum to detect breast cancer across the range of tumor stages and sizes.

Methods

Previously, a library of ~260,000 oncRNAs from 32 different cancers was compiled based on smRNA sequences found in tumor tissues and largely absent in tumor-adjacent normal tissues from The Cancer Genome Atlas (TCGA). To refine this library for applications in serum, we sequenced smRNA in 31 control serum samples. These smRNA sequences were filtered from the larger library, reducing its size to 250,332 oncRNAs. The diagnostic performance of these oncRNAs was then assessed in an independent cohort of archived serum samples from 96 female patients with clinically diagnosed, untreated breast cancer and 95 age- and sex-matched individuals with no known history of cancer. We sequenced smRNAs at an average depth of 17.7 million 50-bp single-end reads per sample. Of the 250,332 oncRNAs in our library, 171,981 (68.7%) were detected in our independent study cohort. An ensemble of logistic regression models was trained with 5-fold cross-validation, using only those oncRNAs yielding an odds ratio >1 and observed in >6% of samples within each training set.

Results

The cohort of 96 breast cancer patients and 95 matched controls had mean ages of 59.4 and 56.3 years, respectively. Area under the receiver operating characteristic curve (AUC) for detecting breast cancer was 0.94 (95% CI, 0.85–0.96). Sensitivities for detecting breast cancer at 95% specificity ranged from 0.75 to 0.87 among the four breast cancer stages, including a sensitivity of 0.81 for tumor stage I (Table 1); and from 0.67 to 0.87 among the four main TNM T categories (Table 2). Sensitivities at 95% specificity were relatively high for small tumors, at 0.75 (95% CI, 0.40–0.97) for T1b (>5mm to ≤10mm; n = 9) and 0.80 (0.68–0.94) for T1c (>10mm to ≤20mm; n = 37).

Conclusions

We have demonstrated the potential value of an oncRNA-based liquid biopsy assay by showing that oncRNAs can be used to detect breast cancer in serum samples with high sensitivity, and that detection requires fewer reads than are needed with other platforms. Moreover, we found that this oncRNA-based assay performed well in detecting early-stage breast cancer and small tumors. This suggests that an oncRNA-based liquid biopsy assay may be beneficial for early detection of breast cancer.

Table 1. Model sensitivity by tumor stage

Tumor Stage	N	Sensitivity (95% CI)
I	45	0.81 (0.71–0.94)
II	19	0.75 (0.54–0.94)
III	19	0.80 (0.60–0.97)
IV	13	0.87 (0.64–1.00)

For the indicated numbers of cases (N), sensitivity and Pearson-Clopper 95% confidence intervals are reported for tumor detection by the oncRNA-based model at 95% specificity by tumor stage, as defined by the AJCC 7th Edition breast cancer staging system.

Table 2. Model sensitivity by tumor size

TNM T Category	N	Sensitivity (95% CI)
T1	48	0.80 (0.70–0.93)
T2	30	0.87 (0.73–0.98)
T3	8	0.78 (0.47–1.00)
T4	10	0.67 (0.35–0.93)

For the indicated numbers of cases (N), sensitivity and Pearson-Clopper 95% confidence intervals are reported for tumor detection by the oncRNA-based model at 95% specificity by TNM T category, as defined by the AJCC 7th Edition breast cancer staging system.

Country: United States

Objective: The COVID-19 pandemic has had an impact on health care. In the Netherlands, hospital capacity for non-covid care was limited and population screening temporarily halted. The aim of this study was to investigate the impact of the pandemic on the diagnostic pathway of breast cancer.

Methods: In this study, 48,425 breast cancer patients with a primary breast tumour were selected from the Netherlands Cancer Registry and the Dutch Hospital Data. Patients diagnosed in period January 2020 to July 2021 were divided into six periods, based on the number of hospitalizations due to the COVID-19 pandemic and compared to the same periods in 2017-2019. A t-test was performed to compare the number of diagnosed patients per period. Patient characteristics were compared using chi-squared test. The impact on the procedures performed was analysed using logistic regression. The median time between diagnosis and therapy and the median time between first diagnostic procedure and therapy was analysed using Cox Proportional Hazards Regression. All results were corrected for age, stage and region.

Results: During the first peak of the pandemic in 2020, significantly fewer patients (-48,2%) have been diagnosed with breast cancer. This decrease is mainly seen in lower stage tumours. Mammography and echography were performed significantly less per patient during the first recovery in 2020 (OR=0.83 and OR=0.85 respectively) compared to 2017-2019. PET-CT was performed significantly more often during the first peak and first recovery in 2020 (OR=1.94 and OR=1.39 respectively). The median time between diagnosis and start of therapy significantly decreased in 2020, during the first peak by 3 days (HR=1.26), during first recovery and second peak by 1 day (HR=1.04 and HR=1.16 respectively). The median time between first diagnostic procedure and start of therapy significantly decreased in 2020, during the first peak by 4 days (HR=1.25), during the first recovery by 1 day (HR=1.04) and during the second peak by 2 days (HR=1.13).

Conclusion: The decreased number of diagnosis was related to the temporary halt of the screening. Diagnostics for early stage tumours was limited and for PET-CT was performed more often reflecting the change in proportion of higher stage. A reduced time of the diagnostic pathway is the result of less hospitalized patients with cancer and the effort on keeping the

oncology care in place.

Background In breast cancer, prognosis is marked by histology and stage at diagnosis. Patients presenting with HER-2 positive or triple negative breast (TNBC) often have a worse prognosis. Early detection of breast cancer is mainly based on yearly screening mammograms, which were disrupted during the lockdown stages of the COVID-19 pandemic. In general, underserved populations, especially the Hispanic population often lack access to preventive care due to lack of funding causing delays in access to timely care. The COVID-19 pandemic caused many patients to miss their annual mammogram screening due to lockdown causing subsequent presentation of more advanced cancer. We, therefore, hypothesized that more patients were diagnosed with advanced cancer after lockdown and worse histology in the Hispanic population compared to the non-Hispanic population of San Antonio, Texas. Methods We identified 3 cohorts retrospectively using chart review: Pre-covid-19 era was defined

between 2018 to March 2020. Lockdown is defined as a period between April 2020 to December 2020 followed by the post-vaccine era from January 1st 2021 to 2022. Pearson's Chi-squared and logistic regression tests were used to determine the relationship between time, histology at diagnosis and ethnicity. Results More Hispanic patients were found to present with HER2+ disease (OR: 1.65. p-value .047) compared to non-Hispanic women. When looking at presentation of HER2+ disease in the pre-covid-19 era, there was a 15.11% increase in the presentation of HER2+ disease in the post-vaccine era. When looking at the presentation of TNBC disease in women, there was not a significant correlation seen in the lockdown or post-vaccine period in Hispanic compared non-Hispanic women. Other factors such as funding status were associated with TNBC at presentation independently of ethnicity. In the lockdown era, the number of newly diagnosed breast cancer patients reached an all-time low and during the post-vaccine era, the patient numbers are back to the pre-covid era. Conclusion Ethnicity in part played a role in the number of patients presenting with more aggressive histology such as TNBC and Her 2 positive breast cancer in the post-vaccine era. These findings may be secondary to fact that certain ethnic groups are more likely to miss preventive screenings and the covid 19 pandemic lockdown exacerbated this problem. Diagnosis of advance cancer can further deter patients from seeking care due to socioeconomic factors and possibly increase mortality in these populations. These findings suggest that there seems to be a correlation between race and presentation of more aggressive histology caused by the effects of the pandemic in cancer care affecting minorities.

Objective: Identify changes in breast cancer detection method, stage at diagnosis and treatment prior to, during and after stay-at-home orders and restricted health care access due to COVID-19.

Methods: Statistical comparison of detection method (patient (PtD), mammography (MamD) or other), Anatomic TNM Stage 8 (0-IV) and invasive BC treatment change over time by three time periods (time 1: 2019+Q1 2020; time 2: Q2-Q4 2020; time 3: 2021) using chi-square analysis in an institutional retrospective cohort of first primary breast cancer (BC) patients (n=1799), years 2019-2021.

Results: In the years prior to the study, 2016-2019, there was no difference in detection method or stage at diagnosis by year with 682 to 733 newly diagnosed BC annually (p=.462). In 2020 (n=535) and 2021 (n=582) annual diagnosed cases dropped 22% and 15% from 2019 levels. Compared to time 1, time 2 MamD BC dropped significantly (64% to 58%) with a subsequent increase in MamD BC to 70% in time 3 (p < .001) creating a U-shaped curve for MamD over time. PtD BC increased in time 2 from 30% to 36% but declined in time 3 to 25% (p < .001). Concurrently, stage at diagnosis shifted from time 1 to time 2 with stage 0 and I declining [stage 0: 21% to 16%, stage I: 40% to 38%] and stage II and IV increasing [stage II: 28% to 33%, stage IV: 2% to 4% stage IV] (p<.001). Subsequently in 2021 stage shifted again with an increase in stage 0 to 22% and stage I to 45% and a decline in stage II (33% to 24%), III (9% to 7%) and IV (4% to 2%) (p<.001). Combining stage 0 and I, the percentage of lower stage BC declined from 61% to 54% and increased to 67% in time 3 (2021) when health services became more readily accessible.

There was no change in type of surgery for invasive breast cancer (stage I-III, n=1386) with equivalent numbers of breast conserving surgery (58%), subcutaneous mastectomy (24%) and mastectomy (18%) over the time period. Chemotherapy treatment rates for invasive BC did not change (38%). Radiation therapy increased from 66% (time 1: 2019+Q1 2020) to 73% (time 2: Q2-Q4 2020) then back to 64% in time 3: 2021 (p=.007) independent of surgery type but

concordant with an increase in stage IA and stage IIB BC among invasive breast cancer cases in time 2: Q2-Q4 2020 (p<.001). Likewise, neoadjuvant therapy increased and then declined from 33% to 38% to 29% from time 1 to time 3 (p<.001).

Conclusions: Number of diagnosed BC cases fell after the first quarter of 2020 during the time of COVID-19 related shut downs and decreased access to health services. During the Q2-Q4 2020 time period mammography detected BC declined with a relative increase in patient detected breast cancer. When mammography detection declined, BC stage at diagnosis shifted to higher stage concurrent with increased rates of radiation and neoadjuvant therapy. In 2021, the relative increase in mammography detected BC indicates a return to more normal screening patterns with a catch up for screening lost in the prior year due to access limitations. In the third time period: 2021, with the return to prior levels of mammography detected breast cancer, stage shifted back to pre-pandemic expected distribution and the excess treatment with radiation and neoadjuvant therapy declined to previously observed levels. Although the changes in detection method, stage and treatment did not persist they were statistically significant and could represent a need for re-establishing pre-pandemic screening behavior.

Detection Method by COVID Pandemic Diagnosis Time Periods: 2019-2021 (N=1799)

Table. Detection Method by COVID Pandemic Diagnosis Time Periods: 2019-2021				
	PtD	MamD	Other	
(n=1799)	(n= 538)	(n = 1156)	(n = 105)	p value
	N (%)	N (%)	N (%)	
Time 1: 2019/Q1 2020	219 (30%)	467 (64%)	50 (7%)	<.001
Time 2: Q2-Q4 2020	172 (36%)	279 (58%)	30 (6%)	
Time 3: 2021	147 (25%)	410 (70%)	25 (4%)

Introduction

Breast cancer is the most frequently diagnosed cancer and the second leading cause of cancer death in women in the United States. The significant advances in care over the last decades are largely attributable to early detection and treatment. The pre-COVID-19 pandemic 5-year survival rate of breast cancer was in the range of 90%, however, there has been public concern that the pandemic has led to delayed diagnosis. The objective of this study was to determine if patients diagnosed during the pandemic had more advanced breast cancer at presentation compared to those diagnosed prior.

Methods

This is a retrospective study of patients with an ICD code for Breast Cancer seen within the University of Texas Health San Antonio MD Anderson Cancer Center between 1/1/2018 and

12/31/2021. Data abstractors collected information on gender, age, race, ethnicity, funding, screening mammogram dates, date of cancer diagnosis, stage at diagnosis, and treatment. Those diagnosed before 1/1/2018 or that received initial treatment outside our institution were excluded from the analysis. Pearson's Chi-squared and logistic regression tests were used to determine the relationship between time and stage at diagnosis. The timeline was divided into three periods: from 01/01/2018 to 03/31/2020 as the pre-COVID era, from 04/01/2020 to 12/31/2020 as the lockdown period, and from 01/01/2021 to the present as the post-vaccine era.

Results

A total of 696 patients with breast cancer were included. There was a significant statistical difference between the cancer stage at diagnosis in the pre-COVID-19 era compared to the lockdown period and the post-vaccine era ($p= 0.003$, table 1). Therefore, patients diagnosed after the beginning of lockdown were more likely to have more advanced cancer as time progressed. The odds ratio for Tis stage was 0.38 (95% CI: 0.23-0.60; $P < 0.001$) in the post-vaccine era compared to the pre-COVID era. The OR for Tis stage was not statistically significant (OR, 0.68; 95% CI: 0.42-1.10; $P < 0.12$) when comparing the lockdown period to the pre-COVID era.

Conclusion

Patients diagnosed with breast cancer in the COVID-19 pandemic were more likely to present with more advanced disease at diagnosis compared to those diagnosed in the pre-COVID-19 era confirming our hypothesis. The OR of presenting with Tis disease when diagnosed during the post-vaccine compared to the pre-COVID-19 era was 0.38, however, this was not seen when comparing the lockdown period to the pre-pandemic era. We believe this difference was not significant because delays in cancer care may take months to years to take full effect.

Breast cancer stage at diagnosis per period

Table 1 – Breast cancer stage at diagnosis per period

Introduction: Leptomeningeal metastases (LM) occur in approximately 5% of patients with breast cancer, negatively impacting their prognosis. Reliable diagnosis of LM is challenging, but timely diagnosis could lead to more treatment options and consequently a better prognosis. Circulating tumor DNA (ctDNA) and circulating tumor cells (CTCs) in cerebrospinal fluid (CSF) are potential methods to improve the diagnosis of LM. In this prospective study we compared cytology (current gold standard for CSF analysis in diagnosing LM) with CTC enumeration and ctDNA detection in CSF for diagnosing LM in patients with breast cancer. Methods: In a

prospective study in patients with clinical suspicion of LM who were planned to undergo a diagnostic lumbar puncture (LP) for CSF cytology the presence of CTCs/ctDNA in CSF was compared to the presence of tumor cells in CSF by cytology. CTC enumeration was performed using the FDA approved CellSearch System (Menarini). The detection of ctDNA was performed using the mFAST-Seqs method, which detects aneuploidy throughout the genome by selective amplification of long interspaced nuclear element sequences (LINE-1 elements). In a control group consisting of 15 patients with a hematologic malignancy with suspicion of LM, 2 cases had 1 CTC in their CSF, therefore the cutoff for a positive CTC test was set at 2 CTCs. Results: In total 80 patients with breast cancer were included from January 2016 till January 2022. In 16 out of 80 patients CSF cytology was positive of whom 14 (87.5%) had a positive CTC test. From the 2 patients in which the CTC test was negative, one patient had 1 CTC detected in CSF and for both patients a lower volume of CSF was available for the CTC test compared to the volume used for cytology. In 2 of the 16 cytology positive patients, who underwent a second LP, CTCs were positive in the CSF from the first LP, while cytology was only positive in the CSF of the second LP. Of the 64 patients with a negative cytology, 7 (10.9%) patients had a positive CTC test. Two of these 7 patients had typical symptoms of LM, a suspicious MRI and a course of disease matching with LM according to the neuro-oncologist. Overall survival (OS) was shorter in patients with a positive CTC test compared to patients with a negative test (median OS: 19.2 months vs. 3.4 months, log-rank test, $p=0.007$). When only patients with a negative cytology were included in this analysis, OS remains significantly shorter in the group with a positive CTC test ($n=7$) compared to the group with the negative CTCs ($n=57$) (median OS 19.3 months vs. 3.5 months, long-rank test, $p=0.003$). Additionally, ctDNA detection in CSF was compared to CSF cytology in 51 patients, of which 11 had a positive CSF cytology result. For 8 of these 11 patients ctDNA was detected (72.2%) while 1 of the 40 patients with a negative cytology had ctDNA. Discussion: Both CTC enumeration and ctDNA detection can be used to detect LM in CSF. CTC detection could even improve timely diagnosis of LM in patients with breast cancer. However, the added value of ctDNA seems less evident.

DELAYS in DIAGNOSIS of Adolescent and Young Adult BREAST CANCER and LACK OF BREAST HEALTH EDUCATION, Community Based Research

Presenting Author(s) and Co-Author(s):

Missy Peters, AYA Survivor, *Executive Director - Young Breast Cancer Project*

Office Phone: (619) 929-4661

Cell Phone: (619) 929-4661

City: Sisters

State: Oregon

Country: United States

Steph Tubman, AYA Survivor, *Board President - Young Breast Cancer Project*

Country: United States

INTRO) The average AYA breast cancer patient is diagnosed at a higher stage and has a higher mortality rate compared to their 40+ counterparts [1,2,3]. Ruddy et al. (2014) establish a higher prevalence of delayed diagnosis in AYA patients [4]. Delays in treatment of just 6 weeks have been linked to poorer 5-year survival rates [5]. In this study, we attempt to confirm the findings of Ruddy et al. and further define factors affecting delays in diagnosis. METHODS) We distributed an online survey via social media outlets to women diagnosed < 40 years old in the USA. We interpreted 455 responses. RESULTS) Our findings determined that 70% of respondents (n=320) made extra efforts after detecting an abnormality and taking steps to obtain a diagnosis. This includes those with prompt and delayed diagnosis. 36% of survivors faced delays in diagnosis (defined by 8+ weeks duration from detection to diagnosis). 62% of survivors say that a physician never educated them on breast health prior to diagnosis. 54% have not heard of breast self-awareness (BSA) and 54% incorrectly defined breast self-exams (BSE), suggesting confusion in this distinction. DISCUSSION) These data confirm earlier findings that 1) women under 40 face a significant rate of delayed diagnosis; and 2) patient perceptions and medical provider perceptions contribute to these delays. We propose that earlier diagnosis of breast cancer in young women will initiate quicker treatment interventions which have been shown to increase 5-year survival rates and lower long-term mortality rates in the AYA breast cancer population [5,6]. CONCLUSION) Greater efforts should be made to educate young women on breast health, and the medical community should be made aware of these challenges so they can properly evaluate and assist young women to receive a prompt diagnosis.

Young Breast Cancer Project

YOUNG BREAST CANCER PROJECT

Missy Peters + Steph Tubman || Survivors + Patient Advocates

AAACR Selected Survivor Program 2022
 missy@youngbreastcancer.org | steph@youngbreastcancer.org | www.youngbreastcancer.org | @youngbreast | San Diego, CA | EIN: 84-3061156

These women received diagnoses for an early breast cancer diagnosis due to lack of breast health education and/or lack of cancer care information/awareness presented with symptoms.

These women had delayed diagnosis of early stage breast cancer. We found 47% waited to see a doctor, 17% were assessed by a physician their symptom was OK and no diagnosis was ordered, 27% were a medical professional being told incorrect, and 9% waited to schedule a biopsy because they were reassured it was "nothing".

Mission + Background

The Young Breast Cancer Project advocates for early detection of disease through breast health education. We elevate young survivors' stories and forge alliances with the medical community to reduce delayed diagnoses and help save lives.

After a delayed diagnosis, Missy Peters started photographing fellow women diagnosed +40 to raise awareness that Young Women Get Breast Cancer Too. In doing so, she learned that too many young women face delays and difficulties seeking accurate diagnoses and access to prompt treatment.

Programmatic Areas

BREAST CANCER PORTRAIT PROJECT:
 Target Audience: Survivors. Those diagnosed with adolescent and young adult (AYA) breast cancer are invited to share their story at a portrait session with Missy. They're encouraged to use the great images to raise awareness in their social circles. With almost 100 stories collected, our qualitative dataset reveals the difficulties young women face leading up to a diagnosis of breast cancer.

COMMUNITY-BASED RESEARCH:
 Target Audience: Physicians. We believe in data-backed decision making. Our original survey validates the Portrait Project findings. It quantifies the delay and access difficulties young women face leading up to their breast cancer diagnosis. Missy has been accepted into CBOA's Quickstart program and will partner with an Academic Co-PI in 2022-2023 to seek peer review and publish these findings.

BREAST FRIEND NIGHTS
 Target Audience: Lay Public. An engaging event for "our friends" to learn about breast health - especially the signs and symptoms of breast cancer. Here we utilize live storytelling, the Portrait Project gallery and our signature "Boobie Booth" to educate attendees. We're planning events for 2022 in Los Angeles (Spring), NYC (Summer), San Diego (Fall) and hoping to add cities.

Community-Based Research: Understanding Prevalence + Causes of Delayed / Difficult AYA Diagnoses

INTRODUCTION:
 The average AYA breast cancer patient is diagnosed at a higher stage and has a higher mortality rate compared to their 40+ counterparts [1,2,3]. Hudis et al. (2014) establish a higher prevalence of delayed diagnosis in AYA patients [4]. Delays in treatment of just 6 weeks have been linked to poorer 5-year survival rates [5]. In this study, we attempt to confirm the findings of Hudis et al. and further define factors affecting delays in diagnosis. We distributed an online survey via social media outlets to women diagnosed +40 years old in the USA. We interviewed 407 responses.

RESEARCH QUESTIONS:

- What is the prevalence of delayed and/or difficult diagnosis in patients <40?
- Which factors most contribute to delayed and/or difficult diagnosis?
- To what extent do young breast cancer survivors understand BSE (breast self-exam) + BSA (breast self-awareness) as defined by the medical community?
- To what extent were young breast cancer survivors educated on breast health?

RESULTS + DISCUSSION:

Delayed Diagnosis
 We defined a delay as greater than 8 weeks from decision to diagnosis based on our interviews with survivors. Our findings indicate 36% of survivors that we surveyed faced delays in diagnosis.

Difficulties with Diagnosis
 79% of respondents (n=320) made extra efforts after learning an abnormality and taking steps to obtain a diagnosis. This includes: those with 10% just one of the listed, 27% physician had to press additional diagnoses, 27% sought a second or multiple opinions after learning an abnormality and taking steps to obtain a diagnosis. This includes: those with 10% just one of the listed, 27% physician had to press additional diagnoses, 27% sought a second or multiple opinions after learning an abnormality and taking steps to obtain a diagnosis.

Level of Risk

- 43% Unknown
- 19% Not known
- 38% Not known

Family History of Breast Cancer
 Our results suggest family history of disease alone is not a reliable predictor of breast cancer or average risk scores.

Genetic Link to Breast Cancer
 23% of survivors had a genetic link. Only 4% knew this prior to diagnosis which suggests previous surgery in successful and genetic testing should be more prevalent.

Factors Contributing to Delay
 We found that 88% of women detected their own breast or lymph abnormality, which is higher than previously reported [6]. 63% of those with a delay detected their own abnormality compared to 66% of those without a delay. Survivors with delay were allowed to select multiple reasons:

- 47% wanted to seek medical attention.
- 27% saw a physician and no diagnostic imaging was ordered.
- 22% had diagnostic imaging that did not lead to biopsy.
- 15% wanted to schedule a diagnosis because they were reassured by their provider they had "nothing to worry about".
- 6% had issues with insurance coverage.

Breast Health Knowledge

- 62% say that a physician never educated them on breast health prior to diagnosis.
- 54% have not heard of breast self-awareness (BSA) and 54% incorrectly defined breast self-exams (BSE), suggesting confusion in the distinction.

CONCLUSIONS + IMPLICATIONS FOR ADVOCACY:
 These data confirm earlier findings that 1) women under 40 face a significant rate of delayed diagnosis, and 2) patient perceptions and medical provider perceptions contribute to these delays. We propose that earlier diagnosis of breast cancer in young women will initiate quicker treatment interventions which have been shown to increase 5-year survival rates and lower long-term mortality rates in the AYA breast cancer population [2,6]. Greater efforts should be made to educate young women on breast health, and the medical community should be made aware of these challenges so they can properly evaluate and assist young women to receive a prompt diagnosis.

Sources + Acknowledgements
 These data confirm earlier findings that 1) women under 40 face a significant rate of delayed diagnosis, and 2) patient perceptions and medical provider perceptions contribute to these delays. We propose that earlier diagnosis of breast cancer in young women will initiate quicker treatment interventions which have been shown to increase 5-year survival rates and lower long-term mortality rates in the AYA breast cancer population [2,6]. Greater efforts should be made to educate young women on breast health, and the medical community should be made aware of these challenges so they can properly evaluate and assist young women to receive a prompt diagnosis.

Background: In order to determine the optimal treatment strategy for oligometastatic breast cancer (OMBC), effective and safe treatments for metastatic sites and sensitive and specific imaging techniques are needed. But it is also essential to know the incidence of oligometastatic

breast cancer and its clinical and biological characteristics [1]. Efficient imaging techniques and therapeutic tools exist, but knowledge of incidence, clinical and biological characteristics of OMBC is scarce. This is partly due to the lack of publications describing these data on recent, consecutive, and unselected series of OMBC. Methods: we retrospectively collected data from 998 patients diagnosed with synchronous or metachronous metastatic breast cancer (MBC) between January 2014 and December 2018 at our institution. The only criterion used to define OMBC was the presence of one to five metastases at diagnosis. Hormone receptor (HR) and HER2 receptor status, histology, SBR grade, number of metastases and organs affected were collected. Results: Of 998 MBC, 15.8% were OMBC (158/998). Among the series, 88% (139/158) of OMBC had 1 to 3 metastases and 86.7% (137/158) had only one organ involved. Among 158 patients, 52.5% (n=83) had bone metastases, 20.9% (n=33) had lymph node metastases, 14.6% (n=23) had liver metastases, 13.3% (n=21) had brain metastases, 8.2% (n=13) had lung metastases, and 3.8% (n=6) had others (skin, pancreas, adrenal). Among these 158 patients, 83.4% (n=131) had ductal breast carcinoma, 55.7% (n=88) had HR+/HER2- OMBC, 25.3% (n=40) had HER2+ OMBC and 19% (n=30) had HR-/HER2- OMBC. HR+/HER2- subtype was statistically associated with bone and bone only metastases (p=0.001), HER2+ subtype with brain metastases (p=0.001) and HR-/HER2- subtype with lymph node metastases (p=0.008). Visceral metastases (lung or liver) are not statistically associated with any biological subtypes. The proportion of OMBC with SBR grade III was statistically higher than in a series of 22,109 patients with MBC [2] (49.4% vs 35.2%; p< 0.001). Conclusion: OMBC is a heterogeneous entity. OMBC incidence is certainly much higher than the commonly used values. OMBC is not an indolent disease, and each subgroup, according to its biological and anatomical characteristics, may deserve a specific management. [1] Hellman S, Weichselbaum RR. Background: The metabolic syndrome characterized in part by obesity, hyperinsulinemia, and insulin resistance is associated with increased risk of breast cancer. However there remains a need to establish a circulating biomarker metabolic profile indicative of increased risk of breast cancer. In the current study, we performed a comprehensive metabolomics screen to identify biomarkers indicative of increased risk of breast cancer. Methods: Unbiased metabolomics profiling was conducted on an initial Development Set of plasmas collected from 353 newly-diagnosed breast cancer cases and 141 controls. A deep learning neural network with 3 layers each containing 32 nodes based on 11 individual lipids corresponding to discrete lipid subclasses was built for risk prediction of breast cancer. The model was validated in an independent Test Set consisting of 79 breast cancer cases and 163 controls. Using a nested case:control matched design, we evaluated the performance of the model among body mass index (BMI) strata (≥ 30 or $< 30\text{kg/m}^2$). Results: An 11-marker lipid biomarker panel encompassing lipid subclasses with known pro-inflammatory and tumor promoting roles yielded an AUC of 0.75 (95% CI: 0.70-0.79) for distinguishing breast cancer cases from controls in the Development Set. Predictive performance of the lipid panel was comparable when stratifying cases into hormone-receptor (HR) positive, HER2-positive/HR negative, and triple-negative breast cancer subtypes. The biomarker panel had an AUC of 0.74 (95% CI: 0.68-0.81) in the independent Test Set. The predictive performance of the panel was most pronounced among obese subjects (BMI ≥ 30) with an AUC of 0.81 (95% CI: 0.71-0.91) in the Test Set.

Conclusions: The lipid-based biomarker panel has utility for identifying women with 'metabolic obesity' who are at increased risk of breast cancer and would benefit from tailored screening.

Background: Emerging HER2-targeted drugs especially antibody–drug conjugates (ADCs) are promising and provide more options for breast cancer management. Current assessment of HER2 status and treatment decisions are mainly dependent on immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH) on the primary tumor tissues. With the disease progression, the molecular status of the tumor may evolve and become discordant with the primary site. However, longitudinal monitoring of HER2 status is limited by infeasible repeated sampling of the tumor tissues. A non-invasive and accurate approach to obtaining real-time samples for measuring HER2 alterations is thus an unmet need for surveillance and guiding treatment selection in breast cancer. Detecting HER2 aberration in cell-free DNA (cfDNA) can

allow repeated sampling and avoid effects from tumor heterogeneity of tissue biopsy. Previous approaches for HER2 status determination using liquid biopsy were mostly dependent on the detection of copy number changes in cfDNA, but the limited signal-to-noise ratio poses a great challenge to the accuracy and robustness of the tests. In this study, we identified a group of DNA methylation markers for determining HER2 status in cfDNA for breast cancer. Methods: Genome-wide DNA methylation sequencing was conducted in tissue (25 HER2-positive and 35 HER2-negative) and plasma (32 HER2-positive and 107 HER2-negative) samples to identify specific methylation markers for HER2 status. HER2-positive samples were defined by IHC 3+ and 2+ with FISH positive, while HER2-negative ones were IHC 0/1+ and 2+ with FISH negative. Candidate markers were verified in another two sets of plasma samples (1. 30 HER2-positive and 40 HER2-negative; 2. 33 HER2-positive and 53 HER2-negative) by using quantitative methylation-specific PCR (qMSP). The performance of the markers was estimated by the Wilcoxon test, receiver operating characteristic curve, and logistic regression modelling. Results: 36 HER2 status-specific markers were discovered from genome-wide DNA methylation sequencing. Based on the qMSP results, 11 markers were verified by the performance analyses. The individual area under the curve (AUC) of these markers was from 0.58 to 0.68. From logistic regression modelling and 2-fold cross-validation, a 7-marker diagnostic model was built and validated on plasma samples, with the highest AUC of 0.812. Conclusion: cfDNA methylation detection inferring HER2 overexpression is a novel and non-invasive option for monitoring HER2 status in breast cancer patients, with a potential application in response prediction of HER2-targeted treatments. Further validation of the test is undergoing in large multi-centre cohorts in China.

Background: In metastatic Breast Cancer (mBC), Circulating Tumor Cells (CTCs) are clinical indicators of worse prognosis and indicate patients (pts) not responding to current therapy. However CTCs are rare, found in < 20% of mBC pts, and many pts without CTCs may also progress. Recently an inflammatory pro-tumorigenic PD-L1 expressing macrophage (Cancer associated macrophage-like cell [CAML]) was identified in the blood, which was found in >90% of mBC pts and may indicate tumor response to new therapies (JCO 40[16_Suppl] 2022). SV-BR-1-GM is a mBC cell line derived with antigen presenting characteristics was developed for treatment of mBC as a monotherapy (monoTx), or in combination with checkpoint inhibitors (comboTx). We report preliminary post-hoc results of a pooled analysis of n=18 monoTx mBCs pts and interim results of n=15 comboTx to analyze the predictive value of CTCs & CAMLs, as well as CAML PD-L1 expression, isolated from pt peripheral blood pre & post treatment to predict drug response, with end point outcomes of Progression Free Survival (PFS) and Overall Survival (OS) at 24 months. Methods: The SV-BR-1-GM regimen includes low pre-dose cyclophosphamide, intradermal inoculation of ~20 million irradiated SV-BR-1-GM cells and post-dose local interferon- α with cycles every 2 weeks x 3, then monthly. ComboTx adds an anti-PD-1 antibody with cycles every 3 weeks. Blinded blood samples were taken at baseline (BL), prior to starting SV-BR-1-GM therapy (n=33), and a 2nd sample (T1) taken after therapy initiation (~52 days) obtained as part of the exploratory portion of 2 prospective phase I clinical

drug studies, NCT03066947 & NCT03328026, to evaluate the predictive value of CTCs/CAMLS and CAML PD-L1 measured by LifeTracDx liquid biopsy. The quantities of CTCs & CAMLS were analyzed based on PFS using RECIST v1.1 and OS hazard ratios (HRs) by censored univariate analysis at 24 months. Results: A total of 33 mBC pts were pooled from monoTx (n=18), or comboTx (n =15), all with available blood samples at BL. CTCs were found in 30% (n=10/33) of pts at BL, and CAMLS were found in 94% (n=31/33) at BL. Presence of CTCs at BL did not correlate with worse PFS (HR=1.0, p=0.8550), but did trend for pts with worse survival (HR=5.1, p=0.0641). T1 samples were available from 61% (n=20/33) pts. A drop in CAMLS or CTCs after treatment at T1 was observed in 50% of pts, which correlated with a significantly improved PFS HR=11.8, p=0.0019 and OS HR=226.3, p=0.0397. Overall, pts with a decrease in CTCs/CAMLS after induction of SV-BR-1-GM therapy had a ~350% improvement in median PFS (1.9 mo. vs 6.6 mo.) and a ~200% improvement in median OS (6.3 mo. vs 12.4 mo). When stratified between monoTx and comboTx, pts with a decrease in CTCs/CAMLS had an improved PFS (HR 11.9, p=0.0136) in the monoTx group and an improved PFS (HR 17.5, p=0.0017) in the comboTx group. Further, while expression of CAML PDL1 at BL was not correlated with improved PFS (HR=1.0, p=0.9078), CAML PD-L1 expression at BL was correlated with significantly better OS HR=9.5, p=0.0116, consistent with long term benefit of SV-BR-1-GM therapy in this group of pts. Conclusions: We observed that treatment with the SV-BR-1-GM regimen was associated with decreases in the presence of CTCs and CAMLS in 50% of patients, which also significantly correlated with ~350% better median PFS and ~200% better median OS within 2 years. SV-BR-1-GM therapy alone, or as a combination treatment with anti-PD-1, appears to have improved long term clinical outcomes in a large portion of heavily pre-treated mBC patients compared to other typical standard of care published results.

BACKGROUND: Studies have consistently demonstrated that breast cancers arise in the left breast more often than the right breast, but no factors have been able to account for this. Some studies have shown age younger than 45 years and late age at menarche to be associated with somewhat higher incidence of cancer in the right breast. However, most of these studies were conducted in the 1990s. We sought to determine if demographic factors, pathologic findings, or treatment impact laterality. **METHODS:** We performed a single-institution IRB-approved retrospective chart review of US female breast cancer patients diagnosed with DCIS (stage 0) or stages I-III breast cancer from 1997 to April 2020. Clinicopathologic characteristics, demographic, and treatment information were collected. Statistical analyses evaluated differences in laterality. Association between laterality and continuous variables was determined using Kruskal-Wallis test. Association of laterality and categorical variables was determined using Chi-square test or Fisher exact test if applicable. **RESULTS:** 5328 female patients with 5474 breast cancers were evaluated with a median age of 60 years old. Majority of tumors were stage T1(2542, 54.4%) and 75% were IDC. Overall left-sided cancer showed a predominance (2797, 51.1%). Breast cancer laterality was not significantly associated with grade, receptor status, tumor size, pathologic type, or recurrent tumors. Laterality was evaluated regarding age, based on age less than 61 years old versus greater than or equal to age 61. Laterality was significantly associated with age overall with an increase in left-sided breast cancers (2797 vs 2677, $p=0.029$). Left-sided breast cancer was significantly increased in women greater than or equal to age 61, 1456 (53%) vs right-sided 1290 (47%). Whereas, right-sided breast cancer was significantly associated with age less than 61, (1387, 50.8% vs left 1341, 49.2%, $p=0.004$). **CONCLUSION:** Our analysis confirms prior studies that overall left-

sided breast cancer is more common in women. However, there are age differences with left-sided breast cancers more prevalent in older age women greater than or equal to age 61. On the other hand, right-sided breast cancer was seen more often in women under the age of 61. Further studies are needed to better ascertain why the overall laterality of breast cancer occurs more frequently in the left breast, but also to determine an explanation for the laterality age differences. Anatomical factors such as blood supply, breast size, inherited genetic mutations, tumor genomics, lactation history and others are possible factors that need to be further explored. Studies are ongoing. This information will be potentially helpful in allocating diagnostic and therapeutic resources for breast cancer patients.

Neoadjuvant, i.e. preoperative, systemic antineoplastic treatment (NAT), in patients with breast cancer enables in vivo monitoring of tumor response to applied therapy, tailoring treatment in real-time accordingly, sparing surgical procedures, better quality of life for patients and implies better patient survival for particular patient, if a pathological complete response (pCR) to treatment is achieved. Use of MRI in monitoring response to NAT has shown in various studies sensitivity and specificity of at least 70% in the detection of residual disease, with a high positive and negative predictive value. Studies have shown higher accuracy in predicting pCR in HER2 positive tumors, and a higher rate of false negative results in HER2 negative tumors. Here we report findings of our pilot project where we tested the accuracy of the MRI, and the concordance of preoperative MRI findings after NAT, with the definitive pathology report after the surgery was performed, in breast cancer patients with different disease biology, in the real clinical practice. The focused pathological substrate was the primary tumor in the breast. For the simplicity of this pilot analysis, we did not include here the status of the axilla, which will be included in our larger analysis pending. We performed our analysis on a cohort of 200 breast cancer patients who underwent NAT, in our institution, University Hospital for Tumors, in Zagreb, Croatia. Median age of the analyzed patient cohort was 62 years. The representation of individual breast cancer intrinsic subtype surrogates was as follows: HER2 nonluminal tumor 23.5% (47/200), triple negative breast cancer 21.5% (43/200), luminal HER2 positive 22.5% (45/200) and luminal HER2 negative 32.5% (65/200). According to MRI of the primary tumor in the breast, radiological complete response (rCR) to NAT was achieved in 46.5% (93/200) of patients, and the finding of residual tumor was described in 53.5% (107/200) of patients. Postoperatively, pathology report of the primary breast tumor showed pCR in 29% (58/200) of patients, and residual disease in 71% (142/200) of cases. The overall concordance of MR and pathology reports was 62.4% in the assessment of complete response, and 75.35% in the assessment of residual disease. Analyzed according to subgroups, results are as follows: in the cohort of patients with HER2 nonluminal tumors, concordance of MRI and pathology report in the assessment of complete response was 88%, while for residual disease concordance was 70%; in the cohort with triple-negative breast cancer patients, concordance of MRI and pathology report in the assessment of complete response was 83%, and residual disease 87.8%; in the group with luminal HER2-positive breast cancer concordance of MRI and pathology report in assessing complete response, as well as residual disease, was 97%; while in the group with luminal HER2-negative breast cancer, concordance of MRI and pathology report findings in assessing complete response was only 50.5%, and residual disease 77%. Results of our analysis showed relatively high overall concordance between MRI and pathology findings, which is in line with results of large studies worldwide and confirms MRI as a good method in monitoring response to NAT in breast cancer patients. By subgroup analysis, patients with luminal HER2-negative tumors are distinguished. This group has the lowest prevalence of complete response overall, as well as the lowest concordance of MRI and pathology report findings in the detection of these cases. This confirms the weaker response of this type of tumor to neoadjuvant treatment, but also indicates the need for additional caution when analyzing MRI findings in these patients, as well as for considering additional diagnostic arsenal, complementing the standardly – utilised MRI.

Introduction: Metaplastic breast cancer (MBC) is a rare breast tumor. WHO histological classification of breast tumors in 2019 divided MBC into the following seven types: low-grade adenosquamous carcinoma, fibromatoid metaplastic carcinoma, squamous cell carcinoma, spindle cell carcinoma, metaplastic carcinoma with mesenchymal differentiation, mixed metaplastic carcinoma and myoepithelial carcinoma. Based on single center data, this study intends to conduct a detailed analysis of the clinicopathological features, treatment and prognostic factors of MBC. Methods: We collected 259 MBCs treated in our center from 2006 to 2022. The patient's age, histological type, image feature, tumor size, lymph node metastasis,

tumor stage, immunohistochemical information, surgical plan and systemic adjuvant therapy were summarized and considered to explore the factors affecting the overall survival rate (OS) and disease-free survival rate (DFS). T-test and chi-square test were performed on the data. $P < 0.05$ showed that the difference was statistically significant. Kaplan-Meier survival was used to analyze the long-term efficacy. Results: The incidence rate of MBC in breast cancer patients in our center is about 0.5%. They included 105 cases of squamous cell carcinoma (40.5%), 49 cases of mixed metaplastic carcinoma (18.9%), 41 cases of spindle cell carcinoma (15.8%), 27 cases of metaplasia carcinoma secreting matrix (10.4%), 6 cases of metaplastic carcinoma with mesenchymal differentiation (2.3%), 6 cases of myoepithelial carcinoma (2.3%), 3 cases of low-grade adenosquamous carcinoma (1.2%), 1 case of fibromatoid metaplasia carcinoma (0.4%) and 21 cases of unknown (8.1%). MBC were mainly three negative subtypes, which were 204 cases (78.8%), 41 cases (15.8%) luminal subtypes and 14 cases (5.4%) HER2 positive subtypes. There was no significant difference in the distribution of breast cancer subtypes among different histological types of MBC. There were 63 cases (24.3%) in clinical stage I, 171 cases (66.0%) in stage II, 23 cases (8.9%) in stage III and 2 cases (0.8%) in stage IV. 58 patients underwent core needle biopsy, of which only 7 (12.1%) reported histological types consistent with MBC. Among 154 patients with molybdenum target reports, 59 of them (38.3%) had malignant calcifications. The diagnostic coincidence rates of MRI, ultrasound and molybdenum target were 90.0%, 85.1% and 74.7% respectively. 258 cases of MBC received surgical treatment, including 183 cases of total mastectomy (70.9%), 53 cases of breast conserving surgery (20.5%) and 22 cases of quadrant resection (8.5%); 132 patients (51.2%) underwent axillary lymph node dissection and 93 patients (36.0%) underwent sentinel lymph node biopsy. 24 patients (9.3%) received neoadjuvant chemotherapy, of which only 2 (8.3%) achieved pathological complete remission. 56 patients (21.6%) received adjuvant radiotherapy, with a median of 25 times. 167 patients (64.5%) received adjuvant chemotherapy, and anthracycline sequential paclitaxel was the most commonly used regimen. The median follow-up was 31 months. The five-year DFS was 82.0%, and the five-year OS was 89.4%. Through Cox regression analysis, it was found that patients' N stage ($P=0.036$) and receiving anthracycline sequential paclitaxel adjuvant chemotherapy ($P=0.004$) were independent prognostic factors. Conclusion: The histological types of MBC are complex. MRI is of high value in diagnosis. Conventional CNB is difficult to meet the needs of pathological tissue classification. Patients without lymph node metastasis and receiving anthracycline sequential paclitaxel adjuvant chemotherapy are associated with better prognosis. Through multidisciplinary standardized diagnosis and treatment, there is no significant difference between the prognosis of MBC and the common types of breast cancer. Keyword: metaplastic breast cancer; pathological characteristics; imaging; treatment; prognosis.

INTRODUCTION The incidence of breast cancer is on the rise in the younger population, with 23 percent of all breast cancer diagnoses occurring in those under the age of 50. In Canada, screening mammography in women at average risk of breast cancer is recommended after the age of 50. Breast cancer in younger women is biologically more aggressive with greater rates of recurrence and metastatic disease. The sensitivity of mammograms to detect clinical breast abnormalities may be reduced due to increased breast density in this age group, leading to potential delayed diagnosis and poor outcomes. The frequency of false-negative diagnostic mammograms in young women is unknown. The purpose of this study is to describe the outcomes of diagnostic breast imaging in young women undergoing investigations for abnormal clinical breast findings and the frequency of delayed breast cancer diagnosis (more than 6 months after initial diagnostic mammography). **METHODS** We conducted a retrospective electronic chart review in women at average risk of breast cancer, aged between 30 and 50, who underwent diagnostic mammograms and/or breast ultrasounds (US) at our institution between 2018 to 2019 for symptomatic clinical presentations (breast pain, palpable mass, nipple discharge or breast skin changes). Patients undergoing routine screening mammograms were excluded. We collected demographics, findings of initial and follow-up breast imaging (using the Breast Imaging Reporting and Data System (BI-RADS) & breast density), and breast cancer diagnosis timelines where applicable. The primary outcome measure was the frequency of delayed breast cancer diagnosis defined as > 6 months from initial diagnostic imaging. Secondary outcomes included completion of recommended follow-up investigations and their

outcomes, total number of breast cancer diagnoses and stage. The study was approved by the local research ethics board and the results were summarized using descriptive analysis.

RESULTS We reviewed 400 electronic charts and identified 171 eligible patients. Mean age was 38 years; initial breast imaging included both diagnostic mammogram and US in 168 (87%), US alone in 20 (12%) and mammogram alone in 3 (2%) patients. Breast density was not routinely reported during this time frame. Ninety patients (53%) had benign findings (BIRADS 1 and 2), 41 (24%) had probable benign findings requiring short-term follow-up (BIRADS 3) while 30 (18%) patients had findings suspicious of malignancy (BIRADS 4&5) with biopsy recommended for diagnosis. In the BIRADS 3 group, 93% had recommended follow-up at a median of 7.6 months. Breast US alone was the most common subsequent investigation of which 15 % were benign lesions (BIRADS 1 & 2) and 68% remained in the BIRADS 3 category, while none were scored BIRADS 4 or 5. Among patients with BIRADS 4 & 5 scores, 83% underwent recommended biopsy at a median time of 3 weeks. Ten (6%) out of all 171 patients were diagnosed with breast cancer, all of which had BIRADS 4 or 5 on initial diagnostic imaging. Stage distribution was as follows: stage 0 - 2 patients, stage 1- 7 patients and stage 2 - 1 patients with no locally advanced or metastatic disease. The mean time from initial imaging to breast cancer diagnosis was 1.5 weeks (range 1 to 22 weeks). None of the patients had delayed breast cancer diagnosis in our cohort.

CONCLUSION More than half of patients with clinical breast findings in our cohort had benign findings on diagnostic mammogram and/or US (BIRADS 1&2) with no subsequent breast diagnosis. Majority of patients requiring further investigations (BIRADS 0, 3, 4 and 5) underwent recommended follow-up (imaging or biopsy). Ultimately, a total of 10 patients were diagnosed with breast cancer at a median time of 1.5 weeks from original diagnostic imaging with no delayed breast cancer diagnosis. We, therefore, conclude that diagnostic mammograms and US are appropriate diagnostic investigations for clinical breast concerns in women between 30-50 years.

Background: Extracellular vesicles (EVs) can be released by living cells during the process of tumor metastasis. Since EVs could contain various of molecular with high stability, a growing number of evidences indicated that those molecular can be utilized as biomarkers of liquid biopsy for metastatic prediction. Therefore, we aimed to identify genes and build a model that can predict the risk of metastasis in breast cancer patients with acceptable sensitivity and accuracy. Methods: Pretreatment plasma EV-RNAs of patients diagnosed at Fudan University Shanghai Cancer Center from 2017 to 2018 were extracted and analyzed by next generation sequencing (NGS) and bioinformatics, including breast cancer patients (n=114) and benign cases (n=18). Weighted correlation network analysis (WGCNA) was utilized to determine the relationship between clinical features and genes. The Kaplan-Meier was used for survival analysis in public database. By 100 times of 5 folds cross-validation, we used logistic regression analysis to set up the model. The receiver operating characteristic curve (ROC) and area under curve (AUC) were used to assess the predicted capacity of the model. QRT-PCR was conducted to further confirm the expression of genes selected by the predicting model in 175 breast cancer patients with and without metastasis, along with 5 EV-RNAs of tumor samples and paired normal adjacent breast tissues. The functions of candidate genes on cell proliferation, metastasis, and invasion were determined by a series of in vitro experiments in cancer lines. RNA sequencing and bioinformatic analysis were performed to explore the mechanism of the candidate genes. Moreover, co-immunoprecipitation (Co-IP) was used to reveal interacting proteins. Results: WGCNA screened 40 hub genes which were significantly associated with the distant metastasis in patients with breast cancer. A total of 207 upregulated genes were identified in patients with distant metastasis. After intersection, 6 genes were selected. Survival analysis suggested that high expression of IGFBP5, BCL6B, TGM2, and SH3PXD2A were correlated with poor distant metastasis-free survival (DMFS). The metastasis predicting model built based on those genes showed an AUC value of 0.923 with diagnostic accuracy of 91.2%. In the validation cohort, data showed the AUC value of each single gene were 0.835, 0.818, 0.845, 0.834, for TGM2, IGFBP5, BCL6B, and SH3PXD2A respectively. Among those four genes, TGM2 was significantly upregulated with clinical stages and correlated with poor prognosis. Moreover, TGM2 showed the highest abundance in tumor tissue EVs. Functional experiments revealed that TGM2 promoted breast cancer proliferation, metastasis, and invasion in vitro. The initially upregulated expression of TGM2 in EVs of cell lines was significantly decreased by adding the exosome release inhibitor GW4869. In addition, EVs from TGM2 overexpressed cells promoted cell migration and invasion of wild-type cells. Mechanistically, TGM2 was positively correlated with EMT, Hedgehog and IL6-JAK-STAT3

pathways. Co-IP assay found that TGM2 interacted with TMF1, which was an effector for degradation of STAT3 through the ubiquitin-proteasome pathway. Interfering the expression of TMF1 remarkably promoted the migration ability of cells and reversed by TGM2 overexpression. Conclusion: Based on the plasma EV-RNAs, we constructed a model with promising predicted capacity of distant metastasis in patients with breast cancer. TGM2, as the most effective predictor, can promote the progression and metastasis of breast cancer by targeting TMF1/STAT3. Key words Breast Cancer; Extracellular vesicles; Metastasis; Prediction model; TGM2

Background: Breast cancer (BC) is the most common cancer and the second leading cause of cancer death in American women. BC disproportionately affects women of ethnic minorities, especially Black and Hispanic. While this disparity has been acknowledged and social determinations of health remains an important contributor, BC pathophysiology is yet to be elucidated in minorities. MicroRNAs (miRNA), including but not limited to let-7, 125-3p, 192-5p, 451a, play regulatory roles in cancer pathobiology and progression in many cancer types, including but not limited to BC. In our lab, in vitro and in vivo studies on mouse models demonstrated that miR-23b and miR-27b had crucial roles in cancer progression in BC via mechanisms that involves nischarin, an integrin-binding protein, and were associated with worse outcome. Moreover, miRNAs can be detected and are stable in blood samples, and thus the detection has a profound clinical impact on diagnosis. Study Design: Between April 2021 and May 2022, 30 newly diagnosed patients with BC and 30 patients without any cancer diagnosis at University Medical Center- New Orleans were enrolled on the study (IRB# 936). 86% of patients are African American or Hispanics. Plasma samples were collected before any medical intervention for BC. Plasma miRNAs were isolated and miRNA expression were performed utilizing RT-PCR. Results: Expressions of let-7 and 125a miRNAs are two times higher in plasma of patients with BC compared to patients without a diagnosis of cancer. There was no difference in miRNA expression in circulatory 23b, 27b, 192-5p, and 451a. Among breast cancer types, there are two-fold decreased expression of 192-5p and 451a in triple negative compared to hormone positive BC. Conclusion: This project will add to the body of knowledge on roles of miRNAs as prognostic markers in patients with BC, more importantly,

triple negative BC, and elucidate pathophysiologic mechanism contributing to racial disparity in breast cancer treatment and recurrence. In the near future, we aim to examine effects of chemotherapy and surgery on the expression of circulatory microRNAs.

Background: Circulating tumor cells (CTCs) captured from the blood of cancer patients may serve as a non-invasive surrogate source of tumor material to investigate tumor characteristics in real-time. The Parsortix® PC1 System, the first FDA-cleared medical device for the capture and harvest of CTCs from peripheral blood of metastatic breast cancer (MBC) patients for use in subsequent user-validated downstream analyses, enables the epitope independent capture of CTCs with diverse phenotypes based on cell size and deformability. In this study, CTCs isolated from the blood of MBC patients by the Parsortix® PC1 System were identified using an immunofluorescence (IF) based assay for detection of epithelial CTCs followed by Wright-Giemsa staining and cytomorphological review. The aim of this study was to determine the proportion of MBC patients and self-declared female healthy volunteers (HVs) that had one or more CTCs identified in the population of cells harvested from their peripheral blood by the Parsortix® PC1 System. Methods: Peripheral blood from 75 HVs and 77 patients with MBC was prospectively collected into K2EDTA tubes at the University of Rochester Medical Center. The blood collected from each subject (8.6±1.2mL) was processed on a Parsortix® PC1 System within 8 hours of collection. The cells harvested by the system were cytospun onto a charged slide and IF stained using an optimised antibody panel. The IF panel consisted of a nuclear dye (DAPI), positive selection markers targeting epithelial CTCs (Cytokeratins (CK) and EpCAM), and negative selection markers targeting white blood cells, such as lymphocytes, macrophages, granulocytes, monocytes, fibroblasts, and cells of megakaryoblastic potential. The stained slides were imaged using fluorescence microscopy and CTCs were defined as nucleated cells (DAPI+) that were positive for CK and/or EpCAM and negative for the blood lineage markers. The IF slides were subsequently stained with Wright-Giemsa and analysed by a qualified pathologist using light microscopy. Morphological features of malignant cells were used to define and identify CTCs. All laboratory testing and analysis was performed by

operators blinded to the clinical status of each subject. Results: On the evaluable IF-stained slides, cells classified as CTCs based on their IF staining pattern were identified in 45.3% (34/75) of the MBC patients (range = 0 – 125 CTCs, mean = 7) and in 5.6% (4/71) of the HVs (range = 0 – 8 CTCs, mean = 0). No EpCAM+, CK- CTCs were identified in either MBC patients or HVs. In the 34 MBC patients with one or more CTCs observed, 70.6% had only CK+, EpCAM- cells, while the remaining 29.4% had at least one CK+, EpCAM+ cell. In the HVs, one out of the four CTC-positive donors had only CK+, EpCAM+ cells while the other three had only CK+, EpCAM- cells. On the evaluable Wright-Giemsa stained slides, cells classified as CTCs by the pathologist were identified in 57.1% (40/70) of the MBC patients (range = 0 – 41 CTCs, mean = 4) and in 4.4% (3/68) of the HVs (range = 0 – 14, mean = 0). Conclusions: This study demonstrated the ability of ANGLE's Parsortix® PC1 System to capture and harvest CTCs from a significantly larger proportion of MBC patients compared to HV subjects. The presence of epithelial cells in subjects without diagnosed disease has been previously described in the literature, with their significance being unclear. This study also demonstrated that the cells harvested by the Parsortix® PC1 System can be successfully evaluated using both IF staining and Wright-Giemsa cytomorphological assessment for the identification of CTCs. Interestingly, a high proportion of the identified CTCs did not express EpCAM, further highlighting the limitations of using EpCAM-based approaches to capture CTCs.

Introduction: Long QT syndrome is a common cardiotoxic side effect of various anti-tumor drugs. Previous cardiological monitoring of oncological patients is primarily complex and requires for non-internal oncologists a consultation. Therefore, the QTc-Tracker smartphone APP was developed, which enabled a tele-cardiological diagnosis of the QTc time with standard single-lead ECG devices. As a result, diagnosis times could already be reduced by 99%. The further development examined an automatic determination of the QT time using the smartphone APP. However, since single-lead ECG devices are significantly more susceptible to interference, the determination of the QT time is more complex than with 12-lead ECGs.

Methods: The QTc-Tracker smartphone APP was developed to determine the QT time. Self-tracker single-lead ECG devices were used to record the lead I signal. The ECG recordings were analyzed in the APP and passed on to an external cardiologist as reference. The APP used artificial intelligence and was trained in the first phase and validated in the second phase. The first phase aimed to improve QT time detection. The results of the APP were compared with the findings of the external cardiologist. In both phases, ECGs from breast cancer patients receiving ribociclib were used. Results: A total of 1889 single-lead ECGs were carried out. 248 of these could not be evaluated (13%). QTc prolongation, according to CTCAE, was diagnosed

in 41 cases (2.5%). 878 of the evaluable ECGs were used for the training phase and 763 for the evaluation phase. In the first group (before the improvement), the sensitivity to automatically detect a prolongation of the QT time was 36%, and the specificity was 96%. In the evaluation collective (after the training), the sensitivity went up to 85%, and the specificity was unchanged at 96%. Conclusions: The trained method of the QTc tracker is able to reliably detect a QT time lengthening even without a cardiological diagnosis only by using single-lead self-tracker ECG's. In the rare cases in which an elongation was not detected, the cardiac diagnosis was only a few milliseconds above the threshold value. This artificial intelligence-based smartphone APP is not intended to replace the cardiological diagnosis, but it can simplify routine processes and help to decide which patients need a cardiological examination more urgently.

Breast cancer is the most commonly diagnosed cancer among US women across all racial/ethnic groups. Stage at diagnosis is one of the major factors determining breast cancer prognosis. The 5-year relative survival for breast cancer ranges from 99% for localized stage at diagnosis, to 84% for regional stage, and to 27% for distant (metastatic) stage breast cancer. The proportion of women diagnosed with breast cancer at later stages (regional and distant) in the US are higher among women with lower socio-economic status and among non-Hispanic Black women. Historic mortgage security redlining, implemented by the Home Owners' Loan Corporation (HOLC) in the 1930s across numerous US cities, continues to have a negative influence on breast cancer stage at diagnosis, largely due to continued social and economic isolation and poor living environments resulting in many adverse consequences, including lower education, limited job opportunities, no/limited health insurance coverage, and suboptimal access to care, including cancer screening services. Additionally, studies have reported that living in areas with greater contemporary mortgage lending bias towards the non-Hispanic Black population (measured as higher odds of mortgage denial) is associated with late-stage breast cancer diagnosis in several US metropolitan areas.

In this study, we aim to examine the association between the historic HOLC-based “redlining” and contemporary mortgage lending bias and stage of breast cancer at diagnosis among women aged 18 years and older in New Jersey diagnosed with first primary invasive breast cancer in 2010-2015 (N= 32,939). The study population was derived from the New Jersey State Cancer Registry. Historic “redlining” data based on 1930s neighborhood boundaries and transformed to corresponding 2010 census tracts borders were obtained from Inter-university Consortium for Political and Social Research. Mortgage lending bias score for the study period was calculated at the census tract level following methodology developed by Beyers and colleagues. Associations between census tract-level historic “redlining”, contemporary mortgage lending bias and breast cancer stage at diagnosis were evaluated using multinomial logistic regression models after adjusting for age alone, and then for age, race/ethnicity, marital status, and health insurance status.

The study included 21,038 local, 9,765 regional, and 2,136 distant stage breast cancer cases. After adjusting for age, race/ethnicity, marital status, and health insurance, women living in historically redlined census tracts were more likely to be diagnosed with regional (OR=1.23;

95% CI 1.03-1.48) and distant (OR=1.55; 95% CI 1.09-2.22) stage breast cancer compared to women living in other census tracts. Odds for regional (OR=1.14; 95% CI 1.06-1.23) and distant (OR=1.33; 95% CI 1.16-1.53) stage breast cancer were also significantly higher for women living in areas with highest mortgage lending bias score. Stratifying by age (< 65 and >=65 years) showed similar patterns (data not shown).

Both historic “redlining” and contemporary mortgage lending bias were associated with being diagnosed with breast cancer at later stages, notably distant stage. Targeting the legacy of systematic racism and addressing any contemporary discriminatory policies may help reduce breast cancer disparities in the diagnosis stage and thus mortality.

Association between the historic redlining and contemporary mortgage lending bias and stage of breast cancer at diagnosis among women aged ≥18 years in New Jersey, 2010-2015

Introduction: Despite the recent overall improvement in survival for patients with breast cancer, racial disparities in outcomes persist. While studies have demonstrated that socioeconomic factors and access to treatment play a role, differences in tumor biology may also contribute. Black women are significantly more likely to develop triple negative breast cancer (TNBC), the deadliest of the breast cancer subtypes, with more TNBC patients progressing to incurable, metastatic disease than patients with any other breast cancer subtype. Studies have demonstrated that TNBC patients who achieve a pathologic complete response (pCR), defined as no residual invasive cancer in the breast or lymph nodes after neoadjuvant chemotherapy (NAC), have improved survival. We hypothesize that rates of pCR and overall survival (OS) in patients with TNBC may differ by race/ethnicity, which may account in part for the disparities in outcomes observed. **Methods:** Adult female patients with stage I-III TNBC diagnosed in 2010-2019 who received NAC followed by surgery were identified from the National Cancer Database (NCDB). Race/ethnicity was defined as Hispanic (H), Non-Hispanic White (NHW), Non-Hispanic Black (NHB), Non-Hispanic Asian (NHA), and Non-Hispanic Other (NHO). pCR was defined as no invasive cancer in either the breast or axilla (ypT0/is,N0) at surgery. Logistic regression was used to estimate the association of race/ethnicity with achievement of pCR after adjustment for covariates. Unadjusted OS was estimated using the Kaplan-Meier method, and the log-rank test was used to compare groups. Cox Proportional Hazards models were used to estimate the association of race/ethnicity and achievement of pCR with OS after adjustment for covariates. Additional interaction and subgroup analyses were also conducted. **Results:** Of the 40,890 patients identified, 29.8% (n=12,173) demonstrated pCR after NAC. The unadjusted 5-year OS rates for those who achieved pCR were significantly higher compared to patients with no pCR (0.917, 95% CI 0.911-0.923 vs 0.667, 95% CI 0.661-0.673, log-rank $p < 0.001$). Hispanic patients were more likely to achieve pCR (OR 1.19, 95% CI 1.08-1.31, $p=0.001$), and NHB patients were less likely to achieve pCR (OR 0.89, 95% CI 0.83-0.95, $p=0.001$) compared to NHW, even after adjustment. Unadjusted OS was also notably lower for NHB patients compared to every other race group (5-year OS rate: NHB 0.709 vs NHW 0.746 vs NHO 0.771 vs H 0.772 vs NHA 0.816, log-rank $p < 0.001$); however, this difference did not persist after adjustment for patient and disease factors, including achievement of pCR. Interval from diagnosis to start of chemotherapy (OR 0.95, 95% CI 0.94-0.96, $p < 0.001$) and duration after chemotherapy start to surgery (OR 1.02, 95% CI 1.02-1.03, $p < 0.001$) were associated with the odds of achieving pCR. Overall, the effect of achieving pCR on OS did not differ by race/ethnicity (interaction $p=0.10$). **Discussion:** Achieving pCR after NAC in patients with TNBC is associated with a significant improvement in OS. Yet, rates of pCR appear to differ based on race/ethnicity, with NHB patients demonstrating significantly lower rates of pCR than NHW patients, which may contribute to the disparities in survival outcomes observed. In addition to addressing socioeconomic factors and access to treatment, further research examining whether biological differences exist based on race that influence response of TNBC to current standard therapies is essential for improving survival outcomes for this disproportionately affected patient population.

Differences in Breast Cancers among American-Indians and Whites in the United States
Background - The United States has made substantial progress in improving breast cancer (BC) outcomes over the years, but unfortunately, this improvement has not impacted all races equally. BC death rates have not improved significantly for American Indian (AI) women, whereas, it significantly decreased for White women. In addition, AI women were more likely to be diagnosed at a younger age with a late-stage disease. We sought to determine the reasons for these disparities. Methods - This is a retrospective cohort study using a hospital registry database (the National Cancer Data Base) (NCDB). We identified female AIs and non-Hispanic Whites in the US diagnosed with BC between the years 2004 and 2016. We compared patient and tumor characteristics between the 2 groups and its effect on age and stage at diagnosis.

We also determined hazard ratios (HRs) for overall survival using Cox regression models, both before and after adjustment for covariates. Results – Data on 6,866 AIs and 1,987,324 White women diagnosed with BC were analyzed. The mean (SD) age at diagnosis was significantly younger for AI than for White women (57.72 ± 12.23 vs. 61.87 ± 13.21). AI women traveled double the distance to their treatment facilities, lived in lower median income zip codes, reported a higher percentage of no insurance, and higher comorbidities than Whites. Furthermore, AIs were less likely to be diagnosed with Stage 0 and I BCs, had a larger tumor size, greater number of positive lymph nodes at diagnosis, and higher proportion of triple negative and HER2-positive BCs than Whites. Whites were more likely to have other cancers diagnosed prior to or after their BC diagnosis. All the above tests for comparisons were significant (p -value < 0.001). Correlation between patient/tumor characteristics with age and stage at diagnosis was not significantly different between AIs and Whites. Unadjusted overall survival (OS) was significantly worse for AIs as compared to Whites (HR=1.07; 95% CI: 1.01-1.14, p -value = 0.025). After adjustment of all covariates including age, travel distance, median income of residential zip code, insurance status, cancer sequence, comorbidities, stage, tumor size, number of positive lymph nodes, grade, histology, and hormonal/HER2 status, OS was not significantly different between AIs and Whites (HR=1.04; 95% CI: 0.90-1.20, p -value = 0.601). Conclusion - Our study showed significant differences in patient and tumor characteristics among AI and White BC patients which adversely impacted BC outcomes in AIs. Survival was lower in AIs, but when adjusted for various covariates, the survival difference disappeared. Improvement in BC outcomes in AIs will involve not only improved and early access to screening to identify patients at younger ages and earlier stages at diagnosis, but also long term plans to provide affordable and the full spectrum of cancer care closer to home.

BACKGROUND: The impact of treatment delays on cancer outcomes has been well documented, but few published studies explicitly attempt to identify subgroups which would benefit the most from potential interventions improving timeliness of care. Using the state of North Carolina and breast cancer as an example, we sought to quantify race-specific associations between frontline treatment delay and breast cancer mortality, and estimate the potential impact of improvements in timeliness by racial sub-group. **METHODS:** We conducted a retrospective cohort study, utilizing multipayer insurance claims linked to cancer registry data from the Cancer Information and Population Health Resource, of females diagnosed with stage I-III breast cancer from 2004 to 2014. Our exposure of interest was treatment delay, defined as initial cancer directed therapy received ≥ 60 days after diagnosis. Our outcome was death certificate identified breast cancer mortality within 5-years of follow-up. To quantify the association between treatment delay and mortality we estimated hazard ratios (HR) and 95% confidence limits (CL) where non-breast cancer deaths were treated as competing events. We then simulated the effect of treating all patients within 60 days using inverse probability of treatment weighting (IPTW), and estimated the potential impact by comparing the simulated data with observed data. Models were adjusted for age and stage at diagnosis, tumor grade, hormone receptor status, and modality of first treatment. Models were stratified by race, dichotomized as Black or non-Black, and geographic subregion for evaluation. **RESULTS:** Our analytic cohort comprised 21,200 patients, of whom 19% were Black. Treatment delays >60

days were twice as frequent among Black compared with non-Black patients (13.5% vs. 6.5%). We found a positive association between treatment delay and breast cancer mortality in the overall cohort (HR=1.3; CL: 1.1, 1.6). The association differed between Black (HR=1.4; CL: 1.1, 1.8) and Non-Black (HR=1.2; CL: 0.9, 1.6) patient subgroups. For both racial groups, the strength of the relationship between treatment delay and mortality varied across geographic subregions. The estimated potential improvement in 5-year cumulative breast cancer mortality from delivering timely care to all patients differed in magnitude across sub-populations. The magnitude of potential improvement in breast cancer mortality at 5 years in the overall analytic cohort was 0.3% (5-year risk of breast cancer mortality in observed cohort: 7.2% vs 6.9% with simulated universal timely treatment). In the Black subcohort, the potential decrease in mortality for timely treatment was 1.0% (observed: 12.3% vs simulated: 11.4%), while in the non-Black population the potential decrease was 0.1% (observed: 6.1% vs simulated: 5.9%).

CONCLUSIONS: The magnitude of association between delayed treatment of stage I-III breast cancer and breast cancer mortality differed between Black and non-Black patients, highlighting that interventions to avert treatment delays may have a meaningful impact for this group.

Further research is needed to identify factors underlying this difference, which may include a direct effect of differences in timeliness, or downstream differences in the intensity and quality of cancer care beyond the 60-day landmark for delayed patients. Our findings suggest that comprehensive intervention at the state level to improve the timeliness of breast cancer treatment could potentially reduce breast cancer mortality, and that targeting such intervention to patient groups with larger projected benefit, such as Black patients, may be a more efficient use of resources. We have illustrated how a counterfactual approach may be useful in identifying subgroups where focused intervention efforts may yield greater improvements in outcomes.

Background:

Hispanics are among the most significant minorities in the United States, and assessing their health needs is vital in formulating health policies. The social, environmental, and biological background affect their morbidity and mortality, with cancer being the leading cause of mortality in Hispanics. Although implementing the Affordable Care Act improved access to health care, disparities and challenges in Hispanics' access to health care remain.(1)

In our study, we are trying to assess the COVID-19 pandemic implications on the socioeconomic status of Hispanics with newly diagnosed breast cancer and how that is affecting their outcome.

Methods:

This is a retrospective study demonstrating the nature of breast cancer screening, diagnosis, and management during COVID-19 lockdown and post-vaccine compared to the pre-COVID-19 era. The retrospective review was conducted at Mays Cancer Center in San Antonio, IRB approved by UT Health San Antonio. The data were abstracted from the medical record system (EPIC). Pearson's Chi-squared and logistic regression tests were used to determine the relationship between time and stage at diagnosis and association with funding status

Result:

696 subjects with newly diagnosed breast cancer were identified and divided into three cohorts: Cohort A: 264 pts in a pre-covid era: From 2018-February 2020, Cohort B: 171 patients during the covid-19 lockdown, and Cohort C: from April 2020-Dec-2020 with 261 patients in the post-vaccine era.

A higher percentage of patients had Tis identified in Cohort A (26%) compared to Cohort B (19%) and Cohort C(12%) (p0.003). These numbers have changed to an increasing percentage of patients with T1 or T2. N0 or N1 in Cohort B (62%) and Cohort C (68%), p0.003).

Presentation of locally advanced (T3/T4 with any N) and metastatic disease remained relatively similar in all cohorts, with more metastatic cases at presentation in Cohort A (p0.003). Many patients of Hispanic ethnicity (OR 1.47, p0.1) were not funded by commercial insurance or Medicare. (OR 2.33, 95% CI 1.43, 3.77, p< 0.001). A high proportion of Hispanic ethnicity in post covid era (cohort B and C) OR 1.78, 95% CI (1.16,2.79) (p0.009) required neoadjuvant chemotherapy suggesting more advanced and possibly aggressive cancer histology. We observed that unfunded patients are less likely to have hormonal receptor-positive breast cancer (p0.001).

Conclusion:

Population health is likely affected by socioeconomic status, which eventually affects their health care. In a minority Hispanic population, low average income and educational attainment are likely the obstacles to getting timely appropriate health.(2)

A higher proportion of Hispanic patients were not insured when compared to non-Hispanics leading possibly to more advanced and aggressive histologies at presentation.

Breast cancer (BC) has the highest incidence and mortality rates among Puerto Rican women. However, the representation of Hispanics living in Puerto Rico (PRH) in breast cancer clinical trials may be limited due to the lack of a defined genetic profile from BC tumors in Puerto Rican patients. Mutations in genes associated with tumor suppressors, tumor progression, and genome stability are shared among all BCs. Nonetheless, differences in the frequency of these mutations have been observed among racial/ethnic groups. This study aims to characterize the genomic landscape of BC tumors in PRH and identify the most common genetic mutations. We conducted secondary data analysis to evaluate the mutational profile of 189 BC tumors from PRH who underwent NGS testing from 2015 to 2020 and compared the prevalence of breast tumor somatic mutations and gene amplifications with profiles reported for other races/ethnicities available through The Cancer Genome Atlas (TCGA) and the AACR Genomics Evidence Neoplasia Information Exchange (GENIE). The most mutated genes among PRH breast tumors were TP53, PIK3CA, ARID1A, NF1, and RB1, while the most frequent gene amplifications were FGF19, H3F3B, ZN703, MCL1, and ADGRA2. H1047R and E545K were the most frequent specific mutations in PRH for PIK3CA; R248Q and R273C for TP53 and Q1212*, S634* and Q557fs for ARID1A. Statistically significant differences were found between populations. This study reports a unique mutational profile of BC tumors in PRH and makes comparisons with non-Hispanic and USH populations, providing novel knowledge to increase Hispanic representation in future BC studies and treatments.

Background: Neoadjuvant treatment allows to better distinguish responders from non-responders, and to tailor post-neoadjuvant treatment according to tumor response in patients with HER2+ and triple-negative early breast cancer. For HR+/HER2- tumors, the pathologic complete response is less likely to occur, and residual disease is predictive of inferior recurrence-free or overall survival. Therefore, Ki-67 index, a prognostic biomarker in early breast cancer, is often used in clinical trials as an endpoint for evaluating response to neoadjuvant endocrine therapy (NET). In this systematic review and meta-analysis, we aim to assess if Ki-67 level after NET is associated with disease recurrence and/or survival. Methods: We conducted a systematic literature search of PubMed, Embase, CENTRAL, and conference proceedings (ASCO and ESMO annual meetings, ESMO Breast, and SABCS) up to June 28, 2022, to identify clinical trials or observational studies reporting Ki-67 index after NET in patients with HR+/HER2- early breast cancer treated with NET (PROSPERO number CRD42021282338). We excluded studies in which all patients received neoadjuvant chemotherapy, or from which separate data from patients receiving only NET was not retrieved.

Here we report data from studies screened for the availability of the primary endpoint - recurrence-free survival (RFS), and the secondary endpoint - overall survival (OS), comparing patients with low Ki-67 versus high Ki-67 index after NET, as defined per each study. We performed a sensitivity analysis of the studies measuring the post-NET Ki-67 index in a pre-planned core biopsy. We used the Higgins I2 index to evaluate the heterogeneity between included studies, which did not reach statistical significance. Therefore, we used a fixed effects model to combine RFS and OS hazard ratios (HR) with 95% confidence intervals (CI). Results: We included 11 studies reporting data from 4,231 patients: nine clinical trials (n=3,926), one pooled analysis of two clinical trials (n=217), and one retrospective cohort study (n=88). Nine studies included only post-menopausal women (n=4,069), one included both post- and premenopausal women (n=88), and one included only premenopausal women (n=74). NET was aromatase inhibitor (AI) in four studies (n=3,359), tamoxifen or AI in four (n=465), tamoxifen in two (n=190), and one study with AI or fulvestrant (n=217). There were no studies with targeted agents combined with NET. No study restricted the use of adjuvant chemotherapy in high-risk patients. Three studies evaluated post-NET Ki-67 in a pre-planned core biopsy after a window of treatment of two to four weeks (n=3,348), while the other eight evaluated KI67 in the surgery specimen (n=883). The timing of post-NET evaluation ranged from 2 to 24 weeks. The median follow-up for RFS ranged between 37 and 95 months, and between 62 to 84 months for OS. We found a statistically significant association of adverse RFS (HR 2.43, 95% CI 1.99-2.98) and OS (2.66, 95% CI 1.65-4.28) with higher Ki-67 after NET. The sensitivity analysis of the three studies evaluating post-NET Ki-67 in a pre-planned core biopsy showed the same association with RFS (HR 2.41, 95% CI 1.77-3.30). These three studies did not report OS data. Conclusion: Our data reinforce the role of Ki-67 index after NET as a valuable biomarker of response or resistance to endocrine therapy in women with HR+/HER2- early breast cancer. Despite the use of adjuvant chemotherapy in most of the high-risk patients included in this analysis, the reduction of Ki-67 after NET is strongly associated with survival outcomes (RFS/OS), even after a short course of two to four weeks NET. Ki-67 index post-NET might be a useful tool to help tailoring the use of adjuvant chemotherapy in HR+/HER2-negative breast cancer patients, particularly in low-resource settings where the access to genomic assays is limited.

PURPOSE To examine incremental values of estrogen receptor (ER) status, body mass index (BMI), menopausal status, and a previously reported multi-gene classifier over commonly used clinical factors (i.e. age, tumor grade, comedonecrosis, surgical margins, and treatment) in predicting risk of any ipsilateral recurrence (IR) event within five years after DCIS diagnosis.

METHODS A derivation cohort consisted of participants in the Translational Breast Cancer Research Consortium (TBCRC) 038, a retrospective multicenter cohort study in women undergoing surgical resection for DCIS between 01/01/1998 and 02/29/2016 (n=216). The validation cohort, the Repository of Archival Human Breast Tissue (RAHBT) at Washington University School of Medicine, provided cases meeting the same eligibility criteria as TBCRC038 (n=97). Participants in both cohorts had RNA-seq data and either developed IR 1-5y after initial DCIS diagnosis or were free from subsequent breast events for at least five years. The previously reported 812-gene classifier had been developed from a subset of the TBCRC038 samples using a negative-binomial regression model to identify differentially expressed genes in the primary tumor associated with subsequent recurrence events. This classifier has been shown to be highly correlated with 5-year invasive, DCIS, and all breast cancer events, and validated in the RAHBT cohort. Cox proportional hazards regression was used to estimate hazard ratios (HRs) of IR in the TBCRC038 cohort (76 with IR). The clinical score was developed using clinical predictors (aforementioned clinical factors and ER) and their regression coefficients from the model with the maximum predictive accuracy (e.g. c-index) and the minimum number of predictors; the summary score integrated the clinical score and multi-gene classifier. Predictive performance of both clinical and summary scores was validated in the RAHBT cohort (20 with IR).

RESULTS In the TBCRC cohort derivation set, we used a multivariable model based on clinical factors alone (clinical score) and found that ER status, but not BMI or menopausal status, was independently associated with a higher IR risk (HR=2.06, 95% CI 1.18-3.58). Adding the multi-gene classifier to the clinical factors-based model (summary score) in the TBCRC038 test set increased predictive accuracy (c-index 0.68 to 0.70), with the genomic classifier-adjusted HR of 14.96 (95% CI 8.64-25.91). The summary score had higher predictive performance for IR risk than clinical score alone (c-index 0.82 vs. 0.70). In the RAHBT validation samples, model performance was similarly improved using summary scores clinical factors-based model plus multigene classifier as compared to clinical scores alone (c-index 0.74 vs. 0.58).

CONCLUSION Combining clinical factors and a multigene classifier provided more accurate risk estimates of IR within five years after excision of DCIS than clinical factors alone.

Figure 1. Observed and predicted recurrence-free survival in the first five years after initial DCIS diagnosis in the RAHBT validation cohort, by risk groups defined by clinical scores (left) and clinical score plus multigene classifier (right).

Background: Several Breast Cancer Multigene Signatures (BCMS) are available to profile early breast cancer (eBC) that according to current evidence, can provide reliable information on the risk of recurrence. However, knowledge regarding their perceived value and use in clinical practice is scarce. The first results regarding the panelists' opinions on the clinical utility of BCMS were presented at SABCS Symposium 2021 (Poster P4-06-08). Here we discuss present and future recommendations for improving the use of BCMS resulting from the PROCURE Project. Methods: The Delphi survey developed by the 8 members of the Scientific Committee was administered twice to oncologists, pathologists, and surgeons across Europe. The questionnaire included 5 sections: 1) Participants' profile and experience with BCMS, 2) Current clinical practice in eBC and use of BCMS, 3) Participants' opinion on the utility of the BCMS in eBC according to patient profiles, 4) Agreement with a set of recommendations on the use of BCMS in clinical practice and 5) Identification of unmet needs and future applications of

BCMS. 70% agreement was used to determine consensus on a topic. Results: 133 panelists from 11 European countries completed both rounds of the survey. Experts were mostly medical oncologists (72.2%) with extensive experience (more than 5 years) in the management of BC patients (97.0%) and in the use of BCMS (73.4%). Most of them worked in university hospitals (86.5%). Regarding recommendations for improving BCMS utility, according to panelists' opinion, these genomic tests should provide prognostic as well as predictive information (82.0%), especially to help physicians when deciding on the most appropriate adjuvant chemotherapy (81.2%). Also, their evidence should be based mostly on prospective randomized clinical trials (85.0%) and they should evaluate the clinical and pathological features of the disease (91.0%). Another aspect agreed by panelists is that patients should have the right to access their BCMS results to take part in treatment decisions (85.7%). Finally, when thinking about future applications of BCMS, consensus was only reached after the second Delphi round, and according to panelists, there is a need for validating BCMS in order to know if they can predict treatment benefits in patients with ER-positive advanced/metastatic BC (78.2%) and in triple-negative eBC patients (72.2%). Likewise, panelists also agreed on the need of developing newly validated tests to evaluate the risk of distant recurrence and predict treatment benefits in the neoadjuvant setting (71.4% and 81.2%, respectively). However, no consensus was reached on the need for BCMS to give an accurate prognosis for patients with ER+ advanced and/or metastatic BC (50.4%), HER2+ advanced BC (21.8%), or triple-negative advanced BC (36.8%). Conclusions: The panelists who participated in the PROCURE Project had an extensive experience in the management of eBC patients as well as using BCMS; however, the high degree of importance that they attributed to both prognostic and predictive information reflects a misconception on the correct interpretation of BCMS results because, even if those test can be used to predict the benefit of adjuvant chemotherapy, they are primarily prognostic tools but not predictive about the effect of a specific cytotoxic intervention. These results in conjunction with the agreements regarding treatment benefit prediction reached in the neoadjuvant, the triple-negative eBC, and the metastatic settings reinforce the idea that more training is needed to highlight that BCMS should be used in the context of risk assessment in intermediate-risk eBC as well as the possibility of running those tests in core biopsies.

Introduction: Comorbid conditions can significantly impact various aspects of cancer care and therefore are often utilized as covariates to control for selection bias in observational studies. Oncology based electronic health record (EHR) data is often used as a source for comorbidity information but may be subject to missingness due to differences in clinician documentation. Utilizing additional data sources, such as health care claims data, may allow for greater capture of comorbidities. This study used a claims data linked to oncology EHR to identify comorbidities and related patient characteristics, as well as the association between a claims-derived comorbidity index and real-world overall survival (rwOS) among outpatient metastatic breast cancer (mBC) patients, to characterize the comorbidities data from this data source. Methods: We selected patients diagnosed with mBC between 2013 and 2021 from a linkage of mBC de-identified EHR-derived Flatiron Health Research Database (FHRD) and Komodo Health claims data. Charlson Comorbidity Index (CCI) were identified based on the presence of a pre-specified International Classification of Diseases (ICD) codes within 12 months preceding cancer diagnosis. To understand comorbidity data within this linkage, patient characteristics were assessed after the study cohort was stratified by the presence of any comorbidity assessed as part of CCI. We calculated the CCI for the study cohort as well as the prevalence of comorbid conditions that are used as part of the CCI. Kaplan-Meier estimates and Cox proportional hazards model were used to estimate median survival time and hazard ratios (HRs) of rwOS among patients with a CCI score of 1 and 2+. Results: The study cohort had 3,213 patients with a median age of 63 [IQR(52, 76)] and 98.7% were female. White patients accounted for 60.1% of the study population while Black and Hispanic/Latino patients accounted for 12.5% and 7.4% of the study cohort, respectively. Patients with comorbidities were older (mean age of 65 vs 61), had a higher (2+) ECOG performance status (PS) score (14.0% vs 9.7%), and were more likely to be Black (16.0% vs 11.0%) or Hispanic/Latino 10.8% vs 6.3%). Twenty percent of the patients had diabetes, 8.2% had peripheral vascular disease, 7.5% had mild liver disease, and 6.3% had congestive heart failure. According to index values,

21.0% of the study cohort had a CCI score of 1, and 18.0% had a score of 2 and above. The median survival times in years for patients with a CCI score of 1 and 2+ were 2.51 [95% CI 2.29,2.81] and 2.05 [95% CI 1.83,2.42], respectively. Based on univariate analysis, patients with a CCI score greater than zero had a higher risk of mortality (CCI 1: HR = 1.25 [95%CI 1.10, 1.41, p< 0.01], CCI 2+: HR = 1.54 [95%CI 1.35, 1.76, p< 0.01]). In the multivariate analysis, adjusted for age, ethnicity/race, and baseline ECOG PS score, the HR for the CCI 1 group was not statistically significant (HR=1.12 [95%CI 0.99, 1.27, p=0.08]). However, the risk of mortality was statistically significant for the CCI 2+ group (HR=1.31 [95%CI 1.14, 1.50], p < 0.01) in the adjusted analysis. Conclusion: Claims data linked to EHR can be used to identify comorbidities and describe patient characteristics. As anticipated, generally, the presence of more comorbid conditions was associated with worse rWOS for patients with mBC. This finding supports use of this linked dataset for similar future studies.

Background The 21-gene Recurrence Score (RS) (Oncotype DX®) is one of the most frequently used multigene assays to predict prognosis and response to treatment for estrogen receptor-positive breast cancer. Although the result of two prospective randomized trials, TAILORx and RxPONDER trial have increasingly established the clinical utility of Oncotype DX®, the cost and testing period are disadvantages especially in Asian countries. To overcome these disadvantages, we developed a new multi-gene assay using Loop-Mediated Isothermal Amplification (LAMP) . We have previously selected a twenty-five genes set through comprehensive gene expression analysis of breast cancer samples from more than 500 cases (patent pending). Although these twenty-five genes are different from those used in conventional assays, their physiological functions are similar to those of Oncotype DX®, and it

is expected that the results will be equivalent to Oncotype DX® as a predictor of prognosis and chemotherapeutic efficacy. This new assay can be performed in own institution, and the result can be obtained less than one hour. It can lead to significantly reduce costs and testing time compared to conventional assays. Based on these backgrounds, we constructed the prediction algorithm based on the new gene expression profiles using LAMP and evaluated its performance in this study. Methods Total RNA was extracted using Maxwell® RSC RNA FFPE Kit (Promega) from FFPE tumor samples of postoperative breast cancer tissue which Oncotype DX® have already tested in our institution between January 2009 to January 2021 and was quantified by Reverse-transcription LAMP enabling one-step reaction from reverse transcription to amplification under isothermal condition (63°C). Samples were divided into three groups, low-RS (RS 0-10), RS-intermediate (RS 11-25) and RS-high (RS ≥26) based on Oncotype DX®-RS. Using the obtained mRNA amplification detection time as an explanatory variable and Oncotype DX®-RS as an objective variable, a prediction algorithm based on expression profiles based on LAMP method was constructed and evaluated its performance with 4-fold cross-validation. The prediction algorithm was trained using extreme gradient boosting (XGBoost) algorithm that parameters used default of R package "xgboost". We also performed the quality analysis of mRNA excluded from this analysis due to poor mRNA quality. The percentage of mRNA above 200nt (DV200) was calculated by electrophoresis, and the correlation between the degree of mRNA degradation and the number of years of storage was calculated. Results Of the 221 cases which have tested Oncotype DX® during the study period, 90 samples were used in the analysis, and the remaining samples were excluded from this study due to poor mRNA quality. Of the 90 samples, 19 cases were RS-low, 42 cases were RS-intermediate, and 30 cases were RS-high, respectively. The correlation coefficient between Oncotype DX®-RS and our LAMP method-based predicted RS was $r=0.911$ (95%CI 0.900–0.921, p -value < 0.001). The overall concordance rate with the predicted risk of recurrence (high/intermediated/low-RS) was 0.9343 (95%CI: 0.9174-0.9486, p -value < 0.001). Regarding the quality analysis of mRNA excluded from this analysis, we found the inverse correlation between the degree of mRNA degradation and the storage periods, namely higher DV200 with shorter periods. In particular, there was less mRNA degradation in specimens that had been stored for less than one year. Conclusion Our new gene expression profiling by the LAMP method suggested to have same discriminately ability with Oncotype DX® to predict the risk of recurrence in early breast cancer patients. The duration of mRNA storage and the fixation time in the FFPE preparation process are suggested to be important for maintaining the quality of mRNA. We are planning to further studies with increase sample size and analyze the correlation with prognosis.

Background: BRCA is the most common malignant tumour, and its heterogeneity is one of its major characteristics. m6A, m1A, APA, and A-to-I RNA editing constitute the four most common adenosine-associated RNA modifications and represent the most typical and critical forms of epigenetic regulation contributing to the immunoinflammatory response, tumorigenesis and tumour heterogeneity. However, the cross-talk and potential combined profiles of these RMPs in multivariate prognostic patterns of BRCA remain unknown. Methods: A total of 48 published RMPs were analysed and found to display significant expression alterations and genomic mutation rates between tumour and normal tissues in the TCGA-BRCA cohort. Data from 4188 BRCA patients with clinical outcomes were downloaded from the GEO, METABRIC and TCGA databases, normalized and merged into one cohort. The prognostic value and interconnections of these RMPs were also studied. The four PRGs with the greatest prognostic value were then selected to construct diverse RMP-associated prognostic models through uniCox, differential expression analysis, LASSO regression and multiCox. Alterations in biological functional pathways, genomic mutations, immune infiltrations, RNAss scores and drug sensitivities among different models, as well as their prognostic value, were then explored. Results: Utilizing a large number of samples and a comprehensive set of genes contributing to adenosine-associated RNA modification, our study revealed the joint potential bio-functions and underlying features of these diverse RMPs and provided effective models (PRG clusters, gene clusters and the risk model) for predicting the clinical outcomes of BRCA. The individuals with higher risk scores showed poor prognoses, cell cycle function enrichment, upregulation of stemness scores, higher TMBs, immune activation and specific drug resistance. This work highlights the significance of comprehensively examining post-transcriptional RNA modification genes.

Conclusions: Here, we designed and verified an advanced forecasting model to reveal the underlying links between BRCA and RMPs and precisely predict the clinical outcomes of multivariate prognostic patterns for individuals.

Background The duration of adjuvant endocrine therapy remains a continuous challenge in hormone-receptor positive (HR+) early breast cancer. The Clinical Treatment Score post-five years (CTS5) is an online model used to predict late distant metastasis for women with HR+ breast cancer who are recurrence-free 5 years after endocrine therapy (ET). It incorporates patients age, tumor size, grade, and number of positive lymph nodes, and is an important tool to help in this treatment decision. There is a paucity of data in premenopausal women and whether other variables could add additional information. **Methods** A single-center retrospective analysis of patients that have received adjuvant ET for 5 years, between January 2007 and December 2008 at the Instituto Nacional de Cancer (INCA), Brazil. Disease-Free Survival (DFS) was compared between the low, intermediate, and high-risk subgroups. Data analysis was descriptive and exploratory. Kaplan-Meier estimates and Cox regression models were used. **Results** A total of 183 patients were enrolled, 26.5% being premenopausal. Median age at diagnosis was 66 years. Tumor stage: I (44%) and II (56%). ET consisted of tamoxifen (88%), anastrozol (6%), and a switch (6%). There were 39.5%, 39.5% and 21% of patients in the low, intermediate, and high-risk (L/I/H) subgroups, respectively. Progesterone-receptor was $\geq 20\%$ in 71% of tumors and in 55%, 49% and 34% in the L/I/H subgroups, respectively. Median follow up was 88.9 months. After 5 years, the median DFS was 100%, 96.3% and 68.2% in L/I/H subgroups ($p < 0,001$). Progesterone-receptor was also an independent prognostic factor for late recurrence ($p < 0,05$). **Conclusion** CTS5 performed well in a wider patient population including premenopausal women. Progesterone-receptor was an independent prognostic factor for DFS and should be further considered into the model.

Background: Recent data suggest that HER2-low breast cancer (BC) may represent a distinct entity. Approximately 55-60% of BC are considered as Her2-low, of which 80% are Luminal-like tumors. Recent studies support potential clinic-pathological and molecular features differences between Estrogen Receptor (ER) positive HER2-low and ER positive Her2-0 disease. Among patients (pts) with high genomic risk (Oncotype DX RS) HER2-low expression was associated with a significant improvement in overall survival compared to Her2-0. The objective of our study is to compare disease characteristics and outcomes between HER2-low and Her2-0 in estrogen receptor (ER) positive, early (e) BC. (Murtai R et al. *The Breast*. 60(2021)62-69.

Methods: A single center retrospective study of all pts. with ER positive, Her2 negative eBC, for whom Oncotype DX test was performed between 1/Nov/2012 and 14/Febr/2019. The pts were separated into HER2-low (immunohistochemistry (IHC) +1 or + 2 and in situ hybridization not

amplified) or HER2-0. Clinic-pathological features included were: demographics, tumour size, nodal status, histologic grade, Her2 expression, ER and progesterone receptor (PR), Ki-67, presence of lymph-vascular (LV1) tumor cell invasion and Oncotype recurrence score (RS) result.

Results: A total of 344 pts were screened, of whom 297 pts were included (Exclusion for: Her2 “negative” expression (45 pts); HER2 positive disease by IHC (1 pts); metastatic disease (1 pts)). The distribution of HER2-0 and HER2-low subgroups was 121 pts (41%) and 176 pts (59%). The pathological characteristics according to Her2 expression status are summarized in Table 1.

Median age was 57 year (38-79), similar between both groups: Her2-0 58 yr (41-78) and 56 yr (38-79) in Her2 low.

The postmenopausal status was 76 pts (62,8%) Her2-0 Vs 113 pts (64,2%) in Her2 low. 1 pts was male.

Proliferation Index: Ki67% < 20 was: 65 pts (53,7%) Her2-0 Vs 86 pts (48,5%) in Her2 low; 65 pts (13,5%) had Lympho-vascular invasion in Her2 low; 115 pts (95%) were ER positive in Her2-0 Vs 157 pts (89,2%) in Her2 low; PR positive > 20 was 106 pts (87,6%) in Her2-0 Vs 137 (78,7%) in Her2 Low. The median follow-up was 72 month (SD+- 22,52).

5 pts had a recurrence: 4 pts were Her2 low (1 local and 3 distant metastasis) and 1 Her2-0 with distant metastasis. Most of the pts received adjuvant hormone therapy.

There were no statistically significant differences between both groups owing to neither the clinic-pathologic features nor the recurrence score. It was not reached the minimum number of events for a survival analysis.

Conclusions: Our results show that HER2-low eBC pts have similar characteristics and survival rates compared to HER2-0 BC pts without significant differences.

Table 1. Baseline pathological characteristics.

Characteristics	HER2-0 (n= 121)	HER2-Low (n=176)
Tumor Size n (%)

Background: Despite improved outcomes for patients with metastatic breast cancer (MBC), attributed in part to advancements in precision therapeutics, clinical trial enrollment and genomic testing are relatively underutilized in the community oncology setting. To address this need, we launched a virtual molecular and precision medicine (vMAP) clinic to improve access for patients in our community network. Here we describe the initial results from the virtual clinic initiative. **Methods:** In 2020, the vMAP clinic was launched to provide real-time access to precision medicine expertise through virtual, email-based consultation directed to a multidisciplinary team. As part of the service, providers contacted vMAP regarding patients with MBC at the time of initial presentation or disease progression. Upon receipt, the vMAP team (including breast medical oncologists, a breast oncology research nurse, a research assistant, and ad hoc consultation from cancer genetics and molecular pathology representatives) engaged in discussion to identify potential clinical trials with slot availability or standard of care (SOC) options and provided recommendations to the referring provider within 72 hours. Relevant patient data and vMAP referral outcomes were recorded. Providers across the community network were surveyed at project onset and after seventeen months. **Results:** In its first 14-month period (June 2020-July 2021), 47 cases from 16 providers across seven community oncology sites and one academic site were referred to vMAP. A majority (88.6%) of patients had undergone somatic genomic testing (tissue-based, plasma-based, or both) to inform treatment guidance. All cases were screened for available clinical trials as well as SOC options at the time of referral. The average response time to the referring provider with a finalized recommendation was 1.77 days (range 0-5). Forty cases (85.1%) had clinical trial options identified on vMAP pre-screen. Subsequently, 22 patients (46.8%) screened for vMAP recommended clinical trials with 18 (38.3%) initiating enrollment. Of the remaining patients that did not pursue clinical trial screening, 17 (36.2%) started vMAP-recommended SOC treatment, five (10.6%) pursued a different treatment, one (2.1%) was not a candidate for further treatment, and two (4.3%) opted to receive care at a non-affiliated institution, and subsequent treatment information was not available. Reasons that patients did not enroll on trials included trial ineligibility, formal clinical trial screening failure, and patient/provider preference. At project onset, network provider survey results confirmed a previously suggested demand for improvements in processes surrounding genomic testing interpretation and clinical trial enrollment. Post-referral survey results indicated vMAP recommendations and pre-screenings improved the processes surrounding interpretation of genomic testing and clinical trial screening and enrollment, with high rates of referring provider satisfaction. **Conclusion:** A precision medicine virtual clinic demonstrated an efficient and flexible means to offer real-time interpretation of genomic and molecular test results and identification of appropriate treatment options, including clinical trials when applicable, for patients with MBC. The service highlights an example of an academic-community collaboration model to expand precision medicine and clinical trial access for patients with metastatic breast cancer.

Implementation of Integrative Medicine Program for Breast Medical Oncology Professionals in an Academic Cancer Center

Presenting Author(s) and Co-Author(s):

W. Iris Zhi, MD, *Regional Care Network Site Director, MSK Commack - Memorial Sloan Kettering Cancer Center*

Country: United States

Rui Wanq, MD, *Assistant Attending - Memorial Sloan Kettering Cancer Center*

Country: United States

Ting Bao, MD, *Director, Integrative Breast Oncology - Memorial Sloan Kettering Cancer Center*

Country: United States

BACKGROUND: Integrative medicine such as acupuncture, meditation, yoga and massage are highly desired by breast cancer survivors. Breast medical oncology professionals including physicians, advanced nurse practitioners and physician assistants are often the first clinicians that patients would expect to discuss the use of integrative medicine. Many distressing symptoms, such as hot flashes, insomnia, anxiety, and pain, are common and remain challenging to manage with limited pharmacological intervention available and potential toxicities. Evidence-based integrative medicine approaches, including acupuncture, meditation, yoga, and massage, may help reduce this symptom burden and improve quality of life. However, many breast medical oncology professions are not familiar with current evidence and knowledge in integrative medicine. Therefore, there is an urgent need to educate them on the fundamentals of evidence-based integrative medicine interventions that could improve quality of life for breast cancer survivors. **METHODS:** We designed the Integrative Oncology training Program for breast medicine professionals at our institution. The program faculty are composed of five breast medical oncologists, five integrative medicine faculty, and one education coordinator. **RESULTS:** We developed an online, interdisciplinary five-hour course on evidence-based integrative oncology with essential knowledge on integrative medicine approaches for breast cancer survivors. We determined the topic of interest based on feedback from the program faculty. The integrative medicine approaches in management of hot flashes, arthralgia, insomnia, and cannabis uses are some examples that were highly in-demand. The program summarizes high-quality evidence in herbal supplements, acupuncture, meditation, and yoga, pertinent to the audience, as well as the referral flow to our Integrative Medicine Service. **CONCLUSIONS:** Integrative medicine education programs for oncological professionals are needed to disseminate integrative medicine knowledge and to prepare them to guide our patients on integrative and complementary approaches during and after anticancer treatments.

INTRODUCTION Radiotherapy is an area of medicine that is little known by patients and that requires a long time for the doctor to be able to explain and resolve the doubts that arise in the first consultation, which may cause anxiety and low adherence to treatment recommendations. A mobile app called Canswer was developed to address this problem in a novel way to help patients learn about radiation oncology in their free time. **OBJECTIVE** Developed a mobile app that provides oncology radiotherapy information to patients. **MATERIAL AND METHODS** The patients who attended the consultation for the first time were provided with information and obtained verbal consent, later they were provided with the Canswer application on their mobile device, and at the end, a Likert-type perception survey was applied and the Cancer Treatment Survey (CATS), which analyzed the information needs of patients. Anxiety and depression were analyzed through the Hospital Anxiety and Depression Scale (HADS). **RESULTS** Of the total number of patients recruited, 17 patients from northeast Mexico with breast cancer agreed that the use of the application would be useful to them and were interested in receiving additional information after their first-time radiotherapy consultation from March to June 2022. Average age of respondents was 45 years. A total of 7 patients (41%) had doubts about radiotherapy after consultation. When analyzing their knowledge, only 1 patient identified that radiotherapy works by DNA damage, the rest had wrong information, 14 patients thought that this treatment works by heating the cells; 2 thought that radiation therapy causes cells to burst. 8 patients (47%) understood how teletherapy works and 5 how brachytherapy works (19%). A question was included about the best skin care during breast radiotherapy in which 76% correctly answered that the skin should be washed daily with water and neutral soap, but 24% answered that hydrating creams should be applied just before stepping into the machine. Regarding the duration of the consultation, a total of 10 patients (60%) thought it was too short. 47% felt the limited time of the consultation did not allow an adequate evaluation. 100% of the respondents were satisfied with the information provided about the type of treatment, its benefits, and adverse effects, however, 47% persisted with doubts at the end of the consultation. 47% of patients (n=8) had some level of anxiety with 29% mild, 11% moderate and 6% severe. Incidence of depression was 24% with 18% having mild form and 6% severe. Regarding the information provided by the doctor during the consultation, 8 patients (47%) would like their doctor to have told them more about anxiety and depression, 7 about sexuality concerns (41%), and 6 (35%) about alternative medicine. 79% of patients wanted to know more about the side effects the treatment might cause after their visit, and 71% reported wanting to know more about how to prevent side effects. 66% also reported that they would like more information about how the treatment feels when it begins. **DISCUSSION AND CONCLUSION** This analysis revealed that most patients have doubts about radiotherapy, even after the information provided in their first consultation. This may be multifactorial but a key factor may be work overload at radiotherapy centers and a consultation of short duration. This application seems to be an effective, easily accessible, free tool that provides the necessary information, even on topics that are difficult to explain in a standard consultation. Important aspects that the app needs to focus on in future updates include side effects and their management, sexuality, nutrition, depression, and alternative medicine. This application also revealed misconceptions that should be routinely addressed, such as skin care during treatment. Link to app: https://www.canswer.info/?page_id=393

State: New Jersey

Country: United States

Background: Characterization of the aggressive biology of triple-negative breast cancer (TNBC), defined by its lack of estrogen receptor, progesterone receptor, and human epidermal growth factor 2 (HER2) expression, has led to the development of more effective treatments for patients, but research indicates that clinicians face challenges in maintaining a working knowledge of evolving data. This study was conducted to determine what learning gaps exist in the area of therapeutic advances in TNBC and to investigate whether an online, case-based continuing medical education (CME)/nursing continuing professional development (NCPD)-approved activity could address gaps in clinicians' knowledge regarding the personalized care of patients with metastatic TNBC.

Methods: The CME/NCPD-approved live webinar series titled Metastatic Triple-Negative Breast Cancer: Applying Treatment Advances to Personalized Care was presented by Sara A. Hurvitz, MD, FACP, on July 13 and July 15, 2021, and was made accessible as a CME/NCPD-approved enduring webinar archive starting on July 23, 2021. Learners participated in a 1-hour activity that highlighted emerging therapeutic targets in TNBC, with an emphasis on current challenges and new opportunities in the management of metastatic disease. Learners completed a repeated-pairs pre- and post-activity assessment consisting of case-based questions that gauged their ability to apply emerging data to clinical decision making. Baseline knowledge gaps and subsequent learning gains were calculated based on percentages of learners obtaining correct responses on the pre- and post-activity assessments. Significance was assessed using a chi-squared test. In addition, learners reported self-perceived gains in confidence and competence using 5-point Likert scale questions.

Results: As of June 28, 2022, 811 clinicians had completed the activity for credit; 62 learners participated in the live webinar, while 749 participated in the online enduring activity. Baseline assessment data revealed gaps in knowledge regarding emerging actionable targets and management of treatment-related adverse events (Table 1). Learners participating in the enduring activity scored an average of 43% on pretest topics; after completing the activity, the posttest average rose to 92%. The activity resulted in significant gains in knowledge and competence related to these topics, with $P < 0.0001$ for all learning gains. Upon completion of the activity, 86% of learners self-reported that knowledge acquired from this activity would be

utilized to improve the outcomes of their patients, and 86% of learners self-reported that based on the information learned during the activity, they felt more confident in treating patients with metastatic TNBC.

Conclusions: These data indicate that a substantial knowledge gap exists regarding the latest developments in the treatment of metastatic TNBC. They also demonstrate that online, case-based CME/NCPD-approved activities can result in statistically significant improvements in clinicians' knowledge of therapeutic advances and management of treatment-related adverse events for patients with metastatic TNBC.

Acknowledgements: This activity was supported by an independent educational grant from Merck.

Table 1: Baseline Knowledge Gaps and Post-Activity Learning Gains

Case-based question topic	n	Pretest correct responses (%)	Posttest correct responses (%)	Knowledge gap at baseline (%)	Learning gain (%)
Testing for activating mutations in TNBC	787	14.99	92.38	85.01	77.38
Safety of treatment with olaparib	779	27.98	91.14	72.03	63.16
Management of immune-related adverse events	783	52.49	94.13	47.51	41.63
Selection of systemic therapy for recurrent PD-L1–positive TNBC	792	55.43	83.08	44.57	27.65
Selection of first-line systemic therapy for PD-L1–positive TNBC	772	64.90	97.80	35.10	32.90

Background Immune cells in the tumor microenvironment play an important role in cancer development [1]. In triple negative breast cancer (TNBC), stromal tumor-infiltrating lymphocytes (sTILs) have been identified as a biomarker with both predictive and prognostic clinical values [2]. The High Throughput Truthing project collected sTILs density estimates in hematoxylin and eosin stained invasive breast cancer biopsy specimens. The goal of the project is to produce a dataset to validate artificial intelligence and machine learning models [3]. After collecting annotations from pathologists for a pilot study, we observed a high level of interobserver variability in sTILs density estimates. To improve pathologist accuracy in breast cancer sTILs assessment, we created educational materials using an expert panel and pilot study data. Method The pilot study data consisted of 640 unique regions of interest (ROIs) derived from 64 digital whole slide images. We categorized ROIs based on their mean sTILs density as “10% or less”, “11% to 40%”, or “greater than 40%”, and selected 72 unique ROIs from those with the highest and lowest pathologist variability in each density bin. In a series of eight one-hour sessions, each ROI was reviewed in a group setting by at least three members of our expert panel, which consisted of one clinical scientist and seven board-certified pathologists trained in breast cancer sTILs assessment. Experts provided estimates of the percent of tumor-associated stroma and sTILs density, and commentary on features that confound sTILs assessment for each ROI. Results We created a set of educational materials to teach the sTILs assessment methodology in breast cancer. These materials include an introduction to the clinical relevance of tumor infiltrating lymphocytes in the breast cancer microenvironment, a tutorial for assessing sTILs according to published guidelines [4], and a discussion of specific pitfalls that may be encountered. Expert panel annotations, comments, and pitfalls were used to generate a reference document and interactive tests: one with expert feedback on each ROI and one to determine proficiency. Conclusions Educational materials designed by an expert panel will serve as reference materials for learning sTILs assessment in breast cancer. Our work provides valuable education for pathologists, and directly supports their ability to provide up-to-date diagnostic information used in caring for breast cancer patients. References: 1.

Background: Cancer management is a critical component of healthcare worldwide. Improvement in cancer care has improved the longevity of patients, and they require continued care from healthcare workers, including nurses. Although nurses in India are trained to care for patients in general, courses dedicated to cancer care are few. The present study evaluated the knowledge of nurses involved in cancer management via an online survey. **Materials and methods:** A survey pertaining to nursing practices in cancer management was distributed electronically to nurses in India from January to April 2022. The survey was designed to evaluate treatment-specific knowledge and confidence of the nurses in managing patients with cancer. The data received was analyzed using Microsoft Excel 2016. The responses were divided into two groups: responses marked 4 and 5 on the scale were grouped as confident responses, whereas those marked 1, 2, and 3 were grouped as unconfident responses. Chi-squared analyses were performed using the OpenEpi online tool. **Results:** A total of 422 nurses replied to the questionnaire; of these, 399 (94.55%) said that they have experience in caring for patients with cancer. Of the 399, 198 (49.62%) worked in specialized cancer care centers and the remaining 201 (50.38%) worked in general hospitals. Nearly two-third of the nurses (n = 262; 65.7%) replied that they studied cancer care as a part of their nursing curriculum, whereas the remaining learnt through personal experience. A total of 335 (84%) nurses had undergone a specialized course in chemotherapy management, and most were confident about their knowledge on chemotherapy administration, central line management, and side effect and precaution management. Only 41 (10.3%) had undergone a specialized course in oncology-directed surgical management; yet based on their primary nursing training more than half of the nurses were confident of performing pre- and postoperative management. With respect to a more specialized surgical care, only 144 (36.1%) were confident in providing stoma care and 181 (45.4%) were confident in teaching preventive lymphedema care after surgery. Although a majority had completed a specialized course in post-radiation management (n = 255; 93.2%), only half were confident in identifying skin-induced changes and providing care for patients receiving radiotherapy. Furthermore, only half of the nurses were aware of the role of nursing staff in brachytherapy (n = 200; 50.1%). Most nurses did not undergo any specialized course (n = 360; 90.2%) in palliative management; 124 (31.1%) nurses said that they were not very confident in adequately counselling patient relatives with regard to symptomatic treatment. Nurses working in specialized cancer centers (n = 198) were significantly more confident in administering and managing central lines for chemotherapy; performing adequate chemotherapy drug disposal; and assessing the needs of cancer patients and their family members than their counterparts working in general hospitals (n = 201) (all p < 0.05). Only 54.4% of the respondents were aware of oncology-directed nursing programs available in the country, and only half were able to access them (n = 160; 55.2%) owing to the lack of guidance (n = 130; 32.58%), time (n = 93; 23.31%), and funds (n = 46; 11.53%). Hence, when asked whether they would be inclined to attend a hybrid course, majority (n = 349; 87.47%) indicated in the affirmative. Also, 338 (84.7%) nurses replied that they would be inclined to participate in cancer screening programs after pursuing such a specialized course. **Conclusions:** The results of this study highlight the lacunae in nurses' oncology training. Thus, there is an obvious need to redesign the existing oncology-directed nursing programs to include palliative care and organ-site specific care. Designing these courses in the hybrid format may improve its accessibility and the willingness of nurses to attend.

Educational Opportunities to Improve HER2 Testing and Use of Newer Therapies for HER2-Positive MBC Among Community Healthcare Professionals

Presenting Author(s) and Co-Author(s):

Ryan P. Topping, PhD, *Senior Scientific Director - Clinical Care Options*
Country: United States

Rachael M. Andrie, PhD, *Senior Scientific Director - Clinical Care Options*
Country: United States

Kristen Rosenthal, PhD, *Associate Director, Scientific Services - Clinical Care Options*
Country: United States

Timothy A. Quill, PhD, *Vice President, Scientific Services - Clinical Care Options*
Country: United States

Background: The management of HER2-positive (HER2+) metastatic breast cancer (MBC) has continued to evolve, with multiple FDA approvals of novel HER2-targeted agents since late 2019. Considering the growing HER2+ MBC treatment armamentarium and the emerging HER2-low MBC subtype, we undertook an analysis of the current implementation of guideline and expert recommendations for HER2 testing and treatment of HER2+ MBC with recently approved agents among oncology healthcare professionals (HCPs) participating in educational programs on these topics.

Methods: Between January 2020 and April 2022, we conducted several expert-designed educational activities for HCPs focusing on recommended HER2 testing and treatment of HER2+ MBC. Polling questions on HCP knowledge, practice patterns, and confidence in the evaluation of HER2 status and the use of newer targeted therapies in the setting of HER2+ MBC were assessed across the activities and compared with expert recommendations.

Results: Among 129 HCPs participating in 2 educational activities held from July 2020 to March 2021, 53% reported confidence to appropriately apply current HER2 testing guidelines to patient care. Similarly, among 407 HCPs who participated in 4 educational programs from May 2020 to January 2021, 24% reported confidence to incorporate recently approved drugs (including trastuzumab deruxtecan [T-DXd], neratinib, and tucatinib) into the care of patients with HER2+ MBC. The percentage of HCPs reporting confidence in the use of these new drugs remained low over this time period.

Comparison of treatment recommendations for various HER2+ MBC case scenarios across 7 educational activities from January 2020 through April 2022 showed considerable discordance between experts and HCPs regarding the implementation of newly approved HER2-targeted regimens (Table). For patients with disease progression after 2 lines of therapy and no central nervous system (CNS) metastases, 27% to 57% of HCPs (n = 571) chose T-DXd in agreement with experts. For patients with disease progression after 2 lines of therapy with CNS metastases, 27% to 42% of HCPs (n = 597) chose a tucatinib-based regimen in agreement with experts. Treatment choice concurrence between HCPs and experts did not increase over the course of this study for either of these patient scenarios.

Conclusions: These data suggest that some HCPs are challenged to optimally incorporate

recommendations for HER2 testing and the implementation of novel HER2-targeted therapies in the care of patients with HER2+ MBC. Educational activities designed to improve the knowledge and confidence of HCPs would benefit patients with HER2+ MBC. A detailed analysis of trends over time and by role on the care team will be presented.

Table. Expert and HCP Treatment Selections for Case Scenarios in HER2+ MBC

HER2+ MBC Case	Activity Date, Mo/Yr	Responses, n	Expert Recommendation*	HCP With Treatment Choice Concordant With Expert Choice by Activity Timing, %			
				1/20 - 6/20 Approvals: T-DXd [†] , Tucatinib [‡]	7/20 - 12/20	7/21 - 12/21	1/22 - 4/22 Approvals: T-DXd [†]
Prior adjuvant AC-THP and THP for MBC with PD, no CNS mets	4/22	64	T-DXd	-	-	-	52
Prior THP for MBC with PD, no CNS mets	3/22	20	T-DXd/T-DM1	-	-	-	35/15
Prior THP and T-DM1 with PD, no CNS mets	1/20 - 5/20	223	T-DXd	47	-	-	-
	5/20	48	T-DXd	27	-	-	-
	6/20	44	T-DXd/tucatinib [‡] *	57/20	-	-	-
	9/20 - 12/20	203	T-DXd/tucatinib [‡] *	-	32/24	-	-
	7/21 - 2/22	29	T-DXd	-	-	45	-
Prior THP and T-DM1 with PD, CNS mets	3/22	24	T-DXd	-	-	-	46
	1/20 - 5/20	242	Tucatinib [‡] /neratinib [§] *	27/13	-	-	-
	6/20	37	Tucatinib [‡]	41	-	-	-
	9/20 - 12/20	206	Tucatinib [‡]	-	36	-	-
	12/20	112	Tucatinib [‡] ± SRS	-	42	-	-

*Per expert HCP educators. †For HER2+ unresectable/MBC after ≥2 prior anti-HER2 regimens for MBC. ‡For HER2+ unresectable/MBC (including brain mets) after ≥1 prior anti-HER2 regimens for MBC. §For HER2+ unresectable/MBC after prior anti-HER2 regimen for MBC or in neoadjuvant or adjuvant setting with disease recurrence ≤6 mo after therapy. †With capecitabine and trastuzumab. ‡With capecitabine. §Both treatments considered optimal for case.
AC-THP, docetaxel/cyclophosphamide followed by paclitaxel/trastuzumab/pertuzumab; mets, metastases; PD, progressive disease; SRS, stereotactic radiosurgery; T-DM1, trastuzumab emtansine; THP, docetaxel/trastuzumab/pertuzumab.

Country: United States

Background: Interprofessional collaboration and team-based care in oncology has become increasingly important given the complexity of new therapies and their associated side effect profiles. It has been demonstrated that clear and thorough communication improves patient satisfaction and patient adherence. Previously, students described a deficit of adequate oncology education in their curriculum. Incorporating learners from different educational disciplines to care for oncology patients in a breast clinic is an innovative idea that has not been previously published. Objectives: This study will evaluate patient satisfaction and learners' competencies and confidence after an interprofessional education collaboration aimed at enhancing chemotherapy education and toxicity management. Methods: A single center study was conducted at the University of Maryland Greenebaum Comprehensive Cancer Center (UMGCCC) from August 2020 through April 2021. Patient population was adults receiving chemotherapy for breast cancer. Learner population was medical and pharmacy students and residents. Learners received a brief educational orientation and then completed education and assessment sessions with patients. Sessions were prior to first chemotherapy, 2-4 days after chemotherapy, and then 1-3 days prior to next cycle of chemotherapy. Surveys of satisfaction and competencies were prospective but chart review for symptoms and interventions were retrospective. Results: 20 learners and 9 patients participated in the experience. Median of 4 encounters per patient were completed. 79 chemotherapy issues/toxicities were identified with 11 (14%) interfering in daily activities. 47 interventions were made and improvement was seen in 44 (56%) problems. Patient survey revealed that all 9 patients (100%) reported they were completely satisfied with education aimed at understanding side effects. One patient reported they were somewhat satisfied with understanding how to use their medication correctly and safely while the other 8 reported very satisfied (89%). Learners self-assessment tool revealed improvement in confidence in teach back ($p=0.002$) and interprofessional education competencies ($p=0.01$). Discussion: Incorporating medical and pharmacy learners in interprofessional care can help patients understand their treatment and help in management of toxicity. Limitations of the experience included faculty's involvement in the discussions and interventions may overestimate the contribution of learners. In addition, the retrospective nature

of the chart review may underestimate the symptoms for patients and overestimate the proportion of problems that were improved.

DIVAS - DC Pink Divas Intervening Virtually to Advance Saving Lives: Assessing the impact of digital behavioral health breast cancer education program for Black women

Lori Wilson, MD, FACS, *Professor of Surgery and Chief, Surgical Oncology; Program Director, General Surgery Residency - Howard University*

Country: United States

Breast cancer is now the most common cancer. Thirty years of increased awareness, early diagnosis, and treatment access contributed to a 40% decline in breast cancer deaths. Yet, in 2021, more than 281,550 new cases of invasive and 49,290 new cases of non-invasive breast cancer will be diagnosed in U.S. women. Black women are 40% more likely to die of breast cancer - the highest breast cancer death rate across racial and ethnic groups. Today, the Black-white breast cancer mortality gap persists, and Black metastatic breast cancer (MBC) patients have a poorer prognosis. The pandemic exacerbated breast cancer disparities. In 2020, delays and avoidance contributed to an 85% breast cancer screening drop while MBC patients' risk of severe illness and death from COVID-19 elevated. Therapy interruptions and abandonment increased, and conversely, clinical trial enrollment decreased. COVID-19 has accelerated the digital platform shift to telemedicine, online psychosocial support programs, virtual patient navigation, and digital engagement across the oncology care continuum. DC Pink Divas Intervening Virtually to Advance Saving Lives (DIVAS) is an award-winning evidence-based training, outreach, and patient navigation program developed to address the educational needs of Black early-stage, MBC breast cancer patients, survivors, and caretakers and provide strategies to educate, empower and impact women by increasing breast health knowledge, decreasing gaps in screenings and access, increasing awareness of MBC to ensure that where a woman lives, will not determine if she lives through a 1-year commitment of attendance in 8 cohort-based education modules where Black breast cancer mortality is highest.

The DIVAS Health Behavioral Change Model adapts the Precaution Adoption Process Model, Health Behavior Model, and Social-Ecological Model. DIVAS implements innovative virtual outreach programs, training, and intervention strategies to empower Advocates to educate peers, providers, and policymakers. 3 Cohorts of Black women impacted by breast cancer trained as Lay Breast Health Advocates from 2011, 2020, and 2021 (N = 57; 77.5 % 45 years or younger; 36.7% early-stage 0-II, 50% late stage III-IV, 10.3% caretakers) self-reported their lifestyle behaviors, breast cancer diagnosis, breast health education, social media use, and interest in a digital-based lifestyle intervention. Participants completed pre-and post-surveys, interviews, and journaling over 10.5+ hours of education modules to understand their breast health, provider-related challenges, and community-related resources.

Findings provide evidence that cohort-tailored education is a successful method of supporting

Black women in a behavioral-health intervention. The provision of printed culturally attuned information along with the digital-based instruction from a Black woman health care provider or public health expert is effective in helping Black breast cancer survivors transition into patient empowerment, improve QOL and contribute to better patient outcomes. After the intervention and completion of breast health modules, participants reported increased: self-efficacy in communicating with providers (70%) and self-efficacy in making treatment decisions (70%) self-confidence (85%), and a decrease in lifestyle risk factors (87%). Patient-centric behavioral health interventions in breast cancer education must be advanced digitally to address the pandemic's compounded crisis.

DC Pink Divas provides insights to combat rising disparities by educating, empowering, and mobilizing Black lay breast health advocates to improve outcomes. Collaborative digital interventions across the care continuum to improve awareness, access, adherence, infrastructure, culturally attuned training, and support are evidence-based methods for navigating the cancer care transformation accelerated by COVID-19 to advance breast health equity.

Women with a pathogenic mutation in the BRCA1 or BRCA2 genes have an elevated lifetime risk of developing breast and ovarian cancer. To address this risk, women are managed with a combination of surveillance and/or risk-reduction strategies. Decisions about risk management strategies can be complex, personal and multifactorial. Women often struggle with the decision-

making process. In addition, within the clinical environment, there may be variations in recommendations between clinicians that can leave women uncertain and less able to choose a risk management pathway. The overall aim of this project is the development of a web-based patient decision aid toolkit for BRCA mutation carriers that will improve the decision-making process by providing the user with information about their cancer risk, options for risk management and potential benefits and side effects. Development of the patient decision aid was guided by the International Patient Decision Aid Standards (IPDAS). With appropriate ethical approval, a mixed methods approach was used to identify suitable content for the decision aid. A decision-making needs assessment was conducted to identify the information needs of women with a BRCA mutation. Semi-structured interviews were held with cancer unaffected BRCA mutation carriers (n = 16) and key stakeholders including healthcare professionals, policy makers and patient group representatives (n= 10). Data were analysed by thematic analysis. Systematic scoping reviews were conducted to synthesise relevant evidence on risk-management options, benefits, harms and the development and testing of patient decision aids in general. Content for the decision aid was refined using a Delphi process to build consensus on items for inclusion in the decision aid amongst a diverse panel of experts (n=13). A prototype patient decision aid was developed which included written information as well as visual depictions of risk, videos and photographs to enhance the patient's information experience. A 'values clarification' activity was included to enable women to work through their own values and preferences relating to risk management interventions and their associated benefits and side-effects. Initial 'sandpit' testing of the decision aid prototype was performed by the research team and advisory group. Usability testing was conducted with BRCA mutation carriers (n = 8) and healthcare professionals (n = 8) using both qualitative interviews and quantitative surveys. The research team made final revisions to the decision aid based on participant feedback and committee consensus. This evidence-based patient decision aid can be used by BRCA mutation carriers unaccompanied or during a clinical consultation. We envisage that this decision aid will improve the decision-making process by assisting women and clinicians during shared decision-making regarding cancer risk management.

Using co-design to develop culturally and linguistically appropriate breast cancer education materials

Presenting Author(s) and Co-Author(s):

Michele Rakoff, n/a, *Director - Breast Cancer Care and Research Fund*
Country: United States

Mayra Serrano, DrPH, MPH, *Senior Manager - City of Hope*
Country: United States

Country: United States

Background: Engaging diverse community members in research is vital to communicate and disseminate information to their communities. Co-design is a participatory approach to design solutions to problems and can be used to develop materials by bringing together individuals from diverse backgrounds. There is currently a gap in research of health education materials (i.e., Infographics) being created that employ a community co-design approach. We describe use of the co-design process to develop an infographic on breast cancer risk factors for broad community dissemination. Methods: The Community Leadership Committee (CLC) that represents the demographics of the Greater Los Angeles area was formed in 2015 and members were drawn from community and advocacy organizations, representing the four largest racial/ethnic groups (African American, Chinese, Latina, and Non-Hispanic White). The primary role of the CLC was to help create teachable, culturally-responsive materials on breast cancer and the environment. To address their communities' informational needs about breast cancer and the environment, the CLC determined elected to develop infographics. Focus groups were held in summer of 2017 to evaluate the initial drafts of the infographics for clarity, utility, cultural and linguistic appropriateness and effectiveness. Focus group participants were recruited by the CLC members to and were conducted in English, Spanish, or Mandarin Chinese. Results: CLC members (N=18) informed the design and development of the infographic. Members of the CLC member ages ranged from 49 to 79. All members were female, 42%% were foreign-born, 34%% spoke Spanish, 20% spoke Chinese, and 75% were breast cancer survivors. A total of 6 focus groups were conducted with 53 women. The groups consisted of 4 groups in the English language [African American (N=12), non-Hispanic White (N=7), Chinese (N=9), and Hispanic/Latina (6)], one in Spanish (N=7), and Mandarin Chinese (N=12). The infographic went through 6 versions before being finalized, translated into Spanish and Chinese, and printed. Focus groups occurred between initial draft and draft #3. Some of the common themes included the importance of representation, readability, and visualization. CLC members preferred materials that included less text and more graphics to make it faster and easier to read. Collaboration with the CLC and findings from the focus groups led to the development and refinement of the final infographics Discussion: We have described the development of health education materials through a co-design process to increase the awareness of breast cancer risk. These findings emphasize the importance of involving people with lived experience and end users. Co-design is vital to ensuring the health education materials were appropriate, engaging, culturally and linguistically competent. Health education materials that resonate with their intended audience have the potential to influence health behaviors resulting in risk reduction.

Improving Cancer-related Symptom Burden and Quality of Life with CancerLife™, a Digital Self-Care Therapeutic for Cancer Patients

Presenting Author(s) and Co-Author(s):

Charles Coltman, Dr.

Charles Coltman, Ignatius Beard, and Scott A. Irwin Background Collecting patient-reported outcomes have been shown to improve outcomes in patients with cancer; however, implementing methods to collect and utilize these data, such as remote patient monitoring, has been limited due to staffing resources, workflow disruption, EMR integration, and cost barriers. A self-care patient engagement consumer app is one solution to help alleviate these barriers. The purpose of this study was to demonstrate that the self-reporting of symptoms by patients using a novel patient engagement mobile application, at any time, from anywhere, would have a meaningful impact on symptom burden while improving Quality of Life (QoL) without the aforementioned barriers, most importantly workflow disruption. **Design** A blinded, two-arm, randomized, controlled trial of CancerLife™ was conducted. Participants with breast cancer were recruited nationwide via Facebook ads and asked to complete an online qualification survey. If qualified, they received a text message with a link to complete the consent and enrollment process, then randomly assigned via 1:3 ratio to control or the CancerLife™ intervention. Overall health state (EQ-5D) and QoL (EQ-VAS) were compared with usual care every three weeks from 9 weeks to 24 weeks post-baseline. Virtual monitoring of common cancer-related symptoms (symptom count) was also done for the CancerLife™ group. **Results** A total of 1006 participants were recruited online, and 499 completed the registration, consenting process, and download app procedure and were enrolled. A total of 189 participants in both groups completed the 24-week study. Participants that enrolled represented a wide national geographic area inclusive of 117 different area codes, which suggests the solution can address the challenges of care disparities. A significant main improvement effect of intervention favoring CancerLife™ was found for both the EQ-VAS ($F(1, 5) = 22.1, p < 0.01$) of 14.2% and 9.9% on the EQ5-D ($F(1, 5) = 14.3, p < 0.01$). Post-hoc paired t-test comparisons indicated significantly higher mean differences at 18 and 21 weeks ($p < 0.05$) on the EQ-VAS and at 21 weeks ($p < 0.05$) on the EQ5-D, with similar trends at 9, 15, and 24 weeks on the EQ-VAS and 15, 18, and 24 weeks on the EQ5-D. Further, the CancerLife™ group demonstrated a significant decrease in symptom count (mean $\Delta = -9.11, -78.1\%, t = -2.62, p < 0.001$) at 24 weeks. **Conclusions** This study demonstrates that a patient engagement app with a novel data collection platform could lower symptom burden and improve overall QoL with minimal barriers to implementation. Since remote patient monitoring systems are hard to implement inside cancer care settings due to costs, IT system integration, and workflow disruption, a direct-to-consumer-based app, which can be used in any care setting by any patient, and accessed through any connected device, shows significant promise to ameliorate symptom burden, raise overall QoL, and address disparities of access to care and care outcomes for cancer patients. Providers may consider this as a tool to improve their population quality metrics, care and care utilization outcomes, disparities, and patient satisfaction scores without significant startup, maintenance, resource, and workflow costs.

Background For early-stage breast cancer BCS followed by radiation therapy has been validated as safe alternative to Radical Mastectomy. One peculiar problem faced in developing countries is patients in whom primary tumor has been excised elsewhere. There is a lack of clear treatment history and pre-operative examination and imaging in such patients, which makes accurate staging and planning for definitive surgery much more challenging. We did this retrospective analysis to assess clinical, cosmetic and QOL outcomes in the above-mentioned group of patients. Methods Patients between 18 and 80 years diagnosed with biopsy proven carcinoma breast that had the primary tumor excised outside and underwent BCS at our institute were included. They were subjected to routine history and physical examination as per the institute standard of care. Overall survival was estimated using Kaplan Meier curve. Expected 4 years survival was calculated using percentage of people who were alive out of those patients whose follow up was known at the end of 4 years. Cosmetic outcome was assessed using patient reported BCTOS 12 scores whereas quality of life outcome was assessed using patient reported EORTC and SF 36 questionnaire scores. Results Twenty-two patients were enrolled. Overall survival at 4 years was 72% comparable in NACT and No NACT

($p < 0.29$). 5.45% patients had local recurrence. Cosmetic outcome was excellent to good in 90% patients, similar between NACT and No NACT ($p 0.69$). Quality of life was excellent-good in 65% patients (EORTC) which was significantly higher in No NACT group ($p 0.05$) Conclusion BCS after scar excision following non oncological resection of breast primary may be an acceptable modality of treatment with good cosmetic and Quality of life outcomes.

Background The risk of ipsilateral breast tumor recurrence (IBTR) and the prognostic outcome of breast-conserving surgery (BCS) for germline BRCA1/2 pathogenic variant (BRCA1/2+) carriers remain controversial. We examined differences in IBTR and prognosis between

BRCA1/2+ carriers and non-carriers following BCS for breast cancer. Methods Clinical and pathological data were collected by retrospectively reviewing charts of consecutive patients with stage 0-III breast cancer who underwent genetic testing for germline BRCA1/2 and BCS between 1996 and 2020. Patients with variants of breast cancer-associated genes other than BRCA1/2 were excluded. We compared the incidence of IBTR and prognosis, including overall survival (OS), breast cancer-specific survival (BCSS), and distant recurrence-free survival (DRFS), between BRCA1/2+ carriers and non-carriers. Results We analyzed 551 patients (587 breasts with cancer), including 30 BRCA1+ carriers (32 breasts) and 31 BRCA2+ carriers (32 breasts). The median follow-up was 5.8 years (7.2 and 5.3 years for carriers and non-carriers, respectively). The median age at breast cancer diagnosis was 43 and 46 years for carriers and non-carriers, respectively, indicating younger onset of cancer in carriers (age \leq 40 years; 46.9% for carriers vs. 27.5% for non-carriers, $p = 0.001$). In carriers, breast cancer more frequently expressed estrogen receptor-negative (56.2% for BRCA1+ carriers and 15.6% for BRCA2+ carriers vs. 22.0% for non-carriers, $p = 0.013$), progesterone receptor-negative (62.5% for BRCA1+ carriers and 31.3% for BRCA2+ carriers vs. 29.5%, $p = 0.005$), nuclear grade III (45.3% for carriers vs. 29.5% for non-carriers, $p = 0.010$), or a higher Ki-67 index (Ki-67 index $>$ 20) (89.5% vs. 61.8%, $p = 0.001$) than non-carriers. Moreover, carriers underwent chemotherapy more frequently than non-carriers (62.5% vs. 42.4%, $p = 0.002$). Cancer stage, tumor size, HER2 status, presence of lymphovascular invasion, and the rate of positive or close surgical margins did not statistically differ between the examined groups. No statistical differences were detected in the number of patients who underwent whole-breast radiotherapy following BCS: 59 breasts in carriers and 503 in non-carriers (92.2% vs. 96.4%). During follow-up, we noted that 9 breasts of BRCA1/2+ carriers (5 [15.6%] for BRCA1+ and 4 [12.5%] for BRCA2+) and 35 breasts (6.7%) of non-carriers developed IBTR ($p = 0.035$). In an analysis excluding patients who did not undergo radiotherapy, the rate of IBTR remained significantly higher in BRCA1/2+ carriers ($p = 0.034$) than that in non-carriers. The median time to IBTR was 10.2 years in carriers (10.2 years for BRCA1+ and 8.5 years for BRCA2+) and 3.5 years in non-carriers. Carriers were more likely than non-carriers to exhibit distinct subtypes of recurrent tumors in the ipsilateral breast (66.7% for carriers vs. 19.4% for non-carriers, $p = 0.006$), occurring in a different quadrant from the primary tumor (50.0% vs. 27.3%, $p = 0.215$). No significant differences in OS ($p = 0.068$), BCSS ($p = 0.109$), or DRFS ($p = 0.359$) were noted between carriers and non-carriers. Conclusion BRCA1/2+ carriers exhibited a higher risk of IBTR after BCS and a longer time to IBTR than non-carriers. One limitation of the present study is a longer follow-up period for carriers than for non-carriers, as carriers typically underwent long-term observation at our institution; hence, further data accumulation is warranted for validating these findings. Subtypes and quadrants of IBTR were frequently distinct in carriers, indicating the increased incidence of new primary breast cancer. Although the prognosis did not differ between carriers and non-carriers, our results suggest the necessity for long-term intensive breast surveillance of BRCA1/2+ carriers after BCS.

Background: Mastectomy is the treatment recommended by most national and international guidelines for in-breast-recurrence of breast cancer after breast conserving surgery (BCS) and external beam radiation therapy (EBRT). In selected cases it is possible to preserve the breast if TARGIT-IORT can be given during the second lumpectomy. We present a comparative analysis of overall survival, QoL and side effects. Methods: We identified patients who had local recurrence of breast cancer after BCS and EBRT in our prospectively maintained database. Patients were included if they had undergone either a mastectomy or BCS along with TARGIT-IORT. Patients with distant disease were excluded. Identified patients were contacted and offered participation in a prospective QoL-analysis using the BREAST-Q questionnaire. The cohorts were compared for confounding parameters, overall survival, side effects, physical, sexual and psychosocial wellbeing and satisfaction with the surgical result. Results: 36 patients treated for local recurrence were included in this analysis, 21 had received a mastectomy and 16 patients had chosen to preserve their breast and after interdisciplinary tumor board decision received BCS and TARGIT-IORT. Mean follow-up was 12.8 years since primary diagnosis and 4.2 years since recurrence. There were no significant differences between both groups regarding age, ER, PR, HER2neu, tumor size or nodal status at primary diagnosis or at recurrence and the distribution of invasive versus non-invasive recurrences. 1 patient in the BCT and TARGIT-IORT group (6.7%) and 3 patients in the mastectomy group (14.3%) died during follow up. Overall survival was numerically longer for BCS and TARGIT-IORT either calculated from primary diagnosis (median 18 years versus 8 years) or from recurrence

(median 5.1 years versus 3.2 years). The numbers were too small for formal statistical analysis. No patient had another local recurrence of breast cancer during follow-up. 12 patients in the mastectomy group and 10 patients in the BCS and IORT group returned the BREAST-Q questionnaire. Psychosocial wellbeing, sexual wellbeing and satisfaction with the surgeon did not differ between both groups. Physical wellbeing was significantly superior for those whose breast could be preserved (median score for BCS and TARGIT-IORT group was 91 (71-100) vs. 66 (14-100) for the mastectomy group, p-value = 0.021). Whereas most side effects were comparable and showed no significant differences, patient-reported incidence and severity of lymphedema of the arm on the side of surgery was significantly worse in the mastectomy group (p=0.007). Conclusion: Many patients who have local recurrence of breast cancer are reluctant to lose their breast. We found that preserving the breast by use of TARGIT-IORT was safe with no re-recurrence and no detriment to overall survival. This is necessarily a small series, because local recurrence is rare, yet, this novel approach led to a statistically significant improvement in physical wellbeing and incidence and severity of lymphedema. These data increase the confidence in offering breast preservation and TARGIT-IORT for surgery of in-breast-recurrence of breast cancer.

Purpose/Objectives To assess whether an association exists between surgical localization technique and size of lumpectomy cavity on radiation (RT) planning CT scan. Adjuvant RT with boost to lumpectomy cavity has been shown to improve local control compared to adjuvant whole breast radiation alone, but larger cavity sizes can lead to worse cosmetic outcomes following boost administration, which could lead providers to omit boost. Therefore, decreasing

cavity size could increase guideline-concordant boost administration and minimize adverse cosmetic outcomes. **Materials/Methods** A retrospective review was conducted of all patients undergoing breast conserving surgery with either wire- or magnetic seed -guided lumpectomy followed by adjuvant RT at a single institution from 2018 to 2021. Data were collected from pre-surgical work-up, surgical pathology, and radiation planning. Women undergoing bracketed wire localization and patients treated by a surgeon who only performed wire localized procedures were excluded. The primary outcome was lumpectomy cavity size as measured on planning CT. We first conducted an overlapping weights propensity score analysis to account for imbalance between groups in age, BMI, breast size as measured on planning CT scan, pre-operative imaging tumor volume, neoadjuvant therapies, lumpectomy histology (DCIS alone vs DCIS + invasive vs invasive alone vs invasive with lobular features vs no residual), and multifocality. Multivariable analysis (MVA) of CT cavity volume included the above weighted variables as well as surgeon and radiation oncologist. Secondary analyses included MVA of total pathologic volume, bivariable analysis of boost delivery, bivariable analysis of electron vs photon boost, stratification by surgeon, and fixed effect model for year of surgery. **Results** Of 617 women who received lumpectomy during the study period, 387 were included in final analysis. Patients who underwent seed localization were less likely to have multifocal disease, less likely to have calcifications on mammogram, more likely to have ultrasound measurements for pre-op imaging, and had smaller tumor size on pre-op imaging. Four surgeons performed all cases, with rates of seed use per surgeon ranging from 27.7% to 70.7% but generally increasing throughout the study period. There was no difference between wire and seed localization in the need for additional margins based on intra-operative margin analysis (58.4 vs 62.7%, $p = 0.5$). There was no difference in positive margins (6.4 vs 5.4%, $p = 0.81$) or second surgeries (9.4 vs 8.1%, $p = 0.79$). Rates of close margins were the same for DCIS (23.4 vs 17.3%, $p = 0.35$) and invasive carcinoma (7.6 vs 6.8%, $p = 0.97$) between techniques. Initial uncorrected bivariable analysis shows wire localization has a non-significant trend toward increased CT cavity volume (4.56cc, $p = 0.15$) and a significant association with total pathology volume (21.7cc, $p = 0.004$). For the primary outcome, breast size, time from surgery to simulation, and surgeon were all significantly associated with CT cavity volume but there was no significant difference by localization technique ($p=0.38$). For pathology volume, there was a non-significant trend toward increased specimen volume with wire localization ($p = 0.07$), and significant associations with BMI, histology, and pre-op imaging volume. When stratified by surgeon, there was no surgeon for whom one localization technique led to significantly different CT or pathology volume over the other. There were no significant changes of the treatment effect over time ($p = 0.79$). There was no significant difference between wire and seed localization in indicated boost delivery (85% vs 79%, $p = 0.14$) or electron boost (42% vs 56%, $p = 0.13$). **Conclusion** There was no significant difference in CT cavity size between wire localization and magnetic seed localization, suggesting that the choice between these surgical techniques does not impede RT boost delivery.

Background

Neoadjuvant chemotherapy (NAC) is an established treatment option in early breast cancer. NAC potentially downstages the tumor and, combined with oncoplastic techniques, may increase the eligibility for breast conserving surgery (BCS). NAC can also result in less surgical morbidity of the axilla if axillary clearance can be avoided. In addition, preoperative medical treatment allows for a thorough evaluation of treatment response and lays the foundation for adjuvant treatment decisions. The aim of the study was to prospectively estimate the proportion of BCS post NAC and the relation to well-defined factors associated with BCS post NAC.

Materials and methods

This observational prospective cohort study included 226 patients in the SCAN-B neoadjuvant cohort (Clinical trials: NCT02306096) receiving NAC between 2014 and 2019. Eligibility for BCS was based on the assessment of the surgeon at time of diagnosis and again post NAC. All the covariables were defined at time of diagnosis from mammograms and core needle biopsies, except for pathological complete response (pCR). Treatment generally consisted of 6 to 7 three-weekly treatment cycles of anthracycline- and taxane-based chemotherapy, given in sequence. In HER2-positive disease, HER2-directed antibodies were added as appropriate. The primary aim was to estimate the proportion of BCS after NAC and the secondary aim was to evaluate factors as predictors of BCS, including gene expression and surrogate molecular subtypes (St. Gallen), breast density, and other putative modifying factors. Uni- and multivariable logistic regression analysis were performed including covariates of clinical relevance and/or associated with the outcome measures (BCS versus mastectomy).

Results

The BCS rate increased during the study years, from 37% to 52%. pCR was achieved in 69 patients (30%). Predictors with a negative association to BCS were larger tumor size on mammography (T3 vs T1) (odds ratio (OR)=0.20, 95% confidence interval (CI) [0.06,0.64]), lack of visibility on ultrasound (OR=0.08, 95% CI [0.001,0.63]), lobular histological subtype vs other subtypes (OR=0,20, 95% CI [0.06,0.61]). Factors positively associated with BCS were benign axillary lymph node status (OR=2.26, 95% CI [1.26,4.06]) and surrogate molecular subtypes; patients with triple negative and HER-2 positive tumors had the highest probability of receiving BCS, 65% and 54%, respectively. Gene expression subtypes had a similar trend of being associated with BCS; patients with basal like and HER-2 enriched tumors had higher odds ratio for BCT than patients with luminal subtypes (Table 1). In the multivariable logistic regression analysis, tumor size on mammography and axillary status had the strongest association to BCS (OR=0.95, 95% CI [0.92,0.98] and OR=2.08, 95% CI [0.99,4.35], respectively).

Conclusions

Our study shows that the rate of BCS after NAC increased over the study years, but mastectomy rate in the study was still close to 50%. With increasing number of patients achieving pCR after NAC, the BCS rate should be possible to increase further. Predictors of BCS after NAC were identified, and benign axillary lymph nodes and smaller tumor size defined at time of diagnosis were the strongest predictors of BCS, supporting that initial tumor stage was important for the choice of surgery after NAC.

Omission of Axillary Surgery for Ipsilateral Breast Tumor Recurrence with Negative Nodes after Previous Breast-Conserving Surgery: Is It Oncologically Safe?

Presenting Author(s) and Co-Author(s):

Background

Salvage mastectomy is traditionally recommended for patients who developed ipsilateral breast tumor recurrence (IBTR) in light of the previous breast irradiation. However, it remains controversial whether surgical axillary staging (SAS) is necessary for IBTR patients with negative nodes. This study aimed to evaluate the oncologic safety of omitting SAS for IBTR.

Methods

We retrospectively identified patients who developed invasive IBTR with negative nodes after undergoing breast-conserving surgery (BCS). Patterns of care in nodal staging were analyzed based on prior axillary staging status. Clinicopathologic characteristics and adjuvant treatment of the initial tumor, as well as the IBTR, were compared between SAS and no SAS groups. Kaplan-Meier method and Cox regression model were utilized to compare the loco-regional recurrence-free survival (LRRFS), distant metastasis-free survival (DMFS), and overall survival (OS) rates after IBTR removal between the two groups.

Results

A total of 154 IBTR patients were eligible for final analysis. Compared to no SAS group, SAS group was less likely to undergo ALND (15.1% vs 73.3%, $p < 0.001$) at initial BCS, had a longer recurrence interval (2.8 vs 2.1 years, $p=0.03$), and were more likely to have discordant molecular subtype with primary tumor (35.8% vs 12.9%, $p=0.001$). However, the extent of axillary staging did not affect systemic or radiation recommendations. In the subgroup of patients without previous ALND, the clinicopathologic characteristics were roughly comparable. Pathologic analysis revealed pathologically uninvolved nodal status in approximately 85% of patients receiving SAS at time of IBTR in the overall population and the subgroup (Table 1). No significant differences were observed in LRRFS, DMFS and OS between the two groups (Table 2).

Conclusion

For node-negative IBTR patients, we observed selection bias on the basis of prior ALND, shorter recurrence interval, and concordant molecular subtype favoring no SAS, but comparable LRRFS, DMFS, and OS. These results support wider consideration of sparing SAS in the management of IBTR, especially in patients without previous ALND.

Pathologic axillary staging in patients receiving axillary surgery at time of IBTR

Table 1. Pathologic axillary staging in patients receiving axillary surgery at time of IBTR

Pathologic axillary staging	Surgical axillary staging	
	Total patients (N=53)	No prior ALND (N=45)
pN0	45 (84.9%)	39 (86.7%)
pN1	5 (9.4%)	4 (8.9%)
pN2-3	1 (1.9%)	1 (2.2%)
pNx	2 (3.8%)	1 (2.2%)

Cox regression analysis of LRRFS, DMFS, and OS after IBTR

Table 2. Cox regression analysis of LRRFS, DMFS, and OS after IBTR

Variables	Total patients with IBTR (N=154)			Patients without prior ALND (N=72)		
	No. of events	2-year survival probability (95%CI)	<i>p</i> value	No. of events	2-year survival probability (95%CI)	<i>p</i> value
LRRFS			0.5			0.77
Axilla surgery	2	93.5 (84.8-100.0)		2	91.6 (80.5-100.0)	
No axilla surgery	9	91.0 (84.1-98.4)		1	91.7 (77.3-100.0)

Background: Conventional breast conserving surgery (CBCS) considered as a confined alternative to mastectomy could lead to potentially breast deformities. Oncoplastic breast conserving surgery (OBCS) as well as breast conserving surgery (BCS) plus immediate lipofilling have been shown to be reliable techniques for maintaining the natural breast contours, however, few studies compared those three surgical options for oncological safety, complications and aesthetic outcomes in early breast cancer (EBC). Methods: We retrospectively reviewed the data of BC patients who underwent BCS between January 2017 and December 2021 from The First Affiliated Hospital of Chongqing Medical University. We included female patients who received BCS for unilateral stage 0-III BC. Those who had bilateral BC, incomplete surgical records, unfinished adjuvant therapy, multiple primary malignant tumors and lost to follow-up and were excluded. Patient-reported outcome measures (PROMs) were assessed using the BREAST-Q Version 2.0. We utilized a multivariable linear regression model to identify clinical factors correlated with the BREAST-Q score, and the log-rank test and Cox regression models were used to compare the survival difference between groups. Results: Of 268 patients, 90 (33.6%) underwent CBCS, 53 (19.8%) underwent OBCS and 125 (46.6%) underwent BCS plus immediate lipofilling. Patients in OBCS and BCS plus immediate lipofilling groups were younger than those in CBCS group (mean age: 43.9yrs vs 49.1yrs, $P=0.001$ and 45.7yrs vs 49.1yrs, $P=0.008$). The largest tumor size and heaviest BCS specimen were observed in the OBCS group compared with CBCS (mean tumor size: 23.4mm vs 17.3mm, $P<0.001$ and median excised weight: 122.0g vs 36.5g, $P<0.001$) and BCS plus immediate lipofilling group (mean tumor size: 23.4mm vs 17.4mm, $P<0.001$ and median excised weight: 122.0g vs 37.0g, $P<0.001$). It was balanced for pathological type, Ki-67, ER and PR expression between three groups. In the multivariable linear regression models, with the CBCS group as referent, either OBCS or BCS plus immediate lipofilling groups had a significantly higher score in satisfaction with breast (Estimate: 9.27, $P=0.001$ and Estimate: 13.08, $P<0.001$) and psychosocial well-being (Estimate: 6.06, $P=0.021$ and Estimate: 9.34, $P<0.001$). Additionally, sexual well-being was improved among patients receiving BCS plus immediate lipofilling (Estimate: 6.19, $P=0.029$). Nevertheless, patients in OBCS group harbored worse physical well-being compared with CBCS (Estimate: -15.89, $P<0.001$). There was no significant statistical difference among three groups on re-excision rate ($P=0.721$) and postoperative complications ($P=0.663$). After 37-month median follow-up, identical event-free survival (EFS) was revealed among three groups (HROBCS vs CBCS: 3.93; 95%CI, 0.78-19.81, $P=0.098$; HRBCS plus Lipofilling vs CBCS: 1.15, 95%CI, 0.28-4.67, $P=0.847$). Conclusion: This study demonstrated that OBCS as well as BCS plus immediate lipofilling shared equivalent oncological safety but better cosmetic outcomes and patient satisfaction

when compared with CBCS for EBC patients, suggesting that further prospective randomized clinical trials are warranted to confirm our findings.

Introduction: Patients with triple-negative (TN) or HER2-enriched ipsilateral breast cancer recurrence (IBCR) seem to be excluded from a second breast-conserving surgery (BCS) under the assumption that salvage mastectomy would provide better oncological outcomes.

Objectives: The objective of this study was to describe the clinical features of these patients, to compare the two surgical alternatives (salvage mastectomy versus second BCS) in terms of oncological results, and to identify independent factors influencing prognosis and surgical treatment. Methods: We retrospectively reviewed all the consecutive patients with histologically confirmed TN or HER2-enriched IBCR. Disease-free survival (DFS), distant disease-free survival (DDFS), overall survival (OS), and breast cancer-specific survival (BCSS) were analyzed and compared between the two groups. Results: Eighty-five patients were affected by TN or HER2-enriched IBCR, with a median age of 60 years (range, 32-87 years). The majority of patients (72.9%) were treated with salvage mastectomy. There was no significant difference in terms of DFS between patients receiving a second BCS or mastectomy ($p=0.596$). However, patients undergoing a second BCS had significantly better DDFS, OS, and BCSS compared to

mastectomy ($p=0.009$; $p=0.002$; $p=0.001$, respectively). Tumor dimension < 16 mm (78.3% versus 38.7%, hazard ratio (HR)=3.602, 95% confidence interval (95% CI)=1.534-8.459, $p=0.003$) was found to significantly increase the probability of receiving a second BCS and positively affects recurrence and survival outcomes (DFS: HR=8.065, 95% CI=2.320-28.034, $p=0.001$; DDFS: HR=17.011, 95% CI=3.853-75.099, $p=0.001$; OS: HR: 13.881, 95% CI=2.730-70.579, $p=0.002$; BCSS: HR=36.773, 95% CI=4.579-295.322, $p=0.001$). Second BCS represents an independent protective factor for OS and BCSS (OS: HR=0.246, 95% CI=0.027-0.697, $p=0.002$; BCSS: HR=0.313, 95% CI=0.092-0.511, $p=0.002$). Conclusion: Salvage mastectomy is not always necessary and it does not seem to increase survival compared to a second BCS. This reinforces the concept that the prognosis of TN and HER2-enriched BC recurrence is mainly driven by the biology of the disease, rather than by the extent of surgery. In patients with small (< 16 mm) aggressive subtypes of IBCR, a second conservative approach can still be evaluated and offered, presenting acceptable loco-regional control and survival.

Factors associate with borderline or invaded margins in breast cancer surgery at the Val d'Aurelle Montpellier CRLC Véronique Mboua Batoum*, Esther Dina Bell, Christianne Nsahlai, Junie Annick Metogo Ntsama , Esther Juliette Meka, Marian Gutowski, Simon Thezenas, William Jacot *Corresponding autor : vbatoum@gmail.com Introduction: The inadequate status of the resection margins after breast cancer surgery is an important predictor of local tumor recurrence. The objective of our study was to determine the factors associated with positive or invaded resection margins. Methodology: Our retrospective study included a cohort of 652 patients with early invasive breast cancer who underwent breast cancer conserving surgery at the Val d'Aurelle Regional Cancer Center. We defined positive margins as those with a distance of less than or equal to 2 mm from the tumour. The data were analysed using STATA® 10.0 software. Results: In our study, The median distance from the tumour to the surgical resection site was 5mm [0.0 - 35.0mm]. Resection margins were positive in 208 patients (31.9%). The rate of positive resection margins was significantly higher in non-menopausal patients (P =0,0050) , , in those with tumours less than 2 cm in size (P = 0,0004), with ductal carcinoma in situ (DCIS) component and without lymph node involvement (P =0,0082) . Re-excision surgery was performed in 229 patients (35.1%). Conclusion: Consideration of each of these factors associated with positive resection margins shoud help the surgeons to perform a wider excision, in other to obtain clear resection margin during the initial breast cancer surgery. Key words: breast cancer, conservative surgery, resection margins, risk factors for positive margins

Introduction: Patients with BRCA1/2 mutations have a higher risk of developing breast cancer compared to the wild-type population. For patients with a BRCA mutation, there are no specific recommendations for surgical management. The aim of this study was therefore to retrospectively investigate overall survival (OS) and recurrence-free survival (RFS) of BRCA mutated patients with localized invasive breast cancer, by comparing conservative surgery versus mastectomy. Methods: This study was based on data from the Côte d'Or breast and gynecological cancer registry. Data from patients with a constitutional BRCA1/2 mutation who presented with invasive breast cancer were collected retrospectively from 1998 to 2018. The Kaplan-Meier method was used to describe RFS and OS. Results: A total of 104 patients were included in the analysis, of whom 69 had conservative surgery and 35 underwent mastectomy. Regarding survival, there was no significant difference in OS (HR =1.49; 95% confidence interval (CI) [0.76-2.93], p=0.25). Similarly, there was no significant difference in RFS (HR =1.40; 95% CI [0.81-2.40], p=0.22), survival without homolateral recurrence (HR =0.88; 95% CI [0.30-2.61], p=0.89), without contralateral recurrence (HR =1.50; 95% CI [0.55-4.09], p=0.42), or without distant metastatic recurrence (HR =1.42, 95% CI [0.69-2.90], p=0.33). Conclusion: In invasive breast cancer in a patient with a germline BRCA1/2 mutation, conservative surgery, when possible, appears to be a feasible option over total mastectomy, with no difference in overall survival. However, the patient should be informed of the aggressive nature of recurrence in this population requiring chemotherapy in most cases.

Background/Purpose

This study evaluates the toxicity after radiotherapy after mastectomy without reconstruction in patients irradiated to the chest wall using previously reported technique of PMERT.

Materials/Methods

We included all women irradiated after mastectomy for not metastatic breast cancer with PMERT between 2007 and 2011 in the Department of Radiation Oncology of the Institut Curie. Previously reported technique using mostly electrons was evaluated in terms of efficacy and toxicity.

Acute and late toxicities were assessed retrospectively using CTCAE v.4.0. A clinical exam was weekly performed during radiotherapy and one and three months following the completion of radiotherapy. Patients were then followed as recommended in Institut Curie guidelines (Senorif).

Quantitative and qualitative data were described respectively as means and proportions. Statistical comparisons were computed using X² or Fischer's exact test for categorical data. Recurrence free survival (RFS) was defined as the time between the end of treatment and the date of recurrence or death. Overall survival was the same but recurrences were not taken into account. Patients who did not experienced any event were censored at the date of last news.

Results

Among the 796 women included, 51.3% had multifocal lesions, 10.1% a triple negative (TN) status and 18.8% a HER2+ positive status; 196 (24.6%) received a neoadjuvant chemotherapy, and 208 (26.1 %) a systemic therapy during radiotherapy (chemotherapy and/or targeted therapy); 514 (64.6%) had at least one positive lymph node (LN). Internal mammary chain (IMC) was treated in 85.6% of cases, supraclavicular LN (L4) in 88.3% of cases, infraclavicular (L3-2-IP+/- L1) LN in 77.9% of cases and low axilla (L1) in 14.9% of cases. With a median follow up of 113 months [range : 2-164] locoregional recurrence-free survival and overall survival at 10 years were respectively 94.02 (IC95% : 92.13-98.94) and 79.84 (IC95% : 76.83-

82.97). The median survival was not reached.

In the long term, 29.6% of patients had telangiectasia (grade 1: 23.3%, grade 2: 5.2% Grade 3: 1.1%).

Totally 279 patients (35.1%) had breast reconstruction, on average 21 months after the end of radiotherapy.

Twenty-five patients (3%) had early esophageal toxicity, not exceeding the grade 1. Of these patients, 21 had had chemotherapy and all were irradiated on the lymph nodes (24 including the IMC).

Irradiation of the IMC was not associated with an increased chronic lung toxicity (OR=1.03 [0.98-1.09]).

There were 35 patients who developed heart disease after the end of the treatment. Of them, 30 patients had received anthracyclines ($p=1.05$) and 9 trastuzumab ($p=1.09$). Four patients developed ischemic heart disease, 3/4 irradiated on the left chest wall, all on the CMI and supra and infraclavicular LN, but all of them presented multiple cardiovascular risk factors (2 to 4).

Conclusions

Our series have shown that the PMERT using the Institut Curie technique is effective and well tolerated.

Problem Statement: Radiation therapy (RT) for breast cancer (BC) can induce skin and soft tissue fibrosis, raises concerns over cardiac and pulmonary injury, is associated with higher rates of lymphedema and shoulder dysfunction with regional nodal irradiation, and significantly increases complication rates in women undergoing implant-based reconstruction due to radiation toxicity. Although these toxicities are not generally associated with higher mortality, in general, they can represent significant setbacks with respect to quality of life. These toxicities dissuade some patients from breast conservation leading to unnecessary mastectomy and can lead patients to omit reconstruction after mastectomy or choose more extensive autologous breast reconstruction. Women with implant-based reconstruction and radiotherapy have known higher rates of reconstruction failure. **Purpose:** Ultra-high dose rate radiation (FLASH) has been shown to induce less normal tissue toxicity, therefore if tumor control of FLASH-RT would be comparable to conventional radiotherapy (CONV) then it has the potential to lower morbidity associated with radiotherapy for breast cancer and allow overall improved outcomes. At first, we aimed to determine the effectiveness of FLASH-RT compared to CONV in eradicating small breast tumors in an orthotopic BC model using single-fraction 20 or 30Gy RT to compare effectiveness of FLASH-RT vs CONV. **Methods:** Radiation sensitive, syngeneic mammary tumor cell line Py117, that efficiently forms non-metastatic orthotopic tumors in C57BL/6 mice, were injected (106 cells) into the left 4th mammary fat pad. 30mm³ tumors or a range of greater volumes (200-800mm³) were irradiated with single-fraction 20 or 30Gy with a 2x2cm radiation field (~17MeV beams), exposing only 5mm of the surrounding tissue. FLASH RT was delivered with 2Gy per pulse at dose rate ~200Gy/s compared to CONV dose rate of 0.13Gy/s **Results:** Single-fraction 20Gy suppressed 30mm³ tumor growth until ~day 15 post-RT then regrew for both FLASH and CONV, while 30mm³ tumors were eradicated with both FLASH and CONV at 30Gy. Larger tumors irradiated with 30Gy regressed until ~day 12 post-RT then regrew for both FLASH and CONV. There was no significant difference in growth suppression or tumor eradication between FLASH and CONV in any cohort. **Conclusion:** In this murine model of breast cancer, FLASH is as effective as CONV in controlling tumor growth. Future studies will extend the evaluation of the tumor control using clinically relevant fractionated dose schedules to be followed by comparisons of tumor control in xenograft models. Additional studies will assess normal tissue toxicity of FLASH vs CONV in murine models of implant-based breast reconstruction. We have established collaborations to understand differences in molecular pathways activated by FLASH vs CONV in tumor and normal tissue to explain the observed experimental differences in normal tissue, tumor, and cancer stem cells.

INTRODUCTION Extreme hypofractionation in patients with early-stage breast cancer has been studied in randomized phase III non-inferiority trials. There is scarce data on this strategy in Latin American patients. **OBJECTIVES** To describe the profile of patients diagnosed with breast cancer treated with radiotherapy with an ultra-hypofractionated regimen (5 fractions of 5.2 Gy, in one week), as well as the dosimetric aspects and acute toxicity related to the treatment. **METHOD** Retrospective cohort through a Brazilian uni-institutional series, with analysis of pathological, dosimetric, and toxicity variables. **RESULTS** Between May 2020 and March 2022, 67 patients were included, with a median age at diagnosis of 71 years (41-93). Regarding staging, 25.8% had in situ tumors, 60.6% of patients were IA, and only 3% were stage IIA. Nineteen percent of patients had histological grade 3; 24.6%, had nuclear grade 3. Hormone receptors were positive in 92.1% of patients. The mean ki67 was 19%, and HER2 was negative at 84.5%. All patients underwent conservative surgery, and 5 underwent reconstruction with autologous flaps. Fifty-one patients underwent hormone therapy and only 2 underwent adjuvant chemotherapy. All but two patients were treated with the conformal technique (VMAT was used due to unfavorable anatomy). The mean volume of the irradiated breast was 926 cm³ (ranging from 920 to 932 cm³). Regarding the constraints of the organs at risk, the average V8Gy of the ipsilateral lung was 11.4%, ranging from 0 to 24%. In the heart, the average volumes receiving 1.5Gy and 7Gy were, respectively, 9.2% and 0.7%. No patient had acute toxicity greater than grade 2. The effects on the skin appeared on average 20 days after the end of treatment, with resolution in a maximum of 3 months. The median follow-up time was 10 months (3 - 26). We did not observe any case of local-recurrence, of breast-cancer-related death. **CONCLUSION** Although our follow-up time is premature, we have found that ultra-hypofractionated radiotherapy was feasible, tolerable, and safe, for patients with early breast cancer. Also, the constraints on the organs at risk were respected. There were no high-

grade acute toxicities. Besides convenience, ultra-hypofractionation can improve access to radiotherapy in resource-scarce settings.

Objective Patients with hormone receptor positive (HR+), HER2- metastatic breast cancer frequently require radiation therapy (RT) in addition to systemic therapy for disease control and symptom management. CDK 4/6 inhibitors are increasingly used in the care of hormone positive breast cancers. Stereotactic body radiotherapy (SBRT), a form of very focused high dose radiation, is also increasingly used in the care of metastatic breast cancer. Limited data have reported on the safety of palliative RT with CDK4/6 inhibitors, with some reports demonstrating synergistic effects with potential for increased toxicity. The objective of our study is to assess toxicity among patients who received SBRT, stereotactic radiosurgery (SRS), or other high dose RT along with CDK 4/6 inhibitors for treatment of metastatic breast cancer. Methods Women with metastatic breast cancer who received SBRT, SRS, or other higher dose RT with CDK 4/6 inhibitors at any point in their treatment between 2013 and 2021 were retrospectively identified. Timing of radiation therapy, either before, during, or after CDK 4/6 inhibitor use was assessed, as well as the interval between the two treatments. Treatment sites

for radiotherapy included lung/chest, spine, and brain metastases. Physician assessed adverse events were obtained through clinical follow up and graded using CTCAE v5. Local control and OS were reported. Results Twenty patients met study inclusion criteria. Patients received radiation therapy and CDK 4/6 inhibitors concurrently (within 7 days) [n=7, 35%], within 30 days (RT pre-CDK 4/6 inhibitor use) [n=3, 15%], and greater than 30 days (RT pre-CDK 4/6 inhibitor use [n=6, 30%] and RT post-CDK 4/6 inhibitor use [n=4, 20%]). Radiation treatment sites were spine [n=10, 55%], brain [n=6, 30%], and lung/chest wall [n=3, 15%]. Radiation doses were as follows: 60 Gy in 5 fractions [n=1, 5%], 50 Gy in 5 fractions [n=2, 10%], 55 Gy in 20 fractions (chest wall recurrence) [n=1, 5%], 35 Gy in 15 fractions [n=1, 5%], 30 Gy in 10 fractions [n=6, 30%], 30 Gy in 3 fractions [n= 4, 20%], 24 Gy in 1 fraction [n=3, 15%], 20 Gy in 5 fractions [n=2, 10%]. Palbociclib was used in 85% of patients [n=17] and abemaciclib in 15% [n=3]. Median follow up for surviving patients was 4.7 years [IQR: 2.5-6.8 years]. Local control was achieved in 85% of patients [n=17]. Median OS was 2.7 years [IQR: 0.1-6.8 years]. Grade 2 toxicity [n=9, 45%] and grade 3 toxicity [n=3, 15%] was reported across all three treatment areas, with grade 2 or 3 fatigue [n=7, 35%] being the most frequently reported toxicity. In the spine treatment group, 1 patient who had CDK 4/6 inhibitor use within 30 days of radiotherapy experienced a grade 3 vertebral compression fracture as well as grade 3 fatigue. In the lung/chest wall treatment group, the patient treated to 55 Gy in 20 fractions to the chest wall with concurrent use had grade 3 skin/wound toxicity requiring prolonged wound care before healing. In the intra-cranial SRS group, grade 3 fatigue was reported in 1 patient with concurrent use. Conclusion The use of CDK 4/6 inhibitors concurrently with or within 30 days of radiation therapy was generally well tolerated with limited grade 3 toxicity. Two of three reports of grade 3 toxicity occurred with concurrent treatment. Due to the potential radiosensitizing properties of CDK 4/6 inhibitors, it may be prudent to hold combined treatment when clinically feasible. Further study is needed to validate these results.

Introduction & Objective This report highlights an unusual presentation of skin metastasis of inflammatory breast cancer that resembles a rare condition called Carcinoma en Cuirasse (CeC). CeC was first described by anatomist Alfred Velpeau in 1838 when he observed how the coalescing nodules and diffuse sclerodermoid induration found on the chest and abdomen in CeC resembled the medieval steel breastplate or a cuirasse. **Case Presentation** A 62-year-old female presented to the emergency department for evaluation of a palpable left breast mass and concurrent skin lesions for the past 5 months. Based on the erosion of the nipple, chest CT, as well as core needle and skin biopsy, a diagnosis of stage IV (cT4d, cN3, cM1) ER+, PR-, HER2/neu- advanced/ inflammatory breast carcinoma was made. The patient underwent a 20-week course of neoadjuvant chemotherapy followed by 25 treatments of neoadjuvant external beam radiotherapy (EBRT) with a total dose of 5000cGy to the left breast and the regional lymph node due to disease progression after 4 cycles of neoadjuvant chemotherapy. She proceeded to bilateral modified radical mastectomy and bilateral lymph node involvement was found, and later disease progressed with skin involvement outside the EBRT treatment field. Additional 25 treatment of palliative radiotherapy was utilized with another 5000cGy, followed by 2 months of chemotherapy to provide better palliation and quality of life. Upon completion of therapy, a unique skin metastasis pattern was noticed. Shortly afterward the patient passed away from severe sepsis secondary to multiple wounds infected by drug-resistant *Pseudomonas aeruginosa* followed by *Clostridium difficile* colitis. **Conclusion** This case shows clinical characteristics of Carcinoma en Cuirasse and provides important considerations for more research to be done to highlight the unique pattern of skin metastasis following radiation and the potential use for radiation to treat chemotherapy-resistant skin metastasis from recurrent invasive breast carcinoma.

Purpose: The role of post-mastectomy radiation therapy (PMRT) in breast cancer patients after neoadjuvant chemotherapy (NAC) is highly controversial. This study aimed to evaluate the impact of PMRT according to pathologic nodal status. **Methods and Materials:** We retrospectively reviewed 682 patients with clinical stage II-III breast cancer who underwent NAC and mastectomy from 2013 to 2017. Of total, 596 (87.4%) received PMRT and 86 (12.6%) did not. We investigated the relationship amongst locoregional recurrence-free survival (LRRFS), disease-free survival (DFS), overall survival (OS), and various prognostic factors. Subgroup analyses to identify the patients who may benefit from PMRT were also performed. **Results:** The median follow-up duration was 67 months. In ypN+ patients (n = 368, 51.2%), PMRT showed significant benefit for LRRFS, DFS, and OS (all $p < 0.001$). Based on multivariate analysis, histologic grade (HG) III (hazard ratio [HR] = 3.67, $p = 0.002$), lymphovascular invasion (LVI) (HR = 2.38, $p = 0.045$), and ypN2-3 (HR = 2.37, $p = 0.02$) were identified as significant risk factors for poor LRRFS. In ypN1 patients with more than two factors among (i) luminal subtype (ii) HG I-II and (iii) absence of LVI, PMRT showed no significant difference in LRRFS ($p = 0.18$). In ypN0 patients (n = 351, 48.8%), PMRT was not significantly associated with LRRFS, DFS, and OS. However, PMRT showed better LRRFS in triple-negative breast cancer (TNBC) subtype ($p = 0.04$). **Conclusion:** PMRT had a high impact on treatment outcomes in patients with residual lymph nodes following NAC and mastectomy. Among the ypN0 patients, PMRT may be beneficial only in the TNBC subtype.

Purpose: To determine the rate of rib fracture in a cohort of patients with breast cancer treated with proton therapy and enrolled on a prospective registry. In series investigating photon therapy for breast cancer, the rib fracture rate ranges from 0.3-13% Methods: From a prospective database, we identified patients treated with proton therapy for breast cancer at our institution between January 1, 2012 and December 31, 2020. Clinical and dosimetric data was extracted from the electronic medical record. The cumulative incidence method assessed rib fracture rate; the Fine-Gray test statistic assessed prognostic significance select variables. Results: 225 patients were identified, 223 women and 2 men. Median age at the time of radiation was 57.8 years (range, 25 – 87). 26% of patients were black, 69% white and 5% were other races or race not disclosed. 5% were Hispanic. 74% of patients had left-sided breast cancer, 5% bilateral, and 21% right-sided. DEXA scan was normal in 20%, showed osteopenia in 34%, osteoporosis in 6%, and not performed in 40%. 57% of patients received antiendocrine therapy with an aromatase inhibitor. For 16% of patients, the breast +/- internal mammary nodes (IMN) were treated, while 32% underwent proton therapy to treat the breast and comprehensive regional lymphatics. 1% of patients had chest wall +/- IMN treated, while 51% underwent proton therapy to treat the chest wall and comprehensive regional lymphatics. 41% of patients were treated with passive scatter proton therapy (n=92); 52% of these had mastectomy. 58% of patients received treatment with pencil beam scanning (PBS) proton

therapy (n=131); 53% of these had mastectomy. A combination of passive scatter and PBS was used for 2 patients (1%). 85% of patients received a boost. Median follow-up was 3.1 years (range, 0.2 – 9.1). 97% of patients had > 12 months of follow-up. The 3 year cumulative incidence of in-field rib fracture was 3.7% (95%CI: 1.6%-7.1%). In total, 8 patients developed in-field rib fractures, one symptomatic and 7 identified incidentally on surveillance imaging, for a 0.4% rate of symptomatic rib fracture. Median time from completion of radiation to identification of rib fracture was 1.8 years (range, 0.4-7.4 years). Rib fractures occurred within 2.2 years from radiotherapy completion for seven of the eight patients who experienced this side effect. Three patients developed rib fractures outside of the radiation field, for a cumulative incidence of out-of-field rib fracture of 0.9% (95%CI: 0.2-3.0%). No variables were associated with rib fracture on univariate analysis. Of those with in-field rib fractures, 3 had low and 3 had normal bone density while 2 had not undergone testing; of those with out-of-field rib fractures, 2 had osteopenia and 1 did not have testing. Conclusions: Although a proton beam has higher biological dose deposition at end-of-range than the assumed constant RBE=1.1, the 3 year rate of any in-field rib fractures in our series remains low at 3.7%, with a 0.4% rate of symptomatic rib fracture. Contouring ribs as an OAR and establishing a dose constraint warrants further investigation as a means to maintaining a low rate of rib fracture with proton therapy.

Brain edema is a complication of radiation used to treat brain metastasis (BM) in which the brain parenchyma accumulates fluid and ions, often leading to the suspension of systemic anticancer treatment. While brain edema is often attributed to disruption of the Blood Brain Barrier (BBB), RTx induces cytotoxic-edema, a premorbid cellular process whereby extracellular Na⁺ and other cations enter into neurons and astrocytes and accumulate intracellularly, resulting in osmotic expansion of the cells and necrotic cell death. Aquaporin 4 (AQP4) is a main regulator of osmotic expansion (water intake) in astrocytes and we have shown that RTx upregulates AQP4 in astrocytes and leads to astrocytic swelling in vitro. However, whether pharmacological modulation of AQP4 could be used to prevent cytotoxic brain edema in RTx-treated BM and its impact on metastatic tumor progression remains unknown. Goal: To determine if the FDA-approved drug Topiramate (TPM), an anti-epileptic drug able to inhibit AQP4) can prevent astrocytic swelling in vitro, reduce RTx-induced brain edema and modulate brain metastatic progression. Results: Electron microscopy of brain cortex from mice treated with 35 Gy RTx showed acute astrocytic end-feet swelling and increase in AQP4 expression compared with non-irradiated mice. A single 8 Gy dose increased astrocytic cell area of human astrocytes by 4.8 fold compared with non-irradiated cells 24 h after RTx. This increased cell-swelling did not result from senescence-associated cellular hypertrophy, as staining of senescent β -galactosidase positive (SA- β -Gal+) cells showed that Rtx-induced astrocytic area only increased significantly in non-senescent (SA- β -Gal- cells). shAQP4s reduced AQP4 levels by 60% and 50%, respectively, and significantly reduced RTx-induced

astrocytic swelling. Since there are no FDA-approved AQP4 inhibitors, we tested whether the AQP4-blocking function of TPM could be sufficient to prevent cytotoxic edema, prevent BBB dysfunction and protect from necrotic cell death in vitro. TPM pretreatment did not alter radiation-induced ERK1/2 or AKT activation (a known maker of radioprotection) in astrocytes, but TPM decreased radiation-induced PARP-cleavage, pP38 and pJNK levels. TPM prevented loss of Trans-electric epithelial resistance (TEER) of Rtx-treated astrocytes, but was not able to protect astrocytes from ultimate cell death. Immunohistochemical analysis of a cohort of breast cancer BM showed heterogeneous AQP4 expression in cancer cells ranging from 1.6% to 91% AQP4+ tumoral areas and from 0.6% to 86.9% in stroma. AQP4 inhibition using shRNAs decreased proliferation and survival of AQP4 + 231BR, and EO711 cells in vitro. However, TPM did not alter survival of AQP4+ or AQP4- cells in vitro, suggesting that while AQP4 expression is important for survival of AQP4+ cells in vitro, the inhibition of AQP4 function by TPM is not sufficient to decrease their growth. To determine if TPM could decrease brain edema without negatively impacting tumor progression, female NSG mice were injected intracardially with JmT1BR3 AQP4-cells and ten days later randomized to (1) RTx + vehicle, (2) RTx + TPM (2 days prior to irradiation), (3) Non-RTx + vehicle, and (4) Non-RTx + TPM. TPM decreased brain-water content (a marker of brain edema) in irradiated mice as compared with vehicle-treated mice, without alteration of metastatic burden 21 days post-injection. However, a similar study using AQP4+ E0711 cells in C57Bl6 mice showed TPM was less effective in decreasing brain water content and resulted in a significant increase in extracranial metastatic tumor burden, suggesting that TPM can promote tumor progression by non-tumor intrinsic mechanisms. Conclusions: while TPM shows promise in preventing RTx-induced brain edema, our results show a potential pro-tumorigenic mechanism for TPM that warrants further investigation.

Background Breast cancer is the second most common cause of brain metastases (BM). Despite increasing incidence of BM in elderly patients, there is limited data on the optimal management of BM in this age group. In this study, we assessed the survival outcomes and treatment patterns of elderly breast cancer patients with BM (≥ 65 yo) treated at our institution and compared them to younger patients. **Methods** An IRB-approved single-institutional review of biopsy-proven breast cancer patients with BM treated with 1 to 5-fraction stereotactic radiation therapy (SRT) from 2015 to 2020 was performed. Primary endpoint was intracranial progression free survival (PFS) defined as time interval between end of SRT to date of first CNS progression. Secondary endpoints were overall survival (OS) from end of SRT, and radiation treatment patterns. Kaplan-Meier estimates, and Cox proportional hazard regression method were used for survival analyses. SPSS v26.0 was used for statistical analysis and p -value < 0.05 was considered significant. **Results** A total of 115 metastatic breast cancer patients with BMs were included of which $N=29$ were ≥ 65 yo and $N=86$ were < 65 yo. They received a total of 43 and 143 courses of stereotactic linac-based radiation therapy (RT) respectively to a mean number of 4.3 BM lesions (range 1-22). Median age at RT was 70 years (range 65-84) compared to 50.5 years (31-64) in younger patients. About 55.2% of elderly patients were ER/PR positive/Her2 negative (vs 24.4% in younger cohort), 31% were Her2 positive (vs 41.9%) and 13.8% were triple negative (vs 33.7%). Among patient characteristics, there was significant difference among elderly and young patients in hormone receptor status ($p = 0.016$); CNS only oligometastatic disease (0% vs 11.2%, $p = 0.005$); and the presence of extracranial disease at SRS (97.7% vs 79.7%, $p < 0.001$). There was no significant difference between the two age groups in Karnofsky performance score (KPS) (62.7% vs 45.5% with $KPS \leq 80$, $p = 0.131$), number of brain lesions treated (23.2% vs 30.1% with ≥ 5 BMs, $p = 0.445$), number of patients receiving prior whole brain radiotherapy (WBRT) (10.3% vs 19.8%, $p = 0.062$), surgery (23.2% vs 30.1%, $p = 0.592$), systemic therapy (including chemotherapy, targeted therapy and endocrine therapy) after SRT (86% vs 86.7%, $p = 0.543$), and salvage WBRT (10.3% vs 19.8%, $p = 0.134$). Median OS after RT was poorer in patients ≥ 65 yo compared to younger patients (7.9 months vs 14.4 months, $p = 0.020$), while intracranial PFS from RT was similar (8.5m vs 6.5m, $p = 0.345$). The rates of freedom from neurological death and leptomeningeal disease (LMD) at 1 year were similar between the two groups (83.3% vs 87%, $p = 0.780$ and 87.6% vs 73.3%, $p = 0.627$, respectively). On univariate analysis, significant predictors of survival were age ≥ 65 yo (hazard risk, HR = 1.56), $KPS < 80$ (HR = 1.69), extracranial progression at RT (HR = 2.44), systemic therapy after RT (HR = 0.28) and LMD (HR = 1.57). On multivariate analysis, age was not a significant factor for survival after adjusting for KPS, extracranial progression and systemic therapy. **Conclusions** Although elderly women had poorer OS than younger women, OS was similar after adjusting for KPS, extracranial progression and systemic therapy; and there was no difference in rates of intracranial PFS, neurological deaths and LMD in the different age groups. This study suggests that age alone may not play an independent role in treatment-selection and outcomes for breast cancer patients with BMs and personalized decision making including other clinical factors

should be considered. Future studies are warranted to assess neurocognitive outcomes and other radiation treatment toxicities in elderly patients.

BACKGROUND:

The role of multi-lumen catheter devices in the delivery of high dose rate (HDR) brachytherapy for adjuvant accelerated partial breast irradiation (APBI) for women with DCIS or early-stage breast cancer has been well established. In vivo dosimetry (IVD) using optically stimulating luminescence dosimeters (OSLD) is a feasible way to detect applicator instability that may cause translational and rotational inaccuracies during HDR brachytherapy delivery. Herein, we evaluate the accuracy and effectiveness of IVD to improve patient outcomes following APBI brachytherapy using the Strut Adjusted Volume Irradiation (SAVI) device.

METHODS:

Single-institution cohort study piloting the use of OSLD on the patient's skin during HDR brachytherapy APBI to assess the estimated maximum skin dose (skin D_{max}) and the achievable accuracy of OSLD for skin D_{max} measurements. Women treated with SAVI-based APBI between November 1, 2018 and October 1, 2021 were eligible to enroll in our study. All patients met the American Society for Radiation Oncology "suitable" or "cautionary" criteria and were treated according to the American Brachytherapy Society consensus treatment planning guidelines. A SAVI preplan was created to estimate the probable point of skin D_{max}. During CT simulation, a radiopaque marker was placed on the skin for visualization during treatment planning. Correction factors were applied to account for the OSLD tissue-air interface that is not present in the TG-43 expected dose calculations. Measured and calculated IVD doses were

analyzed to assess agreement and cause for discrepancies found. Breast phantom IVD measurements repeated seven times with two independent dose points were analyzed to assess the best accuracy achievable under ideal conditions.

RESULTS:

We enrolled 41 patients with an average age of 68 years. Table 1 details the brachytherapy treatment delivery and dosimetry data. Higher skin Dmax as a percentage of the radiation prescription was associated with the occurrence of breast volume loss noted on subsequent clinical breast exams (OR 1.84 per each 5% increase in skin Dmax; 95% CI 1.21 – 3.32; p=0.016). The graphically estimated skin Dmax threshold was 80% with all cases of noted breast volume loss occurring above this threshold. The overall level of achievable IVD accuracy was $\pm 3.32\%$ based on breast phantom measurements. Under ideal conditions, all measurements were in the $\pm 7\%$ range. Three of 14 phantom measurement exceeded the 6% discrepancy range. Clinical IVD measurements detected 5 true positive cases (12.2% of cohort) that required intervention due to rotations in the SAVI applicator. For a $\pm 7\%$ tolerance criteria, 90.2% of the patients tested passed IVD. Of the eight patients that failed at the 7% level, IVD detected 3 OSLD placement errors, 2 rotational discrepancy cases, and 1 large air-gap at the point of measurement.

CONCLUSIONS:

Accuracy and reproducibility are imperative tenets of HDR brachytherapy APBI. IVD utilizing OSLD is an effective method for detecting treatment set-up and delivery errors for patients receiving SAVI-based APBI with dose accuracy within $\pm 3.32\%$. Errors requiring intervention due to SAVI device rotation were detected in 12.2% of our cohort, and these errors would have likely gone undetected without IVD. Using OSLD as IVD to measure skin Dmax doses that may increase the risk of breast cosmetic defects should be investigated further.

Table 1. Brachytherapy treatment delivery and dosimetry data

SAVI Applicator Size	Total, no. (n=41)
6-1	16
8-1	23
10-1	2

Purpose

Whilst radiotherapy increases cure rates in breast cancer, lung cancer, among others, it may also involve some cardiac exposure, which in turn may increase the risk of different heart diseases. The heart is a complex anatomical organ that involves many different structures making it difficult to contour cardiac sub-structures reproducibly. Contouring, especially for these cases, suffers from inter- and intra-expert variability while being time consuming. Cardiac atlases have been developed to aid in the delineation of cardiac substructures. However, these methods have many shortcomings, including the inability to overcome variations in patient anatomy. In this study, a deep learning based commercial solution for automatic OAR delineation was trained following international guidelines for heart substructures delineation and tested on an unseen cohort of lung and breast patients to evaluate its clinical acceptability.

Methods

ART-Net, a CE-marked, FDA-cleared anatomically preserving deep-learning ensemble architecture for automatic annotation of OAR was evaluated using data of 20 breast/lung patients from 2 centers. Automatic annotation of 27 different structures (Ventricles (left and right), atria (left and right), left ventricle (anterior, apical, inferior, lateral, septal), LAD coronary (mid, proximal, distal, total), circumflex coronary (distal, proximal, total), RCA (distal, mid, proximal, total), coronary sinus, left main coronary artery, ascending aorta, pulmonary arteries, vena cava inferior, vena cava superior and the heart) was performed and submitted to 2 experts across 2 centers for qualitative evaluation. Contours were scored as A/acceptable, B/ acceptable after minor corrections, and C/ not acceptable for clinical use. To avoid any bias, experts were blind to whether the contour were manually, or AI delineated. The DSC between automatic and manual (ground truth) contours of the heart sub-structures were evaluated and compared with interobserver variability from the literature [1,2] using average and min DSC scores.

Results

Automatic contours were generated in a mean time of 0.5s per scan slice. Out of the 27 structures, 20 were considered clinically acceptable in the qualitative study. In the inter-expert variability study, 12 structures passed the test successfully using initial acceptance criterion over an acceptable sample size and 9 other structures demonstrated performances above the minimal threshold of inter-expert variability, sometimes on smaller datasets due to lack of manual data. Overall, 16 structures were included in the final model. 13 structures were considered clinically acceptable in 100% of the cases with AI contours rated at the same level as manual contours. For the other 3 structures (coronary sinus, left main coronary artery and vena cava inferior), the performance of the AI contours was slightly below that of the manual contours (within 3.4% difference), with the least performing structure being the coronary sinus (84% for AI vs 87% manual).

Conclusion

We show first results for the evaluation of AI-based auto-contouring tool for annotation of the substructures of the heart. The results show very good clinical acceptance, highlighting the high usability of the commercial tool for cardiac cases and its clinical implementation feasibility. The use of this AI tool can facilitate and accelerate future research studies investigating relationships between substructure doses and cardiac outcomes. Future work will include improvement of the sub-structures (mid, proximal, distal) and a retrospective meta-analysis to assess heart sub-structures degree of importance in terms of toxicity.

Purpose: The economic evaluation reports the incremental cost utility ratio and budget impact of APBI vs standard external beam WBI for the treatment of post-menopausal women with early stage breast cancer.

Methods and materials: We compared 488 women in the standard arm (1 fraction per day delivered 5 days per week over 3 or 6/6.5 weeks) to 490 women in the ABPI arm (ten fractions delivered twice per day over one week). We took the perspective of the healthcare system, a 3-year time horizon; the outcomes were quality adjusted life years (QALYs). QALYs were calculated from the EQ5D5L questionnaires at baseline, 3 months, 6 months, 12 months and yearly after irradiation; scores were converted into utilities using the French value set and QALYs computed with the area under the curve approach. Measures of within-trial use of hospital resources were based on routine hospital data via patient-level information. We used the itemized and DRG cost data from each individual patient. Transportation costs were added in a sensitivity analysis. A 2.5% discount rate was applied to costs and QALYs. An incremental analysis with differences in costs and QALYs was performed to calculate the cost utility ratio. Bootstrapping was used to quantify uncertainty on the joint distribution of costs and outcomes, and 1,000 paired estimates of mean differential costs and QALYs were reported on a cost-effectiveness plane. A budget impact analysis based on incidence of breast cancer estimates was added. All analyses followed the intent to treat principle.

Results:

Cost and utilities were available for the entire population. Costs and QALY results are presented in table 1. The 2 925 € (95% IC, -3 364 €; - 2 452 €) significant difference in total costs favoring ABPI was driven by the difference in radiotherapy costs and partly by lower transportation costs. No significant difference was found in QALYs.

Figure 1 shows the uncertainty of the joint distribution of costs and QALYs. All replication are in the lower half of the plane indicating that ABPI is cost saving with QALYs distributed on each side of the vertical axis indicating equal distribution of QALYs.

would be eligible for treatment with ABPI. The uptake of ABPI for 16% of these women would result in a 16 million€ cost saving.

Conclusions

At three years, ABPI for the treatment of postmenopausal women with early-stage breast cancer was found to be cost saving, with no difference in outcome measured by QALYs.

Table 1:

	ABPI N=490	Standard of care N=488	P value
Radiotherapy (€)	2 369 (±1 300)	4 323 (±1 228)	< 0.001
Transportation (€)	657 (± 854)	1 663 (± 1 312)	< 0.001
Subsequent admissions(€)	180 (± 1 494)	145 (± 1 137)	0.678
Total 3-year costs (€)	3 206 (± 2 465)	6 131 (± 2 315)	< 0.001
QALYs	2,383	2,377	0.964

Abstract: Background: There is assumption that omitting the internal mammary chain radiotherapy (IMC RT) in patients with breast cancer (BC) will significantly reduce the cardiac exposure for all patients regardless the cardiac anatomy of each patient. Aim: to evaluate the impact of IMC RT on the dose received by the heart and its chambers in patients with favorable versus unfavorable cardiac anatomy. Patients and methods: CT scans were obtained of 20 patients with left-sided BC, 10 with favorable and 10 with unfavorable cardiac anatomy. Three plans were generated for each patient, one treating only the breast with tangents, and one treating the breast and IMC with wide photon tangents, and one treating the breast and IMC to 50Gy with photon tangent fields and a matching medial electron field. Dose volume histograms (DVHs) were generated for the heart and chambers. The equivalent uniform doses (EUDs) were calculated for each DVH, and the mean EUDs for plans with unfavorable and favorable cardiac anatomy were compared using a two-sided two-sample T-test Results: The mean dose received by the heart from plans with tangents plus IMC fields in patients with favorable cardiac anatomy was significantly lower than that received from plans with tangents only or wide tangents in patients with unfavorable anatomy ($P < .0001$). The average EUD for plans with tangents and IMC fields in the favorable group was 16 Gy (SD = 4.5) as compared to 36 Gy (SD = 3.6) and 37 Gy (SD = 5.1) for plans with tangents only and wide tangents in the unfavorable group, respectively ($P < .0001$). The doses to the right ventricle were not significantly different. Conclusions: Treatment plans should be individualized based on the cardiac anatomy of each patient.

Concious sparing of contralateral thyroid lobe in Ca Breast patients receiving post mastectomy radiotherapy by IMRT technique – A single institution dosimetric study

Purpose/Objective(s):

The purpose of this paper is to report the dosimetric effects of conscious sparing of contralateral lobe of thyroid gland in carcinoma breast patient receiving locoregional radiation by tangential beam Intensity Modulated radiotherapy technique.

Materials/Methods:

Treatment plans of 20 Ca Breast patients , who received post mastectomy adjuvant locoregional radiotherapy, were evaluated. Since October 2021 we adopted a department protocol of conscious sparing of contralateral thyroid in breast radiotherapy. 10 of these had conscious sparing of contralateral thyroid (group A) whereas 10 of old plans were evaluated when C/L thyroid were not given constraints & are being passively spared due to location on contralateral/non treatment side of neck (group B). Treatment planning was done using tangential beam (6 MV) IMRT in Eclipse 13.7 TPS in all of these patients. All of these patients received treatment to chest wall & SCF. RTOG contouring guidelines were followed in all the patients. Prescription Dose was 40Gy in 15# for both groups. The best treatment plans were selected ensuring 95% PTV dose coverage and acceptable dose to OARs. Uniform contouring, plan optimization & evaluation protocols were followed for all of these patients.

Results:

The mean thyroid volume in group A is 4.30cc & in group B is 3.99cc which is not statistically

different (P value -0.639)

The mean dose of thyroid in group A is 7.98Gy whereas in group B it is 17.00Gy which is spastically significant (P value – 0.000003).

Comparison of mean dose to contralateral lobe (in Gy) between the two groups

Groups No. Mean ± SD 't' value P value

Thyroid dose with constraint 10 7.98±1.46 -6.702, df=18 0.000003*

Thyroid dose without constraint 10 17.00±3.99

Unpaired 't' test applied. P value = 0.000003, Significant

Conclusion:

OARs present on contralateral side are passively spared due to the location. This often results in a tendency of not actively prescribing constraints to these. This study emphasizes that conscious sparing of contralateral Thyroid lobe can further reduce the dose to significant levels. This reduction can preserve thyroid function further. Further clinical trials are required to corroborate this dosimetric gain with clinical thyroid function preservation.

Groups	No.	Mean ± SD	't' value	P value
Thyroid dose with constraint	10	7.98±1.46	-6.702, df=18	0.000003*
Thyroid dose without constraint	10	17.00±3.99		

Unpaired 't' test applied. P value = 0.000003, Significant

Introduction: Exposition of cardiac conduction system during breast radiotherapy has never been studied, despite increasing use of intensity modulated radiotherapy which expose larger volume to low dose bath. We evaluated conduction node exposure during breast irradiation with volumetric modulated arctherapy (VMAT) and estimated the potential dosimetric benefit with intensity modulated protontherapy (IMPT). Materials and methods: Atrioventricular (AVN) and sinoatrial (SAN) nodes were retrospectively delineated according to published guidelines on the simulation CT scans of twelve breast cancer patients having undergone conserving surgery and adjuvant locoregional VMAT. IMPT treatment was re-planned on the simulation CT scans for all breast cancer patients. Mean and maximum doses to the SAN and the AVN were retrieved and compared. Correlation coefficients were calculated between doses to the SAN or the AVN and to the whole heart. Results: Average mean doses to the SAN and to the AVN were 2.8 Gy and 2.3 Gy respectively for left-sided irradiation and 9.6 Gy and 3.6 Gy respectively for right-sided irradiation. Average maximum doses to the SAN and to the AVN were 3.5 Gy and 2.8 Gy respectively for left-sided irradiation and 13.1 Gy and 4.6 Gy respectively for right-sided irradiation. IMPT significantly reduces doses to conduction nodes. Correlations between doses to the SAN or the AVN and the whole heart were usually significant. Conclusion: SAN and AVN can be substantially exposed during breast VMAT, especially for right-sided irradiation. Cardiotoxicity studies evaluating conduction node exposure might define dose constraints and criteria for additional cardiac sparing techniques, such as respiratory techniques or proton therapy, which could be beneficial to patients with underlying rhythmic or conduction disorders.

Axillary radiotherapy in selected patients with a preoperative diagnosis of lymph node involvement is a safe alternative to axillary lymph node dissection.

Introduction

Axillary lymph node dissection (ALND) is associated with significant morbidity. Randomised data [1,2] suggest that axillary radiotherapy (RT), or no further axillary treatment beyond sentinel node biopsy (SNB) may be safe. There are very few studies to guide the management of preoperatively diagnosed lymph node metastases either in the context of neoadjuvant

chemotherapy (NACT) or direct to surgery. The current UK recommendation is for ALND. In 2015 our policy changed to RT for carefully selected patients after MDT discussion. These data look at axillary recurrence for those patients having axillary RT

Methods

Data were retrospectively collected on patients with preoperatively diagnosed lymph node metastases between January 2016 and December 2020. Patients undergoing surgery with a curative intent were included. The decision to offer axillary RT was made in the MDT based on clinical and radiological findings and the burden of disease in the axillary sample. Axillary recurrence was defined as disease recurring in the axilla with no distant disease.

Results

Data were collected on 132 patients. Demographics and tumour status are outlined in Table 1. 55% of patients had neoadjuvant chemotherapy with a 52% path CR in the axilla. Table 2 gives the results for the axillary RT group. During the same time period 25 patients had ALND. Of those 2 (8%) had isolated LN recurrence. 18 patients had axillary RT following positive SLN after NACT. There was a single patient with axillary recurrence in this group.

Conclusion:

In the absence of randomised data to guide practice, these data show that in selected patients axillary radiotherapy is safe after axillary node sampling. The decision should be based on axillary burden, tumour biology, MDT and patient discussion. We await with interest the results of the Alliance A011202 trial to guide practice in patients having NACT in N1 disease.

Aims and Objectives – To evaluate the safety of adjuvant chemo-radiation (CTRT) for breast cancer. We report the cardio-pulmonary safety and quality of life outcome of this regimen.

Methods – Stage II-III invasive breast cancer patients planned for adjuvant taxane-based chemotherapy and adjuvant radiotherapy (RT) between April 2019 to December 2020 were eligible irrespective of prior neo-adjuvant therapy. Patients received standard 3D conformal radiotherapy (40 Gy in 15 fractions over 3 weeks ± boost for breast conservation) along with the third cycle of adjuvant taxanes in a 3- weekly schedule or the eighth cycle in a weekly schedule. Troponin T, echo cardiography and pulmonary function test were done pre-RT and repeated at 6 months from RT conclusion while quality of life was evaluated pre-RT, at RT conclusion and after 6 months using EORTC QLQ C30 and BR23.

Results – Sixty patients were analysed. The median ejection fraction pre and post CTRT was 60% (p=0.177). The median value of Troponin T at baseline was 37 which decreased to 20 post CTRT (p=0.009). Of the 54 patients who underwent the PFT, the functional vital capacity (FCV) was 2.29 litres at baseline which was 2.2 litres post CTRT (p=0.375). No significant difference was seen for forced expiratory volume (FEV) at 1 second (1.86 vs. 1.82; p=0.365), FEV1/FVC (81.5 vs. 81.43; p=0.9) and diffusing capacity for carbon monoxide (DLCO) (88.3 vs. 87.6; p=0.62) at baseline and post CTRT respectively. There was a significant improvement in QOL scores for nausea, vomiting, pain, constipation, loss of appetite and hair loss post RT 6 months.

Conclusion- Patients treated with taxane-based adjuvant CTRT had stable cardio-pulmonary profile at 6 months compared to pre-RT. Quality of life scores improved after treatment for most of the domains compared to the pre-RT scores.

Table 1: Calculated scores of EORTC QLQ-C30 and BR23 scales for breast cancer patients at baseline, post CRT and at first follow up of six months.

Background

DESTINY-Breast04 demonstrated that the HER2 targeting antibody–drug conjugate trastuzumab deruxtecan (T-DXd) significantly prolonged progression-free survival (PFS) and overall survival (OS) vs treatment of physician’s choice (TPC) in patients (pts) with HER2-low

(immunohistochemistry [IHC] 1+ or IHC 2+/in situ hybridization negative) metastatic breast cancer (mBC) in pts in the hormone receptor-positive (HR+) cohort and all pts (HR+ and HR-; median PFS, 9.9 vs 5.1 months [mo], hazard ratio: 0.50; median OS, 23.4 vs 16.8 mo, hazard ratio: 0.64; both $P < 0.0001$; Modi et al. N Engl J Med 2022). Objective response rate (ORR) with T-DXd was $\geq 50\%$ across cohorts. These subgroup analyses examine pt history and disease characteristics that may correlate with response to therapy.

Methods

N = 557 pts with centrally confirmed HER2-low mBC were randomized 2:1 to T-DXd or TPC. Randomization was stratified by HER2 status (IHC 1+ vs 2+), 1 vs 2 prior lines of chemotherapy, and HR+ (with vs without prior treatment with cyclin-dependent kinase 4/6 inhibitor [CDK4/6i]) vs HR-. With the exception of the PFS and OS analyses by prior CDK4/6i use, all other described efficacy analyses were assessed post-hoc.

Results

Benefit of T-DXd vs TPC was consistent in pts with or without prior CDK4/6i use (Table 1). Pts with high disease burden (ie, ≥ 3 metastatic sites) also benefited from T-DXd vs TPC (Table 2). There was a small subgroup (n = 22) among all pts (HR+ [n = 18] and HR- disease [n = 4]) with rapid progression prior to enrollment (disease progression within 6 mo of concluding a prior course of chemotherapy in early breast cancer). T-DXd showed responses in 7/14 (50%) pts in this subgroup vs 0/8 with TPC; this subgroup also had prolonged median PFS with T-DXd vs TPC (Table 3). Efficacy data for HER2 IHC 1+ vs 2+ and prior chemotherapy subgroups will be presented. Median OS was not reached for many subgroups (insufficient events in each group [data not shown]); however, subgroups in general showed OS benefit consistent with the primary analysis. With T-DXd, rates of interstitial lung disease/pneumonitis were similar in pts with/without prior CDK4/6i use.

Conclusions

T-DXd treatment for HER2-low mBC in the phase 3 study DESTINY-Breast04 showed consistent efficacy independent of disease burden, prior CDK4/6i treatment, or rapid progression status. ILD is an important identified risk and requires proactive monitoring and management. These data continue to support the use of T-DXd as the new standard of care across subgroups of pts with HER2-low mBC.

Editorial Acknowledgment

Under guidance of the authors, assistance in medical writing and editorial support was provided by Eileen McIver, PhD, and Soniya Patel, PhD, of ApotheCom, and was funded by Daiichi Sankyo.

Funding

This study was funded by Daiichi Sankyo and AstraZeneca.

Table 1. Efficacy by Prior CDK4/6i Treatment in Pts With HER2-Low Breast Cancer, HR+ Cohort

	Prior CDK4/6i		No prior CDK4/6i	
	T-DXd (n = 233)	TPC (n = 115)	T-DXd (n = 96)	TPC (n = 47)
Confirmed ORR, n (% [95% CI]) ^a	118 (50.6 [44.0-57.2])	15 (13.0 [7.5- 20.6])	56 (58.3 [47.8-68.3])	12 (25.5 [13.9-40.3])
Median PFS, months (95% CI) ^b	10.0 (8.3-11.4)	5.4 (4.0-7.8)	11.7 (9.5-17.7)	5.9 (4.3-8.2)
Hazard ratio (95% CI) ^c	0.55 (0.42-0.74)		0.42 (0.28-0.64)	

^aCI based on Clopper-Pearson method.

^bMedian PFS is from Kaplan-Meier analysis. CI for median was computed using the Brookmeyer-Crowley method.

^cHazard ratio is from unstratified Cox proportional hazards model with treatment as the only covariate.

Table 2. Efficacy by Disease Burden^a in Pts With HER2-Low Breast Cancer, ITT

	Low disease burden		High disease burden	
	T-DXd (n = 150)	TPC (n = 85)	T-DXd (n = 223)	TPC (n = 99)
Confirmed ORR, n (% [95% CI])	81 (54.0 [45.7-62.2])	13 (15.3 [8.4- 24.7])	114 (51.1 [44.4-57.9])	17 (17.2 [10.3-45.6])
Median PFS, months (95% CI)	11.4 (9.8- 16.2)	5.1 (3.1-7.3)	9.5 (7.5-10.1)	4.8 (2.9-6.9)
Hazard ratio (95% CI)	0.41 (0.30-0.58)		0.58 (0.43-0.78)	

ITT, intent-to-treat.

^aDisease burden was defined by the number of metastatic disease sites at baseline (low = 0-2; high = 3+).

Table 3. Efficacy by Rapid Progressor Status^a in Pts With HER2-Low Breast Cancer, ITT

	Rapid progression		No rapid progression	
	T-DXd (n = 14)	TPC (n = 8)	T-DXd (n = 359)	TPC (n = 176)
Confirmed ORR, n (% [95% CI])	7 (50.0 [23.0- 77.0])	0	188 (52.4 [47.1-57.6])	30 (17.0 [11.8-23.4])
Median PFS, months (95% CI)	8.2 (1.4-NE)	2.2 (0.6-NE)	9.9 (9.0-11.3)	5.3 (4.2-6.9)
Hazard ratio (95% CI)	0.38 (0.12-1.21)		0.51 (0.41-0.64)	

ITT, intent-to-treat; NE, not estimable.

^aRapid progressor status was defined as disease progression within 6 mo of concluding a prior course of chemotherapy in early breast cancer.

The brain is a common target organ for breast cancer metastasis, and the risk of brain metastasis is usually high for patients with HER2-positive breast cancer. While T-DXd showed positive results in HER2-positive breast cancer brain metastasis (BCBM), its activity and blood-brain barrier (BBB) permeability in active BCBM need to be further validated (TUXEDO-1 included 15 patients with active brain metastasis). Tucatinib plus Trastuzumab and Capecitabine triplet showed efficacy in patients with brain metastasis, but Tucatinib alone has

poor BBB penetration. There is still an unmet medical need for active HER2-positive BCBM. VRN101099 is a highly selective kinase inhibitor of HER2 (Eurofins scanMAX Kinase Profiling, S-score (35) of 0.01). VRN101099 has single- to double-digit nanomolar (IC50) cellular potency in HER2-dependent cancer cells, and Ba/F3 cells expressing HER2 wild type or mutations with selectivity over wildtype EGFR. VRN101099 inhibited proliferation of BT474 with 3.6 nM IC50 but HaCaT with 829.2 nM IC50. VRN101099 binds HER2 kinase by forming a covalent bond to the Cys805 and its irreversible inhibition resulted in a longer target resident time than Tucatinib, confirmed by in vitro washout experiments. Robust in vivo activity of VRN101099 was observed in HER2-positive BT474 xenograft models. Moreover, once daily oral administration of VRN101099 significantly regressed intracranial BT474 tumor, demonstrating greater efficacy than twice daily oral administration of Tucatinib. These results were well explained by the superior brain to plasma exposure of VRN101099 to Tucatinib. Also, VRN101099 showed high exposure in the target organ, the fat pad, which potentiated better clinical translation. These anti-tumor efficacies are correlated with pharmacodynamic responses, as confirmed by decreased HER2, AKT, and ERK phosphorylation. In summary, VRN101099 is a brain penetrant, orally bioavailable, irreversible, and highly selective inhibitor of HER2 with therapeutic potential in HER2-positive BCBM. These data support the clinical development of VRN101099 in HER2-driven cancers.

Background: Up to 6% of patients (pts) with HER2 positive (pos) metastatic breast cancer (MBC) experience a radiologic complete response (rCR) to a first line of therapy, but these results mostly derive from dated and/or limited cohorts. Aim of this study was to define the clinico-pathological characteristics of HER2 positive (pos) MBC pts experiencing a rCR. Methods: Pts were selected from the database of the GIM14 study (NCT02284581) and classified according to the best radiologic response obtained to the first line chemotherapy (CT) and upon time-to-treatment-failure (TTF). rCR was defined as complete response (CR) with a TTF > 3 months. The association across variables was tested through logistic regression and their prognostic impact in terms of overall survival (OS) was estimated using the Kaplan-Meier method and compared using the log-rank test. Results: Of the 3,423 pts included in the GIM14 study, 814 had HER2 pos MBC. After exclusion of pts treated with first line endocrine therapy and/or with TTF < 3 months, 656 pts were included in the present analysis, of which 96 (14.6%) experienced a rCR. Instead, the best response was a partial response for 295 pts (45.0%), stable disease for 221 pts (33.7%), and progression for 44 pts (6.7%). Most pts (59.8%) presented de novo MBC; 379 pts (57.8%) had visceral metastases (mets), 609 pts (92.8%) did not have central nervous system (CNS) involvement and 318 pts (48.5%) had only 1 site of distant mets. Also, 445 pts (67.9%) had hormone receptor (HR) pos disease, a HER2 3+ score at immunohistochemistry (IHC) was present in 59.8% of cases versus 40.2% with HER2 2+ at IHC and in situ hybridization (ISH) + disease. Taxanes were the main CT backbone (489 pts, 74.5%), 341 pts (52.0%) had received a Trastuzumab-Pertuzumab doublet. At multivariable analysis, higher odds of experiencing a rCR were reported for presence of non-visceral mets (OR 1.87, 95%CI 1.10-3.17), low number of metastatic sites (OR 2.42, 95%CI 0.80-7.33 for 1 site only) and HER2 3+ score at IHC (OR 1.80, 95%CI 1.09-2.98). Disease-free interval (DFI) was associated to rCR at univariable but not at multivariable analysis. HR status, CT backbone and type of anti-HER2 regimen were not associated with rCR neither at univariable nor at multivariable analysis. Median follow-up was 76.2 months. Amongst pts with TTF>12 months, those with rCR had a significantly higher OS compared to those not experiencing a rCR (median OS 133 and 90 months, respectively; p=0.0191). OS rates in pts with TTF ≥ 12 months were 97.8% at 2-year follow-up and 59.4% at 5-year follow-up. Instead, in pts with TTF ≥ 60

months, OS rates were 76.7% at 10-year follow-up. Amongst the 96 pts experiencing a CR, 38 had a rCR with TTF between 12 and 60 months, while 22 pts had a rCR with a TTF \geq 60 months. The remaining pts had a CR with a TTF < 12 months. Pts with HR negative (neg) disease were found to be more likely to experience a rCR with a TTF between 12 and 60 months, whilst pts with HR pos disease had a higher probability to experience a rCR with a TTF \geq 60 months ($p=0.0074$). Pts with HER2 3+ score at IHC had a higher probability to achieve a rCR with a TTF \geq 12 months compared to pts with HER2 2+ score at IHC and ISH + ($p=0.0216$). Age at diagnosis, menopausal status, DFI, number and site of mets, CT backbone and anti-HER2 therapy did not influence the duration of the rCR obtained. Conclusions: This study characterized a real-world cohort of HER2 positive MBC patients experiencing radiologic complete response to a first line treatment. Based on these results a clinical trial focused on liquid biopsy-based minimal residual disease is being designed. Novel anti-HER2 agents are gaining momentum as ever increasingly effective treatments and future de-escalation strategies after complete response will represent a growing need.

Background: Human epidermal growth factor receptor 2 (HER2)-targeted therapies are an established treatment for patients with HER2-positive breast cancer, however, these therapies have not proven effective in the HER2-negative setting. Until recently, HER2 status was used to guide treatment decisions based on a binary classification of positive or negative. A new pathological category, HER2-low, has emerged as a subtype of interest within the breast cancer treatment landscape. HER2-low status is defined as a HER2 immunohistochemistry score of 1+ or 2+ and a negative in-situ hybridization result. DESTINY-Breast04 (DB04) was the first trial to evaluate a HER2-targeted agent within the metastatic HER2-low breast cancer setting. The anti-HER2 agent trastuzumab deruxtecan (T-DXd) demonstrated promising clinical activity in HER2-low expressing tumors. However, development of T-DXd-related interstitial lung disease (ILD) remains a concern when using this therapy. This survey-based study aimed to evaluate community oncologists' perceptions of the DB04 data, HER2-low directed treatment, and management of ILD. Methods: U.S.-based oncologists (n=83) convened at two live meetings in June 2022 to review clinical updates presented at ASCO 2022. Participant characteristics and demographic data were collected via an online survey prior to the respective meetings. Perceptions/reactions to clinical updates were captured in real-time via electronic keypad. Data were summarized using descriptive statistics. Results: Among respondents, 83.1% identified as community providers, with an average experience of 20.7 years in practice. On average, participants reported that 88.2% of their time is allocated towards direct patient care, with roughly 18 patients seen per clinic day. Nearly half of respondents (49.4%) reported awareness of HER2-low as a distinct pathological category prior to the presentation of DB04 at ASCO 2022, however, less than 10% of respondents had previously used this sub-category to determine therapy. Increased T-DXd-related ILD, which occurred in 12% of trial participants, was cited as the greatest limitation of the DB04 trial by over one-third (37.3%) of respondents. After reviewing real-world evidence data of ILD incidence in metastatic breast cancer, nearly one-third (31%) of respondents reported that their observed ILD rates are less than DB04, but more (36%) said that ILD can be hard to quantify because patients are not always symptomatic. When asked if the ILD rate associated with T-DXd would limit their selection of this agent for their patients with breast cancer, approximately one-quarter (24.1%) of respondents indicated

that they would reserve T-DXd use for patients without symptomatic pulmonary disease. However, the majority of respondents (60.2%) indicated that they would not limit their use of T-DXd based on ILD rates, with most (55.4%) opting for a risk-management approach involving increased monitoring for the development of ILD-related adverse events. Conclusions: Advancements in assay interpretation have made it possible to differentiate gradients of HER2 expression, creating a space for pathological sub-categories within a formerly binary paradigm. Among providers who reported awareness of HER2-low as a distinct pathological sub-category, few had used this as a benchmark to guide their treatment decisions prior to the presentation of DB04 at ASCO 2022. Newer anti-HER2 agents, such as T-DXd, provide a potential new standard of care for patients with HER2-low expressing tumors. Despite the concern of ILD rates associated with T-DXd use, the majority of providers do not view this as a limiting factor due to the ability to closely monitor patients for the development of adverse events coupled with appropriate provider/patient education.

The current HER2 testing algorithm can distinguish tumors that are completely negative for HER2 (IHC 0, HER2-zero) from HER2-low tumors [low (IHC 1+) or moderate expression (IHC 2+, ISH-)]. Because HER2-zero cases have often been combined with HER2-low cases, the clinical and biological understanding of HER2-low tumors is limited. To provide complementary information and shed light on the molecular characteristics and therapeutic insights of HER2-low breast cancer, we performed this multi-omics study of hormone receptor (HR)-negative and HER2-low breast cancer, also known as HER2-low triple-negative breast cancer (TNBC), and identified three subgroups: basal-like (BSL), receptor tyrosine kinase relevant (TKR), and mesenchymal stem-like (MSL). These three subgroups had distinct features and potential therapeutic targets and were validated in external datasets. Interestingly, the TKR subgroup (which exists in both HR-positive and HR-negative breast cancer) had activated HER2 and downstream MAPK signaling. In vitro and in vivo patient-derived xenograft experiments revealed that pretreatment with tyrosine kinase inhibitor (Lapatinib or Tucatinib) could inhibit HER2-signaling and induce accumulated expression of nonfunctional HER2 via a feedback loop, resulting in increased sensitivity to sequential HER2-targeting antibody-drug conjugate DS-8201. Our findings identify clinically relevant subgroups and provide potential therapeutic strategies for the previously targetless HER2-low TNBC subtype.

GRAPH ABSTRACT

Highlights of characteristics of HR-negative and HER2-low breast cancer subgroups

Table S1. Highlights of characteristics of HR-negative and HER2-low breast cancer subgroups

Subgroup	BSL	TKR	MSL
Clinical	5-years RFS: 87.1%	5-years RFS: 89.7%; high prevalence in Chinese	5-years RFS: 78.8%
Mutation	TP53 (62.5%); low PI3KCA (5.4%); low FOXA1 (0); HRDs high	TP53 (48.7%); high PI3KCA (43.6%); high FOXA1 (10.3%)	TP53 (71.4%); Middle PI3KCA (14.3%); high FOXA1 (14.3%)
Activated pathway	mTOR and mTORC1 signaling	ERBB2 signaling; Receptor tyrosine kinase; MAPK signaling	NF- κ B signaling
Potential therapy	mTOR and mTORC1 signaling inhibitor	Pre-treatment f Lapatinib or Tucatinib and followed by sequential DS-8201; Targeting MAPK signaling inhibitor	Bortezomib; Targeting CSCs

BSL, basal like; TKR, receptor tyrosine kinase relevant; MSL, mesenchymal stem-like; RFS, relapse-free survival; HRD, homologous recombination deficiency.

DS-8201, antibody-drug conjugates (ADC).

Lapatinib and Tucatinib, the small-molecule tyrosine kinase inhibitors (TKIs).

Bortezomib, NF- κ B pathway inhibitor.

Background: The addition of trastuzumab (H) to pre-operative chemotherapy in HER2+ breast cancer (H+BC) increases the rate of pathological complete response (pCR). TCH is a widely used adjuvant regimen in early stage H+BC. Lapatinib (L) is a small molecule HER2 antagonist that produces responses following H failure, and has been reported to augment H activity in combination in vitro. We compared neo-adjuvant docetaxel, carboplatin (TC) + H v TCL v TCHL in pts with H+BC.

Methods: Pts with stages Ic–III H+BC were randomized to receive neo-adjuvant TCH, TCL or TCHL (ICORG/TRIAL-IE 10-05, NCT01485926 www.clinicaltrials.gov). Pts subsequently underwent surgery and received H post-operatively for 1 year from the first dose of H. The primary endpoint of the trial was pCR. Secondary objectives were overall survival (OS) and relapse-free survival (RFS) and molecular and pharmacological markers of response. This study was supported by GSK, Novartis, The Cancer Clinical Research Trust and The Caroline Foundation.

Results: When the NCIC CTG MA.31 trial reported inferior outcomes for L compared to H, we discontinued the TCL arm. This abstract reports data on the 76 pts recruited to the TCH and TCHL arms only, who included stage II (69.7%; n=53) or stage III disease (21.1%; n=16, with stage unknown for 9.2% (n=7)). The final analysis set numbered 75 pts. Clinicopathological characteristics were well balanced between arms. The pCR rate of the two arms TCHL and TCH were virtually identical at 51.6% and 52.8% respectively (Fisher's test p-value: 1.000). TCHL pts had significantly superior 5 year relapse-free survival (relative risk (RR) 0.171, 95% CI 0.041 – 0.713; log-rank test p-value = 0.009). OS was comparable between the TCH and TCHL groups (RR 0.205, 95% CI 0.025 – 1.675); log-rank test p-value = 0.2). Median RFS and OS were not reached. The most frequent serious adverse event was diarrhoea which occurred in 21.3% (n=16/75) pts (Grade 3 diarrhoea 13/16). One pt (TCH arm) who did not have protocol-mandated prophylactic G-CSF had a Grade 5 toxicity. One TCHL pt had a self-limiting diverticular perforation. There was a significantly higher frequency of severe diarrhoea in pts who received the TCHL regimen (Grade 3+, 32.4% vs 10.5%, p=0.038). The use of prophylactic loperamide reduced the frequency of diarrhoea in both the TCHL arm (86.2% vs

44.4%, p=0.004) and in the TCH arm (58.8% vs 24%, p=0.009). A post lock audit with minimum 9-year follow-up showed relapse rates of 15% TCHL vs 33% TCH.

Conclusions: The study did not meet its primary pCR endpoint possibly due to a high TCH pCR rate, and small numbers. TCHL produced a statistically significant improvement in RFS compared to TCH. TCHL produced a higher rate of gastro-intestinal toxicity, but the use of loperamide significantly reduced the frequency of diarrhoea. These data suggest that anti-HER2 TKIs merit further investigation in the neo-adjuvant treatment of early stage H+BC.

Table 1. pCR rates, 5 year RFS and OS results for ICORG/TRIAL-IE 10-05 (NCT01485926) study pts. * significant, p<0.05

Treatment arm	pCR	pCR Rate	p-value Fisher's test	Relapse Rate	5 year Relapse Rate (%)	p-value log-rank test for RFS	Relative Risk For Relapse	Death Rate	5 year Death Rate (%)	p-value log-rank test for OS	Relative Risk For Survival
TCH	19/36	52.8%	1.0	12/38	31.6%	0.009*	TCHL RR 0.171; 95% CI 0.041 – 0.713	5/38	13.2%	0.2	TCHL RR 0.205; 95% CI 0.025 – 1.675

Background: Targeting the human epidermal growth factor receptor (HER) family of tyrosine kinase receptors with small molecule TKIs lapatinib, neratinib and tucatinib, monoclonal antibodies like trastuzumab and more recently with ADCs like T-DM1 and T-DXd has resulted in improved survival rates for patients with HER2+ BC. TKIs are primarily utilised in trastuzumab-refractory disease. Neratinib, and the pan-HER TKI afatinib, bind irreversibly to all members of the HER family, while lapatinib binds reversibly to HER2 and EGFR, and tucatinib binds reversibly to HER2 alone. Previous work in our lab has shown that TKIs like lapatinib are capable of modulating tumour surface HER2 levels and increasing trastuzumab load on tumours. Thus, there is a rationale for the use of TKI/ADC combinations in HER2+ BC. Using innately trastuzumab-resistant HER2+ BC cell lines, this in vitro study aims to assess the anti-proliferative potential of HER2-targeting ADCs T-DM1 or T-DXd in combination with the TKIs afatinib, lapatinib, neratinib or tucatinib.

Methods: HCC1569 and HCC1954 cells (HER2+, estrogen receptor (ER)-negative; innately trastuzumab-resistant) were grown in RPMI1640/10% FBS at 37°C and 5% CO₂. The anti-proliferative effects of afatinib, lapatinib, neratinib and tucatinib; of T-DM1 and T-DXd; and of each TKI/ADC combination thereof were assessed in these cells via 5-day acid phosphatase. ADCs were obtained from Saint Vincent's University Hospital, Dublin, and TKIs were purchased from commercial sources. Calcsyn software was used to generate IC₅₀ values and

combination index (CI) values at ED50. CI values > 1 represent an antagonistic combination, CI values = 1 are additive, and CI values < 1 are synergistic. All assays were carried out in triplicate.

Results: The HCC1569 cell line was more sensitive to all four TKIs (IC50 values were 12.8 ± 0.3 , 453.8 ± 47.1 nM, 4.7 ± 1.4 and 381.5 ± 37.3 nM for afatinib, lapatinib, neratinib and tucatinib respectively) compared to the HCC1954 cell line (IC50 22.3 ± 2.8 , 652.4 ± 36.0 , 57.0 ± 6.3 and 2365.1 ± 185.3 nM for afatinib, lapatinib, neratinib and tucatinib respectively). Despite their innate trastuzumab resistance, both cell lines displayed high sensitivity to T-DM1 (IC50 25.2 ± 8.7 ng/mL for HCC1569 and IC50 30.4 ± 3.2 ng/mL for HCC1954) and to T-DXd (IC50 16.0 ± 3.2 ng/mL for HCC1569 and IC50 36.8 ± 8.7 ng/mL for HCC1954). In both cell lines, co-treatment with ADCs and the irreversible TKIs afatinib and neratinib resulted in additive or synergistic responses, while the combination of the ADCs with the reversible TKIs lapatinib and tucatinib resulted in mild to moderate antagonism (Table 1).

Conclusions: In this pre-clinical study, T-DM1 and T-DXd consistently exhibited antagonistic interactions with reversible HER2-targeting TKIs, and synergy/additivity in combination with the irreversible TKIs tested. Future work will explore the underlying mechanisms of this observed synergy and antagonism, including impacts of TKIs on HER2 expression and real-time ADC internalisation rates.

Table 1

	Drug Combination	HCC1569 CI values	HCC1954 CI values
Irreversible	Afatinib + T-DM1	0.87 ± 0.10	0.73 ± 0.13
	Afatinib + T-DXd	0.85 ± 0.07	0.98 ± 0.11
	Neratinib + T-DM1	0.77 ± 0.07	0.87 ± 0.12
	Neratinib + T-DXd	0.85 ± 0.06	0.85 ± 0.11
Reversible	Lapatinib + T-DM1	1.21 ± 0.14	1.11 ± 0.05
	Lapatinib + T-DXd	1.38 ± 0.22	1.64 ± 0.32
	Tucatinib + T-DM1	1.37 ± 0.16	1.31 ± 0.34
	Tucatinib + T-DXd	1.28 ± 0.11	1.44 ± 0.20

Introduction:

HER2-positive breast cancer is considered aggressive, but due to the development of targeted drugs in the past 20 years, a substantial improvement of therapy results can be postulated. Proven evidence is provided by data of randomized clinical trials. The present study aimed at demonstrating the improvement of therapy results over time using single-center real world data.

Material and Methods:

In our center, we prospectively built a consecutive tumor and data base from 2000 to 2020 and identified patients with early HER2-positive breast cancer (n=396). The cohort was divided in four groups by year of diagnosis according to the changing therapy concepts: A) 2000-2004 (no HER2-directed therapy, n=83), B) 2005-2011 (trastuzumab, n=96), C) 2012-2017 (trastuzumab/pertuzumab, n=135), D) 2018-2020 (T-DM1 in patients with non-pCR), n=55). HER2 was measured by IHC and ISH corresponding to the ASCO-CAP guidelines. HER2-directed therapy was indicated according to the respective national guidelines (AGO). The

median follow-up was 58 months in the entire cohort (1-266), group A 84 months (10-266), group B 94 months (2-201), group C 56 months (1-118), group D 32 months (8-53). The primary endpoint was overall survival (OS), and secondary endpoint was iDFS. Kaplan-Meier estimates were calculated and multivariate analyses were performed using SPSS 28 (IBM, Armonk, NY, USA).

Results:

Overall, 57% of the 396 patients had an age of 50 years or more, 85% had a NST histology, 54% of the tumors were larger than 2cm, 45% were node-positive; 34% were steroid hormone receptor negative. HER2-directed therapy was delivered to 7 of 83 pts in group A (8.4%), to 62 of 96 pts in group B (64.6%), to 119 of 135 in group C (88.15%), and to 50 of 55 pts in group D (90.91%), resp.. Overall, in the first 3 years we observed 19 deaths and the probability for OS was 89.7 % for group A, 92.2 % for group B, 96.4 % for group C and 100% for group D, resp.; iDFS was 77.4% in A, 86.8% in B, 94.9% in C and 95.2% in D, resp.. After adjustment for nodal status, grading and steroid hormone receptor status, we calculated the effect size of the incremental improvement of treatment for OS and iDFS as HRs referred to group A (Table 1).

Conclusion:

With this prospectively established single center cohort, we are able to confirm a significant improvement of the treatment results in patients with HER2-positive early breast cancer over the last 20 years applying individualized HER2-directed therapies.

Background. Clinical trials have demonstrated that trastuzumab deruxtecan (T-DXd) provides a durable responses for patients with HER2-positive and HER2 low metastatic breast cancer (BC). With T-DXd treatment, approximately 50% of patients with HER2+ metastatic BC were still alive and progression-free at 24 months (DESTINY-Breast03). We previously shown that mucin 4 (MUC4) expression is an independent predictor of poor response to trastuzumab in HER2-positive BC patients. We also showed that MUC4 is upregulated by soluble TNF α (sTNF α) secreted by the tumor, which confers primary trastuzumab resistance since it hides trastuzumab epitope on the HER2 molecule, reducing its binding and diminishing its therapeutic effects. In preclinical models of de novo trastuzumab-resistant tumors, we proved that administration of the sTNF α blocking agent INB03 (DN) together with trastuzumab inhibited tumor growth and induced an innate immune response in the tumor microenvironment (TME). DN is a dominant-negative inhibitor of sTNF α that is not immunosuppressive because it does not affect transmembrane TNF α . Our goal is to study whether neutralizing sTNF α can improve T-DXd effects in a multiple HER2-targeted therapy-resistant model. Methods JIMT-1 is a HER2-positive BC cell line resistant to trastuzumab, pertuzumab and lapatinib, which expresses MUC4. JIMT-1 tumor-bearing nude mice were treated with (1) IgG 5 mg/kg, (2) T-DXd 5 mg/kg, (3) T-DXd 2.5 mg/kg, (4) T-DXd 1.25 mg/kg, (5) DN 10 mg/kg, (6) T-DXd 5 mg/kg +DN, (7) T-DXd 2.5 mg/kg +DN and (8) T-DXd 1.25 mg/kg +DN. T-DXd and IgG were administered i.v. on days 0, 7 and 14. DN was administered i.p. twice a week for 3 weeks. Tumor growth was monitored regularly. Tumor-infiltrating macrophages, NK cells and myeloid-derived suppressor cells (MDSCs) were evaluated by immunofluorescence and flow cytometry. Results The dose-response curve of T-DXd exhibited tumor growth inhibitions of 83% (5 mg/kg), 61% (2.5 mg/kg) and 37% (1.25 mg/kg) vs IgG-treated tumors. DN alone had no antitumor effect. Combination of T-DXd with DN resulted in a reinforced antitumor effect, as the tumor growth inhibition escalated to 98% (T-DXd 5 mg/kg+ DN), 81% (T-DXd 2.5 mg/kg+DN) and 73% (T-DXd 1.25 mg/kg+DN). Moreover, we observed that addition of DN to T-DXd 1.25 and 5 mg/kg enhances the infiltration of resident macrophages ($p < 0.05$ and $p < 0.01$, respectively) and promotes polarization to the M1-like phenotype ($p < 0.05$ and $p < 0.001$, respectively). While T-DXd 2.5 and 5 mg/kg alone achieved a decrease in M2-like macrophages ($p < 0.05$), combination of T-

DXd 1.25mg/kg+DN impaired M2-like polarization at similar levels of that observed with 2.5 and 5 mg/kg T-DXd ($p < 0.05$). Notably, the M1/M2 ratio escalated from 10.9% to 51.5% when DN was added to the lowest T-DXd dose ($p < 0.01$). In addition, T-DXd 2.5 and 5 mg/kg induce an increase in the proportion of NK cells in TME ($p < 0.001$ and $p < 0.05$, respectively), which T-DXd 1.25 mg/kg+ DN treatment mimicked ($p < 0.05$). Although an increase in NK cell activation was observed with 1.25 and 2.5 mg/kg treatments ($p < 0.05$ and $p < 0.001$, respectively), adding DN did not further improve this effect. Only the highest dose of T-DXd in combination with DN was able to increase NK cell degranulation ($p < 0.05$), compared to T-DXd alone. Finally, the percentage of MDSCs population decreases with the addition of DN to the T-DXd 2.5 and 5 mg/kg. Conclusions Our results suggest that sTNF α blockade is able to enhance T-DXd effect in a multiple HER2-targeted therapy resistant model. Notably, the administration of T-DXd 1.25 mg/kg+DN achieved a similar antitumor effect to T-DXd 5 mg/kg alone and also transforms the TME to an antitumor one with a reinforced immune response. This finding highlights that sTNF α and MUC4 expression are important variables in the response to T-DXd. Neutralization of sTNF α may open new therapeutic strategies for treatment of patients who present with MUC4 expression or have progression on T-DXd therapy.

INTRODUCTION: Trastuzumab Deruxtecan (TDXd) is an innovative antibody drug conjugate (ADC) comprising an anti-HER2 antibody, a cleavable tetrapeptide-based linker and a potent topoisomerase I inhibitor. TDXd has demonstrated promising clinical efficacy in previously treated HER2-positive metastatic breast cancer patients (pts). Drug-drug interactions (DDIs) can influence drug activity and potentially affect treatment efficacy or determine increased toxicity. Drug-PIN® (Personalized Interactions Network) is a tool able to identify interactions between drugs and combine them with demographic, clinical and biochemical patient data. In this multicentric retrospective study, we aim to describe clinical outcomes, toxicities and drug-drug interactions (DDIs) of TDXd in a real-world population. **METHODS:** Pts with histological and radiological confirmed HER2+ mBC (defined as HER2 3+ or HER2 2+ with an amplification detected in SISH/FISH) who received TDXd were included in the study. The availability of complete data about clinical outcomes, toxicities and concurrent medications was needed. Pts who received at least one month of treatment were eligible. Radiological response and toxicities were evaluated following RECIST 1.1 and CTCAE v5 criteria. Drug-PIN® was used to define DDis, Drug-PIN® score and Drug-PIN® tier (green for no significant DDis and yellow, dark yellow, orange, red for increasing DDis) for each pts. Clinical and pathological features were collected from the referral hospital in an anonymous database and analyzed with R-package. Univariate analysis was conducted calculating the AUC of ROC or the PFS using the Kaplan and Meier curves and log-rank test as appropriate. Multivariate analysis was conducted using logistic or Cox proportional hazard regression model as appropriate. **RESULTS:** One hundred forty-three pts were enrolled from 11 Italian oncological hospitals. Median age was 56 years (33-84). Estrogen receptor (HR) status was positive in 108 (75%) pts and negative in 35 (25%) pts. TDXd was administered as the first, second, third or subsequent line in 4 (3%), 17 (12%), 41 (29%) and 81 (56%) pts, respectively, with an average of 4 treatments received (range 1-11). Among 114 pts with measurable disease, the ORR was 68% (6% of complete response). Eight (7%) pts had a primary resistance to TDXd. Median PFS was not reached and the milestone-1 year PFS was 56.7% in the overall population. PFS at 12 months was 100% vs 54.1 % in pts receiving upfront or second versus subsequent lines ($p=0.094$). A toxicity of any grade was registered in 80 pts (56%). Most common toxicities were nausea (43, 30%), neutropenia (28, 19%) and asthenia (19, 13%). Severe tox was reported in 21 (15%) pts. Most common severe tox were neutropenia, nausea/vomiting and interstitial lung disease (ILD) observed in 14, 2 and 2 pts, respectively. Concomitant medications were taken by 63 pts, with 8 pts receiving more than 5 drugs. Among pts taking any medications, median Drug-PIN® score was 6.3 (range 1.7-190). 127, 11, 3 and 2 pts were in the green, yellow, dark yellow and red Drug-PIN® tier, respectively. Sixteen pts (11%) had a relevant DDI. The median PFS was not reached vs 12 months in pts with green Drug-PIN® tier compared to yellow or more, however the difference did not reach statistical significance and a longer follow up is needed. Asthenia of any grade was associated with an elevated Drug-PIN® score (AUC 0,681; $P=0.011$). Severe ILD was reported in 2/16 pts with DDis while no cases (0/124) occurred in pts with no DDis (threshold Drug-PIN® score: 19.4/ Drug-PIN® tier: >yellow, $P=0.0061$). **CONCLUSIONS:** TDXd demonstrated to be effective and safe in our unselected real world

population, even in heavily pretreated pts. No new safety concerns were reported. DDIs seems to be associated with specific toxicities such as asthenia and ILD.

Background Trastuzumab emtansine (T-DM1) has shown great effectiveness in treating HER2-positive metastatic breast cancer, but therapies subsequent to T-DM1 failure remain controversial. Here, we investigated efficacy and safety of tyrosine kinase inhibitors (TKIs) based therapy in T-DM1 resistant HER2-positive metastatic breast cancer. Methods From August 2019 to April 2022, 53 HER2-positive metastatic breast cancer patients received TKIs-based therapy after T-DM1 failure in Jiangsu Province Hospital. Progression-free survival (PFS), overall survival (OS), objective response rate (ORR), clinical benefit rate (CBR), and safety profiles were reported. Results 53 patients received TKIs-based therapies as a second or later line therapy. 51 (96.2%) patients received a combined therapy, including TKIs plus capecitabine, vinorelbine or trastuzumab. 2 (3.7%) patients received TKIs alone. The median follow-up time was 19.7 months (95%CI 15.4-24.0). The median PFS was 11.9 months (95%CI 7.9-15.9). OS has not reached. ORR was 19.6% and CBR was 72.5%. For patients who had brain metastasis (n=12), the median PFS was 10.5 months (95%CI 7.5-13.5) and intracranial ORR was 33.3%. Compared with lapatinib (n=30), pyrotinib (n=21) provided a better PFS after T-DM1 progression (8.0 months vs. 19.0 months, P=0.033). The most common adverse events were thrombocytopenia (12, 23.6%), diarrhea (8, 15.7%), leucopenia (8, 15.7%) and hand-foot syndrome (8, 15.7%). Conclusion TKIs-based therapy could prolong the survival of HER2-positive metastatic breast cancer patients after T-DM1 failure, including those with brain metastases. Compared with lapatinib, pyrotinib might provide better outcomes for overcoming T-DM1 resistance.

Background Standard treatment in early HER2 positive BC involves the use of neoadjuvant chemotherapy (NACT) with Trastuzumab (T) plus Pertuzumab (P). Dual blockade increases pathological complete response (pCR) and improves disease free survival (DFS). However, Chilean public health system does not include P use in the NACT schedule, while private insurers only provide partial coverage. Here, we aim to compare pCR, Distant DFS (DDFS) and site of recurrence in HER2 positive BC patients treated in the neoadjuvant setting with the use of T with or without P, in the largest BC Chilean registry. Methods We conducted a retrospective population-cohort study involving females with stage I-III HER2 positive BC

treated with NACT in a public and academic private centre between 2012 to 2021. CT regimens for comparison included anthracyclines, taxanes, T and P. pCR was defined as the absence of residual invasive disease in the breast and in the axillary lymph nodes (ypT0/is N0) at the completion of the NACT. DDFS was measured from the time of diagnosis to the event or lost to follow-up. We performed Cox regression analysis to identify factors associated with prognosis and a logistic regression to identify factors related to the first metastasis site. Results 372 patients with HER2 positive BC were included. Median age was 51 years (24 – 79), 57.5% were classified as Hormone Receptor positive (HR), and 4.5% were stage I, 48.2% stage II and 47.3% stage III. 65.8% were treated in a Public Hospital (PH) and 34.2% in an Academic Private Centre (AC). 85.2% received both anthracyclines and taxanes, 10.0% only taxanes and 4.8% only anthracyclines-based CT. 55 patients (14.8%) received both T and P, while 3.3% did not receive any HER2 directed therapy as NA treatment. Median T doses before surgery were 6 (1 – 12). pCR rate was 46.5% which varied according to HR expression: 61.0% in HR-positive BC vs. 36.2% in HR-negative disease ($p=0.0001$). pCR according to treatment were as follows: no-T no-P 22.2%, only-T 49.4%, both T-P 60.0% ($p=0.02$). We found no difference in pCR rate between anthracycline and non-anthracycline based CT (49.1% vs. 45.9%, $p=0.72$). With a median follow-up of 36 months, DDFS at 3 and 5 years differed regarding pathological response: 94.8% vs. 77.1% and 86.3% vs. 69.1% ($p=0.0006$), for pCR and non-pCR group, respectively. In a multivariate analysis, stage III vs. I-II (HR 2.5, $p=0.005$), non-pCR vs. pCR (HR 2.6, $p=0.01$) and not receiving NA anti-HER2 treatment (HR 2.6, $p=0.01$) were associated with higher risk of distant metastasis. Regarding recurrence, 7 out of 198 non-pCR tumors and 6 out of 174 pCR tumors presented brain metastasis (BM) as the first site of distant recurrence($p=0.96$). In contrast, visceral metastasis (VM) as the first site of recurrence, were more frequent in non-pCR (21/198) than pCR patients (3/174, $p=0.001$). In a multivariate analysis, the only factor associated with BM was stage III (HR 5.8 vs stage I-II, $p=0.02$) and with VM was not achieving pCR (HR 6.3, $p=0.02$) and not using T nor P (HR 5.1, $p=0.008$). Conclusion The use of anti-HER2 treatment in a NA scheme is critical in HER2 positive disease. Although P is associated with increased pCR, we found no survival benefit with its use. Retrospective analysis, few events, post-surgical treatment might have influenced these results. Achieving pCR is associated with better prognosis by reducing distant recurrence but not BM. New strategies are needed to prevent the occurrence of this event.

Background: Dual HER2 targeted therapy with trastuzumab (H) and pertuzumab (P) has been approved as neoadjuvant therapy for patients with HER2-positive breast cancer in China in 2019 based on the results from NeoSphere and PEONY study. However, the real-world efficacy and safety data are currently lack of evidence in China. Therefore, this multi-center real-world study aims to retrospectively analyze the efficacy and safety of neoadjuvant trastuzumab and pertuzumab combined with different chemotherapy regimens of HER2-positive early breast cancer. Methods: Patients received trastuzumab and pertuzumab in combination with different chemotherapy regimens, including taxanes (T), cyclophosphamide (C), anthracyclines (A) were collected retrospectively from 12 centers. The primary endpoint was total pathological complete response (tpCR, ypT0/is ypN0) rate. Results: A total of 357 patients were enrolled, among which 204 (57.5%) received TCbHP, 92 (25.9%) received EC-THP, and 51 (14.4%) received THP as chemotherapy regimens. The median age was 48 years old (range, 22-76), 142 (39.8%) of patients were classified as hormone receptor (HR)-positive, and 215 (60.2%) were HR-negative. The overall tpCR rate was 58.5% (95%CI, 53.2%-63.7%). tpCR rate for HR-negative patients was significantly higher than HR-positive patients (65.6% vs. 47.9%, $p=0.001$) and there was not any statistical difference according to chemotherapy regimens (56.9% for TCbHP, 56.5% for EC-THP, and 66.7% for THP, $p=0.445$). The most common adverse events included anemia (40.1%), white blood cell count decreased (34.3%), ejection fraction decreased (19.5%), Alanine aminotransferase increased (18.9%), platelet count decreased (12.8%) and neutrophil count decreased (12.0%). There was not any toxicity leading to death. Conclusions: Multi-center real-world data show satisfactory tpCR rate and tolerable adverse events of trastuzumab and pertuzumab in combination with different chemotherapy regimens in China.

Background. Standard-of-care treatment for HER2-positive metastatic breast cancer (HER2+ mBC) patients has traditionally included targeted therapies such as trastuzumab and/or pertuzumab in first line (1L) and ado-trastuzumab emtansine (T-DM1) in the second line (2L). In 2021, fam-trastuzumab deruxtecan-nxki (T-DXd, Enhertu®) was approved following DESTINY-Breast 03 trial results, demonstrating a significant reduction in the risk of progression compared to T-DM1 in 2L. Contemporary data on treatment patterns and clinical outcomes for HER2+ mBC patients after their 1L therapy in a real-world setting is limited and would help understand whether all eligible patients receive optimal and timely targeted therapies. This study aimed to report 2L treatment patterns and outcomes among HER2+ mBC patients in the United States (US). Methods. Adult HER2+ mBC patients with ≥2 lines of therapy were identified from the Syapse Learning Health Network (LHN) database; a longitudinal US oncology database integrating data from community health systems, labs and other external sources. Included patients initiated 2L treatment for metastatic disease between January 2014-February 2021 (index date), allowing for 12-months of follow-up. Descriptive statistics for patient characteristics, treatment patterns including prior metastatic treatments, time to treatment discontinuation (TTD), and reasons for 2L discontinuation were reported. Results. Of the 15,241 breast cancer patients in the LHN with abstracted data, 312 HER2+ mBC patients received ≥2L treatment. The patients were mostly White (69%) or African American (21%), median age of 59 years (interquartile range [IQR], 50-66) at start of 2L. The African American population was typically diagnosed young (median age 50 [IQR, 44-61] vs. 54 [IQR, 46-62] years) with stage IV disease at initial diagnosis (69% vs 62%) versus Whites. Majority of the 312 patients had stage IV disease at initial diagnosis (62%); most common sites of metastasis

at mBC diagnosis were bone (52%), distant lymph node(s) (38%), liver (36%) and brain (10%). The median length of follow-up was 22 months (IQR, 13-37), 54% had initiated their 2L therapy since 2018. Majority of the 312 patients had received a trastuzumab-based (T-based) regimen in 1L (78%). Among the 312 patients, 37% had received only 2 lines of therapy in the metastatic setting, 28% received 3 and 35% received ≥ 4 lines of therapy. In 2L, 89% of the 312 patients received a HER2-targeted treatment (monotherapy or combination); the most frequent 2L regimens included T-DM1 monotherapy (29%), trastuzumab/pertuzumab/taxane (10%) and T-DM1/trastuzumab (8%). Subsequently, 197 of the 312 patients (63%) received 3L therapy. Among these 197 patients, T-DM1 monotherapy (19%), T-DXd monotherapy (10%) and capecitabine/lapatinib (8%) were the most frequently reported 3L regimens. Around 88% (n=274) of the 312 patients discontinued their 2L therapy. Median TTD of 2L from index date was 7.2 months (95% CI, 6.5-8.9); median TTD was 10.6 months (95% CI, 7.4-14.0) among a sub-group of patients who received a T-based regimen in their 2L (N=116). Approximately 47% of patients discontinued their 2L regimen due to progression/worsening of cancer, 17% discontinued from intolerance/toxicity in the absence of progression. Conclusions. This study suggests the treatment trajectory of US HER2+ mBC patients is variable in the real world clinical practice. Approximately two-thirds of the 2L patients had to receive a subsequent therapy and disease progression was the most common reason for 2L treatment discontinuation, reflecting a remaining need to improve outcomes for patients in 2L HER2+ disease.

Background: The effect of neoadjuvant therapy on tumor downstaging and breast-conserving during surgery is well documented. Pathologic complete response (pCR) after neoadjuvant treatment was associated with long-term survival. HLX02 (Zercepac®), a biosimilar of trastuzumab, showed the same efficacy, safety, and immunogenicity as the reference drug in human epidermal growth factor receptor-2 (HER2)-positive patients. Despite this, real-world evidence of its effectiveness when combined with pertuzumab in neoadjuvant treatment of HER-2 positive breast cancer still lacks.

Methods: In this retrospective real-world study, women with confirmed invasive HER2-positive breast cancer who have received chemotherapy plus HLX02 and pertuzumab (Perjeta®) as neoadjuvant therapy were enrolled. Patients must be over 18 years old, have an Eastern Cooperative Oncology Group performance status score of 0 or 1, and have a baseline left ventricular ejection fraction of $\geq 55\%$. Patients without pathological assessment after neoadjuvant therapy were excluded. Pathologic complete response (pCR) was defined as no residual invasive tumors in mammary glands and axillary lymph nodes. Clinical response was assessed using RECIST1.1. To investigate the factors associated with pCR, univariate and multivariate logistic regression (forward stepwise) analyses were conducted.

Results: A total of 85 patients were enrolled in this study, and 55 patients (64.71%) achieved pCR after neoadjuvant therapy. There were 84 (98.82%) patients with partial response (PR), one (1.18%) patient with stable disease (SD). According to the univariable analysis, when compared to those with a tumor diameter ≤ 5 cm, patients with a tumor diameter > 5 cm at baseline showed a lower pCR rate (odds ratio [OR] = 0.286; 95% confidence interval [CI]:

0.108-0.758, P = 0.01). Patients with preoperative PR positivity > 10% showed lower pCR rate than those with preoperative PR positivity < 1% (OR = 0.115, 95% CI 0.036-0.372, P = 0.02). Besides, pCR was more common in patients with preoperative hormone receptor (HR)-negative than in those with preoperative HR-positive (ER or PR positivity > 10%) (OR = 4.452, 95% CI 1.679-11.804, P < 0.01). Multivariable analyses showed that patients with tumor diameter > 5 cm had a lower pCR rate than those with tumor diameter ≤ 5cm (OR = 0.213; 95% CI 0.070-0.644, P = 0.01). Patients with preoperative HR-negative tumors were more likely to achieve pCR than those with preoperative HR-positive tumors (OR =5.649, 95% CI 1.927-16.556, P < 0.01) (Table 1). The treatment were well tolerated by patients, and no additional adverse events were reported.

Conclusion: According to this real-world study, HLX02 in combination with pertuzumab as neoadjuvant therapy for HER2-positive breast cancer patients showed a similar pCR rate to that of dual-target neoadjuvant therapy reported in previous clinical trials. The treatment showed an encouraging effectiveness, and may become a novel neoadjuvant option for patients with HER2-positive breast cancer.

The study was supported by the Natural Science Foundation of Shanghai (21ZR1414700).

Introduction: Premenopausal women with high-risk hormone receptor-positive (HR+) breast cancer (BC) undergo abrupt menopause induction with anti-estrogen therapy (AE) and ovarian function suppression (OFS). This treatment improves recurrence-free survival but may increase cardiovascular (CV) risk associated with early hypoestrogenemia, as observed in women with non-cancerous reasons for premature menopause. We sought to identify patterns of CV actions including referrals, tests and medication by type of AE therapy in premenopausal women in early follow-up for operable BC as a possible surrogate for early CV disease.

Methods: Consecutive premenopausal women ≤ 50 years (mean age 42.6 years; sd 5.9) with Stage I-III HR+ or triple negative breast cancer (TNBC) diagnosed between 02/2013-06/2020 were identified by retrospective review. Mean follow-up was 4.9 years (sd 2.1 years.) Women were placed into 3 treatment groups based on initial AE approach: HR+ on OFS+AE (HR+OFS), HR+ not on OFS (HRnoOFS), and TNBC. Patient demographics, cancer treatment and CV risk factors as well as post-diagnosis adverse CV events (myocardial infarction, transient ischemic attack) and CV-related clinical actions (CV actions) including referrals, (cardiology, neurology (vascular)), tests (stress test, angiogram, ECHO, EKG, Carotid US) and medications (statin, ACEi, ARB, betablocker, calcium channel blocker, antiarrhythmic, and anti-platelet agents) were recorded. For each CV outcome (events, total actions, referrals, tests,

medications) we created an “any” vs “none” dichotomous variable as well as a variable for number of CV outcome per year of follow-up. Categorical variables were compared among the 3 groups using chi-square and Fisher’s exact tests; continuous outcomes (including the “per year” variables) were compared among the 3 groups using ANOVA. For the ANOVAs we report the global null hypothesis p-value. A two-tailed alpha of 0.05 was used throughout.

Results: 80, 78, and 48 (total n=206) women were identified in the HR+OFS, HRnoOFS and TNBC groups respectively. Mean follow-up was longest in the HRnoOFS group (Table 1). Mean number of CV actions per year were highest in the HR+OFS group compared with HRnoOFS and TNBC (0.41 vs 0.22 and 0.35, respectively; p=0.008.) The HR+OFS group had significantly more referrals during follow-up, as well as more referrals per year than the other two groups. This group also had significantly more tests per year than the other two groups. CV medication initiation did not differ among the groups. The proportion with >3 CV actions during follow-up was 62% higher in women in the HR+OFS group compared to other groups. Experiencing >3 CV actions was associated with having diabetes, hypertension, and hyperlipidemia, being a current smoker, and receipt of left-sided radiation (Table 2).

Conclusions: In this early follow-up period, women on OFS+AE experienced more CV actions per year suggesting concern for CV sequela in this patient group. Future work should seek to further understand the impact of OFS+AE on the CV health of premenopausal women, try to identify who is at greatest risk and test strategies to mitigate cardiotoxicity.

BACKGROUND The introduction of cyclin inhibitors in the treatment of metastatic breast cancer has completely changed the natural history of this disease. In the case of premenopausal women, the use of ovarian suppression + aromatase inhibitor or tamoxifen associated with ribociclib demonstrated not only a gain in disease-free survival, but also in overall survival, making it the first choice of treatment for premenopausal women with HER2 negative hormone receptor-positive metastatic breast cancer. Ribociclib is a very well tolerated drug. Neutropenia, the main side effect, is easily manageable in clinical practice. However, one study showed elevation of ALT and AST grade 3 or 4 in 9.3% of patients, while other studies observed that liver dysfunction was dose-limited, and therefore should always be evaluated when using this drug. The pathophysiology of liver injury, not yet fully understood, is attributed to hepatotoxic metabolites or immunogenic effects with damage to hepatocytes similar to the ones triggered by autoimmune hepatitis. There are successful case reports with re-exposure to either the same drug or another CDK4/6 inhibitor. **METHODS** We describe a case of a premenopausal woman with metastatic breast cancer who experienced severe hepatotoxicity with ribociclib use. When her liver function was back to normal, she did a rechallenge with a lower dose of ribociclib and had another liver disfunction. **RESULTS** A 34-year-old premenopausal and nulliparous woman, was diagnosed in 2020 with a hepatic and lymph nodes metastatic HER2 negative hormone receptor-positive invasive breast carcinoma, (ER 90%, PR 90%, HER2 negative, KI-67: 20%). Genetic evaluation showed pathogenic mutation in ATM and VUS in RET, and positive PIK3CA in the tumor. Her first-line treatment was according to the Monaleesa-7 trial with goserelin 3.6 mg every 28 days + letrozole 2.5 mg daily + ribociclib 600 mg/day for 21 days and a break for 7 days, without delays or dose reductions. After 3 months of treatment, with monthly laboratory tests showing normal results, a new PET-CT was performed, which showed a complete metabolic response, both in lymph nodes and in liver lesions (attached figures). In the 4th month of treatment, the patient presented symptoms of malaise, nausea, vomiting, epigastric pain, and jaundice. Laboratory tests showed: ALT 1439 (Reference value – RV: 13-35); AST 1946 (RV:10-49), Total Bilirubin 5 (RV: 1.1), INR 1.8, GGT

500 (RV< 38), ALP 651 (RV: 46-116). After extensive laboratory investigation, the hypothesis of toxicity by ribociclib was raised, which was suspended. She was started with prednisone 60 mg daily associated with ursodeoxycholic acid 300 mg BID with normalization of the hepatic profile after 2 months, when PET-CT was repeated, maintaining response in all lesion foci. It was decided to reintroduce ribociclib, this time at a dose of 200 mg daily, with further laboratory worsening after 2 weeks and definitive suspension of the drug. The patient is currently with non-evidence of disease, using goserelin 3.6 mg every 28 days associated with letrozole 2.5 mg daily. Last PET-CT was performed 15 months after ribociclib discontinuation, maintaining response in all lesions. **CONCLUSION** Ribociclib is a great therapeutic option for the treatment of HER 2 negative HR+ metastatic breast cancer. It is generally well tolerated, however laboratory monitoring should be performed throughout the treatment period. Hepatotoxicity, although rare, may occur, with improvement after discontinuation of the drug.

Background: Diarrhea is the most common adverse event of pan-HER tyrosine kinase inhibitors. There is no consensus on therapeutic or prophylactic strategy of pyrotinib-related diarrhea. PHAEDRA is an ongoing multicenter, single-arm, phase II trial conducted to evaluate adjuvant pyrotinib plus nab-paclitaxel for patients with low-risk HER2-positive breast cancer. Here, we reported the results from the sub-study of PHAEDRA, which investigated the effect of

different prophylactic strategies with loperamide for diarrhea. Methods: In PHAEDRA, patients with N0/N1mi, HER2-positive invasive breast cancer and primary tumor ≤ 3 cm received nab-paclitaxel 260 mg/m² once every 3 weeks for 12 weeks and pyrotinib 400 mg once daily for one year within 90 days after surgery. In the sub-study, patients were randomly assigned to receive loperamide 4 mg three times a day on days 1-7 and twice a day on days 8-21 (cohort A) or days 8-42 (cohort B) since the initiation of adjuvant therapy. The primary endpoint of the sub-study was the incidence of grade ≥ 3 diarrhea. Results: Between January 2021 and May 2022, the enrollment of 120 patients in the sub-study was completed. Grade ≥ 3 diarrhea was reported in 18 (30%) of 60 patients in cohort A and 19 (32%) of 60 patients in cohort B. The median time to first grade ≥ 3 diarrhea was 4.5 days (IQR, 1.0-6.5) in cohort A and 4 days (IQR, 1.0-6.0) in cohort B. The median number of grade ≥ 3 diarrhea episodes was 1 (IQR, 1-1) in both cohorts. Three (5%) patients in each cohort had constipation events, respectively, which were all grade 1 or 2. One (2%) patient in cohort A and two (3%) in cohort B had dose reductions of loperamide due to constipation, and no patients discontinued loperamide. One (2%) patient in cohort A had dose reduction of pyrotinib and one (2%) in each cohort discontinued pyrotinib due to diarrhea. Conclusions: The effects of both loperamide regimens on antidiarrheal prophylaxis were consistent with that of loperamide prophylaxis in the CONTROL trial, but with extremely fewer constipation events. Long-course and short-course loperamide prophylaxis showed numerically similar incidence of grade ≥ 3 diarrhea. Proactive diarrhea management can promote the full-dose and full-course treatment with pyrotinib. It is still necessary to develop more effective antidiarrheal prophylaxis regimens for pan-HER tyrosine kinase inhibitors.

Background

The introduction of the novel COVID-19 vaccination raised concerns regarding side effects from patients who had undergone breast cancer treatment. Lymph node swelling after the mRNA vaccines (Moderna, Pfizer) is a distressing side effect for women treated for breast cancer as it may indicate cancer progression or recurrence. Patients at risk of breast cancer-related lymphedema (BCRL) are fearful that lymph node swelling from the vaccine could incite or worsen BCRL. Data investigating associated side effects in this population is essential for patient education and future self-advocacy.

Purpose

The purpose of this study was to elicit side effects associated with the COVID vaccine in women treated for breast cancer.

Methods

4,945 surveys were sent to women over the age of 18 who had received breast cancer treatment and had been prospectively screened for BCRL with perometry. 621 participants who received an mRNA vaccine and responded to the survey were included in analysis, 469 of whom completed booster dose surveys. Participants were asked about type and duration of side effects after each vaccine dose. Solicited side effects included injection site soreness, swelling, or redness; swelling, numbness, or heaviness of the arm; generalized muscle soreness (GMS); fatigue; headache; joint pain; chills; nausea; vomiting; fever; Bell's palsy; axillary or supraclavicular lymph node swelling; other; or none of the above. We computed frequencies and the median duration of side effects for each dose. To investigate predictors of side effects, we fit multivariable logistic regression models separately for each side effect, with random effects for participants to account for clustered responses. We considered significant predictors those with $p < 0.05$.

Results

Of the 621 participants, the median follow-up time between breast surgery and date of first vaccine dose was 69 months. The distribution of the top 5 side effects is presented in Table 1. Of note, the majority of participants who reported lymph node swelling (9.8% dose 1, 12.9% dose 2, 11.3% dose 3) reported it in the axilla ipsilateral to the vaccine (54.1% D1, 61.3% D2, 71.7% D3). Lymph node swelling was also reported in the axilla contralateral to the vaccine (45.9% D1, 45% D2, 24.5% D3), supraclavicular region ipsilateral (29.5% D1, 26.3% D2, 32.1% D3) and contralateral (18% D1, 18.8% D2, 9.4% D3) to the vaccine. Older patients reported each side effect significantly less frequently. Those who had received neoadjuvant chemotherapy reported significantly more GMS and headache than those who did not. Those who had received regional lymph node radiation were less likely to report GMS, as were patients who had sentinel lymph node biopsies (vs. no lymph node surgery). The median duration of side effects for all three doses was 48 hours or less, with the plurality (41.0% D1, 38.7% D2, 44.1% D3) of participants reporting side effects lasting 24 hours or less. While all side effects apart from injection site soreness were significantly more common in the second than the first doses, the duration of side effects only increased for 28.1% of participants.

Conclusion

Over 86% of women treated for breast cancer may experience at least one side effect after any dose of the COVID-19 vaccine. This data, collected specifically for patients with breast cancer, will help enhance guidelines for structured and universal education regarding additional doses of the vaccine in the future. This will allow patients to better understand COVID vaccine side effect profiles after breast cancer treatment and self-advocate prior to future doses.

Table 1. Top 5 Side Effects Reported

	Injection site soreness	Fatigue	Generalized muscle soreness (GMS)	Headache	Chills
Dose 1	76.0% (472/621)	42.7% (265/621)	23.0% (143/621)	18.4% (114/621)	9.5% (59/621)
Dose 2	76.2% (473/621)	59.3% (368/621)	31.9% (198/621)	32.4% (201/621)	23.7% (147/621)
Dose 3	69.9% (328/469)	44.3% (208/469)	24.5% (115/469)	21.5% (101/469)	19.2% (90/469)

BACKGROUND: Adjuvant chemotherapy, particularly taxane-based chemotherapies, which are used to treat high-risk breast cancers, has been shown to be efficacious in prolonging overall survival. However, the impact of such therapies on risk of breast cancer-related lymphedema (BCRL) is yet to be fully understood. Available studies have contradictory findings as to whether or not taxanes increase BCRL risk. Unfortunately, methodological flaws, such as not incorporating a preoperative baseline arm volume measurement or utilizing flawed measurement techniques and diagnostic criteria, result in misdiagnosis of the primary outcome of BCRL and it is therefore difficult to draw conclusions from these studies. As such, a more comprehensive understanding of the potential risks associated with these treatment modalities can improve quality of care as patients are better prepared to face a potentially devastating sequela of breast cancer treatment. **PURPOSE:** The purpose of this study is to determine if chemotherapy administered in the adjuvant setting is an independent risk factor of BCRL, as well as to assess any specific risks of taxane-based chemotherapy on BCRL. **METHODS:** From

2005 to 2021, 2049 patients treated for breast cancer were enrolled in a prospective BCRL screening trial and screened from preoperative baseline through last follow-up. Screening included objective arm volume measurements via perometry. Chemotherapy data and clinicopathological and demographic characteristics were collected directly from the electronic medical record. Patients who had not received neoadjuvant chemotherapy were eligible for the current study; they were classified based on whether they had received taxane-based chemotherapy, non-taxane chemotherapy only, or no chemotherapy. Relative volume change (RVC) increase $\geq 10\%$ from preoperative baseline >3 months postoperatively was used to define BCRL. Patients were censored at cancer recurrence or most recent clinic visit. We fit a Cox regression model to estimate adjusted hazard ratios (aHR) for BCRL. The model was adjusted for baseline BMI, axillary lymph node dissection (ALND), regional lymph node radiation (RLNR), age at diagnosis, and smoking history. RESULTS: The eligible cohort included 1759 patients, including 564 (32%) who received taxane-based chemotherapy and 104 (6%) who received non-taxane chemotherapy only. The median follow-up time for the entire cohort was 58 months. 141/1759 (8%) of patients developed BCRL. The median time to develop BCRL was 21 months post-operatively. Compared to no chemotherapy, the aHR associated with taxane-based chemotherapy was 1.04 (95% CI 0.37, 1.8; $p = 0.62$). Compared to no chemotherapy, the aHR for non-taxane chemotherapy was 0.82 (95% CI 0.67, 1.6; $p = 0.86$). There was no significant difference between taxane and non-taxane therapies in terms of BCRL risk ($p = 0.55$). ALND, RLNR, and high BMI remained independent risk factors for BCRL, consistent with the published literature. CONCLUSION: The receipt of adjuvant chemotherapy and specifically adjuvant taxane-based chemotherapy were not associated with increased risk of BCRL in this cohort of 1759 patients at risk of and prospectively screened for BCRL.

Prevalence and Spectrum of Manifestations of Tamoxifen Retinopathy as Assessed by Multimodal and Ultra-widefield Retinal Imaging

Presenting Author(s) and Co-Author(s):

Ethan Zhao, *n/a, Medical Student - Weill Cornell Medical College*

Country: United States

Kyle Kovacs, MD, *Assistant Professor of Ophthalmology - Weill Cornell Medical College*

Country: United States

Introduction Tamoxifen, a selective estrogen antagonist, is part of standard adjuvant therapy for hormone receptor-positive breast cancer. In addition to known systemic toxicities, well-described retinotoxic effects include peripheral and macular crystalline deposits, pseudocystic foveal cavitations, as well as an increased risk of developing punctate pigmentary changes. However, the true prevalence of retinal toxicity is unclear, with the literature reporting rates between 1.5% and 11%, with significant geographic and temporal discrepancies depending on choice of screening modality. Advances in retinal imaging, specifically spectral domain and swept-source optical coherence tomography (OCT), have led to more sensitive diagnosis of toxicity. However, the field of view of commercially available OCT is limited 30 degrees, whereas ultra-widefield (UWF) imaging can image up to 200 degrees of the retina, albeit with a superficial rather than a cross-sectional view. Therefore, UWF imaging may visualize previously underreported signs of toxicity in the peripheral retina such as pigmentary changes better than macula-focused imaging alone like OCT. As such, the goals of the present study were to: 1) determine the prevalence of tamoxifen retinopathy in our cohort, a major northeastern metropolitan area, based on multimodal retinal imaging including macular OCT, fundus photos, and autofluorescence; 2) determine whether the additional field of view captured in UWF imaging contributes to the diagnosis of tamoxifen retinopathy by assessing for peripheral findings, most specifically pigmentary retinopathy. **Methods** This is a retrospective study of patients who visited the retina service of a single academic tertiary referral center between September 2012 and November 2021. Female patients initiated on tamoxifen for at least 6 months before their first retinal exam were identified. Patients with poor image quality, prior vitreoretinal surgery, retinal laser, or confounding pathology such as severe diabetic retinopathy were excluded. Two independent graders performed blinded review of OCT images for evidence of macular toxicity and UWF images for signs of central and peripheral toxicity, and the prevalence of the latter was compared to age- and gender-matched controls. A two-tailed t-test was used to compare ages of patients in the two cohorts. A one-tailed two proportion Z-test was used to determine if eyes in the tamoxifen cohort exhibited a greater rate of peripheral pigmentary changes. **Results** 252 eyes from 128 patients were included in the tamoxifen cohort, and 244 eyes from 125 patients in the control cohort. The average age at first retinal imaging in the tamoxifen cohort (61.1 ± 1.1 , $n=128$) versus the control cohort (61.0 ± 1.3 , $n = 125$) was not significantly different ($p=0.95$). 4 eyes (1.6%) from 2 patients (1.6%) had evidence of definitive tamoxifen retinopathy. One patient had crystalline maculopathy bilaterally visible on OCT and UWF imaging and another had macular pseudocystic cavitations bilaterally on OCT. Neither patient had peripheral findings on UWF. 31 eyes (12.4%) among 16 (12.5%) patients in the tamoxifen cohort displayed peripheral reticular pigmentary changes, compared to 59 eyes (24.2%) among 30 patients (24.0%) in the control group. The rate of peripheral pigmentary change in the tamoxifen cohort was not significantly greater than in the control group ($p=0.99$). **Conclusion** Only 2 patients had definitive tamoxifen retinopathy findings, which were both

concentrated in the macula and clearly visible on OCT imaging. Given the absence of meaningful UWF changes, macular OCT may be the most valuable tool in diagnosing tamoxifen retinopathy. Our prevalence (1.6%) diverges from higher prevalences reported by studies screening with advanced retinal imaging (10-12%), though notably reflects a very different ethnic and geographic population compared with other work. Further large population studies are needed.

Background: Genitourinary symptoms (GUS) such as vaginal dryness, dyspareunia, itching, urinary incontinence, urinary tract infections and discharge are common in patients with breast cancer (BC). Optimal management of GUS remains unclear. Our group previously published a systematic review (SR) on GUS management in 2014 which showed a paucity of RCT evidence addressing this knowledge gap (Mazzarello et al. 2015). We performed an updated SR to

assess if more prospective trial data had been published in the past 7 years to inform management of this common complication of BC. Methods: EMBASE, Ovid Medline and the Cochrane Library were searched for RCTs evaluating treatments for GUS in BC patients from September 2014 to December 2021. A PICOS (population, intervention/comparators, outcomes and study design) framework was utilized. Population: women with breast cancer. Intervention/comparators: all forms of oral, intra-vaginal and topical hormonal and non-hormonal treatments. Outcomes of interest: improvements in vaginal symptoms (e.g., dryness, pain, dyspareunia, itching); vaginal hormone response, measured by validated scales [e.g., Vaginal Health Index (VHI) and Vaginal Maturation Index (VMI)] and quality of life [e.g., Female Sexual Function Index (FSFI)]. Study design: only RCTs were included. Two independent reviewers performed the tasks of study selection, data collection, and risk of bias assessment. Results: Of 842 unique citations identified (412 from this update, 430 from previous SR), eight studies (n = 539 patients) met inclusion criteria. Interventions included 0.005% estriol gel (EG; n=50 patients), intravaginal testosterone (IVT; n=21), intravaginal prebiotic (n=13), hyaluronic acid (HA; n=12), polyacrylic acid (PA; n=25), pH-balanced gel (two studies; n=118), Replens[®] (n=24) and Lidocaine gel (n=22). These interventions were compared to placebo/saline/usual care (n=254). One study had three arms comparing prebiotics, HA and usual care. Study sample sizes ranged from 44 to 136 patients. Given the heterogeneity of the studies, a narrative synthesis was performed. Compared to placebo, FSFI total score was significantly improved by all interventions except IVT (which demonstrated significant improvement in only the satisfaction domain) and 4% aqueous lidocaine before vaginal penetration (which improved significantly all domains except for orgasm). FSFI changes were not reported for Replens[®]. Significant improvements in vaginal hormone responses (VHI and VMI) were reported for 0.005% EG and pH-balanced gel; however, no significant effects were found for IVT, HA or prebiotics. Vaginal symptoms (vaginal dryness, dyspareunia and pruritis) were significantly improved by EG, IVT, and PA. Vaginal symptoms were significantly improved in the single study of pH-balanced gel that reported this outcome. Conclusion: GUS is reported in 75% of BC patients but despite its frequency, the management of GUS remains a challenging issue for patients and health care providers. Due to study heterogeneity, there remains insufficient RCT evidence to define optimal therapy. More prospective trials comparing commonly used interventions are needed. Keywords: Genitourinary symptoms, Topical moisturizers, Intra-vaginal testosterone

Background Previously, we reported the clinical outcomes of the combination of anti-PD-1 Ab, cyclin-dependent kinase 4/6 inhibitors, and endocrine therapy (ET) in patients with ER positive/HER2 negative advanced breast cancer in SABCs2020; biomarker analysis has been performed to provide insight into the hepatotoxicity frequently observed in the study. Methods Subjects received 240 mg nivolumab IV on days 1 and 15, 150 mg abemaciclib PO twice daily, and either 500 mg fulvestrant (FUL) on days 1, 15, 29, and every 4 weeks thereafter (FUL cohort) or 2.5 mg letrozole (LET) once daily (LET cohort). The primary endpoint was objective response rate and secondary endpoints included toxicity evaluated in the CTCAE along with an exploratory endpoint as related to the biomarker analysis. Archival tumor tissues were collected before study entry and blood and stool samples were collected at baseline and on cycle3 day1. Tumor tissues were subjected to IHC analysis and RNA sequencing followed by subtyping using NGS. High throughput cytokine analysis using ELISA-based assay were performed with serum samples and cell sorting analysis of PBMC was performed with FACS. Results From June 2019 to December 2019, 17 subjects were enrolled (FUL cohort [n = 12], LET cohort [n = 5]). The study was prematurely closed due to safety concerns such as hepatotoxicity and interstitial lung disease. AEs \geq Grade 3 were observed in 91.7% and 100% of patients in the FUL and LET cohorts, respectively. The most frequent AEs \geq Grade 3 were elevated liver function tests (LFT; FUL cohort: 50.0%, LET cohort: 60.0%). Serum cytokine analysis from the subjects with severe hepatotoxicity indicated cytokine storm with elevations of sCD30/TNFRSF8, IL-11, -34, Pentraxin-3, sTNF-R1, -R2, TSLP, which was supported by the findings of reduction of effector regulatory T cells in PBMC. IHC study in liver biopsy from three subjects with the toxicity revealed infiltration of CD8+ T cells and FOXP3+ T reg into the liver, suggesting the immune related liver injury upon the treatment with nivolumab and abemaciclib. HLA typing was performed in the 17 patients but no association between HLA type and ILD or hepatotoxicity were observed. Conclusions The frequent and severe immune related hepatotoxicity induced by the combination of anti-DD-1 and CDK 4/6 inhibitors might have been

an immune-boosting therapy as suggested in the preclinical studies. This study was supported by the Ono Pharmaceutical Co., LTD. The registration number of the study is UMIN000036970.

BACKGROUND: Breast cancer-related lymphedema (BCRL) affects approximately 1 in 5 women treated for breast cancer in the United States. Well determined risk factors include axillary lymph node dissection (ALND), regional lymph node radiation (RLNR), and BMI > 25 at diagnosis. The monarchE trial showed benefits of the CDK4/6 inhibitor, abemaciclib, given in the adjuvant setting for patients with high-risk HR+/HER2- early breast cancer. We have previously demonstrated that CDK4/6 inhibitors can be associated with lymphedema in the metastatic setting. However, the impact of adjuvant CDK4/6 inhibitors on development of BCRL is not known. **PURPOSE:** The purpose of this study is to investigate the impact of CDK4/6 inhibitors on BCRL risk in a prospectively screened cohort of patients treated with these agents in the adjuvant setting compared to those who did not receive CDK4/6 inhibitors. **METHODS:** Patients treated for breast cancer were screened prospectively from preoperative baseline for the control group and pre-drug baseline for the study cohort receiving CDK4/6 inhibitors through last follow-up. Screening included objective arm volume measurements via perometry. CDK4/6 inhibitor data and clinicopathological and demographic characteristics were collected directly from the electronic medical record. The control cohort, which did not receive CDK4/6 inhibitors, consisted of patients with ER/PR+, HER2- breast cancer, 3+ malignant lymph nodes, arm measurement data at least 1-year after surgery, and had surgery in 2014 or later. Patients with arm measurement data before and after drug start date were eligible for the current study. Relative volume change (RVC) increase $\geq 10\%$ from preoperative or pre-drug baseline was used to define BCRL. Patients were censored at cancer recurrence, most recent clinic visit, or first follow up date that BCRL was detected. We fit a Cox regression model to estimate adjusted hazard ratios (aHR) for BCRL. The model was adjusted for baseline BMI, ALND, and RLNR. **RESULTS:** The eligible cohort included 98 patients, including 46 (47%) who received CDK4/6 inhibitors and 52 (53%) who did not. The median follow-up time for the entire cohort was 30 months (range 0.36, 93.9 months). 24/98 (24.5%) of patients developed BCRL. The median time to develop BCRL was 16 months (range 0.36, 63.9 months) Compared to the control group, the aHR associated with CDK4/6 inhibitors was 2.08 (95% CI 0.82, 5.24; $p = 0.122$). **CONCLUSION:** The combination of endocrine therapy (ET) and CDK4/6 inhibitors may increase the risk of BCRL compared to ET alone. Further research in larger datasets is needed to validate these hypotheses generating findings, and further refine the efficacy/toxicity ratio of CDK4/6 inhibitors for patients with localized breast cancer.

Superior Effectiveness of Plinabulin (Plin) versus No-Treatment for Docetaxel (Doc)-Induced Neutropenia (N) and other Hematologic Complication in Breast Cancer (BC) Patients

Presenting Author(s) and Co-Author(s):

Country: United States

Introduction: Minimizing hematologic complications (HC) in breast cancer patients (pt) increases pt safety and convenience, minimizes financial toxicity and may lower risk for COVID-19 infection. Plin is a novel small molecule which protects bone marrow progenitor stem cells and is non-inferior to Peg for the prevention of chemotherapy-induced neutropenia (CIN) after Doc (Blayney, JAMA Open 2021). In contrast to pegfilgrastim (Peg), Plin (as a single dose per cycle), is given on the same day of chemotherapy, has minimal bone pain and thrombopenia, has anti-cancer efficacy, and could minimize healthcare system touches (Blayney, JAMA Onc 2020; Han, ESMO 2021). Doc 75 mg/m² in BC pts is typically used without G-CSF prophylaxis ('no treatment'). We evaluated Plin's HC preventive effects in comparison to no-treatment in BC patients receiving Doc from published studies.

Methods: The HC endpoints from the 27 early BC patients with at least one NCCN high FN risk factor (N=27) from the phase 3 CIN trial (PROTECTIVE-1, NCT03102606) were compared with No-Treatment (non-prophylactic Peg or G-CSF) in patients receiving 75 mg/m² Doc. Plin was given by 30 minute (min) IV infusion as a single dose each cycle, 30 min after Doc, over 4 cycles. Cycle 1 hematology measurements in Plin-treated pts were taken pre-dose and days 1, 2, 6, 7, 8, 9, 10, 15 and 21 (10 ANC values in cycle 1); and in cycles 2-4 on days 1, 8, 21 and at end of study and were then analyzed by Covance Central Laboratory. No treatment neutropenia data was obtained from published cancer trials with monotherapy Doc 75 mg/m² in two No-Treatment studies with at least weekly blood sampling (Harvey et al., JCO, 2006: ~3-4 draws in cycle 1), or twice-weekly (Dieras et al., Br J Ca, 1996: ~5-6 draws in cycle 1). The HC endpoints were all grade (Gr) N, Gr4N, Gr3/4N, Gr3/4 febrile N (FN), infections, anemia and thrombopenia. Other endpoints were adverse events (AEs) and Quality of Life (QoL with EORTC QLQ-C30).

Results: Baseline demographics were generally comparable between the Plin and No-Treatment literature studies for age, ECOG, and number of prior lines. Gr4N frequency with Plin was 44%, 11%, 3% and 0% in cycles 1, 2, 3 and 4 respectively, thus no added Gr4N was observed after cycle 4. Plin had significantly less neutropenia, and numerically less anemia and thrombopenia vs No-Treatment. QoL with plinabulin remained unchanged over 4 cycles.

Conclusion: Blood sampling in the No-Treatment studies (Harvey and Dieras) were infrequent, and likely underestimated the true Gr4N frequency. Despite a higher frequency of ANC sampling in cycle 1, Plin was superior vs No-Treatment for Doc-induced neutropenia and HC, while maintaining QoL and with minimal AE and bone pain burden. The same day dosing combined with the avoidance of AEs typically leading to healthcare touches, provides a distinct benefit with Plin for the prevention of Doc-induced neutropenia.

Hematologic Complications

	All GrN	Gr 3/4N	Gr4N	Gr3/4 FN	Gr3/4 Infections	Gr3/4 Anemia	Gr3/4 Thrombopenia
Plin (N=27)	88.9%	70.4%	48.1%	3.7%	0%	7.4%	0%
Dieras et al (N=39)	97%	95%	82%	7.7%	0%	13%	3%
<i>p-value Plin vs Dieras</i>	0.30	0.04*	0.004*	0.64	>0.999	0.70	>0.999
Harvey et al (N=190)	94%	83.7%	67.9%	7.4%	3.2%	8.9%	4.2%
<i>p-value Plin vs Harvey</i>	0.40	0.09	0.04*	0.70	>0.999	>0.999	0.60

*p-value is significant in favor of Plin

Objective: Pyrotinib, an oral irreversible pan-HER receptor tyrosine kinase inhibitor, showed promising efficacy and manageable safety profiles in the treatment of HER-2 positive breast cancer. Diarrhea is the most common adverse event associated with pyrotinib. This study aimed to evaluate the incidence and management of diarrhea secondary to pyrotinib in Chinese patients with HER-2 positive breast cancer.

Methods: In this prospective real-world study, consecutive patients aged over 18 with HER-2 positive breast cancer and an Eastern Cooperative Oncology Group performance status (ECOG PS) of 0-2 who planned to receive pyrotinib-based regimens for at least 21 days were included. Pyrotinib-treated patients and those with preexisting gastrointestinal conditions were excluded. There were no planned management strategy or primary prophylaxis for diarrhea,

while loperamide, montmorillonite powder or Golden Bifid (a live combined Bifidobacterium, Lactobacillus and Streptococcus Thermophilus tablet) were recommended. Treatment was given in accordance with routine clinical practice by investigators. For patients developed grade 3 or higher diarrhea, pyrotinib was suspended until the diarrhea improving to grade 1 or less, and secondary prophylaxis (such as loperamide, loperamide plus montmorillonite powder, or loperamide plus Golden Bifid) was administrated before pyrotinib resumption. The baseline characteristics of patients and details of diarrhea (onset time, duration, severity according to the National Cancer Institute-Common Terminology Criteria for Adverse Events version 4.03, treatment and prognosis) were collected.

Results: Between August, 2020 and April, 2022, a total of 107 eligible patients were included, with a median age of 54 (range: 25-81) years old. Most patients (93.5%) had an ECOG PS of 0-1, and 51 patients (47.7%) were hormone receptor positive. A total of 46 patients (43.0%) received pyrotinib in the early stage and 61 (57.0%) in the advanced stage. Sixty-nine cases (64.5%) used pyrotinib-containing combination therapy (including 40 combined with capecitabine, 13 combined with trastuzumab, and 16 combined with other regimens), and 38 (35.5%) received pyrotinib alone. Ninety-eight cases (91.6%) reported diarrhea of any grade. Grade 1, 2 and 3 diarrhea occurred in 78 (72.9%), 9 (8.4%) and 11 (10.3%) patients, respectively. The median time to first onset of diarrhea of any grade was 2.5 (1-12) days, and the duration of first onset was 4 (1-24) days. The cumulative duration of diarrhea was 10 (1-60) days. Sixty-four, two, thirty, two patients used loperamide alone, montmorillonite powder alone, loperamide plus montmorillonite powder and loperamide plus Golden Bifid for the treatment of diarrhea, respectively. Eleven (10.3%) and seven (6.5%) patients experienced pyrotinib dose reduction and pyrotinib discontinuation. For 11 patients suffered grade 3 diarrhea, the median time to first onset of grade 3 diarrhea was 9 (4-14) days. Two, four and five patients administrated loperamide, loperamide plus Golden Bifid and loperamide plus montmorillonite powder as their secondary prophylaxis. Ten of eleven had grade 1 or 2 diarrhea after secondary prophylaxis, while one patient still suffered grade 3 diarrhea. All of them (11/11) held the pyrotinib dose. The incidence rate of constipation of all patients was 3.7%, which did not increase after treatment or secondary prophylaxis for diarrhea.

Conclusion: In this study, the majority of patients developed pyrotinib associated diarrhea, and most of them were grade 1. About 10% patients reported grade 3 diarrhea, which can be managed by loperamide-based treatment and secondary prophylaxis.

Table 1. Baseline characteristics of patients

Variables	All (n=107)	With grade 3 diarrhea (n=11)
Age (years), median (range)	54 (25-81)	52 (31-64)
ECOG PS, n (%)		
0-1	100 (93.5)	11 (100)
2	7 (6.5)	0
Hormone receptor status, n (%)		
Positive	51(47.7)	6 (54.5)
Negative	56 (52.3)	5 (45.5)
With visceral metastases, n (%)	29 (27.1)	0
With nonvisceral metastases, n (%)	71 (66.4)	6 (54.5)
Metastatic site, n (%)		
Lung	20 (18.7)	0
Liver	12 (11.2)	0
Brain	9 (8.4)	0
Bone	29 (27.1)	1 (9.1)
Lymph nodes	49 (45.8)	6 (54.5)
Others	14 (13.1)	2 (18.1)
Number of metastatic sites, n (%)		
1	37 (34.6)	4 (36.3)
2	20 (18.7)	1 (9.1)
≥3	21 (19.6)	1 (9.1)
Previous radiotherapy, n (%)	29 (27.1)	3 (27.3)

Hormone receptor (HR) positive breast cancer (BC) is a prevalent disease accounting for almost 2 million new cases globally. Almost 70-80% of breast cancer patients are women with a positive score for the estrogen receptor (ER). HR positive BCs of all stages are selectively treated with endocrine therapy targeting ER activity. Intrinsic and acquired resistance are common phenomena, impacting patient outcomes negatively. Palbociclib is an FDA approved checkpoint inhibitor for the treatment of HR+/HER2- breast cancer in combination with aromatase inhibitors or selective estrogen receptor degraders. However, patients responding well to the therapy in the beginning, lose sensitivity to palbociclib with time. Ribonucleotide reductase (RR) is a rate limiting enzyme in DNA synthesis consisting of two subunits RRM1 and RRM2. In our previous study, we have shown that RRM2 is upregulated in ER positive tamoxifen resistant BC. Previously, we have also reported that didox (DDX) which is a unique RRM2 enzyme inhibitor can significantly halt malignant breast cancer cell division in combination with an anthracycline drug doxorubicin by targeting RRM2, mutant p53 and NFkB regulatory proteins. In this study, we target palbociclib resistant BC with DDX to circumvent palbociclib resistance. For this purpose, we have developed palbociclib resistant ER positive MCF7 and ER negative MDA-MB-468 breast cancer cell lines. Here, we report morphological changes in parental as compared to palbociclib resistant cells after treatment with palbociclib alone, DDX alone or with palbociclib as compared to non-treated cells. Cell proliferation studies confirm the synergistic combinatorial effect of palbociclib and DDX compared to palbociclib or DDX alone. We also report that DDX alone or in combination with palbociclib downregulates cell cycle and NFkB proteins in palbociclib resistant ER positive MCF7 and ER negative MBA-MB-468 breast cancer cell lines.

The emergence of acquired drug resistance through therapeutic treatment remains a critical threat to efficient chemotherapy, target therapy, or immune therapy. These resistant cancer cells most often lead to relapse or metastasis. The development of drug resistance is a multi-step evolutionary adaptation for cancer cells. Tumor heterogeneity, cancer cells' plasticity, and microenvironment contribute to the resistant clone's formation. Therefore, a time-lapse adaptation model is critical to define the mechanism of drug resistance evolution. Recently, several studies have revealed that the initial acquired drug resistance might be conferred by transient events, such as drug-tolerant persisters (DTP) that might occur in a subpopulation of the cancer cells at the early stage of the treatment, which were then followed by the transcriptomic reprogramming and secondary-wave genetic mutations in the progression of resistance development. In the clinic, chemotherapy is still the mainstream treatment for TNBC, and one of the primary chemo agents is doxorubicin. Although the initial responsive rate of doxorubicin-based chemotherapy is up to 70%, it is well recognized that TNBC cells usually generate an evolutionary adaptive response that can result in the acquired drug-resistance and multi-drug resistant phenotypes. To date, numerous different mechanisms of acquired chemo-resistance have been reported, but the vast majority of these results have been derived from the continuous-high-dose-exposure acquired resistant cell line models. Since the chemo-treatment dosage in these artificial models is well above what is physiologically achievable in patients, few of them can mimic the actual situation of resistance development or improve the clinical trial outcomes. Moreover, most of these studies only characterized the terminal resistant cells, which are challenging to be resensitized because of their dominant genetic mutations. In this study, we hypothesize that the TNBC chemo-resistant cells may derive from the early-stage reversible chemo-tolerant "DTP-like" (CTP) cells, and early-stage epigenetic landscape perturbation might determine the progression of chemo-resistance development. To test the

hypothesis and overcome the previous model limitations, based on the clinical drug exposure kinetics for doxorubicin, we developed an in vitro “pulsing-treatment CTPs regrowth” model (referred to as CTP model), which could mimic the clinical treatment and provide therapeutically relevant insights into the initial drug-induced stress response and resistance development. Leveraging this CTP model, we are able to define the early event for drug response, in which the doxorubicin-treated cells showed a senescence-like phenotype, and the interferon alpha (type I) pathway was activated. Furthermore, unexpectedly, we found that the expression of HERVs was significantly activated but LINE1s not. To further explore the TEs reactivation, we did the single cell RNA-seq for 0h, 2h, and 4 days samples. With a novel bioinformatic workflow, we integrated the TE expression information with coding genes mRNA profiling from the same single cell RNA-seq dataset and identified the IFN-enriched cluster had higher expression of HERVs. Herein, a subpopulation of HERV^{high} cells with IFN activation was identified as a “hot-cluster” which might be the early determinant in the resistance evolution.

Background: Trastuzumab deruxtecan (DS-8201a) is an antibody-drug conjugate (ADC), consisting of a humanized anti-HER2 (human epidermal growth factor receptor 2) monoclonal antibody linked to a topoisomerase I inhibitor payload using a cleavable tetrapeptide-based linker, approved for the treatment of HER2+ metastatic breast cancer patients refractory to anti-HER2 therapy including T-DM1. While some mechanisms for clinical T-DM1 resistance have been identified, less is known about innate or acquired resistance to DS-8201a. We established two XenoSTART Patient-Derived Xenograft (XPDX) models from tissue samples collected two years apart from a patient with ER+/HER2+ breast cancer before and after HER2 directed therapies. These models designated ST4565 and ST4565C were developed and characterized for receptor expression, genomic alterations, and in vivo drug sensitivities toward multiple chemotherapies and targeted agents, including T-DM1 and DS-8201a. Methods: Models ST4565 and ST4565C were established from breast samples collected from a Caucasian

female with ER+/HER2+ metastatic breast cancer; ST4565 was collected at age 35 prior to therapy and ST4564C at age 37 following several treatment regimens including 5-FU/doxorubicin/cyclophosphamide, docetaxel/trastuzumab/pertuzumab, and T-DM1/anastrozole. Both were grown subcutaneously in female athymic nude mice supplemented with exogenous estradiol. The resulting models were passaged, and receptor expression confirmed immunohistochemically; genomic analysis, including WES and RNAseq, was performed to further characterize the models. For in vivo studies, both models were evaluated using several chemotherapy and targeted agents alone and in combination including: trastuzumab, pertuzumab, T-DM1, DS-8201a, neratinib, tucatinib, fulvestrant, alpelisib, sacituzumab, and irinotecan. In vivo study endpoints included tumor volume and time from treatment initiation with %T/C values and tumor regression reported at study completion; a T/C of $\leq 20\%$ versus control was considered sensitive. Tumor regression ($\%T/C < 0$) versus Day 0 tumor volume was also reported. Results: ST4565 and ST4565C retained comparable receptor expression (ER=2+/HER2=3+) over tested passages with similar histology compared to archival clinical samples. DNA/RNA sequencing identified several conserved variants including loss of CDKN2A/B and MTAP and a CNV=14 for CCND1. In vivo, ST4565 and ST4565C were found resistant to T-DM1 at 3 mg/kg weekly with a T/C of 100% in both models. However, DS-8201a treatment at 3 mg/kg weekly resulted in partial tumor regressions in ST4565 (T/C=-51%) while ST4565C was found resistant (T/C=49%). Both models were found resistant to all tested chemotherapies and all other targeted therapies but reported similar sensitivity to fulvestrant (T/C= $\sim 40\%$). Conclusion: We established two XPDX models representing T-DM1-resistant, ER+/HER2+ breast cancer from breast samples collected two years apart from the same patient that were found differentially responsive to DS-8201a. These models can be utilized as a valuable tool in better understanding innate resistance to T-DM1 and acquired resistance to DS-8201a.

Potentiating Alpelisib in PI3K Pathway Overactive Triple Negative Breast Cancers David C. Boyd^{1,2}, Amy L. Olex³, Tess Leftwich¹, Nicole Hairr¹, Alex K. Duong¹, Narmeen S. Rashid^{1,3}, Mohammad A Alzubi^{1,2}, Holly Byers¹, Aaron D. Valentine¹, Julia E. Altman¹, Emily Zboril¹, Jacqueline M. Grible¹, Madelyn Esquivel¹, Scott A. Turner¹, Andrea Ferreira-Gonzalez¹, Mikhail G. Dozmorov⁵, J. Chuck Harrell^{1,2,6} ¹Department of Pathology, Virginia Commonwealth University; ²Integrative Life Sciences Program, VCU; ³Wright Center for Clinical and Translational Research, VCU; ⁴Department of Biology, University of Richmond; ⁵Department of Biostatistics, VCU; ⁶Massey Cancer Center, VCU. There is an urgent need for new therapeutic options for basal-like Triple Negative Breast Cancers (TNBC). To mirror the NCI-ComboMATCH study, and identify new synergistic drug combinations, we analyzed a set of 20 breast cancer patient-derived xenografts and 14 cell lines to identify targetable targets in each model. The OncoPrint Comprehensive Assay v3 was performed to assess 161 genes for hotspot mutations, focal copy number variants, amplification/deletions, and RNA-fusion genes. Next, each PDX and their isogenic drug-resistant sublines were analyzed with bulk RNA-sequencing (217 samples) and cell single-cell RNA-sequencing (~100,000 cells). Of all NCI-MATCH defined targetable mutations, 37% of the models contained pathogenic PIK3CA amplifications or mutations. PIK3CA is one of the most common oncogenic aberrations identified in patients and the PI3K pathway is overactive in the majority of TNBCs, therefore we sought to target it across all models and identify the most efficacious synergistic drug partner. Short-term cultures of each PDX model were screened with a library of >1,000 FDA-approved/experimental drugs to identify compounds that were cytotoxic. Synergistic drug screens were then performed with each drug in combination with the PI3K inhibitor byl-719 (alpelisib) a current standard-of-care drug used for PI3K mutant ER+ disease. Synergism was identified using coefficient of drug interaction (CDI) calculations and 10 drugs were identified as synergistic across several models. Using several criteria, including clinical status and pathway analysis, 3 drugs were selected for CompuSyn-based synergism testing and each was confirmed to be synergistic in vitro. Testing with in vivo models of each drug combination has thus far confirmed that each is synergistic per CDI metrics. Those combinations are currently being tested for efficacy in the metastatic setting with a set of basal-like PDXs.

Background Extracellular vesicles (EVs), secreted by tumor cells for intercellular communication, play an important role in breast cancer progression. Previous studies have proved that lncRNA could use EVs to transmit signals and affect the progression and treatment of breast cancer. In addition, a previous study has found that, in HER2 therapy-resistant tumors, CDK4/6 activity and cell cycle progression genes were involved and might serve as treatment targets. However, recent clinical trials were not supportive of the use of CDK4/6 inhibitors in HER2 enriched internal subtypes of breast cancer. In this study, we aim to explore the role of EVs-transported long noncoding RNA BCDR1 in the promotion of cell cycle progression in HER2-positive breast cancer, exploring a new potential target in combination with CDK4/6 inhibitor and anti-HER2 treatment. Methods Samples were collected from patients with HER2 overexpression receiving neoadjuvant therapy. RNA-seq was performed to identify differentially expressed RNAs between pathological complete response (pCR) and non-pCR group. In addition, serum extracellular vesicles were collected and determined through RNA-seq. The drug response and proliferation rate of tumor cells were measured in breast cancer cells (HCC-1954, BT-474 and MCF-7). Quantitative RT-PCR (qRT-PCR) was used to detect the expression levels of BCDR1 and its potential target genes. RNA-seq and GSEA analysis was carried out to determine the target pathways regulated by BCDR1. DNA fiber assay, mass spectrometry, and flow cytometry were used to understand the underlying mechanism of BCDR1. Results Core needle biopsy tissues from HER2-positive breast cancer patients with any ER status were collected before NAC. Among genes differentially overexpressed, BCDR1 was found to be downregulated in pCR group compared with non-pCR group. BCDR1 was also elevated in plasma EVs in the non-pCR group. In addition, overexpression of BCDR1 in breast cancer cells promoted cell proliferation and HER2 treatment resistance. Through pathway analysis, we found BCDR1 could facilitate G1/S-phase transition. Flow cytometry confirmed these findings. We also noticed that proteins that regulate DNA licensing including

minichromosome maintenance proteins (MCMs) were enriched in BCDR1 overexpression cells. Through DNA fiber assay, we confirmed that BCDR1 could promote DNA replication initiation. Interestingly, under CDK4/6 inhibitor treatment, BCDR1 was induced, unrevealing an internal treatment-resistant mechanism in these tumor cells. Through EVs RT-qPCR, we found BCDR1 could transport from high expression cells to low, with the same biological function. We also explored antisense oligonucleotide (ASO) use in the inhibition of BCDR1 biological function and transportation. Conclusion BCDR1 promotes cell proliferation and therapy resistance via upregulating DNA licensing in breast cancer. BCDR1 could transported through EVs with same biological function. This study also suggests that BCDR1 could serve as a biomarker and therapeutic target in breast cancer.

Resistance to HER2 inhibitors remains a clinical challenge in HER2+ breast cancer. Therefore, there is an urgent need to 1) understand the mechanisms that underlie resistance to these current treatments and 2) develop improved, and more importantly, curative combination therapies. We recently discovered that two emerging tumor suppressor RasGAPs, DAB2IP and RASAL2, cooperatively drive metastatic breast cancer when lost or inactivated. Interestingly, we have now generated robust data demonstrating that the loss of these RasGAPs also induces resistance to HER2 inhibitors in breast cancer. First, we genetically ablated both RASAL2 and DAB2IP in multiple HER2+ breast cancer cell lines (SKBR3, EFM192A, SUM190, BT474) and performed manual counting experiments after 6 days of TKI (lapatinib, tucatinib) treatment. In all cell lines, RASAL2/DAB2IP knockdown conferred resistance to HER2 inhibitors. Moreover, loss of these RasGAPs prevented TKI-induced caspase-3/7 activation, measured by Incucyte live cell imaging, and enabled the regrowth of cells in long-term 10-day treatment and drug washout experiments, monitored by Incucyte or crystal violet staining. Next, we sought to investigate the individual contribution of each RasGAP to these phenotypes. Surprisingly, we found that RASAL2 and DAB2IP functioned quite differently in this context.

Specifically, while RASAL2 loss prevented apoptosis, DAB2IP loss prevented irreversible cell cycle arrest (measured by functional long-term experiments and EdU staining assays). Mechanistically, RASAL2 loss uniquely impaired BIM induction at both mRNA and protein levels, which is required for lapatinib-induced cell death of HER2+ cancer cells. By contrast, cell cycle progression pathways were uniquely enriched in DAB2IP-deficient cells on lapatinib treatment and immunoblots revealed higher residual levels of pRb and low levels of p27 in these cells. These data suggest that RASAL2 and DAB2IP (loss) mediate resistance to HER2 inhibitors by differentially deregulating unique pathways/phenotypes. We next evaluated the relevance of these findings in a SUM190 orthotopic xenograft model. Importantly, while control tumors (expressing both RASAL2 and DAB2IP) regressed upon lapatinib treatment, DAB2IP- and RASAL2-deficient tumors did not regress and grew with kinetics comparable to vehicle-treated tumors after few days on treatment. These data suggest that the unique phenotypes/pathways induced by both RASAL2 and DAB2IP are important mediators of resistance to HER2 inhibitors. Further understanding the contribution of these pathways to anti-HER2 resistance and determining how RASAL2 and DAB2IP differentially function will be essential for developing effective therapeutic strategies to bypass each type of resistance.

Background: CDK4/6 inhibitors (CDK4/6i) are standard of care for the management of HR+/HER2- metastatic breast cancer (MBC). Genomic alterations that drive resistance to CDK4/6i are diverse, and while the molecular landscape is heterogeneous, several

mechanisms of CDK4/6i resistance converge on the RAS/MAPK and PI3K/AKT/mTOR signaling pathways. NF1 downregulates RAS and dampens cellular proliferation. Laboratory-based models demonstrate that loss of NF1 is associated with resistance to endocrine therapy (ET), and emergence of NF1 mutations (NF1m) are correlated with progressive disease (PD) in circulating tumor DNA (ctDNA). While NF1m may diminish CDK4/6i susceptibility, a clear relationship has not been elucidated. The primary objective of this study was to characterize patient (pt) response to CDK4/6i in NF1m HR+/HER2- MBC. Methods: We identified 47 pts with NF1m via a database with one or more ctDNA samples sequenced at variable time-points as part of routine care for MBC. NF1m were categorized as pathogenic (p)NF1m or variants of uncertain significance (VUS) based on their associated Guardant report. We identified 27 pts with HR+/HER2- MBC and NF1m that received at least 1 line of CDK4/6i in the metastatic setting. Intrinsic resistance was defined as PD < 6 months on a CDK4/6i regimen, and acquired resistance was defined as PD >6 months. Pts with intrinsic resistance or acquired resistance and NF1m detected post-PD were categorized as having a resistance phenotype potentially driven by NF1m. Pts with NF1m detected prior to therapy and >6 months clinical response on a CDK4/6i were categorized as having NF1m tumors sensitive to CDK4/6i. Results: The NF1m cohort (n = 27) had 9 pts with pNF1m, while 18 pts expressed VUS. The median age at MBC diagnosis was 54 years, and 67% had visceral metastasis at ctDNA collection. Pts received a median of 1 prior line (range: 0 - 6) of ET or chemotherapy in the metastatic setting before CDK4/6i. Amongst pts with pathogenic variants (n = 9), we found 3 pts with pNF1m were intrinsically resistant to CDK4/6i. Acquired resistance was seen in 1 pt with pNF1m detected post-PD, and 2 pts had evidence of both acquired and subsequent intrinsic resistance to a later line of CDK4/6i. Overall, 67% (6 / 9) of pNF1m pts demonstrated a CDK4/6i resistance phenotype; mutant allele fraction (AF) ranged from 0.2% - 29.9%, and the mean maximum allele fraction (MAF) was 6.0%. Pre- and post-treatment samples were available on 3 pts with pNF1m, and 1 of these pts had an AF rise from 2.7% to 12.3% when comparing ctDNA pre- and post-CDK4/6i. ctDNA from 4 of 6 resistant tumors harbored other putative drivers including alterations in FGFR, KRAS, PTEN, and RB. We identified 2 counter-examples of pNF1m tumors sensitive to CDK4/6i. These pts expressed relatively low NF1m AF, ranging 0.1% - 0.5% with a mean MAF 0.3%. Another pNF1m pt had intrinsic resistance to initial CDK4/6i but was sensitive to later-line CDK4/6i. In the subgroup of pts with VUS-NF1m (n = 18), a more mixed picture of resistance and sensitivity was seen. 8 pts had intrinsic or acquired resistance, 8 pts had NF1m tumors sensitive to CDK4/6i, and 1 pt had evidence of both; 61% (n = 11) of pts expressed alterations in other resistance mediating genes. 1 pt stopped therapy due to toxicity rather than PD. Conclusions: Our work demonstrates that tumor expression of pNF1m may be associated with CDK4/6i resistance in pts with HR+/HER2- MBC, and allele fraction could be predictive of drug susceptibility. Tumors harboring VUS had varied sensitivity, suggesting that some of these mutations may not be pathogenic, and counter-examples of pNF1m MBC benefiting from CDK4/6i plus ET highlight the complexities in predicting drug response based on single gene alteration. Future effort is warranted to explore the potential impact of NF1 on CDK4/6i resistance, as well as the potential role for therapies targeting the MAPK pathway in this patient population.

The 5-year relative survival rate for triple-negative breast cancer (TNBC) is 77%, which is notably lower than 90%, the overall survival rate for breast cancer. The primary systemic treatment for TNBC remains to be chemotherapy. However, patients frequently develop resistance to conventional chemotherapy, greatly compromising the anti-tumor effects of chemodrugs. Therefore, this study is aimed to enhance the effects of chemotherapy. The RNA-binding protein Hu antigen R (HuR) plays an important role in chemotherapy resistance. HuR post-transcriptionally regulates the stability of the target mRNA by binding to the U- or AU-rich elements (ARE) mainly in the 3' untranslated region (UTR) of mRNA. In most cases, the binding stabilizes mRNA, thereby enhancing the translation of the encoded protein, many of which are implicated in multiple cancer hallmarks, including chemoresistance. The overexpression of HuR, and accumulated cytoplasmic expression, are reported to be related to chemoresistance in many types of cancer cells. We hypothesized that inhibition of HuR function by disrupting its interaction with mRNA can accelerate the decay of mRNA and thus reduce the translation of proteins contributing to chemoresistance. Previously, our lab reported a small molecule HuR inhibitor, KH-3, which potently inhibits HuR function by disrupting the HuR-

mRNA interactions. To test our hypothesis, we utilized KH-3 as a tool compound to assess whether HuR inhibition enhances the efficacy of chemotherapy for TNBC cells. We generated a cell sub-line (231-TR) derived from the human TNBC cell line MDA-MB-231 with acquired resistance against docetaxel (TXT). Compared with the parental cell line, 231-TR exhibited similar sensitivity to KH-3 in the MTT-based cytotoxicity assay and the colony formation assay. The in vitro and in vivo combination of KH-3 and TXT synergized in inhibiting cell proliferation and tumor growth of multiple TNBC cell lines. Regarding mechanisms of action, the apoptosis pathway was downregulated and the Wnt signaling pathway was upregulated in 231-TR cells. KH-3 treatment downregulated β -Catenin, involved in promoting cell proliferation, in a time and dose-dependent manner. KH-3 was also identified to induce apoptosis cell death via inhibiting the anti-apoptotic protein BCL2. The cell cycle analysis revealed that KH-3 treatment caused the S phase accumulation. Therefore, the cell proliferation inhibition by KH-3 results from a combination of apoptosis and cell cycle arrest. Furtherly, KH-3 restored the effects of docetaxel in inducing apoptotic cell death in 231-TR cells. Together, this study provides a new strategy to overcome chemotherapy resistance in TNBC cells by functional inhibiting HuR.

Background: BRCA deficient Triple negative breast cancers (TNBC) are effectively treated with platinum agents but, upon relapse, resistance is common. A number of genes have been shown to mediate chemoresistance in vitro, but none have been clinically useful due to the heterogeneous mechanisms of in vivo tumor chemo-resilience. Methods: We attacked this problem by recapitulating the generation of in vivo resistance to cisplatin in 50 mice bearing a platinum sensitive TNBC patient derived xenograft (PDX) TM00099, a BRCA1 deficient type 1 tandem duplicator phenotype tumor. Untreated tumors were compared to residual tumors that were sampled after the first cycle of cisplatin, upon recovery, and after the second cycle of drug which generated platinum resistant and sensitive tumors. Our earlier work on TM00099 suggested the existence of two major subspecies, designated A and B, with shifts observed in their proportions post treatment (1). We deconvoluted the bulk tumors into their clonal components to assess the precise numerical fluxes after each treatment cycle to gain insight into the cellular basis of the emergence of in vivo resistance. Results: 55 single cell derived clones isolated from bulk TM00099 tumors were genomically characterized identifying five subclonal populations: B, CCR, and variations of the original A: A25, A33 and A50. SNP analyses indicated that these five subclones comprised the vast majority (~93%) of all

TM00099 tumors. Lineage analysis revealed that all A clones were related but distinct from B. CCR however had both A and B SNP markers and relatively higher ploidy indicating that CCR is a fusion of ancestral A and B clones. We found that A50, A33, and CCR were ~1.9X more resistant to cisplatin (mean IC50=4.4 μ M) compared to the sensitive clones A25 and B (mean IC50=2.3 μ M; p=0.002) in vitro. Although B clones had similar IC50 to A25s, B had improved in vitro survival at higher concentrations of cisplatin suggesting a dormancy-like phenotype: the persistent B cells did not recover within 50 days after in vitro exposure to cisplatin. Using clonal markers in bulk tumors, we found excellent concordance with their in vitro phenotypic analysis: after the first cycle of cisplatin, there was a proportional decline in A25, an enrichment of B, and stable proportions of A50, A33, and CCR. After the second platinum cycle, the emerging resistant tumors were mostly devoid of A25, and had low proportions of B, but highly enriched for A50, A33, CCR and an uncharacterized resistant A clone. The sensitive tumor residuals after the second platinum dose were predominantly comprised of B. Genomic analysis of the clones did not reveal any genetic drivers of resistance. Transcriptionally, the sensitive B clones were characterized as mesenchymal or basal-like 1 TNBC subtypes, while the resistant As were categorized as basal-like 2, which have enhanced growth factor signaling and is associated with poorer response to chemotherapy. Correspondingly, the MAPK and stress associated NF- κ B signaling pathways were augmented in As which were indeed more sensitive to blockade of MEK, EGFR and NF- κ B than the platinum sensitive B clone. A25s which are sensitive revertants of the otherwise resistant A group use a mechanism to bypass resistance likely driven by ZNF350 and ZNF93. Conclusions: Our clonal reconstruction of TM00099 showed that acquired resistance can emerge by enrichment of not one but a composite of multiple preexisting resistant clones. The origins and characteristics of these clones are complex and include epigenetically driven resistance (A50 and A33), cell fusion mediated resistance (CCR), reversion to sensitivity (A25), and dormancy despite initial sensitivity (B). These nuances would not be discerned using bulk tumor assessments pointing to single cell genomic analyses as the most precise way to deconvolute the capacity of TNBC tumors to develop resistance. Triple-negative breast cancer (TNBC) is the most aggressive breast cancer subtype. Due to the lack of receptor expression, there are limited targeted therapies available for TNBC. As a result, TNBC patients are primarily treated with chemotherapies such as taxanes. Although TNBCs initially regress in response to taxane treatment, resistance is common. One mechanism of taxol unresponsiveness/resistance is an increase in chromosomal instability (CIN). Increased CIN can confer survival advantages to cancer cells and increase their aggressiveness. However, CIN levels can be leveraged using drugs that inhibit proteins important for chromosomal stability. Combining CIN-inducing drugs, such as taxanes, can improve treatment efficacy or re-sensitize tumor cells to certain drugs by shifting cells towards a state of maladaptive CIN that is incompatible with cell viability. We have found that the non-receptor SRC family kinase YES1 is crucial for chromosomal stability. YES1 is important for cell division, motility, adhesion, and survival in both normal and TNBC cells. Since taxol and YES1 silencing independently increase chromosomal instability, I hypothesized that combining a YES1 inhibitor (YES1i) with taxanes would shift cells toward an irreversible state of maladaptive CIN, decreasing their survival. I found that YES1 mRNA and protein are upregulated in taxane-resistant cells and that YES1 protein expression correlates with the paclitaxel IC50 in a panel of TNBC cell lines, suggesting that YES1 may drive taxane resistance. Furthermore, I found that a selective YES1 inhibitor (CH6953755) synergizes with paclitaxel and improves taxane response in both in vitro and in vivo TNBC models. In addition, the combination of YES1i and paclitaxel treatment increases phenotypes associated with chromosomal instability more than either drug alone. These data suggest that YES1 inhibition in combination with taxanes represents an innovative and novel drug treatment regimen that improves TNBC patient outcomes.

The development of drug resistance is a primary cause of chemotherapy failure in the treatment of triple-negative breast cancer (TNBC). Some cancer cells are resistant to drugs with unrelated structures and mechanisms of action, a phenomenon known as multidrug resistance (MDR). Although taxanes such as docetaxel and paclitaxel are effective against non-metastatic and metastatic TNBC and other types of breast cancer, they eventually become ineffective due to development of drug resistance. Mitochondrial dynamics has gained significant attention as a means to treat MDR and non-MDR cancers. Mitochondrial dynamics determine the number, shape, and location of mitochondria within cells, which are fundamental to the health of the cell. Among its key components is the mitochondrial fission-promoting dynamin-related protein 1 (Drp1). There is mounting evidence indicating that both Drp1 and its phosphorylated form promote cancer survival, resistance to apoptosis, and chemoresistance. We observed increased phosphorylation of Drp1 at Ser616 as well as phosphorylation of its upstream kinase ERK1/2 in TNBC lines SUM159PT and its paclitaxel-resistant derivative that we developed called SUM159PT/PAC200 that displays more than an 80-fold increase in resistance to paclitaxel. Using CRISPR-Cas9 technology, we knocked out the gene encoding Drp1 in both lines. When Drp1 is genetically ablated, paclitaxel resistance in SUM159PT/PAC200 was significantly reversed. Furthermore, proliferation, migration, and invasion capabilities were decreased in both parental and paclitaxel-resistant Drp1 knockout lines. In SUM159PT/PAC200 Drp1-KO cells, a mesenchymal to epithelial transition (MET) was observed as indicated by downregulation of mesenchymal markers such as N-cadherin and β -catenin, and upregulation of the epithelial marker ZO-1. Interestingly, Drp1 knockout halted the ability of SUM159PT/PAC200 to form colonies in soft agar. SUM159PT/PAC200 cells strongly express the MDR pump P-glycoprotein (ABCB1), to which paclitaxel is a known substrate, and genetically targeting Drp1 reduced the expression to almost undetectable levels. Taken together, these findings suggest that Drp1 is both a resistance factor and a key protein in breast cancer proliferation and dissemination, making it a promising actionable molecular target in the treatment of TNBC. Further studies are in progress to understand the role of Drp1 in the development and maintenance of MDR phenotype, proliferation, and invasion.

The sub-classification of invasive breast cancer into Integrated Clusters by a combined analysis of genomic change and expression profiling has revealed novel cancer drivers. The integrated Cluster 2 breast cancer sub-group represents a cohort with aggressive, largely estrogen receptor positive tumours with a high relapse rate. It is characterized by an amplification of chromosome 11 at the heart of which is a little studied gene which codes for the protein Adipocyte-Associated Methionine Domain Containing (AAMDC). Initial cell line and murine studies demonstrated oncogenic behaviours for AAMDC including increased proliferation and invasion, increased colony formation and anti-estrogen resistance. Downstream gene

expression analysis showed the protein to modulate cholesterol biosynthesis, one carbon metabolism and mTOR signaling. To assess the clinical impact of differing levels and sub-localizations of AAMDC, immunohistochemistry for AAMDC was carried out using tissue microarrays from a cohort of 420 patients with invasive breast cancer. Expression was noted in a number of sub-cellular localizations including diffuse cytoplasm, nucleus and nuclear envelope. Using both dichotomous and continuous scoring, no significant association for any expression site with standard prognostic factors was identified including size, lymph node status, grade or receptor statuses. However, both cytoplasmic and nuclear envelope expressions correlated with significantly worse overall survival ($p=0.04$ and $p=0.04$ respectively) whereas nuclear expression showed a trend to better survival ($p=0.06$). Distant relapse and breast cancer deaths were lowest where there was nuclear expression but no nuclear envelope expression (4.7% and 4.7% respectively) but significantly higher for the reverse expression pattern (18.9%, $p=0.02$ and 17.6%, $p=0.03$ respectively). Considering the pre-clinical impact of AAMDC on genes involved in cholesterol biosynthesis, we studied the effects of statin prescription in the early disease setting in the context of AAMDC expression. Statins were found to be generally protective of relapse across the group. Only nuclear envelope AAMDC expression interacted, with a hazard ratio (HR) of 0.33 for distant relapse with high expressors, compared to a HR of 0.90 in low expression ($p=0.02$ for difference). Similarly, considering one carbon metabolism, we explored the impact of the anti-metabolite drug capecitabine compared to other chemotherapy treatments, largely taxane-based, in the metastatic setting. Again, only nuclear envelope expression interacted with median progression-free survivals on capecitabine of 2.0 v 12.2 months for low and high nuclear envelope expression respectively, $p=0.03$. In summary, AAMDC nuclear envelope expression correlates with poor prognosis which may be mitigated by statin administration in the early disease setting. This expression pattern also confers sensitivity to flurouracil-based metastatic treatment.

Background: Triple negative breast cancer (TNBC) represents the most aggressive breast cancer subtype, and despite recent treatment advances, clinical outcomes remain poor, particularly in the metastatic setting. TNBC is a biologically heterogeneous entity, and up to 50% of TNBC express the androgen receptor (AR). Gene expression subtyping has identified a subset of AR-TNBC with a luminal AR-driven (LAR) phenotype. Consequently, there has been great interest in translating androgen receptor signaling inhibitors (ARSIs) approved for use in prostate cancer such as enzalutamide and bicalutamide into the management of LAR-TNBC. However, early phase clinical trials of anti-androgens in metastatic AR-TNBC have had modest results. While multiple mechanisms of anti-androgen resistance have been identified in prostate cancer, including AR amplification and over-expression, emergence of AR splice variants (AR-Vs), and transition to AR independent growth, molecular determinants of anti-androgen resistance in TNBC remain poorly understood, and pre-clinical models to study acquired ARSI resistance in LAR-TNBC have been limited. Methods: A novel pre-clinical model of acquired ARSI resistance was derived from the LAR subtype MDA-MB-453 cell line through serial passaging with increasing concentrations of enzalutamide. Celltiter Blue viability assays were used to determine enzalutamide IC50 of parental and enzalutamide-resistant (EnZR) cell lines.

RNA was extracted from the parental and resistant cells, reverse transcribed and expression of AR, splice-variants and canonical AR target genes were evaluated using RT-qPCR. Immunofluorescence was used to investigate the amount and nuclear localization of the AR protein within the parental and enzalutamide resistant cells. Results: EnzR MDA-MB-453 cells were derived through culture in increasing concentrations of enzalutamide for >6 months, and found to have a significant increase in enzalutamide IC50 compared to the parental cell line. EnzR MDA-MB-453 cells had a 4.5 fold increase in full-length AR expression at the transcriptional level compared to the parental cell line. AR protein expression and nuclear localization were also increased in EnzR cells compared to the parental cell line. Canonical AR targets including NKX3.1 were downregulated in response to enzalutamide in parental but not EnzR cells. While pathogenic AR splice variants (AR-Vs) implicated in ARSI resistance in prostate cancer were detected at low levels in MDA-MB-453 cells, no increase in AR-V expression was observed in the EnzR cell line. Conclusions: We have developed a novel pre-clinical model of anti-androgen/ARSI resistance in LAR-TNBC, and identified AR overexpression and persistent AR signaling associated with acquired enzalutamide resistance in LAR-TNBC. While pathogenic AR splice variants have been implicated in ARSI resistance in metastatic prostate cancer and are detected in the MDA-MB-453 cell line model, enzalutamide resistance was not associated with increased AR splice variant expression in this model. Future work will investigate mechanisms leading to AR overexpression as well as combination therapeutic strategies to overcome acquired ARSI resistance.

Background: -Trastuzumab-based neoadjuvant chemotherapy has shown to have remarkable clinical benefits for HER2-positive breast cancer patients who had higher tumor burden. - Patients who achieved pathological complete response (pCR) are known to have better prognosis. -However, certain patients have little response or are not sensitive to trastuzumab-based treatment regimens. -Understanding the mechanism of trastuzumab resistance is crucial for the development of new therapeutic strategy. Objectives: To investigate the role of TCEAL9 in developing trastuzumab resistance in HER2-positive breast cancer Methods: A total of 83 patients who received paclitaxel, carboplatin and trastuzumab neoadjuvant chemotherapy in Fudan University Shanghai Cancer Center(FUSCC) from 2016 to 2018 were enrolled in this study. After completed neoadjuvant chemotherapy and surgery, gene expressions were compared between the pCR and non-pCR groups. Total RNA from formalin-fixed paraffin-embedded tissue sections was isolated and RNA-sequencing was performed. Gene sets from GEO dataset GSE52707 were used to analyze TCEAL9 expression in resistant and non-resistant cell lines. Gene expression levels were converted into log2 values and row-wised standardized. BT-474 and SK-BR-3 cell lines were transduced with each expression lentivirus, followed by selection with puromycin for stable expression. TCEAL9 mRNA and protein level evaluation was evaluated by qPCR and western blot. The influence of TCEAL9 expression on proliferation and sensitivity to HER2-targeted therapy was evaluated by CCK8. BT-474 and SK-BR-3 transfected cells were plated in 96-well plates with 4,000 cells per well. After 3 or 5 days of incubation with trastuzumab, pertuzumab or lapatinib, the viability of cells was measured using Cell Proliferation Assay. Comparisons between Kaplan-Meier curves were performed using the long-rank test. Results: TCEAL9 was elevated significantly ($P < 0.05$) in non-pCR patients in the FUSCC cohort and was associated with lapatinib resistance in GSE52707 from GEO datasets. Patients with elevated TCEAL9 expression had worse recurrence-free survival (RFS), distant metastasis-free survival (DMFS) and progression-free survival (PPS) (all $P < 0.05$) by using KM-plotter. Overexpression of TCEAL9 was associated with lapatinib($IC_{50} = 5.56$ vs 10.90 nM) and trastuzumab + pertuzumab($IC_{50} = 745$ vs 635 nM) resistance in BT-474 and SK-BR-3 respectively, but has no influence in proliferation. In this study, we found that TCEAL9 could induce HER2-positive breast cancer cells resistance to HER2-targeted therapy through the activation of mTOR signaling pathway. After EGFR stimulation, TCEAL9 has a higher mTOR phosphorylation level in BT-474 cells. TCEAL9 elevation also increased HER2 and mTOR phosphorylation after lapatinib treatment in SK-BR-3 cells. In addition, the elevation of TCEAL9 has a positive correlation with HER2 signaling pathways such as EGFR , PIK3R1 , FOXO1 and AKT3 in TCGA datasets. Conclusions: TCEAL9 expression correlates with trastuzumab resistance and high TCEAL9 expression is associated with poor prognosis in HER2-positive breast cancer patients.

Background: Palbociclib might be less effective than ribociclib in HR+/HER2- and HER2-enriched BC. This hypothesis is currently being tested in the HARMONIA prospective phase III clinical trial (NCT05207709). Here, we evaluated the downstream biological effects of both drugs using cell lines and patient tumor samples. Methods: Three HR+ BC cell lines (i.e., MCF7, T47D and BT474) were treated at 2 different dose levels of palbociclib or ribociclib (i.e., 100 nM and 500 nM) +/- fulvestrant (1 nM) for 72 hours (h). PAM50 gene signatures were determined on the nCounter, as well as phosphorylation of RB (p-RB) by Western Blot and senescence-associated β -galactosidase activity by FACS. In vitro experiments were performed in triplicates. PAM50 gene signatures were obtained from 49 paired baseline versus week-2 samples and 49 paired baseline versus surgery samples of the CORALLEEN phase II study (Prat, *Lancet Oncol.* 2020), which treated 49 women with PAM50 Luminal B HR+/HER2- early BC with neoadjuvant ribociclib (600 mg daily) plus endocrine therapy (ET). PAM50 signature scores were also evaluated in publicly available data from 23 paired baseline versus week-2 samples and 16 paired baseline versus surgery samples of the NEOPALANA phase II trial (Ma, *Clin Cancer Res.* 2017) which treated 50 patients with HR+/HER2- early BC with palbociclib (125 mg daily) plus anastrozole. Changes in PAM50 signatures upon CDK4/6i were determined by paired t-tests and significant analysis of microarray (SAM). Results: Across all cell lines, both palbociclib and ribociclib statistically significantly reduced p-RB at 72h with both doses (i.e., 100 and 500 nM) compared to non-treated cells ($p < 0.001$). Senescence was also observed at 72h with both doses. Both drugs +/- ET significantly increased the Luminal A signature and decreased Luminal B and proliferation signatures with both doses. However, the HER2-enriched signature was only significantly reduced when both CDK4/6 inhibitors were given at 500 nM. In tumor samples from the CORALLEEN and NEOPALANA phase II studies, a similar change in PAM50 biology was observed with both drugs, namely an increase in Luminal A signature and a decrease in Luminal B and proliferation signatures after 2 weeks of treatment and at surgery. At 2 weeks of treatment, the HER2-enriched signature was significantly decreased in both studies with ribociclib ($p < 0.001$) and palbociclib ($p < 0.001$). However, the decrease in the HER2-enriched signature was only observed in surgical samples of patients treated with ribociclib ($p < 0.001$), but not palbociclib ($p = 0.194$). A difference in sample size could explain this result. Nevertheless, in CORALLEEN, the median number of days between the last dose of ribociclib and surgery was 13.1 days (range: 1-78). In NEOPALANA, the median number of days between the last dose of palbociclib and surgery was 29 days (range: 8-49), except for 8 patients who received additional 10-12 days of palbociclib immediately

before surgery (Ma, Clin Cancer Res. 2017). In patients who underwent surgery at 8 days or before, the HER2-enriched signature was significantly decreased for both ribociclib ($p < 0.001$) and palbociclib ($p = 0.013$). Interestingly, in patients that underwent surgery after >8 days from the last dose, a significant reduction of the HER2-enriched signature was only observed with ribociclib ($p < 0.001$), but not with palbociclib ($p = 0.500$). Conclusions: Both palbociclib and ribociclib have similar effects on PAM50 biology when given at the same dose. However, in clinical practice, palbociclib is given at a lower dose than ribociclib, and although HER2-enriched signature is significantly decreased in tumors after 2 weeks of CDK4/6i+ET, this effect is only maintained at later time points with ribociclib, indicating a dose-dependent efficacy of CDK4/6i in this biologically aggressive subtype.

Background: The HER2-specific tyrosine kinase inhibitor (TKI) tucatinib (Tuca) recently approved for advanced HER2+ breast cancer is making a move towards the early setting. Given its growing use, resistance is inevitable, as observed in the HER2CLIMB study, where only one patient with brain metastasis remained progression free after 2 years on Tuca. Driven by the prevailing lack of knowledge about the mechanisms of resistance, in this study, we sought to define these mechanisms and identify treatment strategies to overcome them. We previously reported (SABCS 2021) that our BT474 TucaR models acquired EGFR amplification and showed elevated levels of phosphorylated (p) and total (t) EGFR, pHER2, pHER3, and downstream pAKT and pS6. Since the HER pathway is activated by ligands, here we aim to assess if hyperactivation of EGFR via high levels of its ligands is an alternative mechanism of Tuca resistance. Materials and Methods: Our recently developed HER2+ BT474 (ATCC and AZ) cell models with acquired resistance to Tuca (TucaR) developed through long-term exposure to gradually increasing doses of Tuca and their naïve parental (P) were used. Genomic (DNA-seq), transcriptomic (RNA-seq), and proteomic (western blot) characterization were performed. Changes in cell growth and migration were assessed by methylene blue and Incucyte wound healing assays, respectively. Results: RNA-seq analysis demonstrated that the levels of TGF α was significantly higher in our BT474 TucaR models compared to P cells. Our results now demonstrate that exogenous supplementation of EGF to BT474-P cells rescues the Tuca-mediated inhibition of pEGFR, pHER2, and the downstream pAKT, pERK, and pS6 levels. Exogenous EGF was also found to reduce the levels of apoptosis, as assessed by cleaved PARP, mitigating the Tuca-induced cell death. Exogenous EGF or TGF α rendered naïve BT474 and SKBR3 cells resistant to Tuca while neratinib, a pan-HER TKI, effectively inhibited this ligand-driven cell growth. We previously showed that the HER signaling reactivation observed in our EGFR-amplified TucaR cells was inhibited by the EGFR-specific TKI gefitinib (Gef) (SABCS 2021) and that the TucaR cells displayed enhanced migratory capabilities (AACR 2022). Here, we demonstrate that in addition to curbing the growth of TucaR cells, Gef, either alone or together with Tuca, also markedly reverts the migration of the TucaR cells. Knockdown (KD) of EGFR but not HER2 selectively and substantially inhibited the migration of the TucaR cells. KD of EGFR also had a marked cell killing effect on only the TucaR cells, whereas HER2 KD inhibited the growth of P but not TucaR cells. Our findings are consistent with the notion that while the P cells are functionally dependent on HER2, in TucaR cells the survival dependence could be rewired to rely primarily on the hyperactive EGFR signaling. Genomic analysis further revealed that in addition to EGFR amplification, the AZ TucaR cells also acquired a gain of YES1, a src family receptor tyrosine kinase implicated in cancer cell growth, invasion, and metastasis. Functional studies using 2 siRNAs, however, showed that YES1 KD had no effect on the growth of TucaR cells, and the migration of both TucaR and P cells was equally affected by YES1 KD, precluding the potential role of YES1 in driving the resistant and enhanced migratory phenotypes. Conclusions: Hyperactivation of the

EGFR pathway via amplification of EGFR or increased expression of its ligands confers resistance to Tuca, which may be overcome using dual/pan-HER TKIs or the combination of potent EGFR and HER2 inhibitors. Given the rapidly evolving treatment landscape of HER2+ breast cancer and biomarkers of resistance, our novel findings have potentially crucial therapeutic implications and suggest that rationally sequencing the currently available TKIs may be clinically important.

Breast cancer driven by different hormone receptors, including estrogen receptor (ER+), is responsible for approximately 70-80% of cases among women. While endocrine therapy (ET) of ER+ primary tumors with antiestrogens or aromatase inhibitors is an effective first-line therapy, its success is limited by intrinsic and acquired resistance. Response to ET can be limited due to overexpression of cyclin D1, which promotes the activation of cyclin-dependent kinases 4 and 6 (CDK4/6). Selective inhibition of CDK4/6 and ER signaling is now standard-of-care therapy for ER+ metastatic breast cancer. CDK4/6 inhibitors (CDK4/6i), including palbociclib (PD), ribociclib, and abemaciclib, used in combination with ET, have shown improvement in progression-free survival compared to ET alone in the metastatic setting. However, the inevitable development of acquired resistance significantly limits the efficacy of this targeted therapy. Rewired signaling driven by different oncogenes, including the epidermal growth factor receptor (EGFR), overcomes the targeted inhibition of CDK4/6, which, in turn, allows cell cycle progression contributing to acquired resistance. We evaluated the expression and activity of EGFR in the panel of different matching pairs of ER- and ER+ CDK4/6i-sensitive (pS) and CDK4/6i-resistant (pR) breast cancer cell lines in vitro. Increased EGFR expression in ER+ MCF7/pR cells correlated with elevated ER phosphorylation, suggesting a direct cross-talk between EGFR and ER signaling in PD-resistant cells. Stimulation with EGF promoted ER activation, whereas estrogen stimulation promoted EGFR activation in ER+ pS and pR cell lines, indicating a direct cross-regulation between these molecular targets. Treatment of MCF7/pR cells with CDK4/6i resulted in elevated EGFR mRNA expression, confirming the dependency of resistant cells on EGFR signaling. Moreover, exposure to the EGFR inhibitors dramatically inhibited the proliferation of MCF7/pR cells compared to the parental cells, suggesting that EGFR could be an essential bypass signaling regulator contributing to resistance to CDK4/6i. We found that combined treatment with EGFRi and CDK4/6i significantly inhibited Rb phosphorylation in pR cells improving the effect of CDK4/6i on cell cycle arrest. We evaluated EGFR expression in MCF7/pS and pR mouse xenograft models in vivo. We observed a significant elevation in EGFR expression and phosphorylation in response to PD treatment, confirming the importance of EGFR signaling in maintaining the acquired resistance

to CDK4/6i in ER+ breast cancer cells. Taken together, our findings suggest that EGFR signaling plays an important role in acquired resistance to CDK4/6i in ER+ breast cancer cells in vitro and in vivo and targeting EGFR with small-molecule inhibitors (like erlotinib or gefitinib) or chimeric monoclonal antibodies (i.e. cetuximab) can be a promising approach to improve CDK4/6i efficacy in breast cancer patients.

Background: Trastuzumab combined with pertuzumab is the main therapy for HER2 positive breast cancer, but poor patient response due to drug resistance remains a clinical challenge. Organoids derived from tumor patients can highly maintain the heterogeneity of the original tumor, and have been used in drug sensitivity testing and new drug development. To screen for genes that associated with trastuzumab or pertuzumab drug resistance, this study used HER2-positive breast cancer organoids to establish a model of trastuzumab combined with pertuzumab and conducted high-throughput sequencing to screen the differential genes. We carried out further research to explore the effect of ESAM on drug sensitivity of HER2-targeted therapy and clarify the specific regulatory mechanisms and potential therapeutic targets of ESAM. Method: 8 HER2 positive breast cancer organoids were cultured. Immunohistochemistry, hematoxylin-eosin staining and Immunofluorescence were performed to identify the consistency between organoids and primitive tumors. According to drug sensitivity results of organoids to trastuzumab combined with pertuzumab, organoids were divided into a relatively sensitive group and a relatively insensitive group. Trastuzumab combined with pertuzumab was regularly used to stimulate the two groups. After 3 cycles, high-throughput transcriptome sequencing was used to evaluate their gene expression to find a gene responsible for trastuzumab and pertuzumab resistance. METABRIC and our center database were used to determine the prognostic value of ESAM. ESAM overexpression and knockdown stably transfected cell lines were constructed in SK-BR-3 and BT474 breast cancer cell lines by lentivirus. Colony formation assay, CCK-8 assay, organoid model and mouse xenograft model were conducted to examine the influence of ESAM on proliferation and trastuzumab or pertuzumab sensitization in vitro and in vivo. RNA-seq and GSEA analysis were performed to investigate the downstream pathways of ESAM. Western blot was used to confirm the relationship between ESAM and mTOR pathway. Small interfering RNA and mTOR/PI3K pathway inhibitors were used to confirm the function of mTOR in ESAM-induced drug

resistance of trastuzumab. Results: HER2 positive breast cancer organoids can maintain the pathological characteristics of primitive tumors. The results of high-throughput transcriptome show that ESAM is significantly up-regulated in the relatively insensitive group compared to the relatively sensitive group. METABRIC and our center database suggest that high ESAM mRNA expression was associated with poor OS, RFS, DFS and PFS of HER2-positive breast cancer patients. CCK-8 and cell colony formation assay confirm that ESAM can promote the proliferation of HER2-positive breast cancer cells and inhibit the drug sensitivity of HER2-positive breast cancer cells to trastuzumab and pertuzumab. GSEA analysis shows high ESAM can activate mTORC1 signaling pathway. Western blotting analysis proves the expression of ESAM is positively correlated with mTOR pathway. Inhibition of mTOR pathway in ESAM overexpression cells can suppress ESAM-mediated proliferation and reverse the drug sensitivity of cells to trastuzumab and pertuzumab. In vivo, overexpression of ESAM can promote the proliferation of mouse mammary tumors and reduce the sensitivity of mouse mammary tumors to trastuzumab, combined use of PI3K inhibitor could reverse drug sensitivity of mouse mammary tumors to trastuzumab. Conclusion: High ESAM expression is associated with poor prognosis in patients with HER2 positive breast cancer. ESAM can activate mTOR pathway, promote cell proliferation and reduce the sensitivity of HER2 positive breast cancer cells to trastuzumab and pertuzumab, which can be inhibited by the application of PI3K/mTOR inhibitors. Keywords: ESAM; HER2 positive breast cancer; HER2 targeted therapy; mTOR; drug sensitivity.

Background The formation of resistance against trastuzumab deeply affects the treatment of HER2 positive breast cancer. Although studies have demonstrated several possible reasons that cause the trastuzumab resistance, the precise changes of cell process as well as the interaction between cancer cells and tumor microenvironment during the formation of resistance are still poorly understood. Here we figured out several crucial changes including oncogenic signal pathways as well as metabolism processes especially amino acids and polyunsaturated fatty acids (PUFAs) during the establishment of trastuzumab resistance. We further suggested that the inducers of ferroptosis may be promising reagents for trastuzumab resistant HER2 positive breast cancer. Methods The trastuzumab resistant cell was generated from a sensitive cell line SKBR3. To simulate the adaptation process of HER2 positive tumor to anti-tumor drug, the concentration of trastuzumab was changed gently to prevent cell death. After 8 weeks treatment, trastuzumab concentration in medium was raised from 1µg/ml to 6µg/ml, and a “persister” cell line SKBR3_HP was obtained. The original cell line SKBR3 was cultured for 8 weeks as well to exclude any changes that caused by culture condition. And each cell line includes 3 biological repeats. The viability of two cell lines is measured by CCK8 cell proliferation test with different concentration of trastuzumab. Total RNA of both SKBR3 and SKBR3_HP cells were prepared for sequencing. Activity scores of oncogenic signal pathways as well as metabolism processes were defined and calculated as the relative gene expression value averaged over all genes in this pathway in certain cell type. Flow cytometry was applied for reactive oxygen species measurement with BODIPY-C11. Results After 8 weeks treatment of trastuzumab, the persister cell line SKBR3_HP showed a significant higher viability than original sensitive cell line SKBR3. Oncogenic signal pathway analysis revealed that RTK-Ras, MYC and HIPPO pathways turn into a more active state in SKBR3_HP cells, as well as the upregulation of several cell cycle genes, which are all the response to the blockage of HER2 signal cascade and together maintains cell proliferation. Beside signal pathway, the reprogramming of metabolism is also the consequence of cell adaptation to trastuzumab. Minor changes in energy metabolism, such as glycolysis, citrate cycle and oxidative phosphorylation were observed in SKBR3_HP cells. However, amino acid metabolism, including the synthesis of phenylalanine, histidine, arginine, proline, cysteine and methionine, was largely enhanced in SKBR3_HP cells. Fatty acid, specifically the metabolism of PUFAs, such as linoleic acid, alpha-linolenic acid and arachidonic acid, was activated during the formation of trastuzumab resistance, which was confirmed by the lipid metabolomics data that most n-3/n-6 PUFAs decreased in SKBR3_HP cells. As cysteine and PUFAs metabolism might closely associate

with cellular redox balances, erastin and RSL3 were applied to interrupt the intake of cysteine and potentiate the lipid peroxidation process, respectively. A situation of higher ferroptosis sensitivity accompanies raising peroxidated lipids could be detected in SKBR3_HP cells. Conclusion By analyzing the transcriptome and metabolomics data of trastuzumab sensitive and persister cell lines, we pointed out that the changes of oncogenic signal pathway, together with metabolism variation, particularly amino acids and PUFAs, are all the cellular adaptations to high trastuzumab environment. And the higher ferroptosis sensitivity of persister cells could be a valuable treatment target.

Background Cyclin-Dependent Kinase (CDK) 4/6 inhibitors have significantly improved progression-free survival of Hormone Receptor positive (HR+), Human Epidermal Growth Factor Receptor type 2 negative (HER2-) luminal breast cancers (LBC). Several studies demonstrated that the addition of CDK4/6 inhibitors to endocrine therapy results in a significant prolongation of progression-free survival in patients with endocrine-sensitive or endocrine-resistant LBCs. However, the percentage of patients unresponsive or refractory to these

therapies is as high as 40%, and no reliable and reproducible biomarkers able to select a priori responder or resistant patients have been validated till now. The main cause of resistance is the selection of mutant clones in the target oncoprotein. Other mechanisms, like oncogene amplification/overexpression or mutations in other pathways, have been described in several models. Here, we focused on palbociclib, a selective inhibitor of CDK4/6. Methods: We generated and characterized human luminal breast cancer MCF-7 and T47D derived cell lines, able to survive and proliferate at different palbociclib concentrations, which also shows cross-resistance to abemaciclib. The resistant MCF7 cell line was characterized by RNA sequencing. Results: To confirm resistance, we performed cell viability assays in MCF-7 and T47D palbociclib sensitive cells (MCF-7pS and T47pS) versus MCF-7 and T47D palbociclib resistant cells (MCF-7pR5), showing a 10-fold increase of IC50 in MCF-7pR5 compared to parental MCF-7pS cells (16.7 vs 1.8 μ M) and a 3-fold increase of IC50 in T47DpR5 vs parental T47DpS. We also confirmed a significant cross resistance using abemaciclib in MCF-7pR5 with an IC50 equal to 6.8 vs 0.35 μ M and in T47DpR with an IC50 of 10.72 vs 0.5 μ M. RNA sequencing, qRT-qPCR and Western blot results demonstrated a dramatic downregulation of the CDK4 inhibitor CDKN2B in both cell lines and we found upregulation of an miR-31, a putative regulator of CDKN2B. This finding was further validated in a biopsy from a patient progressing on CDK4/6 inhibitor therapy. Conclusions: This study provides new relevant information regarding the mechanism of resistance to CDK4/6 inhibitors and suggests potential new markers to follow up patients during the treatment.

Background: Several CDK4/6 inhibitors have recently been approved in combination with letrozole or fulvestrant in hormone receptor-positive breast cancer. Although this combination therapy has been found effective in some patients, resistance often develops. To aid in developing new therapies for CDK4/6i-resistant breast cancer and better understand potential resistance mechanisms, we established two XenoSTART Patient-Derived Xenograft (XPDx) models representing ER+/HER2- breast cancer from tissue samples collected seventeen months apart from the same patient before and after palbociclib therapy. These models designated ST4887 and ST4887B were developed and characterized for receptor expression, genomic alterations, and in vivo drug sensitivities toward multiple chemotherapies and targeted agents, including CDK4/6i and fulvestrant. Methods: Models ST4887 and ST4887B were established from metastatic samples collected from a Caucasian female with ER+/HER2- metastatic breast cancer; ST4887 was collected at age 38 from a femur mass biopsy following several treatment regimens including paclitaxel/doxorubicin/cyclophosphamide, radiation and tamoxifen. ST4887B was collected at age 39 from a liver biopsy following treatment with palbociclib/letrozole then palbociclib/fulvestrant, and finally ixabepilone/capecitabine. Both were grown subcutaneously in female athymic nude mice supplemented with exogenous estradiol. The resulting models were passaged, and receptor expression confirmed immunohistochemically; genomic analysis, including WES and RNAseq, was performed to further characterize models. For in vivo studies, both models were evaluated using several

chemotherapy and targeted agents alone and in combination including cisplatin, docetaxel, CDK4/6i, fulvestrant, letrozole, olaparib, niraparib, and sacituzumab. In vivo study endpoints included tumor volume and time from treatment initiation with %T/C values and tumor regression reported at study completion; a T/C of $\leq 20\%$ versus control was considered sensitive. Tumor regression ($\%T/C \leq 0$) versus Day 0 tumor volume was also reported. Results: ST4887 and ST4887B retained comparable receptor expression (ER=3+/HER2=1+) over tested passages with similar histology compared to archival clinical samples. DNA/RNA sequencing identified several conserved variants including a somatic BRCA2 truncation (BRCA2Y2660*); transcriptomic analysis revealed upregulation of several related genes but no notable fusions. In vivo, both models were insensitive to cisplatin or docetaxel, however ST4887 but not ST4887B was sensitive to fulvestrant or CDK4/6i therapies, although abemaciclib demonstrated some activity toward ST4887B. PARP inhibitors were active toward ST4887 and to a lesser extent ST4887B, while sacituzumab did not have a significant effect on either model. Conclusion: We established and characterized two XPDX models from the same patient before and after acquired resistance to the CDK4/6i palbociclib. Both models were found to retain receptor status and drug sensitivities similar to the patient at the time of sample collection. These models can be utilized as a valuable tool in better understanding acquired resistance to palbociclib.

Changes in the three-dimensional (3D) structure of the genome are an emerging hallmark of cancer. Cancer-associated copy number variants and single nucleotide polymorphisms promote rewiring of chromatin loops, disruption of topologically associating domains (TADs), active/inactive chromatin state switching, leading to oncogene expression and silencing of tumor suppressors. However, little is known about 3D changes during cancer progression to a chemotherapy-resistant state. We integrated chromatin conformation capture (Hi-C), RNA-seq, and whole-genome sequencing obtained from triple-negative breast cancer patient-derived xenograft primary tumors (UCD52) and carboplatin-resistant samples and found increased short-range (< 2Mb) interactions, chromatin looping, formation of topologically associating domains (TAD), chromatin state switching into a more active state, and amplification of ATP-binding cassette (ABC) transporters. Transcriptome changes suggested the role of long-noncoding RNAs in carboplatin resistance. Rewiring of the 3D genome was associated with TP53, TP63, BATF, FOS-JUN family of transcription factors and led to activation of aggressiveness-, metastasis- and other cancer-related pathways. Integrative analysis highlighted increased ribosome biogenesis and oxidative phosphorylation, suggesting the role of mitochondrial energy metabolism. Our results suggest that 3D genome remodeling may be a key mechanism underlying carboplatin resistance.

Introduction

Breast cancer (BC) in women age 40 or younger represents approximately 7% of all BC cases. Studies have reported that BC in younger women is more likely to have adverse tumor characteristics and outcomes when compared to elder women. Despite the fact that BC in the Middle East seems to occur at a younger age, data on tumor characteristics in these patients are scarce, especially in the United Arab Emirates.

Objective

This study was conducted to investigate the incidence, clinicopathological characteristics, treatment modalities, and outcomes of young BC patients at a major cancer center in the UAE, Tawam Hospital. This will provide a better insight in local features and enables comparison of UAE data with other parts of the world.

Method

Data of 911 BC patients age ≤ 40 years treated at Tawam Hospital between 2000 and 2020 were analyzed. Information was obtained from the prospective Tawam Hospital Cancer Registry database and analyzed using (Python 3.9.7).

Result

A total of 911 patients were included in this study. Median follow up time 34 months (0.3 -1404). Patients ≤ 40 years of age comprised 24% (911/3782) of all BC cases diagnosed between 2000-2020. The clinical and pathological characteristics of these patients are provided in table 1. Of the total population, 625 (68.6%) patients were diagnosed based on palpable breast mass. 67 (7.3%) had pregnancy-related BC, and 346 (38%) had hereditary genetics testing conducted. Of those, 38 (11%) had pathogenic mutation (13 BRCA1, 16 BRCA2, 4 TP53, 2 PalbB2, 1 ATM, 1 APC, 1 NBN) and 59 (17%) had mutations with variants of unknown significance. Of patients with early-stage disease (N=764), 14 (2%) had excisional biopsy, 314 (41%) had a lumpectomy and 474 (62%) had a mastectomy, 257 (34%) had sentinel lymph node sampling, 439 (57%) had axillary lymph node dissection, 621(81%) had adjuvant radiation therapy, 727 (95%) had adjuvant/neoadjuvant systemic chemotherapy +/- anti-HER2/neu therapy. Of those who received neoadjuvant systemic therapy (N=341/727), 123 (36%) achieved pathologic complete remission. Of those with HR+ status early BC (N=487/764), 455 (93%) received adjuvant hormonal therapy (180 (40%) ovarian suppression, 391 (86%) tamoxifen, 39 (8.5%) aromatase inhibitor). Of all early BC patients, 180 (24%) developed recurrent disease (initial site: 45 (25%) locoregional recurrence, 83 (46%) visceral metastases, 66 (37%) bone metastases, 22 (12%) brain metastases, and 1 other sites). Kaplan Meier with log rank analysis and cox-proportional hazard models to be presented in the meeting.

Conclusion

The findings of this study are in accordance with previous studies on young BC patients. On initial presentation, patients had higher-grade tumors, a significant proportion with HER2/neu positive disease, larger tumor size, and nodal involvement. This study will help clinicians, researchers, and decision-makers better understand the unmet needs for young breast cancer patients in the UAE.

Introduction:

Pregnancy associated breast cancer (PABC) is defined as any breast cancer (BC) diagnosed during pregnancy or one year postpartum. BC considered the most common type of malignancy in pregnant women, occurring approximately once in every 3000 pregnancies. In view of the

fact that PABC is a relatively rare event surrounded by multiple variables, few studies address the best management and treatment options.

Objectives:

The aim of this study is to report the incidence, clinicopathological characteristics and treatment outcomes of PABC diagnosed over 20 years period treated in Tawam hospital. This will help clinician, researchers shed the light of the unmet needs for this entity of BC.

Method:

We reviewed all BC patients \leq 40 years of age diagnosed between 2000 -2020 in Tawam hospital and identified those with PABC as the definition above. Information was obtained from the Tawam Cancer Registry and analyzed. A retrospective data analysis was conducted. The data analyzed using the SPSS software. The study was approved by the hospital Research Ethics Board.

Results:

a total of 67 patients were identified in the study with pregnancy associated BC among all BC patients age \leq 40 years old which compromised 7.4% (67/911) from year 2000 till 2022. The clinical and the pathological characteristics of these patients are provided in table 1.

Around 22 (32.8%) of the patients were diagnosed at the second trimester. Only 6 (8.6%) patients found to have inflammatory breast cancer diagnosis. 31(42%) patients had hereditary genetic testing done of which 5 (16.1%) patients found to have pathogenic genetic mutations. Pathogenic mutations identified including 3 (9.7%) patients with BRCA2 mutation, 1 patient had BRCA1 mutation, and 1 patient had TP53 mutation.

Out of these 67 patients, 36 (65.5%) underwent modified radical mastectomy, 19 (34.5%) had lumpectomy, 37 (55.2%) had axillary lymph node dissection, 14 (20.8%) had sentinel lymph node biopsy, 13 (19.4%) had the surgery during the pregnancy and 45 (67.1%) had adjuvant radiation therapy post delivery. Regarding the chemotherapy, 29 (43.2%) patients received Neoadjuvant chemotherapy, 24 (35.8%) received Adjuvant chemotherapy, 11 (16.4%) were pregnant when they received chemotherapy. Only 7 (10.4%) patients had termination of their pregnancies, while 3 (4.4%) patients had spontaneous miscarriage. 47 (70.1%) patients delivered at our facility and 9 (13.4%) patients delivered at other facilities (unknown delivery details). In terms of delivery type, 24 (35.8%) patients had C-section surgery, and 23 (34.3%) patients had spontaneous vaginal delivery. All of the patients who had delivery in Tawam hospital, delivered healthy baby with no complications. Survival analysis and treatment outcome to be presented in the meeting.

Conclusion:

Our study showed that significant proportion of the patients with PABC diagnosed with HER2neu + disease, stage II-III disease, high grade tumors and nodal involvement on initial presentation. Patients were treated according to the standard of care with trend of favorable delivery outcomes. PABC is a unique entity of BC that requires careful planning and multidisciplinary approach with consideration of factors related to feral, pregnancy and maternal outcomes.

Background: An estimated 30-50% of patients with human epidermal growth factor receptor 2 (HER2)-positive metastatic breast cancer (MBC) will develop brain metastases (BMs), and there are few effective treatment options. Pyrotinib has shown good efficacy in HER2-positive breast cancer patients with BMs in a single-arm phase II trial, but there is a lack of data from randomized controlled trial and real-world study. The purpose of this multi-center real-world study was to evaluate the efficacy and safety of pyrotinib-based therapy in HER2-positive breast cancer patients with BMs in real world. Methods: We reviewed the data of HER2-positive breast cancer patients with BMs who were treated with pyrotinib-based therapy from January 2018 to September 2021 at Shandong Cancer Hospital and Institute and other hospitals in Shandong Province in China. The initial dose of pyrotinib in most patients (n=92, 85.2%) was 400 mg once a day for every 21 days as a cycle. All patients were evaluated for tumor response every two cycles according to RECIST 1.1. The primary endpoint was progression free survival (PFS) and secondary endpoints were compounded objective response rate (ORR) and CNS-ORR (the ORR of central nervous system), compounded disease control rate (DCR) and CNS-DCR (the DCR of central nervous system) and overall survival (OS). The safety profile has also been assessed. The updated graded prognostic assessment for breast cancer patients with brain metastases (Breast GPA) includes age, Karnofsky performance status (KPS), extracranial metastases, number of brain metastases, and tumor subtype. It is divided into four subgroups (0-1.0, 1.5-2.0, 2.5-3.0 and 3.5-4.0) with different prognosis (the median survival: 6 months, 12.9 months, 23.5 months, and 36.3 months). Results: 101 patients were assessed for efficacy and toxicity. The median PFS is 10.0 months (95% CI, 6.9 to 13.1 months), and OS data were not available at the time of analysis. In overall patients, patients with GPA of 0-2.0 achieved shorter PFS (4.8 months vs 12.4 months, P=0.003). Trastuzumab (neo and adjuvant) (P=0.021), local therapy for BMs (P< 0.001) and pyrotinib treatment (P=0.022) had significant positive correlation with PFS. In patients with GPA of 0-2.0, the median PFS of different local treatment methods was significantly different (P< 0.001), stereotactic radiotherapy alone (13.6 months) was better than whole-brain radiotherapy alone (4.8 months) and combined local therapy (6.7 months); patients who received pyrotinib first in the BMs stage had longer PFS than those who did not (6.7 months vs 2.7 months, P=0.009) and radiotherapy for BMs (P=0.036) had correlation with longer PFS. Cox multivariate analysis indicated that GPA (0-2.0 vs 2.5-4.0) was independent predictor of PFS. For overall patients, the ORR was 42.6% and DCR was 88.1%. The CNS-ORR was 45.5% and CNS-DCR was 90.1%. Diarrhea (71.3%) was the most common adverse events (AEs), 47 patients (46.5%) reported grade 1-2 diarrhea, 25 patients (24.8%) reported grade 3 diarrhea. In addition, the more common AEs of grade 3 were loss of appetite (7.9%), hand-foot syndrome (6.9%), nausea (5.9%) and vomiting (5.0%). No grade 4 and 5 AEs occurred. Conclusions: Pyrotinib-based therapy is effective and tolerable in HER2-positive breast cancer patients with BMs. In the subgroup with Breast GPA 0-2.0, patients treated with radiotherapy had a better prognosis, and stereotactic radiosurgery alone was a viable option. Clinical trial information: ChiCTR2000037995.

A Phase 0 Clinical trial of Sacituzumab Govitecan in Patients with Breast Cancer Brain Metastases and Recurrent Glioblastoma

Presenting Author(s) and Co-Author(s):

Pegah Ghamasaee, MD, *Neurosurgery Resident - UT Health San Antonio*

John Floyd, MD, *Chairman, Department of Neurosurgery - UT Health San Antonio*
Country: United States

Purpose: Sacituzumab govitecan has shown efficacy and acceptable tolerability in a multicenter phase I/II clinical trial (NCT01631552) in patients with advanced epithelial cancers. Our study was initiated to determine the bioavailability of Sacituzumab govitecan (SG) in breast brain metastasis and glioblastoma. The goals were to evaluate the extent by which SG can penetrate the blood brain barrier and access tumor tissues by testing free SN-38, SN-38G and total SN-38 concentrations in tumor tissue, serum, and CSF. Patients and methods: Patients diagnosed with brain metastatic breast cancer and recurrent glioblastoma were enrolled in a single-center clinical phase 0 study to receive a single intravenous dose of SG at 10 mg/kg one day before surgical resection. Tumor and corresponding serum were collected during surgery to measure their levels of SN-38 and its metabolites. Following recovery, patients resumed SG treatment at 10 mg/kg on days 1 and 8 of 21-day cycles and were assessed for responses by MRI every third cycle using response assessment in neuro-oncology (RANO) criteria. Total Sn-38 levels were quantified in tumor tissue and corresponding serum from the patients. Trop-2 and carbonic anhydrase IX (CAIX) expression was investigated by IHC. SG activity was tested in a breast cancer intracranial mouse model. Results: An average of 2365 ng/ml in serum and 132 ng/g in tissue of total SN-38 was quantified in our patient samples. Trop-2 expression was observed in 90% of patient tumors. 40% of the samples showed high expression of CAIX. SG significantly inhibited tumor growth in vivo and increased overall survival. 20% of patients in the breast cancer arm of the trial demonstrated a complete response by RANO criteria and the remaining 80% of patients demonstrated a partial response. Ultimately, 80% of the patients in the breast cancer metastasis arm survived. Conclusion: Sacituzumab govitecan is an effective drug that crosses the blood brain barrier to inhibit the growth of metastatic breast cancer to the brain after tumor resection surgery.

Background: Breast cancer (BC) with lymphangitic spread to the chest wall is a rare clinical entity affecting about 2% of pts, with poorer survival outcomes. A brisk immune infiltrate is typically reported, with up-regulation of inflammation and immune-tolerogenic genes. PERICLES clinical trial is testing the administration of pembrolizumab 200 mg Q3w plus cyclophosphamide 50 mg daily for BC with chest wall disease. In this exploratory biomarker analysis, we assessed the prevalence of the TILs score and the PD-L1 combined positive score (CPS) obtained from skin biopsies performed at screening.

Methods: PERICLES (NCT03971045) is a single-center, single-arm, interventional phase 2 trial. Main inclusion criteria: histologically confirmed, inoperable, locally recurrent and/or metastatic BC with lymphangitic spread to the chest wall (including and not limited to inflammatory BC); PD-L1 positive (CPS \geq 1; 22C3 pharmDx®) and/or TILs positive (\geq 1% of CD3 or CD20-positive cells) disease on skin biopsy obtained at screening; progression to at least one prior cytotoxic treatment; no prior immune checkpoint inhibitors. The primary endpoint is objective response rate as per immune-related RECIST criteria. 46 pts will be required for the study to power for the primary hypothesis. In this analysis, we describe the baseline immune-biomarker status, in the overall population enrolled based on hormone receptor status and HER2. Correlative analyses were provided (significance at p-value < 0.05).

Results: 37 pts were screened with skin biopsy of the chest wall disease (June 2020-June 2022). Biopsy and biomarker analysis were successful in 35 pts. Median age was 58 years (range: 35-79). Among the 35 pts included in the biomarker analysis, 25 (71%) pts had visceral disease and 20 (57%) had skin metastases at the diagnosis of metastatic disease; median number of previous lines of therapies was 4 (range: 1-12) and of chemotherapies was 4 (range: 1-10). 2 (6%) pts had HER2-positive disease, 13 (37%) HR-positive/HER2-negative disease, and 20 (20%) had triple-negative breast cancer (TNBC).

TILs and PD-L1 CPS were < 1 in 15 (43%) pts; 20 pts (57%) were eligible for CPS and/or TILs criteria: 16 (43%) were both PD-L1 positive and TILs positive, 4 only PD-L1 positive. Median PD-L1 CPS score was 5 (range: 0-80%) in the overall population and 17 (range: 2-80%) in eligible patients; 16/35 pts (43%) had CPS \geq 10. Median TILs score was 0% (range: 0-55%) in the overall population, 0% (range: 0-40%) in the HER2-negative (n=16), 0% (range 0-20%) in the HER2-low (n=18), and 37.5% (range 20-55%) in the HER2-positive (n=2).

No significant differences in baseline characteristics were found between positive and negative biopsies (Table). Considering only the TILs, a statistically significant correlation between HER2-positive status and TILs score was demonstrated (p < 0.001); no other correlations between receptor status (estrogen receptor, progesterone receptor, HER2) and PD-L1 CPS or TILs emerged.

Conclusions: 57% of patients with chest wall BC have skin metastases positive for PD-L1 CPS and/or TILs score \geq 1%. To our knowledge, these are the first prospective data on the prevalence of PD-L1 and TILs in metastatic BC with lymphangitic spread to the chest wall, highlighting potential actionability through therapeutic strategies with new immune-oncology

agents in this setting.

Characteristics of patients included in the biomarker analysis (n=35)

	Overall population (n=35)	PD-L1+ and/or TILs+ (n=20)	PD-L1- and TILs- (n=15)	p-value* (+ vs -)
Age - median (range)	58 (35-79)	49 (35-73)	60 (37-79)	0.33
Visceral disease - n. (%)	25 (71%)	15 (75%)	10 (67%)	0.71
Skin metastases at the diagnosis of metastatic disease - n. (%)	20 (57%)	12 (60%)	8 (53%)	0.74
Previous lines of therapies for metastatic disease - n. (range)	4 (1-12)	4 (1-10)	5 (1-12)	0.06
Previous lines of CT for metastatic disease - n. (range)	4 (1-10)	3,5 (1-10)	5 (1-7)	0.35
Subtype of BC				
TNBC - n. (%)	20 (57%)	11 (55%)	9 (60%)	1.00
HER2-positive - n. (%)	2 (6%)	2 (10%)	0 (0%)	0.49
HR+/HER2-negative - n. (%)	13 (37%)	7 (35%)	6 (40%)	1.00

Impaired Succinate Metabolism Supports Endocrine Therapy Resistance in ER Positive Breast Cancers

Estrogen receptor positive (ER+) breast cancer is the most common subtype among all breast cancers and is responsible for most breast cancer related deaths. Endocrine therapies, such as selective estrogen receptor modulators (SERM) and aromatase inhibitors (AI), often given in combination with cyclin-dependent kinase 4/6 (CDK4/6) inhibitors, are initially effective but the majority of advanced ER+ breast cancers eventually become refractory to endocrine therapies. Therefore, understanding the underlying molecular mechanisms that enable or promote resistance to endocrine therapies may lead to novel therapeutic targets. Cancer cells consume greater quantities of glucose to meet their energy and anabolic demands to support cell growth and proliferation. In this study, we used breast cancer cell models that are endocrine therapy sensitive and resistant and investigated the metabolites by growing the cells in the presence of the stable glucose isotope, UC13-Glucose. We measured the C13-labelled metabolites of glycolysis and the TCA cycle. Glucose consumption was higher in endocrine therapy resistant MCF7/LCC9 (LCC9) cells compared with parental MCF7 (MCF7) and estrogen independent, endocrine therapy sensitive MCF7/LCC1 (LCC1) cells. Notably, in LCC9 cells the m+4 and m+6 isotopomer of C-13 labelled citrate was absent with a concurrent high succinate:fumarate ratio. Furthermore, in LCC9 cells, most of the fumarate was unlabeled suggesting that fumarate was not generated from glucose. These results suggest that the TCA cycle is impaired in LCC9 cells and the conversion of succinate to fumarate is dysregulated. Succinate dehydrogenase (SDH) enzyme is responsible for reversible catalytic conversion of succinate to fumarate. SDH is a multimeric protein comprised of four different subunits and SDH assembly factor 2 (SDHAF2), which is a tumor suppressor gene. Comparable SDH enzyme activity was observed in LCC9 and LCC1 cells. Intriguingly, when SDH activity was inhibited using dimethylmalonate, the LCC9 cells were re-sensitized to both Fulvestrant and 4-hydroxytamoxifen. Succinate accumulation was accompanied with HIF 1-alpha stabilization and SDH inhibition led to lower levels of HIF1-alpha. This indicated that SDH may function in the conversion of fumarate to succinate in LCC9 cells. Our study further investigates the source of fumarate in LCC9 cells. Overall, this study suggests that targeting succinate metabolism may help to restore sensitivity to Fulvestrant and tamoxifen in endocrine therapy resistance in ER+ breast cancer cells.

Background: Despite advances in diagnosis and treatment, racial and economic disparities in breast cancer-specific survival persist and this is exacerbated by later stage at presentation. It is essential to assess the factors that contribute to later stage at presentation to target racial and socioeconomic disparities in breast cancer mortality. The objective of this study was to analyze the effect of neighborhood socioeconomic status (SES) and race/ethnicity, as measured by the Index of Concentration at the Extremes (ICE), on breast cancer stage at presentation in a diverse metropolitan area that mirrors the projected demographics of many US regions.

Methods: Patients treated at our medical campus, comprised of a safety-net hospital and an academic cancer center, with stage I-IV breast cancer from 2005-2017 were identified from our tumor registry. Census tracts were used as neighborhood proxies. Using 5-year estimates from the American Community Survey, 5 ICE variables were computed: economic (high vs. low), race/ethnicity (non-Hispanic White (NHW) vs. non-Hispanic Black (NHB) and NHW vs. Hispanic) and racialized economic (low-income NHB vs high-income NHW and low-income Hispanics vs. high-income NHW) segregation. ICE uniquely captures spatial economic and racial/ethnic segregation by mapping social inequality not otherwise captured by evaluating a population of a specific socioeconomic level or belonging to a particular racial/ethnic group. We used five separate models based on each of the ICE variables to evaluate economic and racial/ethnic segregation. Model 1 captures economic segregation (high vs. low), Model 2 captures racial segregation (NHB vs. NHW), Model 3 evaluates racialized economic segregation (low-income NHB vs high-income NHW), Model 4 captures segregation by Hispanic ethnicity (Hispanic vs. Non-Hispanic), and Model 5 captures ethnic and economic segregation (low-income Hispanics vs. high-income NHW). Our main outcome was breast cancer stage at presentation categorized as early (Stage I and II) vs. late (Stage III and IV) disease. All models controlled for the following covariates: race/ethnicity, age, insurance status, tumor subtype, and comorbidities including hypertension, diabetes, coronary artery disease,

and hyperlipidemia.

Results:

The study population included 6,145 breast cancer patients. 52.6% were Hispanic, 26.3% were NHW, and 17.2% were NHB. Those living in the most economically marginalized neighborhoods (Quartiles 1 and 2) had significantly increased odds of presenting with later stage disease [ORQ1 1.36 (1.13-1.64), ORQ2 1.43 (1.18-1.75); $p < 0.05$]. Those living in the most racial/ethnic and economically marginalized neighborhoods (Quartile 1 of Models 3 and 5) had statistically significantly increased odds of presenting with later stage after controlling for all covariates compared to a NHW living in more economically advantaged neighborhoods [ORModel3 1.55 (1.21-1.99), ORMModel5 1.43 (1.11-1.85); $p < 0.05$].

Conclusions:

This study is the first to evaluate stage at presentation by ICE, which allows us to uniquely evaluate how residential racial and economic segregation may influence breast cancer disparities. Our study shows that patients in the most economically and racial/ethnically marginalized neighborhoods were more likely to present with later stage disease. This suggests that structural racism is influencing stage at presentation, and therefore effecting racial and economic disparities in breast cancer, even when accounting for demographics and tumor characteristics. To address these disparities, effective interventions are needed that account for the social and environmental contexts in which cancer patients live and can access care.

Purpose: The purpose of this study is to examine the association between race/ethnicity and diagnostic delays in patients with abnormal screening mammograms. **Methods:** HIPAA-compliant, institutional review board exempt retrospective cohort study was performed at a multi-location academic medical center located in the Midwest. Patients included women aged 40-74 years old undergoing screening mammography from 2013-2019 who received a Breast Imaging Reporting and Data System (BI-RADS) category 0 on their screening mammogram, derived from the electronic medical records. Primary outcome variables included timely follow up diagnostic imaging (< 30 days), days to diagnostic exam, timely recommended biopsy (< 60 days), and days to recommended biopsy. Primary exposure variables included race (American Indian/Alaska Native, Asian/Native Hawaiian/Other Pacific Islander, Black or African American, White) and ethnicity (Hispanic/Latino, and Not Hispanic/Latino). Binary outcomes (timely follow up diagnostic imaging, timely recommended biopsy) were analyzed using logistic regression and continuous outcomes (days to diagnostic exam, days to recommended biopsy) were

analyzed using Cox proportional hazards regression, adjusted for potential confounders (insurance, age, preferred language, having primary care doctor, married or domestic partnership, availability of on-site diagnostic imaging). Results: 13,269 unique patients received BI-RADS category 0 on screening mammogram (mean age 54.6). Adjusted for potential confounders, Black (OR 0.54, 95% CI 0.42 to 0.69, $p < 0.001$) and Asian (OR 0.62, 95% CI 0.45 to 0.85, $p = 0.004$) patients were less likely to have timely follow up diagnostic imaging compared to White patients. American Indian and Hispanic patients were comparably likely to have timely follow up diagnostic imaging ($p > 0.05$). Black (HR 0.76, 95% CI 0.69 to 0.84, $p < 0.001$), Asian patients (HR 0.78, 95% CI 0.70 to 0.87, $p < 0.001$), and Hispanic patients (HR 0.90, 95% CI 0.82 to 0.99, $p = 0.041$) experienced increased days to diagnostic examinations compared with White patients. American Indian patients experienced comparable times to diagnostic examinations ($p = 0.136$). 22.3% of patients received recommendations for biopsy (2,796/12,535). No statistically significant differences were found in timely follow up after recommended biopsy (< 60 days) comparing Black, Asian, American Indian, and Hispanic to White patients ($p > 0.05$). Black, American Indian, and Hispanic patients experienced comparable days to recommended biopsy ($p > 0.05$). Asian patients experienced increased days to recommended biopsy (HR 0.76, 95% CI 0.58 to 0.99, $p = 0.046$). Conclusions: Racial/ethnic minority patients are more likely to experience diagnostic delays after screening mammograms. Further research into culturally appropriate patient navigation services and improved accessibility of diagnostic imaging centers (operating hours, same day services, transportation, parking) to reduce disparities in diagnostic imaging delays is warranted.

Background: Neighborhood deprivation is hypothesized as a potential driver of racial disparities in breast cancer mortality. However, research shows that neighborhood deprivation is associated with increased breast cancer mortality among White women, but has little to no association among Black women. No study has previously considered the intersections of race, social cohesion, or urban/rural status in the association between neighborhood deprivation and breast cancer mortality. Methods: Neighborhood deprivation was examined in relation to breast cancer mortality among 31,358 non-Hispanic Black and non-Hispanic White women diagnosed with invasive breast cancer (stage I-IIIa) between 2010-2017, followed through 2019, and identified by the Georgia Cancer Registry. Two composite scores, the Area Deprivation Index (ADI) and neighborhood deprivation index (NDI), were used to characterize neighborhood deprivation. A third composite score, the Yost index, was assessed as a measure of neighborhood socioeconomic status (SES). Each composite score was composed of factors representing six domains: poverty, income, occupation, housing, employment, and education. Data on ADI were obtained from the Neighborhood Atlas and was assessed in deciles. American Community Survey data from 2011-2015 and principal components analysis were used to derive the NDI and Yost index. Both measures were assessed in quartiles. Each composite variable was measured at the block group level and linked to patient data. Cox proportional hazards regression was used to estimate hazard ratios (HR) and 95% confidence intervals (CI) for the association between each composite variable and breast cancer mortality, overall and by race/ethnicity. Intersectionality will be examined by considering the joint effects of race/ethnicity, social cohesion, and urban/rural status. Results: During the 9-year follow-up period, 2,353 (1,347 non-Hispanic White, 1,006 non-Hispanic Black) women died from breast cancer. Regardless of which composite score was assessed, living in the most deprived or lowest SES neighborhoods was associated with an increased risk of breast cancer mortality in models adjusted for age and race (ADI decile 10 vs. 1: HR=1.57, 95% CI 1.26-1.96; NDI quartile 4 vs. 1: HR=1.43, 95% CI 1.26-1.63; Yost index quartile 1 vs 4: HR= 1.34, 95% CI 1.18-1.51). Stratification by race/ethnicity showed associations were slightly stronger among non-Hispanic White women but null among non-Hispanic Black women. Results from analyses examining the joint effects of race/ethnicity, social cohesion, and urban/rural status are

forthcoming and will be presented in December. Conclusions: Consistent with previous studies, our study found that living in a deprived neighborhood may increase breast cancer mortality among non-Hispanic White women, but not non-Hispanic Black women. Investigating the association with an intersectionality framework may help identify subgroups of women who are particularly susceptible to the adverse impact of neighborhood deprivation on breast cancer mortality.

Introduction

Socioeconomic status (SES) of the individual and neighborhood plays an important role in patients' (pts) access to the health system and eventually in the outcomes of their disease. Owing to the inequalities in opportunities, education, income, and developmental infrastructures, the area with deprived individual and neighborhood SES may be associated with a poor prognosis of certain malignancies and worse outcomes. We analyzed the association between Neighborhood Deprivation Index (NDI) and survival of early-stage breast cancer (BC).

Methods

The NDI created by the National Cancer Institute includes variables from dimensions, such as, wealth and income, education, occupation, and housing conditions which have been used for our analysis. We analyzed the impact of NDI in quintiles (qn). We queried the SEER database from 2010-2016 for all early-stage BC pts and studied the overall survival (OS) and disease-specific survival (DSS) of BC in association with NDI. Cox multivariate regression modeling was performed to measure the association between NDI and OS/DSS. Kruskal-Wallis test was used for comparison for continuous and Chi-Square test was used for categorical variables. All analyses were adjusted for age, race, grade, insurance, surgery (SX), radiation (RN), and chemotherapy (CT). Statistics were performed using SAS.

Results

Out of the 88,572 early-stage BC pts, 27.4 % (n= 24,307) were in the most deprivation (MD) qn, 26.5% (n= 23,447) were in the average deprivation (AD) qn, 17% (n= 15,035) were in the

above average deprivation (AA) qn, 15.6% (n= 13,838) were in the least deprivation (LD) qn and 13.5% (n= 11,945) were in the below average deprivation (BA) qn. The median age of pts in the LD qn was 59 and MD qn was 61 yrs, p< 0.001. There was a predominance of racial minorities in the MD and AA qn with Blacks being 13-15% and Hispanics being 15% compared to only 8% Blacks and 6% Hispanics in the LD qn (p< 0.001). There was a higher percentage of uninsured pts in the MD qn compared to LD qn (2.2% vs 1.7%, p< 0.001). There were more rural areas in MD qn compared to LD qn (25.9% vs only 0.7%, p< 0.001). There were more pts with grade III disease in MD qn compared to LD qn (34% vs 31.9%, p< 0.001). 96.1% pts underwent SX in MD qn vs 97.1 % had SX in LD qn, p< 0.001. Similarly, 49.7% underwent RN in MD qn vs 56.5% had RN in the LD qn, p< 0.001. Greater percentage of pts received CT in MD qn compared to LD qn (44.6% vs 42.1%, p< 0.001). There was a higher percentage of more aggressive cancers such as triple-negative breast cancer (TNBC) and HER2 positive (HER2+) in MD qn compared to LD qn (14.5%, 17.7% vs 11.7%, 16.5% respectively, p< 0.001). In multivariate analysis, in the overall cohort, those who live in AA qn and MD qn have inferior OS and DSS when compared to those who live in LD qn (OS in AA: Hazard Ratio (HR) 1.3, 95% CI: 1.2-1.4; OS in MD: HR 1.2, 95% CI: 1.1-1.3; DSS in AA: HR 1.3, 95% CI: 1.2-1.5; DSS in MD: HR 1.2, 95% CI: 1.1-1.4, all p< 0.001). Similar results in OS and DSS were observed in hormone receptor-positive HER2 negative (HR+) and HER2+ subtypes, but not in TNBC (Table 1). The 5-year OS rates and DSS rates were also comparatively low in AA qn and MD qn compared to LD qn (OS: AA- 84%, MD- 85%, LD- 98%; DSS: AA- 91%, MD- 92%, LD- 95%, all p< 0.001).

Conclusion

Early-stage BC pts from areas with worse NDI have poor OS and DSS, after accounting for the demographic, clinicopathological, treatment-related factors. Investments in poor-resource neighborhoods and policies focusing on improving the SES of areas with high deprivation need to be implemented to reduce health care disparities and improve breast cancer outcomes.

Overall Survival and Disease Specific Survival

Subtype	NDI	OS		
		HR	95% CI	P-value
HR+	AA	1.3	1.2 - 1.5	<0.001
	MD	1.2	1.1 - 1.4	<0.001
HER2+	AA	1.2	1.1 - 1.5	0.02
	MD	1.2	0.99- 1.4	0.12
TNBC	AA	1.2	0.9 - 1.4	0.06
	MD	1.1	0.9 - 1.3	0.07
DSS				
HR+	AA	1.4	1.2 - 1.6	0.0002
	MD	1.3	1.1- 1.5	0.0007
HER2+	AA	1.5	1.2 - 2.0	0.001
	MD	1.3	1.0 - 1.6	0.03
TNBC	AA	1.2	0.97 - 1.4	0.08
	MD	1.2	0.96 - 1.4	0.10

Background While racial/ethnic segregation, a form of structural racism, has been linked to health inequities, there is limited information regarding segregation and its potential impact on breast cancer care and outcomes. Here we assessed whether and to what extent racial/ethnic segregation is associated with timeliness of care and real-world overall survival (rwOS) in patients diagnosed with metastatic breast cancer (mBC). Methods This retrospective study used the nationwide Flatiron Health electronic health record-derived de-identified database. The cohort included community oncology patients (≥ 18 years) diagnosed with mBC between January 2011 and April 2022. Census tract data from the American Community Survey (2015-2019) was used to characterize neighborhoods based on the most recent recorded patient address. Segregation was defined as predominant race/ethnicity (e.g., tracts whose population was $\geq 50\%$ non-Latinx Black were labeled as predominantly Black neighborhoods). Timeliness of care was defined as biomarker (estrogen receptor, progesterone receptor, and human epidermal growth factor receptor 2) testing within 30 days and systemic treatment initiation within 60 days of metastatic diagnosis (evaluated using X2 tests). We estimated Cox proportional hazard models adjusted for age and sex to examine rwOS (patients were followed from diagnosis to death or last recorded activity). Results Among 18,884 patients diagnosed with mBC (median age: 65 years), 71.0% lived in predominantly White neighborhoods, 7.5% in Black neighborhoods, and 8.7% in Latinx neighborhoods. Compared with patients residing in predominantly White neighborhoods, patients in Black and Latinx neighborhoods were more likely to be diagnosed with de novo mBC (30.7% vs. 34.8% and 33.5%, respectively) and have Medicaid (7.6% vs. 15.8% and 15.3%). Fewer patients in predominantly Black (74.4%) and Latinx (69.9%) neighborhoods received timely biomarker testing compared to patients in White

(77.7%) neighborhoods ($p < .01$). Similarly, fewer patients in predominantly Black (73.5%) and Latinx (72.6%) neighborhoods had timely treatment initiation compared to patients in White (79.6%) neighborhoods ($p < .01$). Patients in Black neighborhoods (HR 1.24, 95% CI 1.16-1.33) had worse rwOS than patients in White (ref.) and Latinx neighborhoods (HR 0.90, 95% CI 0.83-0.97). Conclusions Our results suggest that racial/ethnic segregation is associated with inequities in breast cancer care and outcomes, where patients in predominantly Black and Latinx neighborhoods are less likely to receive timely care than those in White neighborhoods. Living in predominantly Black neighborhoods was also associated with reduced survival. Therefore, efforts to reduce cancer inequities should target higher-order structural factors associated with worse cancer care and outcomes, including segregation and other forms of structural racism.

Introduction TNBC is overrepresented in Black women, and Black patients with TNBC have worse clinical outcomes compared to non-Black patients. This disparity likely results from racial differences in clinical, biological, and demographic features of TNBC and social determinants of health. Neoadjuvant chemoimmunotherapy is current standard of care for high-risk TNBC. However, Black patients have been poorly represented in immunotherapy TNBC trials, making it difficult to assess comparative efficacy of immunotherapy in Black patients. Methods We utilized two TNBC neoadjuvant trials to assess racial differences in the tumor immune microenvironment composition and evaluate impact of race on response to chemotherapy vs

chemoimmunotherapy. NeoSTOP trial (NCT02413320) randomized 100 stage I-III TNBC patients to receive neoadjuvant carboplatin/paclitaxel + doxorubicin/cyclophosphamide (CbP+AC) or carboplatin/docetaxel (CbD). NeoPACT trial (NCT03639948) enrolled 120 patients with stage I-III TNBC who received neoadjuvant CbD + pembrolizumab (CbD+P). sTILs were centrally quantified, and RNA extracted from pretreatment tissue was subjected to next-generation sequencing. Relative leukocyte fractions were computed by CIBERSORTx. Factors were tested as predictors of pathologic complete response (pCR) using logistic regression analysis. Event-free survival (EFS) was estimated by the Kaplan-Meier method and compared between groups by log-rank test, followed by Cox regression analysis. Results The study population includes 197 patients with known race, sTILs, and gene expression data (84 patients from NeoSTOP, 113 from NeoPACT). 15/84 (18%) patients in NeoSTOP and 20/113 (18%) patients in NeoPACT self-reported Black race. There was no significant difference in age, T or N stage, or germline BRCA1/2 mutation status by race in either study. Black patients had significantly higher sTILs than non-Black patients (median 40% vs 15%, $P=0.048$) and were more likely to have $\geq 20\%$ sTILs than non-Black patients (66% vs 44%, $P=0.026$). There was no significant difference in pCR by race in NeoSTOP (OR=0.60, 95% CI 0.19-1.84, $P=0.37$; pCR 47% for Black vs 59% for non-Black). In contrast, in NeoPACT, Black patients had a significantly higher pCR compared to non-Black patients (OR=3.27, 95% CI 1.01-10.64, $P=0.049$; pCR 79% for Black vs 53% for non-Black). In NeoSTOP, EFS was similar for Black and non-Black patients (3-year EFS 92% and 94%, respectively, HR=0.88, 95% CI 0.11-7.28, $P=0.90$). In NeoPACT, EFS was numerically higher in Black vs non-Black patients (3-year EFS 93% and 81%, respectively, HR=0.43, 95% CI 0.05-3.36, $P=0.40$); NeoPACT survival follow-up is ongoing at the time of this report. On CIBERSORTx analysis, Black patients had relative depletion of immunosuppressive pro-tumorigenic M2 macrophages ($P=0.005$) and CD4+ memory resting T cells ($P=0.021$) compared to non-Black patients. Conclusions Compared to non-Black patients, Black patients with TNBC are more likely to have immune-enriched tumors with lower relative abundance of immunosuppressive leukocytes. These findings suggest potential for higher relative magnitude of benefit from checkpoint inhibitor therapy in Black compared to non-Black patients. Supporting this biological hypothesis, we noted that Black and non-Black patients had equivalent rates of pCR with neoadjuvant chemotherapy; however, pCR rate among Black patients was significantly higher than in non-Black patients when treated with neoadjuvant chemoimmunotherapy. These findings should be confirmed in other studies and can optimize utilization of neoadjuvant chemoimmunotherapy. Our findings also underscore the importance of efforts to address disparity in access and use of immunotherapy in Black patients.

Background

Neoadjuvant chemotherapy (NAC) is the standard of care for locally advanced breast cancer (BC). Patients (pts) who attained pathological complete response (pCR) with NAC have a better prognosis when compared to those who have residual disease (RD). We analyzed the association of race with neoadjuvant chemosensitivity in early BC and the overall survival (OS) based on the chemosensitivity.

Methods

We queried the National Cancer Database for early BC pts who received NAC from 2010-2016. Preoperative chemosensitivity was defined as very sensitive (VS) (ypT0/TisN0), sensitive (S) (pathological TNM stage less than clinical, excluding ypT0N0), and refractory (R) (pathological greater than or equal to clinical). Demographic, clinical, treatment, and survival rates were summarized by race focusing on neoadjuvant chemosensitivity. All associations were compared using Kruskal-Wallis, Pearson's Chi-Squared, and Fisher's Exact Tests. Multivariate cox models were generated for the OS. All analyses were conducted in RStudio v4.0.2 at a significance level of 0.05.

Results

A total of 103,605 pts who received NAC were analyzed. 43.2% (n= 44,796) were R, 34.4% (n= 35,638) were S and 22.4% (n= 23,171) pts were VS. The 3-year (yr) OS rates for R, S, VS groups were 81%, 88%, 95% respectively (rsp) (p< 0.001). The 5-yr OS rates were 73%, 82%, 92% rsp (p < 0.001). In the hormone-receptor positive HER2 negative (HR+) subtype, only 8.9% (n= 3,837) were VS, while among triple negative breast cancer (TNBC) subtype, 28.4% (n= 9,224) pts were VS, among HER2 positive (HER2+) subtype, 36.7% (n=9,665) pts were VS and in both subtypes around 28-36% were R as opposed to 58.4% with R disease among HR+

subtype. Among HR+ group, pts had more R disease regardless of race (all races R: 54-57%, $p < 0.001$). Among HER2+ disease, Blacks had lower percentage of VS disease compared to other races (32% vs 37-40%, $p < 0.001$). Among TNBC, more R disease was seen among Blacks compared to other races (38% vs 30-35%, $p < 0.001$). In whole cohort, as expected, compared to pts with R disease, pts with S and VS disease had lower overall mortality risk (HR= 0.45, 95% CI= 0.43 – 0.46, $P < 0.001$, HR= 0.20, 95% CI = 0.19- 0.21, $p < 0.001$ rsp). In TNBC subgroup among pts with R disease, the median OS of Blacks was significantly lower compared to whites (71.9 vs 101.8 months, $p < 0.001$). Among BC subtypes, the 3-yr and 5-yr OS for R (65%, 56%) and S groups (83%, 76%) were significantly lower in TNBC when compared to other subtypes (HR+ R: 3-yr- 88%, 5-yr- 79% and S: 3-yr- 90%, 5-yr- 83%; HER2+ R: 3-yr- 85%, 5-yr- 77% and S: 3-yr- 92%, 5-yr- 86%, $p < 0.001$). In the whole cohort, Blacks with R, S, VS disease had significantly lower 3yr (73%, 85%, 94% rsp) and 5yr OS (63%, 78%, 91% rsp) compared to all other races and this was more prominent in the R and S groups (Table1).

Conclusion

Blacks diagnosed with TNBC were more resistant while other races were more sensitive to NAC. In all BC subtypes, Blacks had lower 3-yr and 5-yr OS regardless of chemosensitivity (including those who attained pCR), though this disparity was more predominant among those with residual disease after NAC (resistant and sensitive group). Since Blacks who do not attain pCR have worse survival compared to other races, it highlights the need to design more effective and personalized treatment strategies for Blacks to help them attain pCR, especially in the TNBC subtype.

Racial Disparities in Survival in Different Chemosensitivity Groups

Table 1:

Chemosensitivity	Survival Rates	Whites	Blacks	Hispanics	Asian	P-value
R	3-yr	82.8	72.8	83.6	88.2	<0.001
	5-yr	74	63.4	76.1	80.3	
S	3-yr	88.8	85	90	92.8	<0.001
	5-yr	82.2	78.7	85	89.4	
VS	3-yr	95.3	94.4	95.6	97.3	<0.001
	5-yr	92.1	91.4	93.4	95

Background: Black and younger women have poorer breast cancer outcomes. Using a diverse population-based study, we examined the role of biology as measured by genomic assays in outcome disparity among clinically HR+/HER2- women. Methods: Data and biospecimens from the Carolina Breast Cancer Study (CBCS, including 2,103 non-metastatic, invasive breast cancers) were used to perform RNA-based classification according to molecular subtype and research versions of known prognostic assays, the 21-gene Recurrence Score (RS) and the

PAM50-based Risk of Recurrence (ROR-PT) score. Prevalence odds ratios (PORs) and 95% confidence intervals (CIs) for subtype by race and age were estimated. Results: Black women had higher frequency of Luminal B [POR (95% CI): 2.08 (1.60, 2.71)], HER2-enriched [POR (95% CI): 2.01 (1.45, 2.79)], and Basal-like tumors [POR (95% CI): 3.51 (2.81, 4.40)] compared to non-Black women. Similarly, younger (< 50 years) women had higher frequency of Luminal B [POR (95% CI): 1.57 (1.21, 2.04)], HER2-enriched [POR (95% CI): 2.03 (1.46, 2.82)], and Basal-like tumors [POR (95% CI): 2.40 (1.92, 3.01)]. Additionally, within clinically-defined HR+/HER2- tumors, Black women had higher frequency of high ROR-PT among younger women [POR (95% CI): 2.88 (1.19, 6.97)], but this association was attenuated among older women [POR (95% CI): 1.99 (0.84, 4.71)]. Race was not significantly associated with the 21-gene RS among younger or older women. Conclusion: While Black and younger women with clinically-defined HR+/HER2- often have higher burden of non-Luminal/high genomic risk tumors, PAM50 and 21-gene assays show different demographic patterns and heterogeneity within age- and race-defined groups, underscoring the value of genomic testing in understanding outcome disparities.

PD1-09

PD1-09 Associations between the 21-gene Oncotype DX Recurrence Score (RS), Ki67, and Race in Early Breast Cancer (EBC) Using the National Cancer Database (NCDB)

Presenting Author(s) and Co-Author(s):

Rima Patel, MD, *Hematology/Oncology Fellow - Icahn School of Medicine at Mount Sinai*
Country: United States

Deukwoo Kwon, PhD, *Associate Professor - Department of Population Health Science and Policy, Icahn School of Medicine at Mount Sinai*

Amy Tiersten, MD, *Professor - Icahn School of Medicine at Mount Sinai*
Country: United States

Background: The 21-gene RS (Oncotype DX) is a validated genomic signature that provides prognostic information for distant recurrence risk and is predictive of adjuvant chemotherapy benefit in patients with hormone receptor (HR)-positive, HER2-negative early breast cancer (EBC). Ki67 protein expression is a proliferation marker that is determined by immunohistochemistry (IHC) and is a prognostic biomarker in HR-positive EBC. Black race is associated with poorer prognosis in patients with EBC. RS, Ki67 and race have not been evaluated together and the impact of race on the association between Ki67 and RS is unknown. The goal of this study was to evaluate the association between the 21-gene RS and Ki67 based on race in patients with HR-positive EBC using the NCDB.

Methods: Women with HR-positive EBC with 0-3 involved lymph nodes, diagnosed between 2018 and 2019, who had available information on RS, IHC-measured Ki67, and race in the NCDB dataset were identified. Patients were stratified by RS of low (0-10), intermediate (11-25) and high (26-100) and categorized into Ki67 low ($\leq 30\%$) based on the International Ki67 Working Group prognostic classification (PMID: 33369635). Wilcoxon rank test was used to test for continuous variables and chi-square test was used for categorical variables. Agreement between Ki67 and RS was estimated using Fleiss Kappa statistic and corresponding p-value was reported.

Results:

43,898 eligible women were included. 17.43% were lymph node positive. 78% were Non-Hispanic White, 7.98% Non-Hispanic Black, 6.42% Hispanic, and 4.26% Asian American/Pacific Islander (AAPI). The table below describes the distribution of Ki67 and RS in the overall population and racial subgroups. The distribution of Ki67 scores was significantly different between races with a higher proportion of Black patients having high Ki67 scores, $p < 0.0001$. RS distribution varied as well with a greater percentage of high RS in the Black group, $p < 0.0001$. There was only slight agreement (Kappa 0.01-0.20) between Ki67 and RS in the overall population (Kappa=0.1929, $p < 0.0001$), low Ki67 subgroup (Kappa=0.069, $p < 0.0001$) and intermediate group (Kappa=0.066, $p < 0.0001$). However, there was fair agreement (Kappa

0.21-0.40) between high Ki67 and RS (Kappa=0.351, $p < 0.0001$). Based on race as a covariate, in the overall population, agreement between Ki67 and RS remained slight for White, Hispanic, and AAPI groups but was fair for Black patients (Kappa=0.2345, $p < 0.0001$). In the low Ki67 and intermediate Ki67 groups, agreement remained slight across all races, $p < 0.0001$. While there was fair agreement between high Ki67 and RS in all racial subgroups, agreement between high Ki67 and RS was highest in the Black subgroup (Kappa=0.392, $p < 0.0001$) followed by the AAPI (Kappa=0.363, $p < 0.0001$), White (Kappa=0.342, $p < 0.0001$) and Hispanic (Kappa=0.339, $p < 0.0001$) groups.

Conclusions:

In this large patient population from the NCDB, there was only slight agreement between Ki67 and RS in the overall, low Ki67, and intermediate Ki67 groups but fair agreement in the high Ki67 group. Agreement between high Ki67 and RS was greatest in the Black subgroup compared to other races. This may be attributed to the higher proportion of patients with high Ki67 and RS in the Black subgroup. Future analyses on overall survival will determine the impact of race on the prognostic value of Ki67 and RS.

Table 1. Distribution of Ki67 and RS by Racial/Ethnic Subgroup

	Overall	White	Black	Hispanic	AAPI	AIAN/Other/ Unknown
N (%)	43898 (100)	34275 (78.08)	3502 (7.98)	2819 (6.42)	1870 (4.26)	1432 (3.26)

Background: Clinical outcomes in breast cancer differ across racial and ethnic populations. We have previously demonstrated that receipt of genotype-matched therapy targeted to an actionable mutation may potentially improve patient outcomes (Vidula, CCR, 2021). We evaluated the impact of race on clinical, socioeconomic, and genomic characteristics, clinical trial participation, and receipt of genotype-matched therapy among patients with metastatic breast cancer (MBC). **Methods:** We conducted a retrospective study of patients with MBC at an academic institution who underwent cell-free DNA testing (cfDNA, Guardant360, 74 gene panel) as part of routine clinical care from 11/29/2016-11/2/2020. Patient demographics (including self-reported race and ethnicity) and clinical trial enrollment (at same institution) were determined by retrospective data collection. Mutations identified in cfDNA were characterized as actionable based on the variant interpretation performed by Guardant360 using vetted genomic databases, and receipt of genotype-matched therapy targeted to an actionable mutation was determined as previously described (Vidula, CCR, 2021). Pearson's chi-squared and Wilcoxon rank-sum tests were used to compare categorical and continuous variables between groups, with $p < 0.05$ indicating statistical significance. **Results:** Four hundred and twenty-five patients with MBC and cfDNA results were identified, of which 369 were White (87%), 27 Black (6.4%), 15 Hispanic (3.5%), and 14 Asian (3.3%). There were no significant differences in median age at MBC diagnosis ($p=0.064$), disease subtype distribution ($p=0.74$), proportions of de-novo/recurrent MBC ($p=0.95$), presence of visceral metastases ($p=0.84$), Charleston comorbidity index ($p=0.93$), menopausal status ($p=0.3$), and level of education ($p=0.44$) across racial groups. Higher proportions of non-primary English speakers were seen in Hispanic (80%) and Asian (29%) races ($p < 0.001$). Median distance traveled to the institution also varied based on race, with White patients traveling further (White: 39.1 miles, Black: 21.8 miles, Hispanic 9.4 miles, Asian 9.1 miles, $p < 0.001$). In addition, type of insurance varied based on race, with White patients having the highest rates of commercial insurance and Medicare, Black patients having the highest rate of state-supported insurance, and Asian patients having the highest uninsured rates ($p < 0.001$). Clinical trial enrollment rates did not significantly differ by race (White: 44%, Black: 37%, Hispanic: 47%, and Asian 21%, $p=0.34$), but patients without insurance were significantly less likely to be enrolled on a trial than those with commercial insurance ($p=0.03$). The proportion of patients with ≥ 1 actionable mutation in cfDNA did not vary significantly by race (White: 78%, Black: 56%, Hispanic: 73%, Asian 86%, $p=0.18$) and the median number of actionable mutations found in cfDNA was similar across races ($p=0.31$). However, receipt of genotype-matched therapy targeted to an actionable mutation varied by race, with the highest rates of matched therapy in White patients (White: 28%, Black: 11%, Hispanic 13%, Asian 14%, $p < 0.001$). After multivariable logistic regression adjusting for subtype, commercial insurance versus other insurance types, and proximity to the center, White patients remained significantly more likely to receive matched therapy ($p=0.029$). **Conclusions:** We observed significant race-based differences in non-English speaking status, insurance type, and median distance traveled to the institution. Racial/ethnic minority patients were less likely to receive genotype-matched therapy than White patients. Further research is needed to identify barriers and reduce disparities in access to precision medicine.

Breast cancer patients with advanced metastatic disease can exhibit rapid disease progression, disease stabilisation or partial responses of varying duration. However, for reasons that are not fully elucidated, a small fraction of patients will elicit an exceptional durable response to standard anticancer treatments or survive significantly longer than patients with clinically comparable tumours. Here, we investigate the drivers of immune surveillance mechanisms across breast cancer subtypes in stage IV exceptional survivors (n=13) with matched control cohorts of stage IV typical responders (n=6), early breast cancer patients (n=5) and healthy volunteers (n=17). Peripheral blood mononuclear cells (PBMCs) from patients were stained with 8 panels providing 241 non-redundant immune parameters for flow cytometry analysis. Principle Component Analysis (PCA) showed distinct segregation of the exceptional survivors from the other control groups with an immune signature in exceptional survivors constituting of activated NK, CD8 T cells and gamma delta (gd) T cells pointing towards higher innate immunogenicity in these individuals. Specifically, although these metastatic exceptional responder patients possessed comparable NK cell frequencies, the proportion of NKG2D+CD56dimCD16+ NK cells were significantly enriched compared to the typical responders. Additionally, proportions of CD8+ central memory (CD45RA- CD27+) and effector memory (CD45RA- CD27-) gd T cells, were also seen to be significantly increased. Functional in vitro validation of these findings along with scRNA sequencing of lymph node and tumour tissue is currently underway. To our knowledge, this work is the first to explore in depth the immune signatures in the peripheral blood of exceptional survivors with metastatic breast cancer. Elucidating the immunological reasons for favourable atypical responses alongside functional tumour microenvironment analysis offers unique insights for predictive biomarker identification and discovery of axes that could be exploited therapeutically to benefit those with

less favourable responses. Written informed consent was obtained from all individuals in accordance with the Declaration of Helsinki under the following research ethics committee; London-Chelsea approved study (REC ID 13/LO/1248).

Immune checkpoint inhibitors (ICI) have significantly enhanced patient survival in some cancer types but yield limited success in breast cancer. ICIs activate anti-tumor immunity by overriding the inhibition of tumor infiltrating lymphocytes (TILs). Clinical trials in triple negative breast cancer (TNBC) patients, who are more likely to harbor TILs within tumor stroma, have demonstrated increased progression-free survival (IMpassion130) and pathologic complete response (KEYNOTE-522) to ICI. Consequently, combinations of ICI and chemotherapy have been FDA-approved for metastatic TNBC. However, the therapeutic benefit of ICIs is highly heterogeneous among breast cancer patients; as such, we sought to model ICI response in vivo to evaluate therapeutic resistance and response heterogeneity, as well as ascertain predictive biomarkers for favorable outcomes to ICI in breast cancer. We used an immunocompetent EMT6 orthotopic mammary tumor model to investigate the efficacy of ICI (anti-PD-L1). Analysis of the primary tumor immune landscape was performed by flow cytometry and single-cell RNA sequencing. Matched longitudinal samples of the tumor microenvironment (collected by fine-needle aspiration) and peripheral blood (PBMC) from mice were profiled by bulk RNA and T-cell receptor (TCR) sequencing to identify systemic genomic alterations and T-cell expansion, respectively. Single-agent ICI robustly suppressed primary tumor growth ($p = 0.0046$) and extended survival ($p < 0.0001$) beyond the control group in the EMT6 model. The addition of chemotherapy (paclitaxel and/or doxorubicin) demonstrated moderate therapeutic efficacy but failed to enhance ICI benefit. Phenotypic profiling of the tumor microenvironment (TME) revealed increased T cells, dendritic cells, and NK cells in anti-PD-L1 only and chemotherapy combination groups. Despite using a genetically identical tumor model and murine host, we found that PD-L1 blockade induced heterogeneous responses, similar to clinical outcomes in breast cancer patients, ranging from complete response to intrinsic resistance. Analysis of the primary tumor microenvironment showed upregulated signatures of cytotoxic T cell response and activation, specifically inflammatory interferon signaling (both prior to and post ICI administration) that corresponded to favorable response to anti-PD-L1 in individual mice. Longitudinal analysis of the peripheral blood identified modest changes among mice at baseline that progressively deviated by response type (non responders-vs-responder mice). Moreover, mice harbored enriched myeloid signatures and

clonal T cell expansion during therapy corresponding to ICI resistance and response, respectively. Further investigations of matched peripheral blood and the primary tumor microenvironment signatures may identify systemic biomarkers and tumor antigen-specific T cell clones to accurately predict ICI response in patients and uncover mechanisms for sensitizing tumors refractory to ICI. In conclusion, we identify a heterogeneously ICI-responsive in vivo model that emulates TNBC patient response to combinatorial ICI approaches. We describe host-specific signatures, specifically myeloid cell responses, that correlate with differential responses to immunotherapy, which may serve as a basis for tracking immunotherapy response in peripheral blood from breast cancer patients.

Introduction: Despite several therapeutic advancements, metastatic TNBC remains incurable for nearly all patients and is a frequent cause of cancer-related deaths worldwide. We tested the hypothesis that inhibiting suppressive signals sustained by TGF- β and concurrently stimulating recruitment of inflammatory cells with GM-CSF within the TME would result in improved anti-tumor responses. We report here pre-clinical single agent and ICI combination data for a newly developed oncolytic adenovirus rAd.sT.GM (AMUN-003) that expresses both sTGF β RIIFc (a TGF- β protein decoy), and GM-CSF tested in an immunocompetent mouse model. **Methods:** In addition to manufacturing Amun-003 which is a replication competent adenovirus encoding both sTGF β RIIFc and GM-CSF transgenes, we generated multiple replication competent control viruses coding for sTGF β RIIFc alone, GM-CSF alone or no transgene. We implanted 4T1 cells in the flanks of BALB/c mice, a syngeneic tumor model that is immune competent. On day 7 and day 10 post tumor cell inoculation, we performed saline or single agent virus injections into the tumor. We monitored the health of the animals, performed periodic tumor caliper measurements and collected sera for analysis of cytokines and markers of tissue injury. Animals were sacrificed on Day 25 and tissues collected. Similarly, with the same animal model and using reduced dose Amun-003, we tested combinations with systemic anti-CTLA-4, anti-PD-1 monoclonal antibodies, or both. Animals were sacrificed on Day 25 with specimens collected as above but also to report the metastatic burden in distant tissues. **Results:** In single agent experiments, all adenovirus constructs were similarly tolerated by the animals with no notable differences in animal weights. General safety as assessed by serum LDH and IL-6 demonstrated no difference between animal groups treated with the different virus constructs. All adenovirus resulted in delay of cancer growth and on day 25, excised tumors from sacrificed animals weighed less than tumors from animals treated with buffer. However, a single dose of Amun-003 was the most effective at delaying tumor progression than

any other tested constructs (Day 21 and Day 25: $P < 0.0001$ vs the buffer group by two-way ANOVA analysis). Next, we conducted experiments evaluating a single dose of Amun-003 alone or in combination with anti-CTLA4, anti-PD1 or both ICI. Combinations of Amun-003 with ICI delayed progression better than ICI treatments alone or Amun-003 alone. Moreover, the combination with both ICI and Amun-003 was most effective at delay of tumor progression (Day 22 and Day 25: $P < 0.0001$ vs the buffer group; D25: $P=0.0119$ vs dual ICI therapy). Lung surface metastatic nodule counts and lung tissue luciferase assay for 4T1-luc2 cells both showed treatment consisted of Amun003 and both ICI was most potent in inhibiting lung metastasis (Lung nodules: $P < 0.0001$ vs the buffer group; Relative luminescence: $P=0.0036$ vs the buffer group, both by one-way ANOVA analysis). Finally, the metastatic burden in the lung was least in animals treated with Amun-003 and both ICI (42% metastases free) ($P = 0.0373$ vs the buffer group by fisher's exact test). Conclusions: In syngeneic immune competent animals harboring an aggressive TNBC tumor, single agent Amun-003 appeared safe and was more effective at controlling tumor progression following an intratumoral injection when compared to other tested adenovirus constructs. In the same model, combinations of ICI with Amun-003 resulted in delayed tumor growth and control of metastatic spread. These results with Amun-003 support advancement to human clinical testing.

Multiple species of oncolytic viruses (OVs) have been shown to modulate the tumor microenvironment (TME) by increasing immune cell infiltration and activating stimulatory immune responses, leading to the induction of a tumor-specific immune response. Many engineered OVs achieve tumor specificity by either gene deletion or mutations and are then armed with immunomodulatory transgenes to promote anti-tumor immune responses. In an alternative approach, OVs derived from Codagenix's codon/codon pair modification platform aim to leverage the natural immunostimulatory capacity of selected viral species for efficacy and take advantage of defects in innate immune sensing and apoptosis mechanisms in cancer cells as well as receptor overexpression for tumor selectivity. CodaLytic is a novel virotherapeutic derived from influenza virus strain A/California/07/2009, that is synthetically engineered to contain over 600 silent mutations in hemagglutinin and neuraminidase genes and is being developed as a novel immunotherapeutic for breast cancer. In the orthotopic EMT6 triple-negative breast cancer model, known for its moderate sensitivity to immunotherapies, intratumoral injection of 108 PFU three times a week for up to 4 weeks as a monotherapy led to significant tumor growth inhibition by 76% ($p < 0.001$ vs vehicle control), translating into a significant survival benefit with a 66% cure rate. Intravenous rechallenge of EMT6 long-term survivors led to a 27-fold reduction in lung nodule formation and a tumor-specific interferon- γ memory response was observed *ex vivo* in their splenocytes. Anti-tumor efficacy after CodaLytic treatment was accompanied by a change in the composition of the tumor immune infiltrate with significant increases in T, B and NK cells and increased gene expression of pathways and genes related to T cell effector function, dendritic cell activation, antigen presentation and chemoattraction. In immunotherapy-resistant orthotopic 4T1 tumors, combination of CodaLytic with a CTLA-4 inhibitory antibody, but not anti-PD-1 blockade – a combination that had demonstrated combination benefit in several other preclinical models – led to reduction in tumor growth by 75% ($p < 0.0001$ vs vehicle control and PD-1 combination group). Median overall survival improved from 22 to 30 days with addition of CTLA-4 blockade. Triple combination including PD-1 inhibition led to improved long-term survival beyond 50 days with 30% complete regressions. In summary, these preclinical data demonstrate CodaLytic's ability to induce broad innate and adaptive changes in the breast cancer TME, resulting in anti-tumor efficacy and prolonged survival. Characterization of the tumor immune infiltrate after CTLA-4 combination and pharmacodynamic changes achieved after CodaLytic/checkpoint combination treatment in human breast cancer tumoroids will further support identification of correlates of efficacy with translational implications. Together with preclinical toxicology data and demonstrated clinical safety of this attenuated influenza virus after intranasal administration in healthy individuals, CodaLytic emerges as a promising novel viroimmunotherapeutic agent and is planned to enter a phase 1 clinical trial in early 2023.

Background: Increased macrophage infiltration is associated with the poorest outcome following neo-adjuvant chemotherapy in patients with triple negative breast cancer (TNBC). We have extensively characterized three different preclinical syngeneic claudin-low Trp53^{-/-} tumor models (T11, T12 and 2151R), that have high Tumor Associated Macrophage (TAM) infiltration. These “claudin low” models closely phenocopy the EMT/TAM subtype observed in patients. Treatment using conventional chemotherapy, Cyclophosphamide (CTX) in combination with Pexidartinib (PXB, PLX3397) an anti CSF-1R small molecule inhibitor yielded a durable response in two of the models, T12 and 2151R (Singh et al. Cancer Res. 2022). However, due to potential liver toxicity and dual targeting of c-kit and FLT-3, PXB is not moving forward into the clinic for TNBC. Accordingly, we asked if SNDX-ms6352 a specific, high affinity monoclonal antibody targeting CSF-1R in combination with CTX might provide an alternative approach for treating primary TNBC as well as established lung metastases. Methods: Tumor chunks were transplanted into the mammary fat pad to generate primary tumors. Single cells from primary T12 mammary tumors were introduced via tail vein (TV) injection to obtain lung metastases. After fifteen days for primary tumors and twelve days following TV injection, respectively, the mice were randomized into treatment groups and administered four weekly treatments of IgG, CTX, SNDX-ms6352 or CTX+SNDX-ms6352. Primary tumors, lungs and mammary glands were harvested and fixed overnight in 4% paraformaldehyde then placed in 70% EtOH for paraffin embedding and stained for H&E, immunohistochemistry (IHC), immunofluorescence (IF) and imaging mass cytometry (IMC). Results: Following, four weekly treatments of CTX+SNDX-ms6453 we observed a significantly decreased primary tumor volume as compared to IgG, CTX and SNDX-ms6352 alone. Mice that fully responded to the treatment were re-challenged with tumor cells in the contralateral mammary gland to determine if there was a long-term immune memory response. We observed a fifty percent tumor re-challenge rejection in both T12 and 2151R. Increased expression of CD20 B and CD8 T cells was observed within the mammary gland of the complete responders, this was accompanied by macrophage depletion in the SNDX-ms6352 and combination treated mice. SNDX-ms6352 induced macrophage apoptosis as evidenced by the activation of cleaved caspase 3. For lung

metastases TV injected mice were administered BrdU to identify micro-metastatic lesions. Following four weekly combination treatments of CTX+/-SNDX-ms6352 we observed a decreased lung metastatic burden and increased overall survival as compared to IgG, CTX and SNDX-ms6352 alone. Interestingly we also observed increased CD8 T-cell infiltration, but only in the combination treated mice following 28 and 56 days post treatment. Conclusion: These results suggest that targeting macrophages enhances the immunostimulatory effect of low dose cyclophosphamide in treating not only primary tumors, but also established lung metastasis via the activation of the tumor immune microenvironment. Supported by CA148761 and T32 CA203690 grants.

PD2-06 Implications of Heterogeneity in Breast Tumor Cell MHC-I Expression on Immunity and Therapeutic Resistance

Background Immune checkpoint inhibitors (ICIs) targeting the PD-1/L1 axis are approved in early-stage treatment for triple-negative breast cancer (TNBC), but only a fraction of patients benefit. Tumor expressed antigens bound to major histocompatibility complex-I (MHC-I) are required for CD8-mediated tumoricidal activity, and thus, response to anti-PD-1/L1 targeted ICI. However, many breast tumors downregulate, or heterogeneously express, MHC-I, making them less susceptible to ICIs. Tumor cells downregulating MHC-I may be effectively targeted by natural killer (NK) cells due to 'missing self' signals. However, this heterogeneity in MHC-I expression is poorly modeled in most preclinical studies, limiting our understanding of how to overcome ICI resistance in the context of heterogeneous MHC-I expression, as is often observed clinically. Objective We aimed to 1) quantitatively delineate how intratumoral heterogeneity in MHC class I expression affects immune responses and immunotherapy outcomes in mouse models and 2) determine whether targeting inhibitory signals on NK cells can overcome ICI resistance in MHC-I heterogenous TNBC. Methods We performed quantitative immunofluorescence for MHC-I, CD8, CD56, and pan-cytokeratin on breast cancer tumors from diverse subtypes (n=314) to obtain single-cell-resolution MHC-I expression and spatial information of tumor and immune cells. Fluorescence intensity and spatial analysis were processed to output individual tumor/stromal cell MHC-I expression and the composition of the local tumor microenvironment. To determine the functional effect of MHC-I heterogeneity in vivo, we generated a CRISPR-guided B2m knockout (B2m-null) in a murine orthotopic model (EMT6). We then combined MHC-I-proficient and MHC-I-deficient isogenic lines at various ratios to model how populations of MHC-I loss affected the immune microenvironment. We also assessed a second, intrinsically heterogenous (MHC-I expression) TNBC model E0771. To evaluate changes in the microenvironment, we used flow cytometry and an immune NanoString panel to evaluate gene expression patterns in tumor cells and infiltrating immune cells. Results TNBC patients had the highest MHC-I expression level across tumor cells, but also the highest variability and probability of demonstrating bimodal MHC-I expression (consisting of high and low/absent cells within a single tumor). ER+ tumors were unimodally low. Using spatial analysis, we identified that heterogenous MHC-I tumors had significantly higher levels of infiltrating NK cells (Paired T-Test: p=0.03). In murine models, even 10% or less of MHC-I-null

(B2m-null) EMT6 cells in the tumor injection resulted in acquisition of ICI resistance. Interestingly, heterogeneity in expression of MHC-I resulted in a substantial infiltration by NKG2A+ NK cells compared to MHC-I high or -low tumors (Student T-Test: $p=.002$). Activation of these infiltrating NK cells via anti-NKG2A and anti-PD-L1 combination treatment restored complete responses in heterogeneous EMT6 tumors, and significantly extended survival in both E0771 (Mantel-Cox: $p < 0.0001$) and EMT6 models (Mantel-Cox: < 0.0001). Additionally, anti-NKG2A and anti-PDL1 combination treatment improved complete response in the heterogeneous MHC-I EMT6 model to 30% and in the parental EMT-6 tumors to 70%. Conclusion Combined therapy with anti-NKG2A (targeting NK cells) and anti-PD-L1 (targeting CD8+ T cells) can restore immunotherapy responses and overcome resistance due to lack of MHC-I expression in tumor cell subpopulations.

Keywords: CD73, bisphosphonates, zoledronate, B cells, tumor growth, TNBC Background: CD73 is a membrane-bound protein that by extracellular adenosine production, regulates immune cell function. Low CD73 expression is associated with better prognosis among triple-negative breast cancer (TNBC) patients. Adjuvant bisphosphonates (BPs, such as zoledronate) improve survival among post-menopausal breast cancer patients, but the mechanism for this is unknown. Since BPs also affect immune cells, we studied 1) whether zoledronate-treatment has an effect on tumor infiltrating lymphocytes (TILs) and 2) whether tumor CD73 expression affects these responses in TNBC tumors. Methods: 4T1 mouse mammary cells, stably expressing non-targeting shRNA (sh-NT, control cells) or sh-CD73 were inoculated into the mammary fat pads of Balb/c mice. The mice were treated with i.p. vehicle or zoledronate (ZOL) each 4th day for total of six times. Additionally, to deplete B-cells, the mice were treated with an anti-CD20 or control IgG antibody. Tumor sizes were assessed with a caliper, TILs were studied with immunostainings. Blood lymphocytes were analyzed with Flow cytometry. Results: Sh-CD73 cells formed significantly smaller tumors, than sh-NT cells. ZOL significantly inhibited the growth of both sh-CD73 and sh-NT tumors, but at sacrifice, this effect of ZOL was more significant against sh-CD73 tumors. ZOL increased the % of CD19+/CD21+ and CD19+/23+ in blood of both mice groups, and this effect was inhibited by anti-CD20 antibody. Although neither treatment alone had an effect, the % of CD3+/CD8+ cells in blood were increased in both mice groups by the combination of ZOL and anti-CD20-antibody. ZOL induced

accumulation of B220+, CD4+ and CD8+ TILs into both tumor groups. These TIL effects were reduced with anti-CD20 antibody treatment. Anti-CD20 antibody alone inhibited significantly sh-CD73 tumor growth. Anti-CD20 antibody did not interfere with ZOL inhibition of tumor growth in either group. Conclusions: ZOL has inflammatory effects on blood lymphocytes and TILs, which may be affected by tumor expression of immune system regulating proteins, such as CD73. B cell depletion may further prevent tumor growth, in the context of CD73 inhibition. Further studies are needed to investigate whether B-cell inhibition affects ZOL-induced tumor growth inhibition.

Title: Targeting of eIF4A1 along with anti-PD-L1 therapy limits lung metastases efficaciously in triple-negative breast cancer Dharmindra Dulal, Andrew Boring, and Dayanidhi Raman
Department of Cell and Cancer Biology, College of Medicine and Life Sciences, The University of Toledo-Health Science Campus, Toledo, OH Background: Triple-negative breast cancer (TNBC) is the most aggressive subtype of metastatic breast cancer with poor clinical prognosis. Currently used neoadjuvant chemotherapy for TNBC, such as taxanes, and/or anthracyclines demonstrate an initial treatment response but is often followed by drug resistance, tumor relapse, and high proclivity to develop metastases. There is an unmet need to develop effective combination therapies against metastatic TNBC (mTNBC). eIF4A1 is an mRNA helicase that help translate many oncogenic mRNAs including PD-L1 (through STAT1 translational regulation) that are involved in tumor growth, chemoresistance and metastases. Our prior studies pointed out that eIF4A1 is intricately linked to cancer stemness and drug resistance in TNBC. Emerging evidence has revealed that the tumor immune microenvironment (TIME) of TNBC do consist of mononuclear cells and lymphocytes. Combining chemotherapy with immune checkpoint inhibition had demonstrated a significant benefit for high-risk TNBC patients. In this study, we examine the efficacy of targeting eIF4A1 along with anti-PD-L1 therapy as an effective therapeutic strategy to limit cancer stemness, primary tumor progression and metastasis in an immunocompetent murine model of TNBC. Approach: Initially, we examined the human TNBC biospecimens and found that eIF4A1 protein level is upregulated in drug-resistant cases. STAT1 is an upstream regulator of PD-L1 and a downstream effector of eIF4A1. The protein level of STAT1 was significantly elevated as assessed by immunoblotting of human tumor lysates. In human TNBC cells, when eIF4A1 is pharmacologically or genetically targeted, PD-L1 was downregulated at the protein level. Based on this premise, we targeted eIF4A1 with the small molecule inhibitor, Rocaglamide A (RocA), along with anti-PD-L1 immunotherapy in orthotopically implanted 4T1 mouse TNBC tumors in BALB/c mice. The treatment arms were 1) Control (vehicle for RocA + control IgG) 2) RocA 3) RocA + anti-PD-L1 antibodies 4) Control IgG only 5) Anti-PD-L1 antibodies only with 10 mice in each group. Results: The combination treatment comprising of RocA and anti-PD-L1 antibodies worked out efficaciously as the primary tumor volume, wet tumor weight, bioluminescent tumor imaging and quantitation were significantly lower than the combination vehicle control.

Furthermore, metastasis to the lungs were significantly impaired (1 out of 10 mice only had metastasis and that too it was small). On the contrary, 'RocA single arm' group had 6 out of 10 mice with lung metastasis. The lung metastases were observed in 4 out of 10 mice in the PD-L1 single arm and 6 out of 10 mice in control IgG single arm group. The RocA was tolerated well at 0.6 mg/kg with no significant change in the body weight and the liver and kidney function test values were within the normal range. Importantly, the combination treatment with RocA and PD-L1 was also tolerated well. Conclusions: The combination therapy involving RocA and PD-L1 had the significant impact in reducing lung metastases and may pave the way for phase I/II clinical trials.

Background: Metastasis is the leading cause of cancer related deaths in breast cancer patients. Lymphovascular invasion represents one of the earliest stages of metastasis wherein the cells are introduced to a very different and distinct microenvironment. Methods: We leveraged spatial techniques developed for limited specimens in archival tissue to study patient matched cross-sectional tumor samples from different stages of breast neoplasia including normal breast, ductal carcinoma in situ (DCIS), primary invasive carcinoma (IBC), lymphovascular invasion (LVI) and regional lymph node metastasis. We selected a set of 21 patients with ER+ breast cancer to generate cross-sectional samples of each of these stages, for a total of 331 samples. The areas of LVI were identified by a combination of H&E review and immunohistochemistry for podoplanin. We performed smart-3SEQ for gene expression profiling and light pass whole genome sequencing for DNA copy number alterations. Results: We profiled the spectrum of

neoplasia for transcriptome-wide gene expression. Principal component analysis of all 252 DCIS, LVI, IBC, or metastasis samples using the top 500 genes with the highest variance demonstrated that clustering was roughly based on the diagnostic stage (i.e. DCIS, LVI, IBC, or metastasis). Differential gene expression profiling identified thousands of genes increased or decreased in expression across the transitional stages with the largest change in gene expression being the transition from normal breast to DCIS, dominated by gene expression down regulation. We next performed NMF clustering on 62 samples of LVI from 18 cases and identified two patterns of gene expression which define two subgroups. Gene ontology analysis revealed that one cluster was associated with increased proliferation and metabolism, whereas the second cluster was dominated by an immune response. When we analyzed the immune and proliferative LVI subgroups separately, we found that the immune profiles in the patient matched IBC and LVI samples from the LVI Immune cluster were similar, whereas the immune profiles in the patient matched IBC and LVI samples from the Proliferative cluster were significantly different. At the LVI stage, all immune cell populations estimated by CibersortX were decreased in the Proliferative LVI cluster. These changes were validated using immunofluorescence for proliferation (Ki67), T cells (CD3) and macrophages (CD68) on the same samples. Using the LVI centroids, we built a model that could predict the same clusters in the METABRIC IBC. Kaplan-Meier analysis showed a significant difference between groups, with the Proliferative-like IBC group having a worse prognosis than the Immune-like IBC group. Conclusions: We observed a dichotomy at the LVI stage with a more proliferative cluster that may escape the immune response and an immune cluster which has a microenvironment with a similar pattern to its primary IBC. The recognition of two groups of LVI, differing in immune association and proliferation, raises the possibility that the risk of metastasis could be different in these two groups, leading to different biological pathways of progression.

MicroRNA (miRNA) are known as a key player in tumor biology and is shown to epigenetically regulate a large number of protein-coding genes, including tumor-related genes. MiR-150, a hematopoietic cell-specific miRNA, has been suggested to have various effects on cell proliferation, differentiation, apoptosis, migration, and invasion. However, there has been no study that investigated the role of miR-150 in the tumor microenvironment (TME) of breast cancer patients. We hypothesized that miR-150 expressed in breast cancer cells attract infiltration of lymphocytes to tumor microenvironment and is associated with better survival of the patients. In silico analyses of 1961 breast cancer patients were performed using multiple independent large cohorts, and in vitro studies by overexpressing miR-150 using its mimic in triple negative breast cancer (TNBC) cell lines were conducted. We found that miR-150 expression in patient breast tumors were strongly correlated with immune-related gene set scores, Allograft rejection, IL6/JAK/STAT3 signaling, Interferon- γ response, Inflammatory response, IL2/STAT5 signaling, and complement, in Hallmark collection of gene set variation analyses consistently in both METABRIC and TCGA cohorts (all spearman's rank correlation coefficient (r) > 0.50, all p < 0.01). MiR-150 expression was also strongly correlated with

cytolytic activity (CYT) score in both cohorts ($r = 0.824$ and 0.786 , respectively, both $p < 0.01$). Furthermore, miR-150 expression was significantly correlated with infiltrating fraction of CD8+ T cells ($r = 0.799$ and 0.525 , respectively), CD4+ memory T cells ($r = 0.759$ and 0.656 , respectively), dendritic cells ($r = 0.735$ and 0.696 , respectively), and B cells ($r = 0.759$ and 0.576 , respectively), as well as mRNA expression of major immune checkpoint molecules, including PD-1, CTLA4, IDO1, TIGIT, BTLA, and LAG3, in both cohorts (all $r > 0.50$, and all $p < 0.01$). MiR-150 expression in triple negative breast cancer (TNBC) was the highest among the subtypes (both $p < 0.001$). MiR-150 expression level was significantly correlated with Nottingham histologic grade (both $p < 0.001$). MiR-150 high tumor enriched not only immune-related gene sets but also apoptosis, KRAS signaling up, MTORC1, and p53 pathway by gene set enrichment analysis in both cohorts. High miR-150 expression patients were significantly associated with better overall survival (OS) in both cohorts ($p < 0.001$ and $p = 0.030$, respectively). Subgroup analysis revealed that a high miR-150 was associated with better OS in ER-positive/HER2-negative breast cancer in both cohorts ($p = 0.002$ and 0.044 , respectively), and in TNBC in the METABRIC cohort ($p = 0.006$). Unexpectedly, overexpression of miR-150 by its mimic shown no significant effect on cell proliferation, migration, nor invasion consistently in two TNBC cell lines. On the other hand, overexpression of miR-150 by its mimic significantly attracted Jurkat immortalized lymphocytes consistently in two cell lines, which effect was abolished by addition of miR-150 inhibitor. Finally, we found that mimic overexpression of miR-150 significantly expressed multiple cytokines and multiple inflammatory signaling pathways which at least partially explained the increased attraction of T cells in patient samples and in vitro condition. In conclusion, miR-150 expression in breast cancer cells may be associated with better patient survival outcomes by attracting and activating immune cells in breast cancer TME.

Background Brain metastases is a fatal consequence of advanced breast cancer with a poor prognosis. Both tumor intrinsic molecular underpinning of the primary tumor and microenvironmental brain niche factors have been reported to allow invading cancer cells to colonize and outgrow into the brain. A systemic investigation of these tumor intrinsic and microenvironmental factors using same patient paired primary breast and brain metastatic tumor samples are warranted. Methods Nine pairs of primary breast and brain metastatic tumor samples were collected for RNA sequencing. Pairwise differential gene expression analysis and gene set enrichment analysis (GSEA) were conducted. TCGA-BRCA (n=1222) dataset and a combined breast cancer cohort (n=2,765) were used for clinical and immune-infiltration correlation analysis. GSE12276 (n=204) dataset was used for brain-metastasis free survival correlation. Immunohistochemistry staining of HCMV was conducted on a total of 16 primary breast and brain metastatic tumor sections including 2 pairs. Two patient-derived xenograft (PDX) models were used for antiviral treatment and mechanism investigation. Results 371 up-regulated and 2,153 down-regulated genes in the 9 paired brain metastatic tumors vs. breast tumors ($P < 0.05$; $\log_2 FC > 1$ or < -1) were identified from the RNAseq data. Reactome Human cytomegalovirus (HCMV) early and late events was the top enriched pathway for the 371 brain metastasis up-regulated genes, and Reactome IL4 and IL5 signaling was the top enriched pathway for the 2,153 primary breast tumor up-regulated genes. Among the 371 brain metastasis up-regulated genes, 287 genes are also up-regulated in primary breast cancer vs. normal breast in the TCGA 1222 cohort ($P < 0.05$). High expression of 23 out of the 287 genes

are significantly associated with shorter distant metastasis-free survival (DMFS) in a combined breast cancer cohort of 2,765 patients (Logrank $P < 0.05$), and 19 of the 23 genes are associated with poor brain metastasis-free survival (BMFS) in the GEO dataset GSE12276 ($n=204$)(Logrank $P < 0.05$). We further identified that elevated expression of 12 out of the 19 genes are consistently associated with Th2 cell activation and NK cell deactivation in the TCGA 1222 cohort, for which the immunosuppressive Th2 cells are defined by secretion of IL4 and IL5 signature cytokines. Immunoreactive HCMV immediate early proteins indicating virus infection were examined in all the 16 patient tumor tissues, and strong positive signals were seen in both the paired breast tumor and brain metastatic specimens. Preventive treatment of anti-HCMV drug ganciclovir by suppressing viral DNA replication inhibited tumor colonization in the mouse brain in the two HCMV-positive PDX models. Conclusions Our systemic analysis of paired primary breast and brain metastatic tumor tissues identified a causal relationship between HCMV infection and reactivation, immunosuppressive Th2 cell activation and NK cell deactivation, and brain metastatic outgrowth. Since HCMV reactivation frequently induce encephalopathy during chemotherapy or radiation therapy, anti-HCMV agents may represent an effective strategy in preventing and controlling brain metastases.

Background: The phase 3 KEYNOTE-522 study (NCT03036488) showed that pembrolizumab (pembro) administered in combination with neoadjuvant chemotherapy (chemo) and then continued as adjuvant monotherapy resulted in statistically significant and clinically meaningful improvements in pathological complete response (pCR) and event-free survival (EFS) in patients with early triple-negative breast cancer (TNBC). In this post hoc analysis, we assessed outcomes by patterns of adjuvant radiation therapy (RT) administration.

Methods: Patients with previously untreated, nonmetastatic, stage T1c/N1-2 or T2-4/N0-2 TNBC were randomized 2:1 to pembro 200 mg Q3W or placebo, both given with 4 cycles of paclitaxel + carboplatin, then 4 cycles of doxorubicin or epirubicin + cyclophosphamide (neoadjuvant phase). After definitive surgery, patients received pembro or placebo for 9 cycles or until recurrence or unacceptable toxicity (adjuvant phase). Dual primary endpoints are pCR, defined as ypT0/Tis ypN0, and EFS. EFS and adverse events (AEs) that occurred during the adjuvant phase were examined in patient subgroups defined by receipt of adjuvant RT (yes or no) and the pattern of adjuvant RT and pembro administration, either concurrent (the last adjuvant RT exposure was after the first dose of adjuvant pembro or placebo) or sequential (the last adjuvant RT exposure was before the first dose of adjuvant pembro or placebo).

Results: Among 1174 randomized patients, 715 (60.9%) received adjuvant RT (n=454 pembro; n=261 placebo) and 459 (39.1%) did not (n=330 pembro; n=129 placebo). At data cutoff (March 23, 2021), median follow-up was similar (~38 months) in both subgroups. EFS was longer in the pembro arm compared to the placebo arm in patients who received adjuvant RT (either concurrently or sequentially) and those who did not (Table). Grade 3-5 treatment-related AE rates for pembro vs placebo were 5.9% vs 2.7% with adjuvant RT (4.9% vs 2.2% with concurrent RT; 6.8% vs 3.1% with sequential RT) and 7.5% vs 2.9% without adjuvant RT. Treatment-related AEs led to death in 2 patients (0.4%); both occurred in the pembro arm in patients who received adjuvant RT. Immune-mediated AE rates were 10.6% vs 5.0% with

adjuvant RT (9.7% vs 4.4% with concurrent RT; 11.8% vs 5.7% with sequential RT) and 9.0% vs 10.0% without adjuvant RT in the two treatment arms, respectively.

Conclusion: In this post hoc analysis, the addition of pembro to neoadjuvant chemo followed by adjuvant pembro provided a clinically meaningful EFS benefit, independent of adjuvant RT administration. An EFS benefit was observed in patients who received pembro with either concurrent or sequential adjuvant RT. The addition of pembro to adjuvant RT was generally well tolerated. Similar rates of treatment-related AEs and immune-mediated AEs were seen in patients who received adjuvant RT and pembro either concurrently or sequentially, although the sample sizes are modest. These results are consistent with the therapeutic benefit seen with neoadjuvant pembro plus chemo followed by adjuvant pembro in the intention-to-treat population of patients with early TNBC randomized in KEYNOTE-522.

Table. EFS by Adjuvant RT in KEYNOTE-522

Population	Pembro	Placebo	HR
	No. events/No. patients (%)	No. events/No. patients (%)	(95% CI)*
With Adjuvant RT [†]	55/454 (12.1)	52/261 (19.9)	0.58 (0.40 – 0.85)
Concurrent [‡]	16/144 (11.1)	14/91 (15.4)	0.70 (0.34 – 1.44)
Sequential [§]	28/280 (10.0)	35/159 (22.0)	0.42 (0.26 – 0.69)
Without Adjuvant RT	68/330 (20.6)	41/129 (31.8)	0.60 (0.41 – 0.89)

*Based on a Cox regression model with Efron's method of tie handling with treatment as a covariate. [†]Refers to the post-surgery adjuvant RT prior to the date of all treatment discontinuation or completion. [‡]Last adjuvant RT exposure was after the first dose of adjuvant pembro or placebo. [§]Last adjuvant RT exposure was before the first dose of adjuvant pembro or placebo.

Introduction. Breast-conserving surgery (BCS) followed by postoperative radiotherapy (RT) still represents the standard of care for early breast cancer (BC) patients. Hypofractionated schedules in maximum 15 fractions are currently accepted as the gold standard for external beam whole and partial breast irradiation (PBI). PBI for selected early BC patients allowed a shorter overall treatment duration and an improved patient compliance as compared to old-fashioned RT schedules. Preoperative PBI, due to the advantage of treating a well-defined volume, has been gaining attention in this multidisciplinary scenario. It avoids local treatment delay and might allow tumour downstaging with increased rates of BCS and improved cosmetic outcomes. Since local recurrence might be driven by biological mechanisms of radioresistance rather than geographical miss, higher dose per fraction may overcome repair mechanisms allowing tumoral cells to escape from conventional RT damage. We report the results of the phase II ROCK trial (NCT03520894), enrolling early BC patients treated with preoperative robotic radiosurgery (prRS), in terms of acute and early late toxicity, disease control, and cosmesis.

Material and methods. The study recruited between August 2018 and September 2021 at the Radiation Oncology Unit of the University of Florence (Florence, Italy). Eligible patients were women aged 50+ years, with histologically proven invasive early BC, HR+/HER2-disease, without lymph vascular invasion, tumour size up to 25 mm suitable for BCS. Exclusion criteria were clinical node positive disease, multiple foci tumours, and patients with breast lesion limiting within 5 mm from the skin surface. The study aimed to prospectively assess the safety and feasibility of a single Cyberknife® (Accuray Incorporated, Sunnyvale, CA, USA) 21Gy-fraction prRS in preoperative setting, and to identify predictive factors for outcomes based on biologic and clinical features. The primary endpoint was the acute skin toxicity (from the end of prRS to surgery) according to the RTOG and the EORTC scales. Secondary endpoints were the rate of early late skin and non-skin toxicity as measured 90 days from the end of prRS, the rate of pathological complete response (pCR) according to Chevalier score. Cosmetic outcomes were prospectively scored every 6-month using the BCCT.core software.

Results. From August 2018 to September 2021, a total of 70 patients were recruited and enrolled. Of those, 41 were excluded due to tumour biology exclusion criteria and 7 due to multiple foci breast disease evidenced at basal MRI. Therefore, 22 patients were successfully treated with prRS. Median age at diagnosis was 68 years (range 50-86), median tumour size was 14 mm (range 7.5-25). Required target dosimetric parameters were met in all patients, as well as normal tissue constraints. Patients received surgery after a median time of 29 days from biopsy, without any delay or postoperative complication. Overall, three G1 adverse events (13.6%) were recorded within 7 days from prRS (1 erythema, 2 breast pain). Three events (13.6%) were recorded between 7 and 30 days from prRS, one G2 breast oedema and two G1 breast pain. No acute toxicity greater than G2 was recorded. Five patients experienced early late G1 toxicity (1 breast pain, 4 breast induration). One patient reported G2 breast induration. No early late toxicity greater than G2 was observed. At a median follow up of 18 months (range 6-29.8), cosmetic results were scored excellent/good and fair in 14 and 5 patients, respectively, while 3 patients experienced a poor cosmetic outcome. Overall, pCR after surgery was reported in 2 patients (9%). Two patients received postoperative whole breast irradiation, according to histopathological results.

Conclusions. ROCK trial showed that a single 21 Gy dose prRS represents a feasible technique for selected patients affected by early BC, showing a good safety profile and a promising effectiveness.

Purpose: Breast cancer (BC) patients (pts) who are not surgical candidates or decline surgical resection are usually managed with palliative systemic therapy alone or palliative radiotherapy if clinically appropriate. Stereotactic body radiotherapy (SBRT) has shown excellent results for different primary malignancies, and we hypothesized it could improve outcomes in this context with acceptable toxicity. This study aims to assess the local control (LC) and toxicity rates of breast SBRT in pts unsuitable for surgical resection. Methods and Materials: We performed a retrospective analysis using an institutional registry of all BC pts unsuitable for resection who underwent breast and/or regional lymph node (LN) SBRT to a dose of 35-40 Gy in 5 fractions from 2014 to 2021. Patients were deemed unsuitable for resection if they were medically inoperable, declined surgery, had unresectable tumors, or where surgery was not appropriate, such as due to metastatic disease. The primary endpoint was LC (defined as no evidence of

progression of the treated lesion as per RECIST 1.1 criteria) and toxicity grade ≥ 3 (as per CTCAE v5.0). Secondary endpoints included radiological response (RR) of the target tumor at the last follow-up, progression-free survival (PFS), and overall survival (OS). All endpoints were assessed per course of treatment, with death as a competing factor for LC. Results: This study included 61 treatment courses in 57 pts. The median age was 81 years (range 38-99), 74% being older than 70 years of age. Eighteen percent had stage I-II, 44% stage III, and 38% stage IV disease. Unresectable tumor (10%), patient refusal (18%), medically inoperability (34%), and metastatic disease (38%) were the main causes of not having surgery. The molecular subtypes were HER-2 in 3%, basal-like 23%, and luminal disease 74%. Previous systemic treatment consisted of endocrine therapy (ET) alone (49%), chemotherapy (CT) or target therapy (TT) alone (11%), both ET and CT/TT (18%), or none (21%). Seventy-two percent of tumors were progressing on ET (44%) or CT/TT (28%) at the time of SBRT. The median interval from cancer diagnosis to SBRT was 14.6 (range 0.5-180) months (mos). Fifty-four percent had breast SBRT, 15% LN SBRT, and 31% both. For LN treatment, axillary, internal mammary, and supraclavicular nodes were the target in 43%, 3%, and 2% of treatments, respectively. The median clinical and radiological follow-up was 16.8 (range 0.2-87) and 13.4 mos (range 1-81), respectively. The worst acute and late grade ≥ 3 toxicity was 16% and 4%, respectively, and all cases consisted of radiation dermatitis. No patient was unable to complete treatment due to acute toxicity. There was one case of grade 4 skin necrosis 6.3 mos after 35 Gy in 5 fractions to an axillary LN. The LC rate at 1 year was 100% and 2 years 88.6% (95% CI = 79-99%). The median time to local progression among those who progressed was 18.2 mos (95% CI = 12-not reached). At last FU, the RR of treated tumors was: complete response = 8%, partial response = 46%, stable disease = 38%, and progressive disease = 8%. The PFS and OS rates at 1 year was 69.8 % (95% CI = 58-82) and 74.6% (95% IC = 63-86), 2 years 39.1% (95% CI = 26—52) and 50.6% (95% IC = 36-65), 3 years 26.7 % (95% CI = 14-39) and 38.7% (95% IC = 24-54), and 4 years 18.5 % (95% CI = 8-29) and 29.2% (95% CI = 14-44), respectively. The median PFS was 21.7 mos (95% CI = 17-28) and OS 31.1 mos (95% CI = 21- 38). Ongoing analysis intends to identify clinical and pathological predictors of LC, PFS, and OS. Conclusion: Our initial data suggest that breast SBRT safely provides excellent LC rates in non-operable BC pts. This approach may be a treatment option in pts who are not good surgical candidates, particularly in elderly pts with multiple comorbidities, which comprised 74% of our cohort. A clinical trial is underway to determine the optimal dose and side effect profile for primary breast SBRT with curative intent in pts not undergoing definitive surgery.

Purpose: The aim of current analyses is to report toxicity and cosmetic outcomes at 3 and up to 9 years of follow-up of post-menopausal patients randomized to receive either standard external beam whole breast radiotherapy (WBI), including hypofractionated options, versus accelerated partial breast irradiation (APBI). Methods and materials: From December 2010 to July 2015, 1006 patients were enrolled in 34 French centers (503 in each arm). Among the whole population, 28 patients who did not meet the final selection criteria or withdrew consent were excluded leading to a modified intention to treat analysis dataset of 978 patients (WBI: n=488; APBI: n=490). Median age (65y) and tumor stage pT1 (99%) rates were similar in both arms. Patients had conservative surgery with clip placement in the tumor bed. Clear margins (> 2mm) were observed in 99% of the patients. In both arms, 96-97% of the patients had negative sentinel lymph node biopsy (SLNB; median number: 4 in WBI arm and 5 in APBI), luminal BC. Ductal histology was observed 82%. Only 2% and 1% of patients had grade III and pN(i+) disease. The median time interval between surgery and radiotherapy was 57d in WBI vs 62d in APBI. WBI schedules consisted of: 50Gy in 25fr + 16Gy boost (n=212) or 40Gy in 15fr (n=156) or 42.5Gy in 16fr (n=120), while APBI arm consisted of 38.5Gy or 40Gy in 10fr. Overall, 94 patients from the APBI arm finally received standard WBI. For statistical considerations, SHARE trial, sponsored by UNICANCER (NCT01247233) is a non-inferiority randomized controlled trial comparing APBI versus WBI in terms of local control as primary objective. Secondary endpoints were severe toxicity (NCI-CTCAE v4 grade ≥ 2), and cosmetic results, evaluated by doctors and by patients, over the entire follow-up. For both outcomes, we estimated the cumulative incidences (CI) using Kalbfleish and Prentice method, considering

disease relapse, secondary cancer or death as competing events. Treatment effect (APBI vs WBI) was estimated by cause-specific Hazard Ratios (cs-HR) from Cox models adjusted on stratification factors. Results: Median follow-up was 5.8y (range, 0.13-9.5). The number of deaths was 27, and the number of local relapses was 8. Among the 978 patients, 582 and 396 had finally WBI and APBI, respectively. The rates of post-operative hematoma, edema and infection were low: 8-9%, 2%, 3-2%, respectively. When considering any type of severe toxicity, we observed a significant reduction rate in APBI compared to WBI: cs-HR=0.73 (95% confidence interval: 0.61-0.88); p=0.001, and 3-year cumulative incidence (CI) of severe toxicity at 45% (41-49) in WBI vs 36% (32-40) in APBI arm. The difference was also in favor of APBI when considering breast skin toxicity alone: cs-HR=0.55 (0.44-0.70), p< 0.001 and 3-year CI at 36% (32-40) in WBI vs 21% (18-25) in APBI arm. Conversely, for breast other toxicities, WBI was found less toxic than APBI: cs-HR= 2.10 (1.51-2.91), p< 0.001, and 3-year CI at 8% (5-10) vs 15% (12-19), respectively. When considering cosmetic results according to the investigator, we observed no significant difference between the two arms: cs-HR=1.04 (0.81-1.33), p=0.26 and 3-year probability of remaining with good to excellent cosmetic results at 77% (73-81) in WBI arm and 78% (74-81) in APBI arm. Findings were similar when considering results according to the patient: cs-HR=1.07 (0.85-1.37), p=0.23, and 3-year probability at 74% (70-78) and 75% (70-79), respectively. Conclusions Historically SHARE is the first APBI trial that included hypofractionated schedules in the standard arm. We reported increased risk of severe toxicity and skin breast toxicity in standard arm as compared with APBI arm without any difference in terms of cosmetic results. Longer follow-up is needed.

Purpose: Outcomes following adjuvant accelerated partial breast irradiation (APBI) in select women with early-stage breast cancer are comparable to whole breast irradiation. Robotic stereotactic accelerated partial breast irradiation (RSAPBI) with fiducial tracking is an attractive treatment option, but limited outcomes data are available for this approach. We report 2-year outcomes for a prospective multi-institutional trial treating select women with RSAPBI. Materials and Methods: Post-menopausal women with DCIS and Stage IA breast cancer were treated over a five-year period extending from November 2015 to November 2020 and were followed for a minimum of 18 months. Treatments were delivered with a robotic radiosurgery system. Four gold fiducials were implanted around the lumpectomy cavity prior to the start of treatment for tumor bed delineation and target tracking. The CTV was defined as the lumpectomy cavity with a uniform 5-15 mm expansion confined to the breast tissue and the PTV was defined as the CTV with a 0-5 mm uniform expansion. The PTV was prescribed 30 Gy in 5 fractions. Disease status assessments were completed at 4 weeks, 3 months, 6 months, 12 months, 18 months, 24 months and yearly intervals thereafter for five years. Results: Eighty-one patients (median age 68 years) with hormone receptor-positive tumors were treated over a median 9 days (range, 5-15). Sixty-eight women had invasive ductal carcinoma (84%) and thirteen had DCIS (16%). The median treated PTV was 108 cm³ (IQR 66-156) and the median prescription isodose line was 81% (IQR 79-83). The median CTV expansion was 10 mm (range 5-10) and the median PTV expansion was 3 mm (range 0-5). At a median follow up of 2 years there was one new ipsilateral breast tumor diagnosed. There were no local, regional, or distant treatment failures. Conclusions: Two-year results suggest that RSAPBI with fiducial tracking is an effective technique for the adjuvant treatment of post-menopausal women with hormone receptor-positive early-stage breast cancer. Additional follow-up is planned to confirm this preliminary finding.

Background Recent advances in the treatment of human epidermal growth factor receptor positive (HER2+) early breast cancer (eBC) have led to a reduction in recurrence risk; still a relevant percentage of patients relapses over time, predominantly presenting with distant recurrence. Neratinib is registered in Europe as extended adjuvant treatment for adult patients with HER2+, hormone receptor positive (HR+) eBC, who completed adjuvant trastuzumab-based therapy within one year prior to start of neratinib. In the ExteNET study, neratinib improved the absolute 5-year invasive disease-free survival (iDFS) rate by 5.1% versus placebo in this population (90.8% vs. 85.7%; HR 0.58 [95% CI 0.41-0.82]), mainly by reducing the rate of distant metastases. According to explorative analyses from ExteNET, the effect may be even more pronounced in patients with non-pCR after neoadjuvant trastuzumab treatment and/or in patients completing the full duration of neratinib therapy (i.e. ≥ 11 months of neratinib treatment). Diarrhea, the most common grade 3 adverse event (neratinib: 39% without primary diarrhea prophylaxis, median cumulative duration 5 days; placebo: 1%; no grade 4 events) can generally be managed through adequate prophylaxis and treatment management. ELEANOR is the first non-interventional study (NIS) of real-world use of neratinib and its management in eBC patients in Germany, Austria and Switzerland. Methods Enrollment of 300 adult female patients with HER2+/HR+ eBC is planned in accordance with the SmPC specifications. Primary endpoint is the rate of patients adherent to neratinib treatment (i.e. neratinib use for $\geq 75\%$ of treatment days). Secondary objectives include characterization of patients scheduled to receive neratinib, details on neratinib treatment, recurrences, safety / tolerability, and health-related quality of life (HRQoL). CANKADO, an eHealth application developed to support patient/physician communication, is an integral part of the NIS. Here, we report results of the preplanned interim analysis based on 200 enrolled patients. Results At data cut-off (May 2022), 202 patients had been observed for 3 months; patient enrollment is ongoing. Median age was 53.0 years and 66.3% of patients were at increased risk of disease recurrence (defined as non-pCR or AJCC stage > I). Most patients had received prior neoadjuvant treatment (79.7%). Post-neoadjuvant treatment included dual HER2 blockade with trastuzumab and pertuzumab (38.8% / 23.9% of pCR / non-pCR patients) and trastuzumab-emtansine (T-DM1, 53.5% of non-pCR patients). Neratinib treatment had been documented for 187 patients, treatment was ongoing for 46.0% of patients. Diarrhea was the most common adverse event (78.6% any grade, 19.3% grade 3, 2 patients grade 4), but was markedly lower when indirectly compared to ExteNET (39% grade 3). The neratinib dose escalation schedule was chosen for 36.4% of patients and

led to a decreased incidence of severe diarrhea (16.2% grade 3, no grade 4 events). 93.9% (95% CI: 87.9-97.5%) of 115 evaluable patients adhered to neratinib treatment. Conclusion The results of this preplanned interim analysis reflect the current treatment landscape in Germany, Austria and Switzerland. These results confirm, in line with the observed adherence data, that extended adjuvant neratinib use is feasible in typical clinical practice settings. Furthermore, treatment management strategies such as diarrhea prophylaxis or neratinib dose escalation are routinely used and can increase treatment tolerability markedly. The study is funded by Pierre Fabre Pharma GmbH (Freiburg, Germany), Pierre Fabre Pharma Austria (Wels, Austria) and Pierre Fabre Pharma AG (Allschwil, Switzerland).

Title: Clinicopathological characteristics, treatment patterns and disease outcomes of germline gBRCA1/2 carriers with early stage HER2-negative breast cancer and potential eligibility for adjuvant Olaparib

Background: Approximately 5-10% of early breast cancers (eBC) occur in patients (pts) carrying a germline BRCA1/2 (gBRCA1/2) pathogenic (P) or likely P (LP) variant. In the OlympiA trial, 1-year (yr) adjuvant (adj) olaparib (OLA) improved both invasive disease-free survival (iDFS) and overall survival (OS) in gBRCA carriers with high-risk HER2- eBC. Whether benefit of adj OLA might extend beyond the high-risk population defined by the OlympiA criteria remains to be defined.

Methods: Consecutive pts who underwent surgery for a first diagnosis of eBC at Dana-Farber Brigham Cancer Center between 1/2016 and 8/2021 were identified. Genetic data were retrieved from an institutional dataset to identify gBRCA1/2 P/LP carriers tested through Dana-Farber. Clinicopathological variables, treatment and outcomes were characterized. Eligibility for adj OLA was based on the OlympiA study criteria, as follows: triple-negative BC (TNBC) with \geq pT2 or \geq pN1 prior to adj chemotherapy (ACT) or non-pCR after neo-adj CT (NACT); hormone receptor (HR)+ eBC with \geq 4 positive nodes prior to ACT or non-pCR and CPS+EG score \geq 3 after NACT.

Results: We identified 188 gBRCA (105 BRCA1, 83 BRCA2) carriers with newly diagnosed HER2- eBC. Median age was 42.5 years and 119 (63%) were premenopausal. Tumor stage, grade and subtype are reported in Table 1. Recurrence Score (RS) was performed on 46 pts, with a median value of 25 (2% 0-10 RS, 52% 11-25 RS, 46% \geq 26 RS). 97 pts (52%) received NACT, 55 (29%) ACT only and 36 (19%) did not receive CT. Most pts received both anthracyclines and taxanes, either as NACT (68%) or ACT (53%). 19 (20%) and 8 (8%)

received platinum as NACT or ACT, respectively. 4 pts received adj OLA. 43 (44%) pts had a pCR after NACT. The pCR rate was higher in BRCA1 than BRCA2 carriers (52 vs 25%, odds ratio (OR) 3.27, p=0.015) and in pts with TNBC than HR+ eBC (50 vs 32%, OR 2.10, p=0.101). After a median follow up for survival of 37 months, 16 iDFS events were recorded, including 4 second primary tumors (3 ovarian and 1 pancreatic cancer). 3-yr iDFS was 89% (95% CI, 84-95) in the overall cohort, with no significant difference according to BRCA status (BRCA2 vs BRCA1: 85% vs 93%, hazard ratio [HR] 2.65 (95% CI, 0.92-7.63), p=0.071) or tumor subtype (HR+ vs TNBC: 87 vs 93%, HR 1.72 (95% CI, 0.60-4.94), p=0.316). 3-yr relapse-free survival (RFS) was 92% (95% CI, 87-97).

54 (29%) pts were potentially eligible for adj OLA. Eligible pts more frequently had TNBC (67 vs 36%, p< 0.001), higher stage (stage I 9 vs 55%, stage II 63 vs 37%, stage III 28 vs 9%), and grade 3 disease (85 vs 69%, p=0.045), were less likely to have ODX performed (2 vs 34%, p< 0.001), and more likely to have received NACT (83 vs 39%, p< 0.001) and radiation therapy (78 vs 33%, p< 0.001). 3-yr iDFS was 87% and 90% for pts eligible vs not eligible (HR 1.36 (95% CI, 0.49-3.74), p=0.555). 10/16 iDFS events occurred among not eligible pts. 3-yr RFS was lower in eligible pts (87 vs 94%; HR 2.23 (95% CI, 0.72-6.92), p=0.165).

Conclusions: In our cohort, approximately 30% of pts were eligible for adj OLA. 3-yr iDFS was similar between pts eligible and not eligible for adj OLA according to OlympiA criteria. Our findings raise a concern regarding proper selection of all gBRCA carriers who may benefit from adj OLA. Further research is needed to identify additional groups of pts who may benefit from adding OLA to CT in higher risk disease or potentially replacing CT in lower risk settings.

Characteristics and outcomes of gBRCA1 vs gBRCA2

	gBRCA1 carriers (n=105)	gBRCA2 carriers (n=83)
Clinical stage – n (%)		
I	44 (42)	43 (52)
II	54 (51)	30 (36)
III	7 (7)	10 (12)
Tumor subtype - n (%)		
TNBC	68 (65)	16 (19)
HR+	37 (35)	67 (81)
HR-low	8 (8)	3 (4)
HER2-low	47 (45)	48 (58)
Tumor grade – n (%)		
I	3 (3)	4 (5)
II	14 (13)	27 (33)
III	88 (84)	50 (60)
pCR rate (%)	52	25
3-year iDFS (%)	93	85
3-year RFS (%)	94	89
Pts eligible for adj OLA – n (%)	34 (32)	20 (24)
HR+	6 (18)	12 (60)
TNBC	28 (82)	8 (40)

Country: Belgium

Background: One year of adjuvant trastuzumab with 12 cycles of weekly paclitaxel represents the standard of care for patients with pathological tumor size ≤ 2 cm, node-negative, HER2-positive early breast cancer. Data supporting this indication derive from a single-arm, phase II trial that enrolled 410 patients in the United States only, where the 3 years invasive disease-free survival (DFS) rate was 98.7% (95% CI 97.6-99.8). Therefore, real-world data regarding the clinical outcomes of these patients are needed to confirm the efficacy and safety of this adjuvant anthracycline-free regimen in this population. Methods: We conducted a retrospective, observational, multicentric study to investigate survival outcomes of patients with stage I HER2-positive early breast cancer treated with adjuvant paclitaxel and trastuzumab in seven selected sites in two countries (Belgium and Italy). Eligible patients were men and women with early breast cancer of pathological tumor size between 5 and 20 mm, node-negative (N0 or N1mic), and treated with weekly adjuvant paclitaxel for 12 weeks and trastuzumab (6 mg/kg every 3 weeks administration for 1 year). Patients with a history of previous cancers were not included. The primary endpoint was disease-free survival (DFS) at 3 years from diagnosis. Thus, an optimal follow-up of 3 years from surgery was required. Baseline clinico-pathological characteristics, treatment data, disease recurrences and survival status were extracted from medical records. Survival analysis was performed using log-rank regression test. Results: Overall, 240 patients who received their adjuvant treatment between January 2014 and December 2018 were included in the analysis. The median age was 59.5 years (IQR 50.0-66.9), and 69.6% of patients were post-menopausal at the time of diagnosis. Seventy (31.8%) patients had hypertension and 20 (8.3%) had other cardiac comorbidities. Ductal carcinoma was the most represented histological type (86.3%). The median tumor size was 12mm (IQR 9-15), only seven (2.9%) patients had N1mic, and the majority of tumors (85.0%) were ER-positive. Breast-conserving surgery was performed in 80.8% of patients and 78.2% of patients had adjuvant radiotherapy. The median number of administered cycles of weekly paclitaxel was 12 (range 1-12) and for trastuzumab 18 (range 1-19). Only one patient stopped trastuzumab prematurely because of safety reason. Aromatase inhibitors were the most frequently administered endocrine therapy (75.7% of patients with ER-positive disease). With a median follow-up of 4.7 (IQR 3.6-5.6) years, we observed a 3-year DFS rate of 98.8% (95% CI 96.2-99.6), with only three disease recurrences (one local and two distant) and four deaths (none of which was breast cancer related) during the duration of the follow-up. Conclusions: In this real-world clinical outcome of patients with stage I HER2-positive breast cancer treated with adjuvant trastuzumab and paclitaxel appeared excellent, with a 1.2% rate of recurrence at 3 years. Our data support the efficacy of an anthracycline-free regimen in this population. A longer follow-up will provide more mature data on overall survival and late relapses, especially in the ER-positive subgroup of patients.

Triple-negative breast cancer (TNBC) is an aggressive and recurrent type of breast cancer that accounts for over 15% of new diagnoses yearly. Patients with TNBC have limited response to hormonal or targeted therapies due to the lack of ER, PR, and HER2. Therefore, the standard treatment for TNBC is anthracycline/taxane-based chemotherapies, paclitaxel (PXL), and doxorubicin (DOX), for which patients often develop chemoresistance. PXL, particularly, induces metastasis in TNBC patients by activating the Toll-Like Receptor 4 (TLR4)/NF κ B signaling pathway. Since there are few targeted therapies for TNBC, there is an urgent need to identify new “druggable” molecular targets. The oncogenic GTPases Rac and Cdc42, and their downstream effector, p-21 Activated Kinase (PAK), play critical roles in TNBC development and metastatic cancer progression. Therefore, we developed MBQ-167 as a potent Rac/Cdc42 inhibitor that decreases tumor cell growth and metastasis in TNBC mouse models with no apparent toxicity. To test the hypothesis that inhibiting Rac/Cdc42 with MBQ-167 will chemosensitize TNBC cells to PXL and DOX, we treated TNBC human cell lines MDA-MB-231 and MDA-MB-468 with different concentrations of MBQ-167 (250 nM-500 nM), PXL (5 nM-10 nM), DOX (250 nM-500 nM), and their combinations. The efficacy of single and combined treatments was determined on cell proliferation with the MTT assay, apoptosis with the Caspase-Glo 3/7 assay, and cell migration with the wound healing assay. In addition, we evaluated the effect of single or combined MBQ-167 (per oral 50 mg/kg, 5X a week) and PXL (IP 10mg/kg, 1X a week) on tumor growth and metastasis in an orthotopic Luciferase tagged-MDA-MB-468 TNBC mouse model. Our in vitro results demonstrate that treatments with MBQ-

167, PXL, DOX, and their respective combinations, decreased TNBC cell viability and increased apoptosis compared to vehicle controls. Both combination treatments reduced cell viability and increased apoptosis compared to PXL or DOX alone. Moreover, MBQ-167 was more effective than PXL at reducing MDA-MB-231 cell migration. DOX treatment did not affect cell migration, while combination treatment of DOX with MBQ-167 decreased migration. Moreover, in the mouse model, MBQ-167 significantly reduced MDA-MB-468 mammary tumor growth by 85% compared to vehicle treatments. This decrease in tumor growth was comparable to PXL treatment alone and in combination with MBQ-167. As expected, PXL treatment increased metastasis to the lungs and liver, while MBQ-167 prevented lung and liver metastases and reduced PXL-induced metastasis. Therefore, inhibiting Rac/Cdc42 with MBQ-167 improves the responses to current TNBC chemotherapies, PXL and Dox, and reduces PXL-induced metastasis, making MBQ-167 a potential adjuvant treatment against TNBC. This conclusion will be tested since we recently obtained IND approval from the US FDA for MBQ-167 and plan to conduct clinical trials in TNBC patients.

BACKGROUND: Breast cancer is the most common cancer in woman and can be classified based on the expression of hormonal receptor as well as the human epidermal growth factor receptor 2 (HER2). HER2 amplification is associated with an aggressive clinical course and higher recurrence rates following curative intend surgery. For non-metastatic T2 or node-positive HER2-positive disease neoadjuvant treatment is favored. The National Comprehensive Cancer Network (NCCN) guidelines have endorsed the use of dual HER2 blockage with trastuzumab and pertuzumab combined with chemotherapy in the neoadjuvant setting. However, pertuzumab isn't frequently reimbursed in public health care systems for this indication. Patients who don't achieve a pathological complete response (pCR) at surgery are eligible for adjuvant T-DM1, adding significant side effects on patients and cost on the healthcare system.

METHODS: We conducted a retrospective analysis of patients receiving anti-HER2 therapy in the neoadjuvant setting at the Jewish General hospital between 2015 and 2021. After 2019, pertuzumab was routinely added to standard neoadjuvant therapy enabling us to compare patients treated with or without dual-HER2 blockade. Our primary endpoint is the percentage of pCR at surgery. Secondary objectives are to estimate and compare the cost of anti-HER2 targeted therapy in the perioperative setting and side effect burden on patients. Statistical analyses were done using fisher exact test with statistical significance defined p value < 0.05 in a one-sided test. Drug cost was calculated using publicly available resources.

RESULTS: We identified 83 patient who underwent neoadjuvant chemotherapy for HER2 amplified breast cancer. 44 patients received only trastuzumab has anti-HER2 therapy and 39 patients were treated with dual HER2 blockade containing pertuzumab. The addition of pertuzumab was associated with improved the pCR rate (67% vs. 27%; $p = 0.0016$). The increased pCR rate was observed in hormone-receptor positive and negative tumors. We also described a non-statistically significant trend in reduction in the requirement for axillary dissection with the use of pertuzumab (28% vs. 39%; $P=0.2208$). The increased in pCR rate with pertuzumab reduced the number of patients eligible for adjuvant T-DM1. If all patients with residual disease had received adjuvant T-DM1, the cost of neoadjuvant pertuzumab would be neutral, with a mean anti-HER2 drug cost of 65 150 CA\$ in the pertuzumab-trastuzumab group and 66 116 CA\$ in the trastuzumab group.

CONCLUSION: Our real-world analysis confirmed that neoadjuvant chemotherapy with dual HER2-blockade was well tolerated and associated with increased the pCR rate compared to regimens containing trastuzumab only. This measure is neutral on drug cost by reducing the amount of patients eligible for adjuvant T-DM1. Further research is warranted to estimate the overall health-care utilization costs of neoadjuvant pertuzumab-trastuzumab in settings where adjuvant T-DM1 is available.

Table 3: Pathologic complete response (pCR) and type of surgery in patients who received dual HER2 blockade with neoadjuvant pertuzumab-trastuzumab plus chemotherapy and in patients receiving trastuzumab only with chemotherapy at Jewish General Hospital between 2015 and 2021 . ** $p < 0,01$, ns non-statistically significant

Background: Pyrotinib (an irreversible pan-ErbB inhibitor) plus capecitabine have shown clinically and statistically meaningful progression-free survival and overall survival benefits with acceptable tolerability in patients with HER2-positive metastatic breast cancer in phase 3 trials. In this study, we assessed the efficacy and safety of neoadjuvant pyrotinib plus trastuzumab, taxanes and platinum in women with HER2-positive early or locally advanced breast cancer. Methods: In this multicenter, single-arm, phase II trial (ChiCTR2000039286), treatment-naive patients with early or locally advanced (T2-3, N0-3, M0) breast cancer received pyrotinib 400 mg once daily, plus trastuzumab (8 mg/kg loading dose and 6 mg/kg maintenance dose), docetaxel (75 mg/m²) or nab-paclitaxel (125 mg/m²), and carboplatin (AUC=5-7) on day 1 of each 21-day cycle for 6 cycles before surgery. All patients also received 1-year adjuvant pyrotinib combined with trastuzumab after surgery. The primary endpoint of the study was total pathological complete response (tpCR, ypT0/is ypN0) rate. The secondary endpoints were breast pathological complete response (bpCR) rate, objective response rate, adverse events (AEs) and invasive disease-free survival. Results: Between October 2020 and March 2022, a total of 35 patients were enrolled from 7 sites. By the data cut-off date on June 29, 2022, two patients withdrew from the study, and one received other anti-tumor therapies. Thirty-two patients received neoadjuvant therapy and surgery (modified intention-to-treat [mITT] population), and 30 of whom completed the 6-cycle neoadjuvant therapy (per-protocol [PP] population). The local pathologist-assessed tpCR rate was 59.4% (19/32) and 60.0% (18/30) in the mITT and PP populations, and bpCR rate was 65.6% (21/32) and 66.7% (20/30) in the mITT and PP populations, respectively. The tpCR rate was 68.8% (11/16) among patients with hormone receptor-negative disease and 50.0% (8/16) among those with hormone receptor-positive disease in the mITT population. Of 30 patients with preoperative imaging assessments, 26 (86.7%) achieved an objective response. Treatment-related AEs (TRAEs) were reported in 34 (97.1%) of 35 patients, with the most common being diarrhea (82.9%) and platelet decreased (48.6%). The most common grade ≥ 3 TRAEs were diarrhea (25.7%), platelet decreased (8.6%), neutropenia (8.6%), vomiting (5.7%), and alanine aminotransferase increased (5.7%). No grade 4 or 5 diarrhea events occurred. Conclusions: This study showed similar efficacy with previous reports, neoadjuvant pyrotinib plus trastuzumab-based chemotherapy exhibits promising efficacy and manageable toxicity in patients with HER2-positive early or locally advanced breast cancer.

background While neo-adjuvant anthracycline and taxane-based chemotherapy remains the standard of care for locally advanced TNBC, the optimal chemotherapy regimen is debatable. Anlotinib, a novel multi-target tyrosine kinase inhibitor that effectively inhibits VEGFR, FGFR, c-KIT, c-MET, and RET, monotherapy has been proven effective in HER-2 negative metastatic breast cancer. This study aims to evaluate the efficacy and safety of anlotinib combined with TEC in neo-adjuvant treatment for locally advanced TNBC, and to evaluate the value of predicting pathological response by multi-point core needle biopsy during neo-adjuvant therapy. method This study retrospectively analyzed 18 patients (Pts) with locally advanced triple-negative breast cancer who received anlotinib combined with TEC neo-adjuvant therapy and surgical treatment from August 2020 to January 2022 in the Breast Diagnosis and Treatment Center of Anhui Cancer Hospital. Pts with clinical stage IIb/III TNBC were to be treated with 6 cycles of anlotinib (12mg, d1-14, q3w) plus 6 cycles of docetaxel (75 mg/m², d1, q3w), Epirubicin (90 mg/m², d1, q3w) and cyclophosphamide (600 mg/m², d1, q3w) followed by surgery. Before the fifth cycle of treatment, ultrasound-guided multi-point Core needle biopsy was performed to evaluate the efficacy of neo-adjuvant therapy and predict the pathological complete response, as well as to guide the selection of surgical methods. The primary endpoint was pathological complete response (pCR, ypT0/is). Result Eighteen pts, the median age was 48 years (range, 23-60), were included in the statistical analysis. All patients completed 6

cycles of anlotinib combined with TEC neo-adjuvant therapy followed by radical mastectomy for breast cancer. Regarding pathological response, there were 4 (22.2%), 2 (11.1%), and 12 (66.7%) patients realizing Miller-Payne grade G3, G4, and G5, respectively. Besides, 12 (66.7%) patients achieved pCR. Additionally, the accuracy of multi-point core needle biopsy in predicting pCR was 94.4% in the interval between neo-adjuvant therapy. The grade 3 or 4 AEs were neutropenia and thrombocytopenia in 3 cases each, anemia, arrhythmia, and ALT increased in cases 1 case each. One patient dropped out of the group due to tumor rupture and bleeding. conclusion Anlotinib combined with TEC as neo-adjuvant therapy showed manageable toxicity and promising antitumor activity for locally advanced TNBC. It is safe, reliable, feasible and accurate to evaluate the efficacy of neo-adjuvant therapy and to predict pathological complete response by multi-point core needle biopsy. It means that the clinical evaluation of neo-adjuvant therapy can transition from imaging evaluation to pathological evaluation, which is helpful for the choice of surgical methods.

Introduction

Based on trials performed over a 25-year period, the Early Breast Cancer Trialists Collaborative Group (EBCTCG) identified a small but significant benefit of adjuvant bisphosphonates (BP) in reducing bone recurrence with a subsequent modest improvement in breast cancer-specific survival in post-menopausal women. Multiple studies show that contemporary event rates in early-stage breast cancer are much lower than those observed over a decade ago. This observation likely reflects the impact of modern adjuvant systemic therapy such as anthracycline and taxane chemotherapy and aromatase inhibitors. Therefore, re-evaluating the benefit of adjuvant bisphosphonate in the modern era is warranted.

Methods:

We reviewed reports of randomized trials of adjuvant BP that accrued patients exclusively beyond 2000 and extracted 5-year disease free survival (DFS) and overall survival (OS) in BP and control group arm along with hazard ratios (HR) when reported. The mean 5-year DFS and OS weighted by study sample size was calculated for each group. HR for DFS and OS were pooled in a meta-analysis using generic inverse variance and random effects modelling. Trial level absolute differences in DFS and OS between BP and control arms were calculated. Meta-regression comprising linear regression weighted by sample size (mixed effects) was then performed to explore association between disease and treatment related factors and absolute differences in benefit from BP. Quantitative significance was explored using methods described by Burnand et al. Analyses were performed using SPSS version 28 (IBM Corp, Armonk NY) and Review manager v5.4.

Results

Twelve trials comprising 24109 patients were included in the analysis. Weighted mean DFS and OS in patients receiving BP were 85.8% and 91.7% respectively. For control group patients, these estimates respectively were 83.4% and 91.0%. For DFS, pooled HR across

trials was 0.89 (0.81-0.97) with a 2.9% weighted mean difference favoring BP over control. Among patients receiving anthracycline and taxane based chemotherapy (n=3007), relative benefits were smaller; (HR DFS 0.94, 0.85-1.05). There was no significant OS benefit with BP (HR 0.92, 0.82-1.03) and this finding was observed irrespective of type of chemotherapy. The impact of BP on OS was smaller in both relative and absolute terms in studies with recruitment occurring more recently. Meta-regression results are shown in Table. There was lesser benefit in higher risk patients (node+, larger tumor size, ER-, grade 3 or those receiving chemotherapy). Overall, 1.13% patients experienced osteonecrosis related to BP therapy.

Conclusions

Compared to EBCTCG data, relative and absolute benefit from BP is similar or modestly lower among more recent trials. Benefit from adjuvant BP appears smaller in patients treated with more contemporary adjuvant systemic therapy especially anthracycline and taxane containing chemotherapy. It is uncertain if the impact of BP on OS (rather than breast-cancer specific survival) is of a clinically meaningful magnitude. Despite de-escalated dosing compared to metastatic disease, osteonecrosis was observed in >1% of patients. It is possible that the benefits of BP are driven by patients with clinically low-risk disease rather than those with at high-risk. The balance between benefits and risks of adjuvant BP should be considered in individual patients.

Background: HER2, IGFBP-2, and IGF-IR are proteins that are overexpressed in breast cancer. These three proteins, when used as immunogens, provide broad antigenic coverage to all molecular breast cancer subtypes. The proteins are also up-regulated in pre-invasive and high-risk breast lesions which are associated with progression to invasive cancer. Therefore, generating protective immunity against these antigens could have the result of preventing cancer development in high risk patients. We identified epitopes derived from these proteins, termed Th1 selective epitopes, that specifically stimulated T-helper 1 immune responses in humans and mice. The tri-antigen vaccine was effective in preventing the development of breast cancer in a transgenic mouse model of neu-expressing mammary cancer. We conducted a dose finding study of a plasmid-based vaccine encoding three extended Th1 selective epitopes derived from these antigens in breast cancer patients. Methods: Patients with non-metastatic, node positive, HER2 negative breast cancer that are in remission and defined as no evidence of disease were enrolled sequentially to one of 3 dose arms: 150, 300, and 600 mcg of the tri-antigen vaccine plasmid with 10 evaluable patients per arm (NCT02780401). Vaccines were given monthly intradermally for three total doses with rhu-GM-CSF (100mcg) as an adjuvant. The primary endpoint was safety through the 6-month follow-up visit and the secondary endpoints were immunogenicity, persistence of the immune response after vaccination, and assessment of potential stimulation of T-regulatory (T-reg) cells or myeloid derived suppressor cells to the overexpressed non-mutated antigens as well as determining the recommended Phase II dose. Results: Thirty-two patients were enrolled and 97% received all three vaccinations. The mean age at enrollment was 51.9 years with 61% of patients being pre-menopausal and 39% post-menopausal. The majority of patients were Stage II/III. Eighty-eight percent of patients had hormone receptor positive tumors and twelve percent were triple negative disease. The majority of adverse events (AE) (>95%) were grade 1 or 2. The most common AE were injection site reactions, flu like symptoms, fatigue, chills, myalgia, and nausea. All doses were immunogenic with the greatest magnitude antigen specific Type I immune responses seen in the low and intermediate doses. Eighty percent of patients at the 300mcg dose retained high levels of antigen specific immunity at 1 and 6 months after immunization as compared to 57% and 50% at the 100 and 600mcg doses respectively. No antigen specific Th2 cells, MDSC or T-reg were generated with vaccination. Immunizations did not upregulate PD-1 on CD4 or CD8 T-cells. Conclusions: A plasmid-based vaccine encoding extended Th1 selective epitopes derived from HER2, IGFBP-2, and IGF-IR could be administered safely and generate high levels of antigen specific interferon gamma secreting T-cells (Th1). The 300mcg dose elicited significant immune responses in the majority of patients which persisted at least 6 months after the end of immunization. A Phase II study of the vaccine given in the neoadjuvant setting to patients with HER2 positive breast cancer is ongoing (NCT04329065).

Background: Adjuvant regional nodal irradiation together with whole breast or chest wall irradiation is considered standard of care in most node positive early breast cancer. Existing data on adding internal mammary irradiation (IMNI) to the regional nodal fields are inconsistent. The objective of this study was to conduct a meta-analysis to explore the efficacy and safety of adding IMNI to adjuvant radiotherapy in early-stage, high risk breast cancer. Methods: A search of PubMed and EMBASE identified randomized trials that investigated the addition of IMNI to standard adjuvant radiation in early-stage breast cancer. Hazard ratios (HRs) and 95% confidence intervals (CI) were extracted for overall survival (OS), breast cancer specific survival (BCSS), disease-free survival (DFS) and distant-metastasis free survival (DMFS). The odds ratios (ORs) for regional and loco-regional recurrence, non-breast cancer mortality, secondary non-breast cancer, contralateral breast cancer and cardiovascular morbidity and mortality were also extracted. These data were pooled in a meta-analysis using RevMan 5.4. Results: Analysis included 5 trials comprising 10,994 patients. Compared to the control group, IMNI was associated with a small, but statistically significant improvement in OS (HR=0.91, 95% 0.85-0.97, p=0.004), BCSS (HR=0.84, 95% 0.77-0.92, p< 0.001), DFS (HR=0.89, 95% CI 0.82-0.98, p= 0.01) and DMFS (HR=0.89, 95% 0.81-0.98, p=0.02). IMNI was also associated with reduced odds for regional (OR=0.58, 95% 0.44-0.75, p< 0.001) and loco-regional recurrence (OR=0.85, 95% CI 0.72-1.00, p=0.04). Subgroup analyses for OS by tumor location (medial/central vs. lateral) and by nodal burden showed similar benefit in all subgroups. The odds for cardiotoxicity were higher, but did not reach statistical significance (OR=1.23, 95% 0.99-1.53, p=0.07). There was no association with cardiovascular mortality (OR=1.00, 95% 0.69-1.46, p=1.00). There were also comparable odds for non-breast cancer mortality (OR=1.05, 95% 0.79-1.41, p=0.74), secondary cancer (OR=0.95, 95% 0.82-1.10, p=0.51) and contra-lateral breast cancer (OR=1.07, 95% 0.77-1.51, p=0.68). Conclusions: Compared to the control group the addition of IMNI in high-risk patients is associated with a statistically significant improvement in survival, albeit with a magnitude of questionable clinical meaningfulness. Non-significant association with increased cardiovascular toxicity requires further study in longer-term studies.
