dimerizing and blocks ligand-induced protein kinase-mediated phosphorylation of the PgR. The clinical anticancer activity of onapristone, in immediate release formulation, has been previously documented in patients with hormone therapy-naïve (Robertson et al, 1999) or tamoxifen-resistant (Jonat et al, 2002) breast cancer (BC). More recently, onapristone, in extended release formulation, was evaluated in doses up to 50 mg BID in a phase 1 trial that enrolled 52 heavily pretreated patients with metastatic solid tumors, with no dose limiting toxicity observed. Among the 20 breast cancer patients enrolled, 7 (35%) had stable disease (Cottou et al, 2018). Methods: ELONA is a phase 1b/2, open-label, multicenter study. The phase 1b portion of the study will assess the safety, pharmacokinetics (PK), pharmacodynamics, and preliminary efficacy of elacestrant plus onapristone to determine the combinations' recommended phase 2 dose. The primary endpoint of the phase 2 part of the trial is objective response rate and secondary endpoints will include safety, duration of response, clinical benefit rate, PFS, and OS, in addition to pharmacodynamics markers using ctDNA. Eligible patients are pre-, peri- and post-menopausal women and men aged ≥ 18 years with ER+/PgR+,HER2- tumors and an Eastern Cooperative Oncology Group performance status ≤ 2 with at least one measurable lesion at baseline, as per RECIST version 1.1. Prior therapy in the metastatic setting includes at least one anti-hormonal therapy in combination with a CDK4/6i. No prior chemotherapy regimen in the metastatic setting is allowed. The phase 1b dose-escalation portion of the study will evaluate dose-limiting toxicities (DLTs) of the combination in up to 4 cohorts of 6 patients each.

Background: Treatment for premenopausal women with high or intermediate risk hormone receptor (HR)+ breast cancer (BC) now includes the concurrent use of ovarian function suppression (OFS) and an aromatase inhibitor (AI) therapy to induce near complete estrogen

deprivation (NCED). The long-term cardiovascular (CV) sequela for women treated with NCED is unknown. Premature menopause in the non-cancer population is associated with CV disease, including atherosclerosis and coronary artery disease, which can be detected pre-clinically by myocardial perfusion imaging and coronary artery plaques. This, together with the CV morbidity associated with other aspects of BC treatment and future life-years of these women, warrants further investigation with the goal of identifying pre-clinical markers of myocardial compromise. We seek to do this with the following specific aims:

1. Characterize and quantify the extent of coronary microvascular injury and perfusion changes experienced during early NCED therapy.
2. Characterize and quantify the extent of structural and functional alterations to the aorta and left ventricle while on NCED therapy.
3. Identify potential biomarkers and additional risk factors for CV morbidity in patients receiving NCED

Trial Design:

This is a federally funded (NHLBI) prospective cohort study conducted at 3 regional NCI-supported Cancer Centers (Atrium Health Wake Forest Baptist, Virginia Commonwealth and Duke) that will include premenopausal women, age ≤ 55 , with Stage I-III BC following completion of planned chemotherapy, surgery and radiation with an ECOG 0-1. HR+ BC patients will receive an AI and OFS. Women with HR- BC are included as comparators. CV imaging and biomarkers will be obtained at baseline, 1 year and 2 years (Table 1). These assessments will include serial cardiac magnetic resonance (CMR) and coronary computed tomography angiography (CCTA) imaging as well as laboratory measurements, including exploratory biomarkers. The primary outcome is myocardial perfusion reserve (MPR) as measured by CMR imaging stress studies. We will correlate CMR imaging with CCTA to provide complementary detail of coronary plaque changes. The study will also assess the relevance of pre-existing risk factors, including an emphasis on racial disparities, on study outcomes, and dynamic change in modifiable and treatment related risk factors.

Statistical Methods: We plan to enroll 90 women, 67 in the NCED group and 23 in the HR- group, allowing for a 10% drop out rate. There are two primary types of statistical analyses. The first includes testing hypotheses between group (NCED vs HR-) and within group (longitudinal changes within the NCED group) for Aims 1 and 2. Comparisons will be made using longitudinal mixed models to examine effects on outcomes measured. The second analyses, for Aim 3, involve developing predictive equations utilizing a stepwise linear regression approach to determine if patient demographics, clinical parameters and serum biomarkers are associated with MPR. The sample size allows 80% power to address specific aims for between and within group comparisons, including a between group difference of 2.8% in our primary outcome, MPR.

Background: The combination of CDK4/6 inhibitors (CDK4/6i) and endocrine therapy (ET) is standard-of-care for patients with hormone receptor positive (HR+) HER2- metastatic breast cancer (MBC). Immune modulatory effects of CDK4/6i are well documented preclinically but poorly understood in the clinical setting. Our previous study combining letrozole, palbociclib and pembrolizumab in patients with HR+ MBC (NCT02778685) showed a promising complete response rate of 31%. Dynamic changes in peripheral blood mononuclear cell (PBMC) subpopulations indicated that palbociclib may increase CD8+ TEMRA (terminally differentiated effector memory cells) and CD4+ TEM (effector memory cells) and enable immune activation. The current cohort 3 was designed to study the immune modulatory effect of palbociclib as an immune-priming agent with a biomarker enriched design. Methods: Women with ECOG 0-1, HR+ HER2- MBC, RECIST 1.1 measurable disease, no prior therapy for MBC were enrolled. Patients with endocrine therapy, including aromatase inhibitor +/- ovarian suppression or fulvestrant, were eligible. A palbociclib + ET lead-in design was used, starting on day -28 followed by combination therapy with pembrolizumab added on C1D1. Peripheral blood and tumor biopsy at baseline and on-treatment were collected to allow in-depth analysis of biomarkers predicting response to the combination. The primary endpoint was to evaluate if the palbociclib potentiated immune responses as a "priming" agent through PBMC analysis and on treatment tumor biopsy. Secondary endpoints included other immune cell subsets and changes that follow the combination with pembrolizumab. With 25 patients, assuming a standard deviation of 0.51 in the relative change in classic monocytes in PBMCs, there is 90% power to detect a relative change of log(C1D1/baseline) of 34.5% with a type I error (two-sided) of 0.05. Results: Between August 2020 and April 2022, 16 patients were enrolled in cohort 3. Currently 11 patients have adverse event (AEs) and 16 patients have response data. Median age was 57 years (39-72). 8/11 (73%) were non-Hispanic white, 1/11 (9%) Hispanic, 1/11 (9%) Asian, and 1/11 (9%) African American. 87% patients had grade 3 AEs, and 30% had grade 4 AEs. Grade 3 AEs were 9/11 (82%) neutropenia, 5/11 (45%) leukopenia, 1/11 (9%) elevated LFTs, and 1/11 (9%) each lymphopenia, hot flashes, febrile neutropenia, and pneumonitis. Grade 4 AEs

were 1/11 (9%) lymphopenia. 8/16 (50%) patients achieved a partial response (PR), 5/16 (31%) had stable disease (SD), and 1/16 (6%) had progression of disease (PD) by RECIST 1.1. Additionally, 2/16 (13%) patients were too early to determine best overall response. Response rate (CR+PR) was 50%. PBMCs and tumor microenvironment profiling are ongoing. Conclusion: The combination of palbociclib, pembrolizumab and ET is well tolerated, and a response rate of 50% was identified in HR+ MBC patients who received this combination as front-line therapy. Dynamic changes in peripheral blood mononuclear cells and tumor microenvironment profiling are ongoing.

BACKGROUND Endocrine therapy (ET) modulates estrogen synthesis and/or estrogen receptor (ER) activity and is the mainstay of ER+ breast cancer (BC) treatment. ET + a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) is the standard of care in patients (pts) with ER+, HER2– metastatic BC (mBC) in the first-line setting. Fulvestrant ± a CDK4/6i, and everolimus + exemestane, are the current regimens approved for use in the second-line setting. However, therapeutic resistance to some ETs, such as aromatase inhibitors, can arise from ESR1 mutations driving estrogen-independent transcription and proliferation. Current post-CDK4/6i treatment options are suboptimal. New therapy options are therefore needed to reduce this risk and to improve outcomes, tolerability, quality of life, and adherence to treatment. Giredestrant is a highly potent, nonsteroidal oral selective ER antagonist and degrader (SERD) that achieves robust ER occupancy and is active regardless of ESR1 mutation status. While phase I SERD combination data in the post CDK4/6 setting is encouraging, there is no randomized combination data. Combining giredestrant and everolimus may potentially improve outcomes after CDK4/6is and in pts with ESR1-mutated tumors; evERA BC is investigating this combination to address the unmet need in the post-CDK4/6i setting. **TRIAL DESIGN** This phase III, global, randomized, open-label, multicenter study will evaluate the efficacy and safety of giredestrant + everolimus vs exemestane + everolimus in pts with ER+/HER2– locally advanced (LA)/mBC who had previous treatment with a CDK4/6i and ET in the LABC/mBC or adjuvant setting. Pts will be randomized to either giredestrant (30 mg) + everolimus (10 mg) by mouth (PO) every day (QD) on Days 1–28 of each 28-day cycle, or exemestane (25 mg) + everolimus (10 mg) PO QD on Days 1–28 of each 28-day cycle. Pts will receive treatment until disease progression or unacceptable toxicity. Pts will use a dexamethasone mouth rinse four times QD for 8 weeks, started concurrently with study treatment. **ELIGIBILITY** Female/male pts ≥18 years with ER+/HER2– LA/mBC, an Eastern Cooperative Oncology Group Performance Status of 0–1, measurable disease defined per RECIST v.1.1 (or evaluable bone metastases with at least one predominantly lytic bone lesion confirmed by computed tomography or magnetic resonance imaging), disease progression ≥6 months after initiating ET + CDK4/6i in the LABC/mBC setting (and ≥4 months on most recent ET, if ET + a CDK4/6i was not the most recent therapy received), or relapsed either while taking or within 12 months of exposure to combination adjuvant ET (≥12 months) and a CDK4/6i (≥6 months). Availability of a baseline blood sample to determine ESR1 mutation status by circulating tumor DNA assay for testing at a central laboratory. Men and pre-/perimenopausal women will receive a luteinizing hormone-releasing hormone agonist on Day 1 of each 28-day cycle. **AIMS** Primary endpoint: investigator-assessed progression-free survival (PFS; per RECIST v1.1). Secondary endpoints: investigator-assessed PFS in pts with detectable ESR1-mutated tumors in circulating tumor DNA at baseline; overall survival; objective response rate; duration of response; clinical benefit rate; patient-reported outcomes; safety; pharmacokinetics. **STATISTICAL METHODS** The primary endpoint analysis will use a stratified log-rank test at an overall 0.05 significance level (two-sided). An independent data monitoring committee will be in place for safety. **ACCRUAL** Target enrollment is 224 pts globally, and this study is currently recruiting. **CONTACT INFORMATION** For more information or to refer a patient, email global.roche.genentechtrials@roche.com or call 1-888-662-6728 (USA only). [Clinicaltrials.gov](https://clinicaltrials.gov) number NCT05306340.

Goal To investigate the efficacy of alpelisib added to fulvestrant beyond progression in patients with HR+ HER2- advanced breast cancer (ABC). Background The SOLAR-1 study (Andre et al, 2019) has shown that the addition of alpelisib, an alpha-specific PI3K-inhibitor to fulvestrant led to a PFS-benefit of 5.3 months in patients with PIK3CA-mutated HR+ HER2- ABC. In this study, patients were fulvestrant-naive, and only 6% of this population was previously treated with a CDK4/6 inhibitor (CDK4/6i). Nowadays, most patients have been treated with a CDK4/6i, either combined with an aromatase-inhibitor (AI) in 1st line, or with fulvestrant in the 1st or 2nd line setting. Results of the ongoing Dutch SONIA-trial (NCT03425838) will show whether the addition of CDK4/6i to an AI in 1st line is superior to the addition of CDK4/6i to fulvestrant in 2nd line. Patients who have progressed on a CDK4/6i in either line and fulvestrant may be treated with fulvestrant and alpelisib. However, the efficacy of fulvestrant beyond progression combined with alpelisib is unknown. Aim of this study The aim is to determine if treatment with fulvestrant beyond progression and alpelisib results in a clinically meaningful median PFS of ≥ 6 months. Primary endpoint: Progression-free survival (PFS). Secondary endpoints: 'On treatment' PFS Overall survival Objective Response Rate Clinical Benefit Rate Duration of response Safety Risk factors for alpelisib-induced hyperglycemia Quality of life Pharmacokinetics Prognostic value of ctDNA Mechanisms of resistance Trial design The SEQUEL-Breast trial is a nationwide Dutch investigator-initiated phase 2 trial. 25 centers are expected to participate in the SEQUEL-Breast. Clinicaltrials.gov identifier: NCT05392608 Intervention: fulvestrant beyond progression combined with alpelisib. Population Patients must be adults with HR+ HER2- ABC with an activating PIK3CA-mutation. Prior treatment with an AI and fulvestrant is mandatory, as well as prior treatment with a CDK4/6i in either line. Patients must have progressed on fulvestrant (+/- CDK4/6i), and fulvestrant must be the most recent line of therapy. Patients with ECOG performance score 0,1 or 2 are eligible, as well as those with

controlled (HbA1C < 8.4%) diabetes mellitus type 2. Patients with uncontrolled diabetes, visceral crisis, symptomatic CNS metastases or clinically relevant heart disease are ineligible. Patients with diseases or previous surgery that might affect the bioavailability of alpelisib, those in need to use CYP3A4 inhibitors or BRCP inhibitors, as well as patients with any other conditions that would put them at particular risk when partaking in the study, are also ineligible. Accrual Start: June 2022 Accrual, June 27: 3 patients Target: 105 patients (minimum) to 130 patients (maximum) Estimated accrual time: 2-3 years Statistical considerations For sample size calculation, H1 (median PFS \geq 6 months) is weighed against H0 (median PFS \leq 4 months) in a one sample log rank test. $\alpha=0.05$ $\beta=0.1$. 71 events are needed. We estimated that inclusion of 79 patients is required to reach 71 events, given an accrual time of 36 months and a minimum follow-up time of 6 months. To ensure that also PFS 'on treatment' has the desired accuracy, we accounted for 25% non-persistence due to toxicity, hence 105 patients. On top of these 105 patients, another 25 patients may be included, if they harbor rare PIK3CA mutations. Further information Corresponding author: sequel@nki.nl BOOG Study Center acts as sponsor for this trial. This trial is funded by Novartis.

ABEMACARE: Abemaciclib in Combination with Endocrine Therapy as First Line Therapy in Metastatic Breast Cancer Patients with Symptomatic Visceral Metastases or High Tumor Burden – A prospective Multicenter Observational Study Sophia Ramsperger, Franziska Kotzur, Lothar Müller, Stephan Seitz, Peter A. Fasching, Stefanie Jilg, Dorothea Fischer, Silvia Egert-Schwender, Victoria Kehl, Ute Reuning, Lukas Rief, Romina Rösch, Holger Bronger, Christof Winter, Marion Kiechle, Johannes Ettl Background: Combined endocrine therapy with Cyclin-dependent kinase 4 and 6 (CDK 4/6) inhibitors and aromatase inhibitor (AI) or Fulvestrant has become standard of care in first line therapy of estrogen receptor (ER) positive, HER2 negative metastatic breast cancer. Numerical trials have shown excellent results regarding disease control and survival while maintaining quality of life for patients. In the MONARCH 2 and MONARCH 3 trials, patients with liver metastases derived a particularly large benefit from the use of Abemaciclib. Nevertheless, in real world many patients with endocrine sensitive metastatic breast cancer are still being treated with chemotherapy in first line. Symptomatic visceral disease and/or high tumor burden are often seen as reasons for upfront chemotherapy even in the absence of visceral crisis. In this specific patient population Abemacare aims at determining the efficacy of Abemaciclib in combination with endocrine therapy as first line treatment. Further, the question is addressed, whether circulating tumor DNA might serve as a predictive biomarker for early tumor response. Study Design: Abemacare is a prospective multicenter noninterventional, observational study. 96 patients in 10 German cancer centers who receive first line Abemaciclib in combination with AI or Fulvestrant are planned to be enrolled. Recruitment started in December 2020. As of July 1st 2022, 51 patients have been included in six study sites. Patients with documented ER-positive, HER2-negative metastatic breast cancer and measurable visceral disease are eligible if they fulfill one of the following inclusion criteria: Presence of clinical signs or symptoms of visceral disease (e.g. pleural effusion, ascites, abdominal pain from liver or peritoneal metastases, dyspnea from pleural effusion or lymphangiosis of the lung, elevated liver enzymes or bilirubin level (> 2x ULN)) or signs of high tumor burden (e.g. LDH > 399 U/l with K+ in normal range, abnormal CEA or CA 15-3 level (> 2x ULN), radiographic signs of lymphangiosis of the lung, cytologically proven bone marrow infiltration). Patients with prior therapy with a CDK 4/6 inhibitor in any setting or first line therapy for metastatic disease are excluded from the trial. Primary endpoint is best objective response rate (ORR) defined by the proportion of patients who are evaluated using RECIST V1.1 as having partial (PR) or complete response (CR) while being on study treatment. ORR will be analyzed using the one group χ^2 test at the 5% significance level. The test hypotheses are as follows: H0: ORR = 0.43, HA: ORR \neq 0.43. In addition, ORR will be reported with a 95% CI. Several additional endpoints regarding disease control and patient reported outcomes will also be evaluated. Plasma samples for ctDNA are being collected at d1 and d15 of cycle 1 and d1 of cycle 2 and 3. Contact information: For further information please contact the leading physician Dr. Johannes Ettl via johannes.ettl@tum.de This study is supported by Eli Lilly and Company. NCT04681768

WinPro: A window of opportunity study of endocrine therapy with and without prometrym in postmenopausal women with early-stage hormone receptor-positive breast cancer Authors Teesha Downton^{1,2,3}, Davendra Segara³, Andrew Ong⁴, Janne Bingham⁵, Emma-Kate Carson⁴, Julia Chen^{1,2,3}, Kate Middleton³, Geoffrey Lindeman⁶, Andrew Parker³, Elgene Lim^{1,2,3}. Affiliations ¹Garvan Institute of Medical Research, Darlinghurst NSW, Australia; ²School of Clinical Medicine, St Vincent's Healthcare Clinical Campus, Faculty of Medicine and Health, University of New South Wales Sydney, Australia; ³St Vincent's Hospital Sydney, Darlinghurst NSW, Australia; ⁴Campbelltown Hospital, Campbelltown NSW, Australia; ⁵Royal Adelaide Hospital, Adelaide SA, Australia; ⁶Walter & Eliza Hall Institute of Medical Research, Parkville VIC, Australia Disclosures T. Downton: None. D. Segara: None. A. Ong: None. J. Bingham: None. E. Carson: None. J. Chen: None. K. Middleton: None. G. Lindeman: None. A. Parker: None. E. Lim: Advisory Board for Pfizer, Astra Zeneca, Lilly, Roche, Novartis, Gilead Australia. Research Funding from Pfizer, Novartis, Bayer. Abstract Background: Preclinical studies have observed that progesterone has inhibitory effects on the estrogen-stimulated growth of estrogen receptor (ER)-positive, progesterone receptor (PR)-positive breast cancer. Mohammed H et al. (Nature 2015) identified that activated PR associates with the ER and modulates the interactions of the ER with chromatin, with a shift towards the transcription of genes associated with apoptosis and differentiation, and away from genes associated with proliferation. We hypothesize that the addition of prometrym, a microionized progesterone, may enhance the anti-proliferative effects of standard endocrine therapy in women with ER-positive PR-positive breast cancer. Trial Design: WinPro (NCT03906669) is an ongoing multicenter, phase II, randomized, open-label, window of opportunity study comparing the effect on standard endocrine therapy with or without prometrym on breast cancer cell proliferation. The study population is postmenopausal women with early-stage operable breast cancer where the tumor is $\geq 5\text{mm}$ on imaging, ER $\geq 10\%$, PR $\geq 10\%$, and HER2-negative. Patients currently on hormone replacement therapy or the oral contraceptive pill, or who have a history of endometrial cancer or venous thromboembolism are not eligible. Patients are randomized 1:1:1 to letrozole 2.5mg daily, letrozole 2.5mg + prometrym 300mg daily, or tamoxifen 20mg + prometrym 300mg daily. Allocated treatment is taken for 14 days prior to surgery. Primary surgery and adjuvant treatment is as per standard of care. Objectives: The primary objective is to compare the geometric mean suppression of centrally assessed Ki67 between the diagnostic biopsy sample (pre-treatment) and the surgical sample (post-treatment). The secondary objective is to evaluate safety and tolerability. Tertiary objectives include defining genes predictive of a reduction in Ki67, and evaluating the changes in ER, PR, AR, FoxA1, Cyclin D1, and apoptotic markers in breast tumors post-intervention. Accrual: This study opened in February 2018 and as of 13 July 2022, 164 patients have been enrolled. Target accrual is 200 patients. Contact information: This study is led at St Vincent's Hospital Sydney, Australia, and funded by the Cancer Council of NSW and the NHMRC Translational Breast Cancer Project grant. Contact: Elgene Lim MBBS FRACP PhD at e.lim@garvan.org.au.

ctDNA-guided Adaptive Therapy Escalation in ER+ MBC: A Phase 1b Study with Letrozole, Palbociclib and Onapristone ER Background: Extended release onapristone (onapristone ER) is a progesterone receptor (PR) antagonist that inhibits hormone-mediated PR activation and stabilizes PR association with corepressors, resulting in an antineoplastic effect when applied alone or in combination with antiestrogen therapy to breast cancer cells in vitro. Recent preclinical studies further suggest that onapristone adds to inhibition of cell proliferation when combined with CDK4/6 inhibitors and fulvestrant. Elevations in ctDNA can precede overt disease progression by a matter of months in metastatic breast cancer and may represent an opportunity for proactive therapeutic intervention. Trial Design: This is an investigator initiated open-label, single institution phase 1b study of onapristone ER added as escalation therapy in patients with ER+, PR+, HER2 negative MBC, who have detectable ctDNA after six months of treatment with letrozole and palbociclib in the first line. The study is supported by Context Therapeutics and involves two stages. Stage 1 is a dose escalation/de-escalation phase of 18 patients maximum, in which the safety and recommended phase 2 dose (RP2D) will be established for onapristone ER when used in combination with letrozole and palbociclib. In

stage 2, the dose expansion phase, the RP2D of onapristone will be combined with letrozole and palbociclib in 10 patients to further explore the tolerability of the regimen. ctDNA will be collected serially while patients are on this triplet therapy. Eligibility Criteria: This study is enrolling patients with radiologically measurable or evaluable metastatic or unresectable ER+/PR+/HER2-negative MBC in whom a tumor-derived somatic mutation can be detected in ctDNA at a variant allele fraction of 0.5% or greater after 6 months (+/- 4 weeks) of treatment with first line letrozole and palbociclib without progression, using our in house CLIA certified MSK-ACCESS assay. Adequate organ function and functional status for enrollment are stipulated in the protocol. Specific Aims: The primary objective of this study is to define the safety, tolerability, and recommended phase 2 dose of onapristone ER used in combination with letrozole and palbociclib. Secondary objectives include to investigate ctDNA response rate of the triplet therapy regimen, to gather early data regarding the 6-month clinical benefit rate , overall response rate , and progression free survival of this triplet escalation therapy regimen in high risk ctDNA+ patients, and to evaluate the pharmacokinetics of Onapristone ER when used in combination with letrozole and Palbociclib. Exploratory objective include to describe ctDNA dynamics during antiprogesterin therapy escalation in ER+ MBC, as well as the molecular features present in responders vs. non-responders using ctDNA and pre-treatment tissue. Target Accrual: The total planned cohort for the phase I dose escalation is a maximum of 18 patients across 3 dose levels, and the total planned cohort for the dose expansion is 10 patients, with an anticipated maximum total of 28 patients. We will allot for 5 additional patients to account for inevaluability during the dose escalation and expansion portions of the trial. The trial is currently open to enrollment at MSKCC. BACKGROUND Giredestrant is a highly potent, nonsteroidal, oral selective estrogen receptor antagonist and degrader (SERD) that was found to be well tolerated and active as a monotherapy and in combination therapy in Phase I/II studies in early BC and pretreated locally advanced/metastatic BC (LA/mBC). Dual HER2 blockade with pertuzumab + trastuzumab (PH) + a taxane (induction therapy) followed by maintenance PH is the first-line standard of care for most patients (pts) with HER2+ LA/mBC. Despite HER2–ER blockade synergy, paucity of Phase III data evaluating maintenance PH + endocrine therapy (ET) vs. PH in pts with

ER+/HER2+ LA/mBC leads to variable use of ET in this setting. Adding giredestrant to the maintenance phase could improve outcomes. TRIAL DESIGN This is a Phase III, randomized, two-arm, open-label, multicenter study evaluating the efficacy and safety of giredestrant + the fixed-dose combination of PH for subcutaneous injection (PH FDC SC) vs. PH FDC SC after induction therapy with PH FDC SC + a taxane in pts with ER+/HER2+ LA/mBC. In the induction phase, pts will receive 4–6 PH FDC SC cycles (1200 mg P/600 mg H in the first cycle, followed by 600/600 mg every 3 weeks) + a taxane (investigator choice of docetaxel/paclitaxel). Pts deriving clinical benefit may receive two additional cycles per investigator's discretion. Pts completing ≥ 4 induction therapy cycles, achieving at least stable disease, and with a left ventricular ejection fraction (LVEF) $\geq 50\%$ will be randomly assigned 1:1 to maintenance giredestrant 30 mg/day + PH FDC SC every 3 weeks or PH FDC SC only, until disease progression (PD). ET (aromatase inhibitor/tamoxifen) will be allowed in the PH FDC SC-only arm. Study treatment will continue until PD, limiting toxicity, death, or consent withdrawal. ELIGIBILITY Enrolled pts must have ER+/HER2+ LA/mBC, disease-free interval from completion of (neo)adjuvant non-ET ≥ 6 months, Eastern Cooperative Oncology Group performance status 0/1, LVEF $\geq 50\%$, and adequate organ function. Pts with prior SERD treatment or presence of symptomatic central nervous system metastases will be excluded. All men and pre-/perimenopausal women must be eligible for a luteinizing hormone-releasing hormone agonist. AIMS The primary endpoint is investigator-assessed, maintenance progression-free survival. Secondary endpoints include overall survival (OS), objective response rate, duration of response, clinical benefit rate, pt-reported outcomes, and safety. STATISTICAL METHODS The primary endpoint analysis will use a stratified log-rank test at an overall 0.05 significance level (two-sided). An interim OS analysis is planned, and an independent data monitoring committee will be in place. ACCRUAL The study is open for enrollment. Approximately 812 pts will be enrolled in the induction phase, to allow for approximately 730 pts to be randomized in the maintenance phase. CONTACT INFORMATION For more information or to refer a patient, email global.roche.genentechtrials@roche.com or call 1-888-662-6728 (USA only). Clinicaltrials.gov number: NCT05296798.

BACKGROUND Endocrine therapies (ETs) that target estrogen receptor (ER) activity and/or estrogen synthesis are the mainstay of ER+ breast cancer (BC) treatment. Despite best management, $\leq 20\%$ of patients (pts) with ER+/HER2- early BC (eBC) develop resistance (in some cases due to acquisition of tumor mutations in ESR1 that can drive estrogen-independent transcription and proliferation) and still have high recurrence rates on standard ETs. New treatment alternatives for ER+/HER2- eBC are needed to reduce risk of recurrence and improve survival, tolerability, quality of life, and adherence. Giredestrant, a highly potent, nonsteroidal oral selective ER antagonist and degrader (SERD), achieves robust ER occupancy and is active against tumors that retain ER-sensitivity or have ESR1 mutation(s). It has been demonstrated to be more potent in vitro and achieves higher ER occupancy in vivo than fulvestrant, the only currently approved SERD. Early-phase clinical studies have demonstrated that single-agent giredestrant (30 mg daily) has promising clinical and pharmacodynamic activity and is well tolerated in the ER+/HER2- eBC and metastatic BC settings. **TRIAL DESIGN** This is a phase III, global, randomized, open-label, multicenter study evaluating efficacy and safety of adjuvant giredestrant vs physician's choice of adjuvant ET (PCET) in pts with medium- and high-risk stage I-III histologically confirmed ER+/HER2- eBC. Pts are randomized 1:1 to oral 30 mg daily giredestrant or PCET (tamoxifen, anastrozole, letrozole, or exemestane, given according to prescribing information). Stratification factors are risk (medium vs high, based on anatomic [tumor size, nodal status] and biologic features [grade, Ki67, gene signatures if available]); geographic region (US/Canada/Western Europe vs Asia-Pacific vs rest of the world); prior chemotherapy (no vs yes); and menopausal status (pre-/perimenopausal vs postmenopausal). Beginning on Day 1 of Cycle 1, pts will be treated with giredestrant or PCET for ≥ 5 years. Continuing PCET after 5 years is at discretion of the investigator and per local standard of care. **ELIGIBILITY** Female/male pts with medium-/high-risk stage I-III ER+/HER2- eBC; prior curative surgery; completion of (neo)adjuvant chemotherapy (if administered) and/or surgery < 12 months prior to enrollment; no prior ET (≤ 4 weeks of [neo]adjuvant ET is allowed). For men and pre-/perimenopausal women, a luteinizing hormone-releasing hormone agonist will be given per local prescribing information (mandatory for pts in the giredestrant arm). **AIMS** Primary endpoint: Invasive disease-free survival (IDFS). Secondary endpoints: Overall survival; IDFS (STEEP definition, including second non-primary BC); disease-free survival; distant recurrence-free survival; locoregional recurrence-free interval; safety; pharmacokinetics; pt-reported outcomes. In addition, this study aims to improve health equity in research and expand clinical trial access. The study will also use/develop digital healthcare solutions, which will enable better understanding of pts' needs and their adherence

to ET. STATISTICAL METHODS The primary endpoint analysis will use a stratified log-rank test at an overall 0.05 significance level (two-sided). An interim analysis and a futility analysis are planned, and an independent data monitoring committee will be in place. ACCRUAL 1018/4100 pts have been recruited globally. CONTACT INFORMATION For more information or to refer a patient, email global.roche.genentechtrials@roche.com or call 1-888-662-6728 (USA only). Clinicaltrials.gov number NCT04961996. AB, PS and CG contributed equally. This abstract was originally presented at SABCS 2021 (OT2-11-09).

Background: Tumor genomic testing (TGT) has become increasingly adopted as part of standard cancer care for many cancers. Despite national guidelines around patient education prior to TGT, available evidence suggests that most patients' understanding of genomics remains limited, particularly lower income and minority patients, and most patients are not informed regarding potential incidental germline findings. Purpose: The primary object of this ongoing clinical trial is to evaluate the effectiveness of concise, animated videos to provide patient pre-test education prior to TGT as a supplement to patient-provider discussion. Trial Design: This prospective observational cohort study will enroll a total of 150 cancer patients in three clinical cohorts: Cohort 1: breast cancer (n=50); Cohort 2: lung cancer (n=50); Cohort 3:

cancer patients of any tumor type (n=50). The primary objective is to assess change in patient knowledge of TGT following exposure to the video to evaluate the hypothesis that exposure to a brief educational video will increase patient knowledge about tumor genomic testing. Secondary objectives include assessing changes following exposure to the video, including: 1) genomic knowledge 2) trust in Physician 3) comparison of results between the three patient cohorts. Methods: Based on published guidelines around pre-TGT provider-patient education and patient focus groups and interviews, content for a series of videos was developed to standardize patient pretest education of TGT. A base animated video was created to be applicable to any cancer type; additional tumor type content was added for the breast and lung cancer-specific videos. Participant recruitment is occurring at The Ohio State University's Comprehensive Cancer Center. Eligibility criteria include: age 18 years or older, biopsy-confirmed cancer, and provider plan to undergo TGT. This study requires participants to complete surveys at three timepoints: before video viewing (T1), immediately after video viewing (T2), and after provider communicates TGT results to the patient (T3). Four survey instruments are completed at T1/T2/T3: video message-specific recall, objective genomic knowledge/understanding, the 11-item Trust in Physician, and attitudes around genetic/genomic testing. TGT intention surveys are captured at T1 and T2. Participant evaluation of the video is collected at T2. For the primary objective, we will use a two-sided Wilcoxon signed-rank test with alpha of 0.05, giving us 90% power to detect an effect size of 0.47 in change of recall accuracy from pre- to post- video intervention. All secondary outcomes will be summarized using descriptive statistics and compared pre-/post-video using Wilcoxon signed-rank test. For comparisons of MBC and MLC, endpoints will include 1) baseline and pre-/post-video intervention change in genomic knowledge/understanding in MBC versus MLC patients; 2) baseline and pre-/post-video intervention change in trust in provider. The baseline and the change from pre- to post-video intervention in the secondary outcomes will be compared between MBC and MLC patients using Wilcoxon rank sum test. Conclusions: The long-term goal of this project is to test this broadly applicable, modular video-based intervention to be administered prior to tumor NGS to ensure equitable access to informed care. The use of a short video in this setting is innovative and we are demonstrating capacity to complete such a project. Study enrollment began March 30, 2022 and to date, 33 participants have enrolled (n=18 breast cancer; n=9 lung cancer; n=6 other cancer types). ClinicalTrials.gov NCT05215769.

FLEX: 30K Full Transcriptome, Real-World Evidence Database for Early-Stage Breast Cancer, and Investigator-Initiated Protocols BACKGROUND: Genomic signatures, such as the 70-gene MammaPrint, provide additional prognostic information for early-stage breast cancer (EBC), such as tumor metastatic potential, and expand the available information clinicians and patients require for shared treatment decision making beyond the standard clinicopathologic factors. EBC tumors are further stratified into clinically actionable subtypes by molecular assays such as the 80-gene molecular profiling assay BluePrint, improving pathological complete response rates (pCR) and outcomes as evidenced by a number of recent trials. The ongoing FLEX Study (NCT03053193) is designed to expand the genomic information available for EBC cases, and to increase the speed of data generation for rare and underserved research areas. To date, FLEX is the largest international multicenter real-world evidence (RWE) EBC registry, with more than 10,000 patients enrolled in fewer than five years since opening. FLEX pairs full genome data with more than 800 clinical data points collected over 10 years of follow up to provide the most comprehensive big data database available for early-stage breast cancer. The FLEX enrollment has a goal of a minimum of 30,000 patients within 10 years. METHODS: The FLEX study is a multicenter, prospective, observational trial for patients ≥ 18 years old with histologically proven stage I-III invasive breast cancer that is node negative or positive (up to three nodes) who receive MammaPrint, with or without BluePrint as standard of care management. Patients consent to the collection of clinically annotated full transcriptome data. Additionally, this study protocol allows physicians to investigate targeted populations or clinical trial investigator-initiated studies (IIS) upon approval by a peer-driven Scientific Review Committee. As patients enrolled in the FLEX study meet all eligibility criteria for inclusion no additional consent is required. The FLEX enrollment has already surpassed 1/3 of set target goal. As of April 2022, the trial has surpassed 10,000 patients enrolled at nearly 100 trial sites across the US and Europe, Middle East and Africa (EMEA). To date, there have been 36 publications in international scientific congresses with 39 FLEX IIS and in progress. With over 250 active and collaborating physicians leveraging the shared infrastructure, the IIS have enabled the ability to address disparities in treatment to underrepresented populations, rare subtypes, age, and patient centered specific topics. Current and future questions investigated via this platform will continue to strive to improve outcomes for early-stage breast cancer patients.

Background: Women with breast cancer account for the largest cohort (23%) of over 18 million cancer survivors in the United States. Of the nearly 4 million breast cancer survivors, many, including individuals with metastatic breast cancer, will require lifelong treatment for chronic conditions. As part of a multi-site study including diverse tumor types, breast cancer survivors are being recruited to explore the feasibility and outcomes of a digital health coaching (DHC) program following the completion of primary therapy to support self-management of symptoms and general wellness. Trial design: A randomized-wait list control design will evaluate outcomes related to engagement in a DHC program following completion of primary therapy. Participants will be enrolled in a 6-month DHC program delivering evidence-based content via weekly calls, text, and email, in addition to usual support from their respective healthcare teams. The

intervention group will receive coaching upon enrollment. The control group will receive coaching after a 6-month monitoring period. Twelve months of longitudinal clinical, patient-reported outcomes, activity tracking (via Fitbit), and microbiome data will be collected from both groups. Eligibility criteria: The breast cancer cohort will consist of individuals with both localized and metastatic disease within 1 year of completion of primary therapy, defined as treatment of curative intent, first-line or later, from which the individual is advancing to active surveillance or follow-up, with or without maintenance therapy. All study participants must be >18 years old, able to read and speak English, have access to mobile technology, and agree to wear and have data collected from an activity tracker. Specific aims: 1) Assess the feasibility and acceptability of a DHC program and its effect on participant health self-efficacy; 2) characterize associations between participant symptoms, physical/psychosocial well-being, and health self-management and gut microbiota changes; and 3) explore patient-generated health data outcomes among participants (patient reported and wearable biometrics outcomes). Statistical methods: Feasibility and acceptability will be assessed through descriptive statistics. Feasibility for this study is defined as a retention rate $\geq 70\%$, and acceptability is defined as $\leq 20\%$ scoring "not at all helpful." Secondary aims will be assessed using linear mixed models. Cross-cohort analysis of physical function, measured by the PROMIS Physical Function 10a, will be conducted. Assuming a power of 0.8 and significance level of .05, we will be able to detect a 2.51 difference in PROMIS score means between the control and intervention group (SD 10) with a sample of 500 total participants. Sub-group analysis will be conducted with the anticipated 250 participants in the breast cancer cohort with a focus on feasibility, acceptability, and descriptive and exploratory endpoints for this population as a whole and comparing early stage and metastatic participants. Target and present accruals: 500 individuals with diverse tumor types will be enrolled across 5 collaborating sites, of which 4 will include individuals with breast cancer. An estimated 250 breast cancer participants (approximately 50% of the total study population), including 150 with de novo or progressive metastatic breast cancer, are planned to be recruited. To date, 1 Midwestern site has enrolled the first 7 breast cancer survivors. Two additional sites plan to enroll in July 2022, with the remaining 2 sites to begin enrollment by the end of 2022.

Background: Microscopically tumor-free lumpectomy margins are critical for safe breast conserving surgery. With current tools, 15%-25% of lumpectomies have positive margins that require second surgical procedures and increase cost and patient discomfort. Additionally, current lumpectomy margin assessment techniques show poor performance in predicting residual disease at re-excision, with a PPV of 35%. Better detection tools are needed to identify residual cancer during the initial lumpectomy and reduce second operations. LUM015 is a

protease-activated fluorescent imaging agent that accumulates in tumor cells and tumor associated macrophages after preoperative intravenous injection. The LUM Imaging System visualizes activated LUM015 in the lumpectomy cavity via a hand-held wide field detector and proprietary tumor detection software. This system has been tested in multiple single-site studies and two prospective multi-site studies enrolling >600 patients, and demonstrated successful detection of residual lumpectomy cavity tumor. Initial studies excluded the approximately 20% of patients receiving neoadjuvant therapy. Patchy tumor cell death with preoperative therapy can leave small, multifocal deposits of tumor invisible on pre-operative imaging and not palpable or visible during surgery. We now evaluate the LUM Imaging System in patients with and without neoadjuvant therapy. Trial Design and Specific Aims: This prospective, multi-center study at 6 US sites tests the LUM Imaging System in lumpectomy surgery after neoadjuvant therapy to evaluate potential impact of treatment-related tissue changes and tumor cell death on tumor detection algorithms. An initial cohort of 10 patients address the objective of algorithm development. A second cohort of 104 patients will further evaluate the feasibility of the LUM Imaging System after neoadjuvant therapy. A third cohort will enroll 208 patients who have not received neoadjuvant therapy. All cohorts are evaluated for safety and for reduction in residual tumor after LUM Imaging System guidance compared to standard of care lumpectomy. After excision of the main lumpectomy specimen, patients are randomized 3:1 to device or control arms. In the device arm, the cavity is imaged and margins with LUM015 signal are excised. Final comprehensive shaved margins are removed in both arms to evaluate extent of residual disease after the use of the LUM Imaging System or after standard lumpectomy. No LUM Imaging is performed in the control arm, however, all patients are injected with LUM015 to evaluate drug safety. Patient reported outcomes assessing re-excision concerns, breast appearance and preferences for treatment type are collected. Eligibility Criteria: This study seeks to enroll women 18 and older with histologically confirmed primary invasive breast cancer (IBC), ductal carcinoma in situ (DCIS) or a combination of IBC/DCIS undergoing a lumpectomy for their breast malignancy who have received any form of neoadjuvant treatment prior to surgery (cohorts 1 and 2) or who have not received any therapy prior to lumpectomy (cohort 3). Patients allergic to polyethylene glycol or intravenous contrast agents are excluded. Use of blue node mapping dyes before imaging with the LUM015 is not allowed per study protocol. Accrual and Study Progress: Cohort 1 has completed enrollment and interim analysis. No new risks specific to the neoadjuvant population were identified. LUM015 fluorescent signals measured in neoadjuvant patients were within the expected range, and no changes to the tumor detection algorithm were required. Cohorts 2 and 3 have enrolled a total of 38 patients. This trial is registered as NCT04440982. The NIH funds this study through a R01 grant issued to Massachusetts General Hospital.

Background: PD-1/PD-L1 inhibitor plus chemotherapy have shown tolerability and significant clinical benefits in pts with advanced TNBC. As antiangiogenic agent could remodel tumor blood vessels and increase the response to immune-checkpoint inhibitors (ICIs), we designed an investigator initiated trial (IIT) to investigate the efficacy and safety of AK105 (anti-PD-1 antibody), anlotinib (antiangiogenic, multi-target tyrosine kinase inhibitor) combined with nab-P as a first-line therapy in pts with advanced TNBC. Method: In this multicenter, prospective, single arm, phase 2 study, eligible pts were female aged 18-75 years, with ECOG PS 0-1, who had locally advanced or recurrent/metastatic triple-negative (estrogen receptor-, progesterone receptor- and HER2-) breast cancer. The main exclusive criteria were previous use of PD-1/PD-L1 antibody, cytotoxic T lymphocyte-associated antigen-4 (CTLA-4) antibody or antiangiogenic agent, and central nervous system (CNS) metastases. Eligible pts were treated with intravenous AK105(200mg on day 1), oral anlotinib(12mg once daily on days 1-14) and intravenous nab-P (125mg/m² on days 1 and 8) . The triplet combination regimen repeated every 21 days until disease progression, death or intolerable toxicity. The primary endpoint is overall response rate (ORR), and the secondary endpoints are disease control rate (DCR), progression-free survival (PFS), overall survival (OS) and safety. Simon's two-stage design were used to calculate the sample size assuming ORR is improved from 45.9% (nab-P alone) to 65% (AK105, anlotinib combined with nab-P) with the power (1- β) taken as 0.80 and the type I error (α) taken as 0.05 (two-sided). Enrollment began in June 2022 with a total goal of 42 pts at 7 sites in China. Clinical trial information: NCT05244993. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd.

Background Today, there is no clear therapeutic algorithm for patients with metastatic HER2-positive (HER2+) breast cancer (BC) who have progressed to trastuzumab, pertuzumab, tyrosine kinase inhibitors and antibody-drug conjugates (ADC). Among the emerging strategies, the use of immune checkpoint inhibitors in combination therapy is showing promising clinical

benefit in the advanced setting of HER2+ BC by overcoming immune resistance and enhancing antitumor cellular immunity. The intrinsic subtypes Basal-like and HER2-enriched (i.e PAM50 non-luminal tumors) represent approximately the 60% of HER2+ BC and are associated with higher expression of immune-related genes, tumor-infiltrating lymphocytes (TILs) presence and high tumor mutational burden (TMB), compared to luminal subtypes. Additionally, immune infiltration and TMB in HER2+ BC are associated with chemo/antiHER2 responsiveness and with potential benefit from anti-PD-1/PD-L1 inhibitors. We hypothesize that combining atezolizumab with trastuzumab and vinorelbine may improve outcomes in HR- or PAM50 non-luminal/HR-positive (HR+) disease within HER2+ MBC. Methods ATREZZO is an open-label, single-arm, Simon 2-stage, multicenter phase II study. The trial will include 55 pre- or post-menopausal female or male patients with unresectable locally advanced or metastatic HR- or PAM50 non-luminal/HR+ HER2+ BC and progressed to trastuzumab-based chemotherapy and anti-HER2 ADC. Prior pertuzumab is allowed, but not required. Treatment consists of atezolizumab IV 1200 mg every 3 weeks combined with trastuzumab and vinorelbine. Patients with stable, progressing, or untreated brain metastasis not requiring immediate local therapy are eligible. The primary objective is to evaluate the Overall Response Rate (ORR) according to RECIST v 1.1 and secondary endpoints include ORR in patients with PD-L1 positive breast cancer, clinical benefit rate, overall survival and progression-free survival. The final recruited population will contain no more than 60 % of patients with PD-L1 negative tumors. Tumor assessments will be performed every 9 weeks. Incidence, duration and severity of adverse events, and further correlative molecular analyses will be also evaluated. An interim analysis will be conducted when 19 patients are evaluable for ORR and if the number of responses is ≥ 3 , 36 additional patients will be included. As of July 15th, 2022, 48 patients were screened and 15 were included in sixteen Spanish sites. This study was funded by Roche Farma SA. Trial identification: NCT04759248

Background: Combination of immune checkpoint inhibitor pembrolizumab and chemotherapy are standard of care therapy for patients with programmed death-ligand 1 positive (PD-L1+) metastatic triple negative breast cancer (mTNBC). However, a greater understanding of how immune checkpoint inhibitors and chemotherapies synergize to yield anti-tumor T cell responses is needed. The current phase I study evaluated the immunogenicity of doxorubicin plus pembrolizumab in patients with mTNBC. Patients and Methods: Patients with mTNBC, no prior anthracycline use, and 0-2 lines of prior systemic chemotherapies received pembrolizumab 200 mg IV and doxorubicin 50-60 mg/m² IV every 3 weeks for 6 cycles followed by pembrolizumab maintenance until disease progression or intolerance. Patients were not selected based on PD-L1 expression. The primary objectives were safety and objective response rate per RECIST 1.1. Peripheral blood samples were collected at baseline, Cycle 2 Day 1 (C2D1), and post Cycle 3 for analysis by high parameter flow cytometry. Results: Ten patients were enrolled between March 2016 and November 2019. Best responses included one patient with complete response (CR), five with partial responses (PR), two with stable disease (SD), and one with progression of disease (PD). Flow cytometry showed increased CD3⁺ T cells (p=0.03) from pre-treatment to C2D1 with substantial inter-patient variation in CD3⁺ T cells. The expansion of proliferative exhausted-like PD-1⁺ CD8⁺ T cell population was identified in 8/9 patients, and exhausted CD8⁺ T cells were significantly expanded from pre-treatment to C2D1 in the patient with CR (p=0.01). Notably, frequencies of PD-1^{hi} proliferative CD8⁺ T cells contracted significantly from C2D1 to post Cycle 3 (p=0.005), with a return to near baseline frequencies in the majority of the patients. In the context of all identified T cell subsets, PD-1^{hi} proliferative CD8⁺ T cells demonstrated the greatest increase in fold change from pre-treatment to C2D1. In contrast, PD-1^{lo} proliferative CD8⁺ T cells demonstrated the greatest decrease in fold change from pre-treatment to C3D1. Conclusion: Anthracycline-naïve patients with mTNBC treated with the combination of pembrolizumab and doxorubicin yielded robust peripheral blood T cell responses. Further studies dissecting the dynamics and durability of anti-tumor T cell responses and concurrent tumor immune microenvironment changes are needed to optimize combined immune checkpoint inhibitor and chemotherapy treatment for patients with mTNBC.

Background: Metastatic triple negative breast cancer (mTNBC) is associated with high recurrence and mortality rates. Prior studies have shown an immune checkpoint inhibitor (ICI) + chemotherapy improves progression-free survival for patients with PD-L1 positive mTNBC. There remains a need for treatment options in patients who do not respond to ICI or are PD-L1 negative. Preclinical data suggests that a PARP inhibitor (PARPi) may promote innate immune signaling, and combination with an ICI has shown a positive response in patients with mTNBC.

Radiotherapy (RT) is a potent immune stimulator and used for local control in the setting of metastatic breast cancer. This phase II study (NCT04837209) proposes combination of PARPi, ICI, and RT to combat ICI resistance and improve response rates in patients with mTNBC who are PD-L1 negative or who have progressed on prior ICI. Methods: 32 patients with mTNBC defined as ER< 1%, PR< 1%, HER-2-neu 0-1+ by IHC or non-FISH-amplified or patients with metastatic HR+/HER2- breast cancer are anticipated to participate. Eligibility criteria for mTNBC patients includes those who are PD-L1 negative or have progressed on prior ICI. Eligibility criteria for HR+/HER2- patients is specific to those who harbor a deleterious BRCA1 or BRCA2 mutation with or without high tumor mutational burden (TMB). All trial patients should have at least 1 lesion amenable to RT and at least 1 measurable lesion that will not be radiated. Study treatment consists of 3-week cycles, with 500mg dostarlimab given on day 1 of each cycle through cycle 5, then 1000mg given every 6 weeks. RT (24 Gy) is delivered in 3 consecutive fractions starting day 1 of cycle 1. Niraparib (200mg) is dosed orally daily. Tumor biopsies are taken within 28 days pre-treatment, and at C3D1-8. Blood samples are taken at baseline and every odd cycle for cfDNA and PBMC analysis. The primary endpoint is to assess overall response rate as measured by RECIST v1.1 of the combination of niraparib, dostarlimab, and RT. Secondary objectives include assessing safety and toxicity, overall survival, progression free survival, and quality of life. Results: To date, this study has accrued 4 subjects, including 3 with mTNBC, and 1 with HR+/HER2-/BRCA mutant + TMB high mBC. The study is currently open at MGH and Sibley, and the addition of UPenn, Johns Hopkins, and Duke are in progress. Funding for this study was provided by GSK. GSK was provided the opportunity to review a preliminary version of this abstract for factual accuracy, but the authors are solely responsible for final content and interpretation. People with specific interest in the trial should reach out to Elizabeth Scott, Clinical Research Coordinator, at escott@mgh.harvard.edu.

Background: Improving outcomes for patients (pts) with triple-negative breast cancer (TNBC) remains a high unmet need. Immune checkpoint inhibitors (ICIs) + chemotherapy (chemo) and single-agent sacituzumab govitecan, a trophoblast cell-surface antigen 2–targeted antibody-drug conjugate coupled to SN38 via a proprietary, hydrolysable linker, are approved in newly diagnosed pts with programmed death-ligand 1 (PD-L1)–positive tumors and pts who received ≥ 2 prior systemic therapies (≥ 1 for metastatic disease), respectively. However, additional options are urgently needed, particularly for pts with tumors that do not express PD-L1 and for those with progression on chemo \pm ICI. Magrolimab is an antibody blocking CD47, a “don’t eat me” signal overexpressed on cancer cells, including TNBC, inducing tumor phagocytosis by macrophages. Magrolimab has shown preclinical activity and promising clinical efficacy in hematologic and solid tumors. Chemo agents, including taxanes, can enhance prophagocytic signals on tumor cells, leading to the potential for synergistic antitumor activity with magrolimab. This study is evaluating the safety/tolerability and efficacy of magrolimab in combination with nab-paclitaxel/paclitaxel or with sacituzumab govitecan in unresectable locally advanced/metastatic TNBC. Trial Design: This open-label, 2-cohort (C) study consists of safety run-in and phase (ph)2 portions evaluating nab-paclitaxel/paclitaxel (choice) + magrolimab (safety run-in) or \pm magrolimab (ph2, randomized 1:1) in pts with untreated, advanced/metastatic TNBC ineligible for ICI (C1) and magrolimab + sacituzumab govitecan

(safety run-in and ph2) in pts with advanced TNBC who received 1 prior systemic treatment in the metastatic setting (C2). Stratification factors for C1 are neoadjuvant and/or adjuvant taxane therapy, liver metastases, and nab-paclitaxel vs paclitaxel. In both cohorts, magrolimab will be administered intravenously (IV) in de-escalating doses to establish the recommended ph2 dose (RP2D). Nab-paclitaxel/paclitaxel and sacituzumab govitecan will be administered IV per standard of care. Eligibility Criteria: Eligible pts are ≥ 18 y with PD-L1–negative, untreated, unresectable locally advanced/metastatic TNBC (C1) or unresectable locally advanced/metastatic TNBC who received 1 prior line of therapy in the advanced setting, including a taxane and an ICI if PD-L1 positive (C2), with measurable disease per RECIST v1.1. Exclusion criteria include active central nervous system disease, red blood cell transfusion dependence, or prior treatment with CD47/signal regulatory protein α –targeting agents for both cohorts. Additional exclusions are disease progression within 6 months of (neo)adjuvant therapy or rapid visceral progression and/or symptomatic disease, for which single-agent chemo would not be appropriate (C1); chronic inflammatory bowel disease and a history of bowel obstruction or gastrointestinal perforation within 6 months of enrollment, prior treatment with topoisomerase I inhibitors or antibody-drug conjugates containing a topoisomerase inhibitor, and receipt of high-dose systemic corticosteroids within 2 weeks of cycle 1 day 1 (C2). Specific Aims: The primary objectives are safety/tolerability and magrolimab RP2D (safety run-in) and efficacy (ph2: C1, progression-free survival [PFS]; C2, objective response rate [ORR]; both by investigator). Secondary objectives include ORR, PFS, and duration of response by investigator and independent central review, overall survival, and magrolimab concentration vs time and antidrug antibodies. Present and Target Accrual: The study is enrolling in the US, Australia, and Hong Kong. Target accrual is 144 pts. Contact Information: ClinicalTrials.gov: NCT04958785.

Background: Triple-negative breast cancer (TNBC) is the subtype of breast cancer with the worst prognosis and is the subtype most often associated with germline mutations of BRCA1 as well as other genes. Alpha-lactalbumin (aLA) is a milk protein expressed in lactating breasts but not at other times or in other normal tissues. Expression of aLA is found in approximately 70% of TNBC (Cancers PMID: 27322324) so is an attractive immunologic target for TNBC based on the “retired protein hypothesis” (Semin Immunol PMID: 31926646). Pre-clinical studies have shown that vaccination with aLA inhibits the growth of established breast tumors and provides potent protection from development of autochthonous tumors in transgenic murine models of breast cancer and against 4T1 transplantable breast cancer in BALB/c mice (Nat Med PMID: 20512124). **Specific Aims:** We are conducting a Phase I trial of vaccination with an aLA vaccine in patients with early stage TNBC to demonstrate the safety of this approach and to document the ability to produce a relevant immunologic response to aLA. **Trial Design:** Patients are being entered into a Phase I trial of alpha-lactalbumin with GMP-grade zymosan adjuvant in Montanide ISA 51 VG vehicle. Subjects receive a total of 3 vaccinations administered once every 2 weeks. Toxic events of Common Terminology Criteria for Adverse Events (CTCAE) grade 2 or greater are considered dose-limiting. Dose levels being tested in the current protocol are alpha-lactalbumin/zymosan 0.01/0.01, 0.1/0.01, 0.5/0.01, 0.5/0.03, and 0.5 mg/0.06 mg. Patients are being monitored for toxicity until 84 days after the first vaccination or resolution of toxicity, whichever is later. Blood is being drawn prior to therapy and 14, 28, and 56 days after the first vaccination to assess cellular response using enzyme-linked immunosorbent spot (ELISpot) assays of interferon-gamma and interleukin-17 production in response to aLA. Humoral response to aLA vaccination is being assessed by enzyme-linked immunosorbent assay (ELISA). **Eligibility Criteria:** Patients with ER-negative, PR-negative, HER2-negative breast cancer of pathologic stage II-III or who had residual disease after standard pre-operative systemic therapy. Participants must be within 3 years of initiation of treatment and have no evidence of recurrence. **Dose Selection:** Doses are being escalated using a 3+3 trial design to determine the maximum tolerated dose, the lowest immunologic dose and the optimal immunologic dose **Present Accrual and Target Accrual:** Dependent on toxicity, 18-30 patients will be treated. **Future Plans and Contact Information:** After identification of the maximum tolerated dose and expansion of the dose levels associated with effective tumor immunity we plan to enroll 2 additional cohorts of patients: 1) patients who have completed pre-operative chemo-immunotherapy and are receiving pembrolizumab as standard of care therapy, and 2) patients without cancer planning to undergo prophylactic bilateral mastectomy. Interested parties may contact Dr. Budd at buddg@ccf.org. **Funding Source:** Department of Defense (W81XWH-17-1-0592 and W81XWH-17-1-0593)

Background Although immunotherapy (IO) in combination with chemotherapy has improved progression free and overall survival in patients with PD-L1+ metastatic triple negative breast cancer (mTNBC), prognosis remains poor. A potential therapeutic strategy to restore sensitivity to IO in patients with progressive disease is to introduce agents that re-sensitize the immune system to IO leading to a more tumor-specific and less toxic treatment in the second-line setting or beyond. Both talazoparib, a PARP inhibitor, and radiation (XRT) independently increase PD-L1 expression on the tumor cell surface resulting in heightened sensitivity to IO agents like atezolizumab, a PD-L1 inhibitor. Although a local treatment, XRT has the ability to produce an abscopal effect resulting in systemic shrinkage of non-irradiated tumors outside/distant to the

XRT field, a phenomenon observed in patients receiving concurrent IO. While talazoparib is standard treatment in patients with gBRCA1 and 2 mutations, it is also a potent radiosensitizing agent that suppresses homologous recombination and PARP-1-dependent nonhomologous end joining (NHEJ) repair while promoting error-prone alt-NHEJ. When combined with IO, talazoparib can amplify immune responses by generating immunogenic neo-antigens independent of gBRCA1/2 status. We, therefore, hypothesize that the combination of talazoparib, XRT, and atezolizumab will re-sensitize mTNBC tumors to IO and promote a durable tumor-specific response that spares patients from toxicities associated with traditional chemotherapy regimens. Methods This is a Phase II multi-institutional study designed to assess efficacy and safety of talazoparib, high dose XRT, and atezolizumab given in the second-, third-, or fourth-line settings to patients with mTNBC that is PD-L1 positive. A total of 23 patients with mTNBC who do not carry gBRCA pathogenic variants will be enrolled. All patients will be treated with induction talazoparib of 1mg PO daily starting Day 1 of a 28-day cycle. Patients will then receive 8 Gy x 3 fractions to 1-4 metastatic lesions QOD beginning Day 12, 13, or 14. Atezolizumab will be given intravenously (840 mg) on Day 15 of the 1st cycle and then on Day 1 and Day 15 of the subsequent cycles. Talazoparib and atezolizumab treatment will continue until progression or severe toxicity. The primary endpoint is objective response rate (ORR) in non-irradiated lesions 8 weeks after the first dose of atezolizumab. Key inclusion criteria include biopsy proven mTNBC (ER< 10%, PR< 10%, Her2-) with at least 2 extracranial metastatic lesions. Patients must have at least 1 extracranial metastatic lesion amenable to high dose radiotherapy and at least one additional extracranial lesion of measurable disease by Response Evaluation Criteria in Solid Tumors (RECIST v1.1) that will not receive radiotherapy. Tumors must be PD-L1 positive as defined as >1% on IHC using the SP142 Ventana Assay. Key exclusion criteria include patients with germline BRCA pathogenic variants, more than three previous lines of chemotherapy treatment in the advanced setting with or without IO, and breast cancer progression within the first 3 months of previous IO treatment for non-metastatic or metastatic breast cancer. Sample size was determined using Simon's 2-stage Minimax design to detect a 20% increase in ORR. The null hypothesis that the true response rate among gBRCA1/2 negative patients of 10% will be tested against a one-sided alternative. Inflammatory cytokines, circulating B cells, and ctDNA will be collected for correlative analysis. Enrollment began in April 2021. The study is managed by the Hoosier Cancer Research Network and is open to accrual at Emory University and University of Alabama at Birmingham. Clinical trial information: NCT04690855

Background Metastatic triple-negative breast cancer (mTNBC) exhibits a particularly poor clinical outcome, generally with rapid progression and worse overall survival (OS) than other BC subtypes. Among the few therapeutic options, chemotherapy-based combinations are associated with increased toxicity and limited survival benefit, being treatment with sequential single agents, such as paclitaxel considered an appropriate first-line regimen for the metastatic setting for PDL-1 negative patients. Herein, there is an urgent need for clinically active agents for the mTNBC. Adoptive cell transfer (ACT)-based immunotherapy using ex vivo activated and expanded tumor-infiltrating lymphocytes (TILs) has shown promising therapeutic outcomes in some patients with metastatic tumors. The identification, selection, and enrichment of tumor-reactive lymphocytes at the early stages of the ACT generation could enhance their clinical activity. Thus, the selection of reactive T cells, such as PD1-positive (PD1+) TILs, could improve the responses achieved in those settings. TILS001 trial aims to explore the safety, tolerability and efficacy of selected PD1+ T-cell infusion with a previous pre-selection of mRNA PD1-high expression in patients with mTNBC. Study design: TILs001 trial is an open-label, single-arm, multicenter phase I/II prospective study with a two-stage design evaluating treatment with PD1+ TILs infusion in advanced or mTNBC, defined as HER2 negative and Hormonal Receptor < 10%. The study involves three different parts before PD1+TILs treatment. Tumor samples evaluable for PD1 mRNA expression and life expectancy ≥ 6 months are mandatory for part 1. Patients with high levels of PD1 mRNA, defined by the pre-specified cutoff, candidates for receiving a first-line taxane-based containing regimen and with at least 1 accessible target lesion to generate TILs are eligible for part 2. Finally, once the complete expansion of PD1+TILs is reached, patients will receive the non-myeloablative lymphodepleting chemotherapy regimen followed by PD1+TIL infusion and IL-2 treatment. Allogeneic hematopoietic stem cell transplantation, immune system-related disease or clinically active cerebral metastasis are not allowed. The primary objectives are to evaluate the safety and tolerability of the PD1+ TIL product, as per incidence of grade 3-5 adverse events (AE) or any grade AE that leads to treatment discontinuation and to assess the efficacy of ACT therapy with selected PD1+ TILs in mTNBC in terms of progression-free survival (PFS) at 6 months. The secondary endpoints are clinical benefit rate at 6 months (CBR6), overall response rate, duration of response (DoR), PFS and OS. Further translational research including immunophenotyping, TCR sequencing and mutational analysis will also be performed. The first 3 patients will be included in a safety run-in phase where safety will be evaluated 24h after PD1+/TILs infusion (before IL-2 treatment) and a phase II stage where efficacy will be evaluated, which will include up to 20 patients. Patients will be enrolled in 4 sites in Spain. Recruitment is expected to start by July 2022 and to be completed within 24 months. This study is financially supported by the Asociación Española Contra el Cáncer (GCAEC19010PRAT). NCT05451784

HER2Pro: A Phase 1b dose de-escalation study of high dose prochlorperazine added to paclitaxel, trastuzumab and pertuzumab in patients with previously untreated HER2-positive metastatic breast cancer Authors Teesha Downton^{1,2}, Emma Karlsen¹, Katharine Cuff^{3,4}, Euan Walpole^{3,4}, Fiona Simpson^{3,4}, Elgene Lim^{1,2}. Affiliations ¹Garvan Institute of Medical Research, Darlinghurst NSW, Australia; ²School of Clinical Medicine, St Vincent's Healthcare Clinical Campus, Faculty of Medicine and Health, University of New South Wales Sydney, Australia; ³Diamantina Institute, University of Queensland, Woolloongabba QLD, Australia; ⁴Princess Alexandra Hospital, Brisbane QLD, Australia Disclosures T. Downton: None. E. Karlsen: None. K. Cuff: None. E. Walpole: None. F. Simpson: None. E. Lim. Advisory Board for Pfizer, Astra Zeneca, Lilly, Roche, Novartis, Gilead Australia. Research Funding from Pfizer, Novartis, Bayer. Abstract Background: The anti-emetic prochlorperazine reversibly inhibits dynamin-mediated endocytosis. Preclinical studies have demonstrated that through this mechanism, high dose prochlorperazine can temporarily increase tumor cell antigen presentation, enhance interaction of tumor antigens with therapeutic monoclonal antibodies, and improve antibody-dependent cellular cytotoxicity (Chew H et al. Cell 2020). High dose

prochlorperazine has been well tolerated and proof of mechanism demonstrated in a pilot study (ACTRN12619001051134), and in a phase Ib trial (ACTRN12619001527156) of prochlorperazine with cetuximab in patients with EGFR-expressing advanced head and neck squamous cell carcinoma or breast cancer. Prochlorperazine potentially offers a novel approach to improve the efficacy of a range of therapeutic antibodies. This study HER2Pro (ACTRN12622000016730) aims to evaluate the feasibility and safety of high dose prochlorperazine in combination with paclitaxel, trastuzumab, and pertuzumab in patients with HER2-positive metastatic breast cancer. Trial Design: In this phase Ib single-arm trial, patients receive standard of care trastuzumab and pertuzumab 3-weekly and paclitaxel weekly. From cycle 2, patients in addition receive de-escalating doses of prochlorperazine weekly for 6 weeks, though an additional 6 weeks may be given if there are no treatment associated serious adverse events. Dose de-escalation will be evaluated using a 3+3 design, commencing at a prochlorperazine intravenous dose of 0.8mg/kg weekly. Eligibility: Eligible patients must have previously untreated HER2-positive metastatic breast cancer, Eastern Cooperative Oncology Group performance status 0-1, and baseline left ventricular ejection fraction \geq 50%. Key exclusion criteria include current daily treatment with corticosteroids at a dose $>$ 10mg prednisolone or equivalent, blood pressure $<$ 90/50 mmHg, prolonged QT interval, and Parkinson's disease. Objectives: The primary objective is to determine the recommended phase 2 dose. Secondary objectives include determining the frequency and severity of adverse events, rates of cardiotoxicity, objective response rate, duration of response and progression free survival. Tertiary objectives include analysis of receptor trafficking and immune system activation on paired tumor biopsies obtained before and after first prochlorperazine dose. Accrual: 6-12 patients will be enrolled across 2 Australian sites. Enrollment for this trial is expected to commence late 2022.

Background: GP2 is a biologic nine amino acid peptide of the HER2/neu protein delivered in combination with Granulocyte-Macrophage Colony Stimulating Factor (GM-CSF) that stimulates an immune response targeting HER2/neu expressing cancers, the combination known as GLSI-100. In a prospective, randomized, single-blinded, placebo-controlled, multicenter Phase IIb study, no recurrences were observed in the HER2+ population after 5 years of follow-up, if the patient was treated with GLSI-100, survived and was followed for more than 6 months ($p = 0.0338$). Immunotherapy elicited a potent response measured by skin tests and immunological assays. Of the 146 patients that have been treated with GLSI-100 over 4 clinical trials, GLSI-100 was well-tolerated and no serious adverse events were observed considered related to the immunotherapy. Method: This Phase III trial is a prospective, randomized, double-blinded, multi-center study. After 1 year of trastuzumab-based therapy, 6 intradermal injections of GLSI-100 or placebo will be administered over the first 6 months and 5 subsequent boosters will be administered over the next 2.5 years for a total of 11 injections over 3 years. The participant duration of the trial will be 3 years treatment plus 1 additional year follow-up for a total of 4 years following the first year of treatment with trastuzumab-based therapy. Patients will be stratified based on residual disease status at surgery, hormone receptor status and region. Study Size – Interim Analysis: Approximately 498 patients will be enrolled. To detect a hazard ratio of 0.3 in invasive breast cancer free survival (IBCFS), 28 events will be required. An interim analysis for superiority and futility will be conducted when at least 14 events have occurred. This sample size provides 80% power if the annual rate of events in placebo patients is 2.4% or greater. Up to 100 non-HLA-A*02 subjects will be enrolled in an open-label arm. Eligibility Criteria: The patient population is defined by these key eligibility criteria: 1. HER2/neu positive and HLA-A*02 2. Residual disease or High risk pCR (Stage III at presentation) post neo-adjuvant therapy 3. Exclude Stage IV 4. Completed at least 90% of

planned trastuzumab-based therapy Trial Objectives: 1. To determine if GP2 therapy increases IBCFS 2. To assess the safety profile of GP2 3. To monitor immunologic responses to treatment and assess relationship to efficacy and safety Contact information: Snehal Patel Greenwich LifeSciences, Inc. MT-5111 is a 55kD engineered toxin body targeting HER2 in solid tumors that binds to an epitope distinct from trastuzumab and pertuzumab, offering potential combination strategies with other HER2-targeting agents. MT-5111 works by internalizing, self-routing through intracellular compartments to the cytosol, and inducing potent cell-kill via the enzymatic and permanent inactivation of ribosomes.

This is a phase 1 study in adults with advanced HER2+ solid tumors. MT-5111 is dosed weekly IV over 30 min in every 21-day cycle until disease progression, unacceptable toxicity, death, or withdrawn consent. The study has dose escalation (Part A) cohorts enrolling patients (pts) with any HER2+ cancer (CA) and expansion (Part B) cohorts for HER2+ breast cancer (BC), Gastric or Gastroesophageal junction adenocarcinoma (GEA), or other HER2+ solid CA.

As of 30 June 2022, 42 total pts had enrolled (36 in Part A on 0.5-23 µg/kg/dose, 6 pts with BC in Part B1 on 10 µg/kg/dose). Median age 65 years, 28 (66.78%) pts were female, median of 4 prior systemic and 2 prior HER2-targeting treatment (tx). 17 pts with BC, 6 with biliary CA, 9 with GEA, and 10 with other solid CA have enrolled. Of the 17 BC pts, 15 received ≥ 10 µg/kg/dose.

Tx emergent adverse events (TEAEs) have been reported in 40 (95%) pts, and tx-related AEs (TRAE) occurred in 23 (55%) pts. No pt experienced G4-G5 TRAE. G1 troponin elevations were noted in 5 pts without clinical signs of cardiotoxicity (1 pt 6.75 µg/kg, 2 pts 10 µg/kg, 1 pt 17 µg/kg, 1 pt 23 µg/kg). Reversible G1/G2 infusion-related reactions were reported in 2 pts. Tx-related G1-G3 rash was observed in 5 pts (4 pts ≥ 10 µg/kg/dose); maculopapular in 2 pts, acneiform in 1 pt and associated with pruritus in 3 pts. The G3 rash developed one wk after first dose of 23 µg/kg, was declared a DLT, improved with systemic steroid therapy and the pt continued tx at the same dose without recurrence.

Best overall response per RECIST thus far is stable disease (SD) in 17 pts, non-CR/non-PD in 1 pt, and progressive disease (PD) in 14 pts. 1 pt had non-CR/non-PD for 30 wks (1 µg/kg, BC); 1 pt had SD for 24wks (10 µg/kg, pancreatic); 1 pt is on tx with SD through 8 cycles (10 µg/kg, BC). Of the 10 BC pts who received ≥ 10 µg/kg/dose, the best response was 5 SD.

The mean serum concentration of MT-5111 has increased in a dose-proportional manner starting at 6.75µg/kg/dose (Table 1). The soluble HER2 (sHER2) levels at end of tx were higher compared to baseline in cohorts that received ≤ 4.5µg/kg/dose, but similar or lower in cohorts that received ≥ 6.75µg/kg/dose. Higher MT-5111 doses have been well tolerated and may saturate circulating sHER2, leading to more predictable serum concentrations and tumor penetration. The C_{max} in humans at doses ≥6.75 µg/kg/dose is above the in vitro IC₅₀ for high HER2+ cell lines (0.029nM) and at 17 µg/kg/dose, above the IC₅₀ for moderate HER2+ cells (1.6nM).

In conclusion, the dose proportionate increase in serum concentration with levels above the in

vitro IC50 and the leveling off/reduction of sHER2 indicate exposure to MT-5111 is at clinically therapeutic levels. Skin toxicity at higher doses may indicate on-target effect as observed in other EGFR-targeted therapies where it is associated with clinical response and a better prognosis. sHER2 biomarker data is expected for all cohorts with PK correlation and 23µg/kg safety and efficacy data.

PK profile of MT-5111, C1D1 values

Dose (µg/kg)	N	C _{max} (ng/mL)	C _{max} (nM)*	t _{1/2} (hr)
6.75	5	33 (± 12)	0.6 (±0.22)	3.9 (± 2.0)
10.0	11	54 (± 24)	0.98 (±0.44)	6.9 (± 6.3) ^
13.0	3	81 (± 46)	1.47 (±0.84)	5.3 (± 4.0)
17.0	4	93 (± 27)	1.69 (±0.49)	6.6 (± 4.0)

C_{max} = maximum serum concentration; C_{max} and t_{1/2} values are mean (± SD).
 *nM= (ng/mL)/(molecular weight of MT-5111) ^Data available for 10 pts.
 Note: PK values for doses 0.5, 1, 2, 3, and 4.5 µg/kg are not presented. C_{max} values were below or just above IC₅₀ for cell lines with high HER2+ and below that for moderate HER2+.

Background: Individuals with Li-Fraumeni Syndrome (LFS) have increased risk of developing cancers of several types, such as early-onset breast cancer, soft-tissue/bone sarcoma, leukemia, brain tumors, and more, throughout their lifetime. LFS is primarily caused by autosomal dominant germline mutations in the TP53 tumor suppressor gene. It is difficult to identify TP53 mutation carriers because of the overlap in the occurrence of multiple cancer types in LFS with other inherited cancer syndromes. In order to improve the accuracy of risk assessment for these families, the LFSPRO risk model was created to predict the likelihood of

a proband having LFS based off detailed patient and family history information, as well as predict cancer-specific risks for patients who have already been identified as having LFS. Specific Aims: The primary aim of this study is to evaluate the concordance of LFSPRO and clinical criteria in predicting TP53 mutation status in patients undergoing germline TP53 testing. Trial Design: After receiving standard genetic counseling, patients identified as concerning for a potential TP53 mutation by a MD Anderson genetic counselor (GC) are run through LFSPRO. LFSPRO TP53 mutation carrier risk, whether the patient meets Chompret and/or Classic criteria, decision to test, and genetic test results are collected. Select GCs are then asked to complete a survey regarding their experience with LFSPRO. Eligibility Criteria: Through standard genetic counseling practice, MD Anderson GCs identify patients with a clinical suspicion for a TP53 germline mutation. All patients identified are run through LFSPRO. Out of these identified patients, select GCs that participated in the initial genetic counseling session are asked to complete a survey over their experience using the LFSPRO. Statistical methods: We will evaluate the concordance in the prediction of TP53 mutation carrier status between LFSPRO and current clinical criteria as compared to the outcome of genetic testing results. We will cross-tabulate the predicted TP53-mutation status (positive vs. negative) with the carrier status in a 2x2 table and calculate the sensitivity and specificity of each prediction tool separately (LFSPRO, clinical criteria), with 95% confidence interval. Accrual: Currently, 72 patients have been run through LFSPRO. Select GCs have completed the survey regarding their experience with LFSPRO on 20 of these patients. Data collection began in December 2021 and is currently ongoing. Funding: This research is supported by the Cancer Research and Prevention Institute of Texas. Background: Individuals with Li-Fraumeni Syndrome (LFS) have increased risk of developing breast cancer, sarcomas, brain tumors, leukemia, and other cancers throughout their lifetime. LFS is primarily caused by autosomal dominant germline mutations in the TP53 tumor suppressor gene. Due to the large number of cancers caused by LFS, and their variable age of presentation, each LFS family often presents very differently. Currently, standard genetic counseling for patients with LFS often involves general lifetime risk predictions for developing several primary cancers. At present, there are no standard tools available to help genetics providers obtain a personalized risk assessment for a patient with LFS based on their unique personal and family history data. To address this, the LFSPRO risk model was developed to estimate the likelihood of a proband having LFS, to provide cancer-specific risks of a first primary cancer, and to estimate risk of time to second primary cancer diagnosis by utilizing

detailed personal and family history information. Specific Aims: This study aims to understand patients' willingness to participate in a randomized trial comparing standard genetic counseling practice to personalized genetic counseling via LFSPRO risk estimates. Trial Design: Eligible patients or parents/guardians are invited via email to complete a survey assessing interest in a hypothetical clinical trial scenario where patients are randomized to receive one of two types of post-disclosure genetic counseling approaches: standard genetic counseling for TP53 results, involving generic risk predictions for developing cancers, or personalized risk information provided from LFSPRO. Following the hypothetical scenario, participants are asked about their perceived benefits and barriers to this research scenario and interest in receiving personalized risk results. Demographic information is also collected. Eligibility Criteria: Individuals who receive genetic counseling through MD Anderson Cancer Center genetics clinics specifically for TP53 genetic testing and who consent to undergo TP53 genetic testing or individuals who genetic testing already indicates a TP53 germline mutation are offered this survey. Patients must be 13 years or older to complete the survey, otherwise a parent/guardian may complete the survey on their behalf. Patients must have English fluency. Statistical methods: Descriptive statistics will be used to analyze the data and summarize the opinion of the participants. Accrual: Enrollment is set to open in July 2022. Currently, 157 patients have been identified to be invited to participate in the study. Funding: This research is supported by the Cancer Research and Prevention Institute of Texas. Objective: Trastuzumab-based adjuvant therapy was demonstrated to improve the prognosis of early human epidermal growth factor receptor 2 (HER-2) positive breast cancer, while about 10% of patients showed primary resistance. ExteNET study showed that 1 year of neratinib, an irreversible pan-HER tyrosine kinase inhibitor, after trastuzumab-based adjuvant therapy significantly improved invasive disease-free survival (iDFS) in women with HER2-positive breast cancer. Besides, for patients with early hormone receptor positive breast cancer within 1 year of prior trastuzumab with residual disease after neoadjuvant therapy, extended adjuvant neratinib showed prolonged overall survival, which suggested the potential benefit of extended adjuvant therapy for high-risk patients. Pyrotinib is an oral irreversible pan-HER receptor tyrosine kinase inhibitor targeting epidermal growth factor receptor, HER2, and HER4, which showed promising efficacy and manageable safety profiles in the treatment of HER-2 positive advanced breast cancer. In this study, we aimed to evaluate the efficacy and safety of extended adjuvant pyrotinib following trastuzumab-based adjuvant therapy in patients with high-risk early HER-2 positive breast cancer.

Methods: In this ongoing multicenter, open-label, phase II trial at 23 centers in China, women with operable high-risk early HER-2 positive breast cancer and known hormone receptor status, who have completed trastuzumab-based adjuvant therapy within 6 months were enrolled. High-risk patients must meet one of the following criteria: N stage ≥ 1 ; T stage ≥ 2 ; did not achieve pathological complete response (pCR) after neoadjuvant therapy; had pCR after neoadjuvant therapy but with tumor size ≥ 5 cm or N stage ≥ 2 ; or tumor size less than 2cm but with high Ki67, histologic grade 3 or with lymph node micrometastasis. Eligible patients were assigned to receive 6 month or 1 year of oral pyrotinib 400mg/day. The primary endpoint was the 2-year iDFS rate.

Results: Between January, 2019 and February, 2022, a total of 142 eligible women were enrolled and assigned to receive pyrotinib, with a median age of 50 (range: 25-72) years old. Ninety-seven patients had a T stage ≥ 2 . A total of 108 patients (76.1%) had node-positive disease, and 64 (45.1%) were hormone receptor positive. Twenty-five patients used neoadjuvant therapy previously, and all of them did not receive pCR (Table 1). After a median follow-up of 20 (range: 0.25-41) months, the 2-year iDFS rate was not available. Two and four patients reported invasive disease events after 6-month and 1-year of follow-up, with the 6-month and 1-year iDFS rates of 98.6% and 97.2%, respectively. The most common adverse events reported was diarrhea (78.2%), followed by fatigue (36.6%), lymphocyte count decreased (36.6%), nausea (33.1%) and hand-foot syndrome (33.1%). Forty-three patients experienced grade 3 diarrhea, and no grade 4 or higher adverse event was reported (Table 2). Adverse event leading to treatment discontinuation occurred in 12 (8.5%) patients.

Conclusion: Extended adjuvant pyrotinib administrated after trastuzumab-based adjuvant therapy was well-tolerated and showed potential efficacy in high-risk early HER-2 positive breast cancer. The follow-up is ongoing to determine the long-term benefit of extended adjuvant pyrotinib.

Table 1. Baseline characteristics of patients

Variables	All (n=142)
Age (years), median (range)	50 (25-72)
T stage, n (%)

Background

Patients with metastatic breast cancer (MBC) are usually treated with palliative systemic therapy until progression or unacceptable toxicity. When progression occurs, clinicians typically switch to the next line of systemic therapy. However, this strategy might be suboptimal in case of mixed response or oligoprogression.

Oligoprogression refers to a situation in which inter-lesion heterogeneity causes one or few metastatic lesions to progress while the vast majority of the metastatic burden responds to the treatment. Locally ablative treatment of the progressive lesion(s) with radiotherapy, resection or radiofrequency ablation may enable continuation of otherwise effective systemic treatment. Solid data to support this approach, however, is lacking at this moment.

Study design

The COSMO study is an investigator-initiated single-arm phase 2 study. It is intended to be a multicenter study.

Eligibility criteria

Patients with MBC and oligoprogression, defined as 1-2 progressive lesions while the majority of the metastatic burden remains stable or in remission, are eligible. Current systemic therapy must be 1st or 2nd line and patients must have responded to this systemic therapy for at least

six months prior to the occurrence of oligoprogression. The aberrant lesion must be amenable to locally ablative therapy.

All eligibility criteria may be found in table 1: eligibility criteria.

Aim

To investigate efficacy of local ablation of aberrant lesions combined with continuation of the same systemic therapy in patients with oligoprogression of MBC.

Primary endpoint:

Progression-free survival rate at six months (PFS-6).

Secondary endpoints:

- PFS
 - Overall survival
 - Time to next line of systemic therapy
- Primary and secondary endpoints will also be stratified by localization of progressive lesion and BC subtype (ER+/HER2- vs. HER2+ vs. TN).

- Local control rate of lesion treated with LAT at 12 months
- Complications due to LAT
- Quality of life
- Incidence of visceral crisis

Exploratory endpoints:

- Biomarkers, including receptor (ER/PR/HER2), PD-L1 and gene expression patterns in biopsies from progressive and responding lesions
- Prognostic value of ctDNA at oligoprogression and during the course of treatment

Statistical methods

An A'hern design was chosen to conduct this study. As null-hypothesis (H0), PFS-6 rate $\leq 25\%$ is set. The alternative hypothesis (H1) is PFS-6-rate $\geq 40\%$. Hypotheses were set to meet criteria for clinical significance, as stated by experts in the field. Setting one-sided $\alpha = 0.05$ and a desirable power=95%, 107 evaluable patients are needed. To account for 10% of the patients to be unevaluable, 118 included patients are needed. An early stopping rule for safety is applicable: if out of the first 45 patients ≥ 4 of these patients have developed visceral crisis, the study will be closed early.

Accrual

Start: July 2022

Target: 118 patients

Estimated accrual time: 2-3 years

Further information

This study was developed during the 21st EORTC/ESMO/AACR workshop on methods in

clinical cancer research (MCCR).

Eligibility criteria

Inclusion criteria	Exclusion criteria
<ul style="list-style-type: none"> • Adults with MBC according to TNM-staging • Oligoprogression, defined as: 1-2 distant metastatic progressive lesions, limited to one organ, OR progression of primary tumor (+/-lymph nodes) while distant metastases remain stable/responding • Patients are currently receiving 1st or 2nd line systemic therapy • SD/PR/CR for at least six months prior to occurrence of oligoprogression under one systemic treatment regimen • Oligoprogression is detected by same imaging modality as used at start of systemic therapy, and confirmed six weeks after its first detection • WHO performance status 0 or 1 • Willingness and ability to comply with study procedures • Signed informed consent. 	<ul style="list-style-type: none"> • Having received >2 lines of systemic therapy for MBC • Diagnosis of any other malignancy with an influence on general prognosis of the patient • Current pregnancy or breastfeeding. Women of childbearing potential must use adequate contraceptive protection • Any other condition that would pose an unacceptable risk, when partaking in the study, or potentially hamper patient's ability to comply with the protocol.

Table 1. Eligibility criteria.

Objective: The objective of this Phase 2, open-label, multicenter study is to investigate the antitumor activity of navicixizumab monotherapy or in combination with chemotherapy in patients with advanced solid tumors. Cohort C will enroll triple-negative breast cancer (TNBC) patients. Background: Navicixizumab is a bispecific humanized monoclonal immunoglobulin G2 kappa antibody directed against human delta-like ligand 4, a critical ligand of the NOTCH pathway, and human vascular endothelial growth factor (VEGF). Aberrant NOTCH signaling is associated with chemotherapy resistance, tumor plasticity, enhanced metastatic potential, promotion of a cancer stem cell phenotype, and immune evasion. In TNBC, aberrant NOTCH expression is associated with poor prognosis, making targeting of this pathway an attractive therapeutic strategy. Additionally, NOTCH may mediate resistance to angiogenesis inhibition. While VEGF inhibitors are approved for the treatment of multiple solid tumors, observed anti-tumor activity is limited in breast cancer. Pre-clinical data show that co-inhibition of NOTCH and angiogenesis have superior antitumor activity compared to individual pathway targeting. We postulate that navicixizumab will demonstrate anticancer efficacy against TNBC. Methods: Eligible TNBC patients will have locally advanced or metastatic disease and have received at

least 2 and no more than 4 prior lines of standard therapy for metastatic disease, including immunotherapy (for PD-L1 positive TNBC patients), and sacituzumab govitecan. TNBC is defined as ER and PR < 1%, and HER2-negative (IHC 0, 1+, or 2+ and negative fluorescence in situ hybridization [FISH]). Formalin-fixed paraffin-embedded tissue from an archival or a core tumor sample must be available for biomarker analysis. Samples will be tested using Oncomap™ ExTra with the Xerna TME Panel™ to classify patient samples into one of four tumor microenvironment (TME) subtypes based on angiogenic and immune gene expression signatures. Up to 30 patients will be enrolled to each TNBC cohort from approximately 8 sites in the US and will receive 3 mg/kg navicixizumab alone (Cohort C1) or in combination with paclitaxel (80 mg/m² on Days 1, 8, and 15 of a 28-day cycle) (Cohort C2). Patients will have radiologic tumor assessments every 8 weeks and will continue to receive treatment until disease progression per RECIST v1.1 (as assessed by the investigator), unacceptable toxicity, withdrawal of consent, another protocol-defined discontinuation criterion is met, or the sponsor terminates the study, whichever occurs first. The primary endpoints of the study are objective response rate (ORR) and progression-free survival (PFS). The historical benchmarks for this patient population are estimated at an ORR of < 5% and a 20% PFS rate at 4 months, with targets of 15% and 40% respectively considered promising for this study. Interim efficacy assessments will be at 10-patient increments following the time patients have had at least 1 post-baseline scan. Cohort continuation and future evaluation decisions will be guided by the boundaries identified by a sequential monitoring procedure. Secondary efficacy endpoints include overall survival, time to response, disease control rate, duration of response, and the relationship between antitumor activity of navicixizumab and Xerna TME Panel™ biomarker subtypes.

Background: Patients (pts) with human epidermal growth factor receptor 2–positive breast cancer (HER2+ BC) have a high incidence (up to 50%) of brain metastasis (BM) despite advances in treatment (Zimmer AS et al. *Cancer Rep (Hoboken)*. 2020;e1274; Hurvitz SA et al. *Clin Cancer Res*. 2019;25:2433-2441). Although several agents have been studied in pts with HER2+ BC with BM, an unmet medical need remains. In DESTINY-Breast01, T-DXd demonstrated efficacy in the overall population and preliminary efficacy in a pt subgroup with

stable BM (n=24), with a confirmed objective response rate (ORR) of 61.4%, an extracranial confirmed ORR by independent central review (ICR) of 58.3%, respectively, and median progression-free survival (PFS) of 19.4 and 18.1 months, respectively (Modi S et al. Cancer Res. 2021. Abst PD3-06; Jerusalem G et al. Ann Oncol. 2020. Abst 138O). T-DXd also demonstrated preliminary efficacy in a subgroup of pts with BM in the DESTINY-Breast03 trial, with an extracranial ORR of 67.4%, intracranial ORR of 63.9%, and median PFS of 15.0 months (Hurvitz S et al. SABCs 2021. Abst GS3-01). However, both trials excluded pts with active/progressive BM. Here we describe a trial evaluating T-DXd in a real-world setting in pts with stable or active BM and pts without BM with previously treated advanced/metastatic HER2+ BC. The data generated by this study will complement previous and ongoing studies, providing a more robust understanding of T-DXd treatment in patients with and without BM. Trial design: DESTINY-Breast12 (NCT04739761) is an open-label, multicenter, international (91 sites in the US, Europe, Australia, Canada, and Japan), phase 3b/4 study assessing the efficacy and safety of T-DXd 5.4 mg/kg every 3 weeks in pts with HER2+ BC ± BM. As part of prescreening, all pts will provide informed consent for tumor tissue samples (archival tumor tissue or fresh biopsy) to be collected and tested for HER2 status. Pts will be enrolled in 1 of 2 cohorts (250 pts each): cohort 1 (no BM at baseline) and cohort 2 (BM at baseline). Pts must have previously treated HER2-positive BC that has progressed on or after ≥1 prior anti-HER2-based regimen (including disease progression ≤6 months after adjuvant treatment with HER2-targeted therapies) and received ≤2 lines of therapy in the metastatic setting (excluding pts with prior tucatinib). Cohort 1 will be limited to include ≤25% third-line pts. Pts with BM must have untreated BM not needing immediate local therapy or previously treated stable or progressing BM. Primary endpoints are ORR in cohort 1 and PFS in cohort 2 (both by Response Evaluation Criteria in Solid Tumors [RECIST] version 1.1 per ICR). Secondary endpoints in both cohorts are overall survival, DOR, time to progression, duration of subsequent therapy, PFS2, safety, and changes in symptoms, functioning, and quality of life. Incidence of new symptomatic central nervous system (CNS) metastasis is a secondary endpoint in cohort 1, and ORR and CNS ORR by RECIST 1.1 per ICR, CNS PFS and DOR, and time to new CNS metastasis are secondary endpoints in cohort 2.

Background: The current first-line (1L) standard of care (SOC) for human epidermal growth factor receptor 2-positive (HER2+) metastatic breast cancer (MBC) is trastuzumab (T) plus pertuzumab (P) and a taxane. Despite advances in 1L SOC, most patients (pts) progress during maintenance therapy with T+P. Tucatinib is a tyrosine kinase inhibitor (TKI) approved in combination with T and capecitabine for adults with HER2+ MBC, with and without brain metastases (BM). In HER2CLIMB, the addition of tucatinib significantly prolonged progression-

free survival (PFS) and overall survival (OS) in pts with HER2+ MBC and was well tolerated. Adding tucatinib also reduced the risk of disease progression or death in pts with untreated and/or active BM (Murthy et al. 2020, Curigliano et al. 2021). HER2CLIMB-05 investigates whether adding tucatinib to 1L SOC as maintenance therapy will extend PFS while maintaining quality of life (QOL). Methods: HER2CLIMB-05 (NCT05132582) is a phase 3, randomized, double-blind study evaluating tucatinib plus T+P as maintenance therapy for HER2+ MBC. Approximately 650 pts will be enrolled. Eligible pts will have advanced HER2+ disease, no progression on 4–8 cycles of prior 1L SOC, ECOG Performance Status of 0 or 1, and no or asymptomatic BM. Exclusion criteria include prior treatment with anti-HER2 and/or anti-epidermal growth factor receptor TKI (prior SOC for early BC is permitted) or inability to undergo contrast magnetic resonance imaging of the brain. Pts will be randomized 1:1 to receive either tucatinib or placebo twice daily, with T+P once every 21 days. Pts with HR+ disease may receive endocrine therapy. The primary endpoint is investigator-assessed PFS. Secondary endpoints include OS (key endpoint), time to deterioration of health-related QOL, central nervous system PFS, safety, and pharmacokinetic (PK) parameters. PFS and OS will be compared using a 2-sided stratified log-rank test between treatment groups. Time-to-event endpoints will be summarized using the Kaplan–Meier method. PK and safety data will be summarized using descriptive statistics. Enrollment is ongoing in the US, with additional sites planned.

Background: Despite the use of targeted therapy has revolutionized the treatment in the neoadjuvant setting for early, locally advanced, HER2-positive breast cancer, these approaches still have limited efficacy, which calls for persistent exploration for optimized treatment strategy. KN026 is a bispecific monoclonal antibody that targets the distinct extra-cellular domains II (Pertuzumab binding site) and IV (Trastuzumab binding site) of HER2. KN026 has better anti-tumor activity than either Trastuzumab or Pertuzumab used alone, and also aimed to demonstrate similar or better anti-tumor response than Trastuzumab in combination with Pertuzumab. Here we report the preliminary results of KN026 and docetaxel as neoadjuvant treatment in patients with HER2-positive early or locally advanced breast cancer (LABC). Methods: Treatment naive patients with HER2-positive early (T1c or 2, N1, M0; T2 or 3, N0, M0) or locally advanced breast cancer (T1c or 2 or 3, N2, M0; T3N1M0; T1c or 2 or 3, N3a or 3b, M0) were enrolled to receive 4 cycles of KN026 (30mg/kg, ivgtt d1, q3w) and docetaxel (75 mg/m² ivgtt d1, q3w) neoadjuvant treatment. The primary endpoint was total pCR rate (tpCR;

defined as absence of any residual invasive cancer in the breast and lymph nodes) [ypT0/is, ypN0]). Secondary endpoints were pCR in the breast (bpCR, defined as absence of any residual invasive cancer in the breast [ypT0/is]), ORR (objective response rate), safety · PK (pharmacokinetics) and immunogenicity. The study is still ongoing, and the planned enrollment number is 30. This study is registered in ClinicalTrials.gov, number NCT04881929. The data cutoff date was April 15, 2022. Results: Between August 8, 2021, and April 15, 2022, a total of 15 patients were enrolled from 5 sites. 7 (46.7%) patients were stage II, and 8 (53.3%) patients were stage III; 12 (80%) patients with lymph node metastases, and 3 (20%) patients without lymph node metastases; 7 (46.7%) patients were hormone receptor positive, and 8 (53.3%) patients were hormone receptor negative. As of April 15, 2022, 4 patients are still under neoadjuvant therapy, 1 patient withdrew from the study earlier due to AE during neoadjuvant treatment period, and 10 patients completed the surgery. Of the 10 patients who completed surgery, tpCR rate were 50% (5/10, 95% CI: 18.7%-81.3%), bpCR rate were 50% (5/10, 95% CI:18.7%-81.3%), and ORR were 100% (10/10, 95% CI: 69.2%-100%). The incidence of TRAE and Grade ≥3 TRAEs were 100% (15/15) and 53.3% (8/15) respectively. The most common TRAE were alopecia (14/15, 93.3%), white blood cell decreased (10/15, 66.7%), anemia (10/15, 66.7%), diarrhea (9/15, 60.0%), neutrophil count decreased (9/15, 60.0%), alanine aminotransferase increased (8/15, 53.3%) and hypoalbuminemia (8/15, 53.3%). The Grade ≥3 TRAE include neutrophil count decreased (8/15, 53.3%), white blood cell decreased (5/15, 33.3%), alanine aminotransferase increased (1/15, 6.7%), and lymphocyte count decreased (1/15, 6.7%). No Grade 5 TRAEs occurred. 3 TRAEs (Alanine aminotransferase increased, blood bilirubin increased and neutrophil count decreased) leading to KN026 interruption, and no TRAE leading to KN026 discontinuation. 1 SAE (hepatitis E-not TRAE; outcome: recovered) occurred in 1 patient, without other SAE or death throughout the study. Conclusions: KN026 and docetaxel as neoadjuvant treatment has shown promising clinical benefit for patients with HER2-positive early or locally advanced breast cancer with an acceptable and manageable safety profile. Further validation in a large-scale randomized controlled trial is warranted.

Background: The CLEOPATRA trial established trastuzumab, pertuzumab and a taxane (THP) as a standard of care for first line metastatic, HER2-positive breast cancer with median progression-free survival (PFS) of 18.7 months and median OS of 57 months. NRG BR004 was a phase III, placebo-controlled trial designed to determine whether the addition of the PD-L1 inhibitor, atezolizumab, to THP would improve progression-free survival (PFS), relative to THP/placebo in patients with newly documented HER2-positive measurable metastatic breast cancer.

Methods: BR004 was designed to detect an improvement in the primary endpoint of PFS in patients with measurable disease from 16.5 to 22.5 months with addition of atezolizumab (HR 0.733). A sample size of 600 would provide 80% power with a type I error rate of 0.05 to detect such an improvement when 326 PFS events had been reported. Monthly accrual was projected at 30 patients per month with completion of accrual in 24 months. In addition to routine monitoring of safety data by the IDMC every 6 months, a formal analysis of the toxicity data was to be performed 16 weeks after the 100th patient had been randomized with review by the IDMC.

Results: First patient was randomized on May 1, 2019, and after 37 months 190 patients had

been randomized. Several amendments were not successful in addressing the low accrual rate. The IDMC began regular monitoring of safety and accrual data in July 2020 and reviewed the formal safety analysis in February 2022. As of the February 2022 IDMC meeting, four Grade 5 adverse events (AEs) had been reported (2 occurring in 2020 and 2 in 2021), one of which occurred in a patient with evolving liver failure due to rapid disease progression at the start of therapy. The recommendation was to continue without modification, but notice was given the Grade 5 AEs had occurred on the same treatment arm without unblinding. When additional Grade 5 AEs occurred on 3/4/2022 and 4/27/2022 both on the same study arm with none reported on the other arm, accrual was held until the IDMC could review updated safety data, narratives of the Grade 5 AEs and the overall context of the trial. There was no evidence of clinically important imbalances between Grade 3 and Grade 4 AEs between the arms., Based on an uncertain but material safety signal, the ongoing accrual challenges, and determination that the clinical question being addressed was no longer sufficiently compelling, the IDMC recommended that the trial should be permanently closed to further enrollment. Summary safety data from 187 treated patients are provided in the Table. A decision was made to discontinue atezolizumab/placebo in patients receiving the investigational component of the trial therapy and unblind investigators and patients. The study will continue to collect information on PFS events, deaths and late immune AEs through April of 2024 when PFS and OS will be analyzed.

Conclusions: The imbalance in Grade 5 AEs which occurred on BR004 coupled with continued poor accrual and the changing landscape in HER2+ MBC resulted in early closure of enrollment and unblinding of patients. Follow-up continues to assess PFS, OS and monitor for delayed immune AEs.

Background: Only a subset of patients with metastatic triple-negative breast cancers (TNBC) demonstrate response to FDA approved PD-1 immune checkpoint blockade (ICB), and few have durable responses. Data suggests that breast cancers have defects in antigen presentation and that antigen presenting cells especially the DC1 subtype of dendritic cells (DCs) are required for response to ICB. CD40 agonists activate antigen presenting cells including DCs and B cells and also repolarize macrophages to an anti-tumor phenotype. Flt3 ligand is a growth factor that increases differentiation and expansion of DCs. We recently demonstrated in pre-clinical TNBC models that the combination of liposomal-doxorubicin chemotherapy, a CD40 agonist, and a Flt3 ligand improves outcomes compared to alternate combinations. Methods: This is a single arm phase I pilot study of liposomal-doxorubicin, CDX-1140 (CD40 agonist), and CDX-301 (Flt3 ligand) combination therapy in patients with metastatic or unresectable locally advanced metastatic TNBC. Patients will be randomized to 3 lead-in arms (triplet therapy, doublet immunotherapy only, or liposomal-doxorubicin only) for 1 cycle prior to receiving triplet therapy with fresh tissue biopsies before and after the lead-in treatment. CDX-301 will be discontinued after 2 cycles; liposomal-doxorubicin and CDX-1140 will be continued until disease progression or clinically limiting toxicities. Primary endpoint is determination of a recommended phase 2 dose based on treatment-related adverse events including dose-limiting toxicities. Secondary endpoints include anti-tumor immune response after triplet therapy, after immunotherapy alone, and after liposomal-doxorubicin alone; median progression-free survival, overall response rate, duration of response, and clinical benefit rate. Key eligibility criteria are unresectable stage III or stage IV TNBC (ER \leq 10%, PR \leq 10%, HER2/neu negative), 1st to 3rd line metastatic treatment setting (1st line patients need to be PD-L1 negative by 22C3 assay), measurable disease by RECIST 1.1 criteria, consent for pre-treatment and on-treatment biopsies of amenable soft tissue tumor lesions, no prior treatment with an anti-CD40 antibody or a Flt3 ligand, no anthracycline treatment in the metastatic setting, no prior progression while on anthracycline-based therapy or within 6 months of completing neoadjuvant chemotherapy, and no history of non-infectious pneumonitis or current pneumonitis. This trial will enroll up to 45 patients across multiple sites (NCT05029999).

Background: The prognosis for advanced/metastatic triple negative breast cancer (TNBC) remains poor and novel therapeutic strategies are urgently needed to improve outcomes. Insulin resistance and obesity contribute to cancer progression and are independent predictors of worse survival after TNBC diagnosis. Chemotherapy worsens insulin resistance, body mass index, and multiple other metabolic parameters which can paradoxically limit treatment efficacy and survival. Methionine aminopeptidase 2 (MetAP2/p67) is overexpressed in many tumor types and MetAP2 inhibitors exhibit broad anti-tumor activity. Additionally, MetAP2 inhibitors improve insulin resistance, reduce adiposity, and normalize levels of adipokines, attenuating the effects of metabolic dysfunction on tumor growth. Evexomostat (SDX-7320) is a second-generation MetAP2 inhibitor designed to improve drug-like properties and minimize central nervous system toxicities. Evexomostat improved insulin sensitivity, reduced fat mass and normalized adipokine levels in preclinical models of obesity, and reduced tumor growth in preclinical models of TNBC. In phase 1 trials, MetAP2 inhibition combined with chemotherapy was safe and well tolerated, while evexomostat monotherapy partially restored insulin sensitivity, reduced angiogenic factors as well as adipokines and showed anti-metastatic effects in patients with advanced solid tumors. The goal of this phase 2 study is to test whether evexomostat in combination with eribulin chemotherapy prevents worsening of insulin resistance and augments tumor response in patients with metastatic TNBC and concomitant metabolic dysfunction. Methods: This is a single-center, placebo-controlled phase 2 randomized control trial of evexomostat, a MetAP2 inhibitor, in combination with eribulin chemotherapy. Eligible patients must have histologically confirmed metastatic TNBC, measurable disease or ≥ 1 predominantly lytic bone lesion, baseline metabolic dysfunction defined as hemoglobin A1c $> 5.5\%$ and/or BMI ≥ 30 kg/m², have received ≤ 2 prior lines of therapy in the advanced/metastatic setting, have ECOG performance status ≤ 1 , and adequate

organ function. Patients with uncontrolled or insulin-dependent type II diabetes, or who require combination antihyperglycemic therapy are excluded. During the safety run-in period, 15 patients will be assigned to receive evexomostat 49 mg/m² every 2 weeks in combination with eribulin 1.4 mg/m² administered on days 1 and 8 of a 21-day cycle. Upon safety confirmation, an additional 40 patients will be randomized 2:1 to receive evexomostat or placebo in combination with eribulin. The primary endpoint is metabolic efficacy assessed by change in Homeostatic Model Assessment for Insulin Resistance (HOMA-IR) score. Secondary endpoints include objective response rate, progression-free survival, duration of response, safety and tolerability, patient-reported outcomes, changes in metabolic markers, and changes in body composition parameters. Historically, HOMA-IR scores double during chemotherapy, and this trial will test whether evexomostat will attenuate the expected rise in HOMA-IR. Specifically, the trial will have >90% power to detect a difference between a 1.5-fold change in HOMA-IR in the control arm versus no change in the investigational arm while controlling the Type I error at 5%. This trial opened to accrual in July 2022. A total accrual of 61 patients is planned with a goal of 55 evaluable patients. For any inquiries/questions, please contact Sherry Shen at shens1@mskcc.org. Clinical trial registry number: pending Funding, study drug evexomostat and other support provided by: SynDevRx, Inc.

Purpose: The anti-tumor activity of nab-paclitaxel followed by epirubicin/cyclophosphamide (EC) as neoadjuvant chemotherapy (NAC) in Asian patients remains unclear, particularly in the aggressive subtype triple-negative breast cancer (TNBC). This study aimed to evaluate the efficacy and safety of this NAC regimen in TNBC. **Methods:** In this Simon's two-stage, phase II study, treatment-naïve patients with resectable unilateral primary invasive TNBC were enrolled. Eligible patients received nab-paclitaxel 125 mg/m² weekly on day 1 for 12 weeks, followed by dose-dense EC (epirubicin 90 mg/m²; cyclophosphamide 600 mg/m²) on day 1 for four 2-week cycles. The primary endpoint was the total pathological complete response (tpCR, ypT0/is ypN0) rate. Secondary endpoints included breast pathological complete response (bpCR, ypT0/is) rate, objective response rate (ORR), the proportion of patients requiring breast-conserving surgery, and safety. **Results:** 55 eligible patients were enrolled and treated. After neoadjuvant therapy, tpCR and bpCR were respectively observed in 43.1% (95% CI, 29.3%-57.8%) and 49.0% (95% CI, 34.8%-63.4%) of 51 evaluable patients for pathological response evaluation. 44 had an ORR as their best response (80.0%; 95% CI, 67.0%-89.6%). No correlations between clinicopathological variables and pathological/clinical response were observed. Grade 3 or more AEs occurred in 63.6% of 55 patients. The most frequent AEs were alopecia. No treatment-related surgical delay or death occurred. **Conclusions:** Nab-paclitaxel followed by dose-dense EC as NAC demonstrates promising anti-tumor activity and acceptable tolerability for patients with TNBC.

Background: In early breast cancer (BC), neoadjuvant therapy can promote de-escalation of surgery or treat micrometastases. Pathological complete response (pCR) is a standard primary endpoint in neoadjuvant BC studies, and correlates with long-term outcomes such as event-free survival (EFS). The poly(ADP-ribose) polymerase (PARP) inhibitors olaparib and talazoparib are approved in the metastatic setting for patients with BC and a germline BRCA1 and/or BRCA2 pathogenic/likely pathogenic mutation (gBRCAm). Following the phase 3 OlympiA trial primary analysis (data cut-off [DCO] Mar 2020), the PARP inhibitor olaparib was FDA approved for the adjuvant treatment of patients with gBRCAm and HER2-negative, high-risk early BC who have been treated with neoadjuvant/adjuvant chemotherapy. At the second pre-specified OlympiA analysis (DCO Jul 2021), olaparib treatment sustained improvements in invasive disease-free survival (IDFS HR 0.63, 95% CI 0.50–0.78) and distant disease-free survival (DDFS HR 0.61, 95% CI 0.48–0.77), and also significantly reduced the risk of death (overall survival [OS] HR 0.68, 98.5% CI 0.47–0.97) vs placebo. PARP inhibitors have also shown efficacy in the neoadjuvant setting in smaller studies. Durvalumab, a programmed death-ligand 1 inhibitor, has been studied as neoadjuvant therapy in triple negative BC and showed improved IDFS, DDFS and OS vs placebo (GeparNuevo). For BRCAm carriers at low risk of recurrence, olaparib monotherapy may provide adequate neoadjuvant treatment, allowing de-escalation or omission of chemotherapy. For those at high risk of recurrence, it is hypothesized that addition of the immune checkpoint inhibitor durvalumab will enhance immunogenicity provided through cell death following PARP inhibition. Feasibility for a larger study will be assessed. Methods: OlympiaN is a phase 2, international, multicenter, open-label trial examining the efficacy and safety of neoadjuvant olaparib monotherapy and olaparib plus durvalumab in adults with deleterious/suspected deleterious BRCAm and operable, early-stage,

HER2-negative, ER-negative or ER-low BC (immunohistochemistry nuclear staining < 10%). Patients will be enrolled in two cohorts: (A) patients at lower risk of recurrence: tumor size >5 to < 20 mm and nodal status N0 will receive olaparib 300 mg orally twice daily continuously in 28-day cycles; (B) patients at higher risk of recurrence: tumor size >20 to ≤50 mm and N0, or T1 and N1 will receive olaparib 300 mg orally twice daily continuously in 28-day cycles plus durvalumab 1500 mg IV infusion every four weeks. After four to six cycles, patients will undergo definitive surgery, then systemic and radiation therapy in accordance with local standard of care. Patients who achieve pCR at surgery will be able to receive adjuvant olaparib monotherapy in lieu of standard adjuvant systemic therapy for a total of twelve 28-day cycles of neoadjuvant and adjuvant olaparib therapy. The primary endpoint is the pCR rate after completion of neoadjuvant systemic therapy, assessed by central pathology review. Secondary endpoints include the pCR rate assessed by local pathology review, residual cancer burden, tumor volumetric analysis, EFS, safety and tolerability. Tumor tissue will be collected pre-treatment and at surgery to evaluate the mechanism of action of therapy. Baseline and longitudinal assessment of ctDNA and its association with clinical outcomes will also be performed. The primary pCR analysis will occur ~6 months after last participant enrollment; the final DCO will be 3 years after last participant dosed or once all participants have had an EFS event. No formal statistical analyses are planned, data will be summarized descriptively. Enrollment is planned to commence by late 2022, across ~65 sites in 10 countries; the target accrual is ~25 patients per cohort to ensure adequate precision in the estimated pCR rate. Funding: This study is funded by AstraZeneca UK Plc.

BACKGROUND: Antiangiogenic agent plus neoadjuvant chemotherapy confers an improvement in pathological complete response (pCR) rate among patients with HER2-negative breast cancer. Anlotinib is a novel multi-target tyrosine kinase inhibitor that effectively inhibit VEGFR, FGFR, c-KIT, c-MET, and RET. This phase II study aims to evaluate the efficacy and safety of anlotinib combined with chemotherapy as neoadjuvant treatment in HER2-negative breast cancer. **PATIENTS AND METHODS:** Eligible patients (pts) were women, aged 18-70 years, ECOG status 0-2, previously untreated HER2-negative breast cancer. The HER2-negative, defined as immunohistochemistry of 0, 1+, and 2+/*ISH*-. Pts were required to have a palpable primary tumor at least 200mm in diameter in the breast, as assessed by physical examination, and to be classified as having tumor stage T1c to T3, nodal stage N0 to N2a, and metastasis stage M0. Thirty pts will be enrolled and received 5 cycles of anlotinib (12 mg qd, d1-14; 21 days per cycle) plus 6 cycles of nab-paclitaxel (200 mg/m², once every 3 weeks), anthracycline (pirarubicin 50 mg/m²) and cyclophosphamide at 500 mg/m², followed by surgery. The primary endpoint is pCR rate (ypT0/Tis ypN0) and the secondary endpoints include disease-free survival (DFS), overall survival (OS), and safety. The study was initiated in August 2021. This study is currently open and 10 patients had been enrolled. The estimated primary completion date is October 1, 2023. Results: The trial is in progress. Conclusion: The trial is in progress.

Background The recent introduction of CDK4/6 inhibitors has been one of the most pivotal breakthroughs in breast cancer therapy during the last decades. A growing body of evidence proposes that CDK4/6 inhibitors influence the recruitment of immune cells in the tumor microenvironment with potential effects on the outcome. **Study design** The NeoLetRib-study is a multicenter, single-arm, open-label, neoadjuvant, phase II trial aiming at treating 100 locally advanced luminal-A and luminal-B breast cancer patients, defined as either large T2, or T3/T4, and/or N2-3. Patients receive neoadjuvant therapy for 6 months: ribociclib (600 mg daily, 21 days on / 7 days off) and letrozole (2.5 mg daily). Peri- and premenopausal women also receive therapy with goserelin 3.6 mg s.c every 28 days. **Methods** Three sequential tumor biopsies were collected: pre-treatment and on-treatment (cycle 1 - day 21 and cycle 6 - day 21 with ribociclib). These biopsies were subjected to single-cell transcriptome, T cell receptor and B cell receptor profiling using the Chromium Single-Cell v2 5' Chemistry (10x Genomics). Libraries were paired-end sequenced on a NovaSeq6000. Single cell gene expression matrices were analyzed with the Seurat package (v4.0.2). After filtering out stressed / dying cells or cells with low quality sequencing, gene expression of the remaining good quality cells was normalized and scaled to construct principal components and further cluster cells. **Results** In this planned interim analysis, we clustered 242315 cells from longitudinal tumor biopsies from 18 patients at pre-treatment, 18 at cycle 1 - day 21 and 9 at cycle 6 - day 21, respectively. We identified 8 main cell types: T cells, B cells, epithelial cells, fibroblasts, endothelial cells, macrophages, mast cells and dendritic cells. To further identify specific and specialized cell subtypes, we clustered the cells belonging to the above-mentioned cell types and annotated the clusters obtained using validated marker genes. Statistical methods and algorithms were then used to characterize how the proportion of different cell types changes in tumors under treatment pressure. We identified significant changes in immune cell proportions, including regulatory T cells, CD14 monocytes, SLC2A1-Macrophages among others. **Conclusions** In this unique patient cohort, we used single cell transcriptome profiling to obtain a high-resolution map of cell types found in tumor biopsies from the NeoLetRib trial. We characterized the effects of the combination of ribociclib and letrozole on the tumor microenvironment and identified cells sensitive and resistant to treatment. In this interim analysis, the observed longitudinal changes of immune cell types proportions in the tumor microenvironment might suggest immune related effects of the treatment combination.

Background: HR+ early stage breast cancer (ESBC) is associated with suboptimal pathologic complete response rate (pCR, ~10%) following neoadjuvant cytotoxic chemotherapy. Neoadjuvant endocrine therapy with aromatase inhibitors (AI) may serve as an effective alternative as gauged using the surrogate Ki67 cell proliferation histologic marker. Patients with poor Ki67 response (defined as Ki67>10%) following neoadjuvant AI exhibit poor prognosis and therapeutic resistance to both endocrine therapy and chemotherapy. In a genomic analysis of Ki67-high HR+ tumors, we identified 8-fold upregulation of BIRC5 (survivin), a gene that regulates apoptosis and the cell cycle and is associated with poor clinical outcome. Maveropemiput-S (MVP-S) leverages the non-aqueous, lipid-based DPX delivery platform to educate a specific and persistent T cell-based immune response to 5 HLA-restricted peptides from Survivin. Treatment with MVP-S and intermittent, low-dose cyclophosphamide (CPA) has shown to increase tumor infiltration of survivin-specific T cells. Previous clinical trials have shown that MVP-S is well-tolerated, immunogenic, and could lead to clinical response in several cancer indications. Further exploration of the regimen in breast cancer could extend the application of this immunotherapy for the unmet medical need of improving clinical response in high ki67 HR+ ESBC prior to surgery. Trial Design: NCT04895761 is phase I trial evaluating the safety and immunologic effects of neoadjuvant MVP-S plus letrozole (arm A, n=6), with/without tumor-directed MR-guided radiotherapy (arm B, n=6), or intermittent low-dose cyclophosphamide (CPA, arm C, n=6). Postmenopausal patients with T1c+ HR+HER2- breast cancer with Ki67>10% will receive two doses of MVP-S and 7 weeks of neoadjuvant letrozole prior to surgery (all arms), arm B will be treated additionally with concurrent 10Gy x 2 tumor boost radiation to facilitate immunogenic cell death, and arm C (n=6) will be treated additionally with intermittent low-dose CPA (50mg BID) to facilitate regulatory T cell depletion. Specific Aims: The primary objective is safety. Biomarker objectives are to evaluate for each treatment arm: 1) systemic type I survivin-specific immune response, as measured by IFN- γ ELISPOT; 2) changes in immune environment by GeoMx digital spatial genomic profiling; 3) and changes in tumor infiltrating lymphocytes (TILs) and Ki67. These data will be used to identify the most immunogenic MVP-S combination therapy for study in phase II trial powered to assess clinical outcome (pCR). Accrual: 3 of 6 patients in the MVP-S+ letrozole arm have been enrolled. Arm B and C will enroll after completion of arm A.

Background: Populations of African ancestry are underrepresented in global oncology clinical trials resulting in paucity of data on safety and efficacy of cancer medicines in vulnerable Black populations. The ARETTA clinical trial was initiated by the Nigerian Breast Cancer Study Team in partnership with the University of Chicago Comprehensive Cancer Center to build local capacity for biomarker informed clinical trials and translational breast cancer research. ARETTA is a pragmatic single-arm, phase II clinical trial to optimize therapy and determine the safety and efficacy of neoadjuvant taxotere and trastuzumab in women with HER2-positive breast cancer. The study sought to 1) determine the pathological complete response (pCR) rate of patients with early stage breast cancer to neoadjuvant docetaxel and subcutaneous trastuzumab 2) develop the capacity of investigators in Nigeria to improve quality of care through participation in oncology clinical trials using upgraded facilities and trained personnel and 3) determine accrual rate and retention of participants. Methods: Inclusion criteria include treatment naïve women aged 18 years to 70 years with HER-2 positive breast cancer stages II-IIIC (AJCC). Eligible participants receive four cycles of docetaxel 75mg/m² and trastuzumab every 3 weeks. Those with incomplete clinical response by breast ultrasound volume measurements receive 3 additional cycles of chemotherapy; cyclophosphamide 600mg/m², epirubicin 90mg/m² and 5-fluorouracil 600mg/m² every 3 weeks before re-evaluation for surgery. All participants receive a fixed dose of sub-cutaneous Herceptin (600mg) every 3 weeks (total of 18 doses). The primary endpoint is pCR rate. Secondary objectives are to evaluate invasive disease-free survival (iDFS), the pattern of response and mechanisms of resistance to treatment based on genomic markers, the pharmacokinetics of Herceptin SC, quality of life, and adverse event rates, including cardiac toxicity. Planned enrollment is 47 evaluable patients, which will provide 90% power to test the null hypothesis that the pCR rate is 20% versus a 40% alternative (one-sided alpha=0.05). More protocol details can be found at ClinicalTRial.gov NCT03879577 and JCO Glob Oncol2020 doi: 10.1200/GO.20.00043
Progress: The study has met its primary endpoint and will be closed to accrual by the time of the meeting. Results will be submitting as Late Breaking before the meeting

Background: Dual HER2 targeted therapy with pyrotinib (a tyrosine kinase inhibitor targeting HER1, HER2, and HER4) and trastuzumab plus chemotherapy has been approved as neoadjuvant therapy for patients with HER2-positive breast cancer in China based on the results from phase 3 PHEDRA study. However, the optimal chemotherapy partner still needs exploration. This multicenter phase 2 trial (ChiCTR1900022293) aimed to investigate the efficacy and safety of epirubicin, cyclophosphamide and pyrotinib followed by docetaxel, trastuzumab and pyrotinib (ECP-THP) as neoadjuvant therapy for patients with stage II-III HER2-positive breast cancer. Methods: Patients received intravenous epirubicin (90 mg/m²) and cyclophosphamide (600 mg/m²) on day 1 of each cycle for four 21-day cycles, followed by intravenous docetaxel (75 mg/m²) and trastuzumab (8 mg/kg loading dose, followed by 6

mg/kg) on day 1 for 4 cycles. Pyrotinib 400 mg was given orally once daily throughout the neoadjuvant therapy period. Surgery was performed within 16-20 days after the last neoadjuvant therapy. The primary endpoint was total pathological complete response (tpCR, ypT0/is ypN0) rate. Results: Between May 2020 and May 2022, a total of 175 patients enrolled. As of May 31, 2022, 144 patients had undergone surgery; the median age was 51 years (range, 26-67). Sixty-seven (46.5%) of 144 patients had hormone receptor (HR)-negative disease, and 77 (53.5%) had HR-positive disease. The tpCR rate was 67.4% (97/144; 95%CI, 59.3%-74.5%). Patients with HR-negative disease had numerically higher tpCR rate than those with HR-positive disease (73.1% [95%CI, 61.5%-82.3%] vs. 62.3% [95%CI, 51.2%-72.3%]), but without statistical significance (P=0.230). Miller-Payne grade 4 and 5 pathological responses were found in 22 (15.3%) and 97 (67.4%) of 144 patients, respectively. Regarding clinical response to neoadjuvant therapy before surgery, 31 (21.5%) of 144 patients achieved complete response and 99 (68.8%) achieved partial response, with an objective response rate of 90.3% (95%CI, 84.3%-94.1%). Of 161 patients with available safety data, the most common grade ≥ 3 adverse events included diarrhea (57.1%), white blood cell count decreased (8.7%), and neutrophil count decreased (5.6%). No treatment-related deaths occurred. Conclusions: Patients with stage II-III HER2-positive breast cancer show favorable clinical and pathological response to this ECP-THP neoadjuvant regimen, with an acceptable safety profile.

Background: Breast cancer (BC) is the most frequent cancer in women in Brazil, with more than 60,000 cases estimated annually. Forty percent of patients present with stages III and IV and neoadjuvant chemotherapy (NACT) remains the mainstay of treatment for locally advanced breast cancer (LABC). Taxanes usually follow anthracyclines in breast cancer neo/adjuvant treatment, likely because of their later introduction into clinical practice. However, the potential impact of alternative sequencing remains to be studied. A single-center phase II randomized clinical trial conducted in the Brazilian National Cancer Institute showed an improvement in overall survival with taxane-first compared with anthracycline-first sequencing in HER2-negative LABC (Bines J et al, *The Oncologist* 2020). As a taxane-before-anthracycline sequence carries neither an incremental cost nor increased toxicity, the optimal sequencing of these agents could have significant implications for clinical practice. To confirm this finding, we are currently conducting a multicenter randomized phase III trial comparing a taxane followed by an anthracycline-based regimen with the reverse sequence in the neoadjuvant setting. Trial Design: This randomized, open-label, phase III trial will be conducted in 15 research centers in

Brazil. It was approved by the local ethics committee in 2020 and is registered in ClinTrials.gov with the identifier NCT04540692. Women with HER2-negative LABC are randomized in a 1:1 ratio to anthracycline-before-taxane (AC-T arm) or taxane-before-anthracycline (T-AC arm), stratified by hormone receptor status (positive vs. negative) and axillary lymph node status (N0 vs. N+). The anthracycline-based therapy recommended in this trial is AC (doxorubicin 60 mg/m² and cyclophosphamide 600 mg/m²) every three weeks for four cycles, whilst the taxane-based therapy is either weekly paclitaxel 80 mg/m² weekly for 12 weeks, paclitaxel 175 mg/m² every three weeks, or docetaxel 75-100 mg/m² every three weeks. The use of carboplatin concomitantly with taxane for triple-negative tumors and dose-dense regimens is allowed following institutional guidelines. Further therapies (surgery, radiotherapy, and endocrine therapy) are performed according to the physicians' discretion. Tumor samples are collected and stored for translational studies. Eligibility: Inclusion criteria: women ≥18 years of age; histologically confirmed HER2-negative breast cancer (by ASCO/CAP guidelines); stage ≥ IIB (if TNBC) or ≥ III (if HR-positive); PS ECOG 0-2 and adequate organ function. Exclusion criteria: previous use of anti-cancer therapies; bilateral BC and pregnancy. Specific Aims: The primary objective is invasive disease-free survival (iDFS). Secondary objectives include pathological complete response (pCR) rates, overall survival (OS) and safety. Statistical Methods: Considering an uncausal type I error of 0.05, a type II error of 0.2, and an estimated iDFS of 50% in 5 years in the control arm, a total of 227 evaluable patients should be included per arm to demonstrate a HR of 0.7 favoring the taxane-first arm. Estimating a dropout rate of 10%, 494 patients will need to be included in the study. Present Accrual and Target Accrual: A total of 9 sites of 15 planned are activated. The first patient was enrolled on January 12, 2021, and as of June 24, 2022, a total of 113 patients have been accrued. The target goal of 494 patients is expected to be achieved by 2025 and initial study results will be reported by 2026. Funding: Brazilian Health Ministry, Programa Nacional de Apoio à Atenção Oncológica (PRONON), NUP 25000.183207/2019-50. Acknowledgements: CURA Project, SAS.

Background: The cyclin-dependent kinase 4/6 inhibitor palbociclib (PAL) is approved for the treatment of HR+/HER2– advanced breast cancer (ABC) in combination with an aromatase inhibitor (AI) as initial endocrine-based therapy or with fulvestrant (FUL) in patients whose disease progressed on prior endocrine therapy (ET). In clinical trials, the most common any-grade adverse event (AE) associated with PAL treatment was neutropenia. Here we evaluated the incidence of and risk factors for neutropenia by treatment cycle and line of therapy (LOT), as well as incidence of dose modification due to neutropenia, in patients with HR+/HER2– ABC receiving PAL in a real-world setting. **Methods:** POLARIS is a prospective, noninterventional, multicenter, real-world study of patients with HR+/HER2– ABC receiving PAL in routine clinical practice in the United States and Canada. Per protocol, sites were instructed to report absolute neutrophil count at baseline, anytime during the first 3 cycles, then at Day 1 (or before the start of a new cycle) of subsequent cycles per standard of care or as needed up to 6 months. The safety analysis set included all patients enrolled in the study who received at least one dose of study medication. **Results:** As of March 30, 2022, 1242 patients had enrolled in the study (median age, 64.0 years; 98.8% female; 94.8% stage IV; 39.1% visceral disease). Of these, 902 (72.6%) patients received PAL as first LOT and 340 (27.4%) as second LOT or greater. Among all patients, 722 received PAL + AI, 487 PAL + FUL, and 33 PAL + none or other ET (other than letrozole, anastrozole, fulvestrant, or exemestane); 90% of all patients started with 125 mg of PAL in the first cycle. Incidence of neutropenia among patients receiving PAL by cycle and LOT is shown in the Table. Percentages of patients experiencing on-treatment neutropenia were similar regardless of LOT. Over the course of treatment grade ≥ 3 neutropenia and febrile neutropenia were reported in 16.1% and 0.8% patients, respectively, and 19.2% of patients experienced a decreased neutrophil count. A total of 337 (27.1%) had a dose modification due to neutropenia. Of these 337 patients, 190 (56.4%) had a dose reduction associated with neutropenia. **Conclusions:** In this real-world study, incidences of treatment-related neutropenia associated with PAL were consistent with those reported in randomized clinical trials and were manageable by dose modification. Febrile neutropenia was uncommon. Incidences of neutropenia reported within the first 6 months were comparable among patients regardless of LOT. Further research is needed to understand the impact of the incidence of and risk factors for treatment-related neutropenia on therapy. **Clinical trial identification:** Pfizer; NCT03280303

Introduction Since the approval a decade ago of everolimus in combination with endocrine therapy (ET), the treatment landscape of metastatic breast cancer (mBC) has changed dramatically. Endocrine monotherapy after progression to CDK4/6 inhibitors has shown a limited progression-free survival (PFS) below 3 months. Evidence of the efficacy of everolimus plus ET after CDK4/6 inhibitors is scarce. **Methods** We performed a retrospective observational study of patients with mBC treated with everolimus between September 2011 and April 2022 in 4 Spanish hospitals. Clinical and demographic data were collected from medical records. Our main objective was to estimate the median progression-free survival (mPFS) for everolimus + ET in patients previously treated with a CDK4/6 inhibitor. We also collected the adverse events (AE) related to everolimus. Quantitative variables were summarized with medians (range), and qualitative variables with proportions. We used the Kaplan-Meier method for survival estimates. **Results** We identified a total of 297 mBC patients treated with everolimus plus ET. The median follow-up time was 20 months (interquartile range: 1 – 97 months). In this cohort, the median age at diagnosis was 49 years (26 – 84 years). At the moment of starting everolimus, the median number of previous lines of treatment was 2 (0 – 12), 22% of patients were 'de novo' metastatic, 67% presented visceral involvement, 40% had received previous chemotherapy for advanced disease, and 51% (n=152) had received a previous CDK4/6 inhibitor. The ET combined with everolimus was exemestane (77%), fulvestrant (18%), and tamoxifen (5%). 45% of patients were alive at data cut-off. In patients previously treated with a CDK4/6 inhibitor, the estimated median PFS (mPFS) was 5.9 months (95%CI: 5.0 – 7.8 months). In patients without visceral involvement (n=52), mPFS was 7.2 months (95%CI: 5.5 – 11.0 months), and 5.6 months (95%CI: 3.9 – 7.8 months) in the presence of visceral metastasis (n=100). In patients without previous chemotherapy in the metastatic setting (n=109), mPFS was 7.2 months

(95%CI: 5.9 – 8.4 months), and 4.6 months (95%CI: 3.1 – 5.7 months) for patients who had received previous chemotherapy (n=43). For patients without a previous CDK4/6 inhibitor (n=145), the median PFS was 8.3 months (95%CI: 6.4 – 10.3 months). Everolimus starting doses were 10 mg (83%), 5 mg (15%), and 7.5 mg (2%). Dexamethasone mouthwash was used by 44% of patients. The most frequent AE were mucositis (51%; 3% grade 3), anemia (41%; 3% grade 3), hyperglycemia (34%; 2% grade 3), rash (28%; 2% grade 3), pneumonitis (21%; 2% grade 3), and diarrhea (17%; 1% grade 3). There were no grade 4-5 adverse events. Dose reduction was made in 35% of patients, and in 16% of patients the treatment was discontinued due to toxicity. Conclusions In our cohort, the use of everolimus plus ET in mBC patients previously treated with a CDK4/6 inhibitor showed a clinically significant benefit in terms of PFS, especially in patients without visceral metastasis, and no previous chemotherapy for advanced disease. In this real-world study, the toxicity profile of everolimus was manageable.

Background:

Palbociclib (PAL) is a cyclin-dependent kinase 4/6 inhibitor indicated for the treatment of HR+/HER2– advanced breast cancer (ABC) in combination with an aromatase inhibitor (AI) as initial endocrine-based therapy or with fulvestrant (FUL) in patients whose disease progressed on prior endocrine therapy (ET). Neutropenia was the most commonly reported adverse event in clinical trials. Per the prescribing information for PAL, complete blood counts (CBCs) should be monitored before initiation of PAL (Cycle 1, Day 1 [C1D1]), at the beginning of each subsequent cycle, on Day 15 of the first 2 cycles, and as clinically indicated for at least the first 6 cycles.

Methods:

POLARIS is a prospective, observational, multicenter, real-world study of patients with HR+/HER2– ABC who received PAL as deemed appropriate by the treating physician. CBC collected at baseline, anytime during the first 3 cycles, then on Day 1 (or before the start of a new cycle) of subsequent cycles as per standard of care were recorded. We analyzed the frequency of laboratory monitoring for patients with HR+/HER2– ABC receiving PAL in routine clinical practice. Lab collections outside these windows were also obtained (data not shown).

Results:

At data cutoff (March 30, 2022), 1242 patients were treated with PAL + ET; 902 patients as first-line (1L) and 340 as second-line or later ($\geq 2L$) therapies for ABC; 90% of all patients received 125 mg of PAL in the first cycle. The frequency of laboratory collection, overall and by site category (academic vs. community), within the first 6 months of treatment is reported in the Table. CBC collection reported by investigators and analyzed within the defined window of day 1 of each cycle (C1–C6). Day 1 CBC collection was 87% at C1D1, 69.4% at C2D1, 66.5% at C3D1, 63.2% at C4D1, 61.4% at C5D1, to 59.9% at C6D1. Reports of CBC collection on Day 15 for the first two cycles was 37.3% (C1D15) and 31.2% (C2D15). CBC collection pattern was comparable across the community and academic sites.

Conclusions:

In this real-world CBC monitoring data set analyzed in a defined cycle window, most sites reported CBC collection prior to PAL initiation, and over two thirds of sites in the subsequent cycles. Day 15 of Cycles 1 and 2 monitoring was conducted in one third of the patients. These results suggest that CBC collections in real-world clinical practice are performed less frequently than in clinical trials, which may reflect the sites' desire to reduce patient and/or clinic procedural burden, and treating physician's familiarity with PAL safety profile and their comfort level of managing patients in clinical practice.

Clinical trial identification: Pfizer; NCT03280303

Background: CDK4/6 inhibition (CDK4/6i) with endocrine therapy (ET) is a standard first line treatment for individuals with HR+, HER2- metastatic breast cancer (MBC). The anti-proliferative effect of CDK4/6i may reverse upon discontinuation, and the role of continuing CDK4/6i after progression on a CDK4/6i with aromatase inhibitor (AI) is not known. We examine the clinical activity of palbociclib and fulvestrant after disease progression on palbociclib with AI in a phase II trial in individuals with HR+, HER2- MBC (NCT02738866).

Methods: We conducted a prospective, phase II, multicenter, open-label study of palbociclib with fulvestrant in patients with HR+ HER2- MBC with disease progression after at least 6 months of first line palbociclib and AI. Previous chemotherapy was allowed. Eligible participants received fulvestrant and continued on the same palbociclib dose. Premenopausal women received a concomitant GnRH agonist. We obtained a baseline tumor biopsy, when accessible, for correlative studies, and serial blood samples for ctDNA and circulating tumor cells (CTCs) analysis. Participants received disease assessment with imaging every 2 cycles (8 weeks) for the first year, followed by every 3 cycles (12 weeks) for participants who had been on study for >12 months. The primary endpoint was progression-free survival (PFS), estimated using the Kaplan Meier method. Other key endpoints included objective response rate (ORR) and clinical benefit rate (CBR) per RECIST v1.1 .

Results: As of June 1, 2022, a total of 58 of 60 participants were enrolled, with median age 57.9 (range 28.2-82.1 years). 17 patients (29%) were premenopausal. 41 (71%) of participants were white and 12 (21%) of participants were black/African American. Median PFS (mPFS) among the entire cohort was 3.7 months; among pre-menopausal patients, mPFS was 2.5 months and among post-menopausal patients, mPFS was 4.0 months). 22 (38%) of patients were on treatment for 6 or more months, with 11 (19%) of patients experiencing long term response beyond one year (Table 1). 13/58 (22%) of participants required further dose reductions of palbociclib after initiating fulvestrant despite previously being on a stable dose of palbociclib with an AI; no unexpected treatment-related toxicities were noted . Updated results for the entire 60 patient cohort will be presented at the meeting.

Conclusions: Second line ET with palbociclib and fulvestrant following palbociclib and AI resulted in limited overall PFS. However, 38% of participants remained on therapy for greater than 6 months, suggesting clinical benefit in a subset of participants. Correlative studies, including of tissue, serial ctDNA and CTCs, are ongoing to further characterize this subset.

Table 1: Preliminary efficacy of palbociclib and fulvestrant

	Baseline (C1, D1)	3 mo	6 mo	12 mo	18 mo	24 mo
On Treatment - no. (%)	58 (100%)	33 (57%)	22 (38%)	11 (19%)	5 (9%)	3 (5%)

Introduction: The development of resistance to endocrine treatment (HTH) can result from various biological mechanisms not only related to ER function but also to activation of multiple signaling pathways, which make HTH insufficient to control cancer cells. The combination of HTH with CDK4/6 inhibitors, which largely resemble phase-specific antiproliferative cytotoxic agents, demonstrated a striking clinical activity and became a standard treatment in ER+ breast cancer. Therefore, we have hypothesized that combining HTH (ER degraded) with metronomic polychemotherapy might improve clinical outcomes in advanced, endocrine-resistant ER+ breast cancer patients. Material and methods: The treatment (FulVEC) combined fulvestrant (500 mg i.m. d 1, 14, 28, and q4w thereafter) with a VEC regimen (vinorelbine 40 mg p.o. 3x/week, capecitabine 500 mg p.o. tid, cyclophosphamide 50 mg p.o. qd). After local ethical committee approval, this treatment was initially offered as a salvage therapy for advanced ER+ BC patients who exhausted available treatment options, and latter also for patients who refused or were ineligible for standard intravenous chemotherapy. All patients were previously treated with at least 1 line of palliative systemic therapy (47% received 3+ lines and 21% 5+ lines). Most (53%) have previously failed fulvestrant, and 34%, 32%, and 29% have previously failed palliative treatment with capecitabine, vinorelbine, and cyclophosphamide, respectively. Almost half of the patients (47%) received CDK4/6i previously. Most patients presented with bone (82%) and liver (66%) metastases. Three patients (8%) had OUN metastases, and 5% showed only locally advanced disease. Results: Between 2017-2022 – 38 patients (median age 49.1 years) received the FulVEC regimen, and all data was prospectively collected. In the ITT administration of FulVEC led to at least disease stabilization in 87% of patients and was associated with median PFS and OS of 8.5 months and 21.5 months, respectively. Previous treatment with capecitabine and vinorelbine was associated with non-significantly shorter PFS of 6.5 and 6.3 months, respectively. However, previous utilization with fulvestrant or cyclophosphamide had no impact on patient outcomes. Surprisingly, previous treatment with CDK4/6 inhibitors did not impact either PFS or OS (8.5 and 20.8 months, respectively). Patients

with liver metastases had a higher (non-significant) risk of progression or death compared to other locations of metastases. Three patients with symptomatic OUN metastases (2 with leptomeningeal dissemination) treated with FulVEC responded to the treatment with median PFS and OS of 11.6 and 25.8 months, respectively. FulVEC regimen was generally well tolerated with no toxicity-related treatment cessation and temporary treatment interruption in 18% of patients due to G3-4 myelotoxicity, mainly neutropenia. Dose reduction, required in 47% of patients, was due to myelotoxicity, capecitabine-induced hand-foot-syndrome, and cyclophosphamide-induced cystitis. Conclusion: Chemo-endocrine therapy (FulVEC) comprising fulvestrant and metronomic polychemotherapy demonstrated surprisingly high activity in pretreated, endocrine-refractory breast cancer patients. Besides its significant antitumor activity and good safety profile, one of the most critical aspects of this therapy is its cost. FulVEC regimen consists of old, widely available, and inexpensive drugs and thus costs at least a level of magnitude less than any novel, targeted therapies considered for advanced ER+ BC. FulVEC and similar affordable strategies are critical for patients from low and middle-income countries. The activity of FulVEC proves that combining chemo- and hormone therapy in a palliative setting cannot be assumed as a no-go strategy. A phase III trial comparing FulVEC with physician treatment of choice in advanced BC patients who failed first-line HTH+CDK4/6i is warranted.

Background: Approximately one third of HR-positive, metastatic BC patients receive CT as initial treatment. Longer duration of CT is associated with a better long-term outcome. However, the duration of CT is usually limited by toxicities and patients and physicians' preferences, resulting in treatment duration < 6 months. Replacing CT by maintenance endocrine treatment is an accepted treatment strategy in everyday clinical practice, but prospective data are lacking. Well tolerated maintenance treatments with the potential to prolong progression-free survival (PFS) and even overall survival (OS) are urgently needed. Methods: The AMICA trial (NCT03555877) is a multicenter, prospective, open-label phase II study to test the addition of the CDK4/6 inhibitor ribociclib to ET as maintenance therapy in patients with disease control after at least 4 cycles of 1st line mono- or poly-CT at investigator's discretion. Initially patients were randomized to receive ET +/- ribociclib. Due to slow accrual the study was amended after inclusion of 37 patients and all subsequent patients received ET+ribociclib. Treatment was given until disease progression, unacceptable toxicity, or withdrawal of consent. Maintenance ET could have already been started up to 6 weeks before enrolment. One previous line of ET including prior use of CDK4/6 inhibitor was allowed. The primary objective was to estimate the median PFS of patients treated with ET+ribociclib. Secondary objectives were median OS, safety, compliance, clinical benefit rate (CBR) and patient reported outcomes. The trial was closed prematurely due to slow recruitment. Results: Between March 2018 and December 2021, 56 patients were enrolled and started treatment (n=44 received ET+ribociclib, 12 ET alone). Median age of patients treated with ET+ribociclib was 60 years, 52.3% were overweight/obese, 88.6% were postmenopausal at study entry, 39.5% were M1 at primary diagnosis. Overall, 46.5% of the patients received letrozole, 14% anastrozole, 7.0% exemestane, 32.6% fulvestrant. A total of 10 (22.7%) patients in the ET+ribociclib arm had at least one serious adverse event, 2 at least one adverse event of special interest (N=1 hepatotoxicity, N=1 overdose). Conclusions: Results on the primary and secondary objectives will be presented at the meeting.

Background: Oncologists are often asked to provide information about expected survival times for patients with metastatic breast cancer (MBC). We have previously demonstrated that using estimates of best-case, typical and worst-case scenarios for survival to explain life expectancy conveys more meaning and hope than simply providing single point estimates of the median overall survival (OS). Our aim was to assess whether using simple multiples of the median could accurately assess scenarios for survival for patients with estrogen receptor (ER) positive, MBC starting endocrine therapy (ET) using simple multiples of the median. Methods: We systematically searched for randomised trials of ET for ER positive MBC. We then recorded the following percentiles (representative scenarios) from the OS curve of each trial using UN-SCAN-IT® graph digitising software: 90th (worst-case), 75th (lower-typical), 50th (median) 25th (upper-typical), and 10th (best-case). We assessed the accuracy of estimating these percentiles for each OS curve by multiplying the median OS by four simple multiples: 0.25 (to estimate the 90th percentile), 0.5 (75th), 2 (25th) and 3 (10th). Estimates were deemed accurate if within 0.75 -1.33 times the actual value. Results: We identified 24 trials with 10,068 patients. The median OS (interquartile range [IQR]) was: 61.3 months (53.4-64.8) for first-line ET with cyclin-dependant kinase 4/6 inhibitors (CDK4/6i) (4 treatment groups); 42.6 months (40.9-50.4) for first-line ET alone (23 treatment groups) and 29.2 months (24.8-33.4) for subsequent line ET (21 treatment groups). The median OS (IQR) for each scenario for first-line ET with CDK4/6i was: worst-case 17.4 months (13.8-20.7); lower-typical 32.5 months (29.3-34.9); upper-typical and best-case percentiles were not available. Simple multiples of the median OS accurately estimated the 90th percentile in 79%; 75th percentile in 93%; and 25th percentile in 76% of curves. The 10th percentile was only available for four OS curves and could not be accurately assessed. Conclusion: Using simple multiples of the median OS to estimate and explain survival times to patients with MBC starting ET, is accurate and meaningful. Longer follow-up of trials is required to help clinician's estimate the best-case scenario for these patients.

Background: Chidamide is an oral subtype-selective histone deacetylase inhibitor. The ACE study demonstrated that chidamide plus exemestane improved progression-free survival compared with placebo plus exemestane in patients (pts) with advanced, HR-positive, HER2-negative breast cancer that progressed after previous endocrine therapy. This phase 2 study aims to evaluate the efficacy and safety of chidamide plus fulvestrant in the treatment of HR-positive and HER2-negative advanced breast cancer that had progressed after previous endocrine therapy.

Methods: Eligible pts were women aged 18-75 years with histologically confirmed HR-positive, HER2-negative, advanced invasive breast cancer, whose disease relapsed or progressed after at least one endocrine therapy with or without a CDK4/6i (either in the advanced or metastatic or adjuvant setting). Eligible pts were treated with oral chidamide (30mg twice a week for 4 consecutive weeks in a 4-week cycle) plus intramuscular fulvestrant (500 mg intramuscular injection; on days 0, 14, 28, then every 28 days thereafter) till disease progression or intolerant toxicity. Premenopausal women received a concomitant GnRH analogue. The primary endpoint is progression-free survival (PFS) and the secondary endpoints include overall response rate (ORR), duration of response (DoR), disease control rate (DCR), overall survival (OS), and safety.

Results: Between Mar 8, 2021 and May 20, 2022, a total of 18 pts were enrolled. Median age was 53.5 years (range 45-67), 18 (100%) pts had ECOG PS 1, 16 (89%) had visceral disease, 14 (78%) pts had prior treatments with the median lines of 2, including 12 (86%) received endocrine treatment, and 11 (79%) received chemotherapy in the metastatic setting. At data cutoff (Jul 3, 2022), 8 (44.4%) pts were still receiving the drug regimen. The median PFS was 7.2 (95% CI, 5.83-8.49) months. In the 17 efficacy evaluable pts, the ORR was 17.6% (95% CI, 3.8%-43.4%), DCR was 88.2% (95% CI, 63.6%-98.5%). Treatment related adverse events (TRAEs) of any grade occurred in 18 (100%) pts, in which 4 (22.2%) were \geq grade 3. The most common grade 3 or 4 TRAEs (incidence \geq 10%) were leucopenia (22.2%), and neutropenia (22.2%). No treatment-related deaths occurred. The trial is ongoing.

Conclusions: Chidamide combined with fulvestrant showed encouraging antitumor activity and tolerable toxicity in pts with HR-positive and HER2-negative advanced breast cancer that had progressed after previous endocrine therapy. Clinical trial information: ChiCTR2100044282. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd and Shenzhen Chipscreen Biosciences Co., Ltd.

Introduction and objectives

Cyclin dependent kinase (CDK) 4/6 inhibitors along with endocrine therapy (ET) is the standard first-line for endocrine receptor (ER)-positive HER2-negative metastatic breast cancer. Three CDK 4/6 inhibitors have the FDA and EMA approval: abemaciclib, palbociclib and ribociclib. They appear to have notable differences in their pharmacokinetic characteristics and ability to inhibit every cyclin. Nevertheless, the natural history of disease associated with each CDK 4/6 inhibitor remains unclear. The aim of this study is to establish a risk prediction model for disease progression under the different therapeutic regimes and assess whether there are differences in terms of efficacy between them.

Methods

This is a retrospective observational study in which patients treated with ET plus abemaciclib,

palbociclib or ribociclib as front line for metastatic breast cancer in Virgen del Rocio Hospital between April 2014 and April 2021 were selected. Patients in this population were followed for a period of 36 months. They were studied according to their clinical characteristics and disease outcome using descriptive analysis. The risk of progression was studied by a transversal method using a univariate logistic regression model. Moreover, Kaplan Meier curves were used to estimate progression-free survival (PFS) and the Breslow test to estimate the p value. All statistical analyses were performed with SPSS 28.0 (Statistical Package for the Social Sciences).

Results

A total of 189 patients were selected. 55(29.1%) of them received abemaciclib, 83(44%) palbociclib and 51(27%) ribociclib. 50(27%) patients had de novo metastatic disease, while 139(73%) were recurrences of previous disease. Almost half of the patients (45%) received fulvestrant and 104 (55%) patients received aromatase inhibitors. Table 1 represents the proportion of patients with visceral involvement and endocrine resistance in each arm. The univariate logistic regression model showed that patients treated with palbociclib had 2.36(CI95% 1.165-4.765) times the risk of progression compared to abemaciclib, while patients treated with ribociclib had 2.50(CI95% 1.139-5.475) times the risk of progression compared to abemaciclib. Overall PFS was 30.03 months. A tendency towards best PFS with abemaciclib in comparison with the other CDK 4/6 inhibitors was appreciated, but it did not reach statistical significance (abemaciclib-palbociclib p=0.289; abemaciclib-ribociclib; p= 0.293; palbociclib-ribociclib p=0.979).

Conclusions

In our sample of patients with ER-positive HER2-negative metastatic breast cancer treated with the different CDK 4/6 inhibitors as front line therapy, patients with abemaciclib achieved a lower risk of progression and a trend toward longer PFS. Further follow-up will be necessary to determine whether abemaciclib provides greater benefit in PFS.

Table 1. Proportion of patients with visceral involvement and endocrine resistance in each arm.

		CDK 4/6 Inhibitors		
		Abemaciclib	Palbociclib	Ribociclib
Metastasis site (N= 189)	Non-visceral	22 (40%)	41 (49.4%)	21(41.2%)
	visceral	33 (60%)	42 (50.6%)	30 (58.8%)
Endocrine resistance (N =188)	Non-endocrine resistance	35 (63.6%)	51 (62.2%)	31 (60.8%)
	Endocrine resistance	20 (36.4%)	31 (37.8%)	20 (39.2%)

Visceral metastases: Liver, Lung, central nervous System; Non-Visceral: Bone, skin, Lymph node.

Background

CDK4/6 inhibitor in combination with an aromatase inhibitor (AI) or fulvestrant as initial endocrine therapy are standard of care for patients with HR+/HER2- advanced/metastatic breast cancer (mBC). This analysis describes treatment patterns including dosing patterns and time to subsequent treatment in patients receiving first line Palbociclib (PB)+AI therapy compared to AI alone, for HR+/HER2- mBC in the US routine clinical setting.

Methods

This was a retrospective analysis of Flatiron Health's nationwide longitudinal electronic health records from over 280 cancer clinics representing more than 3 million actively treated cancer patients in the US. Between February 2015 and March 2020, 2888 postmenopausal mBC women and men aged ≥ 18 years started first-line PB+AI or AI therapy. Patients were followed from start of therapy to September 2020, death, or last visit, whichever came first. PB treatment patterns were captured as starting dose and dose adjustments from medical records during the observation period. Comparative time to subsequent therapy (TTNT) or chemotherapy (TTC) was defined as length of time from the start of treatment to next line of anticancer therapy/chemotherapy, death from any cause, last visit, or end of study, whichever came first. Cox proportional-hazards models were used to estimate the relative effectiveness of PB+AI vs AI. Stabilized inverse probability treatment weighting (sIPTW) and propensity score matching

(PSM) statistical methods were used to balance of baseline demographics and clinical characteristics.

Results

Of the 2888 eligible pts (1324 with PB+AI and 1564 with AI), median age was 70.0 years, 67.8% were white, 34.8% had de novo mBC, 29.4% had lung or liver involvement, 38.7% had bone-only disease. Median follow-up was 25.0 months in the PB+AI arm and 23.3 months in the AI alone arm. Of the 1342 patients receiving PB, therapy was started at 125 mg, 100 mg, and 75 mg/day in 83.8%, 10.9%, 3.6%, respectively (1.7% undocumented PB dose) with dose changes in 41.1%, 36.8%, 31.3% of patients in each starting dose category with dosing information. After sIPTW median TTNT was 18.4 months (95%CI: 16.3-20.3) in the PB +AI group and 8.3 months (95%CI: 7.2-10.0) in the AI group; HR=0.56 (95%CI: 0.51-0.62), p< 0.0001. After sIPTW median TTC was 37.4 months (95%CI: 33.7-40.7) PB+AI group and 29.2 months (95%CI: 26.8-33.5) in the AI group; HR=0.77 (95%CI: 0.69-0.86), p< 0.0001. Results for the PSM analyses were similar. The table presents full results in detail.

Conclusions

These treatment patterns analyses in a heterogeneous mBC patients from real world US clinical practice, provide support for first line PB+AI treatment for HR+/HER2- mBC. The majority of patients initiated therapy at the 125 mg/daily dose (84%). Importantly, these analyses also report meaningful differences in the delay to next line of therapy and chemotherapy in the PB+AI compared to AI therapy arm.

Table. Median time to next line of therapy or chemotherapy

Variable	PB+AI (N=1324)	AI alone (N=1564)	HR
Months duration of follow-up, Median, 95% CI	25.0	23.3	--
Months TTNT, Median, 95%CI (unadjusted)	19.3 (95%CI 16.8-21.1)	8.2 (95%CI 7.1-9.8)	0.55 (95%CI 0.50-0.60) p<0.0001
Months TTNT, Median, 95%CI (sIPTW)	18.4 (95%CI 16.3-20.3)	8.3 (95%CI 7.2-10.0)	0.56 (95%CI 0.51-0.62) p<0.0001
Months TTNT, Median, 95%CI (PSM)	19.8 (95%CI 16.8-21.6)	9.8 (95% CI 15.8-21.6)	0.56 (95%CI 0.50-0.63) p<0.0001
Months TTC, Median, 95%CI (unadjusted)	38.1 (95%CI 35.0-41.1)	28.1 (95%CI 25.5-30.9)	0.74 (95%CI 0.66-0.82) p<0.0001
Months TTC, Median, 95%CI (sIPTW)	37.4 (95%CI 33.7-40.7)	29.2 (95%CI 26.8-33.5)	0.77 (95%CI 0.69-0.86) p<0.0001
Months TTC, Median, 95%CI (PSM)	37.8 (95%CI 33.7-41.3)	30.7 (95%CI 27.2-35.7)	0.78 (95%CI 0.68-0.89) p=0.0002

Background

Randomized clinical trials and a growing body of real-world evidence have demonstrated clinical benefit of cyclin dependent kinase 4/6 inhibitors (CDK4/6i) in combination with endocrine therapy for HR+/HER2- (MBC). In the National Comprehensive Cancer Network (NCCN) guidelines, CDK4/6i + AI or Fulvestrant is recognized as a preferred regimen for HR+/HER2- MBC. Disparities in survival and clinical outcomes between AA and white breast cancer patients are well documented, but AA patients were not well represented in CDK4/6i randomized clinical trials. We compared real-world progression free survival (rwPFS) and overall survival (OS) of palbociclib plus AI (PB+AI) vs AI alone in AA patients with HR+/HER2- MBC in US clinical practices.

Methods

The Flatiron Health longitudinal database contains electronic health records from >280 cancer clinics representing > 2.4 million actively treated cancer patients in the US. We conducted a retrospective analysis of 270 AA patients from the Flatiron database with HR+/HER2- MBC who started PB+AI or AI as first-line therapy between February 2015 and March 2020, Patients were evaluated from start of PB+AI or AI to September 30, 2020 (Data cutoff date), death, or last visit, whichever came first. OS was defined as months from start of PB+AI or AI to death. Patients were censored at the end of the study if they were living. rwPFS was defined as months from start of PB+AI or AI to death or disease progression, evaluated based on clinical assessment or radiographic scan/tissue biopsy. Cox proportional-hazards models were used to estimate the relative effectiveness of PB+AI vs AI without and with adjustment of baseline

demographics and clinical characteristics.

Results

Of the 270 eligible patients, 127 (47.0%) were treated with PB+AI and 143 (53.0%) were treated with AI. Median age was 64.0 years in PB+AI patients and 68.0 years in AI patients, respectively. Median follow-up was 24.0 months for PB+AI and 18.2 months for AI treated patients. Compared with AI patients, those treated with PB+AI were more likely to have de novo MBC (48.6% vs 30.8%) and to have ≥ 2 metastatic sites (41.7% vs 29.4%). Of the PB+AI patients, 82.7% started PB at 125mg/day and 30.7% experienced dose adjustment. Median OS was not reached (NR, 95%CI=(38.2-NR)) in PB+AI patients vs 28.2 months (95%CI=19.2-52.8) in AI patients (HR=0.46, 95%CI=0.31-0.68, $p < 0.001$; adjusted HR=0.56, 95%CI=0.36-0.89, $p=0.013$). Median rwPFS was 18.0 months (95%CI = 12.4 – 26.7) in PB+AI patients and 10.5 months (95%CI=7.0-13.4) in AI patients (HR=0.63, 95%CI=0.44-0.88, $p < 0.007$; Adjusted HR=0.74, 95%CI=0.47-1.17, $p =0.199$).

Conclusions

This comparative analysis of palbociclib plus AI vs AI alone provides evidence that first-line palbociclib in combination with endocrine is associated with improved effectiveness for AA patients with HR+/HER2- MBC in the real-world setting. Additional studies with larger cohorts are needed to provide additional evidence of outcomes and safety for AA patients in routine clinical practice.

Table. Patient characteristics and effectiveness outcomes

Introduction Cancer during pregnancy is uncommon but the incidence is increasing, particularly in breast cancer, the most common tumor diagnosed in this scenario. The treatment decision in pregnant patients with triple-negative breast cancer is challenging, even more so in cases with advanced disease. Clinical case A 36-year-old woman was referred to our hospital in January, 2020 with the diagnosis of an early (T2N0M0, stage IIA) invasive carcinoma of no special type triple-negative tumor on the left breast and germinative CHEK2 mutation. She received neoadjuvant treatment with four cycles of ACdd followed by nine weeks of paclitaxel and carboplatin, interrupted for local disease progression. The patient underwent a nipple-sparing mastectomy plus sentinel lymph node biopsy without complications. The pathology report showed gross residual disease, so we decided on adjuvant treatment with radiotherapy followed by capecitabine. Twelve months after the end of the treatment, she received the diagnosis of second-trimester pregnancy but also presented suspicion of pulmonary, nodal, and liver relapse. The liver biopsy confirmed triple-negative histology with CPS > 10. The first-line chemotherapy was liposomal doxorubicin, which showed hepatic disease progression after two cycles. As second-line, we started carboplatin, gemcitabine, and pembrolizumab. The radiologic evaluation after two cycles showed a partial response in the lung and liver, with the patient presenting excellent tolerability without fetal complications. The treatment plan is to wait until the term for delivery and continue treatment until progression or toxicity. Conclusion We report the first stage IV triple-negative breast cancer case in a pregnant patient treated with chemotherapy plus immunotherapy. This case indicates that the treatment is feasible and should be considered in this scenario.

Real-World Time-to-Treatment Discontinuation in Hormone-Receptor-Positive Metastatic Breast Cancer Patients following CDK4/6 Inhibitor Treatment, Based on Observational Data Collected Through Patient-Partnered Research

Presenting Author(s) and Co-Author(s):

Background: Cancer treatment decisions are often made without specific and representative information that can inform personalized treatment. The aim of this study was to determine if we can predict, based on clinical features, which treatment regimen may maximize real-world time-to-treatment discontinuation (rwTTD) after a hormone-receptor-positive (HR+) metastatic breast cancer (MBC) patient stops responding to a first CDK4/6 inhibitor in any line.

Methods: We used patient reported data (PRD) about diagnosis and treatment and medical records from 1,777 patients across the U.S. and Canada from Count Me In's Metastatic Breast Cancer Project (MBCproject). We interviewed 17 people, academic and community based medical oncologists and MBC patients, to inform the analysis plan. Patient eligibility criteria were prior HR+ MBC diagnosis, received exactly one prior CDK4/6 inhibitor (CDK4/6) containing regimen, start date of any subsequent regimen within four months of the end date of the CDK4/6-containing regimen, and completion of MBCproject's follow-up questionnaire at least one month after the start date of the subsequent regimen. We processed RWD from the follow-up questionnaire, performed chart review in ambiguous cases of patient eligibility, performed conformance, completeness, and plausibility verification checks to determine the dataset's fit-for-use, and described treatment variation seen in real-world settings. We designed a new user, active-comparator cohort study with rwTTD as the continuous outcome measure, used known and hypothesized confounders to control for treatment-by-indication bias, assessed covariate balance across cohorts, and conducted Cox proportional hazards (PH) outcome regressions to identify clinically relevant associations and estimate treatment effects across regimens. The analysis plan was publicly registered with the Center for Open Science prior to performing the analysis.

Results: 261 eligible HR+ MBC patients were identified, with 110 unique pairs of CDK4/6-containing and subsequent regimens. The most common CDK4/6-containing regimen was

Letrozole and Palbociclib (n=98) and subsequent regimen was Capecitabine (n=63). Three mutually exclusive and clinically relevant groupings of subsequent regimens chosen for analysis were chemotherapy only (n=99), fulvestrant-containing (n=53), and everolimus-containing (n=42). Among patients in these three groups, 93.9%+ are white race, 95%+ are non-hispanic, 2.7-9.4% live in a medically underserved area, 7.1-13.1% have HR+/HER2+ MBC, mean age at subsequent treatment was 52.6-53.8 years, 17-36% had bone-only metastasis and 14.3-25.3% had liver metastasis at MBC diagnosis, median number of past treatment regimens was one, and median time on CDK4/6-containing regimen was 9-14 months. The median rwTTD was 9, 15, and 5 months in the three groups, respectively. Out of 11 covariates, nine covariates failed to reject the null hypothesis that the distribution of values are the same across the three cohorts ($p>0.05$). Outcome regression Cox PH revealed rwTTD hazard ratio (HR) of 2.52 [1.53-4.15; 95% confidence interval (CI)] for presence of liver metastasis, HR of 1.09 [0.63-1.89; 95% CI] for presence of bone-only metastasis, HR of 2.00 [1.20-3.33; 95% CI] for everolimus-containing regimen vs. chemotherapy only, HR of 0.85 [0.50-1.46; 95% CI] for fulvestrant-containing regimen vs. chemotherapy only, and HR of 0.82 [0.65-1.00; 95% CI] for every six months rwTTD on previous CDK4/6-containing regimen.

Conclusion: In this cohort, chemotherapy was the most common treatment regimen following CDK4/6 even in second and third line settings and in patients with bone-only metastasis, which is a deviation from guideline-based treatment for many HR+ MBC patients. PRD helps develop hypotheses about patient response to treatment following CDK4/6 that can be further evaluated in larger, more diverse observational studies and clinical trials.

Table 1. Characteristics of eligible patients who received chemotherapy only, everolimus containing, or fulvestrant containing regimens.

Background: Metastatic TNBC is an aggressive breast cancer subtype with poor prognosis and limited systemic therapy options. While pembrolizumab in combination with chemotherapy is approved for PD-L1 positive TNBC, limited immunotherapy options exist for patients with progressive and/or PD-L1 negative disease. TGF β released by cancer cells and stromal fibroblasts attenuates the intrinsic antitumor potential of immune cells within the tumor microenvironment mediating resistance to immunotherapy. Consequently, inhibition of TGF β signaling could potentially enhance antitumor responses to anti-PD-L1/PD-1 therapies. Bintrafusp alfa is a bifunctional fusion protein composed of the extracellular domain of TGF- β receptor II (a TGF- β "trap") fused to a human IgG1 monoclonal antibody blocking programmed cell death ligand 1. Preclinical studies have shown that eribulin downregulates TGF β by phosphorylation of Smad proteins. Therefore, combining eribulin with bintrafusp alfa may have a synergistic effect. This study evaluated the combination of bintrafusp alfa with eribulin in patients with metastatic TNBC. Methods: This is a phase 1b, open label, single center study evaluating bintrafusp alfa in combination with eribulin in patients with metastatic TNBC who had relapsed/progressed on prior therapies. Patients with ER/PR \leq 10% with measurable disease were enrolled. Patients who received prior anti-PD-1/PD-L1 therapies in the metastatic setting were excluded. Patients received bintrafusp alfa 1200 mg intravenously every 2 weeks in combination with eribulin (1.4 mg/m² (dose level 1), 1.1 mg/m², or 0.7 mg/m²) on days 1, 8, 22, 29 on every 6-week cycle. Primary objectives were to determine the recommended phase II dose (RP2D) as well as to evaluate the safety and tolerability of eribulin in combination with the fixed dose of bintrafusp alfa. Secondary objective was to determine the overall response rate (ORR) according to RECIST 1.1. Bayesian optimal interval (BOIN) design was employed to identify the RP2D. Toxicities assessed using CTCAE v4.03. Tumor assessments were performed every 6 weeks. Results: A total of 25 patients were enrolled on the study. Twenty-one patients were evaluable (3 screen failures, 1 received only one dose of study treatment). Median age 59 (range 27-85). Median number of prior therapies 2 (range 0-8). The most common reason for protocol discontinuation was disease progression (n = 15, 71%). Four patients experienced dose limiting toxicities (DLTs); 3 with decreased neutrophil count and 1 with increased aspartate aminotransferase. Five patients (24%) experienced grade 4 toxicities (increased aspartate aminotransferase, hypokalemia, hypophosphatemia, neutropenia). Nine patients (43%) experienced grade 3 toxicities. Three patients (14%) discontinued study due to toxicity. Total of 2 deaths were observed, none related to treatment. Most common toxicities (any grade) include anemia (n = 13 patients), elevated aspartate aminotransferase (11), neutropenia (n = 10), elevated aminotransferase (9), headache (n = 9), hypokalemia (n = 8), hyperglycemia (n = 8), leukopenia (n = 8), and fatigue (n = 8). RP2D was eribulin 1.1 mg/m² with bintrafusp alfa 1200 mg. Six patients had PR (28.6%), 2 had SD (9.5%) and 12 had PD (57.1%) as the best response. One patient withdrew before response evaluation. Median PFS was 1.7 months (95% CI: (1.2, 5.9) and median OS was 11.1 months (95%CI: (5.2, 15.7). Conclusions: The combination of bintrafusp alfa with eribulin has manageable safety profile with meaningful clinical activity in patients with TNBC. Further studies evaluating TGF β inhibitors in breast cancer are warranted.

Accumulating physical and hematologic toxicities make the indefinite use of chemotherapy unfeasible for many patients with metastatic/recurrent HER2- IBC or TNBC. Whether maintenance immunotherapy has a role in the treatment of these patients is unclear. We conducted a single-arm phase II trial of pembrolizumab monotherapy in patients with metastatic/recurrent HER2- IBC or TNBC (regardless of their PD-L1 expression status) and report here the clinical data from this trial. Methods: Eligible patients were enrolled between 2015 and 2022 and had had a CR, a PR, or SD after a minimum of 3 cycles of chemotherapy for metastatic/recurrent disease. PD-L1 expression status was not used to determine eligibility. Patients received 200 mg of pembrolizumab every 3 weeks (q3w) until disease progression, intolerable toxicity, or 2 years. In late 2021, the study was amended to allow patients who had received ≥ 8 cycles of q3w therapy to transition to q6w dosing (400 mg), based on the FDA's approval of both dosing regimens across all indications. The primary endpoint was the 4-month disease control rate (DCR); exploratory endpoints included safety and correlative biomarkers from tissue and blood to ascertain associations between clinical response and PD-L1 expression, T-cell clonality, and immune profiling. Results: Of 43 patients (median age, 54 years; range, 34-77 years), 11 had IBC (10 with triple-negative IBC and 1 with ER+ HER2-

IBC), and 32 had TNBC. The 4-month DCR was 58.1% (95% CI: 43.4%-72.9%). During a median follow-up of 11.4 months, 25 patients died. The entire cohort's median OS and PFS times were 26.0 months (95% CI: 11.0-33.5 months) and 4.8 months (95% CI: 3.0-7.1 months), respectively. The median OS times of the IBC and TNBC groups did not differ significantly, nor did those of the CR, PR, and SD groups. The median PFS times of the IBC group (2.2 months) and TNBC group (4.8 months) did not differ significantly ($p = .12$), but those of the CR, PR, and SD groups did (not reached, 10.3 months, and 3.4 months, respectively; $p = .01$). Among the 37 patients who are off study treatment, most patients (84%; $n=31/37$) discontinued treatment owing to disease progression rather than toxicities ($n=2$), and the toxicities overall were consistent with the known profile of single-agent anti-PD1. Five patients had grade 3 events; there were no grade 4 or 5 events. Three patients had irreversible endocrinopathies (thyroiditis and adrenal insufficiency) requiring hormone replacement, but only 1 patient discontinued pembrolizumab because of these events. One patient discontinued treatment because of optic neuritis requiring steroids. Four patients completed 2 years of treatment without disease progression. Conclusions: Pembrolizumab maintenance therapy achieves acceptable disease control after induction chemotherapy. The PFS in this trial compares favorably to the expected durations of response to later lines of therapy. The toxicity profile of pembrolizumab compares favorably with those of chemotherapy and ADCs, which may provide a rationale for the use of ICIs in this setting. However, whether pembrolizumab maintenance therapy is helpful in TNBC patients who have received concurrent pembrolizumab with neoadjuvant chemotherapy is unknown, as these patients were excluded from the trial. Acknowledgements: This trial was supported by Merck.

BACKGROUND: Metastatic breast cancer (MBC) is incurable, with the primary goal of treatment being to extend survival while preserving quality of life. Treatment options available to patients (pts) with human epidermal growth factor receptor-2 positive breast cancer (HER2+ BC) may vary between countries, in terms of both the drugs used and the sequence in which they are used. There is limited data available on the clinical characteristics and outcomes in pts with unresectable locally advanced (LA) BC. This study aimed to capture real-world data on treatment patterns and clinical outcomes in HER2+ unresectable LABC and MBC.

METHODS: SAMANTHA (NCT02913456) is an ongoing, prospective, multicentre non-interventional study designed to observe pts with HER2+ unresectable LABC or MBC for a period of up to 8 years on study. The primary objectives are progression-free survival (PFS), assessed according to standard medical practice, and the treatment received. Secondary objectives included overall survival (OS), duration of response and safety. This pre-planned interim analysis reports baseline characteristics, treatment regimens received, first-line (1L) PFS by advanced BC status and the incidence of adverse events (AEs).

RESULTS: The study enrolled 647 pts from five European (EU) countries (Nov 2016-Nov 2019); 629 received 1L treatment and were included in data analysis. At data cut-off date (16 Nov 2021), median follow-up on study was 30.4 months (mo; range: 0.1; 60.0); 342 (54%) pts discontinued 1L treatments, of whom 170 (50%) pts received 2L treatments, 74 pts died, 49 pts were lost to follow-up, 35 pts withdrew consent and 14 pts withdrew due to physician decision. The full analysis set (FAS) included 222 (35%) LABC pts and 407 (65%) MBC pts [Table]. Pertuzumab/trastuzumab based regimens were given as 1L in the majority of pts [462 (73 %)]. The FAS Median (m) PFS in 1L was 41.3 mo (95% CI: 36.1, 54.1) for LABC and 23.5 mo (95% CI: 20.6, 27.6) for MBC. Median OS was not reached. In the FAS, any AEs were reported in 352 (56%) pts; of these 212 (34%) had a grade 3 or higher AE. Serious (S) AEs were reported in 135 (22%) pts; of whom, 36 (6%) pts had treatment related SAEs.

CONCLUSIONS: This interim analysis of SAMANTHA provides a snapshot of LABC/MBC treatment practices in five EU countries, where pertuzumab/trastuzumab based regimens appear to be the most used 1L treatment options, which aligns with the recommended standard of care. The mPFS is consistent with previous literature although higher than what was reported in the pivotal clinical trial CLEOPATRA. Given the good outcome observed in 1L and the current follow-up period of 30.4 mo, the data are not yet mature enough to provide complete insights into the treatment sequencing patterns and the clinical outcomes associated with these treatments.

Acknowledgments: The study is sponsored by F. Hoffmann-La Roche Ltd.

Background: Although HER2 is an aggressive subtype of BC, the outcomes have improved over the past two decades due to advances in targeted therapies. Here, we present data of HER2-positive subset from the multicenter registry study of the Turkish Oncology Group (TOG) for metastatic breast cancer with an evolving treatment landscape for over a decade (MBC). Methods: The study of TOG for MBC was a retrospective registry study aimed to collect the data of adult metastatic BC patients diagnosed between 2010-2019, at seven tertiary oncology clinics in Turkey. Patient and disease characteristics were recorded from chart reviews. HER2 (+) was defined as IHC scores of IHC3+ or IHC2+ and ISH (+). Overall survival (OS) and progression-free survival (PFS) were calculated by the Kaplan-Meier method. Correlations between demographic, prognostic variables and survival outcomes were carried out in database aggregates comprising of cohorts based on disease presentation (recurrent vs de-novo) and the diagnosis date of MBC (Cohort I: patient diagnosed between January 2010-December 2014 and Cohort II: between January 2015-December 2019). Results: Of the 1381 patients analyzed over the whole period, 333 (24.1%) HER2 (+) MBC patients were identified. 55.0% of the patients were in Cohort I. The majority (56.8%) had de novo MBC. Despite a decreasing frequency over time (63.4% in Cohort I vs 48.7% in Cohort II, $p=0.007$), this was the largest group with among all pathological subgroups presenting with de novo disease. 17 patients (2.4% of recurrent patients) demonstrated changes in HER2 receptor status from negative to positive between the primary tumor and subsequent metastasis. Recurrent BC patients were significantly younger than de novo MBC patients [44 (22-80) years vs 49 (20-91) years, $p=0.006$] and 43.1% ($n=62$) had relapsed within two years from initial diagnosis. Recurrent BC patients showed a higher frequency of brain metastasis as compared to de novo patients (13.2% vs 1.1%), whereas non-CNS visceral organ metastases were more common in de novo MBC patients (58.7% vs 47.9%, respectively, $p<0.001$). Following conditional approval of use in de novo visceral metastatic disease in 2016, dual-HER2 blockade including pertuzumab was more frequently used in Cohort II compared to Cohort I ($p<0.001$). Although overall median PFS was not statistically significant between the two cohorts (Cohort II vs I; 22 vs 17 months, respectively, $p=0.609$), there was a significantly higher PFS in the de novo group in Cohort II (29 vs 17 months, $p=0.037$). Furthermore, there was a significant improvement in median OS in Cohort II compared to Cohort I [not reached vs 48.0 (40.0-71.0) months, respectively; $p=0.017$]; mainly driven by the de novo group in alignment with the approval indication for dual blockade (Cohort I vs II; 3-year OS; 62.0% vs 84.7%; $p=0.009$); especially those with visceral metastatic presentation (59.4% vs 83.4%, $p=0.020$); HR (+) HER2 (+) disease (61.2% vs 89.2%; $p=0.013$) and age < 40 years (40.0% vs 94.7%; $p=0.009$). Conclusion: There was a significant survival benefit achieved in patients with metastatic HER2 (+) disease over time, regardless of high-risk factors such as visceral involvement or young age, mirroring advances in the timeline of anti-HER2 treatment.

Background Fulvestrant have demonstrated synergistic antitumor effect with chemotherapy regimen. This study evaluates the efficacy and safety of Fulvestrant with Vinorelbine in patients with hormone receptor positive (HR+)/ human epidermal growth factor receptor-2-negative (HER2-) recurrent or metastatic breast cancer. Methods In this prospective, single-arm and investigator-initiated clinical study, patients with recurrent or metastatic HR+/HER2- breast cancer after the first line adjuvant endocrine therapy for > 1 year were eligible, in which the subjects of the first line was defined as the patients with recurrence and metastasis after adjuvant endocrine therapy for over 1 year and did not receive treatment for the recurrence and metastasis and the second-line defined as the patients who had disease progression after receiving first-line endocrine therapy or first-line chemotherapy). Patients were administered i.m. Fulvestrant 500mg (day 1 per cycle for 28 days) and oral Vinorelbine (60 mg/m² on day 1, 8 and 15 of each cycle). The primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS), objective response rate (ORR), disease control rate (DCR), duration of response (DoR), and safety. The Kaplan–Meier method and log-rank test were used to evaluate PFS and OS. Results Total 38 HR+/HER2- advanced breast cancer patients with median follow-up time (25.1 months) were enrolled in, and median PFS [9.86 months (95% CI: 7.2, 23.13)] were discovered. The median PFS of the first-line and the second-line treatment population were 20.73 months (95% CI: 9.82, NR) and 4.27 months

(95% CI: 3.68, NR), respectively. The median OS of the intent-to-treat (ITT) and the first-line treatment population were not reached, and the OS of the second-line treatment was 28.2 months (95% CI: 11.5, NR). The ORR of the ITT population was 39.47% (95% CI: 23.93, 55.01). The ORR of the patients receiving first-line and second-line treatments were 44.44% (95% CI: 25.70, 63.19) and 27.27% (95% CI: 0.95, 53.59), respectively. The DCR of ITT population was 92.11% (95% CI: 83.54, 100.00)], and the median DoR was approximately 15.33 months (95% CI: 7.23, 22.54)]. In the safety analysis, most of the adverse events were grade of 1/2, and none of grade 4/5 adverse events were reported. Conclusion This is the first exploratory study of Fulvestrant with oral Vinorelbine regimen in the treatment of HR+/HER2– recurrent and metastatic breast cancer conducted worldwide. The combinative chemo-endocrine therapy was efficacious, safe and promising for patients with HR+/HER2– advanced breast cancer.

The impact of the COVID19 pandemic on treatment practices for patients diagnosed with early breast cancer: a cross-sectional study from a large comprehensive cancer centre in Italy.

Introduction

The Coronavirus Disease 2019 (COVID19) has disrupted health services worldwide. The evidence on the impact of the pandemic on cancer care provision, however, is conflicting. Some reports found that management for patients diagnosed with early breast cancer (EBC) during the pandemic did not differ from pre-pandemic practices; other reports suggested that delays in breast cancer surgery may have occurred. We aimed to audit the management of patients diagnosed with EBC during the pandemic in a large, tertiary-level cancer centre in Italy.

Methods

We conducted a cross-sectional study to track the route to first treatment for patients diagnosed with EBC during 2019, 2020, and 2021. We abstracted data for all consecutive patients referred to the Veneto Institute of Oncology (Padua, Italy). We defined as point of contact (POC) the

date of the first consultation with a breast cancer specialist of the breast unit. We considered patients with a first POC in the 6 months preceding the multidisciplinary (MDT) meeting and initiating a treatment within 6 months from the POC. We chose the 3-month period April-June because in 2020 it was when health services were first acutely disrupted. We analysed the same period for 2019 and 2021. First treatment was defined as either upfront surgery or neoadjuvant chemotherapy (NACT). The time to first treatment was defined as the interval between the first POC and the first treatment. We used the median time to first treatment in 2019 to define the threshold for treatment delay.

Results

We reviewed medical records for 878 patients for whom an MDT report during 2019-2021 (April through June) was available. Of these, 431 (49%) were eligible: 144 in 2019, 127 in 2020 and 150 in 2021. Median age at first POC was 61 years. The proportion of screen-detected tumours was larger in 2019 and 2021 than in 2020 (59%). Conversely, the proportion of screen-detected tumours was offset by the proportion of palpable tumours in 2020 (44% versus 56%). These differences were statistically significant (chi-square test 11.12, $p=0.004$). Distribution of tumour and nodal stage was unchanged over time, but in-situ tumours were slightly fewer in 2020 than in 2019 or 2021. The odds ratio for treatment delay (45 days or more) was 0.87 for 2020 versus 2019 (95% CI, 0.5-1.53) and 0.9 for 2021 versus 2019 (95% CI, 0.52-1.55), after adjusting for type of POC, presentation with symptoms, treatment type, tumour stage, nodal stage, and EBC subtype (i.e., luminal, HER2-positive, triple-negative).

Conclusions

There was no evidence for major changes in the management of EBC patients during 2019-2021 and no treatment delays were observed. However, our results show a slight decrease in the absolute number of patients being treated in 2020, offset by an increase in 2021 to levels comparable to 2019. Our findings suggest that disruption of breast cancer screening programmes may have impacted on the characteristics of the patient population, with a larger proportion of women presenting with palpable nodules. Validation on a larger, population-based cohort of patients is warranted to robustly assess the impact of the COVID19 pandemic on treatment practices and outcome for EBC patients.

Characteristics of the population

	Apr-Jun 2019	Apr-Jun 2020	Apr-Jun 2021
Number of patients	144	127	150
Age (median)	60	63	63
Presentation			p=0.004
With symptoms	85 (59)*	56 (44)	95 (63)
Without symptoms	59 (41)	71 (56)	55 (37)
POC type			p=0.153
Breast radiologist	51 (35)	29 (23)	55 (37)
Breast surgeon	88 (61)	92 (72)	87 (58)

Can artificial intelligence derived ultrasound breast density provide comparable breast cancer risk estimates to density derived from mammograms Dustin Valdez^{1,2}, Arianna Bunnell², Thomas Wolfgruber¹, Aleen V. Altamirano³, Brandon Quon¹, Gertraud Maskarinec¹, Peter Sadowski², John A. Shepherd¹ ¹ University of Hawaii Cancer Center, Honolulu, HI ² University of Hawaii at Manoa, Honolulu, HI ³ Instituto Radiodiagnóstico, Managua, Nicaragua
Background: Breast cancer is the second leading cause of cancer-related death among women in Hawaii and the Pacific. However, while there are programs like the Breast and Cervical Cancer Early Detection Program (BCCEDP) implemented throughout the Pacific, the lack of access to mammography screening and low screening participation rates contributes to very high advanced breast cancer rates in most cases over 50%. Portable breast ultrasound is a promising screening technology for low resource areas. However, without mammography, mammographic density is not available for risk modeling to determine who should participate in screening programs or at what frequency. In this study, we ask if breast ultrasound (US) images can be used to derive an equivalent mammographic density for risk modeling. We utilized artificial intelligence to derive breast density from diagnostic ultrasound images and compared to BI-RADS mammographic density in an established breast cancer risk model¹.
Methods: We selected women with negative screening visit who either later developed cancer (positives) or did not (negatives) over a 10-year period. Temporally-matched negative mammographic and ultrasound images, cancer outcome status and cancer risk information were sourced from the Hawaii and Pacific Islands Mammography Registry. US images had to have occurred within a year of the mammogram. BI-RADS mammographic density was derived using an existing deep neural network model². Mammographic density was estimated from US images by training a deep-learning convolutional neural network model. A hold out set of images (Test set of 20% of the total) was used to compare 10-year breast cancer risk using the

Tyrer-Cuzick (TC) risk model¹ when calculated using breast density from either mammograms or US. The AUC values, confidence intervals, ROC plots and Pearson correlation were calculated and compared. Results: Over the 10-year study period, 1337 had matched mammograms and US images and 65 went on to develop breast cancer. Using the test set, the Pearson's correlation between breast density from mammography and US was 0.31 (moderate correlation). There were no covariates found to improve this association. The AUC for TC 10-year personal risk was higher when breast density from mammograms was used 0.71 (95% CI=0.57-0.86) versus US images 0.65 (95% CI=0.53-0.76). Conclusion: Overall breast cancer risk was similar when breast density was derived from either mammograms or US. The performance of our US breast density model is expected to improve further when more US training data becomes available. Breast cancer screening programs exclusively using US imaging may be able to provide equivalent risk modeling to clinics using mammography.

Risk factors associated with chemotherapy-induced nausea and vomiting among breast cancer patients receiving highly emetogenic chemotherapy

Purpose: Although risk factors related to chemotherapy-induced nausea and vomiting (CINV) have been identified by prior studies, there are only few studies evaluating risk factors associated with the contemporary antiemetic prophylaxis, including that of olanzapine/aprepitant- or NEPA- containing regimens. The present study aimed to identify the risk factors related to CINV development in Chinese breast cancer patients receiving doxorubicin and cyclophosphamide chemotherapy. Methods: Data from 304 patients who were enrolled to 3 previously reported prospective antiemetic studies were included. Multivariate logistic regression models were used to predict risk factors associated with the occurrence of CINV. Additionally, likelihood of treatment failure in relation to number of risk factors of individual patient was evaluated. Results: Multivariate analysis of the entire study group revealed that obese status (defined as body mass index ≥ 25.0 kg/m²) and the use of olanzapine/aprepitant- or NEPA- containing antiemetic regimens were associated with high likelihood, while history of motion sickness was associated with lower likelihood, of complete response (CR) and 'no nausea' in the overall phase. History of vomiting in pregnancy was also associated with lower likelihood of overall CR. Patients with increasing number of risk factors had higher likelihood of treatment failure as well as shorter time to first vomiting. Those who did not achieve CR and 'no nausea' in the first cycle were less likely to achieve these parameters in the subsequent cycle of chemotherapy. Conclusions: This present study confirmed the previously reported risk factors to be important for CINV in Chinese breast cancer patients receiving doxorubicin and cyclophosphamide. Further optimization of CINV control is required for patients with identifiable risk factors; olanzapine/aprepitant- or NEPA- containing prophylaxes are the preferred contemporary antiemetics regimens for Chinese breast cancer patients undergoing doxorubicin and cyclophosphamide chemotherapy.

Introduction

More than 2 years after the WHO declaration of a pandemic, SARS-Cov-2 still represents a public health problem

The pandemic has increased the complexity of cancer treatments including breast cancer.

These difficulties were highlighted in adjuvant treatments but above all in metastatic disease.

Vaccination has been one of the most important public health factors that has reduced deaths, hospitalizations and the severity of symptoms related to infection.

In metastatic breast cancer hormone receptor positive and HER2/neu negative currently the first line of treatment is given by the association between cyclin 4/6 inhibitors and hormone therapy (aromatase inhibitors or fulvestrant)

A well-known and frequent side effect of this therapy is the reduction of white blood cell values and neutrophils.

The hypothesis that this study is to evaluate whether treatment with cyclin inhibitors initiated before the period of vaccinations may have influenced, due to the reduction in white blood cell values, an increased risk of infection in these patients.

Materials and methods

In our study, we selected patients who had started treatment with cyclin inhibitors before

starting the vaccination cycle (in Italy up to the fourth dose in cancer patients) and continue it without evidence of disease progression.

All patients were offered a vaccination cycle with mRNA COVID vaccines and were followed during their cancer treatments.

All patients, at least 90 days after the last dose of vaccine, have been tested for antibodies against SARS CoV-2 (trimeric spike protein) with a value expressed in binding antibodies unit (BAU) according to international standard WHO

During the observation period (starting from the first dose of vaccine administered) the patients were clinically checked and in case of suspicion of infectious pathology with symptoms suggestive of SARS-COV-19 infection, they were tested with molecular swab

Results

We evaluated 52 patients who started cyclin treatment before the vaccination course and who are currently without signs of disease recurrence

During the study period we found 14 SARS-COV19 infections (28% of patients) and one patient with two infectious episodes.

No patients needed treatment in a hospital or resuscitation setting. All patients have fully recovered from the infection and at most after 21 days have resumed the treatment still in place. Statistically, a linear regression calculation was applied to evaluate a functional relationship between variables measured on the basis of sample data.

We did not find a relationship between spikes or infections compared to the start date of the vaccination cycle; instead we observed a relationship between the value of the spike and the date of last immunization (considered as an active infection or fourth dose of vaccine) with a reduction in the values the further you go away

Conclusion

The data of the study show that there is a correlation between the time elapsed between the last vaccination and the risk of getting sick. For this reason, the fourth recall represents a strong help to reduce this risk.

We did not find any ranges we could refer to regarding the dosage of trimeric spike protein. Considering the positivity rate of infections that does not exceed the general vaccinated population and the absence of serious infectious symptoms with hospitalization, treatment with cyclin inhibitors appears to be a safe treatment even in a pandemic period.

Last day immunization and spike with IA or fulvestrant

Background: Although screening mammography leads to an early detection of breast cancer and a reduction in breast cancer mortality, many women have apprehension about mammograms due to reported discomfort and pain [would cite the source]. A study showed that pain was the cause of non-attendance of screening mammograms in 25-46% of reported cases by women. Despite this, there is limited research on strategies to reduce discomfort and anxiety associated with mammography screening and improve patient experience and compliance with national screening recommendations. Herein, we performed a double-blind randomized clinical study to determine if the use of local analgesia and calming music can improve patient satisfaction during routine screening mammogram. Methods: This study was designed as a double-blind randomized clinical trial with a 2x2 factorial design. A total of 251 patients who presented for mammographic screening were randomized to receive: breast lidocaine gel at a dose of 1200 mg or placebo gel on both breast and experience calming music or no music. Patients with history of mastectomy, breast cancer or recent (within 24 hours) analgesic use were excluded. Pain was measured with a 5-point face pain scale. Benjamini-Hochberg false discovery rate was used for analysis. Results: Of the 251 patients who were randomized between June 2017 and October 2019, 195 self-identified as Hispanics (77%). Median age was 58.5 years old and there were no differences in between groups. 100% were female. 99.3% presented for screening with no concerning symptoms. A total of 126 patients were randomized to music vs 125 to no Music. 79 patients in music group and 51 patients in no music group were randomized to lidocaine. Regarding pain assessment, 18.96% of patients had a pain score of 4 and 5 in the music group randomized to lidocaine gel as opposed to 10.64% to placebo gel. In the non-music group, 17.65% of patients expressed pain score of 4 and 5 to lidocaine gel vs. 18.91% to placebo gel. (P value music: 0.95, P value lidocaine: 0.93 P value music and lidocaine: 1). Patients randomized to lidocaine gel to music reported their

prior mammogram to be at a pain score of 4 to 5 in 41.7% of the subjects vs 45% of patients in the no music group. (P value music: 0.45, P value lidocaine: 0.93 P value music and lidocaine: 1). Despite this, majority patients in both groups expressed no reluctance for future mammograms. Conclusion: The addition of calming music and breast lidocaine gel did not show a statistically significant difference in the level of pain perceived by patients getting screening mammography. The data appear to suggest less severe pain (pain score 4 and 5) when these strategies are combined. Further prospective trials with larger patient populations are needed to explore these interventions. Despite the perceived pain most patients were still willing to return for a mammogram the following year.

Objectives and rationale: Racial and ethnic minorities are disproportionately exposed to environmental chemicals that have been linked to cardiovascular disease, cognitive decline, metabolic disease, and premature mortality. Recent evidence suggests that personal care products are a source of such exposures and that these products are more frequently used among Black and Hispanic women. Minoritized populations also tend to experience worse breast cancer outcomes compared to White patients. However, few studies have examined personal care product use and environmental exposures among minority cancer survivors. The aim of the present study was to describe personal care product use and chemical exposures, including ambient and dermal sources of exposure, in a pilot study of Black and Hispanic breast cancer survivors. Methods: In November 2020 – December 2021, self-identified Black and Hispanic breast cancer survivors aged ≥ 21 years were recruited in Washington, DC and Hackensack, NJ. Eligible survivors had been diagnosed with primary Stage I-III breast cancer and had completed breast cancer treatment except endocrine therapy. Surveys collected data on demographics, breast cancer diagnosis, personal care product use, and potential covariates. Participants wore silicone wristbands for 1 week for passive sampling of environmental exposures. Extracts from the wristbands were assessed using a gas chromatograph-mass spectrometer to detect chemical exposures. Values were adjusted for wear time and wristband size to provide sample concentrations of detected chemicals. Results: Among the 25 study participants, 17 were Black and 8 were Hispanic, with a mean age of 58 years. Most survivors (58%) had been diagnosed with Stage I breast cancer. Survivors reported using perfume (52%), make-up (80%), and nail polish (68%) during the week, with common daily use of facial

creams, lotions, or moisturizers (60%) and body creams, lotions, or moisturizers (68%). Drinking bottled water every day (64%) or most days (24%); eating prepared food from a fast food restaurant at least once per week (88%); and eating food reheated in a plastic container at least once per week (71%) were also prevalent. However, the majority of survivors reported never using pesticides indoors (76%) or outdoors (79%). The wristbands detected 60 distinct chemicals. On average, 21.8 chemicals were detected per wristband and 19 chemicals were detected in more than half of the samples. Exposure to flame retardants and pesticides was ubiquitous. All participants were exposed to chemicals found in personal care products and in commercial products. Several of the most commonly detected chemicals, including benzyl salicylate (a UV light absorber and fragrance), diisobutyl phthalate (a plasticizer), and linal (a perfume), are biologically active compounds with potential genotoxic or endocrine effects. Discussion: Exposure to environmental chemicals was ubiquitous among Black and Hispanic breast cancer survivors in DC and New Jersey. Frequent use of personal care products and commercial products suggest an opportunity to reduce potentially harmful exposures. Future studies are needed to investigate the role of environmental chemicals in health outcomes among breast cancer survivors and whether environmental exposures contribute to cancer health disparities.

The Breast Cancer Prevention Clinic: A Single Institution's Experience Authors: Joe J. Stephenson MD¹, LeAnn Perkins, FNP-BC, DipACLM¹, Erinn Crowe, RN, BSN, OCN¹, Regina Franco, MSN, NP-C, DipACLM¹, Pamela Cloys, MSN, ANP-C¹, Carmen Hancock, MSN, APRN, FNP-C, AOCNP¹, Marie Smith, MS¹ ¹Prisma Health Cancer Institute, Center for Integrative Oncology & Survivorship Background: Roughly 1 in 8 women will be diagnosed with invasive breast cancer in their lifetime¹. Some women have higher risk for developing breast cancer due to numerous factors such as elevated risk modeling scores, a history of chest radiation therapy, a history of atypical cells on a breast biopsy or a pathogenic genetic mutation. Enhanced surveillance to detect cancers early and addressing modifiable lifestyle risks are helpful to mitigate risks. Methods: The Prisma Health's Breast Cancer Prevention Clinic (BCPC) approaches prevention by monitoring non-modifiable risks with regular surveillance and education on optimizing lifestyle habits to decrease modifiable risks. Established in 2017, the BCPC team now includes multiple medical oncologists and nurse practitioners, allowing the clinic to be offered any day of the week. During the visit, patients receive a personal risk assessment. Recommendations are given for surveillance imaging, risk-reducing endocrine therapy, and risk-reducing lifestyle modifications such as diet, alcohol consumption, and exercise routines. Family history is also reviewed to recommend Genetic Counseling if appropriate. In March 2022, a statement was added to patient mammograms, generating referrals for those with calculated elevated risk (a calculated lifetime risk >20% using

the Tyrer-Cuzick or International Breast Cancer Intervention Study model and/or a 5-year risk >1.7% using the National Cancer Institute Breast Cancer Risk Assessment Tool or Gail model). Results: In a 12-month period from June 1, 2021 through May 31, 2022, 56.2% of patients were referred based on family history, 26.9% for higher-risk breast pathology, 8.1% for calculated elevated risk, 4.4 % for a pathogenic genetic variant that increases breast cancer risk and 4.1% for mammographic identification risk modeling. Following the BCPC visit, referrals for patients may include imaging such as mammograms, MRIs, genetic counseling or testing, or surgical evaluations. Referrals for lifestyle modifications may include nutrition, exercise navigation, mindfulness classes, or Sexual Health Evaluations. From June 2021 through May 2022, 41.4% of patients were referred for a breast MRI, 26.6% were referred to genetic counselors for genetic testing recommendations, 11.1% were referred to nutrition or exercise services, 8.42% were referred for a Bone Density Scan (DXA), 4% were referred to a Breast Surgeon and 3.7% were referred to the Genetic Management Clinic. Additionally, 79.5% of patients were referred to the High-Risk Breast Lifetime Clinic for continued monitoring and surveillance for early detection of breast cancer, continued reinforcement of lifestyle modifications, and management of risk-reduction endocrine therapy. Conclusion: The unique structure of this model allows for enhanced surveillance through greater use of evidence-based cancer prevention, early detection methods, and increased education for lifestyle medicine practices with the overall goals of reducing breast cancer risk, earlier breast cancer detection, and increasing quality of life. Background: The importance of mental health to improve the quality of cancer survivorship and outcomes is gaining increased attention. Major depressive disorder (MDD) has been associated with higher breast cancer (BC) incidence, BC-specific and all-cause mortality. The effect of MDD on BC recurrence remains under-studied. The Veterans Health Administration (VHA) provides a unique opportunity to examine this relationship as it mandates annual MDD screening in the primary care setting and reports national screening rates of 96%. **Objective:** To examine the relationship between pre-existing MDD and BC recurrence among a diverse cohort of women in the United States. **Methods:** We established a retrospective cohort of women (age ≥ 18 years) diagnosed with early-stage incident BC from 2010 through 2019 using the VHA's electronic medical record database. We used a two-year window to identify women with clinically diagnosed MDD prior to their BC diagnosis. Our outcome of interest was BC recurrence (local recurrence/second primary and distant recurrence). We used multivariable proportional hazards regression to examine the association between MDD and BC recurrence, accounting for competing risk of death. Our analyses were adjusted for age, race, ethnicity, marital status, priority group rating (proxy for socioeconomic status), rurality of primary residence, geographical region, cancer stage, year of BC diagnosis, and comorbidity burden. Priority group rating is a metric that incorporates patients' income, receipt of VHA assistance benefits, capacity for gainful employment, and severity of service-connected conditions. We conducted subgroup analyses by tumor subtype. **RESULTS:** Our cohort consists of 6,045 women with BC, of whom 1,750 (29.0%) had a pre-existing MDD diagnosis. The median length of follow-up from BC diagnosis was 4.5 years (IQR=4.8 years). The average age at BC diagnosis was 57 years (SD=11 years) overall and 56 years (SD=10 years) among women with

MDD. Sixty-one percent of women were white, 29% were black, 27% were married, and 28% were rural dwelling. Forty-four percent of invasive carcinomas were localized and 21% were regional. Thirty-five percent of patients had ductal carcinoma in situ. Women with MDD had a higher average Charlson Comorbidity Index score (mean=0.75, SD=1.13 vs. mean=0.58, SD=1.03) and proportion with a priority group rating between 1-4 (40% vs. 32%). The distribution of other described patient characteristics among women with MDD were similar to the overall cohort. On multivariable analysis, women with MDD had a 31% (95% CI: 1.11, 1.56) higher risk of BC recurrence compared to women without MDD. MDD was associated with a 29% (95% CI: 1.01, 1.66) and 33% (95% CI: 1.05, 1.67) higher risk of local recurrence/second primary and distant recurrence, respectively. The relationship between MDD and BC recurrence remained significant after adjusting for tumor subtype (HR=1.40, 95% CI: 1.07, 1.83). In subgroup analyses stratified by tumor subtype, MDD was associated with a higher risk of BC recurrence among women with estrogen receptor positive versus negative tumors (HR=1.65, 95% CI: 1.27, 2.14 vs. HR=0.71, 95% CI: 0.34, 1.46) and HER2/neu negative versus positive tumors (HR=1.53, 95% CI: 1.16, 2.00 vs. HR=1.24, 95% CI: 0.51, 2.96). The interaction between estrogen receptor status and MDD was statistically significant (p-interaction=0.02). CONCLUSION: Women with incident BC should be screened for MDD early in the cancer care continuum given the prevalence of MDD and association with increased risk of local recurrence/second primary and distant BC recurrence. Further research is needed to understand the interplay between these two diseases and their treatments.

Background: Most cytotoxic drugs are dosed according to body surface area (BSA), yet not all patients receive the full BSA-determined dose. Prior work suggests that dose reduction may occur more frequently in obese patients, likely due to concern about inducing toxicity at high doses. Other factors, such as race/ethnicity, have been suggested to be associated with dosing, yet the factors associated with dose reduction remain poorly understood, with little known about dosing patterns in integrated healthcare delivery systems and how such patterns have changed over time. Methods: We examined chemotherapy dosing in 452 women diagnosed with stage I-IIIa primary breast cancer at Kaiser Permanente Northern California. All study participants were a part of the Pathways Study, diagnosed between 2006-2013, and treated with the common breast cancer regimen, ACT (cyclophosphamide and doxorubicin, followed by paclitaxel). We explored the association between obesity and dose reduction, and further explored other factors in relation to dose reduction, including various sociodemographic characteristics, tumor characteristics, and comorbidities. We assessed dosing using first cycle dose proportion (< 90% expected dose) and average relative dose intensity (ARDI, a metric of dose intensity over the entire course of chemotherapy). Results: Overall, 8% of women received a dose reduction >10% in the first cycle of chemotherapy and 21.2% of patients had an ARDI < 90%. Obesity was a strong predictor of dose reduction, both in the first cycle and across all cycles. In the first cycle, 21.9% of severely obese patients (body mass index, BMI: 35+ kg/m²) were dose reduced, whereas no normal weight patients (BMI: 18.5-< 25 kg/m²) experienced a first cycle dose reduction. Across all cycles, 38.4% of severely obese women had an ARDI < 90%, as compared 12.8% of normal weight women. In logistic regression models adjusted for age, race/ethnicity, and white blood cell count, obese women had 4.1-fold higher odds of receiving a dose reduction of 10% or more over the course of chemotherapy than their normal weight counterparts (95% CI: 1.9, 8.9; p-trend: 0.006). Increasing age was positively associated with dose reduction across the course of chemotherapy, as was the presence of comorbidity. Importantly, dose reduction was less common in later calendar years. Sensitivity analyses revealed that the positive association between obesity and dosing was robust to further adjustment for these other significantly associated factors. Impact: These results offer insight on factors associated with variation in chemotherapy dosing for a common breast cancer treatment regimen. Larger studies are required to evaluate relevance of these findings to other treatment regimens. Further work will be needed to determine whether dose reductions impact breast cancer outcomes.

Introduction Type 2 diabetes (T2D) is associated with obesity and other comorbidities involving multiple organ systems, which may increase the risk of postsurgical complications. Knowledge is sparse on the impact of T2D on the postsurgical outcome after breast cancer (BC) surgery in primary BC. Objectives To investigate the association of T2D and risk of complications after primary BC surgery, and according to neoadjuvant chemotherapy. Methods Our cohort included all Danish women diagnosed with early-stage operable BC during 1996-2018 registered in the Danish Breast Cancer Group clinical database. All patients had primary surgical treatment—mastectomy or breast conserving surgery. Information on prevalent T2D was collected from Danish medical and prescription registries, defining T2D via diagnostic codes or redemption of ≥ 2 prescriptions for glucose-lowering drugs. We defined postoperative complications as hospital admissions for medical or surgical complications (re-operations (excluding seromas), bleeding, infection, thrombosis, kidney or arterial cardiovascular disease) up to 30 days after primary BC surgery. We calculated the 30-day cumulative incidence function (CIF) of postoperative complications and used Cox regression to estimate hazard ratios (HR) and associated 95% confidence intervals (95% CI) overall, and stratified by the receipt of neoadjuvant chemotherapy, adjusting for potential confounders. Results Among 84,491 women with operable BC, 4,669 (5.5%) had prevalent T2D at time of BC surgery. Overall, 800 (17.1%) and 8,621 (10.8%) of BC patients with and without T2D developed postoperative complications corresponding to CIFs of 17% (95%CI: 16% - 18%) and 11% (95%CI: 10% - 11%), respectively, and a HR of 1.44 (95%CI: 1.34-1.56). 173 (3.7%) BC patients with T2D and 2,805 (3.5%) without T2D received neoadjuvant chemotherapy. Among those who did not receive neoadjuvant chemotherapy, the CIFs of postoperative complications was 17% (95% CI: 16% - 18%) and 11% (95% CI: 10% - 11%) for women with and without T2D, respectively, with a corresponding HR of 1.42 (95% CI: 1.31-1.53). For those with and without T2D who received

neoadjuvant chemotherapy, the CIFs were 24% (95% CI: 18% - 30%) and 10% (95% CI: 9% - 11%), respectively, and with a corresponding HR of 2.08 (95% CI: 1.49-2.91). Conclusion Among women with BC, prevalent T2D at the time of primary BC surgery increases the risk of postoperative complications. This excess risk is particularly pronounced among patients who undergo neoadjuvant chemotherapy.

Purpose: Studies conducted prior to COVID-19 suggested that racial/ethnic disparities in breast cancer screening percentages have substantially reduced over time. COVID-19 has had devastating effects on racial/ethnic minorities and resulted in delays in preventive breast cancer screening. Our purpose was to determine if racial/ethnic minorities were less likely to receive recommended breast cancer screening after the resumption of preventive care during the COVID-19 pandemic. Methods: HIPAA-compliant, institutional review board exempt retrospective cohort study was performed at a multi-location academic medical center located in the Midwest. Patients included women aged 50-74 years old between June 2021 and May 2022, derived from the electronic medical records. Primary outcomes variables included receipt of screening mammogram within the last two years. Primary exposure variables included race (American Indian/Alaska Native, Asian/Native Hawaiian/Other Pacific Islander, Black or African American, White) and ethnicity (Hispanic/Latino, and Not Hispanic/Latino). Binary outcomes were analyzed using logistic regression, adjusted for potential confounders (insurance, age, preferred language, employment status, rural status). Results: 37,509 female patients without

histories of mastectomies were included (mean age 63.1). 73.8% of eligible patients received a mammogram within the last two years. By race, 74.7% of White patients, 57.6% of Black patients, 67.0% of Asian/Pacific Islander patients, and 60.1% of American Indian patients received a screening mammogram within the last two years. In our unadjusted analyses, Black (OR 0.46, 95% CI 0.41 to 0.52, $p < 0.001$), Asian (OR 0.69, 95% CI 0.60 to 0.79, $p < 0.001$), and American Indian patients (OR 0.51, 95% CI 0.39 to 0.66, $p < 0.001$) were less likely to receive recommended mammography screening. In our adjusted analyses, Black (OR 0.54, 95% CI 0.47 to 0.61, $p < 0.001$), Asian (OR 0.79, 95% CI 0.68 to 0.92, $p = 0.003$), and American Indian patients (OR 0.63, 95% CI 0.48 to 0.82, $p = 0.001$) were less likely to receive recommended mammography screening. By ethnicity, 74.1% of Non-Hispanic patients and 64.2% of Hispanic patients received a screening mammogram within the last two years. In our unadjusted analyses, Hispanic patients (OR 0.62, 95% CI 0.55 to 0.71, $p < 0.001$) were less likely to receive recommended mammography screening. In our adjusted analyses, Hispanic patients (OR 0.92, 95% CI 0.79 to 1.08, $p = 0.338$) were comparably likely to receive recommended mammography screening. Patients with non-English preferred languages, uninsured or Medicaid patients, and patients living in rural areas were less likely to receive recommended mammography screening ($p < 0.001$). Conclusions: Racial/ethnic minority patients were less likely to receive recommended cancer screening after the resumption of preventive breast cancer screening during the COVID-19 pandemic. Targeted outreach efforts are required to ensure equitable access to breast cancer screening for racial/ethnic minorities, patients with non-English preferred languages, uninsured, Medicaid, and rural patients.

Background The recommended 5-10 years of adjuvant endocrine therapy (ET) as standard of care has improved outcomes in patients with HR+/HER2- early breast cancer (EBC); however, risk of recurrence persists. The monarchE study demonstrated improvement in invasive disease-free survival (iDFS) with abemaciclib in node-positive, high-risk EBC, the majority of which were stage III (Johnston SRD, et al. J Clin Oncol. 2021;38:3987); however, monarchE's relatively short follow-up time to date only allowed for observation of early recurrences—longer follow-up is needed to evaluate late recurrences. Risk of recurrence is a concern for patients

with all stages of EBC (Pan H, et al. N Engl J Med. 2017;377:1836). We assessed the risk of recurrence in a real-world setting among patients with stage II-III HR+/HER2- EBC after initiation of adjuvant ET. **Methods** This was a retrospective analysis of ConcertAI's deidentified electronic medical records data set among patients treated from January 1, 1995, to April 30, 2021. The cohort included stage II-III patients with HR+/HER2- EBC who underwent surgery and initiated adjuvant ET (if IIIB or IIIC, confirmation was required on residual tumor status). Patients were from academic and community oncology clinics across the US. Data were missing from the database for some variables; thus, percentages may not add up to 100%. iDFS was assessed to determine the risk of disease recurrence, death, or second primary tumor and was defined as the time interval between start of ET and first iDFS event. Kaplan-Meier methods were used to estimate cumulative probabilities of experiencing an iDFS event at 5 and 10 years from the start of ET. **Results** A total of 3133 patients (98.8% female) with stage II-III HR+/HER2- EBC were included in the analysis. The median follow-up time was 68.1 months. The median age was 59 years; 22.2% of female patients were pre/perimenopausal and 44.7% were postmenopausal; 80.9% of all patients had stage II disease, while 19.1% had stage III disease. In total, 42.1% and 3.7% of those with stage II and III disease had no nodal involvement, respectively. Overall, 51.2% of patients did not receive radiotherapy, and 59.5% of patients did not receive (neo)adjuvant chemotherapy. In the total sample, the 5- and 10-year risk of an iDFS event was 26.1% and 45.0%, respectively. In patients with stage II disease, the 5- and 10-year risks were 22.7% and 40.5%, respectively, and 40.4% and 62.9% among stage III. **Conclusions** These real-world data demonstrate that the risk of recurrence with adjuvant ET, particularly in those with stage II EBC, is higher than reported in many randomized controlled trials. Importantly, our data show that, in the real-world setting, the stage II population represents a significant proportion of patients (nearly 4 times more than stage III). These findings confirm and underscore the clear unmet need in this population and highlight the need for improved treatment options in this broader EBC population. The NATALEE study will investigate ribociclib + ET in a broad population of patients including stage II and stage III HR+/HER2- EBC with high-risk features, regardless of nodal status.

Background: Cardiotoxicity associated with use of trastuzumab (T) in breast cancer has been assessed in multiple studies with short-term follow up. However, long-term risk of clinical heart failure (CHF) with the use of T, either with or without anthracyclines (A), is poorly understood. Since the approval of T for use in early-stage breast cancer (ESBC) in 2006, long-term follow up data is now available in the SEER-Medicare database.

Methods: We performed a retrospective cohort study in patients (pts) with ESBC identified in the SEER-Medicare database, diagnosed between 2005-2016, excluding pts with in-situ or metastatic disease at time of diagnosis or a history of CHF prior to diagnosis. Primary exposure variables were identified using HCPCS codes and included receipt of T or A. The reference baseline population used for univariate logistic regression of the primary exposure variables was pts with ESBC who received neither T nor A. For multivariate analyses, to avoid collinearity in the final model, the exposure variables were categorized as either having or not having the exposure (i.e. with or without T, with or without A). The primary outcome variable was CHF, identified using codes 428.0-9, 402.11, 402.91 (ICD9) and I50.0-9, I110 (ICD10). Covariates used in multivariate logistic regression (MLR) included hypertension (HTN), valve disease, hyperthyroidism, diabetes (DM), emphysema, coronary artery disease (CAD), left sided radiation, age, and race. MLR models were constructed using a stepwise-up approach and confirmed using the stepwise-down method with a cutoff of $p < 0.05$ for inclusion in the final model.

Results: A total of 244,129 pts were identified with a median follow up of 6.7 years (7.7 years in the T cohort). Median age was 68. Other demographics are listed in Table 1. Of these, 10,603 were HER2-positive (HER2+) pts who all received T and all of whom also received some form of chemotherapy. Of the HER2+ pts, 19.1% (2,026) also received A in addition to T as part of

their treatment regimen. Pts who received T had significantly higher baseline rates of HTN, valve disease, hyperthyroidism, DM, emphysema, and CAD as compared to pts who did not receive T. Compared to pts who received T without A, pts who received T with A had significantly higher baseline rates of HTN, valve disease, hyperthyroidism, emphysema, and CAD with no difference in baseline rate of DM. Risk of CHF with exposure variables are summarized in Table 2. The overall rate of CHF for the entire 244,129 population was 21.3% with a rate of 20.8% in pts who did not receive any T or A (the baseline population). The rate of CHF in pts who received T without A was 19.1% (OR 0.90, 95% CI 0.85-0.95), and 29.0% for those who received T with A (OR 1.55, 95% CI 1.41-1.71). Associations of covariates of interest with risk of CHF as well as MLR models are summarized in Table 3. After adjusting for all baseline cardiac comorbidities as well as other covariates, receipt of T was associated with a reduced risk of CHF (OR 0.74, 95% CI 0.70-0.79, $p < 0.001$), and receipt of A remained associated with an increased risk of CHF (OR 1.19, 95% CI 1.15-1.24, $p < 0.001$).

Conclusions: With long-term follow up, the addition of A to T significantly increased the risk of CHF over T without A (from 19.1% to 29.0%) in pts with ESBC. Additionally, pts who received T without A had a similar risk of CHF compared to the baseline population who received neither T nor A. After adjusting for potential confounders in the MLR model, T was associated with a slightly decreased overall risk of CHF, while A remained associated with an increased risk of CHF. Possible explanations for these findings include potential increased cardiac monitoring in the T population which may have led to optimization of cardiac comorbidities, which were higher in the T population at baseline. Taken together, these data indicate concern with use of T plus A in ESBC regarding the long-term development of clinical CHF; especially when non-A regimens with similar efficacy are available.

Background: Chemoprevention with selective estrogen receptor modulators (SERMs) and aromatase inhibitors (AIs) has been shown in randomized controlled trials to decrease breast cancer incidence by 50-65% among women at high risk for breast cancer. However, chemoprevention uptake remains low among high-risk women. Women with atypical hyperplasia (AH) or lobular carcinoma in situ (LCIS) derive the greatest benefit from SERMs and AIs for breast cancer risk reduction. A potential barrier to chemoprevention uptake is competing comorbidities, including atherosclerotic cardiovascular disease (ASCVD). We calculated risk of breast cancer and ASCVD among women with AH or LCIS and assessed uptake of chemoprevention and statins among women who met high-risk criteria for both breast cancer and ASCVD. Methods: We conducted a retrospective cohort study among women, age 40-74 years, with AH or LCIS diagnosed in 2007-2015 at Columbia University Irving Medical Center (CUIMC) in New York City. Eligible women had sufficient data in the electronic health record (EHR) to calculate 5 and 10-year invasive breast cancer risk according to the Breast

Cancer Surveillance Consortium (BCSC) risk calculator, including age, race/ethnicity, first-degree family history of breast cancer, breast biopsy results, and mammographic density. We calculated 10-year ASCVD risk using the 2013 American College of Cardiology (ACC)/American Heart Association (AHA) ASCVD risk calculator using additional EHR data, including systolic blood pressure, total and HDL cholesterol, history of diabetes, treatment for hypertension, and current smoking status. High-risk criteria to determine eligibility for SERMs/AIs and statins was defined as a 5-year invasive breast cancer risk \geq 1.67% and 10-year ASCVD risk \geq 7.5%, respectively. We compared mean 10-year risk of breast cancer vs. ASCVD using a paired t-test and uptake of SERMs/AIs vs. statins among women at high risk for breast cancer and ASCVD, respectively, using McNemar's test. Results: Among 298 evaluable women, mean age was 58.2 years (standard deviation [SD], 8.34), with 33% non-Hispanic White, 41% Hispanic, 9% non-Hispanic Black, 6% Asian, and 11% other/unknown race/ethnicity. About 98% of women met high-risk criteria for breast cancer and 30% were high risk for ASCVD. Mean 10-year risk of breast cancer was higher than mean 10-year risk of ASCVD (9.14% vs. 6.69%, $p < 0.001$). Among women who met high-risk criteria for both breast cancer and ASCVD, uptake of statins was higher compared to SERMs/AIs (58% vs. 21%, $p < 0.001$). Comparing non-Hispanic Whites vs. racial/ethnic minorities, mean 10-year breast cancer risk was higher (12.12% vs. 7.71%, $p < 0.001$), but there were no statistically significant differences in ASCVD risk or uptake of chemoprevention or statins. Conclusions: Among women with AH or LCIS, mean absolute risk of breast cancer was higher compared to risk of ASCVD, however, uptake of statins was higher compared to chemoprevention with SERMs or AIs. To address under-utilization of chemoprevention among high-risk women, use of SERMs or AIs should be placed in the context of medications used for other chronic diseases, such as statins for ASCVD.

Physical Activity and Risk of Death in Breast Cancer Survivors: A Prospective Study

Presenting Author(s) and Co-Author(s):

BACKGROUND. Strong evidence exists supporting the protective effect of physical activity on the risk of developing breast cancer; however, its impact on survival after breast cancer diagnosis remains controversial with limited research in long-term survivors. The aim of the current study was to evaluate the association of physical activity and risk of all-cause mortality in long-term breast cancer survivors.

METHODS. We conducted a prospective cohort of 315 post-menopausal breast cancer survivors who were at least 2 years post their initial diagnosis (median 6 years of survivorship). They initially were diagnosed with early stage (AJCC TNM Stages 0-II) breast cancer between January 1996-December 2012. Baseline interviews were conducted between August 2013 and March 2015, and participants were followed until date of death or study's end (April 2022). Subjects were queried on physical activity and fatigue using validated questionnaires, Godin Leisure Physical Activity Scale (GLPAS) and Fatigue Symptom Inventory (FSI). Physical activity was defined in 3 levels (active, moderately active, insufficiently active). Cox proportional hazards regression model was used to estimate the association of physical activity with risk of all-cause mortality, adjusted for age at baseline, breast cancer stage, Charlson comorbidity index (CCI), years since cancer diagnosis, fatigue, race/ethnicity, lifetime history of insomnia and depression, and adjuvant cancer treatments (endocrine, chemotherapy and radiation).

RESULTS. Of the 315 women, mean age at interview was 71 years (range: 57-86). The cohort included 30% women of color, mainly African American/Black and Asian/Pacific Islander women. Over a maximum follow-up of 8.7 years (median:7.8, IQR:7.3-8.3) after their baseline interview, 45 subjects (14.3%) died due to all causes. The mortality rates were: 12.9 per 1000 person years (PY) for active; 13.4 per 1000 PY for moderately active; and 32.9 per 1000 PY for insufficiently active. In multivariable analysis, compared to insufficiently active women, those who were active or moderately active had a markedly 60% decreased risk of death (active: HR=0.42, 95% CI: 0.21-0.85; moderately active: HR=0.40, 95% CI:0.17-0.95).

CONCLUSION: We found that even moderate physical activity was associated with a significantly decreased risk of all-cause death in long-term breast cancer survivors.

Survivorship care plans should consider incorporating physical activity because even moderate activity is vital for extending survival as well as health-related quality of life.

	N Deaths	Rates per 1000 PY (95% CI)	Adjusted HR (95% CI)
Total	45	18.9 (14.1-25.3)	
Godin Physical Activity			
Active (>24 units)	14	12.9 (7.6-21.8)	0.42 (0.21-0.85)
Moderately Active (14-23 units)	8	13.4 (6.7-26.8)	0.40 (0.17-0.95)
Insufficiently Active (< 14 units)	23	32.9 (21.9-49.5)	1.00 (ref)

Introduction Chemotherapy administration in real-world cancer care can differ extensively from clinical trials. It is important to understand real-world practice to identify dose reductions, delays, regimen changes and early discontinuations that impact cancer outcomes. Such variables require knowledge of intended regimens, which may not be well-documented in structured data in electronic health records (EHRs). We examined EHR data from the Kaiser Permanente Northern California (KPNC) site of the Optimal Breast Cancer Chemotherapy Dosing (OBCD) study to develop a process to identify each patient's intended regimen. Methods In this study of women diagnosed and treated with primary stage I-IIIa breast cancer at KPNC from 2006-2019, and ages 18+y at diagnosis, we analyzed treatment patterns using structured EHR data on the drugs, dosages, and dates at which they were administered (from which intervals and total length can be derived). Chemotherapy agents were identified using the NCI's CANMED database augmented with other sources. We used these data to categorize patients into the 22 drug combinations described in the National Cancer Care Network (NCCN) guidelines for breast cancer treatment. Within these 22 drug combinations, women were then subcategorized into 45 distinct chemotherapy administration schedules, defined as NCCN guideline regimens (NGRs). For this step, algorithms were developed that categorized patients into NGRs if they received the exact regimen described in the guidelines. For the second step, we conducted a manual review of the EHR data for patients who were unable to be categorized. This enabled us to gradually loosen the criteria (in terms of cycle intervals or number of cycles) so patients whose chemotherapy administration aligned closely with NGRs were categorized into each of the 45 NGRs. Clear patterns emerged of regimens that were administered to multiple patients, despite being outside of the NCCN guidelines, which we have defined as non-standard NGRs. For example, in the drug combination TC (cyclophosphamide and docetaxel) the NGR was TC every 21 days for 4 cycles. We found approximately 1 in 10

patients received 6 cycles , which we defined as a non-NGR. For the remaining uncategorized patients, medical chart abstraction was undertaken as a third step, at which point patients were categorized into either existing regimens or new non-NGRs if their intended regimen had not been previously described in the guidelines. Results Among 31,418 women with breast cancer, 12,427 (39.6%) received chemotherapy. We determined the intended chemotherapy regimens for 6,559 (52.8%) receiving the 45 NGRs using EHR data. We further expanded the algorithms through a manual review of the EHR data, which enabled us to categorize 2,977 (24.0%) additional women into their intended regimens. Abstracted medical notes were reviewed for the remaining patients for whom we had not been able to identify the intended regimen. Across both the manual review and abstraction processes, we were able to identify additional non-standard NGR regimens. In total, 9,536 (76.7%) of women were categorized into their intended regimen through the algorithm/manual review process, while 2891 (23.3%) of women underwent medical chart abstraction to identify the intended regimen. Conclusion Here, we describe the challenges and approaches to operationalize complex, real-world data to identify intended chemotherapy regimens at a granularity and scale not seen previously. We are adapting this method at a second OBCD study site, Kaiser Permanente Washington, where all women have undergone medical chart abstraction. We hope this methodology leads to increased feasibility and efficiency of use of large-scale clinical data, in turn improving cancer care delivery, patient outcome evaluation, and other real-world questions.

Background Among breast cancer (BC) survivors, cardiovascular disease (CVD) is one of the most common comorbidities contributing to mortality. Data on to what extent CVD risk impacts disease progression and second cancers in younger women is limited. We conducted a prospective cohort study to examine whether CVD risk is associated with disease recurrence or new primary cancer among female BC survivors enrolled in a cohort of women with a family history of BC. Methods The study included 301 females with a first primary diagnosis of BC in the Breast and Ovarian Surveillance Service (BOSS) Cohort, after excluding those who had a history of recurrence or second primary cancer prior to enrollment (N=125), a diagnosis of ductal carcinoma in situ (DCIS) (N=66), and with missing CVD risk factors (N=3). A risk score based on 7 CVD risk factors (age 65 or older, diabetes, hypertension, high cholesterol, body mass index (BMI), smoking status, and physical activity) was assessed at baseline and updated 4 and 8 years after enrollment. Each risk factor was given a score (0, 1, or 2) and was summed and categorized into low (score=0 or 1), intermediate (score=2 or 3), and high (score >3) risk. The primary outcome was either BC progression or all second primary cancers. Analyses limited to BC progression and second BC only were also conducted. Outcomes were ascertained through active follow-up and confirmed by pathology records. Kaplan-Meier graphs and two different Cox regression models were used to compare risk groups: model 1 adjusted

for participants' age, race, BMI, time from diagnosis, education, tumor stage, and estrogen receptor (ER) status; model 2 included further adjustment of cancer treatments (chemotherapy, hormone therapy, radiation), statin use, baby aspirin use, and specifically cardiotoxic treatments. For subgroup analyses, a more parsimonious model was used including age, race, BMI, education, cancer treatments, and cardiotoxic treatment. Results Participants' mean age of BC diagnosis was 47.4 years and the median follow-up time was 11.5 years. The incidence rate of recurrence or any second cancer was 21 cases per 1000 person-years. At baseline, there were 168, 130, and 84 survivors in the low, intermediate, and high CVD risk groups respectively, and their use of statins increased from 12.7%, 34.5% to 52.7%. In the multivariable model, BC survivors with an intermediate CVD risk score had a 2.23 times greater risk of recurrence or second primary cancer as compared to those with a low CVD risk score (95% CI=1.20- 4.17). After further adjusting for cancer and CVD treatment in model 2, the HR was attenuated but still significant to 2.01 (95% CI = 1.20- 4.17). Interestingly, the association was attenuated and non-significant in the high-risk group (model 2: HR=1.37, 95% CI = 0.54-3.45). The positive association between intermediate CVD risk score and recurrence or second cancer was also observed among subgroups of BC survivors including those who were postmenopausal (HR = 2.23, 95% CI = 1.01-4.93), with ER-positive BC (HR=2.07, 95% CI=1.08-3.99), regional disease (HR = 2.74, 95% CI = 1.06-7.04), diagnosed 5 years or greater (HR = 4.85, 95% CI = 1.14-20.66). There was a significant interaction between intermediated CVD risk and diagnosis time of 5 years (P interaction = 0.033). Restricting the outcome to disease progression and second BC alone led to similar results. The HR comparing the intermediate risk group and low risk group was 2.65 (95% CI = 1.27-5.55) in model 1 and decreased to 2.28 (95% CI = 1.06-4.89) in model 2. Conclusion There was a significant association between CVD risk and subsequent cancer progression in female breast cancer survivors, particularly among long-term BC survivors. The non-significant results among the women with high CVD risk scores may reflect the fact that a greater proportion of these women compared to women in the intermediate group reported taking cardiac treatments that can favorably impact cancer progression.

Background At the moment, over 180,000 breast cancer survivors are living in the Netherlands and survival after a breast cancer diagnosis and treatment is still increasing. Therefore, the number of survivors is rising, and these patients are at risk of metachronous metastases. Data at a national level on the development of metachronous metastases are limited, as this is not registered in the Netherlands Cancer Registry on a regular basis. Due to the vast amount of survivors, it is not feasible to actively monitor all patients to signal and register metachronous metastases. Applying machine learning may be an option to overcome this issue. The aim of our study is to develop a M1 detection algorithm based on hospital data to signal patients who developed metachronous metastases after their primary breast cancer treatment. **Methods** The Netherlands Cancer Registry (NCR) collects data on all individuals newly diagnosed with cancer in one of the 76 hospitals in the Netherlands since 1989. Dutch Hospital Data (DHD) collects and processes data from hospitals, including data on diagnosis and treatment. DHD data from 2019-2020 were linked to the NCR using a probabilistic matching method. We matched on date of birth, gender, diagnosis, postal code, hospital and patient ID. Column values that matched were weighted inversely proportional to the respective column's probability distribution, where a match on a rare column value (e.g. postal codes with a relatively small population) increased the probability that the match was correct. Scores for each column were combined and patients with high matching scores were included in the algorithm development, validation and deployment. Actively signaled and manually registered data on metastases were available for subgroups of breast cancer patients included in previous studies ('the golden standard'). First, 80% of these data was used to train the model, 20% was used to validate the model. Second, a pilot study was performed in which patients files were checked for 928 patients, sampled with variance in prediction probability, to evaluate a diverse range of cases. **Results** We included 4,395 patients. Variables that were included to predict metastases were

i.e. specific medication for metastatic disease (palbociclib), counselling for metastatic breast cancer, Carcinoembryonic Antigen test, a confirmed diagnosis of metastases, and number of patient visits. The first validation step (including 20% of known data) showed that the model had a precision of 0.91 to predict metachronous metastases, 0.93 to predict free of metastases. The pilot study confirmed that a higher prediction probability of >0.8 correlated with a higher chance that a patient has metachronous metastases. However, false positive predictions did occur. Conclusion We developed a M1 detection algorithm to signal patients with metachronous metastases after breast cancer treatment on a national level. With this algorithm we are one step closer to identify all patients with metachronous metastases and to reach a complete registration of all breast cancer metastases reusing existing data sources. After review of patients with a high prediction probability, the model will be re-trained using these data and updated data from DHD.

Background: triple-negative breast cancer (TNBC) is associated with hereditary and environmental risk factors plus an overall worse prognosis compared to other Breast Cancer (BC) subtypes. While TNBC risk factors, prevalence, clinical characteristics and prognosis may vary throughout different populations, limited data on Latin American patients forces clinical decisions to be based predominantly on data coming from non-Hispanic women. To obtain local epidemiological information, regarding risk factors and clinical outcomes, we analysed the largest Chilean BC registry.

Methods: we conducted a retrospective population-cohort study involving females with any stage TNBC, treated at a community hospital (mid-low income) and at an academic private hospital (high income), between the years 2010 and 2021. Risk factors, reason for consultation, clinical and pathological characteristics and prognosis were separately analysed for both TNBC

and non-TNBC subgroups. Univariate and multivariate analyses were performed to identify prognostic factors for survival on TNBC patients.

Results: From 5,806 patients, 647 (11.2%) were identified as TNBC. Compared to non-TNBC patients, women were younger (median age 55.2 vs. 57.2, $p=0.0001$), with 15.8% of TNBC patients having been diagnosed before the age of 40 compared to 9.6% in non-TNBC ($p=0.0001$). TNBC had a significantly lower screen-detected cancer rate (14.5% vs. 31.6% $p=0.0001$) and worse stage at diagnosis. No differences were seen between patients seen at a community hospital and private centre, for both TNBC rate and stage. Other risk factors such as parity, age at first gestation, menarche, hormone therapy replacement and obesity showed no significant differences between TNBC and no-TNBC patients (table 1).

With a median follow up of 57 months, 5-year overall survival (OS) and BC specific death were significantly shorter for TNBC compared to non-TNBC (76.4% vs 88.1% and 78.9% vs 91.2%, respectively; $p=0.0001$) (table 2). In the multivariate analysis, TN subtype (HR=2.3, $p=0.0001$), stage (HR=2.05 for stage II vs stage I, HR=7.04 for stage III vs. stage I, $p=0.0001$), lower income (HR= 1.64, $p=0.0001$), and non-screened detected BC (HR=1.32, $p=0.03$) were all associated with worse overall survival (table 3).

Conclusion: This is the first study focusing on TNBC characteristics in Chilean BC patients and to our knowledge, the largest performed in a Latin American population. We identified a lower proportion of TNBC patients when compared with data reported from other LA groups and worldwide, a very low screen detected cancer rate and as expected significantly lower TNBC survival rate compared to non-TNBC women. While TNBC patients were younger compared to the non-TNBC group, this age difference was marginal compared to other reported studies. Community hospital patients (with mid-low income) were associated with lower survival rates for both all-cause mortality and BC specific survival, regardless of a similar stage distribution at diagnosis. Reflecting an underlying interaction between social and biological factors that needs to be addressed.

Table 1. Patient characteristics: Triple-negative versus non-triple negative breast cancer

Variables	TNBC: 647 (11.2%)	Non-TNBC: 5,159 (88.8%)	p valu

Background Breast cancer (BC) continues to be highly prevalent and lethal among women worldwide. Obesity is an established risk factor for several types of cancer, including BC, particularly in postmenopausal women. Obesity may also be a prognostic factor for BC in all ages, as it increases the risk of surgery complication, decreases the response to chemotherapy, and increases mortality. This study aimed to evaluate if obesity was related to poor prognosis of patients with BC in Brazil. Methods In this retrospective, single center, cohort study, an electronic database from Pérola Byington Hospital (in São Paulo, SP, Brazil) was used to select patients with BC followed between January 2011 and June 2021. All included women had a confirmed diagnosis of BC and were divided in four groups according to BMI categories, defined by weight (kg)/height² (m): < 18.5 kg/m²: underweight; 18.5 to < 25 kg/m²: healthy weight; 25 to < 30 kg/m²: overweight; ≥30 kg/m²: obese. This study was approved by the local Institutional Review Board. Outcomes The overall survival (OS) was the primary outcome, evaluated by the comparison of the incidence of death from BC among groups. Progression-free disease survival (PFS) was also measured. Statistic methods The descriptive analysis was expressed as continuous variables in summary measures (mean, median, standard deviation, and quartiles), while categorical variables were expressed in frequencies and percentages. The Kaplan-Meier method was used for survival graphs, the Log-rank method to evaluate the difference between the survival curves, and Cox regression to calculate the hazard ratio (HR) and OR for death. The significance level adopted in the tests was 0.05, two-tailed hypotheses considered, and the confidence intervals (CI) constructed are 95%. R version 4.1.1 software was used to carry out all analyses. Results A total of 10,117 patients were screened, 7,424 were included, and 6,992 were considered for the survival analysis. The mean age was 55.12 ±12.47 years at diagnosis and the mean BMI was 27.97 ±5.55 kg/m². Patients with obesity corresponded to 30.81% of the study population, and 64.82% of them were ≥ 50 years old (postmenopausal), p < 0.001. For each BMI group, most patients were postmenopausal, p < 0.001; without significant difference among groups, p=0.2133. Considering staging by breast (n=6,872), 42.97% of the underweight group were stage III; 41.90% of the healthy weight, 42.79% of overweight, and 39.38% of obese groups were stage II, p < 0.001 (within-group), and p=0.0944 among groups. Molecular subtype did not differ neither within the

group ($p=0.068$) nor among groups, $p=0.1155$. A total of 6,992 patients were included in the survival analyses, corresponding to 7,090 breasts. During the 10 years-follow up, 265 patients (3.79 %) died from BC. Figure 2 shows the Kaplan–Meier estimates of OS according to BMI, $p=0.12$. There was no difference in OS according to menopausal status. According to the multivariate Cox-regression analysis results, none of the variables evaluated significantly impacted the OS of patients with BC. BMI did not significantly impact the results. The variables that significantly impacted the chances of pCR were HER2+ and triple-negative compared with luminal A, staging zero compared with I, recurrence, adjuvant therapy, age, and time between diagnosis and surgery. Conclusion In conclusion, obesity did not impact the survival or progression of BC in this retrospective analyses. This study, despite not demonstrating significance in its primary objective, brings important epidemiological data from the Brazilian population with BC not previously published, with high prevalence of overweight and obesity among Brazilian women with BC and highlights the importance of further studies, especially prospective, addressing obesity and BC.

Background: The incidence of early-onset breast cancer (BC) in adults < 40 years old has increased dramatically in the US over recent decades. The increase in incidence means that identifying higher risk individuals through family-history based guidelines will miss many young adults. As no population-based screening is recommended for adults under 40, so how they detect their BC remains unclear. Using data from a nested case-control study in the Breast Cancer Family Registry, we found that the steroid metabolome may improve risk assessment. If replicated in larger studies, it will be important to know more about the clinical contexts in which this biomarker screening could be implemented from both the provider and patient perspectives. One way to fill these gaps is to identify biocultural drivers of risk that deepen our etiologic understanding and inform risk assessment. We use quantitative and qualitative (mixed) methods to integrate “emics”—the on the ground perspective—from young adults with BC into metabolomic studies. Methods: For the provider perspective, we administered a survey to Obstetricians/gynecologists (OBGYNs) about their knowledge of American College of Obstetrics and Gynecology (ACOG) breast cancer screening guidelines for women under 40 and determined the proportion of correct responses. For the patient perspective, we examined qualitative data from the Young Survival Coalition (YSC). The YSC hosts an online forum where young adults with breast cancer “tell their story” in posts. We reviewed text from posts published between March 2009 and December 2019 and coded text (n=750 posts) according to themes: “first signs and symptoms,” “steps to diagnosis,” “staging type,” and “patient-provider feelings.” Then, we used natural language processing and machine learning with the support vector machine algorithm to build classification models and detect the themes in all posts (n=571,602). We repeated this process for sub-themes. Results: ACOG guidelines recommend that women at “average risk” of breast cancer are counseled about breast self-awareness, and 75% of OBGYN respondents answered this survey question correctly. Our qualitative, “emic” data suggest that the vast majority of young adults find their BC through self-awareness and

first seek care from OBGYNs. They first noticed signs (n=3,266) of breast changes through self-detection of lumps (56.5%), self-detected breast and health changes (25.0%), and through a provider (17.2%). The first steps to diagnosis (n=31,640) mainly started with clinic visits (66.5%), others with surgery (23.3%). Stage at diagnoses (n=71,879) were Stage 4 (7.3%), followed by Stage 0 (7.2%), Stage 2-3 (5.5%), and Stage 1 (4.8%), while others mentioned being diagnosed with any invasive cancer (7.3%). Out of 24,648 posts, 70.3% were not satisfied with their providers and felt ignored, their treatment delayed, lacked trust, and felt their providers were not informed. One person said, "My doctor has not had a patient as young as me get diagnosed with cancer and has not suggested ANYONE." Conclusions: In addition to counseling about breast self-awareness as a means of detection, the OBGYN setting may be a place to implement biomarker-based screening for early-onset BC. These results are derived from our mixed-methods approach, designed to identify biocultural drivers of cancer prevention by incorporating "omics" and "emics". In the era of "omics," when molecular markers are incorporated into cancer risk reduction and early detection, "emics" are equally important to identify what is feasible in "real-world" settings.

Overweight and obesity trends over 5 years in early stage and metastatic breast cancer patients

Presenting Author(s) and Co-Author(s):

Terrence Tsou, *n/a, Medical Student - The Johns Hopkins University School of Medicine*
Country: United States

Amanda L. Blackford, ScM, *Senior Data Scientist - Johns Hopkins University*

Jennifer Y. Sheng, MD, *Assistant Professor of Oncology - Johns Hopkins University*
Country: United States

Background: Obesity is associated with 25-33% of all breast cancer (BC) cases, and BC survivors with obesity have a 35% higher risk of BC-related death and 41% higher risk of all-cause mortality. We hypothesized that the prevalence of overweight (body mass index [BMI] 25-29.9 kg/m²) and obesity (BMI \geq 30) after a diagnosis of early stage or metastatic BC increases, and baseline characteristics may increase risk of weight gain.

Methods: We conducted a retrospective chart review of 222 patients with Stage 0-IV BC who newly presented to Johns Hopkins from 2015-2018. Patients were part of the BC Program Quality Improvement Project Database, had 1 chest CT scan within 6 months of initial visit, and at least 1 subsequent CT. Data extracted from the medical record included: demographics, menopausal status, diagnosis date, cancer characteristics/treatment, recurrence/vital status, family history of BC, and tobacco/alcohol use. All BMI measured on patients were collected. Baseline BMI was defined as the closest measurement to BC diagnosis between 1 year prior and 1 month after diagnosis. We estimated time to overweight/obesity from diagnosis using the Kaplan Meier method and compared between subgroups with the log rank test. Patients who were overweight/obese at diagnosis were included in the analysis with an event time of zero.

Results: Among 222 patients, 110 patients (50%) had newly diagnosed early-stage BC, 98 (44%) had de-novo or recurrent metastatic BC, and 14 (6.3%) had locally recurrent BC. Most patients were women (98%) and non-Hispanic (93%). Patients identified as White (62%), Black (23%), and Asian (8%). Among 34% with alcohol use, 5% reported \geq 8 drinks/week. There were current (6%) and former smokers (34%). Family history of BC was present in 10%. Among those with early-stage primary BC, most were postmenopausal (61%) and received chemotherapy (61%). Hormone receptor (HR)-positive, HER2-positive and triple negative subtypes were 70%, 24% and 19%, respectively. For those with metastatic BC, most were postmenopausal (62%). Hormone receptor (HR)-positive, HER2-positive and triple negative subtypes were 71%, 12% and 24%. At diagnosis, 73% of the whole cohort had BMI \geq 25 kg/m², with the whole cohort and subgroups having mean BMI \geq 25 kg/m². The incidence of elevated BMI increased in all groups and overall, over 5 years (Table 1). Weight gain was significantly associated with premenopausal status ($p=0.04$). Stage at diagnosis, smoking/alcohol use,

receipt of chemotherapy/radiation/endocrine therapy, and subtype were not associated with weight gain.

Conclusion: Patients with early stage and metastatic BC have elevated BMI at diagnosis, and this risk increases over 5 years, especially for those who are premenopausal. Further investigation of the implications of these changes is needed. Additionally, while BMI is accessible, it may underestimate body fat in older people and others who have lost muscle, does not identify fat distribution (a major factor in metabolic health risk), and may not be equally valid across gender, race and ethnicities and age groups. We will assess body composition by CT scan and report correlations with BMI and cancer-related outcomes.

Prevalence of BMI \geq 25 kg/m² in patients with breast cancer at diagnosis and by 1-, 2-, and 5-years after

	N	At Diagnosis [95% CI]	2y [95% CI]	5y [95% CI]	P
Entire Cohort	222	71 [65, 77]	82 [75, 86]	85 [77, 90]	N/A
Stage					
Early stage primary	110	75 [66, 82]	85 [76, 90]	85 [76, 90]	0.34
Metastatic	98	79 [42, 92]	79 [42, 92]	100 [NA,NA]	
Locally recurrent	14	65 [54, 74]	79 [67, 86]	86 [67, 94]	
Menopausal status					
Pre	43	60 [43, 73]	76 [58, 86]	79 [61, 89]	0.04
Post	76	83 [72, 90]	88 [78, 94]	88 [78, 94]	

Prevalence of BMI \geq 25 kg/m² increased over 5 years post-diagnosis. Premenopausal status was more associated with BMI \geq 25 kg/m² versus postmenopausal status.

Introduction Due to improvements in breast cancer (BC) diagnostics and treatment, the population of BC survivors is growing. BC treatments may have adverse effects that lead to an increased risk of developing type 2 diabetes mellitus (T2D). It is therefore important to investigate the risk of T2D in patients with BC in general and according to type of adjuvant BC treatment. **Objectives** To conduct a systematic review and meta-analysis investigating the association between early BC and the risk of subsequent T2D diagnosis. A secondary aim was to examine this association according to type of adjuvant BC treatment—chemotherapy and endocrine therapy (ET). **Methods** We searched PubMed and Embase using variations of the search terms breast cancer (population), ET, tamoxifen, aromatase inhibitors (AIs) and chemotherapy (exposures), and diabetes mellitus (outcome). Two authors screened papers for eligibility by title and abstract using Covidence and reviewed full texts of eligible papers. Guided by the Meta-analysis of Observational Studies in Epidemiology (MOOSE) checklist, study data were extracted. Using random-effects models, we calculated relative risks (RRs) and associated 95% confidence intervals (CIs) for the association between BC, adjuvant BC treatment (ET overall, tamoxifen, and AIs), and subsequent T2D. We used funnel plots to assess publication bias in the analyses. **Results** Among 16 eligible studies, 11 reported on T2D risk after BC, chemotherapy, or ET; five studies investigated more than one association. Compared with patients without BC, those with BC had elevated risk of T2D overall (RR=1.27, 95%CI=1.15-1.41), particularly those who received any ET (RR=1.23, 95% CI=1.16-1.32). Among BC patients only, risk of T2D was higher for those who received tamoxifen compared with those who did not receive tamoxifen (RR=1.19, 95% CI=1.13-1.25). Due to few studies, analyses investigating T2D risk after treatment with AIs and chemotherapy were inconclusive. **Conclusion** Our findings support an association between BC and subsequently elevated risk of T2D, particularly after tamoxifen use. Further research is needed to determine the impact of ET overall, AIs and chemotherapy on the incidence of T2D in patients with early BC. **Funding** This

project was funded from the following source: The Novo Nordisk Foundation

BACKGROUND WISDOM (Women Informed to Screen Depending on Measures of risk) is a pragmatic trial comparing the safety, efficacy, cost, and patient acceptability of personalized versus annual breast cancer screening in women ages 40-74 years with no personal history of breast cancer. Cancer registry reporting is considered the gold standard for ascertaining cancer diagnosis data; however, the time lag between diagnosis and reporting (1-2 years or more) by the California Cancer Registry (CCR) presents challenges. The WISDOM study must quickly ascertain and report accurate cancer diagnoses to the Data Safety Monitoring Board; delays could lead to preventable harm, unnecessary costs, and unwarranted early trial termination. To ascertain cancer diagnoses in a timely manner, we used multiple data collection methods and compared self-reported with Electronic Health Records (EHR) information, and in some cases verified with chart review. Specifically, we conducted a procedural study with WISDOM participants who sought care at a University of California (UC) health system by extracting their data from the University of California Data Warehouse (UCDW) to 1) verify self-reported breast cancer diagnoses in WISDOM; 2) ensure that all on-study breast cancer diagnoses have been captured within the WISDOM study cohort; and 3) assess the accuracy and reliability of self-reported data. The UCDW provides harmonized EHR data from the six University of California (UC) health systems and constitutes ~120 billion data points from 7.8 million patient records.

METHODS We provided the UCDW with a list of WISDOM participants who indicated they had sought care from a UC health system. Participants with recorded breast cancer diagnostic code (ICD-10CM C50.) were matched with the WISDOM self-reported cancer dataset to uncover participants who had no recorded breast cancer diagnosis in the study system. For those individuals with no recorded self-report diagnosis, coordinators conducted manual chart review to determine whether the participants had been diagnosed with breast cancer.

RESULTS This cohort included 11,314 enrolled WISDOM participants who self-reported care at a UC and had at least one diagnostic or procedural breast care code. Among these participants, 160 had a ICD-10-CM C50 breast cancer diagnostic code of which 132 breast cancer cases were confirmed: 111 were already self-reported through WISDOM and 21 additional confirmed breast cancer cases were identified through the UCDW. As a standard process, only WISDOM self-reported cancer cases that were confirmed by chart review are entered into the study database. The percentage of confirmed UCDW-identified cases that were not also self-reported was greater for recent diagnoses (16% overall and 6% for period prior to June 2020). Among the 11,314 participants in our cohort, the CCR identified 61 pre-June 2020 cancer diagnoses. Of these 61 diagnoses, 92% (56) were identified by the UCDW procedural process. If the UCDW had been used as the single source for cancer diagnosis, 21 participants without cancer and 7 participants with unclear status (unlocated or inaccessible records) would have been classified as cancer cases.

DISCUSSION/CONCLUSION Self-reported data provides quick ascertainment with relative accuracy compared to cancer registry. Cancer ascertainment can be further improved by combining self-reported data with EHR data from a health system data warehouse registry, particularly for self-reported questionnaire issues such as timing and lack of response. Accuracy of self-reported cancer diagnosis from annually distributed questionnaires improves over time. Identifying cancer diagnosis discordance between data sources can inform processes to improve self-reported study accuracy.

Background: As opposed to conventional age-based population-level breast screening strategies, risk-stratified breast screening programs are emerging as a new approach to balanced population screening methodology where the screening frequency and choice of modality (mammography/tomosynthesis or magnetic resonance imaging) is determined based on accurate personalized estimation of an individual's risk score. A woman identified with low risk can now be screened less frequently, avoiding repeated mammography screening where radiation risk outweighs the benefits in that particular individual. The standard questionnaire based risk stratification is found to be less reliable and imaging based risk stratification mechanisms are being explored in recent years. In this study, we evaluate the performance of a new computer-aided image analysis technique called Thermalytix that automatically generates a personalized risk score using a combination of imaging and questionnaire information for risk stratification of women.

Methodology: Thermalytix is an artificial intelligence system that uses thermal imaging and questionnaire data for predicting the risk of breast cancer. Thermalytix analyzes spatio-thermal signatures and vascular patterns in the breast region along with patients' complaints and age to generate a score called B-Score (or BHARATI Score) which ranges from 1 to 5. B-Score of 1 indicates low risk of malignancy and a B-Score of 5 indicates the highest risk of malignancy. To evaluate the effectiveness of risk stratification using B-Scores, we performed retrospective analysis of thermal and participants' data acquired from two registered clinical studies. One study (CTRI/2017/10/0 10 115) is a multi-site study conducted in Bangalore, India, and the other study (NCT04688086) is a single site study conducted in Delhi, India. Both these study sites are geographically distant with 2000 KM apart from each other and comprise a diversified population from India.

Results: In total, 717 eligible women were considered in this study with age varying from 18 years to 80 years. Reports from standard of care procedures involving mammography,

ultrasound and biopsy (as needed), were collectively considered by a radiologist to determine the ground truth for malignancy. Out of 717 women, 85 women were thus concluded as malignant. When used in a blinded fashion, Thermalytix graded 275 women as B-Score 1 (lowest risk), 225 women as B-Score 2, 44 women as B-Score 3, 137 women as B-Score 4 and 36 women as B-Score 5 (highest risk). The fraction of malignancies in the cohorts corresponding to B-Score categories from 1 to 5 were found to be progressively higher (0.36%, 1.33%, 29.55%, 33.58% and 61.11%, respectively) - showing the correctness of the proposed personalized risk scoring methodology.

Conclusion: Thermalytix test, a low-cost, radiation-free, contactless and privacy aware test was used as a technique to determine the breast cancer risk of a woman.. The results obtained in the study show that a high B-score of 5 indicates a high risk for malignancy with 61.11% chance of breast cancer. Likewise the lowest B-Score of 1 indicates low risk for malignancy with just 0.36% percentage of women in the cohort found with malignancy. These results combined with other experiential benefits of Thermalytix test makes it a promising risk stratification mechanism enabling differential frequency of screening while balancing the cost and risk versus benefit. Large scale studies, however, need to be conducted to see the ground benefits of the proposed approach in a screening program implementation.

Distribution of study population in different risk cohorts

Risk Stratification	No. of Women in the Cohort (n=717)	No. of malignant cases (n=85)	Malignancy Rate
B-Score 1 (Lowest Risk)	275	1	0.36%
B-Score 2	225	3	1.33%
B-Score 3	44	13	29.55%
B-Score 4	137	46	33.58%
B-Score 5 (Highest Risk)	36	22	61.11%

Higher risk correlates with higher malignancy rate

Osteopenia and osteoporosis in women with breast cancer in Taiwan: single center retrospective data

Presenting Author(s) and Co-Author(s):

Chia-Hua Liu, *n/a, Resident - Division of Breast Surgery, Department of Surgery, Taichung Veterans General Hospital, Taichung, Taiwan*

Country: United States

Chih-Chiang Hung, *n/a, Attending Physician Surgeon - Division of Breast Surgery, Department of Surgery, Taichung Veterans General Hospital, Taichung, Taiwan*

Country: United States

I-Chen Tsai, *n/a, Attending Surgeon - Taichung Veterans General Hospital*

Country: United States

Purpose:

Osteopenia and osteoporosis are commonly encountered in elder women. One third of women older than fifty years suffer a fracture second to osteoporosis around the world. Standard treatments for breast cancer such as chemotherapy or hormonal therapy may increase the risk of both osteopenia and osteoporosis. Premenopausal women treated with standard adjuvant chemotherapy frequently develop ovarian failure, or early menopause, which is associated with accelerated bone loss.

Trabecular bone score (TBS), an index extracted by DXA that provides an indirect measurement of bone axial microarchitecture. In addition to the BMD, TBS are warranted to improve the prediction of fracture risk at the individual level.

However, due to regulations of National Health Insurance in Taiwan, data are limited on the incidence of osteopenia and osteoporosis in women with breast cancer in Taiwan. In this study, we investigated the proportion of osteopenia and osteoporosis in women with breast cancer in Taiwan.

Materials and Methods:

There were enrolled 201 female who diagnosed with breast cancer between May 2019 and December 2020 in this retrospective study. Patients with bone metastasis (n=11) and double cancer (n=3) were excluded. All patients received dual energy X-ray absorptiometry (DXA) at least once, including bone mineral density (BMD), T-score (spine and total hip) and trabecular bone score (TBS) data.

The data were retrospectively analyzed baseline age, BMD, breast cancer type, aromatase inhibitors (AIs) usage status by Kruskal-Wallis test.

Results:

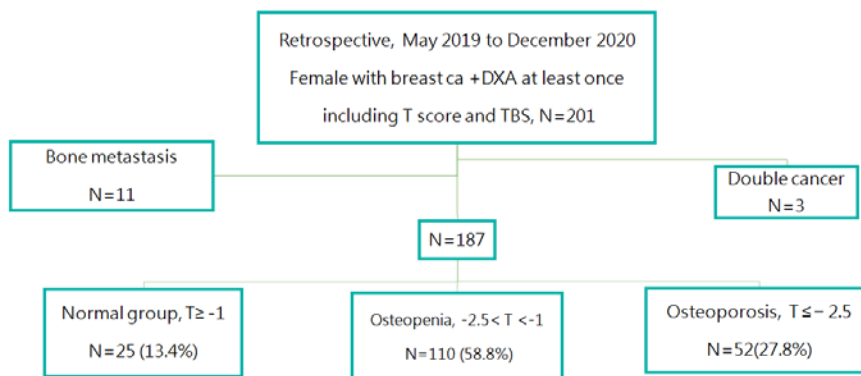

Based on the lowest T-score from measurements at the spine or total hip, 58.8% (n=110) of osteopenia ($-2.5 \leq T < -1$) and 27.8% (n=52) of osteoporosis ($T < -2.5$) were identified in women with breast cancer (figure 1). Statistics significance was noted in patients' age and BMI between three groups. There was no difference in bone mineral density according to breast cancer subtype. (table 1)

Patients who ever use aromatase inhibitors (n=90) had lower BMD ($T = -2.14$) and trabecular bone score (TBS=1.3) than non-AI group (n=97, $T = -1.84$, TBS=1.34). (figure 2) (table 2)

Conclusions:

According to Taiwan's NHI sampling data from 1999 to 2001, the averaged prevalence of osteoporosis in those aged ≥ 50 years was 11.35% for women. Breast cancer survivors are at higher risk for osteopenia and osteoporosis compared to cancer-free women in Taiwan. Aromatase inhibitors (AIs) group had lower BMD and TBS ($p < 0.05$). In our study, forty percent of TNBC patients diagnosed osteoporosis, which is compatible with increased bone loss due to chemotherapy-induced ovarian failure. Therefore, clinicians should be aware not only of AI-associated bone loss but also of patients who ever accepted long-term chemotherapy. A normal range for TBS values in postmenopausal women has been proposed: a TBS of ≥ 1.350 is considered normal; a TBS between 1.20 and 1.35 is considered consistent with partially degraded microarchitecture, and a TBS of ≤ 1.200 defines degraded microarchitecture. In our study, mean TBS in women with breast cancer ($n=187$) is 1.32. Further research is needed to determine the validity of cut-points for guiding treatment decisions.

The molecular mechanisms related to the breast cancer development are poorly understood, particularly those associated with estrogen. Evidence is mounting that developmental differences may influence the risk of cancer. However, understanding breast development, morphology and the biochemical factors that influence them is pertinent to study pre-malignant and malignant conditions that affect the breasts.

Objective: To evaluate the proliferative activity of normal breast epithelium, through the c-myc expression, after the administration of combined oral hormonal contraceptive, associated or not with estriol.

Retrospective double-blind study, in which the effect of combined oral contraceptives on the normal breast epithelium in women with fibroadenoma was evaluated. We analyzed 33 women in a cohort of 70 selected (37 excluded). The control group (1) received a compound containing levonorgestrel 0.15mg (LNG) and ethinylestradiol 0.03mg (EE), associated with 2mg of placebo (PLC) manufactured in the same capsule ingested daily for 21 days with an interval of 7 days, during four cycles. The study group (2) received a compound containing levonorgestrel 0.15 mg (LNG) and ethinylestradiol 0.03 mg (EE), associated with estriol 2 mg (E3) manufactured in the same capsule ingested daily for 21 days with an interval of 7 days, up to four cycles, when was proceeded the lumpectomy plus normal breast tissue sample. The UNIFESP-EPM Department of Pathology received the samples collected and fixed in 10% buffered formalin. We used an automation device to perform the Immunohistochemistry reactions, using c-myc antibodies, added DAB developer (diaminobenzidine) that provides a bright brown color that provides good contrast. We used conventional optical microscopy to read TMA slides. We considered positive the nuclei stained with dark brown in contrast to the blue negative to the c-myc reactions. We evaluated the epithelial areas at least five acinar units were present in the sample at 40X magnification. In the statistical analysis, the initial stages of consolidation as well as the analysis were performed in Software R (2020) and Rstudio (version 4.1), using the packages Tidyverse (2016), Psycho, SummaryTools, Janitor and DataExplorer. After verifying the assumptions of normality, independence and linearity, Student's T test was performed for independent samples. An alpha of 0.05 was chosen for rejection of the null hypothesis, that is, a confidence interval of the test results of 95%. An effect size measure of the difference

between the groups was also performed, called Cohen's D; it ranges from -1 to 1, and the closer to 0, the smaller the effect size of the difference between the groups. Regarding the control group (30.30%) and the case group (69.70%). The table 2 presents the results for group 1 (COC + Placebo), while table 3 presents the results for group 2 (COC + Estriol). The T test was performed to verify a possible significant difference in the levels of cell proliferation in patients with or without Estriol. The normality was verified by the Shapiro-Wilk test, with data following a normal distribution ($W = 0.901$ and 0.96 , p value > 0.3). The equitable variance was verified by the Levine test, which verified the equitable variance in both groups ($F(1) = 0.24$, p value $= 0.62$).

A mean positive nucleus of 14 (SD = 10.65) was observed in the group of patients with contraceptive plus placebo and a mean of positive nuclei of 20.81 (SD = 9.88) in the group of patients with contraceptive plus Estriol. The ratio of positive nuclei to total was higher in the estriol group than in the control group. However, it was not possible to verify a significant difference in the two groups ($T(14.57) = 1.3$, p value $= 0.215$, d Cohen $= 0.53$). Cohen's d pointed to a moderate difference effect (table 4).

Clinicopathological Risk Factors of Brain Metastasis in Breast Cancer Patients: A Systematic Review and Meta-analysis

Presenting Author(s) and Co-Author(s):

Korina Blanca C. Garcia, *n/a, Surgery Resident - Pasig City General Hospital - Mary Chiles General Hospital Consortium*

Country: Philippines

April Ann A. Lubay, *n/a, Surgery Resident - Pasig City General Hospital - Mary Chiles General Hospital Consortium*

State: National Capital Region

Country: Philippines

BACKGROUND: Breast cancer brain metastasis (BCBM) has an incidence rate of 5.1% among Breast Cancer (BC) patients. In BCBM, cancerous cells come from a primary tumor that implant and grow in the brain leading to potentially lethal neurologic symptoms and signs. With more clinical options and therapeutics strategies becoming available, a multi-disciplinary approach for treatment is needed in order to best meet BCBM patients' needs, however, systematic guidelines for the screening of high-risk asymptomatic patients are still lacking and the BCBM diagnoses are performed only after symptoms manifestation. Therefore, understanding the clinical and pathologic drivers of BCBM aids in improving medical interventions by guiding future research directions. This study aims to determine the clinicopathological risk factors of brain metastasis (BM) among BC patients. **METHODS:** Retrospective cohort studies on the clinicopathological characteristics of BM versus non-BM (NBM) patients were retrieved through reputable search databases. Review Manager version 5.4.1 was used for statistical analyses. In the presence of heterogeneities, a pragmatic approach was undertaken to employ both random-effects (RE) and fixed-effect (FE) meta-analyses. The statistical significance of the pooled effect estimates was examined by the Z-test. Interstudy variations and heterogeneities were estimated using Cochran's Q-statistic with $P < 0.05$ indicating a statistically significant heterogeneity. The risk of bias and the quality of studies were assessed at a study level using ROBINS-I tool. **RESULTS:** A total of four (4) retrospective cohort studies were included in the analyses. Random-effects meta-analyses with $i^2 < 50\%$ ($P > 0.05$) had shown significant association ($P < 0.05$) on the increased incidences of BCBM development for HER2+ expression [OR: 2.43, 95% CI: 1.88 – 3.12, $P < 0.00001$] and for pre-menopausal status [OR: 1.77, 95% CI: 1.13 – 2.76, $P = 0.01$]. Fixed-effect meta-analyses had shown significant association ($P < 0.05$) on the decreased incidence of BCBM development for TNBC disease [OR: 0.66; 95% CI: 0.47 – 0.92; $P = 0.02$]. The risk of bias was low to moderate in the majority of studies. **CONCLUSION:** HER2 positivity and pre-menopausal status are risk factors for increased BCBM development while the absence of regional lymph node metastases and ILC findings are less likely to progress to BCBM. Higher T and N categories, higher histological grade, ER negativity, and PR negativity may be associated with higher risks of BCBM while lower T categories, HER2 negativity, and TNBC may likely be associated to less BCBM development. More powerful relevant and upcoming randomized clinical trials with larger sample sizes among BCBM patients versus non-BM patients must be made exploring certainty on the clinicopathological factors contributing to BM among BC patients. **Keyword/s:** risk factors, breast cancer, brain metastasis

Introduction Breast cancer survivors are at greater risk for cardiovascular-related mortality compared to women without breast cancer. Accordingly, attention to reducing the risk of cardiovascular disease must be a priority in the long-term management of these patients. **Objective** To assess the efficacy of a smartphone-based model of care for exercise promotion, cardiovascular risk reduction and psychological wellbeing in women undergoing treatment for breast cancer. **Methods** Female patients with breast cancer across four tertiary Australian hospitals were screened for inclusion in this randomized controlled trial. Patients were randomized to standard care (SC), with or without an adjunctive smartphone application 'BreastMate' (SP) at time of diagnosis. The primary endpoint was change in exercise capacity, measured by the change in six-minute walk test (6MWT) distance at 12-months when compared to baseline, between groups. Secondary endpoints included changes in cardiovascular risk factors, psychological wellbeing, and major adverse cardiovascular events (MACE). **Results** Of the 103 patients recruited, complete follow-up data was available in 80 (77.7%) patients (age 60±12 years, SP=41, SC=39). At 12-months follow-up, the SP group had a statistically and clinically significant improvement in 6MWT distance (Median Δ46 (IQR 28 to 63) metres vs. Δ8 (-10 to 35) metres; p< 0.001). Compared to SC, patients in the SP group had a greater reduction in systolic blood pressure (Δ-5.1 (-10 to 0) vs 0 (-10 to 7) mmHg; p=0.03) and waist circumference (Δ-1 (-4 to 0) vs 0 (-1.5 to 1) centimetres; p=0.003) as well as a greater improvement in vitality as measured by the sf-36 questionnaire (48.1 ± 18.4 to 63.3±19.2 vs 48.3 ± 24.2 to 59.6±18.8; p=0.04). There was no significant difference in

cholesterol levels, diabetes control, smoking cessation or incidence of MACE between groups (p-value for all=NS). Conclusion In patients with breast cancer, a smartphone-based cardiovascular risk reduction program, as an adjunct to standard care, improved exercise capacity, systolic blood pressure, waist circumference and patient-reported vitality at 12-months. This innovative model of care could be implemented to improve the cardiovascular risk profile of breast cancer survivors. Australia and New Zealand Clinical Trials Registry (ANZCTR12620000007932).

Introduction:

The use of routine post-operative mammogram (RPM) in search of residual calcifications after breast conserving surgery (BCS) remains controversial due to a paucity of data and conflicting results. In our institution it is common practice is to send all patients who presented with malignant calcifications and underwent BCS with negative surgical margins for RPM before radiotherapy. Patients are also sent for post-operative mammogram if they had malignant calcifications and positive surgical margins, to look for residual calcifications and use localization to ensure their removal in the re-excision.

Methods:

We reviewed the records of 182 patients in our institution referred for RPM between January 7, 2018, and July 14, 2021. Continuous variables were described using medians and interquartile range (IQR). Categorical variables were described as frequencies and percentages. Logistic regression was used to examine factors associated with residual calcifications.

Results:

Median patient age was 59 (48-67) and 39 (21.4%) patients received neoadjuvant systemic treatment. Eighty-five (46.7%) patients had pure DCIS and 66 (36.3%) had mixed IDC with DCIS. On surgical pathology 14 (7.7%) patients had involved surgical margins and an additional 28 (15.3%) had margins less than 2 mm to pure DCIS. Tumor characteristics and RPM results are presented in table 1. Of the 19 (10.4%) patients with suspicious residual calcifications on RPM, 17 (89%) underwent biopsy of the calcifications and the other 2 (11%) patients were referred directly for re-excision. Seven (36.8%) of the patients with suspicious residual calcifications had DCIS. No patients had residual invasive disease. The pathology results of patients with residual calcifications on RPM are presented table 2. Of the 7 patients with residual DCIS, 4 underwent re-lumpectomy, 2 underwent completion mastectomy and 1 patient was lost to follow-up. Additional DCIS was found in all the re-excisions. Two patients with residual DCIS had surgical margins under 2mm from pure DCIS while 5 patients (2.7% of all patients) had no indication for postoperative imaging or re-excision and the residual disease was identified solely based on the mammographic findings. Close or involved surgical margins

were not significantly associated with residual calcifications on post-operative mammogram. Age under 50 was the only factor significantly associated with residual calcifications (OR 3.2 95% CI 1.1-9.7) and residual DCIS (OR=11 95% CI 1.13-109).

Conclusion:

In our cohort RPM revealed a small percentage of cases of residual DCIS that would have otherwise gone untreated. Larger studies are required to better identify factors associated with residual disease on RPM and to identify its impact on local recurrences.

Tumor histology	DCIS	IDC	ILC	MIXED DCIS+IDC	ypTis	ypT0
	85 (46.7%)	15 (8.2%)	5 (2.7%)	66 (36.3%)	4 (2.2%)	7 (3.8%)
Multifocal	No	Yes				
	124 (68.1%)	58 (31.9%)				
Margins	Uninvolved	Involved	Pure DCIS<2mm			
	140 (76.9%)	14 (7.7%)	28 (15.4%)			
Suspicious calcifications on RPM	No	Yes				
	163 (89.6%)	19 (10.4%)				

DCIS- ductal carcinoma in situ, IDC-invasive ductal carcinoma, ILC-invasive lobular carcinoma, ypTis-residual DCIS only post-neoadjuvant, ypT0-no residual invasive or in situ disease, RPM-routine postoperative mammogram

Table 1: Tumor characteristics and RPM results

RPM suspicious calcification pathology	Number (%)
DCIS	7 (37%)
Atypical hyperplasia	4 (21%)
Fat necrosis	3 (16%)
Papillary lesion	2 (11%)
LCIS	1 (5%)
Fibrocystic changes	1 (5%)
Giant cell reaction	1 (5%)

Population level access to diagnostic mammography and ultrasound guided breast biopsy in Nigeria: a geospatial analysis

Presenting Author(s) and Co-Author(s):

Adeleye Omisore, MD, *Radiologist - Obafemi Awolowo University*

Country: United States

Elizabeth J. Sutton, MD, *Radiologist - Memorial Sloan Kettering Cancer Center*

Gregory Knapp, MD, *Surgical Oncologist - Dalhousie University*

Country: United States

Introduction: Breast cancer is the most common cause of cancer-related mortality among women in Nigeria. Physical proximity to a diagnostic center is an important component of access, which has direct implication on the cost and timeliness of diagnosis and treatment. Beyond diagnostic mammography, ultrasound (US)-guided biopsy is an essential tool in the diagnostic pathway for suspicious lesions of the breast and is recommended by the Whole Health Organization Breast Health Global Initiative for LMICs. Unfortunately, there is a dearth of data on the population level access to mammography and US-guided breast biopsy in Nigeria and little is known about the geospatial inequities in access that targeted programming or investment could potentially address. This study undertook a comprehensive evaluation of breast imaging and diagnostic services in Nigeria and using a previously validated geographic information system (GIS) model, evaluated geospatial access to diagnostic mammography and US-guided breast biopsy in Nigeria. Methods: A comprehensive list of public and private facilities offering diagnostic mammography and/or US-guided breast biopsy was compiled using publicly available facility data from the Nigerian Ministry of Health, a survey administered to members of the Breast Imaging Society of Nigeria (BISON) as well as key stakeholder interviews from each of the countries six geopolitical zones. A novel survey was delivered to BISON members to identify additional / new facilities not captured by the latest Nigerian Ministry of Health data. Facility location, administration (public vs. private) and duration of service delivery were elicited from respondents and paired with the Ministry of Health facility dataset. Data on provider training and volume were also captured in the survey. All facilities were geolocated using Google Earth™ (Google, Mountain View, CA). A previously described cost-distance model, that uses open-source population density data to 100m2 (GeoData Institute) and road network data (OpenStreetMap) was used to estimate population level travel time to the nearest diagnostic center. Any portion of a route that included travel over terrain without roads was assigned a walking speed of 5 kmh-1. Geospatial access was calculated for mammography and US-guided biopsy separately and as well as by geopolitical zone. This study was approved by the research ethics board at Obafemi Awolowo University. Results: In addition to publicly available data from the Ministry of Health, facility and practice data was obtained from 63 Nigerian Radiologists from across the country. In total, 124 centers were identified that offer diagnostic mammography, of which 78 (63%) are privately administered. Nine of the countries 36 states did not have a center offering this service. Across the country,

33 centers offer US-guided breast biopsy, of which the majority (72.7%) are public. At a population level, 83.1% of the population has access within 120 minutes of continuous one-way travel to a center with diagnostic mammogram or US. At 240 minutes of continuous one-way travel, which corresponds to a full day of travel round-trip, 80.8% of the population has access to US-guided breast biopsy. However, there are differences in access between geopolitical zones. Just 68.7% of the population in the North East geopolitical zone has access to US-guided biopsy within a day's travel (i.e. 240 minutes one-way). The remaining five geopolitical zones have population level access to this service of $\geq 80\%$. Conclusions: This is the first comprehensive evaluation of breast cancer imaging and diagnostic services in Nigeria. Our results, demonstrate that the majority of the population in Nigeria has reasonable geospatial access to basic breast cancer imaging services. However, there are inequalities in access between states and geopolitical zones in the north and south of the country, which may have an impact on timely diagnosis and care.

Introduction: SN132D is a manganese (Mn) -containing, polymeric nanomaterial developed as an intravenous contrast agent for tumor selective MRI. It was designed for optimal physiological targeting and preferential accumulation in malignant lesions by means of the Enhanced Permeability and Retention (EPR) effect. Combined non-clinical data have demonstrated proof of concept (PoC) in various in vivo cancer models and a safety profile in line with FIH administration of SN132D in the SPAGOPIX-01 clinical study. Methods: SPAGOPIX-01 is a Phase I, FIH, open-label, non-randomized and non-placebo-controlled study in participants with diagnosed breast cancer. MRI was performed prior to and at 2 h and 4 h after the end of the SN132D infusion. SN132D safety and tolerability were the primary objectives. MRI enhancing properties of SN132D in primary tumor, liver, and pancreas as well as pharmacokinetics of SN132D were secondary objectives. Results: So far, 12 female breast cancer patients of planned up to 20 have been enrolled between September 2019 and December 2021. Of these,

six patients received SN132D at 10 $\mu\text{mol Mn/kg}$ (cohort 1) and six patients at 20 $\mu\text{mol Mn/kg}$ (cohort 2). In cohort 1 (10 $\mu\text{mol Mn/kg}$), SN132D was well-tolerated. No clinically significant findings were observed for clinical laboratory tests, vital signs, 12-lead electrocardiogram (ECG), or physical examination. No serious adverse events (SAEs) were registered; nine mild AEs were reported for four subjects. The most reported AEs in patients administered 10 $\mu\text{mol Mn/kg}$ SN132D were injection site reactions (2 AEs) and flushing (2 AEs). In cohort 2, SN132D was also well-tolerated. No clinically significant findings were observed for vital signs, ECG, or physical examination. No SAEs were registered; 12 AEs were reported for six patients. The most common AE was transiently elevated transaminase levels, with single reports from four patients. The second and third most common AEs were moderate vomiting (reported twice from a single patient) and mild flushing. Remaining AEs were single events reported by single patients. None of the AEs required treatment and all resolved without any intervention. Pharmacokinetics of SN132D was assessed at up to 24 h post dose. In cohort 1, SN132D, based on Mn plasma concentrations, had a mean C_{max} of $0.915 \pm 0.187 \mu\text{g/mL}$, a mean initial half-life of $7.17 \pm 1.02 \text{ min}$, a mean AUC_{inf} of $0.890 \pm 0.20 \text{ h} \cdot \mu\text{g/mL}$ and a mean plasma clearance of $0.646 \pm 0.157 \text{ L/h/kg}$. In cohort 2, SN132D had a mean C_{max} of $2.0 \pm 0.341 \mu\text{g/mL}$, a mean initial half-life of $7.0 \pm 1.60 \text{ min}$, a mean AUC_{inf} of $2.04 \pm 0.28 \text{ h} \cdot \mu\text{g/mL}$ and a mean plasma clearance of $0.548 \pm 0.068 \text{ L/h/kg}$. MR image analysis in cohort 1 revealed that although contrast was insufficient for the generation of clinically relevant tumor images at the 10 $\mu\text{mol Mn/kg}$ dose level, there was still a measurable enhancement. In cohort 2, MR images were analyzed for five subjects and clinically relevant contrast increase in the primary tumor without signal increase in the background was observed in all patients. In addition, all MRI images, including both dose cohorts, showed contrast increase in both liver and pancreas at post-dose imaging timepoints. Conclusions: Initial clinical data generated to date demonstrate an acceptable safety profile and PoC for SN132D in the breast cancer patients. Physiological targeting with functional nanoparticles appears suitable for tumor MRI imaging. Our data are in agreement with preclinical data in rodent tumor models. The data are supporting the continuation of the SPAGOPIX-01 clinical trial and we will further explore SN132D in a cohort of pancreatic cancer patients with liver involvement.

Introduction: Benefits of neoadjuvant chemotherapy (NAC) in breast cancer include de-escalating surgical management, treating occult systemic metastases and the assessment of in-vivo tumor response. Guidelines for post-NAC imaging to assess response lack specificity on appropriateness and utility of individual imaging modalities for surgical planning. Mammographic microcalcifications are a confounder that are not well studied. We examined the correlation between the mammographic extent of microcalcifications present post-NAC, corresponding MRI lesions, and definitive surgical pathology.

Methods: In this retrospective cohort study, patients with calcifications on pre-NAC mammograms were collected from a database of consecutive breast cancer patients receiving NAC at an academic center between January 1st 2014 – December 31st 2019. The primary objective was to determine how the maximum diameter of post-NAC calcifications correlates with final surgical pathology, stratified by tumor receptor subtype. The secondary objectives were to assess correlation of the maximum diameter on final pathology with the maximum diameter of (1) post-NAC mammographic mass (if present) and (2) post-NAC MRI, mass (ME) and non-mass enhancement (NME). Parameters on final surgical pathology included the diameters of invasive disease, ductal carcinoma in-situ (DCIS) and the tumor bed (TB). Pearson's correlation coefficient was used to evaluate statistical significance and considered strong if $R^2 \geq 70\%$, moderate if $R^2 = 25-70\%$ and weak if $R^2 \leq 25\%$.

Results: 343 patients received NAC, of which 157 were excluded for lack of calcifications (n=147), lack of imaging reports (n=8) or inflammatory breast cancer (n=2). 186 patients met the inclusion criteria with a mean age of 49.9 years. 34 (18.3%) patients had triple negative breast cancers (TNBCs).

Mammographic calcifications correlated poorly with residual invasive disease ($R^2 = 10.8\%$), overestimating by 57%. TNBCs demonstrated the strongest correlation between

microcalcifications and invasive disease (R²=83%), but calcifications overestimated pathology by 41%. Mammographic calcifications correlated moderately with the TB (R²= 50.3%) and poorly with DCIS (R² = 3.4%). By subtype, both correlations were strong in TNBCs (R² = 76.3% and 77.9% respectively). Similarly, focal mass on mammography correlated poorly with pathology except in TNBCs, which correlated moderately with all three pathology parameters (Table 1). In patients with calcifications on mammography, MRI ME and NME correlated weakly with invasive disease, except in TNBCs, where correlation was moderate in ME (R² = 37.7%) and NME (R² = 28.4%).

Conclusion: In breast cancer patients with microcalcifications, current post-NAC imaging modalities appear to overestimate the extent of residual disease. Surgical excision of all residual microcalcifications may maximize oncologic safety but may also represent over-treatment. Ongoing feasibility trials on surgical omission rely on post-NAC imaging to determine trial candidacy. Our data suggests that potentially eligible patients are excluded on the basis of post-NAC imaging overestimating the extent of residual disease. Further studies are needed to determine the most accurate imaging correlate of residual disease after NAC to plan better surgeries, identify candidates for surgical omission and establish optimal post-NAC imaging guidelines. Current imaging modalities appear most accurate for TNBCs and may be more reliable at identifying exceptional responders for surgical omission in this subtype.

Table 1. Summary of Correlation Analyses in Overall and Triple Negative Breast Cancer (TNBC) cohorts.

	Overall Average % Difference*	Overall Correlation (R ²)	Average % Difference in TNBC	Correlation (R ²) in TNBC
Post-NAC Calcifications				
Invasive Disease	-57.0%	10.8%	-41.5%	83.0%
Tumor Bed	-20.2%	50.1%	-11.7%	76.3%
In-situ Disease	-46.4%	3.4%	-18.1%	77.9%
Post-NAC Mammographic Mass				
Invasive Disease	-0.2%	4.5%	34.5%	16.5%
Tumor Bed	54.0%	19.2%	54.7%	39.1%
In-situ Disease	40.0%	13.6%	40.2%	14.5%
Post-NAC MRI Mass Enhancement				
Invasive Disease	7.7%	12.6%	-46.1%	37.7%
Tumor Bed	79.6%	3.4%	14.5%	25.6%
In-situ Disease	37.3%	17.9%	4.7%	11.3%
Post-NAC MRI Non-Mass Enhancement				
Invasive Disease	-44.4%	9.6%	-44.0%	28.4%
Tumor Bed	16.5%	18.3%	19.5%	37.6%
In-situ Disease	-23.7%	0.0%	-24.7%	11.1%

Purpose Many low-middle income countries (LMIC) suffer from chronic shortages of resources that inhibit the implementation of effective breast cancer screening programs. Advanced breast cancer rates in the U.S. Affiliated Pacific Islands substantially exceed that of the United States. We propose the use of portable breast ultrasound coupled with artificial intelligence (AI) algorithms to assist non-radiologist field personnel in real-time field lesion detection, classification, and biopsy, as well as determination of breast density for risk assessment. In this study, we examine the ability of an AI algorithm to detect and describe breast cancer lesions in clinically-acquired breast ultrasound images in 40,000 women participating in a Hawaii screening program. Materials and Methods The Hawaii and Pacific Islands Mammography Registry (HIPIMR) collects breast health questionnaires and breast imaging (mammography, ultrasound, and MRI) from participating centers in Hawaii and the Pacific and links this information to the Hawaii Tumor Registry for cancer findings. From the women with either screening or diagnostic B-mode breast ultrasound exams, we selected 3 negative cases (no cancer) for every positive case matched by age, excluding Doppler and elastography images. The blinded images were read by the study radiologist to delineate all lesions and describe in terms of the BI-RADS lexicon. These images were split by woman into training (70%), validation and hyperparameter selection (20%) and testing (20%) subsets. An AI model was fine-tuned for lesion and BI-RADS category classification from a Detectron2 framework [1] pre-trained on the COCO Instance Segmentation Dataset [2]. Model performance was evaluated by computation of precision and sensitivity percentages, as well as Area under the Receiver Operator Curve (AUROC). Detections were considered positive if they overlapped a ground truth lesion delineation by at least 50% (Intersection over Union = 0.5), and a maximum of 4 detections were generated for each image. Timing experiments were run on a GPU-enabled (Nvidia Tesla V100) machine on unbatched images. Results Over the 10-year observation period, we identified 5,214 women with US images meeting our criterion. Of these, 111 were diagnosed with malignant breast cancer and 333 were selected as non-cases for a total of 444

women. These 444 women had a total of 4,623 ultrasound images with 2,028 benign and 1,431 malignant lesions identified by the study radiologist. For cancerous lesions, the AI algorithm had 8% precision at a sensitivity of 90% on the testing set. For benign lesions, a sensitivity of 90% resulted in 5% precision on the testing set. The AUROC for bounding box detections of cancerous lesions was 0.90. The AUROC for bounding box detections of benign lesions was 0.87. The model made predictions at a rate of 25 frames/second time (38.7 milliseconds per image). Conclusion Detection, segmentation, and cancer classification of breast lesions are possible in clinically-acquired ultrasound images using AI. Based on our timing experiments, the model is capable of detecting and classifying lesions in real-time during ultrasound capture. Model performance is expected to improve as more data becomes available for training. Future work would involve further fine-tuning of the model on portable breast ultrasound images and increasing model evaluation speed in order to assess utility in low-resource populations [1] Wu Y, Kirillov A, Massa F, Lo W-Y, Girshick R. Introduction: Deep learning (DL) has shown promising results for mammographic breast cancer diagnosis. However, the impact of artificial intelligence (AI) in the screening process have not yet been fully addressed in terms of workload reduction, which has potential to decrease healthcare disparities. Radiologists are tasked with overwhelming volumes of screening mammograms, particularly in medically underserved areas. Therefore, when applied to workflow improvement, AI might be a tool to reduce healthcare disparities. The purpose of this systematic review and meta-analysis was to assess if AI-based triaging of breast cancer screening mammograms could reduce the radiologist's workload with non-inferior sensitivity. Methods: PubMed, EMBASE, Cochrane Central and Web of Science databases were systematically searched for studies that evaluated AI algorithms on computer-aided triage of breast cancer screening mammograms. We extracted data from homogenous studies and performed a proportion meta-analysis with random-effects model to verify the radiologist's workload reduction and the software's sensitivity. Results: A total of 14 studies were systematically selected. Three studies using the same commercially available DL algorithm were included in the meta-analysis, with 156852 examinations evaluated at the threshold of 8. The radiologist's workload decreased by 68.3% (95%CI 0.655-0.711, $I^2 = 98.76%$, $p < 0.001$), with a sensitivity of 93.1% (95%CI 0.882-0.979, $I^2 = 83.86%$, $p = 0.002$). Conclusion: Our findings suggest that DL computer-aided triage of breast cancer screening mammograms significantly reduces the radiologist's workload with high sensitivity. Although AI's implementation remains complex and heterogeneous, it is a promising tool to optimize healthcare resources with a potential large impact in low resource settings that struggle with workforce shortage.

Background: The lack of safety clearance of several metallic breast implants in 7T(Tesla) poses a significant hurdle to standard clinical breast cancer care and research from reaping the benefits of ultra-high resolution MR imaging. A breast biopsy clip (Ultracor Twirl, Becton, Dickinson and Company, Vernon Hills, IL) composed of nitinol, was tested for safety and artifact susceptibility clearance in a 7T MRI scanner, using standardized procedures. This clearance is significant in henceforth allowing patients with this implant to be scanned in now FDA approved ultra-high-field MRI scanners of 7T or less for clinical and research purposes. Methods: Tests for magnetic susceptibility (torque and translational attraction), MRI-related heating, and artifacts were conducted as per standardized protocols. The torque and translational attraction tests evaluated the effects of magnetic force by the MRI to cause the clip to move and twist respectively. The heating test was conducted with customized MR parameters of short TR (repetition time) and maximum echo-train length, designed to induce temperature change. The artifact test using T1 weighted spin and gradient echo imaging sequences, evaluated potential localized signal loss that may result in misrepresentation of the

imaged area. This may occur due to the presence of the metallic clip in the MR environment. Results: The torque and translational attraction tests respectively indicated that the MR environment did not induce any movement in the clip in eight orientations, with a deflection angle of 0 degrees. Results of the heating test indicated no significant temperature change of the clip. A temperature change of less than 0.45C° was observed in the phantom gel in both the absence and presence of the clip, which is well within the safety threshold (< 1°C). Results of the artifact test indicated a very small artifact, with the largest artifact cross-sectional area appearing on gradient echo images. Conclusion: These cumulative results indicate that the Ultracor Twirl breast biopsy clip is safe for imaging patients at 7T.

Comparison Of Cone Beam Breast CT And Breast MRI In Preoperative Assessment Of Primary Breast Cancer Tumor Size Yinan Ji * 1, Geyi Liao * 1, Ningbing Luo², Yi Jiang¹, Xiaoming Liao¹, Wei Tang¹, Huawei Yang¹. 1Department of Breast Surgery, 2Department of Radiology, Guangxi Medical University Tumor Hospital, Nanning, China Correspondence to: Dr. Huawei Yang, Department of Breast Surgery, Guangxi Medical University Cancer Hospital, 71 Hedi Road, Nanning, Guangxi Zhuang Autonomous Region 530021, P.R. China Email: Lordyhw@163.com * Contributed equally Background: Breast cancer is the malignant tumor with the highest incidence among women in China, seriously endangering women's health. After breast cancer is diagnosed, surgery is one of the primary treatments. Assessing the extent of breast cancer is vitally important to formulate the best surgical option, obtain clear margins while minimizing the volume of removed tissue, and improve the treatment outcome and patient's quality of life. Currently, breast surgery relies heavily on Breast MRI (bMRI) for preoperative assessment. However, bMRI may overestimate the tumor sizes. bMRI is contraindicated in patients with claustrophobia, metal implants, and allergy to gadolinium contrast medium. In addition, bMRI is generally expensive and time-consuming. Some patients find bMRI less favorable for cost and time concerns. Cone Beam Breast CT (CBBCT) is a new modality using Cone Beam CT technology and iodinated contrast media for true 3D high-resolution imaging of the breast. Our previous studies have proved the feasibility of CBBCT in the preoperative assessment of breast cancer. A large-scale study has been done to further examine the clinical significance of CBBCT in pre-operative assessment compared with bMRI. Methods: 273 female primary breast cancer patients were included in this study. The maximal diameters of the tumors were measured in CBBCT and bMRI images by an experienced radiologist. The differences between the image-measured size and surgical pathology size (gold standard) were calculated as Δ DCT and Δ DMR. Δ D > 5mm was considered an overestimation and Δ D < -5mm was considered an underestimation. The absolute values of Δ DCT and Δ DMR were also calculated as Δ DCT_abs and Δ DMR_abs. A Student t-test was

used to compare the statistical differences between Δ DCT_abs and Δ DMR_abs. Among Δ DCT_abs and Δ DMR_abs, a 5mm cut-off value was used to determine the concordance between image and pathology. The concordance rates of CBBCT-Pathology and bMRI-Pathology were tested with the χ^2 method. Factors that may affect the accuracy of tumor size measurement were analyzed. Results: Overall there were no statistically significant differences between Δ DCT_abs and Δ DMR_abs. (0.58 ± 0.68 cm vs. 0.65 ± 0.68 cm; $t=1.653$, $P=0.100$). Using 5mm as the cut-off value of concordance, there was no significant difference in the CBBCT-Pathology and bMRI-Pathology concordance rates (64.8% vs. 60.1%, $\chi^2 = 1.320$, $P=0.251$). The overestimation rate of CBBCT was significantly lower than that of bMRI (11.4% vs. 19.4%, $\chi^2=6.810$, $P=0.009$). But there was no significant difference in the underestimation rates (23.8% vs. 20.5%, $\chi^2=0.860$, $P=0.354$). Δ DCT_abs is significantly smaller than Δ DMR_abs among the invasive ductal carcinoma group ($P=0.017$), the premenopausal group ($P=0.004$), and the small tumor size (≤ 2 cm) group ($P=0.003$). Δ DCT_abs and Δ DMR_abs have no significant differences among the lymph node metastasis group, multi-lesion group, and enhancement type group ($P > 0.05$). Conclusions: CBBCT is concordant with surgical pathology in breast tumor size measurement and provides more accurate tumor size estimation compared with bMRI. CBBCT can be used as a valuable modality for pre-operative assessment.

Introduction:

Breast conserving therapy, has generally been accepted as treatment of choice for early invasive breast cancer.

However adequate local control depends on obtaining negative margins and receipt of radiation. In 20-30 % of patients with breast conserving surgery a second re-excision procedure is due to tumor-positive margins at histopathology. Margins re-excision rate are variable across the countries.

Mean re-excision rate of 17.2% across units in UK. Intraoperative specimen radiography, used to evaluate partial mastectomy specimens ensure that the lesion is adequately removed.

Objective:

to determine whether 3D-intraoperative imaging better predicts margin status and reduces the re-excision rate than conventional 2D imaging.

Methods:

Retrospective study comparing two cohorts of patients

360 screen-detected breast cancer (2D cohort). April 2015 to March 2018

300 screen-detected breast cancer (3D cohort) April 2018 to March 2021

Royal Cornwall Hospital (RCHT) introduced a 3D intraoperative system for all cases in April 2018

Prior to the introduction of 3D intraoperative imaging at RCHT the re-excision rate was stable at approximately 15%.

All patient had undergone preoperative digital mammogram and ultrasound.

All patients had core biopsy diagnosis

All malignancies were localised with ROLL (Radio-guided occult lesion localization) techniques.

All wide local excision were performed by 5 fully trained oncoplastic breast surgeons (similar distribution within the two cohort)

Specimen radiograph was performed intraoperatively using:

2D x-ray device (Faxitron system; Trident Hologic, Marlborough, MA) or

3D tomosynthesis (Mozart system; Kubtec Medical imaging, Stratford, CT).

For both methods of assessment, specimen was placed in the device and auto exposed without any compression of tissue.

All specimens were marked with orienting sutures and clips according to local protocol.

All specimens were painted in theatre by the operating surgeon.

All specimens were examined by the same pathologists.

No change in margin protocol for 12 years (already compliant to ABS guidelines)

- A clear margin for invasive cancer was defined as tumour found within 1mm of margin. For ductal carcinoma in situ (DCIS), a margin was classified as positive if ink on tumour, was classified as close ink is found in under 2 mm from tumour and as negative if more or equal to 2 mm, in accordance with NICE guidelines. (22)

Statistical Analysis:

- The study compares patient demographics, histology, and re-excision rates between 2D and 3D
- Descriptive and comparative statistics are be calculated for all collected data

TABLE 1:

3D/2D RR 0.59 (P:0.01), CI 0,3369-09068, Z -2.3473, P 0.0189

Conclusions:

The use of intraoperative 3D specimen X-ray reduced the relative risk of re-excision rate by

41% (P=0.01) without any negative impact on other parameters.

Table 1: Results

	2D Cohort		3D Cohort	
Screening patients	336		300	
Re-excision rate	51	15.17%	27	9.00%
Wle average weight	27.87 gm		28.64 gm	
Cavity shaves average weight	3.00 gm		3.00 gm	
DCIS only	85	5.29%	80	26.33%
Invasive only	176	52.38%	157	52.33%
Invasive + DCIS	75	22.32%	63	21.00%

Background: Tumor-infiltrating lymphocytes (TILs) are a useful prognostic factor and predictive biomarker of neoadjuvant chemotherapy treatment response for breast cancer, especially in

human epidermal growth factor receptor type 2 (HER2)-positive breast cancer and triple-negative breast cancer (TNBC). However, due to heterogeneity of TIL expression and distribution in the tissues, accurately predicting TIL expression, especially using limited core-needle biopsy specimens, is difficult. Therefore, an accurate and simple preoperative evaluation method is needed. We have reported that the TILs-ultrasonography (US) score determined by characteristic US findings has a predictive performance for lymphocyte-predominant breast cancer (LPBC). This study aimed to investigate whether the TILs-US score with added vascularity assessment has a better predictive performance for LPBC.

Methods: This multicenter, retrospective study investigated the validation and scoring of the LPBC characteristic imaging findings and applied it for LPBC and non-LPBC prediction. A total of 100 patients with HER2-positive breast cancer (n = 59) and TNBC (n = 41) treated by curative surgery between January 2014 and December 2021 were evaluated. Stromal lymphocytes in surgical pathological specimens were evaluated; the cutoff value for predicting LPBC was defined as $\geq 50\%$ stromal TILs. Preoperative US was examined for TIL indicators. The US images with characteristic TILs were scored for LPBC prediction. Univariate and multivariate logistic regression analyses were employed for each potential predictor variable of LPBC.

Results: A total of 40 patients with $\geq 50\%$ stromal TILs were defined as having LPBC. The examined characteristic US findings for predicting LPBC, shape (more lobulated), internal echo level (weaker), posterior echoes (stronger), and vascularity assessment (hypervascularity), were significantly associated with LPBC and used to assign the scoring for predicting LPBC. As previously reported, the TILs-US score ranged from 0–7 points based on three ultrasonic tissue characteristics: shape (round, oval, and polygonal or irregular, 0 points; lobulated, 1 point; and small lobulated, 2 points), internal echo level (high or equal, 0 points; low, 1 point; and extremely low, 2 points), and posterior echoes (shadowing or attenuating, 0 points; no change, 1 point; accentuated, 2 points; and extremely accentuated, 3 points). We further added vascularity assessment (avascular or hypovascular, 0 point; moderately vascular, 1 point; and hypervascular, 2 points) to this scoring system. Based on the receiver operating characteristics (ROC) curves (AUC [Area Under the Curve] 0.77), the score cutoff for predicting LPBC was 4 points for TILs-US score (sensitivity, 0.83; specificity, 0.55; and accuracy, 0.66). Multivariate logistic regression analysis revealed that cT ($< T_2$), estrogen receptor (ER) negativity, and a TILs-US score of ≥ 4 points were significant LPBC predictors (odds ratio [OR] 3.60; $p = 0.028$; OR 8.68; $p = 0.020$; OR 5.99; $p = 0.005$). Conversely, based on the ROC curves (AUC 0.78), the score cutoff for predicting LPBC was 5 points after adding vascularity assessment (sensitivity, 0.93; specificity, 0.57; and accuracy, 0.71). Multivariate logistic regression analysis revealed that cT ($< T_2$), ER negativity, and a TILs-US score adding vascularity assessment of ≥ 5 points were significant LPBC predictors (OR 5.12; $p = 0.010$; OR 10.3; $p = 0.019$; OR 20.1; $p < 0.001$).

Conclusions: Including the vascularity assessment to the TILs-US score, which can be noninvasively obtained using US, is a more accurate preoperative predictor of LPBC. Vascularity assessment may be an auxiliary factor in predicting LPBC.

Univariate and multivariate logistic analysis of significant clinicopathological factors predicting lymphocyte-predominant breast cancer.

Characteristic	Univariate logistic regression analysis			Multivariate logistic regression analysis

Background Mammographic Artificial intelligence (AI) algorithms (Lunit insight MMG) draws attention as a diagnostic support tool for breast cancer detection. Lunit insight MMG provides a location suspected of breast cancer with a heatmap and a score reflecting the probability of the presence of suspicious areas. We investigated whether the Lunit insight MMG score is relevant for predicting the response to adjuvant tamoxifen. Methods Patients diagnosed with DCIS and underwent treatment at Seoul National University Hospital in 2010 were retrospectively enrolled. Clinical characteristics, tamoxifen use, survival data, and mammography images were extracted from the electronic medical records, and Lunit insight MMG scores were calculated retrospectively. We classified two groups according to tamoxifen treatment and compared the score change of contralateral breast from baseline to 5 years after surgery for DCIS. Change categories of Lunit insight MMG score included maintaining high risk, maintaining low risk,

increasing from low risk to high risk, and decreasing from high risk to low risk. Results Of 100 patients, 50 (50%) had undergone tamoxifen treatment (group 1) and 50 (50%) had not (group 2). The median age of the patients was 48.4 years for group 1 and 51.5 years for group 2 (p=0.172). The median follow-up duration was 8.7 years for the whole cohort. Using Lunit insight MMG score, more patients in group 1 decreased in contralateral breast cancer (CBC) risk compared with group 2 (6.0% vs. 2.0%; P=.008). No patients in group 1 had an increase in CBC risk while 9 patients increased in group 2 (0% vs. 18.0%; P =.008). There was no ipsilateral breast cancer recurrence for the whole cohort, and two patients experienced contralateral invasive breast cancer in group 2. In two patients with CBC, the Lunit insight MMG score increased five years after surgery, one year and three years before the CBC diagnosis. Conclusions Longitudinal Changes of Mammographic AI algorithms Score may be a predictive surrogate marker for response to tamoxifen therapy in hormone receptor-positive DCIS.

Background. Surgical method is fundamental in complex and combined approach of the treatment of the early breast cancer. It is a common fact, that purity of the resection margin is the main indicator of oncological safety of the breast-conserving surgery (BCS). The presence of tumor cells in examined margin is one of the predictors of the development of local recurrence after BCS with breast cancer. Currently the necessity of searching for adequate and quick method of intraoperative valuation of the state of the resection margin is kept. Intraoperative valuation of the resection margin state with the usage of digital two-point sectorography (Faxitron BioVision) appeared as the alternative of urgent histological test, providing the optimum size of the information about adequacy of the carried out surgical treatment. Objective – to evaluate diagnostic features of the digital two-point sectorography Faxitron BioVision in the intraoperative valuation of the resection margin status after the

conducted surgical treatment in comparison with planned histologic study. Materials and methods. 368 conducted conservative surgeries were analyzed, patients were divided in two groups depending on carrying out of non-adjuvant chemotherapy (NAC). The first group of patients included 236 patients, who didn't received NAC before operative treatment stage; second group included 132 patients, who received NAC. Subset analysis of detection rate of the positive resection margin was carried out with the usage of the intraoperative valuation of the resection margin on the X-ray apparatus Faxitron BioVision or without carrying out this method. After each BCS conducted when planned histologic study resection margin were tested for the presence of the tumor cells and the frequency of carrying out of reoperations when positive margin were found. Results. From 368 tested anatomic medications after BCS positive resection margin (R1) is found in 25 cases, which is 6,8 %. From 236 patients of the first group after BCS R1 is found in 20 cases, which is 8,5 %; from 132 conducted operations in the second group in 5 (3,8%) cases – the presence of R1 is found. Reoperations were conducted in 13 cases, when repeated pathomorphological study tumor cells found in 3 cases in the subgroup, which didn't receive intraoperative valuation on the X-ray apparatus Faxitron BioVision. Conclusion. Assessing the results of our study we can make a conclusion about the positive experience of conducting of BCS and intraoperative evaluation of conservative surgery and intraoperative valuation with the usage of the digital two-point sectorography (Faxitron BioVision) and low frequency of positive margin (3,8%) in comparison with refusal from carrying out of this method (8,5%).

Authors: Mary Yamashita, MD; Rachel Brem, MD; Lauren Baker, Ph.D; MD; Taylor Mahoney, PhD; Patrick Walker, PharmD, MPH; Rachel Treat, MA; Linda Hovanessian Larsen, MD. Title: Patient experience with automated SoftVue 3D whole breast tomographic ultrasound. Purpose: SoftVue (SV) is an automated, 3D whole breast ultrasound tomographic imaging device which is FDA PMA approved as adjunct to mammography for women with dense breasts. Screening with handheld US is labor intensive and with ABUS is associated with significant patient

discomfort. A benefit of SV is that image acquisition is not operator dependent and does not require compression. Because acceptance by patients is crucial to implementation of US screening, we evaluated patients' experience with SV, specifically, asymptomatic women with BI-RADS c or d density undergoing FFDM. Materials and Methods: As part of a prospective, 10-site study, 7,439 asymptomatic women with BI-RADS density category c or d were screened on the same day with FFDM and SV. Each patient's experience was assessed for perceived pain, discomfort and anxiety, discretion and modesty, overall satisfaction, and whether they would recommend it to others. The responses were measured on a Likert scale with 5 choices from strongly agree to strongly disagree, then studied by Chi-Squared analysis. Results: The mean age was 53.9 ± 9.7 yo, mostly white women (87.7%). The median BMI was 24.4. Majority had no personal history of breast cancer (97.2%), but 24.8% had a previous biopsy and almost half (46.3%) had a family history of breast cancer. Almost all patients (99.6%) completed the survey. SV was perceived as significantly more comfortable than FFDM (83.7% vs 52.2%, $p < 0.001$), was painless (94.9% vs 53.1%, $p < 0.001$), and was associated with less anxiety during the procedure (95.1% vs 79.9, $p < 0.001$). Lastly, 99.3% felt the experience was private and discreet, and 95% would recommend the SV exam to other women. Conclusion: Pain, fear, anxiety, and modesty concerns are some of the barriers preventing widespread implementation of screening breast US. This data suggests that SV, an FDA PMA approved adjunctive screening exam for women with dense breast tissue, is painless, offers a private and discreet scan that limits anxiety, and is well accepted by patients. Clinical relevance statement: SV is a novel automated US tomographic screening technology that is comfortable, well-accepted, FDA PMA approved, and will likely result in improved implementation of screening breast ultrasound in women with dense breasts.

Background Estrogen receptor positive (ER+) progesterone receptor negative (PR-) tumors are a distinct subset of breast cancers that are not well characterized. It is critical to better understand the biology of ER+PR- tumors and tailor therapy accordingly for this unique subgroup. The objective of this study is to compare the ER+PR- subgroup of breast cancer as compared to the double positive ER+PR+ group in a large, well-characterized database to determine if the tumors that are PR- are associated with higher rates of genomic testing and chemotherapy receipt. Methods We identified patients diagnosed with ER+Her2-, Stage 1-3 invasive breast cancer from 2010-2015 in the National Cancer Database. We excluded patients who received neoadjuvant therapy. Demographics and clinical characteristics for the ER+PR+ and ER+PR- groups were obtained. Differences between groups were assessed using the chi-square test. Multivariable logistic regression analysis was performed on both the node negative and node positive patients in order to identify factors independently associated with having a genomic test and receiving chemotherapy in the ER+PR+ and ER+PR- cohorts. Results Of the 363,945 eligible patients, 327,357 (89.9%) patients had ER+PR+ breast cancer and 36,588 (10.1%) had ER+PR- breast cancer. A trend towards larger tumor size in the ER+PR- population as compared to the ER+PR+ population was noted with 23.1% vs 17.3% of tumors 2-5cm and 2.2% vs 1.2% of tumors > 5cm, respectively. Higher grade was also seen in the ER+PR- group as compared to the ER+PR+ group with 27.1% versus 11.7% grade 3 tumors. In both the node negative and node positive populations, genomic testing was less likely to be sent on a PR- breast cancer than a PR+ breast cancer. When genomic testing was sent, there were more high risk Oncotype Recurrence scores (RS > 30) in the PR- group than the PR+ group. For node negative breast cancer high risk Oncotype recurrence scores were found in 32.4% of the ER+PR- population versus 5.6% in the ER+PR+ population. In the node positive cohort high risk Oncotype Recurrence scores were seen in 27.8% of the ER+PR- population as compared to 5.0% in the ER+PR+ population. Patients with discordant ER+PR- breast cancer were more likely to receive chemotherapy than their ER+PR+ counterparts in both the node negative cohort (32.2% vs 12.7%) and the node positive cohort (73.2% vs 64.5%). Conclusion There have been limited studies to date specifically focused on the ER+PR- subgroup. Patients with ER+PR- breast cancer have a higher grade, larger size, higher risk genomic testing, and

are more likely to receive chemotherapy than their ER+PR+ counterparts. Discordance in hormone receptor status contributes to a more aggressive type of breast cancer that may impact clinical and treatment decisions.

Background: Women with estrogen receptor (ER)-positive disease have a long-term risk of distant recurrence. The poor survival of premenopausal women diagnosed with breast cancer combined with the otherwise long life expectancy makes it especially important to identify tumor characteristics associated with long-term survival. Intra-tumor heterogeneity, having cancer cells of varying characteristics across the tumor, may promote therapeutic resistance and metastatic capacity. We have previously shown that high intra-tumor heterogeneity of ER increases the risk of fatal breast cancer. To our knowledge, the relation between intra-tumor heterogeneity of progesterone receptor (PR) expression and long-term survival is not known. We aimed to study the association between intra-tumor heterogeneity of PR and long-term survival of premenopausal women in the Stockholm tamoxifen trial (STO-5), with 20-years complete follow-up.

Methods: This study was a secondary analysis of 504 ER-positive/PR-positive premenopausal women from the STO-5 trial (1990-1997). 451 women had human epidermal growth factor receptor 2 (HER2)-negative tumors. Patients were randomized to receive either 2 years of endocrine treatment (tamoxifen and/or goserelin) or no endocrine treatment. Lymph node-positive patients (n=251) also received standard chemotherapy (CMF). Immunohistochemical analysis, including estimating the proportion of tumor cells for each PR intensity level (0, 1+, 2+, or 3+), was completed in 2020. Intra-tumor heterogeneity of PR was calculated using Rao's quadratic entropy and then categorized into low and high intra-tumor heterogeneity groups, using a predefined cutoff at the second tertile. Complete long-term (20 year) follow-up was obtained from high-quality Swedish registries. Long-term distant recurrence-free interval (DRFI) was assessed using univariate Kaplan-Meier analysis and multivariable Cox proportional hazard modeling, adjusting for patient and tumor characteristics.

Results: A statistically significant difference in 20-year DRFI was seen between patients with high and low intra-tumor heterogeneity of PR in the univariate Kaplan-Meier analysis (log-rank $P < 0.01$). Survival proportions for DRFI at 20 years were 60.2% (95% CI, 53.2%-68.1%) and 73.3% (95% CI, 68.6%-78.3%) for patients with high and low PR intra-tumor heterogeneity, respectively. Analysis in patients with HER2-negative tumors yielded similar results.

In the multivariable analysis, women with high intra-tumor heterogeneity of PR had a significantly increased long-term risk of distant recurrence, compared to women with low intra-tumor heterogeneity, hazard ratio (HR)=1.49 (95% CI, 1.08-2.06). The same pattern was seen in HER2-negative women, HR=1.50 (95% CI, 1.06-2.12), see Table.

Conclusions: This study suggests an increased long-term risk of distant recurrences in ER-positive/PR-positive premenopausal women with high intra-tumor heterogeneity of PR as compared to women with low intra-tumor heterogeneity of PR, independent of HER2 status. Ongoing analyses include using deep learning for image analysis of breast cancer tumors to examine intra-tumor heterogeneity at higher resolution and for various tumor characteristics. Better understanding of tumor characteristics associated with long-term risk in premenopausal women is needed, given the poor prognosis and early onset of the disease.

Long-term risk of distant recurrence by PR intra-tumor heterogeneity and HER2 status

ER-positive/PR-positive premenopausal breast cancer patients	PR intra-tumor heterogeneity	No. patients	No. events	Crude model	Full model
				HR (95% CI)	HR (95% CI)
All patients (n=504)	High	172	67	1.53 (1.11-2.11)	1.49 (1.08-2.06)
	Low	332	87	1.00 (Ref)	1.00 (Ref)
HER2-negative patients (n=451)	High	150	58	1.55 (1.10-2.18)	1.50 (1.06-2.12)
	Low	301	77	1.00 (Ref)	1.00 (Ref)

Multivariable Cox proportional hazard regression modeling of 20-year distant recurrence-free interval (DRFI) by high and low PR intra-tumor heterogeneity. ER-positive/PR-positive and ER-positive/PR-positive/HER2-negative premenopausal women were analyzed separately. The crude model was adjusted for age, randomization year, lymph node status, and endocrine treatment. The full model was adjusted for age, randomization year, lymph node status, endocrine treatment, tumor size, Ki-67 status, and HER2 status.

Background: Lobular carcinoma in situ (LCIS) is known to be a risk factor for the development of invasive lobular carcinoma (ILC). Recent genetic analysis indicates that LCIS is a facultative precursor of ILC. It was reported that ~50% of ILC co-occur with LCIS, however it is unclear whether patients with this co-occurrence behave similarly to patients with pure ILC.

Methods: We retrospectively searched for patients treated at MD Anderson Cancer Center with a diagnosis of stage I-III ILC in our prospectively collected electronic database. Patients were divided into 2 groups: those with ILC with co-occurring ipsilateral LCIS (ILC/LCIS) and those with pure ILC without a histologically detected co-occurring ipsilateral in situ lesion (ILC alone). We obtained data on demographics, tumor size (T), lymph nodes (N) involvement, estrogen (ER), progesterone (PR) receptor status, HER2 expression, Ki67, treatment received, distant

recurrence and survival status. The Kaplan-Meier product-limit method was used to compare distant recurrence-free survival (DRFS) and overall survival (OS) between the two groups. Multivariate analysis using Cox regression was used to assess association between co-variables and recurrence/survival.

Results: We identified 4,217 patients with stage I-III ILC treated at MDACC between 1966 and 2021. 45% of cases (n = 1,881) had co-existing LCIS . 90% of ILCs were classical and 96% of LCIS were classical. Overall, the median age was 56 years, 95% of cases were ER+, 80% PR+, 5% HER2+. 40% of cases were T1, 60% N0 and 70% of tumors with available Ki67 data had low Ki67 (< 20%). Around 65% underwent mastectomy, 20% received neoadjuvant chemotherapy, and 35% received adjuvant chemotherapy. Statistically and numerically, ILC alone tended to have more T4 and N3 disease (P < 0.001), more ER/PR negative disease (P = 0.0002), more HER2+ disease (P = 0.010), higher Ki67 (P = 0.005), more non-classical ILC subtype (P = 0.04) and more exposure to neoadjuvant chemotherapy (P = 0.0002) than the ILC/LCIS group. The median follow-up time was 6.5 years. Patients with ILC co-existing with LCIS had better DRFS (28.0 vs 14.3 years, Hazard ratio (HR) 0.53, 95% confidence interval (CI) 0.47 – 0.59, P < 0.0001) and better OS (18.9 vs 13.7 years, HR 0.62, 95% CI 0.56 – 0.69; P < 0.0001). Multivariate (MV) analysis showed the absence of LCIS to be a poor prognostic factor along with a higher T and higher N for distant recurrence and overall survival (Table 1).

Conclusion: The findings of this study suggests that the co-existence of LCIS with ILC is a good prognostic factor and that further studies are warranted to understand this phenomenon.

Table 1. Multivariate Analysis between Clinico-Pathological Variables and Distant Recurrence-free Survival/Overall Survival

	DRFS		OS	
	MV-HR	95% CI	MV-HR	95% CI
Absence of LCIS	2.361	1.810 – 3.104	1.605	1.260 – 2.051
T2	2.493	1.753 – 3.591	1.404	1.027 – 1.923
T3	2.447	1.618 – 3.725	1.492	1.018 – 2.181
T4	5.269	3.399 – 8.212	3.189	2.126 – 4.763
N1	5.579	4.061 – 7.725	2.343	1.763 – 3.110
N2	5.850	3.081 – 10.39	3.421	1.832 – 5.937
N3	10.02	6.758 – 14.86	3.181	2.148 – 4.650

Background: Neoadjuvant systemic therapy (NAT) is typically administered to patients diagnosed with non-metastatic invasive breast cancer (IBC) with high-risk features. The goal of NAT in this setting is a pathologic complete response (pCR), meaning no residual invasive disease observed on final review of surgical pathology . It is broadly accepted that pCR may be used as a surrogate marker of predicted long term benefit of treatment and overall survival. Prior studies have demonstrated that the time interval between a diagnosis and initiating NAT may impact the overall outcome for patients.

In this study we sought to determine if there were any differences between African American (AA) patients and other races with respect to time-to-treatment (TTT) in initiating NAT. In addition, we explored the relationship between TTT and pCR rates and the factors influencing this relationship.

Methods: This is a single-institution retrospective study, all patients diagnosed with non-

metastatic IBC who were treated with NAT and completed definitive surgery between 2015-2021 were included. Demographic and clinicopathologic details were abstracted from the electronic medical record. Data was analyzed in aggregate; subgroup analysis was completed according to race and histopathologic subtype of breast cancer.

Results: A total of 392 female patients were included in this study: 59.2% White, 35.7% AA, 5.1% were of other races. The average age at the time of diagnosis was 54.1 ± 13.4 years old for the total population, and 54.0 ± 13.0 years old for AA patients.

Mean TTT was 33.4 (SD = 18.7) days for all patients, 37.0 (SD = 21.3) days for AA patients and 31.3 (SD = 16.9) days for White patients. A significant difference was identified in AA patients versus the total population (p=0.017), and particularly AA versus White patients (p=0.005).

A pCR was achieved in 40.7% of AA patients and 34.7% in the total population (p=0.050). Multivariate analysis of the factors impacting the pCR rate showed that TTT, age, tumor grade and histologic subtype independently influenced the pCR rate. However, race was not an independent factor. Among the studied factors influencing pCR rate only TTT is modifiable (Table 1).

Conclusion: The results of our study show that although AA patients achieve pCR at higher rates than the general population, they do experience delays in TTT which is an independent factor influencing pCR rates. Other factors inherently play a role in achieving a pCR, however, race is not one of them. pCR rates among AA patients may be further improved by reducing TTT and maximizing the potential benefit of neoadjuvant systemic therapy.

Table 1: Association between TTT, race, pCR.

	% Black patients	Mean TTT for total population (days/SD)	Mean TTT for Black patients (days/SD)	pCR (%)	TTT for pCR (days/SD)	
Total population	35.7	33.4 (18.7)	37.0 (21.3)*	34.7*	30.0 (16.2)*	
Subgroup Analyses	HR+	32.1	34.8 (18.6)	41.1 (19.6)*	16.0	31.0 (15.3)
	HER2+	31.4	31.7 (22.0)	29.2 (6.5)	70.6	32.7 (25.6)
	HRHER2+	39.5	34.5 (22.0)	37.4 (31.0)	45.3	28.6 (8.8)
	TNC	40.9	30.6 (12.5)	34.2 (15.6)*	37.6	28.5 (11.3)

Table 1 depicts the demographic distribution related to the mean time-to-treatment (TTT), total population and percentage of Black patients. Data was analyzed as an aggregate and subgroup analyses were conducted according to histologic subtypes. Multivariate analyses were used to explore the association between TTT and pathologic complete response (pCR). HR+=Estrogen/progesterone receptor positive; HER2+= human epidermal growth factor receptor 2 (HER2) present by IHC 3+ score or FISH ≥2 ratio; TNC=triple negative cancer. *Indicates a statistically significant finding (i.e.: p<0.05).

Background: Obesity, the modern 'epidemic', has shared correlation with fatty liver disease and breast cancer. However, previous studies on the relation between fatty liver and breast cancer have shown conflicting results on the impact of fatty liver on the survival and recurrence of breast cancer patients. And there was no attempt to find out the effect of liver fibrosis, which is the consequence of fatty liver disease, on female breast cancer patients. So we attempted to

investigate the prognostic value of non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis(NASH)-related liver fibrosis in patients with breast cancer undergoing surgery, using noninvasive tools like liver-to-spleen attenuation(L/S) ratio and Fibrosis-4(FIB-4) score, respectively. Methods: A total of 933 patients diagnosed with primary invasive breast cancer and receiving surgery at the university-affiliated referral center between April 2006 and December 2019 were included. After excluding patients who had significant alcohol consumption and hepatitis viral infection,838 patients were divided into two groups according to the L/S ratio of 1 measured by the preoperative low-dose computed tomography: 91 patients(10.9%) with a L/S ratio< 1 vs 747 patients(89.1%) with a L/S ratio≥1. They were also divided into two groups based on the FIB-4 score of 2.67: 804 patients (95.9%) with a FIB-4 score< 2.67 vs 34 patients (4.1%) with a FIB-4 score≥2.67. The Cox proportional hazards model was used to calculate the hazard ratio (HR) and the 95% confidence interval (CI). Results: Patients with NAFLD were older, had higher BMI, and had a higher proportion of mastectomy and hyper-transaminasemia. They showed worse overall, disease-free, and regional recurrence-free survivals compared to those without NAFLD (p=0.008, 0.043, and 0.017, respectively), but no significant differences in local recurrence-free, systemic recurrence-free, and contralateral breast cancer-free survivals. The survival outcome of breast cancer did not show any relationship with NASH-related liver fibrosis (overall survival; p=0.061, disease-free survival; p=0.557). NAFLD was a significant risk factor for mortality in multivariable analysis (HR, 2.077; 95% CI, 1.052–4.102; p=0.035). After stratifying for subtypes of breast cancer, the L/S ratio remained a significant predictor of overall, disease-free, local recurrence-free, and regional recurrence-free survivals in only the hormone receptor-positive/HER2–negative subtype (p=0.007, 0.005, 0.009, and < 0.001, respectively). Conclusion: NAFLD is significantly associated with decreased overall survival, disease-free survival and increased regional recurrence in patients with breast cancer especially the hormone receptor-positive/HER2–negative subtype. NASH-related fibrosis was not associated with survival. Therefore, NAFLD should be assessed in the preoperative setting for predicting long-term prognoses of breast cancer patients

Introduction Neuroendocrine tumours (NET) are thought to arise from cells throughout the diffuse endocrine system and can occur almost everywhere in the body. Most NETs arise from the gastrointestinal tract, lung, thymus, and pancreas. Primary neuroendocrine carcinoma (NEC) of the breast is a rare and under-recognized subtype, accounting for less than 1% of breast carcinomas. Only a few small studies and case reports have been reported and there are no clear diagnostic criteria and established treatment options. World Health Organization (WHO) classification of tumor series' fifth edition was published in 2019 and adopted 'Neuroendocrine neoplasm (NEN)' as a term encompassing all tumour classes with predominant neuroendocrine differentiation. NENs of the breast are classified into invasive ductal carcinoma (IDC) with neuroendocrine differentiation (NED), NET, and NEC of small cell or large cell types. Thus we aim to report pathologic reviews and treatment outcomes of patients with NENs of the breast at a single center. **Methods** We retrospectively screened the medical record of 34,370 patients diagnosed with breast cancer from 2007 to 2022 by Corporate Data Warehouse (CDW) and revealed there were 22 patients diagnosed with primary breast NEN. The pathologist reviewed the pathology slides and reclassified the diagnosis according to the WHO classification of tumor series' fifth edition. Clinical characteristics, treatment modalities, and therapeutic outcomes were reviewed retrospectively. **Results** We reviewed pathology slides of 22 patients with histologically proven diagnoses of primary breast NEN from 2007 to 2022. We found only 8 patients meet the criteria of primary breast NEC (large cell 2, small cell 6), 3 patients with NET, and 3 patients with IDC with NED. We excluded 8 patients who did not fulfill the criteria of NEN. The median age of NEN was 48.5 years (range, 31-70) and 6 patients (42.9%) were postmenopausal women. The median follow-up duration was 25.3 months (Interquartile range(IQR), 15.0-54.7). All patients underwent surgery, 3 patients underwent a mastectomy and 11 patients underwent breast-conserving surgery (BCS) with a curative aim. Five patients had lymph node metastasis. There was no expression of the human epidermal growth factor receptor 2 (HER2) in all 14 cases. Hormone receptor expression was shown in 4 of NECs (50%) and all NETs or IDC with NED patients. Patients with primary breast NEC had a median recurrence-free period (RFP) of 14.6 months (95% confidence interval (CI), 11.0-18.2) and median overall survival (OS) of 52.1 months (95% CI, 0.0-120.0). Patients with NET or IDC with NED had an overall favorable outcome, none of the patients died and only one patient with IDC with NED experienced disease progression. The median PFS and OS were not reached in NET or IDC with NED subgroups. **Conclusion** NETs are rare tumours with a wide range of clinical presentations according to the site of involvement. Primary breast NENs are extremely rare and there are no specific guidelines for treatment. NENs are often underdiagnosed, as neuroendocrine markers are not routinely tested in breast cancer. In this retrospective single-center study, the incidence of primary breast NENs was 0.04% (14 of 34,370 patients) and primary breast NEC was associated with poor prognosis compared with breast NET or IDC with NED. Identifying innovative treatment strategies is needed to overcome poor outcomes of primary breast NEC.

Introduction: Estrogen receptor (ER) loss occurs in about 20% of recurrent breast cancers (BC) and is associated with unresponsiveness to endocrine therapy (ET) and poor prognosis. Prior studies evaluating ER-loss included predominately patients with invasive ductal carcinoma (IDC), and therefore the impact of ER-loss in invasive lobular carcinoma (ILC) is unknown. In this retrospective analysis, using real-world data, we aimed to determine the prevalence and clinical significance of ER-loss in ILC. **Methods:** Advanced BC were molecularly profiled at Caris Life Sciences (Phoenix, AZ) with NextGen Sequencing of DNA (592-gene panel or whole-exome sequencing), RNA (whole transcriptome sequencing, WTS) and immunohistochemistry (IHC) of select markers. A large real-world evidence (RWE) database combining Caris' molecular data with clinical information obtained from insurance claims data (CODEai) was interrogated and overall survival (OS) was calculated from time of tissue collection to last patient contact. A tumor was considered to have ER-loss if therapies approved only for ER-positive BC were prescribed prior to obtaining a negative ER IHC result. OS was compared using Kaplan-Meier estimates for defined patient cohorts; significance was determined as p values < 0.05. For molecular analyses, Fisher-Exact or Chi-Square tests were used to determine p values. Correction for multiple comparisons was performed using Benjamini-Hochberg to calculate q values. **Results:** The RWE database included 24,824 patients with advanced BC. At the time of tissue collection for molecular profiling, 6,786 advanced BC patients had been previously treated with ET (with or without mTOR or CDK4/6 inhibitors), of whom 1,338 had data available on histologic classification and ER IHC. The final analytical cohort included 263 patients with ILC and 1,075 with IDC. ER-loss was identified in 11.4% of ILC (n=30/263) and 19.6% (n=210/1075) of IDC (p=0.0017). In ILC, ER-loss was associated with significantly worse OS (HR: 1.75, 95%CI: 1.10-2.79, p=0.016) compared with no ER-loss. In the cohort of patients with ER-loss, patients with ILC had significantly worse OS compared with IDC (HR=2.03, 95% CI: 1.267-3.251, p=0.003). Further, when 1,016 tumors with ER-loss (regardless of histology) were stratified by the median OS (mOS=11mo), positive PD-L1 expression (34% vs. 22%, p=0.04, q=0.22), HER2 IHC positivity (16% vs. 7.8%, p=0.003, q=0.08) and HER2 amplification (16% vs. 4.7%, p=0.0006, q=0.04) were enriched in patients with longer mOS; while amplification of TEFB (0.38% vs. 2.6%, p=0.047, q=0.23) and MYB (0.38% vs. 2.6%, p=0.047, q=0.23) were enriched in patients with shorter mOS. WTS identified 197 differentially expressed genes, the majority of which were enriched in patients with longer mOS (q< 0.05). **Conclusions:** In this large real-world dataset, ER-loss likely occurred in 11.4% of ILC and was associated with worse OS compared to both patients with IDC and ER-loss and ILC without ER-loss. Our analysis had several limitations; notably, our definition of ER-loss was based on prior treatment, we could not distinguish between de novo or recurrent metastatic disease and time of tissue collection was not standardized during the course of treatment. Thus, additional studies are needed to confirm these findings. However, this study does suggest that ER-loss occurs in a subset of patients with ILC and has poor prognostic implications.

Significance: Triple negative breast carcinoma (TNBC), characterized by lack of estrogen (ER) and progesterone receptors (PR) and absence of Her2/neu (Her2) receptor amplification, typically follows an aggressive course that includes high relapse rates, rapid progression, and poor outcome. Advances in treatment have been limited by molecular heterogeneity within TNBCs and lack of effective molecular targets. Although a subset of TNBC associated with tumor infiltrating lymphocytes (TILs) is more immunogenic than other breast cancers, response to immunotherapy has been variable and reported in only 10-40% of cases. Identification of prognostic immune biomarkers will identify novel therapeutic targets and facilitate appropriate patient selection for therapy. Aim: To analyze the immune gene expression profile in TNBC and identify a prognostic marker. Methods: Targeted mRNA sequencing was performed on formalin fixed paraffin embedded whole sections from 30 treatment naïve TNBC with TILs (15 cases with a favorable outcome (recurrence free overall survival (OS) ≥ 5 yrs) and 15 with unfavorable outcome (never disease free or dead of disease in < 5 yrs) using the HTG Edge Seq Assay (HTG Molecular Diagnostics, Inc. Tucson AZ) to analyze the differential expression of 1392 immune related genes in their Precision Immuno-Oncology Panel. The top 40 up- and down-regulated DE genes with adjusted p-value of < 0.001 were then validated against the TNBC mRNA profiles in The Cancer Genome Atlas (TCGA) database. LAG3 was one of four genes that showed significant differential expression in both data sets. We used immunohistochemistry (IHC) (Rabbit monoclonal AntiLAG3 antibody, Abcam plc.) to analyze LAG3 expression in whole sections from 57 consecutive TNBCs where tumor excision had been the first line treatment. All patients were female, age 29-89 years (median 55 yrs). The

infiltrating ductal carcinomas varied from 0.6 to 9.0 cm (median 2.6 cm). All tumors were ER-, PR-, Her2- with a median Ki67 of 42%. 26 patients had metastatic carcinoma in 1-17 lymph nodes (median 2). Two patients had metastatic disease at presentation. Disease free survival (DFS) varied from 0 to 114.8 months (median 81.4 mos.), and overall survival (OS) varied from 7.6 to 114.8 months (median 81.5 mos.). LAG3 expression was categorized as negative (0), low (1+) and high (2+). The student t-test was used to correlate LAG3 expression with DFS and OS. Results: Differential expression analysis from our data set yielded 222 statistically significant differentially expressed genes. Validation against the TCGA TNBC data set revealed 4 common genes, one of which is LAG3. Only TILS showed LAG3 expression by IHC: 10 cases no expression, 17 low expression and 29 high expression. Median DFS and OS in TNBC with no LAG3 expression was 32.3 and 55.2 months, in TNBC with low expression 83.3 and 81.1 and those with high expression was 82 and 82.1 month. Median DFS and OS in LAG3 negative cases was significantly different from those in LAG3 positive cases ($p=0.038$, $p=0.013$) and between LAG3 0 and LAG3 2+ positive cases ($p=0.002$, $p=0.0018$). No difference in either median DFS or OS was seen when LAG3 1+ and LAG3 2+ cases were compared. Conclusions: 1. LAG3 is a prognostic marker for TNBCs. 2. LAG3 is expressed only on TILS and shows heterogenous expression. 3. TNBC with no LAG3 expression had a median survival of 32 months, suggesting they might benefit from more aggressive therapy than TNBC that express LAG3. 4. Confirmation of these results requires a larger TNBC cohort.

Background: Breast cancer in younger women has been characterized as a more aggressive disease with relatively poor outcomes compared to breast cancer in older women. This pattern has been attributed to a variety of clinicopathologic characteristics including the enrichment of aggressive HER2+ and TNBC subtypes in younger patients. However, similar to older breast cancer patients, the majority of young breast cancer patients are HR+/HER2-. Here we have evaluated the clinicopathologic characteristics and genomic profiles of real-world HR+/HER2-MBC patients to examine the determinants of outcome for younger vs. older patients in this subtype. Patients and Methods: This study included 65 Chinese patients presenting with HR+/HER2- MBC at the Peking University Cancer Hospital. Blood samples were collected upon metastatic disease diagnosis before treatment and profiled with the targeted 152-gene PredicineCARE™ sequencing panel. Fourteen patients were < 40 years, 19 were 40-50 years, and 32 were > 50 years at the time of primary cancer diagnosis. Kaplan-Meier survival analysis was performed to analyze outcomes including overall survival (OS), disease free survival (DFS) and progression free survival (PFS) in association with clinicopathologic and genomic variables. OS was also evaluated in association with age in separate multivariate models using Cox proportional hazards regression. Results: Significant variation across age groups was observed for several clinicopathological features, including molecular subtype classification ($p = 0.045$),

de novo Stage IV disease ($p = 0.011$), type of adjuvant endocrine therapy ($p = 5.56E-06$), resistance to adjuvant endocrine therapy ($p = 0.015$) and receipt of adjuvant chemotherapy ($p = 0.042$). Luminal B status was most frequent in patients < 40 years (92.31%), whereas de novo Stage IV disease was more prevalent in patients > 50 years (37.5%). Aromatase inhibitors (AIs) were administered as adjuvant endocrine therapy (ET) to 73.68% of women > 50 years vs. 16.67% and 0% of women aged 40-50 years and < 40 years, respectively. Resistance to adjuvant ET was observed in 23.08% of patients < 40 years but was not observed in the other age groups. Adjuvant chemotherapy was received by a higher proportion of patients in the 40-50 year age group (94.44%) compared to patients < 40 years (69.23%) and patients > 50 years (60%). No differences in somatic gene alteration frequencies were observed across age groups, menopausal status, germline mutation status or tumor grade. However, a higher frequency of FGFR1 alterations was observed in patients classified as Luminal B vs. A ($p = 0.048$). Comparison of profiles across women who received adjuvant ET revealed a higher prevalence of FGFR1 ($p = 0.012$), ATM ($p = 0.047$) and CCND2 ($p = 0.04$) alterations in patients treated with AIs vs. SERMS. In addition, a higher frequency of APC alterations was observed in patients with high ($\geq 20\%$) vs. low ($< 20\%$) Ki67 index ($p = 0.035$). At the univariate level OS was significantly associated with age ($p = 0.039$). OS was shortest in patients > 50 years, intermediate in patients < 40 years, and longest in patients 40-50 years. Across all patients, shorter OS was also associated with de novo Stage IV disease ($p = 0.0001$), Luminal B subtype ($p = 0.008$), adjuvant ET with AIs vs SERMS ($p = 0.028$) and the presence of an FGFR1 ($p = 0.028$) or CCND2 ($p = 0.033$) alteration. In multivariate analyses, OS remained significantly longer for patients aged 40-50 years after adjustment for de novo Stage IV disease, Luminal B subtype and FGFR1 status (all $p < 0.05$). Conclusions: In this group of real-world HR+/HER2- MBC breast cancer patients, younger age was not associated with worse outcomes. While current guidelines recommend treatment decisions based on tumor biology rather than age, young HR+ breast cancer patients are more likely to receive chemotherapy. Our findings support the development of biomarker-driven treatment strategies for these patients.

INTRODUCTION: Our knowledge regarding the levonorgestrel intra-uterine device (LNG-IUD) and breast cancer (BC) risk is limited. As the LNG-IUD is a widely used contraception method, we here explored receptor expression in BC, in women < 56 years, by having a LNG-IUD at diagnosis. We aim to validate the findings of a previous cohort treated in the University Hospitals Leuven, where we observed proportionally more progesterone receptor (PR), lower human epidermal growth factor receptor 2 (HER2) expression and more ER+PR+HER2- subtypes in LNG-IUD users compared to non-LNG-IUD users. **MATERIALS AND METHODS:** We conducted a retrospective observational monocentric study from 2015 until 2020. We included patients < 56 years consulting the University Hospitals Leuven for primary invasive BC, who were treated with primary breast surgery or neoadjuvant therapy. We compared patient and tumor characteristics, especially receptor subtypes in LNG-IUD users at diagnosis with non- LNG-IUD users. Group comparisons with regards to receptor subtypes were performed by the Chi-square test, all tests were evaluated at a two-sided 5% significance level. **RESULTS:** Of the 1347 patients with BC included in this study, 272 had a LNG-IUD at diagnosis. The LNG-IUD users were more likely ER (85.29% vs 77.77%, p=0.006) and PR positive (80.88% vs 70.95%, p< 0.001) compared to the control group. Additionally, we observed more ER+PR+HER2- (68.75% vs 58.62%, p=0.002) and fewer ER-PR- HER2- (10.29% vs 15.66%, p=0.025) subtypes when comparing with the control group. **CONCLUSION:** This internal validation study confirmed invasive BC, diagnosed in women under age 56, to be more likely PR+ and ER+PR+HER2- if they used a LNG- IUD at BC diagnosis when compared to non-LNG-IUD users.

Background: Patients with germline TP53 pathogenic variants (Li-Fraumeni syndrome - LFS) have an increased risk of breast cancer, which is the most common type of cancer in premenopausal women with LFS. These women are also at risk of other second malignancies, including radiotherapy-induced malignancies. On the other hand, little is known about the prognosis of breast cancer in patients with LFS or if the disease behavior differs from non-hereditary BC. The objective of this study was to characterize the phenotype and prognosis of early BC in patients with LFS compared to a matched cohort of patients without germline pathogenic variants (PV) related to BC.

Methods: This retrospective study evaluated patients with early BC treated in an academic cancer center from Dec 1999 to Mar 2022. The LFS cohort included consecutive patients with BC who harbored a PV or likely PV of TP53. The matched control cohort (2:1) included patients with BC with no germline PV in a panel test. Primary endpoint was disease-free survival (DFS).

Since LFS is associated with an increased risk of new primary malignancies, only locoregional and distant BC recurrence were considered as events in the DFS analysis. Secondary endpoints included response to systemic therapy, sites of recurrence, and breast cancer-related deaths.

Results:

Forty-six patients with LFS were evaluated; the control cohort included 91 matched patients. In the LFS cohort, 14 different PV or likely PV were identified, with TP53 p.R337H being the most common (n=32). Median age was 40 years in both groups. In the LFS cohort, 35% of the pts had HER2-positive BC compared to 21% in the control cohort. Primary tumors greater than 5 cm were observed in 15% of pts in the LFS cohort and 25% of pts in the control cohort. Positive lymph nodes were observed in 11% and 14%, respectively.

Among 15 pts with LFS who received neoadjuvant chemotherapy, all (100%) had a response, with 5 (33%) complete responses. Thirty-five patients in the control group received neoadjuvant chemotherapy: 83% responded, with 11 (31%) presenting a complete response.

With a median follow-up of 43 months, 5-year DFS rates were 82.6% (95% CI 65.1 – 91.9%) in the LFS cohort and 91.5% (95% CI 79.1 – 96.6%) in the control cohort (P=0.427). Rates and sites of recurrence, new primary BC, and deaths are detailed in the table.

Conclusions:

In addition to a higher risk of new primary breast cancer, LFS patients with early breast cancer had numerically higher rates of locoregional and distant recurrence in comparison with a matched cohort. Nevertheless, further studies are required to understand if these differences are due to tumor behavior particularities or to differences in therapeutic management.

Recurrence and death events

Characteristic	No of Patients (%)	
	TP53 mutated (N = 46)	TP53 Wild-type (N = 91)
Recurrence	6 (13%)	7 (7.7%)
Local only	1 (2.2%)	1 (1.1%)
Distant only	4 (8.7%)	6 (6.6%)
Both (local and distant)	1 (2.2%)	0 (0%)
New primary breast cancer	6 (13%)	1 (1.1%)
Death	5 (10.9%)	4 (4.4%)
Breast cancer-related death	2 (4.6%)	1 (1.1%)

Introduction: Metabolic syndrome can be defined as a set of conditions - central obesity (waist circumference), elevated blood pressure, reduced HDL cholesterol, increased triglycerides and glucose intolerance - which is known to be associated with a higher risk in the development of cardiovascular disease and type 2 diabetes. It affects approximately 30% of the population of women over 50 years of age. In view of the risk factors described above, it is important to seek, in addition to the screening recommended by the Ministry of Health (a mammogram every two years in women aged 50 to 69 years), ways to reduce the risk of breast cancer with regard to behavioral factors. Practicing the maintenance of adequate weight and physical activities can contribute to the reduction of this pathology. Therefore, even in the pathophysiology of breast

cancer, its relationship with the metabolic syndrome is seen, which is often the cause - and even consequence - women treated for breast cancer seem to have an additional risk of metabolic syndrome, resulting from excess adiposity. and effect of treatments.

Objectives: To evaluate the relationship between metabolic syndrome at the diagnosis of breast cancer and overall survival, disease-free survival and invasive disease-free survival.

Methodology: Retrospective longitudinal observational study of the cohort type carried out in the Mastology sector of the Gynecology and Obstetrics Service of the Hospital do Servidor Público Estadual de São Paulo "Francisco Morato Oliveira. We evaluated the rates of local recurrence, distant metastases and overall survival of patients with malignant breast cancer in each group.

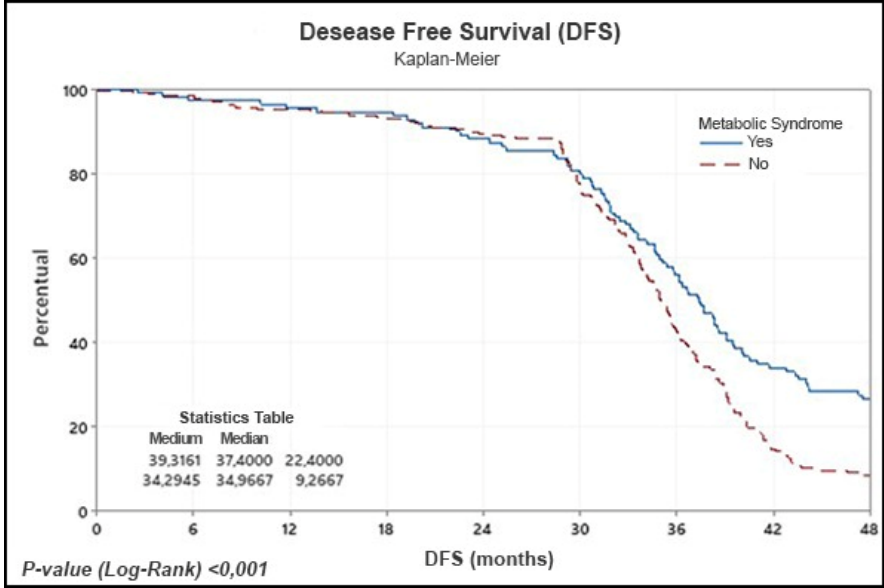

Results: From January 2017 to December 2020, 375 patients underwent surgical treatment for breast cancer at the Hospital do Servidor Público Estadual, of which 25 were excluded due to loss of follow-up, 10 due to incomplete data and 5 due to diagnosis of metastases. Thus, 335 patients were eligible for the study, with a mean age of 63.4 ± 1.4 years, and a mean follow-up time of 48 ± 1.4 years. Metabolic syndrome (MS) is present in 109 (32.5%) patients, while 226 (67.5%) do not have MS. Regarding the characteristics of prognostic factors, that is, KI 67, molecular classification and staging, in table 3 we can observe that patients with metabolic syndrome have a very similar distribution, while those without MS have a KI 67 $\geq 14\%$ in 62.4% of the patients. patients with a significant difference. The molecular profile in MS patients is 39.4% Luminal A patients and 42.5% Luminal B patients without MS, with a significant difference in distribution. Regarding clinical staging, patients with MS have initial clinical stage I and IIA in 54.1%, and advanced stage IIB 20.2% III 25.7%, while patients without MS have initial clinical stage 65%, advanced stage IIB 11.1% III 23.9, results with a significant difference. When we evaluated the presence of obesity as a factor of worsening of prognostic factors, we did not find significant differences. We evaluated the temporal outcomes of overall survival, disease-free survival, and invasive disease-free survival. The overall sample survival was 37.3 years with a CI 1.1 years, disease-free survival was 35.9 years with a CI 1.2 years, and invasive disease-free survival was 36.9 years with CI 1.3 years. When we compared these outcomes with the presence of MS, we observed a significant difference in all outcomes.

Conclusions: The presence of MS at diagnosis does not worsen overall survival, disease-free survival or invasive disease-free survival.

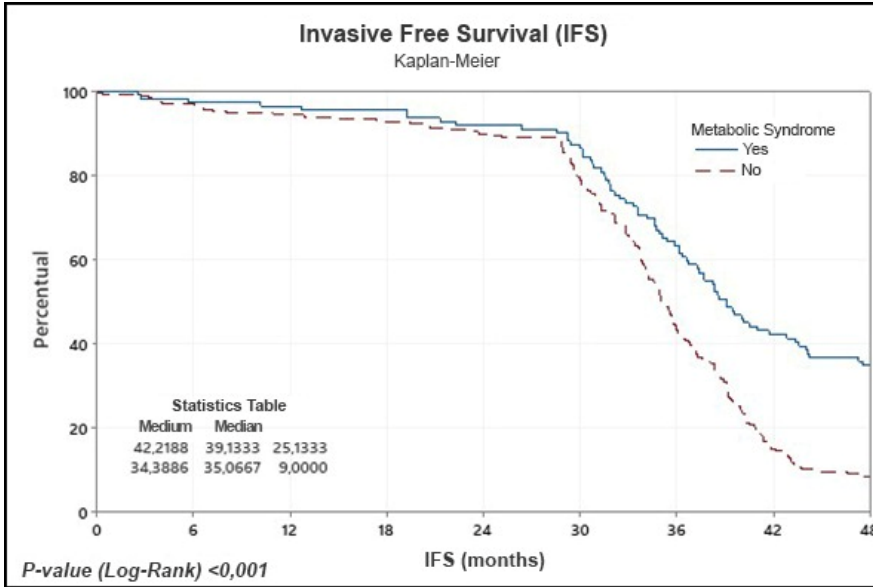

Overall Survival (OS) for Breast Cancer and Metabolic Syndrome

Disease Free Survival (DFS) for Breast Cancer and Metabolic Syndrome

Invasive Free Survival (IFS) for Breast Cancer and Metabolic Syndrome

Background

Breast cancer incidence is constantly increasing in Japan. The age-specific incidence rates (ASIRs) of breast cancer shows two peaks, at ages 45-49 and 60-64, in Japan. Therefore, the incidence rate of breast cancer in Japanese premenopausal women is higher compared to the Western countries. In our study, we clarified the clinicopathological characteristics of Japanese premenopausal breast cancer.

Patients and Methods

The total of 1,220 premenopausal breast cancer patients treated for early breast cancer, at stage 0-III, between 2010 and 2021. The patients were divided into three age groups; aged under 40 (group A, n=258, 21.1%), aged 40 to 45 (group B, n=428, 35.1 %), and aged 46 and over (group C, n=533, 43.7%). Information regarding the clinicopathological characteristics was collected from the medical records.

Result

Significantly longer periods from menarche to the breast cancer onset ($p < 0.0001$), larger number of history of pregnancy ($p < 0.0001$), and higher BMI (25 or higher) ($p = 0.0091$), and more habitual drinking histories ($p = 0.0029$) were recognized in group C. In premenopausal onset, ER-positive status is higher ($p = 0.0022$), the histological grade is lower ($p = 0.0094$), as age increases, and more negative PgR status ($p = 0.0019$), and more triple negative breast cancer ($p = 0.0002$) were shown in group A. Hormone receptor-positive HER2-negative breast cancers under 45 years of age (group A, B) were more likely to receive neoadjuvant chemotherapy than those aged 46 years and older (group C) ($p = 0.0077$), but there was no age-related difference for other subtypes. The association between clinicopathological factors and

distant relapse-free survival (DRFS) in each age group was analyzed. is associated with higher grades (group A, p=0.0638 , group B, p=0.0208, group C, p=0.0006) , negative PgR status (group A, p=0.0379,group B, p=0.0683,group C, p=0.0042), and lower ER expression (group B, p=0.0395 group C, p=0.0021) were significantly associated with poor DRFS. Similarly, in overall survival, higher grades (group A, p=0.0257,group B, p=0.0027,group C, p=0.0111) ,negative PgR status (group A, p=0.0162,group B, p< 0.0001,group C, p=0.0003), and lower ER expression (group C, p=0.0003) were significantly poor prognosis. In univariate analyses, higher grade, negative PgR status, and ER negative/low-positives were risk factors, and in multivariate analyses, higher grade was a risk factor for poor prognosis

Conclusion

We found that there are many clinicopathological characteristics related to poor prognosis in premenopausal breast cancer patients aged under 40, such as low or negative ER expression, higher histological grade, and negative PgR status.

Breast cancer resistance protein (BCRP), also known as ATP-binding cassette transporter G2 (ABCG2), is associated with chemotherapy resistance. BCRP is also implicated in breast cancer stem cells and has been reported as a poor prognostic factor. However, the relationship of BCRP levels in breast cancer tissues with chemotherapy resistance and prognosis has not been clarified to date. Our laboratory recently developed nanoparticles suitable for the quantitative immunohistochemical (IHC) method called phosphor-integrated dots (PIDs). Using PID-based IHC (IHC-PIDs), many biomarker proteins can be visualized and quantitatively analyzed at the single-particle level in paraffine-embedded, formalin-fixed tumor samples. We aimed to evaluate the correlation between quantitatively analyzed BCRP expression and prognosis in breast cancer tissue samples using immunohistochemistry with IHC-PIDs. Thirty-seven Japanese patients diagnosed with invasive ductal carcinoma of the breast who underwent mastectomy and lymph node dissection at Tohoku University Hospital (Sendai, Japan) between 2004 and 2010 were included. All patients had undergone NAC and were pathologically diagnosed with non-pathological complete response or progressive disease and

lymph node metastasis postoperatively. The patients were followed up within a median of 10.1 years (range, 1.1–18.2 years). Among the thirty-seven patients, twenty-eight patients had core needle biopsy specimens taken before NAC. BCRP levels in breast cancer tissue and metastatic lymph nodes were quantitatively detected after preoperative chemotherapy and core needle biopsy. Biomarker assay with IHC-PIDs showed high accuracy for quantitative assessment of BCRP with low expression. The optimal PT+LN BCRP cut-off score for predicting survival was 27.4, with a sensitivity of 60.6% and a specificity of 77.3%. BCRP expression in PT+LN samples was dichotomized into high and low groups at this cutoff value, and OS was compared between these group. The results showed that OS was significantly worse in the high BCRP-expression group (log-rank $p=0.0089$). In conclusion, high BCRP levels are associated with poor prognosis in patients with breast cancer with residual tumors within the primary tumor and lymph nodes after preoperative chemotherapy. These findings provide a basis for further appropriate adjuvant therapy in these patients.

Introduction: Replication Protein A (RPA) is a critical single-stranded DNA (ssDNA)-binding protein that coats and protects exposed ssDNA from endogenous nucleases. RPA is a heterotrimeric complex consisting of RPA1 (70kDa), RPA2 (32kDa), and RPA3 (14kDa) subunits. RPA provides a platform for recruitment of factors required during replication, checkpoint regulation, DNA repair [including homologous recombination (HR), nucleotide excision repair (NER), base excision repair (BER) and mismatch repair (MMR)], telomere maintenance and retro-transposition. To understand the role of RPA in breast cancer pathogenesis we conducted a comprehensive genomic, transcriptomic, bioinformatic, proteomic and preclinical study. **Patients and methods:** RPA1, RPA2 and RPA3 protein expression was evaluated in 4221 primary invasive breast carcinomas and 776 breast ductal carcinoma in situ (DCIS). Transcriptomic investigation was completed in the METABRIC cohort (n=1980). Detailed bioinformatics was conducted in the TCGA cohort (n=1090). RPA deficient breast cancer cell lines were tested for Cisplatin, Palbociclib and Olaparib sensitivity. **Results:** RPA1, RPA2 and RPA3 loss is frequent in DCIS and linked to aggressive phenotype (including high grade, ER and PR negativity) (all p values < 0.01). DCIS with low RPA1 was also associated with poor local recurrence-free interval (p< 0.00001). In invasive breast cancers, low RPA1, low RPA2 and low RPA3 were all associated with larger size, lympho-vascular invasion, higher histological grade, high stage, ER negativity and poor breast cancer specific survival. Transcriptomic alterations in low RPA tumors included those genes involved in steroid hormone biosynthesis, chemical carcinogenesis, and drug metabolism. Pre-clinically, RPA deficient breast cancer cells were sensitive to Cisplatin and Palbociclib (CDK4/6 inhibitor) therapy compared to controls. Additionally, the PARP1 inhibitor Olaparib was synthetically lethal in RPA1 and RPA2 deficient cells compared to controls. Increased Olaparib sensitivity was associated with double strand breaks, S-phase cell cycle arrest and increased apoptosis. **Conclusions:** We provide the first comprehensive evidence that RPA loss is an early event during breast cancer pathogenesis and promotes aggressive phenotypes. Pre-clinically RPA deficient breast cancer cells were selectively toxic to Cisplatin, Palbociclib and Olaparib.

Background: The predictive and prognostic value of the 21-gene recurrence score (RS) has emphasized the importance of tumor biology and minimized the credence of a limited (1-3 positive) nodal burden. The practice changing results of RxPonder demonstrated that post-menopausal women with 1-3 positive lymph nodes (pN1) and a RS of ≤ 25 did not necessarily benefit from adjuvant chemotherapy. Given that RS influences adjuvant therapy decision-making more significantly than nodal status, it is unclear whether axillary staging with sentinel lymph node biopsy (SLNB) has a continued role in the surgical care of post-menopausal patients otherwise presenting with early stage, clinically node negative (cN0) hormone receptor positive (HR+), human epidermal growth factor receptor 2 negative (HER2-) invasive breast cancer. In this context, the de-escalation of axillary staging, especially in the presence of a low RS, is an area of active investigation. To help elucidate this further, we sought to estimate the association of RS with pathologic nodal stage.

Methods: Using the 2004-2019 National Cancer Database (NCDB) Patient User File (2022 release), we evaluated the association of RS with the incidence of pN0, pN1 and pN2-3 disease. Only female patients diagnosed who were age 50 and older with HR+/HER2- invasive breast cancer were eligible, and only those presenting with cT1-T2N0 who underwent upfront surgery with a SLNB comprised our study population. Those with Oncotype DX testing performed with an available RS were included. Given the limitations within the dataset, age 50 and over was selected as a surrogate for post-menopausal status. Categorical variables were compared between RS groups (≤ 25 vs. > 25) using chi-square tests and continuous variables were compared using t-tests. A logistic regression analysis was performed to estimate the association between RS (≤ 25 vs. > 25) and nodal burden (pN2-3 vs pN0-1).

Results: There were 151,447 patients with an invasive breast cancer diagnosis between 2015 and 2019 who met inclusion criteria. The average age at diagnosis was 64.1 (IQR 58-69) and almost 75% of tumors displayed ductal histology. There were 130,568 (86.2%) patients with a RS ≤ 25 and 20,879 (13.8%) with a RS > 25 . On final pathology, 85.2% were pN0 and 14.8% were pN1-3. For those with a RS ≤ 25 , 84.9% were pN0, 14.8% were pN1 and 0.3% were pN2-3. For those with a RS > 25 , 86.8% were pN0, 12.9% were pN1 and 0.3% were pN2-3. Overall, 14.5% demonstrated pN1 disease, of which 12.3% yielded a RS > 25 . Of the 461 patients with pN2-3 disease for whom RS was available, 12.4% (57 patients) had RS > 25 . After adjustment, RS > 25 was associated with reduced incidence of pN2-3 compared to pN0-1 (OR=0.64, 95% CI 0.47-0.87, $p=0.004$).

Conclusion: In this population of post-menopausal patients with cT1-T2N0, HR+/HER2- invasive breast cancer and an available RS, almost 86% displayed pN0 or pN1 disease in conjunction with a RS ≤ 25 . Based on the current available literature, less than 5% of cT1-2N0 patients are thought to harbor $> pN1$ disease. These data add further support, suggesting that this patient population is unlikely to harbor a higher than limited nodal burden given a clinically negative axilla. Though less than 0.5% of the studied patient population demonstrated pN2-3 disease, an important caveat to make is that these patients would not have met criteria for RS, and it's likely this low number reflects the absence of testing. Given that RS has not been validated for this higher nodal stage, we cannot make recommendations to omit axillary surgery in this cohort of patients. The data presented here provides further rationale for the two large prospective studies addressing whether SLNB could be eliminated in patients with otherwise small HR+/HER2- tumors which are currently ongoing.

Pathologic Nodal Staging Based on Recurrence Score

Table 1: Pathologic Nodal Staging Based on Recurrence Score

Recurrence Score	Final Pathologic Nodal Status				P-Value
	pN0 N(%)	pN1 N (%)	pN2 N(%)	pN3 N (%)	
RS ≤25 (N=130568)	110872 (84.9)	19292 (14.8)	331 (0.3)	73 (0.06)	<0.001
RS >25 (N=20879)	18123 (86.8)	2699 (12.9)	44 (0.2)	13 (0.06)	
Total (N=151447)	128995 (85.2)	21991 (14.5)	375 (0.2)	86 (0.06)	

Data presented as N (row percentage). pN: pathologic nodal status, pN0: node negative, pN1: 1-3 positive nodes, pN2: 4-9 positive nodes, pN3: 10 or more positives nodes, RS: Recurrence Score

Background

Genomic testing such as OncotypeDx remains an important component of the treatment decision process for many breast cancer (BC) patients. Evidence from Sparano et al. JCO 2021;39:557-564 demonstrated the importance of combining clinical features such as tumor grade, size and age with the 21-gene recurrence score (i.e., RSclin). Given the challenges associated with reliability of BC grading as a prognostic feature, we sought to develop a broadly accessible AI-digital test (PDxBr) which included a BC AI-grade combined with clinical features (i.e., age, tumor size, stage and lymph node status) to predict recurrence risk in an Oncotype categorized cohort.

Methods

We evaluated performance of the PDxBr test along with the AI-grade, clinical feature (i.e., age, size, tumor stage and LN status) and histology grade models in a subgroup analysis from a retrospective longitudinal clinical development validation study utilizing samples from breast cancer (BC) patients in the Mount Sinai Health Care System (NYC, NY) from 2004-2016.

Eligible

participants were ≥ 23 years old with infiltrating ductal or mixed ductal and lobular carcinoma of the breast (IDC) and all with an Oncotype RS, and a median 6-year follow-up. All participants had H&E slides or paraffin blocks (for slide generation) from the resected BC specimen. H&E slides were digitized (40X magnification) using a Philips UltraFast Digital slide scanner (Netherlands) and a single whole slide image (WSI) was selected for model development. The AUC/C-index was used to demonstrate performance.

Results

599 patients with Oncotype RS results were interrogated: 57% white, mean age 57, mean tumor size 1.3cm, 100% T1/2 and HR+ve, 55% grade 2, 26% grade 3 and 18% grade 1; 95% pN0

with 36 events (6%). 21 (60%) of events were local-regional recurrences. Of note, there were 55% histologic Grade 2 cases in this population. Combining Oncotype RS with assorted sub-models including histologic grade, clinical features, AI-grade, or PDxBr model in a SVRc analysis

demonstrated incremental improvement in the C-index for predicting BC recurrence (Table 1).

Conclusions

Both PDxBr test and AI-grade when combined with Oncotype were superior to Oncotype alone, or Oncotype with grade or clinical features suggesting that the incorporation of an improved BC grade with Oncotype RS enhances overall risk discrimination. PDxBr is the first digital BC test combining automated AI-BC prognostic grade with clinical-pathologic features to predict risk of early-stage BC recurrence. Additional validation studies are underway to confirm these results.

AUC comparison of Oncotype alone and then combined with histology grade, clinical data (age, stage, tumor size and LN pos), AI-grade, and the PDxBr model.

Model	C-index	CI Lower Limit	CI Upper Limit
Oncotype Rs	0.35	0.26	0.48
Oncotype + grade	0.51	0.42	0.60
Oncotype + Clinical	0.64	0.57	0.71
Oncotype + AI grade	0.72	0.67	0.79
Oncotype + PDX Br	0.76	0.70	0.82

Background: Inflammatory breast cancer (IBC) is a rare and extremely aggressive form of breast cancer with an increased propensity to disseminate to distant organs such as the brain; indeed, a previous study reported that 37% of patients with HER2+ IBC present with brain metastasis as the first site of relapse. Our group recently generated new sublines from HER2+ IBC that exhibited a high brain metastatic propensity and further demonstrated that the stress response protein N-myc downstream regulated gene 1 (NDRG1) is a driver of breast cancer brain metastasis. Transcriptome analysis comparing NDRG1-expressing brain-metastasizing and NDRG1-depleted brain-non-metastasizing cells revealed prominent downregulation of two

S100 calcium binding proteins, S100A8 and S100A9, in NDRG1-depleted cells. S100A8/S100A9 are known to facilitate the homing of tumor cells to the brain and lung pre-metastatic niche. Recent studies elegantly demonstrated a critical role for S100A9 in brain relapse and radioresistance in brain metastasis mouse models. The purpose of the present study was to evaluate whether S100A8/S100A9 serum levels predict the risk of brain metastasis in aggressive breast cancers. Methods: In a retrospective cohort of 304 IBC patients, we measured serum S100A8/S100A9 levels by using ELISA. Overall survival (OS) and breast cancer-specific survival (BCSS) were analyzed using Kaplan-Meier curves, log-rank test, and Cox proportional hazard regression. Results: The overall median follow-up time was 64 months. Forty-six percent of patients had estrogen receptor (ER)-negative tumors, 61.3% were stage III-IV, 77% high grade, 16.8% received adjuvant chemotherapy and 53.6% received adjuvant radiation. On univariate analysis, S100A8/S100A9 levels, disease stage, ER status, PR status, HER2 status, adjuvant chemotherapy, and adjuvant radiation therapy were significantly associated with OS and BCSS. Patients with high S100A8/S100A9 serum levels (>3rd quartile vs. ≤ 3rd quartile) had poor OS ($p=0.01$) and BCSS ($p=0.006$). Also, patients with high S100A8/S100A9 serum levels had a higher risk of developing brain metastasis ($p=0.01$). S100A8/S100A9 serum levels was not significantly correlated with any other metastasis. On multivariate analysis, high S100A8/S100A9 serum levels was independently associated with reduced OS (hazard ratio [HR] = 1.8, 95% CI 1.1 to 3.0, $p=0.01$), reduced BCSS (HR = 1.8, 95% CI 1.2 to 2.8, $p=0.006$) and increased risk of developing brain metastasis (HR = 2.1, 95% CI 1.2 to 3.8, $p=0.01$). Conclusions: We found that having high levels of serum S100A8/S100A9 is an independent prognostic factor for reduced OS and BCSS and for the development of brain metastasis in patients with IBC. Thus, S100A8/ S100A9 may represent a biomarker for unfavorable clinical outcome and brain metastasis in patients with aggressive breast cancers.

ABSTRACT Background: Half of HER2-negative breast cancers (BC) show HER2-low expression. The strong efficacy of recent anti-HER2 antibody-drug conjugates (ADC) in HER2-low tumors has risen the interest of HER2-low as a proper BC subtype. Chemosensitivity and prognosis of this subtype are not clear when compared to HER2-0 tumors. We investigated the pathological complete response (pCR) and disease-free survival (DFS) rates in BC patients receiving neoadjuvant chemotherapy for HER2-low or HER2-0 tumors. Methods: Data were collected from the Institut Paoli-Calmettes European Comprehensive Cancer Center database. HER2-low tumors were defined by HER2 IHC score of 1+ or 2+ with negative FISH, and HER2-0 by IHC score of 0+. Clinicopathological characteristics, pCR (defined as [ypT0/ypTis] and [pN0sn or ypN0]) and DFS rates were compared between the two cohorts. Results: From Jan/2005 to Jun/2021, 1,111 patients receiving neoadjuvant chemotherapy were evaluable. The incidence of HER2-low was 41%, including 63% of hormone receptor (HR)-positive and 37% of HR-negative tumors ($p < 0.001$). In the whole population, the pCR rate was lower in HER2-low (23%) versus HER2-0 (30%) tumors ($p = 0.013$), but this association was lost in multivariate analysis. In HR-positive patients, HER2-low negatively impacted pCR rates when compared to HER2-0 (10% vs. 16%, $p = 0.046$), but not in HR-negatives (46% vs. 42%), and this result was maintained in multivariate analysis (OR 0.60 [95CI 0.36-1.00]; $p = 0.049$, and OR 1.15 [95CI 0.77-1.71]; $p = 0.490$, respectively). No correlation existed between DFS and HER2-status. Conclusion: HER2-low is associated with HR positivity. HER2 status did not impact pCR in HR-negative patients, whereas HER2-low was associated with lower pCR rate in HR-positive patients, supporting the development of anti-HER2 ADC in this setting.

Background: Breast cancer is the most common cancer in women. The five-year survival rate of patients with stage 0 and stage I breast cancer is more than 95%, that of patients with stage II breast cancer is 80%, that of patients with stage III breast cancer is about 50%, and that of stage IV breast cancer is less than 30%. The stage of breast cancer is closely related to the prognosis. Exosomes are membrane vesicles secreted by living cells, which carry donor cell specific genetic information. They can exist stably in the circulatory system, so they are ideal biomarkers. Method: We collected 128 breast cancer patients (17 benign cases, 26 stage I cases, 36 stage II cases, 15 stage III cases and 34 stage IV cases) treated in our center from 2018 to 2019. We collected patients' plasma and extracted exosomes, then we sent them for

sequencing. We analyzed the difference between benign cases' and stage IV cases' sequencing results, and then we screen them by comprehensively considering the change trend of gene expression from benign cases to stage IV cases, the survival curve of patients and the lymph node metastasis. The clinicopathological factors and progression free survival (PFS) of breast cancer patients were analyzed by Cox regression. Finally, JCAD was selected. Using virus to stably overexpress JCAD and shRNA technology to knock down JCAD, the function of JCAD for the proliferation and metastasis of breast cancer was discussed through CCK8 cell proliferation experiment, EdU cell proliferation experiment, plate cloning experiment, transwell cell migration experiment. T-test and chi square test were performed on the data. $P < 0.05$ showed that the difference was statistically significant. Kaplan-Meier survival was used to analyze the long-term efficacy. Result 1. The expression of JCAD mRNA in exosomes increased from benign to stage 4 ($P < 0.001$). In addition, patients with lymph node metastasis had significantly higher expression of exosome JCAD ($p=0.009$), and the prognosis of patients with high expression of exosome JCAD was poor ($p=0.003$). This conclusion has also been verified in TCGA database. Finally, Cox regression analysis showed that JCAD was an independent prognostic factor affecting PFS ($p=0.005$). 2. JCAD is transmitted between cells in the form of exosomes: In breast cancer cells, stable transgenic strains with overexpression of JCAD and shRNA knockdown strains of JCAD were constructed. The exosomes were extracted by ultracentrifugation for RNA and protein level verification. It shows that there was a difference in the expression of JCAD in the exosomes of overexpression and knockdown strains. After adding exosome inhibitor GW4869 to culture cells, it was found that the level of JCAD mRNA secreted by exosomes decreased significantly. In addition, through PKH26 exosome fluorescence labeling method, it was found that JCAD was transmitted between cells in the form of exosomes. 3. JCAD can promote the proliferation and migration of breast cancer cells: This experiment verified the ability of JCAD to promote the proliferation of breast cancer cells through CCK8 cell proliferation experiment, EdU cell proliferation experiment, plate cloning experiment. Then the ability of JCAD to promote the migration of breast cancer cells was verified by transwell cell migration experiment. The exosomes were added to wild type cells for co-culture. It was further found that the exosomes with high expression of JCAD could promote the proliferation and migration of breast cancer cells. Conclusion JCAD is significantly overexpressed in stage IV patients and patients with lymph node metastasis. Moreover, JCAD is an independent prognostic factor affecting PFS, and the exosome JCAD is expected to become a potential prognostic liquid biopsy marker. Further cell experiments showed that JCAD can be transmitted between breast cancer cells through exosomes and promote the proliferation and metastasis of breast cancer cells.

Background Metaplastic breast cancer (MBC) is a rare and aggressive subtype of breast cancer (BC) defined by presence of both epithelial and mesenchymal components. Most are

triple negative but are often chemo-refractory and associated with poor survival outcomes compared to non-metaplastic triple negative BC. Advances in therapy have led to improvements in survival outcomes of patients (pts) with BC over the last decade. Our multicenter retrospective study aims to assess (1) progression free survival (PFS) and overall survival (OS) (2) factors predictive of survival outcomes in MBC pts

Methods We performed a retrospective analysis of pts diagnosed with MBC from 1997-2021 at Mayo Clinic (Florida, Arizona and Rochester) under IRB approval. Kaplan-Meier method was used to estimate OS and PFS at 1, 3 and 5 years. Cox regression models were used to examine the association between risk factors and survival outcomes. All tests were two-sided with p value < 0.05 considered statistically significant

Results We evaluated 158 pts with MBC. Median age and tumor size was 61 (range: 20-91) years and 2.8 (range: 0.5-21) cm, respectively, with 80% of pts being postmenopausal. At diagnosis, 14.6% of pts had clinical T3/T4 disease, 16.4% were clinically node-positive, and 6.3% (10 pts) had distant metastases (DM). Spindle cell histology was seen in 36 pts. Most MBC pts were triple-negative (68.3%), high grade (77.2%) and high Ki-67 (36/47; 76.5%). Of the 61 pts tested for germline mutation, 8 (13.1%) were positive, with BRCA1/2, PTEN, NBN, CHEK2, and BARD1 mutations. Most pts had lumpectomy (53.8%), followed by simple mastectomy (38.5), and modified radical mastectomy (7.7%). Majority of pts had sentinel lymph node biopsy (71.8%). Adjuvant radiation therapy was performed in 65.6% of pts. Pathologic complete response (pCR) was noted in 4/38 (10.5%) evaluable pts who received neoadjuvant chemotherapy (NACT). Residual cancer burden (RCB) scores of 2 and 3 were seen in 76.2% of evaluable pts. Median follow-up time was 2.2 years (range: 6 days-24.6 years). Overall, 1-, 3-, and 5-year OS was 93.3%, 81.7%, and 76.0%, while PFS was 80.8%, 67.9%, and 60.9%, respectively. The presence of DM at diagnosis [HR 38.55 (11.18, 132.93), p < 0.001] and spindle cell histology (SC) [HR 2.57 (1.19, 5.53), p = 0.02] predicted worse OS in multivariable analysis. Inferior PFS was predicted by DM [HR 18.84 (6.53, 54.35), p < 0.001], SC [HR 2.46 (1.25, 4.86), p = 0.009], and node-positivity at diagnosis [HR 3.65 (1.5, 8.89), p = 0.004]. The 5-year OS and PFS were 22.2% and 0% for DM pts versus 80.0% and 65.6% for non-DM pts. The 5-year OS and PFS were 71.5% and 54.7% for SC pts versus 81% and 66.6% for non-SC pts. 5-year OS and PFS for NACT pts was 67.3% and 52.6% for NACT pts versus 78.2% and 62.8% for non-NACT pts. Age at diagnosis, menopausal status, family history of BC, grade, stage, tumor size, hormone-receptor and HER2 status, and use of NACT were not found to be significantly associated with OS or PFS in multivariate analysis.

Conclusion This study is one of the largest and most recent review of institutional experiences with MBC. Overall, OS at 5 years was improved compared to prior older studies of MBC but still remains very low for those with DM, representing an area of unmet clinical need. SC and DM correlated with worse outcomes for both PFS and OS. Additionally, node positivity at diagnosis was a predictor of worse PFS. In contrast, no association was seen between survival and tumor size, stage, hormone receptor-positivity, HER2 receptor-positivity. The low pCR rates following NACT in our study are consistent with reported literature. Further, use of NACT does not impact survival, suggesting pts with resectable disease should proceed with surgery first.

Introduction: Observational data investigating the relationship between body habitus and survival or toxicity in breast cancer has been largely centered in the curative setting and focused on weight- based metrics, with variable and inconsistent results. Muscle is a large, active endocrine organ that affects physical function, drug metabolism, inflammation, and quality of life, but is not adequately measured by body weight alone. Very few studies have evaluated muscle measures in metastatic breast cancer (MBC) and have been focused on patients receiving cytotoxic chemotherapy. Here, we evaluate the impact of muscle mass and muscle density measured on CT scan on outcomes in patients with MBC receiving endocrine-based therapy. Methods: Baseline CT scans done at the time of study enrollment were centrally collected from participants in ECOG-ACRIN E2112, a randomized phase III study of exemestane with or without entinostat in MBC, which ultimately did not impact survival. A transverse cut at the L3 level was extracted and processed using semi-automated SliceOmatic software (Tomovision) by two independent investigators to obtain total body skeletal muscle mass and muscle attenuation. Low muscle mass was defined as skeletal muscle index (SMI, lean muscle area/height, cm²/m²) less than 41 and low skeletal muscle attenuation (SMA) was defined as average muscle density less than 41 HU, or less than 33 HU if the patient is overweight or obese by BMI. Chi-square tests were used to determine the association between

SMI and SMA and other clinical characteristics, including body weight, race, and performance status. Multivariable Cox proportional hazard models were used to determine the association between low SMI or low SMA and overall survival (OS), progression free survival (PFS), and patient-reported outcomes. Results: Of the 608 patients randomized in E2112, 546 had analyzable CT scans and follow up data available. 45% (n=246) of participants had obesity by BMI (≥ 30); 39% (n=212) had low SMI and 56% (n=305) had low SMA. Obese patients were more likely to have higher SMI ($p < 0.001$); however, 9.5% (n=52) of the study population had both obesity and low SMI. Low SMA was associated with higher rate of obesity and worse performance status ($p < 0.001$), consistent with muscle quality being a predictor of functional status. Low SMI was not associated with survival outcomes (OS HR 1.04 95%CI 0.83-1.30, PFS HR 1.12 95% CI 0.92-1.36), nor was low SMA (OS HR 1.02 95%CI 0.81-1.28; PFS HR 1.02 95%CI 0.84-1.23). In addition, BMI was not related to survival outcomes. Conclusions: Low muscle mass and low muscle density are prevalent in estrogen receptor positive MBC patients. Muscle measures correlated with obesity and performance status; however, neither low SMI nor low SMA were associated with worse prognosis in this population. Further work is needed to refine body composition measurements and select optimal cutoffs and meaningful endpoints in specific breast cancer populations, particularly in those living with metastatic disease.

Background: Invasive early breast cancer (IBC) often presents with a co-existing ductal carcinoma in situ (DCIS) component, while about 5% of the cases present with an extensive (>25%) intraductal component (EIC). The presence of a DCIS component was previously shown to be associated with favorable clinico-pathological characteristics and survival outcomes. However, the association between co-existing DCIS and genomic risk of recurrence is unclear. Methods: Patients with early hormone receptor positive (HR+) HER2neu-negative (HER2-) breast cancer and known OncotypeDX breast recurrence score (RS), who underwent breast surgery in our institute, were included. A natural language processing (NLP) algorithm was used to identify co-existence of extensive DCIS (DCIS-H) and non-extensive DCIS (DCIS-L) in surgical pathological reports. Genomic risk was determined using OncotypeDX RS, while clinical risk was calculated according to the MINDACT criteria, based on tumor size and grade. The genomic and clinical risks of DCIS-H, DCIS-L and pure IBC (No-DCIS) were compared. Results: A total of 45 (5%) DCIS-H cases, 468 (56%) DCIS-L cases and 328 (39%) No-DCIS

cases were identified. DCIS-H cases presented with less aggressive clinico-pathological characteristics, such as lower proportions of histologic grade III (10% vs 26% vs 21%) and lower proportions of node-positive disease (13% vs 18% vs 21%), compared to DCIS-L and No-DCIS cases, respectively. The distribution of OncotypeDX RS significantly varied between the groups. DCIS-H tumors were less likely to have a high RS and more likely to have a low or intermediate RS compared to DCIS-L and No-DCIS tumors (High RS: 4% vs 20% vs 20%, Low + intermediate RS: 96% vs 80% vs 80%, respectively; $p=0.04$). Additionally, the proportions of high clinical risk cases were lower in the DCIS-H group compared to the DCIS-L and No-DCIS groups (42% vs 53% vs 50%, respectively; $p=0.002$). Based on genomic and clinical risk and current guidelines, we found that women presented with an extensive DCIS component (DCIS-H) had a lower probability of receiving an adjuvant chemotherapy recommendation compared to women presented with a non-extensive DCIS component (DCIS-L) or pure IBC (No-DCIS) (11% vs 29% vs 25%, respectively; $p=.035$). No differences in disease recurrence were detected between the groups. Conclusions: Co-existing extensive DCIS in invasive early HR+Her2- breast cancer is significantly correlated with lower genomic and clinical risk of recurrence and a smaller chance for chemotherapy recommendation. The rarity of this condition (5% of cases) limited our ability to detect differences in outcomes. These findings warrant future studies of the underlying genomic landscape of co-existing extensive DCIS.

Background: The risk of late distant recurrence (≥ 5 years) in post-menopausal patients with ER+ BC remains significant even after standard adjuvant endocrine therapy (ET). Obesity, which has reached high proportions in Western Countries, is one of the modifiable factors that can contribute to BC recurrences. While body mass index (BMI) is an easily available surrogate measure of adiposity, it might not reflect accurately patient adiposity, especially in post-menopausal patients. We therefore hypothesize that mammary adipocyte measurements might better capture the adiposity of the patient. In this study, we retrospectively evaluated the prognostic role of both BMI and adipocyte measurements in the SOLE trial.

Patients & Methods: The SOLE trial (NCT00553410) consisted of 4,884 postmenopausal women with hormone receptor positive, lymph node-positive BC treated with 5 years of letrozole after having completed 4-6 years of adjuvant ET. BMI was available for 3,606 patients with ER+/HER2- BC and categorized according to the WHO classification (underweight: < 18.5 , normal weight $18.5 - 24.9$, overweight $25 - 29.9$, obesity ≥ 30 kg/m²). Considering the small

sample size, patients with underweight (n=35) were grouped together with patients with normal weight for the subsequent analyses. We evaluated the association between clinico-pathological characteristics and BMI using Fisher exact test and Kruskal-Wallis test. Given the previously reported association of BMI with distant recurrences (PMID: 21115856), we considered distant-relapse free interval (DRFI) as the main study endpoint. Cox regression analyses were adjusted for histology, chemotherapy (yes/no), type of local therapy, in addition to previously reported clinico-pathological variables (PMID: 29158011). Then, we conducted a stratified case-cohort study consisting of 311 patients (97 with distant relapse-cases) with successful digital assessment of adipocytes on normal mammary adipose tissue sample collected at surgery, as previously described (PMID: 33120083). Stratification factors were treatment arm and type of prior ET. Weighted Cox regression models (PMID: 17554753, 18712477) were used to evaluate prognostic association with adipocyte size (area in μm^2) categorized in quartile of the 75th percentile (Q4 vs Q1-3), as done previously (PMID: 33753731).

Results: 1392 (39%) patients were normal weight, 1315 (36%) were overweight and 899 (25%) were obese. Older age at diagnosis, lymph node involvement (≥ 4), large tumor size and menopausal status were associated with overweight and obesity. After a median follow-up of 84 months, no associations were found between DRFI and BMI in the univariable and multivariable analysis (adjusted HR overweight vs normal=0.99, 95%CI: 0.76 – 1.29, p=0.977 and HR obese vs normal=1.11, 95%CI: 0.84 - 1.47, p=0.425). In the case-cohort study, patients with larger adipocytes had an increased hazard of distant recurrence in the univariable and multivariable analysis (see table 1).

Conclusion: In this study, we did not detect any association between BMI and survival outcomes. We however found that larger mammary adipocytes were independently associated with an increased hazard of distant recurrence. These results suggest that mammary adipocytes, which can be easily evaluated on H&E slides using digital pathology, should be considered as a novel marker to evaluate the risk of late recurrence in patients with breast cancer.

Use of Bioimpedance Spectroscopy as a Surrogate for Bone Mineral Content in Oncology Patients: Practical Application of the SOZO Device

Presenting Author(s) and Co-Author(s):

Frank Vicini, n/a, *Physician - GenesisCare*
Country: United States

Chirag Shah, MD, *Co-Director Comprehensive Breast Program - Cleveland Clinic*

State: Ohio
Country: United States

Background: Many cancer patients, particularly those with breast or prostate cancer, receive hormonal manipulation therapies that can significantly impact their bone mineral content (BMC), potentially leading to osteoporotic associated life-threatening fractures, particularly given the median age of patients diagnosed with these malignancies. Bioimpedance spectroscopy (BIS) is a non-invasive tool that measures fluid and body composition values including skeletal muscle mass (SMM) and fat free mass (FFM). BIS devices can be used easily and quickly at point-of-care at the time of vital signs, with the patient standing on the device placing their hands and feet on metal electrodes and a reading obtained in less than a minute. Multiple previous studies have shown strong correlation between SMM and BMC, suggesting that a BIS reading can provide a reproducible, simple and quick estimate of BMC. To that end, we present initial findings correlating BIS readings obtained with a SOZO device (ImpediMed) with dual x-ray absorptiometry (DXA) to determine if BIS readings can be applied as an accurate point of care surrogate measure of BMC. Materials and Methods: Concurrent BIS measures and DXA scans, were performed in 75 healthy volunteers and 93 cancer patients (during and after cancer treatment) Group 1: 75 healthy volunteers (32 male, 43 female), mean age 27.4 (18-66 years); Group 2: 44 patients undergoing cancer treatment (11 male, 33 female; 18 breast, 7 lung, 4 endometrial, 4 colorectal, 4 prostate, 7 other), mean age 61.3 (38-79 years); and Group 3: 49 patients participating in a 12-week exercise program after cancer treatment (15 males, 34 females; 22 breast, 6 prostate, 3 colorectal, 3 endometrial, 2 lung, 13 other), mean age 57.8 (19-79 years). The healthy volunteers in Group 1 were further randomized into two subsets. Group A was used to develop a BIS predicted BMC algorithm and Group B was used to validate the algorithm. Results: The Pearson correlation coefficients (R) for DXA BMC and SOZO SMM were strong for all 3 groups (R=0.92, 0.85, and 0.80 for Groups 1, 2, and 3, respectively). Stepwise multiple linear regression for BMC was performed for Group A based on BIS parameters. For Group A, SMM resulted in a multiple correlation coefficient of 0.94 (P< 0.0001). The correlation coefficient between the BIS predicted BMC and DXA BMC of Group B was 0.87 (P< 0.0001, 95%CI 0.78-0.93). For Groups 2 and 3 combined, the correlation coefficient between the BIS predicted BMC and DXA BMC was 0.82 (P< 0.0001, 95%CI 0.73-0.87). Conclusions: Concurrent measures of SMM obtained with BIS using SOZO correlated strongly with DXA BMC, demonstrating that SOZO SMM may be a useful surrogate in the clinic to provide a quick, easy, and reproducible indicator of change in BMC, particularly for those patients undergoing treatments that may affect BMC. Tracking SMM during or after cancer treatment with SOZO may provide an estimate of changes in BMC allowing clinicians to obtain additional diagnostic testing and/or consider treatment modifications.

Purpose There are many studies reporting survival after development of contralateral breast cancer(CBC) but with inconsistent results. Also, many studies were based on European or North American population and few on Asian population. However, Korean breast cancer patients have different characteristics such as age distribution. Therefore, purpose of this study is to investigate whether development of CBC has influence on survival in Korean breast cancer population. **Methods** In this retrospective study, we included patients who were diagnosed with a first primary unilateral non-metastatic breast cancer at Asan Medical Center, Korea, between 1999-2013 followed through 2018. In this population, patients who developed CBC during the follow-up period were divided into the CBC cohort, and who did not into the non-CBC cohort. Survival of CBC cohort and non-CBC cohort was compared in the whole study population and in subgroup analysis by interval of CBC development, and breast cancer subtype. **Results** Over median follow-up of 107 months, 418 patients developed CBC out of

16,251 patients. Development of CBC did not influence overall survival or breast cancer-specific survival. In subgroup analysis by interval of CBC development, patients who developed CBC within one year after diagnosis of the first breast cancer had higher risk for overall death in CBC cohort (hazard ratio 2.58; 95% CI 1.28-5.18), and patients who developed CBC after one year showed no significant difference in survival compared with non-CBC cohort. In subgroup analysis by the subtype, patients with hormone receptor-positive/human epidermal growth factor receptor 2-negative subtype for the first breast cancer showed higher risk for overall death in CBC cohort (hazard ratio 1.88; 95% CI 1.14-3.10) whereas patients with triple negative subtype for the first breast cancer showed lower risk for overall survival in CBC cohort (hazard ratio 0.42; 95% CI 0.19-0.95). Conclusion Development of CBC in Korean breast cancer patients did not have significant impact on survival. However, development of CBC early after diagnosis of first breast or having certain subtype of breast cancer may have affect on survival. Such information can be important information when counseling patients who are considering contralateral prophylactic mastectomy.

PVT1, CASC16, TNFRSF13B and NAMPT may be the key genes correlated with recurrence and metastasis of breast cancer

Background: It is vital to find the risk genes and loci related to recurrence and metastasis in breast cancer (BC) patients. The Genome-wide association study (GWAS) can detect the risk of single nucleotide polymorphism (SNP) and help us understand the mechanism of disease progression by analyzing the SNP information of the whole genome. At present, GWAS have identified several genetic susceptibility SNPs for BC, but it is unclear about its significance in the recurrence and metastasis of BC patients. Therefore, in this study we aimed to identify the risk SNPs related to recurrence and metastasis of BC based on GWAS analysis. Methods: This study adopts a two-stage GWAS research strategy. In the first stage, according to propensity score matching, we chose 97 pairs of BC patients with or without recurrence and metastasis who were treated in Shandong Cancer Hospital and Institute from November 2013 to April 2014. Their peripheral blood samples were collected and DNA was extracted for genome-wide detection by Illumina ASA chip. The SNP loci related to recurrence and metastasis of BC were obtained by logistic regression analysis of GWAS. In the second stage, 854 BC patients from the same hospital were verified from May 2014 to June 2015. The SNP genotyping was detected by time-of-flight mass spectrometry to verify its correlation with recurrence and metastasis of BC. The SNP loci and their corresponding genes and pathways were analyzed using DAVID (<https://david.ncifcrf.gov/>) online enrichment analysis website. Results: In the first stage, 191 SNPs were obtained from GWAS analysis ($P < 0.001$). Based on these SNPs and their corresponding genes, we further found that glutamatergic synaptic transmission may be related to BC recurrence and metastasis through GO analysis. Similar results were found in

calcium signaling pathway and insulin secretion pathway through KEGG enrichment analysis. And 21 SNPs were screened for their association with the tumor evolution process and whether they are located in the gene coding functional region. In the second stage, Cox regression analysis showed that the genotyping of the four SNPs was consistent with the results of GWAS analysis, and these SNPs are located in the intron region of the gene. Specifically, compared with homozygous AA, BC patients carrying TNFRSF13B rs4273077(AG/GG) and PVT1 rs10108514(AG/GG) had a 26% (HR: 0.74, 95%CI: 0.54-1.01) and 27% (HR: 0.73, 95%CI: 0.54-0.98) reduced risk of recurrence and metastasis, respectively; compared with homozygous CC, patients with BC carrying NAMPT rs4730155(CT/TT) had a 35% (HR: 0.65, 95%CI: 0.45-0.93) reduced risk of recurrence and metastasis; while compared with CASC16 rs12920540(CA/AA), BC patients with homozygous CC has a 52% (HR: 1.52, 95%CI: 1.06-2.18) increased risk of recurrence and metastasis. Analysis of TCGA and GTEx databases showed that the expression levels of PVT1 and CASC16 in breast tumors were significantly higher than those in normal tissues and matched para-cancerous tissues ($P < 0.001$), whereas the expression level of NAMPT in breast tumors was significantly lower than that in normal tissues ($P < 0.001$). No significant difference was shown about the expression level of TNFRSF13B between breast tumor and normal tissues or matched para-cancerous tissues ($P \geq 0.05$). Conclusion: Our study suggested that PVT1, CASC16, TNFRSF13B and NAMPT may be correlated with the risk of recurrence and metastasis of BC. Glutamatergic synaptic transmission, calcium signaling pathway and insulin secretion pathway may be involved in BC recurrence and metastasis.

Eunyoung Kang, Department of surgery, *Associate professor - Seoul National University Bundang Hospital*

Country: United States

Backgrounds: The ACOSOG Z0011 trial revealed oncologic outcomes in patients who underwent breast conserving surgery (BCS) and sentinel lymph node biopsy only versus completion axillary dissection to be equivalent. It was also reported that axillary recurrence rate to be not different between axillary dissection group and SLNB only group, despite the positive rate of over 20% in non-sentinel lymph nodes. It led to suspicion that the role of SLNB in local control to be less significant than previously recognized. Currently trials such as SOUND trial and NAUTILUS trial are being conducted in cT1N0 breast cancer undergoing BCS to compare the outcomes between the current standard surgery and no axillary surgery.

Purposes: This study aimed to investigate the factors associated with positive SLN in patients with T1 breast cancer, including T substages. We also evaluated the oncologic outcomes according to SLN positivity.

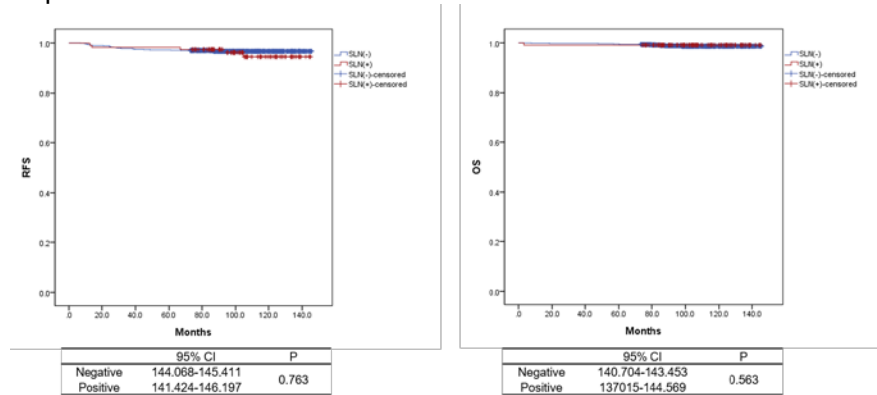

Method: We retrospectively reviewed medical records of patients with pT1 breast cancer who underwent BCS including SLNB at Seoul National University Bundang Hospital from 2010 to 2015 (n=986). SLN positive was defined as one or more micro- to macro-metastasis in axillary lymph node specimen. Overall, regional, and systemic recurrence-free survival (RFS, RRFS, SRFS) and overall survival (OS) were estimated by the Kaplan-Meier analysis.

Result: Of 986 patients, positive SLN was observed in 116 patients (11.8%). Regarding T substages, T1mic, T1a, and T1b groups showed SLN positive rate of 0%, 3.4%, and 8.5% respectively whereas T1c showed 15.3%. Multivariable logistic regression analyses revealed clinical T stage (OR 1.791, 95% CI 1.061-3.023, P=0.029), >C2 finding in preoperative axillary ultrasonography (OR 3.021, 95% CI 1.740-5.248, P< 0.001), usual histologic type including invasive ductal carcinoma, invasive lobular carcinoma, and metaplastic carcinoma confirmed in preoperative biopsy (OR 4.406, 95% CI 1.357-14.305, P=0.014) to be independent predictive factors for SLN positivity. The median follow-up period was 103.03 months. The 5 year RFS, RRFS, SRFS, and OS showed no statistical difference between SLN positive group and

negative group. In multivariable Cox regression analysis, serum CEA level higher than 5ng/ml at diagnosis (HR 7.534, 95% CI 3.336-17.019, P=0.002) and Ki-67 level higher than 20% (HR 7.534, 95% CI 3.336-17.019, P< 0.001) were shown to be the independent prognostic factors for RFS.

Conclusion: Our data implicates that patients with T1c breast cancer should undergo SLNB at all times presently, considering substantially higher SLN positive rate compared to other T1 substages (16.8% vs. 6.1%, P< 0.001) although no survival difference was observed between SLN positive group and negative group.

Kaplan-Meier curve of recurrence-free survival and overall survival

Kaplan-Meier analyses revealed no difference of recurrence-free survival, overall survival between SLN-positive and SLN-negative group.

Higher Ki-67 expression, ER negativity, PR negativity, HER2 positivity were shown to be independent risk factors associated with shorter RFS. Multivariable analysis showed higher Ki-67 expression as the sole independent risk factor for shorter RFS.

Background: MicroRNA (miR) is single stranded RNA which regulates the gene expression epigenetically by inhibiting the mRNA translation as well as promoting mRNA degradation. MiR-99b is known as a regulator of mechanistic target of rapamycin (mTOR) signaling and was reported as both onco-miR that promote cell proliferation and tumor suppressor-miR in multiple cancers. We hypothesized that there is a complex interaction between miR-99b and cancer signaling pathways as well as tumor microenvironment, which may influence outcomes.

Methods: We studied the clinical relevance of miR-99b expression by performing in silico analyses of 1,961 breast cancer patients using two independent large cohorts; METABRIC and TCGA. Results: We found that high miR-99b breast cancer enriched MTORC1 signaling gene set (normalized enrichment score (NES)>1.50 in both cohorts), but not epithelial mesenchymal transition, NF- κ B, nor TGF- β signaling gene sets (all false discovery rate (FDR)>0.40). High miR-99b breast cancer was significantly associated with high rates of mutation scores; silent- and non-silent-mutation rate, fraction altered, single-nucleotide variant neoantigens, as well as intratumor heterogeneity and homologous recombination defects. MiR-99b high tumors also enriched several cell proliferation-related gene sets; E2F targets, G2M checkpoint, and Mitotic spindle signaling, and was significantly associated with pathological grade, but not with subtype nor AJCC stage. High miR-99b breast cancer was significantly associated with low fraction of several stromal cells, including adipocytes cells, keratinocytes cells, and lymphatic endothelial

cells in tumor microenvironment (all $p < 0.001$). On the other hand, miR-99b expression was not associated with immune function nor immune cell infiltration in breast cancer, except for dendritic cells ($p=0.006$ and 0.020 , respectively). Finally, breast cancer with high miR-99b expression was significantly associated with worse overall survival (OS) (hazard ratio (HR)=1.23 ($p < 0.001$) and 1.26 ($p=0.027$), respectively) and disease-specific survival (DSS) (HR=1.28 ($p < 0.001$) and 1.39 ($p=0.022$), respectively), particularly DSS for ER-positive/HER2-negative breast cancer (HR=1.29 ($p < 0.001$) and 1.82 ($p=0.017$), respectively), consistently in two cohorts. In conclusion, we found that high miR-99b expressing breast cancer was significantly associated with not only MTORC1 but also cell proliferation and worse patient outcomes particularly in ER-positive/HER2-negative breast cancer.

Purpose:

Skin damage is the most common and most important toxicity during and after radiotherapy. Its assessment and understanding of the factors influencing its occurrence, is a major issue in the management of patients irradiated for an early breast cancer (BC).

Method:

CANTO (NCT01993498) is a prospective clinical cohort study of 10 150 patients with stage I-III BC treated from 2012-2017 in 26 cancer centers.

In this study, we used CANTO-RT, a sub-cohort of CANTO, including 3480 patients who received RT. We are focus on specifical skin toxicities: Erythema, fibrosis, telangectasia and skin color change (CTCAE v4.0). These toxicities were assessed at baseline 0-3-6 (M0), 12 (M12), 36 (M36) months.

The RT-related variables were independent variables. Multivariable logistic regression models

assessed associations between RT-related variables and skin toxicities of interest.

Results:

We studied 3480 patients from 2012 to 2017. Patients had a median age of 56.8 years and a mean BMI of 26. The majority of patients had SBR grade 1-2, TNM 1-2, RH+/HER2- breast cancer. Most patients had conservative surgery and 52.7% received chemotherapy. All the patients received radiotherapy mainly normofractionated 50Gy in 25 fractions, in 3D, with a boost of 16Gy in 8fractions.

The prevalence of toxicities of interest varied over time, so at M0, 41.1% of patients had erythema while 24.8% of patients had fibrosis.

At M12 and M36, the prevalence of erythema decreased from 8.8% to 2.9% respectively while fibrosis remains stable from 25.1% to 22.5%.

The prevalence of telangiectasia increases from 1% to 7.1% from M0 to M36. The prevalence of the skin color change decreased from 31.7% to 17.5% from M12 to M36. After adjustments, at M0 and M12, we showed a statistically significant association between the occurrence of skin erythema and obesity (OR: 1.3 p < 0.003); the presence of axillary dissection (OR: 1.33 p < 0.003); the type of surgery (OR: 0.71 p < 0.001); the use of taxane- based chemotherapy (OR: 1.46 p < 0.005) and the 3DvsIMRT irradiation technique (OR: 0.42 p < 0.001). However, no radiotherapy factors were statistically related to erythema from M12.

Regarding fibrosis, a statistically significant association is found, at M0, with age at diagnosis (OR: 1.43 p < 0.018), obesity (OR: 1.44 p < 0.001), tobacco (OR: 1.4 p < 0.008), and the use of boost (OR: 1.61 p < 0.001). Only obesity and the type of surgery received by the patient remained statistically significant factors at M12 and M36.

Obesity and age at diagnosis represented at M12 and M36 a risk associated with the onset of telangiectasias.

The skin color change is consistently correlated at M12-M36 with obesity and smoking. The use of a boost increases the skin color change at M36.

Conclusion:

In this study we identified several risk factors for acute and late skin toxicity such as obesity in the occurrence of skin erythema, fibrosis or telangiectasia. The use of a boost was mainly related to the occurrence of skin color change while the use of IMRT-type technique decreased the occurrence of skin erythema. The knowledge of its predictive factors allows a personalized management of the patient by adapting our treatments and our monitoring according to these different factors.

Relationship between radiation therapy parameters and the occurrence of skin toxicity

Country: Belgium

Background: The impact of reproductive factors on breast cancer has proven to be complex. The risk for estrogen receptor positive/ HER2-negative (ER+/HER2-) breast cancer is estimated to be transiently augmented in the years after giving birth (up to 20 years) while later in life high parity and early first full-term pregnancy (1st FTP) seem to protect against ER+/HER2- breast cancer (BC). Invasive lobular carcinomas (ILC) represents the second most common histological subtype of BC and >90% are ER+/HER2-. In this study, we aimed at investigating whether parity and age at 1st FTP are associated with: 1) the prevalence of ER+/HER2- pure ILC (i.e., not mixed) in an ER+/HER2- BC cohort (overall and according to the age at breast cancer diagnosis), and, 2) standard clinical and pathological features of pure ILC.

Patients and methods: We performed a single center retrospective study in UZ Leuven, Belgium of patients diagnosed with non-metastatic ER+/HER2- breast cancer between January 2000 and November 2020. Both patient and tumor characteristics were collected from clinical files. Firth's logistic regression was performed to investigate the association of BC histology (pure ILC vs all other BC histological subtypes = control group) with parity (yes vs. no and nulliparous, 1 child, 2 children, >2 children) in univariable models and multivariable models adjusted for age group at diagnosis (< 30, 31-40, 41-50, 51-60, 61-70, >70), age at 1st FTP (continuous and per age group: < 21, 21-25, 26-30, >30), Interval between 1st FTP and diagnosis (continuous), year of birth and BMI. Analyses were done in the overall group as well as per age group at diagnosis. Similarly, regression analyses were performed in patients with ER+/HER2- ILC to assess the association of parity (yes vs. no and nulliparous, 1 child, 2 children, >2 children) with the following variables: age at diagnosis, BMI, histological grade, tumor size, nodal involvement and progesterone receptor positivity.

Results: 7360 patients were included of which 1121 (15.2%) were diagnosed with pure ER+/HER2- ILC, the remaining 6239 (84.8%) patients were considered as the control group. Overall, in multivariable analyses, parity with >2 children was associated with a higher prevalence of pure ILC as compared to uniparous patients (odds ratio, OR 1.257, 95CI 1.039-1.521, p= 0.019). No significant association was seen for age at 1st FTP and interval 1st FTP – diagnosis. The subgroup analyses per age group are summarized in Table 1. Only for the age group 41-50, an increased age 1st FTP was associated with an increased prevalence of pure ILC.

In patients with pure ER+/HER2- ILC, nulliparous women were less likely to have a progesterone receptor (PR)-positive tumor as compared to parous women (OR 0.477, 95CI 0.224-0.907, p= 0.022). No other significant associations were seen for clinicopathological features between nulliparous and parous women, and between uniparous and multiparous women in the overall cohort nor any age group.

Conclusions: Within an ER+/HER2- breast cancer cohort, higher parity seems to be associated with a higher prevalence of pure ILC, which is especially seen in the patients diagnosed with

breast cancer between the age of 51 and 60. Increased age at the 1st FTP only seems to increase the incidence of ILC in the age group 41-50. With the exception of nulliparous women having less PR positive tumors, parity does not seem to affect the clinicopathological features of ER+/HER2- pure ILC.

Table 1: subgroup analyses per age group of association of histology (pure ILC vs control group) with parity, age 1st FTP and interval 1st FTP – diagnosis

Background: Mucinous carcinoma is the third most common histological subtype of breast cancer after ductal and lobular carcinomas, accounting for approximately 3% of invasive breast cancers. Although considered a favourable subtype with de-escalation of treatment recommended in the National Comprehensive Cancer Network guidelines, recurrence can occur and supporting data is limited. We thus examined prognostic factors of pure mucinous breast cancer (PMBC) in an international multicentre cohort study. Methods: Patients diagnosed between January 2000 to December 2015 with hormone receptor-positive HER2-negative stage I to III PMBC, invasive ductal carcinoma (IDC) and invasive lobular carcinoma (ILC) at 6 centers in Singapore, Taiwan, Korea and Japan were evaluated. Cox proportional hazards regression analyses were used to compare relapse-free survival (RFS), distant relapse-free survival (DRFS) and overall survival (OS) by histological subtypes, and to identify prognostic factors for PMBC. Results: Of 23,105 women eligible for analysis, 20,684 had IDC, 1,475 had ILC and 946 had PMBC. The median follow-up was 6.6 years; 5-year RFS, DRFS and OS for PMBC were 94.6%, 96.5% and 98.1% respectively. On multivariable cox regression analyses, PMBC demonstrated superior RFS (hazard ratio [HR] = 0.70, 95% CI: 0.56 - 0.88), DRFS (HR = 0.69, 95% CI: 0.53 - 0.89) and OS (HR = 0.70, 95% CI: 0.52 - 0.93) compared to IDC, while ILC had comparable survival outcomes as IDC. When restricted to only PMBC, significant independent prognostic factors for RFS included ethnicity (vs Chinese, "Others" [non-Chinese/Japanese/Korean, mainly Malay and Indian]: HR = 2.62, 95% CI 1.23 – 5.57),

older age (vs < 40 years, >70 years: HR = 3.53, 95% CI 1.67 – 7.46), tumor size (vs T1, T3-4: HR = 2.79, 95% CI 1.45 – 5.37), positive lymph nodes (HR = 2.04, 95% CI: 1.10 – 3.77), use of radiotherapy (HR = 0.54, 95% CI 0.33 – 0.91) and endocrine therapy (HR = 0.31, 95% CI 0.12 – 0.77). On further analysis, the inferior RFS, DRFS and OS in older patients (>70 years) were driven largely by non-breast cancer deaths rather than relapses. Use of endocrine therapy was also associated with superior DRFS (HR = 0.26, 95% CI 0.09 – 0.73) but not OS. In a subgroup analysis, use of chemotherapy was associated with improved DRFS (HR = 0.25, 95% CI 0.08 – 0.82) and OS (HR = 0.07, 95% CI 0.01 – 0.37) with a trend in RFS (HR = 0.41, 95% CI 0.14 – 1.24) for lymph node-positive PMBC; no differences in outcomes were observed for the lymph node-negative subgroup. Conclusions: Larger tumor size, lymph node positivity and ethnicity were significant factors for RFS in PMBC. Use of endocrine therapy was associated with superior RFS and DRFS, while chemotherapy was associated with better DRFS and OS for lymph-node positive PMBC.

Objective: Pregnancy-associated breast cancer (PABC) is defined as diagnosed during pregnancy or within one year of childbirth, in which current evidence associates with poor prognosis, without showing what clinical characteristics could impact in survival. We aim to explore the impact of heterogeneity in risks on death and disease relapse, suggesting clinical characteristics that might improve PABC clinical outcomes.

Methods: Medline, Embase, Cochrane, Lilacs and congress abstracts published since 2000 were used as data sources. Two reviewers independently selected manuscripts and extracted data and a third reviewer solved discrepancies. The primary outcome was overall survival (death), and secondary outcome was disease-free survival (death or relapse). Summarized hazard ratios were recalculated based on reported data. All metaanalyses used a random-effects model and heterogeneity was reported using the I² method.

Results: A total of 7143 studies were identified and 30 studies were included for metaanalyses. PABC is associated with a 96% (HR=1.96, 95%CI 1.58;2.35) higher risk of death and an additional 82% (HR=1.82, 95%CI 1.45;2.20) risk of death or disease relapse in comparison to a population of non-PABC or nulliparous BC. Through sensitivity analyses, we identified that

clinical outcomes was impacted, possibly due to Ki-67 levels, poorly differentiated tumors, and triple negative breast cancer (TNBC) frequency in the study.

Conclusions: PABC is correlated with poorer prognosis, suggesting that besides early diagnosis, Ki-67 levels, poorly differentiated tumors and TNBC might be relevant sources of inconsistency. So, such clinical sources of heterogeneity should be better investigated regarding the potential to evaluate alternative therapeutic strategies.

PABC deaths compared to non-PABC population, represented as hazard ratio

PABC deaths or disease relapse compared to non-PABC population, represented as hazard ratio

Biology and clinical course of lobular cancer in breast cancer (BC)

Background: Invasive lobular carcinoma (ILC) accounts for 10–15% of all breast cancers. Due to its distinctive growth pattern and biology, lobular carcinoma often fails to form distinct masses that can be easily detected by palpation or mammography. Because it is substantially less common than infiltrating ductal carcinoma (IDC), knowledge about clinical outcomes of ILC has been based on studies including relatively small patient (pt) numbers. Thus, we sought to assess the biologic and genomic features of ILC in the context of clinical outcomes.

Methods: Eligible pts were adults with metastatic lobular or ductal BC seen at MD Anderson between 1997 and 2020. Overall survival (OS), progression-free survival (PFS), and disease-free interval (DFI) from the initial diagnosis were estimated using the Kaplan-Meier method. Survival distributions were compared using the log-rank test. Multivariate Cox proportional hazards regression models were applied to assess effect of covariates of interest on OS and DFS. No statistical adjustment was made for multiple testing.

Results: A total of 7642 IDC and 1159 ILC female metastatic BC pts were included in the analysis. Clinical characteristics are presented in the table. Pts with ILC were on average older, had fewer metastases, and were more likely to have a family history of breast or ovarian cancer than pts with IDC. Lobular cases were less likely to be HER2+, had lower Ki-67, and lower nuclear grade than ductal cancer cases.

The median follow-up was 4.37 years. The median OS for all pts from initial diagnosis was 5.38 years; 5.21 years and 6.57 years for IDC and ILC, respectively. ER positivity was associated with longer OS in both IDC [Hazard ratio (HR) 0.47, 95% confidence interval (CI): 0.45 - 0.49, $P < 0.0001$] and ILC (HR 0.63, 95% CI: 0.54 - 0.75, $P < 0.0001$). In de novo metastatic disease,

the median OS was 3.74 years in IDC and 4.15 years in ILC. In recurrent IDC and ILC, the median OS was 5.84 and 7.89 years, respectively. De novo presentation had better OS from time of metastatic disease diagnosis for pts with both ILC and IDC than those presenting with recurrent cancer; however, de novo presentation was associated with worse PFS on 1st line therapy. In ILC, grade III had a poorer prognosis than grade I/II; (HR 1.47, 95% CI: 1.30 - 1.68, P< 0:0001). Among pts with IDC, grade I had the best outcomes, followed by grade II, then grade III. In IDC, significantly improved OS was observed in HER2+ BC (HR 0.85, 95% CI: 0.79 - 0.92), P< 0:0001). The median PFS for all pts was 0.53 years and the median DFI was 2.61 years. In both ILC and IDC, PFS and DFI were better in cancers that were ER+ or grade I/II. Conclusions: In metastatic BC pts, the biologic phenotypes and clinical behavior of ILC and IDC differ. More complete and reliable characterization of ILC may yield useful information regarding the biologic nature of ILC resulting in discovery of actionable findings leading to more personalized therapy. Further analyses of genomic features and patterns of metastatic sites between IDC and ILC will be presented.

PURPOSE: There is currently no standardised definition for patients at high risk of recurrence of HER2-negative early breast cancer (eBC, stages 1–3) after surgery. Recognising that the assessment of high risk is often multifactorial, the aim of this modified Delphi panel was to establish expert UK consensus on this definition, separately considering HR-positive and triple-negative (TN) patients. **METHODS:** A total of 45 UK-based clinicians, including breast cancer oncologists and surgeons, were invited to participate. The number of respondents in each of three rounds was 29, 24 and 22 respectively. Statements were developed using the results

from a targeted literature review and the guidance of a lead clinician, and comprised free-text, single-choice or numerical formats. The first round aimed to determine which factors are currently used in clinical practice to assess risk of recurrence in the populations of interest. In the subsequent rounds, the objective was to establish thresholds indicative of high risk in a 10-year timeframe for each of the factors retained in Round 1. Between each round, statements were refined, considering the distribution of responses and free-text notes provided by participants. Consensus for single-choice questions was set at a pre-defined threshold of $\geq 70\%$ of respondents. **RESULTS:** Consensus was achieved on the need to assess age, tumour size, tumour grade, number of positive nodes, presence of inflammatory breast cancer and one or more risk prediction tools to define high risk of recurrence in all HER2-negative patients. In HR-positive patients, there was agreement on the use of one or more tumour profiling tests and biomarkers to define high risk of recurrence. However, there was no consensus on biomarker use in TN patients, and support for specific biomarkers (such as Ki-67) was conflicting for both sub-populations based on the analysis of free-text notes. Similarly, while there was consensus on the use of pCR status/residual disease to indicate high risk in TN patients, this factor failed to reach consensus for the HR-positive sub-population. Germline BRCA status and menopausal status were not considered to be key factors for risk of recurrence in either biological subtype. In the second and third rounds, thresholds indicative of high recurrence risk were agreed; it should be noted that the free-text responses provided by the participants frequently highlighted that many of the factors should be considered along a continuous scale when assessing the risk of individual patients. In HR-positive patients, these thresholds included: age < 35 years, tumour size > 5 cm (each when considered independently from other risk factors); tumour grade 3 (independently or in combination with other factors); number of positive lymph nodes ≥ 4 when considered independently or ≥ 1 in combination with other factors. For patients with TN tumours, the following thresholds reached consensus, whether considered independently or in combination with other factors: tumour size > 2 cm, tumour grade 3, number of positive lymph nodes ≥ 1 . In several cases, however, no consensus could be reached on the appropriate threshold indicating high risk of recurrence. In the HR-positive sub-population, these included thresholds for age and tumour size, when considered in combination with other factors. In the TN sub-population, this included age, whether independently or in combination with other factors. **CONCLUSIONS:** The expert consensus reached in this panel highlights that an integrated model is important in assessing recurrence risk in eBC and that definitions of high risk differ according to biological subtype. The results may serve as a valuable reference point for clinicians to use in assessing risk of disease recurrence and in making treatment decisions after surgery in the HER2-negative eBC population. **FUNDING:** AstraZeneca UK Ltd. Background: Invasive lobular carcinoma (ILC) represents up to 15% of all breast carcinomas. The majority of ILC express the estrogen receptor (ER) and have no amplification/overexpression of the human epidermal growth factor receptor 2 (HER2). A high body mass index (BMI) has been associated with an increased risk of developing ILC in postmenopausal women, similar to what is seen for breast cancer of no special type (NST). It is however unknown if BMI impacts the clinicopathological features and the prognosis of ILC.

Methods: We performed a multicentric retrospective study in 5 European centers of patients diagnosed between January 2000 and December 2020 with ER+/HER2- non-metastatic pure (i.e., not mixed) ILC. Patient and tumor characteristics and event-related data were collected. BMI was categorized into underweight ($\leq 18.5 \text{ kg/m}^2$), lean ($> 18.5 \text{ kg/m}^2$ and $< 25 \text{ kg/m}^2$), overweight ($\geq 25 \text{ kg/m}^2$ and $< 30 \text{ kg/m}^2$) and obese ($\geq 30 \text{ kg/m}^2$). The association of BMI as either a continuous or a categorical variable with clinicopathological variables was assessed using linear regression or ordinal logistic regression, respectively. Median follow-up was calculated using the reverse Kaplan-Meier estimator. Survival analyses using univariable (stratified by center) and multivariable (adjusted for all included variables and stratified by center) Cox regression were performed to evaluate the association of BMI with disease free survival (DFS), distant recurrence free survival (DRFS) and overall survival (OS). DFS and DRFS were analyzed in the presence of death without event as the competing risk.

Results: The data of 2476 patients were collected and BMI was available for 2346 patients. In total, 1299 (55%) patients were lean, 638 (27%) overweight and 339 (14%) obese. Underweight patients only represented 3% of all patients and were thus excluded from further analyses. A higher age at diagnosis, higher grade, larger tumor size, nodal involvement and multifocality were significantly associated with higher BMI (Table 1). The median follow-up was 8,5 years (interquartile range 59.24 – 142.13 months). In univariable analysis, higher BMI was associated with worse survival outcomes (Table 2). However, this association was not seen in multivariable analysis while grade, tumor size and nodal involvement were still prognostic for all endpoints. Similar results were seen with BMI as a continuous variable.

Conclusion: Larger tumors and nodal involvement were more likely to be found in patients with ER+/HER2- ILC with higher BMI which might be explained by a delayed diagnosis in these patients. Higher grade also seemed to be associated with higher BMI. In multivariable analyses, BMI was not found to be an independent prognostic factor. Tumor grade, tumor size, and nodal

status remained strongly prognostic for survival outcomes in multivariable survival analyses which is consistent with their known prognostic importance in luminal tumors. We hypothesize that the prognostic effect of BMI is mediated through these variables for patients with ER+/HER2- ILC.

Introduction. The CUB domain containing protein 1, also known as TRASK (Transmembrane and associated with Src kinases) or CD318, has been suggested as a biomarker for stem cells or stem like cells. The transmembrane CDCP1 protein is known to activate the Src kinase and has recently shown to play a key part in the aggressiveness of breast cancer cells including migration, invasiveness and possibly growth induced by the motogenic Hepatocyte Growth Factor (HGF) and its receptor MET (Kawase et al 2022), a process requires Rho-GEF, PI3K and STAT5. This appears to allow identification of a subset of cancer cells that are aggressive in their biological behaviours. Here, we examined the expression profile of CDCP1, SRC, the HGF/HGF receptor complex and HGF activation regulators in a cohort of breast cancer and attempt to establish if such protein axis is able to identify patients with high risk of poor clinical outcome. Methods. Using an establish breast cancer cohort which is comprised of both normal mammary tissues and breast cancer tissues freshly obtained after surgery, we quantified the gene transcripts of CDCP1/CD318 and examined its clinical and pathological relevance. Integrated analysis was conducted for CDCP1 and the expression profile of SRC, PI3K, HGF, the HGF receptor cMET, HGF activator (HGFA), HGF activation regulators including HAI-1, HAI2, matriptase-1 and matriptase-2, and STAT family members. This was done against the clinical outcome of the patients as well as the clinical and pathological factors. Results. Breast cancer tissues expressed high levels of CDCP1 compared with normal mammary tissues. CDCP1 itself had a weak yet significant value in predicting the overall survival of the patients

($p=0.047$). The expression levels of these CDCP1 related molecules aren't significantly correlated with CDCP1. However, integrated analyses revealed that CDCP1, together with its pathway regulators SRC, HGF, the HGF receptor (MET) and the HGF activation regulators matriptases form a power prognostic indicator for the clinical outcome of the patients ($p < 0.0001$, HR=1.8 for overall survival (OS) and $p=0.002$, HR=1.5 for disease-free survival (DFS)). This integrated profile has also identified subgroups of patients with highly favourable and very poor clinical outcomes over a ten-year follow-up period, with the respective survival at 100% and 36% respectively. The predictive power for OS and DFS is highly independent of other clinical and pathological factors in a multivariate analysis ($p=0.003$ and $p=0.017$ respectively). The predictive power is applicable to ER negative and HER2 positive tumours. Discussion. CDCP1/CD318, a factor known to stimulate cancer cell aggressiveness, together with its pathway kinase SRC and newly identified extracellular activator HGF and the HGF regulators forms a significant independent prognostic factor. It identifies subgroups of patients with favourable and poor prognosis, allowing consideration of targeted therapies for the patients. Background: With the rise of genomic testing, more clinicians are using panels to understand the genetic profile of breast cancer to help aid in clinical management. However, little is known about the relationship between the results of genomic tests and the likelihood of identifying an underlying germline variant, and how this should integrate into clinical decision making.

Methods: Data was obtained from the Informed Genetics Annotated Patient Registry (iGAP), an IRB-approved, multi-centered longitudinal registry designed to capture biomarker test results and their impact on treatment practices and outcomes. Two genomic tumor profiling tests were studied - MammaPrint recurrence risk and Blueprint molecular subtypes, including Luminal type A, Luminal type B, Basal, and HER 2 type. Of the 3400 patients currently enrolled in the registry, 528 have been diagnosed with breast cancer and underwent tumor profiling by both MammaPrint and BluePrint as well as germline genetic testing, including analyses of 24 cancer susceptibility genes (ATM, BARD1, BRCA1, BRCA2, BRIP1, CDH1, CHEK2, NBN, PALB2, PTEN, STK11, TP53, APC, BMPR1A, CDK4, EPCAM, MLH1, MSH2, MSH6, MUTYH, PMS2, RAD51C, RAD51D, SMAD4). Differences in positive germline variant rates were tested for with two-sided, Chi-Square tests using the prop.test function in R. Results: 231 (44.17%) were classified as High-Risk for recurrence on MammaPrint, with a 0.13 PVs detected per patient tested (positive germline variant (PV) Rate), 269 (51.34%) were identified as having a Low-Risk, with a 0.0849 PV rate, and 23 (4.4%) Ultra-Low-Risk, with a 0.0455 PV rate. There is not a significant difference between the High-Risk and Low-Risk for recurrence ($p=0.09$). 45 (8.54%) Basal molecular subtype identified by BluePrint panel, with a 0.1778 PV rate, 292 (55.41%) classified as Luminal A type, with a 0.0819 PV rate, 171 (32.45%) Luminal B with 0.1078 PV rate, and 13 (2.47%) HER2 Type with 0.07 PV rate. There was a significant difference between Basal and Luminal A PV rates ($p=0.042$), but no other statistically significant differences were found.

Conclusions: Patients with a Basal molecular subtype have a significantly higher likelihood of having a germline pathogenic variant compared to Luminal A subtype. There was a trend that did not reach statistical significance for MammaPrint High Risk to have a higher likelihood of germline pathogenic result compared to MammaPrint Low Risk. This data adds another parameter for germline testing in those breast cancer patients who fall outside of current NCCN testing criteria.

Background: Genetic resources are underutilized when it comes to being incorporated into a breast cancer patient's treatment, but that isn't the only piece being overlooked. The Ki-67 proliferation index expressed (Ki-67%) is an established marker of tumor proliferation and aggressive behavior. We hypothesized that Ki-67% could have increased clinical utility when correlated with genomic testing results. Methods: Data was obtained from the Informed Genetics Annotated Patient Registry (iGAP), an IRB-approved, multi-center longitudinal registry designed to capture biomarker test results and their impact on treatment practices and outcomes. Tumor grades and Ki-67% were taken from patient pathology reports. The average Ki-67% was then calculated and compared for each tumor grade, MammaPrint genomic recurrence risk category (ultra low risk, low risk, and high risk), and Blueprint molecular subtype (Luminal type A, Luminal type B, Basal, and HER 2 type). ANOVA statistical analysis was performed for significance values. Results: Of 3102 patients enrolled in the iGAP Registry, 733 were diagnosed with breast cancer and had available tumor grade and Ki-67% data. Among these patients, 357 had genomic recurrence risk (MammaPrint) and 220 genomic molecular subtyping (BluePrint) reports. As expected, tumor grades were significantly positively correlated with Ki-67% ($p < 0.0001$ between all 3 tumor grade groups). Average Ki-67% in each genomic recurrence risk revealed a significant difference between Low Risk (14%, range 1-70%) and High Risk (36%, range 1-95%, $p < 0.0001$). Among the genomic molecular subtypes, there were significant differences in Ki-67% between Basal (avg 69%, 17-95%) and Luminal type A (avg 13%, 1-70%, $p < 0.0001$) and all other subtypes, while Luminal type B (avg 24%, 1-80%) and HER 2 (avg 38%, 29-45%) were not significantly different from each other ($p = 0.2817$), but still significantly different to all other subtypes. Conclusion: From these results, we can deduce that molecular subtype correlates with, but is clinically distinct from, Ki-67 proliferation index. These results also indicate that molecular subtype correlates with higher tumor grades, possibly due to increased cell proliferation. Achieving truly personalized clinical decision making requires utilizing multiple modalities and biomarkers, integrating the results into management.

Background: In the era of targeted therapies, chemotherapy (CT) is still a valuable treatment option for patients (pts) with HER2 negative metastatic breast cancer (MBC). The identification of predictive and prognostic markers might improve treatment response and survival. Here we investigated the role of tumor subtypes, circulating tumor cells (CTCs), and mutations in genes or pathways of interest, in predicting response to CT and prognosis of HER2 negative MBC pts within AARES trial. Methods: AARES is an open label multicentric randomised phase 2 trial comparing a DNA-damaging (arm A: cisplatin 25 mg/m²/day, day 1-3 + cyclophosphamide 600 mg/m² day 1) versus (vs) a non-DNA-damaging (arm B: capecitabine 1000 mg/m² bid/day, day 1-14 + vinorelbine 60 mg/m²/day, day 1,8) CT regimen in pts with HER2 negative MBC. Archival tumor tissue samples and blood samples were collected at baseline. The Cell SearchTM system was used for CTCs isolation and enumeration and a cut-off of 5 CTC/7,5 ml was used. Tumor subtypes were based on locally assessed hormone receptors and HER2 status. The luminal-like subtype (Lum) was defined by ER or PR positivity, while the triple negative subtype (TN) by ER, PR, and HER2 negativity. Tissue samples were used for DNA extraction and next generation sequencing analysis using a target enrichment panel of 170 genes (TruSight 170, Illumina). Primary endpoint was objective response rate (ORR) assessed for the two treatment arms. Progression free survival (PFS) and overall survival (OS) were evaluated as secondary endpoints, and estimated with the Kaplan-Meier method. ORR, PFS and OS were correlated with CTC counts, tumor subtypes, and mutational status of genes/pathway of interest (PIK3CA, TP53, BRCA1, BRCA2, PI3K/AKT pathway (PI3K/AKT)). Results: AARES enrolled 102 pts from 2011 to 2016 across 9 Italian centers. Of these, 77 pts were evaluable for ORR. Median follow up was 32 months. Overall, median age was 57. The majority of pts had Lum tumors (73%), while 27% had TN. 86% of pts had visceral metastases, and 52% had 3 or more metastatic sites. 48% of pts received the study treatment as 1st line,

32% as 2nd line, and 19% as 3rd line. Out of the 77 pts with ORR data, 41 (53%) were CTC- and 36 (47%) CTC+. A larger proportion of pts with Lum tumors were CTC+ (54% n=30), while TN tumors were mainly CTC- (71% n=15). 49 pts had adequate tumor tissue for sequencing analysis. TP53 mutations (mut) were found in 33% of pts, BRCA1/2 mut in 14%, PIK3CA mut in 35%, and PI3K/AKT mut in 47%. ORR was 24% and 37% in arm A vs arm B, respectively (p=0.2), and no difference in ORR was observed by tumor subtypes (Lum vs TN), and CTCs count (+ vs -). PFS and OS were assessable on the whole population (n=102) and did not significantly differ by treatment arms. Median OS (mOS) was higher in Lum pts compared to TN (24 months (mo) vs 15.4 mo, p=0.048) while median PFS (mPFS) did not differ according to tumor subtypes (p=0.28). Overall, CTCs count was not significantly associated with mPFS or OS however in pts with TN tumors and CTC-, mPFS and mOS were significantly longer (mPFS: 4.44 mo vs 2.56 mo in CTC- and CTC+ subgroups, respectively, p=0.00087 and mOS: 22.07 mo vs 3.57 mo in CTC- and CTC+ subgroups, respectively, p<0.0001). On the other hand, no differences were observed in Lum pts categorized according to CTC status (p=0.83 for mPFS, p=0.54 for mOS). Finally, pts with PI3K/AKT mut had a significantly worse PFS compared to wild type in the overall population (p=0.0091) as well as in Lum (p=0.034) and TN pts (p=0.0052). Conclusions: CTCs and tumor subtypes were not predictive of response to CT regimens in HER2 negative MBC pts. A number of CTC >5 in TN MBC, and mutations in the PI3K/AKT pathway, identified a subgroup of pts with worse prognosis, potentially candidates for alternative treatments. Further studies are needed to confirm these results in a larger population.

ABSTRACT Background: Breast cancer has become the most common cancer worldwide and triple-negative breast cancer (TNBC) is the most aggressive subtype due to the lacks of hormone receptors and HER2 expression. Increasing rate of breast cancer metastasis also need to be solved. Nearly one in four breast cancer patients developed metastasis after treatment, which attributed to 90% cancer related death. Considering highly aggressive pattern of TNBC, TNBC showed higher metastasis probability rather than other subtypes. Therefore, exploring more biomarkers and therapeutic targets are on urgent. Methods: We profiled the transcriptomes of 59646 cells from 12 primary and 4 metastatic tumor samples from Gene Expression Omnibus (GEO) database (<https://www.ncbi.nlm.nih.gov/geo/>). Results: Comparing with primary site, metastatic site was predominated with immunosuppressive tumor microenvironment. In brief, metastatic samples showed increasing numbers of macrophages, lower anti-tumor microenvironment scores, higher malignant cell properties scores, less effective T cells and macrophages, enhanced immune escape potential tumor cells and a later pseudotime state of malignant cells, compared with primary samples. Remarkably, metastatic samples exhibited a stronger interaction of THBS1-SDC1 axis between macrophage subcluster named angiogenesis-1 and malignant cell subcluster named CDKN2A epithelial cells. We subsequently confirmed that higher THBS1-SDC1 expression indicated with poor overall survival and distant metastatic free survival of TNBC patients in The Cancer Genome Atlas (TCGA) TNBC cohort. Conclusion: Our immune landscape of TNBC ecosystem provide deeper insights into tumor metastasis and offer potential biomarkers and therapeutic target for TNBC. Key words: Breast cancer; immune-microenvironment; THBS1; SDC1; metastasis

Background: The evaluation of regional lymph nodes in patients with breast cancer is one of the main predictive and prognostic factors for treatment. The most frequently methods of percutaneous evaluation for suspicious lymph nodes are fine needle aspiration (FNA) and core needle biopsy (CNB). According to the international literature, CNB and FNA are considered diagnostic methods with high specificity (98% vs. 99%), however FNA can present up to 21% of inconclusive results due to insufficient material, which leads to recall and delay in treatment approach. Although CNB is well established as a percutaneous method for the diagnostic evaluation of suspicious breast lesions, the literature is still scarce regarding the use of this method for the evaluation of suspicious regional lymph nodes in patients with breast cancer. **Objectives:** To analyze the results of percutaneous biopsies performed in suspected lymph nodes according to the topography and the type of needle used, and to verify the preferred method used. **Methods:** This was a retrospective study evaluating a public Hospital in São Paulo – Brazil (Pérola Byington Hospital database). Patients who underwent ultrasound-guided percutaneous lymph node biopsy from May 2015 to November 2017 were included. Data were analyzed and the type of biopsy (FNA or CNB) and the results were analyzed. **Results:** 106 medical records of patients with previous breast cancer and that underwent lymph node biopsy were reviewed. The mean age was 54.7 years (SD±12.4) in the CNB group and 54.7 years (SD±10.8) in the FNA group. Most of the patients were submitted to CNB (66% - 71 patients) and 34% were evaluated with FNA (35 patients). According to the topography of the lymph nodes, 80% were in the axilla (n=84), 10% in the supraclavicular region (n=11) and 10% in the

cervical region (n=11). When analyzing the FNA results, 31% did not present sufficient material (n=11), 37% were malignant (n=13), 20% were benign (n=7) and 12% showed cellular atypia (n=12). Among the CNB performed in suspected lymph nodes, 53% were malignant (n=38) and 31% were benign (n=33), and no one had insufficient material. There were no reports of complications related to the procedures. In the insufficient material group, 27% (n=3) of the patients underwent a new percutaneous biopsy (2 CNB with malignant result and 1 FNA with inconclusive result) and 73% (8) were maintained in follow-up. The mean follow-up time was 24 months, and clinical and imaging stability was confirmed after this period. In the CNB group with malignant result, 10% (4) were diagnosed with neoplasia of other sites (cervix, lymphoma, melanoma and gastrointestinal), 78% (30) presented immunohistochemistry in agreement with that of the breast, 3% (1) presented different immunohistochemistry and in 9% (3) this evaluation was not performed. Conclusion: CNB was the preferred diagnostic method in our Hospital (66% vs 34%), being considered a viable procedure to evaluate lymph nodes in various topographies and with low rates of inconclusive results. Besides that, immunohistochemistry was done in 91% of the cases showing the importance of this analysis in the treatment of the recurrence or even in the diagnosis of other primary tumors. In the future, studies that assess indirect costs may confirm the applicability of CNB in patients with suspicious lymph nodes in terms of achieving greater agility and resolution.

Background Breast cancer patients with estrogen receptor (ER)+/HER2- (and usually node-negative) tumors can avail themselves of Oncotype DX Breast Recurrence Score[®] (ODXRS) testing to predict their risk of distant recurrence within 9 years and, consequently, putative chemotherapy benefit. However, ODXRS testing requires sufficient tumour availability and specimen shipping, which imposes time and financial burdens to testing which have to be met by healthcare systems. The advent of digital pathology offers a potential avenue for exploring computer-aided diagnostic solutions which may overcome these hurdles by extracting the requisite information from hematoxylin and eosin (H&E)-stained tissue whole slide images (WSIs) alone. In turn, this technology could significantly reduce diagnostic turnaround times and cost, and improve accessibility and test reproducibility, thereby enabling healthcare systems to run more efficiently and offer patients more timely results. Ideally, such a platform should incorporate a measure of the underlying tumor biology to provide a fully explainable, white box solution, and may offer further insights into the identification of early recurrence events. Aims The aim of this study was to establish whether our computer-aided solution's (Q-Plasia OncoReader Breast, QPORB) digital biomarker representing G1/S cell cycle deformations extracted from H&E WSIs was prognostic for disease-free survival (DFS) and

could predict disease recurrence, particularly in the setting of low risk ODXRS breast cancers. Methods Primary breast cancer resection/excision specimens (n=70 cases) sent for ODXRS testing from St James's University Hospital, UK (2016-2019) were collected. Anonymised diagnostic glass slides (n=198 slides) of H&E-stained tumors were scanned at x20 magnification on an Aperio AT2 scanner. In parallel, relevant clinical and histological data were collected from pathology reports and electronic patient records, including both ODXRS and recurrence events during follow-up. The QPORB recurrence scale (QPORB-RS), which combines statistical physics and tumor biology to identify image-based malignant cell cycle deformation, extracts prognostic information from WSIs. The contribution of potential confounders (age, stage, grade, lesion size, Nottingham prognostic index and Charlson score) were accounted for. Results The QPORB-RS was prognostic for DFS for patients with predominantly node-negative (including node micro-metastases) HR+/HER2- tumors over a median follow-up period of 5 years (P=0.02; dichotomized Kaplan Meyer with median cut-off). The QPORB-RS concurred with ODXRS's high vs. low recurrence risk in 73% (19/26) and 61% (27/44) of cases, respectively, with an overall agreement of 66% (46/70). Moreover, the QPORB-RS identified all 5 patients who had recurrences (with ODXRS of 6, 9, 10, 21 and 26, and ages of 55, 66, 42, 35 and 50 years, respectively) as being high risk in the subset of those given a low (including historically intermediate) ODXRS and who did not receive chemotherapy. Conclusion The QPORB-RS is a good prognostic test of risk of disease recurrence in breast cancer patients with predominantly node-negative (including node micro-metastases) HR+/HER2- tumors within a median 5-year follow-up period. Our efforts are now focussed on extending this cohort and establishing the prognostic value of the QPORB-RS across all breast carcinomas, regardless of molecular subtype, stage/node positivity and menopausal status.

Background: Hormone-receptor (HR) status, HER2 Status, de novo metastatic disease, distant recurrence-free interval (DRFI), and visceral disease are known prognostic factors in metastatic breast cancer (MBC). Therefore, in the majority of clinical trials, randomization is stratified for these parameters. Whether the number of involved organs at baseline has an additional prognostic value was examined in this analysis.

Patients and methods: The AGMT-MBC-Registry is a multicenter nationwide ongoing retrospective and prospective registry for MBC patients in Austria. In this analysis, patients with known HR status, HER2 status, and available survival data were included. Multivariable hazard ratios were estimated by COX proportional hazard models. For variable selection a backward stepwise model selection using the Akaike information criterion was performed.

Results: As of 04/05/2022, 2,235 patients have been included in the registry, of which 1,840 patients fulfilled the inclusion criteria. In two different multivariable COX proportional hazard models for overall survival, the number of involved organs was a highly statistically significant independent prognostic factor: (1) a model including the number of involved organs at baseline together with known prognostic factors (see Table 1); (2) a stepwise selection model additionally including menopausal status and involved metastatic organ sites (bone, liver, lung, brain, and lymph nodes) separately. This effect was maintained in sensitivity analysis taking different breast cancer subtypes as well as visceral and non-visceral disease into account.

Table 1: Multivariable Model for overall survival

Conclusion: The number of involved organs at baseline is an independent prognostic factor in MBC and should be considered as a stratification factor in randomized trials.

Table 1: Multivariable Model for overall survival

Characteristic	HR ¹	95% CI ¹	p-value

Background: Breast cancer is becoming a tumor with the highest morbidity rate, and inflammation-induced cell death namely pyroptosis reportedly plays dual roles in cancers. However, the specific mechanism between pyroptosis and the clinical prognosis of breast cancer patients is indistinct. Hence, novel pyroptosis-related biomarkers and their contributing factors deserve further exploration to predict the prognosis in breast cancer. Methods: Pearson's correlation analysis, and univariate and multivariate Cox regression analysis were utilized to obtain six optimal pyroptosis-related gene prognostic signatures (Pyro-GPS). The risk score of each breast cancer patient was calculated. Next, a Pyro-GPS risk model was constructed and verified in TCGA cohort (n=1,089) and GSE20711 cohort (n=88). Then analyses of immune microenvironment, genomic variation, functional enrichment, drug response and clinicopathologic feature stratification associated with the risk score of Pyro-GPS were performed. Ultimately, a nomogram based on the risk score and several significant clinicopathologic features was established. Results: The low-risk breast cancer patients have better survival outcomes than the high-risk patients. The low-risk patients also show higher immune cell infiltration levels and immune-oncology target expression levels. There is no significant difference in genetic variation between the two risk groups, but the frequency of gene mutations varies. Functional enrichment analysis shows that the low-risk patients are prominently correlated with immune-related pathways, whereas the high-risk patients are enriched in cell cycle, ubiquitination, mismatch repair, homologous recombination and biosynthesis-related pathways. Pyro-GPS is positively correlated with the IC50 of anti-tumor drugs. Furthermore, comprehensive analyses based on risk score and clinicopathological features were performed to predict the prognosis of breast cancer patients. Conclusions: The risk score of Pyro-GPS can serve as a promising hallmark to predict the prognosis of BRCA patients. Risk score evaluation may assist to acquire relevant information of tumor immune microenvironment, genomic mutation status, functional pathways and drug sensitivity, and thus provide more effective personalized strategies.

Patients with low expression of BCL 2 experience more late recurrence than patients who do not, which neutralized the protective effect of low BCL2 expression in patients with estrogen receptor positive breast cancer

Presenting Author(s) and Co-Author(s):

Background) BCL2 is a key factor for the regulation of cellular apoptosis and its overexpression inhibits apoptotic cell death and activates cellular proliferation, resulting tumor progression. Although BCL2 are expected to be associated with an adverse prognosis in breast cancer, previous studies have reported inconsistent results and some reported even favorable features. The aim of this study is to investigate what characteristics of BCL2 yield this discrepant result in patients with breast cancer. Materials and methods) Female patients with breast cancer who completed primary treatment against breast cancer between 2003 and 2018 at Wonju Severance Hospital, Korea, were included. Clinicopathological characteristics including BCL2 expression were collected. Patients were categorized into two groups, BCL2 expression in more or less than 10% of tumor cells. Kaplan-Meier curves were generated to compare recurrence-free interval (RFI) and overall survival (OS). Result) The final cohort included 616 patients with a mean age of 54.79 ± 11.2 (25-86) years. Patients with estrogen receptor positive breast cancer were more frequent in patients with tumor in which BCL2 was expressed in less than 10% of tumor cells (70.7% vs. 57.7%). Patients with tumor in which BCL2 was expressed in less than 10% of tumor cells showed better survival than their counterpart. Subgroup analysis according to the estrogen receptor and HER2 overexpression status was done. In patients with tumor in which HER2 was not overexpressed, patients with tumors in which BCL2 expressed less than 10% of tumor cells showed better survival ($p=0.007$). Survival difference maintained in patients with triple negative disease ($p=0.010$). However, in patients with estrogen receptor positive breast cancer, survival of two groups of patients with high and low BCL2 expression become not significant over time as late recurrence occurred ($p=0.227$). In contrast, patients with HER2 positive disease breast cancer showed worse prognosis than their counterpart when their tumor showed BCL2 expression in less than 10% of tumor cells. Conclusion) BCL2 overexpression showed different contribution to the patients' survival according to the subtypes. Patients with HER2 overexpression showed better survival when BCL2 was overexpressed and patients with HER2 negative disease does not. First, similar survival was resulted from late recurrence in patients with estrogen receptor positive disease.

Second, apoptotic capacity of tumor cells may not be major survival factor if tumor cells are exactly targeted.

Background: Sarcopenia, characterized by the loss of muscle mass, has emerged as a negative prognostic factor in cancer patients. It has been associated with poorer outcomes and increased treatment-related morbidity. Post-mastectomy breast radiation therapy (RT) increases the likelihood of reconstructive complication, with up to 20% of reconstructed women requiring implant removal. The factors that lead to these complications are poorly understood and likely multifaceted. We investigated the relationship between pre-radiation therapy sarcopenia and post-mastectomy reconstruction outcomes. Methods: Chart review was performed to determine demographic, medical, and treatment variables, including reconstruction complication events and failures in breasts treated with mastectomy, immediate reconstruction, and RT. Reconstruction failure was defined as tissue expander or implant removal, resulting in no final reconstruction or autologous reconstruction only. Reconstruction

complications included surgical site infection, late infection (1 year post-RT), seroma development, flap necrosis, nipple necrosis, wound dehiscence, capsular contracture, hematoma, extrusion, leak, venous congestion, and unplanned reoperation. An axial slice at the L2 or L3 vertebral body from the radiation therapy planning CT scan was analyzed for skeletal muscle area using a previously validated algorithm, with manual review and adjustment as indicated. Sarcopenia was defined by skeletal muscle index (SMI, skeletal muscle area in cm² divided by patient's height squared) below 34.4 cm²/m². Chi-square, Kaplan Meier, and univariate Cox regression tests were used for analysis. Results: Ninety-nine women with breast cancer who underwent mastectomy, reconstruction, and RT were included in this study. All women had immediate reconstruction: 93 women had tissue expander placement while six women had permanent implant placement. Mean age was 47.5 years (SD 10.6) at diagnosis and median BMI was 24.8. Seventy-six percent were non-smokers, 24% were former smokers, and only 16 (16.2%) and 3 (3.0%) had hypertension or diabetes, respectively. Median follow-up was 2.7 years. Median SMI was 38 cm²/m² and 18 (18%) met criteria for sarcopenia (SMI < 34.4 cm²/m²). Mastectomy was bilateral in 79 women, skin-sparing in 61, and nipple sparing in 31. Bilateral mastectomy was less frequent amongst women with sarcopenia (61%) compared to 84% of those without sarcopenia (p=0.03). After RT, twenty-three women required unplanned reoperation. Within these 23 women, there were 45 total complications. Complications included surgical site infection (n=18), capsular contracture (n=12), seroma (n=4), wound dehiscence (n=3), and others (n=8). However, only 8 women had reconstructive failure and none were sarcopenic at the time of the RT planning scan. Any complication or failure after RT occurred in similar proportions of patients with and without sarcopenia: 38% and 30%, respectively. Kaplan-Meier curves and univariate Cox regression models showed no significant difference in time to failure (p = 0.380) or time to any event (complication or failure) (p=0.53), between sarcopenic and non-sarcopenic patients. Conclusion: Sarcopenia, using SMI < 34.4 cm²/m² on pre-radiotherapy planning scans, was not associated with an increased risk of post-radiotherapy reconstructive complication or failure in this selected cohort of non-smokers. Few women had sarcopenia at the time of operation, and results should be validated in a larger series.

Introduction

Breast cancer (BC) it is highly prevalent in the world with a significant mortality rate despite advances in systemic therapies. Obesity increases the risk of this cancer specially in post-menopause women and may even affect the prognosis at all ages.

Objective

To evaluate the impact of BMI on overall (OS) and disease free interval (DFI) of Brazilian women with BC undergoing NACT and who achieved pCR.

Methods

This is a retrospective study that included patients with confirmed breast cancer clinical stage I to III, age more than 18 years old and complete records that were submitted to NACT. These patients were divided in four groups based on their BMI by the World Health Organization definition BMI < 18,5 kg/m²: underweight; BMI 18,5 to < 25 kg/m²: healthy weight; BMI 25 a < 30 kg/m²: overweight; BMI ≥30kg/m²: obesity. pCR was defined as absent of invasive tumor in the breast or axilla. Student t test or chi-square test were used to analyze the association of each variable between groups with and without pCR. Univariate and multivariate analyzes were used to calculate odds ratios (OR) and 95% of confidence intervals (CI) of the independent

variables BMI, age, clinical stage, immunohistochemistry and correlated with pCR (p value < 0.05 was assumed as statistically significant). The study was approved by local ethics committee.

Results

A total of 1.481 patients from a single reference center between January 2011 to May 2020 were included. The mean age was 50 years and mean BMI was 28,08 (SD 5,59). Most of the patients presented clinical stage III (67,3%) at diagnosis. Invasive carcinoma nonspecial type was the most frequent (95,11%). After NACT 1.138 (76.84%) still had invasive disease and only 343 (23.16%) had pCR. BMI ratio was 1.6% underweight, 30.5% healthy weight, 34.9% overweight and 33.0% obese. Regarding survival analyses, there was no statistical significance for the different BMI categories for both OS (p=0.43) and DFS (p=0.7) and no statistical significance when evaluated pCR and BMI OS (p=0.26) and DFS (p=0.22). OS was estimated for three groups (healthy weigh: 109 months, overweight: 105 months, obese: 79 months). For patients with underweight, the median OS was not reached. The 5-year OS rate in Brazil, according to this study, was 85.4%. Of these 1,481 women, 387 relapsed after surgery (22 cases: local relapse; 355: systemic relapse; 10: both relapses). Only the underweight reached the median (58 months) but this group is very small, and the other categories still have immature data because the median was not reached to define DFS.

The association of the most aggressive subtypes of cancer as predictors of pCR was statistically significant (Luminal B: p=0.019; HER 2: p< 0.001; Triple negative: p< 0.001, in relation to Luminal A). There wasn't any statistical significance for the different BMI categories.

Conclusion

This study did not show interference of BMI on OS and/or DFS in Brazilian women with BC undergoing NAC. Few patients reached pCR (23.16%) probably due to the advanced initial stage. On the other hand, pCR was much more frequent in the more aggressive subtypes (Triple negative, HER 2 and Luminal B). Obesity as an independent chronic condition and despite not having an impact on survival in these analyses, most women were overweight or obese (72.85%), showing the frequency of obesity in Brazilian women, which should be understood as a public health problem in the country. In addition, following these women for 10 years can help to understand better the real impact of obesity in breast cancer survival.

Table 1. Percentual of breast cancer in different clinical stages

STAGE	PATIENTS (number)	PATIENTES (%)
I	37	2.5
II	447	30.2
III	997	67.3
TOTAL	1481	100

Table 1. Percentual of breast cancer in different clinical stages

Table 2. Logistic regression considering pCR as an outcome

SUBTYPE BC	OR	IC 95%	P- value
Luminal A	1.00	-	-
Luminal B	1.97	1.15-3.58	0.019
HER 2	5.65	3.36-10.11	<0.001
Triple negative	6.09	3.66-10.83	<0.001

Background: Neoadjuvant chemotherapy has been used in a variety of cancer treatments to transform inoperable tumors to operable tumors. Within breast cancer treatment, it has successfully been used to increase the rates of breast conservation therapy. Neoadjuvant chemotherapy is being used to downgrade locally advanced breast cancer, as well as treat inflammatory breast cancer, and node negative breast cancers with genetic expression profiling results that predict the need for adjuvant chemotherapy. There have been several studies that have evaluated the effects of age and comorbidities of patients with breast cancer on treatment decisions, particularly chemotherapy. However, very few studies have reviewed additional factors outside of tumor characteristics for predicting complete response to neoadjuvant chemotherapy. The purpose of this study is to determine if there are any patient factors, particularly comorbidities, that play a role in modifying chemotherapy regimens and if that affects the patient's response to chemotherapy. Methods: A retrospective chart review was performed on patients between 18-89 years of age at the time of their breast cancer diagnosis, who underwent neoadjuvant between 1/1/2014 and 1/1/2019. Patients included were treated by Dr. Kara Friend or Dr. Jennifer Reed at Sentara Leigh Memorial Hospital. Data collected included demographics, tumor characteristics, treatment regimens (chemotherapy, radiation therapy, antihormone therapy, and surgery), noting when chemotherapy regimens had to be modified, pathologic response to neoadjuvant chemotherapy, and long term outcomes. Comorbidities were identified and used to calculate the Charlson Comorbidity Index (CCI), which was used to categorize patients. Results: A total of 111 patients were reviewed. All patients were female and ages ranged from 24 to 84, with most patients being in their fourth or fifth decade. 30% of the patients had triple negative tumors, and 48% had HER2+ tumors. Most patients had invasive ductal carcinoma, with only 6 patients (5.4%) having invasive lobular carcinoma. 26 patients had positive genetic panels, 10 of which were BRCA positive. 28 patients had negative panels, and 57 were not tested. The most common chemotherapy regimens were TCHP, AC/T, and TCH. Two patient's cycles were reduced from the beginning due to low ejection fractions, 3 were modified due to pulmonary reactions, 1 for renal failure, 1 for Hepatitis C activation, and 10 for neutropenia or infections. One patient self-discontinued chemotherapy in favor of alternative medicine. 65.7% of the patients underwent antihormone therapy. 27% of the patients underwent radiation. Most patients had CCI scores of 0. Of those with a CCI score of 0, 4 needed modified regimens (8.3%). Of those with a CCI score of 1,

three needed modified regimens (10.3%). Of those with a CCI score of 2, three patients needed modified regimens (23.3%). Of those with a CCI score of 3 or greater, 8 needed modified regimens (38.1%) When evaluating the effect of a CCI of 0-2 compared to 3 or greater on likelihood of reduced chemotherapy, there was not a statistically significant result ($p = 0.99$). However, there appeared to be a trend of increasing need for modified regimens with increasing CCI score. When evaluating if a reduced chemotherapy regimen led to progression during neoadjuvant chemotherapy or no response, the result was not statistically significant ($p=0.24$). Conclusion: Our study suggests that an increasing CCI score corresponds to an increased likelihood of needing a modified regimen, however this result was not statistically significant. Increased comorbidities and the need for modifying chemotherapy regimens do not appear to have an effect on pathologic response to neoadjuvant chemotherapy. This study is limited by the sample size, and a greater sample size will be necessary to make further conclusions.

Introduction: More than half of the results of axillary lymph node dissection followed by metastasis in sentinel lymph node(SLN) biopsy are negative. For deescalating axillary surgery, it is necessary to predict the non-SLN metastasis state, where metastasis was confirmed in the SLN biopsy. Method: Breast cancer patients with T1 and T2 stage were retrospectively reviewed from January 2008 to December 2016. A total of 818 patients underwent surgery as the primary treatment and the result of SLN biopsy was positive for metastasis. Patients who skipped SLN biopsy procedure and were proven metastatic axillary lymph nodes by needle-aspiration biopsy (NAB) were excluded. SLN was defined as lymph nodes detected by the dual method with hot-uptake by radioisotope and dyed by blue dye, or lymph nodes with palpable or suspected metastatic findings during SLN biopsy. Clinicopathological factors including and extra-nodal invasiveness were analyzed. Result: The median follow-up period was 73 months. Non-SLN metastasis was significantly seen in patients with older than 50 years, positive node metastases by preoperative NAB, high T stage, and extra-nodal invasion. In subgroup analysis, patients who underwent total mastectomy had the similar patterns of the increased risk of having non-SLN. Poor overall survival was observed in the patients with the presence of non-SLN metastasis. Conclusion: We confirmed predictive factors with a high probability of non-SLN metastasis. Axillary lymph node dissection cannot be overlooked in the patients proven the metastatic result of preoperative NAB.

Background-

Dissemination of cancer cells and their colonization at distant sites (metastases) is the primary cause of death in patients with solid tumors. Despite of popular theories of cancer metastases, there are several lacunae in our understanding of extent of Metastatic Disease at Presentation (MDP). The aim of this study was to evaluate if organ sites could be grouped together based on the available knowledge extent of lympho-vascular communication (LVC) and probable respiratory pressure changes they undergo and whether this correlated with incidence of MDP.

Methods-

We analyzed a prospectively maintained database of patients with solid tumors presenting between January and December 2017 at our tertiary care cancer center. The tumors were hypothetically divided into four regions (R) depending on extent of LVC and respiratory pressure changes. All patients had clinico-radiological staging after pathological confirmation of cancer. The hypothetical region grouping R1-R4 was independently evaluated by unsupervised k-means clustering. The incidence of MDP was compared in subgroups defined by primary tumor stage, anatomical region, histology, gender, and age using logistic regression.

Results-

Of 17,467 patients included with median age 54 years, 6714 (38.4%) had MDP. The incidence of M1 disease in R1 vs R2 vs R3 vs R4 regions, older (>50 years) vs younger (Conclusion- Primary anatomical regions defined by LVC and respiratory pressure changes; primary tumor histology (type and grade) and male gender are significant determinants of MDP in solid tumors.

Region grouping of solid organs based on extent of lymphaticovenous communications and rhythmic respiratory pressure changes and % MDP

Region	LV communication	Pressure changes	Anatomical sites	Sample size N	MDP (%)	95% CI
R1	None	None	Head and neck region Pelvic viscera below levator ani- cervix, vulva, vagina and anal canal	3219	148 (4.6)	3.93 – 5.38
R2	Few, open with lymphatic blockade	None	Breast, extremities, chest and abdominal wall, skin	4116	841 (20.4)	19.23 – 21.69
R3	Present	Low	Pelvic viscera within peritoneal reflection- colorectal, small intestine, ovary, urinary bladder, body uterus, prostate, testis	3673	1609 (43.8)	42.21 – 45.42
R4	Present	High	Intra-thoracic and intra-abdominal organs- lung, oesophagus, mediastinum, liver, gall bladder, kidney, stomach	6459	4116 (63.7)	62.55 – 64.89
Overall	-	-	-	17467	6714 (38.4)	37.72 – 39.16

Country: Mexico

Background

Breast cancer (BC) is the leading cause of cancer and cancer-related death in Mexican women. Recently, low expression of HER2 (HER2-low), defined as immunohistochemically 1+ or 2+ and lack of HER2 gene amplification, has gained increased attention as a promising new predictive biomarker for treatment with antibody-drug conjugates, such as trastuzumab-deruxtecan, not currently available in Mexico. To date, the frequency and prognostic value of HER2-low status in the Mexican population with metastatic BC remains unknown.

Methods

Single center retrospective cohort of patients diagnosed with metastatic BC between 2017 and 2020. Only patients with known HER2 status and available survival data were included. Patients' sociodemographic and clinicopathological characteristics, and outcomes were collected from medical records. Descriptive statistics were used to analyze sociodemographic and clinicopathological characteristics. X2 tests were used to evaluate associations between HER2 status and other characteristics. Progression-free survival (PFS) and overall survival (OS) were calculated using the Kaplan-Meier method and compared by the log-rank test according to HER2 status. Multivariable adjusted hazard ratios were estimated by Cox regression models. A p value of < 0.05 was considered statistically significant.

Results

Among 55 patients with metastatic BC, median age at diagnosis was 51 years, 56.4% were postmenopausal and 25.5% had family history of BC. The most frequent histologic subtype was ductal (65.5%), followed by lobular (20%). Approximately 2/3 presented with metastatic disease de novo (67.3%), 69.1% presented with visceral metastases and the median number of lines of treatment was 2. According to intrinsic subtypes 54.5% were luminal HER2-negative (HER2-), 16.4% luminal HER2-positive (HER2+), 10.9% HER2 enriched, and 18.2% triple negative. According to HER2 status, 11 (20%) were HER2+, 26 (47.3%) were HER2-low, and 18 (32.7%) were HER2-. HER2-low expression was more frequent in the hormone-receptor positive (HR+) (51.3%) than in HR negative (HR-) (31.3%), however, this difference was not statistically significant ($p = 0.11$). Patients' characteristics according to HER2 status are shown in Table 1.

With a median follow-up of 39.9 months, there were no differences in PFS and OS according to HER2 status. Median OS was 45, 30.8, and 46.4 months, for HER2+, HER2-low, and HER2-, respectively ($p = 0.48$). On univariate analysis, age, menopausal status, RH status, HER2 status, disease presentation and visceral metastases were not associated with improved OS. In patients with HER2-low status, median OS was 36.6 and 15.8 months for patients with HR+ and HR- disease ($p = 0.009$). In the HER2-low subgroup, multivariate analysis showed that HR status (hazard ratio 10.96 [95% CI 2.11-56.92], $p = 0.004$) and having received ≥ 2 lines of treatment (hazard ratio 13.34 [95% CI 1.97-90.37], $p = 0.008$) were statistically associated with better OS.

Conclusion

Our findings show that almost half of patients with metastatic BC have a low HER2 expression. Although HER2-low status did not impact survival in a small cohort of Mexican patients, HR status and lines of treatment were associated with better prognosis in patients with HER2-low disease. These results demonstrate the high burden of Mexican patients with HER2-low disease who could benefit from targeted therapies after first line therapy, and the importance of ensuring access to effective treatment options.

Table 1

Characteristic	HER2+		HER2-low		HER2-		<i>p</i>

Background: The RS assay is a validated prognosticator/predictor of chemotherapy (CT) benefit in ER+ HER2-negative early-stage breast cancer (BC). It is offered to pts irrespective of BRCA1/2 status. We compared RS results, single-gene expression and gene group scores, between pts with germline BRCA1/2 mutations and the general BC pt population undergoing RS testing. Treatments/outcomes in the mBRCA1/2 cohort were also examined.

Methods: This real-life retrospective cohort study included consecutive ER+ HER2-negative mBRCA1/2 female carriers BC pts who had RS testing in 2004-2015. RS and gene expression data were compared to a previously described commercial use database (DB) (J Surg Oncol. 2020;122:611). Chi-square test and 1-sample t-test were used to compare RS distribution and single gene/gene group scores, respectively, between the cohort and the DB. Independent sample t-test was used to compare gene expression/gene group scores across pt subgroups within the mBRCA1/2 cohort. Fisher's test/logistic regression were used to identify variables associated with distant recurrence in the mBRCA1/2 cohort.

Results: The analysis included 81 pts in the mBRCA1/2 cohort and 799,986 BC samples in the DB. Age at diagnosis was younger in the mBRCA1/2 pts vs the DB (median [IQR], 56 [47-61.5] vs 60 [51-67] yrs; $P < .001$). In mBRCA1 and mBRCA2 pts (32 and 48 pts, respectively; for 1 pt, the BRCA gene involved was unknown), RS distribution shifted towards the high RS category when compared to the DB (Table). Comparing single-gene expression and gene group scores in mBRCA1 pts vs the DB, revealed statistically significant differences in 12 of the 16 cancer genes in the RS assay, and in 2 gene group scores, all in a direction contributing to higher RS results. Similar analysis with mBRCA2 pts, revealed significant differences in expression of 10 genes and 3 gene group scores, all in a direction contributing to higher RS results. The only statistically significant difference in gene expression between the mBRCA1 and mBRCA2 pts was in the ESR (higher in mBRCA2 pts; $P = .0407$) and MYBL2 gene (higher in mBRCA1 pts; $P = .0365$) (Table). Of the 32 mBRCA1 pts, 18 (56%) received CT (RS 0-25, 1/14 [7%]; RS 26-100, 17/18 [94%]; treatment information was unavailable for 1 pt). Of the 48 mBRCA2 pts, 19 (40%) received CT (RS 0-25, 5/27 [19%]; RS 26-100, 14/21 [67%]). With a median (IQR) follow up of 8.2 (5.6-9.7) yrs from diagnosis, 9 pts had distant recurrence (1 mBRCA1 pt, 8 mBRCA2 pts). Their median RS result was 25 (range, 16-41), and 4 received adjuvant CT. No statistically significant differences were observed between these 9 pts and the 72 non-recurring pts in terms of pt/disease characteristics and CT treatment. A trend towards significance was observed with respect to the BRCA gene involved (recurrence rate of 3.1% in mBRCA1 pts vs 16.7% in mBRCA2 pts, $P = .078$). A statistically significant association was found between the proliferation and invasion gene group scores and the odds of having distant recurrence (proliferation group score: odds ratio [OR], 23.60 [95% CI, 1.4-397], $P = .0281$; invasion group score: OR, 5.1 [95% CI, 1.1-23], $P = .0339$). The ER and HER2 gene groups scores were not associated with distant recurrence.

Conclusions: Both mBRCA1 and mBRCA2 carriers are characterized by higher RS results that stem from a distinct gene expression profile of most genes in the RS assay.

Background: Recent studies suggest racial and ethnic differences in tumor genomics and receipt of systemic treatment may be drivers of racial and ethnic disparities in clinical outcomes (e.g., mortality, recurrence) in patients with breast cancer (BC). For patients of Hispanic ethnicity, the relationship between ethnoracial categories (i.e., Hispanic Black, Hispanic White), tumor genomics, and receipt of systemic has not been well elucidated. The objective of this study is to examine implications of ethnoracial categories on Oncotype DX recurrence score (RS), receipt of chemotherapy for high risk RS and endocrine therapy (ET) use in the National Cancer Database (NCDB). **Materials/Methods:** Patients diagnosed from 2004-2017 with stage I or stage II HR+/HER2- BC with RS available in the NCDB were identified. The data was divided into Black and White patients then stratified by ethnicity. Study ethnoracial categories included non-Hispanic White (NHW), Hispanic White (HW), non-Hispanic Black (NHB) and Hispanic Black (HB). High-risk RS was defined using the original definition of RS>30. On univariable analysis, intra-racial differences in RS score (t-test) and the proportion of patients with high-risk RS (chi-square test) were examined by ethnicity. Systemic therapy (chemotherapy and ET) were assessed with univariable analysis within racial groups by ethnicity (chi-square test). **Results:** The ethnoracial composition of the cohort was 220,490 (87.5%) NHW, 20,690 (8.2%) HB, 10,477(4.2%) HW and 296 (< 1%) HB. Overall, Hispanic patients had higher mean RS relative to non-Hispanic patients (18.4 [11.8] vs. 18.0 [10.8], p=0.0004) and a higher proportion of RS>30 (10.4% vs. 9.6%, p=0.0028). Amongst White patients, Hispanic ethnicity was

associated with higher mean RS (18.3 [11.7] HW vs. 17.8 [10.6] NHW) and higher rate of RS>30 (10.4% HW vs. 9.1% NHW, $p < 0.0001$). There was no significant difference in mean RS between NHB and HB patients (19.0 [13.5] HB vs. 20.0 [12.7], $p = 0.1855$) but there was a trend towards a lower proportion of RS>30 in HB patients (10.8% HB vs. 14.6% NHB, $p = 0.0688$). In patients with RS>30, the proportion that received chemotherapy was similar based on ethnicity within White (80.7% HW vs. 82.3% NHW, $p = 0.1843$) and Black (78.1% HB vs. 81.2% NHB, $p = 0.6601$) patients. ET use was slightly lower in HW vs. NHW patients (90.6% vs. 91.7%, $p < 0.0001$). There was no significant difference in ET use in NHB vs HB patients (89.9% vs. 89.9%, $p = 0.9651$). Conclusions: In our examination of the early-stage breast cancer patients in the NCDB, Hispanic ethnicity was associated with higher RS amongst White patients with an opposite trend in Black women. Systemic therapy use was largely similar across ethnoracial categories. Future, studies should disaggregate Hispanic ethnicity by race to better understand tumor characteristics and clinical outcomes in this population.

Country: Netherlands

Background Although treatment options and survival of HER2+ metastatic breast cancer (MBC) patients have greatly improved, the majority of MBC-patients still die of this disease. The relatively high levels of TILs observed in this BC subtype provide a rationale for immunomodulatory strategies, however, PD1-blockade has only shown modest response rates in this setting. While PD-1 blockade mainly acts on T cells, monalizumab targets the inhibitory immune checkpoint NKG2A which interacts with HLA-E on tumor cells, thereby unleashing NK- as well as CD8 T cells. We hypothesize that monalizumab can promote antibody-dependent

cell-mediated cytotoxicity (ADCC) which is critical for trastuzumab efficacy. Clinical activity was shown in patients with head and neck cancer when monalizumab was combined with cetuximab (anti-EGFR). Here, we present the first results of the MIMOSA-trial investigating the efficacy of the novel combination monalizumab and trastuzumab in patients with HER2+ MBC. Methods In the phase II MIMOSA-trial (NTC04307329), HER2+ MBC patients were treated biweekly with 4mg/kg trastuzumab and 750mg monalizumab. Key eligibility criteria were progressive disease despite anti-HER2 therapy, had received a minimum of one and a maximum of three lines of palliative chemotherapy, had measurable disease according to RECIST1.1, and a serum LDH-level below 500U/L. Primary endpoint was objective response rate according to RECIST1.1. Secondary endpoints included clinical benefit rate (complete response CR, partial response PR or stable disease SD for at least 6 months) according to RECIST1.1, progression-free survival, overall survival and safety. Dose-limiting toxicities were continuously monitored throughout the trial and evaluated using a pre-defined Pocock-type boundary rule. Following a Simon's two-stage design, 11 patients were included in stage I of the trial. If two or more responders were observed, further exploration is warranted in stage II. Results Between January 2021 and April 2022, eleven women of which ten are currently evaluable were enrolled in the trial. Patients received a median of two lines of prior treatment for MBC, of which 6 out of 11 patients were treated with trastuzumab emtansine (T-DM1). The majority of patients had hormone receptor positive BC (72% of the patients) and had low levels of tumor-infiltrating lymphocytes (TILs) with a median of 1% (ranging from 1% to 20%). Patients received a median of four cycles of trastuzumab and monalizumab. Treatment was well tolerated with no dose-limiting toxicities. No objective responses were observed in the first ten out of eleven evaluable patients. Therefore, MIMOSA stage I did not meet its primary endpoint, leading to discontinuation of the trial. Conclusions The novel combination of trastuzumab and monalizumab did not induce objective responses in heavily pre-treated HER2+ MBC patients.

Background Within HR+/HER2- disease, patients with non-luminal subtypes of breast cancer (HER2-enriched [HER2-E] and Basal-like) have poorer prognosis than those with luminal subtypes, may be more sensitive to chemotherapy, and have higher expression of immune-related genes and tumor infiltrating lymphocytes (TILs). Here, we report the interim efficacy and safety data of the TATEN trial (NCT04251169), the first study designed to evaluate pembrolizumab and paclitaxel in HR+/HER2-negative, PAM50 non-luminal, metastatic breast cancer (MBC). Methods TATEN is a single-arm, multicenter phase II study evaluating pembrolizumab in combination with paclitaxel in patients with HR+/HER2-, PAM50 non-luminal, MBC. Key inclusion criteria include progression to prior CDK4/6 inhibitors, presence of measurable disease by RECIST V1.1, no prior chemotherapy for MBC, and ECOG 0-1. Patients receive pembrolizumab at 200 mg every 3 weeks (on D1 of each 21-day cycle, beginning at cycle 1) in combination with weekly paclitaxel at 80 mg/m², beginning at cycle 2. The primary endpoint is to evaluate overall response rate (ORR), defined as the rate of complete (CR) and partial response (PR) according to RECIST V1.1. Secondary endpoints include clinical benefit rate (CBR; CR + PR + stable disease >24 weeks), progression free survival, overall survival, safety, and predictive biomarkers. Tumor samples collected during advanced/metastatic disease are mandatory to assess PAM50 and other translational endpoints. This study had a planned interim analysis after 15 patients were evaluable for ORR based on a Simon's two stage design with 80% power and a type I error rate of 0.05. Stage I of the trial would be considered successful if at least 6 patients achieved a PR and/or CR. In that case, the trial would recruit up to 46 evaluable patients for a target ORR \geq 41. Here we report results from the patients who received at least one dose of combination treatment and had a first, post-baseline, tumor assessment according to RECIST v1.1 (evaluable population). Results From July 2020 to December 2021, 119 patients were screened, and 25 PAM50 non-luminal tumors were identified (21%). From these, 17 (68%) patients were recruited, and 15 were evaluable for primary endpoint. Two patients discontinued the trial before the first dose of pembrolizumab and paclitaxel, because of clinical progressive disease (PD). Baseline patient characteristics were as follows: median age 53 years (range: 40-77), ECOG 0 52.9%, de novo MBC at diagnosis 29.4%, and visceral disease 64.7% (including 53.3% with liver metastasis). Ten patients had received paclitaxel treatment in the adjuvant setting. Regarding PAM50 intrinsic subtype, two patients had basal-like and 13 HER2-E tumors. At the time of data cut-off (May 17, 2022), 8 patients (53.3%) had stopped their treatment because of PD and 2 (13.3%) due to toxicity. Five patients (33.3%) were still on treatment. The ORR was 53.3% (8 of 15, 95% CI 26.6-78.7), meeting the pre-specified ORR for the first stage of the trial. The CBR was 86.6% (13 of 15, 95% CI 59.5-98.34), and median PFS was 7.5 months (95% CI: 5.6 – 10.2). Overall, all patients experienced treatment-related adverse events (TRAEs) of any grade, while 53.3% of patients experienced grade 3 TRAEs. No grade 4 or 5 TRAEs were reported in the evaluable population. Correlative analysis including gene expression analysis and centralized TILs scoring and PD-L1 IHC will be presented. Conclusions The first stage of TATEN

combining pembrolizumab with paclitaxel after progression to CDK4/6 inhibitors in patients with HR+/HER2-negative, PAM50 non-luminal MBC met its pre-specified endpoint. Completion of the stage II part of the trial with the inclusion of up to 46 patients is warranted to assess the activity of this combination in this group of patients. Correlative studies to find predictive biomarkers of response to this regimen are ongoing and will be presented at the meeting. This study was funded by MSD.

Background: In early-stage triple-negative breast cancer (TNBC), there is accumulating evidence of a correlation between tumor-infiltrating lymphocytes in tumor tissue and favorable clinical outcomes, with a high CD8+/regulatory T-cell (Treg) ratio after neoadjuvant chemotherapy being predictive of overall survival and associated with pathologic complete response (Ladoire S, et al. Br J Cancer. 2011; Park YH, et al. Nat Commun. 2020). Trilaciclib is a transient inhibitor of cyclin-dependent kinase 4/6 that is administered intravenously prior to chemotherapy. In preclinical studies, trilaciclib has been shown to have immune-enhancing effects by differentially arresting CD8+ T-cell and Treg subsets, which is followed by the faster recovery of CD8+ T cells than Tregs in the tumor microenvironment. **Methods:** This phase 2, single-arm, open-label study aims to evaluate neoadjuvant, single-dose trilaciclib followed by trilaciclib plus dose-dense anthracycline/cyclophosphamide and taxane in patients with early-stage TNBC (NCT05112536). Patients with previously untreated, non-metastatic, confirmed TNBC and a primary tumor ≥ 1.5 cm of any nodal status receive a single dose of trilaciclib 240 mg/m² during the lead-in phase, followed by 4 cycles of doxorubicin 60 mg/m² plus cyclophosphamide 600 mg/m², and 12 weekly cycles of paclitaxel 80 mg/m². Trilaciclib 240 mg/m² is administered prior to the first chemotherapy dose of each cycle. Pembrolizumab 400 mg every 6 weeks starting on day 1, cycle 1, and/or carboplatin AUC 1.5 every week starting on day 1, cycle 5, is allowed per investigator discretion. Tumor biopsies and peripheral blood samples are collected prior to any treatment, 7 days \pm 1 day post administration of trilaciclib, and during surgery, with an additional blood sample collection on day 1, cycle 2. The primary objective is to evaluate the immune-based mechanism of action of trilaciclib after a single dose of trilaciclib, as measured by changes in the CD8+/Treg ratio in tumor tissue. Pathologic complete response, safety and tolerability, and additional exploratory immune biomarker endpoints will also be assessed. **Results:** As of June 3, 2022, 9 patients with early-stage TNBC had been enrolled and 8 patients had received the trilaciclib lead-in dose and initiated doxorubicin/cyclophosphamide. Patients had a median age of 53.0 years, and all had stage II tumors at diagnosis, with 7 having ductal carcinoma. The median number of chemotherapy cycles received was 3 (range 1–6), and all 8 patients received pembrolizumab. Seven patients continue study treatment; 1 patient discontinued due to disease progression. Five patients had an adverse event (AE) related to any study treatment, including 4 patients with ≥ 1 trilaciclib-related AE. There were no grade ≥ 3 treatment-related AEs or serious AEs. On-treatment, post-trilaciclib monotherapy biopsies were available for 4 patients. Following neoadjuvant trilaciclib treatment, the median density of stromal CD8+ T cells increased from 103.1/mm² at baseline to 229.8 /mm² at day 7. The median CD8+/Treg ratio increased in 2 patients from 1.85 at baseline to 1.90 at day 7. **Conclusions:** Preliminary analysis of on-treatment tumor biopsies from 4 patients suggests that a single dose of trilaciclib may modulate the immune cell composition in the tumor microenvironment to support antitumor immune responses. The increase in CD8+ T cells following 7-day neoadjuvant treatment with trilaciclib supports previous data suggesting a role in T-cell infiltration. The complete dataset from all patients (estimated enrollment: N \approx 24) and additional biomarker analyses will be presented.

Background: Metastatic breast cancer (MBC) which causes significant morbidity and mortality worldwide is in need of more effective treatment regimens. In combination with chemotherapy, anti-PD1 antibody pembrolizumab has been shown to prolong progression-free survival (PFS) of patients with triple-negative subtype MBC (TN-MBC), however, its efficacy remains low for the other 80% of patients with MBC. MBC's heterogenous pattern of immune infiltration and expression make it challenging to treat with single immunotherapeutic agents such as pembrolizumab and successful immunotherapy must therefore target multiple pathways. To augment antitumor host immune responses during treatment, studies have examined adjunct agents such as "oncolytic" adenovirus (OAd), which are vectors that preferentially replicate in and lyse tumor cells leading to the activation of host immunity. OAd have been tested in a myriad of clinical trials with the hope to enhance host immune activation but those trials have shown limited successes. Methods: To overcome the multiple immunogenic barriers in solid tumors, our group developed a binary oncolytic/helper-dependent adeno-immunotherapy (CAAdVEC). The first generation CAAdVEC (CAAdTrio) contains an OAd and a "helper-dependent" adenovirus (HAd) that produces immunostimulant molecules including interleukin (IL)-12p70 and anti-PD-L1 antibody. Based on successful results using animal models, a first-in-human Phase 1 study with CAAdTrio was conducted among patients with all solid tumors (NCT03740256). Four patients with MBC were enrolled in the virus dose-escalation phase of the trial and received an intra-tumor injection of CAAdTrio. Given the novelty of this binary agent, starting dose of CAAdTrio was more than 2-logs lower than that used in other OAd trials. Three patients received dose level (DL) 1 and one patient received DL2. All patients also received pembrolizumab 6 weeks after the virus injection. The primary endpoint for this phase I dose escalation was dose-limiting toxicities (DLT). Secondary outcomes included overall response rates (ORR), disease control rate (DCR), PFS, overall survival (OS), and treatment-related adverse events. Results: No patients developed DLT. The most common toxicities were fever, fatigue and pain around the injection site, but none were greater than grade 2. No significant elevation in liver enzymes were observed. Three of the four patients had partial response (PR). One patient progressed after ten weeks of stable disease and passed away. The three patients with PR received pembrolizumab within 7 weeks of CAAdVEC injection. Analysis of injected tissues prior to pembrolizumab treatment showed that CAAdTrio repolarized the tumor microenvironment toward immune activity by increasing the number of infiltrating Th1 immune cells, leading to responses in some treated tumors and even in one distant metastasis,

demonstrating the potent systemic immune response to local CAdTrio treatment in patients with MBC. Conclusions: Our study demonstrated that intra-tumor injection with CAdTrio was safe and effective in patients with MBC but the significance of the results was limited by the small sample size. An MBC dedicated phase II trial is planned to be conducted to fully evaluate the efficacy and safety of CAdVEC treatment and to further elucidate mechanisms of resistance/sensitivity among patients with MBC.

Although immune checkpoint blockers (ICBs) have revolutionized the treatment of many cancers, only less than 30% of patients respond to any ICB as a monotherapy. Estrogens, produced by the adipose tissue in the mammary glands, are immunomodulators in the tumor microenvironment (TME). Estrogens suppress anti-tumor immunity and activate immunosuppression through the estrogen receptor α (ER α) in the immune cells but activate anti-tumor immunity through ER β . Genistein (GEN) is a biologically active isoflavone and is structurally similar to estradiol (E2). However, in contrast to E2, GEN binds preferentially to ER β . Here we studied if GEN combined with ER α inhibitor fulvestrant (Fulv) alters response to anti-PD1 therapy in ER α negative, ER β positive E0771 mouse mammary tumors. Syngeneic C57BL/6 mice were fed either a control (CON) diet or GEN supplemented diet for 5 weeks and then allografted E0771 mammary tumor cell into the 4th mammary fat pad. When tumors reached an average size of 16mm², mice in both diet groups were further divided into 4 sub-groups treated with: 1) anti-PD1 (150 μ g or 100 μ g every 3 days for a total of 3 doses), 2) Fulv (1mg) once weekly, 3) anti-PD1+Fulv or 4) IgG control group. We found that three doses of 150 μ g of anti-PD1 alone effectively reduced tumor growth in the CON ($p=0.0005$) group and its efficacy was notably weakened in the GEN group ($p=0.04$). Combination with Fulv did not improve PD1 response. These findings suggest that when using a highly effective anti-PD1 dose, GEN may reduce rather than improve the response, and anti-ER α does not add to anti-PD1's effect in control of GEN group. A suboptimal dose (100 μ g) of anti-PD1 alone did not inhibit E0771 tumor growth in mice fed CON diet, but in the GEN group the tumor inhibition by anti-PD1 alone almost reached statistical significance ($p=0.057$). The combination of suboptimal PD1+Fulv significantly reduced tumor growth compared with IgG ($p=0.04$) or Fulv ($p=0.02$). During GEN feeding, anti-PD1+Fulv was even more potent in inhibiting tumor growth when compared with IgG group ($p=0.02$) and Fulv group ($p=0.007$). Thus, when anti-PD1 alone is not effective, either Fulv or GEN will improve responsiveness to anti-PD1. In the suboptimal anti-PD1 dose experiment, GEN feeding increased CD8+ T cells ($P=0.04$) and decreased

CD4⁺Foxp3⁺ cells ($p=0.01$) in the TME. Further, GEN reduced the proportion of immunosuppressive MDSC cells (CD3⁺CD11B⁺Ly6G^{high}6C^{low}) in the PD1⁺ Fulv group ($p=0.01$) in the Peyer's patches. In vitro experiments showed that both GEN and Fulv, and especially their combination, inhibited the E0771 cells proliferation, indicating that these two treatments can also directly suppress the growth of ER α negative but ER β positive breast cancer cells. Taken together, the data show that anti-estrogens and GEN in the diet may improve response to anti-PD1 therapy, possibly both through activation of tumor immune response and inhibition of tumor cell proliferation and induction of tumor cell death.

Background: KEYNOTE-522 was a randomized, double-blind, placebo-controlled phase 3 trial which resulted in the FDA approval of pembrolizumab with neoadjuvant chemotherapy for patients (pts) with newly diagnosed, high-risk, early-stage triple negative breast cancer (TNBC). Given the improvement in pathological complete response (pCR) and event-free survival rates, this regimen has emerged as standard-of-care (SOC) therapy. Adverse events in pts on this treatment regimen in clinical practice is unknown and understanding the real-world toxicity of this regimen is critical.

Methods: In this IRB approved retrospective, single-center study we examined pts with early-stage TNBC who received planned treatment per KEYNOTE-522 per SOC from 2021-present. This regimen includes a year of pembrolizumab combined with 4 cycles of neoadjuvant carboplatin/paclitaxel followed by 4 cycles of doxorubicin/cyclophosphamide. Number and length of treatment delays, treatment related toxicities of all grades, and pCR rate were collected from the electronic medical record.

Results: Of the 87 identified pts, 2 were excluded due to locally recurrent or metastatic disease and 6 did not receive immunotherapy due to concerns for toxicity or patient preference. Of the 79 pts who initiated treatment with chemotherapy and immunotherapy, median age of the cohort was 52 (27-77). 9 pts had a BRCA1 mutation and 1 pt had a BRCA2 mutation. 41 (51.9%) had T1-2 disease and 38 (48.1%) had T3-4 disease. 37 (46.8%) pts had N0 disease and 42 (53.2%) had N1-3 disease. 15 pts had baseline comorbidities, including heart disease, kidney disease, type II DM, and/or peripheral neuropathy. 68 pts (86.1%) had baseline ECOG 0, 9 (11.4%) had ECOG 1, and 2 (2.5%) had ECOG 2. At the time of analysis, 70 pts (88.6%) were receiving active treatment, of which 47 (67.1%) had completed $\geq 50\%$ of the planned neoadjuvant therapy. Of pts completing $\geq 50\%$ of planned neoadjuvant therapy and pts off therapy (N=56), 31 (55.4%) had 1 or more hospitalizations and 23 (41.1%) had 1 or more emergency room visits. 30 pts had treatment delays (53.6%) and 21 pts (37.5%) had dose reductions. Rates of adverse events are presented in Table 1. Of the 79 analyzed pts, 35 have undergone surgery. pCR rate was 45.7% (N=16). 8 (22.9%) pts had RCB-I, 4 (11.4%) pts had RCB-II, 3 (8.6%) pts had RCB-III, and 4 (11.4%) pts had residual disease without RCB calculation. Updated analysis will be included at time of presentation.

Conclusions: In this single-center retrospective study of pts receiving chemoimmunotherapy for TNBC, we found higher rates of grade 3 toxicity, including nausea, fatigue, neutropenia, diarrhea, peripheral neuropathy, and hypothyroidism, and lower pCR rate than was reported in the KEYNOTE-522 trial. This may reflect a more heterogeneous population of pts treated in routine clinical practice who are typically less fit than pts on clinical trials. Additionally, pts in this study had higher T stages (48.1% with T3-4 disease vs 26.0% in trial) and node positive disease (53.7% with N1-3 disease vs 48.8% in trial). Limitations include immaturity of data and small sample size; however, these data warrant validation through longer-term follow-up and multicenter validation.

Adverse Events

Adverse Event	Standard of Care (N=56) Any Reported	Grade 3 or higher	Keynote-522 Pembrolizumab-Chemotherapy (N=781) Any reported	Keynote-522 Grade 3 or Higher
Nausea	38 (67.9%)	9 (16.1%)	490 (62.7%)	26 (3.3%)
Neutropenia	41 (73.2%)	31 (55.4%)	365 (46.7%)	370 (34.6%)
Fatigue	37 (66.1%)	15 (26.8%)	321 (41.1%)	27 (3.5%)
Diarrhea	25 (44.6%)	8 (14.3%)	230 (29.4%)	17 (2.2%)
Peripheral Neuropathy	25 (44.6%)	6 (10.7%)	154 (19.7%)	15 (1.9%)
Rash	5 (8.9%)	2 (3.6%)	170 (21.8%)	7 (0.9%)
Immune-related adverse events				
Hypothyroidism	7 (12.5%)	3 (5.4%)	107 (13.7%)	3 (0.4%)
Hyperthyroidism	1 (1.8%)	1 (1.8%)	36 (4.6%)	2 (0.3%)
Type I Diabetes	1 (1.8%)	1 (1.8%)		
Primary Adrenal Insufficiency	4 (7.1%)	1 (1.8%)	18 (2.3%)	10 (1.3%)
Colitis	3 (5.4%)	3 (5.4%)	13 (1.7%)	7 (0.9%)
Pancreatitis	2 (3.6%)	1 (1.8%)	4 (0.5%)	4 (0.5%)
Hepatitis	1 (1.8%)	1 (1.8%)	11 (1.4%)	9 (1.2%)
Pneumonitis	1 (1.8%)	0 (0%)	10 (1.3%)	3 (0.4%)

Adverse Events in pts receiving Keynote-522 regimen as SOC and on clinical trial

Background: Neoadjuvant immune checkpoint inhibition (ICI) in combination with chemotherapy is approved for patients with high-risk, early-stage triple-negative breast cancer (TNBC) based on improved outcomes in the KEYNOTE-522 trial. However, some patients have primary resistant disease and do not achieve a pathological complete response (pCR), while others experience significant toxicity. Tumor-associated macrophages (TAMs) are a potential resistance mechanism for ICIs and are dependent on colony-stimulating factor 1 receptor (CSF1R). Therefore, we examined the addition of cabiralizumab, a CSF1R inhibitor, to neoadjuvant paclitaxel, carboplatin, and nivolumab to assess the safety, tolerability, and changes in the tumor microenvironment (TME) in patients with early-stage TNBC. Methods: This is a phase Ib/II, single-institution, randomized controlled clinical trial (NCT04331067) in patients with newly diagnosed Stage II-III TNBC. The primary endpoints include: (1) to determine the safety of a 12-week neoadjuvant regimen of paclitaxel (80 mg/m² IV q week) + carboplatin (AUC5 IV q3 weeks) + nivolumab (240 mg IV q2 weeks) with or without cabiralizumab (4 mg/kg IV q2 weeks) and (2) to evaluate the effect of cabiralizumab on TAMs and changes in tumor infiltrating lymphocytes (TILs) in the TME between baseline and an on-treatment biopsy after 4 weeks of therapy. Adjuvant treatment is per investigator's choice. Secondary objectives include evaluation of pCR rate and recurrence-free survival. Paired tissue and bone marrow biopsies are collected for evaluation of the TME and disseminated tumor cells, respectively. The study was designed to enroll 50 patients, including a 12-patient safety lead-in cohort. Here, we report the planned interim analysis of the safety lead-in cohort. Results: Between December 2020 and May 2022, we enrolled 12 patients to the safety lead-in, including 6 patients in each arm. 5 of 12 patients (41.7%) enrolled are underrepresented minorities, including 4 Black patients and 1 Hispanic patient. 2 of 6 patients in the nivolumab arm experienced grade 3 severe toxicity, including 1 patient who developed sepsis and 1 who developed peripheral neuropathy. 3 of 6 patients in the nivolumab + cabiralizumab arm developed grade 3 severe toxicity including 2 patients who experienced myositis and 1 patient who developed periorbital edema. Of the first 10 patients enrolled, 5 had a pCR (2 pCR in cabiralizumab arm, 3 pCR in non-cabiralizumab arm) and 3 had non-pCR (1 RCB-1 and 1 RCB-3 in cabiralizumab arm, 1 RCB-1 in non-cabiralizumab arm). 2 patients came off study prior to surgery (1 due to toxicity and 1 due to missing study visits). Data from the final 2 patients still on treatment will be available at the time of presentation. Discussion: Full safety, pathologic, and clinical response data in the safety lead-in cohort for patients with early-stage TNBC receiving neoadjuvant chemotherapy + nivolumab with or without cabiralizumab, will be presented.

Miguel Lopez-Lago¹, Sagarika pachhal¹, Charles L. Wiseman¹, William V. Williams¹. ¹BriaCell Therapeutics Corporation, Philadelphia, PA Turning tumor cells into antigen-presenting cells for cancer immunotherapy Background: Therapeutic cancer vaccines are based on specific stimulation of the immune system using tumor antigens to elicit an antitumor response. We have been conducting clinical trials using the breast cancer cell line SV-BR-1-GM as a therapeutic vaccine. SV-BR-1-GM is a GM-CSF expressing breast cancer cell line with features of an antigen presenting cell (APC) owing to the expression of several immunomodulatory molecules, including MHC-I (HLA-A, B & C) and MHC-II (HLA-DRB3 & -DRA). Initial results in patients treated with irradiated SV-BR-1-GM cells, low dose cyclophosphamide and local IFN α suggest that patients that match SV-BR-1-GM at least at 1 HLA allele are more likely to derive clinical benefit. This clinical observation, together with the fact that SV-BR-1-GM cells can directly activate CD4+ T-cells in an antigen-specific HLA-restricted manner, as demonstrated by an in vitro antigen presentation assay (1), lead us to hypothesize that SV-BR-1 (the parent cell line) can function as APC. To further enhance direct antigen presentation to T-cells, SV-BR-1 cells have been genetically modified to express co-stimulatory molecules, immunomodulatory cytokines, and an extended repertoire of HLA alleles. Methods: To generate an off-the-shelf semi-allogeneic cell therapy covering most of the population, SV-BR-1 was genetically modified to express an extended repertoire of HLA alleles. Based on population analysis, four cell lines, each carrying two (2) HLA-A and two (2) HLA-DRB3/4/5 alleles, should produce at least a single match in 99% of the population, with a 92% match at Class I HLA-A alleles and a 98% match at Class II HLA-DRB3/4/5 alleles. SV-BR-1 was genetically modified using CRISPR/cas9 deletion of the endogenous HLA-A and HLA-DRB3 alleles and subsequent lentiviral mediated expression of alternative HLA-A and DRB3 alleles. To generate tumor cell lines with enhanced direct antigen presentation to T-cells, SV-BR-1 cells were genetically modified to express co-stimulatory molecules and immunomodulatory cytokines by using a lentiviral mediated expression system. Results: Following sequential CRISPR/Cas9 editing, the SV-BR-1 cells were cloned, and one clone selected (clone 17) for further engineering. Lack of expression of HLA-A and HLA-DRB3 was confirmed using flow cytometry and DNA sequencing. Clone 17 was subsequently transduced with 6 lentiviral vectors each expressing 2 genes under the control of separate promoters: CD86-IL12, CD80-HLA-DRA, 4-1BBL-IL7, GM-CSF-IFN α , HLA-allele-1-HLA-allele-2 and HLA-DR-allele-1-HLA-DR-allele-2. Four cell lines were generated with different combinations of HLA alleles. Following selection, cells were evaluated by ELISA, flow

cytometry and RT-PCR to confirm gene expression. Cell lines that secreted GM-CSF, IFN γ , IL12, IL7 and expressed CD80, CD86, 4-1BBL, and both Class I and Class II HLA alleles are then transferred to GMP manufacturing. These modified breast cancer cell lines will be used in clinical studies designed to first evaluate the safety of intradermal inoculation with the irradiated cells and later combined with other agents to augment the immune response. Each patient will be treated with the cell line(s) that match them at least at one HLA allele. 1. Lacher M. D. et al, Front Immunol. 2018 May 15;9:776

Background Pembrolizumab (pembro, anti-PD-1 antibody) combined to chemotherapy (CT) in neoadjuvant/adjuvant setting has demonstrated its efficacy for early triple negative breast cancer (eTNBC). Pembro obtained FDA marketing authorization on July 26, 2021 and is available in France through the French Early Access Program. Methods We built an ambispective cohort that aimed to evaluate the efficacy and safety of the pembro-CT combination in the real world setting in patients with eTNBC. This study included patients treated from September 2021 to May 2022, at Institut Curie, France. Patients provided written authorization to report their clinical data. We report here the safety results. Results Between September 2021 and May 2022, 51 patients were included. Median age was 49 years [29; 68].

Germline mutations were recorded in 8 patients (22.2% of 36 tested patients). All pts were ECOG PS 0 or 1. Baseline clinical TNM stage were T1 (8 pts, 15.7%), T2 (30 pts, 58.9%), T3 (7 pts, 13.7%) and T4 (6 pts, 11.7%). Out of 37 pts (72.5%) with radiological axillary lymph node involvement, 19 pts (51.4%) had positive node involvement confirmed by guided fine needle aspiration. SBR grade 2 and 3 were observed in 9 (17.6%) and 42 (82.4%) pts, respectively. HER2 score was 0 or 1+/2+(FISH neg) for 31 (60.8 %) and 20 pts (39.2 %), respectively. A CPS score ≥ 10 was observed in 19 pts (50% of 38 tested patients). The CT backbone was a combination of carboplatin (Cb) plus weekly paclitaxel (wP) 4 courses (with Cb regimen AUC 5 q3W (81.1%), AUC4 q3w (5.4%) and AUC1,5 q1w (13.5%), and wP 80 mg/m²), followed by standard AC60/600 q3w for 4 courses. Out of the 37 pts (72.5%) who completed the Cb + wP 4 courses, all experienced adverse events (AEs), including 21 pts (56.8%) with at least 1 grade ≥ 3 AE (anemia 5.4%, thrombopenia 5.4%, neutropenia 51.5%, neuropathy 2.7%). Transfusion support was needed for 8 pts (21.6%). Grade ≥ 2 neuropathy occurred in 3 pts (8.1 %). Dose reduction and drug discontinuation were performed in 9 (24.3%) and 5 pts (13.5%), respectively. On the entire cohort, 15 pts (29.4%) had IrAE all grades: dysthyroidism (6 pts, 11.7%), skin toxicity (2 pts, 3.9%), adrenal insufficiency (1 pt, 2%), hypophysitis (1 pt, 2%), immune-allergic nephropathy (1 pt, 2%), suspicion of myocarditis (1 pt, 2%), hepatitis (1 pt, 2%) and ophthalmologic AE (1 pt, 2%). Consequently, after a median follow up of 5 months, pembro postponement and permanent discontinuation were performed in 7 (13,7%) and 5 pts (9,8%), respectively. At abstract submission 6 pts had breast surgery (pCR in 5 pts = 83.3%).

Conclusions Our real-world data are consistent with the results of the KEYNOTE-522 trial in terms of patients characteristics. We observed a very high rate of hematological and immune related adverse events, frequently leading to dose reduction or discontinuation, underlying the need for a very close clinical management of those patients. Updated data including toxicity during the whole neoadjuvant sequence and pCR rate will be presented at the meeting.

Background and Significance: Recently, the addition of the immune checkpoint-inhibitor PEM to CHT was shown to increase pCR rates and invasive event-free survival in the Keynote-522 (KN522) trial. Several irAEs are known to occur during use of PEM in various cancer entities. In our multicenter analysis we aimed to identify real-world occurrence rates of irAEs and pCR rates in women receiving PEM and CHT, analogously to KN522, for eTNBC treatment.

Methods: All patients receiving CHT + PEM for eTNBC treatment at participating centers were followed prospectively and monitored for occurrence of irAEs and neoadjuvant treatment outcome as defined by pCR from October 2020 until data cut-off on September 15th 2022. Only patients who underwent surgery for their primary tumor before data cut-off were included.

Results: A total number of 22 patients with available pCR outcomes were included. All patients were female. Median age was 51 years (range 25-72). Mean tumor size at baseline was 29mm (range 10-75). 41% (9/22) of patients exhibited nodal involvement according to baseline radiological findings. Median MIB-1/Ki67 expression at biopsy was 70%. Patients received a median of 8 (range 1-8) neoadjuvant cycles of PEM and exhibited a median duration of CHT of 24 weeks (range 4-24). Neoadjuvant PEM was discontinued in 32% (7/22) of patients. Discontinuation of neoadjuvant treatment before week 18 occurred in 22,7% (5/22) of patients. We report irAE rates of any kind and all grades of 50% (11/22) and of grade 3-4 in 9% of patients (2/22). Steroids were administered in 7/11 patients experiencing irAEs (64%). 8 irAEs

occurred during the neoadjuvant treatment phase, 3 during postneoadjuvant treatment with PEM. No grade 5 toxicity was observed. irAEs observed were hypothyroidism (n=3, all grade 2), arthritis (n=3, all grade 2), myocarditis (n=2, one grade 3/one grade 4), and single cases of hepatitis (grade 2), nephritis (grade 3) and pneumonitis (grade 1). 18% (4/22) of patients underwent mastectomy and 36% (8/22) of patients underwent axillary dissection. Lastly, upon definitive surgery of the primary tumor, we observed pCR in 50% (11/22) of cases. Patients who completed >18 weeks of neoadjuvant therapy exhibited a pCR rate of 59% (10/17), whilst patients who completed ≤18 weeks of neoadjuvant therapy reached pCR in 20% of cases (1/5). Conclusion: We report real-world prospective data about irAE as well as pCR rates during eTNBC treatment with PEM and CHT. irAEs occurred in similar rates as observed in KN522, although numerically higher for irAEs of all grades. The pCR rate within our cohort was numerically lower than reported for KN522, most probably due to a low pCR rate observed for 5 of 22 patients included in this analysis who completed ≤18 weeks of neoadjuvant treatment. Looking at our data, we hypothesize that clinical benefit from combination therapy of PEM and CHT depends on reaching an adequate duration of >18 weeks of neoadjuvant treatment.

Mebendazole displays selective anti-breast cancer cytotoxicity via the induction of mitotic catastrophe

Presenting Author(s) and Co-Author(s):

Metastatic breast cancer (mBC) is still an incurable disease and is responsible for the majority of breast cancer-related death, despite tremendous efforts spent on developing better regimens for mBC. Microtubule-targeting chemotherapy agents (MTAs) have been on the front lines of treating mBC. However, many of these drugs become ineffective following treatment, as a consequence of either primary or acquired resistance, which leads to refractory disease. Furthermore, failures of the first-line MTA treatment will negatively affect the effectiveness of the second- and third-line agents in the patients, as the overall response rates of the subsequent treatments are in a range of only ~12% to 35%. Thus, there is an urgent need for alternative MTAs that are significantly different in biological characteristics from those currently used MTAs for mBC therapy. For this purpose, we investigated Mebendazole (methyl 5-benzoyl-2-benzimidazole-carbamate (MEB), which binds different sites on the α/β -tubulin remote from the binding sites of other MTAs, for its potential against mBC cells. MEB has much lower in vivo toxicity than the other MTAs used to treat mBC and it can be orally administrated. We explored MEB for its effectiveness in anti-mBC cells with a panel of human breast normal and mBC cell lines. The data from clonogenic survival studies indicate that MEB delivers < 10-fold greater cytotoxicity toward mBC cells compared to normal mammary epithelial (HME) or benign breast tumor cells. Furthermore, the cytotoxicity in detected in mBC cells was attributed to the induction of mitotic catastrophe, as demonstrated by the increased mitotic cell population (cells with 4N-DNA content and Histon-H3-Ser10 phosphorylation) and concurrent nuclear fragmentation. In contrast, under the same dose range, MEB did not cause mitotic catastrophe in HME cells. In addition, our data also show that MEB is much more efficient in killing p53-deficient mBC cells than p53-proficient mBC cells for the same reason, induction of mitotic catastrophe, which suggest the protective function of p53 against MEB-induced mitotic catastrophe. Collectively, our data support a great potential for MEB as an innovative regimen for improving mBC treatment.

Anti-tumor efficacy of GMF-1A3, an MMAE-based antibody drug conjugate targeting cell surface cleaved Amphiregulin in breast cancer

The Epidermal Growth Factor Receptor ligand, Amphiregulin, is a key proliferative effector of estrogen receptor signaling in breast cancer and also plays a role in other malignancies. Amphiregulin is a single-pass transmembrane protein proteolytically processed by TACE/ADAM17 to release the soluble EGFR ligand, leaving a residual transmembrane stalk that is subsequently internalized. Here, we describe the development of an antibody drug conjugate, GMF-1A3-MMAE, targeting an AREG neo-epitope revealed following ADAM17-mediated cleavage. The antibody does not interact with uncleaved Amphiregulin, providing a novel means of targeting cells with high rates of Amphiregulin shedding. Using fluorescent dye conjugation, we demonstrated that the antibody is internalized by cancer cells in a manner dependent on the presence of cell surface cleaved Amphiregulin. Antibodies conjugated with monomethyl auristatin E (MMAE) were cytotoxic in vitro and induced rapid regression of established breast tumor xenografts in immunocompromised mice. We further demonstrate that these antibodies recognize the Amphiregulin neo-epitope in formalin fixed paraffin embedded tumor tissue, suggesting their utility as a companion diagnostic for patient selection. A pan-cancer tissue microarray analysis indicates that the target is commonly detected (> 50% of cases) in breast, prostate, liver and lung cancer.

Anti-tumor activity of a liposomal formulation of Eribulin compared with the same dose of Eribulin in patient-derived breast cancer xenografts

Presenting Author(s) and Co-Author(s):

Maki Tanioka, M.D, Ph.D, *Associate professor - Medical AI project, Okayama University*
Country: United States

Taro Semba, Ph.D, *Researcher - Eisai*
City: Tsukuba, Ibaraki
Country: Japan

Tatsunori Shimoi, MD, PhD, *Chief Physician - Medical Oncology, National Cancer Center Hospital*
Country: United States

Yuki Niwa, PhD, *Researcher - Eisai*
Country: United States

Kan Yonemori, M.D, Ph.D, *Director - Medical Oncology, National Cancer Center Hospital,*
Country: United States

Backgrounds:

A liposomal formulation of Eribulin, E7389-LF may allow increased access to tumor tissues and has been under development for breast cancer. In a phase 1, expansion cohort as a late line treatment, objective response rate was observed to be 35.7% (Her2-negative breast cancer), and 42.9% for hormone receptor-positive (HR+ve) patients (Masuda, *European Journal of Cancer*, 2022). However, survival benefit and its mode of action of E7389-LF remains unclear, although E7389-LF seems more effective than Eribulin in clinic.

Methods:

PDX#1 is a breast cancer patient-derived xenograft (PDX) from a patient with triple negative breast cancer who later received Eribulin for 7 cycles until progression in lung metastases. PDX#2 is also a breast cancer PDX from paclitaxel-resistant HR+ve/ HER2-ve breast cancer, respectively. These two PDXs were provided by the National Cancer Center J-PDX library, Japan, and were bred in NOD/Shi-scid, IL-2R γ null (NOG) mice and observed until the onset of a mammary tumor approximately 180 and 240 mm³ in volume (Day 0). PDX tumors were randomized and monitored with tumor growth measurements. Each group received either saline, 0.34mg/kg, or 0.67 mg/kg (clinically relevant dose of E7389-LF, estimated) of Eribulin or E7389-LF at Day 0 and 7 (Experiment 1). For short-term experiments, 9 PDX#1 or 12 PDX#2 tumors were removed one week after an injection of saline, 0.67 mg/kg of Eribulin, or 0.67 mg/kg of E7389-LF (n=3/group for PDX#1, n=4/group for PDX#2), and tumors were immunohistochemically stained with anti-CD31 antibody, an endothelial cell marker, to investigate microvessel density and RNA sequencing was additionally performed (Experiment 2).

Results:

Table 1 summarizes the results. In Experiment 1, both E7389-LF and Eribulin showed significant antitumor activity compared with saline in a dose-dependent manner with respect to tumor growth inhibition and survival benefit, extension of tumor doubling time (earlier day with relative tumor volume >200%), in PDX#1 and #2. Tumor shrinkage was seen in PDX#1, and E7389-LF at 0.34 mg/kg, or 0.67 mg/kg were more potent than the same doses of Eribulin at Day 21 in both PDXs (p < 0.05). E7389-LF at 0.67 mg/kg also showed relative tumor growth

inhibition compared with the same dose of Eribulin in PDX#2 ($p < 0.05$). As for survival, PDX#1 with E7389-LF at 0.67 mg/kg demonstrated significantly longer survival ($p=0.03$) than Eribulin at 0.67 mg/kg, while PDX#2 with E7389-LF at 0.67 mg/kg did not ($p=0.10$). In Experiment 2, microvessel density increased in PDX#1 after receiving eribulin and E7389-LF compared with untreated ones, with a significant difference for E7389-LF ($p=0.006$), and showed an increasing tendency over Eribulin ($p=0.06$), while microvessel density in PDX#2 did not differ between groups.

Conclusions:

Pre-clinical data demonstrates that E7389-LF is more potent than the same dose of Eribulin in patient-derived breast cancer xenografts. Survival benefit was observed in a PDX with a tumor shrinkage and an increase in microvessel density.

Table 1. Summary of the findings

	PDX#1					PDX#2				
	Experiment 1			Experiment 2		Experiment 1			Experiment 2	
	n	Mean Tumor volume at Day21 (mm ³ , %)	Median survival (days)	n	Microvessel density (count/mm ²)	n	Mean Tumor volume at Day10 (mm ³ , %)	Median survival (days)	n	Microvessel density (count/mm ²)
Saline	5	773 (426)	7	3	114	5	1741 (690)	7	4	75
E7389-LF at 0.34 mg/kg	5	68 (36) ^{##}	49 [#]			5	532 (223) [#]	14 [#]		
Eribulin at 0.34 mg/kg	5	136 (75) [#]	42 [#]			5	227 (110) [#]	10 [#]		
E7389-LF at 0.68 mg/kg	5	27 (14) ^{##}	77 ^{##}	3	195 [#]	5	639 (287) ^{##}	21 [#]	4	75
Eribulin at 0.68 mg/kg	5	55 (30) [#]	83 [#]	3	149	5	421 (190) [#]	14 [#]	4	83

#: $p < 0.05$ vs Saline (at the indicated time point for tumor volume), *: $p < 0.05$ E7389-LF vs Eribulin (at Day 21 for tumor volume)

A multicenter, single-arm, open-label Phase I study of AN1004 (Pelareorep) oncolytic virus plus paclitaxel in Chinese patients with Hormone receptor-positive and HER2-negative advanced/metastatic breast cancer (REO 026-1) Background: AN1004, also known as Pelareorep is an intravenously delivered immuno-oncolytic unmodified reovirus being evaluated to treat multiple malignancies. AN1004 was shown to be safe and well-tolerated in both monotherapy and combination therapy in multiple clinical trials in North American and European populations, including two completed and two ongoing breast cancer studies. The completed phase 2 study (NCT01656538) in advanced/metastatic breast cancer demonstrated improved median overall survival (OS) in Canadian patients treated with AN1004 plus paclitaxel (PTX) versus PTX alone, and the greatest benefit in OS was observed in patients with hormone receptor-positive/human epidermal growth factor receptor 2-negative (HR+/HER2-) subtype. Since there has been no clinical trial assessing AN1004 in Chinese population, a bridging study (REO 026-1) was initiated to evaluate its safety and tolerability in combination with PTX in Chinese patients with HR+/HER2- advanced/metastatic breast cancer. Methods: Eligible

Chinese patients must be female with good performance status (ECOG PS: 0 or 1), have had histopathological diagnosis with HR+/HER2- advanced/metastatic breast cancer, and were previously treated with at least one endocrine therapy with no more than one line of chemotherapy regimen for recurrent/metastatic disease. Patients are intravenously infused with AN1004 at escalating dose levels of 1.5×10^{10} (Dose Level 1, DL1 group), 3×10^{10} (DL2 group) and 4.5×10^{10} TCID50 (DL3 group) on days 1, 2, 8, 9, 15, and 16 every 28 days plus PTX 80 mg/m² intravenously on days 1, 8, and 15 every 28 days. Three to six patients will be enrolled in the DL1 group, and 6 patients will be enrolled in each of the DL2 and DL3 groups. The primary objective is to assess the safety and tolerability of AN1004 in combination with PTX. A secondary objective is to evaluate the preliminary activity of AN1004 and PTX combination therapy. Results: By the data cutoff date of June 2nd, 2022, a total of 10 female patients were enrolled, with a median age of 58 years (range 36-67). Two (20%) patients had failed more than one prior line of endocrine therapy for advanced/metastatic disease, and 3 (30%) patients were previously treated with a CDK4/6 inhibitor. Three patients were treated with AN1004 and PTX in DL1 group; six patients were treated in DL2 group; one patient was treated in DL3 group. The most common (>50%, and/or liver function related) treatment emergent adverse events (TEAEs) included neutrophil count decreased and white blood cell count decreased (90% each), hypertriglyceridemia (70%), pyrexia, ALT increased and anemia (60% each), and AST increased (40%). Three (30%) patients had Grade 3 or above TEAEs, including neutrophil count decreased (30%), white blood cell count decreased (20%), hypertriglyceridemia, ALT increased and GGT increased (10% each). No serious AE or AE leading to treatment discontinuation was reported to date. One patient was not evaluable for dose-limiting toxicity (DLT) due to early withdrawal, and there were no DLTs observed in the 9 evaluable patients. Among the 10 treated patients, 2 (20%) patients achieved confirmed partial response (PR), 2 (20%) patients achieved unconfirmed PR, and 5 (50%) patients showed stable disease (SD). One patient in DL1 group achieved a confirmed PR and later progressed, and the other 8 patients who had PR or SD continue to receive treatment as of the data cut. Conclusion: To date, intravenous administration of AN1004 plus PTX is safe and well-tolerated in Chinese patients with advanced/metastatic breast cancer, and demonstrates anti-tumor activity.

Background: More than half of Breast Cancer (BC) patients take chronically used non-cancer treatments (denoted as comedications) at BC diagnosis. Epidemiological evidence has reported that several non-cancer treatments may modify BC risk, BC recurrence, and overall survival (OS). The ADRENALINE project (Atlas for DRug and brEast caNcer survivAL INtEraction) analyses the impact of the use of each commonly prescribed non-cancer treatment at BC diagnosis on OS using the French social security system data on a comprehensive cohort of French BC patients. Methods: We identified all women diagnosed with an incident BC treated with surgery in France from 2011 to 2017 and affiliated to the general health insurance scheme. Women with concomitant cancer or metastases at diagnosis were discarded from the analyses. Comedication intake was defined as the delivery in pharmacy of at least 3 months of full treatment (e.g. 90 pills) the 6 months preceding BC diagnosis. A Cox proportional hazard model was used to estimate the hazard ratio (HR) for each molecule. The model was adjusted on more than 100 confounding variables: social factors, comorbidities and other comedications by Inverse Probability of Treatment Weighting (IPTW). We assumed that the adjustment was sufficient to control for confounding if the standardized mean difference of each confounder after adjustment did not exceed 0.1. Molecules which did not pass the adjustment quality test were discarded. Results: Overall, 235,368 patients were included in the study. Among 219 selected drugs, 91 passed the adjustment quality test. The full set of results is available on a web application (<https://adrenaline.curie.fr>). Several drugs or drug classes were associated with an improved survival: statins (e.g. rosuvastatin, HR=0.65, p< 0.001); proton-pump inhibitors (HR=0.93; p=0.002); or beta-blocking agents (atenolol, HR=0.78, p=0.003). Conversely, anti-anemic preparations (folic acid and ferrous sulfate) had a significant deleterious effect (HR = 1.63; p< 0.001). Drugs from the same therapeutic class, could have different effects: within benzodiazepines, bromazepam was protective (HR = 0.91; p = 0.038) while oxazepam was deleterious (HR = 1.37; p < 0.001). Conclusion: ADRENALINE reports the impact on BC survival of 219 widely prescribed drugs. It can be used to identify molecules with a potential protective or deleterious effect relative to BC. Some of them are currently under mechanistical investigation within a drug screening program. This atlas highlights candidates to drug-

repurposing trials or pharmacovigilance warnings, and will be extended to cancers of other localizations in a near future.

Introduction In hormone receptor-positive, HER2-negative early-stage breast cancer (BC), cyclin-dependent kinases 4 and 6 inhibition (CDK4/6i) in combination with endocrine therapy (ET) could represent an alternative to neoadjuvant chemotherapy (NAC). Methods NEOLBC is a randomized phase II trial that tailored neoadjuvant therapy in postmenopausal patients with

early, luminal (ER >50%, PR any), HER2-negative, stage II/III BC based on the percentage of Ki67 positive cancer cells after a window of opportunity of two weeks letrozole. Patients with a Ki67 \geq 1% after 2 weeks were randomized between ribociclib plus letrozole (RL) and chemotherapy (CT; AC-T regimen). The primary objective was to determine if RL gives a doubling in complete cell cycle arrest (CCCA; Ki67 < 1% on IHC) as compared to CT in the surgical specimen (70% vs. 35% of patients, respectively). Secondary endpoints included pathological response, toxicity and ER pathway activity (measured by the OncoSIGNaI qPCR test). Results Out of 161 registered patients, 70 patients were randomized and 66 patients started treatment; 34 RL and 32 CT. Patient characteristics were equally distributed between the two groups, except for the PR status (RL 23.5% negative vs. 50.0% negative in the CT group). In the intention to treat analysis, the CCCA in the surgical specimen was similar for both groups: 35.3% in the RL vs. 31.3% in the CT group ($p = 0.73$). The pathological complete response (pCR) in the breast was not significantly different between the two groups (11.8% vs. 3.1%, $p = 0.36$) nor was the pCR rate in breast plus lymph nodes (8.8% vs. 3.1%, $p = 0.61$) for the RL vs. CT group, respectively. An explorative analysis on the difference in Ki67% (decline, no change, increase) from baseline to surgery showed a decline in 73.5% vs. 50.0%, no change in 17.6% vs. 31.3% and an increase in 8.8% vs. 18.8% of patients ($p = 0.06$) for the RL vs. CT group, respectively. In the RL group eight patients (23.5%) discontinued ribociclib early due to toxicity (two SAE's were observed) vs. 10 patients (31.3%) discontinuing treatment in the CT group (one SAE was observed). Secondary endpoints, including the ER pathway activity analysis, will be presented in-depth during the meeting. Conclusion Although the primary endpoint was not met, the NEOLBC trial showed a similar CCCA and pathological response at surgery for RL vs. CT. Therefore, RL as an alternative for NAC merits further investigation in follow-up studies. ClinicalTrials.gov: NCT03283384

Background: SG is a Trop-2-directed antibody-drug conjugate approved by the FDA for patients (pts) with metastatic triple-negative breast cancer who received ≥ 2 prior chemotherapies (≥ 1 for MBC). In the phase 3 TROPiCS-02 study, SG demonstrated a 34% reduction in risk of progression or death vs TPC in heavily pretreated, endocrine-resistant HR+/HER2- MBC (Rugo H, et al. ASCO 2022. LBA1001). The safety profile was manageable, with neutropenia and diarrhea as the key AEs. Absolute incidence rate is the most used metric to summarize AEs in routine clinical safety analyses. However, when the treatment duration differs

significantly between treatment arms, these rates may need adjustment to account for longer treatment exposure, which may incur a higher incidence of AEs. Given that the median treatment duration was longer for SG in TROPiCS-02, EAIRs were assessed in post hoc safety analyses.

Methods: Pts with HR+/HER2– unresectable locally advanced or MBC and 2-4 prior chemotherapy regimens for MBC were randomized 1:1 to receive SG or TPC (capecitabine, eribulin, vinorelbine, or gemcitabine) until unacceptable toxicity or disease progression. The primary endpoint was progression-free survival per RECIST 1.1 by central review. Safety was a secondary endpoint. Time-at-risk EAIR considers pts' exposure of a specific AE in quantifying the risk of AE, defined as the number of pts who experienced at least 1 specific AE, divided by the total exposure time (pt-year of exposure [PYE]) in each arm. For pts who experienced specific AEs, exposure time was calculated from first dose date up to the first AE onset, and for pts who did not, from first dose up to data cutoff (if still on study treatment) or up to last dose (if discontinued study treatment). The 95% CI of the EAIR difference is a standard method to assess the statistical significance of AE incidence rate differences between arms.

Results: Of 543 pts enrolled (median age, 56 y; visceral metastases, 95%; prior CDK4/6 inhibitor for MBC, 99%; median lines of chemotherapy for MBC, 3), 517 pts (SG, n=268; TPC, n=249) received ≥ 1 dose of study treatment. At data cutoff (Jan 3, 2022), 18 pts (7%) vs 4 pts (2%) remained on treatment in the SG vs TPC arms; median treatment duration was 4.1 months and 2.3 months, respectively. The absolute incidence, EAIRs (incidence per 1 PYE), and EAIR differences for the overall safety summary and most common grade ≥ 3 TEAEs are provided (Table). Overall, SG had higher absolute incidence rates vs TPC for grade ≥ 3 treatment-emergent AEs (TEAEs), serious AEs, and TEAEs leading to death, but the EAIRs were similar between arms, suggesting an association with duration of treatment exposure. When adjusted for exposure, the incidence of grade ≥ 3 diarrhea remained higher for SG vs TPC; however, the incidence of grade ≥ 3 neutropenia was similar between arms.

Conclusions: The safety profile of SG was manageable in pts with heavily pretreated HR+/HER2– endocrine-resistant, unresectable locally advanced or MBC. Though there was a higher absolute incidence of TEAEs leading to death and grade ≥ 3 neutropenia with SG vs TPC, the EAIRs were similar. Taken together with the efficacy benefit with SG, this supports a favorable risk/benefit profile for SG compared with standard chemotherapy in this pt population with limited therapeutic options.

Table. Overall Safety Summary and Summary of Common (Absolute Incidence $\geq 5\%$) Grade ≥ 3 TEAEs With Absolute Incidence, Exposure-Adjusted Incidence Rates (EAIRs),^a and EAIR Differences^{b, c}

	SG (n=268)	TPC (n=249)

EAIR difference vs TPC (95% CI)	0.03 (-0.10-0.13)	

^aReported as events per 1 patient year. ^bSG and TPC EAIRs were similar if the 95% CI covers 0, nominally not statistically significant based on informal testing. ^cPositive upper and lower bound for EAIR difference 95% CI favors the TPC arm. Nominally statistically significant based on informal testing. ^dOne patient experienced a treatment-related AE leading to death (septic shock due to neutropenic colitis). The AEs leading to death in the remaining 5 patients included (n=1 each) arrhythmia, COVID-19 pneumonia, pulmonary embolism, pneumonia, and nervous system disorder; these events were not considered to be treatment-related.

AE, adverse event; EAIR, exposure-adjusted incidence rate; SG, sacituzumab govitecan; TEAE, treatment-emergent adverse event; TPC, treatment of physician's choice.

Background: Obesity is associated with increased risk of triple negative breast cancer (TNBC). Obese patients with TNBC have worse outcomes compared to patients with normal weight. Both obesity and TNBC are associated with chronic inflammation including elevated nitric oxide (NO). In a recently completed Phase I/II clinical trial using a pan-NOS inhibitor L-NMMA in combination with chemotherapy docetaxel in chemorefractory and metastatic TNBC, a higher response rate was observed in obese patients. Furthermore, tumor microenvironment analysis from responders revealed a neutrophil phenotype shift from protumor N2 to antitumor N1. We thus hypothesize that combining pan-NOS inhibitor L-NMMA with docetaxel can modulate neutrophil mediated pathways, and further enhance antitumor effect in obese mice with TNBC. Methods: Three-week old syngeneic female C57/black mice were randomized to high fat diet (HFD, 18% protein, 21% carbohydrates, and 61% fat, n=50) and normal diet (ND, 20% protein, 70% carbohydrates, and 10% fat, n=50) for 10 weeks. Mouse weights were measured weekly. After 10 weeks on their respective diets, glucose tolerance test, serum cytokine and leptin analysis were performed. At week 13, TNBC E0771 tumor cells (1×10^5) were injected into the right mammary fat pads. Tumor progression was monitored twice weekly and tumor volume $[0.5 \times (\text{long dimension}) \times (\text{short dimension})^2]$ was calculated. Once the tumor reached 80-100 mm³, mice in both HFD and ND groups were randomized to vehicle [saline, intraperitoneal (IP), n=10], docetaxel (20 mg/kg, IP, n=10), L-NMMA (400 mg/kg on day 1, 200 mg/kg on days 2-5, n=10), docetaxel and L-NMMA combination (same doses and schedule as in single agent groups, n=10). Tumor volume was measured throughout the experiment and tumor growth was calculated (tumor volume on day X/tumor volume at baseline). RNA sequencing of tumors from vehicle and combination groups in HFD and ND (n=6 in each arm) was performed

(Azenta/Genewiz, NJ) and BioJupies was utilized for pathway analysis. GraphPad Software (La Jolla, CA, USA) was used to perform two-tailed Student's t test and ANOVA statistical analysis. A p-value < 0.05 was considered statistically significant. Results: Compared to ND group, HFD group mice had significantly higher weight gain (64.8% vs 83.2%, $p < 0.0001$); they also demonstrated significant glucose intolerance, and higher serum leptin level consistent with metabolic changes observed in diet-induced obesity. After tumor injection, tumor growth rate was much higher in HFD mice compared to that in ND mice. At end-of-treatment, compared with vehicle, a significantly slower tumor growth in HFD mice ($p = .015$), and a trend of slower tumor growth was observed in ND mice ($p = .92$) in docetaxel and L-NMMA combination treatment. The reduction of tumor growth was significantly higher in HFD mice than that in ND mice (median of differences -2.0, $p = .031$). Differential gene expressions from RNA sequencing showed that HFD mice displayed higher expression of genes related to neutrophil degranulation and neutrophil mediated immunity compared to ND mice at baseline; while treatment with L-NMMA and docetaxel combination downregulated these genes. Conclusion: HFD mice had significantly faster tumor growth and higher expression of genes related to neutrophil mediated pathways, while treatment with pan-NOS inhibitor L-NMMA and docetaxel combination downregulated these genes. The combination treatment resulted in a more significant anti-tumor effect in HFD mice, likely through remodeling neutrophils. Future spatial analysis including CODEX and immunophenotyping are planned to further explore the role neutrophils play in the pathogenesis of obesity associated TNBC and its response to combination treatment.

CCTG IND.236: A Phase 1b trial of combined CFI-402257 and weekly paclitaxel in patients with HER2-negative (HER2-) advanced breast cancer (aBC) Philippe L. Bedard, Mihaela Mates, John Hilton, Nathalie Levasseur, Arif Awan, Amirrtha Srikanthan, David Cescon, Karen Gelmon, Andrew Robinson, Nancy Drummond-Ivars, Irene Li, Laleh Rastgou, Jackie Edwards, Linda Hagerman, Siwei Zhang, Mark Bray, Lesley Seymour, Moira Rushton-Marovac, Pierre-Olivier Gaudreau Background: CFI-402257 is a selective oral inhibitor of TTK protein kinase, a critical regulator of the mitotic spindle assembly checkpoint overexpressed in breast cancer (BC). CFI-402257 monotherapy has anti-proliferative and cytotoxic activity and enhances antitumor activity of paclitaxel in BC xenograft models. Material and methods: Primary objectives were to establish safety and Recommended Phase 2 dose (RP2D) of CFI-402257 combined with weekly paclitaxel (Phase 1b) and Overall Response Rate (ORR) as per RECIST 1.1 (Phase 2). Patients with HER2- aBC with adequate organ function, PS 0-1, previously treated with >1 non-taxane chemotherapy, were eligible. A 3+3 design was used for Phase 1b, with dose limiting toxicities (DLTs) assessed during cycle 1 (28 days). Starting dose CFI-402257 was 84mg (DL1 = 84mg, DL2 = 112mg, DL3 = 168mg, DL4 = 210mg and DL5 = 252mg) on a 2-day on, 5-day off schedule with paclitaxel 80mg/m² day 1, 8, 15. Safety assessments were performed weekly (CTCAE v5.0) and response every 2 cycles. A Simon 2-stage design was used for Phase 2 (stage 2 required ≥4 responses in 17 evaluable patients from stage 1). Results: 37 patients received a total of 260 cycles including all 5 dose levels. Median age was 59; 92% ER+/HER2-; 49% PS1; 22% ≤3 prior chemotherapy lines; 41% ≤4 sites of metastatic disease, and 81% had received prior CDK4/6 inhibitors. Grade ≤3 hematological adverse events (AEs, all dose levels) were neutropenia (70%), lymphopenia (41%) and anemia (14%). Six DLTs occurred: 5 dose-related grade 4 neutropenia and 1 febrile neutropenia. Three DLTs occurred at DL3, two at DL4, and one at DL5. Three serious AEs (two at DL3, and one at DL4) at least possibly related to treatment were seen: 2 febrile neutropenia and 1 skin infection (all grade 3). Frequent AEs (>5%; all dose levels) considered at least possibly related to treatment were: diarrhea (38%), nausea (30%), fatigue (27%), vomiting (16%), anorexia (14%), maculo-papular rash (14%), oral mucositis (11%), alopecia (11%) and pruritus (8%). DL3 (168mg) was selected as RP2D. ORR was 3/36=8% and 1/17=5.9% in all vs Phase 2 evaluable patients, respectively. Clinical Benefit Rate (CBR; defined as complete response, partial response or stable disease >16 weeks in duration) was 18/33=54.6% and 10/17=58.8% in all vs Phase 2 evaluable patients, respectively. During Phase 2, the 17 evaluable patients from stage 1 did not meet pre-specified threshold for anti-tumor activity to proceed to stage 2. Conclusions: CFI-402257 and paclitaxel was well tolerated, with neutropenia as the main toxicity. DL3 (168mg) was selected as RP2D. Phase 2 ORR and CBR was 5.9% and 58.8%, respectively; during Phase 2, the 17 evaluable patients from stage 1 did not meet the pre-specified threshold for anti-tumor activity to proceed to stage 2 and the trial was closed to accrual on April 7, 2022. Final analysis and correlative analyses are ongoing. Acknowledgements: Coordinated by the CCTG. Funding supported by SU2C Canada - Canadian Cancer Society Breast Cancer Dream Team Research Funding (SU2C-AACR-DT-18-15) and OICR. CFI-402257 provided by Treadwell Therapeutics.

Background: SV-BR-1-GM is an irradiated allogeneic cell line derived from a hormone receptor-negative (HR-) HER2-positive (HER2+) breast cancer (BC), now engineered to express HLA class I and II antigens, secrete GM-CSF and function as an antigen-presenting cell. Here we report post-hoc exploratory data for metastatic BC (MBC) patients treated with the SV-BR-1-GM regimen (SV) alone (NCT03066947) and in combination (CO) with immune checkpoint inhibitors (ICIs) (NCT03328026).

Methods: SV includes cyclophosphamide 300 mg/m² i.v. 48-72 hours prior to SV-BR-1-GM (20 x 10⁶ cells) intradermally followed by interferon-alpha-2b at the SV-BR-1-GM inoculation sites on days 2 and 4. SV was given every 2 weeks for 3 cycles and then monthly in NCT03066947, and every 3 weeks in combination with PD-1 inhibitors in NCT03328026. Treatment was continued until disease progression or unacceptable toxicities.

Results: A total of 34 refractory MBC patients (pts) were treated, including 24 with SV, and 14 with CO, including 4 who crossed over from SV to CO plus one who restarted the SV after a protocol specified administrative interruption in treatment. Median prior regimens were 5; 55% of pts had hormone receptor-positive (HR+) BC, 42% had HER2+ BC, and 16% were triple-negative BC (TNBC). Objective response rates (ORR) were 4% for monotherapy and 7% for combination. Clinical benefit rate (CBR) was 21% for monotherapy and 29% for combination. Responses and clinical benefits were seen across most BC subtypes (see table). Notably, CBR among 10 pts with HR+ BC (any HER2) who received the combination was 50% (5/10). The duration of response (DOR) among 4 patients treated with monotherapy was 49-223 days and DOR among 6 patients treated with combination was 72-292 days. Median PFS was 2.8 months for monotherapy and 4.2 months for combination. Median OS was 7.0 months for monotherapy, and 12.0 months for combination. Of 28 pts with available prior treatment data, 12 (43%) had PFS on study treatment exceeded PFS on prior treatment, of these 8/12 had >1 HLA match and 5/8 had ≥ 2 loci HLA-matched with SV-BR-1-GM. PFS ratio improvement was independent of the prior number of lines of therapy or BC subtypes. The SV-BR-1GM regimen was well tolerated with the most common treatment-related adverse events (AEs) being injection site reaction in 67%. There was no dose-limiting toxicity, special interest AEs such as cytokine storm, and no grade 5 observed. There were 2 non-treatment-related grade 4 AEs: worsening pleural effusion and altered mental status. Significant improvement in PFS was observed in patients with matched HLA and in association with the delayed-type hypersensitivity skin test, peripheral blood circulating tumor cells, and cancer-associated macrophages.

Conclusions: SV-BR-1-GM demonstrated promising activity in patients with MBC. Treatment was well tolerated with no concerning AEs. The PFS ratio compares favorably with prior penultimate standards of care, more notably in patients with matched HLA. Clinical benefits were observed across multiple subtypes of BC, particularly in patients with HR+ disease receiving combination therapy. Phase II clinical trial is currently ongoing to evaluate the efficacy of SV-BR-1-GM in combination with ICIs.

Endocrine therapy forms the backbone treatment for patients with estrogen receptor (ER) positive tumors in both the adjuvant and metastatic setting. Aromatase inhibitors (AI) are the most common endocrine treatment option. Mutation of ESR1, the gene encoding ER α , is a common mechanism of resistance to AIs which leads to ligand independent activity of ER α . Camizestrant (AZD9833) is a next generation SERD and pure ER antagonist that is in Phase 3 trials (SERENA-4: NCT04711252; SERENA-6: NCT04964934). Here we report the preclinical and clinical activity of camizestrant in patients with ESR1 wild-type (ESR1wt) and mutant (ESR1m) tumors. The binding affinities of camizestrant, fulvestrant, and estradiol to wt ER α and ER α variants with mutations in the ligand binding domain were assessed. All three compounds exhibited reduced binding to mutant forms of ER α compared with wt ER α ; the Y537S mutation had the greatest impact on binding. This was reflected in requirement for greater concentrations of camizestrant and fulvestrant to degrade and antagonize mutated ER α and to impact cellular proliferation in MCF-7 cells that expressed Y537S ESR1m compared to ESR1wt MCF-7 cells. Furthermore, while a 3 mg/kg dose of camizestrant achieved a maximal anti-tumor effect in a ESR1wt patient derived xenograft model, a 10 mg/kg was required for maximal effect in a D538G ESR1m model. Considering this difference between ESR1m and ESR1wt, pharmacokinetic/pharmacodynamic modelling of preclinical data predicted that a camizestrant dose of 75 mg would be maximally efficacious in patients with ESR1m tumors. Indeed, analysis of ESR1m circulating tumor DNA levels in patients from the SERENA-1 (NCT03616587) Phase

1 trial showed a clear effect of 14 days treatment with 75 mg camizestrant resulting in a >2-fold reduction in ESR1m variant allele frequency in 12/13 (92%) cases with complete clearance of ESR1m ctDNA in 7/13 (54%) cases. Interestingly, the clinical activity of camizestrant was higher in heavily pretreated patients with metastatic breast cancer with ESR1m tumors compared to those with no detectable mutation (ESR1m not detected). At a camizestrant dose of 75 mg, median progression-free survival was 8.3 months (maturity 12/15) in patients with ESR1m tumors compared to 5.6 months (8/9) in those with ESR1m not detected (data cut-off 6 October 2021). Camizestrant-induced ER α degradation was seen in both groups (mean reduction in H-score 42% in ESR1m tumors (n= 12 evaluable pairs) and 46% in tumors with ESR1m not detected (n=7)). Whole transcriptome analysis revealed a trend towards higher ER α activity at baseline in ESR1m tumors compared to ESR1m not detected; ER α activity reduced on treatment in both groups. Consistent with the clinical activity data, camizestrant induced more profound reductions in cell proliferation in ESR1m tumors compared to ESR1m not detected tumors (as seen by greater reductions in Ki67-positive tumor cells). These data demonstrate the activity of camizestrant in patients with ESR1m tumors. Clinical activity along with degradation and antagonism of the ER α is also seen in patients with tumors in which ESR1 mutations are not detected. In this heavily pre-treated Phase 1 patient population from SERENA-1, ESR1m may be a predictive biomarker to enrich for patients with maintained endocrine sensitivity. The SERENA-6 trial is investigating the efficacy and safety of camizestrant plus a CDK4/6 inhibitor in patients with metastatic breast cancer and detectable ESR1m. We acknowledge Helen Heffron, PhD, from InterComm International who provided medical writing support funded by AstraZeneca.

Background:

CFI-400945 is a selective oral inhibitor of Polo-like Kinase 4 (PLK4), a controller of centriole duplication and mitotic progression identified by functional screening of genomically unstable breast cancer (BC). IND.237 (NCT01954316) is an open label, multicentre, phase 2 study in HER2 negative metastatic breast cancer (MBC) with 3 cohorts, 1 enriched for PTEN loss of function. Enrollment started in 2018 at 64mg based on a previously established recommended phase 2 dose (RP2D). The initial patients had higher than expected grade 3/4 neutropenia which led to a voluntary hold and dose de-escalation; the new RP2D was declared at 32mg as previously reported Here we report the results of the phase 2 study of CFI-400945 in advanced BC patients.

Materials and Methods:

49 patients were enrolled across 3 cohorts: 1: triple negative; 2: ER+/HER2- PTEN low (by IHC); 3: ER+/HER2-, PTEN intact. The primary outcome is objective response rate (ORR); secondary outcomes included disease control rate (DCR) >16w, and safety. A Simon 2-stage design was used (9 – 25 pts planned for each cohort). CFI-400945 would be considered active if ≥3 responses were observed in any given cohort. Eligibility included ECOG 0-1, adequate organ function and receipt of at ≥1 prior line of cytotoxic chemotherapy in any setting including anthracycline taxane (unless contraindicated). Treatment was 32mg 7d on 7d off in cycle 1 (cycle length=28d), then continuously starting cycle 2. Safety assessments were performed each cycle and response (RECIST 1.1) every 2 cycles.

Results:

60 patients have been screened, 49 enrolled: 10 were in initial dose ranging and were excluded from phase 2 response assessment. 10 patients were enrolled in cohort 1, 4 in cohort 2, and 25 in cohort 3. Table 1 presents patient characteristics and response results. 1 patient in cohort 3 has not had disease re-assessed at time of abstract submission. The most common adverse events have been cytopenias, nausea, fatigue, headache, constipation and vomiting. Less than 5% of patients experienced a non-hematologic AE > grade 3; 33% experienced ≥ grade 3

neutropenia.

Patient Characteristics Cohort 1 Cohort 2 Cohort 3 Overall
 (n=10) (n=4) (n=25) (n=39)
 Age median (range) 58 (47-77) 63 (40-71) 57 (41-73) 58 (40-77)
 Performance Status (0/1) 60%/40% 25%/75% 56%/44% 54%/46%
 Liver metastases 3 (30%) 4 (100%) 21 (84%) 28 (72%)
 ≥ 3 prior chemotherapy regimens 4 (40%) 2 (50%) 14 (56%) 20 (51%)
 Best overall response Cohort 1 Cohort 2 Cohort 3
 (n=10) (n=4) (n=25)
 Partial Response 0 0 2
 Stable Disease 3 2 5
 SD > 16wks 1 0 1
 Progressive Disease 6 0 16
 Inevaluable 1 1 2
 ORR (evaluable pts) 0% 0% 8.7%
 DCR (evaluable pts) 11.1% 0% 13.0%

Table 1: Patient characteristics and response rates in each cohort treated with CFI-400945

Conclusions:

CFI-400945 32mg is well tolerated in this MBC population with moderate incidence of uncomplicated neutropenia. The TNBC cohort so this arm has been closed to further accrual for lack of responses. The PTEN loss group has been slow to accrue and remains open. Responses in the ER+/HER2- arm are encouraging – results from patients remaining on study are awaited and correlative studies to identify features associated with responses are underway.

Background: OP-1250 is a small molecule oral complete estrogen receptor antagonist (CERAN) that binds the ligand binding domain of the ER and completely blocks ER-driven transcriptional activity. CDK4/6 inhibitors in combination with endocrine therapy have improved progression free survival and overall survival for patients (pts) with metastatic breast cancer (MBC) in the first- and second-line settings. However, most patients will progress and newer combinations such as with OP-1250 may provide improved clinical outcome. OP-1250 potentially inactivates both wild-type ER and mutant forms of ER. The latter confers ligand independent activity and is a mechanism of resistance to standard of care endocrine therapies. In preclinical studies, OP-1250 in combination with palbociclib demonstrated synergistic activity in models of wild-type ER and those containing ESR1 activating mutations, and in models of brain metastasis. A Phase 1/2 monotherapy study of OP-1250 is ongoing in MBC subjects who have received 1 or more prior endocrine therapies (NCT04505826). Monotherapy is well tolerated and the recommended phase 2 dose is 120 mg QD. The aim of this combination trial is to define the maximum tolerated dose (MTD), safety, tolerability, and pharmacokinetics (PK) of

OP-1250 in combination with palbociclib. Methods: Eligibility criteria include pts with MBC or locally advanced breast cancer who have received no more than 1 prior line of endocrine therapy (prior CDK4/6 inhibitors and one line of chemotherapy are permitted) and measurable or non-measurable disease. Using a 3+3 design, cohorts are sequentially enrolled, and pts receive escalating doses of OP-1250 orally QD continuously in combination with 125 mg of palbociclib orally for 21 of 28 days. Pts are evaluable for dose limiting toxicities (DLTs) if >75% of both treatments were administered within the first 28-day treatment cycle. Blood is collected for PK on cycle 1 days 1, 2 and cycle 2 days 15, 16 for OP-1250 and cycle 1 day 15 for palbociclib. PK profiles, exposure parameters, and drug-drug interactions (DDIs) are assessed. Pts are monitored for adverse events (AE) and tumor assessments (RECIST 1.1) are conducted every two cycles. Results: As of July 7, 2022, 9 pts were evaluable for DLTs after 28 days of treatment in dose levels 30 mg, 60 mg, and 90 mg of OP-1250 in combination with palbociclib. No DLTs occurred at any of the dose levels. As of May 13, 2022, of the 7 pt safety data set, the most common Grade 1/2 treatment emergent adverse events (TEAE), which occurred in 2 patients, were nausea, gastroesophageal reflux, vomiting, and fatigue. Grade 3 neutropenia occurred in 4 pts and all were attributed to palbociclib by the investigator. No Grade 4 events were observed. OP-1250 was highly bioavailable and showed dose proportional exposure in combination with palbociclib. The single and multiple dose exposure of OP-1250 was consistent with that observed in the monotherapy study, indicating an absence of effect of palbociclib on OP-1250 PK. 90 mg steady-state evaluation is ongoing. Palbociclib concentrations at steady state did not demonstrate a meaningful difference from published exposure parameters for the three dose levels evaluated, indicating an absence of DDI. Conclusions: In the first three cohorts of OP-1250 and palbociclib, the combination was well tolerated and no DLTs occurred. There were no clinically significant DDIs observed between OP-1250 and palbociclib at the doses evaluated and exposure of each drug was consistent with observed monotherapy exposure levels. Dose escalation of OP-1250 continues to 120 mg, to be followed by dose expansion. Updated data will be presented. (NCT05266105)

Cancer immunotherapy has had a significant impact on the management of many types of solid tumors. While some patients respond favorably to it, a significant number of patients do not respond or initially respond but develop resistance later, highlighting an unmet need to improve the effectiveness of this treatment. Cancers with intrinsic resistance include breast cancer, not only respond poorly to single agent immunotherapy, but also often show no durable response. Tumor microenvironment (TME) plays a critical role in both pre-existing and acquired immune resistance which is responsible for the low immunogenicity of cancers. We previously reported that an electrical engineering technology generating nanosecond length electric pulses (nsEP) can greatly enhance the immunogenicity of poorly immunogenic cancers including 4T1 breast and Pan02 pancreatic in animal models. To understand how nsEPs overcome predominant immunosuppression in the TME to induce a strong immune response, we further investigated the effects of nsEPs on the breast TME by performing transcriptomic and immune profiling of 4T1 breast cancer cells treated with nsEP. RNAseq data and cell death signaling results demonstrated that nsEPs induced regulated necrotic cell death rather than apoptosis. nsEPs-treated cancer cells greatly decreased angiogenic factors and multiple chemoattracts for myeloid-derived suppressor cells (MDSCs) and macrophages. On the other hand, nsEP-treated cancer cells significantly upregulated chemoattracts for T lymphocytes and a number of proinflammatory/immunostimulatory cytokines. Flow cytometry analysis showed that the dynamic changes of TME following nsEP treatment included: (1) the significant reduction of immunosuppressive cells (MDSCs, Tregs and TAMs); (2) the preservation of cytotoxic CD8+ T cells and conventional CD4+ T cells; and (3) a persistent elevation in cytotoxic cells vs Treg ratio and tissue resident memory CD8+ T cells. Taken together, our results suggest nsEP is a TME modifier that can potentially overturn the immunosuppressive hurdle in the TME to promote antitumor immunity.

CCTG IND.239: A phase 2 study of combined CFI-400945 and durvalumab in patients with advanced triple negative breast cancer (aTNBC) John Hilton, David W. Cescon, Andrew Robinson, Sukhbinder Dhesy-Thind, Sara Kristina Taylor, Arif Awan, Terry Ng, Moira Rushton, Marie-France Savard, Lindsay Muyot, Marie Claude Reeves, Linda Hagerman, Hongbo Lui, Mark Bray, Dongsheng Tu, Lesley Seymour, Pierre-Olivier Gaudreau Background: CFI-400945 is a selective oral inhibitor of Polo-like Kinase 4 (PLK4), which controls centriole duplication and mitotic progression, and was identified as a drug target based on functional screening of genomically unstable breast cancers. CFI-400945 monotherapy has anti-proliferative activity and enhances antitumor activity when combined with anti-PD-1 immune checkpoint blockade in transplantable murine cancer models. Material and methods: In this multi-centre phase II trial of CFI-400945 and durvalumab combination therapy, the primary objective was overall response rate (ORR) per RECIST 1.1. Patients with aTNBC with adequate organ function, PS 0-1, previously treated with >1 line of chemotherapy including anthracycline and/or taxane, were eligible. CFI-400945 32mg monotherapy was administered on a 7-day on, 7-day off schedule for cycle 1 (which reduced the likelihood of significant hematologic toxicity). From cycle 2 onwards, CFI-400945 32mg daily was administered in combination with durvalumab 1500mg IV every 28 days; responses were assessed every 8 weeks. Following trial activation, 3 patients received a CFI-400945 dose of 40mg (same schedule) for a total of 9 cycles before 32mg was declared as the new recommended phase 2 dose (based on other ongoing trials using CFI-400945). A Simon 2-stage design was used; $\geq 3/15$ responses in stage 1 were required to expand to stage 2. Exploratory PD-L1 expression was measured on immune and tumor cells using the SP263 assay. Results: 15 patients received a total of 45 cycles (1-12 cycles per patient). Median age was 56 (31-76); 53% PS1; 20% ≥ 3 prior chemotherapy lines and; 27% ≥ 4 sites of metastatic disease. Immune vs tumor cell PD-L1 expression was $\leq 1\%$ in 50% and 23% of patients, respectively (immune and tumor cell expression was mutually exclusive). Immune vs tumor cell PD-L1 expression was $\leq 10\%$ in 17% and 15% of patients, respectively. Grade ≥ 3 hematological adverse events (AEs) were lymphopenia (40%), neutropenia (20%), anemia and thrombocytopenia (7% for both). One serious AE at least possibly related to treatment was seen: grade 3 febrile neutropenia. Frequent AEs (>5%) considered at least possibly related to CFI-400945 were: nausea and anorexia (both 20%), fatigue and dysgeusia (both 13%), headache, dizziness, maculo-papular rash, back pain and gastroesophageal reflux disease (all 7%), Frequent AEs (>5%) considered at least possibly related to durvalumab were: anorexia (13%), arthritis, fatigue, back pain, pain in extremity and hot flashes (all 7%). No responses were observed in 14 evaluable patients during stage 1, therefore the pre-specified threshold for anti-tumor activity to proceed to stage 2 was not met. Disease control rate (complete response, partial response or stable disease >16 weeks in duration) was 7% (1/14). Conclusions: CFI-400945 and durvalumab was well tolerated, with no unexpected toxicities of the combination. However, in this heavily pretreated and PD-L1 unselected TNBC population, no responses were observed and the pre-specified threshold for anti-tumor activity for stage 2 was not met. The trial was closed to accrual on April 26, 2022. Final analysis and correlative analyses are ongoing. Acknowledgements: Coordinated by the CCTG. Funding supported by Astra Zeneca. CFI-400945 provided by Treadwell Therapeutics and durvalumab provided by Astra Zeneca.

Anti-depressant Amitriptyline Augments the Efficacy of Tamoxifen in ER positive breast cancer
Pitta Venkata Prabhakar¹, Arhan D Rao¹, Timilsina Santosh¹, Deepika Singh¹, Ratna Vadlamudi^{1,2}, Virginia Kaklamani³, Manjeet Rao^{1,2}. ¹Greehey Children's Cancer Research Institute, University of Texas Health San Antonio, San Antonio, TX, USA. ²Mays Cancer Center, University of Texas Health San Antonio, San Antonio, TX, USA. ³Department of Medicine, UT Health, San Antonio, USA. Background: Breast cancer (BC) is the most common cancer in women and the leading cause of cancer-related deaths in women worldwide, with 1 out of 8 women being diagnosed with invasive breast cancer during their lifetime. The majority of breast cancer patients (80%) are diagnosed with Estrogen Receptor positive (ER+) breast cancer. The most commonly used treatment option for ER+ Breast cancer is endocrine therapy, such as Tamoxifen(TAM). Although survival of breast cancer patients has dramatically improved with the use of endocrine therapy, acquired resistance and debilitating side effects of treatment became major concerns. Therefore, safer treatment options that effectively suppress cancer progression, reduce treatment associated side effects, and improve efficacy of standard of care therapies are much needed. Repurposing of clinically approved or investigational drugs has become promising alternative approach for treating cancer. Therefore, we tested the repurposing potential of anti-depressant Amitriptyline for the treatment of ER+ breast cancer. Methods: The anti-cancer effect of Amitriptyline was determined in vitro using short and long-term viability, migration, and apoptosis assays. To substantiate the in vitro data, the effect of

Amitriptyline on tumor growth was assessed using orthotopic xenograft model. RNA-seq analysis was performed in Vehicle and Amitriptyline treated breast cancer cells to understand the mechanism of action. Finally, to test whether amitriptyline can sensitize ER+ breast cancer cells to endocrine therapy, we performed cell viability assays after treatment with Amitriptyline and Tamoxifen. Results: Amitriptyline treatment resulted in significant reduction of short term and long term viability, as well as, migration of ER+ BC cells. Furthermore, Amitriptyline treatment significantly increased apoptosis in BC cells. Our RNA-seq analysis revealed that Amitriptyline treatment inhibited important genes involved in cancer growth and survival including E2F signaling, G2/M pathway, and DNA repair pathways. Confirming our in vitro findings, Amitriptyline treatment blocked the growth of ER+ BC growth in pre-clinical orthotopic xenograft model of breast cancer. Importantly, Amitriptyline treatment sensitized ER+ BC to TAM, showing highly synergistic effects. Amitriptyline treatment significantly improved the effects of TAM on cell viability, survival, migration, and apoptosis. Furthermore, Amitriptyline augmented the efficacy of Tamoxifen in TAM resistant BC cells. Conclusion: Our study establishes potential of Amitriptyline as a repurposable drug as safe and robust treatment option for ER+ patients, either as a monotherapy or in combination. We are poised to begin a clinical trial and test the therapeutic efficacy of Amitriptyline for treating breast cancer patients.

Adenoviral vectors have been used extensively for gene therapy. However, efficient infection of cells requires expression of the coxsackie-adenoviral receptor (CAR). Many tumor cells lack adequate expression of CAR and, hence, are not good targets for adenoviral based vectors. We have developed a unique nanoparticle (Epi-039) that can be used to efficiently introduce adenoviral vectors into tumor cells that have low or no CAR expression. We used the CAR-negative 4T1 mammary carcinoma model system, which represents a typical triple-negative breast cancer cell line (ER-, PR-, HER2-) and which is refractory to adenoviral infection to demonstrate effective transduction of an encapsulated oncolytic adenovirus. The adenovirus that was used is called AdAPT-001. This armed oncolytic virus, which is currently in a phase I/II clinical trial called BETA PRIME for the treatment of refractory cancers, expresses a TGFb receptor trap to neutralize the immunosuppressive cytokine, TGF beta. Overexpression of TGF-beta positively correlates with metastasis in breast carcinoma and thus confers a poorer prognosis. In this study, the unique Epi-039 nanoparticle carrying AdAPT-001 not only significantly enhanced the transduction efficiency of AdAPT-001 but also protected it from neutralization by natural antibodies in human whole blood. Accordingly, we demonstrate a significant increase (P value= 0.0029) in the expression of green fluorescent protein (GFP) in CAR-negative 4T1 cells infected with the encapsulated AdAPT-001 adenovirus but not the unencapsulated AdAPT-001 adenovirus. Additional in vivo studies using nanoparticle encapsulated adenoviral vectors including AdAPT-001 to treat breast cancer are underway for rapid translation to the clinic.

Aberrant metabolic reprogramming is known to drive triple negative breast cancer progression and metastasis. The increase in glycolytic flux in cancer cells creates a lactate-rich tumor microenvironment (TME) that is exploited by tumors to their advantage by activating

immunosuppressive cell populations, such as Tregs and MDSCs, that thrive on lactate as a fuel source. Therefore, blockade of lactate export from glycolytic cancer cells while inhibiting lactate entry into suppressive immune cells is a novel therapeutic strategy to treat cancer. Lactate transport in cells is predominantly mediated by MCT1 and MCT4 transporters. We have developed a compound, NGY-091, that is a first-in-class small molecule dual inhibitor of the MCT1 and MCT4 lactate transporters. NGY-091 treatment exhibited a potent in vitro cytotoxicity against breast cancer cells with various levels of MCT1 and MCT4 expressions. The on-target activity of NGY-091 was validated by measuring intracellular and extracellular lactate levels. NGY-091 strongly blocked MCT1 mediated lactate import and lactate export through MCT4 in vitro. Furthermore, a direct in vivo tumor cell killing was evident in human TNBC CDX (MDA MB 231) and PDX models with the treatment of NGY-091. In a syngeneic model of 4T1, we observed a significant reduction in tumor growth and synergistic tumor regression when combined with immune checkpoint blockade therapy. Profiling of lymphoid and myeloid cells in NGY-091 treated tumors by flow cytometry revealed a significant alteration in immune architecture suggesting activation of antitumor immunity. NGY-091 treated tumors induced a profound increase in effector T cell populations, CD8/Treg ratio and tumor-suppressive M1 macrophages while significantly downregulating M2 macrophages. To further investigate if NGY-091 directly alters immune cell activation and functionality in vitro, we treated CD4 T, CD8 T, Tregs and MDSCs in a lactate-rich culture condition mimicking lactate level in the TME. NGY-091 treatment strongly increased effector CD4 and CD8 T cells while significantly reducing suppressive function of Treg and MDSCs in vitro. These findings indicate the direct effect of NGY-091 on immune cell and validate the in vivo observations in 4T1 tumors. Therefore, NGY-091 intervenes two key hallmarks of cancer – metabolism and immunity and provides a novel avenue to therapeutically target aggressive breast cancer.

Introduction:

Metformin is an oral anti-diabetic agent that exhibits direct anti-proliferative effects on pre-clinical models through activation of the AMPK pathway. However, pre-surgical studies of metformin alone among women with operable breast cancer have not consistently shown reductions in tumor proliferation, and adjuvant metformin in women with high-risk operable breast cancer did not improve invasive disease-free survival compared with placebo. Dysregulation of the mevalonate pathway of cholesterol synthesis can also lead to cell proliferation, and inhibition of HMG-CoA reductase by statins can decrease tumor proliferation. There is close interaction between the AMPK and mevalonate pathways, and dual therapy with a statin and metformin might be synergistic to decrease cell proliferation. We evaluated the effect of combination therapy with metformin plus atorvastatin on markers of proliferation (i.e. Ki67 proliferation index) in women with operable breast cancer.

Methods:

We conducted an open-label, single-arm presurgical “window of opportunity” study of metformin plus atorvastatin in non-diabetic women age 21+ years with newly-diagnosed stage 0-III operable breast cancer at Columbia University Irving Medical Center (CUIMC). Enrolled patients received metformin 1500mg oral [p.o.] daily (500mg in the morning/1000mg in the afternoon) and atorvastatin 80mg p.o. nightly for up to 4 weeks before breast surgery. The primary endpoint was change in Ki67 proliferation index from baseline (diagnostic biopsy) to post-treatment (surgical specimen). Secondary endpoints included change in body mass index (BMI), waist and hip circumferences, tumor assessment of AMPK/mTOR signaling and apoptosis, and reduction of fasting markers of the insulin growth factor pathway. Paired t-tests were conducted to assess difference in ln(Ki67) pre- and post-therapy, as well as differences in absolute Ki67, BMI, and waist/hip circumferences pre- and post-therapy, at a level of significance of 0.05.

Results:

Between Nov. 2013 and Jan. 2018, 22 women were enrolled, and two withdrew consent prior to study treatment. Among evaluable participants (n=20), 45% were Hispanic with median age 56 years (range, 33-73) and median baseline BMI 28.4 kg/m² (range, 22.5-45.8). All had hormone receptor-positive (HR+), HER2-negative breast cancer, and 16 (80%) had invasive cancer. Median time on study treatment was 11 days (range, 5-29). Changes in Ki67 and anthropomorphic measures are shown in Table 1. There was no significant change in BMI, waist or hip circumference with study treatment. Among women with available Ki67 measurements (n=11), there was no significant difference in pre- and post-treatment ln(Ki67) (p=0.25). There was a numeric decrease in absolute Ki67, though statistical significance was not reached (p=0.09).

Discussion:

There was a numeric reduction in absolute Ki-67 with presurgical metformin plus atorvastatin in patients with newly diagnosed HR+/HER2- breast cancer, although our analysis was limited by small sample size and statistical significance was not achieved. There was no difference in ln(Ki67) or anthropometric measurements. Analyses of additional tissue and serum biomarkers, including markers of insulin resistance, are ongoing to identify associations with absolute Ki67

Table 1

Variable	Median Pre-Treatment (Range)	Median Post-Treatment (Range)	Mean Change (SD)	p-value
Absolute Ki67 (n=11)	20.6 (0, 80.3)	14.0 (2.6, 60.2)	-6.5 (11.3)	0.09
ln(Ki67) (n=11)	3.0 (1.0, 4.4)	2.4 (4.1, 2.6)	-0.4 (1.0)	0.25
BMI, kg/m ²	28.4 (22.5, 45.8)	29.0 (22.3, 46.6)	-0.1 (0.6)	0.39
Waist circumference (cm)	91.4 (66.0, 123.0)	91.4 (66.0, 123.0)	-0.1 (0.9)	0.62
Hip circumference (cm)	106.3 (90.0, 147.0)	105.4 (90.0, 147.0)	-0.1 (0.6)	0.53

BACKGROUND Relative dose intensity (RDI) of chemotherapy (CT) < 85% significantly decrease therapy efficiency (including overall survival) in early breast cancer (BC) patients (pts). Pathological complete response (pCR) reflects better outcomes and correlates with the RDI of neoadjuvant CT (NAC). Neutropenia is the most common AE leading to RDI drop. Recent studies demonstrate that G-CSF could switch immunosuppressive tumor microenvironment via neutrophils plasticity. In early BC neutrophils, can mediated antitumor responses by direct killing of tumor cells and by participating in cellular networks that mediate antitumor resistance. Primary G-CSF prophylaxis (PP) with prolonged G-CSF may be an option for optimal therapy results. This multicenter prospective study was designed to evaluate the RDI and treatment outcomes of cytotoxic therapy under PP by empegfilgrastim (E) in pts with high-risk early BC. **METHODS** High-risk BC pts (n=195) with II-III stages are getting NAC of the following regimens: 4 dose dense doxorubicin/cyclophosphamide with E followed by 12 weekly paclitaxel/carboplatin (4ddAC+E/12P+carbo) for triple negative (TN) pts or 4 dose dense doxorubicin/cyclophosphamide with E followed by 4 dose dense paclitaxel with E (4ddAC+E/4ddP+E) for HR+HER2- pts and 6 docetaxel/carboplatin trastuzumab/pertuzumab (TCHP+E) for HER2+ pts. RDI of therapy course was primary endpoint and presented here for pts who completed the planned regimen. For each agent, the planned and actual dose intensity were calculated by dividing the total cumulative dose by treatment duration in days. RDI was calculated for each single agent in CT regimen and for CT regimen in total. These descriptive analyses were performed for the whole CT regimen. The secondary endpoint: pCR (ypT0/is, ypN0) is also presented here. ClinicalTrials.gov No NCT04905329. **RESULTS** At the data cut-off (April'2022) 111 pts with BC (HER2+ (n=56); HR+ HER2- (n=17); TN (n=38)) underwent ≥ 1 cycle of NAC with E. The planned CT course completed in 67 (60%) BC pts. RDI≥85% were fixed in 56 (84%) pts: 93% RDI for 4ddAC+E/4ddP+E regimen; 90,3% RDI for 6TCHP+E; 94,1% RDI for 4ddAC+E/12P+carbo. Preliminary, in HER2+ BC pts pCR rate exceeds KRISTINE trial data despite a more enriched pts' population with poor prognosis (36% pts with IIIB - III C and 65% pts with IIA-III A stages per TNM v.8): 93,3% (15 pts HR-) and 70,4% (34 pts

HR+). In TNBC pts pCR rate is 56% (9 pts) according to historical control. In HR+ HER2- BC – pCR rate is 20% (10/17 pts under surgery). Neutropenia as a reason of RDI drop was in 1 (0,9%) case in HER2+BC pt. The mature data are awaited. CONCLUSION PP with E allows to maintain RDI efficiently and safely in high-risk recurrence pts populations. High pCR rate under E in HER2+ BC pts focused on further confirmation with translational research. KEY WORDS: empegfilgrastim, neutropenia, pCR, dose intensity, G-CSF, breast carcinoma, neoadjuvant therapy

Role of tumor cell-derived lactic acid in the PD-1/PD-L1 blockade resistant tumor

Presenting Author(s) and Co-Author(s):

Seung-Oe Lim, *n/a, Assistant Professor - Purdue University*
Country: United States

Immune checkpoint blockade therapy targeting the PD-1/PD-L1 axis (PD-1/PD-L1 blockade therapy) has shown remarkable clinical impact in multiple cancer types. Despite the recent success of PD-1/PD-L1 blockade therapy, acquired resistance, emerging as late relapses or recurrences, has been reported in the long-term follow-up of clinical trials. The altered metabolic activity of cancer cells shapes the anti-tumor immune response by affecting the activity of immune cells. In particular, glycolytic metabolites, such as glucose and lactate, regulate T cell proliferation and function. However, it remains mostly unknown how the altered metabolic activity of cancer cells impacts the therapeutic efficacy of, and resistance to, PD-1/PD-L1 blockade therapy. Here, we found that increased lactic acid functionally contributes to an immunosuppressive tumor microenvironment in the PD-1/PD-L1 blockade therapy resistant tumors through decreasing PD-L1 and PD-L1 antibody interaction. Furthermore, combining PD-L1 targeting with our PD-L1-antibody-drug conjugate (ADC) and reducing lactic acid by an MCT-1 inhibitor, AZD3965, within the tumor microenvironment effectively eradicated the resistant tumor cells. Together, our results suggest a new combination treatment strategy to improve the therapeutic efficacy of immune checkpoint blockade therapies

Background: Despite that dual anti-HER2 therapy (Trastuzumab and Pertuzumab, TP) is one of the commonly used regimens for neoadjuvant treatment of HER2-positive breast cancer, previous studies showed that its pCR rate rarely exceeds 63%. Additionally, it is associated with higher risk of cardiac adverse events. TQB2440, a biosimilar of pertuzumab, with strong affinity and specificity, can effectively bind with HER2 epitope. In the PDX mouse model, TQB2440 showed promising biological activity and minimal cardiotoxicity. In this study, we designed a single-arm trial of dual anti-HER2 therapy (TQB2440 and trastuzumab, TT) plus docetaxel in neoadjuvant therapy of HER2 positive breast cancer. We aimed to examine the

efficacy and safety of TQB2440 and study whether new dual anti-HER2 therapy (TT) can boost pCR rate in the neoadjuvant treatment. The cardiotoxicity and other adverse reactions were closely monitored. Methods: Upon approval by the Medical Ethics Committee of Xijing Hospital, patients with HR negative HER2-positive breast cancer (cT2-3/N0-1/M0) receiving neoadjuvant therapy were enrolled. The patients were treated with docetaxel 75 mg/m², trastuzumab 8 mg/kg loading, then 6 mg/kg, TQB2440 840 mg loading, then 420 mg, iv, q3w for 4 cycles, with strict monitoring of cardiotoxicity. The primary endpoint was pCR rate, and secondary endpoint was cardiotoxicity. Results: From April 2021 to February 2022, a total of 28 patients were recruited. Among the 28 patients with a median age of 52 (28-74), 12 patients had positive lymph node status. Overall, the pCR rate was 67.9% (19/28). The pCR rate was higher than that in the NeoSphere trial (pCR 63.2%) and the PEONY study (pCR 52.5%). The lymph-positive tumor achieved a higher pCR rate than lymph-negative tumor (70.8% vs 52.3%, p = .019). Multivariate regression analysis showed that for participants aged 50 or above, HER2 3+ (IHC) showed a statistically significant positive influence on pCR rate. The common adverse reactions of grade \geq 3 were leukopenia (46.4%), neutropenia (35.7%), asthenia (3.6%), and peripheral sensory neuropathy (2.3%). Left ventricular insufficiency was detected in 1 patient, and no cardiotoxic events higher than grade 2 occurred during the neoadjuvant therapy. There was no treatment-related death. Conclusion: TQB2440 and trastuzumab plus docetaxel is a feasible and effective neoadjuvant therapy for early-stage HR negative HER2-positive breast cancer, showing high pCR rate and acceptable cardiotoxicity. These results support a further random controlled trial testing for dual anti-HER2 therapy using TQB2440 in neoadjuvant or adjuvant therapy of HER2 positive breast cancer.

Country: United States

There are several growing evidences of anticancer complementary and alternative medicines worldwide. *Trigonella foenum graecum* (Fenugreek) is traditionally applied to treat several disorders such as diabetes, inflammation, and gastrointestinal ailments. Previously, we reported that Fenugreek has anticancer properties against liver cancer due to its active beneficial chemical constituents. Herein, Fenugreek-loaded poly (l-lactic-co-glycolic acid) (PLGA) hyaluronic acid (HA)-coated nanoparticles have been formulated to improve and enhance the anticancer potential of Fenugreek against human breast cancer cell lines. The cytotoxic effects, physicochemical characterization in vitro and pharmacodynamic study of optimized formulation of the FCE-loaded (PLGA)-(HA)-coated nanoparticles in vivo were investigated in (ER-positive) and (triple-negative), breast cancer cell lines, ZR-75-1 and MDA-MB-231, respectively. The particle size, PDI, zeta potential, entrapment efficiency, and loading capacity of FCE-loaded nanoparticles were 188.5 ± 3.1 d.nm, 0.198 ± 0.114 , -0.118 mV, $38.41 \pm 1.4\%$, and $6.37 \pm 1.08\%$, respectively. The in vitro cytotoxicity study of FCE-loaded NPs by Wst-1 proliferation assay on both tested breast cancer cell lines showed an anti-cancer activity after 48 h of treatment in a dose-dependent manner. Furthermore, the anticancer effect of FCE-loaded nanoparticles was examined by the morphological cell changes, histone release, caspase-3 activity, and modulation of the oncogenic signal pathways of m-tor, β -catenin, cyclin D-1 and STAT3 that are constitutively active in wide variety of breast cancer cell lines which in turn could be important as therapeutic targets in breast cancer. 66 μ g/mL FCE-loaded PLGA nanoparticles induced 67.3% apoptosis in both tested cell lines after 48 h that was associated with increased expression of caspase 3, Bax, Bak, p53, and cell cycle arrest at G0/G1 in a time-and dose-dependent manner compared to unloaded-nanoparticles or untreated cells. Moreover, there were significant inhibition in m-tor, β -catenin, cyclin-D1, and STAT3 expression levels in both tested cell lines compared to un-loaded-nanoparticles or untreated cells. All in all, our results showed that the formulated FCE-loaded (PLGA)-(HA)-coated nanoparticles induced apoptosis in both ER-positive and triple-negative breast cancer cell lines respectively by increase the expression of pro-apoptotic genes and inhibited several oncogenic genes that might hold a promise for the complementary therapy for human breast cancer.

Breast cancer is the most frequent malignant tumor among women and is the leading cause of death from cancer worldwide. In 2020, 90,222 deaths from breast cancer were reported in México. However, cancer cells resistant to antineoplastic drugs are frequent, which compromises the patient's survival. For this reason, in oncology, it is essential to search for new sources of anticancer compounds. Endophytic fungi are currently considered potential reservoirs for compounds with antitumor activity. More than 100 different classes of secondary metabolites have been reported with activity against different types of cancer, including breast cancer. Therefore, the objective of this study was to evaluate the activity of methanol extracts of endophytic fungi isolated from *Lophocereus marginatus* against the MCF-7 breast cancer cell line, using as controls the MA-104 cell line human peripheral blood mononuclear cells. Fungal strains were isolated from stems of *L. marginatus* and molecularly identified from ribosomal DNA internal transcript spacer region sequencing. Extraction of the secondary metabolites was performed from the maceration of mycelium fungus in methanol. The solvent was removed with a rotary evaporator and the extract was reconstituted with dimethyl sulfoxide (DMSO). Next, cells were incubated with the extract at concentrations ranging from 31.25 µg/mL to 250 µg/mL for 48 h at 37 °C and 5% CO₂. Growth inhibition was assessed by the 3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide reduction assay, using 1% DMSO was used as a negative control. IC₅₀ values and selectivity indexes (SI) were then calculated. It was found that tumor

cells growth inhibition by the extracts increased in a concentration-dependent manner. *A. versicolor* PME-H005 strain extract showed the highest antitumor activity, with up to 58.9% growth inhibition at 250 µg/mL and IC50 value of 95.21 ± 1 µg/mL against MCF-7 cells. The highest SI was obtained with MCF-7 cells with 2.77, as compared with normal PBMC with an IC50 of 264 ± 1.5 µg/mL. In addition, the *M. anisopliae* PME-H007 strain presented a high SI value of 2.1 and an IC50 of 245.9 ± 1.9 µg/mL, using the MCF-7 cell line. This study shows the potential of the endophytic fungus *A. versicolor* PME-H005 isolated from *L. marginatus* for production of secondary metabolites with antitumor activity against MCF-7 cells.

Background: SERENA-1 (NCT03616587) is a Phase 1, multi-part, open-label study of camizestrant in women with ER+/HER2- advanced breast cancer. Parts A/B and C/D (escalation/expansion) examined camizestrant as monotherapy and in combination with palbociclib respectively and have been presented previously.^{1,2} Here we present data from parts G/H which examined camizestrant in combination with abemaciclib. Methods: The primary objective was to determine the safety and tolerability of camizestrant 75 mg once daily (QD) in combination with abemaciclib 150 mg twice daily (BID). Secondary objectives included investigation of anti-tumor response and pharmacokinetics (PK). Participants were previously treated women of any menopausal status (pre-menopausal women received this combination alongside ongoing ovarian function suppressors). Prior treatment with ≤ 2 lines of chemotherapy in the advanced setting was permitted. There was no limit on the number of lines of prior endocrine treatment in the advanced setting; previous treatment with CDK4/6 inhibitors

(CDK4/6i) and fulvestrant was permitted. Results: As of 1st June 2022, 24 patients had received camizestrant in combination with abemaciclib with a median 7.7 month follow up. Tolerability of the combination of camizestrant and abemaciclib was consistent with that of each drug individually. No patient required camizestrant dose reduction. All camizestrant-related heart rate decreases were Grade 1 (asymptomatic). PK data for camizestrant in combination with abemaciclib were consistent with camizestrant as monotherapy and published abemaciclib steady-state PK data, indicating no clinically relevant drug-drug interaction. In these heavily pre-treated patients (46% prior chemotherapy, 75% prior CDK4/6i, 54% prior fulvestrant; all in the advanced disease setting) and of whom 67% had visceral metastases, the objective response rate was 5/19 (26.3%), the clinical benefit rate at 24 weeks was 16/24 (66.7%) and the median progression-free survival had not been reached, with 8/24 patients experiencing a progression event. These data support the use of camizestrant 75 mg QD combined with the approved abemaciclib dose. Conclusions: Camizestrant 75 mg QD in combination with abemaciclib 150 mg BID was well tolerated with encouraging clinical activity. The inclusion of this regimen in the ongoing Phase 3, SERENA-6 trial 3, of camizestrant combined with CDK4/6i versus an aromatase inhibitor, will further clarify the role of this combination in the treatment of patients with ER+/HER2- advanced breast cancer with tumors expressing ESR1 mutations. Loss of NF1 plays a major role as an oncogenic driver in many cancer types and can be found in up to 33% of all breast cancers (BC). Loss of NF1 is also a prognostic indicator for increased cancer risk at an earlier age, poorer outcomes, and therapeutic resistance. In addition, certain NF1 genotypes may increase cancer risks, while others do not. NF1 is largely perceived as a classic Ras-opathy syndrome due to inactivating mutations in neurofibromin affecting RAS-MAPK signaling. However, recently it has been shown that NF1 binds estrogen receptor alpha (ER) and acts as a transcriptional corepressor. This helps explain some BC findings specifically in ER+ BC. In this model, specific changes to NF1 that abrogate ER signaling lead to Ras driven tumor resistance to endocrine therapy as cells are able to grow in low levels of E2 (and tamoxifen). Hence, NF1-mutant tumors represent a distinct molecular class in need of new therapeutics. A preclinical mammalian model of NF1 loss and BC would be helpful in both evaluating the role of NF1/ER transcriptional signaling in BC, evaluating the role of immune cells in BC, and testing therapeutics. Novel Nf1 rat models have a very robust ER+ BC phenotype, therefore more closely recapitulating clinical tumors compared to other preclinical models. Our models include a pathogenic patient missense allele c.3827G>A, p.R1276Q (knockin or KI), associated in humans with familial spinal NF1 and malignancy, as well as a 14 base pair deletion c.3661_3674del, p.P1220fs*1223 (knockout or KO) model. Heterozygous (het) Nf1 females develop mammary gland adenocarcinoma spontaneously, but het KO rats develop multiple tumors with earlier onset while het KI rats tend to develop fewer tumors with later onset. Tumors are generally Grade 2 and do not differ by genotype. By 16 weeks, 70% of

KO females have developed at least one tumor whereas only 20% of KI rats and 2% of WT rats have developed tumors. This impacts survival as by 1 year 76% of KI females survive yet only 58% of KO females survive. However, by 2 years, both alleles have 54% survival. The divergence in phenotype between patient and null alleles may be due to residual function of R1276Q missense NF1 protein. A more in-depth analysis indicates that mammary tumor formation likely begins relatively early, as we find evidence of aberrant morphology and hyperplasia prior to the formation of palpable tumors. Interestingly, we find histological evidence of lung metastases and expression of breast markers GCDFP15, MGA, and CEA in the lung. Again, we see allele-specific effects in that KO rats develop lung tumors earlier than KI rats. While het male rats also develop mammary tumors at low rates, they experience longer survival times (76% of KO males survive 1 year and 98% of KI males survive 1 year) and males also develop tumors in other locations. Using single nuclei RNASeq to characterize the transcriptional profile of the mammary tumors, we find allele-specific effects beyond repression of Ras activity that drive aggressive tumor development. We identified different tumor cell populations (2 epithelial cell populations, Myeloid cells, B cells, T cells, Basal mammary cells, and WT specific cells) and identified different pathways altered due to the loss of Nf1 including Ephrin B signaling, Cyclin and Cell Cycle signaling, and Glycolysis signaling. Our overall goal is to characterize the phenotype of these rat models in terms of histopathology, Ras signaling, hormone signaling, immune components, and targeted drug response and compare/contrast them with what is known regarding patients with somatic or germline inactivation of NF1 and breast cancer. Ultimately, this will provide better prognostic predictions for patients and better therapeutic options for treatment.

Despite many advances in cancer treatment, metastatic disease is estimated to be responsible for 90% of all cancer-related deaths. Current treatments for metastatic disease target various aspects of carcinogenesis but not specifically the metastatic process, representing a major unmet clinical need. MicroRNA-10b, a small non-coding RNA, offers tremendous potential as a treatment target for metastatic disease. It is implicated in invasion, migration, and viability of metastatic cells across a variety of cancer types, and it is upregulated in metastases compared to their matched primary tumor, establishing miR-10b as a potential treatment target unique to metastatic niche. We have previously developed a therapeutic targeting miR-10b in metastases and tested it in murine models of metastatic breast cancer. This therapeutic, consisting of an anti-miR-10b antisense oligonucleotide conjugated to iron oxide-based nanoparticles, prevents metastasis and eradicates pre-existing metastases in murine breast cancer models. With an outlook to clinical translation of our approach, we seek to test our therapeutic strategy in larger animal models. Feline mammary carcinomas are considered by most to be the best large animal model for human breast cancer due to similarities such as relative age of onset, histopathology, metastatic patterns, and treatment response. To support the use of this model with our therapeutic, we investigated the characteristics of miR-10b expression in spontaneous metastatic breast cancer in companion cats. Archival blocks of matched primary tumors and metastatic lymph nodes from companion cats diagnosed with mammary carcinoma (n=9, 44%TNBC, 56%HER2+) were obtained from the tissue bank of the Michigan State University (MSU) Veterinary Diagnostic Laboratory (VDL). Tissues were analyzed for miR-10b and its target HOXD10 expression using qRT-PCR and in situ hybridization. qRT-PCR revealed that miR-10b expression was significantly upregulated in 55.5% of lymph node metastases compared to their matched primary tumor, mirroring findings in human metastatic cancer. This was validated by qRT-PCR for HOXD10 gene expression (a direct target of miR-10b), which was significantly downregulated in these metastases compared to their matched primary tumor. In situ hybridization demonstrated that miR-10b expression was increased at the invasive edge of tumors and in actively invading cells, suggesting miR-10b plays a similar role in invasion in

feline breast cancer as it does in human breast cancer. Altogether, these findings support the use of feline mammary carcinomas as a model of human breast cancer and as an excellent candidate for treatment with our therapeutic.

Breast cancer (BC) is a heterogeneous disease comprising different clinical, histopathological, and molecular subtypes. Triple negative breast cancer (TNBC) is among the most aggressive clinical manifestations of breast cancer (BC), and represents a significant clinical challenge to the effective treatment of early metastatic and treatment-refractory disease because of its poor outcomes. Therefore, there exists a need to develop pre-clinical models that retain the characteristics of the original TNBC tumor—e.g., PDX tumor models—to better understand the mechanisms of drug resistance in metastatic TNBC and to effectively evaluate the effects of anti-cancer drugs on patients with this disease. Furthermore, quantitative changes in cellular element signatures, which indicate levels of enzymatic activity, are emerging new biomarkers for cancer in the clinic, but are of yet systematically understudied in tumor samples from breast cancer patients or/and PDX models of these tumors. Due to limitations in current cellular element signature quantitation profiles, there also exists a need to investigate further. Seven samples of advanced BC patient pleural effusion were obtained from Northwestern Memorial Hospital to establish a PDX tumor model in immunodeficient NSG female mice using breast fat pad xenografting and to develop derived 3D spheroid cultures for anti-cancer drug evaluation. To authenticate, STR profiling against with original patient tumor DNA was conducted. Five developed BC PDX tumor models were shown by pathology to have highly heterogeneous characteristics and the metastatic features of the origin patient tumor. Liver and lung metastases were observed in breast fat pad xenografted PDX tumor mice. 3D tumor spheroid cultures were successfully established from original BC pleural effusion or/and PDX tumor

cultures. Using the newly developed, highly sensitive, and reliable Wash-Free Inductively Coupled Plasma Mass Spectrometry (WF ICP-MS) method, we evaluated the inorganic phenotypes from samples of breast cancer patient tumor tissue and of the established PDX tumor to quantify the mobile elements (Na, K, and Ca) and less mobile elements (P, Mg, Mn, Fe, Cu, and Zn) simultaneously within the same sample. The data was collected for further analysis of breast cancer inorganic signatures from normal and tumor cells. Our results suggested that BC 3D spheroid cultures and PDX tumor models could serve as models to further study the mechanisms of MBC and serve as promising tools for in vivo and in vitro quick testing and mechanistic studies of novel antitumor drugs respectively. Identifying quantitative elemental profiles is fundamental to understanding the pathologies of various metal-related cancers and thus opens up new opportunities for disease management and therapeutic intervention

Human breast cancer (BRCA) shows tremendous genomic, gene expression, clinical, and phenotypic heterogeneity. Known driver gene alterations can only explain a portion of this heterogeneity, some of which likely arise from variation in the target cell for transformation, in addition to incompletely understood gene copy number and epigenetic alterations. These factors are difficult to identify with certainty using human patient samples due to widely varying germline genetic backgrounds, thousands of gene copy and epigenetic changes per sample, and, unknown target cell transformation. Activating mutations in the p110 α catalytic subunit of PI3K are one of the most common genetic alterations in human BRCA. Here, we report results from two Sleeping Beauty (SB) transposon-accelerated mouse models of Pik3ca-mutant

mammary cancer showing how genotype-phenotype correlations can be drawn providing strong candidates for mediating tumor phenotypes, including estrogen-receptor (ER)-dependent gene expression, high cell cycle activity, and immune cell exclusion. We used SB transposon mutagenesis in mice on a Pik3caH1047R activated mutant background to model mammary cancer development in two different mammary epithelial compartments. Both the target cell for mutagenesis and the specific transposon-induced mutations correlated with specific tumor phenotypes, including whether the tumors were ER positive or negative. RNA sequencing of tumors revealed novel genotype-phenotype correlations implicating specific transposon-altered gene drivers of high cell cycle activity, ER-dependent gene expression, and white blood cell exclusion from the tumor. Many transposon-implicated genes are altered at the gene copy number or epigenetic/methylation level in human BRCA, and several were functionally validated. These models provide a source of genetically heterogeneous mouse mammary tumors with a uniform initiating mutation, Pik3caH1047R, useful for identifying cooperating pathways and drivers of specific tumor phenotypes.

Background: Sacituzumab govitecan (SG) is an antibody-drug conjugate targeting Trop2 with an SN-38 payload recently approved for pretreated patients with locally advanced or metastatic triple-negative breast cancer (TNBC). The XenoSTART Patient-Derived Xenograft (XPDX) breast cancer platform includes over 180 models spanning all subtypes characterized with immunohistochemistry (IHC) including ER α , PR, and HER2 protein levels, genomic and transcriptomic sequencing, and in vivo drug sensitivity. To better understand potential benefit of SG in breast cancers other than TNBC and further annotate our platform, Trop2 protein levels were determined in all breast models by IHC. We evaluated tumor growth inhibition by SG in 125 of our XPDX breast models and compared protein expression with agent activity. Methods: 180 breast XPDX models were evaluated for Trop2 expression (AF650, R&D Systems) and 125 were evaluated in vivo against SG; responses were grouped by ER and Trop2 status (+/-). Models were grown subcutaneously in female athymic nude mice and ER+ models supplemented with estradiol. Models were also characterized for PR, HER2, and AR protein expression by IHC and profiled using WES and RNAseq. For in vivo studies, SG was administered by intravenous injection biweekly for two cycles at 1 mg, flat; endpoints included tumor volume and time from treatment initiation with %T/C values and tumor regression reported at study completion; a T/C of $\leq 20\%$ versus control was considered sensitive. Tumor regression (%T/C < 0%) versus Day 0 tumor volume was also reported. Results: 180 breast models were examined by IHC with 75/180 (42%) classified as ER+ and 105/180 (58%) ER-. In ER+ models 38/75 (51%) were Trop2+ and 37/75 (49%) Trop2-, and in ER- models 41/105 (39%) were Trop2+ and 64/105 (61%) Trop2-. In vivo, 20% of ER+/Trop2+ models reported sensitivity to SG, most notably models from patients with acquired resistance to CDK4/6 inhibitors, including STM001 and ST4316B. Interestingly, >70% of ER+/HER2+/Trop2+ models were insensitive to SG, including ST225 and ST340. Of 41 ER-/Trop2+ models, approximately 40% reported some response to SG with 50% of these sensitive to therapy, including ST5954 established from a patient who began treatment with SG following sample collection and is currently in remission. >75% of Trop2- models were insensitive to SG regardless of ER status. Conclusion: We screened 180 models in our XPDX breast cancer platform for Trop2 expression and compared expression with in vivo SG efficacy in 125 models. Analysis is underway to correlate receptor and molecular profiles with SG sensitivity in breast models and we are expanding expression and in vivo testing to additional indications.

Background: Lymphovascular invasion (LVI) is a major route of metastatic dissemination and recent studies indicate its value as an independent prognostic indicator for advanced breast, colorectal, squamous cell, prostate, brain cancers. LVI is a clinicopathological hallmark of inflammatory breast cancer (IBC), an understudied and most lethal breast cancer. IBC is often misdiagnosed due to an absence of a solid mass and its unique presentation of diffuse tumor cell clusters/emboli in the dermal lymphatics. Widely used mammary tumor implantation models coupled with bioluminescence or fluorescence imaging to monitor tumor growth kinetics are ineffective for evaluating spatial and temporal changes in growth and migration patterns of individual tumor cells and clusters within their microenvironmental context. The goal of this study was to develop a murine model to simulate the unique clinicopathological features of IBC patients and to assess both qualitatively and quantitatively local tumor growth, motility, and LVI.

Methods: To specifically facilitate visualization of lymphatic and endothelial vessels along with tumor-vessel interactions, we generated a transgenic nude mice model (ProxTom RFP Nu/Nu) wherein, the mice exhibit red, fluorescent lymphatics [tdTomato fluorophore under control of a Prox1 promoter, which encodes a transcription factor (prospero-related homeobox 1) necessary for the formation and maintenance of lymphatic vessels]. Next, we employed a surgical technique, wherein a window chamber is placed on the dorsal skinfold of mice, which allows for microscopic examination of implanted tumor cells and ability to track dynamic changes of the tumor in its local microenvironment from the time of implantation up to 10 days. Patient-derived IBC or PDX stably transfected to express green, red fluorescent and/or dual tagged with luciferase reporters were transplanted in mice bearing window chambers. Intravital fluorescence microscopy and IVIS imaging were used to serially quantify local tumor growth, motility, length density of lymph and blood vessels, and degree of tumor cell lymphatic invasion over 0-140h. Results: Multichannel optical imaging of the window chamber in the ProxTom RFP Nu/Nu mice demonstrated co-localization of IBC tumor cells and lymphatics. Diffuse tumor cells were observed along regions of lymphatic vessels both proximal and distal to the primary tumor site. However, measurement of blood and lymph vessel density showed no significant change over time. Next, these datasets were used for quantitative analysis by setting the tumor cell channel (GFP) at a threshold to count any clusters greater than 50 pixels² (~0.0013mm²) and with greater than the mean + 2 standard deviations of the background signal while avoiding noise/artifacts from very small regions (<~0.001mm²). This allowed for computation of the total tumor area including average area of each cluster. In addition, the area moment, which describes the basic directional growth pattern of the tumor cells, was quantified by multiplying a cluster distance from the center of mass by its area. Conclusions: A key novel finding from structured illumination imaging data was the observation of LVI occurring early, similar with the clinical presentation in IBC patients. This model was able to effectively track tumor cluster migration. This approach of short-term longitudinal imaging time frame in studying transient or dynamic events of diffuse, collectively migrating tumor cells in the local environment and quantitative analysis of the tumor area, motility and vessel characteristics is an innovation that can be used to investigate other cancer cell types exhibiting LVI. Background: Stable humanized immune mice transplanted with peripheral blood mononuclear cells (PBMcs) derived from breast cancer patients are important models for assessing the tumor immune responses and the tumor immune microenvironment in breast cancer, helping to advance both pre-clinical and clinical research. The PBMcs of breast cancer patients exhibit various differences from those of healthy individuals depending on the stage of cancer progression, subtype, and type of treatment. Recent studies indicate an association of the self-

renewal signatures of T cells with successful generation of a humanized mouse model; however, the optimal T cell signature for the successful generation of a humanized mouse model derived from cancer patient cells is poorly understood. Therefore, we examined the relationship between the signature of T cell subsets, focusing on the self-renewal signatures, in PBMCs derived from patients with breast cancer and the successful generation of a humanized immune mouse model. **Materials and Methods:** We collected PBMCs from 12 patients with breast cancer. All samples were stimulated with interleukin-2 and beads coated with CD3 and CD28 agonist antibodies to expand T cells. After washing, 1×10^7 cells/mouse were intraperitoneally injected into NOD/Shi-scid IL2rgamma (null) (NOG) mice. Transplants were performed on three mice per case. Successful engraftment of immune cells into NOG mice was defined by the presence of human CD45+ cells in one or more mice. Self-renewal signatures of in vitro expanded T cells before injection into NOG mice, including the markers T cell factor-1 (TCF-1), CD45RA, CCR7, CD95, and CXCR3, were determined using flow cytometry, mass cytometry and quantitative RT-PCR. Comparisons between groups of data were evaluated by t-test. **Results:** The success rate of engraftment of immune cells derived from breast cancer patients into NOG mice was 66.7% (8 out of 12 patients). After expansion, the magnitude of the CD8+ stem cell memory subset and the TCF-1 expression level on the CD4+ and CD8+ T cells in the engrafted group were significantly higher than those in non-engrafted group. TCF-1 and CCR7 mRNA levels in the engrafted group were upregulated compared with those in non-engrafted group. The success of engraftment was not associated with clinical characteristics such as breast cancer progression, subtype, or prior chemotherapy treatment. **Conclusion:** The self-renewal signatures of T cells from breast cancer patients were associated with successful engraftment of a humanized mouse model. These results suggest that prior identification of the self-renewal signatures of the T-cell population is of direct relevance to the appropriate design of a pre-clinical model for testing immunotherapies and for elucidating the characteristics of the tumor immune microenvironment.

Establishment of a Breast Cancer Rat Model of Chemotherapy-Induced Cardiotoxicity

Katherine Wallis, Marjan Boerma, Antiño Allen, Joseph Su, Sam Makhoul, Ping-Ching Hsu
Background. Doxorubicin (DOX) is a highly effective chemotherapy agent that is commonly used in combination with precision medicine to treat a wide range of cancers, including 32% of breast cancer (BC) cases. Although the treatment has greatly increased the number of long-term cancer survivors, it has also increased the number of patients experiencing DOX-induced cardiotoxicity (DIC). Animal models have played a vital role in the development of basic and translational breast cancer research in humans, and rat is a preferred animal to study breast cancer for the similarity to human neoplasms and metabolism. However, most studies were established using mouse models, male rats and commonly non-cancer bearing animals. Currently no single universal cancer-bearing female rat model is utilized for DOX-induced chronic cardiotoxicity. The number of cancer cells to be injected to mimic human experience is not known. Large numbers of injected cancer cells grow quickly and kill the animal before the investigators have the time to assess for cardiac toxicity. Here we aimed to identify the minimal number of cancer cell injections to mimic tumor growth of BC patients and to achieve chemotherapy-induced toxicities. Methods. Various numbers (5×10^4 – 1×10^6) of MAT B III

adenocarcinoma cancer cells derived from Fischer 344 (F344) rats were injected in the mammary fat pad of female F344 rats, followed by six intraperitoneal (IP) injections of either DOX (1.25mg/kg per dose) or saline post tumor cell injection. The treatments were administered on day 4 from cell injection, and every third day after for a total of six injections. Echocardiography (Vevo 3100, VisualSonics) was conducted before and after the end of chemotherapy. Results. Tumor burden reduced significantly among rats treated with DOX compared with the saline group. In the Kaplan-Meier survival curve, an injection of 5×10^4 cancer cells was associated with tumor growth but the tumor burden was low enough to allow long-term follow-up of both DOX and saline treated rats and assess signs of cardiotoxicity. At 4 days after the final DOX administration, increased left ventricular ejection fraction and fractional shortening in the absence of increased stroke volume were an indication of adverse cardiac effects in the DOX animals but not the saline-treated rats. Plasma was collected from the animals to be subjected to metabolomics testing so that a preliminary assessment of metabolites associated with DIC could be gathered. Conclusion. We have established a breast cancer rat model in which DIC can be studied. Research in this model can aid in identifying mechanisms of DIC and testing novel interventions.

Invasive breast carcinoma is a combination of heterogeneous diseases with distinct molecular and clinical features. Some subsets of breast cancer present major clinical challenges, including triple-negative, metastatic/recurrent disease and rare breast histologies. Previously, we developed a unique resource of 37 hard-to-treat breast cancer patient-derived xenografts (PDX). This set included mainly triple negative breast cancer (TNBC) patients that presented poor response to neoadjuvant chemotherapies (Savage et al. 2020 - PMID: 32546838). PDXs accurately reproduce the molecular heterogeneity of the primary tumors and show that multi-

drug chemoresistance was retained upon xenotransplantation. Here, we present the characterization of PDX 3-dimensional cultures organoids (8) and PDX derived epithelial cell lines (11). Using single-cell RNAseq we showed that an organoid cultured for several passages (P8) maintained the heterogeneity of the matched PDX. Although in different proportions, all cancer cell populations found in the PDX were retained in matched organoids supporting that organoids are suitable models that recapitulates the tumor heterogeneity and are therefore a suitable model for drug screening. Among our new PDXs models (30), we have developed four PDXs from rare metaplastic breast cancers (MpBC), an aggressive subtype of breast cancer that present the poorest response to standard of care chemotherapy. We also developed one male breast cancer PDX with matched organoid. Omic analysis on our pre-clinical models and patient primary tumor and metastasis will inform development of therapeutic opportunities. This molecular information will guide selection of compounds that will be validated using our high throughput organoid drug screening pipeline. This will allow rapid screens of thousands of approved drugs, enhancing drug repurposing with potential for rapid clinical translation. The combined use of 3D tumor organoids and PDXs, is an important opportunity poised to transform identification of new therapeutic options for hard-to-treat lethal breast cancers.

Background Most breast cancers (~85%) are of no special histologic subtype (NST), and the most common special subtype is invasive lobular cancer (ILC). ILC accounts for 10-15% of all breast cancers, and there will be ~40,000 new cases in 2022 in the US alone. If considered an "independent" cancer type, ILC is the 6th most common cancer in women. The pathognomonic feature of ILC is loss of E-cadherin (CDH1). The resulting lack of adherens junctions causes the unique single-file growth pattern of discohesive ILC cells, which decreases the ability for detection by mammography, in turn resulting in late detection and hence larger tumors. Although ILCs show better prognostic factors than NST, patients with ILC have worse long-term outcome, which is not well understood. Additionally, ILC has historically been understudied, which is in part due to lack of appropriate research models. For example, the Cancer Cell Line

Encyclopedia (CCLE) contains 54 NST cell lines but only 2 ILC cell lines, and only a limited number of patient-derived xenograft (PDX) models are evident in the published literature. There is a critical need for additional in vitro and in vivo models to study ILC biology, as well as to test targeted therapies. ILC PDX and patient derived xenograft organoids (PDXO) are particularly valuable tools to enable target validation and assess drug treatment response. Methods To identify and validate new ILC PDX models, we used Champions Oncology's Lumin Bioinformatics to screen Champions' collection of breast cancer models (n=126) for PDX harboring CDH1 mutation and/or low E-cadherin expression. We performed histological analysis on selected PDX models including H&E staining, and immunohistochemical assessment of E-cadherin, P120, estrogen receptor, progesterone receptor, HER2 and Ki67. Models with 2+ HER2 staining were assessed by FISH. All staining was interpreted by a certified breast pathologist. PDX tumor tissue was further used to develop PDXO models. Results Using Champions Oncology's Lumin tool, we identified 10 putative ILC PDX models based upon CDH1 mutation, low E-cadherin mRNA expression, or clinical annotation of ILC (Table 1). Of the 10 PDX models analyzed, two cases were clinically annotated as ILC, while the remainder were classified as 'carcinoma' (n=5) or as NST (n=3). Histologic analysis revealed loss of E-cadherin and cytoplasmic P120 (lobular pattern) in 8/10 models assessed, and pathologic assessment confirmed these as having a lobular histology. IHC analysis classified these PDXs as 5 TNBC and 5 ER+ tumors, with none showing amplification of HER2 by FISH. All tumors demonstrated high (35%, n=1) or very high (>55%, n=9) Ki67 proliferation marker levels. We further developed PDXOs from one PDX model as proof of concept, and the resulting organoid demonstrated classic 'grape-like' ILC morphology. Conclusion Our study demonstrates how existing PDX banks with in-depth multi-omic and pathology analyses can be interrogated to identify models of unique histological and molecular subtypes of breast cancer. Of the PDX models selected from Champions Oncology's breast cancer cohort, 7 models were classified as ILC either through re-classification from NST/carcinoma to ILC or confirmation of ILC histology. In addition, 1 PDX was re-classified as mixed type. Some of these models are ER+/HER- and thus have the classic molecular features of ILC. Our collaborative omics guided approach allows for reclassification of PDX models to increase available research models for unique breast cancer subtypes such as ILC which in turn will enhance translational research in unique histological subtypes of breast cancer.

Background: Circulating cancer stem cells (cCSCs) are a small aggressive subset of circulating tumor cells with cancer stem cells features: resistance to diverse cancer treatments and the capacity for generating new metastases. Patient-derived xenografts (PDX) are an increasingly accepted tool in oncology, providing biologically meaningful models of many cancer types, and potential platforms for the development of precision oncology approaches. Commonly, mouse models are used for the xenotransplant assessment of potential new therapeutic targets in cancers. However, animal models do not necessarily represent the real world scenario and are costly and time consuming. An attractive alternative to such animal experiments is the chicken chorioallantoic membrane (CAM) assay. CAM assay is increasingly used as a rapid cost-effective in vivo drug-testing platform that recapitulates many aspects of human cancers. Methods: In this study, primary cultures from circulating cancer stem cells were established using sphere-forming assays. Subsequently, tumorspheres were transplanted onto the CAM membrane of fertilized chicken eggs to form secondary microtumors. Histopathological analyses were performed to confirm that the CAM tumor had the original morphological profile of the patient tumor. Results: We have developed an innovative reliable in vitro platform for cultivation of CSCs from peripheral blood of breast cancer patients. The number of tumorspheres increased significantly with tumor progression. Patients with metastatic disease had statistically more tumorspheres as compared to patients without metastasis (30 vs 10/100 μ l blood, $p < 0.05$). Patients with multiple metastases had more tumorspheres compared to patients with single metastases (60 vs 30/100 μ l blood, $p < 0.05$). The number of tumorspheres was positively correlated with Ki-67, Her2 status and grade score in primary breast tumors. Tumorspheres showed self-renewal, growth potential, invasion and differentiation in vivo. Tumorspheres could be successfully grafted onto the CAM and grafting positively correlated with aggressiveness and proliferation capacity of the primary tumor. These tumors growing on the CAM pathologically closely resembled the primary tumor. Conclusion: The number of tumorspheres cultured from peripheral blood of cancer patients and the success rate of establishing PDX directly reflect the aggressiveness and proliferation capacity of the primary tumor. Our results support the CAM model using cCSC as a valuable alternative for xenotransplant models. It allows the establishment of new PDXs and provides a fast, cost-effective, and easy to use preclinical platform for cancer biology research, new drug development, treatment individualization, and biomarker discovery.

Background: Treatment of estrogen receptor (ER)-positive breast cancer with selective estrogen receptor degraders (SERDs) frequently results in the loss or reduction of ER expression. Whether these changes are due to on-target effects of SERDs degrading ER or arise as a mechanism of tumor resistance with associated changes in cellular phenotypes remains unknown. It is critical to distinguish between these possibilities to accurately assess treatment response and determine the most appropriate subsequent therapy. To this end, we created and conducted molecular analyses on patient-derived organoid cultures from post-treatment tissue in patients receiving neoadjuvant SERD therapy for early-stage ER+ breast cancer in the I-SPY2 Endocrine Optimization Protocol (EOP). Methods: The I-SPY2 EOP study is a prospective, randomized substudy within the I-SPY TRIAL testing the oral SERD amcenestrant alone or in combination with letrozole or abemaciclib in stage 2/3 ER+ Her2-negative breast cancer. Enrollment is ongoing, with patients receiving amcenestrant neoadjuvantly for 6 months until the day before surgery. Tumor tissue is collected at baseline, 3 weeks, and at surgery. Organoids were generated from post-treatment surgical samples. Organoid cultures were optimized based on established methods (Dekkers et al., *Nature Protocols*, 2021) to assess ER levels and activity. Pre- and post-treatment tissue samples were also assessed for ER, PR, Ki67, and GATA3, a luminal marker and transcription factor that is

functionally linked with ER, via immunohistochemistry. Results: In 7 patients with both pre- and post-treatment tissue samples including fresh surgical samples for organoid generation, the ER in baseline tumor tissue was $\geq 90\%$ in all patients, PR ranged from 40-90%, and Ki67 ranged from 5-30%. In post-treatment surgical tissue from these cases, ER ranged from 0-30%, PR from 0-50%, Ki67 from $< 1\%$ -10%, and GATA3 was positive in 5 of 5 cases tested to-date. The creation of organoids from residual disease at surgery was attempted for these 7 patients, with organoids successfully propagated in 5 cases thus far. 3 of 5 organoid cultures were ready for analysis and in all cases strong ER and PR expression in organoids was observed after culture for > 1 month in the absence of amcenestrant. Detailed gene expression profiling (including Mammaprint/Blueprint) and gene set enrichment analyses (GSEA) to assess for intrinsic breast cancer subtype and ER activity in each sample and corresponding organoid culture are in progress and will be reported with the full dataset. Conclusion: Patient-derived organoid culturing of residual disease after neoadjuvant endocrine therapy is feasible. Neoadjuvant treatment with a SERD can render ER and PR low or absent at the time of surgical resection, which does not necessarily imply the presence of endocrine therapy resistant disease. The use of organoids and additional IHC markers (GATA3) demonstrate that receptor negativity may be an indicator of the drug hitting its target, suggesting ER signaling is still intact. In general, patient-derived tumor organoid cultures modeling residual disease states can be a useful adjunct to existing methods used to monitor the effects of neoadjuvant endocrine therapy and is being explored in the I-SPY EOP trial.

Introduction: Breast cancer is one of the most frequently diagnosed cancer in women with a high mortality rate. More than 20 different subtypes of breast cancer are identified. Advancement in patient-derived organoid technology makes it possible to preserve cellular, structural, and tissue microenvironment which mimics the tissue in vivo. Method: We developed patient derived breast organoids both from normal and cancer biopsies recapitulate the structure of breast tissue. Breast biopsies were enzymatically digested to yield a single cell suspension. About 1×10^5 cells were encapsulated in a specialized hydrogel mixture. Immune enhanced breast tumor organoids (iTOs) included 2×10^5 patient matched PMBCs. Results: Histological analyses of the breast organoids shows the characteristics of the breast tissue with well-defined acini in H&E. In tumor organoids acini were somewhat perturbed compared to normal breast organoids. Immuno-fluorescence staining shows the expression of breast biomarkers including EGF receptor 2 (HER2), Progesterone receptor (PR), Estrogen receptor (ER). Zona occludin 1 and 2 and keratin 19 expression in luminal cells and expression of Keratin 14 and P63 in basal cells suggested correct polarization in the organoids. Immunofluorescence staining of (iTOs), with T cell markers including CD3, CD4, and CD8 indicated that immune cells remained viable in the iTOs. Drug responses to Doxorubicin, Paclitaxel and a combination of Doxorubicin-Paclitaxel showed significant inhibition of cell growth in normal and tumor organoids ($p < 0.04$, $n=11$) except for Paclitaxel failed to inhibit tumor cell growth. However, immunotherapy with nivolumab (anti PD-1) showed no significant effect on cell growth. Conclusions: Patient Derived Breast cancer organoids recapitulate the histological features of breast tissue in culture and response to chemotherapies. In the future, patient-derived tumor organoids can provide a platform for personalized medicine.

BACKGROUND: Deregulation of cellular proliferation represents a defining hallmark of cancer. The mechanisms driving aberrant cell cycle progression across different breast cancer subtypes is highly diverse and likely contributes to therapeutic resistance in a variety of contexts. The significance of cell cycle heterogeneity is most clear in the context of metastatic HR+/HER2- breast cancer, wherein acquired and intrinsic resistance to CDK4/6 inhibition represents a significant clinical challenge. However, aberrant cell cycle regulatory networks likely further confound the use of targeted therapies in the context of TNBC. **METHODS AND RESULTS:** We employed unbiased analyses of large number of breast cancer models to decipher the genetic requirements for different CDK and Cyclins which drive proliferation and the significance to response to CDK4/6 inhibitors. Breast cancer cells harbor heterogeneity in the requirement for a given G1/S regulatory CDK or Cyclin. These dependencies are conditioned by the expression of the respective CDK or Cyclin, as well as other gene expression or genetic features present within the tumor that could represent putative biomarkers. In general, conventional dependency for CDK4 and Cyclin D1 is strongest in HR+/HER2- breast cancer models, whereas TNBC exhibits dependency on a variety of different CDK or Cyclin genes. Resistance to CDK4/6 inhibitors in HR+/HER2- breast cancer models, while occurring through a number of different primary mechanisms, functionally deregulates the phosphorylation of RB. However, genetically enforcing RB activation is sufficient to block proliferation, underscoring the opportunity to ameliorate resistance to CDK inhibitory strategies. CRISPR screens in HR+/HER2- and TNBC models are identifying new mediators of sensitivity

and resistance to CDK4/6 inhibitors. Inherently, elevated expression of Cyclin E and p16INK4A are associated with resistance to multiple therapeutic approaches, including CDK4/6 inhibitors, but denote a requirement for CDK2. The cell cycle conditions disparately dependent on CDK4/D1 vs. CDK2/E can be visualized by multispectral imaging and used to direct CDK inhibitor based strategies. CONCLUSIONS: Together these studies illustrate the complex nature of breast cancer cell cycles which can confound therapy. However, understanding of this heterogeneity can create new opportunities for precision approaches targeting CDK/Cyclin-dependence therapeutically.

Cell cycle dysregulation is a prerequisite for cancer formation. However, whether the type of cell cycle dysregulation event a cell incurs during transformation to malignancy influences the type of cancer that evolves or clinical outcome is unknown. In a comprehensive analysis of cell cycle dysregulation in breast cancer patient tumors, we associate mutations in each of four cell cycle checkpoint kinase genes, ATM, CHEK2, ATR and CHEK1, with known tumor characteristics and clinical outcome, and test these associations experimentally using transgenic mice, patient-derived xenografts and breast cancer cell line model systems. Results of this work demonstrate that dysregulation of specific cell cycle checkpoint kinases differently impacts the type of breast cancer that evolves in patients and in experimental model systems, and influences treatment responsiveness and disease progression. For instance, CHEK2 mutations associate preferentially with the incidence of metastatic, premenopausal estrogen receptor (ER)+/HER2- breast cancer in patient data ($p=0.001$) that is resistant to standard frontline therapy ($HR=6.15$, $p=0.01$). These associations appear causal when tested in an immune-competent genetically-engineered mouse model of Chk2 loss, in patient-derived xenograft, and in cell line experiments. On the other hand, ATR mutation by itself is not frequent in ER+/HER2- breast cancer, but co-incident mutation of ATR and TP53 is 2-fold enriched ($p=0.002$) and associates with metastatic progression ($HR=2.01$, $p=0.007$). Concordantly, ATR dysregulation induces metastatic phenotypes in ER+/HER- TP53 mutant,

but not in TP53 wildtype, cell lines. Together, these results systematize the impact of individual cell cycle checkpoint kinases on the evolution of cancer subtypes, and on disease progression. **Statement of Significance** These findings reframe the paradigm of breast cancer classification through the lens of early cell cycle dysregulation events by demonstrating that cell cycle decisions during malignant transformation can direct the type of breast cancer that evolves, how it will respond to treatment, and whether it will metastasize. This work provides rationale for streamlined testing of checkpoint kinase dysregulation to improve precision diagnostics for cancer patients.

Increasing DAXX Expression in ER+ Breast Cancer Cells to Overcome Endocrine Therapy Resistance

Presenting Author(s) and Co-Author(s):

Background: New treatment paradigms are needed to overcome resistance to endocrine therapy (ET; tamoxifen or aromatase inhibitors, AI) in ER+ breast cancer (BC). ET resistance is due to survival of breast cancer stem cells (BCSCs) that contribute to relapse of ER+ BC. Notch signaling drives BCSCs. In order to identify Notch specific biomarkers for the purpose of patient selection for anti-Notch therapy, we conducted a pre-surgical biomarker window study combining ET plus MK-0752, a γ -secretase inhibitor (GSI). Death Associated Protein 6 (DAXX) was discovered to be a novel Notch1 target gene and necessary for GSI-mediated inhibition of BCSCs. Subsequently, we found that DAXX alone was sufficient to inhibit BCSCs. In this current study, we investigated the mechanism by which high DAXX expression inhibited growth of ET resistant ER+ BC cells in vitro and in vivo. Methods: Isogenic ER+ BC cell lines (parental MCF-7, ET resistant MCF-7/5C, parental T47D, and ET resistant T47D-ED) were used. Cells were cultured in estrogen-deprived medium for more than 1 year to mimic AI use. DAXX was depleted using siRNA or overexpressed using a pCMV-expression vector. Bulk cell proliferation was analyzed in response to estrogen depletion or increasing concentrations of 17 β -estradiol. BCSC survival was measured using the mammosphere-forming assay. Tumor onset and burden were measured by injecting DAXX-expressing or depleted mammospheres into mammary fat pads of female, athymic nude mice. Recurrence of an ER+ PDX tumor (BCM 5097) was measured after withdrawal of estrogen. RNA sequencing identified enriched genes and pathways that required DAXX. Based on these results, cell death was assessed using Annexin V/7-AAD flow cytometry, PARP-1 and Caspase 8 cleavage, phosphorylation of JNK, and expression of apoptotic protein regulators, BIM, BAX, Bcl-2, and Bcl-xL. JNK signaling was inhibited using SB600125. Results: Estradiol stimulated proliferation of parental, ER+ MCF-7 and T47D cells. In contrast, estradiol inhibited proliferation of isogenic ET resistant MCF-7/5C and T47D-ED cells in a concentration and ER-dependent manner. Estradiol induced the DAXX protein in both ET sensitive and resistant cells. DAXX was required for BCSC survival in ET sensitive cells. However, once ER+ cells acquired resistance to ET, DAXX was necessary and sufficient to inhibit both bulk cell proliferation and BCSC survival, suggesting that increasing DAXX might be a novel approach to overcome ET resistance. In mice, high DAXX expression significantly inhibited tumor onset and burden of ET resistant tumors compared to DAXX-depleted tumors. Low DAXX expression was significantly associated with recurrence of an ER+

PDX tumor (BCM 5097) after withdrawal of estrogen. RNA sequencing revealed that DAXX activated an anti-neoplastic gene signature, including transcription factors that regulate cell death genes including the Bcl2-family. DAXX was required for high BIM expression and low levels of Bcl-xL. DAXX was necessary and sufficient to induce apoptosis, PARP-1 cleavage, and phosphorylation of JNK in ET resistant cells. A selective JNK inhibitor, SB600125 rescued DAXX-mediated inhibition of ET resistant bulk cell proliferation and BCSC survival, suggesting that high DAXX expression activates JNK signaling to regulate apoptotic proteins to induce cell death of BCSCs-derived from ET resistant BC. Conclusions: Expressing high DAXX levels is a potent method to inhibit ET-resistant BC cell proliferation and BCSC survival. The mechanism by which DAXX inhibits ET-resistant BC is through activation of JNK signaling, regulation of pro-apoptotic genes, and induction of apoptosis. The translational impact of this research is to identify novel agents that can increase DAXX expression and test them pre-clinically and in clinical trials for patients with ET-resistant breast cancer.

CST1 Interaction with RAB1B Modulates Tamoxifen resistance of Breast Cancer by Regulating Autophagy

Background:

Breast cancer is a prominent cause of cancer-related death among women worldwide. Approximately, 70% of breast cancers (BC) are estrogen and progesterone receptor-positive (HR+) at diagnosis. Adjuvant endocrine therapy is a pivotal component of treatment for this type of patient. Tamoxifen (TAM), a widely recommended drug in endocrine therapy, is confronted with a high risk of recurrence after 5 years of treatment among breast cancer patients, which shows big clinical demands. Therefore, it is urgent to find new targets for tamoxifen resistance therapy. Recently, our team found that enhanced expression of Cystatin SN (CST1) was detected in tissues that had undergone tamoxifen treatment appearing to recurrence and metastasis in ER-positive breast cancer patients. However, the molecular mechanisms of modulating tamoxifen resistance remain unknown. Therefore, our team suspected that there might be a correlation between the abnormal expression of CST1 and tamoxifen resistance. To investigate whether CST1 is involved in tamoxifen resistance and its molecular mechanism, we conducted further research. It is critical to elucidate the molecular mechanisms of tamoxifen resistance and to explore a novel effective therapeutic target.

Method:

Enhanced expression of CST1 was confirmed by immunohistochemistry in breast cancer tissue samples and by quantitative real-time PCR in Tamoxifen-resistant cancer cell lines MCF-7R/T47DR. To further investigate the molecular function of CST1, we knockdown its expression in MCF-7R/T47DR cells by transfecting with the lentiviral particles of shCST1 and corresponding negative control (Shanghai Genechem Co., Ltd.) and overexpressed CST1 in MCF-7/T47D cells using over-expressed GST-CST1, over-expressed HA-RAB1B plasmids. The effects of CST1 on cell viability and proliferation in breast cancer cells were detected by cell counting kit-8 and colony formation assays, respectively. The interaction between CST1 and RAB1B was validated by Co-immunoprecipitation and Western blot. Autophagosomes were found using transmission electron microscopy (TEM) along with Western blotting to detect the transformation of LC3-I to LC3-II protein (i.e., the LC3-II/LC3-I ratio) and P62 protein levels.

Results:

We found that aberrant expression of Cystatin SN (CST1) was identified in ER-positive breast cancer (BC) cells (Figure 1) and which is crucial in contributing to Tamoxifen resistance (Figure 2). The direct promotion of autophagy by RAPA can facilitate cells to endocrine resistance. And knockdown of CST1 not only suppressed autophagy in Tamoxifen-resistant cells but also attenuated the resistance, which determined the correlation of CST1 with autophagy in BC (Figure 3). Rab1b (Ras-related protein Rab-1B), a membrane protein essential for autophagosome formation, was verified to have interaction with CST1 through Coimmunoprecipitation (CO-IP) experiments (Figure 4). Meanwhile, RAB1B expression was

also reduced by CST1 knockdown in the resistant cells. The interaction between CST1 and RAB1B induces autophagy which decreases Tamoxifen's therapeutic efficacy. Furthermore, rescue experiments suggested that CST1 knockdown-induced sensitization in the efficacy of TAM Therapy and decreased autophagy could be restored via RAB1B overexpression. Conclusions: These results indicate that CST1 interacts with RAB1B to facilitate BC resistant to TAM through regulation of autophagy and CST1 might be a potential therapeutic target to overcome endocrine therapy resistance.

Novel Targeting of Semaphorin 7a-Mediated Survival Signaling in ER+ Breast Cancer

Endocrine receptor-positive (ER+) breast cancers (BC) comprise over 70% of all breast cancers and are the leading cause of BC-related deaths in women. Despite available targeted therapies against ER+ BC, recurrence arises primarily due to the development of endocrine therapy resistance and metastases. Thus, there is an unmet need to identify novel biomarkers for treating ER+ BC patients with metastases. We have identified a neuroimmune molecule, Semaphorin 7a (SEMA7A), as a potential biomarker for endocrine therapy resistance, increased relapse and decreased overall survival in ER+ BC patients. We have also found that SEMA7A promotes tumor growth, angio- and lymphangiogenesis, epithelial-to-mesenchymal transition (EMT), metastasis and endocrine therapy resistance in pre-clinical models. Specifically, we have shown that SEMA7A+ ER+ MCF7 tumors result in lung metastases that are resistant to the endocrine therapy, fulvestrant, in part, via downregulation of ER in vivo -- posing the need to identify novel, druggable targets for SEMA7A+ ER+ BC. SEMA7A is a membrane-bound protein that we have shown can inhibit tumor cell death via integrin-mediated activation of PI3K/Akt pro-survival signaling. Thus, we hypothesized that SEMA7A+ ER+ BC cells may be sensitive to PI3K inhibition in combination with fulvestrant. Our results demonstrate that SEMA7A+ MCF7 cells are sensitive to the combination of fulvestrant and PI3K inhibition by alpelisib, which is FDA approved for ER+ BC patients with activating mutations in PI3K; this combination also inhibited tumor cell growth and decreased tumor sphere formation. In complementary studies, we identified that Single-minded 2s (SIM2s), which is expressed in breast epithelial cells and inhibits EMT, is downregulated SEMA7A+ MCF7 tumors. Additionally, our studies show that while ER-mediated signaling turns on SEMA7A expression prolonged expression of SEMA7A results in downregulation of ER, and the loss of SIM2s causes downregulation of ER expression and upregulation of SEMA7A in MCF7 cells. Further, while SEMA7A-overexpressing (OE) tumor cells exhibit increased tumor-promoting PI3K/Akt survival signaling, we found that SIM2s plays a role in suppression of PI3K/Akt survival signaling. Therefore, we are investigating the interactions between SIM2s, SEMA7A and the survival signaling pathways involved in their crosstalk. Our recent results show that MCF7 SIM2-knockout (KO) cells exhibit increased SEMA7A promoter activity, SEMA7A expression, activation of Akt signaling, EMT phenotypes and decreased ER expression. Also, addition of exogenous SEMA7A protein reduces SIM2s expression and promoter activity. Since SIM2s correlates with inhibition of PI3K/Akt signaling and decreased SEMA7A, and SEMA7A promotes survival signaling, we are investigating additional therapeutic strategies to prevent

endocrine therapy resistance via direct inhibition of SEMA7A and/or restoration of SIM2s, including inhibition of COX-2 and Akt signaling.

Background: In phase I/II clinical trials, the tamoxifen metabolite Z-endoxifen (ENDX) demonstrated substantial oral bioavailability and promising antitumor activity in endocrine-refractory estrogen-receptor positive breast cancer (ER+ BC) and other solid tumors, with ENDX plasma concentrations reaching as high as 5 μM , a concentration that far exceeds the ER α -targeting nanomolar concentrations. We previously identified protein kinase C beta 1 (PKC β 1), an oncogenic signaling kinase which regulates cell proliferation and tumorigenic transformation, as a novel ENDX receptor. ENDX-bound PKC β 1 (KD: 100 nM) and inhibited PKC β 1 kinase activity (IC50: 357 nM) in vitro, at concentrations achieved in phase I/II ENDX studies. Given the observations that ENDX induces antitumor activity in breast cancers resistant to endocrine therapies, including AIs, tamoxifen and fulvestrant, we postulated that ENDX may impact additional signaling pathways. Therefore, in this study we performed unbiased mass spectrometry to analyze the effects of ENDX on the phosphoproteome and total proteome. Methods: In estrogen unstimulated aromatase-expressing ER+/human epidermal growth factor 2 receptor negative (HER2-) MCF7AC1 breast cancer cells, the effects of ENDX on the phosphoproteome and total proteome were analyzed using ENDX concentrations achieved in tamoxifen treated patients (0.01 and 0.1 μM) and concentrations observed in the ENDX phase I/II trials (5 μM). NetWorKIN and RoKAI prediction tools were utilized to identify the upstream kinases of ENDX downregulated phosphoproteins. In estrogen unstimulated MCF7AC1 as well as in the ER+/HER2- T47D breast cancer cells, the ability of ENDX, tamoxifen, fulvestrant and PKC kinase inhibitor enzastaurin to block insulin or PKC agonist phorbol 12-myristate 13-acetate (PMA)-stimulated AKTSer473 phosphorylation was analyzed by immunoblot (IB) assay. Additionally, ENDX effects on AKTSer473 phosphorylation in the MCF7AC1 xenograft model in vivo was analyzed by IB assay. Further, the effects of PKC β 1 silencing in MCF7AC1 cells and the effects of AKT inhibitor MK-2206 treatment on growth and AKTSer473 phosphorylation in the MCF7AC1 as well as long-term estrogen deprived T47D (T47D-LTED) cell lines were analyzed by cell proliferation and IB assays. Results: In MCF7AC1 cells unstimulated with estrogen, ENDX at 5 μM but not at 0.01 and 0.1 μM concentrations inhibited growth, and induced apoptosis, suggesting an ER α -independent effect. Further, ENDX at 5 μM displayed three-fold greater effects in downregulating the phosphoproteome compared to the other concentrations, with minimal impact on the total proteome. Protein kinase C beta (PKC β) and AKT1 were identified as the prevalent upstream kinases for ENDX downregulated protein phosphorylations. Notably, in estrogen unstimulated MCF7AC1 and T47D cells, ENDX at 5 μM attenuated phosphorylation of AKTSer473 and AKT substrates in vitro in the presence of insulin and in vivo. In MCF7AC1 cells, PMA-induced phosphorylation of PKC β 1 as well as

AKTSer473 and AKT substrate phosphorylations were blocked by ENDX at 5 μ M, with ENDX inducing PKC β 1 protein degradation both in the presence of insulin and PMA. Further, ENDX effects on growth and AKTSer473 phosphorylation were phenocopied by siRNA-mediated PKC β 1 knockdown as well as treatment with the pan-AKT inhibitor, MK-2206. Notably, the potent PKC β 1 kinase inhibitor, enzastaurin, had no effects either on PKC β 1 protein degradation nor on downstream AKT signaling. Conclusion: Taken together, these findings suggest that ENDX may exert anticancer activity via dual effects on blocking ER α as well as by targeting PKC β 1 for degradation, thus suppressing AKT signaling and induction of apoptosis. These preclinical findings will be studied in a planned neoadjuvant trial comparing ENDX with exemestane and ovarian function suppression (EVANGELINE) that will activate in the Fall of 2022.

Background: While estrogen typically promotes the progression of hormone-dependent breast cancer via the activation of estrogen receptor (ER)- α , estrogen-induced suppression of ER+ breast cancer has been clinically observed. Our previous study demonstrated that estrogen increased the percentage of cells expressing IL24, linking to the estrogen-dependent growth inhibition of an ER+ aromatase inhibitor (AI)-resistant tumor (Mori et al. *Cancers*, 2021). To continue our evaluation, we investigated whether progesterone (P4) and dihydrotestosterone (DHT) would affect the growth of this estrogen-suppressive tumor. Methods: An estrogen-suppressive patient-derived xenograft (PDX) model (named GS3) was established from an AI resistant ER+/HER2- brain metastatic breast cancer. E2 (1mg), P4 (10mg), DHT (12.5mg), or placebo pellets were implanted in mice carrying GS3 for in vivo drug efficacy examination. Beside tumor growth response, immunohistochemistry (IHC) and RNA sequencing of PDX specimens were conducted to decipher molecular changes after each treatment. The single-cell RNAseq analysis was further performed to examine gene expression profiles in individual cells. Results: ER α , ER β , Progesterone receptor (PR), and androgen receptor (AR) genes in GS3 are wild-type and are not amplified. Measurements of tumor volume showed that E2, E2+P4, and DHT suppressed the growth of GS3. The Tumor growth was not modulated by P4 treatment. IHC indicated that the number of Ki-67+ cells were decreased after E2, E2+P4, and DHT treatments, but were not changed after P4 treatment. PR+ cells appeared after E2 and E2+P4 treatments, and the AR+ cells increased after DHT treatment. Bulk-RNA sequencing indicated that E2 and E2+P4 treatments resulted in comparable gene expression patterns, while those of placebo and P4-treated tumors were similar. GSEA analysis showed that in E2 treatment, the hallmark estrogen response gene sets were upregulated, and the hallmark G2M checkpoint

gene set was downregulated. However, in DHT treatment, the hallmark interferon alpha/gamma response gene sets and androgen response gene set were upregulated, and the hallmark TNFA signaling via NFkB gene set was downregulated. Single-cell RNA sequencing analysis of Placebo/E2/DHT samples revealed 9 clusters; cells from E2-treated and DHT-treated tumors were placed in different clusters based on principle component analysis of Highly Variable Genes, although both E2 and DHT treatments resulted in tumor regression. DHT promoted cell cycle arrest, but it did not increase IL24 expression. The hallmark oxidative phosphorylation and androgen response gene sets were upregulated in all clusters from DHT-treated tumors. Trajectory analysis of single cells revealed that three major branches associated with clusters selective to the treatments of placebo, E2, and DHT were separated from a common branch which are consist of G2M phase cells. Conclusions: E2 and DHT were effective suppressor of GS3, but not P4. Based on the results from IHC, bulk-RNAseq, and Single-cell RNAseq, the mechanism of DHT-induced tumor regression is different from that by E2. Our results suggest that DHT/E2 could be treatment options for patients with relapsed ER+ AI-resistance breast cancer.

Current data using gene expression and DNA modification profiles yield limited information for evaluating the potential resistance to therapies. Recent studies show that the chromatin landscape is dynamic and defines cell identity and disease status. Thus, changes in open chromatin sites could provide important information on disease progression and identify potential therapeutic targets. The majority of breast cancers express estrogen receptor (ER) and initially respond to endocrine therapies blocking ER activity. However, endocrine therapy resistance (ETR) occurs de novo or follows an initial response. Recent studies have identified new drivers of ETR, such as mTOR and CDK4/6. Therapy with these inhibitors in combination with endocrine therapy have improved patient survival, but the molecular mechanism of ETR is not fully understood and additional therapeutic options for ETR are needed. To investigate the molecular mechanisms of ETR, we established in vitro Long-Term Estrogen Deprivation (LTED) model using multiple human ER-positive breast cancer cell lines. These cells showed differential time-dependent patterns of ESR1 expression upon LTED with ESR1 upregulation in some cell lines and downregulation in others. LTEDs with ESR1 upregulation were sensitive to fulvestrant, while the others were resistant. We analyzed time-course of chromatin landscape transitions during acquisition of ETR in ESR1 up- and downregulated LTEDs cells by Assay for Transposase Accessible Chromatin (ATAC-seq) combined with RNA-seq. Because transcription factors play a primary key role in gene expression and in cell-fate changes including response to therapies, we performed bioinformatic analysis to uncover differential open chromatin sites, select enhancer signatures and identify digital footprints of transcription factors. Unlike ChIP-seq, which identifies binding sites for a known transcription factor, ATAC-seq permits analysis of all sites potentially accessible to the transcriptional machinery and predict occupancy by ~700 different transcription factors at once. With these algorithms, we found that Grainyhead-like 2 (GRHL2) is associated with development of both ESR1 overexpressed and downregulated types of LTEDs. Furthermore, RNA-seq analysis showed that GRHL2 target genes are upregulated in LTEDs. Furthermore, in the METABRIC database, high GRHL2 expression is significantly associated with poor outcome in ER+ breast cancer patients treated with endocrine therapy. Taken together, these data suggest that GRHL2 may

be a novel important transcription factor in endocrine therapy resistant breast cancer regardless of fulvestrant sensitivity. Our studies provide evidence that chromatin landscape analysis, coupled with the transcription factor network algorithm, is capable of identifying novel biomarkers or therapeutic targets, This approach will expand the range of translational research as it is applicable to many cancers and diseases.

Inhibition of FASN as a potential treatment of advanced endocrine therapy-resistant breast cancer

Presenting Author(s) and Co-Author(s):

Henriette Balinda, Ph.D, *Research Scientist - UT Health San Antonio*

Country: United States

INTRODUCTION: The past decade has seen significant advancement in increasing survival in estrogen receptor alpha (ER α) positive breast cancer. The use of selective estrogen receptor down-regulators and modulators (SERMs) (e.g. fulvestrant and tamoxifen), mTOR inhibitors (e.g. everolimus), aromatase inhibitors (AIs), and cyclin-dependent kinase inhibitors (e.g. palbociclib, ribociclib, and abemaciclib) have helped to extend overall survival of breast cancer patients. Unfortunately, resistance to endocrine therapy is a common occurrence and all patients will eventually succumb to their disease. Fatty acid synthase (FASN) is a key enzyme in lipid biosynthesis and is overexpressed in more aggressive and therapy-resistant tumors, including breast cancers. FASN inhibitor, TVB-2640, has been evaluated in multiple tumor cell lines and in a phase 1 clinical study, and showed partial responses in 5 patients and multiple patients with prolonged stable disease (≥ 16 weeks). **METHODS:** We generated tamoxifen- and fulvestrant-resistant MCF7 cells by long term exposure to tamoxifen (MCF7/TamR cells) and fulvestrant (MCF7/FR cells), and palbociclib-resistant (MCF7/RB1Crispr and ZR75/RB1Crispr) cells were generated through CRISPR/Cas9 knockout of the retinoblastoma (RB) gene. We assessed the impact of TVB-3166 inhibitor (and analog of TVB-2640 with slightly lower molecular weight for in vitro use) on proliferation, viability, cell cycle, and apoptosis in these cells. We evaluated the impact of TVB on proliferation and ER α expression in patient derived explants, and tumor growth in xenografts. RNA sequencing of tamoxifen- and fulvestrant-resistant cells was performed to investigate alterations in gene expression. Subcellular localization of ER α was assessed using subcellular fractionations. Palmitoylation and ubiquitination of ER α were assessed by immunoprecipitation. ER α and p-eIF2 α protein levels were analyzed by western blotting after treatment with TVB with or without the addition of palmitate or BAPTA. **RESULTS:** TVB treatment leads to a marked inhibition of proliferation in tamoxifen-, fulvestrant- and palbociclib-resistant cells compared to the parental cells. RNA sequencing of explants of patients with ER α positive disease showed down regulation of ESR1 related genes and genes involved in invasiveness. RNA sequencing of fulvestrant-resistant cells showed that treatment with TVB results in down regulation of EMT and E2F target genes, cholesterol homeostasis genes and mTORC1 signaling. Additionally, TVB significantly inhibited tumor growth in mice and decreased proliferation of primary tumor explants compared to untreated controls. FASN inhibition significantly reduced ER α levels most prominently in endocrine resistant cells and altered its subcellular localization. Furthermore, we showed that the reduction of ER α expression upon TVB treatment is mediated through the induction of endoplasmic reticulum stress in tamoxifen-resistant cells. **CONCLUSION:** Our preclinical data provide evidence that FASN inhibition by TVB-3166 presents a promising therapeutic strategy for treatment of endocrine-resistant breast cancer. Further clinical development of FASN inhibitors for endocrine resistant breast cancer should be considered.

Endocrine therapy can lead to nutrient deprivation by reducing glucose and glutamine uptake and total cellular ATP production. The ability of cells to bypass this metabolic stress is fundamental to how they regulate BC growth and acquire endocrine resistance. Sirtuins (SIRT3) are NAD⁺-dependent deacetylases and regulate a widerange of intracellular processes including metabolism. SIRT3, activated by calorie restriction, modulates mitochondrial adaptation to low energy input. It has a key role in mitochondrial integrity and function, regulating cell survival, death and metabolic pathways, regulating the shift to amino-acid and fatty-acid catabolism. SIRT3 can maintain ROS levels at the appropriate levels for sustaining a proliferative phenotype, preventing apoptosis and promoting carcinogenesis. A role of SIRT3 in epigenetic regulation has also been reported. We used Differential Dependency Network analysis to compare the wiring of the SIRT3 and key metabolism-related genes in matched antiestrogen- sensitive vs. resistant breast cancer (BC) cells, which identified several novel signaling hubs including CDKN2A (p16), linking SIRT3 to cell proliferation. The ability of SIRT3 to sense and respond to changes in energy, coupled with their deacetylase/deacetylase functions, could provide a mechanism for the cell to rewire signaling and maintain a newly acquired drug-resistant phenotype. Using endocrine sensitive (LCC1) and resistant (LCC9) BC cells, we confirmed the higher expression of SIRT3 in LCC9, compared to LCC1 cells. Upregulation of SIRT3 expression within 24 hrs of Fulvestrant (ICI 1 μ M) treatment ($p=0.0176$) in LCC1 was shown, but no effect was observed in LCC9 cells. Conversely, treatment with 17 β -estradiol (E2- 10 nM) did not significantly affect SIRT3 expression in either LCC1 or LCC9 cells. Inhibition of SIRT3 activity, using the LC0296 inhibitor (15 μ M), reduced growth rate in LCC1 and SIRT3-silenced LCC9 cells under treatment with ICI (1 nM and 1 μ M, respectively) ($p < 0.0001$, $p < 0.001$ respectively). Treatment with SIRTUIN 3 inhibitor and ICI induced apoptosis in LCC1 and SIRT3-silenced LCC9 cells compared to the untreated control and ICI only treated

cells ($p < 0.001$). The combination SIRT3 inhibitor ($15 \mu\text{M}$) plus ICI ($0.5 \mu\text{M}$) increased ROS production in LCC9-SIRT3 silenced cells in 24 hours of treatment compared to the untreated control and ICI only treated cells ($p < 0.001$). SIRT3 inhibitor ($15 \mu\text{M}$) decreased LCC1 cell spheroid formation ($p < 0.05$), however it didn't show additive effect to the effect of ICI ($0.5 \mu\text{M}$) in the same conditions. The combination of SIRT3 inhibitor ($15 \mu\text{M}$) and ICI ($1 \mu\text{M}$) reduced the growth of LCC9 SIRT3-silenced cells in detached condition compared to untreated control and ICI only treated cells ($p < 0.001$). The results show that SIRT3 may have a role in Fulvestrant response in BC cells; the mechanism is under investigation in our laboratory.

CONTEXT: Endocrine therapy combined with CDK4/6 inhibitor is the standard frontline treatment for the vast majority of HR+/HER2- metastatic breast cancer (MBC) patients. Despite an overall survival benefit, patients eventually progress and mechanisms of resistance to this combination are not well identified. Non-invasive monitoring of the efficacy of treatment could help into tailoring therapeutic regimen. Extracellular vesicles (EVs) are a group of heterogeneous nanosized bioparticles (30-1000nm), released by almost all cell types - including tumor, platelets, and immune cells - carrying informative biological material emanating from the mother cell and circulating in the blood stream. In this project, we ambition to assess whether the vesiclemia, i.e. plasmatic extracellular vesicle concentration can be used as a clinic-biological parameter to assist in the monitoring of patients. **METHODS:** EPICURE is an ongoing pilot prospective cohort study of heterogeneous and massive data integration, i.e. multi-omics approaches in MBC patients. The present study focused on patients with HR+/HER2- MBC receiving frontline endocrine therapy+CDK4/6. Plasma samples were drawn every 3 months during the treatment until progression. The workflow for the enrichment of circulating EVs was developed from frozen plasma. A semi-automatized isolation procedure using size exclusion chromatography combined with the newly developed interference light microscopy apparatus Videodrop allowed to routinely separate plasmatic EVs and quantify vesiclemia in a fast and reliable manner for a large number of samples (longitudinal follow-up of MBC patients). **RESULTS:** 26 patients were included and monitored for vesiclemia. Median age was 58.5y (± 13.7). Metastatic disease sites were distributed as follows: bone metastases (21; 84%), liver (21; 84%), thoracic (10; 40%), node (2; 8%), brain (1; 4%), others (2; 8%). Endocrine therapy included aromatase inhibitors (20; 77%), fulvestrant (6; 29%), GnRH agonists (5; 19%) and CDK4/6 inhibitors palbociclib (15; 57%), abemaciclib (8; 31%) and ribociclib (3; 11%). With a median follow-up time of 22.1 months (95%CI 21.2 - not reached), median progression free survival was 21.8 months (95%CI 18.1 - not reached). Median time on treatment was 19.4 months (IQR 11.6 - 22.1). Objective response rate was confirmed in 12 patients (6 with complete response). Out of the 26 patients, 12 stopped the frontline treatment due to disease progression. 135 longitudinal follow-up samples were analyzed for EVs. All patients who progressed rapidly after treatment initiation (i.e median PFS < 6 months) had an increased vesiclemia at the months 2 and 6 after inclusion. Conversely, patients who had a median PFS >18m had a stable vesiclemia during this period. **CONCLUSION** This study aims to use circulating EVs as a therapeutic companion to anticipate treatment resistance and tumor progression in MBC patients. Our preliminary data suggest that the vesiclemia could be used as a predictive tool to anticipate treatment failure, and thus might be used to tailor treatments in time.

Estrogen receptor reprogramming by HOXB13 and GATA3 in ER-positive breast cancer cells

Background: The Breast Cancer Index (BCI) is a gene expression-based signature comprising two functional biomarker panels. The Molecular Grade Index (MGI) is composed of five genes that measure tumor proliferation. BCI (H/I) is a ratio of the HOXB13 and IL17BR genes and measures estrogen signaling. Integration of MGI and BCI (H/I) provides a single prognostic score that quantifies the risk of both late (5-10 years) and overall (0-10 years) distant recurrence. BCI (H/I) has been validated to predict benefit from extended endocrine therapy across multiple adjuvant endocrine treatment backgrounds in several prospective-retrospective studies. Hormone receptor responses are dependent on genome-wide hormone receptor binding patterns. In hormone-dependent cancers, nuclear receptor binding patterns are frequently reprogrammed by other transcription factors. The homeobox transcription factor HOXB13 has previously been shown to reprogram genome-wide binding of the androgen receptor (AR) during prostate cancer tumorigenesis, where it colocalizes with FOXA1 at reprogrammed AR binding sites. Similarly, the transcription factor GATA3 was found to mediate enhancer accessibility at regulatory regions involved in estrogen receptor (ER)-mediated transcription. We have shown previously that HOXB13 overexpression reprograms and expands the ER binding pattern in breast cancer cells. In this study, we have further characterized the role of HOXB13 in reprogramming the ER cistrome and evaluated potential interactions with GATA3. Methods: HOXB13 was expressed in MCF-7 and T47D cells by electroporating HOXB13 mRNA or eGFP mRNA as control. Cells were harvested after 18 hours and analyzed by western blot and chromatin immunoprecipitation followed by high-throughput sequencing (ChIP-seq) using antibodies against ER, HOXB13, FOXA1, GATA3 and histone H3K27ac. Chromatin accessibility was assessed by ATAC-seq. After aligning reads with Bowtie2, peak calling, data integration and motif enrichment analysis was performed using HOMER v4.10. Results: ChIP-seq analysis of T47D cells expressing HOXB13 confirmed previous results in MCF-7 cells, where binding of HOXB13 to a significant number of genomic binding sites induced changes in binding of ER, FOXA1 and GATA3 compared to control cells. Integrative analysis of ATAC-seq and ChIP-seq data revealed that HOXB13-induced reprogramming results in open chromatin that frequently exhibits increased acetylation of histone H3K27, a hallmark of transcriptional activation. While both increased chromatin accessibility and H3K27 acetylation were associated with HOX and AP-1 motif enrichment of the underlying DNA sequences, newly open chromatin was specifically co-enriched for motifs for pioneering factors such as FOXA1 and GRHL1. Conclusion: This study lends further support to a model of HOXB13-mediated reprogramming of the ER cistrome in breast cancer. Motif analysis of HOXB13-induced chromatin opening suggests interactions with other pioneer transcription factors including FOXA1 and GRHL1, while HOXB13-induced transcriptional

activation is associated with motifs for activating factors such as AP-1. These results will be expanded to inducible cell lines to further characterize the effects of HOXB13 expression on ER binding and function.

Background: Brain metastases (BM) occur in 20%-50% of patients (pts) with HER2-positive (HER2+) metastatic breast cancer (MBC), and their presence is a poor prognostic factor. Leptomeningeal carcinomatosis (LMC) occurs in 12%–43% of pts with MBC. Therapeutic options for BC pts with BM and/or LMC are limited. Results of the DESTINY-Breast01 and DESTINY-Breast03 studies have shown the clinical benefit of trastuzumab deruxtecan (T-DXd) in HER2+ MBC pts with stable BM; however, the study populations were small and did not include pts with active BM (untreated or progressive) and/or LMC. This data gap is addressed in the present study. Methods: ROSET-BM (UMIN000044995) is a multicenter, retrospective chart review study of pts who received T-DXd for HER2+ MBC with BM and LMC between May 25, 2020, and April 30, 2021, in a standard-of-care setting. Overall response rate (ORR), progression-free survival (PFS), and overall survival (OS) were evaluated. Additionally, in the pts with brain imaging data, intracranial (IC)-ORR and IC-PFS were evaluated by independent radiologists to provide central review according to RECIST v1.1. Active BM were determined by independent central review (ICR). Pts whose baseline and pre-baseline brain imaging data were compared and confirmed increased tumor size, or pts with new lesions were classified as active BM. LMC was determined by ICR using brain imaging. Results: In the study period, 62 sites participated, enrolling 113 pts with HER2+ MBC and BM were treated with T-DXd. After exclusion of data from 9 who did not meet the criteria for inclusion, 104 pts were included in the analysis. In the 104 pts, 70.2% (n=73) were active BM, 16.3% (n=17) were active BM with LMC, 5.8% (n=6) were stable BM, 1.9% (n=2) were only LMC, and 5.8% (n=6) were not classified. Symptomatic BM were observed in 30.8% (n=32). Median number of prior lines of therapy was 4 (range, 1–15). Median duration of follow up from first T-DXd treatment was 11.2 months. ORR assessed by investigator was 55.7% (complete response [CR], 5.2%) in all pts, 51.7% (CR, 6.9%) in symptomatic BM pts (n=29), and 57.4% (CR, 4.4%) in asymptomatic BM pts (n=68). Among all pts, median PFS was 16.1 months (95%CI, 12.0–n/a), and median OS was not reached (OS at 1 year was 74.9%). In the 19 pts with LMC, 1-year PFS and OS were 60.7% (95%CI, 34.5–79.1) and 87.1% (95%CI, 57.3–96.6), respectively (neither reached the median). Of the 89 pts with brain lesion imaging data (at both baseline and follow-up), IC-ORR

was 62.7% (CR, 0.0%). IC-PD was observed in 5.9% (n=3) of pts. Median IC-PFS was 16.1 months (95%CI, 12.2–n/a). In all pts, the most common event and adverse event leading to discontinuation of T-DXd were PD (27 pts, 26.0%) and interstitial lung disease (19 pts, 18.3%), respectively. Conclusion: The results of this retrospective chart review show that T-DXd has promising efficacy in HER2+ MBC pts with active BM and LMC. This study was funded by Daiichi Sankyo Co., Ltd.

Background: The antibody-drug conjugate trastuzumab deruxtecan (T-DXd) significantly improved survival outcomes of HER2-low advanced breast cancer (ABC) patients (pts) compared to standard chemotherapy in the DESTINY-Breast04 trial. DEBBRAH is assessing the efficacy and safety of T-DXd in HER2[+] and HER2-low ABC pts with a history of brain metastases (BM) and/or leptomeningeal carcinomatosis (LMC); here, we report results of HER2-low ABC pts. Methods: DEBBRAH (NCT04420598) is a multicenter, open-label, five-cohort, non-comparative, phase 2 study across 18 hospitals in 2 countries. A total of 39 pts aged ≥ 18 years with pretreated HER2[+] or HER2-low ABC with stable, progressing, or untreated BM and/or LMC, were enrolled in 5 cohorts: (1) HER2[+] ABC with non-progressing BM after radiotherapy and/or surgery; (2) HER2[+] or HER2-low ABC with asymptomatic untreated BM; (3) HER2[+] ABC with progressing BM after local treatment; (4) HER2-low ABC with progressing BM after local treatment; (5) HER2[+] or HER2-low ABC with LMC. Pts received 5.4 mg/kg T-DXd intravenously once every 21 days until disease progression, unacceptable toxicity, or consent withdrawal. Primary endpoint for cohorts 2 and 4 was intracranial overall response rate (ORR-IC) according to RANO-BM. Secondary endpoints included overall response (ORR) according to RECIST v1.1, progression-free survival (PFS), duration of response (DoR), clinical benefit rate (CBR); and safety and tolerability as per NCI-CTCAE v.5.0. Primary analysis is the estimation of ORR-IC (H_0 : ORR-IC $\leq 5\%$; H_1 : ORR-IC $\geq 40\%$) based on the one-sided binomial exact test. Sample size was planned to attain an 80% power at a nominal α level of 0.05 in each cohort. Results from cohort 2 should be considered descriptive since formal testing has to be performed in the whole cohort of pts with HER2[+] or HER2-low ABC and asymptomatic untreated BM. Results: From Oct 23, 2020, through Feb 15, 2022, 6 pts and 7 pts were allocated into cohorts 2 and 4, respectively. One patient with LMC included in cohort 4 was excluded from analysis. Median age was 54 (range 40–73) years. Median number of previous lines of therapy for advanced disease was 7 (range, 4-8) and 3 (range, 2-4) for cohorts 2 and 4, respectively. Median follow-up was 9.5 months (range, 1.6-

15.7). At data cutoff (Apr 29, 2022), no patient of cohort 2 and 3 (50.0%) pts of cohort 4 remained on therapy. In cohort 2, ORR-IC was 66.7% (4 of 6 pts had intracranial partial response [PR]; 95% CI, 22.3–95.7). In cohort 4, ORR-IC was 33.3% meeting the primary endpoint (2 of 6 pts had intracranial PR; 95% CI, 4.3–77.7; P = .033). Overall, ORR-IC in all pts was 50% (6 of 12 pts; 95% CI, 21.1–78.9) and CBR was 66.7% (8 of 12 pts; 95% CI, 34.9–90.1). Combining pts with measurable intracranial or extracranial disease from cohorts 2 and 4, ORR, CBR and median DoR were 41.7% (5 of 12 pts; 95% CI, 15.2–72.3), 50.0% (6 of 12 pts; 95% CI, 21.1–78.9), and 7.2 months (95% CI, 2.5–16.4), respectively. Median PFS was 5.7 months (95% CI, 4.7-NA) among these pts. The most common treatment emergent adverse events (TEAEs) of any grade (G) were fatigue (58.3%; 8.3% G≥3) and nausea (50.0%; 0% G≥3). Two (16.7%; 0% G≥3) cases of interstitial lung disease/pneumonitis were reported. Serious unrelated TEAEs occurred in 2 (16.7%) of 12 pts; 1 case of general pain (G3) and 1 case of venous embolism (G5) that led to death. There were no drug-related deaths due to TEAEs. Conclusions: T-DXd showed a preliminary antitumor activity in pretreated HER2-low ABC pts with asymptomatic untreated or progressing BM after local treatment. The substantial response of BM to T-DXd in this setting is promising and warrants further investigation.

PURPOSE: Treatment options for patients (pts) with HER2+ BCBM remain limited. We previously reported that neratinib monotherapy is associated with a volumetric central nervous system objective response rate (CNS ORR) of 8%, whereas the combination of neratinib and

capecitabine resulted in a volumetric CNS ORR of 49% (in lapatinib-naïve pts). Preclinical data suggest that neratinib may overcome resistance to trastuzumab-emtansine (T-DM1) and that the combination has potential CNS efficacy. Here, we report results of neratinib plus T-DM1 in pts with HER2+ BCBM. PATIENTS AND METHODS: In this prospective, multicenter, phase II study, pts with measurable HER2+ BCBM received neratinib 160 mg orally once daily plus T-DM1 3.6 mg/kg IV every 21 days in three parallel-enrolling cohorts. Cohort 4A enrolled pts with previously untreated brain metastases. Cohort 4B enrolled pts with BCBM progressing after prior local CNS-directed therapy without prior exposure to T-DM1. Cohort 4C enrolled pts with BCBM progressing after prior local CNS-directed therapy who had previous exposure to T-DM1. Diarrhea prophylaxis with colestipol and loperamide was required during cycle 1. Cohorts 4A and 4B were single-stage with a planned enrollment of 20 patients; cohort 4C had a two-stage design, with a requirement for at least 1 of the first 9 pts to achieve a response in order to enroll a total of 24 patients. The primary endpoint was Response Assessment in Neuro-Oncology-Brain Metastases (RANO BM) in each cohort separately. Correlative studies included patient-reported outcomes (PROs) for gastrointestinal toxicity. RESULTS: We enrolled 6, 17, and 21 patients to cohorts 4A, 4B, and 4C, during 11/07/2018 – 11/01/2021. Enrollment was stopped prematurely due to slow accrual. Across Cohorts 4A-4C, the median number of prior lines of chemotherapy prior to enrollment was 2 (range 1-10); 25% received prior lapatinib and no patients received prior tucatinib. In cohorts 4B and 4C (prior CNS-treated cohorts), 33% had prior CNS surgery and >94% had prior CNS radiation. Among evaluable patients, CNS ORR in cohorts 4A (n=6), 4B (n=16), and 4C (n=21) was 50.0% (95% CI 18.8- 81.2%), 25.0% (95% CI 8.3-52.6%), and 38.1% (95% CI 19.0-61.3%), respectively. Median (range) number of cycles completed for 4A, 4B, and 4C was 4.5 (1-15), 4 (range 0-49+), and 6 (0-23); three patients on Cohort 4B remain on protocol therapy (cycles 14, 45, and 49). The overall survival at 12-months for cohorts 4A, 4B, and 4C was 83.3% (95% CI, 58.3-100%), 86.2% (95% CI 70-100%), and 83.3% (95% CI 67.6-100%). Diarrhea was the most common grade 3 toxicity (19.0–33.3% across cohorts); one grade 4 liver function event occurred in cohort 4B. Updated efficacy results will be reported at the meeting; PRO analyses are ongoing. CONCLUSION: Intracranial activity was observed for the combination of neratinib plus T-DM1 across all three enrolled cohorts, including those with prior T-DM1 exposure, suggesting synergistic effects of this treatment combination. Our data provide additional evidence for consideration of neratinib-based combinations in pts with HER2+ BCBM.

BACKGROUND: Central nervous system (CNS) is a common site of metastases from breast cancer (BC). The efficacy of systemic therapy for CNS metastases from HER2-negative BC is limited. Although new anti-HER2 therapies seem to be more effective in this scenario, these drugs are not widely available yet. Chemotherapy with capecitabine is often used in patients (pts) with CNS metastases, but data supporting its activity is scarce. We aimed to evaluate the effectiveness of capecitabine for CNS metastases from BC.

METHODS: This retrospective study included pts with BC and confirmed CNS metastases treated with capecitabine at a tertiary cancer center from 2010-2021. Study endpoints included intracranial objective response rate (CNS-ORR) and intracranial disease control rate (CNS-DCR), intracranial progression-free survival (CNS-PFS), and overall survival (OS). Survival analysis were estimated by Kaplan-Meier method and compared using log-rank test.

RESULTS

Among 209 pts included, 41.6% were hormone receptor-positive (HR+) HER2-negative 33.9% HER2-positive, and 26.4% triple-negative (TNBC). Most pts had ECOG 0-1 (56.9%) and had received < 2 chemotherapy lines (77.9%) before capecitabine. Brain parenchymal metastases were present in 85.5%; 43.1% had ≥ 5 brain lesions. Radiotherapy was performed in 90.4% of the cases and CNS surgery in 27.5%. Among 124 pts accessible for intracranial response, CNS-ORR and CNS-DCR were 31.4% and 79% in 3-months. In 6 months, 76 pts were accessible, and CNS-ORR and CNS-DCR were 23.6% and 73.6%. The median CNS-PFS was 5.6 months and median OS was 7.9 months. Table 1 shows CNS-ORR and CNS-DCR at 3 months according to immunohistochemical subtype. Although TNBC had higher 3-month IORR (48%), this subgroup had a worse prognosis compared to HR+ (OS: HR = 1.87, CI 95% = 1.28 – 2.73, p = 0.001). mOS was 8.7 months and 9.1 months for HR+ and HER2+ subtypes respectively, and 4.5 months for TNBC. OS was worse in patients with ECOG-PS ≥ 2 (p = 0.017) and was not influenced by the number or size of brain metastases, number of previous chemotherapy lines and previous surgery or radiotherapy to CNS.

CONCLUSION

Our results showed that pts with CNS metastases from BC still have a poor prognosis. TNBC subtype and ECOG-PS ≥ 2 were detrimental prognostic factors. Nevertheless, among pts accessible for intracranial response, satisfactory CNS-DCR was observed with capecitabine, suggesting activity of this drug for selected pts.

Intracranial response rate (CNS-ORR) and disease control rate (CNS-DCR) of central nervous system metastases from breast cancer treated with capecitabine.

	HR+HER2- BC (n=50)	HER2+ BC (n=49)	TNBC (n=25)	P-value*
CNS-ORR, n (%)	12 (24)	15 (31)	12 (48)	0.113
CNS-DCR, n (%)	47 (94)	36 (73)	15 (60)	0.001

Background

Brain metastases (BM) is a challenging presentation of breast cancer (BC) and has historically been associated with poor prognosis. The risk of BM is higher in patients (pts) with hormone receptor (HR) negative, human epidermal growth factor receptor 2 (HER2)-positive, or triple negative (TN) tumors.

There have been significant advances in the treatment of metastatic BC over the past several years, and long-term outcomes after a diagnosis of breast cancer brain metastases (BCBM) are lacking; therefore, this study aimed to identify clinical predictors of BM at initial BC diagnosis, to describe trends in overall survival (OS) over the past decade, and to identify factors associated with OS after BM diagnosis.

Methods

We evaluated pts with de novo stage IV BC using the Surveillance, Epidemiology and End Results (SEER) database from 2010-2019. A multivariate logistic regression model was conducted among all pts with stage IV BC to assess predictors of BM at initial BC diagnosis. OS probabilities were estimated using the Kaplan-Meier method and log rank test was used to compare differences between groups. Among pts with BM at initial BC diagnosis, univariate analyses were performed to determine the effects of each variable on OS. A Cox proportional hazards regression was used to assess the independent association of several variables with OS.

Results

A total of 425,110 pts with BC were identified from 2010-2019; 25,113 had stage IV BC at diagnosis and among these, 1,939 pts had BM at initial BC diagnosis. For this last group

median age was 60 years and median follow up was 54 months .

We performed a logistic regression model to evaluate the factors correlated with BM at initial BC diagnosis among all stage IV BC pts and found that lobular vs ductal histology (OR 0.68; 95% CI 0.55-0.85), HR-/HER2+ vs HR+/HER2- tumors (OR 1.93; 95% CI 1.64-2.29), and the presence of bone (OR 1.19; 95% CI 1.07-1.32), liver (OR 1.25; 95% CI 1.12-1.39), lung (OR 1.72; 95% CI 1.55-1.89), or lymph node (OR 1.21; 95% CI 1.03-1.42) metastases, were significantly associated with this presentation.

The table shows OS by tumor subtype among all pts with BM at initial BC diagnosis, as well as the survival rate at 2, 5 and 8 years. We observed significant differences in survival by tumor subtype, where pts with HR+/HER2+ disease had the longest OS (median 18 months; 95% CI: 13-22 months; p = < 0.0001) and the highest rate of OS at 8 years (12.2%; 95% CI 7.61%-17.95%). In contrast, TN BC had a median OS of 6 months (95% CI 5-8 months) and a rate of OS at 8 years of 2.57% (95% CI 0.1%-5.48%).

Multivariate analysis among pts with BM at initial BC diagnosis revealed differences in OS in those who were >64 years vs < 50 years (Hazard Ratio [HzR] 1.51; 95% CI 1.29-1.77), married vs single (HzR 0.79; 95% CI 0.70-0.91), lower vs higher income (HzR 1.45; 95% CI 1.19-1.76), tumor grade III/IV vs grade I (HzR 1.68; 95% CI 1.24-2.28), TN subtype vs HR+/HER2- (HzR 2.13; 95% CI 1.81-2.49), as well as pts with additional liver (HzR 1.34; 95% CI 1.20-1.51) or lung metastases (HzR 1.34; 95% CI 1.20-1.49).

We did not observe significant changes in OS over time (adjusted HzR 0.996 per year; 95% CI: 0.96-1.02, p = 0.837).

Conclusions:

Over the last decade, the median OS of pts with BM at initial BC diagnosis has remained poor. However, a substantial minority of pts survive 5 or more years, with long-term survival rates higher in pts with HER2+ tumors. In addition to tumor subtype, OS varied according to age, the presence of metastases to other organs, and sociodemographic factors.

		N	Median OS in months (95% CI)	% OS at 2 years (95% CI)	% OS at 5 years (95% CI)	% OS at 8 years (95% CI)
Tumor subtype	HR+/HER2-	725	14 (12-16)	34.43 (30.72-38.17)	10.56 (7.86-13.72)	5.53 (3.28-8.61)
	HR+/HER2+	310	18 (13-22)	42.24 (36.36-47.99)	20.31 (15.09-26.07)	12.2 (7.61-17.95)
	HR-/HER2+	238	14 (11-17)	34.19 (27.87-40.60)	14.29 (9.53-19.97)	11.2 (6.18-17.89)
	Triple negative	334	6 (5-8)	10.27 (7.09-14.11)	3.21 (1.43-6.19)	2.57 (0.1-5.48)

Background: Advances in imaging and systemic therapy have improved the survival for patients with breast cancer brain metastases (BCBM). However, an improved understanding of patients

with long-term survival after stereotactic radiation (SRT) for BCBM is warranted and could allow for better prognostication and personalized treatment. Methods: This is a single institution retrospective review of 188 patients who underwent SRT sessions to 685 BCBM from August 2004 to June 2020. Patients who were lost to follow up within 2 years after SRT were excluded. Patients were stratified into 2 groups: those with overall survival (OS) from SRT less than 2 years (short-term survival, STS) and those with OS from SRT of at least 2 years (long-term survival, LTS). Patient, tumor, and treatment characteristics were compared between the 2 groups via the student t-test and Chi-square testing as appropriate. The Kaplan-Meier (KM) method was used to calculate OS, local control (LC), and distant intracranial control (DIC) from the date of SRT. The reverse KM method was used to estimate follow-up from SRT. Results: The median follow up from BCBM diagnosis was 52.8 months (95% CI: 40.5-75.2 months). Of the 685 treated BCBMs, 552 (81%) received stereotactic radiosurgery (SRS) to a median dose of 21 Gy (12-24 Gy) and 133 received fractionated stereotactic radiation therapy (FSRT) to a median dose of 25 Gy (20-35 Gy) in 3-5 fractions. The 2-year LC, DIC, and OS was 78.4%, 26.5%, and 38.3%, respectively. The 5-year OS was 19%. There were 72 patients (38%) in the LTS group and 116 patients (62%) in the STS group. The LTS group had lower rates of invasive lobular carcinoma (0% vs 6%, $p=0.001$) and higher rate of HER2+ disease (61% vs 30%, $p<0.001$). The LTS group had lower rates of concurrent extracranial metastasis (74% vs 89%, $p=0.008$) and lung metastasis (33% vs 53%, $p=0.009$), though there were no differences in the rates of bone or liver metastasis. The LTS group had less BCBM at the time of SRT (mean 1.9 vs 2.5, $p=0.013$) and more often received SRT to a single BCBM (65% vs 42%, $p=0.002$). There were no significant differences in age or performance status between the groups. Conclusion: Prognosis for patients with BCBM is heterogeneous, as a minority of patients have prolonged OS after SRT. These patients more often have limited BCBM, HER2+ disease, and a lower extracranial disease burden.

Background: Despite advances in treatment options, outcomes remain poor for many pts with breast cancer brain metastases (BCBMs). Identifying genomic predictors of brain metastasis from primary tumors could lead to better stratification of pts at risk and drive the development of preventative strategies. The objective of this study was to describe the landscape of genomic alterations in primary tumors from pts with MBC who subsequently did or did not develop BCBMs.

Methods: We performed a case control study to identify somatic alterations in primary tumors associated with a higher incidence of brain metastases. We reviewed outcomes for 2562 unique MBC patients from a single institution who underwent targeted next-generation DNA sequencing of > 280 cancer-related genes (OncoPanel) from their tumor between July 1, 2013 and December 31, 2020. Pts were included in this analysis if they had at least 2 years of follow-up from date of metastatic diagnosis and OncoPanel testing on a primary breast tumor. We compared single nucleotide variants (oncogenic or likely oncogenic), copy number variation (amplification and deep deletions) and tumor mutation burden in the primary tumors of pts in this cohort. Copy number variation was corrected for Panel version and tumor purity. Wilcoxon rank sum test and Fisher exact test was used to compare genomic differences between groups. False discovery rate was used to correct for multiple hypothesis testing and $q < 0.1$ was considered significant

Results: A total of 369 pts were included in the final analytic cohort. Of these, 115 were diagnosed with brain mets (cases, BM group) and 224 were not (controls, nBM group). The BM group was enriched for patients with HER2-positive breast cancer (33 vs 12.5%), consistent with previous work. In the whole cohort, the most common and clinically significant somatic alterations (oncogenic single nucleotide variants or copy number high amplification or two copy deletion) are shown in Table 1. When adjusting for subtype there were no significantly enriched SNVs in BM vs nBM group. When adjusting for subtype, FGFR1 amplification was significantly enriched in hormone receptor positive HER2 negative (HR+ HER2-) patients with BM (log2 odds ratio 1.22, $q < 0.1$). Tumor mutation burden was not significantly different in primary tumors between the BM and nBM groups (median TMB 7.3 vs 6.1, Wilcoxon $p = 0.08$).

Pathway analysis combining all subtypes revealed that RTK_RAS pathway (log2 odds ratio 1.64, q value < 0.1) and TP53 pathway (log2 odds ratio 1.15, q value < 0.1) gene sets were significantly enriched in the BM group. When controlling for subtype, pathway analysis revealed that RTK_RAS pathway gene set was significantly enriched in HR+ HER2- BM group (log2 odds ratio 1.36 $q < 0.1$).

Conclusions: In this case control series of patients with metastatic breast cancer with or without brain metastases, we found that primary tumors that are enriched for somatic alterations in the RTK_RAS and TP53 pathway may be associated with higher risk of developing brain metastases. Further validation in larger cohorts is warranted.

Table 1

Table 1: Frequency of somatic alterations in primary tumor by brain metastasis outcome			
GENE	No brain metastasis (nBM, n = 224)	Brain metastasis (BM, n = 115)	Cohort (n = 339)
PIK3CA	36%	35%	36%
TP53	25%	48%	32%
CCND1	16%	11%	14%
GATA3	12%	11%	12%
CDH1	10%	14%	12%
ERBB2	10%	33%	18%
FGFR1	8%	10%	8%
BRCA2	6%	7%	6%
ARID1A	4%	6%	5%
PTEN	5%	8%	6%

Background: The incidence of breast cancer (BC) brain metastases (BM) is increasing as a result of both improved diagnostic techniques and longer survival due to better treatment approaches. However, the biological complexity of BCBMs is still poorly understood. We here evaluate the genomic profile of BCBMs and assess its prognostic implications.

Methods: Clinical data and BM samples (FFPE) from BC patients undergoing neurosurgery (2003-2019) at three institutions were collected. Hormone receptor (HR) and HER2 status were evaluated on the BCBM. RNA extracted from BM samples was used to measure the expression of 758 BC-related genes and 18 housekeeping genes using the Breast Cancer 360 Panel on an nCounter platform (NanoString Technologies). Intrinsic molecular subtyping was determined using the previously reported PAM50 subtype predictor (Parker et al. JCO 2009). Median overall survival from neurosurgery (OS) was calculated using the Kaplan-Meier method. The correlations between expression of each gene/PAM50 signature, BC subtype and OS were studied using univariate and multivariate Cox-models.

Results: Sixty-five BCBM samples were analyzed: 32% (N=21) were HR+/HER2-, 38% (N=25) HER2+ and 29% (N=19) HR-/HER2-. With a median follow-up of 33 months, no clinical variable was significantly associated with OS, despite a trend towards a shorter survival for patients with HR-/HER2- BMs, as compared to patients with HR+/HER2- and HER2+ subtypes (median OS 9.4 versus 22.1 and 20.0 months, respectively, log-rank p=NS).

The intrinsic subtype distribution, as assessed by gene-expression profiling, was 37% Basal-like, 46% HER2-enriched (HER2-E), 15% Luminal B and 2% Normal-like. Non-luminal subtypes (basal-like and HER2-E) were extensively represented, both overall and in each BC subtype (52% in HR+/HER2- subgroup, 96% in HER2+ subgroup, see Table).

The PAM50 basal-like signature was significantly associated with a worse OS (HR 2.7, 95% CI 1.0-7.2, p=0.045), even after correcting for BC subtype (HR 5.2, 95% CI 1.1-23.4, p=0.032). In fact, even within the subgroup of HR+/HER2- BCBMs, the PAM50 basal-like signature was strongly associated with a worse OS (HR 92.6, 95% CI 5.0-1860.1, p=0.003) and patients with basal-like HR+/HER2- BCBMs presented a median OS similar to patients with HR-/HER2- BCBMs (mOS 9.0 vs 9.4 months).

We identified 36 genes whose high expression was significantly associated with a worse OS (p< 0.05) and one gene (LINC02381) whose high expression was significantly associated with better OS (p< 0.05); for 33 of these genes (BCL11A, BMP2, BNIP3, CAV1, CDH3, CDK6, CKB, CRYAB, CXCL12, EGFR, EYA4, FOXC1, FZD8, FZD9, GABRP, GAS1, GDF5, GPC4, IL6, KRT17, KRT5, KRT6B, KRT7, LAMB3, LINC02381, MYC, NOTCH1, PRKX, PSAT1, RUNX3, SNAI1, SPRY2, TTYH1), the association was confirmed even after correcting for BC subtype (p< 0.05).

Conclusions: Non-luminal intrinsic subtypes are extensively represented in resected BCBMs, even if clinically classified as HR+/HER2-. Our data suggest that basal-like genomic features might be enriched in BCBMs and might be associated with worse survival.

Distribution of PAM50 intrinsic subtyping on the 65 brain metastases evaluated according to hormone receptor (HR) and HER2 status

PAM50 Intrinsic subtype	HR+/HER2- BCBM N (%)	HER2+ BCBM N (%)	HR-/HER2- BCBM N (%)
HER2-enriched	6 (29%)	21 (84%)	3 (16%)
Basal-like	5 (24%)	3 (12%)	16 (84%)
Luminal B	9 (43%)	1 (4%)	-
Normal-like	1 (5%)	-	-
Luminal A	0	0	0

Background: Rates of delayed CINV remain high at over 50% following adjuvant chemotherapy for breast cancer, despite the use of multiple antiemetics. Delayed CINV is complex, distressing to patients and its incidence is underestimated by physicians. Anti-emetics used with early breast cancer chemotherapy are often directed against acute rather than delayed CINV. Chemotherapy is virtually eliminated from the circulation prior to the delayed phase (24-120 hours post-chemotherapy), suggesting the etiologies for acute and delayed CINV may differ. Chemotherapy and steroids can alter the gastric environment and acid secretion, while chemotherapy can cause gastroesophageal mucositis. We hypothesized that the altered gastric environment, combined with disrupted gastroesophageal mucosa, could contribute to delayed nausea in a proportion of patients. Anecdotal experience suggested proton pump inhibitors, such as Pantoprazole, reduced symptoms in this setting. Methods: This study incorporated a double-blinded crossover design to determine whether Pantoprazole would reduce the incidence of delayed CINV in patients receiving adjuvant, or neoadjuvant breast cancer chemotherapy. Patients were randomized to either pantoprazole or placebo from Day 1-5 after cycle 1, changing to the other intervention for cycle 2. CINV symptoms during the delayed phase were assessed using the Multinational Association of Supportive Care in Cancer (MASCC) Antiemesis Tool and recorded in real time by patients using the PantoCIN ePRO application. With 160 patients, this approach had an 80% power to detect a statistically significant effect (one-sided α (type 1) error of 0.025) of Pantoprazole, if the true effect of Pantoprazole is a 10% reduction in the rates of any delayed CINV compared to placebo. The primary endpoint was the proportion of patients with complete absence of both nausea and vomiting during days 2-5, with severity of CINV and patient preference for intervention described as secondary endpoints. Results: 160 patients were recruited between June 2019 and October 2021, from 10 different cancer centers in New Zealand. Primary statistical analysis has shown a significant reduction in absolute CINV with pantoprazole as the primary end point, with incidence of any CINV symptoms reducing from 61.0% to 49.6% (OR=1.8, 95% confidence interval (1.0 to 3.3); p-value=0.04), in patients with full data. There was also a clear preference for patients to prefer the blinded pantoprazole arm of the 2 cycles of treatment under study, with the proportion of participants who preferred pantoprazole to placebo being 49% and the proportion who preferred placebo to pantoprazole was 25.2%, (difference in proportions 23.8% and 95% confidence interval 12.4 to 35.2; p=0.0017). Conclusion: CINV is a common and distressing complication of early breast cancer chemotherapy, which persists despite the use of a range of current antiemetics. Pantoprazole is a cheap, well-tolerated agent without significant drug interactions, which clearly ameliorates this symptom in a significant proportion of patients and should be considered as a standard prophylactic intervention.

Background: HG is an on-target AE of PI3K inhibition, reported in 63.7% (36.6% G \geq 3) of HR[+]/HER2[-] ABC patients (pts) treated with ALP plus fulvestrant in SOLAR-1. HG was the most frequent adverse event (AE) leading to ALP discontinuation (6.3%). MET reduces systemic insulin resistance and suppress PI3K and Ras signaling. METALLICA is assessing the prophylactic use of MET for prevention of ALP-induced G3-4 HG in PIK3CA-mutated, HR[+]/HER2[-] ABC pts with normal fasting glycemia or prediabetic criteria. Methods: This is an open-label, single-arm, two-cohort, phase 2 trial. Pts aged \geq 18 years, ECOG PS of 0–1, and PIK3CA-mutated, HR[+]/HER2[-] ABC, progressing to an aromatase inhibitor (AI)-containing regimen, \leq 2 previous endocrine therapy (ET) and \leq 1 prior chemotherapy regimens for ABC

were eligible. Pts were enrolled into cohorts according to glycemia at baseline: (A) pts with normal fasting glycemia < 100 mg/dL and glycosylated hemoglobin (HbA1c) < 5.7%; (B) pts with prediabetic fasting glycaemia 100–140 mg/dL and/or HbA1c 5.7–6.4%. Pts received oral ALP 300 mg/day, starting from C1D8, in combination with ET; fulvestrant, letrozole, or exemestane as per standard of care; and oral MET 1000 mg/day on days 1-3 and 2000 mg/day thereafter. The primary endpoint was G3-4 HG incidence as per NCI-CTCAE v.4.03 at 2 first cycles of treatment. Assessment of glycemia was performed by rigorous self-monitoring blood glucose and local laboratory confirmation in fasting conditions. Secondary endpoints included objective response (ORR), clinical benefit rate (CBR), duration of response (DoR), progression-free survival (PFS), and safety. Sample size was based on a Simon's two-stage design in cohorts A (H0: G3-4 HG \geq 25%; H1: G3-4 HG \leq 10%) and B (H0: G3-4 HG \geq 40%; H1: G3-4 HG \leq 15%). We planned to attain 80% power at the nominal one-sided α level of 0.05 for each cohort. Results: Between Aug 30, 2020, and Mar 10, 2022, 68 pts were enrolled at 18 sites (48 cohort A, 20 cohort B). Median age was 55 (range, 29–79) years and 58.8% pts had visceral disease and an ECOG PS 0. A total of 66 (97.1%) pts had been previously treated with a CDK4/6i and 13 (19.2%) pts had received chemotherapy for advanced disease. Sixty-three (92.6%) pts received fulvestrant as ET (45 cohort A, 18 cohort B). With a median follow-up of 8 (range, 1.6–14.9) months, 28 (41.2%) pts remain on study treatment. Disease progression was the main reason for discontinuation, reported in 32 (47.1%) pts. The primary endpoint of the study was reached, with 1 (2.1%) pts (95%CI, 0.8–9.5; $p < 0.001$) in cohort A and 3 (15%) pts (95%CI, 4.5–33; $p = 0.012$) in cohort B experiencing a G3-4 HG episode over the 2 first cycles of treatment. For patients on fulvestrant, G3-4 HG rates were 1 pts (2.2%) and 3 (16.7%) pts for cohorts A and B, respectively. No ALP discontinuation related to HG was reported during the first 2 treatment cycles. Median PFS in all patients was 7.4 months (95%CI, 6–NA). Among pts with measurable disease, ORR was 14 (36.8%) pts (95%CI, 21.8–54). At the time of this analysis, DoR and CBR were still immature. The most common AEs were diarrhea (67.6%; 13.2% $G \geq 3$), nausea (67.6%; 0% $G \geq 3$), and fatigue (45.6%; 2.9% $G \geq 3$). Serious AEs occurred in 15 (22.1%) pts. The main serious AEs were rash (2.9% $G \geq 3$) and vomiting (1.5% $G \geq 3$). No additional pts reported $G \geq 3$ HG after the first 2 cycles. The dose of ALP was reduced according to the protocol in 19 (27.9%) pts. Eight (11.8%) pts permanently discontinued ALP due to AEs, none of whom related to HG. No treatment-related deaths were reported. Conclusions: Prophylactic use of MET substantially reduced the incidence and severity of ALP-related HG with no additional toxicities and could be a new standard for PIK3CA-mutated, HR[+]/HER2[-] ABC pts receiving ALP plus fulvestrant or other ET.

Introduction. Several studies have evaluated cardioprotective strategies to prevent myocardial dysfunction in patients who are receiving cardiotoxic therapies. Angiotensin-converting enzyme inhibitors and β -blockers are recommended first-line agents for heart failure. However, the optimal approach still represents a controversial issue. We hypothesized whether pharmacological cardioprotection could reduce subclinical heart damage in patients with breast cancer who are being treated with an anthracycline-based chemotherapy. **Patients and methods.** The SAFE trial was a 4-arm, randomized, phase 3, double-blind, placebo-controlled, national multicentric study conducted at eight oncology departments in Italy. The study recruitment was conducted between July 2015 and June 2020. A prespecified interim analysis on 174 women at 12 months was reported in 2020. Patients were eligible for trial inclusion if they had indication to receive primary or postoperative systemic therapy using an anthracycline-based regimen. Patients with a prior diagnosis of cardiovascular disease were excluded. Cardioprotective therapy (bisoprolol, ramipril, or both drugs compared with placebo) was administered for one year from the initiation of chemotherapy or until the end of trastuzumab therapy in case of ERBB2-positive patients. Doses for all groups were systematically up-titrated up to the daily target dose of bisoprolol (5mg, once daily), ramipril (5mg, once daily), and placebo, if tolerated. The primary end point was defined as detection of any subclinical impairment (worsening 10%) in myocardial function and deformation measured at 24 months using 3-dimensional (3D) echocardiography, left ventricular ejection fraction (LVEF), and global longitudinal strain (GLS). ClinicalTrials.gov identifier: NCT2236806. **Results.** 262 women (median age, 48 years; range, 24-75 years) were enrolled and treated in the study. We analyzed patients who had completed the pre-planned cardiological assessment at 24 months. Baseline demographic, tumor, and cardiovascular profiles were similar between groups. All patients received an anthracycline-based chemotherapy, 215 patients received at least three cycles of anthracyclines (range 1-6), 223 patients received also a taxanes-based chemotherapy, and 84 cases were treated with adjuvant trastuzumab. Sixty patients were treated with neoadjuvant chemotherapy, 157 cases received adjuvant endocrine therapy, and 128 patients had postoperative radiation therapy. GLS worsened 10% or greater in 68% of patients enrolled in the placebo arm, 15%, 13%, and 13% in the ramipril, bisoprolol, and ramipril plus bisoprolol arms, respectively ($P < 0.05$). A reduction of 10% or greater in 3D-LVEF was observed in 19% in the placebo arm, 11% in the ramipril arm, 11% in the bisoprolol arm, and 7% in the ramipril plus bisoprolol arm ($P < 0.05$). Study drugs were well tolerated with no serious adverse events, the ramipril plus bisoprolol arm showed significantly more toxic effects and had a significantly higher rate of allocated treatment discontinuation as compared to the other arms. **Conclusions.** Cardioprotective pharmacological strategies in patients who were affected by breast cancer and were receiving an anthracycline-based chemotherapy are well tolerated and protect against cancer therapy-related LVEF decline and heart remodeling.

Background: Yoga has been tested in multiple small-randomized studies for its impact on quality of life (QOL) on breast cancer (BC). We conducted a randomized controlled trial, to study the effect of yoga on disease free survival as the primary endpoint in women with operable breast cancer. (NCT02161900). Methods: Women with non-metastatic BC during and after standard treatment, were randomized to yoga and conventional exercise(YCE) versus conventional exercise only(CE). The primary endpoint was disease free survival (DFS) with secondary endpoints of overall survival (OS) and QOL, which was assessed using the EORTC QLQC30, BR23, Brief fatigue inventory (BFI), Visual pain scores (VPS) and a spirituality questionnaire (SQ). EORTC QLQ was assessed at baseline (BL), 6-9 months (mo), 18-21 mo. BFI and VPS at BL, 6-8 mo and 12-15 mo and SQ at BL and 12-15 mo. We report the final analysis of DFS, OS and QOL in 850 women randomized to the study. The groups were balanced for clinic-pathologic factors in both arms. Results: Of the 850 women randomized on the study, 426 were on YCE arm and 424 on CE arm. The median age was 47 versus (vs) 48 years, median pT size was 3 vs 2.85cm, grade 3 tumors were 82.7 vs 82.1%, hormone receptor positive was in 69% vs 69.4% and HER2neu positive was in 14.4 vs13.7% in YCE and CE arms respectively. At a median follow-up of 80 months the disease free survival was 80% vs 76.7% (HR= 0.85, 95% CI= 0.64 – 1.14, p=0.28), and overall survival was 85.4% vs 83.1% (HR= 0.86, 95%CI = 0.61 – 1.21, p=0.38) in YCE and CE respectively. Physical(p=0.043) and emotional function (0.017), fatigue (p=0.002), pain (p=0.031), appetite loss (< 0.001) arm symptoms (0.035) and systemic therapy side effects (0.036) reduced at 6-9mo in YCE, with sustained improvements in physical (p=0.036) and emotional function (p=0.008) at 54mo. The median score of fatigue after adjuvant therapy measured by QLQ C30 was lower in YCE compared to CE (11.11vs 22.22, p = 0.002). Similarly, in BFI the baseline median scores of

severity of fatigue were 5 in YCE and 6 in CE which reduced to 3 at one year in both groups. A further reduction to 0 was observed in the YCE arm at 2 years and then sustained till 4 years compared to the median score of fatigue in CE which stayed at 3. ($p=0.04$, 0.03 2 and 4 years respectively). In VPS the number of patients experiencing severe pain in YCE group were less than CE group with specific reduction noted in pain over the breast/ chest wall ($p=0.018$ at 24mo). Lastly SQ assessed spirituality and showed no difference, but less deterioration compared to baseline scores were noted in YCE. Fifty-three percent women on YCE showed an improvement in QOL from baseline compared to 47% in CE, however the global score of QOL did not differ significantly between the two arms. This cohort had overall compliance of 61% to yoga and physiotherapy in YCE with 91.75% compliance among those who did yoga for 6-9mo and 85% to physiotherapy alone in CE. Conclusions: Yoga resulted in a 15% relative improvement in DFS and 14% in OS, that did not reach statistical significance in this trial. Yoga is a low-risk, low-cost therapy that improves day-to-day activity, including pain, fatigue and quality of life in women with breast cancer. This is the first study where the long term benefits in quality of life have been noted with the addition of yoga for women undergoing treatment for breast cancer.

Introduction: Chronic musculoskeletal pain is common and debilitating among breast cancer survivors. Recently, the Personalized Electroacupuncture (EA) versus Auricular Acupuncture (AA) Comparative Effectiveness (PEACE) trial demonstrated that both acupuncture methods reduced pain more than usual care (UC) in cancer survivors. However, the comparative effectiveness between EA and AA among breast cancer survivors is unknown. Here, we report the results of subgroup analysis of breast cancer survivors enrolled in the PEACE trial.

Methods: PEACE is a three-arm, parallel, single center randomized trial investigating the effectiveness of EA and AA versus UC for chronic musculoskeletal pain in 360 cancer survivors. Patients in both EA and AA received ten weekly treatments. Patients in UC could receive ten EA treatments after week 12. The primary endpoint was the change in mean Brief Pain Inventory (BPI) pain intensity from baseline to week 12; change from baseline to week 24 and change in quality of life were secondary endpoints. We analyzed the subset of 46% of trial participants with a primary diagnosis of breast cancer. We conducted constrained linear mixed model analyses, which constrained all arms to have a common pre-randomization baseline mean. Model-based mean estimates at weeks 12 and 24 were compared between arms using model contrasts. Results: Among 165 breast cancer survivors, the baseline mean pain severity was 5.35 (95% Confidence Interval [CI]: 5.04, 5.66). At week 12, the BPI pain severity score was 2.69 (2.26, 3.13) in EA, 3.60 (3.17, 4.02) in AA, and 5.06 (4.47, 5.65) in UC. At week 24, the mean BPI pain severity was 2.84 (95% CI: 2.40, 3.28) in EA and 3.67 (95% CI: 3.23, 4.10) in AA. EA reduced pain severity significantly more than AA at both week 12, (-0.90 [-1.45, -0.36], p=0.001) and week 24 (-0.82, [-1.38, -0.27], p=0.004). There were no differences between EA and AA in improvements in PROMIS physical health or mental health component scores, but both EA and AA significantly improved both PROMIS scores at week 12 compared to UC. Mild toxicities were reported, more patients dropped out of the AA arm due to ear pain. Conclusions: EA was more effective than AA at reducing pain severity, but both similarly improved physical and mental health scores. Breast cancer survivors with chronic musculoskeletal pain may consider EA before AA.

Background: Taxanes play an important role in the treatment of early-stage breast cancer. Chemotherapy induced peripheral neuropathy (CIPN) is a complication of taxane therapy and can lead to treatment dose reduction or discontinuation, which may ultimately affect overall survival, and can substantially impact quality of life and functional status in survivors. The trajectory of CIPN symptoms is not well described. Methods: SWOG S1714 enrolled participants 18 years or older with Stage I-III primary non-small cell lung, primary breast, or primary ovarian/fallopian tube/peritoneal cancer starting treatment with a taxane-based regimen. Participants with baseline neuropathy were eligible to enroll. Neuropathy was assessed with the patient-reported European Organization for Research and Treatment of Cancer QLQ-CIPN20 (CIPN-20). The occurrence of clinically meaningful sensory neuropathy was defined as an increase of 8 or more points (on a 0-100 scale, with a higher score indicating more severe symptoms) between baseline and follow-up in the sensory neuropathy subscale of the CIPN-20. Assessments occurred at baseline and at 4, 8, and 12 weeks +/- 14 days and 24, 52, 104, and 156 weeks +/- 28 days after registration. Results: Among N=1336 enrolled participants, 1321 were eligible (99%). Of the eligible participants, we will report on the 1198 (90.7%) with breast cancer. The median age was 55 years (range 23-84) and 99.3% were female. The breast cancer cohort included 72.2% White, 11.7% Black, 4.9% Asian, and 11.0% Hispanic/Latino participants. Paclitaxel (every week for 12 weeks or every 2 weeks for 8 weeks) was administered to 56.2% and docetaxel (every 3 weeks for 12-18 weeks) to 43.8%. The mean baseline patient-reported CIPN-20 sensory neuropathy subscale score was 6.2 (standard deviation 12.0). Through one full year of follow up, 1084 participants (90.5%) were evaluable for sensory neuropathy at any time point. At individual assessment times, clinically meaningful sensory neuropathy was reported by 18.7% of participants at week 4, 33.0% at week 8, 46.3% at week 12, 44.8% at week 24, and 47.4% at week 52. Clinically meaningful sensory neuropathy at one or more assessments was reported by 67.8% of participants. Conclusions: In this large prospective cohort of racially/ethnically diverse participants with breast cancer receiving taxane-based therapy, 2 out of every 3 experienced clinically meaningful sensory neuropathy symptoms during the first year of treatment and nearly 50% continue to experience clinically meaningful sensory neuropathy symptoms at the end of the first year. Given the high incidence of symptoms during taxane treatment and persistence of symptoms after treatment completion, it is critical to develop effective methods to predict, prevent, and treat this toxicity. Follow up of data at 104 and 156 weeks will further characterize the trajectory of long term CIPN symptoms. Funding: NIH/NCI/NCORP grant UG1CA189974

Background: Nearly 9% of new breast cancer diagnoses in the United States are in women under the age of 45. In 2012, Living Beyond Breast Cancer (LBBC) conducted a four-phase needs assessment of young women diagnosed with breast cancer at or before age 45, which identified needs and service gaps in resources addressing the unique needs of this age group and explored how these women prefer to receive emotional support and breast cancer information. In 2020, LBBC conducted another assessment to better understand young women's service preferences and information needs. The 2020 assessment focused specifically on demographic differences and targeted content areas, including sexual health and long-term impacts on physical and emotional health. Methods: An 88-item online questionnaire was administered via REDCap between August and September 2020. Inclusion criteria were women diagnosed with breast cancer at or before age of 45 who were living in the United States. The survey included questions about respondents' experiences with treatment side effects, communication with their healthcare providers, and how they sought emotional support services, and breast cancer information. Questions centered on sexual, physical, and emotional health needs of respondents throughout their treatment journey. Special focus was placed on participants' demographic information, including race/ethnicity, cancer stage, and time elapsed since diagnosis. Results: Overall, breast cancer diagnosis and treatment caused significant physical and emotional impacts on women diagnosed before age 45 (N=717), and a woman's race/ethnicity, cancer stage, and time elapsed since diagnosis resulted in differences in their experiences. In addition, how a woman preferred to receive emotional support services and breast cancer information differed based on her race/ethnicity, and cancer stage. Many participants (64%) also reported significant impacts to their sexual health, yet their healthcare providers were unable to address those needs. Compared to women diagnosed at other stages, those diagnosed with stage III and stage IV breast cancer reported significantly higher

percentages of problems with little or no interest in sex. How a woman preferred to receive emotional support services and breast cancer information differed based on her race/ethnicity, and cancer stage. The 2020 survey also showed that although eight years have passed since the original LBBC needs assessment, the percentage of young women reporting discussions about fertility with healthcare providers (48%) remain largely unchanged. Additionally, more respondents in the 2020 survey reported accessing genetic counseling (72%) and testing services (90%) than the 2012 survey participants, but in 2020, the data indicated significant disparities in both counseling and testing based on race/ethnicity. Conclusion: Young women diagnosed with breast cancer before age 45 reported several significant differences in service preferences and information needs based on race/ethnicity and cancer stage. While some aspects of the breast cancer experience have improved, there remain several gaps in care and survivorship needs, including sexual health. Informational materials and supportive programming may address these gaps by accounting for differences among the diversity of people diagnosed in this age group.

Background: Breast cancer diagnosis and treatment generates disruption in multiple aspects in the life of patients, including work-related outcomes. The disruption in employment may exacerbate the economic burden on patients and their families, contributing to financial toxicity and ultimately impacting quality of life, especially in young women. However, the evidence of employment status at diagnosis for this group and its trajectory thereafter is limited. This study

aims to document the first change in employment experienced by Mexican young women with a recent diagnosis of breast cancer and determine which factors are associated with a decrease in work activities. Methods: Mexican women from the Joven & Fuerte prospective multicenter cohort, aged ≤ 40 , diagnosed with stage I-III breast cancer between 2015-2021 with at least 6 months of follow-up were included. Participants with a documented disease recurrence, missing employment status information, diagnosis of a new primary breast cancer or a second type of cancer were excluded from the analysis. Patients completed surveys at baseline, 6 months, and yearly for up to 5 years to assess sociodemographic characteristics, employment status, medical and treatment data. Employment status was categorized on a scale as follows: full-time > part-time > student > medical leave > unemployed. Only the first employment status change was included in this analysis. The Kaplan-Meier failure estimate was employed to calculate the increase or decrease in employment status at 1 year and 2 years post-diagnosis. Competing risk regression models were undertaken to explore variables associated with a decrease in employment status. Results: A total of 142 women with a median age at diagnosis of 36.5 years (IQR 33-39) and median follow-up of 17 months were included in the analysis. Baseline employment status for these patients was: employed - full time (27%), employed - part time (14%), student (1%), medical leave (4%) and unemployed (54%). At 12 months, 18.5% of participants had a reduction in their work activity (95% CI 12.8 - 26.4%) and this proportion further increased to 25.8% at 24 months (95% CI 18.7 - 34.8%). In contrast, 11.8% (95% CI 7.3 - 19.0%) and 23.2% (95% CI 15.9 - 33.2%) of participants exhibited an increase in their work activity at 12 and 24 months, respectively. The most common patterns in first employment status change were from unemployed to employed - full time (19%), employed - full time to employed - part time (13%) and employed - full time to unemployed (13%). In univariable analysis, having a partner at diagnosis demonstrated a lower hazard for experiencing a decrease in work activities; in contrast, postmenopausal status at 1 year was associated with a higher hazard of experiencing a decrease in employment status. However, in a competing-risks model including both partner and menopausal status, only the latter was associated with a higher hazard for experiencing a reduction in work activity (SHR=3.05, 95% CI 1.38 - 6.72, $p=0.006$). Age, education, monthly income, number of people who contribute to the household, having a partner at diagnosis, number of children, being financially responsible for another person, mastectomy, chemotherapy, radiotherapy and endocrine treatment were not associated with a higher probability of reduction in work activity. Conclusion: This cohort is one of the few initiatives assessing the impact of diagnosis and treatment of BC in young patients, specifically Latin American women. Our results show that there are relevant employment status changes after BC, possibly as a consequence of their treatment. Physical and psychological elements of menopause might influence the decrease in work status. Further studies are needed to deepen our understanding of employment changes in Latin American young women and guide interventions that address unintended limitations of work activities.

Introduction: Women living in disadvantaged neighborhoods consistently having worse breast cancer survival. Recent studies have identified that disparities by neighborhood disadvantage persist after controlling for patient, tumor, and National Comprehensive Cancer Network-guideline concordant treatment. This suggests unaccounted mechanisms by which neighborhood disadvantage “gets under the skin” to impact to shorter breast cancer survival.

Methods: Women with stage 0-3 breast cancer between 1998-2005 were enrolled in a clinical trial for stress management 2-10 weeks post-surgery and before initiating adjuvant treatment. At baseline, women provided an evening-time serum cortisol sample and were administered a structured clinical interview of anxiety symptoms (Hamilton Anxiety Rating Scale; HAM-A). Of the 240 women who enrolled in the study and completed baseline procedures, home addresses were provided by 225 women (93.8%). The addresses were used to determine the Area Deprivation Index (ADI), a validated measure of neighborhood disadvantage. Women were categorized as low (1-3) versus high (4-10) ADI. Linear regression analysis was used to assess the relationship between ADI and serum cortisol and logistic regression to assess whether ADI group predicted the presence of clinically significant anxiety per the HAM-A. Cox regression analysis was used to determine predictors of breast cancer-specific survival.

Results: The average age of our population was 50.4 years old (range 23-70 years) and the majority were non-Hispanic White (63.6%). Most patients had stage 1 (37.8%) or 2 (38.2%) disease. The majority lived in advantaged neighborhoods (low ADI, 77.8%). On the HAM-A, 46.8% of women reported clinically significant anxiety symptoms. When controlling for age, stage, and type of surgery, women with a high ADI had higher cortisol levels than women in with a low ADI (Beta=.19, $t(117)=2.18$, $p=.031$). Moreover, accounting for age, stage, and type of surgery, women with a high ADI were nearly two times as likely to have clinically significant anxiety symptoms in the HAM-A clinical interview (OR 1.99, 95%CI 1.01, 3.90, $p=.046$).

Moreover, after controlling for study condition (stress intervention vs. control), age, stage, Black race, and treatment, women with living in neighborhoods with an increasing ADI (disadvantaged neighborhoods) had shorter 5-year breast cancer-specific survival (HR=.096 95%CI 0.02, 0.64) compared to women living in neighborhoods with a lower ADI (advantaged neighborhoods).

Conclusion: This study identified that neighborhood disadvantage is significantly associated with higher levels of cortisol, clinical anxiety, and shorter 5-year breast cancer-specific survival. Future studies need to evaluate stress pathways as a potential mechanism by which neighborhood disadvantage impacts breast cancer-specific survival.

Background: More than 150,000 men and women are currently living with mBC in the United States. A diagnosis of mBC and its associated treatment can have pronounced consequences on patients' psychosocial well-being. However, to date, few studies have described patterns of psychosocial care among this population. Identifying disparities in psychosocial care utilization at the systems level may uncover gaps in mBC supportive care more broadly. Using a large retrospective cohort inclusive of patients treated at six health systems across New York City (NYC), we sought to determine if there were racial or ethnic differences in receipt of outpatient psychosocial care and psychosocial medications.

Methods: Adults diagnosed with mBC between 2010-2020 were identified using ICD-9 and ICD-10 diagnosis codes from the INSIGHT-Clinical Research Network database, which includes electronic health record, administrative, and clinical data from 12 million patients who received care across six NYC health systems. Receipt of outpatient psychosocial care was operationalized using Common Procedure Terminology codes for receipt of any outpatient psychotherapy or counseling visit with a licensed provider. Receipt of psychosocial medications (e.g., antidepressants, anxiolytics, sleep aids, benzodiazepines) were identified using RxCUI codes. Associations between race/ethnicity and outpatient psychosocial care and medications use was evaluated using logistic regression. Odds ratios (OR) and 95% confidence intervals (95% CI) were calculated for all estimates.

Results: We included 6,934 adults with mBC. Mean age was 61 (SD: 14) years and < 1% were male. Overall, 42% were non-Hispanic white, 17% non-Hispanic Black, 12%, Hispanic/Latinx, 4.8% Asian/Native Hawaiian/Pacific Islander, and 24.4% "other or unknown." Only 159 patients (2.3%) had ≥ 1 outpatient psychosocial care visits with a mean of 17 (SD: 42) visits per patient.

Of the overall cohort, 4,308 patients (62%) were prescribed at least one psychosocial medication during the study period. Both psychosocial outpatient care and psychosocial medication use differed by race/ethnicity (see Table). Compared to Non-Hispanic Whites, Black (OR 1.81; 95% CI 1.12-2.90) and Hispanic/Latinx (OR 4.46; 95% CI 2.96-6.77) mBC patients were more likely to have a documented outpatient psychosocial visit. Black (OR 0.63; 95% CI 0.54-0.72) and Asian (OR 0.40; 95% CI 0.32-0.50) mBC patients were less likely to be prescribed psychosocial medications compared to Non-Hispanic White patients.

Conclusion: Among a large, diverse cohort of mBC patients treated across NYC, we observed low utilization of outpatient psychosocial care. This finding may be attributable in part to patterns of referral/use of psychosocial support in the private practice setting that cannot be captured in administrative data. Sub-optimal health insurance coverage for psychosocial support may also be responsible for low utilization of outpatient psychosocial care. In contrast, psychosocial medication use was far more prevalent than outpatient care among our mBC cohort with significant differences observed by race/ethnicity. Identified differences suggest that unmet needs may exist and warrant further investigation.

Table. Psychosocial Outpatient Care & Medication Use by Race/Ethnicity

	Non-Hispanic White N=2910 (%)	Non-Hispanic Black N=1161 (%)	Hispanic/Latinx N=864 (%)	Asian/Native Hawaiian/ Pacific Islander N=330 (%)	Other/Unknown N=1669 (%)
Outpatient care	42 (1.4)	30 (2.6)	53 (6.1)	0 (0)	34 (2)
Medication use	1969 (67.7)	658 (56.7)	578 (66.9)	150 (45.5)	953 (57)

Triple negative breast cancer (TNBC) is the most aggressive breast cancer subtype with poor prognosis and limited treatment options. One of the mechanisms contributing to this is the ability of TNBC tumors to evade anti-tumour response, limiting the success of immune-checkpoint therapy. In recent studies of the tumor microenvironment, stromal cells have emerged as potential important mediators of lymphocyte function in TNBC. Multi-omics studies from our group and others have elucidated the heterogeneity of stromal cells and their interactions with immune cells in TNBC. However, the clinical relevance and functional characteristics of these relationships remain poorly explored. Our previous work revealed functionally distinct subpopulations of stromal cells in breast cancer: endothelial cells, myofibroblast-like cancer-associated fibroblasts (myCAFs), inflammatory-CAFs (iCAFs), and perivascular-like cells which resemble pericyte and smooth muscle cells in immature and differentiated states (impVLS; dPVLs), respectively. Here we directly explored the clinical relevance of these stromal subpopulations and their association with immune evasion in a large independent TNBC cohort with long-term survival data. Using markers derived from our single-cell multi-omics studies, we performed multiplex immunofluorescence using the OPAL9 platform on tumor microarrays from 222 TNBC patients to mark myCAFs, iCAFs, dPVLs, endothelial cells, CD8 and/or PD1 positive T-cells. Digital imaging analysis (QuPath) revealed a significant negative correlation between the abundance of stromal cells and CD8 T cells. This

cytotoxic T-cell exclusion is primarily driven by smooth muscle dPVLs. Parallel to this T-cell exclusion, our functional studies demonstrate that stromal cells suppress T-cell proliferation. Using multiple ex vivo co-culture models of primary TNBC CAFs and peripheral blood mononuclear cells (PBMCs) from healthy and matched donors, we show that CAFs suppress the proliferative capability of CD4 and CD8 T-cells. ScRNA-seq of these co-culture models demonstrate that CAF educated T cells are driven into a LAG3+ exhausted state enriched for canonical pathways of immunosuppressive cytokine signaling. Our findings suggest that manipulation of these stromal subpopulations could elicit a more effective immune response in a subset of patients through inhibiting T-cell dysfunction and exclusion.

PD9-02

PD9-02 MHC class I and PD-L1 expression in triple-negative breast cancer subtypes: impact on T-cell infiltration and clinical outcome

Presenting Author(s) and Co-Author(s):

ji shin lee, *n/a, professor - Chonnam National University Hwasun Hospital*
Country: United States

nah ihm kim, *n/a, professor - Chonnam National University Hwasun Hospital*
Country: United States

min ho park, *n/a, professor - Chonnam National University Hwasun Hospital*
Country: United States

Background: Triple-negative breast cancer (TNBC) is a heterogeneous group of cancer with dismal prognosis. In an effort to discover therapeutic targets, TNBC has been further stratified into molecular subtypes. Immune checkpoint inhibitors targeting programmed cell death protein 1 (PD-1) and its ligand (PD-L1) have been increasingly utilized for the treatment of TNBC. Difficulty remains, however, in appropriate patient selection for treatment, as many PD-L1-positive cancers fail to show durable responses to PD-1/PD-L1 inhibition. Major histocompatibility complex (MHC) class I molecules play a crucial role in the presentation of tumor antigenic peptides to cytotoxic T cells. Loss of MHC class I expression in tumor cells represents a possible mechanism of immunotherapeutic resistance in PD-L1-positive cancers. However, little is known about the clinical impact and value of MHC class I expression in TNBC subtypes. Thus, this study examined MHC class I expression in TNBC subtypes with attention to PD-L1 expression and T cell infiltration. Materials and methods: MHC class I and PD-L1 expression were assessed by immunohistochemistry in 256 TNBC samples using tissue microarray. Immunohistochemistry for the TNBC molecular subtype-surrogate markers [cytokeratin 5/6 (CK5/6), CK14, epidermal growth factor receptor (EGFR), and androgen receptor (AR)], CD3, and CD8 was also performed. TNBC subtypes were classified into three subtypes: basal-like (BL), luminal AR (LAR), and unclassifiable type (UN). Results: All immunohistochemical markers were interpretable in 240 cases. TNBCs were classified into BL (65.8%), LAR (11.3%), and UN (22.9%) subtypes. Loss of MHC class I expression was found in 62 of 240 (25.8%) cases and was observed in 23.4% of BL, 40.7% of LAR, and 25.9% of UN subtype. PD-L1 expression in tumor-associated immune cells ($\geq 1\%$) was seen in 69.2% (166/240). Among 166 PD-L1-positive TNBC cases, loss of MHC class I expression was seen in 16.4% of BL, 31.3% of LAR, and 20.0% of UN subtype. Loss of MHC class I expression was associated with low stromal TILs density and low CD3+ and CD8+ T-cell infiltration in BL subtype. CD3+ and CD8+ T-cell infiltration in TNBC subtype had a positive correlation with PD-L1 expression. In PD-L1 positive BL subtype, MHC class I lost expression showed a lower infiltration with CD3+ and CD8+ T-cells than MHC class I intact expression. In BL subtype, PD-L1 expression was associated with better disease-free survival and loss of MHC class I expression was associated with poor overall survival. However, MHC class I and PD-L1 expressions were not independent prognostic factors for disease-free or overall survival. Conclusions: Loss of MHC class I expression was found in TNBC, including PD-L1 positive cases. In PD-L1 positive BL subtype, loss of MHC class I expression was associated with low CD3 and CD8+ T-cell infiltration. Our results suggest that the evaluation of PD-L1 and MHC class I expression together is very important for the selection of potential responders to anti-PD-1/PD-L1 therapy for the TNBCs, especially the BL subtype.

Background: Estrogen receptor positive (ER+) / HER-2 negative breast cancer (BC) is considered to be an immunologically cold tumor compared to triple negative breast cancer. Therefore, the tumor microenvironment (TME) of ER+ / HER-2 negative BC is understudied.

The receptor activator of nuclear factor- κ B ligand (RANKL)-RANK pathway was first identified, as mediator of T and dendritic cells interaction, but it is mostly known for its role as key regulator of bone remodeling and pathophysiology of bone metastases. RANK is a member of the tumor necrosis factor receptor (TNFR) superfamily that is activated upon RANKL binding, promoting cell proliferation, survival and differentiation. The RANKL-RANK pathway also emerged as a major mediator of hormone-driven breast carcinogenesis. The aim of this study is to investigate the TME and the immune response during neoadjuvant endocrine therapy (NET) and to correlate this with the treatment response in a real life setting.

Methods: Expressions of immune checkpoint receptors and immune cells were examined immunohistochemically in pre- and post- NET on a cohort of 44 ER+ / HER-2 negative BC patients. They were treated with tamoxifen (N=8), an aromatase inhibitor (N=36) or a combination of an aromatase inhibitor with a PI3K inhibitor (N= 7) for a median duration of 6 months (range 1-32) months. Monoclonal antibodies for PD-L1, PD-1, TIM-3, LAG-3, CTLA-4, CD4, CD68, FOXP3, RANK and RANKL were used. All staining were done according to validated protocols and scoring was done by a pathologist specialized in breast cancer. Positivity was defined as staining > 1% on TILs. Response to NET was evaluated according to tumor size change on imaging and Ki-67 change.

Results: The median age was 62.5 (44–90.3) years. Diameter of tumor size decreased with a mean of 7.818 mm ($p < 0.0001$) during NET and the value of Ki-67 value decreased significantly after NET (value, $p < 0.0004$). An increase in PD-L1 expression after NET showed a trend towards significant ($p = 0.088$) and RANK expression on TILs significantly decreased with a median of 30% (range= -70 to 85) ($p = 0.0007$) after NET. A good response to NET defined as a decrease in tumor size and/or decrease of Ki-67 was found to be associated with a longer duration of NET, a change of CD4+ T-cells, a change of RANK expression on TILs and a higher number of CD68+ tumor-associated macrophages before the start of NET and also RANK expression on TILs before the start of NET.

Conclusion: The immune micro-environment plays an important role in ER+ / HER-2 negative BC. NET influences the composition and/or functional state of the infiltrating immune cells. Furthermore, changes in the immune micro-environment are also associated with treatment response.

Breast Cancer Microenvironment Change After Neoadjuvant Endocrine Treatment

	Continuous parameters		
	(median (min-max))		
	Before NET	After NET	p value
Tumour Size	23.5 (6-65)	13 (0-70)	<0.001
Ki-67	15 (1-45)	3 (1-45)	<0.001
sTIL	5 (1-85)	5 (1-80)	0.08
CD-68	15 (5-40)	10 (5-50)	0.11
CD-4	5 (1-13)	10 (1-70)	0.03
FOXP3	22.5 (0-60)	15 (1-60)	0.14
FOXP3/CD-4	2.307(0-15)	1 (0.03-12)	0.04
	Categorical parameters n (%)		
	Before NET	After NET	p value
PD-L1	4 (9)	11 (25)	0.088
PD-1	8 (18)	15 (34)	0.16
CTLA-4	10 (23)	12 (27)	0.69
TIM-3	28 (64)	23 (52)	0.53
LAG-3	19 (43)	29 (66)	0.22

Comparison of continuous and categorical parameters before and after NET. Comparison of the continuous parameters was done using Wilcoxon signed rank test. Comparison of the categorical parameters was done using a Chi-square test. sTIL: stromal tumour infiltrating lymphocytes and NET: neoadjuvant endocrine therapy. Bold values denote statistical significance at the $p < 0.05$ level.

Background: The implementation of immune checkpoint inhibitors in the therapy of different cancer types has provided promising results, but only a limited number of patients respond. Therefore, biomarkers to identify these responding patients are urgently needed. Methods: The GeparNuevo was a randomized, double-blind phase II trial in which triple-negative breast cancer (TNBC) patients were treated with neoadjuvant chemotherapy (NACT) consisting of nanoparticle albumin-bound paclitaxel in an initial phase followed by treatment with epirubicin and cyclophosphamide. Placebo or durvalumab were given throughout the neo-adjuvant treatment and in the “window” sub-cohort also prior to chemotherapy. Primary objective of this report was to evaluate changes in the blood immune cell repertoires of TNBC patients receiving durvalumab (anti-PD-L1) versus placebo in combination with NACT. At up to 4 different time points during therapy, blood samples were taken and underwent immunomonitoring using multicolor flow cytometry. The absolute counts of the major immune cell subtypes in the blood as well as the frequencies of different immune cell subpopulations and their functional phenotypes along treatment were determined and correlated to clinico-pathologic characteristics of the patients and to treatment response. Results: 120 out of 174 patients included in the GeparNuevo trial underwent blood immunomonitoring; 63 patients belonged to the “window” sub-cohort. Durvalumab administration almost completely blocked the detection of the inhibitory ligand PD-L1 and induced changes in the composition of the immune cell subpopulations. Evaluation of the “window” sub-cohort, in which an enhanced, but not significant pathological clinical response was observed within the immunomonitoring patients, identified different markers correlating with clinical response to durvalumab. Higher frequencies

of CD4+ T cells at recruitment as well as increased frequencies of T cells bearing the gamma delta TCR along treatment were some of the characteristics of patients responding to durvalumab treatment. Conclusions: The flow cytometry-based immunomonitoring of the clinical trial identified different immune-relevant biomarkers at recruitment as well as during treatment that predict clinical response to durvalumab. After validation of this data in an independent patient cohort, these markers could be implemented for an improved patient stratification to immunotherapy.

Background: The prognostic value of stromal tumor-infiltrating lymphocytes (TILs) as a biomarker for triple-negative breast cancer (TNBC) has been extensively demonstrated in patients (pts) receiving (neo)adjuvant systemic therapy. In addition, several small studies suggest that a subset of pts with early-stage TNBC and high TILs have excellent long-term outcomes, even in the absence of systemic therapy [1-3]. However, data on the absolute risk of TNBC recurrence according to TIL levels in the absence of systemic therapy are limited and critical to inform the design of future systemic therapy de-escalation clinical trials.

Methods: We conducted an individual patient data pooled analysis of 12 international cohorts of pts with TNBC treated with locoregional therapy but no systemic therapy. TNBC was defined as tumors with estrogen and progesterone receptor of < 1% and HER2 negative (IHC 0, 1+ or IHC 2+ and FISH negative) per local evaluation. TILs were locally assessed in hematoxylin & eosin-stained slides according to the International Immuno-Oncology Biomarker Working Group guidelines (www.tilsinbreastcancer.org). We used the Kaplan-Meier method to assess survival outcomes according to prespecified TIL thresholds: 30% and 50%. Confidence intervals (CI) for survival probabilities were calculated using a percentile bootstrap method. The primary endpoint was invasive disease-free survival (iDFS, STEEP 2.0 definition). Key secondary outcomes included recurrence-free survival (RFS), distant disease-free survival (DDFS) and overall survival (OS).

Results: 1,835 pts diagnosed with TNBC between 1982 and 2017 who did not receive systemic therapy were included. The median age at diagnosis was 56 (IQR 38-71). Menopausal status was known in 1,184 women, of whom 78% were post-menopausal. The median tumor size was 2.0 cm (IQR 1.2-2.6). Most pts (87%) had no axillary lymph node involvement (N0). Most tumors were invasive ductal carcinoma (74%) and grade 3 (70%). The median level of TILs was 15% (IQR 5-40). The median duration of follow-up was 30.4 years (95% CI 29.9, 31.1). A total of 950 (52%) iDFS, 828 (45%) RFS, 767 (42%) DDFS events, and 604 (33%) deaths were observed. In multivariable analyses, higher TILs were independently associated with improved iDFS, RFS, DDFS, and OS beyond clinicopathological factors (likelihood ratio $p < 10e-6$). Each 10% increment in stromal TILs was associated with an 8% (95% CI: 6-11), 10% (95% CI: 7-13), and 13% (95% CI: 10-15) reduction in the risk of experiencing an iDFS, RFS or DDFS event, and with a 12% (95% CI: 9-15) reduction in the risk of death. iDFS, RFS, DDFS and OS rates according to different TIL thresholds and nodal status are shown in the Table. Of note, the RFS estimates (which exclude second non-breast primaries and contralateral breast cancers) were consistently higher than the iDFS counterparts (which include both), consistent with a high rate of contralateral breast cancers and second primary tumors in this cohort. Notably, patients with node-negative—and especially stage I—TNBC with high TILs had excellent survival rates at 10-

year follow-up.

Conclusion: TILs are highly prognostic in pts with systemically untreated early-stage TNBC. Pts with pN0 (and especially stage I) TNBC with high TILs exhibited very favorable long-term outcomes even in the absence of systemic therapy. These data define the natural history of TIL-rich TNBC pts and are crucial to identifying the optimal patient population for future chemotherapy and immunotherapy de-escalation clinical trials.

Background The TNT trial (NCT00532727) showed no evidence of carboplatin (C) superiority over docetaxel (D) overall in metastatic triple negative breast cancers (TNBC), but a C benefit was observed in the pre-specified sub-group analysis in patients with a gBRCA1/2 mutation (Tutt et al, Nat Med 2018). Given only ~30% of patients have a gBRCA1/2 mutation, broader predictive biomarkers of response are needed. In this cohort we previously found that DNA Damage Response (DDR) signatures were associated with improved C response in chemotherapy (CT) naïve patients only (Tovey et al, ASCO 2020). Since DDR activities influence tumour immune-microenvironment, we explored the predictive ability of immune cell markers and performed integrative analyses on multi-omics features to identify novel TNBC subgroups. Patients and Methods Tumour infiltrating lymphocytes (TILs) were evaluated on haematoxylin and eosin stained primary tumour (PT) slides for 222/376 TNT patients. Formalin-fixed paraffin-embedded PT tissues from 186/376 TNT patients were successfully profiled using total RNA-sequencing. Matched recurrence (REC) was also sequenced for 13 patients. Twenty-five immune signatures were assessed. Logistic regression and restricted mean progression free survival (PFS) were applied to delineate the relationship of these features with treatment outcomes. Random forest clustering of multi-omics DDR and immune biology markers, including gene expression signatures and mutation/methylation status, was applied to identify subgroups. We further molecularly characterised these clusters through supervised clustering of 693 gene expression "modules" (sets of co-expressed genes), immune cell deconvolution and genomic scars. Results Immune gene expression signatures and TILs were highly correlated. Average immune infiltration based on ConsensusTME was lower in mutated/methylated tumours compared with BRCA1 wildtype tumours (p=0.04). Immune signature score markers decreased from PT to REC, demonstrating a dynamic immune microenvironment. In the overall population and when restricting to prior CT treated patients,

high immune infiltration (gene expression based & TILs) was associated with response to D while C response rates were not associated with immune scores (interaction p-values < 0.05). This did not translate to a PFS benefit. Multi-omics clustering identified 6 biological subgroups including immune enriched, immune depleted, DDR deficient and proficient clusters as well as 2 small clusters with no obvious distinguishing features. Immune enriched TNBC were predominantly basal-like immune activated with high B-cell/T-cell diversity. Immune depleted TNBC showed higher activity of proliferation and DDR pathway modules. DDR proficient tumours had low expression of immune markers and enrichment for ESR1/PGR expression, markers of extra cellular formation, cell structure, lipid metabolism and proliferation. The DDR deficient cluster was enriched for proliferation and demonstrated high number of TILs despite no apparent enrichment for gene expression-based immune modules. In the prior CT treated cohort, the immune enriched cluster had preferential response to D (62.5% (D) vs. 29.4% (C) ; $p=0.02$). The immune depleted cluster had preferential response to C (8.0% (D) vs. 40.0% (C); $p=0.01$). Numbers were too small to assess differential response within the other clusters or in the CT naïve cohort. Conclusions Tumours with high immune features have high response to D while those with low immune features have preferential response to C in advanced TNBC. Combining multi-omics markers of DDR deficiency and immune biology can identify clusters of patients with distinct biological profiles and differential treatment specific response rates.

BACKGROUND: Although the triple-negative breast cancer (TNBC) tumor microenvironment (TME) has been deeply characterized, much remains unknown about pathways attributing to an immunosuppressive TME in this disease. The phosphorylation of JNK (c-Jun N-terminal kinase) pathway has been associated with promoting an immunosuppressive phenotype, enhancing TNBC aggressiveness. Here, we aimed to explore the role of the JNK pathway in TNBC using a gene signature inferring the level of JNK phosphorylation. For this purpose, we used the TNBC cohort from the phase III adjuvant IBCSG 22-00 trial, which evaluated low-dose cyclophosphamide and methotrexate (CM) chemotherapy showing no clinical benefit in the overall population. **METHODS:** JNK gene signature was developed in TNBC samples by integrating RNA-seq gene expression data and phospho-JNK-targeted proteomic data in The Cancer Genome Atlas. Stochastic subsampling was performed to select the candidate markers. LASSO regression was performed to determine the final transcriptional signature to reflect JNK phosphorylation. The signature was then applied in a cohort composed of 498 TNBCs selected using stratified 1:3 relapse cases and non-relapse subcohort ratio from the IBCSG 22-00 trial. RNA-seq data from FFPE tumor samples were available for 347 patients. The JNK signature was calculated as the mean of the products between gene expression and signature coefficients, defining high and low levels using the median cut-off. Immune hot tumors were defined according to TNBC molecular subtypes or tumor-infiltrating lymphocytes (TILs) levels higher than 30%. Multivariable Cox models were used for disease-free survival (DFS) analysis. Wilcoxon test was used to evaluate the association between gene signatures and the levels of JNK. **RESULTS:** Tumors with either immunomodulatory (IM) phenotype or high TILs showed better DFS when presenting low levels of JNK compared to high levels (HR = 0.75, 95% CI, 0.57 to 0.99; P-value = 0.024 and HR = 0.62, 95% CI, 0.43 to 0.89, P-value = 0.0013). No significant differences in DFS were observed in other TNBC subtypes or tumors with low TILs, further highlighting the relevance of JNK signaling pathway in tumors presenting immune infiltration. Moreover, immune hot tumors with high levels of JNK were enriched for angiogenesis and eosinophils signatures and linked to immunosuppression. The immune targets B7-H3, CSF1R, GITR, and GARP were significantly associated with high levels of JNK.

Of note, these genes are involved in the immune escape, activation of macrophages, and regulation of Tregs population. On the other hand, low levels of JNK were associated with higher levels of activated CD8+ T cells, pointing to an anti-tumor immune response, as well as with higher levels of the immune targets PDL-1, CTLA4, CD47, DCIR, and TIGIT. Of interest, a significant DFS benefit was found in IM tumors with high levels of JNK when treated with low-dose CM, compared to those who were not (HR = 0.52, 95% CI, 0.28 to 0.99; P interaction = 0.045). CONCLUSIONS: We developed a JNK gene signature to estimate the phosphorylation level of JNK from gene expression data in TNBC, and validated the associated biological and prognostic value in the IBCSG 22-00 trial. Our results are in line with the immunosuppressive effect described by the JNK gene signature and highlight the heterogeneity of immune response in immune hot TNBCs. Of note, high levels of JNK were associated with worse DFS, as well as with a benefit from low-dose CM potentially related to the immunomodulatory effect described for metronomic regimens. Overall, our findings suggest a potential role of the JNK signature in identifying TNBCs with an immunosuppressive TME and provide the rationale to explore its role as a biomarker for immunotherapy. Further validation of these findings is required.

BACKGROUND: Immune checkpoint inhibitors in combination with chemotherapy have demonstrated an improvement of pathologic complete response (pCR) in patients with HR-HER2- and MammaPrint (MP) High Risk, HR+HER2- tumors in the I-SPY2 TRIAL. However, not all patients benefit from immune checkpoint blockade and these new agents come with additional financial burden and significant long-lasting side effects such as adrenal insufficiency. Thus, it is imperative to better understand who benefits. Response Predictive Subtypes (RPS) were developed in the I-SPY2 TRIAL using pre-treatment expression data

from 987 MP High Risk patients; 39% of HR+HER2- tumors and 63% of HR-HER2- tumors were identified as immune sensitive. In I-SPY2.2, RPS tumor classification uses ImPrint, a 53-gene signature that has been independently validated to predict the likelihood of a pCR with PD1-PDL1 immune checkpoint inhibitors with high sensitivity and specificity. Using a real-world dataset of 10,000 patients enrolled in the FLEX trial, we identified immune sensitive (ImPrint+) patients within immunohistochemistry (IHC) subtypes and within MP and BluePrint (BP) subgroups.

METHODS: FLEX (NCT03053193) is an ongoing registry trial with 97 sites open in the United States and 2 international sites. Patients enrolled in FLEX have early-stage breast cancer and receive standard of care MP testing with or without BP molecular subtyping and consent to clinically annotated full genome data collection. MP is a 70-gene risk of distant recurrence signature that classifies patients as Low Risk or High Risk. MP High Risk can be further stratified into High 1 and High 2, which have demonstrated differences in chemosensitivity and pCR rates in the I-SPY2 TRIAL (NCT01042379). BP, an 80-gene molecular subtyping signature, categorizes patients' tumors as Luminal-, HER2- or Basal-Type.

RESULTS: Of the 10,021 patients, 9.1% of the FLEX patient population are ImPrint+ and are predicted to have a meaningful pCR rate with immune checkpoint inhibitors. Younger (≤ 50 years) or pre/peri-menopausal patients, patients with larger or node-positive tumors, and patients of Black or Latin race/ethnicity independently had a higher likelihood of having ImPrint+ tumors (Table 1). ImPrint+ tumors were identified in all clinical subtypes by IHC. There is a higher likelihood of ImPrint+ tumors being MP High 2 or BP Basal-Type tumors. Within BP Basal tumors, 74.7% of HR+ and 66.0% of HR- tumors were ImPrint+.

CONCLUSIONS: The focus of immune therapy trials has been on patients with HR-HER2-, MP High Risk patients. Indeed, most patients who are predicted to benefit have MP High 2 or BP Basal-Type tumors, including some HR+ patients, which is consistent with I-SPY2 results. Importantly, this large real-world dataset enables the identification of populations who may benefit from immune therapy outside of traditional clinical trial populations and supports the testing of checkpoint inhibitors in the immune-positive subtype. Younger women and patients of Black or Latin race/ethnicity who typically have more aggressive tumors also have higher proportions of ImPrint+ tumors. Thus, it is critical that these populations be included in clinical trials. This first look at immune sensitivity in over 10,000 FLEX patients with ImPrint generates preliminary data and hypotheses that will be explored in future FLEX substudies, including an analysis of lobular cancers and long-term outcomes in ImPrint+ patients across all races and ages.

Clinical characteristics of ImPrint+ and ImPrint- tumors

Background: The RxPONDER and TAILORx trials demonstrated benefit from adjuvant chemotherapy in patients < 50 years with node-positive breast cancer and Recurrence Score (RS) 0-25, and with node-negative disease and RS 16-25, respectively. Neither trial showed benefit in older women with RS < 26. It is unclear what explains the interaction between age and adjuvant chemotherapy benefit. Methods: We analyzed transcriptomic and genomic data from n=4,507 ER+/HER2- breast cancers to compare differences in estrogen receptor (ER), proliferation, and immune-related gene expressions, and somatic mutation patterns and mutation burden between younger (< 50 years of age) and older (>55 years) patients. We restricted our analysis to patients in the lower 80% range of in silico RS distribution to mimic the RxPONDER and TAILORx populations. Results: Five data sets were analyzed independently to assess consistency of results (TCGA n=530; microarray cohort A n=865; Cohort B n=609, METABRIC n=867, SCAN-B n=1636). Older patients had significantly higher somatic mutation

burden and more frequent copy number gain in ESR1, LATS1, ARID1B, SGK1, and MYB genes (odds ratio [OR] > 8.5, FDR < 0.05), but lower frequency of GATA3 mutations (12% versus 26%, P < 0.0001). Younger patients had higher rate of ESR1 copy number loss (OR: 0.45, FDR: 0.03). There was no difference in proliferation-related gene expression. ESR1 mRNA expression was significantly lower in younger women in all cohorts (P < 0.001). A regression model of ESR1 mRNA expression using age and ER IHC positivity indicated that lower ER expression in younger patients is primarily driven by lower ESR1 mRNA per cancer cell and not by fewer ER positive cells. We also assessed four gene signatures associated with endocrine therapy sensitivity including a 4-gene ERS, a 7-gene ERS-Lum, a 106-gene ERS-Pos signature, and a 59-gene ERS-Neg signature associated with endocrine resistance. In the TCGA and METABRIC cohorts, the ERS, ERS-Lum, and ERS-Pos signatures were all lower (FDR < 0.03) while the ERS-Neg signature was higher (FDR < 0.001) in younger patients. Similarly, in both microarray cohorts, and in the SCAN-B-cohort, the ERS-Pos signature was lower and the ERS-Neg signature was higher in younger patients (FDR < 0.002). Next, we assessed 4 different immune cell signatures that have been associated with response to chemotherapy. In the TCGA, B-cell, T-cell, Mast-cell, and TIS signatures were significantly higher (FDR < 0.05). In the microarray Cohort-A, B cells and mast cells were significantly higher, and the T cell and TIS signatures showed a trend for higher expression. In Cohort-B, T cells, B cells, TIS, and dendritic cells signatures were significantly higher in younger patients. Significantly higher expression of immune gene signatures in younger patients were also seen in the METABRIC and SCAN-B data sets. The ER-related and immune-related gene signatures showed negative correlation and joint analysis defined three subpopulations in younger women: (i) immune-high/ER-low, (ii) immune-intermediate/ER-intermediate and (iii) immune-low/ER-intermediate, whereas in older women the dominant pattern was immune-low/ER-high. Conclusion: ESR1 mRNA and ER-associated gene expression is lower in ER positive cancers of younger compared to older patients, while immune infiltration is higher. The cytotoxic and endocrine effects of adjuvant chemotherapy could both contribute to the survival benefit seen in younger patients, but the relative contributions of these effects may vary by ER and immune phenotype. We hypothesize that in immune-high/ER-low cancers, the cytotoxic effect of chemotherapy may drive the benefit, whereas in immune-low/ER-intermediate cancers chemotherapy induced ovarian suppression may play a more important role.

Background: HER2DX (Prat et al. EBiomedicine 2022) is a 27-gene prognostic (risk-score) and predictive (pathological complete response [pCR]-score) assay in early-stage HER2+ breast cancer based on clinical data and the expression of 4 gene signatures (immune, proliferation, luminal differentiation and HER2 amplicon). Here, we aim to evaluate, for the first time, the ability of HER2DX to predict pCR following neoadjuvant TCH or TCHP in HER2+ disease. Methods: Standardized HER2DX was performed in a central lab on baseline pre-treatment FFPE tumor biopsies from the GOM-HGUGM-2018-05 study in Spain, a consecutive retrospective series of patients (pts) with newly diagnosed stage I-III HER2+ breast cancer eligible for neoadjuvant therapy. Pts received standard 6 cycles of docetaxel, carboplatin and trastuzumab (TCH) or TCH with pertuzumab (TCHP) regimens. Primary aim was to test the ability of HER2DX pCR score to predict pCR (ypT0/is ypN0). Secondary objectives were to test the ability of HER2DX pCR score to predict pCR independently of clinical-pathological variables and the PAM50 subtype (HER2-enriched versus not), and to evaluate the association of HER2DX pCR score with the HER2DX risk-score. Logistic regression and receiver-operator curve (ROC) analysis were assessed. Statistical analyses were performed in R code 4.0.5. Results: HER2DX was evaluated in 155 pts (97%) enrolled in the study with available RNA (as of June 2022). Mean age of pts was 50 (range 22-74) and 55.2% of pts (n=85) were pre-menopausal. Clinical T2-4 disease represented 77.4% of cases (n=120), clinical node-positive disease (cN1-3) represented 63.9% of cases (n=99), and 68.0% of tumors (n=105) were hormone receptor-positive. The overall pCR rate was 57.4% (95% confidence interval [CI] 50-65): 52.2% (95% CI 40-64) with TCH (n=67) and 61.4% (95% CI 50-72) with TCHP (n=88). The proportion of HER2DX low-, medium- and high-pCR groups was 34.2%, 34.8% and 31.0%, respectively. HER2DX pCR score (as a continuous variable from 0 to 100) was significantly associated with pCR (odd ratio [OR]=1.03, p=5.91e-07). The pCR rates in HER2DX pCR-high and pCR-low groups were 75.0% and 28.0% (OR=7.6, 95% CI 3.2-19.1, p=7.14e-06), respectively. In pts treated with TCHP, the pCR rates in HER2DX pCR-high and pCR-low groups were 85.7% and 27.3% (OR=16.0, 95% CI 4.3-59.01, p=3.2e-05), respectively. The AUC ROC of HER2DX pCR score (as a continuous variable) and pCR status was 0.746 (in all pts) and 0.812 (in pts treated with TCHP). HER2DX pCR score was significantly associated with pCR independently of hormone receptor status, Ki67, age, menopausal status, pertuzumab use, clinical stage and PAM50 HER2-enriched subtype. The proportion of HER2DX low- and high-risk of relapse disease was 32.0% and 68.0%, respectively. The

correlation of HER2DX pCR score and HER2DX risk-score was weak (coefficient=-0.17), as previously described. Proportion of cases according to both HER2DX scores and absolute difference of pCR rates between TCHP and TCH in each combined group is shown in Table. Conclusion: The HER2DX genomic test predicts pCR following neoadjuvant TCH or TCHP regimens independently of clinical-pathological variables and intrinsic subtype. The combination of both HER2DX scores might help better tailor systemic therapy in patients with newly diagnosed stage I-III HER2+ breast cancer.

Background: Ribociclib (RIB) plus endocrine therapy (ET) has demonstrated a statistically significant survival benefit across the three phase 3 MONALEESA (ML) trials, irrespective of menopausal status, line of therapy, or combination partner. RIBANNA (CLEE011ADE03), a prospective, noninterventional study assessing the efficacy and safety of RIB + ET, or ET monotherapy or chemotherapy (CT) in first-line (1L) setting in pre-, peri- and postmenopausal patients (pts) with hormone receptor-positive (HR+), human epidermal growth factor receptor-2-negative (HER2-) advanced breast cancer (ABC) is ongoing in Germany since October 2017 to gain insights into real-world scenario. In the 5th interim analysis (IA) from RIBANNA, a matched-pair analysis of 1L PFS data from the three treatment cohorts and comparison of 1L PFS data on RIB + ET from RIBANNA versus (vs) ML trials will be performed.

Methods: Pre-, peri- and postmenopausal women receiving RIB + ET, ET monotherapy, or CT as 1L treatments for HR+, HER2- ABC, in accordance with German treatment guidelines, were included. Propensity score matched (PSM) analysis of PFS data from the 3 treatment cohorts will be conducted to reduce the bias due to confounding variables. In addition to safety analyses, comparison of 1L PFS data on RIB + ET from RIBANNA vs ML trials will be performed.

Results: By the cutoff date of the 4th IA (October 11, 2021), data were available for 2187 pts, including 1849 (83.0%), 193 (78.1%), and 145 (73.6%) pts from the RIB + ET, ET monotherapy, and CT cohorts in 1L setting, respectively (Table 1). Of these 2187 pts, 1111 postmenopausal pts received 1L RIB + letrozole; 357 postmenopausal pts received 1L RIB + fulvestrant, and 158 pre- and perimenopausal pts received 1L RIB + anastrozole/letrozole. The unadjusted Kaplan-Meier estimate for median PFS was 31.7 months (95% confidence interval [CI], 28.5–36.2) in the RIB + ET cohort, 25.7 months (95% CI, 18.0–not reached) in the ET monotherapy cohort, and 15.3 months (95% CI, 9.5–17.5) in the CT cohort. The most frequent treatment-emergent adverse events (grade 3 or 4) in the RIB + ET and ET monotherapy cohorts were neutropenia (14.8% and 6.6%, respectively) while that in CT cohort was general physical health deterioration (9.1%).

Conclusions: In RIBANNA, a diverse pt population is being analyzed in a real-world setting; treatment with RIB + ET has been observed to be well adopted. The 5th IA is planned in October 2022 and data will be presented in SABCS 2022, which will include PSM analysis to compare 1L PFS data across treatment cohorts as well as comparison of 1L PFS data on RIB + ET from RIBANNA vs ML trials. The safety profile of RIB was found to be similar to those observed in ML trials.

Table 1. Patient demographics and baseline clinical characteristics from the 4th IA

Table 1. Patient demographics and baseline clinical characteristics from the 4th IA

Demographic variable	1L RIB + ET (n=1849)	1L ET monotherapy (n=193)	1L CT (n=145)
Mean age, years (SD)	65.5 (11.6)	70.7 (11.5)	61.6 (11.6)
Menopausal status*, n (%)			
Postmenopausal	1640 (88.7)	178 (92.2)	123 (84.8)
Premenopausal/ perimenopausal	192 (10.4)	13 (6.7)	20 (13.8)
ECOG performance status*, n (%)			
0	818 (44.2)	67 (34.7)	61 (42.1)
>1	1031 (55.8)	125 (64.8)	84 (57.9)
Mean time since initial diagnosis, years (SD)	5.9 (7.3)	6.8 (8.3)	4.7 (6.1)
Grading at initial diagnosis*, n (%)			
G1	113 (6.1)	5 (2.6)	2 (1.4)
G2	1095 (59.2)	117 (60.6)	73 (50.3)
G3	466 (25.2)	39 (20.2)	55 (37.9)
Metastatic sites*, n (%)			
CNS, liver, and lung	761 (42.6)	51 (26.8)	94 (67.1)
Bone only	551 (30.8)	91 (47.9)	21 (15.0)
Skin, lymph nodes, and others	434 (24.3)	45 (23.7)	20 (14.3)

*Remaining cases are missing
CNS, central nervous system; CT, chemotherapy; ECOG, Eastern Cooperative Oncology Group; ET, endocrine therapy; IA, interim analysis; RIB, ribociclib; SD, standard deviation

Background CDK4/6 inhibitors may trigger anti-tumour immunity, both through tumour cell intrinsic and extrinsic mechanisms, which can be enhanced by immune checkpoint blockade in pre-clinical studies. Although most triple negative breast cancers (TNBC) are resistant to CDK4/6 inhibition, palbociclib (palbo) has activity in pre-clinical models of the luminal androgen receptor (LAR) subtype. Here we report the dose finding phase 1b cohort A of the PAVeMenT trial combining avelumab and palbociclib. Methods The PAVeMenT phase 1b trial consists of a dose finding phase (cohort A), to be followed by an expansion in androgen receptor positive (AR+) TNBC (Cohort B). The phase 1B phase investigated palbo dosing schedules (75mg intermittent dosing (ID), 100mg continuous dosing (CD) and 125mg ID) in combination with the anti-PD-L1 antibody, avelumab 10mg/kg 2-weekly (cohort A) to determine the optimal schedule for cohort B. The CD dose-level was pre-specified as the preferred schedule if tolerated, due to the proliferative nature of TNBC and potential for tumour re-growth with ID. Patients with previously treated advanced breast cancer (ABC) of any histology with measurable disease and adequate organ function, who had not received prior immunotherapy or CDK4/6 inhibitors or more than 2 lines of chemotherapy for ABC, were eligible for cohort A. Dose-limiting toxicities (DLTs) were defined as Grade(G) 4 neutropenia, complicated G3 neutropenia or G4 thrombocytopenia, or \geq G3 immune toxicity during cycle 1. AR staining of \geq 10% using the SP107 antibody (Ventana) was considered AR+. PD-L1 was evaluated using CC23 Pharma Dx antibody (DAKO) and PD-L1 positive defined as CPS score of \geq 10%. Results Fourteen patients were recruited to Part A, all female, 12 with TNBC, two with ER positive/HER2 negative ABC, median age 53.5 years. Three evaluable patients received palbo 75mg/day ID without DLTs, therefore two further dose levels were opened in parallel. Three evaluable patients received palbo 125mg/day ID without DLTs. Due to a DLT of fever with G3 neutropenia in one of 3 patients receiving palbo 100mg CD, 3 further evaluable patients received 100mg CD without DLTs. Two patients were not evaluable for DLTs having not received a full cycle of treatment so were replaced. One case of grade 3 colitis and one case of grade 2 hypothyroidism (both 100mg CD) occurred outside the DLT period. Amongst 12 patients with TNBC, metastatic tissue was available for 11, archival breast tissue for one. Four of 12 patients were AR+. Five of 10 TNBC patients with sufficient tissue were PD-L1 positive, all of whom had previously tested negative with the SP142 antibody (Ventana). One of the 5 PD-L1+ and 2/5 PD-L1 negative TNBC cases were also AR+. TNBC patients received a median of 2 cycles of treatment (range 1-17). Both ER+ patients were AR+ and PD-L1 negative; one progressed after 4 cycles, the other remains on treatment at 12 cycles. The 100mg CD schedule was selected for cohort B. Conclusions All schedules were tolerable, with activity observed in patients with both ER positive and TNBC cancers. Cohort B of the study is open to recruitment for patients with AR+ TNBC. NCT04360941.

Background: Ribociclib in combination with endocrine therapy (ET) has demonstrated survival benefits in a broad patient population with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-) advanced breast cancer (ABC). RIBANNA (CLEE011ADE03) is an ongoing, prospective, noninterventional study assessing the efficacy and safety of first-line (1L) ribociclib in combination with ET in routine clinical practice in women with HR+, HER2- ABC. This study will provide insights into the use of ribociclib in combination with ET with regard to effectiveness and patient-reported outcomes (PRO) in the real-world setting in a large patient population.

Methods: Patients with HR+, HER2- ABC starting their 1L treatment with ribociclib + ET, or ET monotherapy, or chemotherapy (CT) were included. Data after disease progression to second-line (2L) and further lines of therapy are being collected too. The progression-free survival (PFS) in 1L, 2L and PFS2 (time from inclusion into the trial in the 1L setting until progression from 2L to third-line therapy) for individual treatment sequences will be analyzed using the Kaplan-Meier method. PRO for all the patients in the 1L and 2L treatment cohorts are being evaluated using the Morisky Medication Adherence Scale (MMAS-8), questionnaires related to quality-of-life (EORTC QLQ-C30) and its breast cancer-specific module (EORTC QLQ-BR23) as well as the Hospital Anxiety and Depression Scale (HADS). Data were collected at baseline and at every 3 months until the end of treatment.

Results: By the cutoff date (October 11, 2021) of the fourth interim analysis, data were available for 2187 patients (Table 1). Overall, 633 patients progressed after 1L therapy, including 27.6%, 30.6%, and 43.4% of patients from the 1L ribociclib + ET, ET monotherapy, and CT cohorts, respectively. A total of 286 patients received CDK4/6 inhibitors in 2L, which represents 48.3%, 37.3%, and 27.0% of patients from the 1L ribociclib + ET, ET monotherapy, and CT cohorts, respectively. The PFS in 1L, 2L and PFS2 results for individual treatment sequences will be presented at SABCs 2022. PRO compliance rates at baseline were 88.2%, 89.8%, and 89.4% for EORTC QLQ-C30 global health status, QLQ-BR23, and HADS-D/A, respectively, in the overall population, and 84.5% for MMAS-8 in the 1L ribociclib + ET cohort. Data for patient-reported adherence to 1L ribociclib + ET and for questionnaires related to global health-related

quality of life, functioning, and symptoms from patients receiving treatment in 1L and 2L settings will be analyzed and presented at SABCS 2022.

Conclusion: The RIBANNA study has shown diverse population characteristics among patients who received ribociclib treatment in a real-world setting. The 5th interim analysis is planned in October 2022. Data on PFS, PFS2, specific therapy sequences and PRO from 1L and 2L that will provide insights on therapy sequencing strategy will be presented at SABCS 2022.

Table 1. Patient disposition at the data cutoff date (October 11, 2021)

Table 1. Patient disposition at the data cutoff date (October 11, 2021)

Patients	Total (N = 2187)	Ribociclib + endocrine therapy (n = 1849)	Endocrine monotherapy (n = 193)	Chemotherapy (n = 145)
First-line treatment, n (%)	2187 (100.0)	1849 (100.0)	193 (100.0)	145 (100.0)
Second-line treatment, n (%)	633 (28.9)	511 (27.6)	59 (30.6)	63 (43.4)
Third-line treatment, n (%)	239 (10.9)	183 (9.9)	25 (13.0)	31 (21.4)
