**BACKGROUND:** Brain metastatic disease occurs in 10-30% of metastatic breast cancer cases. The incidence of brain metastases is increasing, yet overall survival remains < 2 years. Treatment of brain metastases is limited with current clinical practice centered on radiation, chemotherapy and surgery. Although these treatments may prolong survival in the short term, targeting oncogenic alterations in brain metastases may deliver a more sustained clinical benefit. In this multicenter study, we comprehensively characterized DNA and RNA alterations that aberrantly drive specific oncogenic pathway activity pertinent to breast cancer brain metastases (BCBM).

**METHODS:** RNA sequencing was performed on a cohort of patient-matched primary and resected brain metastatic tumours (45 patients; N=90 samples). Whole exome DNA sequencing (WXS) was performed for 18/45 patients (54 trios consisting of primary tumor, brain metastasis and matched normal tissue). An independent brain metastatic WXS cohort (N=21 patients) (PMID: 26410082) was also analysed resulting in a total of 39 patient samples. Recurrent somatic copy number alterations (SCNA), somatic single nucleotide variants (SNVs) and mutational signatures were identified from WXS data. Expressed gene fusions were detected computationally from RNA-Seq (N=45 cases)

**RESULTS:** Of the 45 BCBM patients, median age at diagnosis was 51 years [25, 67], median overall survival 57 months (range 18-255) with median brain metastases free survival 34 months (range 5-216). Clinical molecular subtype of the primary tumour included 13 ER+/HER2- (29%), 16 HER2+ (35.5%) and 16 TNBC (35.5%). Regions of significant recurrent amplifications and deletions in BCBM (N=39 patients) were identified in 4q12, 10q11.21, 8p11.23, 8q23.3 and 17q12 (FDR < 0.10). Recurrent expressed gene fusions identified in known cancer driver genes were associated with chromatin modification, MAPK and HER signaling pathways. Mutational signature analysis of SNVs identified signatures associated with ageing, mismatch repair and homologous recombination deficiency (HRD) mutational processes. The relative contribution of the HRD signature was significantly increased in brain metastases compared to matched primary tumour (p < 0.05). Concordantly increased HRD in the brain metastatic transcriptome was confirmed in these patients by gene set variation analysis (GSVA) of homologous recombination pathway genes from KEGG database in RNA-Seq data. Moreover, in the extended BCBM RNA-Seq (N=45 patients) GSVA pathway scores were elevated in brain metastases relative to primary tumours, validating the functional significance of altered DNA repair defects in brain metastases

**CONCLUSIONS:** Here, we report recurrent genetic drivers, supported by altered functional transcriptome, unique to brain metastasis that may have clinical implications for prognosis and treatment choice. Specifically, targeting defects in the homologous recombination repair mechanism may represent new therapeutic strategies and management opportunities for breast cancer brain metastases patients.

Where you live matters: Impact of economic, racial/ethnic, and racialized economic residential segregation on breast cancer survival

Neha Goel<sup>1</sup>, Kristin N Kelly<sup>1</sup>, Sina Yadegarynia<sup>1</sup>, Seraphina Choi<sup>1</sup>, Susan B Kesmodel<sup>1</sup> and Ashly Westrick<sup>2</sup>. <sup>1</sup>University of Miami, Miami, FL; <sup>2</sup>Florida International University, Miami, FL

**Background:** Racial and economic residential segregation remains a problem within the United States (US). Although advances in screening, detection, diagnosis, and treatment have reduced overall breast cancer mortality, well-documented socioeconomic and racial/ethnic survival disparities persist. The objective of this study was to analyze the effect of economic and racial/ethnic residential segregation as measured by the Index of Concentration at the Extremes (ICE) on breast cancer survival in South Florida.

**Methods:** Patients treated at our medical campus with stage I-IV breast cancer from 2005-2017 were identified from our local tumor registry. Census tracts were used as neighborhood proxies. Using 5-year estimates from the American Community Survey, 5 ICE variables were computed: economic (high vs. low), race/ethnicity (non-Hispanic White (NHW) vs. non-Hispanic Black (NHB) and NHW vs. Hispanic) and racialized economic (low-income NHB vs high-income NHW and low-income Hispanics vs. high-income NHW) segregation. ICE captures spatial socioeconomic and racial/ethnic segregation by literally mapping a critical dimension of social inequality not otherwise captured by metrics that characterize areas solely in terms of the proportion of the population at a specified socioeconomic level or identified as belonging to a particular racial/ethnic group. Random effects frailty models were conducted for all patients and then stratified by race/ethnicity controlling for sociodemographics, tumor characteristics, and NCCN-guideline appropriate treatment.

**Results:** The study population included 6,145 breast cancer patients. 52.6% were Hispanic, 26.3% were NHW, and 17.2% were NHB. After controlling for multiple covariates, those living in extreme economically disadvantaged neighborhoods had a statistically significant increased mortality compared to those living in more economically advantaged neighborhoods (HR: 1.58 95%CI: 1.29, 1.92,  $p < 0.001$ ), Table 1. Patients living in an economically disadvantaged NHB neighborhood also had a statistically significant increased mortality compared to those living in more economically advantaged NHW neighborhoods (HR: 2.0 95% CI: 1.54, 2.60,  $p < 0.001$ ). In race-stratified analyses, an NHW person living in a predominantly economically disadvantaged NHB neighborhood had increased mortality compared to a NHW person living in an economically advantaged NHW neighborhood (HR: 2.02 95%CI: 1.19-3.41,  $p < 0.0071$ ) controlling for tumor subtype and NCCN-guideline appropriate treatment.

**Conclusion:** This is the first study to evaluate breast cancer survival by ICE, which identifies inequitable associations by conveying extreme concentrations of both economic deprivation/privilege and racial/ethnic segregation. Our study suggests that breast cancer survival disparities is partly influenced by extreme racial/ethnic and economic segregation. Even when accounting for sociodemographics, tumor characteristics, and NCCN-guideline appropriate treatment, survival disparities remained, suggesting potential social and environmental factors impacting survival. To address these disparities, effective interventions are needed that account for the social and environmental contexts in which cancer patients live and are treated.

**Background:** KEYNOTE-119 (NCT02555657) is a randomized, open-label phase 3 study of pembrolizumab (pembro) monotherapy vs single-agent chemotherapy (chemo) in patients with previously treated metastatic triple-negative breast cancer (mTNBC). The results showed directionally favorable improvement in overall survival (OS) with pembro compared to chemo in patients with PD-L1-positive tumors, although statistical superiority was not demonstrated. The pembro treatment effect increased with PD-L1 enrichment, as measured by the combined positive score (CPS). Since treatment outcomes may vary by location of metastasis, we performed a retrospective, exploratory analysis to evaluate the efficacy of pembro vs chemo among patients with lung or liver metastasis at baseline enrolled in KEYNOTE-119.

**Methods:** Patients with centrally confirmed TNBC, 1-2 prior systemic treatments for metastatic disease, documented progression on most recent therapy and prior treatment with an anthracycline and/or taxane were randomized 1:1 to pembro 200 mg Q3W or single-agent chemo per investigator's choice of capecitabine, eribulin, gemcitabine, or vinorelbine (60% enrollment cap for each). Patients were stratified by PD-L1 status (CPS <1 vs ≥1) and history of prior neoadjuvant/adjuvant treatment vs de novo metastatic disease at initial diagnosis. Primary study end points were OS in patients with PD-L1 CPS ≥10, patients with CPS ≥1, and all patients.

**Results:** Overall, 622 patients were randomized in KEYNOTE-119 (pembro, n=312; chemo, n=310); median follow-up was 31 months at the April 11, 2019 data cutoff date. At baseline, 403 (65%) patients had lung metastasis and 173 (28%) had liver metastasis. Pembro did not improve OS vs chemo in patients with lung or liver metastases in the ITT population, although the HRs decreased as tumor PD-L1 expression increased, with the greatest benefit observed in patients with PD-L1 CPS ≥20 tumors (**Table**). Similar trends were observed for progression-free survival, objective response rate, and duration of response. In both treatment groups, presence of liver metastases at baseline was associated with shorter OS as compared to absence of liver metastases at baseline; this trend was not observed for lung metastases. Results should be interpreted with caution due to modest patient sample size in some subgroups.

**Conclusion:** Among patients with previously treated mTNBC who had lung or liver metastases for whom prognosis is typically poor, pembro monotherapy showed a benefit vs single-agent chemo in patients with increasing PD-L1 tumor enrichment. These findings are consistent with the results from the global study population.

Towards personalized medicine - patient-derived breast tumor grafts as predictors of relapse and response to therapy. Preliminary results

Christos Vaklavas, Zhengtao Chu, Rachel E Factor, Alana L Welm, Bryan E Welm and Cindy B Matsen. Huntsman Cancer Institute, Salt Lake City, UT

**Background:** Predicting the risk of relapse in patients with non-metastatic breast cancer is important for medical decisions and patient counseling. For patients who receive neoadjuvant chemotherapy, pathologic response and especially pathologic complete response (pCR) has been associated with risk of relapse; however this association is imperfect. Our prior work in patient-derived xenograft (PDX) models indicated that tumor engraftment in mice correlated with risk of recurrence. To understand further the prognostic utility of PDX, we designed a prospective clinical trial to determine the correlation between PDX generation with residual disease following neoadjuvant chemotherapy and relapse. Preliminary data are presented.

**Methods:** Women with newly diagnosed non-metastatic hormone receptor low-positive (HR-low, ER and/or PR  $\leq$  10%) or negative breast cancer planned to receive systemic chemotherapy prior to definitive surgery were eligible. Tumor tissue at diagnosis was orthotopically implanted in NOD/SCID mice. The primary objective of the study is to correlate the ability of a tumor to engraft in mice with pathologic responses and clinical outcomes.

**Results:** Between 12/2016 and 2/2020, 58 patients enrolled (triple negative breast cancer (TNBC), n=37; HR-low or negative/Her2+, n=11; or HR-low/Her2-, n=8; mixed, n=1). PDXs were successfully established from 16 patients. Patients uniformly received intensive preoperative chemotherapy per standard of care.

Among the 12 patients whose tumors engrafted in mice (PDX(+)) and underwent surgery, the pCR rate was 41.7%. In the subgroup of patients with postoperative follow up >6 months (n=9), 3 patients had achieved a pCR, 1 of whom recurred; and 6 patients had residual disease, 3 of whom recurred (overall relapse rate 44.4%). All patients who relapsed (TNBC n=3; HR-low/Her2- n=1), experienced a very early relapse (<12 months) after their definitive surgery. Disease progressed to metastatic during preoperative chemotherapy in one patient and 2 patients with residual disease relapsed while on adjuvant capecitabine. One patient experienced an early relapse despite having achieved a pCR. Patients who relapsed, died of breast cancer  $\leq$  1 year after diagnosis; the only surviving patient has not reached this landmark yet.

Among the 38 patients whose tumors did not engraft (PDX(-)) and underwent surgery, the overall pCR rate was 60.6%. In the subgroup of patients with postoperative follow up >6 months (n=30), 18 patients had achieved a pCR of whom none recurred, and 12 had residual disease of whom 1 patient (with TNBC) had locoregional recurrence 35.1 months after her definitive surgery (relapse rate 3.3%). She underwent repeat surgery followed by radiation therapy and 5.5 months after her recurrence, she remains disease-free.

Achievement of pCR was not statistically different between the PDX(+) and PDX(-) group. In the entire cohort, the presence of residual disease was associated with high risk of relapse (22.2%) as compared to the achievement of pCR (4.8%,  $p = 0.16$ ). However, successful tumor engraftment was associated not only with a higher risk of relapse (44.4% vs 3.3%,  $p = 0.0068$ , odds ratio 20.45), but also an early and exceptionally aggressive relapse.

**Conclusion.** Our functional studies not only identify a patient population with a high risk of relapse with greater precision than the achievement of pCR, but also identify patients whose relapse has a particularly aggressive natural history. We established models that recapitulate this aggressive disease and in-depth genomic studies are underway. These studies will lead us to better patient stratification on the basis of risk of relapse and novel therapeutic strategies focused on patients with exceptionally aggressive breast cancers that our current diagnostic methods cannot identify.

Comprehensive genomic profiling (CGP) of metastatic invasive lobular carcinomas reveals heterogeneity in immune biomarkers and resistance alterations across biopsy sites

Ethan Sokol<sup>1</sup>, Dexter X Jin<sup>1</sup>, Jeffrey Ross<sup>1</sup>, Garrett M Frampton<sup>1</sup> and Steffi Oesterreich<sup>2</sup>. <sup>1</sup>Foundation Medicine, Cambridge, MA; <sup>2</sup>University of Pittsburgh, Pittsburgh, PA

**Introduction** Metastatic breast cancer is a clinically challenging disease with poor outcomes. Invasive lobular carcinoma (ILC) is a rarer subtype of breast cancer with distinct patterns of metastasis, including frequent GI and female reproductive (FR) metastases (mets). Due to their relative rarity, little is known about the genomic characteristic of ILC across met sites. Here we explore the genomic landscape of 1909 ILC, stratified by met site, with an examination of immune checkpoint inhibitor (ICPI) biomarkers, therapeutic alterations, and resistance mutations.

**Methods** CGP was carried out at Foundation Medicine with hybrid capture for exons from up to 395 cancer-related genes plus select introns from up to 31 genes (PMID 24142049). Tumor mutational burden (TMB) was determined on 0.8-1.1 Mb (PMID: 28420421). Ventana PD-L1 IC staining (SP142; positive >= 1% staining) was available for a subset of samples. 1071 breast-biopsied and 1909 met-biopsied ILC and 6926 breast-biopsied and 1901 met-biopsied IDC were available for analysis.

**Results** High TMB (>= 10 muts/mb) and PD-L1 IC staining are associated with response to ICPI. ILC mets overall had a greater rate of high TMB relative to IDC mets (21% v 9%, p = 7E-25) and breast-biopsied (breast) ILC (21% v 10%; p = 9E-15) with the highest frequency in GI (23%) and skin (21%). PD-L1 IC+ rates were lower in ILC mets (18%) relative to IDC mets (34%) and breast ILC (31%), but were variable across sites, with relatively high rates of positivity in GI (48%), skin (29%), and FR (18%) mets, and no positive staining in bone mets (0/37).

Alterations in *PIK3CA* were higher in ILC mets (58%) relative to IDC mets (34%) and generally exhibited a similar frequency across ILC met sites, with modestly lower prevalence in skin (48%, p = 0.005). Pathogenic alterations in *BRCA1/2* were observed in 4.8% of ILC mets overall, with a lower frequency in GI mets (1.3%, p = 0.03).

A comparison of ILC breast biopsies to ILC mets revealed 19 genes with higher prevalence in at least one ILC met site, most with known roles in therapy resistance (eg *ESR1*, *NF1*, *RB1*, *KRAS*, *ERBB2*, *BRAF*), though significant heterogeneity was observed across sites. Met-enriched (ME) alterations were highest in ILC from the liver (71%) and lowest in FR (33%). *ERBB2* mutations, which are may be targetable with HER2 kinase inhibitors, were predominantly found in liver mets (21%) with significantly lower prevalence in skin (11%), bone (10%), GI (3%), and FR (3%). *ESR1* alterations were common in most ILC sites, with the highest prevalence in liver (26%) and low frequency in FR (4%). While FR ILC harbored few ME alterations, the rare alterations were primarily found in *NF1* (5%) and *NCOR1* (5%).

**Conclusions** CGP revealed significant heterogeneity in ILC mets across tissues. ICPI biomarkers were variable across sites with the highest frequency in ILC GI mets, offering additional potential treatment avenues for these tumors. Alterations in *PIK3CA* were common in ILC mets with high prevalence across sites, suggesting utility for *PIK3CA* inhibitors. Therapy-resistant alterations were common in ILC mets but varied across sites. Notably, *ERBB2* alterations were most prevalent in ILC liver mets, but less common at other sites.

The high prevalence of therapeutic and resistance alterations suggests value in profiling metastatic lesions.

Magnetic resonance imaging insights from an active surveillance cohort of women with DCIS

Heather Greenwood, Rita Freimanis, Case Brabham, Rita Mukhtar, Gillian Hirst, Paul Kim, April Liang, Laura Esserman, Nola Hylton and Amrita Basu. UCSF, San Francisco, CA

**Purpose:** Standard treatment for ductal carcinoma in situ (DCIS) involves surgical excision usually with radiation therapy or mastectomy and often endocrine therapy, treatments that are the same as for invasive cancer (IDC). It is clear, however that not all patients with DCIS will develop IDC and so the question is who benefits from early surgical intervention? Active Surveillance (AS) with endocrine risk reduction presents an opportunity to improve outcomes by identifying those lesions that can be managed with endocrine therapy alone without immediate surgical intervention. An active surveillance cohort of women who chose not to have surgery at diagnosis were followed with serial MRIs to identify the imaging features associated with successful AS and those with IDC. **Methods:** Patients with DCIS were enrolled in MRI surveillance studies between 2002 and 2019 and analyzed retrospectively with IRB approval. Per medical record review, these patients sought to avoid surgical intervention. Inclusion criteria included at least two breast MRIs performed for purposes of surveillance. The final cohort of patients included 64 cases with at least two breast MRIs, with 27 patients having more than 4 MRIs. All breast MRIs consisted of routine sequences, including both pre and post IV contrast images with at least 2 post-contrast time points. Lesion conspicuity, change in lesion, background parenchymal enhancement (BPE), change in BPE, and likelihood of invasive cancer at each MRI timepoint, were subjectively measured independently by two breast radiologists. A Likert scale was used to grade each imaging feature. Radiologists were blinded to the clinical outcome of whether the patient had IDC at surgery or not. Input variables included all imaging features collected and classification trees were trained and bootstrapped on 90% of the data using recursive partitioning to distinguish imaging features predictive of clinical outcome. Proportionality tests were conducted to test whether IDC was associated with age, menopausal status, and breast composition among other clinical variables. **Results:** Women in the cohort had a mean age of 53.6 years (range 29.8 to 78.9). 98.3% were HR+. Of the 64 cases in the cohort, 57 received endocrine therapy (89.1%). A total of 31 cases (48.4%) eventually had surgical excision and 33 (51.6%) remained on AS. At surgery, 17 patients had IDC (26.6%). Classification trees revealed that the most distinguishing features in the model correlating with IDC were if the lesion was distinct from background at MRI timepoint 1, an increase in BPE between MRI timepoints 1 and 2, and an increase in the lesion size or conspicuity between MRI timepoints 1 and 2. At diagnosis, 56.3% demonstrated a more diffuse pattern of enhancement where the DCIS lesion was not distinguishable above background. Of those with lesions that did not stand out above background at diagnosis and whose BPE did not increase, only 1 of 31 patients developed IDC (3%) with mean follow up of 4.62 years. Patients with IDC were proportionately older (>60) and post-menopausal (73% with IDC were postmenopausal), although only 57% were postmenopausal at diagnosis. Other variables such as breast composition were not enriched in either the IDC versus the non-IDC population. **Conclusion:** Our study suggests that imaging markers such as BPE and conspicuity of lesion enhancement may provide information to better understand and stratify the risk of DCIS and avoid overtreatment. Importantly, MRI may provide insight as to when a diagnosis of DCIS is more likely to be a global risk factor amenable to endocrine risk reduction, versus a lesion best treated with surgical excision. Pathology correlation is underway. We are currently developing methods to improve reproducibility and harmonization between radiologists, and performance on a validation set will be presented.

Trends in genetic testing and results for women diagnosed with breast cancer or ovarian cancer, 2013-2017

Allison W Kurian<sup>1</sup>, Monica Morrow<sup>2</sup> and Steven Katz<sup>3</sup>. <sup>1</sup>Stanford University, Stanford, CA; <sup>2</sup>Memorial Sloan-Kettering, New York City, NY; <sup>3</sup>University of Michigan, Ann Arbor, MI

**Background:** Genetic testing is increasingly important for breast and ovarian cancer risk reduction and treatment. However, little is known about trends and disparities in receipt of testing in the community and test results after diagnosis. **Methods:** We linked records of all women with breast cancer or ovarian cancer diagnosed from 2013-2017 in Georgia and California and reported to Surveillance, Epidemiology and End Results (SEER) registries to genetic testing results from four laboratories that did most clinical testing in the studied regions (Ambry Genetics, GeneDx, Invitae, Myriad Genetics). We combined test results performed by all laboratories over 2012-2019 with SEER data. We measured use of any test, median number of genes tested, rates of variants of uncertain significance (VUS) and pathogenic variants (PVs). **Results:** A total of 25.2% of 187,535 breast cancer patients, and 34.3% of 14,689 ovarian cancer patients, had genetic testing. Testing increased annually by 2% while the median number of genes tested increased annually by 28%. Among tested patients diagnosed with breast cancer in 2017, 5.2% had *BRCA1/2* PVs while 4.9% had PVs in genes associated with a recognized cancer syndrome (*APC*, *CDH1*, *MLH1*, *MSH2*, *MSH6*, *NF1*, *PMS2*, *PTEN*, *RET* and *TP53*) or with emerging evidence for an increased risk of breast cancer and/or ovarian cancer (*ATM*, *BARD1*, *BRIP1*, *CHEK2*, *NBN*, *PALB2*, *RAD51C* and *RAD51D*). Among tested patients diagnosed with ovarian cancer in 2017, 11.0% had *BRCA1/2* PVs while 2.3% had PVs in a syndromic gene (*APC*, *MLH1*, *MSH2*, *MSH6*, *NF1*, *PMS2*, and *TP53*) or an emerging breast/ovarian cancer gene (*ATM*, *BARD1*, *BRIP1*, *CHEK2*, *NBN*, *PALB2*, *RAD51C* and *RAD51D*). PVs in other tested genes were rare (generally <1%). VUS rates increased from patients diagnosed in 2013 (11.2% breast, 11.2% ovarian) to 2017 (26.4% breast, 26.8% ovarian) and were higher in racial/ethnic minorities (47.8% Asian, 46.0% Black, 40% Hispanic versus 24.6% non-Hispanic Whites diagnosed with ovarian cancer in 2017;  $p < .001$ ). **Conclusions:** A substantial gap persists in testing ovarian cancer patients (34.5% versus nearly 100% recommended) while testing more genes was associated with a substantial racial/ethnic gap in VUS. Most clinically relevant PVs occurred in the 17 genes (ovarian cancer patients) to 20 genes (breast cancer patients) reported above; testing only these genes may optimize the clinically salient PV-to-VUS ratio, particularly for racial/ethnic minorities.

A trial of endocrine therapy after breast conserving surgery will aid in patient treatment decisions regarding choice of adjuvant therapy

Vonetta M Williams. University of Washington, Seattle, WA

**Purpose/Objective(s):** In the United States, more than a quarter of a million women are diagnosed with breast cancer each year. Fortunately, advances in detection and therapies have decreased breast cancer mortality significantly. Focus has been placed on improving quality of life through safely de-escalating treatment. Adjuvant monotherapy with endocrine therapy is an acceptable alternative to adjuvant radiotherapy and endocrine therapy in elderly women with favorable early stage breast cancer. The decision to omit radiation in this low-risk cohort is based on the patient's commitment to 5 years of endocrine therapy. However, compliance is poor and studies demonstrate a premature discontinuance rate of 23-50% within 1-4 years. Of the factors that may lead to non-compliance, side effects of treatment appear to be the most significant. Primary objective:

1. To assess the tolerability of the anti-endocrine therapy following breast conserving surgery in breast cancer women patients

Secondary objective:

1. To identify factors associated with intolerance of treatment.

**Methods:** 40 women who are willing to trial an 8 week course of endocrine therapy will be enrolled after breast conserving surgery. The trial must start within 8 weeks of surgery. Questionnaires will be collected at the time of enrollment (baseline) and at the end of the trial (to assess tolerance). Additionally, a medication log will be collected to assess medication compliance.

**Inclusion and exclusion criteria:** Inclusion criteria are 1) patients with pathological T1N0 invasive breast cancer following breast conserving surgery 2) 70 years of age and older 3) estrogen receptor positive per ASCO/CAP guidelines and 4) negative margins Exclusion criteria are 1) patients who have undergone previous radiation therapy to the ipsilateral breast, chest wall, or axilla are excluded, 2) patients with evidence of metastatic disease and 3) previous or concurrent malignant disease.

**Statistical Plan:** We plan to recruit 40 patients in one year. This study is not powered based on a specific null hypothesis, but if 40 patients are followed, with two-sided type I error rate at 5%, we will have 91% power to observe a statistically significant difference between the alternative hypothesis to observing 75% women to continue treatment versus the null hypothesis of only 50% will continue.

Outcome without adjuvant systemic treatment in breast cancer patients included in the MINDACT trial

Josephine MN Lopes Cardozo<sup>1</sup>, Danalyn Byng<sup>1</sup>, Caroline A Drukker<sup>2</sup>, Marjanka K Schmidt<sup>1</sup>, Laura J van 't Veer<sup>3</sup>, Fatima Cardoso<sup>4</sup>, Martine Piccart<sup>5</sup>, Coralie Poncet<sup>6</sup> and Emiel JTh Rutgers<sup>1</sup>. <sup>1</sup>Netherlands Cancer Institute, Amsterdam, Netherlands<sup>2</sup>Tergooi Hospital, Hilversum, Netherlands<sup>3</sup>Univ California San Francisco, San Francisco, CA;<sup>4</sup>Champalimaud Clinical Center/Champalimaud Foundation, Lisbon, Portugal<sup>5</sup>Institut Jules Bordet, Universite Libre de Bruxelles, Brussels, Belgium<sup>6</sup>EORTC Headquarters, Brussels, Belgium

**Background:** Adjuvant systemic treatments have played an important role in the decline of breast cancer mortality over the years. Because of the extensive short- and long-term toxicities associated with these treatments, careful selection of patients likely to benefit from them is needed. Studies have shown excellent survival in subgroups of patients receiving no adjuvant systemic treatments. Some national guidelines advise no adjuvant systemic treatments in specific groups of patients with clinical low risk breast cancer. The aim of this study is to investigate the survival of breast cancer patients who received no adjuvant treatment (chemotherapy nor endocrine therapy) using data from the EORTC 10041/BIG 3-04 MINDACT trial. **Material and methods:** Of the 6693 patients enrolled in the MINDACT trial, accrued 2007-2011, 509 patients with hormone receptor positive, HER2 negative, lymph node negative tumors <2cm received no adjuvant systemic treatment, mostly following local recommendations. Median follow-up was 8.7 years. Using propensity score matching and exact matching, we will identify groups of patients treated with adjuvant endocrine therapy and/or chemotherapy with similar tumor characteristics to the untreated patients. We will use the Kaplan-Meier method to estimate distant metastasis free interval and overall survival at 5 and 8 years for each group. Differences between groups will be evaluated using the log-rank test, and hazard ratios with 95% CI derived from Cox proportional hazards models. **Planned analyses:** The long-term data of the MINDACT trial has recently become available. The date of planned analysis is August 10<sup>th</sup> 2020. For this study, the primary clinical endpoint will be distant metastasis free interval, which will be assessed in the matched groups of untreated patients, patients who received endocrine therapy only, and patients who received chemotherapy with or without endocrine therapy. Kaplan-Meier estimates will be provided at 5 years, and at 8 years to assess the long-term outcomes in this population. A statistical plan for this analysis was specifically developed and approved prior to performing any analysis.

Glucocorticoid receptor expression in early-stage triple-negative breast cancer is associated with a high level of tumor immune cell infiltrates

Deniz N Dolcen<sup>1</sup>, Marie Dreyer<sup>2</sup>, Aaron Miller<sup>2</sup>, Anna Biernacka<sup>2</sup>, Ken Hatogai<sup>2</sup>, Randy Sweis<sup>2</sup>, Rita Nanda<sup>2</sup> and Suzanne D Conzen<sup>1</sup>. <sup>1</sup>UTSW, Dallas, TX; <sup>2</sup>The University of Chicago, Chicago, IL

**Background:** Triple-negative breast cancer (TNBC) with high glucocorticoid receptor activity (GR-high) is associated with a high risk of relapse and chemotherapy resistance. Glucocorticoids (GC) are essential for the regulation of immune and inflammatory responses. Multiple mechanisms of GC-induced immunosuppression have been proposed, including suppression of T cell proliferation and dendritic cell antigen presentation and function. The importance of intact immune surveillance in controlling neoplastic transformation is well-established, and accumulating evidence demonstrates a correlation between tumor-infiltrating lymphocytes (TILs) in cancer tissue and favorable prognosis. In particular, the presence of CD8+ T-cells and the ratio of CD8+ effector T-cells / Foxp3+ regulatory T-cells (Tregs) appears to correlate with improved prognosis and long-term survival. We hypothesized that tumor GR activity would modulate the tumor immune microenvironment (TME), thereby suppressing anti-tumor immunity in TNBC. **Methods:** We identified 46 patients with TNBC who received neoadjuvant chemotherapy at The University of Chicago between 2002-2014, and had pretreatment tissue available for study. Tumors were stained for GR expression using the anti-GR rabbit monoclonal XP antibody (Cell Signaling, 1:200 dilution). GR expression was determined independently by two pathologists. Using multiplex immunohistochemistry, six phenotypes for immune cell markers (BATF3+ dendritic cells, CD8+ T-cells, Foxp3+ Tregs, PD-L1+tumor, PD-L1-tumor, PD-L1+immune cells) were identified in the tumor and stroma of the pretreatment biopsy specimens. Absolute counts of each type of immune cell as well as ratios between immune cell types were compared in GR-low, GR-moderate, and GR-high expressing TNBC specimens using the Kruskal-Wallis test.

**Results:** There were 8 GR-low, 23 GR-moderate, and 15 GR-high expressing tumors in our cohort. When comparing GR-low to GR-moderate or GR-moderate to GR-high expressing tumors, there were no significant difference observed in immune cell types. However, when comparing GR-high to GR-low expressing TNBCs, there were significantly higher levels of CD8+ T-cells, Foxp3+ Treg cells, and BATF3+ dendritic cells in GR-high vs GR-low TNBC tumors ( $p=0.0004$ ,  $p=0.011$ , and  $p=0.0072$ , respectively). When comparing the ratio of CD8+ T-cells to Foxp3+ Treg cells, PD-L1+ tumor or immune cells, no significant differences were observed by level of GR expression ( $p=ns$  for all comparisons).

**Conclusions:** We report for the first time that GR-high, treatment-naïve, primary TNBCs have significantly higher CD8+ T cells, Foxp3+ T cells, and BATF3+ dendritic cells compared to GR-low TNBCs, consistent with an inflamed TME. While historically a robust immune infiltrate in the TME in early TNBC has been associated with a better response to chemotherapy and a more favorable long-term outcome, high GR activity in early TNBC has been associated with a worse outcome. Our observation that GR-high tumors have an inflamed TME, suggests that checkpoint blockade to either suppress Foxp3+ Tregs or activate CD8+ T cells may be able to restore anti-tumor immunity.

Clinical and genomic correlation of a CLIA certified organoid based functional test in breast cancer patients

Astrid Margossian<sup>1</sup>, Anne Richardson<sup>1</sup>, Madison Pollastro<sup>1</sup>, Michael Churchill<sup>1</sup>, Franz Schaub<sup>1</sup>, Shalini Pereira<sup>1</sup>, Payel Chatterjee<sup>1</sup>, Rachele Rosati<sup>1</sup>, Lauren Appleyard<sup>1</sup>, Grace Durenberger<sup>1</sup>, Alex Federation<sup>1</sup>, G. Adam Whitney<sup>1</sup>, Hallie Swan<sup>1</sup>, Trevor Ainge<sup>1</sup>, Robert Diaz<sup>1</sup>, Natasha Hunter<sup>2</sup>, Eric Gamboa<sup>3</sup>, Chris Kemp<sup>4</sup>, Vijayakrishna Gadi<sup>5</sup> and Carla Grandori<sup>1</sup>. <sup>1</sup>Sengine Precision Medicine, Seattle, WA; <sup>2</sup>University of Washington, Seattle, WA; <sup>3</sup>Kadlec Medical Center, Richland, WA; <sup>4</sup>Fred Hutchinson Cancer Center, Seattle, WA; <sup>5</sup>University of Illinois, Chicago, IL

The goal of precision medicine is to match the right drug to the right patient. However, every individual cancer carries a unique and complex mosaic of genetic and molecular changes making it difficult to identify the right drug based solely on genomic analysis. We developed a CLIA-certified functional drug assay (PARIS® test) for solid tumors which provides an actionable report of tumor derived organoid sensitivities to targeted, endocrine and chemotherapy agents as a tool for clinical therapeutic decisions. **Objectives:** 1. To establish the concordance between organoid drug sensitivity with well-known genomic or immunohistochemical IHC biomarkers 2. To correlate organoid drug sensitivity with clinical outcomes. **Methods:** From 2015 to 2020, organoids from 410 tumor samples were subjected to functional testing at SEngine Precision Medicine, including 61 breast tumor samples from 48 patients. Fresh samples of tumor cells from core biopsies, surgical excisions, or from fluids arrived <48 hrs following collection and were cultured as 3D organoids. Samples were evaluated using a multi-dose drug response format with a library of up to 130 oncology drugs. Drug sensitivity was quantified using the SPM score (1-15) that combines sensitivity and personalization of each patient's response relative to a reference population. Known genomic anchors and IHC subtypes were compared to drug sensitivity to determine concordance. **Results:** 61 breast cancer samples from 48 patients were analyzed. The median age of patients was 53.4 (r26-76). 65 drugs on average were tested per patient with a mean turnaround time of 21 days (r9 -37). A mean of 6 drugs per patient were identified as top scoring sensitive drugs. In 42 patients with genomic or IHC data, we found high concordance of drug sensitivity with known biomarkers (e.g., HER2+ or ERBB2 amplification: HER2 or EGFR inhibitor, BRCA1 mutation: PARP inhibitor, FGFR1-2 mutation or amplification: FGFR inhibitor, PIK3CA mutation: PI3K inhibitor), measured as sensitivity to the cognate targeted drugs. For PIK3CAmut we found an 80% correlation of organoid sensitivity to alpelisib and taselisib. For HER2/ EGFRinh the correlation was 100%. We also found organoid sensitivity to targeted agents in the absence of known genomic or IHC biomarkers, for example tamoxifen and fulvestrant sensitivity in triple negative breast tumors, or HER2 inhibitor sensitivity in HER2 IHC negative tumors or PARP inhibitor sensitivity with BRCA2 variant of unknown significance (VUS). In a cohort of 18 analyzable patients, the retrospective and prospective correlation between organoid based drug sensitivity and clinical outcome was >90%. **Conclusions:** Organoid based drug testing exhibits strong concordance with genomic or IHC biomarkers and clinical response. In addition, functional testing identifies candidate therapies in patients lacking biomarkers and can nominate variants of unknown significance as candidate biomarkers. This study highlights the utility of functional assays to support clinical decision making in a genetically heterogeneous cancer such as breast cancer.

The breast pre-cancer atlas illustrates the molecular and micro-environmental diversity of ductal carcinoma in situ

Olivier Harismendy<sup>1</sup>, Daniela Nachmanson<sup>1</sup>, Mark F. Evans<sup>2</sup>, Hidetoshi Mori<sup>3</sup>, Adam Officer<sup>1</sup>, Christina Yau<sup>4</sup>, Joseph Steward<sup>1</sup>, Huazhen Yao<sup>1</sup>, Thomas O'Keefe<sup>1</sup>, Farnaz Hasteh<sup>1</sup>, Gary S. Stein<sup>2</sup>, Kristen Jepsen<sup>1</sup>, Michael Campbell<sup>4</sup>, Donald L. Weaver<sup>2</sup>, Gillian L. Hirst<sup>4</sup>, Brian L. Sprague<sup>2</sup>, Laura J. Esserman<sup>4</sup>, Jonathan A. Gordon<sup>2</sup>, Alexander Borowsky<sup>3</sup> and Janet L. Stein<sup>2</sup>. <sup>1</sup>UC San Diego, San Diego, CA; <sup>2</sup>University of Vermont, Burlington, VT; <sup>3</sup>UC Davis, Davis, CA; <sup>4</sup>UC San Francisco, San Francisco, CA

**Background:** With the implementation of widespread breast cancer screening, the diagnosis of Ductal Carcinoma In Situ (DCIS) has increased 5 fold. Most cases are treated with combinations of surgery, radiation and endocrine therapy, reducing the risk of second events, including ipsilateral invasive cancer. Without standard markers to confidently identify the most indolent lesions, a subset of cases are likely over-treated. The mutational landscapes of DCIS and invasive ductal carcinoma (IDC) are similar and not sufficient to identify higher risk lesions with recent studies suggesting that clonal selection plays a limited role in progression. Histological analysis highlighted the role of the extracellular matrix and immune-surveillance to maintain duct integrity and limit progression. Due to the small size, limited availability and quality of research specimens, few biomarker studies investigated pure DCIS with adequate follow-up or genome-wide methods, let alone integrated more than one type of biomarker. Unlike breast cancer, there is no comprehensive, systematic, multi-modal atlas of DCIS, limiting the ability to test broad and novel hypotheses and characterize processes maintaining breast tissue homeostasis.

**Methods:** Through sequential sectioning of pure DCIS archived specimens, a total of 70 histological regions from 40 cases were annotated and profiled using up to 3 platforms: multiplex immuno-histochemistry (mIHC), RNA-seq, and whole-exome sequencing. Stromal and epithelial spatial distribution of immune cells and states were quantified using mIHC. The epithelial compartments were microdissected and profiled using genome-wide gene expression, DNA mutations and copy number alterations.

**Results:** Epithelial regions were classified according to expression subtypes consistent with histological markers, highlighting associations with the lesion architecture and grade. Compared to solid pattern, cribriform pattern DCIS has induced EMT processes and repressed proliferation processes, a trend reminiscent of low-recurrence-risk expression signatures measured in IDC. The DNA copy number burden increased with grade and the mutational burden was the highest in solid DCIS. Both were higher in Her2+ cases. The clustering of mutations at chromosome 17p - attributed to the *APOBEC*-driven Kataegis phenomenon - was observed in a subset of regions, suggesting this event can occur in pre-invasive lesions. All DCIS had somatic alterations of at least one known driver gene with some associated with grade (*TP53*) or expression subtype (*ERBB2*). Multi-region profiling available in a subset of samples revealed genetic heterogeneity of likely-driver events between proximal regions of similar histological characteristics. The density and proliferative states of selected immune cells - including T-cells, B-cells and Macrophages - highlights the diversity of the tumor immune environment with the highest densities observed in Her2+ ducts and stroma, minimal ductal infiltration in other lesions, fewer dividing B- and T-cells around the more proliferative areas and a small number of regions depleted from any adaptive immune cells.

**Conclusion:** This first multi-modal profiling of pure DCIS reveals an unsuspected diversity of molecular and microenvironmental states and presents their association with progression risk factors. The observations support the need for stronger integration of molecular and clinicopathology features, especially at sub-histological levels, to ensure the findings can be interpreted in the correct clinical and phenotypic context. The compatibility of the approach with archived specimens supports the expansion to larger retrospective DCIS collections with outcomes.

Biomarkers of resistance to palbociclib in ER+ primary breast cancer in the PALLET trial

Eugene F Schuster<sup>1</sup>, Hui Xiao<sup>1</sup>, Elena Lopez-Knowles<sup>1</sup>, Lucy Kilburn<sup>2</sup>, Mothaffar Rimawi<sup>3</sup>, David A Wheeler<sup>3</sup>, Katherine Pogue-Geile<sup>4</sup>, Yuan Lui<sup>5</sup>, Samuel A Jacobs<sup>4</sup>, Chet Cornman<sup>4</sup>, Shannon Puhalla<sup>6</sup>, Maggie Cheang<sup>7</sup>, Judith Bliss<sup>7</sup>, Stephen Johnston<sup>8</sup>, Mitch Dowsett<sup>1</sup>, On behalf of the PALLET Trialists. <sup>1</sup>The Breast Cancer Now Toby Robins Research Centre at The Institute of Cancer Research and Ralph Lauren Centre for Breast Cancer Research at Royal Marsden Hospital, London, United Kingdom<sup>2</sup>Clinical Trials and Statistics Unit, The Institute of Cancer Research, London, United Kingdom<sup>3</sup>Baylor College of Medicine, Houston, TX;<sup>4</sup>National Surgical Adjuvant Breast and Bowel Project (NSABP), Pittsburgh, PA;<sup>5</sup>Pfizer, San Diego, CA;<sup>6</sup>UPMC Cancer Center at Magee Womens Hospital, Pittsburgh, PA;<sup>7</sup>Clinical Trials and Statistics Unit, The Institute of Cancer Research, Sutton, United Kingdom<sup>8</sup>Breast Unit, Royal Marsden Hospital, London, United Kingdom

**Background:** CDK4/6 inhibitors are being used in combination with aromatase inhibitors as therapy for advanced ER+ breast cancer (BC) and are being explored for use in primary BC. Few mechanisms driving resistance to added CDK4/6 inhibitors have been defined. The PALLET phase II randomized neoadjuvant trial of letrozole (LET) ± palbociclib (PALBO) in postmenopausal ER+HER2- primary BC reported that clinical response rate over 14wks was not significantly increased by adding PALBO to LET but suppression of Ki67 was significantly increased (Johnston *et al*, JCO 2018, 37, 178): after 14wks complete cell cycle arrest (CCCA, Ki67<2.7%) was present in 59% on LET and 90% on LET+PALBO. Here we sought to identify biomarkers of de novo resistance to allow selection of patients most likely to benefit from added PALBO.

**Methods:** 307 patients were randomized to LET (n=103) or LET+PALBO (n=204) for 14 wks. The first 2wks of LET+PALBO patients were randomised to LET, PALBO, or LET+PALBO. Biopsies were taken at baseline, 2wks and 14wks. Biomarker data are presented here for baseline only, other than Ki67 at both baseline and 14wks. IHC analyses were conducted on FFPE biopsies for ER, PgR, RB1, cyclin-E1, and cyclin-D1 (also FISH). RNA-seq was performed on fresh frozen biopsies. Association of each biomarker with CCCA was determined by logistic regression. Differentially expressed genes (DEGs) were identified between patients sensitive (CCCA) (n=94) and resistant (non-CCCA) (n=10) to treatments with or without PALBO at 14wks by DESeq2. Fifty hallmark gene sets were tested for significant enrichment with DEGs and differential gene sets were identified by using Gene Set Enrichment Analysis (GSEA).

**Results:** The association of IHC biomarkers with CCCA is shown in the table. Lower levels of ER, higher levels of cyclin-E1, and amplification of cyclin-D1 were each significantly associated with a greater chance of non-CCCA with LET+PALBO. High cyclin-E1 levels were also associated with reduced chance of CCCA with LET only. Patients with high baseline Ki67 also exhibited higher non-CCCA with LET+PALBO at 14wks (p=0.0002). In the RNAseq data we identified 1973 DEGs between the 14wk CCCA and non-CCCA patients for LET+PALBO. E2F and MYC targets, PI3K/AKT/MTOR signalling and interferon response gene sets were among the hallmark gene sets enriched for genes with higher expression in non-CCCA patients at 14wks for LET+PALBO (FDR<0.05). For LET-only, 311 DEGs were identified and the "Estrogen Response Early" gene set was significantly enriched in genes with higher expression in CCCA samples. At the individual gene level, genes significantly associated with non-CCCA after 14wks LET+PALBO included *CCNE1*, *CDK2* and several E2F-related genes (p<0.05). Their expression was not significantly different between non-CCCA and CCCA patients with LET alone.

**Conclusion:** Biomarkers associated with response/resistance to added PALBO were different from LET only. PALBO resistance was associated with higher baseline expression of cyclin-E1 (both IHC and RNA), CDK2, and genes related to E2F, MYC, interferon and MTOR signalling. These results suggest that multiple identifiable mechanisms of de novo resistance to PALBO are likely to exist in primary ER+ BC. On-going WES analyses will allow the significance of alterations at the DNA level to be presented.

**Table 1.** Continuous measurement in a logistic regression for CCCA at 14 weeks; Odds ratio calculated separately for group A and groups B,C,D and were adjusted for region (UK vs NA); \* amplified vs non-amplified

A sense-antisense RNA interaction drives metabolic reprogramming in metastatic breast cancer

Hani Goodarzi, Bruce Culbertson, Kristle Garcia and Lisa Fish. UCSF, San Francisco, CA

**Background:** Metabolic reprogramming is a hallmark of breast cancer progression. However, the underlying regulatory pathways that initiate and maintain this process remain largely unexplored. Recently, we have identified a novel antisense RNA that helps protect breast cancer cells against oxidative stress by reprogramming their metabolic redox state. Using cell line and patient-derived xenograft models, as well as direct measurements in clinical samples, we have demonstrated the unique regulatory functions of this antisense RNA in increasing the metastatic capacity of breast cancer cells. **Results:** Non-coding RNAs have emerged as major drivers of metastatic progression. We have recently demonstrated that specific classes of non-coding RNAs, such as tRNAs (Goodarzi et al, Cell, 2016) and tRNA fragments (Goodarzi et al, Cell, 2015), play major roles in breast cancer metastasis as post-transcriptional regulators of gene expression. However, these types of regulatory RNAs constitute only a fraction of the non-coding RNAs that are aberrantly expressed in highly metastatic cells. For example, antisense RNAs are a large but often ignored class of RNAs with poorly understood cellular functions. We recently developed a new computational algorithm to systematically annotate antisense RNAs and identify those that are associated with metastatic progression based on data from cell line and patient-derived xenograft models, as well as matched primary and metastatic tumors from triple-negative breast cancer patients. We identified a previously unknown antisense RNA, which is transcribed from a locus in the 3' UTR of the gene NQO1 (and is hence named NQO1-AS). Both NQO1-AS and NQO1 are significantly upregulated in highly metastatic breast cancer cells, and we have shown that the NQO1 sense mRNA is stabilized by the expression of NQO1-AS. Our results indicate that NQO1-AS forms a stable duplex with the 3' UTR of NQO1 and induces the expression of a longer and more stable isoform of NQO1 mRNA. Metabolomic measurements in NQO1 knockdown and control cells revealed that increased NQO1 activity enables cancer cells to better tolerate the oxidative stress experienced during metastasis. We demonstrated this by performing lung metastasis assays in xenograft models. To confirm the clinical relevance of these findings, we performed comprehensive clinical association studies, and also used quantitative PCR and immunohistochemistry to measure NQO1 levels across all disease stages. We observed a highly significant association between higher NQO1 and NQO1-AS expression and metastatic relapse. **Methods:** We developed a method named iRAS to annotate and quantify antisense RNAs. We used global run-on assays (GRO-seq) and RNA sequencing in poorly and highly metastatic breast cancer cells to identify NQO1-AS as a novel pro-metastatic antisense RNA. We used both Gapmers and CRISPR-i to knock down NQO1-AS and to measure its impact on NQO1 mRNA stability and expression. We used CRISPRi to silence NQO1 in both MDA-231 and HCC-1806 breast cancer lines, and measured the metabolic consequences of NQO1 knockdown by measuring NADPH flux as well as performing general metabolomic profiling. We also used *in vivo* lung colonization assays (n=5 mice in each arm) to measure the metastatic capacity of NQO1 knockdown cells. Log-rank test (univariate) and Cox Proportional Hazard Models (multivariate) were used to perform survival analyses in METABRIC and the kmplot aggregate dataset. Mann-Whitney or ANOVA was used to compare expression of NQO1 and NQO1-AS across samples stratified based on sub-type and tumor grade/stage in public datasets as well as our own measurements in clinical samples (n=96; 5 healthy, 23 stage I, 30 stage II, 29 stage III, and 9 stage IV). IHC was performed on tissue microarrays from CHTN (Breast Progression), and blinded scoring was used to assess NQO1 levels.

Combined analysis of the WORTH 1 and WORTH 2 studies of ipsilateral breast tumor recurrence after breast conservative surgery without radiotherapy using the “5-mm thick slice and 5-mm free margin method”

Norikazu Masuda<sup>1</sup>, Shozo Ohsumi<sup>2</sup>, Reiki Nishimura<sup>3</sup>, Sadako Akashi-Tanaka<sup>4</sup>, Kimito Suemasu<sup>5</sup>, Hideko Yamauchi<sup>6</sup>, Eriko Tokunaga<sup>7</sup>, Tadashi Ikeda<sup>8</sup>, Tsunehiro Nishi<sup>9</sup>, Hiroto Hayashi<sup>10</sup>, Yuichi Iino<sup>11</sup>, Yuichi Takatsuka<sup>12</sup> and Hideo Inaji<sup>13</sup>. <sup>1</sup>National Hospital Organization Osaka National Hospital, Osaka, Japan<sup>2</sup>National Hospital Organization Shikoku Cancer Center, Matsuyama, Japan<sup>3</sup>Kumamoto Shinto General Hospital, Kumamoto, Japan<sup>4</sup>Show University School of Medicine, Tokyo, Japan<sup>5</sup>ARCHE Clinic, Saitama, Japan<sup>6</sup>St. Luke's International Hospital, Tokyo, Japan<sup>7</sup>National Hospital Organization Kyushu Cancer Center, Fukuoka, Japan<sup>8</sup>Kitasato University Kitasato Institute Hospital, Tokyo, Japan<sup>9</sup>Toda Chuo Health Exam Center, Toda, Japan<sup>10</sup>National Hospital Organization Kanmon Medical Center, Shimonoseki, Japan<sup>11</sup>Kusunoki Hospital, Fujioka, Japan<sup>12</sup>Kansai Rosai Hospital, Amagasaki, Japan<sup>13</sup>Kaizuka City Hospital, Kaizuka, Japan

**Background:** Breast conserving surgery with radiotherapy is one of the standard treatment methods for early breast cancer. However, it is regarded as an option to treat elderly patients with small hormone receptor positive breast cancer with breast conserving surgery and hormone therapy without radiotherapy. Two sequential prospective studies were conducted to examine the efficacy of breast conserving surgery without radiotherapy from 2002. **Patients and Methods:** Primary breast cancer patients were divided into the WORTH 1 (n=123) group (Oct. 2002 and Mar. 2005) and the WORTH 2 (n=198) group (Dec. 2006 and Nov. 2011) and the data was retrospectively combined and analyzed. The eligibility criteria of the two sequential studies were a tumor  $\geq 3$ cm determined by palpation, pathologically node negative by axillary dissection or sentinel node biopsy and M0, no preoperative treatment, postmenopausal patients  $\geq 50$  years of age at surgery, no tumor cells within 5 mm from the margins, no lymphatic invasion around the primary tumor, and estrogen receptor positive. The surgical specimens were sliced at 5 mm intervals and all the slices were examined microscopically. Postoperative radiotherapy was not conducted and adjuvant chemotherapy was optional. The patients were treated with tamoxifen or anastrozole in WORTH 1 and anastrozole in WORTH 2 for 5 years. Ipsilateral breast tumor recurrence (IBTR)-free survival and distant relapse-free survival (DRFS) were recorded as the interval from initial surgery until IBTR or distant relapse. The factors related to IBTR were evaluated using the proportional hazard model. Patients who did not develop IBTR or distant relapse were statistically censored at the time of the last follow-up or death. Survival rates were calculated using the Kaplan-Meier method. Statistical analyses were conducted using the log rank test. Values  $< 0.05$  were considered statistically significant. **Results:** The median age at surgery was 65 (range 50-84). The median tumor size was 1.5 cm (range 0-4.0 cm). The median follow-up period for IBTR was 95 months (range 4-192 months). Only 3 patients were treated with adjuvant chemotherapy. The 5- and 10-year overall survival rates were 98.7% and 95.1%, respectively and the 5- and 10-year distant DRFS rates were 99.3% and 96.3%, respectively. The 5- and 10-year IBTR free rates were 97.0% and 89.7%, respectively. Older patients had significantly less IBTR rates (5-year IBTR free rates: 95.8% for  $\leq 64$  vs. 98.1% for  $\geq 65$ ,  $p=0.019$ ). There was no difference in IBTR rates between the large and small tumors (5-year IBTR free rates: 96.9%  $\leq 1.4$  cm vs. 96.8% for  $\geq 1.5$  cm,  $p=0.094$ ). PR positivity had a significantly lower IBTR free rates (5-year IBTR free rates: 98.3% for PR positive vs. 91.5% for PR negative,  $p=0.009$ ). The age at surgery ( $\leq 64$ ,  $p=0.017$ , Hazard ratio 3.07, 95% CI 1.22-7.70) and the PR status (PR negative,  $p=0.024$ , Hazard ratio 2.54, 95% CI 1.13-5.69) independently affected the IBTR rates. Both the 5- and 10-year IBTR free rates of the patients who were  $\geq 65$  at surgery and had PR positive tumors (n=136) were 98.4%. **Conclusions:** The findings suggest that the “5-mm thick slice and 5-mm free margin” method may be effective in selecting patients who can be treated with breast conserving surgery and hormone therapy without radiotherapy.

**Background** With 8.7 years follow-up, the prospective phase III randomized MINDACT trial (EORTC 10041/BIG3-04) continues to meet its primary objective, i.e. 95.1% (95%CI 93.1-96.6), 5-year distant metastasis-free survival (DMFS) in clinical high (C-High)/genomic low (G-Low) risk patients who did not receive adjuvant chemotherapy (ACT) (Cardoso et al., ASCO 2020). In addition, about half of the MINDACT patients had a low clinical risk (C-Low) defined by pre-specified clinical-pathological characteristics. Here, we evaluated the outcome of this C-Low population stratified by the 70-gene signature (MammaPrint®) (G-Low or G-High) for outcome considering age, and present data on the total G-low population (C-Low and C-High combined). **Methods** Of 6693 patients enrolled in the MINDACT trial between 2007 and 2011, 3337 were C-Low, characterized as mainly T1, grade 1 or 2, and node negative. We evaluated the pre-specified DMFS, distant metastasis free interval (DMFI), and overall survival (OS) rates at 5 and 8 years in the C-Low population: i) in patients with genomic low risk (C-Low/G-Low, n=2744) who were recommended to receive endocrine therapy only (for 99% HR+), and ii) in C-Low/G-High who received ACT or not following randomization (ITT, n=690, 81% HR+). Exploratory analyses by age, ≤50 and >50, were conducted for ACT vs no ACT received in C-Low/G-High. In parallel we estimated survival rates for all G-low patients if all would have followed the genomic low risk assignment and received no ACT (C-Low/G-Low, and C-High/G-Low randomized to no ACT double weighted, n=4130). We used Kaplan-Meier estimates for time to event endpoints and hazard ratios with 95%CI from Cox-regression models adjusted for stratification factors used for the randomization. **Results** C-low/G-low patients who were recommended endocrine therapy only (compliance > 79%, based on local guidelines) have excellent 5 and 8 year survival rates for all endpoints (Table 1). The estimated survival rates for all G-Low patients, if all would have followed the genomic low risk assignment and received no ACT, is excellent as well (Table 1), albeit this population includes both C-Low and C-High patients. The survival estimates for C-Low/G-High patients are for all endpoints a few percentage points lower than for the C-Low/G-Low group (Table 1). At 8 years of follow-up, in the relatively small subset of 690 patients with C-Low/G-High tumors assigned to ACT or not by randomization (ITT), a 1.5% (SE ±2.3%) higher DMFS is seen in the ACT group, and a 2.9% (SE ±2.0%) higher DMFI. This suggested benefit is mostly seen in patients under 50 years of age (absolute Δ in DMFS for ACT vs no ACT at 8 years: 5.4% for age ≤50 vs -0.3% for age >50). **Conclusion** Patients with a 70-gene G-Low risk tumor have an excellent 8 year outcome in the context of C-Low characteristics when recommended for endocrine therapy only, very close to the outcome in the larger group of all G-Low patients regardless of clinical risk. Stratification of C-Low patients in to G-Low and G-high provides meaningful information. The benefit of ACT in C-Low patients with a 70-gene G-High risk tumor needs further confirmation, especially relevant in younger women.

**Objectives:** The key objectives of CONTESSA are to evaluate the efficacy and safety of tesetaxel plus a reduced dose of capecitabine as an all-oral regimen versus capecitabine alone in patients with HER2-, HR+ MBC previously treated with a taxane.

**Rationale:** Tesetaxel is a novel, oral taxane with several properties that make it unique, including: oral administration with a low pill burden; a long (8-day) terminal plasma half-life in humans, enabling infrequent, once-every-3 weeks (Q3W) dosing; no observed hypersensitivity reactions; and significant activity against chemotherapy-resistant breast cancer cell lines. More than 1,000 patients have been treated with tesetaxel in clinical studies. Tesetaxel had encouraging monotherapy activity in a Phase 2 study in 38 patients with HER2-, HR+ MBC, with a confirmed objective response rate (ORR) per RECIST 1.1 of 45% and median progression-free survival (PFS) of 5.4 months (Seidman et al, 2018 ASCO Annual Meeting).

**Methodology:** CONTESSA is a multinational, multicenter, randomized (1:1), Phase 3 registration study comparing tesetaxel (27 mg/m<sup>2</sup> on Day 1 of a 21-day cycle) plus a reduced dose of capecitabine (1,650 mg/m<sup>2</sup>/day on Days 1-14 of a 21-day cycle) to the approved dose of capecitabine alone (2,500 mg/m<sup>2</sup>/day on Days 1-14 of a 21-day cycle) in patients with HER2-, HR+ MBC who have received no more than one chemotherapy regimen for advanced disease and have received a taxane in the (neo)adjuvant setting. There was no restriction on the disease-free interval following taxane therapy. The primary endpoint is PFS assessed by an Independent Radiologic Review Committee (IRC). CONTESSA was designed with 90% power to detect a 2.5-month improvement in median PFS (HR=0.71). Secondary endpoints are overall survival (OS), ORR and disease control rate.

**Results:** CONTESSA, which enrolled 685 patients, met the primary endpoint of improved PFS as assessed by the IRC. Median PFS was 9.8 months for tesetaxel plus a reduced dose of capecitabine versus 6.9 months for capecitabine alone, an improvement of 2.9 months [HR=0.716 (95% CI: 0.573-0.895); p=0.003]. ORR was 57% for tesetaxel plus a reduced dose of capecitabine versus 41% for capecitabine alone (p=0.0002). OS data are immature. Tesetaxel plus capecitabine was associated with a manageable side effect profile consistent with previous clinical studies. Grade ≥3 treatment-emergent adverse events (TEAEs) that occurred in ≥5% of patients (tesetaxel plus capecitabine vs. capecitabine alone) were: neutropenia (71.2% vs. 8.3%); diarrhea (13.4% vs. 8.9%); hand-foot syndrome (6.8% vs. 12.2%); febrile neutropenia (12.8% vs. 1.2%); fatigue (8.6% vs. 4.5%); hypokalemia (8.6% vs. 2.7%); leukopenia (10.1% vs. 0.9%); and anemia (8.0% vs. 2.1%). TEAEs resulting in treatment discontinuation in ≥1% of patients (tesetaxel plus capecitabine vs. capecitabine alone) were: neutropenia or febrile neutropenia (4.2% vs. 1.5%); neuropathy (3.6% vs. 0.3%); diarrhea (0.9% vs. 1.5%); and hand-foot syndrome (0.6% vs. 2.1%). Treatment discontinuation due to any adverse event occurred in 23.1% of patients treated with tesetaxel plus capecitabine versus 11.9% of patients treated with capecitabine alone. Grade 2 alopecia occurred in 8.0% of patients treated with tesetaxel plus capecitabine versus 0.3% of patients treated with capecitabine alone. Grade ≥3 neuropathy occurred in 5.9% of patients treated with tesetaxel plus capecitabine versus 0.9% of patients treated with capecitabine alone.

**Conclusion:** An all-oral regimen of tesetaxel plus a reduced dose of capecitabine significantly improved PFS versus capecitabine alone. Neutropenia was the most frequent Grade ≥3 TEAE. Rates of clinically significant alopecia and neuropathy were low.

A metabolomic signature as screening method for breast cancer diagnosis

Concetta Elisa Onesti<sup>1</sup>, Francois Boemer<sup>1</sup>, Claire Josse<sup>2</sup>, Ahmed Debit<sup>2</sup>, Christophe Poulet<sup>3</sup>, Vincent Bours<sup>4</sup> and Guy Jerusalem<sup>5</sup>. <sup>1</sup>CHU Liege, Liege, Belgium<sup>2</sup>GIGA Research Center, Liege, Belgium<sup>3</sup>GIGA Research Center, Liege, Belgium<sup>4</sup>CHU Liege, GIGA Research Center and University of Liege, Liege, Belgium<sup>5</sup>CHU Liege and University of Liege, Liege, Belgium

**Introduction:** There is a close relationship between metabolism and cancer, which modifies its metabolic network to support cell survival. This may be reflected in a release of metabolites into the circulating blood, which may allow the identification of a signature associated with a tumor. Here we analyze a metabolomic profile of non-metastatic breast cancer patients and healthy controls to identify a diagnostic signature. **Materials and methods:** We prospectively enrolled 350 subjects in our study. A blood sample withdrawal at breast cancer diagnosis or the day of the screening mammography for the control group was done. After centrifugation, plasma was collected and stored at -80 °C. A panel of 61 metabolites was tested on a TQ5500 tandem mass spectrometer in triplicate for each sample and with internal standard and inter-run calibrators. ComBat tool from GenePattern platform was used to remove the batch effect. After outliers removal with Tukey's method and mean value calculation for each replicate, a Z-standardization was done. A 10-fold cross-validation (CV) was used to find the best representative validation set containing 106 subjects (78 cancerous and 28 healthy), which represents 30% of the dataset. The remaining 70% was used as a training set, containing 244 subjects (126 cancerous and 118 healthy). After feature selection, the best signatures were identified on the training set with Random Forest method and validated on the validation set. Statistical analysis was performed with R-studio software. **Results:** We enrolled in our study 350 subjects, 204 breast cancer patients and 146 healthy controls. The median age in the breast cancer group was 56 years (range 26-86), and in the healthy controls group was 53 years (range 40-74). Breast cancer patients were all at an early stage: 44 at stage I (21.5%), 111 at stage II (54.4%), and 49 at stage III (24%). The breast cancer patients were of all subtypes: 61 luminal A (29.9%), 90 luminal B (44.1%), 14 hormone receptor-negative/HER2-positive (6.9%), and 39 triples negative (19.1%). A feature selection was performed on the training set using Random Forest method, and 10 metabolites were identified as the most important in discriminating cancerous from healthy subjects. From this reduced set, 1023 combinations were generated and evaluated for their AUC performance using 10-CV on the same training set. A total of 512 combinations were identified with an AUC  $\geq$  0.90. To predict breast cancers, the best signature comprised 4 variables (C6-Carnitine, C3/C2, C2-Carnitine, C8/C2), with an AUC of 0.996 (SD 0.0073) in the training set and of 0.998 (SD 0.0002) for the validation set, at a specificity of 99.4% and a sensitivity of 98.7%. **Conclusions:** With our work, we identified a metabolite-based predictive signature of breast cancer with a validation performance of AUC 0.99 (specificity of 99.4% and sensitivity of 98.7%), thus outperforming the mammography screening test. Furthermore, the signature-based test is fast, cheap, and does not expose patients to ionizing radiation. Our study's limitation is a difficult application to clinical practices due to the statistical technique used. Thus, a refinement of the analysis technique and a validation on a larger and independent cohort are mandatory. Also, there are some differences in metabolism related to genetic, environmental factors, and feeding. Therefore, this result should be confirmed on different ethnicities, geographical regions, and the timing of blood withdrawal should be standardized.

**Background:** MammaPrint (MP) is used to identify breast cancer (BC) patients who can safely forego adjuvant chemotherapy. MP combined with the Blueprint (BP) molecular subtyping signature identifies BC subtypes with distinct therapeutic response rates and survival outcomes. In the Neoadjuvant Breast Symphony Trial (NBRST), MP and BP (MP/BP) predicted rates of pathologic complete response to neoadjuvant chemotherapy (NCT) and partial response to neoadjuvant endocrine therapy (NET). Here, we report 5-year overall survival (OS) and distant metastasis-free survival (DMFS) in patients from the NBRST registry according to MP/BP molecular classification. **Methods:** The NBRST trial (NCT01479101) prospectively enrolled 1072 patients from 2011 to 2014, who received MP and BP testing. Patients were assigned to receive NCT or NET according to NCCN guidelines and consented to 5 years post-surgery follow-up (FU). Clinical outcomes were available for 913 patients from 67 US institutions. Median FU for OS and DMFS was 5 and 4.6 years, respectively. Tumors classified by MP as High Risk (HR) or Low Risk (LR) were further stratified into four molecular subtypes by BP: Luminal A, Luminal B, HER2, and Basal. Differences in OS and DMFS at 3 and 5 years were assessed by Kaplan Meier analysis and log-rank test. **Results:** MP results from neoadjuvant patients (N=913) classified 16% of tumors as MP LR and 84% as MP HR. MP and BP classified 15.7% (143/913) of tumors as Luminal A, 32.5% (297/913) as Luminal B, 17.1% (156/913) as HER2, and 34.7% (317/913) as Basal. The 5-year OS and DMFS probabilities were significantly lower in HR compared to LR patients ( $p < 0.001$  for OS and DMFS), and lowest in Basal and Luminal B compared to Luminal A and HER2 subtypes ( $p < 0.001$  for OS and DMFS). Most DMFS events in BP Basal tumors occurred within the first 3 years. Of 841 patients that received NCT with or without HER2-targeted therapy, 12.2% (103/841) were LR and 87.8% (738/841) were HR. MP and BP classified 11.9% (100/841) of these patients as Luminal A, 32.6% (274/841) as Luminal B, 8.3% (154/841) as HER2 subtype, and 37.2% (313/841) as Basal. The 5-year OS and DMFS probabilities were lowest in HR, Basal or Luminal B patients ( $p < 0.001$ ). In 59 patients who received NET alone, 5-year OS and DMFS were significantly worse in HR patients that had Luminal B or HER2 tumors compared to LR Luminal A patients. In the 39 patients with Luminal A tumors, response to NET at the time of surgery was: 46.2% partial response, 41.0% stable disease, 5.1% progressive disease, 2.6% not reported. Five year DMFS in patients with Luminal A tumors treated with NCT or NET was not significantly different ( $p=0.67$ ). **Conclusions:** MammaPrint remained prognostic in BC patients undergoing neoadjuvant therapy. Long-term prognosis was excellent in LR groups who received NCT or NET alone. MP and BP can accurately classify patients into specific subtypes with distinct OS and DMFS outcomes at five years, with BP Basals having the worst outcomes, followed by Luminal B, HER2, and Luminal A subtypes. BP Basal patients had the highest frequency of events within the first 3 years post-surgery, suggesting a genomic risk timeline distinct from other BP subtypes and a potential benefit from a secondary therapeutic immediately post-surgery. Additionally, Luminal A patients had a very low risk of progressive disease while on NET alone prior to surgery, with similar DMFS outcomes to Luminal A-types who received NCT.

Impact of the COVID-19 pandemic on the multidisciplinary management of breast cancer: Initial analysis of the American Society of Breast Surgeons Mastectomy COVID-19 registry

Lee Gravatt Wilke<sup>1</sup>, Toan T Nguyen<sup>2</sup>, Qiuyu Yang<sup>1</sup>, Bret M Hanlon<sup>1</sup>, Kathryn A Wagner<sup>3</sup>, Pamela Strickland<sup>4</sup>, Eric A Brown<sup>5</sup>, Jill Dietz<sup>6</sup> and Judy C Boughey<sup>7</sup>. <sup>1</sup>University of Wisconsin School of Medicine and Public Health, Madison, WI; <sup>2</sup>Lakeland Regional Health, Lakeland, FL; <sup>3</sup>Texas Breast Specialists, San Antonio, TX; <sup>4</sup>University of Alabama/Baptist Medical Center South, Montgomery, AL; <sup>5</sup>Comprehensive Breast Care, A Division of Michigan Healthcare Professionals, Troy, MI; <sup>6</sup>Case Western Reserve University School of Medicine, Cleveland, OH; <sup>7</sup>Mayo Clinic, Rochester, MN

**Background:** The COVID-19 pandemic rapidly altered health care worldwide. To save protective equipment and minimize exposures, many hospitals stopped some or all cancer surgery, leading oncologic providers to quickly adjust patient management. The goal of this study is to describe the breast cancer patient level changes which occurred during the initial months of COVID-19 in the United States. **Methods:** The American Society of Breast Surgeons developed a COVID-19 specific registry, within the established HIPAA compliant Mastectomy of Breast Surgery Program. Surgeons entered patient demographic data as well as their surgical and medical care (Neoadjuvant endocrine (NET) vs Neoadjuvant chemotherapy (NCT)). Data fields tracked whether decisions were usual for that practice, or modified due to COVID-19. **Results:** Between 3/1 and 6/17/2020, data from 1781 patients was entered by 154 surgeons. Mean age was 63, 78% Caucasian, 10% African American, 6% Hispanic; with geographic distribution ranging from 10.8% Northwest to 29.5% Northeast. Initial consultation took place in-person for 94.8% and only 5.2% (89) occurred via video/telephone. To date, just over 1% (14) of patients tested positive for COVID-19. Mean invasive tumor size was 21.2mm and 15.7% were node positive. Of 1445 invasive breast cancers 75% (1081) were ER+/HER2-, 13.5% (195) HER2+, 11.1% (160) triple negative (TNBC) (9/missing data). DCIS comprised 18.2% (325) of the cohort. Of 267 cases of ER+ DCIS, 49% (131) had primary surgery and 49% (130) received NET. The majority of NET use was due to COVID-19, 95% (124). Almost all (50/52) ER- DCIS underwent primary surgery (6/missing ER). Table 1 describes the management for the 1436 patients with invasive cancer with known biomarkers. NET due to COVID-19 was utilized in 45% (482), with only 5% (54) as part of usual practice. Increasing age was not a statistically significant factor in the use of NET (OR 0.99, 95% CI 0.97-1.01). In comparison to patients from the Northwest, patients from the Southwest and Northeast had the greatest use of NET(COVID-19) vs NET(usual) (ORs 14.4 and 4.6). Genomic assay testing was performed on the core biopsy in 216 patients, with 65% (141) due to COVID-19. Among the patients who had genomic testing due to COVID-19, 116 (82%) had NET, 18 (13%) had NCT, with the remaining having primary surgery. Of 472 patients treated with primary surgery for which the impact of COVID-19 was provided, surgery was delayed in 20% (96). Patients from the Northeast had a 2.1 x greater odds of having surgery delayed in comparison to those from the Midwest. Patients also experienced changes to their surgical plan with the most common changes being 6% (27) converting from mastectomy to breast conservation and 7% (34) from mastectomy with reconstruction to mastectomy without reconstruction. **Conclusion:** COVID-19 led to significant modifications in breast cancer treatment, including high rates of NET, genomic assay testing on core biopsies as well as delays in surgery; each of which were consistent with the prioritization and treatment recommendations from the COVID-19 Pandemic Breast Cancer Consortium. The majority of patients with TNBC and HER2+ disease received guideline concordant NCT. The ASBrS Mastectomy COVID-19 registry provides a snapshot into the rapid care changes caused by the pandemic, has ongoing data entry and analysis and will enable understanding of the impact on long term breast cancer outcomes.

Table 1: Biomarker specific treatments

	ER+/HER2- (1081)	TNBC (160)	HER2+/any ER (195)
Mean Age	65	61	59
African American (%)	97(9%)	21(13%)	27(14%)
Primary Surgery (usual)	386 (36%)	50 (31%)	37 (19%)
Primary Surgery (COVID-19)	28 (2.6%)	6 (3.7%)	6 (3.1%)
NET (usual)	54 (5%)	NA	1(0.5%)
NET (COVID-19)	482 (45%)	NA	6 (3.6%)
NCT (usual)	90 (8.3%)	98 (61%)	137 (70%)
NCT (COVID-19)	39 (3.6%)	6 (3.7%)	8 (4.1%)

Radiation therapy improves survival in early-stage HER2-positive breast cancer with high-level of tumor infiltrating lymphocytes

Jason A Mouabbi<sup>1</sup>, Momal Chand<sup>2</sup>, Ramen Sakhi<sup>2</sup>, Ishaq A Asghar<sup>2</sup>, Daniel Ockner<sup>2</sup>, Tarik Hadid<sup>2</sup>, Carrie L Dul<sup>2</sup>, Mothaffar F Rimawi<sup>1</sup> and Amer Aref<sup>2</sup>. <sup>1</sup>Baylor College of Medicine, Houston, TX; <sup>2</sup>Ascension St John Hospital, Detroit, MI

**Background:** Scientific evidence strongly indicates that locoregional control in early-stage breast cancer (BC) by lumpectomy with radiation therapy or by mastectomy yields similar disease-free survival (DFS) and overall survival (OS). A recent retrospective review of a Danish prospective database demonstrated strong favorable interaction between radiotherapy (RT) and all BC subtypes that contain high amount of tumor infiltrating lymphocytes (TILs).

**Objective:** We aim to compare DFS and OS in patients with early-stage HER2-positive BC, whose tumors demonstrate high involvement by TILs after locoregional treatment by either mastectomy or lumpectomy and whole breast radiotherapy.

**Methods:** We retrospectively reviewed the charts and histopathology slides of patients with HER2-positive BC with clinical stage T<sub>1</sub>-T<sub>2</sub> N<sub>0</sub>, who were treated in our center between January 2009 and December 2018. Locoregional management included either mastectomy (no radiation group) or lumpectomy with whole breast irradiation (radiation group). Stromal TILs were estimated using hematoxylin-eosin staining, according to the recommendations of the TILs working group 2014. This was performed by 3 independent pathologists who were blinded to the clinical course of the patients. A competing risk model, Kaplan-Meier analysis and multivariate Cox regression analysis were used to estimate correlations between TILs and clinical outcomes.

**Results:** A total of 110 charts were reviewed and 99 were included in the final analysis. Patients were dichotomized into groups of "low-TILs" and "high-TILs" using a 40% cut off. Approximately 25% of patients (26/99) were "high-TILs" and around 50% of the "high-TILs" and "low-TILs" patients received RT. In all groups, around 90% of patients received chemotherapy and anti-HER2 therapy. All hormone receptor-positive patients received adjuvant endocrine therapy. While RT did not result in significant DFS or OS advantage in the low-TILs group, patients with high-TILs had significant improvement of DFS and OS with the addition of RT. Table 1 depict the 5-year DFS and 5-year OS in "high-TILs" and "low-TILs" groups in relation to RT, respectively.

**Conclusion:** In this retrospective analysis, our findings indicate that in high-TILs early-stage HER2-positive BC, RT was associated with significant improvement of 5-year DFS and OS. The exact mechanism is not well understood. However, this observation is important and warrants confirmation in prospective clinical trials.

	5-year DFS		5-year OS	
	High TILs	Low TILs	High TILs	Low TILs
RT group	100%	90%	100%	83%
No RT group	65%	90%	72%	93%
p-value	<b>0.027</b>	0.96	<b>0.025</b>	0.184

Adherence to the new WCRF cancer prevention recommendations associates with a decreased breast cancer risk

Melanie Deschasaux<sup>1</sup>, Laurent Bourhis<sup>1</sup>, Laurent Zelek<sup>2</sup>, Eloi Chazelas<sup>1</sup>, Charlotte Debras<sup>1</sup>, Serge Hercberg<sup>1</sup>, Paule Latino-Martel<sup>1</sup>, Chantal Julia<sup>1</sup>, Emmanuelle Kesse-Guyot<sup>1</sup>, Bernard Srour<sup>1</sup> and Mathilde Touvier<sup>1</sup>. <sup>1</sup>Sorbonne Paris Nord University, U1153 Inserm, Inrae, Cnam, Bobigny, France<sup>2</sup>Sorbonne Paris Nord University, U1153 Inserm, Inrae, Cnam, Avicenne Hospital, Bobigny, France

**Background:** Breast cancer remains the leading cancer in women. In 2018, following its summary report, the World Cancer Research Fund (WCRF) issued its recommendations for cancer prevention based on the nutritional risk factors with a sufficient level of evidence, several of which being related to breast cancer. Our objective was to study whether adherence to these new recommendations was actually associated with reduced risk of breast cancer.

**Methods:** A total of 62,546 women from the NutriNet-Santé population-based cohort study (2009-2019) were included in our analyses. Adherence to the 2018 WCRF recommendations was assessed using the operationalized score on a 7-point scale, proposed by Shams-White et al (Nutrients 2019), including: weight, physical activity, fruit and vegetables, dietary fibers, ultra-processed foods, red and processed meat, sugary drinks and alcohol. Usual dietary intakes were assessed using repeated 24h-dietary records and physical activity level using the IPAQ questionnaire. Cox proportional hazard models were computed with adjustment for the following potential confounders: educational level, height, smoking status, number of 24h dietary records, family history of cancer, number of biological children, age at menarche, age at parity, menopausal status, use of oral contraception or hormonal treatment for menopause.

**Results:** During a median follow-up of 7.3 years, 745 women were diagnosed with a first incident breast cancer. The median WCRF 2018 adherence score was 3.75 (IQR: 3.25-4.50). An increase of 1-point increment in the score was associated with a decreased risk of breast cancer (HR=0.92; 95%CI 0.85-1.00; P=0.05), and especially of breast cancer post-menopause (n=456 cases, HR=0.88; 0.79-0.98; P=0.02). No association was observed for breast cancer pre-menopause (n=289, HR=0.99; 0.87-1.12; P=0.8). Sugary drink, alcohol and weight components of the score particularly contributed to the observed association.

**Conclusions:** Our results suggest that a higher adherence to the WCRF 2018 recommendations for cancer prevention is associated to a decreased risk of breast cancer. Considering that the WCRF cancer recommendations are consistent with overall food-based dietary guidelines, such recommendations should be promoted to the general public and transposed as public health actions to contribute to decrease the burden of cancer.

BluePrint performance in predicting pertuzumab benefit in genomically HER2-positive patients: A biomarker analysis of the APHINITY trial

Ian Krop<sup>1</sup>, Lorenza Mittenpergher<sup>2</sup>, Joseph Paulson<sup>3</sup>, Fabrice Andre<sup>4</sup>, Herve Bonnefoi<sup>5</sup>, Sherene Loi<sup>6</sup>, Sibylle Loibl<sup>7</sup>, Richard D Gelber<sup>1</sup>, Carmela Caballero<sup>8</sup>, Debora Fumagalli<sup>8</sup>, Christa Dreezen<sup>2</sup>, Rene Bernards<sup>2</sup>, Laura van 't Veer<sup>2</sup> and Martine Piccart<sup>9</sup>. <sup>1</sup>Dana-Farber Cancer Institute, Boston, MA; <sup>2</sup>Agendia, Amsterdam, Netherlands; <sup>3</sup>Genentech, San Francisco, CA; <sup>4</sup>Gustave Roussy, Paris, France; <sup>5</sup>Bergonie Cancer Institute, Bordeaux, France; <sup>6</sup>Peter MacCallum Cancer Centre, Melbourne, Australia; <sup>7</sup>Goethe University, Frankfurt, Germany; <sup>8</sup>Breast International Group, Brussels, Belgium; <sup>9</sup>Institut Jules Bordet, Brussels, Belgium

**BACKGROUND:** APHINITY is a phase III study (NCT01358877) which included 4805 patients (pts) with histologically centrally confirmed HER2+ early breast cancer (EBC) randomized to standard adjuvant chemotherapy (C) plus trastuzumab (T), plus either pertuzumab (P) or placebo<sup>1</sup> for 1 year. With median follow up of 45 months, the primary analysis showed significant invasive disease-free survival (iDFS) benefit at 3 years with a hazard ratio (HR) of 0.81 (95% CI: 0.66-1.00;  $P = 0.045$ ) for the addition of P to C/T<sup>1</sup>. BluePrint (BP) is an 80-gene molecular subtyping test that classifies EBC into functional basal, luminal and HER2 BP-subtypes<sup>3</sup> according to gene expression. Previous studies showed that this genomic test can reclassify HER2+ EBC (as determined by IHC/FISH) into basal, luminal or HER2 BP-subtypes<sup>4</sup>. Recently, it was revealed that a smaller proportion of breast tumours may display two functionally activated BP pathways (BP dual activated subtypes, of which one is usually less pronounced), whereas the majority has clearly only one activated functional BP pathway (BP single activated subtypes)<sup>5</sup>. We hypothesized that BluePrint could identify a subgroup of patients within the APHINITY population who derived additional benefit from the addition of P to C/T. **METHODS:** Genomic results were obtained using RNA sequencing (RNAseq) data<sup>6</sup> from a subset of APHINITY pts (N=970) derived from a 1023 unique patients nested case-control (NCC) set where event and matched controls were selected (1 iDFS event matched to 3 controls from the primary analysis database with 45 months median follow-up). Raw read counts were log<sub>2</sub> transformed followed by quantile normalization prior to genomic assessment. BP subtype scores were calculated equally to the standard microarray diagnostic testing and calibrated based on a bridge analysis with matched microarray and RNAseq data. iDFS outcome based on genomic subtype and the treatment arm (P+C/T vs placebo + C/T) was analysed. Results are reported descriptively with 95% CIs. **RESULTS:** From the patients within the NCC subset, BP subtype testing classified the 970 pts as basal, n=210 (22%); luminal, n=485 (50%) and HER2, 275 (28%) subtypes, an expected finding since the majority were hormone receptor positive (N=598/970, 62%). Further dissection of the BP results showed single activated subtype in 123 of 210 (59%) basal, 413 of 485 (85%) luminal and 139 of 275 (51%) of HER2 subtype cancers.

After NCC-inverse probability weighted corrected multivariate Cox regression analysis, no significant differences in iDFS were observed among the different genomic subtypes. A greater benefit with the addition of P to T/C was suggested in the 'single activated' HER2 BP-subtype compared with other groups (single HER2 HR=0.56, 95% CI 0.27-1.15, single basal HR=0.89, 95% CI 0.44-1.79 and single luminal HR=0.93, 95% CI 0.61-1.41).

**CONCLUSIONS:** In this exploratory analysis, HER2+ tumors with a single transcriptional HER2 activated pathway showed a trend for greater benefit from pertuzumab than tumors in which multiple mitogenic pathways are activated. Further research is ongoing to confirm these findings.

**Background:** The primary analysis of the randomized, double-blind, placebo-controlled APHINITY trial, published in 2017, including 4804 patients (pts) with HER2-positive, early breast cancer with 45.4 months' median follow-up, demonstrated that adjuvant pertuzumab (P) added to trastuzumab and chemotherapy, statistically significantly improved invasive disease-free survival (IDFS) compared with placebo (Pla) added to trastuzumab and chemotherapy overall and for pts with node-positive (N+) disease. In 2019, updated descriptive analyses of IDFS with 74.1 months' median follow-up, demonstrated sustained benefit of adding P both overall (HR, 0.76; 95% CI, 0.64-0.91), and for N+ disease (HR, 0.72; 95% CI, 0.59-0.87), while confidence intervals remained wide for the node-negative (N-) cohort (HR, 1.02; 95% CI, 0.69-1.53). There is great interest to explore how these significant overall results translate into absolute treatment benefits for different patient subpopulations.

**Methods:** Subpopulation Treatment Effect Pattern Plot (STEPP) is an exploratory, graphical method that plots estimates of treatment effect for overlapping patient subpopulations defined by a covariate of interest. Four continuous covariates of interest are considered for defining subpopulations in this report: i) a clinical composite risk score (see below), ii) TILs percentage, iii) HER2 FISH copy number, and iv) a clinical-biological composite risk score combining the previous three factors. Pts with lowest values for the covariate comprise the extreme left STEPP subpopulation, and pts with highest values comprise the extreme right subpopulation. The clinical composite risk score for IDFS based on the overall cohort was calculated using a Cox regression model including the following prespecified clinical characteristics: number of positive nodes, tumor size, age, and centrally-reviewed hormone receptor status. Composite risk scores were scaled between 0 and 100 with higher scores reflecting higher risk of an IDFS event. An example of low clinical risk factors would be T1N0 and aged 40-64; while high risk would be T3N2 or higher and ages <40 or ≥65. At 74.1 months' median follow-up, the composite risk of an IDFS event did not depend on hormone receptor status. Differences in Kaplan-Meier estimates of 6-year IDFS percents (P minus Pla) were used as estimates of treatment effect for each subpopulation. The overall analyses (N=4804) used 9 overlapping subpopulations with ~1000 pts in each, the N- analyses (N=1799) used 5 subpopulations with ~500 pts in each, and the N+ analyses (N=3005) used 7 subpopulations with ~750 pts in each. Intermediate (middle) subpopulations were the 5th, 3rd, and 4th, respectively.

**Results:** Table of 6-year IDFS percents (%) from Aphinity STEPPs, Overall and for N- and N+ cohorts. For each analysis, results are shown for the two subpopulations at either extreme of the STEPP (i.e. lowest and highest risk or values) as well as the intermediate STEPP subpopulation.

**Conclusions:** Based on the two extreme and one intermediate subpopulations of the STEPP analyses shown in the table, the intermediate clinical composite risk subpopulation and the highest TILs percentages had the largest absolute improvements in 6-year IDFS percents for P compared with Pla.

Table of 6-year IDFS percents (%) from Aphinity STEPPs, Overall and for N- and N+ cohorts.

Snord67 promotes lymph node metastasis through U6-mediated alternative splicing in breast cancer

Yvonne Chao<sup>1</sup>, Yinzhou Zhu<sup>2</sup>, Hannah J Wiedner<sup>1</sup>, Yi-Hsuan Tsai<sup>1</sup>, Lily Wilkinson<sup>1</sup>, Alessandro Porrello<sup>1</sup>, Amanda ED Van Swearingen<sup>1</sup>, Lisa Carey<sup>1</sup>, Jimena Giudice<sup>1</sup>, Christopher L Holley<sup>2</sup> and Chad V Pecot<sup>1</sup>. <sup>1</sup>University of North Carolina, Chapel Hill, NC; <sup>2</sup>Duke University, Durham, NC

**Background:** While the presence of lymph node (LN) metastases in solid tumor malignancies is clinically significant and associated with increased risk for distant metastases, there is little evidence that lymphatic metastasis is distinct from hematogenous dissemination. Recent studies showed that cancer cells in LNs can directly give rise to distant metastases, but the mechanisms behind how cancer cells exit lymph nodes to establish distant metastases is still unknown.

**Materials and Methods:** We developed an immunocompetent mouse model of lymph node metastasis using the 4T1 murine breast cancer cell line. In this model, 4T1 cells micro-surgically injected into axillary lymph nodes (AxLN) are capable of spontaneously establishing distant metastases. We then performed microarray analyses of subclones derived from MFP tumors, AxLN-injected tumors (AxLN), and lung metastases that arose from AxLN-injected tumors (AxLN-LuM) to evaluate for non-coding RNAs (ncRNAs) that were differentially expressed in AxLN tumors.

**Results:** Microarray analyses of ncRNAs expressed in MFP, AxLN, and AxLN-LuM subclones showed that a class of ncRNAs, small nucleolar RNAs (snoRNAs), were enriched in AxLN tumors compared to MFP and AxLN-LuM. We identified the snoRNA SNORD67 as a key regulator of LN metastasis. Knockout of SNORD67 by both CRISPR and antisense oligonucleotide (ASO) resulted in significantly decreased LN tumor growth and subsequent development of distant metastases. This was at least in-part due to loss of targeted 2'-O-methylation of the small nuclear RNA U6, a component of the spliceosome. RNA-Seq analyses revealed distinct alternative splicing in SNORD67 knockouts. Using rapid autopsy breast cancer cases, we found that matched primary tumor and LN metastases revealed similar alternatively spliced genes, including several genes with previously described cancer-promoting splice variants.

**Conclusions:** Small nucleolar RNAs (snoRNAs) have long been regarded as “housekeeping genes”, important for ribosomal biogenesis and protein synthesis. However, there is increasing evidence that this largely ignored class of non-coding RNAs (ncRNAs) also have wide-ranging, non-canonical functions in diseases, including cancer. SnoRNAs have been shown to have both oncogenic and tumor suppressor roles, yet whether snoRNAs regulate metastasis is unknown. Here we show that expression of certain snoRNAs are enriched in lymph node (LN) metastases in a micro-surgical, immune-competent mouse model of breast cancer. Moreover, our results show that SNORD67 is critical for growth of LN metastases and subsequent spread to distant metastases, and suggest that snoRNA-guided modifications of the spliceosome represent a previously unappreciated, yet targetable pathway in cancer.

**Background:** Overall, patients with cancer experience a greater risk of adverse outcomes following SARS-CoV-2 infection; however, little is known for those with BC.

**Methods:** CCC19 (NCT04354701) is an international cohort study aimed at investigating the impact of COVID-19 in patients with a history of or active cancer using de-identified data on patient demographics, cancer history, clinical course and outcomes of COVID-19. The current analysis includes patients from U.S. and Canada with invasive BC and laboratory-confirmed SARS-CoV-2 entered between March 17, 2020 and July 2, 2020. Co-primary outcomes were hospitalization during COVID-19 illness and 30-day all-cause mortality. Frequencies for categorical variables and medians (range) for continuous variables were estimated. Final presentation will include bivariable and multivariable Cox proportional hazards regression analysis to identify risk factors (including BC subtypes and therapies, for which data collection is ongoing) associated with 30-day all-cause mortality and severe COVID-19 illness (composite of any hospitalization requiring supplemental oxygen, admission to an intensive care unit [ICU], use of mechanical ventilation, or death).

**Results:** During the study period, a total of 2683 patients with cancer and COVID-19 were accrued in the CCC19 registry including 529 (20%) with invasive BC. Among patients with BC, 352 (67%) were 60 years or older; 518 (98%) were women; 275 (52%) non-Hispanic White, 116 (22%) non-Hispanic Black, 70 (13%) Hispanic, 56 (11%) in other categorizations; 178 (34%) had a smoking history; 75 (14%) ECOG performance status  $\geq 2$ ; 191 (36%) with  $>2$  active comorbidities; 64 (12%) with AJCC stage IV disease at BC diagnosis; and 267 (50%) were on anti-cancer treatment including systemic therapy, radiation, or surgery within 3 months of COVID-19 diagnosis. At least 323 (61%) patients with BC had 30-day follow-up after COVID-19 diagnosis, and 35 (7%) had 90-day follow-up. COVID-19 illness at initial diagnosis required outpatient care in 288 (54%), inpatient care in 193 (36%), and ICU care in 40 (8%). Overall, 247 (47%) were hospitalized and 30-day all-cause mortality was 9%. 30-day all-cause mortality rates by receipt of major BC treatment modalities (within past 3 months) were: 10% for those on cytotoxic systemic therapy vs 5% and 12% for noncytotoxic systemic therapy and local therapy, respectively. The table shows hospitalization and mortality outcomes by major demographic and BC treatment strata. The final presentation will incorporate the latest patient accrual and evaluate independent clinical risk factors associated with serious COVID-19 outcomes in patients with BC.

**Conclusions:** This represents the largest study to date of COVID-19 outcomes in patients with invasive BC. Nearly half of the patients with BC required hospitalization during their COVID-19 disease course and we observed a 9% 30-day all-cause mortality.

Submitted on behalf of the COVID-19 and Cancer Consortium (ccc19us.org)

**Background:** Pembrolizumab (pembro) monotherapy showed durable antitumor activity and manageable safety in patients (pts) with metastatic triple-negative breast cancer (TNBC) in the KEYNOTE-012, -086, and -119 studies. In a prespecified interim analysis of KEYNOTE-355 (NCT02819518), pembro combined with chemotherapy (chemo) showed a statistically significant improvement in PFS versus chemo alone in pts with previously untreated locally recurrent inoperable or metastatic TNBC whose tumors expressed PD-L1 CPS  $\geq 10$  (HR for progression or death, 0.65, 95% CI, 0.49-0.86; one-sided  $P=0.0012$  [prespecified statistical criterion was  $\alpha=0.00411$  at this interim analysis]). Additionally, pembro + chemo was generally well tolerated, with no new safety signals. Here, we examine PFS outcomes for each chemo partner and present key secondary endpoints from KEYNOTE-355.

**Methods:** 847 pts with measurable disease per RECIST v1.1, ECOG PS 0-1, and  $\geq 6$  mo DFI were randomized 2:1 to pembro + chemo (nab-paclitaxel 100 mg/m<sup>2</sup> days 1, 8, and 15 every 28 days; paclitaxel 90 mg/m<sup>2</sup> days 1, 8, and 15 every 28 days; or gemcitabine 1000 mg/m<sup>2</sup> + carboplatin AUC 2 days 1 and 8 every 21 days) or pbo + chemo for up to 35 administrations of pembro/pbo or until progression/intolerable toxicity. Steroid premedication for paclitaxel was given according to local guidelines and practices, and was not restricted by the protocol. Crossover between arms was not allowed. Pts were stratified by chemo type (taxane vs gemcitabine/carboplatin), PD-L1 status (CPS  $\geq 1$  vs  $<1$ ), and prior (neo)adjuvant treatment with same-class chemo (yes vs no). Dual primary endpoints are PFS (RECIST v1.1, blinded independent central review) and OS in pts with PD-L1 positive tumors (CPS  $\geq 10$  and  $\geq 1$ ) and in all pts. Secondary endpoints include ORR, DCR (CR + PR + SD  $\geq 24$  weeks), and DOR. The PFS treatment effect was assessed in subgroups descriptively using HRs and 95% CIs; although subgroup analysis by on-study chemo were pre-specified, the trial was not powered to compare efficacy among treatment groups by different chemo regimens.

**Results:** As of Dec 11 2019, median follow-up was 25.9 mo for pembro + chemo (n=566) and 26.3 mo for pbo + chemo (n=281). The HR for PFS favored pembro regardless of choice of chemo or CPS population (**Table**). Results for the key secondary endpoints of ORR, DCR, and DOR favored pembro + chemo, with the treatment effect increasing as CPS increased (**Table**).

**Conclusion:** In subgroup analysis, PFS with pembro + chemo compared to pbo + chemo in pts with metastatic TNBC was improved regardless of chemo partner. A trend toward improved efficacy with PD-L1 enrichment with pembro + chemo was observed for ORR, DCR and DOR endpoints. These data further support the potential of pembro + chemo as a first-line treatment option for metastatic TNBC.

Preservation of axillary lymph nodes compared to complete dissection in T1-T2 breast cancer patients presenting 1-2 metastatic sentinel lymph nodes : A multicenter randomized clinical trial. Sinodar One.

Corrado Tinterri, Emilia Marrazzo, Chiara Anghelone, Erika Barbieri, Andrea Sagona, Alberto Bottini, Arianna Rubino, Damiano Gentile, Wolfgang Gatzemeier, Valentina Errico, Alberto Testori and Giuseppe Canavese. Humanitas Clinical and Research Center, Milano, Italy

**Introduction:** Sentinel lymph node (SLN) staging is currently used to avoid complete axillary lymph node dissection (ALND) in breast cancer (BC) patients. The SLN is the only site of axillary metastasis (MTS) in  $\leq 60\%$  of cases. Recently, a randomized controlled trial (Z0011) comparing SLN biopsy (SLNB) alone with SLNB followed by ALND in patients with 1-2 SLNs+ demonstrated no significant statistical difference in relapse and overall survival rates among the two different groups. However, this study had some limitations: small tumor size ( $\leq 2\text{cm}$  in 70% of cases), frequent presence of only microMTS in SLN (40%), prevalent use of "whole breast" adjuvant radiotherapy ( $>90\%$ ). Given these considerations, the SINODAR-ONE study started in April 2015. **Objectives:** The aims are to assess whether ALND omission in BC patients with 1-2 SLNs+ is associated with worse survival and/or increased rate of regional/distant relapse. Thus evaluating whether SLNB is or is not inferior to ALND. Primary endpoint is overall survival (OS). Secondary endpoints are disease-free survival (DFS) referring to distant MTS and loco-regional recurrence. **Methods:** Patients receive either mastectomy or conservative surgery plus radiotherapy. They all undergo SLNB and are randomly divided into two arms of treatment: standard (SLNB plus ALND) or experimental treatment (only SLNB). According to multidisciplinary evaluation, patients may undergo additional adjuvant radiotherapy, chemo- and/or hormonal therapy, or no further therapy. Eligibility criteria: age 40-75 years; primary invasive T1-T2 tumor; axillary nodes clinically N0; no more than 2 macro-metastatic SLNs; no distant MTS; no neo-adjuvant therapy; no previous invasive BC; signed informed consent. Exclusion criteria: in situ, inflammatory, contralateral BC; micro-metastatic SLNs; pregnancy or breast feeding; comorbidity impeding adjuvant therapy. All analyses are performed both on all patients according to the Intention-To-Treat principle and excluding those patients who did not receive the axillary treatment randomly assigned. Statistical analysis: OS and DFS are calculated using the Kaplan-Meier Product Limit Estimator and differences between arms are assessed with the log-rank test. **Results:** The enrollment of patients ended in April 2020 with a total of 889 cases (443: standard arm; 446: experimental arm). In June 2020, we conducted an ad interim analysis on 889 patients. We found the two groups homogeneous for epidemiologic characteristics (age and menopausal status), tumor characteristics (tumor size, pTNM, immunohistochemistry, histology, grading, vascular and lymphatic invasion), adjuvant therapies and surgery on T. In particular we have performed a 23,1% of mastectomies in the standard arm and 20,1% in the experimental arm. We found a median of 2 sentinel lymph nodes removed in both arms and 1 non-sentinel positive lymph node in the experimental arm, and only 3 micro-metastases (1 in the standard arm and 2 in the experimental arm). **Conclusion:** In sum, with a median follow-up of 30 months, there have been no axillary recurrence in both arms. In the standard arm we found 8 total events (2 deaths and 6 distant relapses) and in the experimental arm 6 events (1 death and 5 distant relapses), with a projected 5-years cumulative incidence of 6,5% in standard arm and 4,85% in the experimental arm.

Evaluation of sleep problems and their association with febrile neutropenia, leucopenia and infections in women receiving adjuvant chemotherapy for breast cancer in the Canadian Cancer Trials Group MA.21 trial

Audreylie Lemelin<sup>1</sup>, Josee Savard<sup>1</sup>, Michelle Chen<sup>2</sup>, Margot Burnell<sup>3</sup>, Mark N Levine<sup>4</sup>, Lois Shepherd<sup>2</sup>, Bingshu E Chen<sup>2</sup> and Julie Lemieux<sup>1</sup>. <sup>1</sup>CHU de Quebec - Universite Laval, Quebec, QC, Canada<sup>2</sup>Canadian Cancer Trials Group - Queens University, Kingston, ON, Canada<sup>3</sup>Dalhousie University, Halifax, NS, Canada<sup>4</sup>McMaster University, Hamilton, ON, Canada

**Background** Insomnia is a frequent complaint in patients with cancer. Sleep problems can affect immune functioning in healthy individuals. Our aim was to evaluate the association between sleep disturbance and the risk of febrile neutropenia, leukopenia and infections in patients treated with chemotherapy in an adjuvant setting for breast cancer. **Methodology** This is a retrospective study using the Canadian Cancer Trial Group data collected for the MA.21 trial, in which three adjuvant chemotherapy regimens (CEF, EC-T dose dense or AC-T) were compared in 2104 patients with node positive or high-risk node negative breast cancer. A total of 1731 patients had completed the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire C30 (EORTC QLQ-C30) and 1727 patients had completed the Breast Cancer Chemotherapy Questionnaire (BCQ) quality of life questionnaires, which both include a question about sleep difficulties. The primary definition for patients with insomnia was a score of three (quite a bit) or greater at Question 11 (Have you had trouble sleeping? with answers ranging from one (not at all) to four (very much)) on the EORTC QLQ-C30 questionnaire. We compared patients classified as having "clinical insomnia" based on their response to this question with patients considered "good sleepers". The primary endpoint was the risk of febrile neutropenia. Secondary endpoints were the risks of grade one or more leukopenia, neutropenia and infection. **Results** Febrile neutropenia was more frequent in patients with sleep problems compared with those without, with 16.3% and 12.2% of patients having at least one episode in each group respectively (p value = 0.01 in the univariate analysis (table 1)). However, after adjustment for potential confounders in the multi-variate analysis, it was not statistically significant with an odds ratio of 1.07, a 95% confidence interval of 0.76-1.50 and a p value of 0.71. Similarly, no statistically significant difference in the risk of leukopenia could be demonstrated in the multi-variate analysis for patients with sleep problems with an odds ratio of 0.92 a 95% confidence interval of 0.69-1.24 and a p value of 0.59. No significant association could be found between sleep problems and neutropenia and infections. In an unplanned exploratory analysis, chemotherapy dose reductions were significantly more frequent in patients with sleep problems with 30.6% in this group compared to 21.8% in good sleepers, with a p value <0.0001. **Conclusion** While our univariate analysis suggested an increased risk of febrile neutropenia and leucopenia in patients with sleep problems, after adjustment for confounders, we could not show a statistically significant association in women undergoing adjuvant chemotherapy for high-risk locoregional breast cancer.

Identification of women at high risk of breast cancer and in need of supplemental screening - A cohort study

Mikael Eriksson, Kamils Czene and Per Hall. Karolinska Institutet, Stockholm, Sweden

**Background.** Mammography screening reduces breast cancer mortality, but a large proportion of breast cancers are missed and detected at later stages or develop in between screening intervals. We developed the KARMA model which identifies women who are likely to be diagnosed with breast cancer before or at the next screen.

**Materials and Methods.** The study was based on the prospective screening cohort KARMA including 70,877 participants. We identified 974 incident cancers and sampled 9,376 healthy individuals from the cohort. An image-based risk score was developed using mammographic features (density, masses, microcalcifications), their left-right asymmetries, and age. The lifestyle extended score also included menopausal status, family history of breast cancer, body-mass-index, hormone replacement therapy, and use of tobacco and alcohol. The genetic extended score also included a polygenic risk score including 313 single nucleotide polymorphisms. Relative risks were estimated using age stratified logistic regression. Tumor sub-type specific risks were estimated. Absolute risks were estimated including relative risks and national incidence rates.

**Results.** The image-based model reached an area under the curve (AUC) of 0.73 (95% CI 0.71,0.74). The lifestyle and genetic extended model AUCs were 0.74 (95% CI 0.72,0.75) and 0.77 (95% CI 0.75,0.79) respectively. There was a relative 8-fold difference in risk between the women at high and general risk. High risk women were more likely diagnosed with stage II and  $\geq 20$  mm tumors and less likely with stage I and estrogen receptor-positive tumors. The image-based model was validated in two external cohorts.

**Conclusion.** By combining three mammographic features, their left-right asymmetries, and optionally lifestyle factors, family history, and a polygenic risk score we generated a model that identifies women at high likelihood of being diagnosed with breast cancer within two years of a negative screen and in possible need of supplemental screening or preventive intervention.

**Table 1.** Discrimination performance (AUC) of the risk score in relation to the three models of the study. The 2-year risk Model 1 is compared with the two external validation datasets.

Model	AUC (95% CI) <sup>1</sup>
<i>KARMA case-cohort (974 cancers, 9,376 healthy subjects)</i>	
1. Model 1; mammographic density, microcalcifications, masses, age	0.73 (0.71,0.74)
2. Model 2; Model 1 + lifestyle and familial risk factors <sup>2</sup>	0.74 (0.72,0.75)
3. Model 3; Model 2 + PRS <sup>3</sup>	0.77 (0.75,0.79)
<i>MBTST cohort (104 cancers, 9,745 healthy subjects), Model 1</i>	0.71 (0.67,0.75)
<i>CSAW (613 cancers, 8,489 healthy subjects), Model 1</i>	0.73 (0.71,0.76)
<i>KARMA independent test set (179 cancers, 9,491 healthy subjects), Model 1</i>	0.73 (0.69, 0.77)

Polygenic risk score included 313 SNPs.

**Table 2.** Comparison discrimination performance (AUC) of the PRS, Tyrer-Cuzick, and Gail risk scores with and without mammographic density in KARMA case-cohort.

Model	AUC (95% CI) <sup>1</sup>
PRS <sup>2</sup>	0.64 (0.62,0.66)
PRS <sup>2</sup> + mammographic density <sup>3</sup>	0.67 (0.65,0.69)
Tyrer-Cuzick <sup>4</sup>	0.58 (0.56,0.60)
Tyrer-Cuzick <sup>4</sup> + mammographic density <sup>3</sup>	0.62 (0.60,0.64)
Gail <sup>5</sup>	0.56 (0.54,0.58)
Gail <sup>5</sup> + mammographic density <sup>3</sup>	0.61 (0.60,0.63)

Polygenic Risk Score included 313 SNPs. Mammographic density were adjusted for age and BMI.

Quantitative dynamic contrast-enhanced (DCE) MRI radiomic phenotypes for prediction of nodal and distal metastasis in breast cancer patients

Gaiane Margishvili Rauch<sup>1</sup>, Karen Drukker<sup>2</sup>, Nabil Elshafeey<sup>3</sup>, Rania M.m. Mohamed<sup>3</sup>, Medina Boge<sup>3</sup>, Beatriz E. Adrada<sup>3</sup>, Rosalind P Candelaria<sup>3</sup>, Mo Salama<sup>4</sup>, Irene Shkatova<sup>5</sup>, Maryellen Giger<sup>6</sup> and Wei T Yang<sup>3</sup>. <sup>1</sup>Breast and Abdominal Imaging, The University of Texas MD Anderson Cancer Center, Houston, TX; <sup>2</sup>Biological Sciences Division, Radiology The University of Chicago, Chicago, IL; <sup>3</sup>Breast Imaging, The University of Texas MD Anderson Cancer Center, Houston, TX; <sup>4</sup>Diagnostic Imaging, The University of Texas MD Anderson Cancer Center, Houston, TX; <sup>5</sup>EHR Clinical Ancillaries, The University of Texas MD Anderson Cancer Center, Houston, TX; <sup>6</sup>Department of Radiology, The University of Chicago, Chicago, IL

**Background and Purpose:** Image-based tumor phenotypes by using computer extraction techniques have been studied for evaluation of breast cancer invasiveness, stage, lymph node involvement, molecular subtypes and genomics. In this project we aimed to investigate ability of computer-extracted breast MR imaging radiomic phenotypes to predict nodal and distant metastasis in breast cancer patients.

**MATERIALS AND METHODS:** This retrospective IRB approved study included 416 biopsy proven breast cancer patients who had pretreatment DCE MRI in a single institution between 2014 and 2018. Patient's demographic, clinical data, pathology at diagnosis and surgery, nodal and distant metastasis (M1) at follow up were documented. Using QuantX imaging software, the tumor volume of interest was automatically-segmented using the multiple dynamic phases of DCE MRI. A total of 33 radiomic features describing tumor phenotype were extracted from each tumor site. A linear discriminant analysis (LDA) as a classifier with nested feature selection 10-fold cross validation was used to build the radiomic signature for prediction of nodal and distant metastasis occurrence. Receiver operating characteristic (ROC) and precision-recall analyses were used to evaluate performance, with 95% confidence intervals from 1000 bootstraps, and Kaplan-Meier was used to calculate the progression-free survival estimates and associated hazard ratio at the median cutpoint of the probability of metastasis calculated by the LDA in the 10-fold cross-validation.

**RESULTS:** The quantitative DCE MRI radiomic model was able to differentiate between breast cancer patients with and without distant metastatic disease at follow up with area under the ROC of 0.75 (95% CI 0.65; 0.82) and precision-recall curves 0.46 (0.33; 0.69), hazard ratio at median cut point is 3.76 (2.27; 6.24),  $p < 0.001$ . Volume, surface area, sphericity, margin, maximum uptake, and washout rate variation features played the most important role in differentiating between breast cancer patients with and without distant metastasis.

The DCE radiomic model was able predict presence of ipsilateral nodal disease ( $\geq 1$  positive lymph nodes) at surgery with AUC 0.66 (95% CI: 0.60; 0.71),  $\geq 4$  positive lymph nodes at surgery with AUC 0.67 (95% CI: 0.60; 0.74), and N2/N3 disease with AUC 0.64 (95% CI: 0.56; 0.72). Effective radius was most important feature for nodal disease prediction.

**CONCLUSIONS:** Our results show that DCE MRI based radiomic phenotypes were able to predict nodal involvement and distant metastasis in breast cancer patients. Quantitative breast DCE MRI radiomics shows promise for noninvasive image based phenotyping for prediction of nodal and distant metastatic disease in breast cancer patients.

Background: Endocrine therapy(ET) and Chemotherapy(CT) are used as standard maintenance therapy for HR+ and HER2- metastatic breast cancer(MBC) in clinical practice. There was no prospective study data on which is better. In OVERSTEP, we provide some strong evidence for clinical practice. Methods: OVERSTEP(NCT02597868) is a multicenter, randomized, open-label, prospective clinical trial that enrolled 181 patients in China. patients aged 18-70 years without chemotherapy for ABC/MBC previously, histologically confirmed metastatic HR+ and HER2- breast cancer, and ECOG performance status of 0-1. These patients were received capecitabine plus another chemotherapy drug as 1<sup>st</sup>-line salvage chemotherapy at least 4 cycles. The patients response are CR, PR and SD carried maintenance treatment next, randomly assigned (1:1) to receive either capecitabine single or endocrine therapy. Randomization was done centrally with stratification by endocrine resistance and visceral metastasis. The primary endpoint was progression-free survival(PFS) and analyses were base on all patients who received at least one dose maintenance therapy. We take superiority test in the 2 groups. Results: 136(75.14%) patients were randomized after combined chemotherapy to capecitabine single or endocrine therapy groups for maintenance treatment. 45(24.86%) patients are progress disease (PD) after combined chemotherapy. After a median follow-up of 24.3 months (IQR 20.46-37.25 ) in the endocrine maintenance therapy group and 24.1 months(IQR 20.67-36.77) in the Capecitabine maintenance therapy group ,the hazard ratio for PFS was 0.625(95%CI 0.429-0.909 P=0.013),Median PFS was 17.5 months(95%CI 11.544-23.856) in endocrine maintenance therapy group and 12.2 months(95%CI 11.170-13.230) in capecitabine maintenance therapy group. In endocrine sensitive group, the hazard ratio for PFS was 0.515(95%CI0.269-0.988 P=0.042), Median PFS was 29.3 months(95%CI 14.605-43.995) in endocrine maintenance therapy group and 14.8 months(95%CI 7.445-22.155) in capecitabine maintenance therapy group. In endocrine resistance group, the hazard ratio for PFS was 0.791(95%CI 0.499-1.253 P=0.314), Median PFS was 13.6 months(95%CI 9.111-18.089) in endocrine maintenance therapy group and 12.0 months(95%CI10.357-13.643) in capecitabine maintenance therapy group. In visceral metastasis group, the hazard ratio for PFS was 0.668(95%CI0.410-1.089 P=0.101), Median PFS was 14.3 months(95%CI 11.113-17.487) in endocrine maintenance therapy group and 11.0 months(95%CI 8.140-13.860) in capecitabine maintenance therapy group. In non-visceral metastasis group, the hazard ratio for PFS was 0.54(95%CI0.300-0.972 P=0.037), Median PFS was 25.3 months(95%CI 15.278-35.322) in endocrine maintenance therapy group and 17.0months(95%CI 10.783-23.217) in capecitabine maintenance therapy group. Conclusions: For HR+ and HER2- MBC, after 1<sup>st</sup>-line salvage combined chemotherapy, ET maintenance has a better survival benefits than CT,especially for ET-sensitive and non-visceral involved cases. So ET maintenance is the first choice for ABC/MBC after 1<sup>st</sup>-line combined chemotherapy.

Coleman<sup>1</sup>, Georgeta Fried<sup>2</sup>, Sung-Bae Kim<sup>3</sup>, Iryna Kuchuk<sup>4</sup>, David Kies<sup>5</sup>, Manuel Ramos<sup>6</sup>, Joohyuk Sohn<sup>7</sup>, Jonathan Siegel<sup>8</sup>, Rui Li<sup>8</sup>, Deise Uema<sup>8</sup>, Volker Wagner<sup>9</sup> and Hope S. Rugo<sup>10</sup>. <sup>1</sup>University of Sheffield, Sheffield, United Kingdom<sup>2</sup>Rambam Health Care Campus, Haifa, Israel<sup>3</sup>Asan Medical Center, Seoul, Korea, Republic of<sup>4</sup>Meir Medical Center, Kfar-Saba, Israel<sup>5</sup>Kepler University Hospital, Linz, Austria<sup>6</sup>Cancer Center of Galicia, Coruna, Spain<sup>7</sup>Yonsei University College of Medicine, Seoul, Korea, Republic of<sup>8</sup>Bayer HealthCare Pharmaceuticals Inc., Whippany, NJ;<sup>9</sup>Bayer Consumer Care AG, Basel, Switzerland<sup>10</sup>University of California San Francisco Comprehensive Cancer Center, San Francisco, CA

**Background:** Approximately 65-75% of women with metastatic breast cancer (mBC) have skeletal involvement, which can result in bone pain, pathologic fractures, and spinal-cord compression (SCC), impairing quality of life and function. Radium-223 dichloride (Ra-223) is a targeted alpha-emitting radionuclide therapy that is approved for treatment of bone metastases from castration-resistant prostate cancer, but has been little studied in mBC. **Objective:** To assess the efficacy and safety of Ra-223 in women with bone-metastatic hormone receptor (HR)-positive breast cancer receiving endocrine monotherapy. **Methods:** This international, phase 2, randomized, double-blind, placebo-controlled trial (NCT02258464) involved women ≥18 years with HER2-negative, HR-positive, bone-dominant (≥2 skeletal lesions) mBC. Women with 1-2 skeletal-related events before study entry, treated with ≥1 line of hormonal therapy in the metastatic setting and bone-supportive agents, were randomized 1:1 to receive Ra-223 55 kBq/kg or placebo intravenously every 4 weeks for up to 6 cycles, combined with local standard of practice endocrine monotherapy and bone-targeted therapy with denosumab or a bisphosphonate. The primary endpoint was symptomatic skeletal event-free survival (SSE-FS). SSE was defined as external beam radiotherapy to relieve skeletal symptoms, symptomatic pathologic fractures, SCC, cancer-related orthopedic surgery, or death from any cause. Secondary endpoints included overall survival (OS), radiologic progression-free survival (rPFS), pain measurements, and safety. **Results:** Considering the evolving treatment landscape and slow recruitment, enrollment was closed early, and patients who completed treatment were permitted to roll over early to a follow-up study. Of the planned 227 women, 99 were randomized (Ra-223 n=49, placebo n=50; median age 57 years, range 28-85 years; 89% postmenopausal). The median number of injections received was 6 (range 1-6) in both arms. Median SSE-FS was 30 months (80% confidence interval [CI] 22, 43) in the Ra-223 arm vs 18 months (80% CI 9, 28) in the placebo arm; hazard ratio 0.75 (95% CI 0.41, 1.36; P=0.334). Trends in favor of Ra-223 over placebo were found for OS and pain measurements (Table). Treatment-emergent adverse events (TEAEs) occurred in 96% of patients in the Ra-223 arm and 94% in the placebo arm; drug-related TEAEs occurred in 44% and 33% of patients, respectively, and grade 3/4 TEAEs in 31% and 39%, respectively. In the Ra-223 vs placebo arms, there were fewer serious TEAEs (6% vs 25%, respectively, most commonly bone pain), bone-associated TEAEs (21% vs 27%, respectively; fracture 4% vs 12%, respectively), and TEAEs leading to treatment discontinuation (2% vs 6%, respectively). **Conclusion:** Although the primary endpoint was not met, possibly because of the small sample size, early discontinuation of follow-up, and lower than anticipated event rates, numerical trends consistently favored Ra-223 over placebo for SSE-FS, OS, and bone pain measurements. The overall TEAE rate was similar in both arms, but fewer serious or severe TEAEs were observed with Ra-223 than placebo.

Efficacy endpoints with Ra-223 vs placebo in women with mBC on background hormone monotherapy

	Radium-223 (n=49)	Placebo (n=50)	Difference between treatment arms

## Background

T-DXd (Enhertu®) is an FDA-approved antibody-drug conjugate (ADC) targeting HER2. T-DXd has shown anti-tumor activity, not only in patients with HER2-overexpressing (IHC3+/2+ ISH+) breast cancer (BC) but also in patients with BC with low HER2 expression (IHC1+/2+ ISH-). Current HER2 protein expression assessment is based on manual pathologist scoring that classifies tumors by the percentage of tumor cells with highest intensity and completeness of staining. A critical need exists for more objective and quantitative methods to assess HER2 expression, specifically to better identify patients with low-level expression if T-DXd proves to be efficacious in this patient population.

## Methods

We used deep learning (DL)-based image analysis (IA) to generate a novel HER2 **Quantitative Continuous Score (QCS)**. Data analytic techniques determined optimal HER2 QCS for the J101 trial (NCT02564900) of 151 patients with varying HER2 expression levels (1+, 2+, 3+). HER2 QCS consists of DL models to detect membrane, cytoplasm, and nuclei of all tumor cells. QCS was extensively trained using pathologists' annotations, and the performance was validated on unseen data to ensure its generalization and robustness. QCS was blindly applied to J101 data. The optical density (OD; level of brown stain intensity) was computed on detected membrane to derive features that could be linked to survival prediction. QCS features were selected to maximize ORR in positive group, minimize ORR in negative group maintaining while high prevalence in the positive group.

## Results

Analytical validation showed high correlation between QCS from automatically detected membranes and QCS from those annotated by pathologists (R=0.993). This is in the same range as correlation between three pathologists (R=0.995). HER2 QCS was largely consistent with pathologist HER2 scoring as well but showed broad quantitative overlap between IHC and ISH categories. HER2 QCS showed a direct linear relationship between ORR and increased HER2 expression across the entire assay range. In the HER2-low population (n = 65), for whom HER2-targeting therapies are not currently approved, 42% of patients responded to T-DXd, with a median PFS (mPFS) of 11 mo. Using HER2 QCS, we were able to further stratify this population into a subgroup of QCS-high patients (above a staining intensity cut-off determined by IA), with response and mPFS increased to 53% (95% CI: 36%-68%) and 14.5 mo (95% CI: 10.9 mo-NR) respectively, while the QCS-low group only showed ORR of 24% (95% CI: 9%-45%) and mPFS of 8.6 mo (95% CI: 4.2 mo-NR). Generally, best-performing QCS cutoffs were driven by most tumor cells expressing a minimal amount of HER2, in contrast to current clinical guidelines that are driven by a minority of cells expressing higher levels of HER2. We also examined spatial heterogeneity by characterizing cells as either bearing membrane stain above a determined OD threshold (positive cell) or lying within certain distances from a positive cell. We observed similar efficacy with best performing-cutoffs, again, being found when a minimal level of HER2 expression (OD) was examined.

## Conclusions

Taken together, these data establish a first proof-of-concept demonstrating that use of HER2 QCS can potentially enhance prediction of patient outcome with T-DXd by increasing sensitivity and specificity of response, especially in the HER2-low population. The ability to identify patients in the HER2-low group who could benefit from T-DXd is critical for its use in a patient population with a high unmet need that would otherwise not be treated with anti-HER2 therapy. Further clinical verification and validation is ongoing.

Intra-epithelial tumor immune landscapes are associated with clinical outcomes in early-stage triple-negative breast cancer

Jodi M Carter<sup>1</sup>, Saranya Chumsri<sup>2</sup>, David W Hillman<sup>1</sup>, David M Zahrieh<sup>1</sup>, Yaohua Ma<sup>2</sup>, Xue Wang<sup>2</sup>, Jennifer M Kachergus<sup>2</sup>, Judy C Boughey<sup>1</sup>, Minetta C Liu<sup>1</sup>, Krishna R Kalari<sup>1</sup>, JC Villasboas<sup>1</sup>, Roberto A Leon Ferre<sup>1</sup>, Fergus J Couch<sup>1</sup>, Matthew P Goetz<sup>1</sup> and E. Aubrey Thompson<sup>2</sup>. <sup>1</sup>Mayo Clinic, Rochester, MN; <sup>2</sup>Mayo Clinic, Jacksonville, FL

**Introduction:** Stromal tumor-infiltrating lymphocytes (sTILs) have established prognostic and predictive significance in triple-negative breast cancer (TNBC). However, the roles of other immune cells in TNBC are less well-established. We performed high-plex quantitative spatial profiling in a cohort of early-stage TNBC to 1) apply spatial context to tumoral immune landscapes and 2) identify immune proteins associated with clinical outcomes, independently of TILs and other established prognostic clinicopathologic variables, in patients (pts) treated with or without adjuvant chemotherapy (CTX). **Methods:** The Mayo TNBC cohort comprises pts with centrally-verified, CTX-naïve tumors resected from 1985-2012. Using a cohort-based TMA, with Nanostring GeoMX DSP, we quantitated 58 proteins within spatially-distinct intra-epithelial, cytokeratin-positive tumor segments and adjacent cytokeratin-negative/nuclei-positive stromal segments. Differentially-expressed (DE) proteins were identified using a negative binomial generalized linear model (SNR>2,  $p < 0.05$ ) and a target DE protein set was dichotomized (80<sup>th</sup> percentile). After adjusting for prognostic clinicopathologic variables, proteins associated with recurrence-free survival (RFS, defined as time from surgery to either local, regional, and distant recurrence, or death by any cause) were identified by performing variable selection using the Akaike Information Criterion (AIC) obtained from fitting all possible Cox proportional hazards regression models (performed separately for intra-epithelial/stromal segments, and in groups +/- adjuvant CTX). **Results:** From the TNBC TMA, DSP data (N=250 tumors) included 169 pts who received adjuvant CTX+ and 81 who did not (CTX-). Overall, 85/250 developed recurrent disease. In the CTX+ group, intra-epithelial tumor segments from pts without recurrent disease were enriched in 10 immune proteins, including CD8, markers involved in antigen presentation/dendritic cells (CD11c, CD40, HLA-DR) or NK cells (CD56) (FC: 1.4-2.1,  $p < 0.05$ ); CD14 was increased in stroma (FC: 1.5,  $p < 0.05$ ). In contrast, in the CTX- group, both the intra-epithelial tumor and stromal segments from pts without recurrences were enriched in immune proteins (N= 12 and 15 respectively; FC 1.6-5.5,  $p < 0.05$ ) most markedly CD40, IDO1 and HLA-DR (FC: 3.2-5.5,  $p < 0.05$ ). Overall, CD3, CD4, CD27, CD44, and ICOS among others were enriched only in the CTX- group; CD14 and CD56 were enriched only in the CTX+ group. Based on these spatial data, biologic function and DSP data from another set of TNBC (FinXX trial), CD11c, CD14, CD27, CD40, CD56, and IDO1 were selected for RFS analysis. After applying our model selection criterion and adjusting for pt age at surgery, tumor size, lymph node status, and sTILs, intra-epithelial CD56 was independently associated with improved RFS in the CTX+ group (HR: 0.31[0.12, 0.81]). In the CTX- group, intra-epithelial CD11c was independently associated with improved RFS (0.10 [0.01, 0.81]). **Conclusion:** In this early-stage TNBC cohort, spatially-distinct tumor immune landscapes were associated with RFS but differed according to receipt of CTX after surgical resection. In the patients who received CTX, the intra-epithelial compartment, rather than stromal compartment, was immune-enriched in pts without recurrences. Among a targeted protein set, intra-epithelial CD56 remained associated with improved outcomes, independent of sTILs and other clinicopathologic features. In the CTX-group, spatial landscapes were more balanced, and intra-epithelial CD11c was independently associated with improved outcomes. These data provide insight into the spatial context of intrinsic immune landscapes in TNBC, and identify candidate prognostic immune biomarkers which may inform therapeutic strategies.

Consumer and patient reactions to trials of chemotherapy reductions reveal an urgent need to name and explain the concept

Mary L Smith<sup>1</sup>, Elda Railey<sup>1</sup>, Carol B White<sup>2</sup>, Janine Hill<sup>3</sup>, Courtney J Andrews<sup>4</sup> and Gabrielle B Rocque<sup>4</sup>. <sup>1</sup>Research Advocacy Network, Plano, TX; <sup>2</sup>CBWhite, Evanston, IL; <sup>3</sup>Soar Strategies, Evanston, IL; <sup>4</sup>University of Alabama at Birmingham, Birmingham, AL

**Introduction:** A growing trend in cancer research is the study of de-escalation of treatment, particularly chemotherapy. The hope is that eliminating or reducing drug(s) from treatment regimens will reduce toxicity burden and increase quality of life without increasing risk of recurrence and death. Large well-designed clinical trials are needed to ensure this hope is a reality. One such trial is EA1181 CompassHER2 pCR, which has an accrual goal of 1,250 patients.

**Methods:** This qualitative study included: (A) 2 focus groups with patients diagnosed with HER2+ breast cancer 3-5 years ago, for their ability to draw on their experience and react to the trial and (B) 3 focus groups with consumers who have never had a cancer diagnosis, for their ability to provide the “cancer-naïve” perspective that may more closely match that of newly diagnosed patients (the EA1181 population). One of the consumer groups was composed of Black women and moderated by a Black facilitator to allow issues to surface that may be specific to this group. Patients were identified via Living Beyond Breast Cancer; consumers were identified via a nationwide market research panel. Groups took place online in April and May 2020, after the COVID pandemic had begun. After a brief introduction to the trial, questions focused on: Reactions and questions, motivations, concerns, and descriptive language.

**Results:** A total of 30 women (11 patients and 19 consumers) participated, representing a mix of age groups, educational attainment, and racial and ethnic social identities.

The trial description raised many questions in participants' minds. Some of the more frequent responses from both patients and consumers related to the rationale for reducing treatment and the side effects and benefits of each drug. Consumers demonstrated confusion between what is to be tested in the trial versus what is part of the neoadjuvant process. Patients questioned the timeline and length of each step.

Motivations for participation centered on avoiding some chemotherapy and the associated side effects, costs, and recovery time. Some discussed taking only what is needed.

Concerns were significant and centered on: (A) Fear and the feeling that it is best to take everything, (B) Possible lengthened duration of treatment since chemotherapy may be needed after surgery (versus the certainty of having all chemo prior to surgery). The duration issue generated strongly negative reactions among patients who felt they would prefer chemo and its side effects all at once.

Some motivations and barriers also seemed tied to the likelihood of not needing post-surgical chemo, with participants expecting thresholds (unaided) of 50% to 80% of the perceived desirable outcome.

Language around the concept is a critical issue. Participants expressed many ideas related to possible milder treatment that is modified. The word, de-escalation, garnered very negative reactions including many comparisons to military action. Toxicity is also a term that was less familiar to consumers and disliked by many as it elicits additional fear; “side effects” seems more familiar and palatable.

**Conclusion:** Communication about trials with reduced chemotherapy will need to be effective to lead to successful accrual. Providing tools to oncologists and patients to enhance two-way communication may be necessary to ensure concepts are understood. Since de-escalation is already becoming a term commonly used by researchers, replacing it with a more effective descriptor that is clear and connects to the benefits appears time-critical. Quantifying reactions to language options and other qualitative findings via a survey with a larger sample of consumers and patients is advised. Including patient voices in trial design, as well as consumers particularly for trials for the newly-diagnosed, sheds light on communication needs.

**Background:** CDK 4/6 inhibitors (CDK 4/6i) with endocrine therapy (ET) combination therapy have improved outcomes in patients (pts) with hormonal receptor positive (HR+)/human epidermal growth factor receptor negative (HER2-) advanced breast cancer (ABC). However, most pts eventually develop resistance to these drugs, and one third never respond. Aside from HR positivity, predictive markers of clinical benefit from CDK 4/6i remains elusive. We aimed to identify biomarkers of response to palbociclib (PAL) and analyze potential therapeutic targets to reverse resistance. **Methods:** PEARL trial is a multicenter phase 3 study that assigned 601 postmenopausal HR+/HER2- ABC pts, whose disease progressed on aromatase inhibitors (AIs), to receive PAL + ET vs capecitabine (CAPE). We performed a differential gene expression analysis in pre-treatment tumors in extreme responders to PAL using the HTG EdgeSeq Oncology Biomarker Panel (HTG Molecular Diagnostics, Inc.), containing 2534 cancer related genes. Samples were subset in 2 categories: refractory (progressive disease as best response) vs sensitive (progression-free survival (PFS) within the upper quartile). Cox regression and Significance Analysis of Microarrays (SAM) analysis adjusting for multiple comparisons were performed. **Results:** We analyzed 455 (75.7%) pts with pre-treatment tumors available [from them, PAL + ET arm: 229 (50.3%) pts; CAPE arm: 226 (49.7%) pts]. Fifty genes (false discovery rate (FDR)<0.05) were differentially expressed in pts sensitive vs refractory to PAL (E2F target genes, epithelial-to-mesenchymal transition (EMT) and cell cycle genes, mainly). Unsupervised hierarchical clustering of pts based on the expression of these genes revealed two clusters. Cluster 1 is composed mostly of resistant tumors, highly proliferative (Ki67≥20%: 70%) with a great proportion of luminal B (59%) and non-luminal tumors (19%). Cluster 2 is composed of sensitive, low proliferative (Ki67<20%: 58%), mostly luminal A tumors (75%). There was no difference in ESR1 mutations distribution between the two clusters (Table 1). Forty genes were up-regulated and associated with resistance, including CCNE1 and PLK1 (Polo Like Kinase 1). In the whole cohort, pts with high levels (> median) of PLK1 (PLK1-high) treated with PAL, had a worse PFS in a multivariate model (5.7 months (m) vs 9.3 m of median PFS in PLK1-High vs -Low; HR=1.64, 95% CI (1.25-2.34), p=0.0008; adjusted model for confounders: age, site of disease, sites of metastasis, prior chemotherapy and Ki67). There were no differences in population treated with CAPE (9.9 m vs 9.4 m, PLK1-High vs -Low; HR=0.82, 95% CI (0.56-1.21), p=0.3189). In the METABRIC cohort, PLK1-High was associated with worse overall survival in HR+/HER2- BC but not in triple negative nor in HER2+ tumors. Among HR+/HER2- tumors, PLK1 expression was higher in luminal B and HER2-enriched intrinsic subtypes. We interrogated DepMap database and found that in BC cells lines there was an inverse correlation between PLK1 expression and effect on cell viability of CDK4 CRISPR knock-out (Pearson correlation r:0.54, p=0.009), but not of CDK6 knock-out. Also, HR+/HER2-/High Ki67 BC cell lines (HCC1428, EFM19 and MCF7) showed resistance to PAL on cell proliferation assays but sensitivity to the PLK1 inhibitor BI-2536. **Conclusion:** High expression of PLK1 is associated with intrinsic resistance to PAL and ET, this might be overcome with PLK1 inhibition. **Table 1**

**Background:** Sapanisertib (S) is an investigational, oral, and highly selective adenosine triphosphate (ATP)-competitive inhibitor of target of rapamycin complex 1/2 (TORC1/2). Simultaneous inhibition of ER and phosphoinositide 3kinase (PI3K)/serine/threonine-specific protein kinase (AKT)/mammalian target of rapamycin (mTOR) pathway with S may restore sensitivity to endocrine therapies in patients (pts) with breast cancer, who have progressed during or after aromatase inhibitor (AI) therapy. Here we report data from a phase 2 study of continuous once-daily or once-weekly S + fulvestrant (F) compared with single-agent F in pts with breast cancer. **Methods:** Postmenopausal women with ER+ and HER2- advanced or metastatic breast cancer following progression during/after AI therapy were randomized 1:1:1 to receive F (500 mg intramuscularly on day 1 of a 28-day cycle) alone (Arm A) or in combination with oral S either daily (4 mg; Arm B) or weekly (30 mg; Arm C) until progressive disease (PD), unacceptable toxicity, or consent withdrawal. Pts were stratified according to presence/absence of visceral metastases, previous sensitivity to hormonal therapy, and previous exposure to cyclin-dependent kinase (CDK) 4/6 inhibitors. Pts on Arm A could receive S at PD. Key exclusion criteria were: prior therapy with mTOR inhibitors, PI3K inhibitors, or F; >1 prior line of chemotherapy for MBC; recurrent disease or PD on >2 endocrine therapies for MBC. The primary endpoint was progression-free survival (PFS). Secondary endpoints included objective response rate (ORR), clinical benefit rate (CBR; any duration and at 24 weeks), overall survival (OS), and safety. **Results:** Between Aug 2016 and May 2018, 141 pts were randomized (Arm A: 46; Arm B: 47; Arm C: 48). One patient in Arm C was not treated. Median age was 58 years (range 33-84). Stratification was well balanced across arms; overall, 65% had visceral metastases, 84% had prior sensitivity to hormonal therapy, and 34% had received prior CDK 4/6 inhibitors. Pts received a median of 4 cycles (range 1-40) of F on Arm A, 5 cycles (range 1-33) of daily S + F on Arm B, and 4 cycles (range 1-39) of weekly S + F on Arm C. The last follow-up visit was in Nov 2019. The main reasons for treatment discontinuation included PD (76%, 60%, 53%; Arm A, B, and C, respectively) and adverse events (AEs; 4%, 32%, 36%; Arm A, B, and C, respectively). Of the pts in Arm A with confirmed PD, 18 crossed over to Arm B and C (9 each); crossover was analyzed separately. Efficacy data are shown in the table; median PFS was 3.5, 7.2, and 5.6 months in Arm A, B, and C, respectively. OS data were immature at the primary data cut-off. Three pts died during the study (2 and 1 in Arm A and B, respectively); all deaths were attributed to underlying disease. Most common any-grade AEs were: asthenia (24%), hyperglycemia, fatigue, and headache (22% each) in Arm A; hyperglycemia (57%) and nausea (49%) in Arm B; nausea (87%) and vomiting (70%) in Arm C. **Conclusion:** Daily or weekly treatment with S + F demonstrated modest clinical benefit in ER+/HER2- advanced or MBC pts who progressed during/after AI compared with single-agent F. The S + F combinations had increased toxicity leading to more treatment discontinuations compared with single-agent F.

**Table: PFS and response data**

	Arm A Single-agent F (n = 46)	Arm B S (QD) + F (n = 47)	Arm C S (QW) + F (n = 48)

**Background:** Achieving a pathologic complete response (pCR) has been shown on the patient level to predict excellent long-term event-free survival outcomes. Residual cancer burden (RCB) quantifies the extent of residual disease for patients who did not achieve pCR. We have previously observed in the I-SPY 2 TRIAL that while metastatic events outside the central nervous system (CNS) were dramatically reduced in the setting of pCR, the incidence of CNS metastasis remained similar across RCB classes, raising the possibility that these CNS events may be independent of response in the breast. In this study, we evaluate the type and sites of recurrences by RCB in a large pooled dataset, which allows for analysis within subtype, to validate these findings. **Methods:** 5161 patients pooled across 12 institutions/trials with available RCB and event-free survival (EFS) data were included in this analysis. EFS was calculated as the interval between treatment initiation, and locoregional recurrence, distant recurrence or death from any cause; patients without event are censored at time of last follow-up. The median follow-up is 4.6 years. We summarized the EFS event type, further sub-dividing the distant recurrence events (DR) by their site of relapse (CNS-only, CNS and other sites, Non-CNS). We used a competing risk (Fine-Gray) model to assess which of these site-specific relapses differ between RCB classes and estimated the cumulative incidence of CNS-only and non-CNS events at 5 years. Analyses were performed across the entire study population and within HR/HER2 defined subtypes. **Results:** Among the 5161 subjects, there were 1164 EFS events, including 92 (7.9%) local recurrences (without distant recurrence and/or death) and 1072 distant recurrence-free survival (DRFS) events. Among the DRFS events, 158 patients died without a distant recurrence. 914 experienced distant recurrences, including 90 (9.8%) with CNS-only, 145 (15.9%) with CNS and other sites, 664 (72.6%) with non-CNS distant recurrence; 15 (1.6%) patients had missing recurrence site information. Table 1 summarizes the cumulative incidence of CNS-only and non-CNS recurrence at 5 years and the proportion of CNS-only recurrences among DR events by RCB class overall and within each HR/HER2 subtypes. The incidence of CNS-only recurrences was low and similar across RCB classes. In contrast, the incidence of non-CNS recurrences increases with increasing RCB. As a result, CNS-only recurrences are proportionally higher within the RCB-0 and RCB-I than in the RCB-II and RCB-III groups, largely because of the low DR event rate and relative low frequency of non-CNS recurrence events within the RCB-0 and RCB-I classes. Overall, 27% of the recurrences in the setting of pCR (RCB-0) are due to CNS-only recurrences. **Conclusions:** Consistent with previous studies, our large pooled analysis confirmed that CNS-only recurrences are uncommon but appear similar across RCB groups, independent of response, suggesting that the CNS is a treatment sanctuary site. In contrast, non-CNS recurrence rates increase as RCB increases. These findings suggest that inclusion of CNS-only recurrences as an outcome event may impact the association between neoadjuvant therapy response and long-term outcomes in the context of current therapies. Novel therapies that cross the blood brain barrier will be needed to impact CNS recurrence rates.

Table 1: Cumulative Incidence of CNS Only and non-CNS Distant Recurrences at 5 years and proportion of CNS-only events among DR events

	RCB Class	0	I	II	III	p

Biomarkers predicting response to durvalumab combined with olaparib in the neoadjuvant I-SPY 2 TRIAL for high-risk breast cancer

Denise M Wolf<sup>1</sup>, Christina Yau<sup>1</sup>, Lamorna Brown-Swigart<sup>1</sup>, Nick O'Grady<sup>1</sup>, Gillian Hirst<sup>1</sup>, Laura Sit<sup>1</sup>, I-SPY 2 TRIAL Consortium<sup>2</sup>, Smita Asare<sup>2</sup>, Don Berry<sup>3</sup>, Laura Esserman<sup>1</sup>, Hyo Han<sup>4</sup>, Lajos Pusztai<sup>5</sup> and Laura van 't Veer<sup>1</sup>. <sup>1</sup>University of California, San Francisco, San Francisco, CA; <sup>2</sup>QuantumLeap Healthcare Collaborative, San Francisco, CA; <sup>3</sup>Berry Consultants, LTD, Austin, TX; <sup>4</sup>Moffitt Cancer Center, Tampa, FL; <sup>5</sup>Yale University, New Haven, CT

**Background:** Preclinical studies suggest synergy between PARP inhibitors and immune checkpoint inhibitors. In the I-SPY 2 TRIAL, the anti-PDL1 therapeutic antibody durvalumab combined with the PARP inhibitor olaparib showed increased efficacy relative to control in both the HR+/HER2- and TN subtypes. Pre-specified biomarker analysis was performed to test 7 immune genes/signatures previously associated with response to pembrolizumab [Pembro] and/or durvalumab and a DNA Repair Deficiency (DRD) signature previously associated with response to veliparib/carboplatin, as specific predictors of response to durvalumab/olaparib [Durva]. We also assessed MammaPrint (MP) High1/(ultra)High2 risk class (MP1/2), a prognostic signature used in the trial's adaptive randomization engine, and performed exploratory analysis on additional signatures. **Methods:** 105 patients (Durva: 71, controls: 34) had Agilent 44K gene expression from FFPE pre-treatment biopsies and pCR data; and 370 (Durva: 71, controls: 299) had MP1/2 and pCR data. We evaluated 13 genes/signatures (10 immune, 1 DRD, 1 ER, 1 proliferation) and MP1/2 as biomarkers of Durva response, using logistic modeling to assess performance. A biomarker is considered a specific predictor of Durva response if it associates with response in the Durva arm, and if the biomarker x treatment interaction is significant (likelihood ratio test,  $p < 0.05$ ). pCR rates within MP1/2 classes are estimated using Bayesian logistic modeling. Analysis is also performed adjusting for HR status as a covariate, and numbers permitting, within receptor subsets. Our statistics are descriptive rather than inferential and do not adjust for multiplicities.

**Results:** 8/10 immune biomarkers, including the genes PD1 and PDL1, and B-cell, dendritic cell and mast cell (but not T-cell or CD68) signatures associate with response to Durva in the population as a whole and in a model adjusting for HR status. As seen in previous immunotherapy trials, higher levels generally associate with pCR, with the exception of the mast cell signature, where high levels associate with non-response as was also shown for Pembro (I-SPY 2). In addition, high levels of the DRD (PARPi7) and proliferation signatures associate with response, as do low levels of ER signaling (ESR1/PGR average). Many of these biomarkers also associate with response in the control arm, and for no immune biomarker is the treatment interaction significant, suggesting a lack of predictive specificity. In subset analysis, 13/14 biomarkers (all but CD68) predict Durva response in the HR+/HER2- subset, with the strongest association to pCR being a low level of ESR1/PGR ( $p = 2E-08$ ). In our Bayesian analysis, the difference in estimated pCR rates between arms are primarily observed in the MP2 subtype, particularly in the HR+/HER2- MP2 patients (estimated pCR rate of 64% in Durv vs 22% in Ctr). In the TN subset, only 3/14 biomarkers associate with response: the STAT1 and TAM/TcCassII-ratio signatures that also associate with durvalumab response in a prior study (NCT02489448) and, interestingly, the proliferation signature. Notably, the dendritic, T-cell and tumor inflammatory signatures (TIS) predicting TN response to Pembro (I-SPY2, GeparSixto) do not associate with Durva response in TNBC, suggesting differences in the biology underlying response to PD1 and PDL1 inhibitors.

**Conclusion:** Multiple immune, DRD, proliferation, and ER signatures associate with response to durvalumab/olaparib therapy, but many lack predictive specificity. MP2 class and/or low ESR1/PGR are the strongest predictors of pCR in the HR+/HER2- subset; whereas for TNs, cytokine- and monocyte-dominated immune signatures like STAT1 [PMID: 19272155] and TAM/TcCassII ratio [PMID: 24205370] are most predictive of response. These results require validation.

Patient perception of breast and gynecologic cancer care during the SARS-CoV-2 (COVID-19) pandemic in NYC: A single center survey-based study

Brittney S Zimmerman, Danielle Seidman, Natalie Berger, Krystal P Cascetta, Michelle Nezolosky, Kara Trlica, Alisa Ryncarz, Caitlin Keeton, Erin Moshier and Amy Tiersten. Icahn School of Medicine at Mount Sinai, New York, NY

**Background:** The 2019 novel coronavirus has become a world-wide pandemic which has disproportionately affected patients undergoing treatment for cancer. Within the field of medical oncology, dramatic changes in practice patterns occurred rapidly to accommodate transition of resources, while maintaining safety of oncology patients. At our large cancer treatment center in NYC, there have been significant changes in the delivery of surgical and medical treatments, with a shift towards neo-adjuvant therapy, oral chemotherapy administration, extended ovarian suppression, as well as closure or delay of many clinical trials. This study aims to determine the impact of the COVID-19 pandemic on the perceived oncology related care of patients with breast/gynecologic cancers as measured by survey results, as well as the impact on quality of life (QOL) and overall health (OH).

**Methods:** A 34-question survey was administered to all patients receiving care at our outpatient center between March 1, 2020 and June 30, 2020. Of the 622 patients who received the survey via RedCap online or physical copy in clinic, 211 (34%) completed the survey. Survey questions were answered on a 5-point Likert scale and 7-point EORTC *QLQ-C30* QOL scale. There is no existing COVID specific questionnaire, therefore we designed several original questions. Difference in mean QOL scores prior to the pandemic and at the end of the response period were evaluated using a paired t-test. **Results:** Of the 184 patients who responded to the question about their diagnostic history, 54 (30%) of patients had a history of DCIS (ductal carcinoma in situ)/ADH (atypical ductal hyperplasia)/LCIS (lobular carcinoma in situ), 94 (51%) had a history of invasive breast cancer, 6 (3%) had a gynecologic malignancy and 30 (16%) responded "other." Due to the COVID pandemic, 121 patients (58%) reported that they had a medical oncology visit cancelled, delayed or changed from in-person to video telehealth. Of the 156 respondents that had endocrine therapy or chemotherapy scheduled, 26 (17%) reported a cancellation or delay of their medical treatment. As a result of the pandemic, 186 (91%), 110 (57%) and 119 (60%) of patients reported new or increased levels of anxiety, depression and mood swings, respectively. A minority of patients (n=39, 19%) felt that the COVID pandemic negatively impacted their cancer care, and a majority (n=151, 73%) felt that the changes in delivering cancer care during the pandemic were in their best interest (somewhat/strongly agree). Overall, QOL was reported with a mean (SD) of 5.5 (1.3) out of 7 (1=very poor, 7=excellent) prior to the pandemic, and 5.1 (1.4) out of 7 by the end of the pandemic period (March 1 through June 30, 2020);  $p<0.0001$ . Fifty-three (26%) of patients reported having excellent (7) QOL prior to pandemic which decreased to 32 (16%) after the pandemic period;  $p<0.0001$ . Overall health was reported with a mean (SD) of 5.3 (1.3) out of 7 prior to the pandemic, and 5.1 (1.3) out of 7 by the end of the response period;  $p=0.0368$ . **Conclusions:** The COVID-19 pandemic required major changes in the care of patients with breast and gynecologic cancer in order to balance continued oncologic care with safety of COVID exposure. In our study population, 17% of patients at our center reported a delay or cancellation in their medical treatment and 58% reported a change to their medical oncology visits. Despite this, only 19% of all patients felt that the changes in care delivery as a result of the COVID-19 pandemic negatively impacted their cancer care, and the large majority (73%) felt that the changes were made in their best interest. The QOL for our patients was significantly affected by the pandemic, with increases in anxiety, depression and mood swings, and a numeric decrease in QOL and OH.

Gut pathogen, *Bacteroides fragilis* promotes breast cancer liver and lung metastasis

Sheetal Parida<sup>1</sup>, Sumit Siddharth<sup>1</sup>, Guannan Wang<sup>2</sup>, Himavanth Gatla<sup>1</sup>, Shaoguang Wu<sup>1</sup>, Brian Ladle<sup>1</sup>, Kathleen Gabrielson<sup>1</sup>, Cynthia L. Sears<sup>1</sup> and Dipali Sharma<sup>1</sup>. <sup>1</sup>Johns Hopkins University-School of Medicine, Baltimore, MD; <sup>2</sup>Georgetown University, Georgetown, DC

**Background:** The last decade established significant contributions of microbiome to many organ specific cancers. Existence of distinct breast microbiota has been recently established but their biological impact in breast cancer progression remains elusive. A few recent studies suggested the existence of distinct breast microbiota and a shift in microbial community composition in diseased breast compared to normal breast however, their functional impact and underlying mechanisms are unknown. Present study was designed to examine the contribution of pro-carcinogenic bacteria in breast cancer initiation, progression and metastasis. Utilizing extensive data mining and metagenomic analyses, we discovered the presence of toxin producing enterotoxigenic *Bacteroides fragilis* (ETBF) in malignant breast. ETBF is a pro-carcinogenic bacteria known for its potential to initiate and/or promote colon cancer and its pathogenicity has been attributed to its unique toxin *B. fragilis* toxin (BFT)'.

**Results:** Using mammary intraductal model we discovered that ETBF can successfully colonize the breast confirmed by qPCR and Fluorescent *in situ* hybridization where it induces local inflammation, fibrosis and hyperproliferation of breast epithelial cells. Mice bearing gut ETBF infection exhibit significant circulating BFT confirmed by qPCR and ELISA and distinct morphological alterations in mammary gland as observed from whole breast mounting and histological evaluation. Gut colonization with ETBF rapidly induces hyperplasia in mammary glands with systemic and local breast inflammation validated by flow cytometry, immunohistochemistry and cytokine profiling. While no changes are observed in cell growth and clonogenicity upon BFT treatment, significant increase in migration and invasion potential and decreased adhesion of MCF10A and MCF7 cells are observed. BFT leads to prominent cytoskeletal reorganization, and increase in migration, invasion and stemness potential of breast cancer cells. Our results indicate that breast cancer cells exposed to BFT ensue to exhibit increase tumor growth, form multifocal tumors and show a striking increase in tumor-initiating cells upon *in vivo* limiting dilution in immunocompromised mice exhibiting retention of 'BFT memory' from the initial exposure. Mechanistically, RNA-sequencing shows enrichment of  $\beta$ catenin and Notch pathway in secondary tumors derived from BFT-exposed breast cancer cells. Inhibitors of  $\beta$ catenin and Notch axis abrogates BFT-induced migration and invasion potential indicating the functional importance of this axis. Intriguingly, gut colonization with ETBF at a physiologically relevant level strongly induces growth and metastatic progression of 4T1 tumor cells implanted in mammary ducts monitored by whole animal bioluminescent imaging. *In vivo* and *ex vivo* analyses of tumors and distant organs reveal a significant induction of lung and liver metastasis of breast cancer by ETBF while gut colonization with non-toxigenic *Bacteroides fragilis* (NTBF) does not exhibit any tumor-augmenting impact. We mechanistically evaluate the oncogenic impact of alpha bug ETBF on breast cancer progression and its role in promoting liver and lung metastasis using multiple mice models and multiple techniques including multi-color flow cytometry, immunohistochemistry, quantitative PCR, multiplexed ELISA, *ex vivo* functional assays and western blotting.

**Conclusion:** Collectively, these findings present the first evidence to show that gut colonization with *Bacteroides fragilis* rapidly induces inflammation, fibrosis and hyperplasia in the breast. In syngeneic breast cancer model, gut colonization with ETBF aggravates breast cancer progression and induces enhanced lung and liver metastasis *via* systemic immune modulation, cytokine synthesis and activation of pro-oncogenic pathways.

Highly multiplexed tissue-based cyclic immunofluorescence (t-CyCIF) for precision oncology identifies novel patterns of HER2 heterogeneity in breast cancer

Jennifer L Guerriero<sup>1</sup>, Jia-Ren Lin<sup>2</sup>, Ricardo G Pastorello<sup>1</sup>, Ziming Du<sup>3</sup>, Shaolin Mei<sup>2</sup>, Krishan Taneja<sup>3</sup>, Stuart J Schnitt<sup>3</sup>, Deborah A Dillon<sup>3</sup>, Peter K Sorger<sup>2</sup>, Sandro Santagata<sup>3</sup> and Elizabeth A Mittendorf<sup>1</sup>. <sup>1</sup>Dana-Farber Cancer Institute, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA; <sup>3</sup>Brigham and Women's Hospital, Boston, MA

## Background

Immunohistochemical (IHC) evaluation has shown that human epidermal growth factor receptor 2 (HER2) may not be expressed homogeneously among all cancer cells within a given tumor. The clinical significance of intratumoral HER2 heterogeneity is unclear. Exploration of tumor heterogeneity is facilitated by tissue imaging technologies such as t-CyCIF, a highly multiplexed immunofluorescence microscopy technique that permits visualization of up to 60 antigens and analysis on a single cell level from formalin-fixed, paraffin-embedded tissue. To utilize t-CyCIF for the evaluation of breast tumors, this study was undertaken to: 1) validate antibodies to be used against the clinically relevant markers HER2, estrogen receptor (ER) and progesterone receptor (PR), and 2) use these antibodies along with other validated antibodies to define the tumor microenvironment (TME) to interrogate breast tumors at a single cell level.

## Methods

T-CyCIF is an iterative whole-slide imaging process, in which successive four-channel images, each involving different antibodies, are collected from the same sample and then merged to generate a high-dimensional representation used for visualization and analysis. In phase one of this study, 948 tissue cores (representing 295 patients in triplicate) were used to validate HER2, ER, and PR antibodies against a single antibody commonly used in clinical practice as a reference. Analyses were performed at the level of tissue cores, cells and pixels. Inter-assay analyses were performed comparing: t-CyCIF vs. IHC, the latter assessed by digital pathology and two pathologists; and also, t-CyCIF vs. fluorescence *in situ* hybridization (FISH) for HER2. In the second phase, following selection of validated HER2, ER and PR antibodies, expression of CD45, CD68, PD-L1, p53, Ki67, pRB and the androgen receptor (AR) were evaluated at a single cell level in 312 HER2<sup>+</sup> invasive breast cancer samples, representing 104 patients, to better understand the TME, cancer cell heterogeneity and the cell identities/states present in breast carcinomas.

## Results

In the first phase of the study, 13 different ER, PR or HER2 antibodies were analyzed. The pixel-to-pixel evaluation, which evaluates concordance in staining, resulted in r scores of 0.86 (ER; Pearson correlation), 0.93 (PR) and 0.94 (HER2) and correlation scores in single-cell comparisons ranged from 0.76 to 0.81. Correlation scores on the tissue core level were high in the inter-assay analyses, i.e. t-CyCIF vs. IHC (e.g. r scores up to 0.87 and 0.91 for ER and HER2, respectively, on t-CyCIF vs. Aperio; and 0.85 to 0.94 by pathology review) and t-CyCIF vs. HER2 FISH (r scores up to 0.71). This resulted in validated fluorophore-conjugated antibody panels for use in t-CyCIF that correspond well to established standards. In the second phase, single cell analysis of HER2<sup>+</sup> breast cancer was performed. Cancer cells were defined as keratin positive and using t-Distributed Stochastic Neighbor Embedding (t-SNE) seven cancer cell clusters were identified including two HER2<sup>hi</sup> clusters differing in ER, p53, AR and PD-L1 expression, two HER2<sup>lo</sup> clusters differing in PR, Ki67, pRB, p53 and AR and three HER2<sup>neg</sup> clusters differing in PR, Ki67, ER, PD-L1 and AR. Heterogeneity scores were calculated based on diversity among clusters.

## Conclusion

This study is the first to evaluate the performance of breast cancer-specific antibodies in a highly multiplexed imaging platform such as t-CyCIF. Using the validated antibody panel, we uncovered patterns of expression of markers relevant to breast cancer biology that correlate with HER2 high, low and negative states. Ongoing studies are looking at correlations between HER2 heterogeneity, responses to therapy and clinical outcomes.

## Background

Circulating tumor cells (CTCs) have been reported to predict clinical outcome in metastatic breast cancer (MBC). Biology of CTCs may differ from the primary tumor and HER2-positive CTCs are found in some patients with HER2-negative disease. In this analysis, we evaluated the clinical relevance of the HER2 status of CTCs in patients screened for participation in the DETECT trials, the largest study program for CTC-based therapy interventions in MBC.

## Methods

Patients with HER2-negative MBC were screened for CTCs using CellSearch. CTCs were labeled with an anti-HER2 antibody and classified according to staining intensity (negative, weak, moderate, or strong staining). Patients with HER2-positive CTCs were invited to participate in the randomized phase III DETECT III trial, which evaluated treatment with physicians' choice therapy with and without lapatinib. Patients with HER2-negative CTCs could participate in the DETECT IVa/b trials which investigated serial blood measurements during in-label systemic therapy. Patients who participated in the screening but were not enrolled in the DETECT III or DETECT IV trials were treated at discretion of their physician and followed up for progression and death.

## Results

Screening blood samples were analyzed in 1933 patients with HER2-negative MBC. Out of these, 102 were enrolled in the DETECT III and 213 in the DETECT IVa/b trials, respectively. 1217 out of the 1933 screened patients (63.0%) had  $\geq 1$  CTC per 7.5 ml blood.  $\geq 5$  CTCs were detected in 735 patients (38.0%; range 1 – 35,078 CTCs, median 8 CTCs). Patients with ER-positive tumors were more likely to be CTC-positive than patients with ER-negative disease ( $\geq 1$  CTC in 64.7% vs. 57.1% patients, respectively,  $p = 0.011$ ;  $\geq 5$  CTCs in 40.8% vs. 29.5%,  $p < 0.001$ ). CTC status was also associated with ECOG performance status ( $\geq 1$  CTC in 63.2% of patients with ECOG 0 vs. 69.0% with ECOG 1-3,  $p = 0.020$ ;  $\geq 5$  CTCs in 36.3% vs. 47.2%,  $p < 0.001$ ). HER2 status of CTCs was assessed in 1159 CTC-positive patients. At least one CTC with strong HER2 staining was found in 174 (15.0%) patients. The proportion of CTCs with strong HER2 staining among all CTCs of an individual patient ranged between 0.06% to 100% (mean: 15.8%). Patients with ER- and PR-positive tumors were more likely to harbor  $\geq 1$  CTC with strong HER2 staining. For survival analysis, 52 patients receiving anti-HER2-therapy with lapatinib in the interventional arm of the DETECT III trial were excluded. CTC status was significantly associated with OS (median OS in patients with  $\geq 1$  CTC: 15.5 [95%-CI: 14.2-16.8] months vs. 37.2 [32.7-41.7] months in CTC-negative patients,  $p < 0.001$ , HR 2.359; median OS in  $\geq 5$  CTCs vs.  $< 5$  CTCs: 12.0 [10.0-14.0] vs. 28.6 [25.5-31.6] months,  $p < 0.001$ , HR 2.204). Detection of  $\geq 1$  CTC with strong HER2 staining was associated with shorter OS (9.7 [7.1-12.3] vs. 16.5 [14.9-18.1] months in patients with CTCs with negative-to-moderate HER2 staining only,  $p = 0.013$ ). In the multivariate analysis, only age, ER status, PR status, ECOG performance status, therapy line, and CTC status independently predicted OS.

## Conclusion

To our knowledge, this is the largest analysis to date regarding the clinical relevance of HER2 status of CTCs in MBC. We confirm the high prognostic value of CTC detection in patients with HER2-negative disease. Presence of  $\geq 1$  CTC with strong HER2 staining was significantly associated with shorter OS in univariate analysis. However, the CTC-HER2 status did not correlate with survival in multivariate analysis.

The influence of pathogenic variants in breast cancer predisposition genes on secondary breast cancer events in a prospectively collected cohort of breast cancer patients

Judy C. Boughey, Tanya L. Hoskin, Siddhartha Yadav and Fergus J. Couch. Mayo Clinic, Rochester, MN

**Background:** About 10-20% of breast cancers (BC) are hereditary. Patients (pts) with BC and pathogenic variants (PVs) in the *BRCA1* or *BRCA2* gene are at increased risk of contralateral breast cancer (CBC). However, risks of CBC and recurrent BC associated with PVs in other established BC predisposition genes (e.g. *PALB2*, *CHEK2*, *ATM*) are less well established. We performed research genetic testing of over 4000 pts with BC treated at Mayo Clinic. Because most pts were unaware of their mutation status prior to selection of therapy, this cohort provides a unique opportunity to evaluate the natural history of BC recurrence after treatment of the index BC in pts with a deleterious mutation in predisposition genes. **Methods:** Women diagnosed and treated for BC at Mayo Clinic between 2001-2016 were enrolled in an IRB-approved research cohort. Pts were not selected for age of diagnosis or family history. Coding regions and consensus splice sites of established BC predisposition genes were subjected to amplicon-based deep sequencing using the QIAseq method in germline DNA extracted from peripheral blood or buccal samples. PVs in the genes were identified using GATK haplotype caller and Vardict. Patient, tumor, oncologic management and follow up data were reviewed. Herein we report on the differences in the incidence of local recurrence and CBC, among carriers and non-carriers and by predisposition gene using the cumulative incidence estimator and Fine and Gray regression to account for competing risks. **Results:** Of 4272 women with BC (median age 57, range 21-94), a PV in a BC predisposition gene was identified in 287 (6.7%). The most common PVs were seen in *CHEK2* (67, 1.6%), *BRCA1* (62, 1.5%), *BRCA2* (60, 1.4%), *ATM* (47, 1.1%); 8 (0.2%) patients had more than one PV. Pts with any PVs presented at younger age (median 51 vs 58 years,  $p<0.001$ ), were more likely to have stage IV disease (4.5% vs 2.3%,  $p=0.02$ ), estrogen receptor (ER) negative BC (19.5% vs 13.5%,  $p=0.005$ ), and bilateral cancer (8.8% vs 4.3%,  $p<0.001$ ). ER- BC proportion varied by gene - 38.9% in pts with PVs associated with ER- BC (*BRCA1*, *BARD1*, *BRIP1*, *RAD51C*, *RAD51D*) and 11.9% in those with PVs associated with ER+ BC (*BRCA2*, *ATM*, *CDH1*, *CHEK2*),  $p<0.001$ . NCCN criteria for genetic testing were assessed for 3763, with 69.9% of those with PVs qualifying for testing compared to 46.3% of those without PVs ( $p<0.001$ ). Among 3973 pts (249 with PVs, 3724 without) with unilateral stage 0-III cancer, 168 pts developed local recurrence, 131 pts developed CBC and 248 pts developed distant disease with median 5 years of follow-up. Patients with any PV had higher rates of local recurrence after breast conserving surgery (HR 2.3, 95% CI: 1.2-4.2,  $p=0.01$ ) but overall did not have significantly higher risk of CBC if contralateral prophylactic mastectomy was not performed (HR 1.7, 95% CI: 0.9-3.2,  $p=0.11$ ). Specifically, pts with PVs in genes other than *BRCA1* or *BRCA2* did not have a higher risk of CBC compared to pts with no PV (HR 1.0, 95% CI: 0.4-2.7,  $p=0.96$ ); the comparison of CBC risk in *BRCA1* or *BRCA2* versus those with no PV was HR 2.9 (95% CI: 1.3-6.5,  $p=0.01$ ), while *BRCA1* or *BRCA2* compared to those with other PVs was HR 2.7 (95% CI: 0.8-9.3,  $p=0.13$ ). In pts with *CHEK2* PVs, the probability of CBC at 10-years follow-up was 5.4%, which was similar to pts without a mutation (5.3%),  $p=0.47$ . **Conclusion:** While PVs in known BC predisposition genes increase risk of BC development, risk of CBC in carriers of PVs in non-*BRCA* predisposition genes with BC are not as high as seen with *BRCA1* or 2 PV carriers. This information regarding future BC will be helpful in personalizing decisions on the extent of surgery in carriers of PVs in BC predisposition genes.

Spatially defined immune-related proteins and outcome in triple negative breast cancer in the FinXX trial and Mayo Clinic cohort

Saranya Chumsri<sup>1</sup>, Jodi M. Carter<sup>2</sup>, Yaohua Ma<sup>1</sup>, Douglas Hinerfeld<sup>3</sup>, Heather Ann Brauer<sup>3</sup>, Sarah Warren<sup>3</sup>, Torsten O. Nielsen<sup>4</sup>, Karama Asleh<sup>4</sup>, Heikki Joensuu<sup>5</sup>, Edith A. Perez<sup>1</sup>, Roberto A. Leon-Ferre<sup>2</sup>, David W. Hillman<sup>2</sup>, Judy C. Boughey<sup>2</sup>, Minetta C. Liu<sup>2</sup>, James N. Ingle<sup>2</sup>, Krishna R. Kalari<sup>2</sup>, Fergus J. Couch<sup>2</sup>, Keith L. Knutson<sup>1</sup>, Matthew P. Goetz<sup>2</sup> and E. A. Thompson<sup>1</sup>. <sup>1</sup>Mayo Clinic, Jacksonville, FL; <sup>2</sup>Mayo Clinic, Rochester, MN; <sup>3</sup>NanoString, Seattle, WA; <sup>4</sup>University of British Columbia, Vancouver, BC, Canada; <sup>5</sup>Helsinki University Hospital, Helsinki, Finland

**Background:** Growing data established the pivotal role of preexisting immune response in triple negative breast cancer (TNBC). Conventionally, preexisting immune response can be evaluated by quantifying tumor infiltrating lymphocytes mainly in the stroma or gene expression analysis from the whole tumor section. Due to technical challenges with these conventional methods, limited data regarding specific subtypes and spatial distribution of these immune infiltrates are currently available. **Methods:** NanoString IO360 gene expression analysis and Digital Spatial Profiling (DSP) were used. DSP was used to quantify 29 immune-related proteins in stromal and tumor-enriched segments from 44 TNBC samples from the FinXX trial (NCT00114816) and 335 samples from the Mayo Clinic (MC) cohort of centrally reviewed TNBC (Leon-Ferre BCRT 2018). In FinXX trial, 22 patients with recurrence and 22 patients without recurrence were included. In MC cohort, 217/335 patients received adjuvant chemotherapy while 118 patients had surgery only without adjuvant chemotherapy. Regions were segmented based on pancytokeratin staining. The general linear model was used for statistical analysis of differential expression with recurrence free survival (RFS) as a categorical variable (recur yes or no). Kaplan-Meier (KM) estimates and Cox regression models were also used for analysis. **Results:** In the FinXX trial, there were 12 out of 29 proteins in tumor epithelial segments (intraepithelial) which were significantly expressed at higher levels among patients who were free of recurrence. These proteins include Beta-2 microglobulin, CD11c, CD20, CD40, CD56, CD8, Granzyme B, HLA-DR, ICOS, PD-L1, PD-L2, and TGFB1. In contrast, merely 5 out of 29 proteins in stromal segments were significantly differentially expressed in these 2 groups of patients. Granzyme B, IDO1, PD-L1, and PD-L2 in stroma were significantly higher and SMA was significantly lower in patients without recurrence. Using Cox regression models, intraepithelial CD56, CD40, and HLA-DR were significantly associated with outcome. When comparing between highest and lowest intraepithelial protein expression by tertile, intraepithelial CD56 (HR 0.12, 95%CI 0.03-0.39,  $p < 0.001$ ), CD40 (HR 0.13, 95%CI 0.04-0.46,  $p = 0.002$ ), and HLA-DR (HR 0.24, 95%CI 0.06-0.89,  $p = 0.032$ ) were significantly associated with improved outcome. However, expression of these same proteins in stroma was not associated with outcome. Using KM estimates, intraepithelial CD56 ( $p < 0.0001$ ), CD40 ( $p = 0.0006$ ), and HLA-DR ( $p = 0.013$ ) were also significantly associated with improved outcome. Nonetheless, RNA expression of these proteins by IO360 from whole tumor sections were not significantly associated with outcome (CD56  $p = 0.27$ , CD40  $p = 0.21$ , HLA-DR  $p = 0.48$ ). Similar findings with DSP were observed in MC TNBC cohort. Comparing between the highest and lowest quartiles, there were significantly fewer patients who developed recurrence with high protein expression of intraepithelial CD56 ( $p < 0.001$ ), CD40 ( $p = 0.002$ ), and HLA-DR ( $p = 0.006$ ). **Conclusions:** Using an in-depth analysis with spatially defined context, we identify that there were numerically more intraepithelial immune-related proteins associated with outcome compared to proteins in stroma. Specifically, intraepithelial CD56, CD40, and HLA-DR were significantly associated with improved outcome in both FinXX and MC TNBC cohorts. However, neither expression of these proteins in stroma nor RNA expression from whole tumor were associated with outcome. Our study highlights the impact of spatial biology and the importance of evaluating each potential biomarker in a spatially defined manner. **Support:** W81XWH-15-1-0292, BCRF 19-161, P50CA116201-9, P50CA015083

Global myocardial perfusion is reduced in premenopausal breast cancer patients treated with ovarian function suppression and aromatase inhibitor therapy: An adenosine stress T1 map CMR study

Alexandra Thomas<sup>1</sup>, Ralph B. D'Agostino, Jr.<sup>1</sup>, Katherine C. Ansley<sup>1</sup>, Sung Park<sup>2</sup>, Anuj Kotak<sup>2</sup>, Steven M. Sorscher<sup>1</sup>, Susan Melin<sup>1</sup>, Emily H. Douglas<sup>1</sup>, Sujethra Vasu<sup>1</sup>, Paul A. Romitti<sup>3</sup>, William G. Hundley<sup>2</sup> and Jennifer H. Jordan<sup>2</sup>. <sup>1</sup>Wake Forest Baptist Health, Winston-Salem, NC; <sup>2</sup>Virginia Commonwealth University, Richmond, VA; <sup>3</sup>University of Iowa, Iowa City, IA

**Introduction:** Premenopausal women with high-risk hormone receptor-positive (HR+) breast cancer (BC) undergo abrupt menopause induction with aromatase inhibitor (AI) anti-estrogen therapy and ovarian function suppression (OFS). This treatment improves recurrence-free survival but may increase cardiovascular (CV) risk associated with early hypoestrogenemia as observed in women with non-cancerous reasons for early loss of ovarian function. We sought to identify if OFS+AI therapy is associated with myocardial perfusion changes, a subclinical marker of coronary heart disease. **Methods:** We evaluated women with paired adenosine cardiovascular magnetic resonance imaging scans at 3-to 6-month intervals using cines and T1 maps in standard short-axis planes. As increased blood flow from vasodilation increases adenosine stress parametric T1 values of the myocardial tissue, the myocardial perfusion reactivity was calculated from the percent increase of stress versus native (pre-stress) T1 maps. Double-blinded post-processing of images was performed in CircleCVI software. Statistical analyses were performed in MATLAB (p<0.05 defined as statistically significant) using paired t-tests for within-group comparisons and two-sample t-tests for between-group comparisons. **Results:** Twenty-one premenopausal women (16 Caucasian, 5 African American; median age 44.7 years) were accrued in 16 months - 14 with HR+ BC within 3 years of initiating OFS+AI (median 8 months) and 7 with triple negative BC within 3 years of chemotherapy (median 10 months) for comparators. Global myocardial perfusion reactivity to adenosine stress declined in HR+ women on OFS+AI therapy during the 3-6 month study interval (-1.3%; 95%CI: -3.4-0.7%) which was significantly different (p=0.02) from changes observed in comparators who had an improvement in perfusion during the interval (3.2%; 95%CI: -1.2-7.6%) (Table). Left ventricular (LV) function remained unchanged during the 3-6 month interval for all groups (p>0.05). The cardiovascular stress tests identified two HR+ women (14%) with abnormal results during stress imaging who were sent for further cardiovascular evaluations. **Conclusions:** Women with HR+ BC treated with OFS+AI exhibited a decline in global microcirculatory perfusion during an adenosine cardiac stress test with normal LV functional parameters. Alternatively, triple negative BC patients trended to have an improvement in LV function during the interval with non-significant improvement in myocardial perfusion. This study demonstrates a decline in myocardial perfusion in premenopausal women on OFS+AI therapy, suggesting subclinical coronary artery effects due to early hypoestrogenemia. Future work should confirm these results, identify women at higher risk, and test strategies to mitigate cardiotoxicity in premenopausal women with HR+ BC.

**Background:** Endocrine therapy resistance in advanced breast cancer remains a significant clinical problem that may be overcome with use of histone deacetylase (HDAC) inhibitors such as entinostat. The ENCORE 301 randomized phase II study reported an improvement in progression-free (PFS) and overall survival (OS) with the addition of entinostat to the steroidal aromatase inhibitor (AI) exemestane in patients with advanced hormone receptor (HR)-positive, HER2-negative breast cancer. Protein lysine acetylation in peripheral blood mononuclear cells (PBMCs) was associated with prolonged PFS in the entinostat arm.

**Methods:** E2112 is a multicenter randomized double-blind, placebo-controlled phase III study that enrolled men or women with advanced HR-positive, HER2-negative breast cancer whose disease had progressed on a non-steroidal AI in the adjuvant or metastatic setting (NCT02115282). Study participants were also required to have an ECOG performance status 0-1 with measurable or non-measurable (limited to 20% of the study population) disease. One prior chemotherapy for metastatic disease and prior treatment with fulvestrant and a CDK4/6 inhibitor was permitted but not required. Participants received exemestane 25mg po daily and entinostat (EE)/placebo (EP) 5mg po every week. Primary endpoints were PFS (central review) and OS. One-sided type 1 error 0.025 was split between two hypothesis tests: 0.001 for PFS test and 0.024 for OS. PFS tested in the first 360 pts, 88.5% power to detect 42% reduction in the hazard of PFS failure (median PFS, 4.1 to 7.1 months); OS tested in all 600 pts, 80% power to detect 25% reduction in the hazard of death (median OS, 22 to 29.3 months). Secondary endpoints included safety, objective response rate (ORR), and changes in protein lysine acetylation status in PBMCs (CD3+ T cells, CD14+ monocytes, CD19+ B cells, pan-leukocyte marker CD45+ cells, CD56+ NK cells) between C1D1 and C1D15 (integrated biomarker).

**Results:** A total of 608 participants were randomized between March 2014 and October 2018 (305 EE, 303 EP), 98% enrolled in USA. Characteristics were well balanced between the arms. Median age was 63 years (range, 29-91), 99% female, 95% postmenopausal, 80% white and 15% black. A majority (84%) had disease resistant to AI in the metastatic setting at study entry, 78% had measurable disease and 60% visceral disease. Prior treatments included chemotherapy (60%), fulvestrant (30%), CDK4/6 inhibitor (35%), everolimus (3%). Median prior lines of chemotherapy was 1 (range, 0-4) and endocrine therapy was 2 (range, 1-7); in adjuvant/metastatic setting. Grade 3/4 adverse events in EE arm included neutrophil count decreased (20%), hypophosphatemia (14%), anemia (8%), white blood cell decreased (6%), fatigue (4%), diarrhea (4%), and platelet count decreased (3%). At final analysis, median PFS was 3.3 months (EE) versus 3.1 months (EP) (HR=0.87, 95% CI: 0.67, 1.13, p=0.30). Median OS was 23.4 months (EE) versus 21.7 months (EP) (HR=0.99, 95% CI: 0.82, 1.21, p=0.94). ORR was 4.6% (EE) and 4.3% (EP). The median fold change in lysine acetylation in PBMCs was approximately 1.5 in EE arm, and 1 in EP arm. Participants on EE had significantly higher increase in lysine acetylation by C1D15 than patients on EP (397 paired samples available for analysis, p<0.001 for all). Additional biomarker analyses will be presented at time of meeting.

**Conclusion:** The combination of exemestane and entinostat did not improve survival in AI resistant advanced HR-positive, HER2-negative breast cancer. Pharmacodynamic analysis confirmed target inhibition in entinostat-treated patients.

**Background:** Patients with HER2+ breast cancer who have residual disease after neoadjuvant anti-HER2 plus chemotherapy have a high risk of recurrence and benefit from adjuvant trastuzumab emtansine (T-DM1). We hypothesize that endocrine-responsive residual tumors after neoadjuvant treatments may have good outcomes among patients receiving only adjuvant endocrine therapy plus trastuzumab. Using paired pre- and post-treatment samples from CALGB 40601 and other neoadjuvant cohorts that did not include adjuvant T-DM1, we investigated survival by pretreatment and residual disease *ESR1* and *PgR* gene expression in CALGB 40601, and by estrogen receptor (ER) and progesterone receptor (PR) immunohistochemistry (IHC) in the other cohorts. We considered endocrine-responsive tumors those with ER and/or PR expression by gene expression or IHC.

**Methods:** CALGB 40601 is a randomized neoadjuvant trial of single vs. dual HER2-targeting (trastuzumab and/or lapatinib added to paclitaxel). We only included those patients who had not suffered from disease progression or death during their preoperative treatments. In total, 77 patients with paired pretreatment and residual disease tumors were profiled by mRNA sequencing and studied. Cutoffs for *ESR1* and *PgR* mRNA expression mimicking clinical positivity were obtained using 265 pretreatment CALGB 40601 tumors (and 1,045 TCGA samples for *ESR1*). We also examined ER and PR IHC in paired tumors from 202 patients treated at 4 different collaborating institutions; all had residual disease after neoadjuvant HER2 targeting plus chemotherapy. We considered ER- or PR-positive as ≥10% positively staining cells. The primary endpoint was EFS, defined as the time from randomization to event in CALGB 40601 and from the first systemic therapy to event in the 4-institution validation cohort.

**Results:** In 77 patients from CALGB 40601 with paired (pretreatment/residual disease) specimens, 38 (49.3%) had *ESR1*+/*ESR1*+ tumors. The EFS was superior in the *ESR1*+/*ESR1*+ (n=38) group than in the remaining others (the log-rank test,  $p=0.011$ ). The 5- and 7-year EFS rates for the *ESR1*+/*ESR1*+ (n=38) were 92.1% and 89.2%, whereas the rates were uniformly < 70% in the others. In particular, the 5-year EFS rate among 11 patients with *ESR1*+/*ESR1*- tumors was 61.4%. This remained significant in multivariable analysis with clinical stage and treatment arm; the hazard ratio (HR) for EFS in *ESR1*+/*ESR1*+ versus all others was 0.29 (95% CI, 0.09-0.90). In *ESR1*+/*ESR1*+ tumors, 5-year EFS rates were high for those whose residual disease and also being *PgR*+ (n=32) or PAM50 LumA or Normal-like (n=34) (93.8% and 97.1%, respectively). In the institutional validation cohort, pretreatment /residual disease ER(+)/ER(+) tumors (n=113) had superior 3-year EFS versus all others ( $p=0.010$ ). At a median follow-up of 35.9 months, the 3-year EFS rates for ER(+)/ER(+) and all other groups were 96.6% and 82.6%, respectively. This remained strongly significant in multivariable analysis with clinical stage; the HR for EFS in ER(+)/ER(+) versus all other groups was 0.28 (95% CI, 0.09-0.88). Among 46 who also had PR+ in the residual disease, the 3-year EFS was 100.0%.

**Conclusions:** HER2+ patients with ER+ pretreatment and ER+ residual disease after neoadjuvant chemotherapy + HER2-targeting have a very good survival outcome despite not receiving additional anti-HER2 targeting with T-DM1. This may provide a simple mechanism to better tailor therapy within residual disease patients using serial ER measurements.

Sentinel node biopsy should not be routine in older patients with ER positive breast cancer

Elaine McKeivitt<sup>1</sup>, Rona Cheifetz<sup>1</sup>, Kimberly DeVries<sup>1</sup>, Alison Laws<sup>2</sup>, Rebecca Warburton<sup>1</sup>, Lovedeep Gondara<sup>1</sup>, Caroline Lohrisch<sup>1</sup> and Alan Nichol<sup>1</sup>.  
<sup>1</sup>BC Cancer, Vancouver, BC, Canada<sup>2</sup>University of Calgary, Calgary, AB, Canada

**Background:**Based on randomized controlled trials demonstrating no survival benefit of axillary dissection in elderly breast cancer patients, the SSO/Choosing Wisely campaign recommended against the routine use of sentinel lymph node biopsy (SLNB) in clinically node negative patients aged  $\geq 70$  with estrogen receptor (ER) positive breast cancer in 2016. SLNB is still performed in  $>80\%$  of such patients and we have previously shown that at our institution, SLNB positivity influences adjuvant therapy decisions in this population. In this study, we sought to validate the association of SLNB positivity and adjuvant treatment in a larger population-based cohort, and to evaluate the impact of this finding on oncologic outcomes.

**Methods:**The Breast Cancer Outcome Unit (BCOU) prospectively collects demographic, pathologic, treatment and outcomes data on all patients referred to BC Cancer with breast cancer in British Columbia, Canada. Female patients aged  $\geq 70$  with newly diagnosed estrogen receptor-positive invasive breast cancer who underwent SLNB from 2010-2016 were included. Patients with HER2-positive disease or those treated with neoadjuvant therapy were excluded. Multivariable analysis was used to assess the effect of SLNB positivity on adjuvant treatment. Overall survival (OS) and breast cancer specific survival (BCSS) were assessed using Kaplan-Meier analysis and Cox regression was used to assess contribution of SLNB positivity and adjuvant treatment. A nomogram was created to model the effect of nodal positivity and adjuvant treatment on BCSS.

**Results:**We identified 2580 patients who met study criteria with a median age of 75 and a median tumor size of 15 mm. SLNB was positive in 23%. Sixty-seven percent of patients had breast conserving surgery (BCS) and 62% of patients had RT (BCS 79%, mastectomy 25%). As systemic therapy 5% of patients had chemotherapy (CT) and 78% of patients had hormone therapy (HT). Use of adjuvant therapies was associated with SLNB positivity: Systemic therapy (HR = 2.4, 95% CI: 1.84-3.14,  $p < 0.0001$ ), RT (HR = 4.94, 95% CI: 3.91-6.25,  $p < 0.0001$ ) and nodal RT (HR = 61.4, 95% CI: 26.6-141.7,  $p < 0.0001$ ). The 5-year OS was 86% and BCSS was 96% with a median follow-up of 4.33 years (95% CI 4.21-4.47 years). There was improved BCSS with receipt of HT (HR 0.51 95% CI 0.301-0.875,  $p = 0.0142$ ) and worse BCSS with grade 3 vs grade 1 disease (HR 4.09, 95% CI 2.06-8.10,  $p < 0.0001$ ). Age, tumor size, status of SLNB and use of RT were not significant prognostic variables. Patients with a positive SLNB who did not receive any adjuvant therapy had lower BCSS (HR 3.22 95% CI 1.235-8.418,  $p = 0.0168$ ) than those with a negative SLNB. However, amongst those who received any combination of CT, HT and RT, there was no significant difference in BCSS regardless of nodal status. A nomogram was developed incorporating tumor size, grade, SLNB status and adjuvant treatment. Using the nomogram, patients aged 75-79 with T1, grade 1-2 tumors, with or without positive SLNB and treated with or without adjuvant therapy had 5-year BCSS  $\geq 95\%$ . The nomogram also indicated that 5-year BCSS was similar for patients with positive and negative SLNB for all combinations of tumor features when patients received HT.

**Conclusions:**In this modern, population-based cohort of patients over 70 with ER-positive breast cancer, 5-year BCSS was excellent at 96%. Although the use of adjuvant treatment was associated with a positive SLNB, BCSS was not changed based on nodal status when patients received HT. Our results support the Choosing Wisely recommendations; SLNB can be safely omitted in elderly patients willing to take HT, and we advocate that SLNB can be omitted in low-risk patients aged  $\geq 75$  even in the absence of planned HT.

**Background:** About one third of patients with hormone-receptor-positive (HR+), HER2- primary breast cancer with residual invasive disease after neoadjuvant chemotherapy will relapse despite adjuvant endocrine therapy. The risk of relapse can be assessed more accurately using the CPS-EG scoring system (Mittendorf et al. JCO 2011). Therapeutic inhibition of cyclin-dependent kinase 4 and 6 (CDK 4/6) by palbociclib combined with endocrine therapy demonstrated highly relevant efficacy in metastatic breast cancer. Thus, we hypothesize that palbociclib may also be active in these high-risk patients with primary breast cancer. **Methods:** PENELOPE-B (NCT01864746) is a double-blind, placebo-controlled, phase III study in women with centrally confirmed HR+, HER2- primary breast cancer without a pathological complete response after taxane-containing neoadjuvant chemotherapy and at high-risk of relapse (CPS-EG score  $\geq 3$  or 2 and ypN+). After completion of neoadjuvant chemotherapy and locoregional therapy, patients were randomized (1:1) to receive 13 cycles of palbociclib 125mg daily or placebo on days 1-21 in a 28d cycle in addition to standard endocrine therapy. Randomization was stratified by lymph node status (at surgery), age, Ki-67, global region, and CPS-EG score. Primary endpoint is invasive disease-free survival (iDFS). Final analysis was planned after 290 iDFS events with efficacy boundary  $p < 0.0463$  due to 2 interim analyses. Main secondary endpoints include iDFS excluding second primary invasive non-breast cancers, overall survival, and safety. **Results:** A total of 1250 patients were randomized between 2/2014 and 12/2017. Median age was 49.7 years [range 19-79]; 96.8% had residual disease in the breast, 94.6% were ypN+; G3 was reported in 47.4%, Ki-67  $> 15\%$  in 27.7 %; 54.7% of patients had risk status CPS-EG score  $\geq 3$ . 1118 patients (89%) completed at least 7 cycles of therapy. 50.1% of patients received aromatase inhibitor (AI), 49.8% tamoxifen, 6.6% AI + gonadotropin-releasing hormone (GnRH) and 9.7% tamoxifen + GnRH. Most common related serious adverse events (SAEs) were infections and vascular disorders. 8 fatal SAEs were reported. **Conclusions:** PENELOPE-B evaluates the effect of palbociclib for 1 year compared to placebo in addition to endocrine therapy in high-risk primary breast cancer patients. The database was locked with 308 events on September 25<sup>th</sup> 2020. After breaking the blind for analysis, top line results will be available as of mid October 2020. Results of the final iDFS analysis will be presented at the meeting.

Moving in the fast lane: Test design and validation to produce up-to-date hereditary breast and gynecologic cancer tests

Taraneh E Angeloni<sup>1</sup>, Anindya Bhattacharya<sup>1</sup>, Linda L Cheng<sup>1</sup>, Hansook K Chong<sup>1</sup>, Kelli M Conlan<sup>1</sup>, Christopher D Elzinga<sup>2</sup>, Anna Gerasimova<sup>1</sup>, David Grover<sup>1</sup>, Andrew Grupe<sup>1</sup>, Michael Hua<sup>1</sup>, Domagoj Hodko<sup>1</sup>, Krista Kazmierkiewicz<sup>1</sup>, Rebecca E Nakles<sup>1</sup>, Camille R Nery<sup>1</sup>, Renius Owen<sup>1</sup>, Dana M Goos-Root<sup>1</sup>, Charles M Rowland<sup>1</sup>, Alla Smolgovsky<sup>1</sup>, Elaine C Weltmer<sup>1</sup>, Ke Zhang<sup>1</sup> and Felicitas L Lacbawan<sup>1</sup>. <sup>1</sup>Quest Diagnostics, San Juan Capistrano, CA; <sup>2</sup>Athena Diagnostics, Marlborough, MA

#### Introduction

Germline genetic testing is increasingly relevant to breast and gynecologic (GYN) cancer clinicians for monitoring and managing high-risk patients. In particular, multi-gene panels (MGPs) can identify unsuspected cancer syndromes and variants that may become clinically significant. Effective MGPs must be comprehensive and up-to-date. For the current study, we used a probe panel designed for targeted enrichment of 4,500 genes associated with various inherited diseases to develop and validate a 66-gene comprehensive hereditary cancer panel, including subsets of genes associated with breast and GYN cancers.

#### Materials and Methods

Genomic DNA was extracted and taken through next generation sequencing (NGS) library preparation to be sequenced on an Illumina NovaSeq instrument. Targeted capture-based enrichment with a long-range PCR (LR-PCR) component was used to interrogate all protein-coding exons, intron-exon splice sites (+/-10bp), as well as clinically relevant deep intronic, 5'UTR, and 3'UTR regions for single nucleotide variants (SNVs) and insertions/deletions (indels) of all genes of interest. Copy number variations (CNVs) were also interrogated for all applicable regions. Data analysis was performed using a proprietary in-house bioinformatics variant analysis pipeline.

For validation, samples from the Coriell Repository and more than 100 unique de-identified genomic DNA specimens from whole blood and saliva were analyzed for 17,911 variants in 508 genes. Variants were previously identified by orthogonal methods (in-house Sanger sequencing, CLIA validated NGS assays, and microarray). The well-characterized Genome in a Bottle (GIAB) NA12878 and Ashkenazim Trio samples (NA24149, NA24385, and NA24143) were also included. The analytic sensitivity (Positive Percent Agreement, %PPA) and specificity (Technical Positive Predictive Value, %TPPV and Negative Percent Agreement, %NPA) were determined for each variant type (SNV, indel, and CNV).

The 66-gene hereditary cancer panel includes genes that confer ≥2-fold increased risk or 5% lifetime risk for developing cancer (*APC*, *ATM*, *AXIN2*, *BAP1*, *BARD1*, *BLM*, *BMPR1A*, *BRCA1*, *BRCA2*, *BRIP1*, *CDH1*, *CDK4*, *CDKN1B*, *CDKN2A* (*p16*, *p14*), *CHEK2*, *DICER1*, *EGFR*, *EPCAM*, *FANCA*, *FANCC*, *FANCM*, *FH*, *FLCN*, *GALNT12*, *GREM1*, *HOXB13*, *MAX*, *MEN1*, *MET*, *MITF*, *MLH1*, *MRE11* (*MRE11A*), *MSH2*, *MSH3*, *MSH6*, *MUTYH*, *NBN*, *NF1*, *NTHL1*, *PALB2*, *PMS2*, *POLD1*, *POLE*, *POT1*, *PTCH1*, *PTEN*, *RAD50*, *RAD51C*, *RAD51D*, *RECQL*, *RET*, *SDHA*, *SDHAF2*, *SDHB*, *SDHC*, *SDHD*, *SMARCA4*, *SMAD4*, *STK11*, *SUFU*, *TMEM127*, *TP53*, *TSC1*, *TSC2*, *VHL*, and *XRCC2*). Of these, 30 genes increase the lifetime risk of breast and/or GYN cancers and are also distributed among smaller phenotype-specific panels.

#### Results

The analytical sensitivity (%PPA) for SNVs and indels was 100.0% and 97.8% for CNVs. The overall specificity for SNVs, indels, and CNVs was >99.0%. The %TPPV for SNVs, Indels, and CNVs was 100.0%, 99.3%, and 100.0%, respectively. The %NPA for SNVs, Indels, and CNVs was 100.0%. The %PPA, %TPPV, and %NPA for LR-PCR was 100.0%.

#### Conclusion

Validation of the 66-gene hereditary cancer panel demonstrated high analytical sensitivity and specificity. As additional gene-cancer associations are established, using an already designed and developed comprehensive 4,500 gene panel will expedite the process of updating panel tests to include relevant candidate genes, allowing clinicians and patients to benefit from up-to-date and comprehensive testing.

Adaptlate -a randomized, controlled, open-label, phase-iii trial on adjuvant dynamic marker - adjusted personalized therapy comparing abemaciclib combined with standard adjuvant endocrine therapy versus standard adjuvant endocrine therapy in (clinical or genomic) high risk, hr+/her2- early breast cancer

Oleg Gluz<sup>1</sup>, Tom Degenhardt<sup>2</sup>, Norbert Marschner<sup>3</sup>, Matthias Christgen<sup>4</sup>, Hans Heinrich Kreipe<sup>4</sup>, Ulrike Nitz<sup>5</sup>, Ronald Kates<sup>6</sup>, Timo Schinkoethe<sup>7</sup>, Monika Graeser<sup>5</sup>, Rachel Wurstein<sup>2</sup>, Sherko Kuemmel<sup>8</sup>, Nadia Harbeck<sup>2</sup>, West German Study Group. <sup>1</sup>Breast Center Niederrhein, Johanniter Bethesda Moenchengladbach and West German Study Group and University of Cologne, Moenchengladbach, Germany<sup>2</sup>Breast Center, Dept. OB&GYN and CCCLMU, LMU University Hospital, Munich, Germany, Munich, Germany<sup>3</sup>Oncology Practice Freiburg and Iomedico, Freiburg, Germany<sup>4</sup>Medical College of Hannover, Institute for Pathology, Hannover, Germany, Hannover, Germany<sup>5</sup>Breast Center Niederrhein, Johanniter Bethesda Moenchengladbach and West German Study Group, Moenchengladbach, Germany<sup>6</sup>West German Study Group, Moenchengladbach, Germany<sup>7</sup>CANKADO Service GmbH, Kirchheim, Germany<sup>8</sup>Breast Unit, Clinics Essen-Mitte, Essen and West German Study Group, Essen, Germany

**Goals:** The WSG ADAPT trial program is one of the first new generation trials addressing the issue of individualization of (neo)-adjuvant decision-making in early breast cancer (EBC) in a subtype-specific manner. The first WSG ADAPT umbrella trial (NCT01779206) aimed to establish early predictive molecular surrogate markers for response after a short 3-week induction treatment and to omit chemotherapy in a large cohort of early high risk HR+/HER2- patients. The aim of the ADAPTlate phase-III-trial is to improve adjuvant therapy for patients at high risk for late disease recurrence, who have completed definite locoregional therapy (with or without neoadjuvant or adjuvant chemotherapy) and are under adjuvant endocrine treatment. This high-risk population does not derive optimal benefit from standard ET, often develops secondary resistance against ET and consequently late recurrences. With ADAPTlate, it is planned to evaluate whether patients with high-risk EBC derive additional benefit from adding abemaciclib to ET even 2-6 year after their initial diagnosis. Abemaciclib has been shown to improve outcome in metastatic breast cancer and recently, even in early breast cancer when given as part of primary therapy. **Methods:** WSG-ADAPTcycle is a prospective, multi-center, interventional, two-arm, non-blinded, randomized, controlled adjuvant phase III trial (NCT not yet assigned). It investigates whether patients with HR+/HER2- EBC identified as high-risk during screening (based on clinical or genomic risk) derive additional benefit from 2 years of the CDK4/6 inhibitor abemaciclib combined with ET compared to ET alone. Starting Q3 2020 (enrollment 36 months, 50 sites), 1250 patients will be screened and 903 randomized in a ratio 3:2 (602 to abemaciclib + ET; 301 to standard ET). Pre-/postmenopausal patients with histologically confirmed invasive HR+/HER2- EBC and 2-6 years after primary diagnosis, with either known high clinical risk (c/pN 2-3 OR high CTS score in pN 0-1 OR non-pCR after neoadjuvant chemotherapy in cN 1 or G3 tumors OR G3 and Ki-67 ≥ 40% in pN 0-1) or known high genomic risk (Oncotype Dx® / RS >25 in c/pN 0, RS >18 in c/pN 1 OR high risk Prosigna®, EPclin® or MammaPrint® in pN 0-1) or intermediate clinical, but unknown genomic risk (luminal B-like (G3 or Ki-67 ≥20%) in c/pN 0-1 AND Oncotype DX® in screening either RS >25 in c/pN 0 or RS >18 in c/pN 1) will be eligible. Treatment duration is 2 years for the interventional abemaciclib + ET (premenopausal: AI+GnRH) arm, followed by at least 3-6 years ET alone. Patients in control arm will receive 5-8-years ET at investigator's choice. ePROs are collected using CANKADO. Primary objective is to demonstrate superiority of invasive disease-free survival (iDFS) of abemaciclib + ET vs. standard ET. Secondary objectives include overall survival (OS), distant disease-free survival (ddFS), occurrence of CNS metastases, quality of life (EORTC QLQ-C30, QLQ-BR23, EQ-5D-5L) and translational research. Translational analyses: Exploratory tissue biomarker research will be conducted to assess alterations in molecular markers (e.g., ESR1, PIK3CA, CCND1, CDKN2A, RB1). In addition, ctDNA/ctRNA from optional blood samples will be assessed for mutations and gene expression relevant for HR+/HER2- EBC using the most appropriate technology at the time of testing. **Conclusions:** ADAPTlate seeks to evaluate whether enhancing ET with a CDK 4/6 inhibitor is superior to ET alone in patients with clinical or genomic high risk EBC even 2-6 years after their initial diagnosis. Translational research aims at assessing potential mechanisms of resistance to endocrine and/or CDK4/6 targeted therapy.

### Background

GDC-0077 is a PI3K $\alpha$ -selective inhibitor and mutant PI3K $\alpha$  degrader that demonstrates antitumor activity in *PIK3CA*mut BC xenograft models. A phase I/Ib study of GDC-0077 alone and combined with endocrine therapy  $\pm$  the CDK4/6 inhibitor (i) palbo is ongoing (NCT03006172). Data from GDC-0077 + palbo + fulvestrant in pts with *PIK3CA*mut, HR+/HER2- mBC are presented herein.

### Methods

Safety (NCI-CTCAE v4), pharmacokinetics (PK), and preliminary antitumor activity (clinical benefit rate [CBR]; RECIST v1.1 stable disease for  $\geq$  24 weeks, partial response [PR], or complete response) of 9 mg oral once daily GDC-0077 + 125 mg palbo 21/28 days + 500 mg intramuscular fulvestrant on day 1 (and day 15 of cycle 1) of 28-day cycles were assessed in Arms E and F, until intolerable toxicity or disease progression. In Arm F, pts were obese and/or pre-diabetic (body mass index  $\geq$  30 kg/m<sup>2</sup> and/or HbA1c  $\geq$  5.7%) and also received metformin up to 2000 mg daily starting at 500 mg in cycle 1 day 1, prior to initiating GDC-0077 at cycle 1 day 15 instead of day 1 as in Arm E. Additional key eligibility criteria included Eastern Cooperative Oncology Group performance status (ECOG PS) 0-1, no prior PI3Ki therapy, no prior CDK4/6i, and  $\leq$  1 prior chemotherapy for Arm E (no restrictions on prior CDK4/6i or chemotherapy for Arm F). *PIK3CA*mut allele frequency was assessed in circulating tumor (ct) DNA from serial plasma collections.

### Results

At clinical cutoff (03/20/2020), 28 pts were enrolled (13 in Arm E and 15 in Arm F). Median age was 55 years in Arm E and 65 years in Arm F. ECOG PS was 0 in 8 pts (62%) in Arm E and in 7 pts (47%) in Arm F. Three (23%) and 12 (80%) pts in Arm E and F, respectively, had received  $\geq$  2 prior lines of therapy for mBC. One pt (8%) in Arm E and 10 pts (67%) in Arm F received prior fulvestrant. Nine pts (60%) received prior CDK4/6i (all Arm F). Median GDC-0077 treatment duration was 7.8 months (range 0.1-13.9) in Arm E and 6.5 months (1.2-11.2) in Arm F. GDC-0077 cumulative dose intensity was 98% in Arm E and 88% in Arm F. Thirteen pts (46%) discontinued treatment: 11, due to radiographic disease progression (3 in Arm E, 8 in Arm F); 1, due to an adverse event (AE; treatment-related grade 2 panniculitis in Arm F); and 1 pt withdrew (Arm F). The most common treatment-related AEs ( $\geq$  4 pts) were stomatitis (grouped term; 92%), neutropenia (85%), diarrhea and hyperglycemia (62% each), fatigue (38%), alopecia, nausea, and thrombocytopenia (31% each) in Arm E; and hyperglycemia (67%), diarrhea and neutropenia (53% each), nausea (47%), stomatitis (grouped term; 47%), anemia, decreased appetite, and blurred vision (27% each) in Arm F. Grade  $\geq$  3 treatment-related AEs ( $\geq$  2 pts) were neutropenia (62%) and hyperglycemia (23%) in Arm E; and hyperglycemia and neutropenia (47% each), and anemia (13%) in Arm F. AEs led to GDC-0077 dose reduction in 2 pts (15%) in Arm E and 4 pts (27%) in Arm F. The PK of GDC-0077 in combination with palbo + fulvestrant was similar to single agent GDC-0077. Overall, 7/25 pts (28%) with measurable disease had a PR (5/10 [50%] pts in Arm E; 2/15 [13%] pts in Arm F, both received prior fulvestrant), of whom 6 pts (24%; 4 in Arm E; 2 in Arm F) had a confirmed PR. CBR was 61% (17/28 pts: 8 in Arm E; 9 in Arm F). *PIK3CA*mut allele frequency by ctDNA analysis decreased during treatment in most pts.

### Conclusion

This study demonstrated a manageable safety profile when combining GDC-0077 at its single agent recommended phase II dose of 9 mg with palbo + fulvestrant at standard doses, similar PK to GDC-0077 alone, preliminary anti-tumor activity, and modulation of *PIK3CA*mut allele frequency in ctDNA. In obese and/or pre-diabetic patients enrolled to Arm F, hyperglycemia was frequent despite initiating metformin prior to GDC-0077. A phase III study of GDC-0077 + palbo + fulvestrant is enrolling currently (NCT04191499).

Racial disparities persist despite with uptake of digital breast tomosynthesis (DBT) for breast cancer screening

Emily B Ambinder, Eniola Oluyemi and Kala Visvanathan. Johns Hopkins, Baltimore, MD

**Background:** Breast cancer screening with digital breast tomosynthesis (DBT) has been shown to improve recall rates and detection of invasive cancer compared to 2D full field digital mammography (FFDM). The Federal Drug Administration (FDA) approved the use of DBT in 2011, and the Centers for Medicare and Medicaid Services (CMS) approved coverage in 2015. We report a single institution's longitudinal experience of the utilization and effectiveness of DBT for breast cancer screening over time with a focus on racial differences.

**Materials and Methods:** The analytic population (n = 140,346) included females >18 years who underwent one or more breast cancer screening examinations performed at Johns Hopkins (a tertiary care institution) and affiliated sites between 4/1/2013 and 3/30/2020. Females were categorized as having only FFDM for screening (n = 43,323) or including DBT views (n = 97,023). Recall rate and cancer detection rate were compared between the two groups overall and stratified by race using the Chi-squared test and Fishers Exact test. Univariate and multivariate logistic regression was used to calculate odds ratios (ORs) and 95% confidence intervals (CIs) of having a DBT screening mammogram compared to an FFDM mammogram adjusted for year, race, and an interaction term between year and race.

**Results:** The mean age was 58.9 +/- 10.8 years for the FFDM group and 60.3 +/- 11.1 years for the DBT group. A larger percentage of White patients (62% FFDM vs 71.1% DBT) than Black patients (30.4% FFDM vs 22.6% DBT) or Asian patients (3.8% FFDM vs 3.0% DBT) were in the DBT group (p<0.001).

During the study period, there was rapid increased in utilization of DBT. In year 1 (4/1/2013-3/30/2014), 2791/14841 (18.8%) of patients had a screening mammogram with DBT. By year 3, during which CMS approved coverage of DBT, this increased to 15069/21304 (70.7%). By year 6, 18759/20929 (90.0%) included DBT views.

All women irrespective of race had similar increases in utilization rates of DBT during the study period (effect modifier term OR 0.99, 95% CI 0.98-1.00). However, Black women and Asian women were significantly less likely to have a screening study with DBT compared to White women (Black women: OR 0.51, 95% CI 0.48-0.70; Asian women: OR 0.59, 95% CI 0.57-0.80).

Overall the DBT group had lower recall rate compared to the FFDM group (9.1% versus 11.2%, p<0.001). This was observed for White women (8.6% vs 10.7, p<0.001), Black women: 10.4% vs 11.9% p=0.001) but not Asian women (11.5% vs 11.6%, p=0.97). The DBT group also had higher cancer detection rate overall compared to the FFDM group (6.0 vs 4.1, p<0.001). This was observed for White women (7.3 vs 4.5, p<0.0001); Black women (7.1 vs 4.3, p=0.001), and Asian women (10.4 vs 2.6, p=0.01).

**Conclusions:** We observed racial differences in the utilization of DBT for screening mammography, which could have significant clinical implications given the improved recall rate and cancer detection of DBT over the study period. Longer follow up is needed to understand the impact of these racial differences. Studies are also needed to understand and address existing obstacles such as socioeconomic level, insurance status, and education to reduce the disparity preventing all patients equitable access to DBT.

Randomized trial of 12 months of omega-3 fatty acids vs placebo during a weight loss intervention in post-menopausal women at increased risk for breast cancer

Carol J Fabian<sup>1</sup>, Christie A Befort<sup>1</sup>, Debra K Sullivan<sup>1</sup>, Susan E Carlson<sup>1</sup>, Jennifer L Nydegger<sup>1</sup>, Amy L Kreutzjans<sup>1</sup>, Kandy R Powers<sup>1</sup>, Teresa A. Phillips<sup>1</sup>, Trina Metheny<sup>1</sup>, Carola M Zalles<sup>2</sup>, Erin D Giles<sup>3</sup>, Stephen D Hursting<sup>4</sup> and Bruce F Kimler<sup>1</sup>. <sup>1</sup>University of Kansas Medical Center, Kansas City, KS; <sup>2</sup>Boca Raton Hospital, Boca Raton, FL; <sup>3</sup>Texas A & M University, College Station, TX; <sup>4</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC

**Objectives:** The primary objective was to determine tolerability of  $\omega$ -3 fatty acids (2150 mg of eicosapentaenoic acid (EPA) and 1050 docosahexaenoic acid (DHA) ethyl esters) vs placebo in women in undergoing a behavioral weight loss intervention (6 months loss and 6 months maintenance). Secondary objectives were to explore potential differences in modulation of blood and benign breast tissue risk biomarkers, satiety and quality of life indices, and weight loss. **Results:** 46 peri and postmenopausal women were randomized and 42 completed the 6 months of the weight loss intervention and were biomarker evaluable (22 placebo and 20  $\omega$ -3 FA). Median baseline BMI in the 42 evaluable women was 31 kg/m<sup>2</sup> with a median 6-month relative weight loss of 11% and relative fat mass loss of 20% (DXA). Median 12-month relative mass loss was 10% in the 35 women completing 12 months of the intervention.  $\omega$ -3 fatty acids increased the ratio of (EPA+DHA): arachidonic acid 2.6-fold (median, range 1.8 - 3.8) vs no change for placebo. There was no difference by randomization group in relative weight or fat mass loss at 6 or 12 months, grade 2 and 3 adverse events, early discontinuation, satiety or other quality of life measures. More serum biomarkers exhibited significant within-group improvement at 6 and 12 months for evaluable women randomized to  $\omega$ -3 FA than to placebo. At 6 months, significant change ( $P < 0.05$ ) was observed for adiponectin, leptin, adiponectin:leptin ratio, insulin, lipocalin-2, resistin, PAI-1, HGF, CRP, SHBG, and bioavailable testosterone in women randomized to  $\omega$ -3 FA but only for leptin, adiponectin:leptin ratio and SHBG in those randomized to placebo. At 6 months, the 21 women who lost  $>10\%$  weight (median 15%) showed significant within-group improvement in adiponectin, leptin, adiponectin:leptin ratio, insulin, lipocalin-2, resistin, PAI-1, HGF, CRP, SHBG, bioavailable estradiol and bioavailable testosterone. For women with  $<10\%$  weight loss (median 6%) there was significant within-group improvement only for leptin, the adiponectin:leptin ratio, and SHBG. Little change was observed for inflammatory cytokines IL-6, TNF-alpha, MCP-1 or FABP4, or FGF-21 with  $\omega$ -3 FA or  $>10\%$  weight loss. Given the dramatic effect of weight loss on biomarkers, we examined within-group and between-group change from baseline to 6 and 12 months for the four subgroups (10-11 women in each) defined by  $\omega$ -3 FA or placebo and  $<$  or  $> 10\%$  weight loss at 6 months. The subgroup of  $>10\%$  loss +  $\omega$ -3 FA had the greatest within-group change in the proportion of significantly modulated biomarkers at 6 months.  $>10\%$  loss +  $\omega$ -3 FA was the only subgroup with a significant within-group increase in adiponectin at both 6 and 12 months and achievement of a beneficial ratio of adiponectin (ug/ml) to leptin (ng/ml) of  $> 1.0$  in 100% of participants. There was a significant between-group effect for adiponectin for  $>10\%$  loss +  $\omega$ -3 FA vs each of the other groups. Biomarkers were assessed in tissue acquired by random periareolar fine needle aspiration (RPFNA). There were no significant differences in change in cytomorphology or Ki-67 between women randomized to  $\omega$ -3 FA or placebo but there were significant within-group increases in benign breast adiponectin (pg/ug protein) at 12 months ( $p = 0.014$ ) for women randomized to  $\omega$ -3 FA. **Conclusions:** EPA + DHA ethyl esters (3150 mg/day), added to a behavioral weight loss program in overweight women at increased risk for breast cancer, is well-tolerated and may further improve risk biomarker modulation. The increase in adiponectin when  $\omega$ -3 FA is added to weight loss is of particular interest given that adiponectin opposes the oncogenic effect of leptin and is associated with improved insulin sensitivity and reduced mTOR signaling. Further study is warranted with enough subjects to detect between-group differences.

Dcis as a risk lesion for invasive breast cancer and death from other cancers

Alastair Thompson<sup>1</sup>, Bridget Hilton<sup>2</sup>, Joanna Dulson-Cox<sup>2</sup>, Karen Clements<sup>2</sup>, Sloane Project NHS Breast Screening Group. <sup>1</sup>Baylor College of Medicine, Houston, TX; <sup>2</sup>Public Health England, Birmingham, United Kingdom

**Introduction:** Ductal carcinoma in situ (DCIS) is considered a non-obligatory precursor of invasive breast cancer. Using a prospective cohort study of screen detected non-invasive neoplasia from a national breast screening program, this analysis examined subsequent DCIS or invasive cancers and death due to other cancers or other causes. **Methods:** Prospective data on 9191 screen detected non-invasive breast neoplasia with a median 9.2 years follow up was matched to a subsequent diagnosis of invasive breast cancer or death from another primary, non-breast cancer at any site or other cause of death, cross validating data from the National Cancer Registry, Hospital Episode Statistics and mortality data.

**Results:** Following a diagnosis of screen detected DCIS, in 9191 women, for those undergoing breast conservation surgery (BCS), 413 women developed ipsilateral invasive breast cancer, at a proportion of 5/1000 per annum consistent over a decade and more. By contrast DCIS re-occurrences in the same, conserved, breast (in 222 women) occurred at a similar rate for the first 5 years then the rate halved beyond 5 years. Contralateral breast cancer (DCIS or invasive) occurred in 431 women over the same time period. Mortality occurred in 1062/9191 (11.6%) women, attributed to breast cancer in 130/1062 (12.2%) and due to cancer at other sites in 397/1062 (37.4%). Death from other, non-breast, cancers was predominantly from primaries of the lung (98 women), ovary (43), pancreas (37) and colon (23) and rarely associated with a confounding diagnosis of invasive breast cancer (present in only 8% of those patients). Non-cancer mortality was identified in 496/1062 (46.7%) women, most commonly attributed to cardiovascular disease (in 188 women) or disease of the respiratory system (in 93). **Conclusion:** Screen detected DCIS is a marker for subsequent invasive breast cancer, but mortality from other, non-breast, cancers following treatment for DCIS is three times more likely than death due to breast cancer, suggesting DCIS is a more general marker for subsequent cancers than hitherto recognized. Awareness of, and potentially screening for, other cancers should be considered in women treated for DCIS.

Assessment of early ctDNA dynamics to predict efficacy of targeted therapies in metastatic breast cancer: Results from plasmaMATCH trial

Javier Pascual<sup>1</sup>, Rosalind J Cutts<sup>2</sup>, Belinda Kingston<sup>2</sup>, Sarah Hrebien<sup>2</sup>, Lucy S Kilburn<sup>2</sup>, Sarah Kernaghan<sup>2</sup>, Laura Moretti<sup>2</sup>, Katie Wilkinson<sup>2</sup>, Andrew M Wardley<sup>3</sup>, Iain R Macpherson<sup>4</sup>, Richard D Baird<sup>5</sup>, Rebecca Roylance<sup>6</sup>, Michael Hubank<sup>2</sup>, Giselle Walsh<sup>2</sup>, Iris Fauli<sup>7</sup>, Kimberly C Banks<sup>7</sup>, Richard B Lanman<sup>7</sup>, Isaac Garcia-Murillas<sup>2</sup>, Judith M Bliss<sup>2</sup>, Alistair Ring<sup>1</sup> and Nicholas C Turner<sup>1</sup>. <sup>1</sup>The Royal Marsden NHS Foundation Trust and The Institute of Cancer Research, London, United Kingdom<sup>2</sup>The Institute of Cancer Research, London, United Kingdom<sup>3</sup>The Christie NHS Foundation Trust, Manchester, United Kingdom<sup>4</sup>Institute of Cancer Sciences, University of Glasgow, Glasgow, United Kingdom<sup>5</sup>Cancer Research UK Cambridge Centre, Cambridge, United Kingdom<sup>6</sup>University College London Hospitals NHS Foundation Trust, London, United Kingdom<sup>7</sup>Guardant Health, Redwood City, CA

**Background:** Early changes in circulating tumour DNA (ctDNA) levels may identify which patients respond to therapy earlier than imaging, with ctDNA levels falling rapidly in patients who respond to therapy. The plasmaMATCH trial assessed the utility of ctDNA testing with an error-corrected 73-gene targeted panel (Guardant360, Guardant Health) to allocate patients to four mutation matched therapy cohorts. *ESR1*-extended fulvestrant (A), *HER2*-neratinib +/- fulvestrant (B), *AKT1*-capivasertib + fulvestrant (C), *AKT* basket-capivasertib (D). Here, we report paired baseline and early on treatment ctDNA analysis from plasmaMATCH, to establish the optimal criteria for predicting progression free survival (PFS). **Methods:** In plasmaMATCH treatment cohorts, plasma samples were collected for ctDNA analysis pre-treatment at cycle 1-day 1 (C1D1) and cycle 2-day 1 (C2D1) timepoints, and sequenced with the Guardant 360 assay. Patients were included if they had a minimum of 14 days of treatment in the first cycle. Multiple different methods were investigated to integrate variant allele fractions (VAF) of mutations identified at each timepoint to estimate the level of ctDNA, including maximum VAF, mean VAF and weighted mean VAF, and weighted mean VAF of clonal mutations at C1D1. Variants with a VAF <0.3%, set as the limit of detection, in C1D1 were excluded. Genes frequently mutated in CHIP were excluded (*GNAS*, *JAK2*, *IDH1*, *IDH2* and *ATM*) from the weighted mean VAF of clonal mutations method. The circulating DNA ratio (CDR) was calculated as the ratio of C2D1 level relative to C1D1 level. The optimal cut-point for predicting PFS was assessed by fitting a range of cutpoints for each VAF integration method, identifying the cut-point with the highest Harrell's C-index. **Results:** A total of 142 patients were enrolled into plasmaMATCH cohorts A-D, 79 patients had samples sent for paired C1D1-C2D1 plasma ctDNA sequencing, 1 failed sequencing and 1 insufficient treatment, and 77 (54%) patients had assessable C1D1-C2D1 plasma ctDNA sequencing results (45 cohort A, 12 cohort B, 12 cohort C, 8 cohort D). A weighted mean of clonal mutations in C1D1 ctDNA sequencing was the optimal method for integrating VAF, with peak C-Index 0.67. At the optimal C-index cutoff of 0.132, median PFS with high ctDNA CDR was 2.4 months (95% CI 2.0-3.7) and with suppressed ctDNA CDR was 9.9 months (95% CI 7.0-13.7) (HR 4.3, 95% CI 2.4-7.6, p<0.0001). Early changes in ctDNA level were also predictive in cohorts A extended dose fulvestrant alone (HR 5.8, 95% CI 2.2-16, p=0.0001) and cohorts B-D of targeted therapy (HR 3.8, 95% CI 1.7-8.6, p=0.00063). In analysis that was not pre-planned, patients with undetectable ctDNA at C2D1 had a particularly good outcome (p<0.0001, table 1). **Conclusions:** We identify an optimal methodology for assessing early dynamic changes in ctDNA that predicts treatment efficacy in patients with metastatic breast cancer. This methodology will require validation in independent data-sets, and if validated would allow trials of adapting therapy on the basis of early ctDNA dynamics.

Table 1

ctDNA dynamics category	Median PFS months (95%CI)	6-month PFS	ORR
Undetectable (N=11) CDR=0	18.2 (10.2-NA)	91%	9/11 (82%)
Suppressed (N=14) CDR <0.132 and >0	5.4 (4.6-NA)	48%	6/14 (43%)
High (N=52) CDR >=0.132	2.4 (2.0-3.7)	8%	4/52 (8%)

Permanent marker free surface-guided breast radiotherapy: Implementing a new technique

Christy Goldsmith, Deirdre Dobson, Adam Littler, Elinor Sawyer, Georgina Moriggi and Roshni Chauhan. Guys Hospital, London, United Kingdom

**Background:** It is standard practice in our centre for patients to be given permanent skin marks during breast radiotherapy planning, for use as reliable landmarks in daily reproduction of their positioning for treatment. However, these permanent marks (tattoos) may have a significant psychological impact on patients (1). In recent years, there have been technological advances in surface-guided radiotherapy techniques (SGRT) which may provide improved set-up accuracy compared to permanent markers. **Aims:** 1. To evaluate if surface-guided set-up is as good, if not better, than set-up with permanent markers alone. 2. To safely implement a permanent marker (PM) free, surface-guided set-up technique. **Methods:** A pilot study was conducted with tangents-only breast patients treated in free breathing (FB). All treatments were delivered on Varian TrueBeam linear accelerators, with patients immobilised on a couch indexed breast board. The study group (n=20) were set up using PMs with adjustments guided by the AlignRT® SGRT system to optimise patient positioning. Imaging (MV tangent images) was performed as per standard protocol on fractions 1-3, 8 and 12. Additional imaging was performed if indicated. The translational and rotational displacements calculated by the TrueBeam verification system for this group were compared to average displacements calculated for patients set up using PMs alone (the control group, n=20). Encouraged by the results of the pilot study, the centre moved to safely roll-out the PM-free technique to include additional applications. The step-wise approach taken will be described. **Results:** The mean displacements calculated from the verification imaging are shown in Table 1 below:

Displacement	20 patients PM only (106 #s)	20 patients PM + SGRT (114 #s)	Statistical significance
Lateral (mm)	2.27	1.56	yes
Vertical (mm)	2.69	2	yes
Longitudinal (mm)	1.44	1.53	no
Total translation/Vector (mm)	4.1	3.21	yes
Pitch (°)	0.61	0.42	yes
Yaw (°)	0.67	0.53	yes

SGRT set-up demonstrated statistically-significant improvements compared to PM set-up alone with respect to lateral, vertical and total translational displacements. Longitudinal displacements favoured PM set-up alone but this did not reach statistical significance. Rotational displacements favoured SGRT set-up and the results reached statistical significance. Given the improved set-up accuracy with SGRT, and the wish to reduce the psychological morbidity of radiotherapy for our breast cancer patients, the centre moved to safely implement a PM free SGRT technique along agreed timelines as shown in Table 2:

Development stage	Detail	Date
Set up tangents only FB patients using PM + SGRT	Patients set up using PM + SGRT – pilot study showed comparable or better than PM alone (see Table 1)	Oct 2018
Breast Working Party decision to use PM + SGRT for all set-ups	To build on SGRT experience from pilot study to include all breast set-ups (nodal regions & Deep Inspiration Breath Hold, DIBH)	Sept 2019
Site visit to Birmingham, UK	Radiographer-led visit to observe PM free breast technique	Oct 2019
Report to Breast Working Party about PM + SGRT guided set up	Report showed improved consistency using SGRT and reduction in displacements for all set-ups	Nov 2019
Site Visit to Inverness, UK	Multi-disciplinary team (ClinOnc/Rad/Dosimetry) attended Inverness to review PM free CT, Planning & Treatment	March 2020
Need to Improve Social distancing from COVID19	Increased use of SGRT to maintain social distancing in RT treatment room at outbreak of pandemic	March 2020
Removal of breast borders	To simplify set up process	May 2020
Use treatment capture images to resolve set up issues + use SGRT for electron sets with PMs	Staff will have time to practice SGRT set up without using PMs before the PM-free technique is implemented	26 <sup>th</sup> May 2020
New CT protocol for DIBH	This allows fusion of scans so that patients can be set up in FB and monitored during treatment in DIBH	8 <sup>th</sup> June 2020
1 <sup>st</sup> PM free Tangent only FB patient treated	Mean translational displacements (mm) 0.05 Vert/0 Long/0.04 LatMean rotational displacements (o) Pitch 1.3/Roll 0/Yaw 0.9	17 <sup>th</sup> June 2020

**Conclusions:** Our pilot study demonstrated that surface-guided radiotherapy (SGRT) set-up is as good, if not better, than set-up with permanent markers (PM) alone in tangent-only free-breathing patients. Subsequent further analysis showed improved consistency of set-up guided by PM plus SGRT for all breast set-ups (to include nodal regions and DIBH). We have described our step-wise approach to setting up PM free radiotherapy delivery for breast cancer patients, which has additional advantages in maintaining social distancing in the COVID19 era. **Refs1. Digital MammaPrint and Blueprint using machine learning and whole slide imaging

Annuska M Glas<sup>1</sup>, Jorge S Reis-Filho<sup>2</sup>, Diederik Wehkamp<sup>1</sup>, Belma Dodgas<sup>3</sup>, Leonie Delahaye<sup>1</sup>, Ran Godrich<sup>3</sup>, Jeroen Mollink<sup>1</sup>, Adam Casson<sup>3</sup>, Anke Witteveen<sup>1</sup>, Julian Viret<sup>3</sup>, Donghun Lee<sup>3</sup>, Matthew Lee<sup>3</sup>, Hugo Horlings<sup>4</sup>, Leo Grady<sup>3</sup>, Thomas Fuchs<sup>3</sup>, William Audeh<sup>5</sup>, Christopher Kanan<sup>3</sup> and Laura J van't Veer<sup>1</sup>. <sup>1</sup>Agendia, Amsterdam, Netherlands<sup>2</sup>Memorial Sloan Kettering Cancer Center, New York, NY;<sup>3</sup>Paige.AI, New York, NY;<sup>4</sup>Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands<sup>5</sup>Agendia, Irvine, CA

**Background:** The rise of whole slide imaging systems has enabled pathologists to remotely view cases in high resolution to diagnose cancer, and efficiently archive images. The advent of machine learning techniques and their application in digital pathology have facilitated the identification of histological patterns for effective diagnosis of disease. Deep learning-based solutions have been developed to detect and recognize cancer types, and automatically grade and stage tumors through evaluation of pathological features and patterns. However, no image-based solutions have been able to replicate a multivariate test, such as a risk-of-recurrence assay for early stage breast cancer. Traditionally, subtle differences in gene expression have been measured by microarray or NGS, however these changes may also be recognized phenotypically from hematoxylin and eosin stained (H&E) slides by digital biomarkers developed using novel machine learning techniques. The large repository of images with MammaPrint and Blueprint results may enable us to develop digital MammaPrint and digital Blueprint biomarkers that predict the risk of distant recurrences and the molecular subtypes of a tumor sample using only H&E stained digitized tumor slides. **Methods:** Using over 70,000 H&E images of early stage breast cancer patients in combination with machine learning techniques, digital versions of MammaPrint and Blueprint were developed. In total 20,000 images were used for feasibility and algorithm optimization, another 50,000 images were used for further finetuning. MammaPrint indices and Blueprint scores and categorical results were used to train the system. After the algorithms were optimized, they were locked and validated in an independent set of 5000 H&E stained images. The MammaPrint and Blueprint predictions were compared to the original MammaPrint and Blueprint results obtained from the microarray assay. The finalized and locked algorithms were further validated for precision and reproducibility in a large data set of xx Images and processed multiple times. Multicenter clinical validation was performed in H&E stained images of multiple series with long term follow up (tbd), totaling ###k images. In this ###K cohort of patients, ##% were HR+/HER2-, ##% were clinically HER2+ and x% were triple negative. **Results:** Using an independent dataset of 5000 samples, we compared the MammaPrint and Blueprint predictions obtained from the H&E slides to the traditional versions of MammaPrint and Blueprint based on a microarray. The binary performance of the digital MammaPrint had a concordance of xx% (with an AUC of xx%), %NPA and %PPA when compared to the traditional MammaPrint high-low classification. For digital Blueprint, the system had a concordance of xx% and a classification accuracy of xx%. The analytical performance showed a precision and reproducibility of xx%. In a multicenter clinical validation the DRFI was xx% in dMP low risk and yy% in dMP high risk groups. The xxx dataset the performance was *similar* to the microarray and better than compared to clinical parameters. *Analyses will be available by the Placeholder Abstract deadline.* **Conclusions:** The combination of machine learning and digital pathology has enabled development of rapid and highly accurate *in silico* versions of MammaPrint and Blueprint. Implementation of digital H&E based risk of recurrence and molecular subtyping could enable preservation of valuable diagnostic tissue, faster turnaround time for test results, and a more cost effective approach to treatment planning tools, especially in countries that do not allow send out of human tissue and this adoption of risk scoring is low. *Final conclusions tbd*

Patient-reported outcomes (PROs) from the Ph 3 IMpassion031 trial of neoadjuvant (NA) atezolizumab + chemo in early triple-negative breast cancer (eTNBC)

Elizabeth A. Mittendorf<sup>1</sup>, Nadia Harbeck<sup>2</sup>, Hong Zhang<sup>3</sup>, Shigehira Saji<sup>4</sup>, Kyung Hae Jung<sup>5</sup>, Sheetal Patel<sup>6</sup>, Shilpen Patel<sup>6</sup>, Anh Nguyen Duc<sup>7</sup>, Mario Liste-Hermoso<sup>7</sup>, Stephen Y. Chui<sup>6</sup> and Carlos H. Barrios<sup>8</sup>. <sup>1</sup>Dana-Farber/ Brigham and Womens Cancer Center, Boston, MA; <sup>2</sup>Breast Center, Ludwig-Maximilians-University (LMU), Munich, Germany; <sup>3</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>4</sup>Fukushima Medical University, Fukushima, Japan; <sup>5</sup>Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of; <sup>6</sup>Genentech, Inc., South San Francisco, CA; <sup>7</sup>F. Hoffmann-La Roche, Ltd., Basel, Switzerland; <sup>8</sup>Oncology Research Center, HSL, PUCRS, Porto Alegre, Brazil

**Background:** In IMpassion031 (NCT03197935), patients (pts) (N = 333) with invasive stage II or III eTNBC who received NA treatment (tx) with atezolizumab (A) + nab-paclitaxel (nP) followed by doxorubicin + cyclophosphamide (AC; A-chemo) had significantly improved pathologic complete response (pCR, primary endpoint) regardless of PD-L1 status vs placebo (P) with nP and AC (P-chemo). Balancing efficacy and toxicity is key in this potentially curable eTNBC setting. PROs were collected to comprehensively assess tx burden from the pts' perspective, inform clinical benefit and decision-making and address the lack of pt-reported data in this setting. **Methods:** Pts received double-blind A 840 mg or P every 2 weeks (q2w) with nP 125 mg/m<sup>2</sup> once weekly for 12 wk followed by A 840 mg or P q2w with AC q2w for 4 doses. After surgery and pathological evaluation, pts in the A-chemo arm received open-label A 1200 mg every 3 weeks for 11 doses. The P-chemo arm was observed. To capture pts' experience of tx-related symptoms, associated bother, and impact on day-to-day functioning and health-related quality of life (HRQoL), pts completed the EORTC Quality of Life Questionnaire Core 30 (QLQ-C30) and single-item GP5 from the Functional Assessment of Cancer Therapy-General (FACT-G) questionnaire at baseline (BL) and day (D)1 of each cycle (C) of NA and adjuvant (adj) tx, at end of tx and in follow-up every 3 mo (year 1), every 6 mo (years 2-3), then annually. Mean and mean change from BL scores ( $\geq 10$ -point change considered clinically meaningful) by C and between tx arms in the QLQ-C30 function (role and physical) and global health status/QoL scales were predefined secondary endpoints. Mean and mean change from BL scores in tx-related symptoms, as well as an assessment of tx side-effect bother, were exploratory endpoints. **Results:** QLQ-C30 completion rates (ITT) in both arms were 100% at BL and  $> 90\%$  in the NA phase and  $> 89\%$  in the adj phase through C16. GP5 completion rates in both arms were  $> 98\%$  at BL (C2D1) and  $> 88\%$  in the NA and adj phases. BL mean [95% CI] values were high for physical function (A-chemo, 91 [89-93]; P-chemo, 90 [88-92]), role function (A-chemo, 89 [86-93]; P-chemo, 89 [86-92]), and HRQoL (A-chemo, 79 [76-82]; P-chemo, 76 [73-79]). Physical and role function, and HRQoL mean values were similar between arms across on-tx assessments to C16 and through follow up. Mean change from BL values for physical and role function, and HRQoL were similar between arms and of the same magnitude. In both arms mean physical function had a clinically meaningful decline during the NA period from C3 to C5, rebounding in the adj period, and stabilizing starting C7. In both arms mean role function had a clinically meaningful decline in the NA period from C2 (A-chemo) or C3 (P-chemo) to C5, rebounding in the adj period, and stabilizing at C9 in the P-chemo arm only. In both arms mean HRQoL had a clinically meaningful decline in the NA period from C3 to C5, rebounding in the adj period and stabilizing from C6. Tx symptoms of fatigue, diarrhea, nausea, and vomiting in the NA period worsened through C5 in both arms with trends in mean and mean change from BL values similar to the functional and HRQoL data. In the adj period, mean symptom scores in both arms through C16 were similar to BL except for fatigue. 65% (A-chemo) and 66% (P-chemo) of pts reported their level of bother with tx side effects to be "somewhat" or "quite a bit" by C5. During the adj period, no added side-effect bother was experienced by pts receiving A compared with the P-chemo arm under observation, with a similar % of pts in each arm reporting being bothered "somewhat," "quite a bit," or "very much" by C16. **Conclusions:** Adding A to nP-AC improved pCR without added tx burden to pts. These results address the paucity of PRO data informing clinical benefit and decision-making in this potentially curable setting.

The immune microenvironment of liver metastasis as a guide for immunotherapeutic potential in breast cancer

Sofi Castanon<sup>1</sup>, Daniel Flores<sup>1</sup>, Joanne Xiu<sup>2</sup>, Paula R. Pohlmann<sup>3</sup>, Foluso Ademuyiwa<sup>4</sup>, Elia Obeid<sup>5</sup>, Jasjit Sachdev<sup>6</sup>, Michael Simon<sup>7</sup>, Elisa Krill Jackson<sup>8</sup>, Lee Schwartzberg<sup>9</sup>, Antoinette R Tan<sup>10</sup>, Neelima Denduluri<sup>11</sup>, W. Michael Korn<sup>2</sup> and Evantheia T Roussos Torres<sup>1</sup>. <sup>1</sup>University of Southern California, Los Angeles, CA; <sup>2</sup>Caris Life Sciences, Phoenix, AZ; <sup>3</sup>Medstar, Baltimore, MD; <sup>4</sup>Washington University, St. Louis, MO; <sup>5</sup>Fox Chase Comprehensive Cancer, Philadelphia, PA; <sup>6</sup>Honor Health, Scottsdale, AZ; <sup>7</sup>Karmanos Cancer Institute, Detroit, MI; <sup>8</sup>University of Miami, Miami, FL; <sup>9</sup>West Clinic, Memphis, TN; <sup>10</sup>Atrium Health, Charlotte, NC; <sup>11</sup>US Oncology, Arlington, VA

**Background:** The benefits of immune check point inhibition (ICI) are primarily seen in immunogenic cancer types. Unfortunately, most breast cancers are non-immunogenic, and therefore new approaches that target tumor immunogenicity are key to increasing the efficacy of ICI. Even within a single breast cancer subtype, patients with liver metastases are less responsive to ICI as compared to other metastatic sites. Therefore, the objective of this analysis is to investigate differences in prognostic and predictive ICI related biomarkers such as PD-L1 expression, tumor mutation burden (TMB), and immune-cell populations between primary tumors, liver metastases (LM) and non-liver metastatic (NLM) sites from breast cancer patients. Our goal is to provide an in-depth analysis of current and potential markers of immunogenicity within LM and NLM.

**Methods:** Unpaired samples taken from primary and recurrent breast (BT), liver metastases (LM) and non-liver metastases (NLM) (all identified as breast cancer) were compared using Fisher-exact or Chi<sup>2</sup> and corrected for multiple comparison. Tumors were classified as hormone receptor positive (HR+), HER2+ or triple negative breast cancer (TNBC). Breast cancer samples were tested using NextGen DNA sequencing (NextSeq, 592 gene panel) and whole transcriptome RNA sequencing (NovaSeq). PDL1 was scored on immune cells using VENTANA PD-L1 (SP142) assay. TMB was measured by counting somatic non-synonymous missense mutations on the 592 gene panel and ≥ 10 mutations/Megabase (mut/Mb) was considered high. MCP counter was used to evaluate relative cell abundance (in arbitrary units) in TME using transcriptome data.

**Results:** Biopsies from 3166 tumors were queried, 1268 of which were from BT, 495 from LM, and 1403 from NLM, all are unpaired. All histologic subtypes are represented. HR+ breast cancer was the most prevalent among LM. Both metastatic groups (LM and NLM) were significantly more likely to have a high TMB as compared to BT (24.8 & 24.8 vs. 16.6%, p<0.0001). PD-L1 expression in immune cells however, was significantly decreased in LM as compared to BT (12 vs. 34%, p<0.0001) and NLM (12 vs. 28%, p<0.0001), a trend largely driven by HER2+ and TNBC subtypes. Comparison of immune cells within tumor biopsies of LM vs. BT demonstrated significantly fewer cytotoxic CD8+ T cells (1.38 vs. 0.69, p<0.001), B cells (234 vs. 98, p<0.001), and myeloid dendritic cells (DCs) (1.5 vs. 1.02, p<0.001). These observations were most predominant in TNBC and HR+ breast cancers. HR+ LM also had fewer natural killer cells (0.85 vs. 0.03, p<0.005). Cytotoxic T cells and DCs were not significantly altered in HER2+ LM. All immune cell types, except for the monocytic lineage, were significantly (p<0.001) higher within NLM as compared to LM. Investigation of molecular alterations revealed significant differences in LM vs. NLM vs. BT, e.g, LM from all subtypes were enriched for copy number alterations in genes such as CCND1 and FGF19/14, FGFR1. Significant (p<0.001) enrichment of mutations in ESR1 (2.8 vs. 27.1%), HER2 (1.9 vs. 6.1%), and GATA3 (7.8 vs. 12.9%), were observed in LM vs. BT.

**Conclusions:** In this patient cohort, immune cells within the TME of LM were less abundant and suggest the liver is a less immunogenic niche. However, LM had increased TMB as compared to breast tumors, suggesting that immunosuppressive cells (i.e. Tregs and MDSCs) or cytokines, may be preventing cytotoxic immune cell infiltration into the TME. Moreover, immune cell populations within LM had decreased PD-L1 expression when compared to breast tumors, suggesting another mechanism that could explain the lack of response to ICI in such patients. Further characterization of the genetic and molecular alterations of breast cancer LM and NLM will help identify additional biomarkers of response and determine their role in defining tumor immune response to ICI.

Safety and efficacy of an alternative schedule of palbociclib (PAL) in hormone receptor positive (HR+), HER2 negative (HER2-) metastatic breast cancer (MBC) and the utility of serum thymidine kinase 1 (sTK1) activity in predicting PAL response

Jairam Krishnamurthy<sup>1</sup>, Jingqin Luo<sup>2</sup>, Rama Suresh<sup>2</sup>, Foluso Ademuyiwa<sup>2</sup>, Caron Rigden<sup>2</sup>, Timothy Reardon<sup>2</sup>, Katherine Clifton<sup>2</sup>, Katherine Weilbaecher<sup>2</sup>, Ashley Frith<sup>2</sup>, Anna Roshal<sup>2</sup>, Pavan Tandra<sup>1</sup>, Mathew Cherian<sup>2</sup>, Tracy Summa<sup>2</sup>, Shana Thomas<sup>2</sup>, Leonel Hernandez-Aya<sup>2</sup>, Mattias Bergqvist<sup>3</sup>, Lindsay Peterson<sup>2</sup> and Cynthia X Ma<sup>2</sup>. <sup>1</sup>University of Nebraska Medical Center, Omaha, NE; <sup>2</sup>Washington University School of Medicine, St. Louis, MO; <sup>3</sup>Biovica International AB, Uppsala, Sweden

**Background:** The approved 3 weeks (wks) on/1 wk off schedule of PAL results in grade (G)3+ neutropenia (ANC) up to 66%. We hypothesized that an alternative schedule (Alt Dose Pal), 5 on/2 off every 7 days, reduces the rate of G3+ ANC, allowing continued weekly dosing. In addition, based on our previous study supporting sTK1, an E2F-dependent enzyme critical for DNA synthesis, as a pharmacodynamic indicator of CDK4/6 inhibition, we hypothesized that Alt Dose Pal inhibits sTK1 and sTK1 dynamics predicts PAL response. **Methods:** A single arm phase II trial was conducted in HR+ HER2- MBC, ≤1 prior endocrine therapy (ET) for MBC (NCT03007979). Pts received PAL 125 mg daily, 5 on/2 off weekly, plus letrozole (LET) or fulvestrant (FUL) per physician choice, on a 28-day cycle (C). Goserelin was added if premenopausal. Complete blood count and chemistry panel were done at baseline (BL), C1&2D15, and D1 of C2+. The primary objective was to determine the rate of G3+ ANC in C1 D1-D29. Secondary objectives were to assess the rate of all cycle G3+ ANC, PAL dose reduction/discontinuation, adverse events (AE) per CTCAE v5, progression free survival (PFS), objective response rate (ORR: CR+PR (complete and partial responses)) and clinical benefit rate (CBR: no progression (PD) in 24 wks) by RECIST 1.1. The sample size of 47 provides 90% power, 1-sample binomial exact test, 5% alpha, to test the 1-sided null hypothesis of G3+ ANC rate >62% vs the alternative of <40%. Serial sTK1 was analyzed at BL, C1D15, C2D1, every 3 cycles with tumor imaging, and at PD, using the DiviTum™ assay. **Results:** From July 2017 to Feb 2020, 54 pts were enrolled. 3 pts went off in C1, unrelated to study, leaving 51 pts (38 LET, 13 FUL), median age of 62 (range 34-87) years, 8 (16%) premenopausal, 26 (51%) with visceral mets. 22 (43%) and 29 (57%) had adjuvant chemo or ET, respectively. 4 (8%) had 1 prior ET for MBC. 22 (43%) had primary or secondary ET resistance defined by ESMO. 17 (33%) had de novo MBC. The median follow up was 12 months (mo). Treatment is ongoing for 23 (45%) pts. Among 47 evaluable pts, 10 (21.3%, 95% CI: 11.2%-36.1%) had G3 ANC in C1 D1-29, with no G4 AE. 22 of 54 (40.7%; 95% CI: 27.9%-54.9%) had G3 (n=21) or G4 (n=1) ANC in all cycles. 37 pts in C1 and 32 pts in all cycles, were without G3+ ANC, exceeding the predefined boundary for better tolerability. PAL was dose reduced in 11 (20.3%) pts and discontinued in 3 (4.8%) due to AE. Table 1 lists treatment related AEs of >10% or G3+. The ORR was 50% (2 CR, 13 PR, 95% CI: 33.15%-66.85%) in 30 pts with measurable disease (n=29) or non-measurable but CR (n=1). The CBR was 81.63% (95% CI: 67.5%-90.76%) in 40 (2CR, 13 PR, 25 SD ≥24 wks) of 49 evaluable pts. The median PFS (mPFS) was 24.3 mo (95% CI 15-not reached (NR)) overall. The mPFS was 33.5 mo (95% CI 17.3-NR) and 12 mo (95% CI: 10.4-NR), in ET sensitive and resistant population, respectively. sTK1 was significantly reduced, 80% down to undetectable, as early as C1D15 (p=7.77E-07). BL sTK1 levels correlated with PD vs non-PD (p=0.003) as best response and negatively correlated with PFS (p=0.002). sTK1 rose significantly at PD (p=0.0003). A median lead time of 80.6 (IQ range 6.8-189.2) days was observed for rising TK before RECIST PD. **Conclusion:** The Alt Dose Pal trial met its primary endpoint with reduced G3+ ANC. The efficacy data is comparable to prior reports. sTK1 shows promise for PAL response prediction and monitoring. **Table 1 AE**

Kinome profiling of ER+ breast cancer PDXs identifies PKMYT1 as a marker of hormone independent growth and poor outcome

Anran Chen<sup>1</sup>, Beom-Jun Kim<sup>1</sup>, Doug W Chan<sup>1</sup>, Purba Singh<sup>1</sup>, Lacey E Dobrolecki<sup>1</sup>, Jonathan T Lei<sup>1</sup>, Shunqiang Li<sup>2</sup>, Alana L Welm<sup>3</sup>, Michael T Lewis<sup>1</sup> and Matthew J Ellis<sup>1</sup>. <sup>1</sup>Baylor College of Medicine, Houston, TX; <sup>2</sup>Washington University in St. Louis, St. Louis, MO; <sup>3</sup>Huntsman Cancer Institute, Salt Lake City, UT

**Background:** Endocrine therapy resistance is common and is a leading cause of breast cancer-related death. Thus, the search for therapeutic targets based on mechanistic insights into endocrine therapy resistance continues. Kinases are important drug targets and regulators in cells, many of which are involved in tumorigenesis and the development of treatment resistance. Mass spectrometry-based kinome analysis has been impeded by the low abundance of individual kinases. Here we utilized kinase inhibitor-conjugated beads to enrich and thereby sensitively profile the kinome of estrogen receptor-positive (ER+) breast cancer patient-derived xenograft (PDX) tumors under estradiol-deprivation treatment.

**Experimental design and methods:** We harvested tumor samples from 20 breast PDX lines with various degrees of estradiol (E2) dependence in ovariectomized SCID-beige mice with and without E2 supplementation (n=3 per PDX line per arm). The kinases in the tumor lysates were enriched using kinase inhibitor pulldown (KIP) beads and the tightly bound kinases were quantified by mass spectrometry. To identify candidates, we selected for kinases that were highly E2-regulated in the E2-dependent PDX lines but constitutively expressed in E2-independent PDX lines. Survival analysis of candidate kinases in patients with ER+ breast cancer was performed using the METABRIC dataset.

**Results:** Each PDX line had a unique yet reproducible kinome. To seek kinases with consistent relationships with estrogen dependence, we sought kinases that were statistically differentially expressed in tumors between E2 supplied and deprived conditions. Noticeably, membrane-associated tyrosine-and threonine-specific cdc2-inhibitory kinase (PKMYT1), a WEE family kinase known to have estrogen response elements (EREs) in its regulatory region, was significantly decreased after E2 deprivation in E2-dependent PDXs (log2 fold change = -7.86, p<0.001) but was constitutive in E2-independent PDXs. High *PKMYT1* mRNA expression was associated with poor prognosis in the ER+ samples in METABRIC (hazard ratio=2.2, p<0.001). In contrast, the more studied member of the WEE family, *WEE1*, lacks an estrogen response element (ERE) and is not E2-regulated from the kinome profiling result. *WEE1* mRNA expression level is not associated with the outcome of patients with ER+ breast cancer, suggesting that PKMYT1 has evolved a specific role in the cell cycle of ER+ tumors.

**Conclusion:** Here, we analyzed the kinomes of 20 ER+ breast cancer PDX tumors with or without E2 by mass spectrometry. We discovered that PKMYT1 is a marker of hormone independent growth and poor outcome. Ongoing experiments that study the effects of PKMYT1 inhibition in both ER-dependent and independent circumstances will be presented.

Publication Number: PS8-02

Influence of a breast cancer polygenic risk score on adherence to preventive endocrine therapy in high risk women at 1 and 2 year follow-up: The genetic risk estimate (GENRE) trial

Daniela Stan<sup>1</sup>, Julian Kim<sup>2</sup>, Daniel Schaid<sup>1</sup>, Erin Carlson<sup>1</sup>, Andrew Cooke<sup>2</sup>, Christina A. Kim<sup>2</sup>, Benjamin Goldenberg<sup>2</sup>, Jason Sinnwell<sup>1</sup>, Debjani Grenier<sup>2</sup>, Amy Degnim<sup>1</sup>, Fergus Couch<sup>1</sup>, Celine Vachon<sup>1</sup> and Sandhya Pruthi<sup>1</sup>. <sup>1</sup>Mayo Clinic, Rochester, MN, Rochester, MN; <sup>2</sup>CancerCare Manitoba, Winnipeg, MB, Canada

**Background:** Preventive endocrine therapy (ET) has been proven extensively to decrease breast cancer (BC) risk by 50-65%. Despite this significant reduction, a small proportion of high risk women take ET, due to attitudes toward medications, inaccurate risk perception and drug side-effects. The addition of a polygenic risk score (PRS), comprised of 77 BC genetic susceptibility loci (Single Nucleotide Polymorphisms (SNP)), to the standard risk calculator estimates, can be used to improve BC risk estimation. We previously reported on the influence of the PRS-adjusted BC risk estimates on the intent to use ET (Abstract, SABCS, 2019). Here we report on the influence of PRS-adjusted BC risk estimates on ET adherence at 1 and 2 year follow-up. We also report on ET side effects over this same time period.

**Methods:** Women older than age 35 were eligible if they were deemed at high risk for BC by either a 5 year Gail Model risk of  $\geq 3\%$  or 10 year Tyrer-Cuzick risk (IBIS) of  $\geq 5\%$ . We excluded women with a personal history of BC or hereditary BC syndromes. At baseline, participants were counseled on their BC risk using standard risk calculators: Gail and IBIS risk scores (5 yr, 10 yr, & lifetime) and ET options were discussed, including benefits and risks. Blood samples were obtained and genotyped for 77 SNPs, and an updated BC -PRS risk report was shared with study participants that reflected the IBIS and Gail risk predictions for 5 yr, 10 yr, & lifetime BC risk with and without the PRS. A baseline self-reported questionnaire assessed understanding of BC risk and decision to take ET. Follow-up questionnaires at 1 and 2 years assessed self-reported ET adherence and ET side effects (vasomotor symptoms, vaginal symptoms, sexual dysfunction, weight gain, GI symptoms, headaches, breast sensitivity, mood changes, and joint pain). Adherence to ET at 1 and 2 year follow-up was stratified by three categories of lifetime PRS-BC risk: 0-20%; 20-40%; 40-100%.

**Results:** 151 women at Mayo Clinic Rochester and CancerCare Manitoba were enrolled in the study from 2016 to 2017. Of the 149 participants with evaluable data at 1 and 2 year follow-up, 57 (38%) started on ET therapy, all within 1 year of the baseline visit; 43 (29%) were taking ET at 1 year and 33 (22%) were taking ET at 2 year follow-up, representing a discontinuation rate of 26% at 1 year and 42% at 2 year follow-up.

Adherence to ET use at 1 year and 2 year follow-ups correlated significantly with the category of PRS-BC risk estimation: at 1 year follow up, 17% of those in the lowest PRS-IBIS risk category, 23% in the middle risk category and 50% of those in the highest risk category were taking ET ( $p=0.001$ ). At 2 year follow up, 12% of those in the lowest PRS-IBIS risk category, 18% in the middle risk category and 38% of those in the highest risk category were taking ET ( $p=0.008$ ).

At 1 year follow up, participants taking ET reported significantly more bothersome symptoms of vaginal itching ( $p=0.010$ ), weight gain ( $p=0.015$ ) and joint pain ( $p=0.044$ ), compared with those not on ET. There was a trend towards increased irritability and mood swings on those taking ET ( $p=0.059$ ). At year 2 there was no significant difference in side effects between those taking and not taking ET.

**Conclusion:** Adherence to ET in a population of women at high risk for BC decreased overtime and strongly correlated with the level of risk, with 38% of those at highest risk of breast cancer taking ET at 2 year follow up. Side effects of vaginal itching, weight gain and body aches were more common on those taking ET versus not taking ET at the 1 year follow-up, but did not differ at 2 year follow-up, possibly due to the fact that those with the most bothersome symptoms have discontinued ET by the 2 year follow up.

Radiologic review to refine selection of candidates for de-escalation of neoadjuvant therapy

Natsuko Onishi<sup>1</sup>, Wen Li<sup>1</sup>, Sara J Venters<sup>1</sup>, Denise M Wolf<sup>1</sup>, David C Newitt<sup>1</sup>, Elissa R Price<sup>1</sup>, Jessica Gibbs<sup>1</sup>, Barbara LeStage<sup>2</sup>, the I-SPY 2 Pathology Working Group, the I-SPY 2 Imaging Working Group, the I-SPY 2 Consortium, William F Symmans<sup>3</sup> and Nola M Hylton<sup>1</sup>. <sup>1</sup>University of California, San Francisco, San Francisco, CA;<sup>2</sup>I-SPY 2 Advocacy Group, San Francisco, CA;<sup>3</sup>MD Anderson Cancer Center, Houston, TX

**Purpose**In the on-going I-SPY2 TRIAL, participants receive 12 cycles of weekly paclitaxel with or without addition of experimental agents for 12 weeks (first regimen), followed by 4 cycles of anthracycline-cyclophosphamide (AC, second regimen) prior to surgery. A de-escalation strategy currently being introduced in I-SPY2 will give patients the option to skip AC if it is highly likely that they have achieved early pathologic complete response (pCR) at the inter-regimen time point (12 weeks). To guide selection of candidates for this option, a prediction model combining subtype-specific MRI predictive probabilities with mid-treatment percutaneous core biopsy pathology has been developed. The combined model predicts a patient as early pCR if the MRI model based on a quantitative measure of functional tumor volume predicts a high likelihood of pCR, and pathology determines that there are no invasive cancer cells detected in the mid-treatment core biopsy. This study was performed to develop radiologic criteria for post-selection review to further reduce the possibility for incorrect de-escalation recommendation.

**Methods**A review of 87 I-SPY2 patients with serial MRI and inter-regimen core biopsy identified 25 patients where both the subtype specific MRI model and at least 2 of 11 I-SPY2 pathologists predicted early pCR. One radiologist retrospectively reviewed MRIs at pre-treatment and inter-regimen for the 25 patients in a blinded fashion, and labeled the presence of residual disease on MRI at inter-regimen as follows: rank 0, no residual disease; rank 1, possible residual disease; rank 2, obvious residual disease. To evaluate the accuracy of selecting candidates for de-escalation of neoadjuvant therapy (i.e. predicting patients with early pCR at inter-regimen), surgical pathology of pCR after the completion of NAC (both first and second regimens) was defined as a surrogate "truth" in this study. Positive predictive value (PPV) and sensitivity for the combined MRI-pathology model were computed for all pathologist pairs. After adding qualitative radiologic review, patients labeled as rank 2 were excluded from the candidates with predicted early pCR by the combined MRI-pathology model. PPV and sensitivity before and after radiologic review were compared.

**Results**The 25 patients included 21 patients that ultimately achieved pCR, and 4 patients that did not. Radiologic review of the inter-regimen MRI for these patients classified their MRIs as 20% (5/25) rank 0 (no residual disease), 36% (9/25) rank 1 (possible residual disease), and 44% (11/25) rank 2 (obvious residual disease). Most (3/4) non-pCR patients were classified rank 2, however one (1/4) was assessed rank 0. Eight of the 21 pCR patients (38%) were classified as having obvious residual disease on inter-regimen MRI. Without radiologic review, the combined MRI-pathology model predicted pCR with a mean PPV of 92% (range 83-100%) and a mean sensitivity of 91% (range 76-100%). When patients labeled as rank 2 by radiologic review were excluded from candidates with predicted early pCR, PPV increased to 99% (range 93-100%) at the expense of lower sensitivity of 59% (range 52-62%).

#### **Conclusion**

In this study, elimination of rank 2 lesions resulted in substantial improvement in PPV (92% to 99%) with a consequent reduction in sensitivity from 91% to 59%. Notably, none of the rank 1 lesions, where diagnostic interpretation was less certain, were found to be non-pCR at surgery. High PPV is essential to ensure high accuracy and safety in directing early pCR patients to therapy de-escalation. These findings will be further validated in continuing studies and radiologic re-review will be included in the de-escalation strategy for omission of AC in the I-SPY2 TRIAL.

Molecular alterations in the androgen receptor and associated clinical outcomes in hormone receptor-positive/HER2- metastatic breast cancer

Charles Dai<sup>1</sup>, Andrzej Niemierko<sup>2</sup>, Neelima Vidula<sup>3</sup>, Laura M Spring<sup>3</sup>, Seth A Wander<sup>3</sup>, Arielle J Medford<sup>1</sup>, Katherine A Hesler<sup>4</sup>, Giuliana Malvarosa<sup>4</sup>, Jeffrey Peppercorn<sup>3</sup>, Dejan Juric<sup>3</sup>, Steven J Isakoff<sup>3</sup>, Beverly Moy<sup>3</sup>, Leif W Ellisen<sup>2</sup> and Aditya Bardia<sup>2</sup>. <sup>1</sup>Department of Medicine, Massachusetts General Hospital, Boston, MA; <sup>2</sup>Massachusetts General Hospital Cancer Center; Harvard Medical School, Boston, MA; <sup>3</sup>Massachusetts General Hospital Cancer Center, Boston, MA; <sup>4</sup>Massachusetts General Hospital, Boston, MA

**Background:** Although the androgen receptor (AR) is frequently co-expressed with ER and PR in hormone receptor-positive (HR+)/HER2- breast cancer, the biological significance of detectable AR alterations (AR<sup>alt</sup>) in metastatic disease (MBC) remains poorly understood. The primary objective of this study was to evaluate the association of AR<sup>alt</sup> status with clinical outcomes among women with HR+/HER2- MBC.

**Methods:** Retrospective review was performed on patients with HR+/HER2- MBC treated at an academic institution, for whom genotyping information was available. AR<sup>alt</sup> status was determined using Guardant360, a 73-gene next-generation sequencing assay that detects both AR mutations and amplifications in circulating tumor DNA. Women with positive or unknown HER2 status and triple-negative breast cancer were excluded from analysis, as were cases of male breast cancer. Time-to-progression on the therapy initiated immediately following Guardant testing was compared based on AR<sup>alt</sup> status, excluding patients treated with androgen-directed therapies given potential for confounding. Cumulative incidence plots were generated and analyzed by Gray's test, and propensity score-adjusted competing risk models were generated with the probability of treatment as a function of age at metastatic diagnosis, presence of visceral metastasis, presence of *de novo* metastases, as well as number of prior therapies. Additional analysis was performed to assess progression stratified by treatment type (endocrine or non-endocrine based).

**Results:** Among women with HR+/HER2- MBC (n=222), 16 patients (7%) had detectable AR<sup>alt</sup> (12 point mutations, 4 amplifications). No baseline differences were observed between women with AR<sup>alt</sup> and those without AR alterations (AR<sup>wt</sup>), with respect to age at primary or metastatic diagnosis, menopause status, time to onset of metastasis or *de novo* metastatic disease, presence of visceral metastases, or number of endocrine/chemotherapies received prior to Guardant testing. AR<sup>alt</sup> tumors had a higher frequency of detected mutations (14% vs. 5%, p<0.01), and frequently co-altered genes included *TP53*, *PIK3CA*, *ERBB2*, *SMAD4*, and *NF1*. Genes with a tendency towards co-alteration in AR<sup>alt</sup> but not in AR<sup>wt</sup> included *MAP2K2*, *ARAF1*, *MAPK1*, *SMAD4*, *MYC*, *ROS1*, *TERT*, and *NRAS*. In a multivariable model adjusting for age, *de novo* metastases, visceral metastases, and number of prior therapies, AR<sup>alt</sup> status was associated with a higher rate of progression (HR 2.5; 95% CI 1.2-5.0, p=0.01), particularly among patients treated with endocrine-based therapies following Guardant testing (HR 4.2, 95% CI 2.4-7.2, p<0.0005) but was not statistically different in women treated with non-endocrine based therapies (HR 1.6; 95% CI 0.5-4.9, p=0.4).

**Conclusions:** AR<sup>alt</sup> tumors demonstrate a higher rate of progression on endocrine-based therapy as compared to AR<sup>wt</sup> tumors, highlighting a potential role of AR in mediating resistance to endocrine therapy in HR+/HER2- disease. Further translational investigations are warranted to determine whether AR<sup>alt</sup>/HR+/HER2- disease represents a unique biological subtype that predominantly relies on AR signaling and may thus benefit from blockade with AR antagonists.

Table 1. Multivariable competing risks model for endocrine progression.

Covariate	PFS

Final analysis of PERTAIN: A randomized, two-arm, open-label, multicenter phase II trial assessing the efficacy and safety of first-line pertuzumab given in combination with trastuzumab plus an aromatase inhibitor in patients with HER2-positive and hormone receptor-positive metastatic or locally advanced breast cancer

Grazia Arpino<sup>1</sup>, Juan de la Haba-Rodriguez<sup>2</sup>, Jean-Marc Ferrero<sup>3</sup>, Sabino De Placido<sup>1</sup>, Dirk Klingbiel<sup>4</sup>, Valentine Revelant<sup>4</sup>, Christine Wohlfarth<sup>4</sup>, Raf Poppe<sup>4</sup> and Mothaffar F Rimawi<sup>5</sup>. <sup>1</sup>University Federico II, Naples, Italy<sup>2</sup>Reina Sofia Hospital, University of Cordoba, Cordoba, Spain<sup>3</sup>Centre Antoine Lacassagne, Nice, France<sup>4</sup>F. Hoffmann-La Roche Ltd, Basel, Switzerland<sup>5</sup>Dan L. Duncan Comprehensive Cancer Center, Baylor College of Medicine, Houston, TX

**Background** The role of bidirectional cross talk between the HER2 and estrogen receptors in resistance to anti-HER2 and endocrine therapy has been studied extensively (Kaufman et al. J Clin Oncol 2009; Arpino et al. J Natl Cancer Inst 2007). The CLEOPATRA study showed that first-line pertuzumab (P) + trastuzumab (H) + docetaxel (T) improved progression-free survival (PFS) and overall survival (OS) significantly compared with placebo + H + T in patients (pts) with HER2-positive metastatic BC (MBC) (Baselga et al. N Engl J Med 2012; Swain et al. Lancet Oncol 2013; N Engl J Med 2015; N Engl J Med 2020). PERTAIN (NCT01491737) was the first randomized phase II trial to assess the addition of P to H + an aromatase inhibitor (AI) ± induction chemotherapy for the first-line treatment of pts with HER2-positive and hormone receptor-positive MBC or locally advanced BC (LABC). PERTAIN met its primary PFS endpoint at 31 months' median follow-up, with a potentially enhanced effect in some groups, such as pts who did not receive induction chemotherapy (Rimawi et al. J Clin Oncol 2018). We present the final analysis at more than 6 years' median follow-up, including updated PFS, mature OS (secondary endpoint), and updated safety. **Methods** Pts were randomized 1:1 to P + H + AI (Arm A) or H + AI (Arm B). P was given as an 840 mg intravenous (IV) loading dose followed by 420 mg every 3 weeks (q3w); H IV, at 8 mg/kg followed by 6 mg/kg q3w; anastrozole, at 1 mg daily; or letrozole, at 2.5 mg daily. Induction IV chemotherapy with T q3w or weekly paclitaxel could be given for 18-24 weeks at the investigator's discretion before the start of endocrine therapy. Treatment was given until disease progression or unacceptable toxicity. Pts were stratified by induction chemotherapy (yes/no) and time since adjuvant hormone therapy (<12 months, ≥12 months, no adjuvant hormone therapy). Time-to-event endpoints were analyzed using Kaplan-Meier methods. **Results** Pts were randomized across 71 sites and 8 countries between Feb 2012 and Oct 2014. Intent-to-treat populations were 129 pts per arm; safety populations, 127 and 124 in Arms A and B, respectively; induction chemotherapy was received by 75 and 71 pts, respectively. Baseline demographics and disease characteristics were generally balanced between arms. Efficacy results are shown in the table. One hundred twenty-two pts per arm reported adverse events (AEs) at any grade (96.1% in Arm A; 98.4% in Arm B); 72 (56.7%) and 51 pts (41.1%) had grade ≥3 AEs, the most common grade ≥3 AEs (≥5.0%; Arm A vs. Arm B) being hypertension (11.8% vs. 10.5%), diarrhea (9.4% vs. 2.4%), and neutropenia (3.1% vs. 7.3%).

	Arm A	Arm B
Median PFS, mo HR (95% CI)		
ITT	21	16
	0.7 (0.5-0.9) p=0.006	
With induction	17	17
	0.7 (0.5-1.0) p=0.08	
No induction	27	12
	0.7 (0.4-1.0) p=0.07	
Median OS, mo HR (95% CI)		
ITT	60	57
	1.1 (0.7-1.5) p=0.8	
With induction	59	66
	1.2 (0.7-1.9) p=0.5	
No induction	65	54
	0.9 (0.5-1.6) p=0.7	
CI, confidence interval; HR, hazard ratio; ITT, intent-to-treat; mo, months.		

**Conclusions** With a median follow-up of more than 6 years at final analysis, the PFS benefit of adding P to H + an AI was maintained. OS was similar between arms. A potentially enhanced treatment effect was observed by addition of P to H + an AI in pts who did not receive induction chemotherapy after randomization. There were no new safety concerns at final analysis. Overall, PERTAIN provides additional evidence on the role of P + H in the first-line treatment of HER2-positive MBC/LABC and suggests that some pts benefit from P + H + AI without induction chemotherapy.

A randomised phase IB/IIA study of CApecitabine plus Radium-223 in breast cancer patients with BONE metastases (CARBON) - Safety and preliminary efficacy findings

Matthew Winter<sup>1</sup>, Jessica Kendall<sup>2</sup>, Sarah Brown<sup>2</sup>, Emma Rathbone<sup>3</sup>, Caroline Wilson<sup>1</sup>, Sacha Howell<sup>4</sup>, Chris Twelves<sup>5</sup>, Carlo Palmieri<sup>6</sup>, Anjana Anand<sup>7</sup>, Iain MacPherson<sup>8</sup>, Rob Coleman<sup>9</sup> and Janet Brown<sup>9</sup>. <sup>1</sup>Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom<sup>2</sup>CTRU, University of Leeds, Leeds, United Kingdom<sup>3</sup>Calderdale and Huddersfield NHS Foundation Trust, Huddersfield, United Kingdom<sup>4</sup>The Christie NHS Foundation Trust, Manchester, United Kingdom<sup>5</sup>St James's University Hospital, Leeds, United Kingdom<sup>6</sup>Clatterbridge Cancer Centre NHS Foundation Trust, Liverpool, United Kingdom<sup>7</sup>Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom<sup>8</sup>Institute of Cancer Sciences, University of Glasgow, Glasgow, United Kingdom<sup>9</sup>The University of Sheffield, Sheffield, United Kingdom

**Background:** Bone metastases (BMs) occur in approximately 70% of patients (pts) with metastatic breast cancer (MBC). Despite significant advances in the management of BMs with bone-targeted agents and the associated reduction in skeletal-related events, there remains an unmet need for further treatment options to improve median overall survival beyond 2-3 years. Radium-223 [R] dichloride is an alpha-emitting radiopharmaceutical that is avidly taken up, like calcium, into the bone where it emits high-energy, short-range alpha-particles resulting in a targeted anti-tumour effect on BMs. Combining R with current systemic therapy could potentially enhance efficacy in MBC with BMs. **Methods:** CARBON is a UK, open-label, multi-centre phase IB/IIA study evaluating the combination of capecitabine [C] (1000mg/m<sup>2</sup> bd days 4-17, 12x21 day cycles) with R 55kBq/kg day 1 given on a 6-weekly schedule in pts with BMs from MBC (+/- other sites of disease) with ≥2 bone lesions on radionuclide bone scan and/or ≥1 lesion confirmed on plain radiographs, CT or MRI. Other eligibility criteria included ECOG PS 0-2, ≤ 2 lines of chemotherapy for MBC and current use of a bisphosphonate / denosumab for ≥6 weeks. To establish the feasibility and safety of C+R the phase IB opened in August 2016 registering 6 pts; the primary endpoint was dose-limiting toxicities (DLTs), defined as ≥grade 3 gastrointestinal toxicity lasting >48 hours or ≥grade 4 haematological toxicity lasting >7 days. Subsequently, between April 2017 and March 2019 28 pts were randomised (2:1) to C+R vs C in phase IIA to further characterise the safety profile, with frequency of CTC grade 3-4 toxicities and diarrhoea as primary endpoints. Preliminary evaluation of efficacy through assessment of bone turnover marker changes from baseline to end of cycle 5 and time to progression in bone and overall was made. **Results:** Baseline clinico-pathologic characteristics and prior treatments were well balanced between the arms; 13 C+R and 9 C pts had visceral metastases. There were 0 DLTs in the 6 phase IB pts, therefore the same C+R dose and schedule was studied in phase IIA. 2 pts randomised to C+R received C alone and are included in the C arm. The safety population consists of 34 pts (23 C+R, 11 C). Median number of cycles received was 8.5 (range 3-12) in C+R arm and 12 (range 1-12) in C arm. 38/307 (12%) treatment cycles were delayed (25 [13%] C+R arm, 13 [12%] C arm). 11 (48%) C+R and 6 (55%) C pts had a permanent C dose reduction. 94/95 (99%) prescribed R cycles were administered. 9 (39%) C+R and 9 (82%) C pts completed all 12 cycles. Other reasons for discontinuation were: progressive disease in 12 (52%) C+R and 0 in C pts; toxicity in 1 (4%) C+R and 1 (9%) C pt; clinician decision in 1 (9%) C pt; progressive disease and toxicity in 1 (4%) C+R pt. Only 25/575 (4%) reported AEs were grade 3-4 (n=21 in 11 [48%] C+R pts, n=4 in 4 [36%] C pts) with 0 episodes of grade 3-4 diarrhoea. Table 1 shows maximum grades of diarrhoea and haematological AEs experienced by arm. 18 SAEs occurred (n=11 in 8 C+R pts, n=7 in 2 C pts). 8 (44%) SAEs were grade 3 (C+R: 6, C: 2); none were related to diarrhoea. There were 0 SUSARs. **Conclusion:** In the first completed trial evaluating R with chemotherapy in MBC pts, the combination of C+R is safe and well-tolerated. Preliminary efficacy analyses including bone markers are ongoing and will be presented at the meeting. The creation of the data was supported in part by Bayer Plc and Yorkshire Cancer Research.

Table 1: Maximum CTCAE grade (G) experienced - diarrhoea and haematological AEs.

			C+R (n=23)					C (n=11)			
	Not experienced	G1	G2	G3	G4	Not experienced	G1	G2	G3	G4

Estrogen-induced cell cycle arrest as an unexpected outcome of aromatase inhibitor-resistance: Insights from single-cell trajectory analysis of a patient-derived xenograft model

Hitomi Mori, Kohei Saeki, Gregory Chang, Xiwei Wu, Pei-Yin Hsu, Noriko Kanaya, George Somlo and Shiuan Chen. City of Hope, Duarte, CA

**Background:** Estrogen such as estradiol (E2) is known to promote ER<sup>+</sup> breast cancer. However, several clinical trials reported the unexpected therapeutic benefit of E2 for aromatase inhibitor (AI)-resistant cases of ER<sup>+</sup> postmenopausal breast cancer. The objective of this study is to uncover the mechanisms of E2-induced tumor regression, leading to an unconventional treatment of AI resistance. **Methods:** An E2-suppressive patient-derived xenograft model (named GS3) was established from an AI resistant ER<sup>+</sup>/PR<sup>+</sup>/HER2<sup>-</sup> brain metastatic breast cancer. Placebo or E2 pellets were implanted in mice carrying GS3 for evaluating the effects of E2. Immunohistochemistry (IHC) and RNA sequencing of GS3 were conducted to decipher molecular changes after E2 treatments. Since the cancer tissue has a heterogeneous structure, the single-cell analysis was further performed to examine gene expression profiles in individual cells. In addition, *in vitro* cell proliferation analysis was carried out using organoids from GS3. **Results:** E2 inhibited the growth of GS3 both *in vivo* and *in vitro*. ER $\alpha$  and ER $\beta$  genes in GS3 are wild-type and not amplified. ER $\alpha$  is involved because E2-mediated inhibition of GS3-organoids can be reversed by the co-treatment of ER $\alpha$  antagonist, not by ER $\beta$  antagonist. IHC showed that ER, Ki-67 and CEA expressions decreased and PR expression appeared after E2 treatment. Gene set enrichment analysis (GSEA) using RNAseq results showed that the E2 response gene sets were significantly up-regulated after E2 treatment. However, the cell cycle gene sets and the TNFA/NFkB gene set were down-regulated. GS3 gained an E2 independence after three cycles of intermittent E2 treatment (E2 pellet on/off every 4 weeks; Int-E2). Interestingly, the cell cycle and TNFA/NFkB gene sets were up-regulated after Int-E2 treatment. Single-cell RNAseq analysis revealed that cells from one-week E2-treated and Placebo-treated GS3 were placed in different clusters based on principle component analysis of Highly Variable Genes. Although E2 response genes were up-regulated, the percent of *ESR1*<sup>+</sup> cells decreased after E2 treatment (41.3% vs. 31.5%). The number of cells arrested at the G1 phase increased (+12.5%) after E2 treatment. GSEA using genes expressed in only *ESR1*<sup>+</sup> cells showed that the TNFA/NFkB gene set was significantly down-regulated after E2 treatment. Meanwhile, GSEA using genes expressed in only *ESR1*<sup>-</sup> cells showed that cell cycle gene sets were significantly down-regulated. Single-cell trajectory analysis disclosed three major branches; 1) common E2 and placebo, 2) E2, and 3) placebo. In the E2 only branch, the cell cycle arrested at the G1 phase, the E2 response gene sets were up-regulated, and the NFkB gene set was down-regulated in *ESR1*<sup>+</sup> cells. Significantly, E2 response gene sets were also up-regulated and cell cycle genes were down-regulated even in *ESR1*<sup>-</sup> cells. In the placebo branch, E2 response gene sets were not up-regulated and cell cycle genes were not down regulated. A group of *MKI67*<sup>+</sup> cells (at G2M phase), including some *ESR1*<sup>+</sup> cells, were present in both E2-treated and placebo-treated tumors. **Conclusions:** E2-induced suppression is an unexpected outcome of AI resistance. In these cases, elimination of estrogen by AI results in maintaining tumor growth. Analysis of GS3 PDX has revealed that estrogen can induce cell cycle arrest and the expression of estrogen-regulated genes. Our results also suggest the cross-talk between *ESR1*<sup>+</sup> and *ESR1*<sup>-</sup> cells as well as potential roles of the TNFA/NFkB pathway. Our findings point out the need of markers for such patients who can benefit from E2 treatment after AI resistance, and measurements of ER and PR expression are not sufficient. An intermittent treatment strategy does not sustain the effect of estrogen-mediated suppression.

Chronic interpersonal stress predicts depressive outcomes in the first year of invasive breast cancer: Moderation by the serotonin-transporter polymorphism

Jacqueline HJ Kim<sup>1</sup>, Steve W Cole<sup>1</sup>, Karen L Weihs<sup>2</sup> and Annette L Stanton<sup>1</sup>. <sup>1</sup>UCLA, Los Angeles, CA; <sup>2</sup>University of Arizona, Tucson, AZ

**Background:** Depression in cancer patients predicts lower survival, and early identification of individuals at highest risk for depression is needed. In the general population, depression is higher in contexts of both childhood adversity and chronic interpersonal stress, but their collective influence on depressive outcomes in the first year after breast cancer diagnosis is unknown. Genetic polymorphisms related to socioemotional functioning (e.g., the serotonin transporter) may moderate the associations among childhood adversity, chronic interpersonal stress, and depressive outcomes, specifying which women are most at risk.

**Methods:** 460 women with invasive breast cancer were assessed for depressive symptoms and major depressive episodes (MDEs) seven times across one year. Associations between depressive symptoms and childhood adversity, chronic interpersonal stress, and the 5-HTTLPR polymorphism were examined. We used multilevel modeling for predicting longitudinal depressive symptoms, logistic regression for predicting any MDEs over the year, and multinomial logistic regression for predicting odds of belonging to Low/Recovery/High depressive symptom trajectory classes (Stanton et al., 2015). Models controlled for known sociodemographic and clinical confounding variables such as age, ethnicity, SES, cancer stage, treatments received, medical comorbidities, history of depression, and neuroticism.

**Results:** Higher chronic interpersonal stress predicted greater depressive symptoms at study entry ( $b=4.56$ , 95% CI [2.60, 6.52]), greater odds for belonging to a High vs. Low depressive trajectory class (OR=3.16, [1.53, 6.51]), and greater odds of having an MDE (OR=2.28, [1.10, 4.73]). 5-HTTLPR moderated the influence of chronic interpersonal stress on depressive symptoms over time ( $b=0.24$ , [0.06, 0.41]), with no decline in symptoms for SS genotype women under high chronic interpersonal stress vs. significant improvement in symptoms despite high chronic interpersonal stress for LL/LS genotype women. There were no significant effects of childhood adversity on depressive outcomes considered.

**Conclusion:** Women with greater chronic interpersonal stress are at risk for high, unrelenting depressive symptom trajectories and MDEs in the first year after invasive breast cancer diagnosis. Unchanged depressive symptoms across the year were most pronounced for women bearing the SS allele of the 5-HTTLPR polymorphism. Women with high chronic interpersonal stress and the SS genotype may benefit from early intervention to prevent depression after breast cancer diagnosis.

12 year results of anastrozole versus tamoxifen for the prevention of breast cancer in postmenopausal women with locally excised ductal carcinoma in situ

Ivana Sestak<sup>1</sup>, Jack Cuzick<sup>1</sup>, Bernardo Bonanni<sup>2</sup>, Nigel Bundred<sup>3</sup>, Christelle Levy<sup>4</sup>, Sibylle Loib<sup>5</sup>, Patrick Neven<sup>6</sup>, Michael Stierer<sup>7</sup>, Chris Holcombe<sup>8</sup>, Robert Coleman<sup>9</sup>, John Forbes<sup>10</sup> and Anthony Howell<sup>3</sup>. <sup>1</sup>Centre for Cancer Prevention, London, United Kingdom<sup>2</sup>Istituto Europeo di Oncologia, Milan, Italy<sup>3</sup>University of Manchester, Manchester, United Kingdom<sup>4</sup>Centre Francois Baclesse, Caen, France<sup>5</sup>German Breast Group, Frankfurt, Germany<sup>6</sup>UZ Leuven, Leuven, Belgium<sup>7</sup>Austrian Breast and Colorectal Cancer Study Group, Vienna, Austria<sup>8</sup>Royal Liverpool University Hospital, Liverpool, United Kingdom<sup>9</sup>University of Sheffield, Sheffield, United Kingdom<sup>10</sup>Breast Cancer Trials, Newcastle, Australia

**Background:** Two large clinical trials have reported divergent results in their initial analysis of the benefit of aromatase inhibitors compared to tamoxifen in women with ductal carcinoma in situ (DCIS) (IBIS-II and NSABP B-35). Here, we report blinded 12-year median follow-up efficacy and adverse event data for the IBIS-II trial, which compared anastrozole to tamoxifen in women with hormone receptor positive DCIS and focus on the post-treatment follow-up period. **Methods:** A multi-centre randomised trial of 1mg/day anastrozole (N=1471) vs. 20mg/day tamoxifen (N=1509) for five years was conducted in postmenopausal women with locally excised DCIS diagnosed between 2003 and 2009. The primary objective of this analysis was to determine the efficacy of anastrozole compared to tamoxifen in preventing recurrences overall, and in particular in the post 5-year treatment period. Secondary endpoints included type of recurrence, breast cancer mortality, other cancers, cardiovascular disease, fractures, adverse events and non-breast cancer deaths. **Results:** After a median follow-up of 11.6 years (IQR 9.9 to 13.4), a total of 221 breast cancer recurrences (7.4%) have been recorded. No difference in overall recurrence was observed (102 (6.9%) anastrozole vs. 119 (7.9%) tamoxifen; HR=0.87 (0.67-1.14), P=0.32) overall (Table), in the 5-year treatment period (HR=0.82 (0.53-1.27), P=0.37), or the post treatment follow-up period (HR=0.91 (0.65-1.27), P=0.57). Oestrogen receptor (ER) positive breast cancers were reduced by 28% with anastrozole when compared to tamoxifen (58 vs. 82; HR=0.72 (0.52-1.01), P=0.056) but this did not reach significance. In contrast, no effect was observed for ER-negative breast cancer with anastrozole (Table). No significant difference for the reduction in invasive breast cancer recurrence was observed with anastrozole when compared to tamoxifen (Table). Invasive ER-positive breast cancer was non-significantly reduced by 24% with anastrozole when compared to tamoxifen (44 vs. 59; HR=0.76 (0.51-1.12), P=0.17). A total of 127 deaths have been reported, with no significant difference in all-cause mortality between the two treatment arms (61 vs. 66; HR=0.94 (0.67-1.33), P=0.74). Only 7 deaths from breast cancer (3 vs. 4) were reported, with so few deaths from breast cancer at 12 years, any impact on survival is unlikely to emerge with longer follow-up. 214 cancers other than breast were reported, with a non-significant decrease observed with anastrozole (97 vs. 117, OR=0.84 (0.63-1.12), P=0.22). Endometrial (2 vs. 13, OR=0.16 (0.02-0.69)), ovarian cancer (1 vs. 9, OR=0.11 (0.003-0.82)), and non-melanoma skin cancer (11 vs. 21) were less common with anastrozole. Significantly higher rates of fractures (181 vs. 145, OR=1.32 (1.04-1.68)) and transient ischaemic attacks (15 vs. 5, OR=3.10 (1.07-10.92)) were observed with anastrozole compared to tamoxifen. A comprehensive adverse event profile will be reported.

**Conclusions:** No clear efficacy differences were seen between the two treatments, although the data suggests possible greater efficacy for anastrozole over tamoxifen for prevention of ER-positive breast cancers. There were some clear differences in adverse events and anastrozole may be more appropriate for some women with contraindications for tamoxifen. **Table:** Number of events and Hazard Ratios (95% CI) according to treatment allocation.

	Anastrozole(N=1471)	Tamoxifen(N=1509)	HR (95% CI)
Any recurrence	102	119	0.87 (0.67-1.14)
ER-positive	58	82	0.72 (0.52-1.01)
ER-negative	24	15	1.63 (0.86-3.11)
Invasive	66	76	0.89 (0.64-1.23)
ER-positive	44	59	0.76 (0.51-1.12)
ER-negative	17	12	1.44 (0.69-3.02)
DCIS	35	42	0.85 (0.54-1.33)
ER-positive	14	23	0.62 (0.32-1.21)
ER-negative	7	3	2.38 (0.61-9.20)

Cx3cl1-cx3cr1 axis in liver metastasis of triple negative breast cancer

Woohang Heo<sup>1</sup>, Hye-Youn Son<sup>2</sup>, Ju hee Kim<sup>2</sup>, Kyu Jin Lee<sup>1</sup>, Myeonghee Jeon<sup>1</sup>, Songbin Li<sup>1</sup>, Jeehee Jang<sup>2</sup>, Dong-Young Noh<sup>3</sup>, Wonsik Han<sup>3</sup> and Hyeong-Gon Moon<sup>3</sup>. <sup>1</sup>Interdisciplinary Program on Tumor Biology, Seoul National University College of Medicine, Seoul, Korea, Republic of<sup>2</sup>Center for Medical Innovation, Seoul National University Hospital, Seoul, Korea, Republic of<sup>3</sup>Department of Surgery, Seoul National University Hospital, Seoul, Korea, Republic of

Triple negative breast cancer (TNBC) is a breast cancer subtype with increased risk of distant metastasis, especially to visceral organs. However, the detailed molecular mechanism underlying the visceral metastasis of TNBC is unknown. We used three patient-derived xenograft models derived from TNBC tumors with different metastatic capacities. PDX1 and PDX2 model developed distant metastasis in only lung and liver, respectively. In contrast, PDX3 tumor metastasized to both lung and liver. RNA sequencing of the primary tumor and distant metastatic sites of these three PDX models was performed. The gene expression profiles of the primary tumors of the three models showed minimally overlapping genes. However, the microenvironment gene expression profiles, measured by using the sequencing reads aligned to mouse genome, showed distinct difference between the models. Among the differentially expressed genes, we identified Cx3cr1 as a significantly upregulated gene in the liver microenvironment of the PDX models that metastasized to liver. Next, we used 4T1 syngeneic mouse mammary carcinoma model to validate the Cx3cr1 in the mouse liver tissues. Interestingly, the Cx3cr1 up-regulation occurred during the pre-metastatic period, and Cx3cl1, the ligand of the Cx3cr1, was also up-regulated in the liver tissue prior to the development of metastasis suggesting the Cx3cr1 regulates the formation of pre-metastatic niche. Cx3cl1, the ligand of the Cx3cr1, was also up-regulated in the liver tissue prior to the development of metastasis. These data suggest that Cx3cl1 and Cx3cr1-mediated tumor-microenvironment interaction is critical in developing liver metastasis in TNBC. Cx3cl1 increased the invasion and migration of Raw264.7 monocyte/macrophage cells and this effect was abrogated by the Cx3cr1 silencing in Raw264.7 cells or treating Cx3cl1 neutralizing antibody. Pathway analysis of the RNA sequencing data showed that genes involved in extracellular matrix remodeling was significantly dysregulated in the liver tissues including Lysyl Oxidase (Lox). Cx3cl1 treatment in Raw264.7 cells resulted in increased expression of Lox and MMP9 mRNA in three-dimensional culture system. The Raw264.7 cells caused increased invasion of 4T1 cells in vitro. In conclusion, our data suggest that Cx3cl1-Cx3cr1 axis plays critical role during the liver metastasis of TNBC.

Treatment exposure and discontinuation in the PALLAS trial: PALbociclib CoLlaborative Adjuvant Study of palbociclib with adjuvant endocrine therapy for HR+/HER2- early breast cancer

Erica L. Mayer<sup>1</sup>, Christian Fesl<sup>2</sup>, Amylou Dueck<sup>3</sup>, Michael Gnant<sup>4</sup>, Angela DeMichele<sup>5</sup>, on behalf of the PALLAS study team. <sup>1</sup>Dana-Farber Cancer Institute, Boston, MA; <sup>2</sup>Austrian Breast and Colorectal Cancer Study Group, Vienna, Austria; <sup>3</sup>Mayo Clinic Scottsdale, Scottsdale, AZ; <sup>4</sup>Medical University of Vienna, Vienna, Austria; <sup>5</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA

**Background:** Adherence to and tolerability of oral agents for the treatment of hormone receptor positive (HR+) breast cancer in the adjuvant setting may be challenging and can limit drug exposure. Palbociclib (P) is an oral CDK4/6 inhibitor; P in combination with endocrine therapy (ET) has demonstrated efficacy in HR+/HER2- negative (HER2-) metastatic breast cancer (MBC). The global PALLAS study (NCT02513394) was designed to determine if the addition of P to adjuvant ET improves outcomes over ET alone in early breast cancer. The goal of this analysis is to describe P exposure and discontinuation in PALLAS, and explore any impact on study endpoints. **Methods:** Pts with stage II-III HR+/HER2- disease were randomized to receive 2 years of P (starting dose 125 mg daily, 3 weeks on, 1 week off) in combination with adjuvant ET (Arm A) or ET alone (Arm B). The primary objective was to compare invasive disease-free survival (iDFS) between arms; secondary endpoints included safety, quality of life, adherence, and translational science. Dose adjustments were defined per protocol in the setting of emergent toxicity. Continuous monitoring of toxicity, dose modifications, and early discontinuations was performed throughout the trial. Statistical analysis included tabulation of dose levels/reductions and reasons for treatment discontinuation, as well as landmark analysis comparing iDFS between those receiving  $\geq 12$  months (mo) vs  $< 12$  mo of P. Ongoing analyses include exploration of relative dose intensity and modeling of P dose intensity/duration and impact on iDFS. **Results:** A total of 5760 pts were randomized; 83% had received prior chemotherapy; 68% initiated aromatase inhibitor and 33% tamoxifen, with or without ovarian suppression. Grade 3/4 neutropenia was more common in Arm A vs B (62% vs 0.4%); febrile neutropenia was uncommon (1%). Other all-grade adverse events (AEs) more common in Arm A included other hematologic toxicity, fatigue, upper respiratory infection, nausea, diarrhea, and alopecia. A total of 55% of pts required P dose reduction to 100mg, and 34% to 75 mg, at some point during treatment. At a median follow-up of 23.7 mo at the second interim analysis, no significant difference in iDFS was observed between the arms (3-year iDFS of 87.9% vs 88.4%, HR 0.93, 95% CI 0.76, 1.15); consequently, pts in Arm A stopped P, and all pts moved to long-term follow-up. At time of data cut-off, 32% had completed the planned 2 years of P, 26% were still receiving P, and 42% had discontinued P prematurely. P discontinuation was 18% at 6 mo, 30% at 12 mo, 38% at 18 mo, and 45% projected at 24 mo. A total of 27% of Arm A pts (770 of 2840) discontinued therapy due to AEs, primarily neutropenia (460, 16%) and fatigue (71, 3%). Other reasons for P discontinuation included non-compliance (128, 5%), recurrent disease or second malignancy (104, 4%), or withdrawal of consent (100, 3%). Last observed dose level was 125mg, 100mg, and 75mg for 45%, 22%, and 33% pts, respectively. Among those discontinuing due to AEs, dose level at time of discontinuation was 75mg for 62%, suggesting some discontinuations occurred without maximum dose reduction. Pts who received  $\geq 12$  mo of P had a 2-year iDFS of 96.6%; those receiving  $< 12$  mo had 2-year iDFS of 95.7% (HR 0.86, 95% CI 0.55-1.34). **Conclusions:** An early analysis of PALLAS has demonstrated that 2 years of adjuvant P in combination with adjuvant ET did not improve iDFS when compared with ET alone in pts with HR+/HER2- breast cancer. While 2 years of adjuvant P was feasible for the majority of pts, 42% discontinued P early, primarily for AEs. Further data examining drug discontinuations and relationships between drug exposure and clinical outcomes will be presented, expanding upon initial point estimates suggestive of a possible explanation of trial results.

Personalized ctDNA as a predictive biomarker in high-risk early stage breast cancer (EBC) treated with neoadjuvant chemotherapy (NAC) with or without pembrolizumab (P)

Mark Jesus M Magbanua<sup>1</sup>, Denise Wolf<sup>1</sup>, Derrick Renner<sup>2</sup>, Svetlana Shchegrova<sup>2</sup>, Lamorna Brown Swigart<sup>1</sup>, Christina Yau<sup>1</sup>, Gillian Hirst<sup>1</sup>, Hsin-Ta Wu<sup>2</sup>, Ekaterina Kalashnikova<sup>2</sup>, Antony Tin<sup>2</sup>, Amy Delson<sup>1</sup>, Douglas Yee<sup>3</sup>, Angela DeMichele<sup>4</sup>, Raheleh Salari<sup>2</sup>, Angel Rodriguez<sup>2</sup>, Bernhard Zimmermann<sup>2</sup>, Himanshu Sethi<sup>2</sup>, Alexey Aleshin<sup>2</sup>, Paul Billings<sup>2</sup>, Laura Esserman<sup>1</sup>, Minetta Liu<sup>5</sup>, Rita Nanda<sup>6</sup>, Laura van 't Veer<sup>1</sup>, I-SPY 2 Investigators. <sup>1</sup>University of California San Francisco, San Francisco, CA; <sup>2</sup>Natera, Inc., San Carlos, CA; <sup>3</sup>University of Minnesota, Minneapolis, MN; <sup>4</sup>University of Pennsylvania, Philadelphia, PA; <sup>5</sup>Mayo Clinic, Rochester, MN; <sup>6</sup>University of Chicago, San Francisco, CA

**Background:** In the I-SPY 2 TRIAL, the addition of P to standard NAC resulted in more than doubling of the pathologic complete response (pCR) rates for both hormone receptor-positive (HR+)/HER2- and triple-negative (TN) early breast cancer (EBC) patients (pts) compared to NAC only (Nanda et al, JAMA Oncol, 2020). At 3 years, distant recurrence-free survival (DRFS) rates in pts with pCR following NAC+P was >95%. We hypothesized that ctDNA can serve as a predictive biomarker of response and survival in pts treated with NAC.

**Methods:** A personalized ctDNA test (Signatera) was performed on 511 serial plasma samples from 138 pts with high-risk HR+/HER2- (n=77) or TN (n=61) stage II/III EBC. Pts received P with paclitaxel (Tx) followed by AC (P arm, n=42) or standard NAC only (n=96), an exploratory subset of pts evaluated for P efficacy. Plasma was collected; pretreatment (T0), 3 weeks after treatment initiation (T1), between Tx+/-P and AC regimens (T2), and prior to surgery (T3). ctDNA was deemed positive with a minimum of 2 of the pt specific tumor mutation fragments detected in cfDNA. Association of ctDNA with response and survival was analyzed using logistic and Cox regressions with pCR and DRFS as endpoints. Median follow-up was 2.8 years.

**Results:** Detection of ctDNA decreased over time (P arm: T0-81%, T1-50%, T2-19%, T3-3%) and NAC only: T0-82%, T1-65%, T2-26%, T3-10%). ctDNA data at T0 and T1 was available for 96% (132/138) of pts in P arm or NAC only (Table). Among ctDNA+ patients at baseline, clearance at T1 was significantly associated with pCR (OR=1.92, ctDNA+/-; OR=0.27, ctDNA+/-; LR p<0.001). This association remained significant after adjustment for HR status and treatment (LR p<0.001) and P arm or NAC only (P: LR p=0.03; NAC: LR p=0.01).

ctDNA data at T0, T1, and T2 was available for 86% (118/138) pts. (Table). Among all ctDNA+ pts at baseline, dynamics through T2 was associated with pCR (OR=1.44, ctDNA+/-/-; OR=0.33, ctDNA+/-/-, OR=0.12, ctDNA+/-/+; LR p=0.0011). This association remained significant when adjusted for HR status and treatment (LR p<0.001). Analysis within individual treatments showed significant association for NAC (LR p=0.040) and a non-significant trend in NAC+P (LR p=0.063), likely due to smaller sample size.

All pts who achieved pCR were ctDNA- at T3 (n=34). Among those who failed to achieve pCR (n=81), DRFS was significantly better in ctDNA- (n=72/81; 20 in P and 52 in NAC) versus ctDNA+ pts (n=9/81; 1 in P and 8 in NAC) (adjusted HR 0.13; 95% CI 0.05-0.37).

**Conclusions:** These exploratory results align with our previous findings that early clearance of ctDNA during NAC treatment was significantly associated with increased likelihood of achieving pCR. Additionally, we show that ctDNA clearance can be an early surrogate marker for therapy response assessment. Residual ctDNA after neoadjuvant treatment was a significant predictor of metastatic recurrence and death. Personalized monitoring of ctDNA during the course of NAC is feasible and provides information that can be combined with imaging and pathology, and may help to optimize decision making for de-escalation or escalation of therapy. Larger studies are ongoing.

**Background:** The FDA approved neratinib (N), an irreversible pan-HER tyrosine kinase inhibitor, in combination with capecitabine (C) for patients with HER2+ advanced or metastatic breast cancer who have received ≥2 prior HER2-directed regimens in the metastatic setting based on the NALA clinical study, where N+C significantly improved PFS vs. lapatinib (L)+C. Characterizing HRQoL associated with this regimen can help inform treatment decision-making for these patients. The objective of this analysis was to characterize HRQoL among patients with HER2+ metastatic breast cancer from the NALA clinical study.

**Methods:** NALA was a multinational, randomized, open-label, phase III clinical study of N+C vs. L+C in patients with HER2+ metastatic breast cancer and ≥2 prior HER2-directed regimens. From May 2013 to July 2017, patients were randomized 1:1 to N (240 mg qd) + C (750 mg/m<sup>2</sup> bid 14d/21d) with loperamide prophylaxis during the first cycle, or to L (1250 mg qd) + C (1000 mg/m<sup>2</sup> bid 14d/21d). HRQoL, a prespecified secondary endpoint of the NALA study, was measured using the EORTC QLQ-C30 and the breast cancer-specific QLQ-BR23 at baseline and every 6 weeks (±3 days) until the end of treatment (data collection through treatment cycle 19, 12.5 months). The QLQ-C30 summary and global health status scores range from 0 (worst) to 100 (best) and the systemic therapy side-effects scores range from 0 (best) to 100 (worst). Patients were included in the analysis for a particular scale if they had a baseline assessment and at least 1 follow-up assessment. For these analyses, a change of ≥10 points was considered to be clinically meaningful. Descriptive statistics summarized observed scores and changes from baseline, Kaplan-Meier and log-rank tests were used for time-to-deterioration (TTD) of ≥10 points and mixed models estimated the change over time for 7 prespecified scales: QLQ-C30 summary score, global health status, physical functioning, fatigue, constipation and diarrhea, and the EORTC QLQ-BR23 systemic therapy side effects subscale. No adjustments for multiplicity were performed.

**Results:** 621 patients from 28 countries were randomized (307 N+C; 314 L+C). The mean completion rate of the QLQ-C30 over the course of the study was 91% for both treatment arms. Discontinuation due to any treatment-emergent adverse event (TEAE) was lower in the N+C vs. L+C arm (14% vs. 18%). At baseline, the mean (SD) QLQ-C30 summary scores were 79.8 (14.1) for N+C and 79.9 (15.7) for L+C. After 19 treatment cycles, the mean (SD) QLQ-C30 summary scores were similar to baseline scores: 81.8 (16.7) for N+C and 81.3 (15.3) for L+C. There were no differences in TTD of ≥10 points for the QLQ-C30 summary score between treatment arms; the HR for N+C vs. L+C was 0.94 (95% CI 0.63-1.40). All prespecified HRQoL subscales had similar statistically non-significant results for TTD with the exception of diarrhea (HR=1.71; 95% CI 1.32-2.23). The mixed models analyzing change in HRQoL from baseline did not demonstrate persistent declines nor meaningful differences between the treatment arms.

**Conclusion:** In these results from the NALA study, among patients with HER2+ metastatic breast cancer, at study end and throughout most of the study, there were no differences observed between the two treatment arms in HRQoL scores. HRQoL was sustained over the study period despite the early transient presence of diarrhea in some patients. Discontinuation due to any TEAE was lower in the N+C vs. the L+C arm. These results may help guide healthcare providers, patients and carers in selection of optimal treatment for HER2+ metastatic breast cancer.

Comprehensive comparative analysis of invasive ductal and lobular breast cancer cases in great lakes breast cancer consortium

Steffi Oesterreich<sup>1</sup>, Azadeh Nasrazadani<sup>2</sup>, Jian Zou<sup>3</sup>, Tiffany Onger<sup>4</sup>, Matthew Wright<sup>5</sup>, George Tseng<sup>3</sup>, Bhuvana Ramaswamy<sup>6</sup>, Adrian V Lee<sup>1</sup>, Nicole Williams<sup>7</sup> and Megan Kruse<sup>4</sup>. <sup>1</sup>UPMC Hillman Cancer Center, University of Pittsburgh, Magee Womens Research Institute, Pittsburgh, PA; <sup>2</sup>UPMC Hillman Cancer Center, Pittsburgh, PA; <sup>3</sup>University of Pittsburgh, Pittsburgh, PA; <sup>4</sup>Cleveland Clinic Taussig Cancer Institute, Cleveland, OH; <sup>5</sup>Cleveland Clinic Taussig Cancer Institute, Cleveland, PA; <sup>6</sup>James Cancer Hospital/The Ohio State University Wexner Medical Center (OSU), Columbus, OH; <sup>7</sup>James Cancer Hospital/The Ohio State University Wexner Medical Center (OSU), Columbus, PA

**Background:** Invasive lobular breast cancer (ILC) is the second most common histologic subtype of breast cancer following invasive ductal cancer (IDC). ILC accounts for ~10-15% of all breast cancers (~26-40,000 cases annually in the US) and ranks as the 6<sup>th</sup> most common cancer in women in the US. While there is increasing recognition that ILC has distinct clinical, histologic, molecular, and biological characteristics compared to IDC, it remains understudied. There are very few large cohort analyses comparing clinic-pathological features of ILC, and therefore we performed a large multi-institutional retrospective cohort study. **Methods:** Investigators from UPMC Hillman Cancer Center, James Cancer Hospital/OSU, and Cleveland Clinic Taussig Cancer Institute/CWRU formed the Great Lakes Breast Cancer consortium, and worked with their respective cancer registries to collect comprehensive data on patients with IDC and ILC seen at their institutions between 1990 and 2017. Descriptive statistics were performed to compare clinic-pathological features, treatments, metastases sites, and co-morbidities. Survival rates were analyzed using the Kaplan-Meier (KM) method and compared using the Cox proportional hazards model. A total of N=38,175 records (N=15,792 for UPMC, N=13,040 for CCF, and N=9,343 for OSU) were included in the study. **Results** Among the N=38,175 records, we identified N=30,100 unique IDC (not otherwise specific, NOS) (89.3%) and N=3,618 unique ILC cases (10.7%). There were no significant differences between IDC and ILC with respect to laterality of the cancer (IDC: Left 51%, Right 49%; 0.2% Other vs ILC: Left 51%, Right 48%, Other 0.5%) and body mass index (IDC: 28.4 vs ILC: 28.2). In contrast, we observed significant difference with respect to age - patients with ILC were significantly older (61.2 vs 57.5 years; p<0.0001), and there were significant differences in race (7.6% vs 9.2% African American patients in ILC vs IDC, respectively; p=0.004). Among ILC cases, there were fewer grade III tumors (11.4% vs 40.3% in IDC; p<0.0001). ILCs were more frequently stage III (16.6% vs 8.0% in IDC) and stage IV (3.7% vs 2.4% in IDC) (p<0.0001), and ILC were significantly larger than IDC (13.7% T3 vs 2.8% in IDC, p<0.0001). There was also significantly more lymph node involvement in patients with ILC (N2: 5.3% vs 4.0%; N3: 4.6% vs 1.5%) (p<0.0001). The ILC cohort had significantly fewer HER2+ cases (5.5% vs 18.1% in IDC) (p<0.0001), and the proportion of patients with a high recurrence score as determined by 21 gene recurrence score was significantly lower in ILC compared to IDC (1.7% vs 10.4% in IDC; p<0.0001). As expected, there was a significant enrichment of ER+ tumors in ILC (96.1% compared to IDC (76.6%) (p<0.0001). Age, stage, grade, ER, Her2, and lymph node involvement remained significantly associated with histology in a logistic regression analysis. KM analysis showed significantly shortened disease-free (p=0.041) and overall survival (p<0.0001) for patients with ER+ ILC (N=2,565) compared to ER+ IDC (N=17,278). The estimated 5yr and 10yr DFS rates for patients with IDC are 0.94 and 0.89, and for ILC 0.94 and 0.86, confirming prior data of late recurrences in patients with ILC. **Conclusions:** In the largest cohort of patients with ILC made possible by multi-center collaborations we show that lobular histology carries distinct prognostic implications and that outcomes are significantly worse. This highlights the need for more ILC research and clinical trials for patients with ILC.

A living biobank of normal mammary organoids derived from patients at low and increased risk of developing breast cancer

Jennifer M Rosenbluth<sup>1</sup>, Carman Man-Chung Li<sup>2</sup>, Kenneth G Gray<sup>2</sup>, Walter Gao<sup>2</sup>, Ron CJ Schackmann<sup>2</sup>, Jason J Zoeller<sup>2</sup>, Laura M Selfors<sup>2</sup>, Kaitlin Moore<sup>2</sup>, Deborah Dillon<sup>3</sup>, Judy Garber<sup>1</sup> and Joan S Brugge<sup>2</sup>. <sup>1</sup>Dana-Farber Cancer Institute, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA; <sup>3</sup>Brigham & Women's Hospital, Boston, MA

**Background:** Mutations in *BRCA1* and *BRCA2* are associated with a high risk of developing breast cancer, but the earliest molecular changes that lead to the transformation of mammary cells in the setting of *BRCA1/2* heterozygosity remain unknown. We previously demonstrated that breast organoid cultures derived from histologically normal tissues can preserve all of the major mammary epithelial lineages for further study in vitro<sup>1</sup>. In addition, organoid culture medium is fully defined, enabling modulation of the medium to enhance the growth of distinct mammary subpopulations. Here, we undertook the development of a large biobank of breast organoids derived from patients with and without increased breast cancer risk, including patients with inherited mutations in *BRCA1* and *BRCA2*. **Methods:** Breast samples with normal histology (taken from reduction mammoplasties or prophylactic mastectomies), were digested for ~2 hours using collagenase, embedded in basement membrane extract, and grown in a fully-defined organoid medium<sup>1</sup>. CyTOF profiling was performed using our previously published mammary-specific heavy metal-tagged antibody panel<sup>1</sup>. Lentiviral transduction was performed to knock-down *BRCA1* and/or overexpress mutant p53. Murine engraftment of normal breast organoids was performed by intra-ductal injection of ~1,000 organoids into NCG mice using a modification of protocols for breast cancer cell lines<sup>2</sup>, with removal of mammary glands after 3 months for detailed immunohistochemistry analysis. **Results:** A living biobank of > 100 normal breast organoids derived from patients with and without inherited mutations in breast cancer predisposition genes, including *BRCA1* and *BRCA2*, was established. Cultures were generated with high efficiency (>95%) and could be serially passaged with the longest cultures > 16 months. CyTOF profiling of organoids revealed the maintenance of multiple epithelial cell subtypes, with at least one subtype of luminal cells enriched in tissues and organoids from *BRCA1/2* mutation carriers. Protein and RNA expression patterns of breast organoids were found to correlate with patient tissues analyzed using a combination of single-cell analyses (CyTOF, single-cell RNA sequencing, and immunohistochemistry). The impact of factors present in the organoid medium on distinct mammary epithelial cell subtypes was assessed by CyTOF, enabling identification of conditions that promote expansion of cell populations that are enriched in tissues from *BRCA1/2* mutation carriers. Furthermore, normal breast cell types could be engrafted into the murine mammary gland, and could be modified by lentiviral transduction for gene transfer, enabling future studies of the tumorigenic potential of distinct normal and premalignant epithelial cell subtypes. **Conclusion:** We have shown that organoid cultures can be used to propagate normal breast tissues with high efficiency, preserve normal as well as potential premalignant breast epithelial cell types, and model methods to inhibit precancerous cells in vitro. Thus, organoids are a useful complement to murine and other models of breast cancer development, and can ultimately be used to identify potential cancer interception strategies for patients at high risk of developing breast cancer.

CelTIL score and long-term survival outcome in early stage HER2-positive (HER2+) breast cancer treated with anti-HER2-based chemotherapy: A correlative analysis of neoALTTO trial

Nuria Chic<sup>1</sup>, Stephen Luen<sup>2</sup>, Paolo Nuciforo<sup>3</sup>, Roberto Salgado<sup>2</sup>, Debora Fumagalli<sup>4</sup>, Florentine Hilbers<sup>5</sup>, Yingbo Wang<sup>6</sup>, Evandro de Azambuja<sup>7</sup>, Itsvan Lang<sup>8</sup>, Serena Di Cosimo<sup>9</sup>, Cristina Saura<sup>10</sup>, Jens Huober<sup>11</sup>, Aleix Prat<sup>1</sup> and Sherene Loi<sup>2</sup>. <sup>1</sup>Hospital Clinic of Barcelona, Barcelona, Spain<sup>2</sup>Peter MacCallum Cancer Center, Melbourne, Australia<sup>3</sup>Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain<sup>4</sup>Institut Jules Bordet, Brussels, Belgium<sup>5</sup>Breast International Group, Brussels, Belgium<sup>6</sup>Pharma AG, Basel, Switzerland<sup>7</sup>Institut Jules Bordet and l'Universite Libre de Bruxelles (U.L.B), Brussels, Belgium<sup>8</sup>National Institute for Oncology Rath Gyorgy., Budapest, Hungary<sup>9</sup>SOLTI Group, Barcelona, Spain<sup>10</sup>Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain<sup>11</sup>Department of Obstetrics and Gynaecology of the University of Ulm, Ulm, Germany

**Background:** Biomarkers to help escalate or de-escalate systemic therapies are urgently needed in early-stage HER2+ breast cancer patients. The combination of high stromal tumor infiltrating lymphocytes (TILs) and low tumor cellularity at 2 weeks of anti-HER2 therapy (CelTIL score) has been associated with high rates of pathologic complete response (pCR) after completion of neoadjuvant therapy. However, the value of CelTIL as a prognostic biomarker is unknown. Here, we present an independent validation of CelTIL in the NeoALTTO phase III trial. **Methods:** NeoALTTO randomized 455 patients (pts) with HER2+ early breast cancer to receive lapatinib (arm A), trastuzumab (Arm B) or lapatinib and trastuzumab (Arm C) for 6 weeks, followed by the assigned anti-HER2 treatment combined with paclitaxel weekly for 12 weeks. After surgery, patients received 3 cycles of fluorouracil, epirubicin and cyclophosphamide, and then continued the assigned anti-HER2 treatment for 34 weeks. CelTIL was centrally evaluated in tumor biopsies performed at week 2 in arms B and C using the pre-established formula (CelTIL score =  $-0.8 \times \text{tumor cellularity [\%]} + 1.3 \times \text{TILs [\%]}$ ). The primary objective was to evaluate the association of CelTIL (as a continuous variable and using the pre-established 33.59% cut-off as defined by Nuciforo P, et al; *Ann Oncol.* 2018) with event-free survival (EFS). Secondary objectives were to evaluate the association of CelTIL with overall survival (OS) and pCR. Univariable and multivariable analyses were performed adjusting for hormone-receptor status, pre-treatment tumor size and nodal status, planned type of surgery, pCR status, and treatment arm. **Results:** The CelTIL score was evaluable in 196 samples (108 samples in arm B and 88 samples in arm C), of which 45.4% (89/196) had low CelTIL score and 54.6% (107/196) had a high CelTIL score. As a continuous score, higher CelTIL levels were independently associated with improved EFS (hazard ratio [HR]=0.84 per 10% increment; 95% CI 0.73-0.97; P=0.006), but not OS (HR=0.85; 95% CI 0.71-1.03; P=0.094). Using the pre-established cutoff, the 5-year EFS estimate was 76% (95% CI 68-85%) and 60% (95% CI 50-72%) in pts with high- and low-CelTIL, respectively (adjusted HR=0.53; 95% CI 0.30-0.94; p=0.030). Moreover, the 5-year OS rate was 86% (95% CI 80-94%) and 73% (95 CI 64-84%) in high- and low-CelTIL respectively (adjusted HR=0.43; 95% CI 0.20-0.92; p=0.029). CelTIL as a continuous score was also independently associated with higher rates of pCR (odds ratio [OR]=1.18; 95% CI 1.02-1.36; p=0.024). The pCR rate in the high-CelTIL group was 37% (40/107) versus 18% (16/89) in the low-CelTIL group (adjusted OR=2.60; 95% CI 1.31-5.14; p=0.006). **Conclusions:** CelTIL score measured at week 2 of anti-HER2 therapy is significantly associated with long-term survival outcomes in early-stage HER2+ breast cancer, independently of pCR status and other prognostic variables. Further validation of this biomarker could help select early-on pts candidates for escalation or de-escalation of systemic therapy.

Reported concerns and acceptance of information or referrals among survivors with breast cancer seen for survivorship care planning visits: Results from the University of Wisconsin Carbone Cancer Center (UWCCC) Survivorship Program

Leah Cha<sup>1</sup>, Amye J Tevaarwerk<sup>2</sup>, Elena M Smith<sup>3</sup>, Thevaa Chandereng<sup>4</sup>, Karol J Huenerberg<sup>3</sup>, Lori A Seaborne<sup>3</sup> and Mary E Sesto<sup>2</sup>. <sup>1</sup>University of Wisconsin School of Medicine and Public Health, Madison, WI; <sup>2</sup>University of Wisconsin, Department of Medicine and Carbone Cancer Center, Madison, WI; <sup>3</sup>UW Health, Madison, WI; <sup>4</sup>University of Wisconsin-Madison, Madison, WI

**Background:** Survivors diagnosed with breast cancer experience a wide range of physical, psychosocial, and socioeconomic challenges following curative-intent treatment. Given survivors' unique and complex needs, a coordinated transition from active treatment to post-treatment care is crucial and is often facilitated by survivorship care planning visits. Care planning visits are expected to identify survivors' specific needs and provide information or referrals for additional services. However, little is known about survivors' need for and acceptance of information or referrals at the end of curative-intent treatment, particularly in the context of care planning visits. To understand how we can improve delivery of post-treatment care for curatively treated survivors, we examined the frequency and patterns of concerns reported by survivors seen for care planning visits, as well as their acceptance of information and/or referrals.

**Methods:** Survivors diagnosed with Stage 0-3 breast cancer seen at the UWCCC for survivorship care planning visits at roughly one month after radiation therapy were identified using the electronic health record (EHR). An EHR data pull of a cohort seen between January 2016 to January 2020 was performed to extract discrete data on survivor demographics, clinical characteristics, concerns, and acceptance of information or referrals at the time of the initial survivorship care planning visit.

**Results:** A total of 1,016 survivors with breast cancer were seen for at least one care planning visit following radiation therapy as standard of care. Most survivors were middle-aged (mean = 58; range = 22-88), female (n = 1,014; 99.8%), and White (n = 962; 94.7%). Most survivors had private health insurance (n = 626; 61.6%) and received endocrine therapy (n = 718; 70.7%). About one-third of survivors received chemotherapy (n = 354; 34.8%). Nearly all survivors reported at least one concern (n = 975; 96.0%). Activity-related concerns, such as fatigue and desire to increase physical activity, were most commonly reported among survivors (n = 739; 72.7%), followed by concerns related to nutrition (n = 677; 66.6%) and pain or swelling (n = 630; 62.0%). Among survivors who reported a concern, most accepted information about activity or pain (n = 842; 98.6%). Acceptance of referrals to services were generally fewer in number than of information, with the most accepted referrals being for nutrition (n = 46; 6.8%). More than ninety percent of survivors who reported a concern related to activity or pain (n = 842; 98.6%), nutrition (n = 669; 98.8%), and substance use (n = 50; 92.6%) accepted information or referrals for services. Most survivors who reported a concern related to endocrine therapy (n = 221; 95.7%) and employment or insurance (n = 118; 88.7%), however, did not seek additional support.

**Conclusions:** Our analysis of discretely collected EHR data of survivors with breast cancer suggests that although survivors seen for care planning visits report a range of concerns at the end of active curative-intent treatment, they may not necessarily accept information or referrals for services to address some of their concerns. A possible reason for this occurrence may be that these routinely seen survivors have already received resources to address their concerns at visits prior to the care planning visits. Survivors may have also declined resources due to barriers to health care access, such as those related to finances, transportation, and child care. Further studies are needed to understand this discrepancy and determine how to effectively meet both the desires and needs of this population.

<sup>1</sup>Gustave Roussy, Villejuif, France<sup>2</sup>Curie, Paris, France<sup>3</sup>Institut du Cancer Montpellier, Montpellier, France<sup>4</sup>Centre Georges Francois Leclerc, Dijon, France<sup>5</sup>Centre Leon Berard, Lyon, France<sup>6</sup>Universite Catholique de Louvain, Louvain, Belgium<sup>7</sup>Centre Francois Baclesse, Caen, France<sup>8</sup>Curie Institute, Saint Cloud, France<sup>9</sup>Centre Jean Perrin, Clermont Ferrand, France<sup>10</sup>Oncopole Toulouse IUCT, Toulouse, France<sup>11</sup>Institut de Cancerologie de l'Ouest, Nantes, France<sup>12</sup>Institut Jean Godinot, Nancy, France<sup>13</sup>CHU Limoges, Limoges, France<sup>14</sup>Centre Hospitalier de Pau, Pau, France<sup>15</sup>Institut Curie, Paris, France<sup>16</sup>Unicancer, Paris, France

**Background** Palbociclib is a CDK4/6 inhibitor with demonstrated survival benefits in combination with endocrine therapy in advanced luminal breast cancer (LBC). Its potential role in early breast cancer is currently explored. The NeoPAL trial compared letrozole-palbociclib (LETPAL) combination to standard chemotherapy (CT) as neoadjuvant treatment in patients with high-risk LBC. Both LETPAL and CT were associated with poor pathological response, and equivalent clinical responses, while LETPAL let to encouraging biomarker responses in Prosigna®-defined high-risk LBC. We now evaluate the survival outcomes of both groups.

**Patients and Methods** NeoPAL (UCBG10/4, NCT02400567) is a randomized, parallel, non-comparative phase II study. Postmenopausal women with ER-positive, HER2-negative, Prosigna®-defined luminal B, or luminal A and node-positive, stage II-III breast cancer, not candidate for breast-conserving surgery, were randomly assigned to either letrozole (2.5 mg daily) and palbociclib (125 mg daily, 3 weeks/4) during 19 weeks (LETPAL), or to FEC100 (5FU 500 mg/m<sup>2</sup>, epirubicin 100 mg/m<sup>2</sup>, cyclophosphamide 500 mg/m<sup>2</sup>) x3 21-day courses followed by docetaxel 100 mg/m<sup>2</sup> x3 21-day courses (CT). Secondary endpoints included progression-free survival (PFS) and invasive-disease free survival (iDFS), all measured from the date of randomization. Exploratory objectives aimed at evaluating the impact of PEPI score and residual cancer burden (RCB) on survival outcomes in both arms.

**Results** 53 pts were randomized in each arm (both with 11% Luminal A N+ and 89% Luminal B). 23 of the 53 pts in the LETPAL arm received postoperative adjuvant chemotherapy. Median follow-up is 40.4 months [0-56.6]. 11 progressions have been observed (10 metastatic events, 1 regional progression), of which 3 were in the LETPAL and 8 in the control arm. Two additional iDFS events were observed in the LETPAL arm (secondary malignancies). PFS (HR = 1.01; 95%CI [0.36; 2.90], p=0.98) and iDFS (HR= 0.83; 95%CI [0.31; 2.23], p=0.71) did not differ between both arms. 40 months PFS rate is 86.7% (78.0-96.4) and 87.2% (78.1-97.4) in LETPAL and CT arms respectively. PEPI (PEPI II/II vs I: HR 0.80, 95%CI 0.18-3.67) and RCB scores (RCB II/III vs 0/I: HR 1.36; 95%CI 0.17-10.6) did not appear as independent predictors of PFS or iDFS.

**Conclusions** Despite its small size, NeoPAL suggests that a neoadjuvant LETPAL strategy, together with selected postoperative administration of chemotherapy, may spare chemotherapy in some pts with luminal breast cancer while allowing very good long-term outcomes.

Genomic profiling of breast cancer leptomeningeal metastasis (BCLM) reveals a divergent evolution and therapeutic targets

Amanda Fitzpatrick<sup>1</sup>, Marjan Iravani<sup>1</sup>, Adam Mills<sup>1</sup>, Eleanor Knight<sup>1</sup>, Thanussuyah Alaguthurai<sup>2</sup>, Vandna Shah<sup>2</sup>, Alicia Okines<sup>3</sup>, Nick Turner<sup>3</sup>, Mark Harries<sup>4</sup>, Syed Haider<sup>1</sup>, Andrew Tutt<sup>1</sup> and Clare Isacke<sup>1</sup>. <sup>1</sup>Division of Breast Cancer Research, Institute of Cancer Research, London, United Kingdom<sup>2</sup>Breast Cancer Now Research Unit, Guy's Hospital, King's College London, London, United Kingdom<sup>3</sup>Breast Unit, The Royal Marsden Hospital, London, United Kingdom<sup>4</sup>Guy's & St Thomas' Hospitals NHS Foundation Trust, London, United Kingdom

**Background:** Leptomeningeal metastasis remains a devastating development in breast cancer, with a median survival of 3-4 months, no widely accepted standard treatment, and limited access to trials of novel therapies. In addition, lack of access to leptomeningeal metastatic material hampers the pre-clinical investigation of the disease process and molecular drivers. This project uses CSF as a liquid biopsy to characterise BCLM, through genomic analysis of the cell-free DNA (cfDNA), and the development of pre-clinical BCLM models by the expansion of CSF disseminated tumour cells.

**Methods:** CSF (surplus to clinical requirements) and blood were collected from patients undergoing evaluation of leptomeningeal metastasis. cfDNA was extracted from CSF and plasma, and subjected to ultra-low pass whole genome sequencing (ulpWGS) to assess tumour-derived cfDNA fraction. Samples with >10% tumour fraction underwent whole exome sequencing, along with matched archival primary tumour, archival extra-cranial metastatic site(s) and germline DNA. CSF cells were expanded *in vitro* (to establish 3D patient-derived organoids (PDOs)).

**Results:** Cohort demographics are shown in Table 1. Whole exome sequencing (WES) in 21 patients reveals that 65.2% of variants found in CSF cfDNA were not shared with the primary tumour or other matched samples. Phylogenetic analysis shows a divergent evolution from extra-cranial metastatic sites, represented by plasma cfDNA (n = 12) and/or metastatic site tissue DNA (n = 7). The most frequently mutated cancer-associated genes in CSF were *MUC16* (12/21), *TP53* (11/21), *CDH1* (10/21), and *KMT2D* (7/21). The common occurrence of *CDH1* loss-of-function mutations was in keeping with the large number of lobular cases, however were also discovered in CSF of two cases with E-cadherin positive ductal primary tumours. Furthermore, mutations (including frameshift indels) in JAK family proteins (*JAK1*, *JAK3* and *TYK2*) were present in 5/21 cases, and were private to CSF in 4/21. Potential actionable gene alterations private to CSF include; *IDH2* (3/21), *GLI1* (3/21), *PIK3CA* (2/21) and *PTCH1* (2/21). Further, there was an enrichment for somatic *BRCA1/2* mutations (5/21, 2 private to CSF) indicating potential for platinum and/or PARP inhibitor therapy in these individuals. Patient-derived organoids (PDOs) were established using CSF tumour cells from 3 ER+/HER2- and 2 TNBC BCLM cases. WES of PDOs revealed high concordance with genomic variants identified in the matched CSF cfDNA. Therapeutic compound testing revealed 3/5 PDOs did not display sensitivity to methotrexate, the most commonly used BCLM intrathecal treatment. Patient-derived xenograft (PDX) models have been established by mammary fat pad, intraductal, intracardiac and intracerebroventricular injection routes.

**Conclusion/future plans:** WES of CSF cfDNA provides insight into genomic changes in BCLM, including the divergent evolution, and BCLM specific alterations, some of which are potentially targetable. Parallel PDO and PDX models are being used to validate potential drivers and therapeutic targets. Treatment options beyond intrathecal methotrexate are urgently needed and in future might be molecularly tailored based on alterations discovered by CSF cfDNA sequencing.

Table 1. Clinical demographics

Demographics	Median, years (range)
Age at BC diagnosis	45 (24 – 66)
Time from primary BC to BCLM	4.7 (0.7 – 14.7)
Time from first metastasis to BCLM	1.2 (0.0 – 6.5)
<b>Histological Type</b>	<b>n (%)</b>
Lobular	10 (48)

Differential gene expression in luminal-type invasive lobular carcinoma and invasive ductal carcinoma by MammaPrint risk stratification

Beth-Ann Lesnikowski<sup>1</sup>, Jennifer A. Crozier<sup>1</sup>, Gordan Srkalovic<sup>2</sup>, Patricia Robinson<sup>3</sup>, Clodia Osipo<sup>3</sup>, Kaylan Banda<sup>4</sup>, Heather M. Kling<sup>5</sup>, Josien Haan<sup>6</sup>, William Audeh<sup>5</sup>, FLEX Investigators Group. <sup>1</sup>Baptist MD Anderson Cancer Center, Jacksonville, FL; <sup>2</sup>Herbert-Herman Sparrow Cancer Center, Lansing, MI; <sup>3</sup>Loyola University Chicago, Stritch School of Medicine, Maywood, IL; <sup>4</sup>University of Washington, Fred Hutchinson Cancer Research Center, Seattle, WA; <sup>5</sup>Medical Affairs, Agendia, Inc., Irvine, CA; <sup>6</sup>Research and Development, Agendia NV, Amsterdam, Netherlands

**Background:** Invasive lobular carcinoma (ILC) comprises 10-15% of breast tumors and is the second most common histological type after invasive ductal carcinoma (IDC). Patients with ILC are often diagnosed at an older age and more advanced stage than those with IDC. Late recurrences and worse long-term survival suggest the need for improved approaches to treatment optimization and exploration of molecular pathways unique to ILC. Although previous reports have described comprehensive transcriptomic profiling of ILC, these were limited by small sample sizes. Furthermore, differential gene expression between ILC and IDC within genomic risk groups and molecular subtypes has yet to be explored. Here we characterize differential gene expression between ILC and IDC in a large, age-matched patient subset categorized by 70-gene signature/MammaPrint (MP) risk and 80-gene signature/BluePrint (BP) subtype.

**Methods:** The prospective FLEX Registry (NCT03053193) includes stage I-III primary invasive breast cancer patients who receive MP/BP testing and consent to full transcriptome and clinical data collection. This sub-analysis included 450 ILC patients enrolled from 2017 to present. Compared with a random selection of IDC patients (n=450, mean age, 60 years), ILC patients were older (mean, 63 years, p<0.001). Thus, we selected an age-matched subset for differential gene expression analysis. There were few non-Luminal ILCs; thus, gene expression analyses were limited to BP Luminal tumors. A subset of 413 age-matched pairs (n=826) of ILC and IDC were used for analysis. Gene expression data were quantile normalized using R limma package, and differentially expressed genes (DEGs) were compared between groups. DEGs with an adjusted p<0.05 and log<sub>2</sub> fold change > ± 1.0 were considered significant.

**Results:** ILC represented 13% of FLEX cases (n=450/3562), and were 81% lymph node-negative, 99% ER+, 94% HER2-negative, and 68% MP Low Risk (LR). By BP, ILC were 99% Luminal, 1% HER2, and <1% Basal type. BP Luminal ILC were predominantly grade 2 (63%), T1 (61%), node-negative (84%), and MP LR (69%). Menopausal status, nodal status, ethnicity, BMI distribution, and frequency of type 2 diabetes mellitus were similar between ILC and IDC. However, IDC were more likely to be MP HR (46% IDC vs. 31% ILC, p<0.001) and grade 3 (15% IDC vs. 4% ILC, p<0.001). ILC were more likely to be T3 (10% ILC vs. 1% IDC, p<0.001). We found 4 DEGs common to all comparisons: all Luminal ILC vs. IDC, MP LR ILC vs. IDC, and MP HR ILC vs. IDC. ILC had lower expression of *CDH1* (E-cadherin) than IDC, regardless of MP risk. Including *CDH1*, 6 unique genes were differentially expressed in LR ILC compared with IDC, and 21 genes were differentially expressed in HR ILC compared with IDC. Genes with increased expression in HR ILC were related to immune cell migration/chemotaxis, hormone signaling, and growth factor signaling. HR ILCs were also enriched for TGFβ signaling and angiogenesis pathway genes.

**Conclusions:** Here we report differential clinical and molecular characteristics between ILC and IDC in a large, age-matched patient subset. Regardless of MP risk, expression of *CDH1* was lower in ILC compared with IDC. Approximately one-third of ILCs were MP HR, and we report a greater number and diversity of DEGs between HR ILC and HR IDC compared with LR tumors, in particular genes related to TGFβ signaling. TGFβ pathway genes play a variety of roles in the tumor microenvironment, including induction of angiogenesis, fibroblast growth factor stimulation, and inhibition and/or exclusion of an immune response. These results suggest that therapeutic strategies targeting the TGFβ pathway may be future avenues of exploration in ILC, although further studies are warranted to characterize underlying molecular mechanisms.

Double-blind placebo (PBO)-controlled randomized phase III trial evaluating first-line ipatasertib (IPAT) combined with paclitaxel (PAC) for *PIK3CA/AKT1/PTEN*-altered locally advanced unresectable or metastatic triple-negative breast cancer (aTNBC): primary results from IPATunity130 Cohort A

Rebecca Dent<sup>1</sup>, Sung-Bae Kim<sup>2</sup>, Mafalda Oliveira<sup>3</sup>, Carlos Barrios<sup>4</sup>, Joyce O'Shaughnessy<sup>5</sup>, Steven J Isakoff<sup>6</sup>, Shigehira Saji<sup>7</sup>, Ruffo Freitas-Junior<sup>8</sup>, Manuel Philco<sup>9</sup>, Igor Bondarenko<sup>10</sup>, Qinshu Lian<sup>11</sup>, Denise Bradley<sup>12</sup>, Heather Hinton<sup>13</sup>, Matthew J Wongchenko<sup>11</sup>, Aruna Mani<sup>11</sup> and Nicholas Turner<sup>14</sup>. <sup>1</sup>National Cancer Center, Singapore, Singapore<sup>2</sup>Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of<sup>3</sup>Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain<sup>4</sup>Latin American Cooperative Oncology Group, Porto Alegre RS, Brazil<sup>5</sup>Baylor University Medical Center, Texas Oncology, US Oncology, Dallas, TX;<sup>6</sup>Massachusetts General Hospital, Boston, MA;<sup>7</sup>Fukushima Medical University Hospital, Fukushima City, Japan<sup>8</sup>Hospital Araujo Jorge, Goiania, Brazil<sup>9</sup>Unidad de Investigacion, Instituto de Oncologia y Radioterapia, Clinica Ricardo Palma, San Isidro, Peru<sup>10</sup>City Clinical Hospital No. 4, Dnipropetrovsk, Ukraine<sup>11</sup>Genentech, Inc., South San Francisco, CA;<sup>12</sup>Roche Products Ltd, Welwyn Garden City, United Kingdom<sup>13</sup>F Hoffmann-La Roche Ltd, Basel, Switzerland<sup>14</sup>The Royal Marsden NHS Foundation Trust, and Breast Cancer Now Research Centre, The Institute of Cancer Research, London, United Kingdom

**Background:** In the randomized phase II LOTUS trial [Kim, Lancet Oncol 2017], adding IPAT to PAC improved progression-free survival (PFS), with a more pronounced effect in patients with *PIK3CA/AKT1/PTEN*-altered tumors. This effect provided the rationale for the biomarker-selected IPATunity130 phase III trial. Here we report primary results from Cohort A in aTNBC. **Patients and methods:** In Cohort A of this pivotal phase III trial (NCT03337724), eligible patients had *PIK3CA*- and/or *AKT1*- and/or *PTEN*-altered measurable aTNBC, ECOG performance status 0/1, were appropriate candidates for taxane monotherapy, and had received no prior chemotherapy for aTNBC. Patients were randomized 2:1 to receive either oral IPAT 400 mg or PBO (days 1-21), both combined with IV PAC 80 mg/m<sup>2</sup> (days 1, 8, & 15). Cycles were repeated every 28 days until disease progression, unacceptable toxicity, or patient withdrawal. Stratification factors were: prior (neo)adjuvant chemotherapy (yes vs no); geographic region (Asia-Pacific vs Europe vs North America vs rest of world); and tumor alteration status (*PIK3CA/AKT1*-activating mutation vs *PTEN* alteration without *PIK3CA/AKT1*-activating mutation). The primary endpoint was investigator-assessed PFS; secondary endpoints included overall survival (OS; key secondary), objective response rate (ORR), duration of response, clinical benefit rate (CBR), patient-reported outcomes, and safety. **Results:** Between 6 Feb 2018 and 8 Apr 2020, 255 patients were enrolled, of whom 51% had received (neo)adjuvant chemotherapy and 59% had visceral disease; 51% had *PIK3CA/AKT1*-activating mutations and the remaining 49% had *PTEN* alterations (without *PIK3CA/AKT1*-activating mutations). At the clinical cut-off date (7 May 2020), median duration of follow-up was 8.3 months (range 0-26.8 months) and 33% of patients remained on treatment. Mean duration of PAC was similar in the two groups (5.5 vs 5.4 months in the IPAT vs PBO arms, respectively). There was no difference in PFS between treatment groups overall (Table) nor in any prespecified subgroups. OS results are immature (deaths in 20% of patients). Similar proportions of patients in the IPAT and PBO arms experienced grade ≥3 adverse events (AEs) (46% vs 44%, respectively), fatal AEs (1% vs 1%), and AEs leading to discontinuation of any treatment (14% vs 15%), although AEs leading to dose reduction of any treatment were more common with IPAT (35% vs 14%). The most common AEs (any grade) were diarrhea (80% vs 31%; grade ≥3 9% vs 2%), alopecia (46% vs 44%), and nausea (36% vs 23%). **Conclusions:** In contrast to results from the phase II LOTUS trial, this trial showed no PFS improvement with the addition of IPAT to first-line PAC in patients with *PIK3CA/AKT1/PTEN*-altered aTNBC. Biomarker analyses are ongoing to evaluate potential markers of IPAT benefit. Safety was consistent with previously reported results for this combination.

Summary of efficacy

	IPAT + PAC	PBO + PAC
ITT population	(n=168)	(n=87)
PFS events, n (%)	92 (55)	48 (55)
Median PFS, months (95% CI)	7.4 (5.6-8.5)	6.1 (5.5-9.0)
PFS stratified hazard ratio (95% CI)	1.02 (0.71-1.45)	Log-rank p=0.9237
Measurable disease population	(n=167)	(n=86)
ORR, n (%) [95% CI]	65 (39) [32-47]	30 (35) [25-46]
CBR, n (%) [95% CI]	78 (47) [39-55]	39 (45) [35-56]

Clonal relatedness of LCIS with synchronous and asynchronous invasive disease

Elinor Sawyer<sup>1</sup>, Mateja Sborchia<sup>1</sup>, Anargyros Megalios<sup>1</sup>, Vandna Shah<sup>1</sup>, Salpie Nowinski<sup>1</sup>, Cloe Vassart<sup>1</sup>, Anita Grigoriadis<sup>1</sup>, Alastair Thompson<sup>2</sup>, Ian Tomlinson<sup>3</sup>, Rebecca Roylance<sup>4</sup> and Sarah Pinder<sup>1</sup>. <sup>1</sup>KCL, London, United Kingdom<sup>2</sup>Baylor College of Medicine, Houston, TX;<sup>3</sup>Edinburgh University, Edinburgh, United Kingdom<sup>4</sup>UCL, London, United Kingdom

**Background:** Lobular carcinoma *in situ* (LCIS) is typically clinically undetectable but is being increasingly diagnosed as a result of breast screening mammography and is often found associated with other breast pathologies such as invasive lobular breast cancer (ILC), invasive carcinoma of ductal /no special type (IDC) and ductal carcinoma *in situ* (DCIS). It is also considered a risk factor for the development of subsequent invasive breast disease. The aim of this study was to understand the genetic relationship between LCIS that presents with synchronous DCIS, IDC and/or ILC in order to ascertain whether the components have common precursors and also to understand the clonal relationship between LCIS and subsequent invasive disease. **Methods:** 25 cases of LCIS with synchronous ILC, 7 cases of LCIS with synchronous DCIS & IDC, and 8 pure LCIS that developed a subsequent invasive recurrence were identified from the GLACIER study (MREC 06/Q1702/64). DNA was extracted from archival paraffin embedded tissue and underwent copy number analysis using either the *Oncoscan*<sup>TM</sup> Array (*Affymetrix*) or *HumanCytoSNP FFPE-12 BeadChip* (*Illumina*). Four of 7 cases of LCIS with synchronous DCIS & IDC also underwent targeted sequencing using a custom 121 breast cancer-associated gene panel (*SureSelect*<sup>XT HS</sup> kit, *Agilent Technologies*). Clonal relatedness was assessed using a novel methodology based on the presence of shared copy number aberration breakpoints and mutations. **Results:** Of the 25 synchronous LCIS and ILC cases, 17 appeared related, 4 were ambiguous (sharing the typical lobular signature of 1q gain and 16q loss) and 4 demonstrated no evidence of relatedness. Of the 7 cases with synchronous LCIS, DCIS and IDC, all had copy number data available and 4 had mutation data available. In 3 cases the synchronous LCIS, DCIS and IDC were clonally related according to copy number and for two there was mutation data that supported this (one sharing *PIK3CA* and *CDH1* mutations, the other a *TP53* mutation). In two cases the LCIS was not related to the DCIS or IDC, but the DCIS and IDC were related to each other; while in one case LCIS was related to IDC but not to the DCIS by copy number but all components shared the same *CHEK2* mutation. Finally in one case none of the three components were related to each other by copy number but the LCIS and IDC shared a *PIK3CA* mutation, albeit at much lower allele frequency in LCIS than in IDC. Of the 8 patients with pure LCIS, 4 developed an ipsilateral invasive recurrence of various combinations of morphologies: 1 ILC & LCIS, 1 ILC & DCIS, 1 IDC & DCIS, 1 ILC & IDC, and 4 a contralateral recurrence (1 tubular, 1 IDC, 2 ILC), with a median time to recurrence of 69 months (range 34-175). The primary LCIS was related to at least one component of the recurrent disease in all four ipsilateral cases; in two the primary LCIS and all components of the recurrent disease were related, and in the remainder we observed a variety of putative evolutionary patterns. **Conclusions:** The majority (68%) of cases of synchronous LCIS and ILC appeared to be clonally related by copy number. 50% of cases of co-existing LCIS and IDC appeared to have a common clonal origin by either copy number or targeted sequencing. As these are genomically stable tumours, copy number data may also be underestimating relatedness. In the four cases of pure primary LCIS that developed an ipsilateral recurrence, different subtypes of breast cancer were noted as the recurrence morphology, supporting the historical view that LCIS is a risk lesion rather than a true precursor. However, in all cases the preceding LCIS was found to be related to at least one component of the subsequent invasive tumour including DCIS and IDC. This data shows that clonal relatedness between LCIS and both synchronous and asynchronous invasive disease and DCIS is more complex than previously thought, with LCIS acting as a precursor lesion even in some cases of IDC.

Comparison of pathologist reads of sp142 and sp263 with quantitative measurement of protein and mRNA in triple negative breast cancer

Swati Gupta<sup>1</sup>, Vesal Yaghoobi<sup>2</sup>, Aileen Fernandez<sup>2</sup>, Leena McCann<sup>3</sup>, Jodi Weidler<sup>3</sup>, Michael Bates<sup>3</sup>, Emily Reisenbichler<sup>2</sup> and David Rimm<sup>2</sup>. <sup>1</sup>Eisai (H3 Biomedicine), Cambridge, MA; <sup>2</sup>Yale University School of Medicine, New Haven, CT; <sup>3</sup>Cepheid Inc., Sunnyvale, CA

**Background:** PD-L1 SP142 immunohistochemistry (IHC) assay has been approved as a companion test by the US Food and Drug Administration (FDA) to identify eligibility for atezolizumab therapy in patients with advanced triple negative breast cancer (TNBC) but a number of studies suggest the assay suffers from poor reproducibility. Using readings of 70 TNBC chromogenic FDA approved assays from 19 pathologists in a previous study as a baseline, we compared pathologist reads to quantitatively measured mRNA and protein expression **Methods:** Formalin-fixed paraffin-embedded (FFPE) slides representing primary invasive triple negative breast cancer (stage I-III) from 100 patients between 2012-16 were selected from the Yale Pathology archives. Slides were macrodissected to tumor enrichment for quantitative assessment of *CD274* (PD-L1 mRNA) measured using a closed-system, real-time quantitative reverse transcription polymerase chain reaction (RT-qPCR) research use only (RUO)\* prototype assay on the GeneXpert<sup>®</sup> instrument. We also measured protein expression levels using the AQUA method of quantitative immunofluorescence (QIF) in both the tumor and non-tumor compartments on full sections by QIF stained using SP142 in a lab derived test (LDT). The IHC stained slides were prepared using SP142 and SP263 assays prepared exactly according the FDA approved label followed by reading by 19 pathologists. This study was approved by Yale Human Investigation IRB protocol ID 9505008219. **Results:** Previous work from our group showed overall percent agreement for both the SP142 and SP263 IHC assays read by pathologists was in the 40-50% range. We used the median *CD274* score to compare positive (IC $\geq$ 1) vs negative (IC<1) and found that the levels of mRNA were not statistically significantly different between the two categorical scores. However, quantitative measurement of protein expression (including both tumor and non-tumor regions) showed statistically significant differences between pathologist read PD-L1 positive/negative scoring for SP142 ( $p=0.0004$ ) and SP263 ( $p=0.0185$ ). Concordance of quantitative PD-L1 measurement between protein QIF scores and transcript RT-qPCR levels was modest, with a Spearman coefficient  $r = 0.18$ . **Conclusions:** By chromogenic IHC, using the FDA approved assays, pathologist read scoring shows no difference to mRNA for *CD274*. Quantitative continuous scoring of protein expression show that, on average, when pathologists score IC $\geq$ 1, there is more protein present than when they score IC<1. Further studies are needed to determine if RNA and protein for PD-L1 are concordant and to determine which assay(s) and cutoff values are best correlated with clinical outcomes on atezolizumab therapy.

Genomic analysis of the CALGB 40603 (Alliance) neoadjuvant trial in TNBC identifies immune features associated with pathological complete response and event-free survival

Jonathan H Shepherd<sup>1</sup>, Terry Hyslop<sup>2</sup>, Cheng Fan<sup>1</sup>, Aranzazu Fernandez Martinez<sup>1</sup>, Joel Parker<sup>1</sup>, Katherine Hoadley<sup>1</sup>, Zhiyuan Hu<sup>1</sup>, Yun Li<sup>1</sup>, Matthew Soloway<sup>1</sup>, Patricia Spears<sup>1</sup>, Ann Partridge<sup>3</sup>, William Sikov<sup>4</sup>, Lisa A Carey<sup>1</sup> and Charles M Perou<sup>1</sup>. <sup>1</sup>University of North Carolina, Chapel Hill, NC; <sup>2</sup>Duke University, Durham, NC; <sup>3</sup>Dana-Farber/Partners CancerCare, Boston, MA; <sup>4</sup>Warren Alpert Medical School of Brown University, Providence, RI

**Purpose:** CALGB (now part of the Alliance for Clinical Trials in Oncology) 40603 was a randomized Phase II study investigating pathological complete response rates (pCR) in triple-negative breast cancer (TNBC) patients receiving neoadjuvant weekly paclitaxel followed by doxorubicin and cyclophosphamide +/- bevacizumab and/or carboplatin for which 5-year event-free survival (EFS) results are now available. This is a valuable resource to characterize clinical and genomic features associated with response and survival. **Methods:** Clinical parameters and pre-treatment tumor biopsy RNA-sequencing (RNAseq) from 295 TNBC patients were analyzed to identify features associated with pCR and/or EFS. A panel of 689 previously published gene expression signatures were evaluated to provide insights regarding potential associations between clinical endpoints and genomically determined cell types and signaling pathway activities. Additionally, B cell receptor (BCR) and T cell receptor (TCR) sequences were examined, and repertoire abundance, richness, and diversity measures were calculated to investigate correlations with pCR and EFS status. Univariate Mann-Whitney U-Tests were used for continuous variables, and Fisher's test was used for categorical features, with unadjusted p-values < 0.05 designated as significant. **Results:** While the addition of bevacizumab and carboplatin each significantly improved pCR rates, neither improved EFS. We examined outcomes according to race and no differences were seen for either pCR rate or EFS. 131 features, including high proliferation and multiple interferon signatures were significantly associated with pCR, but not with EFS. Alternatively, 69 features, including clinical factors for T stage and node status, were prognostic for EFS, but not significantly associated with pCR. Nevertheless, pCR itself was the strongest predictor of EFS, and was the only feature significantly associated with EFS after adjusting for multiple comparisons (Benjamini-Hochberg False Discovery Rate = 6.7e-3). In total, 52 genomic features were significantly correlated with both pCR and EFS, 44 of which were features of the immune microenvironment. Immune associated features included signatures of T cells, B cells and NK cells, immune checkpoint pathways (PD-1, PD-L1, CTLA4), and antigen presentation (dendritic cells, MHC-I, MHC-II). In particular, low BCR evenness, which is a measure of uniformity of unique BCR sequence abundance, was strongly associated with both pCR and EFS, suggesting that an antigen-specific adaptive immune response with clonally selected B cells is occurring in patients that have improved response and survival. Furthermore, a multivariate Cox Proportional Hazards model assessing BCR evenness along with age, T stage, N stage, grade and pCR found BCR evenness to be an independent prognostic feature for EFS in TNBC. **Conclusions:** Evidence of distinct predictors of pCR and EFS in TNBC patients treated with neoadjuvant chemotherapy suggests that, while pCR is still the strongest prognostic feature, high expression of many immune related gene expression signatures in pretreatment tumor samples are promising biomarkers of improved EFS. In addition to the important role of T cells in an anti-tumor response, these data show high IgG expression and evidence of B cell clonal selection associates with improved response and survival, supporting an important role for B cells in the adaptive response that portends a long-term benefit of chemotherapy in TNBC. **Support:** U10CA180821, U10CA180882, U24CA196171, P50-CA58223, Genentech, and The Breast Cancer Research Foundation. <https://acknowledgments.alliancefound.org>; **ClinicalTrials.gov Identifier:** NCT00861705

Dna repair imbalance and immune response in breast cancer mortality disparities

Andrea Walens, Alina M Hamilton, Markia A Smith, Xiaohua Gao, Erin L Kirk, Stephen D Hursting, Katherine A Hoadley, Cyrus Vaziri and Melissa A Troester. University of North Carolina at Chapel Hill, Chapel Hill, NC

**Background:** Black breast cancer patients have p53 loss in 60% of their tumors, compared to 35% p53 loss in white breast cancer patients. The tumor suppressor p53 has pleiotropic effects on DNA repair, as it regulates both error prone and error-free DNA repair pathways. These effects on DNA repair represent molecular vulnerabilities that influence chemotherapy response, both directly and indirectly through the activation of immune responses. While studies have begun to elucidate DNA repair imbalance and immune response in human cancer, little is known about how these pathways differ by race. **Methods:** To study DNA repair and immune response in breast cancer, we performed gene expression analysis on FFPE samples from the Carolina Breast Cancer Study (CBCS), a large population-based study that oversampled black and younger women. We curated a list of DNA repair genes representing regulators of error prone and error free DNA repair. Pathways included Nucleotide Excision Repair (NER), Fanconi Anemia (FA), Mismatch repair (MMR), Base Excision Repair (BER), Homologous Recombination (HR), Translesion Synthesis (TLS), Alternative End Joining (AEJ), Checkpoint, and APOBEC. In addition, we developed a 50-gene immune panel representing 12 individual immune cell types (B cells, T cells, Treg cells, T help cells, T follicular helper cells, CD8 T cells, NK cells, Eosinophils, Neutrophils, M1 & M2 Macrophages) and both adaptive and innate arms of the immune system. A total of 1464 patients (53% black, 53% under 50) were included in the current analysis. We used consensus clustering to identify groups of patients based on DNA repair gene expression and used linear regression to estimate the relative frequency differences between these classes and demographic and clinical characteristics. **Results:** We found that breast cancers grouped into four clusters based on DNA repair gene expression. One cluster, 'Repair High', represented 32% of the tumors, and had high expression of NER, NHEJ, HR, and FA genes, suggesting a broad DNA repair response. Another group, 'HR/FA High' represented 23% of the tumors and was enriched for high expression of HR and FA genes. An "APOBEC High" group consisted of 32% of the tumors and was enriched for high expression of APOBEC family genes (APOBEC3D, APOBEC1, APOBEC3A, APOBEC3H, APOBEC3B). Finally, 13% of tumors, had a 'Heterogeneous Repair' pattern of high expression of HR, NHEJ, and FA genes, but lower expression of NER genes. The HR/FA and Heterogeneous Repair groups were enriched for TP53 mutant-like tumors (93% vs. 5% and 61% vs. 38% Mutant vs. Wildtype respectively). In addition, the Heterogeneous Repair group was enriched for Hormone Receptor positive samples ([RFD] 8.2% (0.613, 15.3), 77% vs. 23% in positive vs. negative respectively), while the HR/FA High group was significantly enriched for TNBC ([RFD] HR/FA: 51.2% (45.1, 57.1), 75% vs. 25% TNBC vs. non-TNBC respectively). The Repair High group was the only group enriched for non-black race ([RFD]: 10.4% (4.0, 16.7), 42% vs. 58% in blacks vs. non-blacks respectively). Finally, DNA repair classes were associated with immune scores, with the APOBEC High tumors having a significantly higher Eosinophil score ( $p = 0.021$ ) and Neutrophil score ( $p = 0.007$ ) compared to the other four groups. **Conclusion:** DNA repair expression is highly variable across breast tumors and may depend upon TP53 status, tumor subtype, and race. Differential immune marker expression by DNA repair group suggests some DNA repair groups may have differential response to immune-targeted therapies. DNA repair, immune response, and race are inter-related in breast cancer and unraveling and ultimately targeting breast cancer disparities may require coordinated evaluation of these pathways.

A phase Ib trial of fulvestrant + CDK4/6 inhibitor (CDK4/6i) palbociclib + pan-FGFR tyrosine kinase inhibitor (TKI) erdafitinib in *FGFR*-amplified/ ER+/HER2-negative metastatic breast cancer (MBC)

Ingrid A. Mayer<sup>1</sup>, Barbara B. Haley<sup>2</sup>, Vandana G. Abramson<sup>1</sup>, Adam Brufsky<sup>3</sup>, Brent Rexer<sup>1</sup>, Erica Stringer-Reasor<sup>4</sup>, Komal L. Jhaveri<sup>5</sup>, Melinda Sanders<sup>1</sup>, Paula I. Ericsson-Gonzalez<sup>1</sup>, Fei Ye<sup>1</sup> and Carlos L. Arteaga<sup>2</sup>. <sup>1</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>2</sup>UTSW Simmons Cancer Center, Dallas, TX; <sup>3</sup>Magee-Womens Hospital of UPMC, Pittsburgh, PA; <sup>4</sup>University of Alabama at Birmingham, Birmingham, AL; <sup>5</sup>Memorial Sloan-Kettering Cancer Center, New York, NY

**Background:** Somatic alterations in the FGFR pathway (mainly *FGFR1*, amplified in about 15% of ER+ BC) have been implicated in resistance to endocrine therapy (ET), and more recently, to CDK4/6i as well. Based on our preclinical data showing that the FGFR pan-inhibitor erdafitinib when added to fulvestrant/palbociclib resulted in marked PDX regressions, we initiated a phase Ib trial combining erdafitinib with fulvestrant/palbociclib in patients with ER+/HER2-/FGFR-amplified MBC (NCT03238196) to determine safety, tolerability and anti-tumor activity of this combination. **Methods:** Patients with evaluable ER+/HER2- MBC with *FGFR1-4* amplification (detected on tumor next generation sequencing or plasma ctDNA) exposed to at least one ET regimen (but no more than 2 lines of chemotherapy) in the metastatic setting, were treated with fulvestrant, palbociclib (standard of care dosing/ schedule) and oral erdafitinib, tested in 4 doses ranging from 4 mg to 8 mg daily. Once MTD reached, we planned to enroll 20 patients in the expansion portion of the trial. Tumor blocks were collected for *FGFR1* FISH amplification analysis, and plasma ctDNA was collected at baseline, 4 weeks and at treatment discontinuation. Tumor assessments were performed every 8 weeks. **Results:** Since August 2017, 26 eligible patients with evaluable ER+/HER2-/FGFR-amplified MBC were enrolled across 4 institutions. Patient characteristics are summarized in Table 1. Main grade 1 and 2 adverse events (AE) were consistent with on-target toxicities of erdafitinib and/or palbociclib: mucositis (67%), hyperphosphatemia (61%), dysgeusia (52%), diarrhea (48%), fatigue (48%), neutropenia (47%), hand-foot syndrome (38%), anemia (29%), and onycholysis (14%). Febrile neutropenia occurred in 5% patients, no cases of central serous retinopathy were seen. Serious AE were rare: one grade 4 elevation of transaminases (DLT; attributed to fulvestrant), one grade 3 colitis (attributed to erdafitinib), and one thromboembolic event (attributed to palbociclib). In combination with fulvestrant/ palbociclib, the MTD of erdafitinib was 6 mg. No drug-drug interaction was seen. 8 patients were deemed non-evaluable for anti-tumor effect as treatment discontinuation (mainly due to AE) occurred prior to first tumor assessment. Of the 18 evaluable patients: 7 had disease progression, 8 had stable disease (4 of which discontinued treatment due to AE), 3 have not completed their first tumor assessment, 4 are still on treatment; median PFS was 3 months and CBR at 6 months was 28%. However, higher PFS (6 months) was seen in 6/8 patients with high levels of *FGFR1* amplification (FISH FGFR1:CEP8 ratio >5; gene copy number >10) and in both patients with *FGFR3* amplification.

**Conclusion:** To our knowledge, this is the first time an FGFR inhibitor has been tested in combination with ET and CDK4/6i in patients with MBC harboring *FGFR* alterations. Erdafitinib-related side effects appeared to be on target, leading to treatment discontinuation in several patients despite optimal medical treatment. Clinical activity was seen in heavily pre-treated patients with molecular evidence of high *FGFR* amplification despite 100% prior exposure to ET and CDK4/6i. Full clinical and correlative work will be presented at the meeting, and a future phase II trial is being planned.

LGR4 engages a wnt-independent mechanism to enhance EGFR signaling and promote metastasis of triple-negative breast cancer

Fei Yue<sup>1</sup>, Weiyu Jiang<sup>1</sup>, Amy T Ku<sup>1</sup>, Adelaide IJ Young<sup>1</sup>, Weijie Zhang<sup>1</sup>, Eric P Souto<sup>1</sup>, Yankun Gao<sup>2</sup>, Zhihan Yu<sup>2</sup>, Yi Wang<sup>2</sup>, Chad J Creighton<sup>1</sup>, Chandandeep Nagi<sup>1</sup>, Tao Wang<sup>1</sup>, Xin-Hua Feng<sup>1</sup>, Shixia Huang<sup>1</sup>, Cristian Coarfa<sup>1</sup>, Xiang H.-F. Zhang<sup>1</sup>, Qingyun Liu<sup>3</sup>, Xia Lin<sup>1</sup> and Yi Li<sup>1</sup>. <sup>1</sup>Baylor College of Medicine, Houston, TX; <sup>2</sup>Beijing Institute of Lifeomics, Beijing, China; <sup>3</sup>University of Texas Health Science Center at Houston, Houston, TX

Leucine-rich repeat-containing G-protein-coupled receptors 4/5/6 (LGR4/5/6) have crucial functions in embryonic development, adult tissue homeostasis, and diseases. LGR4/5/6 also play important roles in cancer initiation and progression. LGR4 is highly expressed in multiple types of cancer and associated with poor patient outcome. LGR4 promotes tumorigenesis and metastasis and modulates cancer stem cells, while LGR5 and LGR6 mark cancer stem cells and progenitor cells that contribute to tumor initiation. The biological functions of LGR4/5/6 are primarily attributed to their roles in potentiating Wnt signaling, which requires the binding of their four R-spondin ligands (RSPO1-RSPO4). However, it is unclear whether these proteins have Wnt signaling-independent functions. We have previously reported that LGR4 is important in mammary gland development and breast cancer progression and metastasis. Here, we demonstrate that LGR4 enhances triple-negative breast cancer (TNBC) metastasis independently of Wnt signaling. We first found that LGR4 was highly expressed in the TNBC subtype and associated with poor metastasis-free survival in TNBC patients, while a well-validated Wnt signature failed to correlate with metastasis-free survival of this same subset of TNBC patients. These bioinformatic data suggested divergent functions of LGR4 versus Wnt signaling in TNBC progression. Then we showed that depletion of *LGR4* inhibited, while inducible expression of *LGR4* promoted TNBC cell migration and invasion, without added exogenous ligands and any detectable impact on baseline Wnt signaling. Importantly, blockade of Wnt signaling by Wnt inhibitors or by genetic depletion of *Wntless* cannot abolish the effect of LGR4 on TNBC cell metastatic ability. Furthermore, we have generated non-RSPO-binding LGR4 mutants that failed to activate Wnt signaling. These LGR4 mutants that are uncoupled from Wnt signaling can still promote TNBC cell migration and invasion in vitro and TNBC lung metastasis and bone metastasis in vivo, as potently as wild-type LGR4. To identify the molecular mechanisms by which LGR4 promotes TNBC metastasis, we did computational analyses of TCGA data to search for candidate proteins associated with LGR4 and proteomics screenings to uncover protein pathways regulated by LGR4 knockdown in TNBC cells. Both in silico and proteomic analyses identified EGFR as a downstream component of LGR4 signaling in TNBC. We confirmed LGR4 enhanced EGFR signaling by immunoblot analyses and found that EGFR was the crucial mediator of LGR4's role in TNBC metastasis. Ectopic EGFR rescued migration and invasion of *LGR4* knockout cells, while EGFR knockdown and the EGFR inhibitor erlotinib attenuated LGR4-induced cell migration and invasion. In an intra-iliac injection model of bone metastasis, erlotinib also suppressed LGR4-induced TNBC bone metastasis in vivo. Mechanistically, LGR4 did not affect EGFR mRNA levels but EGFR protein stability. LGR4 interacted with EGFR and blocked EGFR ubiquitination and degradation, resulting in persistent EGFR activation. Together, these data uncover a new signaling pathway controlled by LGRs with broad implications for cancer progression and targeted therapy.

Predictors of pain reduction in trials of interventions for aromatase inhibitor (AI)-associated musculoskeletal symptoms (AIMSS)

N. Lynn Henry<sup>1</sup>, Joseph M Unger<sup>2</sup>, Cathee Till<sup>2</sup>, Katherine D Crew<sup>3</sup>, Michael J Fisch<sup>4</sup> and Dawn L Hershman<sup>3</sup>. <sup>1</sup>University of Michigan, Ann Arbor, MI; <sup>2</sup>Fred Hutchinson Cancer Research Center, Seattle, WA; <sup>3</sup>Columbia University, New York, NY; <sup>4</sup>AIM Specialty Health, Chicago, IL

**Background:** Up to half of AI-treated breast cancer patients experience AIMSS, and 20-30% have severe symptoms that lead to treatment discontinuation. Multiple interventions have been examined in randomized clinical trials, including in SWOG S0927 (omega-3 fatty acids vs placebo), S1202 (duloxetine vs placebo), and S1200 (true acupuncture vs sham acupuncture vs wait list control). We hypothesized that we could identify predictors of pain reduction in AIMSS intervention trials by combining data from these trials. **Methods:** The S0927, S1200, and S1202 clinical trials had similar eligibility criteria, and all used the same patient-reported outcomes measures to assess arthralgias and endocrine symptoms. The Brief Pain Inventory (BPI) examines average pain, worst pain, and pain interference; higher numbers reflect more symptoms. Endocrine symptoms were assessed with the Functional Assessment of Cancer Therapy-Endocrine Subscale (FACT-ES), which includes subscales for functional and physical well-being; higher scores reflect better function. We also used validated measures to assess joint symptoms in the knees/hips (WOMAC) and hands (M-SACRAH), where higher scores indicate greater symptom severity. We analyzed the subset of patients enrolled on these three trials who had a baseline BPI average pain score of at least 4/10 (S0927, n=185; S1200, n=158; S1202, n=240). The primary outcome was 50% reduction in BPI average pain from baseline to week 12. Variable cut-point selection was performed on each continuous variable to identify a binary cut-point that optimally distinguished high versus low levels of pain reduction. Logistic regression was performed for each variable. A risk model was built by summing the number of statistically significant baseline predictors and categorizing patients by low vs. medium vs. high likelihood of pain reduction. All analyses were stratified by study and adjusted for treatment arm. **Results:** Of the 583 analyzed patients, median age was 60 years (range 27-84), median body mass index was 30 kg/m<sup>2</sup> (range 18-84), and 208 patients (35.7%) had at least a 50% reduction in BPI average pain. Factors significantly associated with at least a 50% reduction in pain included lower pain and pain interference and better physical and functional status at study enrollment (Table). Patients with 2-4 of the 7 statistically significant factors were twice as likely to experience pain reduction compared to those with fewer than 2 factors (37.8% vs. 22.5%; odds ratio [OR] 2.08, 95% CI 1.38-3.13, p<.001). Those with 5-7 factors were more than 5 times more likely to experience pain reduction (61.2% vs. 22.5%; OR 5.66, 95% CI 3.21-9.98, p<.001). **Conclusions:** Patients with AIMSS who have lower pain and better functional status are more likely to experience meaningful pain reduction in intervention trials for AIMSS. These findings suggest early intervention for treating AIMSS may be important. Baseline pain and functional status should be considered as stratification factors in future interventional trials. **Funding:** NIH/NCI Grant Award CA189974; and in part by the Hope Foundation for Cancer Research.

Association of baseline characteristics with 50% reduction in average pain from baseline to 12 weeks

Factor	Rates of pain reduction	Odds Ratio (95% CI)	P value

**Background:** The prognostic and predictive value of the 4 main intrinsic subtypes of breast cancer (ie, luminal A [LumA], luminal B [LumB], human epidermal growth factor receptor 2 enriched [HER2E], and basal-like) in hormone receptor-positive, HER2- advanced breast cancer (ABC) treated with endocrine therapy (ET) and ribociclib (RIB) is currently unknown. The MONALEESA-2, -3, and -7 trials all showed a significant benefit in progression-free survival (PFS) with RIB over placebo (PBO; Hortobagyi et al. *Ann Oncol.* 2018; Slamon et al. *J Clin Oncol.* 2018; Tripathy et al. *Lancet Oncol.* 2018). Here, we correlate ABC intrinsic subtypes with the PFS benefit of RIB in the MONALEESA trials. **Methods:** Patient samples from the MONALEESA-2, -3, and -7 trials underwent PAM50-based subtyping (blinded from clinical data), and the correlation between intrinsic subtype and PFS was analyzed. Gene expression profiling of formalin-fixed, paraffin-embedded tumor samples was performed using a customized NanoString nCounter GX 800-gene panel. The prognostic and/or predictive relationship of PAM50-based subtypes with PFS and the risk of tumor progression by subtype were evaluated using univariate and multivariable Cox proportional hazards models. Multivariable models were adjusted for known clinical prognostic factors, including age, prior chemotherapy, prior ET, ECOG performance status, visceral disease (presence of liver/lung metastases), bone-only metastases, histological grade, number of metastatic sites, and de novo metastatic disease. **Results:** A total of 1160 tumor samples from both the RIB (n = 672) and PBO (n = 488) treatment arms of the MONALEESA trials were profiled. Subtype distribution was generally consistent across treatment arms (**Table**). The associations between intrinsic subtypes and PFS were statistically significant in both treatment arms ( $P < .0001$ ). Compared with patients with LumA subtype, which is the subtype that is the most prevalent and has the best prognostic outcome, patients with LumB, HER2E, and basal-like subtypes had a 1.41, 2.30, and 3.97 times higher risk of tumor progression, respectively, after adjusting for other clinical-pathologic variables and treatment arm. In terms of treatment benefit, all subtypes except for basal-like showed a significant PFS benefit with RIB treatment (**Table**). Patients with HER2E (hazard ratio [HR], 0.389;  $P < .0001$ ), LumB (HR, 0.521;  $P = .0001$ ), LumA (HR, 0.633;  $P = .0007$ ), and normal-like (HR, 0.467;  $P = .0005$ ) subtypes all derived benefit from RIB treatment, with HER2E demonstrating the greatest benefit. Patients with the basal-like subtype (n = 30) did not derive benefit from RIB (HR, 1.15;  $P = .767$ ), although these results should be interpreted with caution due to the small sample size (RIB: 2%; PBO: 3%). **Conclusions:** This is the largest analysis evaluating the correlation of intrinsic ABC subtype with efficacy outcomes in patients treated with CDK4/6 inhibitors. Patients with HER2E, LumA, LumB, and normal-like subtypes all exhibited a consistent PFS benefit with RIB treatment, while patients with basal-like ABC (RIB: 2%; PBO: 3%) did not. The HER2E subtype (RIB: 14%; PBO: 11%) exhibited the greatest relative reduction in risk of progression or death (61%) with RIB plus ET.

**Table.**

Subtype	Treatment Arm	Distribution, n (%)	Median PFS, months, (95% CI)	HR	P Value
Luminal A	RIB	320 (48)	29.60 (23.03-NA)	0.63	.0007
	PBO	222 (45)	19.48 (15.61-24.80)		
Luminal B	RIB	154 (23)	22.21 (18.79-NA)	0.52	< .0001
	PBO	124 (25)	12.85 (10.98-14.82)		
HER2-enriched	RIB	95 (14)	16.39 (12.71-24.6)	0.39	< .0001
	PBO	52 (11)	5.52 (3.12-9.17)

Recurrent active *ESR1* fusions render a diagnostic transcriptional signature in metastatic breast cancer

Xuxu Gou<sup>1</sup>, Meenakshi Anurag<sup>1</sup>, Jonathan T Lei<sup>1</sup>, Purba Singh<sup>1</sup>, Sinem Seker<sup>1</sup>, Adrian V Lee<sup>2</sup>, Dan R Robinson<sup>3</sup> and Matthew J Ellis<sup>1</sup>. <sup>1</sup>Baylor College of Medicine, Houston, TX; <sup>2</sup>University of Pittsburgh, Pittsburgh, PA; <sup>3</sup>University of Michigan, Ann Arbor, MI

**Background:** We recently reported two *ESR1* fusions (*ESR1*-YAP1 and *ESR1*-PCDH11X) that drive endocrine therapy (ET) resistance and metastasis in estrogen receptor positive (ER+) metastatic breast cancer (MBC) (PMC6171747). Here, we report the functional properties of additional *ESR1* fusions in ET-resistant MBC with an emphasis on the identification of a transcriptional signature designed to diagnose the presence of an active *ESR1* fusion for targeted therapies directed against *ESR1* fusion-driven biology. **Methods:** *ESR1* fusions were detected by RNA-seq in ER+ MBC samples. *ESR1* fusions were reproduced as cDNA constructs and expressed in ER+ breast cancer cell lines. Hormone-independent cell growth was detected by an Alamar blue assay and activated cell motility by a scratch wound assay. The transcriptional properties of *ESR1* fusions was studied by RNA-seq followed by qPCR-based validation. Signature performance was evaluated using a ROC analysis on ER+ patient derived xenografts (PDX) harboring a variety of *ESR1* somatic events. **Results:** All *ESR1* fusions studied encoded the first six exons of *ESR1* fused in-frame to diverse partner genes, thus replacing the *ESR1* drug/ligand binding domain (LBD). Fusions involving a known transcription factor (TF) or coactivator (CoA) gene, including *ESR1*-YAP1, *ESR1*-SOX9 and *ESR1*-ARNT2 drove fulvestrant-resistant cell growth and hormone-independent cell motility. Other *ESR1*-e6 fusions, including *ESR1*-DAB2, *ESR1*-GYG1, *ESR1*-PCMT1 and *ESR1*-ARID1B did not induce these properties. From these examples, a functional rule is emerging whereby inter-chromosomal *ESR1* translocations fused in-frame to 3' partner genes with a positive role in transcription are active. Intra-chromosomal fusions with genes with no transcriptional roles are likely inactive. The *ESR1*-PCDH11X fusion is an exception, suggesting the need for continued functional study of non-TF/CoA partner *ESR1*-e6 fusions. RNA-seq of T47D cells expressing the full panel of gene fusions demonstrated an overlapping pattern of transcriptional activation focused on estrogen response and epithelial-to-mesenchymal transition (EMT) genes driven by active fusions. This gene signature was well-preserved in a PDX naturally expressing the *ESR1*-YAP1 fusion. Interestingly, further study showed that a series of ET-resistant PDXs bearing a variety of *ESR1* LBD point mutations induced a similar pattern to the active *ESR1* fusion signature suggesting overlapping transcriptional regulatory events between *ESR1* fusions and *ESR1* LBD mutations. The *ESR1*-D538G mutation conferred the most comparable gene dysregulation to *ESR1* fusions. The Y537S/N and E380Q mutations also reproduced the signature driving hormone-independent growth but with exceptions. Two PDX lines bearing either a fully heterozygous Y537S or L536P mutations were surprisingly completely estrogen-dependent. Neither of these examples exhibited the *ESR1* fusion gene signature, suggesting an unknown secondary event needed to fully express the phenotype of some *ESR1* mutants. The gene signature distinguished *ESR1* mutations (constitutively active fusions and point mutations) from wild-type *ESR1*, with a 92.0% Area Under Curve. **Conclusion:** Here, we show that *ESR1* fusions are recurrent somatic mutations that lead to drug resistance and metastasis by transcriptional reprogramming. We describe a fusion gene signature that may be useful to determine whether an *ESR1* fusion or mutation is transcriptionally active and is capable of driving hormone-independent growth and endocrine therapy resistance.

Molecular mechanism of ipatasertib (IPAT) and its combination with atezolizumab (atezo) in patients (pts) with locally advanced/metastatic triple-negative breast cancer (aTNBC)

Peter Schmid<sup>1</sup>, Delphine Loirat<sup>2</sup>, Peter Savas<sup>3</sup>, Enrique Espinosa<sup>4</sup>, Valentina Boni<sup>5</sup>, Antoine Italiano<sup>6</sup>, Shane White<sup>7</sup>, Victor Laliman<sup>8</sup>, Geraldine Strasser<sup>9</sup>, Kui Lin<sup>9</sup>, Karen Cheng<sup>9</sup>, Aruna Mani<sup>9</sup>, Matthew Wongchenko<sup>9</sup>, Marie-Paule Sablin<sup>2</sup> and Kalpit Shah<sup>9</sup>. <sup>1</sup>Barts Cancer Institute, Queen Mary University London, London, United Kingdom<sup>2</sup>Institut Curie, Paris, France<sup>3</sup>Peter MacCallum Cancer Centre, Melbourne, Australia<sup>4</sup>Hospital Universitario La Paz, Madrid, Spain<sup>5</sup>START Madrid CIOCC, Madrid, Spain<sup>6</sup>Institut Bergonie, Bordeaux, France<sup>7</sup>Austin Hospital, Melbourne, Australia<sup>8</sup>Hoffmann-La Roche Limited, Mississauga, ON, Canada<sup>9</sup>Genentech, Inc., South San Francisco, CA

**Background:** Phase 3 trials (IMpassion130, KEYNOTE-355) have shown improved efficacy with the addition of immune checkpoint modulators to chemotherapy in PD-L1 +ve aTNBC. However, unmet need remains in the ~60% of pts with aTNBC who have PD-L1 -ve tumors. Preliminary data from a multicenter phase 1b study (NCT03800836) evaluating the safety and efficacy of the oral AKT inhibitor IPAT + atezo + paclitaxel/nab-paclitaxel showed promising antitumor activity (73% confirmed objective response rate) irrespective of PD-L1 status [Schmid, AACR 2019], suggesting a potential role for the triplet independent of PD-L1 status. We report on-treatment changes in the tumor microenvironment in Cohort 2.

**Methods:** In Cohort 2, pts with aTNBC and ≤2 prior lines of chemotherapy for aTNBC received oral IPAT 400 mg on d1-28 of cycle 1 (35-d cycle) and on d1-21 of subsequent cycles (28-d cycles). IV atezo 840 mg was given on d8 & 22 of cycle 1 and on d1 & 15 of subsequent cycles. Biopsies were collected before treatment administration during cycle 1 on d1 (C1D1) & d8 (C1D8), and on d15 of cycle 2 (C2D15). PD-L1 (VENTANA SP142 immune cell ≥1%) and CD8 expression was assessed by immunohistochemistry (IHC); % immune infiltrate was measured by H&E staining. Changes in gene expression were assessed by RNA-Seq. Gene set enrichment analysis was used to study molecular pathway activation (enrichment score [ES] >0 to 1) or inhibition (ES -1 to <0).

**Results:** In Cohort 2, 11 pts had PD-L1 -ve tumors at baseline and are included in the analyses below, 2 had PD-L1 +ve tumors and 3 were unevaluable for PD-L1. IHC analysis of serial biopsies from pts with PD-L1 -ve tumors showed a statistically significant increase in immune infiltrates (mean % infiltrates C1D8/C1D1=1.44; p=0.042) and a trend toward increased CD8 protein expression (mean CD8 % staining C1D8/C1D1=1.75; Kruskal-Wallis p=0.16) at the tumor center during the first week of single-agent IPAT compared with the baseline biopsy. An increase in PD-L1 expression (mean PD-L1 % infiltrating immune cells C2D15/C1D1=4.33; Kruskal-Wallis p=0.044) was seen during IPAT + atezo combination treatment. No significant changes in immune infiltrates or CD8 expression were observed after initiating atezo versus IPAT alone. As expected, MTORC1 activity decreased (ES=-0.43; p<0.005) in response to IPAT. IPAT (± atezo) enhanced key immunogenic pathways, including antigen processing and presentation (ES=0.49; p<0.005), allograft rejection (ES=0.47; p<0.0001), inflammatory response (ES=0.34; p<0.05), and NK cell activation (ES=0.66; p<0.05). In addition, IPAT + atezo enhanced TCR signaling (ES=0.52; p<0.0005) and interferon gamma response (ES=0.30; p<0.05). IPAT treatment was associated with decreased expression of gene sets predicting pathway upregulation, including E2F signaling, G2M checkpoint, and MYC activity. IPAT was also associated with apoptotic pathway enrichment. Using a syngeneic melanoma mouse model, we validated clinical findings and identified additional molecular changes after treatment with IPAT and/or anti-PD-L1. To date, 3 enrolled pts achieved a partial response and 6 had stable disease. Clinical and preclinical studies are ongoing to explore associations between treatment-driven molecular changes and clinical response.

**Conclusion:** Inhibition of AKT signaling may remodel the microenvironment of PD-L1 -ve tumors by increasing immune infiltration, priming immune pathways, promoting tumor cell apoptosis, and inhibiting oncogenic cell proliferative pathways. To our knowledge, these are the first reports evaluating molecular changes during AKT-targeted therapy for aTNBC in the context of immunotherapy irrespective of PD-L1 status. IPAT warrants further investigation combined with atezo as treatment for PD-L1 -ve aTNBC.

[<sup>89</sup>Zr]-pertuzumab pet imaging reveals paclitaxel treatment efficacy is positively correlated with her2 expression in human breast cancer xenograft mouse models

Yun Lu, Adriana Massicano, Patrick Song, Meng Li, Suzanne Lapi and Anna Sorace. University of Alabama at Birmingham, Birmingham, AL

**Introduction:** Paclitaxel (PTX) is one of the most commonly used first-line chemotherapies in the treatment of breast cancer. However, it is reported that overall PTX response rate is between 30-60% for the treatment of metastatic breast cancer. Thus, novel discoveries of molecular mechanisms that account for ineffective response is critical in breast cancer treatment. [<sup>89</sup>Zr]-Pertuzumab (antibody that targets HER2 receptors) and 2-deoxy-2-[fluorine-18] fluoro-D-glucose ([<sup>18</sup>F]-FDG) positron emission tomography/computed tomography (PET/CT) imaging allows us to noninvasively measure the amount and heterogeneity of HER2 expression and tumor glucose metabolism. These methods are clinical translatable and can provide insight into tumor biology changes during the course of therapy. This study evaluates whether HER2 expression level is correlated with PTX treatment efficacy in controlled pre-clinical mouse models of HER2+ breast cancer. **Experimental Design:** BT474 ( $1 \times 10^7$ ), MDA-MB-361 ( $6 \times 10^6$ ), or MDA-MB-231 ( $2 \times 10^6$ ) cells were subcutaneously injected into athymic nude mice (N = 7 per cell line). When the tumor volume reached approximately 200 mm<sup>3</sup>, mice were enrolled in the study. Tumor size was measured with calipers weekly until enrolled and every 3 days after experiment started. *In vivo* HER2 expression level was determined by [<sup>89</sup>Zr]-Pertuzumab PET/CT imaging at one week prior to initiation of treatment and confirmed with immunohistochemistry staining. PTX (15 mg/kg) was administered via i.v. on days 0 and 3. *In vivo* tumor metabolism was quantified by [<sup>18</sup>F]-FDG PET/CT imaging on day 0, 3 and 6. Mean, standard deviation, sum, and frequency histogram of standard uptake value (SUV) were quantified. Tumors were harvested at day 6 for histological analysis. Hematoxylin and eosin (H&E) and cleaved caspase 3 immunohistochemistry (IHC) staining were used to determine tumor apoptosis. Pearson's correlation and ANOVA were used as statistical analysis. **Results:** [<sup>89</sup>Zr]-Pertuzumab SUV<sub>mean</sub> of BT474 (HER2+) tumors were  $4.9 \pm 1.5$ , MDA-MB-361 (HER2+) tumors were  $1.4 \pm 0.2$  ( $p < 0.0001$ , compared with BT474), and MDA-MB-231 (HER2-) tumors were  $1.1 \pm 0.4$  ( $p < 0.0001$ , compared with BT474). [<sup>18</sup>F]-FDG SUV sum was positively correlated with tumor volume ( $R^2 = 0.1669$ ,  $p = 0.0250$ ). Tumor volumes showed no significant changes during the treatment. However, normalized [<sup>18</sup>F]-FDG SUV concentration changes from day 0 to day 3 was negatively correlated with baseline [<sup>89</sup>Zr]-pertuzumab SUV concentration ( $R^2 = 0.3654$ ,  $p = 0.05$ ). **Conclusion:** Preliminary results show paclitaxel treatment efficacy is positively correlated with HER2 expression level in human breast cancer mouse models. [<sup>89</sup>Zr]-Pertuzumab PET/CT imaging quantitatively measured HER2 expression level *in vivo*, and [<sup>18</sup>F]-FDG PET/CT imaging revealed the early signals of drug treatment efficacy. This discovery will help identify chemotherapy responders and potentially enhance clinical decision making.

Ipsilateral invasive cancer risk after diagnosis with ductal carcinoma in situ in patients with and without index surgery: The effects of endocrine therapy and radiation treatment

Marc D Ryser<sup>1</sup>, Christel N Rushing<sup>1</sup>, Samantha M Thomas<sup>1</sup>, Thomas Lynch<sup>1</sup>, Anne McCarthy<sup>2</sup>, Zahed A Mohammed<sup>2</sup>, Amanda B Francescatti<sup>2</sup>, Elizabeth S Frank<sup>3</sup>, Anne H Partridge<sup>4</sup>, Alastair M Thompson<sup>5</sup>, Terry Hyslop<sup>1</sup> and E. Shelley Hwang<sup>1</sup>. <sup>1</sup>Duke University, Durham, NC; <sup>2</sup>Cancer Programs, American College of Surgeons, Chicago, IL; <sup>3</sup>Dana-Farber Cancer Institute, Boston, MA; <sup>4</sup>Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA; <sup>5</sup>Baylor College of Medicine, Houston, TX

**Background.** Ongoing clinical trials are evaluating active surveillance as a potential alternative to immediate surgery in patients diagnosed with low-risk ductal carcinoma in situ (DCIS). Among women undergoing lumpectomy, the risk of ipsilateral invasive breast cancer (iIBC) after a diagnosis of DCIS can be reduced with adjuvant therapy, including endocrine therapy (ET) and radiation treatment (RT). Here we characterize the effects of ET and RT on iIBC risk after diagnosis with DCIS in a national cohort, in patients who received breast conserving surgery (BCS) within 6 months of diagnosis (BCS group) compared to patients who did not receive any locoregional treatment within 6 months of diagnosis (surveillance [SV] group). **Methods.** A treatment-stratified random sample of patients diagnosed with biopsy-confirmed DCIS in 2008-14 was selected from 1,330 Commission on Cancer-accredited facilities (20/site). Patients who received a mastectomy within 6 months of diagnosis were excluded. Subsequent breast events were abstracted up to 10 years after diagnosis. Primary outcomes were the population-averaged 8-year absolute risks of iIBC for the following five treatment modalities: BCS alone, SV alone, BCS + ET, SV+ET, BCS+RT, and BCS+ET+RT (where ET was defined as ≥5 years of continuous treatment). Secondary outcomes were the average treatment effects (ATE) of SV+ET vs SV, BCS+RT vs SV+ET, and BCS+RT+ET vs SV+ET. A propensity score (PS) model for treatment choice BCS vs SV was fitted with sampling design (SD) weighting and random effects for patients within facilities. Relative treatment effects (hazard ratios [HR]) for the five treatment groups were obtained using multivariable Cox proportional hazards models adjusted for tumor and patient characteristics. The models were weighted by SD and PS and included a robust sandwich covariance estimator to account for clustering of patients within facilities. Population-averaged risks and ATEs were derived from the marginal outcome probabilities: assuming that the entire population received the treatment of interest, each patient's counterfactual probability of an iIBC event by 8 years was predicted, and then averaged across the weighted population. 95% confidence intervals (CI) were obtained by bootstrapping. **Results.** The final analytic cohort contained 14,245 (88.2%) BCS and 1,914 (11.8%) SV patients. Overall, median age at diagnosis was 61 years (IQR: 52-69) and median follow-up was 5.8 years (95% CI 5.7-6.1). The majority of patients were Caucasian (81.9%), with hormone receptor-positive (79.9%), and nuclear grade I/II (54.5%) DCIS. Uptake of any ET was 48.5% and 23.7% in BCS and SV patients, respectively. The relative treatment effects (HR) for the receipt of BCS, RT and ≥5 years of ET were 1.65 (95% CI: 1.14-2.39), 0.40 (95% CI: 0.27-0.61) and 0.55 (95% CI: 0.17-1.72) respectively. The 8-year population-averaged iIBC risks and corresponding ATEs are shown Table 1. **Conclusion.** The 8-year risk of iIBC was below 7% for all six management options. Relative and absolute treatment effects of ET and RT were comparable to previously reported estimates. In SV patients, receipt of ≥5 years of ET nearly halved the 8-year risk, indicating a substantial risk reduction potential for ET in patients who do not receive immediate surgery after diagnosis.

Treatment	iIBC risk (%)	95% CI
Surveillance	6.90	6.79-7.01
Surveillance + ET	3.90	3.83-3.96
BCS	4.26	4.21-4.31
BCS + RT	1.76	1.73-1.79
BCS + ET	2.39	2.35-2.43
BCS + ET + RT	0.98	0.96-0.99
Treatment comparison	ATE (%)	95% CI
SV+ET vs SV	3.0	2.95-3.04
BCS+RT vs SV+ET	2.14	2.11-2.17
BCS+RT+ET vs SV+ET	2.92	2.78-2.97

Triple-negative breast cancer (TNBC) risk with pathogenic variants (PV) in hereditary cancer predisposition genes

Michael J Hall<sup>1</sup>, Eric Rosenthal<sup>2</sup>, Susana San Roman<sup>2</sup>, Ryan Bernhisel<sup>2</sup>, John Kidd<sup>2</sup>, Elisha Hughes<sup>2</sup>, Thomas Slavin<sup>2</sup> and Allison Kurian<sup>3</sup>. <sup>1</sup>Fox Chase Cancer Center, Philadelphia, PA; <sup>2</sup>Myriad Genetics, Inc., Salt Lake City, UT; <sup>3</sup>Stanford University, Palo Alto, CA

**BACKGROUND:** TNBC is among the most aggressive subtypes of invasive breast cancer (BC), and accounts for approximately 10-15% of incidental BC diagnoses. TNBC is associated with early age of onset (median age of diagnosis <50) and disproportionately affects African American women. Breast MRI is currently recommended to screen for BC in women with at least a moderate-to-high lifetime risk of BC (a 2-fold or higher increased risk), and may also be superior to mammogram to screen for TNBC. TNBC has been most closely associated with germline PVs in *BRCA1*. However, recent studies have suggested that PVs in other genes previously associated with invasive BC may specifically confer high risks of the TNBC subtype.

**METHODS:** Results were analyzed from 627,219 women undergoing clinical multi-gene panel testing at a single US-based commercial laboratory between 5/2013 and 2/2020, including genes associated with hereditary BC and other cancers. Demographic and personal/family history data were collected on a test requisition form. Individuals who had single- or founder-site testing, or prior *BRCA1* or *BRCA2* testing, were excluded. Multivariable regression analysis was used to examine the association between PVs/suspected PVs and personal history (PHx) of TNBC. Models were adjusted for age, personal/family cancer history, and ancestry. Odds ratios (OR) with 95% confidence intervals (CI) excluding 1.0 were considered significant.

**RESULTS:** In total, 22.4% (140,467/627,219) of women tested reported PHx of BC, of whom 12.8% (17,951/140,467) reported PHx of TNBC. Elevated risks of TNBC were identified in carriers of PVs in 10 genes (see Table). While the highest TNBC risk was associated with PVs in *BRCA1* (OR 21.24, 95% CI 19.71-22.88), high risks were also seen for *BARD1* (OR 7.05, 95% CI 5.71-8.71), *TP53* (OR 5.64, 95% CI 3.08-10.33), *PTEN* (OR 5.52, 95% CI 2.35-13.00) and *PALB2* (OR 5.27, 95% CI 4.55-6.10). Moderate-to-high risks (2-5-fold increased risk) of TNBC were also seen for carriers of PVs in *RAD51C*, *RAD51D*, *BRCA2*, and *CDKN2A/P16*. By contrast, PVs in *NBN*, *ATM*, and *CHEK2* were all associated with an apparent decreased risk of TNBC. **CONCLUSIONS:** PVs in several hereditary cancer genes routinely tested on multi-gene panel tests are associated with high risks (OR>5.0) and moderate-to-high risks (OR 2.0-5.0) of TNBC. These findings can inform practice guidelines about which genes to test when evaluating breast cancer risk and which PV carriers may benefit from intensive breast screening with magnetic resonance imaging (MRI).

An automated DNA methylation assay for monitoring treatment response in patients with metastatic breast cancer

Mary Jo Fackler<sup>1</sup>, Suzana Tulac<sup>2</sup>, Neesha Venkatesan<sup>2</sup>, Adam J. Aslam<sup>2</sup>, Leslie M. Cope<sup>1</sup>, Jennifer Lehman<sup>1</sup>, Rita Denbow<sup>1</sup>, Jeffrey Reynolds<sup>1</sup>, Morgan Buckley<sup>1</sup>, Bradley M. Downs<sup>1</sup>, Kala Visvanathan<sup>1</sup>, Christopher B. Umbricht<sup>1</sup>, Antonio C. Wolff<sup>1</sup>, Vered Stearns<sup>1</sup>, Edwin W. Lai<sup>2</sup> and Saraswati Sukumar<sup>1</sup>. <sup>1</sup>Johns Hopkins University School of Medicine, Baltimore, MD; <sup>2</sup>Cepheid, Sunnyvale, CA

**BACKGROUND:** Previously, we demonstrated the clinical validity of cMethDNA, a circulating methylated tumor DNA (ctDNA) assay, in serum samples from TBCRC 005 (J Clin Oncol, 2017; 35:751-758) to predict progression free- and overall-survival, and to monitor therapeutic response in patients with stage IV breast cancer. Here, Johns Hopkins (JH) and Cepheid partnered to develop an automated GeneXpert (GX) cartridge-based system to provide quantitative measures of DNA methylation within 5 hours. **METHODS:** With a goal of discriminating stage IV breast cancer from healthy and benign breast disease with high sensitivity and specificity, we evaluated breast cancer-specific DNA methylation markers (selected through comprehensive methylome analysis) in STRECK tube plasma of 46 patients with metastatic breast cancer enrolled in Individualized Molecular Analyses Guide Efforts in Breast Cancer (IMAGE II trial), 17 benign breast disease and 9 healthy normal controls (J0888 repository). Blood from IMAGE II participants was collected upon disease progression. A newly designed GX Breast Cancer Monitoring Assay for research use only (RUO\*) first converted unmethylated CpG sites in ctDNA from 1 ml plasma with bisulfite. The sample was then split into two methylation detection cartridges, which quantitated DNA methylation of 9 markers along with an ACTB reference. Cumulative methylation (CM) of the 9-gene panel was calculated using a novel algorithm. Performance was assessed based on Receiver Operating Characteristic (ROC) curves and Mann-Whitney analyses. **RESULTS:** The GX Breast Cancer Monitoring Assay (RUO)\* showed that the 9-gene panel was significantly more methylated in cancer compared to normal/benign plasma samples (median for cancer: 428.0 CM units versus for benign: 0.0 CM units;  $P < 0.0001$ ), and revealed a sensitivity of 85% and specificity of 92%, using a cumulative methylation threshold of 35.5 units based on ROC area under the curve (AUC) = 0.909 (95% CI 0.836 – 0.982,  $P < 0.0001$ ). We will present comparisons of the GX results to cMethDNA, the gold standard assay, which reported 85-90% sensitivity at 90% specificity. **CONCLUSIONS:** We identified a panel of methylated DNA markers that discriminates stage IV breast from benign breast disease and healthy normal subjects using ctDNA. Our automated cartridge-based assay prototype demonstrates high sensitivity and specificity for detecting invasive breast cancer. Its ability to assess changes in DNA methylation will be tested next with clinical trial samples collected longitudinally during treatment. This assay has potential clinical utility in monitoring therapeutic response and predicting disease recurrence.\* *For Research Use Only. Not for use in diagnostic procedures. Not reviewed by any regulatory body.*

Ribociclib + letrozole in male patients with hormone receptor-positive (HR+), human epidermal growth factor receptor-2-negative (HER2-) advanced breast cancer (ABC): Subgroup analysis of the phase IIIb CompLEEment-1 trial

Mario Campone<sup>1</sup>, Michelino De Laurentiis<sup>2</sup>, Claudio Zamagni<sup>3</sup>, Igor Kudryavcev<sup>4</sup>, Mariette Agterof<sup>5</sup>, Ursa Brown-Glaberman<sup>6</sup>, Marketa Palacova<sup>7</sup>, Sanjoy Chatterjee<sup>8</sup>, Lakshmi Menon-Singh<sup>9</sup>, Jiwen Wu<sup>9</sup>, Katie Zhou<sup>9</sup> and Miguel Martin<sup>10</sup>. <sup>1</sup>Western Cancer Institute, Nantes, France<sup>2</sup>National Cancer Institute "Pascale Foundation", Naples, Italy<sup>3</sup>Bologna University Hospital St Orsola-Malpighi Polyclinic, Bologna, Italy<sup>4</sup>Kaluga Regional Clinical Oncology Center, Kaluga, Russian Federation<sup>5</sup>St. Antonius Hospital, Utrecht/Nieuwegein, Utrecht, Netherlands<sup>6</sup>University of New Mexico Cancer Center, Albuquerque, NM;<sup>7</sup>Masaryk Memorial Cancer Institute, Brno, Czech Republic<sup>8</sup>Tata Medical Center, Kolkata, India<sup>9</sup>Novartis Pharmaceuticals, East Hanover, NJ;<sup>10</sup>Gregorio Maranon General University Hospital, Madrid, Spain

**Background:** While the incidence of breast cancer in men is up to 100-fold less than in women, it is estimated that in 2020, 2,620 men in the United States will be diagnosed with breast cancer, and 520 will die from this disease. However, male patients are rarely included in breast cancer clinical trials and treatment guidelines for this population are often proposed based on data from female patients. Ribociclib (RIB), an oral, selective cyclin-dependent kinase 4/6 inhibitor, is approved for use in combination with endocrine therapy (ET) in women with HR+, HER2- ABC. Here, we present a subgroup analysis of male patients from the Core Phase of CompLEEment-1 (NCT02941926), a Phase IIIb trial of RIB in combination with letrozole (LET) in patients with HR+, HER2- ABC. In order to reflect a more typical real-world clinical setting, the eligibility criteria for this study allowed for a more diverse and broader patient population than those of previous Phase III trials of RIB + LET. **Methods:** CompLEEment-1 included women of any menopausal status and men with HR+, HER2- ABC treated with ≤1 line of prior chemotherapy and no prior hormonal therapy for advanced disease. Pts received RIB (600 mg QD, 3 weeks on/1 week off) in combination with LET (2.5 mg QD, continuous). Men and premenopausal women received a luteinizing hormone-releasing hormone agonist (3.6 mg goserelin or 7.5 mg leuprolide, Q28D). This subgroup analysis assessed the primary outcomes (safety and tolerability) and secondary outcomes of time to progression (TTP), overall response rate (ORR), and clinical benefit rate (CBR) in male patients. **Results:** At the data cutoff date (November 8, 2019), 39 male patients (1.2%; N = 3,246) had been evaluated, with a median duration of exposure to RIB of 19.2 months. Adverse events (AEs) were reported in 38 (97.4%) patients; with all but two experiencing a treatment-related AE. Grade ≥ 3 AEs were reported in 26 (66.7%) patients; serious AEs were reported in 6 patients. There were no treatment-related fatal AEs. The most common all-grade AEs were neutropenia (53.8%), hot flush (33.3%), and diarrhea (25.6%), with the most common grade ≥ 3 AE being neutropenia (41.0%). Overall, 7 patients (17.9%) had ≥ 1 dose reduction of RIB, all of whom had at least 1 due to an AE, and 18 patients (46.2%) permanently discontinued treatment, 4 (10.3%) due to AEs. Median TTP was not estimable (95% CI, 16.8-NE); event-free probability was 61.4% (95% CI, 38.4-77.9) at 30 months. For the 32 patients with measurable disease, ORR was 46.9% (95% CI, 29.1-65.3%) and CBR was 71.9% (95% CI, 53.3-86.3%). **Conclusions:** In this subgroup analysis of male patients - a rare population who are often excluded from clinical trials - efficacy results support the use of RIB + LET in HR+, HER2- ABC in a close to real-world setting. The safety profile associated with RIB + LET was manageable, with very few patients discontinuing treatment due to AEs, consistent with previous Phase III trials of RIB + LET.

Examining a decade of racial disparity in partial mastectomy and oncoplastic surgery

Jolie Jean<sup>1</sup>, Michael M. Jonczyk<sup>2</sup>, Christopher Homsy<sup>2</sup>, Stephen Naber<sup>3</sup> and Abhishek Chatterjee<sup>2</sup>. <sup>1</sup>Tufts University School of Medicine, Boston, MA; <sup>2</sup>Tufts Medical Center | Department of Surgery, Boston, MA; <sup>3</sup>Tufts Medical Center | Department of Pathology, Boston, MA

**BACKGROUND:** Breast Conservation Surgery (BCS) includes either partial mastectomy or oncoplastic surgery, of which oncoplastic surgery has become increasingly prevalent. Previous studies have examined BCS rates and post-operative complications, however, no known study has analyzed racial disparity in BCS utilization rates. Understanding racial disparity is crucial to addressing health equality and access to care. Therefore, our study aims to examine racial differences in BCS utilization rates within an 11-year period to determine how these rates have changed over time. **METHODS:** This retrospective cohort analysis utilized the NSQIP (National Surgical Quality Improvement Program) database to identify women who underwent BCS procedures between 2008-2018. All patients were diagnosed with ductal carcinoma in situ or invasive breast cancer. BCS was further sub-divided into partial mastectomy and oncoplastic surgery. Patient demographics were recorded, and racial utilization trends were analyzed using a Cochran-Armitage test and Index of Disparity analysis, which is a method for summarizing proportional changes within a group's population and its subgroups. **RESULTS:** In the 11-year period, 180,700 women underwent a breast cancer resection, of which 46% underwent BCS. Within BCS, 92% underwent a partial mastectomy and 8% received oncoplastic procedures. For both BCS subgroups, Caucasian women held the highest sample size (82%), followed by African Americans (12%), and Asian Americans (5%). Within the total sample size, BCS utilization increased from 38% in 2008 to 53% in 2018. Within the BCS subgroup, the proportion of patients having oncoplastics increased from 3.5% in 2008 to 10% in 2018, leading to a declining proportion of partial mastectomies: 96.5% to 90.0% (all  $p < 0.01$ ). When stratified by race, oncoplastic utilization between 2008 and 2018 increased from 4% to 10% in Asian and Caucasian patients, and 1% to 10% in African American patients ( $p < 0.01$ ). Overall, the racial index of disparity for BCS patients decreased from 17.1% to 9.7%. Interestingly, the index of disparity has remained relatively unchanged for partial mastectomies (1.2% to 0.2%), but significantly decreased in oncoplastics (35% to 1.6%) suggesting an improvement in racial disparities for this surgical option. **CONCLUSION:** As breast conservation surgery becomes the mainstay for early-staged breast cancer interventions, it is crucial to understand the potential for novel procedures to worsen healthcare inequalities. This study demonstrates promising progress within the field of breast conservation surgery with a decreasing index of disparity among races especially in oncoplastic surgery.

**Background:** Pathological complete response (pCR) is associated with improved outcome in patients with high-risk HR+/HER2- breast cancer (BC) but the use of (neo)adjuvant chemotherapy in early HR+/HER2- BC remains controversial. Oncotype DX / Recurrence Score (RS) and dynamic Ki67 response after short preoperative endocrine therapy are potentially predictive for pCR. Still, no prospective data are available so far to predict chemotherapy efficacy in this key patient group. Use of dose-dense chemotherapy is associated with improved outcome in meta-analysis, but its use in the neoadjuvant setting is less studied. Furthermore, use of nab-paclitaxel instead of solvent-based paclitaxel has shown promising results in some studies. Here, we present for the first time data from a randomized prospective trial comparing these risk-selection strategies according to RS and Ki67 decrease in high-risk HR+/HER2- BC. **Methods:** High-risk BC patients [cN0-1 with RS>25 or (RS 12-25 AND (centrally measured) post-endocrine Ki67 >10%) OR [cN2-3 status] OR [G3 AND Ki67>40%] were randomized to (neo)adjuvant 4x paclitaxel<sub>175</sub> q2w or 8xnab-paclitaxel 125 mg/m<sup>2</sup>q1w followed by 4x E<sub>90</sub>C<sub>600</sub> q2w. pCR was defined as no invasive tumor in breast and lymph nodes. **Results:** 858 patients with available surgery data randomized to neoadjuvant Pac-EC (N=423) or nab-Pac-EC (N=435) were analyzed. Median age was 51 years; median RS was 30 (N=572); 34% had node-positive; 46% (locally) G3 tumors. Baseline characteristics were well balanced between study arms. Patients receiving nab-Pac-EC had higher pCR than those with Pac-EC (20.3% vs. 12.3%, p=.002); patients with RS<25 (about 27%) had a lower pCR rate than those with RS>25 (6.5% vs. 15.8%, p=.003). The association of RS with pCR appeared more pronounced in premenopausal women, but a test of interaction was not significant; RS was about 3 points higher (mean 32.9 vs. 29.8, p<.001) in postmenopausal cases (p=.001). Clinical tumor stage cT2-4 was reported in 65%, with a lower pCR rate than in cT1 tumors (14% vs. 20%, p=.02). RS was moderately correlated (R=.45) with baseline Ki67. In multivariable analysis with tumor stage, RS, Ki67, menopausal status, and ER and PR positivity, higher RS and cT1 stage were favorable for pCR. Excluding RS, higher Ki67 and lower ER (as well as cT1) were favorable. In patients with RS<25, there was no pCR with Pac-EC (0/72 pCR); pCR was almost 20% with RS>25 and nab-Pac-EC. Further details and data including impacts of Ki67 dynamics and additional markers on pCR will be presented at the meeting. **Conclusions:** Use of neoadjuvant nab-paclitaxel instead of solvent-based paclitaxel appears promising within a short (16-weeks) dose-dense chemotherapy schedule in high-risk HR+/HER2- BC. For the first time, data from a large neoadjuvant randomized trial confirm RS could help to select patients for neoadjuvant chemotherapy in high-risk HR+/HER2- breast cancer (BC).

Interim safety and efficacy analysis of phase IB / II clinical trial of tucatinib, palbociclib and letrozole in patients with hormone receptor and HER2-positive metastatic breast cancer

Elena Shagisultanova<sup>1</sup>, William Gradishar<sup>2</sup>, Ursula Brown-Glaberman<sup>3</sup>, Pavani Chalasani<sup>4</sup>, Andrew J. Brenner<sup>5</sup>, Alison Stopeck<sup>6</sup>, Jose Mayordomo<sup>1</sup>, Jennifer R. Diamond<sup>1</sup>, Peter Kabos<sup>1</sup> and Virginia F. Borges<sup>1</sup>. <sup>1</sup>University of Colorado Denver, Aurora, CO; <sup>2</sup>North Western University, Chicago, IL; <sup>3</sup>University of New Mexico, Albuquerque, NM; <sup>4</sup>University of Arizona Cancer Center, Tucson, AZ; <sup>5</sup>University of Texas Health San Antonio, San Antonio, TX; <sup>6</sup>Stony Brook University, New York, NY

**Background:** In hormone receptor-positive / HER2-positive (HR+/HER2+) breast cancer, the HER2 and estrogen receptor (ER) signals merge on the cyclin D1-CDK4/6-RB1 pathway. Thus, a combined pharmacological intervention with individual drugs targeting HER2, ER and CDK4/6 is warranted. Here, we present the safety and efficacy results of the combination of tucatinib with letrozole and palbociclib in patients (pts) with HR+/HER2+ metastatic breast cancer (MBC) (NCT03054363).

**Methods:** Pts with HR+/HER2+ MBC previously treated with at least 2 HER2-targeted agents were enrolled in this phase IB/II clinical trial. Pts with untreated asymptomatic or stable treated brain metastasis (BM) were included. Pts with treated progressing BM were enrolled after local treatment and classified as treated stable. Treatment consisted of tucatinib 300mg PO BID and letrozole 2.5mg PO daily continuously, and palbociclib 125mg PO daily 21 days on, 7 days off. Due to drug-drug interaction issues found in the middle of the trial and not related to this study, the dose of sensitive CYP3A4 substrate palbociclib was reduced to 75mg for all study participants, as it became evident that tucatinib is a strong CYP3A4 inhibitor. The primary end-points were assessment of safety using CTCAE v.4.03 criteria, and progression free survival (PFS). Secondary end-points included pharmacokinetic evaluation (PKs) and objective response rate by RECIST 1.1. BM response was evaluated using RANO-BM criteria. All pts who received at least one cycle of therapy were assessed for safety.

**Results:** Between 11.21.2017 and 04.20.2020, we enrolled 42 pts of whom 40 were evaluable. Median age was 52.5 years (range, 22 to 82) and the median number of prior lines of therapy for MBC was 2 (range, 0 to 7); 23 pts (58%) had visceral disease and 15 (38%) had BM. All pts had prior therapy with trastuzumab and pertuzumab and 18 pt (45%) had prior T-DM1. As of 06.15.2020 data cut off, 14 patients were on active therapy while 26 were off study (22 due to progressive disease [PD], 1 due to toxicity and 3 for other reasons). Median follow up time was 6 months. The combination was well tolerated with manageable and expected adverse events (AEs). The most common grade ≥3 AEs were neutropenia (25 pts, 60%), leukopenia (10 pts, 24%), diarrhea (8 pts, 19%), fatigue (6 pts, 14%), and infections (6 pts, 14%). One pt came off study due to asymptomatic grade 4 elevated LFTs that resolved without sequelae. There were no deaths due to AEs. Among 26 pts with measurable disease at the time of data cut-off, 8 pts (31%) had partial response, 16 pts (62%) had stable disease (SD) (7 pts [27%] had SD for ≥ 6 months and 6 pts [23%] have not yet reached 6 months of follow up) and 2 pts (8%) had PD. Among 14 patients with BM and evaluable disease by RANO-BM, 1 pt had complete response in the brain, 6 pts had SD in the brain for ≥6 months, and 7 pts had SD for 2-6 months (4 pts on active therapy have not yet reached 6 months of follow up). Median PFS is 8.7 months (10.1 months for pts without BM and 6.0 months for those with BM). Updated analysis including PKs, tumor response, and PFS will be presented.

**Conclusion:** The combination of tucatinib with letrozole and palbociclib showed a tolerable and manageable safety profile and evidence of considerable anti-tumor activity that warrant further clinical investigation in pts with HR+/HER2+ MBC.

**Background** Healthy lifestyle, including caloric restriction, balanced diet and physical activity, is important in primary and secondary prevention of breast cancer (BC). It is known that Mediterranean diet reduces metabolic syndrome and insulin resistance that are associated with increased risk of BC onset and recurrence. Physical activity decreases BMI, blood concentrations of testosterone, estrogens, insulin, its resistance and strengthens anti-inflammatory pathways against tumor cells. Since January 2014, at our Institution we promoted a project named "Lifestyle Program" for high risk BC patients underwent to primary surgery. Here we presented the results of 12 months of "Lifestyle Program". **Patients and methods** Since January 2014 we have prospectively enrolled all high risk patients between 18 and 70 years treated to our department for invasive early-stage breast cancer (stage I-III). High risk has been defined by one or more of the following inclusion criteria: body mass index (BMI) > 25, diagnosis of metabolic syndrome, increased level of blood testosterone and/or insulin. All high risk patients receive a periodical personalized educational intervention by a physiatrist for physical activity and by a nutritionist for a mediterranean diet low in animals fat and enriched of fibers, fruits and vegetables. All patients underwent to screening for anxiety and depression through HADS questionnaire scores. All data were analyzed by Chi-square test assuming statistical significance at  $p < 0.05$ . **Results** 98 BC patients were included; 21.4% of them had a metabolic syndrome. Median age was 56 years old (range 27-75). Most of patients enrolled had ER+ (85.7%), Her2/neu negative (79.6%), stage I (48%) BC. We observed a statistically significant reduction of BMI (BMI>25 in 94.9% of pts at baseline vs 63.2% after 12 months of lifestyle;  $p < 0.0001$ ), glycemic (>110 mg/dl in 23.5% of pts at baseline vs 10.2% at 12 months;  $p < 0.0001$ ), insulin levels (>27 uU/ml in 20.6% of pts at baseline vs 2.9% after 12 months;  $p < 0.0001$ ), testosterone (>1.2 ng/ml in 17.6% of pts at baseline vs 4.1% at 12 months;  $p < 0.0001$ ), cholesterol (>200 mg/dl in 46.9% of pts at baseline vs 35.7% at 12 months;  $p < 0.0001$ ), triglycerides (>170 mg/dl in 13.3% of pts at baseline vs 10.2% at 12 months;  $p < 0.0001$ ) and arthralgia (37.7% at baseline vs 17.3% at 12 months;  $p = 0.0008$ ). We also noted a significantly reduction of anxiety and depression after 12 months of lifestyle program (25.4% and 12% respectively at diagnosis vs 13.4% and 4.5% at 12 months respectively;  $p = 0.0064$  and  $p < 0.0001$ ). **Conclusions** Promoting healthy lifestyle can reduce risk factors involved in BC recurrence and ensure psychological benefit and compliance to endocrine therapy. A multidisciplinary approach allows greater adherence to healthy attitudes in BC high risk patients.

Prognostic value of clinical treatment score post-5 years (CTS5) and late relapse risk in hormone receptor-positive HER2-positive breast cancer in the North Central Cancer Treatment Group (NCCTG) N9831 (Alliance) and NSABP B-31 (NRG) trials

Tanyami Pai<sup>1</sup>, Angelica Gil<sup>2</sup>, Yaohua Ma<sup>1</sup>, Zhuo Li<sup>1</sup>, Pooja Advani<sup>1</sup>, Moreno Moreno-Aspitia<sup>1</sup>, Gerardo Colon-Otero<sup>1</sup>, Edith A. Perez<sup>1</sup>, Yan Asmann<sup>1</sup>, Katherine Pogue-Geile<sup>3</sup>, E. A. Thompson<sup>1</sup> and Saranya Chumsri<sup>1</sup>. <sup>1</sup>Mayo Clinic, Jacksonville, FL; <sup>2</sup>University of South Florida, Tampa, FL; <sup>3</sup>NSABP/NRG, Pittsburgh, PA

**Background:** Although risk of late relapse in hormone receptor-positive (HR+) breast cancer is well established, most existing data pertain to the HR+ HER2-negative (HER2-) subgroup. CTS5 is one of the models for predicting risk of late relapse in HR+ HER2- breast cancer. However, the value of this model in HR+ HER2+ disease is less known, particularly in the context of adjuvant trastuzumab. Here, we evaluated CTS5 in patients with early stage HR+ HER2+ breast cancer treated in the NCCTG N9831 (Alliance for Clinical Trials in Oncology) and NSABP B-31 (NRG) trials. **Methods:** Stage I-III HR+ (ER+ and/or PR+) HER2+ breast cancer patients who were free of recurrence after 5 years in N9831 and B-31 trials were included. The online CTS5 calculator was used to determine CTS5 score and risk group (low, intermediate, and high) based on age, tumor size, grade, and number of involved nodes. Kaplan-Meier (KM) estimates, Cox regression models, and C index were used for analysis. N9831 and B-31 trials were analyzed separately. **Results:** 1,204 patients in N9831 and 658 patients in B-31 met the entry criteria. Baseline characteristics were similar between both trials, including median age, tumor size, and follow up. Similar distribution within CTS5 risk group was observed in both trials; 68.2% and 70.1% patients were high risk, 24% and 21.9% as intermediate risk, as well as 7.8% and 8.1% as low risk classified in N9831 and B-31, respectively. Using univariate Cox regression analysis, CTS5 score as a continuous variable was associated with recurrence-free survival (RFS) in the entire study cohort, including patients who received chemotherapy alone or in combination with trastuzumab, (HR 1.37, 95%CI 1.03-1.81, p=0.03, C index 0.57 in N9831 and HR 1.36, 95%CI 1.06-1.76, p=0.02, C index 0.54 in B-31), but not in patients who received concurrent trastuzumab (HR 1.19, 95%CI 0.73-1.2, p=0.49, C index 0.54 in N9831 and HR 1.35, 95%CI 0.96-1.9, p=0.08, C index 0.54 in B-31). As categorical variable in the entire study cohort, CTS5 risk group was not significantly associated with RFS among patients with intermediate vs. low (HR 0.47, 95%CI 0.18-1.22, p=0.12 and HR 1.61, 95%CI 0.66-3.92, p=0.29) and high vs. low (HR 1.23, 95%CI 0.57-2.67, p=0.6 and HR 1.93, 95%CI 0.85-4.41, p=0.12) with the C index of 0.58 and 0.53 in N9831 and B-31 respectively. There was also no significant difference in RFS among 3 CTS5 risk groups with Kaplan-Meier estimates. Among patients who received concurrent trastuzumab, similar trends were observed with no statistical difference in RFS between high vs. low (HR 0.68, 95%CI 0.24-1.97, p=0.48 and HR 1.44, 95%CI 0.52-3.96, 0.49) with the C index of 0.55 and 0.51 in N9831 and B-31, respectively. Paradoxically, patients with intermediate risk had better RFS than low risk (HR 0.18, 95%CI 0.03-0.97, p=0.05) in N9831 but no significant difference in B-31 (HR 1.31, 95%CI 0.44-3.95, p=0.63). **Conclusions:** While CTS5 score as a continuous variable was associated with outcome in overall HR+ HER2+ population, this model was not prognostic in patients receiving adjuvant trastuzumab in both N9831 and B-31 trials. Furthermore, the correlation (C index) was modest and CTS5 risk group as a categorical variable could not stratify outcome in this group of patients. This study underlines the need to develop a new prognostic model to better delineate the risk of late relapse in HR+ HER2+ breast cancer patients receiving trastuzumab as this model can facilitate clinical decision for extended adjuvant endocrine therapy. **Support:** BCRF-19-161, U10CA180821, U10CA180868 and U10CA180822 (NRG), Genentech. <https://acknowledgments.alliancefound.org>

Fertility preservation for breast cancer patients before chemotherapy

Chih-Ning Chen<sup>1</sup>, Lu-Te Chang<sup>2</sup> and Ka-Wai Tam<sup>2</sup>. <sup>1</sup>Taipei Medical University, Taipei City, Taiwan<sup>2</sup>Shuang Ho Hospital, New Taipei City, Taiwan

**Background:** Various strategies of fertility preservation for breast cancer patients have been purposed for women at childbearing age. Ovarian stimulation protocols for oocyte/embryo cryopreservation are common means, but are introduced differently and detail regimens vary widely. Protocols for better oocyte cryopreservation outcomes and patients' hormone stability remain to be determined. **Research Objectives and Rationale:** To compare oocyte/embryo cryopreservation outcomes after random-start ovarian stimulations with conventional ones as well as to investigate the effects after double ovarian stimulation cycles, co-administration of aromatase inhibitors or tamoxifen on stabilizing breast cancer patients' estrogen level, the efficiency of oocyte in vitro maturation for fertilization and the impact of patients' genetic background on fertility preservation outcomes. **Methods:** A systematic review followed by a meta-analysis was performed to identify all relevant studies published before June 2020. The primary outcomes were the numbers of retrieved oocytes. The secondary outcomes were the numbers of mature oocytes and peak serum estradiol levels. **Outcomes:** A total of 29 studies met the inclusion criteria. Random-start ovarian stimulations resulted in comparable numbers of retrieved oocytes as conventional protocols did (retrieved oocytes: 503 patients, weighted mean difference [WMD]: -0.01, 95% CI: -2.08 - 2.06,  $P = 0.99$ ;  $I^2 = 0\%$ ). Two cycles of ovarian stimulation have significant higher numbers of total retrieved oocytes compared to a single cycle (102 patients, WMD: 7.91, 95% CI: 3.42 - 12.40,  $P = 0.0006$ ;  $I^2 = 0\%$ ). Both co-administration of letrozole and tamoxifen showed similar results of retrieved oocytes compared to those without (letrozole versus without: 681 patients, WMD: -0.68, 95% CI: -1.96 - 0.61,  $P = 0.30$ ;  $I^2 = 0\%$ ) (tamoxifen versus without: 87 patients, WMD: 0.67, 95% CI: -1.29 - 2.64,  $P = 0.50$ ;  $I^2 = 45\%$ ). Significant lower peak serum estradiol level was observed in letrozole-based groups compared to letrozole-free groups (301 patients, WMD: -1.05, 95% CI: -1.21 - -0.89,  $P < 0.00001$ ;  $I^2 = 0\%$ ). No significant differences were found in peak serum estradiol level between those co-treated with tamoxifen and those without (87 patients, WMD: 0.21, 95% CI: -0.01 - 0.43,  $P = 0.07$ ;  $I^2 = 26\%$ ). Regarding breast cancer patients with different BRCA gene background, lower AMH levels were discovered in those with BRCA mutations (831 patients, WMD: -0.63, 95% CI: -1.18 - -0.08,  $P = 0.03$ ;  $I^2 = 47\%$ ); however, no significant differences were found in the numbers of retrieved oocytes (retrieved oocytes: 550 patients, WMD: -1.33, 95% CI: -2.72 - 0.05,  $P = 0.06$ ;  $I^2 = 0\%$ ). **Wider implications:** We systematically investigated various aspects of ovarian stimulation for oocyte retrieval in breast cancer patients undergoing fertility preservation prior to chemotherapy, our review indicated that (1) random-start controlled ovarian stimulation protocol showed comparable oocyte yields with minimal delays of referral to initiate ovarian stimulation; (2) two ovarian stimulation cycles results in higher numbers of retrieved oocytes while back-to-back and conventional two cycles showed no significant differences; (3) combinations with letrozole demonstrated a safer way over tamoxifen and anastrozole in terms of lowering estradiol level during stimulation processes; (4) in vitro maturation of immature oocytes can maximize the numbers of oocytes for cryopreservation; and (5) regarding patients' genetic backgrounds, those with BRCA mutations have lower AMH levels, but similar in numbers of retrieved oocytes to those without BRCA mutations. Nonetheless, we look forward to higher evidence-level studies to understand the clinical relevance of these protocols for ovarian stimulation in breast cancer patients desiring fertility preservation before chemotherapy.

**Background:** MONALEESA-7 (NCT02278120), the first large randomized phase III clinical trial dedicated to investigating a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) plus ET vs ET + placebo (PBO) in pre- or perimenopausal patients with HR+/HER2- ABC, previously demonstrated a statistically significant improvement in OS with the addition of ribociclib (RIB) to ET vs PBO + ET (median, not reached vs 40.9 months; HR, 0.71 [95% CI, 0.54-0.95];  $P = .00973$ ; Im SA, et al. *N Engl J Med*. 2019). This concluded the protocol-defined final analysis of OS and the patients and investigators were unblinded to their treatment assignment allowing patients on the PBO arm to cross-over to RIB treatment. Longer follow-up allows for more events to further characterize the long-term survival benefits. Here we report an exploratory update of OS after a minimum of ~ four years of follow-up, an additional 20 months since the last report. **Methods:** Pre- or perimenopausal patients with HR+/HER2- ABC were randomized 1:1 to receive RIB or PBO plus goserelin with either a nonsteroidal aromatase inhibitor (NSAI; letrozole or anastrozole) or tamoxifen. RIB is approved in combination with an NSAI in pre- or perimenopausal patients. Patients who had received a prior CDK4/6i or ET in the advanced setting were excluded. Patients who received ET in the (neo)adjuvant setting or ≤ 1 prior line of chemotherapy for advanced disease were eligible to enroll. Updated OS were evaluated by Cox proportional hazards model and summarized using Kaplan-Meier methods. Additional post-progression endpoints such as progression-free survival 2 (PFS2), time to chemotherapy (CT) and CT-free survival were also evaluated and summarized. **Results:** The data cutoff for this updated OS analysis was 29 June 2020, and the median follow-up was 53.5 mo (min, 46.9 mo). These updated results with extended follow-up demonstrated an OS benefit with RIB + ET vs PBO + ET (median, 58.7 vs 48.0 mo; HR, 0.76 [95% CI, 0.61-0.96]). In patients receiving an NSAI, a similar OS benefit was observed with RIB + NSAI vs PBO + NSAI (median, 58.7 vs 47.7 mo; HR, 0.80 [95% CI, 0.62-1.04]). The survival benefit shown in subgroup analyses was consistent with the intent-to-treat (ITT) population. PFS2, time to chemotherapy (CT), and CT-free survival for the ITT and NSAI populations are in the Table. Among the patients who discontinued study treatment, 77.3% and 78.1% in the RIB + ET vs PBO + ET arms received a subsequent antineoplastic therapy, respectively, and 12.9% and 26.1% received a subsequent line of CDK4/6i. Additionally there were 15 patients in the PBO arm that crossed over to the RIB arm following unblinding and prior to disease progression. **Conclusions:** With an extended follow-up of more than 4 years, RIB + ET continued to demonstrate a clinically relevant OS benefit compared with ET alone in pre- or perimenopausal patients with a median OS ~5 years with RIB + ET in HR+/HER2- ABC. A similar benefit with RIB was observed for PFS2, time to CT, and CT-free survival.

Clinical-grade detection of breast cancer in biopsies and excisions using machine learning

Matthew G Hanna<sup>1</sup>, Patricia Raciti<sup>2</sup>, Ran Godrich<sup>2</sup>, Adam Casson<sup>2</sup>, Julian Viret<sup>2</sup>, Donghun Lee<sup>2</sup>, Matthew Lee<sup>2</sup>, Alican Bozkurt<sup>2</sup>, Jillian Sue<sup>2</sup>, Belma Dogdas<sup>2</sup>, Brandon Rothrock<sup>2</sup>, Leo Grady<sup>2</sup>, Christopher Kanan<sup>2</sup> and Thomas Fuchs<sup>2</sup>. <sup>1</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>2</sup>Paige, New York, NY

**Background:** Pathologists reviewing breast tissue slides must identify the presence of many salient features within each slide, including invasive and in situ breast cancer as well as various forms of atypia. In breast pathology particularly, the large volume of slides poses significant challenges for workload management and pathologist productivity (Johnson et al. 2019). The shift to a digital workflow in pathology, augmented by machine learning algorithms, has the potential to increase the efficiency, and productivity of pathologists by identifying cancer and pre-cancerous lesions in digitized slides. While there has been extensive work using machine learning algorithms to detect breast cancer metastasis in lymph nodes (Liu et al. 2018; Steiner et al. 2018), almost no research has been done on using such systems to detect breast cancer in biopsies and excisions.

**Methods:** We created and assessed Paige Breast Alpha, a machine learning system for the detection of breast cancer in hematoxylin and eosin (H&E) stained whole slide images (WSIs) of glass slides. The system is a binary classifier, intended to draw a pathologist's attention to concerning features. Concerning features (the positive category) consisted of invasive breast cancer, in situ breast cancer, and various forms of atypia (atypical ductal hyperplasia, atypical lobular hyperplasia, etc. ). The deep learning system is based on the method proposed in Campanella et al. (2019). It learns directly from diagnosis using multiple instance learning, without the need for pixel-wise annotations. Paige Breast Alpha was trained on 17354 images from 3378 patients, and was assessed on 7921 images from 2443 patients. All slides were scanned on a Leica Aperio AT2.

**Results:** For detecting invasive or in situ cancer at the part level, the system achieved an overall sensitivity of 97.3% and a specificity of 98.0% in biopsies and 96.1% sensitivity and 91.5% specificity in excisions. Each part had between 1—10 slides.

**Conclusions:** We hypothesized that a machine learning system trained to detect predefined types of breast cancer and pre-cancerous lesions could be applied to a range of breast biopsy and resection WSIs to detect for the presence of these lesions. Herein we showed that the presence of these predefined features can be detected with high accuracy. Future studies are being initiated to assess the potential benefits of such a system when used by a pathologist. Additional systems are under development that would have the capability of subtyping the lesion present, in addition to acting as an overall binary classifier.

A FOXA1/FRA1-centered transcriptional axis regulates interferon signaling in high FOXA1-associated endocrine-resistant and metastatic breast cancer

Xiaoyong Fu<sup>1</sup>, Resel Pereira<sup>1</sup>, Lanfang Qin<sup>1</sup>, Carmine De Angelis<sup>1</sup>, Sarmistha Nanda<sup>1</sup>, Martin Shea<sup>1</sup>, Agostina Nardone<sup>2</sup>, Rinath Jeselsohn<sup>2</sup>, Ofir Cohen<sup>2</sup>, Nikhil Waggle<sup>2</sup>, Mothaffar Rimawi<sup>1</sup>, C Kent Osborne<sup>1</sup> and Rachel Schiff<sup>1</sup>. <sup>1</sup>Baylor College of Medicine, Houston, TX; <sup>2</sup>Dana-Farber Cancer Institute, Boston, MA

**Background:** Forkhead box A1 (FOXA1) is an essential pioneer transcription factor (TF) evoking other key TFs-mediated lineage-specific transcriptional programs in several endoderm-derived organs. Aberrant FOXA1 augmentation, via genetic alterations, occurs in 10-15% of ER+ primary and metastatic breast cancer (BC). We have recently shown that high levels of FOXA1 (H-FOXA1) induces enhancer and transcriptional reprogramming to promote endocrine-resistant (EndoR) and pro-metastatic phenotypes. Using the core transcriptional regulatory circuitry (CRC) mapping method, we identified the AP-1 TF JUNB as a key CRC component in BC cells expressing H-FOXA1. In this study, we aimed to further characterize key AP-1 components that play a role in mediating H-FOXA1-induced transcriptional reprogramming in EndoR and metastatic BC. **Methods:** The ROSE and HOMER tools were used to identify super-enhancers (SEs) and the predicted SE-harboring TFs in MCF7-parental (P) cells with ectopic FOXA1 overexpression (OE), and in MCF7 tamoxifen-resistant (TamR) cells with endogenous FOXA1 amplification and OE. Cell growth, migration, and co-immunoprecipitation assays, were performed using ER+ BC P cells with ectopic FRA1 OE. A FOXA1 core gene signature (GS) was deduced using the BETA.plus algorithm to analyze our previously reported RNA-seq and ChIP-seq data derived from MCF7-P cells with ectopic FOXA1 OE. Additional RNA-seq analyses include MCF7-P cells with ectopic FRA1 OE, FOXA1 OE and simultaneous FRA1 siRNA knockdown (KD), and MCF7-TamR cells with FRA1 KD. We identified a FOXA1/FRA1-centered GS and its clinical relevance was examined using expression profiles of TCGA, METABRIC, and a metastatic biopsy study from cohort of patients with ER+ metastatic BC from Dana-Farber Cancer Institute. **Results:** We identified FRA1 as one of the top TFs selectively harboring SEs at their gene loci in MCF7-TamR vs. P cells. Both FRA1 and JUNB expression was elevated in TamR vs. P cells and altered concordantly with FOXA1 in P and TamR cells upon FOXA1 OE or KD, respectively. As we identified JUNB as a CRC component with binding sites enriched at the SEs in BC cells expressing H-FOXA1, we hypothesized that FRA1 and JUNB form a feed-forward transcriptional axis amplifying H-FOXA1-induced enhancer reprogramming. We found that JUNB co-immunoprecipitated with FRA1 in MCF7-TamR and MCF7-P cells with ectopic FRA1 OE, suggesting that FRA1 forms a heterodimer with JUNB to exert AP-1 activity. Ectopic FRA1 OE reduced P cell endocrine sensitivity, increased cell migration, and elicited a transcriptome enriched for the FOXA1-induced core GS. In P cells with ectopic FOXA1 OE, we identified a FRA1-dependent GS ( $n = 27$ ) that is highly enriched for interferon signaling. This FOXA1/FRA1 GS was highly expressed in luminal B vs. A subtype of primary tumors, further elevated in ER+ metastases, where its expression was positively correlated with FRA1 mRNA levels. Notably, this FOXA1/FRA1 GS was not dependent on FRA1 in P cells without FOXA1 OE, suggesting its relevance in the context of H-FOXA1. **Conclusions:** Here we show that a FOXA1/FRA1-centered transcriptional axis induces an interferon signaling-enriched GS associated with poor outcome of ER+ BC and metastasis. A FRA1/JUNB AP-1 complex may form a feed-forward transcriptional axis to amplify H-FOXA1 signaling. The FOXA1/FRA1-centered GS could be used to stratify patients with ER+ BC who may need additional targeted therapies. Further studies are warranted to elucidate the interplay between FOXA1 and FRA1/JUNB in regulating interferon signaling, which may guide approaches to improve patient outcomes, possibly with immunotherapy using immune checkpoint inhibitors.

Patterns of medical behavior in the management of breast cancer during COVID-19. Mexican Experience

Ricardo Villalobos Valencia and Samuel Rivera Rivera. Hospital de Oncología Centro Medico Nacional Siglo XXI. IMSS, Mexico City, Mexico

**Objective.** This survey was conducted with medical oncologists treating breast cancer and explores how the COVID-19 pandemic has impacted their approach to managing breast cancer. **Method.** A questionnaire of ten questions was sent electronically to 123 medical oncologists throughout the Mexican Republic from June 25 to 29, 2020, a critical moment in our patient with the highest reports of new cases of patients with COVID-19. **Results.** Of the respondents, 47.1% work in a public and private hospital, 21.9% and 30.0% exclusively in the public and private respectively. Modification of treatment schemes due to the pandemic is reported in 42.5% (51) and 34.1% (41) occasionally. The dose modification has occurred mainly in the palliative context 71.3%. The modification of intravenous to oral chemotherapy was confirmed in 78.2% of the respondents, but this was in less than 30% of the patients. Only 27.1% of doctors have prolonged their chemotherapy schedules. To the question of postponing visits in patients under surveillance or in adjuvant with endocrine therapy, 80% of the doctors answered confirmatory. Private online consultation has been implemented in 57.8% of doctors. When asked to have patients with breast cancer and a positive test for COVID-19, 37% (43 doctors) confirmed having had patients. Delays in diagnostic protocols for breast cancer were reported in 74.5% (85). Finally 37.7% reported that less than 25% of their patients did not attend their scheduled appointment and 32.4% of the doctors reported that between 25% to 50% of their patients postponed the medical visit. (See images of results). **Conclusion.** In Mexico, like many countries, the treatment and follow-up of patients with breast cancer has been affected by the pandemic, a factor that impacts the results is that in our country we have a shortage of oncological drugs for more than a year, including sometimes cyclophosphamide, anthracyclines and taxanes that are essential for this disease. Management and diagnosis protocols have been delayed since medical care has been prioritized for patients with COVID-19. Unfortunately, there is no national registry of cancer patients, much less the association of cancer with COVID-19. The study, however, reflects similarity of results with other countries in medical behavior.

**Publication Number:** OT-02-01

A longitudinal study assessing sexual dysfunction in postmenopausal women with breast cancer undergoing adjuvant treatment

Heidi Worth, Timothy Panella, Clayton Bell, Mark Rasnake, Patricia Roberson and Lauren Lewis. University of Tennessee, Knoxville, TN

According to the Diagnostic and Statistical Manual of Mental Disorders, 5<sup>th</sup> Edition (DSM-5), Female Sexual Dysfunction is defined as a sexual problem associated with personal distress. It can be caused by any of the following: lack of sexual desire, impaired arousal, inability to achieve orgasm, or pain with sexual activity.

Several studies have demonstrated the negative impact chemotherapy has on sexual functioning, short term and long term in women undergoing breast cancer treatment. Most of the research that has been done in this area only evaluated this problem in premenopausal women. The limited studies investigating this in postmenopausal women have found similar effects in this population group.

The goal of this study is to assess sexual dysfunction in high risk postmenopausal women with breast cancer undergoing adjuvant therapy. We want to define this problem in this poorly studied subgroup, and to assess the degree of dysfunction, time course over which it occurs, and the particular sexual domains this occurs in. T

This longitudinal study will assess sexual functioning utilizing two survey tools- the Female Sexual Function Index (FSFI), and the Female Sexual Distress Scale (FSDS-R). The FSFI is a 19- item questionnaire that assesses six domains of sexual functioning: desire, arousal, lubrication, orgasm, satisfaction, and pain. The FSFI has been proven to have excellent validity and reliability in determining sexual dysfunction in healthy women, as well as women with various cancers including breast cancer. It was designed to be easy to use, and can be used in heterosexual, as well as homosexual women. To be consistent with the DSM 5's definition of sexual dysfunction regarding personal distress, which is not evaluated in the FSFI, the FSDS-R will be utilized. This is a 13-item questionnaire, which has demonstrated excellent validity and reliability in determining sexual distress associated with sexual dysfunction.

Participants will serve as their own control while assessing any change in sexual functioning over the course of the administration of 2-3 survey sets. The 1<sup>st</sup> set of surveys will be administered prior to receiving any treatments, this will serve as a baseline assessment for future comparison. The last 1-2 survey sets will be administered 6 months to 1 year after the initiation of adjuvant therapy.

Data will be analyzed with a Repeated Measures ANOVA if statistical assumptions are met. If statistical assumptions are not met the Friedman ANOVA will be used. Post-Hoc testing will be conducted if significant main effects are found.

At this time, 13 patients are currently enrolled in this trial. The number of participants for this study to achieve statistical power was calculated to be n=42. This calculation was based on one treatment group, with three observations across time, a correlation amount of repeated measures of 0.5, and a non-sphericity correction of 1.0. The

assumed effect size was small to moderate with an F=0.20, an alpha of 0.05, and a beta of 0.20.

**Eligibility Criteria for this trial:** •Must be a postmenopausal female •Diagnosed with Stage I, II, or III breast cancer •Not currently receiving endocrine therapy or chemotherapy •Plans with their physician to receive adjuvant therapy

**Background:** Physical resilience, the ability to resist decline and maintain functional status despite a stressor such as chemotherapy, is a central aspect of successful aging. Understanding clinical and biological factors associated with resilience in older women receiving chemotherapy for early breast cancer may facilitate the development of targeted interventions to maintain an individual's robustness. **Methods:** Women age  $\geq 65$  (N=406) with Stage I-III breast cancer who were part of a clinical study of neo/adjuvant chemotherapy in older women were recruited from 16 sites (NCT01472094, R01AG037037). The Deficit Accumulation Index (DAI), a continuous score (0-1) calculated based on 51-items from geriatric assessment data (Cohen et al Cancer 2017), was measured before and after receipt of chemotherapy. DAI was categorized as robust (0.0<0.2), prefrail (0.2<0.35) and frail ( $\geq 0.35$ ). Baseline blood biomarkers of inflammation (interleukin-6 [IL-6], C-reactive protein [CRP]) and coagulation (D-dimer) were measured and defined as elevated if values were  $\geq$  median values in this cohort. The population of interest was older women who were robust prior to initiation of chemotherapy. The primary outcome was resilience (Yes/No); yes, defined as retaining robustness [DAI 0.0<0.2] before and  $\leq 1$  month after chemotherapy. Demographic, disease, and pretreatment variables associated with resilience in univariate analysis with  $p < 0.1$  were further adjusted using multivariable logistic regression to examine the associations between baseline biomarkers and resilience. **Results:** Before starting chemotherapy, 324 of 406 (80%) older women were robust. The median age was 70 (range 65-86), 61% had stage II or III disease, 29% had HER2+ disease, 22% had TNBC, 37% received an anthracycline-based regimen, 49% had planned duration of treatment  $> 12$  weeks, and 74% received primary prophylaxis with WBC growth factors. Among these 324 robust older women, 253 (78%) remained robust (resilient) at the end of chemotherapy, 63 (19%) became prefrail, and 8 (3%) became frail. In univariate analyses, patients treated with anthracycline (OR=0.63,  $p=0.09$ ), planned duration of treatment  $> 12$  weeks (OR=0.56,  $p=0.04$ ), elevated IL-6  $\geq 2.7$  pg/ml (OR=0.59,  $p=0.05$ ), elevated CRP  $\geq 4.3$   $\mu$ g/ml (OR=0.57,  $p=0.04$ ), elevated D-dimer  $\geq 0.7$   $\mu$ g/ml (OR=0.61,  $p=0.07$ ), or at least one elevated biomarker (OR=0.18,  $p < 0.001$ ) at baseline were less likely to be resilient after systemic chemotherapy. Adjusting for anthracyclines and treatment duration, patients who had one or more elevated biomarker were still significantly less likely to be resilient (OR=0.15, 95 CI 0.04-0.49,  $p=0.002$ ) compared to those with no elevated biomarkers at baseline.

Table 1. Multivariable associations between baseline blood biomarkers and resilience				
	Resilient (n=253) No. %	Non-resilient (n=71) No. %	Multivariable OR (95%CI)	P value
# of elevated biomarkers*				
0	64 (25)	4 (6)	1.00	
1	90 (36)	29 (41)	0.16 (0.05-0.55)	0.004
2	55 (22)	22 (31)	0.14 (0.04-0.49)	0.002
3	44 (17)	16 (23)	0.14 (0.04-0.51)	0.003
No elevated biomarker	64 (25)	4 (6)	1.00	
At least one elevated	189 (75)	67 (94)	0.15 (0.04-0.49)	0.002
*Biomarkers were defined as elevated using the entire cohort median value as cut off points (IL-6 $\geq 2.7$ pg/ml, CRP $\geq 4.3$ $\mu$ g/ml, and D-dimer $\geq 0.7$ $\mu$ g/ml). Combined effects of biomarkers were examined by creating a four-level categorical combination variable: 0=all three biomarkers are <median; 1=one of the biomarkers $\geq$ median; 2=two of the biomarkers $\geq$ median; and, 3=all three biomarkers $\geq$ median. A dichotomized variable was also created comparing none (all three biomarkers are <median) vs at least one biomarker elevated ( $\geq$ median).				

**Conclusions:** In this cohort of older women with early breast cancer who were robust prior to initiation of chemotherapy, 22% became prefrail or frail at end of treatment. Resilience to chemotherapy was related to inflammatory and coagulation biomarkers. Further research is needed to examine the mechanism underlying why some older women are resilient and retain their robustness after receiving treatment, whereas others experience decline, and further explore the role of inflammation/coagulation in this phenomenon.

Active surveillance for DCIS: Clinical outcomes at 5.6 years mean follow-up

Case Brabham<sup>1</sup>, Rita Mukhtar<sup>1</sup>, April Liang<sup>1</sup>, Paul Kim<sup>2</sup>, Gillian Hirst<sup>1</sup>, Amrita Basu<sup>1</sup>, Heather Greenwood<sup>1</sup>, Rita Freimanis<sup>1</sup>, Alexander Borowsky<sup>3</sup>, Shelley Hwang<sup>4</sup>, Rick Baehner<sup>1</sup>, Gregor Krings<sup>1</sup>, Nola Hylton<sup>1</sup> and Laura Esserman<sup>1</sup>. <sup>1</sup>University of California, San Francisco, San Francisco, CA;<sup>2</sup>Frank H Netter MD School of Medicine, Quinnipiac, CT;<sup>3</sup>University of California, Davis, Sacramento, CA;<sup>4</sup>Duke University, Durham, NC

**Introduction:**

Standard treatment for ductal carcinoma in situ (DCIS) involves surgical excision with radiation and often endocrine therapy. However, not all DCIS progresses to invasive ductal carcinoma (IDC); thus, surgical intervention may constitute overtreatment for DCIS that has low risk for progressing to IDC. A period of active surveillance (AS) with magnetic resonance imaging (MRI) monitoring may offer the opportunity to stratify lesions with high and low risk for invasion and to avoid overtreatment of DCIS. The purpose of this study was to characterize the outcomes of a cohort of women who elected to go on AS to avoid surgical intervention and to identify whether clinical and imaging features would identify patients who should convert to operative management.

**Methods:**

The clinicopathologic variables and outcomes of patients with DCIS who prospectively enrolled in MRI monitoring studies between 2002 and 2019 were retrospectively analyzed with IRB approval. We included 64 cases among 63 women who declined standard operative management for DCIS and had at least two breast MRIs. Clinicopathologic data and physician recommendations regarding continuing surveillance versus converting to operative management were recorded from the medical record. Those who had surgical excision showing IDC were considered to have progressed; those with only DCIS at excision or no operative intervention were considered to have stable disease.

**Results:**

Women in the cohort were an average of 53.6 years (29.8 - 78.9) old, and nearly all cases of DCIS with estrogen receptor (ER) status were ER+ (98.3%). Of the 64 cases in the cohort, 57 received endocrine therapy (89.1%). Average length of time on AS was 2.7 years (.2 - 11.9) with a median of 3 (2 - 18) MRIs performed and mean follow-up time 5.6 years (0.9 - 15.3).

A total of 31 cases (48.4%) eventually had surgical excision while 33 (51.6%) remained on AS. There were 17 cases with IDC at surgery (26.6%). The IDC was an average of 1.5 cm (0.1 - 9.0) and most commonly ER + (88.2%), HER2 + (53.3%), grade 2 (58.9%), and node negative (82.4%). Only 7 women did not take endocrine therapy, but 3 of those women had IDC (42.9%). In 15 of the 17 cases with IDC (88.2%), the physician noted concern for progression in their clinic note and recommended surgical excision. This occurred a mean of 1.9 years (0.2 - 6.5) from the start of AS, with 47%, 67%, and 87% of cases identified within 1, 2 and 3 years from the start of AS. Suspicion of progression was based on an increase in lesion size or prominence on MRI and/or increase in calcifications on mammography. Of those that were identified as good candidates to continue AS with no concern for progression (n = 49), 16 chose to undergo surgical excision (32.7%) and 2 had IDC (4.1%).

**Conclusion:**

After over a decade of following women who seek alternatives to surgery for DCIS, we have identified clinicopathologic and imaging features that discriminate good candidates for AS and endocrine risk reducing therapy from those best treated with surgical excision. In our cohort of mostly ER+ patients receiving endocrine therapy on AS, over half of the cohort (51.6%) avoided surgical intervention. Her2 status, Oncotype DCIS, and Mammprint scores of IDC is in process and will be presented. Our data support the study of AS as a method to stratify the risk of IDC and avoid overtreatment. We will present a personalized AS algorithm (based on biology and imaging) that we intend to prospectively test in the ATHENA network and NCI funded MCL consortium.

**Table 1: Cohort Characteristics**

Safety and efficacy of veliparib plus carboplatin/paclitaxel in patients with HER2-negative metastatic or locally advanced breast cancer: A subgroup analysis of germline *BRCA1* or *BRCA2* mutations from the phase 3 BROCADE3 trial

Hans Wildiers<sup>1</sup>, Jean-Pierre Ayoub<sup>2</sup>, Michael Friedlander<sup>3</sup>, Bella Kaufman<sup>4</sup>, Banu K. Arun<sup>5</sup>, Hyo S. Han<sup>6</sup>, Shannon L. Puhalla<sup>7</sup>, David Maag<sup>8</sup>, Dai Feng<sup>8</sup>, Christine K. Ratajczak<sup>8</sup>, Bruce A. Bach<sup>8</sup> and Veronique Dieras<sup>9</sup>. <sup>1</sup>University Hospitals Leuven, Leuven, Belgium<sup>2</sup>Centre Hospitalier de l'Université de Montréal, Montréal, QC, Canada<sup>3</sup>Prince of Wales Clinical School, University of New South Wales and Prince of Wales Hospital, Sydney, Australia<sup>4</sup>Sheba Medical Center, Tel Aviv University, Tel Aviv, Israel<sup>5</sup>The University of Texas MD Anderson Cancer Center, Houston, TX;<sup>6</sup>Moffitt Cancer Center, Tampa, FL;<sup>7</sup>UPMC Hillman Cancer Center, Pittsburgh, PA;<sup>8</sup>AbbVie Inc., North Chicago, IL;<sup>9</sup>Institut Curie, Paris, France

**Background:** Veliparib (Vel) is a potent PARP1/2 inhibitor with demonstrated antitumor activity when administered alone or combined with carboplatin and paclitaxel (C/P). The phase 3 randomized, double-blind, multicenter BROCADE3 study (NCT02163694) evaluated the efficacy and safety of Vel + C/P treatment compared with placebo (Pbo) + C/P treatment in patients (pts) with germline *BRCA1/2* mutations and HER2-negative metastatic or locally advanced breast cancer (BC). Vel + C/P significantly prolonged progression-free survival (PFS) compared with Pbo + C/P treatment (14.5 months [mo] vs 12.6 mo, hazard ratio [HR]=0.71 [95% CI: 0.57, 0.88]; *P*=0.002). Previous studies have identified increased acute hematologic toxicity in response to chemotherapy in pts with BC carrying *BRCA1* mutations compared with *BRCA2* mutations or wildtype *BRCA1/2*. Herein we report a subgroup analysis of the efficacy and safety of Vel + C/P treatment in pts with *BRCA1*- or *BRCA2*-positive BC.

**Methods:** Pts ≥18 years of age who received ≤2 prior lines of cytotoxic chemotherapy for metastatic disease were randomized 2:1 to receive Vel + C/P or Pbo + C/P: Vel (120 mg PO BID) or Pbo on days -2 to 5, C (AUC 6 IV) on day 1, and P (80 mg/m<sup>2</sup> IV) on days 1, 8, and 15 in 21-day cycles. Pts who discontinued C/P in the absence of disease progression could continue receiving Vel or Pbo monotherapy (300-400 mg BID continuous). Subgroup analysis of PFS stratified by *BRCA1/2* status was preplanned. The primary endpoint was investigator-assessed PFS. Adverse events (AEs) were graded according to NCI CTCAE version 4.0. Ten pts with both *BRCA1* and *BRCA2* mutations were excluded from the analyses presented here. **Results:** In the intent-to-treat population, 256 pts had *BRCA1* mutations and 243 pts had *BRCA2* mutations. The proportion of as-treated pts with *BRCA1* or *BRCA2* mutations was comparable between the Vel + C/P (51.4% *BRCA1*, 48.6% *BRCA2*) and Pbo + C/P (50.9% *BRCA1*, 49.1% *BRCA2*) study arms. Investigator-assessed PFS for the Vel + C/P and Pbo + C/P arms was 14.2 mo vs 12.6 mo, respectively, in the *BRCA1* subgroup (HR=0.75 [95% CI: 0.55, 1.03]; *P*=0.073) and 14.6 mo vs 12.6 mo, respectively, in the *BRCA2* subgroup (HR=0.69 [95% CI: 0.50, 0.95]; *P*=0.021). Safety data in the as-treated population are presented in the **Table**. Regarding any grade AEs, thrombocytopenia and anemia were slightly more frequent in pts in the *BRCA1* subgroup compared with the *BRCA2* subgroup, whereas pts in the *BRCA2* subgroup experienced slightly more frequent nausea, fatigue, and neuropathy.

	<b>BRCA1-Positive Subgroup (n=253)</b>		<b>BRCA2-Positive Subgroup (n=241)</b>	
	<b>Vel + C/P (n=168)</b>	<b>Pbo + C/P (n=85)</b>	<b>Vel + C/P (n=159)</b>	<b>Pbo + C/P (n=82)</b>
<b>Any grade AE [≥50% of pts], n (%)</b>				
Any event	167 (99.4)	85 (100)	158 (99.4)	82 (100)

Anemia	73 (43.5)	31 (36.5)	67 (42.1)	35 (42.7)
Leukopenia	54 (32.1)	20 (23.5)	44 (27.7)	25 (30.5)
Neutropenia	136 (81.0)	72 (84.7)	131 (82.4)	67 (81.7)
Thrombocytopenia	72 (42.9)	30 (35.3)	59 (37.1)	18 (22.0)
<b>Serious AEs, n (%)</b>	58 (34.5)	26 (30.6)	56 (35.2)	22 (26.8)
<b>AEs of special interest, n (%)</b>				
Infections within 14 days of neutropenia	64 (38.1)	34 (40.0)	59 (37.1)	25 (30.5)
Hemorrhages within 14 days of thrombocytopenia	14 (8.3)	5 (5.9)	17 (10.7)	7 (8.5)
<b>Any AE leading to study drug discontinuation not due to disease progression, n (%)</b>	16 (9.5)	5 (5.9)	15 (9.4)	4 (4.9)
<b>Any AE leading to study drug interruption, n (%)</b>	153 (91.1)	77 (90.6)	139 (87.4)	67 (81.7)
<b>Any AE leading to study drug reduction, n (%)</b>	28 (16.7)	6 (7.1)	27 (17.0)	7 (8.5)
<b>Any AE leading to death with reasonable possibility related to study drug, n (%)</b>	0 (0)	0 (0)	0 (0)	0 (0)

AE, adverse event; *BRCA*, breast cancer susceptibility gene; C/P, carboplatin plus paclitaxel; Pbo, placebo; pts, patients; Vel, veliparib.

**Conclusions:** Globally, there was no clinically relevant difference in toxicity between *BRCA1* and *BRCA2* subgroups. Comparisons between treatment arms were generally consistent with findings in the overall study population, with more frequent thrombocytopenia and anemia of any grade reported in the Vel + C/P arm within both the *BRCA1* and *BRCA2* subgroups. Vel + C/P treatment improved PFS similarly in both *BRCA1* and *BRCA2* subgroups over C/P alone.

Changes in body mass index (BMI) over the life course are associated with gene expression in postmenopausal women

Yunan Han, Graham A Colditz and Adetunji T Toriola. Washington University School of Medicine, St Louis, MO

**Introduction:** Changes in body mass index (BMI) over the life course are associated with both mammographic breast density and breast cancer risk in postmenopausal women. The underlying biological mechanisms driving these associations are, however, yet to be elucidated. Understanding these mechanisms could provide important insights into breast cancer prevention early in life. To provide insight into the biological mechanisms underlying the associations of BMI change over the life course and breast cancer risk in postmenopausal women, we comprehensively investigated the associations of BMI change from ages 10 and 18 to current age with gene expression of biomarkers that have previously been associated with breast cancer risk: growth factors (IGF1, IGFBP3, FGF1, FGF12, TGFB1), sex hormones (PRL, PGR, ESR1, STAT1, STAT5), and receptor activator of nuclear factor- $\kappa$ B (RANK) pathway (RANK, RANKL, OPG, BMP2, TNFRSF13B, TNFRSF18) gene expression in postmenopausal women. **Methods:** We investigated these in 372 postmenopausal women free from breast cancer recruited during annual screening mammogram. We estimated BMI at age 10 using a validated 9-level pictogram. Gene expression levels were measured using NanoString nCounter system. We investigated the associations of BMI change with gene expression in multivariable linear regression models, adjusted for confounders. **Results:** The mean age of study participants was 58 years. Increase in BMI over the life course was associated with an increase in BMP2 gene expression but a decrease in RANK, RANKL, and TNFRSF13B gene expression. Compared to women who had a BMI gain of 0.1-5 kg/m<sup>2</sup> from age 10, BMP2 gene expression increased in women who had a BMI gain of 5.1-10 kg/m<sup>2</sup> (beta coefficient [ $\beta$ ] = 0.48, 95% confidence interval [95% CI] = 0.04 to 0.92); BMI gain of 10.1-15 kg/m<sup>2</sup> ( $\beta$  = 0.47, 95% CI = 0.03 to 0.91); and BMI gain of > 15 kg/m<sup>2</sup> ( $\beta$  = 0.58, 95% CI = 0.15 to 1.02) (p-trend = 0.04). Similar results were observed for BMI gains from age 18 (p-trend < 0.01). Compared to women who had a BMI gain of 0.1-5 kg/m<sup>2</sup> from age 10, RANK gene expression decreased in women who had a BMI gain of 5.1-10 kg/m<sup>2</sup> ( $\beta$  = -0.21, 95% CI = -0.51 to 0.09); BMI gain of 10.1-15 kg/m<sup>2</sup> ( $\beta$  = -0.29, 95% CI = -0.59 to 0.00); and BMI gain of >15 kg/m<sup>2</sup> ( $\beta$  = -0.37, 95% CI = -0.66 to -0.07) (p-trend < 0.01). Similar results were observed for weight gains from age 10 and RANKL and TNFRSF13B gene expression, although the associations were weaker for RANKL gene expression. Changes in BMI over the life course were not associated with OPG, growth factors or sex hormone gene expression. **Conclusions:** Changes in BMI from childhood, late adolescence, and early adulthood were associated with RANK pathway gene expression in postmenopausal women. Our findings offer important and innovative new insights into how childhood adiposity may confer long-term protection against breast cancer risk in postmenopausal women.

Breast complications in patients who received intraoperative radiation therapy compared to other forms of radiation therapy following breast conserving surgery

James Wheeler<sup>1</sup>, Houman Vaghefi<sup>1</sup>, Laura Morris<sup>1</sup>, Fang Liu<sup>2</sup>, Irina Sparks<sup>1</sup>, Fiona Denham<sup>1</sup>, Leonard Henry<sup>1</sup>, Ashley Hardy<sup>1</sup>, Meghan Schrock<sup>1</sup>, Vanessa DePue<sup>1</sup> and Leon Coody<sup>1</sup>. <sup>1</sup>Goshen Center for Cancer Care, Goshen, IN; <sup>2</sup>University of Notre Dame, Notre Dame, IN

**Introduction:** Intraoperative radiation therapy (IORT) is a convenient treatment option for appropriate women with early stage breast cancer. Some patients undergoing IORT also need adjuvant whole breast radiation therapy due to adverse final pathologic features. Although there are various reports of the complication rates with patients undergoing IORT, comparisons with patients undergoing other forms of radiation therapy such as whole breast or accelerated partial breast radiation are sparse. **Methods:** A total of 293 patients underwent breast conserving surgery at the study institution between January 2016 and December 2019 for either ductal carcinoma in situ (DCIS) or invasive breast cancer. Three patients had bilateral breast cancer and one patient had a local recurrence having refused adjuvant treatment following breast conserving surgery, for a total of 297 treated breasts. 124 received whole breast radiation therapy, 70 did not receive radiation therapy, 47 received IORT alone, 15 received IORT and whole breast radiation therapy, 30 received accelerated partial breast radiation using external beam radiation (APBI-EB), and 9 received Ir-192 based high dose rate accelerated partial breast radiation (APBI-HDR). One patient with bilateral breast cancer did not complete whole breast radiation therapy to either breast. Complications included cellulitis, wound drainage, symptomatic seroma, delayed wound healing, and wet desquamation. Interventions included observation, antibiotics, wound packing, debridement, fluid aspiration, hydrogel dressings, and wound vacuums. **Results:** For the entire group, the incidence of wound complications was 20%. The risk of complications was 27.4% for those undergoing IORT (with or without whole breast radiation) compared to 18.3% for those not receiving IORT, which was not statistically different at the 5% significance level. For those who received both IORT and whole breast radiation, however, the proportion having complication was 53.3% versus 18.4% in the other groups. The difference was significant with a p-value 0.0032. **Conclusion:** Patients who undergo both IORT and whole breast radiation have an increased risk for wound complications.

**Background:** Neratinib (NERLYNX®) is an irreversible pan-HER inhibitor that significantly improves invasive disease-free survival (iDFS) compared with placebo when given as extended adjuvant therapy in patients with HER2-positive (HER2+) early breast cancer after trastuzumab-based adjuvant therapy. In the phase 3 ExteNET trial, an absolute iDFS benefit of 2.5% and distant disease-free survival (DDFS) benefit of 1.7% were observed with neratinib after 5 years' follow-up. As reflected in the approved indication by the European Medicines Agency (EMA), patients with hormone receptor-positive (HR+) disease who initiated neratinib treatment within 1 year of completing trastuzumab (HR+/ $\leq 1$  year) experienced an absolute iDFS benefit of 5.1% and DDFS benefit of 4.7% at 5 years. In HR+/ $\leq 1$  year patients with residual disease after neoadjuvant therapy, absolute 5-year iDFS and DDFS benefits of 7.4% and 7.0%, respectively, were observed. Here we report the final protocol-defined, event-driven analysis of overall survival (OS) from ExteNET, and provide descriptive analyses of subgroups of primary interest according to the EU label and current clinical practice in early-stage HER2+ disease.

**Methods:** ExteNET was a multicenter, randomized, double-blind, placebo-controlled phase 3 trial of women with early-stage HER2+ breast cancer who had completed neoadjuvant or adjuvant trastuzumab plus chemotherapy (NCT00878709). Patients were randomly assigned to oral neratinib 240 mg/day or placebo for 1 year. Hazard ratios (HR) for OS were estimated from Cox proportional hazards models, and survival rates by the Kaplan-Meier method. The OS analysis was event-driven and powered for the intention-to-treat (ITT) population with a target of 248 events. Descriptive analyses were performed in the HR+/ $\leq 1$  year subgroup per the approved indication in the EU, and in higher-risk patients, i.e. HR+/ $\leq 1$  year who have residual disease after neoadjuvant therapy [i.e. those who did not achieve a pathologic complete response (pCR)]. Cut-off date: July 2019.

**Results:** 2840 patients were randomized to study treatment (1420 per group). After a median follow-up of 8.1 years, 127 (8.9%) and 137 (9.6%) patients in the neratinib and placebo ITT groups had died, respectively. The 8-year OS rates were 90.1% (95% CI, 88.3–91.6) in the neratinib group and 90.2% (95% CI, 88.4–91.7) in the placebo group (absolute difference at 8 years -0.1%; stratified HR=0.95; 95% CI, 0.75–1.21;  $p=0.6914$ ). A positive trend was seen in the prespecified HR+ subgroup ( $n=1631$ ; absolute difference at 8 years 1.5%; HR=0.80; 95% CI, 0.58–1.12), and within this population, descriptive analyses suggested greater benefits with neratinib in the HR+/ $\leq 1$  year subgroup ( $n=1334$ ; absolute difference at 8 years 2.1%; HR=0.79; 95% CI, 0.55–1.13) and in the HR+/ $\leq 1$  year subset with no pCR after neoadjuvant therapy ( $n=295$ ; absolute difference at 8 years 9.1%; HR=0.47; 95% CI, 0.23–0.92). No new safety signals were reported with this long-term follow-up to 8 years.

**Conclusions:** In this final OS analysis of ExteNET, there were fewer deaths with neratinib than placebo in the ITT population, but the results did not reach statistical significance. Analyses showed greater OS improvements with neratinib in subgroups including HR+/ $\leq 1$  year, and HR+/ $\leq 1$  year with residual disease after neoadjuvant therapy. These findings are consistent with the results based on the primary endpoint of iDFS, and support the use of neratinib in clinical practice in these patients.

Can genomic profiling eliminate the need for SLNB in ER positive, T1-2 breast cancer?

Rubie Sue Jackson, Elaine Lee, Carol Tweed, Charles Mylander, Laura Martino, Martin Rosman, Kip Waite, Nicholas Huerta and Lorraine Taft. Anne Arundel Medical Center, Annapolis, MD

**Background:** As tumor biology has taken precedence over anatomic staging, NCCN guidelines now allow for genomic profiling to make adjuvant treatment recommendations for Nmi-N1 breast cancer (BC). This makes nodal status, determined by sentinel lymph node biopsy (SLNB), less influential. Although generally safe, SLNB adds an incision, operative time, monetary costs, and carries risks of chronic paresthesia (9%) or lymphedema (2-6%). We hypothesized that, if ultrasound (US) excludes occult nodal metastasis and genomic profiling is used in making chemotherapy recommendations for N0-N1 disease, SLNB will be the sole indicator of a need for chemotherapy in <5% of patients.

**Methods:** This was a retrospective data and tissue analysis of patients treated at our breast center (11/2011 – 12/2015). Postmenopausal women with ER positive, HER2 negative, pT1-2 BC with non-suspicious axillary US who underwent SLNB without preoperative chemotherapy were included. For each patient, we compared recommended adjuvant therapy (per NCCN guidelines) based on SLNB results, versus the recommendation had SLNB been negative. For N0-N1 cases, we used Oncotype DX Breast Recurrence Score® test to determine chemotherapy. For Nmi-N1 cases, chemotherapy was considered for Recurrence Score® (RS) 18-25 and recommended for RS > 25. When not in the electronic medical record (EMR), RS result was obtained from stored specimens, with patient consent. Patients without a RS result were excluded from the chemotherapy outcomes analysis.

**Results:** Of 217 included patients, nodal status was as follows: N0, n=184 (85%); Nmi-N1, n=29 (13%); N2-3, n=4 (2%). Therefore, in 85% of patients SLNB did not influence any adjuvant treatment recommendation. In 4.1% of patients, SLNB resulted in a recommendation for axillary lymph node dissection (Table). In 15.2% of patients (n=33), SLNB resulted in a consideration (13.4%) or recommendation for (1.8%) nodal irradiation. RS result was available in 147 patients (68% of cohort). However, only 8 of those with unknown RS result (4% of cohort) were node-positive; for node-negative patients, RS would not affect any study outcome (change in treatment based on SLNB). Among patients with RS result, based on actual SLNB result, chemotherapy was recommended or considered in 30 patients. In 23 of these, chemotherapy would have been recommended regardless of SLNB result based on RS > 25. Therefore, SLNB made a difference in whether to recommend or consider chemotherapy in 4.7% of patients (7/147).

**Conclusions:** SLNB changed the recommendation whether to receive chemotherapy (no to yes, or no to consider) in only 4.7% of patients. More often, SLNB influenced the chemotherapy regimen recommended (2<sup>nd</sup> vs. 3<sup>rd</sup> generation), or local therapy recommendations. With increasing role for genomic profiling, the role of SLNB in determining adjuvant therapy is diminishing. When chemotherapy would not be considered, omission of SLNB may be considered in postmenopausal patients with ER positive, T1-2 BC and negative axillary US. If genomic profiling were performed prior to surgery, the results could change surgical management. In women with RS 0-11, SLNB is highly unlikely to alter the recommendation against chemotherapy. In women with RS > 25, chemotherapy is recommended regardless of SLN status, but a positive SLN would affect the regimen recommended. SLNB is most influential in patients with RS 18-25. Use of genomic profiling preoperatively to tailor whether SLNB is performed should be prospectively validated.

Table. Comparison of adjuvant treatment recommendations based on SLNB result vs. presumed negative SLNB			
	Based on presumed negative SLNB	Based on actual SLNB result	% for whom SLNB would change treatment recommendation <sup>8</sup>
Axillary lymph node dissection recommended <sup>1</sup>	0	9	4.1% (9/217)
Nodal irradiation recommended <sup>2</sup>	0	4	1.8% (4/217)
Nodal irradiation considered <sup>3</sup>	0	29	13.4% (29/217)
Chemotherapy recommended <sup>4</sup>	23	24	0.6% (1/147)
Chemotherapy considered <sup>5</sup>	0	6	4.1% (6/147)
Third-generation chemotherapy recommended <sup>6</sup>	0	6	4.1% (6/147)
Third-generation chemotherapy considered <sup>7</sup>	0	6	4.1% (6/147)

1)For >2 positive SLN, or gross extranodal extension (ENE). Since surgeon determination of gross ENE was not consistently available, > 2 mm of ENE on pathology was used to defined "gross" extension. 2)For N2-3 disease 3)For Nmi-N1 disease 4)For RS > 25, or N2-3 5)For Nmi-N1 disease, with RS 18-25 6)For Nmi-N1 disease with RS > 25; or N2-3; this group is a subset of those for whom chemotherapy would be recommended 7)For Nmi-N1 disease with RS 18-25; this group is a subset of those for whom chemotherapy would be recommended 8)Patients without Recurrence Score result were excluded from analysis of chemotherapy outcomes; fractions are included to show the denominator used for each calculation.

Utility of rapid- immunohistochemistry using an alternating current electric field for intraoperative diagnosis of sentinel lymph nodes in breast cancer

Kaori Terata<sup>1</sup>, Hiroshi Nanjo<sup>1</sup>, Eriko Takahashi<sup>1</sup>, Ryuta Nakamura<sup>2</sup>, Yoichi Akagami<sup>2</sup>, Ayuko Yamaguchi<sup>1</sup>, Misako Yatsuyanagi<sup>1</sup>, Chiaki Kudo<sup>1</sup> and Yoshihiro Minamiya<sup>1</sup>. <sup>1</sup>Akita University Hospital, Akita, Japan<sup>2</sup>Akita Prefectural Research and Development Center, Akita, Japan

Axillary lymph node status and pathological diagnosis of sentinel lymph nodes (SLNs) is an important factor that influences management of postoperative therapy. Recent reports indicate that one-step nucleic acid amplification (OSNA) and hematoxylin and eosin (HE)-stained frozen sections are effective for intraoperative diagnosis of SLNs. In the present study, we report a rapid-immunohistochemical staining (R-IHC) method that enables intraoperative detection of SLN metastases within 16 min using an anti-cytokeratin antibody. With this R-IHC system, we apply a high-voltage, low-frequency AC electric field to lymph node sections while they are incubating with the antibodies. The antibodies are mixed within microdroplets and the opportunity for contact between the antibody and antigen is increased. This greatly reduces the time required for the antigen-antibody reaction. This is the report on SLN diagnosis using R-IHC in patients with breast cancer. We prospectively examined 632 dissected SLNs from 260 breast cancer patients who underwent surgery at our institute between July 2014 and March 2020. The dissected SLNs were sectioned and conventionally stained with HE or immunohistochemically labeled with anti-cytokeratin antibody using R-IHC procedures. Intraoperative R-IHC analyses were completed within 16 min, after which diagnoses were made by two pathologists. The total time required for intraoperative diagnosis was about 20 min. In this study, R-IHC detected four metastatic SLNs that were undetected using conventional HE staining (10/52, 19.2%). Compared with subsequent permanent diagnosis, R-IHC offered 98.0% sensitivity, 100% specificity and 99.8% accuracy while those values for intraoperative HE were 80.4%, 100%, 98.4%, respectively (isolated tumor cells were counted as negative). These findings indicate R-IHC is a clinically applicable technique that enables precise, and quick intraoperative detection of micro- and macrometastases in breast cancer. Moreover, R-IHC is cost-effective method: its cost is less than a quarter of OSNA and previous report showed that the concentration of primary antibody could be reduced by more than 90% by using R-IHC because AC mixing activated antigen-antibody reaction. Another benefit is its ability to shorten the time needed for microscopic diagnosis itself. When using R-IHC, pathologists are able to readily find metastatic lesions, even within low-power fields (e.g. 40x). This reduces not only the time needed for intraoperative diagnosis, but also the effort necessary to find unclear lesions like small cancer cells (even though it is macrometastasis), micrometastasis, and artifacts of frozen section. This study was conducted at a single institute. Further investigation in a multi-institutional collaborative prospective study will be needed to confirm the utility of this method. But for now, R-IHC appears to be a cost-effective and clinically applicable method for diagnosis of breast cancer and SLN metastasis.

Estrogen receptor (ER) and NFkB activity determines cancer stem cell properties in ER positive breast cancer

Svetlana E. Semina<sup>1</sup>, Irida Kastrati<sup>2</sup>, Luis Alejo Cruz<sup>1</sup>, Tara McCray<sup>3</sup>, Mark Maienschein-Cline<sup>4</sup>, Elaine T. Alarid<sup>5</sup> and Jonna Frasor<sup>1</sup>. <sup>1</sup>Department of Physiology and Biophysics, University of Illinois at Chicago, Chicago, IL; <sup>2</sup>Department of Cancer Biology, Loyola University Chicago, Chicago, IL; <sup>3</sup>Department of Pathology, University of Illinois at Chicago, Chicago, IL; <sup>4</sup>Core for Research Informatics, University of Illinois at Chicago, Chicago, IL; <sup>5</sup>McArdle Laboratory for Cancer Research, Department of Oncology and Carbone Comprehensive Cancer Center, Madison, WI

Approximately 50% of estrogen receptor (ER) positive breast cancer patients will experience relapse. One explanation for this is the presence of breast cancer stem cells (BCSCs), which have self-renewal capability and can contribute to therapy resistance, metastasis, and relapse. Previously, we have shown that cells with active ER and NFkB gain stem cell properties. They are characterized by higher mammosphere (MS) forming efficiency and increased expression of stem-associated markers. NFkB has been previously described as a player in BCSC biology. However, the role of ER remains unclear since some studies have suggested that BCSCs are ER negative. In order to study the role of ER and NFkB in BCSCs in more detail, we utilized single cell RNA sequencing of MS. Dimensionality reduction of single cells identified 4 clusters with unique transcriptional signatures. In order to determine which cluster of these 4 represents BCSCs, we ran functional enrichment analysis (FEA) using MsigDB as a source of various stem cell signatures. Results of FEA showed 1 of 9 stem cell signatures enriched in Cluster 0. Whereas clusters 1, 2 and 3 demonstrated increasing enrichment of different stem cell signatures, respectively. Further analysis of stem cell signatures and genes revealed that cluster 1 included not only classical stem markers (ALDH1A3, KRT8, CD36), but also was enriched for PI3K and p53 signaling pathways. The cluster 2 stem cell signature was associated with DREAM complex activity and BRCA1 mutation. Cluster 3 was enriched for expression of NANOG and SOX2 targets. We also ran FEA to determine ER and NFkB activity in each population. Cluster 0 showed no activity of either ER or NFkB, whereas Cluster 1 was enriched for both, cluster 2 was enriched for ER only, and cluster 3 was enriched for NFkB only. Taken together this data suggests that ER and NFkB may play different roles in promoting BCSC properties. In order to determine how both pathways effect BCSC features, we made a dual reporter cell line expressing ERE-mCherry and NFkB-RE-GFP. It was found ERE activity was constant throughout MS formation, whereas NFkB-RE activity increased proportionally to MS growth over time, suggesting these pathways have different dynamics and further supporting unique roles for each in MS development. To determine which cell population has the capacity to seed MS, an indication of stemness, we sorted cells by reporter activity and tested MS forming efficiency. We discovered that ERE+ cells, either with or without NFkB activity, are more stem-like, whereas activation of NFkB alone is not sufficient to drive MS development. This finding was verified by stem cell-associated gene expression. These data suggest that ER activity is a key driver for BCSC properties and that NFkB may play a supporting role. Furthermore, a novel mechanism of ER regulating the DREAM complex, which is known to be involved in cancer progression and used to evaluate the risk of recurrence in breast cancer, is suggested as a potential ER-mediated mechanism for driving BCSCs. Taken together, our findings suggest novel roles for ER and NFkB in BCSC biology, which could be exploited to target BCSCs therapeutically in ER+ breast cancer patients in order to improve their outcome.

**Background:** Pembrolizumab monotherapy did not significantly improve overall survival (OS) as second- or third-line treatment for metastatic TNBC vs chemotherapy in the randomized, open-label, phase 3 KEYNOTE-119 study (NCT02555657; N = 622). However, the benefit of pembrolizumab compared with chemotherapy appeared to be greater with increasing PD-L1 expression as quantified by combined positive score (CPS; defined as the number of PD-L1–staining cells [tumor cells, lymphocytes, macrophages] divided by the total number of viable tumor cells, multiplied by 100). In the current exploratory analysis, we aimed to determine whether expression of PD-L1 on tumor cells contributes to the value of PD-L1 as a predictive biomarker in metastatic TNBC. **Methods:** Patients with centrally confirmed TNBC and 1 or 2 prior systemic treatments for metastatic disease were enrolled in KEYNOTE-119. Patients were randomly assigned 1:1 to pembrolizumab 200 mg Q3W or investigator's choice of single-agent chemotherapy (capecitabine, eribulin, gemcitabine, or vinorelbine). PD-L1 expression in tumor samples was assessed using PD-L1 IHC 22C3 pharmDx and quantified per tumor proportion score (TPS; defined as the percentage of PD-L1–expressing tumor cells [partial or complete membrane staining] relative to total number of tumor cells) and CPS. Quantitative immune cell density (QID) was defined as CPS minus TPS. QID isolates immune cells but may be truncated when TPS is high. The ability of each scoring method (TPS, CPS, and QID) to predict objective response rate (ORR) with pembrolizumab, including receiver operating characteristics (ROC) analysis, and OS hazard ratios (HRs; pembrolizumab vs chemotherapy) was evaluated. **Results:** Tumor samples were available for 601 patients (pembrolizumab, 309; chemotherapy, 292) in KEYNOTE-119. ORR was 9.7% (30/309) with pembrolizumab and 11.3% (33/292) with chemotherapy when PD-L1 expression status was not considered. In the pembrolizumab arm, the area under the ROC curve (AUROC; 95% CI) was 0.69 (0.58-0.80) for tumor samples scored for CPS, 0.66 (0.55-0.77) for QID, and 0.55 (0.46-0.64) for TPS. ROC analysis is shown in the **Table**. At each cutoff, QID had lower estimated sensitivity (ie, missed responders) and a lower Youden Index compared with CPS. The number of missed responders (of 30 total in the pembrolizumab arm) for QID relative to CPS were 2, 5, 5, 6, 2, and 2 at cutoffs of 1, 10, 20, 30, 40, and 50, respectively. Across all practical cutoffs, the OS HR tended to be slightly smaller for CPS than QID. At cutoffs corresponding to the upper percentiles of 10, 20, 40, and 60, OS HRs were 0.497, 0.658, 0.758, and 0.850, respectively, for CPS vs 0.572, 0.712, 0.814, and 0.863, respectively, for QID. QID appeared to be orthogonal to TPS ( $r = -0.03$  for all 601 observations;  $r = -0.04$  after eliminating 7 potentially truncated values). **Conclusions:** Trends estimated using KN119 suggest that tumor cell expression is an important component of PD-L1 as a predictive biomarker of pembrolizumab efficacy in metastatic TNBC. In this exploratory analysis, when immune cells alone were used to measure PD-L1 expression, a meaningful number of responders was missed and OS benefit trended toward higher HR estimates. Tumor and immune cell PD-L1 expression may represent distinct (presumably negative modulatory) mechanisms.

Tucatinib favourably modulates the immune microenvironment and synergises with anti-PD1 therapy in a trastuzumab resistant HER2+ murine model

Ran Li, Sneha Sant, Emmaline Brown, Franco Caramia, Ann Byrne, Kylie Clarke, Michael Neeson, Paul J Neeson, Phillip K Darcy, Scott Peterson and Sherene Loi. Peter MacCallum Cancer Centre, Melbourne, Australia

**Background:** The efficacy of PD-(L)1 inhibitors in patients with trastuzumab-resistant advanced HER2<sup>+</sup> breast cancer is poor. Although many HER2 targeted therapies are used clinically, their effect on the tumor immune microenvironment (TME) and whether this contributes to efficacy is not understood. Tucatinib is a potent, highly selective, HER2 small molecule tyrosine kinase inhibitor with proven clinical benefit in the advanced setting.

**Methods:** We used two immunocompetent, HER2<sup>+</sup> murine cancer models (trastuzumab-sensitive H2N113 and trastuzumab-resistant fo5) to investigate the effects of tucatinib on tumor growth kinetics, as well as tucatinib anti-tumor efficacy in combination with trastuzumab and PD-1 checkpoint blockade. Effects of tucatinib on the tumor infiltrating lymphocytes were analysed using flow cytometry. To identify genes that were modulated by tucatinib treatment, we performed bulk RNA sequencing on fo5 tumors treated with vehicle or tucatinib. We evaluated healthy donor peripheral blood T cells treated with tucatinib for 96 hours and analysed secreted cytokine levels using cytometric bead array.

**Results:** Treatment of CD4<sup>+</sup> and CD8<sup>+</sup> T cells with tucatinib together with TCR stimulation resulted significantly higher levels of IFN $\gamma$  and TNF $\alpha$  compared with stimulated controls ( $p < 0.0001$ ), suggesting tucatinib can directly modulate human T cell function. In both murine models, tucatinib significantly inhibited tumor growth in a dose-dependent manner and was observed at doses of 25 mg/kg, 50 mg/kg and 100 mg/kg ( $p < 0.05$  between each dose). Median survival was 16 days in the vehicle group vs 50 days with 100 mg/kg of tucatinib ( $p < 0.0001$ ). Ex vivo analysis of tumors by flow cytometry showed increased infiltration of NK cells ( $p=0.01$ ) and, CD8<sup>+</sup> T cells with high PD-1 ( $p = 0.001$ ), TIM-3 ( $p = 0.009$ ), IFN $\gamma$  ( $p = 0.003$ ) and Ki67 ( $p = 0.0003$ ) expression in Tucatinib treated mice compared to vehicle treated mice. Concomitant with these changes there was a significant reduction in numbers of neutrophils ( $p = 0.0085$ ) and MHC-II low expressing macrophage populations ( $p < 0.0001$ ) following tucatinib treatment with an increase in frequency of MHC-II expressing dendritic cells ( $p < 0.0001$ ) and macrophages ( $p < 0.0001$ ) suggesting an increase in anti-tumor immunity.

Similarly, in the fo5 model tucatinib treated tumors had significantly higher interferon- $\gamma$  (IFN $\gamma$ ) produced by CD8<sup>+</sup> T cells ( $p = 0.005$ ). Gene expression profile analysis shows significant enrichment in pathways associated with immune activation, including antigen binding and presentation ( $p = 0.0002$ ), adaptive immune responses ( $p = 0.0002$ ) including IFN $\gamma$  ( $p = 0.0002$ ) and IFN $\alpha$  ( $p = 0.0002$ ). In this model, tucatinib in combination with trastuzumab demonstrated significantly better anti-tumor activity ( $p = 0.03$ ) and survival ( $p < 0.0001$ ) compared with tucatinib alone, with 33% of mice achieving complete tumour regressions. Tucatinib in combination with PD-1 inhibition also demonstrated significantly greater anti-tumor efficacy compared to tucatinib alone ( $p = 0.0079$ ) with increased survival ( $p = 0.05$ ) and 50% of mice achieving complete tumor regression.

**Conclusions:** This study suggests an anti-tumor immune response may be an important component of the efficacy of tucatinib. This is supported by *in vitro* data demonstrating tucatinib stimulated human peripheral T cells and *in vivo* data showing favorable effects on the TME mediated by tucatinib treatment. These changes were associated with improved efficacy when tucatinib was combined with PD-1 inhibition or trastuzumab in the setting of trastuzumab resistance. These findings suggest that the combination of tucatinib and PD-1 inhibition is a rational combination that warrants investigation in the clinical setting, particularly for trastuzumab resistant HER2+ breast tumors.

Clinical and pathological characteristics and screening outcome for secondary cancers in breast cancer patients with li-fraumeni syndrome attending the MD anderson li-fraumeni education and early detection program clinic

Aydah Al-Awadhi<sup>1</sup>, Nour Abuhadra<sup>2</sup>, Diane D Liu<sup>2</sup>, Angelica M Gutierrez Barrera<sup>2</sup>, Jessica Corredor<sup>2</sup>, Louise C Strong<sup>2</sup> and Banu K Arun<sup>2</sup>. <sup>1</sup>Tawam Hospital, Al Ain, United Arab Emirates<sup>2</sup>The University of Texas, MD Anderson Cancer Center, Houston, TX

**Background:** Germline TP53 mutations predispose to early onset breast cancer (BC) and are associated with Li-Fraumeni syndrome (LFS) Published data on the clinical and pathological characteristics and screening outcome for secondary cancers among women with BC and TP53 mutations is limited. The UTMD Anderson's Li-Fraumeni Education and Early Detection (LEAD) program conducts comprehensive cancer screening for patients with LFS. Here we report characteristics and screening outcome of patients with BC and LFS who were referred to the LEAD program.

**Methods:** Patients with BC and LFS were identified from a prospective BC database between 2001 to 2018. Patients had genetic testing at The University of Texas MD Anderson Cancer Center (MDACC) Clinical Cancer Genetics (CCG) program and confirmed to have germline TP53 mutations. Data reviewed included clinical and pathological characteristics of their BC, the pattern of referral to the LEAD program, adherence to screening recommendation and rate of secondary cancer detection in the LEAD program.

**Results:** A total of 78 female patients with positive germline TP53 mutation and BC diagnosis were identified. The clinical and pathological characteristics of these patients are provided in table 1. Out of the 78 patients, 62 patients were referred and followed at the LEAD clinic. 50 were referred after BC diagnosis and 12 were referred to LEAD clinic before BC diagnosis. A total of 137 cancers were diagnosed in the total population. The cancers were further grouped into diagnosed before or after BC diagnosis. (table 2). 24 cancers were diagnosed in LEAD clinic including 12 breast cancers, 2 soft tissue tumors, 2 thyroid cancers, 2 acute myeloid leukemia, 1 brain tumor, 1 lung cancer, 1 pancreatic cancer, 1 melanoma, 1 parotid cancer and 1 Merkel cell cancer. Adherence to follow up and recommended screening in the first year was 77%, second year 75% and third year 65%. 6 patients, who were diagnosed with leukemia, had received adjuvant chemotherapy with anthracycline and/or cyclophosphamide-based therapy for breast cancer with median time from chemotherapy to leukemia diagnosis of 9 years (5-10yrs). 8 patients developed chest wall sarcoma in the same location of prior radiation therapy for breast cancer with median time from radiation therapy to chest wall sarcoma diagnosis of 7 years (3-11yrs).

**Conclusion:** Patients with LFS associated breast cancer are at significant increased risk to develop secondary cancers. Increased surveillance for secondary cancers in a dedicated program can increase adherence to screening, lead to early detection that could potentially lead to improved outcomes. Patient outcome of this cohort will be presented at the meeting.

Prospective evaluation of patients with metaplastic (Mp) triple negative breast cancer (TNBC): Molecular characteristics and outcomes with neoadjuvant therapy (NAT)

Nour Abuhadra<sup>1</sup>, Clinton Yam<sup>1</sup>, Ryan Sun<sup>1</sup>, Lei Huo<sup>1</sup>, Jason White<sup>1</sup>, Elizabeth Ravenberg<sup>1</sup>, Beatriz Adrada<sup>1</sup>, Aysegul Sahin<sup>1</sup>, Jennifer Litton<sup>1</sup>, Bora Lim<sup>1</sup>, Naoto T Ueno<sup>1</sup>, Banu Arun<sup>1</sup>, Debu Tripathy<sup>1</sup>, Senthil Damodaran<sup>1</sup>, Rashmi Murthy<sup>1</sup>, Vicente Valero<sup>1</sup>, Gabriel Hortobagyi<sup>1</sup>, Nuhad Ibrahim<sup>1</sup>, Alastair Thompson<sup>2</sup>, Anthony Lucci<sup>1</sup>, Elizabeth Mittendorf<sup>3</sup>, Stacy Moulder<sup>1</sup> and Jeffrey Chang<sup>4</sup>. <sup>1</sup>University of Texas - MD Anderson Cancer Center, Houston, TX; <sup>2</sup>Baylor College of Medicine, Houston, TX; <sup>3</sup>Dana Farber Cancer Institute, Boston, MA; <sup>4</sup>The University of Texas, Houston, TX

**Background:** MpBC is a rare breast cancer subtype that is commonly triple-negative and associated with a diminished response to NAT in published retrospective data sets, prompting some clinicians to recommend surgical resection followed by adjuvant therapy. **Methods:** The ARTEMIS trial (NCT02276443) uses imaging response and molecular profiling to personalize NAT in early stage TNBC. Patients with sensitive disease after 4 cycles of AC receive standard taxane-based NAT as the second phase of NAT, while those with resistant disease are offered biomarker-guided therapeutic trials. Pathologic response is assessed at surgical resection. Prospective data from 195 patients with early-stage TNBC (MpTNBC: N=37; Non-MpTNBC: N=158) enrolled on the ARTEMIS trial were evaluated. Due to short duration of follow-up, restricted mean survival time up to four years of follow-up was used to evaluate event-free survival (RM-EFS), metastasis-free survival (RM-MFS) and overall survival (RM-OS). RNAseq and whole exome sequencing (WES) were performed on pre-NAT core biopsies (155 and 158 non-MpTNBC respectively; 20 MpTNBC). Stromal tumor infiltrating lymphocytes (sTIL) and PD-L1 staining were also compared. **Results:** Pathologic complete response (pCR) rates were significantly lower in MpTNBC vs non-MpTNBC (18.9% vs. 41.4%, p=0.013). Among MpTNBC without pCR (n=30, 81%), 21 were detected early to have progression (PD) or suboptimal response to standard therapy with ultrasound and clinical exam and were offered the opportunity to participate in clinical trial. Notably, 6 patients (16.2%) had PD after 2 cycles of AC. There was a non-statistically significant trend of lower RM-EFS, RM-MFS, and RM-OS in MpTNBC; however, MpTNBCs with pCR had similar RM-OS compared to non-MpTNBCs with pCR. MpTNBCs had lower rates of high TIL (≥20%) compared to non-MpTNBCs (16% vs. 36%, p=0.02) but similar rates of PD-L1+ disease. Compared to non-MpTNBCs, using Vanderbilt classification methods, MpTNBCs were more frequently M/MSL subtype (50% vs 22%, p=0.011) and less frequently BL-1 subtype (p=0.028). By RNAseq, MpTNBC tumors had significantly lower gene expression of epithelial markers CDH1, EPCAM, ESRP1, and increased expression of EMT inducer TWIST1. WES identified PIK3CA missense mutations in 15% of MpTNBCs. Unsupervised clustering based on expression profiles revealed that 85% of MpTNBCs had a Mp-like expression signature. Interestingly, the Mp-like expression signature was identified in 12% of histologically defined non-MpTNBC. The pCR rate was lowest in the MpTNBC (18.9%) but similar between Mp-like TNBC (36.8%) and non-MpTNBC (42.2%). **Conclusion:** Early-stage MpTNBC has lower rates of pCR with NAT however those with pCR appear to have similar survival rates to non-MpTNBC with pCR. Notably, 16.2% of MpTNBC had PD after 2 cycles of AC NAT suggesting that a neoadjuvant approach with frequent imaging would reduce unnecessary exposure to inactive chemotherapy. 81% of MpTNBCs had either PD or suboptimal response to AC chemotherapy, thus novel treatment strategies need to be developed for this chemorefractory subtype of TNBC. PAM (PI3K/mTOR/AKT) pathway alterations were frequently detected in MpTNBCs and novel inhibitors should be further tested.

Immune checkpoint blockade reprograms tumor microenvironment and systemic immune landscape in obesity associated triple negative breast cancer

Ajeeth K Pingili, Mehdi Chaib, Laura M Sipe, Emily J Miller, Bin Teng, Rahul Sharma, Qusai Al Abdallah, Deidra Daria, Radhika Sekhri, Heejoon Jo, Mims S Tahliyah, D. Neil Hayes, Joseph F Pierre and Liza Makowski. University of Tennessee Health Science Center, Memphis, TN

Few targeted therapies exist for triple negative breast cancer (TNBC), an aggressive and deadly subtype. Obesity exacerbates poor outcomes in TNBC due to elevated invasion and metastasis leading to increased mortality. Obesity has paradoxically been shown to improve immune checkpoint therapies in other cancers, yet the underlying mechanisms are unclear. Despite being an inflammatory state, obesity increases immune checkpoint ligands PD-1 and PD-L1 which drives immunosuppression. Thus, we tested the hypothesis that obesity-driven changes to the immune milieu will improve ICB efficacy in TNBC. Syngeneic tumors were generated via orthotopic engraftment of E0771 basal-like TNBC cell line into age-matched immune-competent C57BL/6J female littermates on obesogenic or low fat diets. Mice were treated with anti-mouse anti-PD-1 or isotype control (IgG2a) every 3rd day until sacrifice. Obese mice gained almost 2-fold greater body weight and 3.6-fold greater adiposity compared to lean mice and immunotherapy did not impact weights or body composition. Obesity led to immunosuppression systemically in bone marrow and spleen in tumor-free mice, which was exacerbated in tumor-bearing mice. Obese mice had significantly greater tumor progression and fewer regressed tumors at endpoint vs. lean mice. Anti-PD-1 significantly reduced tumor progression in obese mice with 4.2-fold reduction in volume and 5.7-fold reduction in tumor weights in obese mice vs. isotype controls. Anti PD-1 significantly reduced immunosuppressive cells including M2-like tumor associated macrophages and monocytic and granulocytic myeloid derived suppressor cells (MDSC) and raised anti-tumor M1-like macrophages, cytotoxic CD8+ T cells, and dendritic cells. Last, the microbiome has potent effects on responses to anti-tumor therapies such as chemotherapy and immune checkpoint blockade. Obesity is a major regulator of the gut microbiome. We found that beneficial bacteria belonging to genus *Bifidobacterium* was higher in lean compared to obese mice, which could limit tumor progression and lead to greater regression through robust anti-tumor immunity. In obese mice, beneficial bacteria belonging to genus *Ruminococcus*, *Adlercreutzia*, *Corpococcus* that promote anti-tumor immunity increased with anti PD-1 immunotherapy. In sum, we show for the first time that obesity-induced systemic and microenvironmental immunosuppression augmented tumor incidence and tumor progression. Furthermore, anti-PD-1 immune checkpoint blockade successfully reduced tumor progression in obese mice through reprogramming not only the TME but systemic immune milieu as well. Immunosuppressive targets unique to the obese TME could be targeted in concert with checkpoint inhibitors in future interventions to enhance durable anti-tumor immunity.

Impact of low versus negative estrogen/progesterone receptor status on clinico-pathologic characteristics and survival outcomes in HER2 negative breast cancer

Rachel Yoder<sup>1</sup>, Bruce F Kimler<sup>2</sup>, Joshua M Staley<sup>1</sup>, Kelsey Schwensen<sup>1</sup>, Yen Y Wang<sup>1</sup>, Karissa Finke<sup>1</sup>, Anne O'Dea<sup>1</sup>, Lauren Nye<sup>1</sup>, Manana Elia<sup>3</sup>, Gregory Crane<sup>4</sup>, Richard McKittrick<sup>4</sup>, Robert Plueneke<sup>5</sup>, Sheshadri Madhusudhana<sup>6</sup>, Larry Beck<sup>7</sup>, Roberto Rodriguez<sup>8</sup>, Anuj Shrestha<sup>6</sup>, Larry Corum<sup>9</sup>, Mark Marsico<sup>10</sup>, Andrew K Godwin<sup>2</sup>, Qamar Khan<sup>1</sup> and Priyanka Sharma<sup>1</sup>. <sup>1</sup>University of Kansas Medical Center, Westwood, KS; <sup>2</sup>University of Kansas Medical Center, Kansas City, KS; <sup>3</sup>University of Kansas Medical Center, Lee's Summit, MO; <sup>4</sup>University of Kansas Medical Center, Overland Park, KS; <sup>5</sup>University of Kansas Medical Center, Kansas City, MO; <sup>6</sup>University of Missouri-Kansas City, Kansas City, MO; <sup>7</sup>Salina Regional Health Center, Salina, KS; <sup>8</sup>Hays Medical Center, Hays, KS; <sup>9</sup>Olathe Medical Center, Olathe, KS; <sup>10</sup>Merck & Co., Inc., Kenilworth, NJ

**Background:** Triple negative breast cancer is defined by lack of expression of ER/PR (immunohistochemistry expression <1%) and absence of *HER2* gene amplification. However, data regarding endocrine therapy benefit in patients with low levels (1-10%) of ER/PR expression are lacking. Furthermore, gene expression studies show tremendous similarities between HER2 negative tumors with low and negative ER/PR status. Accordingly, the 2020 ASCO/CAP guideline designates that ER expression of 1-10% be reported as a distinct "ER low positive" category. Utilizing data from a prospective registry, the aim of this study was to determine the impact of low versus negative ER/PR status on clinico-pathologic characteristics and survival outcomes in patients with HER2 negative breast cancers. **Methods:** 516 subjects with stage I-III HER2 negative breast cancer and ER/PR IHC ≤10% were enrolled in an IRB-approved multisite prospective registry between 2011 and 2019. Demographic, clinical, pathologic, and treatment information was collected, and patients were followed for recurrence and survival. Patients were categorized according to ER/PR expression into two groups: TNBC (ER and PR <1%) and Low-ER (ER and/or PR 1-10%). Recurrence free survival (RFS) and overall survival (OS) were estimated according to the Kaplan-Meier method and compared among groups by log-rank test, followed by Cox regression analysis. **Results:** TNBC and Low-ER groups comprised 451/516 (87.4%) and 65/516 (12.6%) patients, respectively. Demographic, clinical, pathologic, and treatment characteristics of the two groups are described in Table 1. Median follow-up was 39 months. Three-year RFS was 82% for both TNBC and Low-ER groups (p=0.70). Three-year OS was 88% and 83% for TNBC and Low-ER groups, respectively (p=0.63). Twenty percent of patients in the Low-ER group received adjuvant endocrine therapy, and endocrine therapy use did not impact outcomes in the Low-ER group (RFS: p=0.32; OS: p=0.88). On multivariate analysis, T stage, nodal status, and age significantly impacted RFS (T stage 3/4 vs 1/2, HR=2.7, p<0.001; nodal status positive vs negative, HR=2.4, p<0.001; age above vs below median, HR=1.8, p=0.006) and OS (T stage 3/4 vs 1/2, HR=3.6, p<0.001; nodal status positive vs negative, HR=2.8, p<0.001; age above vs below median, HR=1.026, p=0.01). For patients who received neoadjuvant chemotherapy, achievement of pathological complete response (pCR) was associated with superior RFS (3-year RFS of 95% and 67% in those with and without pCR, respectively, HR=0.18, p<0.001). **Conclusions:** Patients with TNBC and Low-ER HER2 negative breast cancer present with similar clinico-pathologic characteristics, including prevalence of germline *BRCA1/2* mutation. Prognosis and rate of pCR (with neo-adjuvant chemotherapy) in patients with Low-ER HER2 negative breast cancer is similar to those with TNBC. The role and efficacy of adjuvant endocrine therapy in patients with Low-ER breast cancer is unclear. These findings support consideration for inclusion of patients with Low-ER disease along with TNBC for future clinical trial eligibility and planning.

Standard temperature husbandry increases tumor aggressiveness via chronic cold stress in murine mammary cancer models

Darius O Gaymon, Marc Lippman, Patricia Foley and Philip Miller. Georgetown University, Washington, DC

Correct interpretation of disease progression and therapeutic responses in mouse models of breast cancer requires interrogation of models and conditions that faithfully recapitulate human disease and conditions that mimic clinical intervention. Historically, standard temperature (ST) for *in vivo* murine research has been approximately 70-72°F (21-22°C), mimicking ambient temperatures in laboratories that are comfortable for researchers. However, previous work from the Repasky lab demonstrated that ST housing results in chronic cold stress and immune suppression mediated by an increase in norepinephrine (NE) levels, leading to increased tumor aggressiveness. In contrast, syngeneic murine mammary tumors in mice housed at higher temperatures [~ 82°F] grew more slowly and resulted in fewer metastases. Based on these findings, we investigated tumor progression and metastasis in a temperature dose response in two syngeneic murine mammary tumor models: the balb/c-4T1 model and the c57bl6/E0771-LMB (a lung metastatic variant of E0771 cells) model. Mice were acclimatized in rooms with three different ambient temperatures and challenged with tumor cells. ST was maintained at 70-72°F, while mid-temperature (MT) was maintained at 78-80°F, and high temperature (HT) was maintained at 84-85°F. Compared to ST and MT, an ambient temperature of 84-85°F resulted in a statistically significant delay in tumor formation and decreased primary tumor growth by unpaired t-test ( $p=.0006$ ). At day 13, when 4T1 tumors are typically well-initiated and measurable by caliper, mean tumor volumes in the ST-housed mice were significantly larger than the HT group. At day 21, ST tumors means were 4 times larger than HT. In the E0771-LMB model, mean tumor volumes on day 14 were nearly 3 times larger in ST-housed mice than HT. At day 27, the mean tumor volumes were 2 times larger in the ST group compared to HT-housed mice. Data on metastasis will be presented at the meeting. Mean NE levels in mice housed at ST were twice as high as those at HT, providing ancillary evidence that traditional "standard" temperatures are a significant stressor for mice ( $p=.0091$ ). These data demonstrate the potential for misleading interpretations of biological significance of chronic cold stress when modeling immunocompetent tumor progression [conditions almost universally employed in most studies]. Furthermore, these data demonstrate that the presence of chronic cold stress and its immunosuppressive effects call into question the interpretation of many previous studies completed at or near standard temperature and may suggest the need to increase ambient temperatures in syngeneic experiments in order to more accurately model human disease.

Association between patient derived xenograft (PDX) take rate and breast cancer recurrence in the prospective breast cancer genome guided therapy study (BEAUTY)

Judy C. Boughey<sup>1</sup>, Vera J. Suman<sup>1</sup>, Jia Yu<sup>1</sup>, Katelyn Santo<sup>1</sup>, Jason P. Sinnwell<sup>1</sup>, Jodi M. Carter<sup>1</sup>, Krishna R. Kalari<sup>1</sup>, Xiaojia Tang<sup>1</sup>, Sarah A. McLaughlin<sup>2</sup>, Alvaro Moreno Aspitia<sup>2</sup>, John A. Copland, III<sup>2</sup>, Donald W. Northfelt<sup>3</sup>, Richard J. Gray<sup>3</sup>, Katie N. Hunt<sup>1</sup>, Amy Lynn Connors<sup>1</sup>, Richard Weinshilboum<sup>1</sup>, Liewei Wang<sup>1</sup> and Matthew P. Goetz<sup>1</sup>. <sup>1</sup>Mayo Clinic, Rochester, MN; <sup>2</sup>Mayo Clinic, Jacksonville, FL; <sup>3</sup>Mayo Clinic, Phoenix, AZ

**Background:** Patient derived xenografts are a standard tool used to study cancer biology and evaluate drug response phenotypes. It is well known that PDX take rate is associated with more aggressive clinical features [higher grade, biologic subtype (e.g. TNBC vs luminal)]. Previous data from a small retrospective cohort of patients (pts) with no prior chemo (n=24) suggested that primary breast tumor PDX take rate was associated with reduced overall survival. (Derose Nat Med. 2011) However, whether take rate is prognostic in newly diagnosed pts receiving standard of care neoadjuvant chemotherapy (NAC) is unknown. From the prospective BEAUTY clinical trial of pts treated with NAC in which PDX was attempted from pre-NAC as well as after chemo (post-NAC), we recently reported no difference in take rate comparing pts with or without a pathologic complete response (pCR) (Yu Breast Canc Res 2018). Herein we report the association between PDX take rate and recurrence from tumor samples implanted pre-NAC as well as post-NAC (time of surgery). **Methods:** The BEAUTY study is a prospective NAC study which enrolled breast cancer pts (Stage I-III; n=140) treated with neoadjuvant weekly taxane +/-trastuzumab followed by anthracycline-based chemotherapy. Percutaneous tumor biopsies were obtained prior to NAC and tumor samples from residual disease at surgery were additionally used to establish PDXs. Tumor take rate was defined as percent of pts with the development of at least one stably transplantable (passed at least for four generations) xenograft that was pathologically confirmed as breast cancer. Time to breast cancer recurrence was defined as the time from surgery to documentation of a local, regional, or distant recurrence. Gray's test was used to assess whether the cumulative incidence (CI) of a breast cancer recurrence differs with respect to either pre-NAC PDX take or post-NAC PDX take. **Results:** Of 140 pts enrolled in the BEAUTY study, tumor tissue for PDX from the pre-NAC tumor was available for implantation in 113. As previously published, PDX take rate from pre-NAC tumor was 27.4% (31/113), and varied according to tumor clinical subtype [51.3% (20/39) in triple negative breast cancer (TNBC), 26.5% (9/34) in HER2+, 5.0% (2/40) in Luminal]. With median follow up of 5.7 years (range: 3 months to 6.75 years), 17 pts developed local, regional or distant disease relapse (4 of whom had a PDX established pre-NAC). The cumulative incidence of breast cancer relapse after surgery was not found to differ according to pre-NAC PDX take (5 yr CI rate: 13.6% no take; 13.4% take; p=0.8911). In pts with TNBC, the group with the highest take rate, there was also no significant difference in incidence of BC recurrence between those without PDX take and those with PDX take (5 yr CI rate: 21.4% vs 16.2% p=0.7314). PDXs were established from residual tissue from surgery (post-NAC) in 6 of 34 pts (17.6%), [specifically, TNBC: 5/9; Her2+: 1/8; and Luminal: 0/17]. Nine of these 34 pts developed a local, regional or distant recurrence. There was a tendency for pts who had a PDX established from their residual disease to have a higher incidence of a breast event (p=0.1092). The 5 year cumulative incidence of a breast event was 19.6% for pts whose post-NAC PDX did not take and 50.0% for pts whose post-NAC PDX took. **Discussion:** In pts receiving NAC for breast cancer, we observed no significant difference between establishment of a pre-NAC PDX and breast cancer relapse. In contrast, post-NAC PDX take rate (from residual tumor obtained from the breast at surgery) was associated with a tendency to have a higher incidence of a breast cancer event. PDXs remain a valuable tool for the evaluation of tumor biology and development of new therapeutics, especially those models established from pts with chemotherapy resistance.

De-escalation of radiation therapy in patients with stage I, node-negative, HER2-positive breast cancer: Patterns of care and survival outcomes using the national cancer database

Jose G Bazan, Sachin Jhawar, Daniel Stover, Ko Un Park, Sasha Beyer, Erin Healy and Julia R White. James Comprehensive Cancer Center, The Ohio State University Medical Center, Columbus, OH

**Background:** In the modern era, highly effective anti-HER2 therapy is associated with very low local-regional recurrence (LRR) rates for early-stage HER2+ breast cancer. One recent prospective study of T1-2N0 HER2+ breast cancer patients treated with lumpectomy and adjuvant paclitaxel+trastuzumab followed by whole breast radiation (RT) demonstrated 7-year LRR-free survival of 99% raising the question of whether local therapy de-escalation by RT omission is possible. To evaluate existing data on radiation omission, we used the National Cancer Database (NCDB) to test the hypothesis that RT omission results in equivalent overall survival (OS) in stage 1 (T1N0) HER2+ breast cancer. **Materials/Methods:** We identified patients with stage I (T1N0) HER2+ breast cancer treated with lumpectomy, adjuvant chemotherapy and anti-HER2 therapy from 2013 (the first year anti-HER2 therapy receipt was reliably collected) to 2015. We excluded patients that received neoadjuvant systemic therapy. We then stratified the cohort by receipt of adjuvant RT. The primary endpoint was OS as LRR is not captured by the NCDB. OS was analyzed by the Kaplan-Meier method (RT and RT omission groups compared by the log-rank test) and multivariate cox regression including variables with  $p < 0.20$  on univariate analysis (hazard ratios [HR], and 95% confidence intervals [CI] are reported). Propensity score matched (PSM) analysis with patients matched on age ( $\geq 70$  vs.  $< 70$ ), comorbidities ( $\geq 1$  vs. 0), grade (3 vs. 1-2), tumor size ( $> 1$  cm vs.  $\leq 1$  cm), ER/PR status (ER-/PR- vs. ER+ and/or PR+), facility type (academic vs. non-academic), and income ( $< \$46,000/\text{yr}$  vs.  $\geq \$46,000/\text{yr}$ ) was performed as an independent test of the Cox regression analysis. **Results:** We identified 6,897 patients that met the study criteria (6,388 RT; 509 no RT). Patients that did not receive RT tended to be older (mean age 64.0 years v. 59.2 years,  $p < 0.0001$ ), have  $\geq 1$  comorbidity (21.4% vs. 14.8%,  $p < 0.0001$ ), and live in lower income areas (60.1% vs. 52%,  $p = 0.0004$ ). Median follow-up was 29.4 months (IQR=19.5-39.9 months) with 155 deaths (95 RT; 60 RT omission). The 2-year OS was significantly worse for patients with RT omission (89.0% vs. 99.2%,  $p < 0.0001$ ). Factors associated with OS on univariate analysis included RT omission ( $p < 0.0001$ ), age  $\geq 70$  ( $p < 0.0001$ ),  $\geq 1$  comorbidity ( $p = 0.0002$ ), tumor size  $> 1$  cm ( $p = 0.14$ ), grade 3 tumors ( $p = 0.14$ ), academic facility ( $p = 0.16$ ) and lower income ( $p = 0.02$ ) but not ER-/PR- status (HR=1.01,  $p = 0.95$ ), distance to treatment facility ( $p = 0.42$ ) or tumor laterality ( $p = 0.66$ ). On multivariate analysis, RT omission (HR=7.55, 95% CI 5.36-10.63,  $p < 0.0001$ ), age  $\geq 70$  (HR=2.30, 95% CI 1.63-3.23,  $p < 0.0001$ ), and  $\geq 1$  comorbidity (HR=1.45, 95% CI 1.00-2.09,  $p = 0.05$ ) remained independently associated with higher risk of death. The PSM cohort consisted of 509 pairs of patients with 73 deaths (13 RT; 60 RT omission) and median follow-up 26.4 months (IQR, 16.5-37.3 months). RT omission remained associated with a 5.42-fold (95% CI 3.02-9.73,  $p < 0.0001$ ) increased risk of death in the PSM cohort. **Conclusion:** This study demonstrates that RT omission is independently associated with an increased risk of death in patients with stage I, HER2+, node-negative breast cancer treated with lumpectomy, adjuvant chemotherapy and anti-HER2 therapy. Patients that did not receive RT tended to be older, have more comorbidities and live in lower income areas. While other selection biases that influence RT omission likely persist, these data should give caution to RT omission in stage I, node-negative HER2+ breast cancer.

Long-term risks of cerebrovascular accidents (CVAs) in patients with breast cancer

Atul Batra<sup>1</sup>, Shiyong Kong<sup>2</sup>, Rodrigo Rigo<sup>1</sup> and Winson Y Cheung<sup>1</sup>. <sup>1</sup>Tom Baker Cancer Center, Calgary, AB, Canada<sup>2</sup>University of Calgary, Calgary, AB, Canada

**Background:** Previous survivorship research has focused primarily on treatment-related risks of coronary artery disease (CAD) and congestive heart failure (CHF) even though they share common pathogenic mechanisms with CVAs. However, there are limited data on the latter. This real-world evidence study aimed to assess the associations of breast cancer treatments with subsequent development of CVAs.

**Methods:** We identified patients diagnosed with stage I-III breast cancer in a large Canadian province from 2004 to 2017. Data from the population-based registry were linked with data from administrative sources to identify a diagnosis of CVA during follow-up after cancer treatment. Adjuvant treatment was classified as receipt of none, one, two or three depending on the number of treatment modalities (chemotherapy, radiotherapy and hormone therapy) administered. Patients with pre-existing cardiovascular disease including CAD, CHF, arrhythmias and CVAs were excluded. Multivariable logistic regression analysis was performed to determine the associations of number of adjuvant treatment modalities with CVAs.

**Results:** A total of 23,259 patients were eligible for analysis. The median age was 58 years (interquartile range, 22-101 years) and 0.5% were men. Stage distribution included 49.6% with stage I, 37.1% with stage II, and 13.4% with stage III breast cancer. Chemotherapy, radiotherapy and hormonal therapy was administered in 45.0%, 60.6%, and 68.1% of patients, respectively. While 11.0% received no adjuvant treatment, 28.7%, 35.9% and 24.4% received one, two and three modalities. At a median follow-up of 5.9 years, 1,586 (6.8%) developed new onset CVAs. The median time from diagnosis of breast cancer to CVA was 3.1 years (interquartile range, 2.7-3.5 years). In comparison, the incidence of CVAs was higher in those who received any chemotherapy (8.2% vs 5.1%,  $P < .001$ ), any radiotherapy (8.3% vs 5.9%,  $P < .001$ ), and any hormonal therapy (7.8% vs 6.4%,  $P < .001$ ). The incidence of CVAs was 4.9%, 5.9%, 8.2% and 10.5% in patients who received none, one, two and three adjuvant treatment modalities ( $P < .001$ ). After adjusting for age, patients who received two or three modalities (odds ratio [OR], 1.20; 95% confidence interval [CI], 1.03-1.41;  $P = .020$  and OR, 1.46; 95% CI, 1.21-1.75;  $P < .001$ ) experienced a higher likelihood of CVAs, compared to those who received no adjuvant therapy, while those who received one modality were at similar risk (OR, 1.00; 95% CI, 0.86-1.17,  $P = .974$ ). In multivariable Cox regression models adjusting for stage and treatment, patients who developed CVAs were at increased risk of death (hazard ratio, 1.44; 95% CI, 1.30-1.58;  $P < .001$ ).

**Conclusions:** The risk of CVAs in patients with resected breast cancer increases with adjuvant treatment administration. It was highest in those who received a combination of chemotherapy, radiotherapy and hormone therapy. While breast cancer survivors are monitored for coronary events and cardiomyopathy, they may benefit from surveillance of risk factors for CVAs.

Therapeutic considerations in microsatellite instability high (MSI-H) breast cancers (BC) identified by comprehensive genomic profiling (CGP)

Kimberly McGregor<sup>1</sup>, Natalie Danzinger<sup>1</sup>, Jeffrey S. Ross<sup>1</sup>, Kyle Gowen<sup>1</sup>, Alexa B. Schrock<sup>1</sup>, Garrett M. Frampton<sup>1</sup>, Dean C. Pavlick<sup>1</sup>, Jan W. Davis<sup>2</sup>, Carl R. Gray<sup>2</sup> and Jeffrey M. Venstrom<sup>1</sup>. <sup>1</sup>Foundation Medicine, Cambridge, MA; <sup>2</sup>Utah Hematology and Oncology, Ogden, UT

**Background:** Non-colorectal MSI-H tumors are increasingly identified by CGP. Rare types such as MSI-H BC remain poorly defined with an evidence gap on how to optimally sequence or combine with standard of care treatment. MSI can be measured by either IHC, PCR, or CGP and can be caused by both sporadic and germline variants within different tumor types. Prior studies in BC have shown evidence of dMMR by IHC cases MSS based on PCR. This could be due to intra-tumor heterogeneity, specific microsatellite loci evaluated, or penetrance of germline, somatic, or epigenetic alterations. Published data suggests carriers of germline pathogenic MMR variants have a BC risk equivalent to the normal population and currently germline testing is recommended only for *BRCA*. Currently in advanced BC, standard tumor biomarker testing includes IHC, PCR, and FISH; however, with increasing use of CGP we demonstrate additional actionable biomarkers as well as potential germline variants in MSI-H BC. **Methods:** DNA was extracted and hybrid capture CGP was performed on 29,160 BC cases. TMB was determined on 0.8-1.2 Mb of DNA and MSI status on 95-114 loci. Genomic LOH was also evaluated. Comparative analysis was done with 101 MSI-H BC, 841 MSS BC and 4,988 non-breast MSI-H cancers. Histological subtype was obtained from the pathology along with orthogonal testing for ER/PR/HER2 status. Somatic-germline-zygosity (SGZ) status was predicted using a published research use algorithm. Select case reports with clinical outcomes will be presented. **Results:** We identified 101 (0.35% of total) MSI-H BC cases: 29 ER+/HER2-, 5 HER2+, 29 TNBC, and 28 unknown. Amongst BC cases with known subtype, TNBC was enriched for MSI-H vs MSS (53.4 vs 35.8%,  $p=0.005$ ). The median TMB in MSI-H BC (26.1 mut/Mb, IQR 17.4;42.8) was significantly lower than that of MSI-H colon (46.1mut/Mb) and higher than that of MSI-H uterine tumors (22.6mut/Mb) in our comparison group ( $p<0.001$  for both, Kruskal-Wallis test). Pathogenic variants in an MMR gene were found in 61.4% of MSI-H BC with *MLH1* loss being the most common (13.6%) and much higher vs. the non-breast MSI-H cohort (2.4%,  $p<0.0001$ ). Germline mutations in MMR genes in BC are rare yet 5/52 MMR short variants identified in 101 MSI-H BCs were predicted to be germline, 34 somatic, and 13 could not be determined. We identified 21 MSI-H BC patients with a total of 25 pathogenic *BRCA1/2* alterations of which 4 were likely germline, 10 were homozygous, and were enriched in TNBC. These were mainly frameshift mutations, including *BRCA2* T3033fs\* in 5/18 (28%) cases; however, 7/25 were deletions, rearrangements, or nonsense mutations. Median gLOH was significantly higher in *BRCA* altered (19.7%) compared to *BRCA* wild-type MSI-H BC cases (9.6%) ( $p=0.007$ , Wilcoxon test). Additional potentially targetable biomarkers included 26 CDx eligible *PIK3CA* mutations, 11 *ERBB2* activating point mutations in the TKD or ECD domain, 1 *FGFR2* rearrangement, and 6 *AKT1* E17K mutations. Four cases also had concurrent (*CD274*) PD-L1 amplifications. **Conclusion:** MSI-H BC is rare but CGP can identify additional therapeutic options for rational combination with targeted therapies such as PI3K, PARP, and HER2 inhibitors. *BRCA* alterations may be of germline or somatic origin and they may be targetable, as demonstrated by gLOH, rather than passenger mutations. Further characterization of these tumors and comparison to both MSS BC and non-breast MSI-H tumor types, combined with treatment outcomes, can provide insights on rationale combinations and/or sequencing of therapeutic agents.

Impact of delayed initiation of adjuvant chemotherapy in early breast cancer: Analysis from Taiwan National breast cancer registry database

Junping Shiau<sup>1</sup>, Fang-Ming Chen<sup>2</sup> and Ming-Feng Hou<sup>1</sup>. <sup>1</sup>Graduate Institute of Clinical Medicine, College of Medicine, Kaohsiung Medical University; Kaohsiung Medical University Hospital, Kaohsiung City, Taiwan<sup>2</sup>Kaohsiung Medical University Hospital, Kaohsiung City, Taiwan

**Background:**In 2017, there are more than 14,000 cases of newly diagnosed breast cancer in Taiwan. With the popularity of early screening policy and social-awareness, the proportion of early breast cancer has increased significantly in the last decades. For the high risk group with early breast cancer, adjuvant systemic chemotherapy could provide lower breast cancer recurrence rate and better overall survival rate. In Taiwan, every citizen must join the National Health Insurance (NHI), and the NHI would cover the whole expense of adjuvant chemotherapy. Theoretically, all breast cancer patients could receive their condign chemotherapy regardless of their social economic status. The optimal initiation timing of adjuvant chemotherapy is undiscovered, and the effect of delay initiation is still under contestation. In this study, we try to identify the relationship between initiation time of chemotherapy and survival outcome, and different breast cancer subtypes would be analyzed separately. We also evaluate many associated factors that may delay chemotherapy initiation or survival status.**Material and Methods:**In this observational, populational-based study using Taiwan national breast cancer registry database, we studied 110,784 patients diagnosed with Stage I–III breast cancer between January 1, 2006 and December 31, 2016. Time to chemotherapy(TCC) was defined as the days between surgery and the initial dose of adjuvant chemotherapy. We categorized patients into initiate chemotherapy within 30 days, 31–60 days, 61–90 days, and more than 91 days. The patient demography, tumor biology, lymph node status, type of breast surgery, receiving reconstructive surgery or not, radiation therapy, immunohistochemistry data (estrogen receptor, progesterone receptor, and human epidermal growth factor 2[HER2]), and we categorized patients according to different breast cancer subtypes. Univariate analysis with Kaplan-Meier method is used to evaluate TTC influence, and log-rank test is used to compare differences between groups. Multivariate logistic regression model is used to identify important factors associated with delayed chemotherapy initiation and survival.**Preliminary Results:**Totally 72840 patients were enrolled in this study, and the median age at initial diagnosis was 52.4 years old. Delayed wound healing and breast reconstruction are the main factors associated with delayed TTC. Comparing with TTC<30 days group, TTC of 31–60 days group showed no difference in disease-free survival and overall survival, while TTC of 61–91 days group had a trend of lower disease-free survival ( $p=0.12$ ). TTC more than 91 days had worse disease-free survival (HR=1.16, 95%CI=1.03–1.38) and overall survival (HR=1.23, 95%CI=1.08–1.52). We assumed initiate first chemotherapy more than 90 days as delayed TTC as generally accepted in previous publications. In subgroup analysis, delayed TTC caused worse disease-free survival especially in triple negative group (HR=1.42, 95%CI=1.21–1.68) and HER2 group (HR=1.38, 95%CI=1.22–1.55).**Conclusion:**For breast cancer patients who assumed to receive adjuvant systemic chemotherapy, delayed in initiation of chemotherapy (more than 90 days) may result in worse outcome, especially in triple negative breast cancer and HER2 group. Besides the above preliminary result, other multivariate analysis and intergroup comparison are still ongoing. More information will reveal in SABCS 2020.

Trop-2 inactivation of E-cadherin drives triple negative breast cancer relapse

Saverio Alberti<sup>1</sup>, Marco Trerotola<sup>2</sup>, Valeria Relli<sup>2</sup>, Rossano Lattanzio<sup>2</sup>, Martina Ceci<sup>2</sup>, Khoulood Boujnah<sup>1</sup>, Valeria Garbo<sup>1</sup>, Antonino Moschella<sup>1</sup>, Patrizia Querzoli<sup>3</sup>, Massimo Pedriali<sup>3</sup>, Laura Antolini<sup>4</sup> and Emanuela Guerra<sup>2</sup>. <sup>1</sup>University of Messina, Messina, Italy<sup>2</sup>University of Chieti, Chieti, Italy<sup>3</sup>University of Ferrara, Ferrara, Italy<sup>4</sup>University of Milano Bicocca, Monza, Italy

Hundreds of proteins/genes have been linked to the metastatic phenotype. However, consistent markers of tumour aggressiveness and metastatic potential in breast cancer patients were not identified, not even including proteomic analysis and large-scale genome sequencing. Metastasis-associated genes were predicted to include not only drivers of the metastatic phenotype, but also secondary events, together with adaptive, counterbalancing changes. Thus, to identify candidates with a required role in metastatic diffusion, we looked for genes that were concordantly dysregulated across orthogonal cancer metastasis settings. This led us to identify Trop-2 as uniquely upregulated and associated to metastasis in experimental models of breast cancer, as well as in other solid tumors. We identified functional inactivation of E-cadherin by Trop-2 as the main motor of metastatic diffusion of such metastatic systems. Trop-2 binding to E-cadherin inactivated its cell-cell adhesion function, through release from the cytoskeleton, for activation of  $\beta$ -catenin transcriptional activity. This led to anti-apoptotic signaling, increased cell migration capacity and enhanced cancer cell survival. We showed that this mechanism led to metastatic diffusion of xenotransplants growing in immunosuppressed mice. An E-cadherin-inactivation metastasis program was then shown to be recapitulated in breast cancer patients, as well as in other solid tumors, over 24 independent case series, encompassing 13,042 primary tumours. Aggressive triple-negative breast cancers were shown to be driven toward global relapse by Trop-2 overexpression, through E-cadherin inactivation and activation of  $\beta$ -catenin transcriptional activity. No disease recurrence was observed in control cases over +12 years of follow-up. These findings lead to a novel paradigm of a Trop-2-driven, E-cadherin-inactivation program as a main metastasis driver in solid tumors. This may open far-reaching perspectives in diagnostic procedures and anti-cancer therapies.

**Background:** The risk of distant recurrence gene signature, MammaPrint (MP), together with the molecular subtyping gene signature, Blueprint (BP), stratifies breast tumors into Luminal A, Luminal B, HER2, and Basal subtypes, independent of immunohistochemistry (IHC) or fluorescent in situ hybridization (FISH) expression. In the Neoadjuvant Breast Registry Symphony Trial (NBRST), MP and BP identified patients likely to respond to neoadjuvant treatment with higher accuracy compared to conventional methods. Here, we report 5-year follow up (FU) data in breast cancer (BC) patients from the NBRST registry with discordant clinical and genomic subtyping. **Methods:** This prospective study enrolled 1072 early-stage BC patients from 2009-2014 who received MP and BP testing. Patients received neoadjuvant therapy following standard of care and consented to 5 years post-surgery FU. IHC determined hormone receptor (HR) status, including ER and PR, and IHC and/or FISH determined HER2 status. Median FU for distant metastasis free survival (DMFS) and overall survival (OS) was 4.6 and 5 years, respectively. Differences in DMFS and OS was assessed by Kaplan Meier analysis and log-rank test. **Results:** Overall, BP reclassified 22% of tumors into different molecular subtypes compared to IHC/FISH (Table). BP reclassified 17% of ER+HER2- tumors as BP Basal, with higher pathological complete response (pCR) rates compared to ER+/BP Luminal tumors (36% vs. 4%). ER+/BP Basal patients had similar pCR rates as triple negative BC (TNBC)/BP Basal patients (36% vs. 37%) following neoadjuvant treatment, and pCR correlated with improved survival outcomes. The 5-year DMFS and OS probabilities were lower in ER+/BP Basal patients compared to TNBC/BP Basal patients and were substantially lower compared to ER+/BP Luminal patients ( $P < 0.001$ ). There were 106 HR-HER2+ patients, of whom BP reclassified 23.6% to Basal and 2.8% as Luminal B; the remaining 73.6% were confirmed HER2 by BP. The 5-year DMFS and OS probabilities were worse in HER2+/BP Basal patients compared to HER2+/BP HER2 patients. Of 142 triple positive (TP, ER+PR+HER2+) patients, BP classified 55% as Luminal, 39% as HER2, and 6% as Basal, with higher pCR rates observed in BP Basal and BP HER2 tumors compared to BP Luminal. The 5-year DMFS and OS probabilities were substantially lower in TP/BP Basal patients compared to TP/BP HER2 and TP/BP Luminal patients ( $P < 0.05$  and  $P < 0.04$ ). Of clinical HER2+ patients (HR+ or HR-) that received pertuzumab, patients that reclassified as BP Basal had worse OS compared to BP HER2 patients ( $P < 0.04$ ). **Conclusion:** ER+HER2- and HER2+ patients that reclassified as BP Basal are more likely to achieve pCR and have improved survival, demonstrating the clinical utility of BP in the neoadjuvant setting. These patients may benefit from optimized chemotherapy used for TNBC, including novel emerging treatments such as PD-1 and PARP1 inhibitors, in addition to HER2-targeted therapy. Furthermore, HER2+ tumors that were confirmed HER2 by BP may have high response rates to regimens containing TDM-1. Lastly, BP identified a subgroup of triple positive BC patients, who reclassified as BP Luminal, that may avoid overtreatment. Overall, molecular subtyping using MP and BP is more accurate in stratifying patients and predicting treatment responses and 5-year disease outcomes than conventional methods and thus, facilitates successful treatment decisions.

Clinical subtype	Frequency of BP classification	Blueprint subtype	pCR%	5-yr DMFS (95% CI)	5-yr OS (95% CI)
<b>TNBC (n=236)</b>	0.42% (1/236)	Luminal A	100% (1/1)	N/A	N/A

Computational drug repositioning for the identification of new agents to sensitize drug-resistant breast tumors across treatment arms and molecular subtypes

Katharine Yu<sup>1</sup>, Amrita Basu<sup>1</sup>, Christina Yau<sup>1</sup>, Denise Wolf<sup>1</sup>, Gillian Hirst<sup>1</sup>, Laura Sit<sup>1</sup>, Nicholas O'Grady<sup>1</sup>, Thelma Brown<sup>2</sup>, I-SPY 2 TRIAL Investigators, Angela DeMichele<sup>3</sup>, Don Berry<sup>4</sup>, Nola Hylton<sup>1</sup>, Doug Yee<sup>5</sup>, Laura Esserman<sup>1</sup>, Laura van 't Veer<sup>1</sup> and Marina Sirota<sup>1</sup>. <sup>1</sup>UCSF, San Francisco, CA; <sup>2</sup>University of Alabama, Tuscaloosa, AL; <sup>3</sup>University of Pennsylvania, Philadelphia, PA; <sup>4</sup>Berry Consultants LLC, Austin, TX; <sup>5</sup>University of Minnesota, Minneapolis, MN

**Introduction:** One of the principal limiting factors to achieving cures in patients with cancer is drug resistance. Drug repositioning is the application of FDA-approved drug compounds for novel indications beyond the scope of the drug's original intended use. This approach offers advantages over traditional drug development by reducing development costs and providing shorter paths to approval, as drug safety has already been established during the drug's original regulatory process. One approach for computational drug repositioning involves generating a disease gene expression signature and then identifying a drug that can reverse this disease signature. In this study, we extracted drug resistance signatures from the I-SPY 2 TRIAL by comparing gene expression profiles of responder and non-responder patients stratified by treatment and molecular subtype. We then applied our drug repositioning pipeline to predict compounds that can reverse the gene expression profiles of these drug resistance signatures. We hypothesize that reversing these drug resistance signatures will resensitize tumors to treatment and improve patient outcome.

**Methods:** We first generated the drug resistance signatures by performing differential expression between responders (RCB 0/I) and non-responders (RCB III) within treatment arms and molecular subtypes. An optimal log fold-change cutoff was selected for each signature by identifying the cutoff that best separates the responder and non-responder samples using k-means clustering. We then applied our drug repositioning pipeline to identify compounds that significantly reverse these signatures using the drug perturbation profiles generated in a breast cancer cell line in the Connectivity Map v2 dataset. Briefly, the pipeline uses a non-parametric, rank-based pattern-matching strategy based on the Kolmogorov-Smirnov (KS) statistic to assess the enrichment of resistance genes in a ranked drug gene expression list. Significance of each prediction is estimated from a null distribution of scores generated from random gene signatures.

**Results:** We found that few individual genes are shared among the resistance signatures across the treatment arms and molecular subtypes, with the most common genes present in only 5/17 of the treatment arm and molecular subtype groups. At the pathway-level, however, we found that immune-related pathways are generally enriched among the responders and estrogen-response pathways are generally enriched among the non-responders. Although most of our drug predictions are unique to treatment arms and molecular subtypes, our drug repositioning pipeline identified the selective estrogen receptor degrader (SERD) fulvestrant as a compound that can potentially reverse resistance across a majority of the treatment arms and molecular subtypes.

**Conclusion:** We applied our drug repositioning pipeline to identify novel agents to sensitize drug-resistant tumors in the I-SPY 2+ clinical trial and identified a SERD, fulvestrant, as a potential candidate for multiple molecular subtypes and treatment arms.

Tailored axillary surgery to omit axillary lymph node dissection independently from the use of neoadjuvant chemotherapy in patients with clinically node-positive breast cancer: Pre-specified subproject within TAXIS (SAKK 23/16 / IBCSG 57-18 / ABCSG-53 / GBG 101)

Walter Paul Weber<sup>1</sup>, Guido Henke<sup>2</sup>, Stefanie Hayoz<sup>3</sup>, Karin Ribi<sup>4</sup>, Stefanie Seiler<sup>3</sup>, Charlotte Maddox<sup>3</sup>, Thomas Ruhstaller<sup>5</sup>, Daniel Rudolf Zwahlen<sup>6</sup>, Simone Muenst<sup>7</sup>, Markus Ackerknecht<sup>8</sup>, Florian Fitzal<sup>9</sup>, Mihaly Ujhelyi<sup>10</sup>, Christian Kurzeder<sup>1</sup>, Loic Lelievre<sup>11</sup>, Christoph Tausch<sup>12</sup>, Daniel Egle<sup>13</sup>, Jorg Heil<sup>14</sup>, Zoltan Matrai<sup>10</sup> and Michael Knauer<sup>5</sup>. <sup>1</sup>Breast Center, University Hospital Basel, Basel, Switzerland<sup>2</sup>Department of Radiation Oncology, St. Gallen Cantonal Hospital, St. Gallen, Switzerland<sup>3</sup>SAKK Coordinating Center, Bern, Switzerland<sup>4</sup>IBCSG Coordinating Center, Bern, Switzerland<sup>5</sup>Breast Center Eastern Switzerland, St. Gallen, Switzerland<sup>6</sup>Department of Radiation Oncology, Cantonal Hospital Winterthur, Winterthur, Switzerland<sup>7</sup>Institute of Medical Genetics and Pathology, University Hospital Basel, Basel, Switzerland<sup>8</sup>Department of Biomedicine, University Hospital Basel, Basel, Switzerland<sup>9</sup>Department of Surgery and Breast Health Center, Medical University of Vienna, Vienna, Austria<sup>10</sup>Department of Breast and Sarcoma Surgery, National Institute of Oncology, Budapest, Hungary<sup>11</sup>Breast Center, CHUV, Lausanne, Switzerland<sup>12</sup>Breast Center, Zurich, Switzerland<sup>13</sup>Medical University Innsbruck, Innsbruck, Austria<sup>14</sup>Breast Center, Heidelberg, Germany

**Introduction:** We developed tailored axillary surgery (TAS) to selectively remove positive nodes and omit axillary lymph node dissection (ALND) in patients with clinically node-positive breast cancer irrespective of the use of neoadjuvant chemotherapy. In this study, we evaluate the performance of this novel surgical concept that tailors the extent of axillary surgery to the extent of axillary disease. **Methods:** A prospective study was pre-specified to assess the performance of TAS in the international multicenter phase-III TAXIS trial randomizing patients with clinically node-positive breast cancer to undergo ALND or axillary radiation after TAS. TAS consists of selective removal of all palpably suspicious findings and the SLNs followed by specimen radiography to document removal of the clip placed in the sampled node. Imaging-guided localization is encouraged to increase the chances of clip removal. Only patients with confirmed nodal disease at the time of surgery can be randomized in TAXIS; the first 200 randomized patients were analyzed together with the ones achieving nodal pCR in this study. ClinicalTrials.gov Identifier: NCT03513614. **Results:** A total of 296 patients with a median age of 56.5 years (range: 25-88 years) were included at 28 breast centers from four European countries, 125 (42.3%) of whom underwent NACT and 75 (25.3%) of whom had nodal pCR. Subtype was hormone receptor (HR) positive (+) and human epidermal growth factor receptor 2 (HER2) negative (-) in 194 (65.5%), HR+/HER2+ in 40 (13.5%), HR-/HER2+ in 17 (5.7%) and HR-/HER2- in 39 (13.2%) patients. Breast-conserving surgery was performed in 178 patients (60%) and mastectomy in 117 (40%). Imaging-guided localization was attempted in 258 patients (87.2%) and was successful in 243 (82.1%). TAS removed a median of two (interquartile range [IQR] 0-3) palpably suspicious lesions and two (IQR 1-3) SLNs, thereby successfully removing the clip in 279 (94.3%) patients. There were no significant differences by use of imaging-guided localization (94.6% with vs 92.1% without,  $p=0.47$ ) or type of clip ( $p=0.19$ ), but a trend toward lower rate of clip removal after NACT (91.2% with vs 96.5% without NACT,  $p=0.075$ ). Palpable disease was left behind after TAS in two (2.1%) patients and no SLN was detected in three (3.1%). In the 200 randomized patients with confirmed nodal disease at the time of surgery, lymph node metastases were palpable at the time of initial diagnosis in 102 (51%) patients and detectable only by imaging in 98 (49%). The median number of lymph nodes removed by TAS was four (IQR 2-8), two (IQR 1-4) of which were positive. Completion ALND following TAS removed additional positive nodes in 71 of 100 (71%) patients in the control group (20% with one additional node, 9% with 2, 8% with 3, 6% with 4, and 28% with >4). The median number of additional lymph nodes removed by ALND was 14 (IQR 10-18), two (IQR 0-6) of which were positive. Of the 200 randomized patients, one in the TAS group received a radiotherapy boost and one in the ALND group returned to the operating room for residual suspicious findings on imaging. **Discussion:** The present results suggest that TAS has the potential to become the new axillary surgery standard in patients with clinically node-positive breast cancer. TAS was successfully performed in the vast majority of patients, with no further improvement by imaging-guided localization, which makes the procedure feasible at most breast centers. TAS selectively removed positive lymph nodes and was much less radical than ALND, but ALND removed additional positive nodes in more than two thirds of patients. Disease-free survival and quality of life will be assessed in the randomized trial.

Camargo Cancer Center, Sao Paulo, Brazil<sup>5</sup>IRCCS Ospedale Policlinico San Martino, Genova, Italy<sup>6</sup>Breast International Group, Brussels, Belgium<sup>7</sup>National Cancer Institute, Bethesda, MD;<sup>8</sup>Mayo Clinic, Jacksonville, FL;<sup>9</sup>Novartis Pharma AG, Basel, Switzerland<sup>10</sup>Jules Bordet and l'Universite Libre de Bruxelles (U.L.B.), Brussels, Belgium<sup>11</sup>Medical Clinic II, Department of Hematology/Oncology, University Hospital Frankfurt, Frankfurt, Germany<sup>12</sup>Institut Jules Bordet and l'Universite Libre de Bruxelles (U.L.B.), Brussels, Belgium

**Background:** In HER2-positive breast cancer patients, timing from the end of (neo)adjuvant trastuzumab (T)-based therapy to diagnosis of metastatic breast cancer is the key factor in determining the optimal first-line treatment. There is currently lack of clear evidence to support the possible prognostic role of this interval and 12 months has been mostly empirically used. The present analysis aimed to investigate patterns of relapse, first-line choice and survival outcomes of patients with HER2-positive early breast cancer who relapsed after adjuvant T-based therapy depending on T-free interval (TFI, i.e. timing from end of adjuvant T to diagnosis of distant metastases).

**Methods:** In ALTTO, HER2-positive early breast cancer patients were randomized to 1 year of either T alone, lapatinib (L) alone, their sequence (T->L) or their combination (T+L). This exploratory analysis included only pts in the T or T+L arms who experienced a distant disease-free survival (DDFS) event. Two cohorts of patients were defined depending on TFI: group A (TFI of <12 months) and group B (>12 months). Baseline characteristics, patterns of relapse, first-line choice and overall survival (OS) were compared. OS was defined as time between date of DDFS event to death; age at diagnosis, tumor size and hormone receptor status were the variables included in the final multivariate models.

**Results:** Out of 8,381 patients included in ALTTO, 404 patients in the T and T+L arms developed a DDFS event, of whom 201 occurred ≤12 months (group A) and 203 >12 months (group B) after the end of adjuvant T. Patients in group A were older (p=0.013), had larger tumors (p=0.004) and more frequently hormone receptor-negative disease (p<0.001). No significant difference in patterns of first DDFS event was observed (p=0.073); however, a numerically higher number of patients in group A compared to group B developed brain metastasis (26% vs. 15%). First-line anti-HER2 therapy was received by 57% of the patients. Choice of first-line anti-HER2 therapy was different between the two groups (p=0.022): the majority of patients received T in both groups (61% vs. 65% in groups A and B, respectively), while more patients in group A received L (25% vs. 11%) and less received pertuzumab (8% vs. 17%). OS survival was significantly shorter in group A compared to group B: median OS was 18.4 and 29.3 months in groups A and B, respectively (adjusted HR 0.69; 95% CI 0.54-0.89; p=0.004). Similar results were observed after the exclusion of patients treated with first-line pertuzumab-based therapy (n=29): median OS was 18.2 and 26.8 months in groups A and B, respectively (adjusted HR 0.66; 95% CI 0.51-0.86; p=0.002). Better outcomes in terms of OS for patients in group B was observed across all analyzed subgroups with no interaction according to hormone receptor status (p=0.814) nor type of adjuvant anti-HER2 treatment (p=0.233): hormone receptor-positive (adjusted HR 0.69; 95% CI 0.48-0.99), hormone receptor-negative (adjusted HR 0.68; 95% CI 0.48-0.98), T+L arm (adjusted HR 0.55; 95% CI 0.38-0.80) and T arm (adjusted HR 0.80; 95% CI 0.55-1.17).

**Conclusions:** In the ALTTO trial, HER2-positive early breast cancer patients who experienced shorter TFI (i.e. ≤12 months vs. >12 months) following adjuvant T-based therapy had inferior OS after the diagnosis of distant recurrence. Given its prognostic value, TFI can help to individualize clinical recommendations and to design future trials in the metastatic setting for patients relapsing after prior exposure to anti-HER2 therapy for early disease.

Comprehensive genomic and transcriptomic profiling of molecular subtypes reveal ancestral differences in the activity of signaling pathways between patients with African and European ancestry

Minoru Miyashita<sup>1</sup>, Joshua SK Bell<sup>2</sup>, Yonglan Zheng<sup>1</sup>, Toshio Yoshimatsu<sup>1</sup>, Padma Sheila Rajagopal<sup>1</sup>, Anna Woodard<sup>1</sup>, Jean Baptiste Reynier<sup>1</sup>, Elisabeth Sveen<sup>1</sup>, Galina Khramtsova<sup>1</sup>, Fang Liu<sup>1</sup>, Abiola Ibraheem<sup>1</sup>, Gini Fleming<sup>1</sup>, Nora Jaskowiak<sup>1</sup>, Rita Nanda<sup>1</sup>, Benjamin Leibowitz<sup>2</sup>, Nike Beaubier<sup>2</sup>, Kevin White<sup>2</sup>, Dezheng Huo<sup>1</sup> and Olufunmilayo I Olopade<sup>1</sup>. <sup>1</sup>The University of Chicago, Chicago, IL; <sup>2</sup>Tempus Inc, Chicago, IL

**Background:** Breast cancer demonstrates heterogeneity in biological features, and the therapeutic strategy depends on tumor subtype. African-Ancestry (AA) patients experience a disproportionately high rate of triple negative breast cancer (TNBC) and worse outcomes than European-Ancestry (EA) patients. However, the biological drivers causing this disparity between ancestral populations are not deeply understood. To address the issue, we performed genomic and transcriptomic sequencing of breast tumors for comparison between AA and EA patients according to breast cancer molecular subtypes. **Materials and Methods:** The study included 221 AA and 341 EA patients. Collected samples underwent the Tempus xT next-generation sequencing panel. Following DNA-panel and whole-transcriptome RNA-sequencing, we compared gene mutation rates, homologous recombination deficiency (HRD) scores, degree of immune infiltration and tumor mutational burden (TMB) between ethnicities and molecular subtypes. Additionally, differences between the activity of relevant signaling pathways were evaluated from RNA-sequencing data. **Results:** Relative to EA TNBC, AA TNBC tumors exhibited higher mutation rates in *TP53* (94% vs 86%), *KMT2C* (17% vs 9%), *APOB* (19% vs 10%), *BRCA2* (11% vs 5%), *EP300* (8% vs 2%), *NOTCH1* (12% vs 4%), and *EGFR* (11% vs 4%). Conversely, AA TNBC tumors had relatively lower rates of *PIK3CA* (10% vs 18%), *RB1* (8% vs 15%), and *NF1* (5% vs 11%) mutations. Among patients with HR+/HER2- breast cancer, AA tumors had higher mutation rates in *CCND1* (23% vs 10%) and *FGF3* (16% vs 10%) than EA tumors, but lower rates in *TP53* (32% vs 39%). HRD scores were higher in TNBC and HR-/HER2+ tumors compared with the other subtypes ( $P < 0.001$ ). However, there was no significant difference between the HRD scores of AA and EA tumors within TNBC or HR-/HER2+ populations. The highest percentage of immune infiltration was observed in HR-/HER2+ tumors ( $P = 0.036$ ), with no difference between AA or EA groups. TMB did not differ across ancestries or subtypes. Although immune pathways were generally more active in TNBC compared to the other subtypes, there was no difference in pathway-specific immune activation between ethnicities. The G2M and E2F pathways were significantly more active in TNBC ( $P < 2 \times 10^{-16}$  for both), in particular more active in AA than EA tumors (G2M,  $P = 0.035$ ; E2F,  $P = 0.037$ ). On the other hand, PI3K, ROS, and xenobiotic metabolism (XM) pathways were significantly less active in TNBC compared to the other subtypes (PI3K,  $P = 2.4 \times 10^{-5}$ ; ROS,  $P = 0.014$ ; and XM,  $P < 2 \times 10^{-16}$ ). Furthermore, these pathways were significantly less active in AA than EA tumors across all subtypes (PI3K,  $P = 0.026$ ; ROS,  $P = 0.00035$ ; and XM,  $P = 0.00041$ ) and within TNBC (PI3K  $P = 0.012$ , ROS  $P = 0.014$ , and XM  $P = 0.00018$ ). **Conclusion:** These data demonstrate significant differences in breast tumor heterogeneity and mutation spectrum in TNBC and HR+/HER2- breast cancers between AA and EA patients. Ancestral differences were also observed in the activity of relevant signaling pathways for TNBC. Overall, the results identify previously unexplored pathways and molecular phenotypes of aggressive disease, providing opportunities for development of more effective biomarker informed treatment of breast cancer in diverse populations.

The optimal living and survivorship program: Piloting a novel cancer survivorship care model

Stacie Corcoran, John Russell, Jill Clayton, Andrea Smith, Kate Keenan, Mark Robson and Neil Iyengar. Memorial Sloan Kettering Cancer Center, New York, NY

**Background:** Multiple national agencies define cancer survivorship as beginning at the time of cancer diagnosis. However, traditional care models typically deliver “survivorship care” months or years after diagnosis, which can lead to disruption in care and “transition anxiety”. We hypothesized that an approach centered around wellbeing could be applied across the cancer continuum (starting at diagnosis) and serve as a novel survivorship care model.

**Methods:** We developed the Optimal Living and Survivorship Program, a novel telehealth platform that is designed to better engage cancer survivors by providing multidisciplinary and individualized lifestyle management during and after cancer therapy. Our multilevel approach relies on three key components: 1) a digitized centralized model that provides automated and coordinated multidisciplinary care; 2) an individualized Wellness Plan (WP); and 3) enrollment at the time of cancer diagnosis in order to mitigate the experience of post-treatment transition. Participants complete a digital wellness questionnaire (WQ) consisting of validated instruments that provide risk assessment for a broad range of lifestyle and psychosocial factors prior to the first medical oncology consult, receive a validated algorithm-based WP reviewed by a Wellness Coordinator, and meet with a specially trained Wellness Advanced Practice Provider (WAPP) via tele-medicine. The WP consists of individualized topic-specific educational materials (e.g., webinars, videos) and referrals to indicated supportive services (e.g., nutrition, exercise physiology, financial counseling, integrative medicine). The WAPP will ultimately assume care of the patient in the post-treatment (“survivorship”) phase. We piloted this approach in patients diagnosed with breast cancer beginning in November 2019. The primary outcome is feasibility defined by completion of the WQ. Secondary outcomes include participation in the WAPP visits, attendance at referral appointments, and quality of life (QOL).

**Results:** As a result of COVID-19, the pilot was paused in February 2020. Data collected from November 2019 through February 2020 reveal a total of 67 eligible patients with newly diagnosed breast cancer were approached, with 65 (97%) enrolled in the program. All participants completed the WQ and all received a WP with indicated supportive referrals and educational resources. All participants engaged partially or fully with WP recommendations. Participants were screened at high risk for an average of 3.8 unmet needs, and 98% were at high risk for 2 or more needs at the time of diagnosis. Exercise was identified as the highest unmet need (83%). There was 76% adherence with referral to the program’s Exercise Physiologist. Other commonly identified areas of needs were nutrition (59%) and sleep quality (51%). WAPP tele-medicine visits began in June 2020 and are ongoing; visit completion rates and interventions will be presented. Qualitative data regarding patient experience and QOL will be obtained via focused interviews and feedback will be categorized in thematic domains.

**Conclusions:** In this pilot, the majority of patients with newly diagnosed breast cancer enrolled in the program, completed a WQ in advance of their initial medical oncology visit, and engaged with the WP. Our findings suggest that this early introduction to survivorship care is feasible. Earlier patient engagement and incorporation of wellness and supportive services from time of diagnosis may significantly improve our ability to address multifactorial needs during and after cancer therapy.

Deep-learning based prediction of homologous recombination deficiency (hrd) status from histological features in breast cancer; a research study

Amaro Taylor-Weiner<sup>1</sup>, Aryan Pedawi<sup>1</sup>, Wan Fung Chui<sup>2</sup>, James Diao<sup>2</sup>, Jason Wang<sup>2</sup>, Victoria Mountain<sup>1</sup>, Benjamin Glass<sup>1</sup>, Hunter Elliott<sup>1</sup>, Ilan Wapinski<sup>1</sup>, Michael Montalto<sup>1</sup>, Aditya Khosla<sup>1</sup> and Andrew H. Beck<sup>1</sup>. <sup>1</sup>PathAI, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA

**Background** Homologous recombination deficiency (HRD), originally described in tumors from patients with germline mutations in *BRCA1/2* genes, renders cells sensitive to poly-ADP ribose polymerase inhibitors (PARPi) (1), but can be caused by mutations in other genes and is prevalent across multiple cancer types (2). HRD status is of clinical interest because it can indicate patient eligibility for treatment with PARPi. Currently, HRD status is determined by sequencing to identify *BRCA* mutations or genomic instability, but this has a high rate of failure (3). In this research study, we apply a deep-learning based computational approach to directly infer HRD status from digitized images of hematoxylin and eosin (H&E) stained histology samples in breast cancer tumors. **Methods** Digitized whole slide images (WSI) of 931 H&E stained, formalin-fixed and paraffin-embedded (FFPE) breast adenocarcinoma (BRCA) tumor biopsies from the cancer genome atlas (TCGA) were used to train machine learning (ML) models to identify patients that are HRD based on human-interpretable features (HIFs) and end-to-end (E2E) modeling. To train the models, samples were split into training and validation sets designated either HRD or homologous recombination proficient (HRP) based on a previously generated aggregate HRD score (calculated from regions of loss of heterozygosity, large scale genomic instability, and telomeric allelic imbalance) by genomic analysis of the PanCancerAtlas (2). We applied an untuned HRD score threshold of 45 to assign class labels resulting in 142/931 (15.3%) HRD cases.

Board certified pathologists (N=93) annotated tissue regions and cellular foci on the PathAI research platform yielding 65,477 annotations. ML models based on convolutional neural networks were trained to recognize breast cancer cells, lymphocytes, macrophages, plasma cells, fibroblasts, and tissue compartments including cancer epithelium, cancer stroma and necrosis within the H&E stained breast cancer samples.

Two pipelines constructed H&E histology-based classifiers of HRD status. A weakly-supervised "end-to-end" model using ResNets extracted features from small image patches with an attention module to aggregate across patches and directly predict HRD status. The HIF-based approach used the tissue segmentation and cell identification classifiers to quantify histological features in the WSI. From the labeled images, we extracted 600 HIFs that capture complex relationships between cell and tissue types. HIFs and patient clinical covariates were applied as input to a Sparse Group Lasso model to predict the HRD status of the associated patients. **Results** ML models predicted HRD status from H&E stained WSI. The area under the receiver operating characteristics curve (AUROC) was 0.87 for the HIF model and 0.80 for the E2E model. Both classifiers achieved high sensitivity for HRD status (0.86) with more moderate precision (F1 score HIF: 0.80 and E2E: 0.72). Our HIF with clinical covariates model revealed morphological features that were significantly associated with HRD compared with HRP. HRD samples were enriched for areas of necrosis, stromal fibroblasts, and tumor infiltrating lymphocytes ( $p < 0.001$ , Mann-Whitney U test).

#### Conclusions

Computational models built with the PathAI research platform identified HRD positive patients directly from routinely collected H&E stained WSIs and identified a histological basis for how mutational signatures impact the tumor microenvironment. **Disclaimer:** The PathAI platform and HRD model are not intended for diagnostic purposes.

**Background:** Estrogen receptor alpha (*ER/ESR1*) mutations are found in 20-40% of endocrine resistant ER+ metastatic breast cancers, and they are associated with worse outcome. Preclinical studies have shown that they cause ligand-independent growth, resistance to endocrine therapy, and there is growing evidence for a role in metastasis. It is not known how *ESR1* mutant cancer cells cause metastases and whether such a mechanism may indicate novel therapeutic options. **Methods:** ddPCR was used to detect hotspot *ESR1* mutations. Transcriptome data were derived from cell line models and clinical samples. For *in vitro* phenotypic characterization, Y537S and D538G genome-edited MCF7 and T47D cell models from four different labs were used. Cell-cell adhesive properties were assessed using calcein-labelled adhesion, spontaneous cell aggregation and microfluidic aggregation assays. Altered expression of cell-cell adhesion genes detected in RNA seq data was validated via qRT-PCR, immunoblot and immune staining. Functional contributions of desmosome and gap junctions were tested by blocking peptide and carbenoxolone respectively. Mutant ER cistromes were profiled using ChIP-sequencing. Tail vein injection was performed on nude mice to evaluate metastasis *in vivo*. Mouse lung micro-metastatic foci were quantified using human-specific CK19 staining. Circulating tumor cells (CTCs) clustering propensity *in vivo* was assessed via intracardiac injection of *ESR1* WT and mutant cells into nude mice following CTC microfilter capture. CTCs enumeration from breast cancer patients' blood samples was performed using CellSearch<sup>TM</sup> system. **Results:** We identified a significant enrichment of *ESR1* mutations in distant (12/48) vs local (0/27) recurrences, confirming the strong association of mutant ER with metastasis. Transcriptomic analysis revealed altered cell-to-cell interaction pathways in *ESR1* mutant tumors compared to *ESR1* WT tumors, suggesting a previously undescribed role of *ESR1* mutations in reprogramming cell-cell adhesome. *ESR1* mutant cells grown in suspension culture revealed more compact multicellular spheroids compared to WT cells. This observation was confirmed under both static and microfluidic conditions, indicative of increased cell-cell interactions. The effect was more pronounced in MCF7 compared to T47D cells, and it correlated with increased expression of multiple desmosome and gap junction pathway genes, which were also significantly enriched in *ESR1* mutant tumors. Pharmacological blockade of desmosome and gap junctions significantly rescued enhanced cell-cell adhesion in *ESR1* mutant cells. Mechanistically, our ER ChIP-seq did not identify any gained mutant ER binding sites in proximity to cell-cell adhesion gene loci, indicating indirect regulation by mutant ER. Consistent with this, expression of Connexin 43, one of the top upregulated gap junction components, was induced by cFOS found to be highly upregulated in *ESR1* mutant cells. Tail vein injection of *ESR1*-mutant cells derived more distant macro- (MCF7) and micro- (T47D) metastases. Given increasing evidence for role of cell-cell attachment in CTC phenotypes, we tested CTC formation for *ESR1* WT and mutant cells. *In vivo* studies showed MCF7 Y537S *ESR1* mutant cells formed larger multi-cellular CTC clusters with increased compactness compared to WT CTCs. These preclinical data translated to clinical observation, where we observed an enrichment of CTC clusters in patients with *ESR1* mutant-metastatic breast cancers. **Conclusion:** Hotspot *ESR1* mutations induce expression of multiple desmosome and gap junction genes and confer increased cell-cell adhesion, which facilitate breast cancer metastasis via increased CTCs clustering propensity. These findings might guide approaches to test potential repurpose of drugs targeting gap junction in ER mutant tumors.

**Background** Patients (pts) with human epidermal growth factor receptor 2 positive (HER2+) metastatic breast cancer (MBC) who have brain metastases (BM) have limited treatment options and lower health-related quality of life (HRQoL) compared with pts without BM (Hurvitz 2019). HER2CLIMB is a randomized trial (2:1) of tucatinib vs. placebo in combination with trastuzumab and capecitabine in pts with HER2+ MBC that included pts with stable and active brain metastases (NCT02614794). In HER2CLIMB, the addition of tucatinib to trastuzumab + capecitabine demonstrated a statistically significant and clinically meaningful improvement in overall survival (OS) in pts with HER2+ MBC and in those with stable and active BM, with importantly, a tolerable and manageable safety profile (Murthy 2020). An evaluation of the impact of tucatinib on HRQoL in pts with stable and active BM is presented here. **Methods** HRQoL data were available from 330 of 612 pts, including 163 pts with BMs. HRQoL was assessed using the EQ-5D-5L tool which includes a visual analog scale (EQ-VAS) and a descriptive system (EQ-5D) comprising 5 dimensions of health: mobility, self-care, usual activities, pain/discomfort, and anxiety/depression. Each dimension has 5 levels: no problems, slight problems, moderate problems, severe problems, and extreme problems. Data were collected at Cycle 1 Day 1, Cycles 3-9 (every 2 cycles; 21-day cycles), Cycle 12 and beyond (every 3 cycles), and at the 30-day follow-up. The EQ-5D-5L scores were summarized by cycle for each treatment arm. Time to deterioration, defined as a  $\geq 7$ -point change from baseline on the EQ-VAS, was estimated by the Kaplan-Meier approach. The median time to deterioration (and 95% CIs) were computed for each arm. **Results** In total, 163 pts with stable and active BM were included in this HRQoL analysis, 107 pts on the tucatinib arm and 56 pts on the placebo arm. Compared to the placebo arm, pts on the tucatinib arm had an approximately 49% reduction in the risk of deterioration (hazard ratio: 0.51; 95% CI: 0.28, 0.93); the median time to deterioration has not been reached in the tucatinib arm with available follow-up and was 5.5 months (95% CI; 4.2, -) in the placebo arm. Decline in all domains of the EQ-5D-5L and the EQ-VAS scores were seen once pts discontinued therapy, particularly on the 'usual activities' domain. Additional available QoL data will be presented. **Conclusions** Pts with MBC and BM treated with tucatinib in combination with trastuzumab + capecitabine demonstrated significantly longer and clinically meaningful time to deterioration of HRQoL. HRQoL was maintained throughout the treatment course, allowing them to receive full benefit of the therapeutic approach and resulting in statistically significant and clinically meaningful improvement in OS. **References** Hurvitz SA, O'Shaughnessy J, Mason G, et al. A picture worth a thousand words - “classic” inflammatory breast cancer (IBC) appearance associated with overall survival

Wintana Balema<sup>1</sup>, Diane Liu<sup>1</sup>, Yu Shen<sup>1</sup>, Randa El-Zein<sup>2</sup>, Megumi Kai<sup>1</sup>, Beth Overmoyer<sup>3</sup>, Kathy D Miller<sup>4</sup>, Carisa Le-Petross<sup>1</sup>, Naoto T Ueno<sup>1</sup> and Wendy A Woodward<sup>1</sup>. <sup>1</sup>University of Texas MD Anderson Cancer Center, Houston, TX; <sup>2</sup>Houston Methodist Hospital, Houston, TX; <sup>3</sup>Dana-Farber Cancer Institute, Boston, MA; <sup>4</sup>Indiana University School of Medicine, Indianapolis, IN

**Background:** IBC is considered a clinical diagnosis characterized by rapid onset of diffuse skin changes in the setting of a breast cancer diagnosis. A wide variety of visual changes are accurately diagnosed as IBC. Here, we sought to determine whether the most subjectively “classic” appearing presentation (swollen, involved breast with nipple inversion and diffuse skin change) was associated with worse outcomes.

**Method:** We reviewed the images and charts of patients from the prospective IBC registry from the MD Anderson IBC Clinic. Breast medical photographs were reviewed by a non-expert and the visual presentation was scored as classic (as above), not classic, and in between. Comparative analyses were used to assess differences between patient groups using Chi-squared test, or Fisher's exact test for categorical variables. Wilcoxon rank sum test was used for continuous measures. We used the Kaplan Meier estimator and the log-rank test to investigate association between scoring and survival distributions. Cox proportional hazard regression was employed to assess the impact of important covariates on the overall survival.

**Results:** We analyzed 245 IBC patients with median age 55 (range, 26-81), M0 vs. M1 status (157 and 88 patients, respectively), 68 TNBC vs. 177 non-TNBC patients. The classic presentation was significantly associated with smoking, post-menopausal status, and metastatic disease at presentation (P = 0.002, 0.018, and 0.004, respectively). Presentation was significantly associated with OS in univariate analysis (P < 0.001). 10 year overall survival was 57% vs. 33% for classic (score 3) versus non-classic or in between presentation. The multivariable Cox regression model adjusting for clinical staging (P<0.001) and TNBC status (P<0.001) demonstrated classic presentation score was significantly associated with poorer OS time (HR 2.4, CI 1.6-3.6, p<0.001).

**Conclusions:** A visual inspection of presentation photograph for “classic” appearance, obvious swelling, skin change, and nipple inversion, independently predicted poorer OS in IBC. Further work is warranted to understand the differences in classic and non-classic presentations, and the relationship between smoking and breast cancer presentation.

Identification of biomarkers associated with therapeutic resistance: Quantitative protein/phosphoprotein analysis of ~750 patients across 8 arms of the neoadjuvant I-SPY 2 TRIAL for high-risk early stage breast cancer

Julia Wulfsberg<sup>1</sup>, Denise Wolf<sup>2</sup>, Christina Yau<sup>2</sup>, Lamorna Brown-Swigart<sup>2</sup>, Rosa I Gallagher<sup>1</sup>, Gillian Hirst<sup>2</sup>, Laura Sit<sup>2</sup>, Smita Asare<sup>3</sup>, I-SPY 2 TRIAL Investigators, Nola Hylton<sup>2</sup>, Angela DeMichele<sup>4</sup>, Douglas Yee<sup>5</sup>, Jo Chien<sup>2</sup>, Hope Rugo<sup>2</sup>, John Park<sup>2</sup>, Kathy Albain<sup>6</sup>, Rita Nanda<sup>7</sup>, Debu Tripathy<sup>8</sup>, Richard Schwab<sup>9</sup>, Don Berry<sup>10</sup>, Laura Esserman<sup>2</sup>, Laura van't Veer<sup>2</sup> and Emanuel Petricoin, III<sup>1</sup>. <sup>1</sup>George Mason University, Manassas, VA; <sup>2</sup>University of California, San Francisco, San Francisco, CA; <sup>3</sup>QuantumLeap Healthcare Collaborative, San Francisco, CA; <sup>4</sup>University of Pennsylvania, Philadelphia, PA; <sup>5</sup>University of Minnesota, Minneapolis, MN; <sup>6</sup>Loyola University, Chicago, IL; <sup>7</sup>University of Chicago, Chicago, IL; <sup>8</sup>MD Anderson Cancer Center, University of Texas, Houston, TX; <sup>9</sup>University of California, San Diego, San Diego, CA; <sup>10</sup>Berry Consultants, Austin, TX

**Background:** The goal of I-SPY 2 is to rapidly test novel therapies in addition to standard of care in high-risk breast cancer patients. It has resulted in increasing response rates, where pCR rates in TNBC and HR-HER2+ subsets have reached ~60% and ~75%, respectively. Yet, there remains a sizeable subset of non-responders, especially among HR+ patients. Identification of 'universal' resistance mechanisms may guide rational selection of agents to improve these patient's outcomes. Thus, we analyzed reverse phase protein array (RPPA) based quantitative protein/phosphoprotein data across arms to assess whether there are common mechanisms rendering these cancers resistant to all agent classes tested to date. **Methods:** 736 patients (260 HR+HER2-, 252 TN, 142 HR+HER2-, and 82 HR-HER2+; over 8 arms: 194 Ctr, 105 neratinib (N), 63 veliparib/carboplatin (VC), 128 AMG386 (anti-ANG1/2), 87 MK2206 (anti-AKT), 43 TH/pertuzumab (P), 49 TDM1/P, and 67 pembrolizumab (Pembro)) with pCR and RPPA data at the pre-treatment time point were considered for this analysis. 141 RPPA endpoints representing key cancer pathways were assessed for association with pCR using logistic regression modeling, with HR, HER2 and treatment arm as covariates (likelihood ratio test; p<0.05). Analysis was also performed in HR/HER2 subsets and within treatment arms. Markers were analyzed individually; multiple comparison correction (Benjamini-Hochberg) was applied to p-values. Our analysis is exploratory, and does not adjust for other biomarkers outside this study. **Results:** Prior to FDR correction, high levels of Cyclin D1, a cell cycle protein implicated in estrogen-mediated DNA damage repair, associate with non-pCR in the population as a whole and within all subtypes except for the HR-HER2+ subset; an association that retains significance after FDR correction overall as well as in HER2- and HR+HER2- subsets. Within individual arms, high Cyclin D1 predicted non-response in VC, control, and AMG386; and trends toward association in Pembro and N. In addition, high quantitative ER and phospho-androgen receptor (pAR; S650) associate with non-pCR in the population as a whole and in the HR+HER2- subset. For both ER and pAR the strongest association with non-pCR was in the Pembro arm. Candidates for universal sensitivity signals include immune proteins JAK-STAT (pSTAT5 (Y694) and pSTAT1 (Y701)) overall; and pERBB2/pEGFR for HER2+ patients. **Conclusions:** High levels of Cyclin D1, but not other cell cycle proteins, predict non-response to chemo-/targeted-therapy across arms and subtypes, suggesting that agents specifically targeting Cyclin D1 may increase chemo-sensitivity. ER/phospho-AR as global resistance signals suggest inclusion of anti-AR agents in combination therapy, and the need for new endocrine-based approaches.

<sup>1</sup>University of Kansas Medical Center, Kansas City, KS; <sup>2</sup>SWOG Statistical Center, Seattle, WA; <sup>3</sup>Yale Cancer Center, New Haven, CT; <sup>4</sup>Myriad Genetics, Inc., Salt Lake City, UT; <sup>5</sup>Almac Group, Craigavon, United Kingdom; <sup>6</sup>Indiana University School of Medicine, Indianapolis, IN; <sup>7</sup>Fred Hutchinson Cancer Research Center, Seattle, WA; <sup>8</sup>University of Washington, Seattle, WA; <sup>9</sup>The University of Texas MD Anderson Cancer Center, Houston, TX; <sup>10</sup>Baylor College of Medicine, Houston, TX; <sup>11</sup>University of Michigan, Ann Arbor, MI; <sup>12</sup>University of Kansas Medical Center, Westwood, KS

**Introduction/Aims:** DDIR signature, HRD, and stromal tumor infiltrating lymphocytes (sTIL) have each been associated with favorable outcomes in early stage TNBC. We assessed the overlap between these markers and created prognostic categories based on their combined use in a prospective trial of TNBC patients uniformly treated with adjuvant doxorubicin (A) and cyclophosphamide (C) on the SWOG S9313 trial. **Methods:** SWOG S9313 trial accrued 3,125 women with early stage breast cancer to two alternative dose schedules of AC, with no difference in outcomes between the two arms. 425 centrally determined TNBC cases from S9313 were identified. DDIR signature (score  $\geq 0.3681$  = DDIR+, Almac Diagnostic Services), HRD status (score  $\geq 42$  = HRD+, Myriad Genetics), and sTIL were assessed. Gene expression data (Xcel™ array) was subjected to clara<sup>T</sup> V3.0.0 biological signature analysis (Almac Diagnostic Services), and co-expression cluster analysis was used to identify signatures associated with DDIR and HRD status. The impact of dual classification by DDIR and HRD status (**Group 1:** DDIR+/HRD+, **Group 2:** DDIR+/HRD-, **Group 3:** DDIR-/HRD+, **Group 4:** DDIR-/HRD-) on disease free survival (DFS) and overall survival (OS) was examined using Cox regression with adjustment for randomized treatment assignment and nodal status. **Results:** For the 425 patients, median age was 45 years, 33% were node-positive, and 5-year DFS and OS were 74% and 82%, respectively. DDIR and HRD status was available for 89% each, sTIL% was available for 99%, and all three markers were available for 77% (328/425) of patients. 60% were DDIR+ and 65% HRD+. Among DDIR- tumors, 58% were HRD+. sTIL% was associated with DDIR status ( $P<0.0001$ ) but not with HRD status ( $P=0.75$ ). The proportion of patients in each group, median sTIL%, and 5-year DFS and OS for each group are outlined in Table 1. DFS and OS were similar for Groups 1, 2, and 3 but significantly lower for Group 4. As expected, cluster analysis showed that immune response signatures dominated Groups 1 and 2 regardless of HRD status. Group 3 tumors were characterized by over-representation of genomic instability signatures, a paucity of immune-related signatures, and low sTIL infiltration. Despite this immune-depleted phenotype, the 5-year OS for Group 3 was similar to that of the immune-enriched DDIR+ groups. Signatures associated with epithelial-mesenchymal transition, mast cell infiltration, and xenobiotic metabolism were over-represented in Group 4. **Conclusions:** Forty percent of patients with early stage TNBC demonstrate immune-deplete (DDIR-) phenotype, and within this phenotype, more than half demonstrate HRD+ status. HRD+ status within the immune-deplete phenotype predicts for better DFS and OS with adjuvant AC, probably due to underlying genomic instability and increased sensitivity to DNA damaging chemotherapy. Sixty percent of early stage TNBC patients demonstrate an immune-enriched (DDIR+) phenotype, and this phenotype is associated with improved survival with adjuvant AC chemotherapy regardless of HRD status. These findings provide important insights for patient selection and stratification in ongoing and future trials assessing DNA damaging therapy (e.g. PARPi, anthracyclines, platinum agents), immunotherapy, and their combinations in TNBC.

Table 1

	Immune-Enriched Groups		Immune-Deplete Groups	
	Group 1 DDIR+/HRD+ N=137 (42%)	Group 2 DDIR+/HRD- N=59 (18%)	Group 3 DDIR-/HRD+ N=77 (23%)	Group 4 DDIR-/HRD- N=55 (17%)
<b>5-year DFS</b>	82%	74%	74%	56%
P=0.001 (Group 1 vs 4); P=0.006 (Group 2 vs 4); P=0.016 (Group 3 vs 4); P=NS (Groups 1 vs 2, 1 vs 3, and 2 vs 3)				
<b>5-year OS</b>	88%	86%	83%	69%
P=0.001 (Group 1 vs 4); P=0.003 (Group 2 vs 4); P=0.026 (Group 3 vs 4); P=NS (Group 1 vs 2, 1 vs 3, and 2 vs 3)				
<b>Median sTIL (%)</b>	20%	20%	5%	5%

**Background:** Rintodestrant (G1T48) is a potent oral selective estrogen receptor degrader (SERD) that competitively binds to the estrogen receptor (ER) and blocks ER signaling in tumors resistant to other endocrine therapies. Preliminary results from Part 1 dose escalation showed robust target engagement on <sup>18</sup>F-fluoroestradiol positron emission tomography (FES-PET), a favorable safety profile, and encouraging antitumor activity in patients with heavily pretreated ER+/HER2- advanced breast cancer (ABC), including those with *ESR1* mutations (Dees et al., ESMO 2019 [abstract #3587]). Here, we present updated results from dose escalation and expansion (Parts 1 and 2). **Methods:** This Phase 1, first-in-human, open-label study evaluated rintodestrant monotherapy in women with ER+/HER2- ABC after progression on endocrine therapy. Part 1 was a 3+3 dose escalation (200-1000 mg once daily [QD]); Part 2 expanded 600 and 1000 mg QD; and Part 3 was added to assess rintodestrant with palbociclib in patients in earlier lines in the advanced setting. Primary objectives included dose-limiting toxicities (DLTs), maximum tolerated dose (MTD), safety, and recommended Phase 2 dose. Secondary objectives included pharmacokinetics and antitumor activity (RECIST v1.1). Exploratory objectives included pharmacodynamic inhibition of ER target engagement (FES-PET), mutation profiling (cell-free DNA [cfDNA]), and change in ER expression from baseline to on-treatment tumor biopsies. **Results:** As of May 13, 2020, 67 patients (Part 1: n = 26; Part 2: n = 41) were treated, with a median age of 61 years (range 34-83) and ECOG PS of 0 (49%) or 1 (51%). Median number of prior lines in the advanced setting was 2 (range 0-9), including prior fulvestrant (64%), CDK4/6 inhibitor (69%), mTOR inhibitor (22%), and/or chemotherapy (46%). Median number of prior lines of endocrine therapy in the advanced setting was 2 (range 0-5), with 61% of patients having received ≥2 lines. Treatment-related adverse events (TRAEs) were reported in 70% of patients. The most common TRAEs in ≥10% of patients included hot flush (24%), fatigue (21%), nausea (19%), diarrhea (18%), and vomiting (10%), mostly grade 1 or 2. No DLTs were reported and MTD was not reached. Dose reduction due to TRAEs occurred in 1 patient (1%), with elevated transaminases (grade 3 ALT and grade 2 AST) at 600 mg. Serious TRAEs occurred in 2 patients at 1000 mg (grade 5 cerebral hemorrhage in the setting of low molecular weight heparin and grade 2 upper abdominal pain). Two patients (3%) discontinued treatment due to TRAEs. Overall, the frequency of patients with TRAEs at 800 mg was comparable with that at 600 mg (57% vs 63%) and less than that at 1000 mg (81%). Of 67 patients, 16 were on study treatment for ≥24 weeks and 3 (n = 1 at 600 mg; n = 2 at 1000 mg, including 1 with *ESR1* mutation) had a confirmed partial response (clinical benefit rate [CBR]: 28%). FES-PET standard uptake values decreased at week 4 with a mean reduction of 87% (±8%) at doses ≥ 600 mg. Of 59 patients tested for baseline cfDNA, 41% harbored ≥1 *ESR1* mutation, with a similar CBR in both groups (33% in *ESR1* mutant and 29% in *ESR1* wild-type). Seven of 9 patients had a decrease in ER immunohistochemistry H-score at both 600 and 1000 mg (median [range]: -27.8% [-33.8%, -3.4%]), irrespective of *ESR1* mutation status. Based on safety, efficacy, and ER degradation, 800 mg was selected as the optimal dose for further study. **Conclusions:** Rintodestrant continues to demonstrate an excellent safety/tolerability profile across all doses, with promising antitumor activity in patients with heavily pretreated ER+/HER2- ABC, including those with tumors harboring *ESR1* mutations. Part 3 of this study, evaluating rintodestrant 800 mg QD with palbociclib in a more endocrine-sensitive population, is ongoing (NCT03455270).

Health maintenance and breast cancer screening during the COVID-19 pandemic

Arash Naeim<sup>1</sup>, Neil Wenger<sup>1</sup>, Karen Sepucha<sup>2</sup>, Annette Stanton<sup>1</sup>, Ryan Baxter-King<sup>1</sup>, Leah Sabacan<sup>3</sup>, Antonia Petruse<sup>1</sup>, Patricia Choy<sup>3</sup>, Susie Brain<sup>3</sup>, Laura Esserman<sup>3</sup>, Wisdom Study and Athena Breast Health Network Investigators and Advocate Partners and Lynn Vavreck<sup>1</sup>. <sup>1</sup>UCLA, Los Angeles, CA; <sup>2</sup>Harvard, Boston, MA; <sup>3</sup>UCSF, San Francisco, CA

**Background:** WISDOM is a large (target enrollment>40,000) healthy women preference-tolerant, pragmatic study comparing traditional annual screening to personalized risk-based breast screening. Cancer screening, routine health care, and elective procedures were disrupted due to attempts to manage resources during the COVID-19 pandemic. Understanding of the impact on COVID-19 on trial participants is important to gain a broader understanding of the effect of the pandemic on healthcare activities. **Methods:** Women aged 40-74 years with no history of breast cancer or DCIS, and no previous double mastectomy can join the WISDOM (NCT02620852) study online at [wisdomstudy.org](http://wisdomstudy.org). A total of 28,600 women have consented to participate. As part of the trial, each patient completes a baseline and interval surveys through a Salesforce platform. In May, the study IRB was amended to add a COVID specific survey with questions related to participants COVID risk perceptions, coexisting conditions, and receipt of healthcare services in the 2 months prior to the survey. An initial survey was sent May 2020, with follow-up surveys planned every 2 months. In addition, national surveys on a population-based cross section of individuals across the nation will be performed in parallel. Data was collected, de-identified, and then analyzed using basic descriptive analysis, chi-2 analysis, and logit regression. **Results:** A total of 7,523 individuals in WISDOM responded to the survey (response rate 27%). Of those that responded, the average age at the time of the survey was 59 (range 40-79). The population was 87% Caucasian, 6% Hispanic, and 4% African-American. Only 3.6% of the sample felt they had COVID-19 either by symptoms or through testing. However, 10.0% felt they were at higher risk compared to similar individuals their age to get COVID-19. Of the sample, 29% had some form of high-risk coexisting condition that put them at higher risk for COVID-19. In terms of healthcare utilization in the prior 2 months, 43% had a routine medical visit cancelled by their primary care provider or health system, whereas 26% cancelled an appointment themselves. In terms of breast cancer screening, 16% had their screening visit either cancelled or delayed. Individuals who believed they were at higher risk (and more likely to have shorter interval screening recommendations on this trial) had a higher Odds Ratio (1.66) for a screening cancellation ( $p<0.001$ ). Those individuals who held the belief that COVID-19 was no more dangerous than the seasonal flu were more likely to have medical visits and routine care in the preceding 2 months than those that did not share that belief. (OR 1.18,  $p=0.032$ ). Individuals were significantly more worried about COVID-19 than developing breast cancer (43% moderate to severely worried about COVID compared to 8.2% for breast cancer). Those worried about COVID were more likely to have screening cancellation (OR 1.18,  $P<0.001$ ) and those more worried about breast cancer were less likely to have a screening cancellation (OR 0.83,  $P<0.001$ ). **Conclusions:** Health maintenance, prevention, and specifically breast cancer screening are important, but these health activities have been significantly disrupted due to the COVID-19 pandemic. Given that the pandemic will likely continue for many months until there is either a vaccine, treatment, or herd immunity, it will be important to define the drivers and messages (healthcare and screening) to ensure patients receive proper health maintenance and prevention to reduce the risks associated with other diseases that are not COVID-19. The preliminary data presented as part of this abstract submission are the early results of an effort to develop a predictive model and targeted strategies for communication and intervention for cancer screening during the course of the COVID-19 pandemic.

Evaluating serum thymidine kinase 1 in hormone receptor positive metastatic breast cancer patients receiving first line endocrine therapy in the SWOG S0226 trial

Costanza Paoletti<sup>1</sup>, William E. Barlow<sup>2</sup>, Mattias Bergqvist<sup>3</sup>, Rita S. Mehta<sup>4</sup>, Julie R. Gralow<sup>5</sup>, Gabriel N. Hortobagyi<sup>6</sup>, Kathy S. Albain<sup>7</sup>, Lajos Pusztai<sup>8</sup>, Priyanka Sharma<sup>9</sup>, Andrew K. Godwin<sup>10</sup>, Alastair M. Thompson<sup>11</sup>, Daniel F. Hayes<sup>1</sup> and James Rae<sup>1</sup>. <sup>1</sup>University of Michigan Rogel Cancer Center, Ann Arbor, MI; <sup>2</sup>SWOG Statistical Center, Seattle, WA; <sup>3</sup>Biovica International, Uppsala, Sweden; <sup>4</sup>Chao Family Comprehensive Cancer Center, University of California Irvine Medical Center, Orange, CA; <sup>5</sup>Seattle Cancer Care Alliance and University of Washington Medical Center, Seattle, WA; <sup>6</sup>Department of Breast Medical Oncology, University of Texas M.D. Anderson Cancer Center, Houston, TX; <sup>7</sup>Loyola University Chicago Stritch School of Medicine, Maywood, IL; <sup>8</sup>Medical Oncology, New Haven, CT; <sup>9</sup>Division of Medical Oncology, Department of Internal Medicine, University of Kansas Medical Center, Kansas City, KS; <sup>10</sup>Department of Pathology and Laboratory Medicine, University of Kansas Medical Center, Kansas City, KS; <sup>11</sup>Baylor College of Medicine, Dan L Duncan Cancer Center, Houston, TX

**Background:** Endocrine therapies (ETs) are effective in hormone receptor positive metastatic breast cancer (MBC), but resistance is a major clinical problem. Thymidine Kinase 1 (TK1) plays a key role in DNA synthesis and is a marker of cellular proliferation. Serum (sTK1) activity is associated with poor prognosis in MBC patients treated with chemotherapy. SWOG S0226 trial demonstrated that anastrozole (A) + fulvestrant (F) is more effective than A alone in post-menopausal women with hormone receptor positive MBC, specifically those without prior adjuvant tamoxifen (Mehta et al NEJM 2019). We hypothesized that baseline (BL) and serial sTK1 levels are prognostic and demonstrate differential activity of A+F vs. A. **Methods:** sTK1 activity was assessed in 1,726 archived S0226 serum samples (BL, cycle 2, 3, 4, and 7) using DiviTum<sup>®</sup> assay (100% evaluation rate). Pre-specified cutoff of  $\geq 200$  DiviTum Unit per liter (Du/L) was considered high. Progression-free survival (PFS) and overall survival (OS) were analyzed by Kaplan-Meier, log-rank tests and Cox regression. **Results:** Serum samples at BL were available in 432/694 (62%) patients. Outcomes on this subset were comparable to those on the full trial. Median sTK1 at BL was 135 Du/L. sTK1 was elevated in 171 (40%) patients. Overall, patients with high vs. low BL sTK1 had significantly worse PFS [hazard ratio (HR)=1.76; 95% CI (1.43-2.16);  $P<0.0001$ ; median PFS 11.2 vs. 17.3 months]. In patients with no prior adjuvant tamoxifen and high sTK1, PFS was significantly better for those treated with A+F vs. A alone [HR=0.64; 95% CI (0.43-0.95);  $P=0.027$ ; median PFS 13.6 vs. 8.7 months], whereas PFS did not differ between A+F vs. A alone for those with low sTK1 ( $P=0.34$ ). Differences in OS for high vs. low sTK1 were even more pronounced [HR=2.38; 95% CI (1.91-2.98);  $p<0.0001$ ; median OS 30 vs. 58 months]. For high sTK1, OS was significantly better for those treated with A+F vs. A alone who did not have prior adjuvant tamoxifen [HR=0.58; 95% CI (0.38-0.87);  $P=0.0087$ ; 46 vs. 21 months], whereas for low sTK1 there was no difference by therapy ( $p=0.44$ ). During serial monitoring, patients with high sTK1 had significantly worse subsequent PFS and OS than those with low sTK1 (at cycle 2: PFS HR=1.70,  $P<0.0001$ , OS HR=2.51,  $P<0.0001$ ). **Conclusions:** High sTK1 at BL and at subsequent time points is associated with worse prognosis in hormone receptor positive MBC patients starting 1st line ET. Patients with low sTK1 at BL may do relatively well on single agent and may not need combination ET. We speculate that patients with low sTK1 need only ET monotherapy and may not benefit from the addition of CDK4/6 or mTOR inhibitors. However, further evaluation of the predictive potential of sTK1 will need prospective clinical trials.

Antitumor activity of Z-endoxifen (ENDX) is mediated via PKC $\beta$ 1-dependent ER $\alpha$  loss and cell cycle arrest in ER $\alpha$ -positive breast cancer

Swaathi Jayaraman, Mary J Kuffel, Krishna R Kalari, Kevin J Thompson, Xiaojia Tang, Vera J Suman, Elizabeth S Bruinsma, Ciara C O'Sullivan, Liewei Wang, Richard Weinshilboum, James N Ingle, John R Hawse and Matthew P Goetz. Mayo Clinic, Rochester, MN

**Background:** The tamoxifen (TAM) metabolite, ENDX, demonstrated promising antitumor activity in endocrine resistant breast cancer (BC) in both phase I and phase II settings. Furthermore, ENDX resulted in superior *in vivo* antitumor activity compared to TAM and letrozole in aromatase-expressing aromatase inhibitor-sensitive and resistant MCF7AC1 models. Recently, we identified protein kinase C beta 1 (PKC $\beta$ 1), which regulates cell proliferation and tumorigenic transformation, as a novel target of ENDX. ENDX-bound PKC $\beta$ 1 at concentrations achieved in phase I/II ENDX studies (100-300 nM). In contrast, TAM binding to PKC $\beta$ 1 occurred at concentrations 7-10 folds higher (2  $\mu$ M) than achievable with TAM 20 mg/day dosing. However, the clinical relevance of targeting PKC $\beta$ 1 kinase activity is unclear, since drugs that target PKC $\beta$ 1 (enzastaurin) have been ineffective in BC and other solid tumors. Therefore, we sought to understand how ENDX altered PKC $\beta$ 1 and to further compare and contrast ENDXs effects to that of PKC $\beta$ 1 kinase inhibition in ER $\alpha$ + BC. **Methods:** The effects of PKC $\beta$ 1 silencing and ENDX treatment on gene expression was analyzed by RNAseq in MCF7AC1 cells. The impact of PKC $\beta$ 1-silencing on cell cycle was evaluated by flow cytometry. Protein expression of cell cycle regulators in PKC $\beta$ 1 and ENDX-treated MCF7AC1 and T47D cells were compared to TAM and enzastaurin *in vitro* and to letrozole, TAM or control *in vivo*. The effects of PKC $\beta$ 1 and drugs on growth were analyzed by cell proliferation assays. *PRKCB* gene amplification was assessed in primary tumors using TCGA data and in metastatic tumors using whole-exome sequencing data from patients enrolled in the PROMISE study (NCT 03281902). **Results:** RNAseq analysis revealed E2F targets and G2M checkpoints as the top hallmark genesets significantly downregulated in both PKC $\beta$ 1-silenced and ENDX-treated MCF7AC1 cells. Flow cytometry demonstrated that PKC $\beta$ 1 silencing increased G1 and reduced S phases of the cell cycle. Western blot analyses of PKC $\beta$ 1-silenced MCF7AC1 and T47D cells displayed reduced protein levels of the cell cycle regulators Cyclin D1, Retinoblastoma (Rb), phospho-Rb<sup>S807/811</sup>, CDK4, Chk1 and E2F1 that regulate G1/S transition. While short term ENDX (48 hours) treatment did not alter PKC $\beta$ 1 levels, prolonged *in vitro* ENDX treatment profoundly reduced PKC $\beta$ 1 protein levels and the aforementioned cell cycle regulators, faithfully replicating PKC $\beta$ 1 silencing effects. In contrast, enzastaurin had no impact on proliferation or cell cycle proteins in either model. Consistent with this finding, ENDX, but not TAM or letrozole, reduced protein levels of ER $\alpha$  and cell cycle regulators *in vivo*. Overexpression of PKC $\beta$ 1 induced TAM, but not ENDX, resistance and had little impact on responsiveness to enzastaurin. While *PRKCB* gene amplification was uncommon in newly diagnosed ER $\alpha$ +HER2- BC (5%, TCGA), *PRKCB* was amplified in 40% of metastatic ER $\alpha$ +HER2- BC (PROMISE study). **Conclusion:** We have confirmed the relevance of a new ENDX target, PKC $\beta$ 1, in ER $\alpha$ +HER2- BC. While targeting PKC $\beta$ 1 kinase activity elicited no anticancer effects in ER $\alpha$ + cells, PKC $\beta$ 1 downregulation, either by siRNA or ENDX, resulted in profound ER $\alpha$  turnover, reduced protein levels of essential cell cycle mediators and profoundly inhibited cell proliferation. Furthermore, PKC $\beta$ 1 protein expression is associated with TAM, but not ENDX, resistance, a finding whose clinical relevance is further magnified by identification of *PRKCB* amplification in metastatic ER $\alpha$ + BC, confirming its potential importance in progression. Efforts are currently underway to elucidate the mechanistic basis for ENDX-induced PKC $\beta$ 1 and ER $\alpha$  degradation and the contribution of these effects to the superior antitumor activity of ENDX in ER $\alpha$ + BC.

The impact of sleep on weight loss in overweight or obese breast cancer survivors

Jennifer Y Sheng, Amanda K Montanari, Amanda L Blackford, David D Lim, Cesar A Santa-Maria, Vered Stearns, Michael T Smith and Janelle W Coughlin. Johns Hopkins University, Baltimore, MD

**BACKGROUND:** Sleep disturbance, common in cancer survivors, is associated with obesity, eating behaviors and metabolism, and may impact weight loss treatment outcomes. Weight loss promotion in breast cancer survivors is important because it can potentially decrease cancer recurrence. We have previously demonstrated the efficacy of a behavioral weight loss (BWL) intervention for overweight/obese breast cancer survivors in the POWER-remote breast cancer trial. In the current study we aimed to evaluate the impact of baseline sleep on weight outcomes at 6 and 12 months. We hypothesized that participants with poor sleep at baseline will lose significantly less weight. **METHODS:** Women with a history of stage 0-III breast cancer, who completed local therapy and chemotherapy, with a body mass index  $\geq 25$  kg/m<sup>2</sup> were randomized to a self-directed approach or the 12-month POWER-remote intervention, a BWL intervention consisting of telephone-based coaching, online educational materials and tracking of diet, physical activity and weight. Participants completed demographic questionnaires at baseline, and patient-reported outcomes (PROs) at baseline, 6 and 12 months, including the 6-item NIH PROMIS Adult Sleep Disturbance Version 1.0 Short Form, assessing sleep quality, depth, and restoration over the last week. Weight was measured at baseline, 6 and 12 months and % total weight loss (%TWL) was calculated from baseline weight. Those with poor sleep were defined as having a sleep T-score  $\geq 55$ , and associations between sleep scores and change in weight at 6 and 12 months were made using a linear regression model, while adjusting for baseline weight. Fisher's exact test was also used to compare the number of patients who had 5% weight-loss between sleep groups.

**RESULTS:** A total of 48 women with early stage breast cancer received BWL. Those with poor sleep in the BWL group (n= 16) lost significantly less weight than those with normal sleep in the BWL group (n=32) at both 6 (-4.06% vs -6.77% TWL, p>0.05) and 12 months (-3.87% vs -7.54% TWL, p>0.05), respectively. Similar findings were seen in poor sleepers in the BWL group and attaining 5% weight loss at 6 (p>0.05) and 12 months (p>0.05). There were no significant differences in weight loss outcomes among those in usual care.

**CONCLUSION:** Breast cancer survivors receiving the weight loss intervention who reported normal sleep at baseline had double the weight loss than those with sleep disturbance at 12 months (-7.54% vs -3.87%). While this is not statistically significant, it is clinically significant and leaves room for further study. These results suggest that sleep may affect weight loss. Updated data, including comparison with control group and analyses by weight loss irrespective of arm, will be reported at the conference. Further studies are need to evaluate the association between baseline sleep and weight loss, and determine if interventions that detect and treat underlying sleep disturbance may augment behavioral interventions for weight loss.

**FUNDING:** Breast Cancer Research Foundation, Cigarette Restitution Fund

Table 1: Weight Loss Summary in BWL group based on Sleep Disturbance

Variables	Poor sleep (T-score >55)	Normal sleep (T-Score <55)	Total
Sample Size	N = 16	N = 32	N = 48
Baseline Weight - Mean (SD)	202.1 (32.26)	182.64 (27.73)	
Weight Loss 6mo. (lbs) - Mean (SD)	-8.5 (10.02)	-11.58 (11.03)	
Weight Loss 12mo. (lbs) - Mean (SD)	-7.92 (14.61)	-12.63 (13.72)	
Percent change in weight from BL to 6mo. - Mean (SD)	-4.06 (4.83)	-6.77 (6.45)	p>0.05
Percent change in weight from BL to 12mo. - Mean (SD)	-3.87 (7.29)	-7.54 (7.91)	p>0.05

Breast tumor targeted fluorescence guidance for intraoperative margin assessment

Narges Tafreshi<sup>1</sup>, Mikalai Budzevich<sup>2</sup>, Weihong Sun<sup>3</sup>, Daruka Mahadevan<sup>4</sup>, Marie Catherine Lee<sup>5</sup> and David L Morse<sup>6</sup>. <sup>1</sup>Dept. of Cancer Physiology, Moffitt Cancer Center and Research Institute, Tampa, FL; <sup>2</sup>Small Animal Imaging Core, Moffitt Cancer Center and Research Institute, Tampa, FL; <sup>3</sup>Comprehensive Breast Program, Moffitt Cancer Center, Tampa, FL; <sup>4</sup>Dept. of Medicine, Division of Hematology and Medical Oncology, University of Texas, San Antonio, TX; <sup>5</sup>Comprehensive Breast Program, Moffitt Cancer Center, Tampa, FL; <sup>6</sup>Dept. of Cancer Physiology, Moffitt Cancer Center, Tampa, FL

**BACKGROUND:** A majority of the 270,000 women diagnosed with breast cancer in the United States annually are candidates for breast conserving surgery (lumpectomy), however, up to 30% of patients require reoperation due to positive margins. The ideal resolution is to make residual in-breast disease visible at the time of surgery. The goal of this research is to develop a systemically administered fluorescent molecular imaging agent that is targeted to breast tumors for intraoperative margin assessment using fluorescence guided surgery (FGS). **METHODS:** To identify targetable cell-surface markers for use in FGS, gene expression profiling of publicly available Affymetrix mRNA microarray data from patients with invasive ductal or invasive lobular carcinoma tumors (n=34) and surrounding normal breast tissues (n=32) was performed. Protein expression of select targets was determined by immunohistochemistry (IHC) staining of patient tissue specimens. A humanized CEACAM6 (carcinoembryonic cell adhesion molecule 6) specific antibody fragment (scFv-Fc [IgG4]) was conjugated to the near-infrared IRDye800CW fluorescent dye (LiCor) by NHS-ester linkage to create CEACAM6-800. The conjugate was characterized for *in vitro* specificity by immunocytochemistry (ICC) and live cell uptake studies. As proof-of-principle, the conjugate (15 µg) was intravenously injected into nude mice bearing orthotopic human MCF-7 breast cancer mammary fat pad (MFP) xenograft tumors with endogenous expression of CEACAM6. FGS was performed using the "SurgVision" clinical imaging platform (approved for clinical use in Europe) at 24 h post-injection. **RESULTS:** We identified 263 genes with higher mRNA expression in tumor relative to normal. From this list, we selected 9 genes for confirmation of protein expression by IHC. Of the 9 targets, only CEACAM6 had no protein expression in normal breast tissues and robust expression in ~50% of tumors. ICC staining using the CEACAM6-800 conjugate and multiple human ductal carcinoma tumor cell lines confirmed the cell surface localization of CEACAM6. In live-cell uptake studies, CEACAM6-800 accumulated on the cell surface as early as 10 min after addition to the media and was internalized after 90 min. Blocking studies demonstrated specificity. In the proof-of-principle FGS study, we observed high fluorescence in MCF-7 MFP tumors relative to background and the tumors and their residuals were completely removed in the first attempt. **CONCLUSION:** We have confirmed CEACAM6 protein as a cell-surface adhesion receptor target for breast cancer FGS. The CEACAM6-800, fluorescent-dye to antibody-fragment conjugate was prepared and tested *in vitro* for sub-cellular localization and specific uptake. *In vivo* studies demonstrated specific uptake into MFP tumors and FGS for tumor resection. We are currently performing studies to determine the *in vivo* pharmacokinetics of CEACAM6-800 uptake and clearance in tumor and normal tissues and pre-clinical post-surgery survival using our pre-clinical models. These studies will enable future translational studies.

DCIS biosignature reclassified patients who met RTOG 9804 or ECOG-ACRIN E5194 'low-risk' clinicopathologic criteria into an elevated invasive risk group who benefited significantly from radiation therapy

Frank Vicini<sup>1</sup>, Chirag Shah<sup>2</sup>, Steven Shivers<sup>3</sup>, Weiwei He<sup>4</sup>, Per Karlsson<sup>5</sup>, Erik Holmberg<sup>5</sup>, Michael C Leo<sup>6</sup>, Yangxin Huang<sup>4</sup>, Sheila Weinmann<sup>6</sup>, Fredrik Warnberg<sup>7</sup> and Troy Bremer<sup>3</sup>. <sup>1</sup>21st Century Oncology, Farmington Hills, MI; <sup>2</sup>Cleveland Clinic, Cleveland, OH; <sup>3</sup>PreludeDx, Laguna Hills, CA; <sup>4</sup>University of South Florida College of Public Health, Tampa, FL; <sup>5</sup>University of Gothenburg, Gothenburg, Sweden; <sup>6</sup>Kaiser Permanente Northwest Center for Health Research, Portland, OR; <sup>7</sup>University of Gothenburg, Uppsala, Sweden

**Background:** The goal of therapy for DCIS is to prevent invasive breast cancer. Randomized clinical trials for DCIS demonstrated that patients benefited from adjuvant radiation therapy (RT) after breast conserving surgery (BCS). However, treatment selection for patients with DCIS remains a challenge. Studies evaluating 'low-risk' clinicopathologic features have not identified a group of patients who do not benefit significantly from RT after BCS. Recently, a biosignature, DCISionRT (PreludeDx, Laguna Hills, CA), has been validated in multiple cohorts. The test provides a continuous 10-year breast event risk for patients treated with and without RT after BCS. In this study, we examined the utility of the biosignature to identify patients who met RTOG 9804 or ECOG 5194 'low-risk' criteria but remained at elevated invasive risk after BCS and benefited from RT.

**Methods:** The analysis was performed in a combined cohort made up of four studies. FFPE tissue samples and patient outcomes were obtained from Uppsala University Hospital and Västmanland County Hospital, Sweden (UUH) between 1986 and 2004, the University of Massachusetts, Worcester (UMass) from 1999 to 2008, from Kaiser Permanente Northwest (KPNW) from 1990-2007, and from the SweDCIS trial cohort (1987-2000). Patients were treated with or without RT after BCS. Treatment decisions were neither randomized nor strictly rules-based, except for the randomized SweDCIS trial for RT. Individual patient outcome and biosignature results were analyzed independently at University of South Florida. Hazard ratios (HR) were determined using Cox proportional hazards analyses, and 10-year risks were assessed with survival analysis.

**Results:** Complete biomarker and clinical data was available for 660 women meeting a 'low-risk' clinico-pathologic criteria like ECOG 5194 grade 1 or 2 and for 535 women meeting RTOG 9804 like criteria. In this subset, there were 49 invasive breast cancer events for ECOG 5194 and 38 for RTOG 9804 within 10 years of diagnosis. In the biosignature low risk group there was no significant reduction from RT ( $p>0.15$ ), where the 10-year absolute invasive benefit from RT varied from 1% to 2% for patients meeting RTOG 9804 or ECOG 5194, Table 1. However, in the biosignature elevated risk group, RT significantly reduced invasive cancer risk ( $p<.0022$ ) for RTOG9804 or ECOG 5194 Grade 1 or 2 criteria. The 10-year absolute invasive benefit from RT was 15% for RTOG 9804, 12% for ECOG 5194 Grade 1 and 2. This corresponded to a 10-year invasive relative risk reduction of 84% for RTOG 9804, 74% for ECOG 5194 Grade 1 or 2. The number needed to treat (NNT) in the biosignature low risk group was  $> 100$  for RTOG 9804 like criteria, while the NNT was 7 in the biosignature elevated risk group.

**Conclusions:** The DCIS biosignature identified patients from four cohorts that met 'low-risk' clinicopathologic criteria like RTOG 9804 or ECOG 5194 grade 1 or 2, and had elevated 10-year risk after BCS but had a substantial 84% relative benefit from RT. In contrast, the biosignature also identified a low risk group of patients with who had minimal (1-2%) risk reduction from RT. In comparison with traditional clinicopathologic features used to make RT recommendations, the DCISionRT score was dramatically associated with RT therapy benefit.

Biosignature low risk group (DS $\leq$ 3)

Trastuzumab deruxtecan (T-DXd; DS-8201) vs trastuzumab emtansine (T-DM1) in high-risk patients with HER2-positive, residual invasive early breast cancer after neoadjuvant therapy: A randomized, phase 3 trial (DESTINY-Breast05)

## Background

Preoperative chemotherapy in combination with trastuzumab and pertuzumab is a preferred regimen for treating patients (pts) with HER2-positive, invasive, early breast cancer (BC). Pts who have received such treatment but still have residual invasive disease in the breast or lymph nodes at surgery are at greater risk for disease recurrence or death than those with a pathological complete response. The antibody-drug conjugate (ADC) T-DM1 was recently approved as a postneoadjuvant treatment for pts with residual invasive disease (in the breast and/or axillary nodes) after optimal neoadjuvant chemotherapy and trastuzumab (or trastuzumab with pertuzumab). T-DXd is a potent HER2-targeted ADC with a humanized HER2 antibody attached to a membrane-permeable topoisomerase I inhibitor payload by a cleavable tetrapeptide-based linker and a drug-to-antibody ratio of  $\approx 8$ . Recently, T-DXd was approved for the treatment of adult pts with HER2-positive, unresectable or metastatic BC who have received  $\geq 2$  prior anti-HER2-based regimens in the metastatic setting (US) or had prior chemotherapy and are refractory to or intolerant of standard treatments (Japan). These approvals were based on a phase 2 study in which T-DXd demonstrated an objective response rate (ORR) of 60.9% (112/184 pts) and duration of response of 14.8 months in pts with HER2-positive (IHC 3+ or ISH+), unresectable or metastatic BC previously treated with T-DM1 (Modi et al. *N Engl J Med.* 2020;382:610-621). Here, we describe a randomized phase 3 trial evaluating T-DXd vs T-DM1 as postneoadjuvant treatment for high-risk pts with HER2-positive primary BC who have residual invasive disease following neoadjuvant therapy.

## Study Description

DESTINY-Breast05 is a multicenter, open-label, randomized, phase 3 trial comparing the efficacy and safety of T-DXd with those of T-DM1 in pts with HER2-positive (IHC 3+ or ISH+, centrally confirmed on pretreatment biopsy), invasive BC with pathological evidence of residual invasive disease in the breast or axillary lymph nodes after neoadjuvant therapy. Additionally, pts must be at higher risk for recurrence, having either inoperable (clinical stages T4, N0-3, M0 or T1-3, N2-3, M0) or operable BC at presentation (clinical stages T1-3, N0-1, M0) with axillary node-positive disease after optimal neoadjuvant chemotherapy and anti-HER2 treatment. The trial is recruiting pts from  $\approx 400$  sites globally. Approximately 1600 pts will be randomized (1:1) to T-DXd or T-DM1. Randomization is stratified by operative status, hormone receptor status, pathological nodal status following neoadjuvant therapy, and type of HER2-targeted neoadjuvant therapy (single vs dual). T-DXd 5.4 mg/kg or T-DM1 3.6 mg/kg will be administered intravenously once every 3 weeks for 14 cycles. Invasive disease-free survival based on investigator assessment is the primary efficacy endpoint; disease-free survival is the key secondary efficacy endpoint. Other secondary endpoints are overall survival, distant recurrence-free interval, and brain metastasis-free interval. Safety assessments include serious and treatment-emergent adverse events, physical examinations, vital signs, on-study chest imaging (to screen for pneumonitis), and clinical laboratory parameters. The pharmacokinetics of T-DXd, biomarkers, and health-related quality of life will also be evaluated. Long-term follow-up will continue after the primary analysis every 6 months until death, withdrawal of consent, loss to follow-up, or trial closure.

Prognostic significance of germline BRCA mutations in patients with HER2-positive breast cancer. Epidemiological analysis in primary BRCA screens

Alessandro Viansone<sup>1</sup>, Claudia Omarini<sup>2</sup>, Daniela Boggiani<sup>3</sup>, Angelica Sikokis<sup>3</sup>, Vera Uliana<sup>4</sup>, Benedetta Pellegrino<sup>5</sup>, Federico Piacentini<sup>2</sup>, Maria Michiara<sup>3</sup> and Antonino Musolino<sup>5</sup>. <sup>1</sup>Institut Gustave Roussy, Villejuif, France<sup>2</sup>Department of Medical and Surgical Sciences for Children and Adults, Division of Oncology, University Hospital of Modena, Modena, Italy<sup>3</sup>Breast Unit and Cancer Genetics Service, University Hospital of Parma, Parma, Italy<sup>4</sup>Department of Breast Unit and Cancer Genetics Service, University Hospital of Parma, Parma, Italy<sup>5</sup>Department of Medicine and Surgery, University of Parma; Breast Unit and Cancer Genetics Service, University Hospital of Parma, Parma, Italy

**Background:** HER2-amplified breast cancers are rare amongst BRCA mutation carriers. No data exist regarding clinico-histological characteristics and prognosis of this subgroup of patients. **Materials and Methods:** Using a retrospective matched cohort design, we collected data from 728 women who were diagnosed with breast cancer from January 2006 to December 2016 and were screened for germline BRCA mutations. Clinical and histological characteristics of the primary tumor, time to relapse, and survival were analyzed by BRCA and HER2 status. **Results:** One hundred and twenty HER2-positive, BRCA mutated cases were evaluated with respect to three control groups: HER2-positive, BRCA wild-type (n=136); HER2-negative, BRCA-mutated (n=226); HER2-negative, BRCA wild-type (n=246). Breast cancers with hormone receptor-negative status or high histologic grade (odds ratio=1.7; 95% confidence interval [CI]: 1.0-2.9) were more likely HER2-positive, with no restriction by BRCA mutation status. Disease-free and overall survival for HER2-positive, BRCA mutated cases were lower than those for the other subgroups. An interaction between BRCA mutations and HER2-positive status was found for poorer overall survival after adjusting for prognostic variables (HR = 3.4; 95% CI: 1.3-16.7). **Conclusions:** Germline BRCA mutations confer worse prognosis in patients with HER2-positive breast cancer. Ongoing trials testing novel therapeutic approaches (e.g. anti-HER2 therapies combined with PARP inhibitors) are warranted.

*BRA-STRAP* is an Australia-wide study of breast cancer predisposition that brings together gene-panel data from 30,000 adult Australian women of all ages, across the breast cancer risk spectrum, with and without a diagnosis of breast cancer. The “*BRA-STRAP* panel” includes 24 genes\* that are involved in, or putatively associated with, predisposition to breast and/or ovarian cancer. Despite insufficient evidence for clinical translation for some of these genes, all 24 are commonly included on panel tests for breast cancer predisposition.

We present findings from the population-based case-control sub-study of *BRA-STRAP*, which involved 1451 women diagnosed with breast cancer and 857 age-matched controls participating in the Australian Breast Cancer Family Registry (ABCFR), and 6101 healthy, elderly Australian women enrolled in the *ASPREE* study. These analyses focus on rare genetic variants predicted to lead to loss of function and/or classified as pathogenic/likely pathogenic (P/LP) in ClinVar. Odds ratios (ORs) for their associations with breast cancer were estimated by aggregating genetic variants for each gene.

For the women diagnosed with breast cancer, the median age at diagnosis (inter-quartile range, IQR) was 40.0 (14.0) years and the overall frequency of P/LP variant carriers across all genes was 156/1451 (10.8%). The median age (IQR) of the ABCFR and *ASPREE* controls were 39.4 (14.9) and 73.9 (5.8) years, respectively. The frequencies of P/LP variant carriers were 33/857 (3.9%) and 268/6101 (4.4%) in the ABCFR and *ASPREE* controls, respectively. We combined both control datasets and, after adjusting for age and other potential confounders, the ORs associated with P/LP variants in *BRCA1* and *BRCA2* were 4.1 [95% confidence interval (CI): 1.8-10.2] and 2.9 [95% CI: 1.5-6], respectively. We also found that the OR for P/LP variants in *ATM* was 4.0 [95% CI: 1.5-10.4] and the OR for P/LP variants in *PALB2* was 2.2 [95% CI: 0.75-5.7] although this did not reach statistical significance.

These results contribute to international efforts to refine the breast cancer risk estimates for genetic variants identified from population-based screening of unselected women using genes that are included on panel tests and thought to be potentially breast cancer predisposition genes. The case-control-family design of the ABCFR will also allow us to estimate the age specific cumulative risk (penetrance) of these genetic variants, which is important for genetic counselling and the clinical management of carrier families.

**Background:** In ER+ breast cancer (BC) models, Aurora A kinase (AURKA) activation is associated with expansion of CD44<sup>+</sup>/CD24<sup>low/-</sup> tumor initiating cells, down-regulation of ER $\alpha$ , and endocrine therapy resistance. Alisertib, a selective AURKA inhibitor, can restore ER $\alpha$  expression and endocrine sensitivity. Early phase studies evaluating alisertib alone or with fulvestrant for ER+ metastatic BC (MBC) demonstrated a favorable safety profile and promising antitumor activity [Haddad, Breast Cancer Res Treat. 2018]. A phase II trial was conducted to determine if the addition of fulvestrant to alisertib improved objective response rate (ORR) and to assess clinical activity of alisertib alone or with fulvestrant in patients (pts) with prior fulvestrant and CDK 4/6 inhibitor (CDK 4/6i). **Methods:** Pts were randomized 1:1 to Arm A, alisertib (50 mg PO BID Days 1-3, 8-10, 15-17 q 28 days) or Arm B, alisertib with fulvestrant (500 mg IM Day 1, 15 for Cycle 1 and q 28 days thereafter). Eligibility included postmenopausal women, history of ER+ BC, prior fulvestrant,  $\leq 2$  prior chemotherapy lines, and measurable disease. Stratification factors included prior CDK4/6i, ER level ( $<10\%$ ,  $\geq 10\%$ ), and primary/secondary endocrine resistance. Pts on Arm A could cross over to Arm B at progression. With 45 pts per arm, a one sided  $\alpha=0.15$  sequential binomial test would have an 85% chance of detecting an increase of  $\geq 20\%$  in the ORR of ArmB when the true ORR for Arm A is  $\leq 20\%$ . ORR was defined as a partial response (PR) + complete response (CR) by RECIST v.1.1 criteria. Secondary endpoints include progression free survival (PFS), 24-week clinical benefit rate (CBR = CR + PR + absence of progression for  $> 6$  cycles), overall survival, duration of response (DoR), and safety. Blood and tumor specimens were collected at baseline, end of Cycle 1, and progression. **Results:** Pts enrolled July 2017 - November 2019 with 118 pre-registered, 96 registered, and 90 evaluable for the primary endpoint (Arm A: 45, Arm B: 45). Median age was 60 (range 33, 85). Nearly all received prior fulvestrant (n=89, 98.9%), aromatase inhibitor (n=83, 92.2%), and CDK4/6i (n=88, 97.8%). Most had secondary endocrine resistance (n=71, 78.9%). Pre-registration biopsy for ER was positive in 84 pts (86.7%) and negative in 6 pts (13.3%). More pts on Arm B had prior everolimus (A: 35.6%, B: 57.8%) and prior chemotherapy (A: 44.4%, B: 55.6%) for MBC. The ORR for alisertib and fulvestrant was 20.0% (90% CI: 10.9-32.3%), not significantly greater than alisertib alone 17.8% (90% CI: 9.2-29.8%). The 24-week CBR for Arm A was 42.2% (90% CI: 29.7-55.6%; n=19, including 7 PR) and Arm B was 31.1% (90% CI: 19.9-44.3%; n=14, including 8 PR). As of July 1, 2020, the median DoR was not reached in either arm. The median PFS time was 5.6 months (95% CI: 3.9 - 9.3) for Arm A and 5.1 months (95%CI: 3.8 - 7.6) for Arm B. Seventeen pts (18.9%) remain on treatment (A: 12, B: 5) having received at least 11 cycles (range up to 32+ cycles). At least one dose reduction was required for pts (A: 19, B: 18), most commonly due to neutropenia. The most common severe (grade  $\geq 3$ ) adverse events included neutropenia (n=19, 42.2% in each arm), anemia (A: 15.6%, B: 8.8%), and fatigue (n=5, 11.1% Arm B only). Pts discontinued therapy due to disease progression equally in each arm (n=28, 62.2%), however more pts on Arm B (n=12) than Arm A (n=5) discontinued therapy due to toxicity, refusal or other reasons. **Conclusion:** While the addition of fulvestrant to alisertib did not improve ORR, promising clinical activity with alisertib monotherapy was observed overall and notably for pts with endocrine and CDK 4/6i-resistant MBC. More severe toxicities and treatment discontinuation were observed in pts receiving combination therapy. Correlative blood (CTC/cfDNA) and tissue (AURKA, ER $\alpha$ , and stemness biomarkers) studies are underway.

A randomized phase III study of radiation doses and fractionation schedules in non-low risk ductal carcinoma in situ (DCIS) of the breast (BIG 3-07/TROG 07.01)

Boon Hui Chua<sup>1</sup>, Emma Link<sup>2</sup>, Ian Kunkler<sup>3</sup>, Ivo Olivotto<sup>4</sup>, Antonia Helen Westenberg<sup>5</sup>, Timothy Whelan<sup>6</sup>, Guenther Gruber<sup>7</sup>, Breast International Group (BIG)-aisbl, Trans Tasman Radiation Oncology Group, Scottish Cancer Trials Breast Group, Canadian Cancer Trials Group, European Organization for Research and Treatment of Cancer, International Breast Cancer Study Group, Cancer Trials Ireland. <sup>1</sup>University of New South Wales, Sydney, Australia<sup>2</sup>Peter MacCallum Cancer Centre, Melbourne, Australia<sup>3</sup>University of Edinburgh, Edinburgh, United Kingdom<sup>4</sup>University of Calgary, Calgary, AB, Canada<sup>5</sup>Radiotherapiegroep Arnhem, Arnhem, Netherlands<sup>6</sup>McMaster University, Hamilton, ON, Canada<sup>7</sup>Klinik Hirslanden, Institute for Radiotherapy, Zurich, Switzerland

**Background:** Wholebreast irradiation (WBI) after breast conserving surgery for DCIS reduces the risk of local recurrence including invasive recurrence. The objective of BIG3-07/TROG 07.01 is to test radiation dose escalation to the tumor bed (tumor bed boost) and fractionation sensitivity of whole breast irradiation (WBI) in patients with non-low risk DCIS treated with breast conserving therapy.

**Methods:** BIG3-07/TROG 07.01 is an international, multicenter, randomized, controlled, phase 3 trial. Eligible women were ≥18 years of age with completely resected non-low risk DCIS defined as age <50 years or age ≥50 years plus at least one of the risk factors for local recurrence (palpable tumor, multifocal disease, tumor size ≥ 1.5cm, intermediate or high nuclear grade, central necrosis, comedo histology and/or surgical margin <10 mm). Patients were randomized to have tumor bed boost (16 Gy in 8 daily fractions) or no boost following conventional WBI (50Gy in 25 daily fractions) or hypofractionated WBI (42.5 Gy in 16 daily fractions) in one of three randomization categories selected by centers prior to study activation. Randomization A was a 4-arm randomization of no boost vs. boost following conventional WBI vs. hypofractionated WBI. Patients in Randomization B and Randomization C were assigned no boost or boost following conventional WBI and hypofractionated WBI, respectively. The primary endpoint was time to local recurrence, analyzed by intention to treat. The trial was designed to detect a 3% difference in 5-year free-from-local recurrence rates between the no boost and boost groups (93% vs 96%; hazard ratio, 0.56) with 90% power and 2-sided alpha level of 5%. The primary effect of boost was assessed on all randomized patients. The secondary effect of WBI dose-fractionation and the interaction between boost and WBI dose-fractionation were assessed on patients in Randomization A and additionally on all patients.

**Results:** Between June 2007 and June 2014, 1608 patients were randomized to have no boost (805 patients) or boost (803 patients) after WBI. Conventional WBI was given in 831 patients (no boost in 416 patients; boost in 415 patients). Hypofractionated WBI was given in 777 patients (no boost in 389 patients; boost in 388 patients). Adjuvant endocrine therapy was planned in 106 patients (13%) in the no boost group and 105 patients (13%) in the boost group. Median follow-up was 6.6 years. The 5-year free-from-local recurrence rates were 93% in the no boost group and 97% in the boost group (hazard ratio, 0.47; 95% confidence interval [CI], 0.31 to 0.72; P<0.001). Forty-four percent and 45% of LRs were invasive in the no boost group and boost group, respectively. The effect of boost did not vary significantly by age, tumor size, nuclear grade, surgical margin or endocrine therapy. There were no significant differences in the 5-year free-from-local recurrence rates between the conventional WBI group and hypofractionated WBI group in Randomization A (94% vs. 94%, P=0.84) and in all randomized patients (95% vs. 95%, P=0.89). The test for interaction between boost and dose-fractionation was not significant in Randomization A or in all randomized patients (both P=0.89). The rates of grade ≥2 breast pain (12% vs. 16%, P=0.84) and skin and subcutaneous tissue fibrosis (6% vs. 15%, P=0.14) did not differ significantly between the groups.

**Conclusions:** In women with non-low risk DCIS treated with breast conserving surgery, the addition of tumor bed boost following conventional or hypofractionated WBI reduced local recurrence rates. There was no difference in local recurrence rates between conventional WBI and hypofractionated WBI. (Registered with ClinicalTrials.gov, NCT00470236.)

**Background:** In hormone receptor (HR) positive/HER2-negative node-negative early breast cancer (EBC), patients (pts) with Recurrence Score™ (RS) <26 (postmenopausal) and <16 (premenopausal) have an excellent prognosis and do not benefit from additional chemotherapy. However, prognostic impact of RS results in node-positive disease and the importance of Ki67 decrease after short preoperative endocrine therapy (ET) in the context of genomic signatures remain unclear. Here, we present for the first time outcome data from the large prospective phase III ADAPT HR+/HER2- trial combining both static (RS result on baseline core biopsy) and dynamic (Ki67 response) biomarkers to optimize the adjuvant therapy approach in luminal EBC. **Methods:** Pts with clinically high-risk EBC (cT2-4 OR clinically node-positive OR G3 OR Ki67≥15% HR+/HER2-) were treated by 3 (+/-1) weeks of standard ET (mostly aromatase inhibitors in postmenopausal and tamoxifen in premenopausal pts) before surgery or sequentially core biopsy. Pts with RS 0-11 OR 12-25 AND post-endocrine central Ki67≤10% were treated by ET alone at investigator choice (Part 1). All pts with high-risk disease (RS>25 or RS 12-25 with postendocrine Ki67>10% or c/pN2-3) were treated by chemotherapy within a phase III chemotherapy protocol (Part 2). Primary objective (Part 1) was non-inferiority of 5-year invasive disease-free survival (iDFS) in a minimum of 1760 patients with RS 12-25 and ET-response vs. RS 0-11. Secondary endpoints included overall survival (OS), distant DFS, and translational research. **Results:** 5323 pts were registered and 4690 finally allocated to ET (n=2355) or CT (n=2335) within ADAPT HR+/HER2-. About 1/3 of pts were premenopausal; about 40% had node-positive disease. Efficacy results will be available in October 2020.

**Introduction** Accurate prediction of local recurrence (LR) after breast conserving surgery (BCS) for ductal carcinoma-in-situ (DCIS) is crucial to personalize recommendations for adjuvant radiotherapy (RT). The 21-gene recurrence score (RS) predicts for distant metastases for woman with invasive breast cancer. We hypothesised that the RS could improve prediction of LR after BCS for DCIS. **Methods** We performed a population-based analysis of 1226 woman aged  $\leq 74$  treated with BCS  $\pm$  RT for pure DCIS. Expert pathology review was obtained for all cases, as was the RS. Treatment and outcomes were obtained by deterministic linkage to administrative databases and chart review. Clinico-pathologic features obtained included: age, tumor size, nuclear grade, presence of comedonecrosis, multifocality, margins, and adjuvant radiation. The outcome assessed was local recurrence by 10 years from diagnosis of DCIS. The LR prediction model was developed using multivariable Cox regression, where a non-parametric approach was implemented to estimate the baseline hazard function. The proportional hazards assumption was assessed and time-interaction terms were included with each covariate in the model. Models were ranked based on c-statistic, log-likelihood estimate, and Akaike information criterion (AIC). Backward selection was used to obtain the final reduced model with time-interaction terms. Calibration for the best model was examined by grouping predicted 10-year risk of LR into deciles and plotting against observed 10-year risk of LR based on mean Kaplan-Meier estimates. Internal validation was performed by bootstrapping. **Results** Of the 1226 woman included, 514 were treated with BCS alone and 712 received adjuvant RT. Median follow up from time of treatment was 16 years (interquartile range (IQR): 14-18). The median age was 56 years (IQR: 49-64). Margins were negative in 90.5% of cases. Tumor size was  $\leq 1$ cm in 430 (35.1%), 1-2.5cm in 633 (51.6%), and  $>2.5$ cm in 163 (13.3%). The median RS was 15 (IQR: 8-30) and the mean RS was 21.37 (SD 18.93). The best predictive model included the RS and had a c-statistic of 0.68 as well as the lowest AIC. This model included the following variables: RS, age, tumor size, nuclear grade, margin status, comedonecrosis ( $\leq 30\%$  vs higher), multifocality, and treatment (BCS vs BCS+RT); it also included the following interaction terms: treatment and time, RS and time, comedonecrosis and time, and treatment and tumor size. Due to the non-linear relationship between certain characteristics and the risk of LR, quadratic terms for RS and age were also included. This model was well calibrated overall, especially in the lower risk range around the 10% risk threshold. It was also well calibrated in this risk range in the subset of woman who were treated with BCS alone. **Conclusion** The best performing model generated to predict LR after BCS for DCIS includes the RS. Work is ongoing to compare RS and the 12-gene DCIS score in terms of prediction of LR, as well as prediction of invasive LR specifically. This work can help guide future clinical de-escalation trials by better identifying woman with truly low risk of LR after BCS for DCIS.

FGFR1 associates with gene promoters and regulates gene transcription: Implications for endocrine resistance in ER+/FGFR1-amplified breast cancer

Alberto Servetto<sup>1</sup>, Rahul Kollipara<sup>1</sup>, Luigi Formisano<sup>2</sup>, Chang-Ching Lin<sup>1</sup>, Kyung-min Lee<sup>1</sup>, Dhivya R Sudhan<sup>1</sup>, Ariella B Hanker<sup>1</sup>, Sumanta Chatterjee<sup>1</sup>, Angel Guerrero-Zotano<sup>3</sup>, Paula Gonzalez-Ericsson<sup>4</sup>, Saurabh Mendiratta<sup>1</sup>, Hiroaki Akamatsu<sup>1</sup>, Nicholas James<sup>5</sup>, Ralf Kittler<sup>1</sup> and Carlos L Arteaga<sup>1</sup>. <sup>1</sup>UT Southwestern Medical Center, Dallas, TX; <sup>2</sup>University of Naples "Federico II", Naples, Italy; <sup>3</sup>Instituto Valenciano de Oncología, Valencia, Spain; <sup>4</sup>Vanderbilt-Ingram Cancer Center, Nashville, TN; <sup>5</sup>University of Hawaii at Manoa, Manoa, HI

**Background:** *FGFR1* amplification occurs in ~ 15% of ER+ breast cancers. In these tumors, nuclear FGFR1 has been shown to interact with DNA, but its role in transcriptional regulation is unclear. Thus, we investigated the genomic role of FGFR1 in ER+/FGFR1-amplified breast cancer. **Results:** FGFR1 ChIP-Seq detected 4,412 DNA binding sites in CAMA1 ER+/FGFR1-amplified breast cancer cells cultured in estrogen-free conditions. Of these binding sites, 67% were enriched at promoter regions. ChIP-qPCR confirmed FGFR1 binding to several promoter regions in a second ER+/FGFR1-amplified cell line, MDA-MB-134, and a patient derived xenograft, HCI-011. To determine the nuclear FGFR1 interactome, we performed FLAG immunoprecipitation of mixed nuclear and chromatin fractions of CAMA1 cells transduced with a 3XFLAG-FGFR1 plasmid, followed by mass spectrometry (MS) of FLAG antibody pulldowns. MS revealed RNA Polymerase II subunits among the top nuclear FGFR1 interacting proteins. FGFR1 mainly bound Pol II phosphorylated on Ser5 (Pol II S5P), a marker of transcription initiation, in CAMA1, MDA-MB-134 and HCI-011 cell extracts. Pol II S5P ChIP-Seq revealed that 2,867/4,412 (65%) FGFR1 peaks were shared with Pol II S5P. ChIP-Seq also showed that 95% of FGFR1 peaks overlapped with both H3K4me3 and H3K27ac, markers of active transcription. Consistent with these results, RNA-Seq of CAMA1 cells showed that expression of FGFR1-bound genes was markedly higher than non FGFR1-bound genes ( $p < 0.0001$ ), suggesting that FGFR1 binds to actively transcribed genes. In addition to Pol II, MS detected FOXA1 among FGFR1 interacting proteins. ChIP-Seq analysis revealed FOXA1 enriched at FGFR1-bound loci. siRNA-mediated FOXA1 knockdown reduced FGFR1 distribution to several genomic loci in CAMA1 cells, as measured by FGFR1 ChIP-Seq, suggesting that FOXA1 mediates FGFR1 recruitment to chromatin. We next transduced MCF-7 cells with an FGFR1(SP-)(NLS) plasmid, where the NLS sequence forces nuclear import of the resulting protein. To determine the role of FGFR1 on transcriptional regulation, we used Binding and Expression Target Analysis (BETA), integrating FGFR1 ChIP-Seq and RNA-Seq results from MCF7<sup>FGFR1(SP-)(NLS)</sup> vs MCF7<sup>EV</sup> cells. This analysis predicted a direct role for genomic-bound FGFR1 in activating gene expression ( $p = 8.01 \times 10^{-6}$ ). MCF7<sup>FGFR1(SP-)(NLS)</sup> cells were markedly less sensitive to fulvestrant compared to control cells. Gene Set Enrichment Analysis (GSEA) of the 1,009 genes upregulated in MCF7<sup>FGFR1(SP-)(NLS)</sup> cells and bound by FGFR1 at a genomic level revealed a strong enrichment of estrogen response early ( $q = 2.2 \times 10^{-44}$ ) and late ( $q = 6.4 \times 10^{-33}$ ) genes, suggesting that nuclear FGFR1 induces an ER $\alpha$ -associated transcriptional profile that may contribute to endocrine resistance. Finally, an expression signature associated with nuclear FGFR1 correlated with endocrine resistance in three cohorts of patients with ER+ breast cancer treated with aromatase inhibitors. We next studied the effect of growth factor stimulation on FGFR1 transcriptional function. Stimulation with FGF2 enhanced nuclear FGFR1 import in CAMA1 cells, as well as FGFR1-Pol II S5P association. Notably, these effects were not abrogated by treatment with the FGFR1 inhibitor erdafitinib. ChIP-Seq revealed that erdafitinib did not impair the FGFR1 genomic distribution. These results do not support a causal link between the FGFR1 activated TK and the receptor's activity in the nucleus. **Conclusions:** We have demonstrated a role for nuclear FGFR1 in transcriptional regulation in breast cancer. FGFR1-induced gene expression contributes to endocrine resistance and is not affected by FGFR TKIs. These findings provide a rationale for developing treatment strategies to inhibit nuclear FGFR1 in ER+/FGFR1-amplified breast cancer.

**Background:** Trophoblast cell-surface antigen-2 (Trop-2) is highly expressed in many epithelial tumors, including triple-negative breast cancer (TNBC). Sacituzumab govitecan (SG) is an antibody-drug conjugate composed of an anti-Trop-2 antibody coupled to SN-38, an active metabolite of irinotecan, via a unique hydrolyzable linker that allows for SN-38 release intracellularly and in the tumor microenvironment (bystander effect). Preclinical studies have shown a great range of efficacy with SG in mice bearing tumors with low, moderate, and high Trop-2 expression levels. We report subgroup analyses by Trop-2 expression from ASCENT, a randomized, phase 3 confirmatory study of SG versus standard-of-care chemotherapy in patients with metastatic TNBC (mTNBC). **Methods:** In the global, multicenter, open-label, phase 3 ASCENT study (NCT02574455), 529 patients with mTNBC refractory to or relapsing after at least 2 prior chemotherapies were randomized 1:1 to receive SG (10 mg/kg intravenously on days 1 and 8 every 21 days) or single-agent treatment of physician's choice (capecitabine, eribulin, vinorelbine, or gemcitabine) until disease progression or unacceptable toxicity. The primary endpoint was progression-free survival (PFS) measured by central independent review per RECIST v1.1. Secondary endpoints included objective response rate (ORR) per RECIST v1.1, duration of response, overall survival (OS), and safety. Exploratory endpoints included biomarker assessments, including Trop-2 and *BRCA1/2*. Trop-2 expression was assessed using a validated immunohistochemistry assay. **Results:** Subgroup analyses by biomarker expression including Trop-2 and *BRCA1/2* were performed, and outcomes by PFS, OS, ORR, and safety results will be reported. **Conclusions:** These analyses will provide further insights into the relationship of Trop-2 expression and the activity of SG in previously treated patients with mTNBC.

Mismatch repair deficiency predicts response to HER2 blockade in HER2-negative breast cancer

Svasti Haricharan<sup>1</sup>, Nindo Punturi<sup>1</sup>, Sinem Seker<sup>1</sup>, Vaishnavi Devarakonda<sup>2</sup>, Rashi Kalra<sup>2</sup>, Ching-Hui Chen<sup>2</sup>, Aloran Mazumder<sup>1</sup>, Shungqiang Li<sup>3</sup>, Tina Primeau<sup>4</sup>, Matthew Ellis<sup>2</sup> and Shyam Kavuri<sup>2</sup>. <sup>1</sup>Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA; <sup>2</sup>Baylor College of Medicine, Houston, TX; <sup>3</sup>Washington University in St. Louis, St. Louis, MO; <sup>4</sup>Washington University in St. Louis, St. Louis, MO

Estrogen receptor positive (ER<sup>+</sup>) breast cancer is a leading cause of cancer-related death globally. Resistance to standard of care endocrine treatment occurs in at least 30% of ER<sup>+</sup> breast cancer patients resulting in ~40,000 deaths every year in the US alone. Preclinical studies strongly implicate activation of growth factor receptor, HER2 in endocrine treatment resistance of ER<sup>+</sup> breast cancer that is HER2<sup>-</sup> at diagnosis. However, clinical trials of pan-HER inhibitors in ER<sup>+</sup>/HER2<sup>-</sup> patients have disappointed, likely due to a lack of predictive biomarkers. Here we demonstrate that loss of *MLH1*, a principal mismatch repair gene, causally activates HER2 in ER<sup>+</sup>/HER2<sup>-</sup> breast cancer upon endocrine treatment. Additionally, we show that HER2 activation is indispensable for endocrine treatment resistant growth of MLH1-defective cells *in vitro* and *in vivo*. Consequently, inhibiting HER2 restores sensitivity to endocrine treatment in multiple experimental models including patient-derived xenograft tumors. Patient data from multiple clinical datasets (TCGA, METABRIC, Alliance (Z1031) and E-GEOD-28826) supports an association between MLH1 loss, HER2 upregulation, and sensitivity to trastuzumab in endocrine treatment-resistant ER<sup>+</sup>/HER2<sup>-</sup> patients. These results provide strong evidence that MLH1 could serve as a first-in-class predictive marker of sensitivity to combinatorial treatment with endocrine drugs and HER2 inhibitors in endocrine treatment-resistant ER<sup>+</sup>/HER2<sup>-</sup> breast cancer patients. Implications of this study extend beyond breast cancer to Lynch Syndrome cancers.

The DAPHNE trial: A feasibility study of chemotherapy de-escalation based on response to neoadjuvant paclitaxel-HP (THP) in HER2-positive breast cancer

Adrienne G. Waks<sup>1</sup>, Neelam V. Desai<sup>2</sup>, Tianyu Li<sup>1</sup>, Philip D. Poorvu<sup>1</sup>, Ann H. Partridge<sup>1</sup>, Natalie Sinclair<sup>1</sup>, Laura M. Spring<sup>3</sup>, Meredith Faggen<sup>1</sup>, Michael Constantine<sup>1</sup>, Jillian C. Alberti<sup>1</sup>, Julia Deane<sup>1</sup>, Shoshana M. Rosenberg<sup>1</sup>, Sara M. Tolaney<sup>1</sup>, Ian E. Krop<sup>1</sup>, Nadine M. Tung<sup>2</sup>, Nabihah Tayob<sup>1</sup>, Tari A. King<sup>1</sup>, Elizabeth A. Mittendorf<sup>1</sup> and Eric P. Winer<sup>1</sup>. <sup>1</sup>Dana-Farber Cancer Institute, Boston, MA; <sup>2</sup>Beth Israel Deaconess Medical Center, Boston, MA; <sup>3</sup>Massachusetts General Hospital, Boston, MA

**Background:** De-escalation of adjuvant therapy following pathologic complete response (pCR) to an abbreviated neoadjuvant regimen in HER2-positive (HER2+) breast cancer is the focus of a recently initiated national trial. However the feasibility of this approach, and its appeal to patients (pts) and providers, has not been formally investigated. **Methods:** We conducted a single arm pilot trial to determine the feasibility of de-escalated adjuvant therapy (HP-only) in patients with pCR following neoadjuvant THP. Eligible pts had clinical anatomic stage II-III treatment-naïve HER2+ breast cancer. All pts received weekly paclitaxel x12 doses, and HP every 3 weeks x4 doses (up to 6 doses allowed in case of surgical delay). The primary objective was to assess adherence to protocol-specified antibody doublet therapy (HP-only, without cytotoxic chemotherapy) in the adjuvant setting among pts with pCR (ypT0/isN0) following neoadjuvant THP; the primary endpoint was receipt of adjuvant cytotoxic chemotherapy, assessed 3 months post-operatively. Trastuzumab emtansine (T-DM1) was not considered cytotoxic chemotherapy. Among pts with pCR to THP, de-escalation would be deemed infeasible if the true rate of adherence to HP-only were  $\leq 80\%$ . With sample size of 100 pts, the study was designed to have  $>90\%$  power to reject the null if the true rate of adherence were  $\geq 95\%$  (Binomial exact test; one-sided  $\alpha=0.05$ ). Questionnaires were administered and records were reviewed to assess pts' and physicians' decision-making about adjuvant systemic therapy following pCR and non-pCR. **Results:** 98 pts received at least one dose of THP on study. Median age was 50 yrs (range 24-78), pts were 99% female, 86% had stage II/14% stage III tumors, 32% ER/PR negative. No pts progressed during neoadjuvant THP. Five pts had incomplete clinical response following THP and received AC prior to surgery. They were classified as non-pCR and censored from further analyses. At the time of analysis, 93 pts were evaluable for response to neoadjuvant therapy (1 pt withdrew from study early; 4 pts had not reached surgery by the data cutoff). Overall pCR rate was 55% (51/93 pts); 10%, 28%, and 2% of pts had RCB I, II, and III responses, respectively (this excluded patients who received AC preoperatively). Of 51 pts who had pCR to THP, 40 had verified data available regarding adjuvant chemotherapy receipt at data cutoff. 39/40 pts (97.5%, 95% CI 86.8-99.9%) who had pCR did not receive adjuvant cytotoxic chemotherapy, meeting the trial's prespecified threshold for declaring this a feasible approach (primary endpoint), though data remain pending for 11 pts with pCR and will be available at presentation. Of 30 pts who did not experience pCR to THP and had adjuvant chemotherapy status verified at data cutoff, 14/30 pts received adjuvant cytotoxic chemotherapy, and 16/30 pts did not receive adjuvant chemotherapy. The most common reasons cited by pts for non-receipt of adjuvant cytotoxic chemotherapy, despite residual disease at surgery, were (N=21): plan for adjuvant T-DM1 alone (67% of pts), good response to preop chemo (38% of pts), and plan for adjuvant hormonal therapy (24% of pts). The most common reason cited by treating physicians for non-administration of adjuvant chemotherapy, despite residual disease at surgery, was plan for adjuvant T-DM1 (17/21 (81%) physicians). With brief follow-up (median 10.2 mos), there were no breast cancer recurrences. **Conclusions:** De-escalation of adjuvant cytotoxic chemotherapy among pts who experience pCR in early stage HER2+ breast cancer appears to be an acceptable approach for both pts and physicians, though data are not yet complete and will be updated at the time of presentation. The long-term efficacy of this approach will be determined in the ongoing national CompassHER2-pCR trial.

Racial differences in breast cancer immune microenvironments

Alina M Hamilton, Linnea T Olsson, Benjamin C Calhoun, Katherine A Hoadley and Melissa A Troester. University of North Carolina at Chapel Hill, Chapel Hill, NC

**Background:** Black women suffer 40% higher mortality from breast cancer (BC) compared to non-Hispanic white women, and the underlying causes of these disparities remain uncertain. Growing evidence supports the importance of the immune microenvironment in BC survival, but immune response differences by race are poorly understood. We sought to characterize the immune microenvironment of BC to evaluate how phenotypes of immune response vary across race and tumor intrinsic subtype to impact clinical outcomes. **Methods:** We leveraged the Carolina Breast Cancer Study (CBCS), a large population-based study that oversampled young ( $\leq 50$ ) and black women with invasive breast cancer and collected tumor tissue on  $>95\%$  of participants. We curated a 48-gene panel representative of 13 individual immune cell types, and performed NanoString gene expression profiling on tissue from 1957 BC patients, including 1033 (53%) Black and 924 (47%) Non-Black women. Consensus clustering was used to identify phenotypes of immune response, and individual immune cell scores were calculated as the median expression of cell-type markers. Immune phenotypes and cell-type scores were compared against validated protein markers and H&E-based quantification of TILs from corresponding tissue microarrays (TMAs). We estimated associations of immune classes with BC intrinsic subtype, ROR-PT scores (calculated as low, medium and high), age and race using relative frequency differences (RFDs), adjusting for age and tumor stage. Cell type scores were compared by race using Welch's t-tests and adjusted for multiple comparisons with the Benjamini-Hochberg procedure. **Results:** We identified three BC immune phenotypes primarily defined by features related to an Adaptive-enriched, Innate-enriched, or a Quiet immune microenvironment. These expression-based groups correlated with histological evidence of immune cells from corresponding TMAs. Similarly, expression-based cell scores correlated strongly with protein-based quantification of immune cells from corresponding TMAs (e.g. B-cell score vs. CD19 immunofluorescence,  $\rho=0.75$ ; ICOS RNA counts vs. protein;  $\rho=0.76$ ). Both Adaptive-enriched and Innate-enriched tumors were associated with high ROR-PT scores [RFD for Adaptive-enriched vs. Quiet: 24.1% (95% CI 19.3-28.8); Innate-enriched vs. Quiet RFD: 13.1 (95% CI 9.1-17); frequencies: 37.2%, 26.2% and 10% for Adaptive, Innate and Quiet, respectively], the basal-like intrinsic subtype [RFD for Adaptive-enriched vs. Quiet: 19.4% (95% CI 14.3-24.6); Innate-enriched vs. Quiet RFD: 9.8 (95% CI 5.6-14.1); frequencies: 43.4%, 27.4% and 8.9% respectively] and Black race [RFD for Adaptive-enriched vs. Quiet: 16.1% (95% CI 10.3-21.9); Innate-enriched vs. Quiet RFD: 9.5 (95% CI 3.9-15); frequencies 60.5%, 53.5% and 42.5% respectively]. After adjusting for tumor subtype, the Adaptive-enriched class remained associated with Black race (RFD for Adaptive-Enriched vs Quiet: 7.5% (95% CI 1.4-13.6). Conversely, tumors in the immune-quiet group were primarily non-basal (90%) with low ROR-PT scores (86.7%). Within the Adaptive-enriched class, Black women displayed decreased CD8 T cell scores ( $p=0.05$ ) but increased T-reg cell scores ( $p=0.02$ ) relative to Non-Black women. **Conclusion:** Immune response appears to be intricately related to race and tumor subtype, with black women having strong associations with adaptive-enriched and innate-enriched immune microenvironments. Differences in CD8 T cell and Treg expression suggest that even within broad classes of immune response, racial differences in specific cell-type distributions exist. Immune response differences may be targetable to improve treatment response, and therefore it is important to identify race- and subtype-specific differences in immune microenvironments.

Axillary recurrence is a rare event in node-positive patients. treated with sentinel node biopsy alone after neoadjuvant chemotherapy: Results of a prospective study

Andrea V Barrio, Giacomo Montagna, Anita Mamtani, Varadan Sevilimedu, Hiram S Cody, III, Mahmoud El-Tamer, Mary L Gemignani, Alexandra S Heerdt, Tracy-Ann Moo, Melissa Pilewskie, George Plitas, Lisa Scalfani, Kimberly J Van Zee and Monica Morrow. Memorial Sloan Kettering Cancer Center, New York, NY

**Background:** Four prospective multi-institutional trials have demonstrated that clinically node-positive patients (cN1) who receive neoadjuvant therapy (NAC) and convert to cN0 can be reliably staged with sentinel lymph node biopsy (SLNB) with false-negative rates (FNRs) of < 10%, when  $\geq 3$  SLNs are retrieved. Since study patients all had axillary lymph node dissection (ALND), the rate of axillary recurrence after SLNB alone is unknown. Of concern is the possibility that residual chemotherapy-resistant axillary disease could lead to higher recurrence rates than seen in the primary surgery setting for cN0 patients where SLN FNRs of 5-10% result in axillary recurrence in < 1% of cases. Here we report regional recurrence rates in a prospectively defined cohort of cN1 patients receiving NAC, followed by a negative SLNB using a standardized technique, and no further axillary surgery. **Methods:** From 06/2014 to 02/2019, patients with cT1-3 biopsy-proven cN1 breast cancer who received NAC and converted to cN0 by physical exam were prospectively managed with SLNB with dual tracer mapping and omission of ALND if  $\geq 3$  SLNs were pathologically negative. Nodes were not routinely clipped, and retrieval of clipped metastatic nodes was not required. Pathologically negative SLNs were defined as the absence of any metastases including isolated tumor cells. **Results:** Of 610 cN1 patients treated with NAC, 555 (91%) converted to cN0 and had SLNB; 234 (42%) had  $\geq 3$  negative SLNs and were treated with SLNB alone. Median patient age was 49 years and median tumor size at presentation was 3 cm; 61% were HER2+ and 18% triple negative. Most (91%) received doxorubicin-based NAC and 88% received adjuvant radiotherapy (RT), with 80% (n = 164) of RT patients receiving nodal RT (Table). At a median follow-up of 35 months, there was only 1 (0.4%) axillary recurrence for the entire cohort, synchronous with a breast recurrence, in a patient who refused RT. Among patients who received RT (n = 205), there were no axillary recurrences. The 4-year rate of distant recurrence for all patients was 6.1% (95% CI, 3.4-10.7%) and 4-year overall survival was 93.9% (95% CI, 87.6-97.1%). **Conclusion:** In cN1 patients treated with NAC, rates of axillary recurrence in patients with  $\geq 3$  pathologically negative SLNs treated with SLNB alone were low, without routine nodal clipping. Although further follow-up is needed, multiple studies have shown that nodal recurrence is an early event, particularly in HER2+ and triple negative patients, who comprised the majority of the population. Our findings support omitting ALND in cN1 patients after NAC when the SLNs are negative using an optimal SLNB technique.

Table. Patient Population

	Overall cohort (n = 234)

Phase 1/2 clinical trial of a topical submicron particle paclitaxel (SOR007) for the treatment of cutaneous metastases

Mario E Lacouture<sup>1</sup>, Julie E Lang<sup>2</sup>, Sant Chawla<sup>3</sup>, Shari Goldfarb<sup>1</sup>, Alina Markova<sup>1</sup>, Alexander Pan<sup>1</sup>, Rose Marie Cavanna-Mast<sup>4</sup>, Peter Mast<sup>4</sup>, Christopher Savoie<sup>4</sup> and Gere diZerega<sup>4</sup>. <sup>1</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>2</sup>USC/Norris Comprehensive Cancer Center, Los Angeles, CA; <sup>3</sup>Sarcoma Oncology Research Center, Santa Monica, CA; <sup>4</sup>US Biotest Inc., San Luis Obispo, CA

**Background:** Cutaneous Metastases (CM) are an infrequent presentation of advanced solid tumors and are usually associated with symptoms of pain, pruritus, and secondary infections, all of which negatively affect quality of life and result in additional morbidity. Systemic chemotherapy, advanced wound care, topical agents, cryo-, electro-, photodynamic-, laser and intralesional therapies have been limited by inconsistent efficacy, inconvenience, or toxicity. In this open-label phase 1/2 clinical trial, submicron particle paclitaxel in an anhydrous base (SOR007) was evaluated for topical treatment of CM from breast cancer (n=21), leiomyosarcoma (n=1) and Paget's disease (n=1). Previously, *in vitro*, *in vivo*, and clinical studies demonstrated penetration of paclitaxel into the dermis with the silicone-based anhydrous producing subtoxic plasma levels in GLP toxicology studies and early clinical trials.

**Trial Design:** The phase 1/2 open label trial evaluated 3 doses of SOR007 (0.15%, 1.0%, 2.0%). Approximately 0.5 grams (1 FTU) of SOR007 per 50 cm<sup>2</sup> treatment area was applied BID during a 3+3 dose-rising phase for 28 days (n=10) or a dose-expansion phase at 2% strength BID for 28 days (n=2) or 56 days (n=11) unless discontinuation became necessary due to clinical course of the underlying disease.

**Results:** At least one eligible lesion was treated per subject and classified per RECIST 1.1. In the 28-day application group, 10 subjects were treated and in the 56-day application group, 11 subjects were treated. Lesion response is summarized in the table below for data to date. Lesion response was evaluated within 2 weeks of last treatment day in most subjects.

**Conclusions:** SOR007 was safe when applied to CM lesions. SOR007 resulted in decreased lesion progression or reduced lesion area in the majority of CM subjects. These clinical benefits became more consistent and pronounced at 2% strength with longer treatment suggesting a dose/duration response. Lesion pain reduction is also suggested from the study. Additional clinical research with more subjects and longer treatment periods is in the early planning stage.

Lesion Response

	Lesion response by <b>SUBJECT</b>	Lesion response by <b>SUBJECT</b>	Lesion response by <b>INDIVIDUAL LESION</b>	Lesion response by <b>INDIVIDUAL LESION</b>
	Dose-rising 0.15%, 1%, 2% & Dose expansion 2% BID x 28 days	Dose-expansion 2% BID x 56 days	Dose-rising 0.15%, 1%, 2% & Dose expansion 2% BID x 28 days	Dose-expansion 2% BID x 56 days
N (subjects or lesions)	8	11	18	23
Complete Response	0% (0/8)	9.1% (1/11)	5.5% (1/18)	26% (6/23)
Objective Response Rate	13% (1/8)	45% (5/11)	17% (3/18)	43% (10/23)

Value of [<sup>18</sup>F]-FES-PET to solve clinical dilemmas in breast cancer patients: A retrospective study

Jorianne Boers, Naila Loudini, Celina L. Brunsch, Sylvia A. Koza, Erik F.J. de Vries, Andor W.J.M. Glaudemans, Geke A.P. Hospers and Carolina P. Schroder. University Medical Center Groningen, Groningen, Netherlands

**Introduction:** Breast cancer (BC) is a heterogeneous disease, in which estrogen receptor (ER) expression plays an important role in the majority of breast tumors. A clinical dilemma may arise when a metastasis biopsy to determine the ER status cannot be performed safely or when ER heterogeneity is suspected between tumor lesions. Whole-body ER imaging, such as 16α-[<sup>18</sup>F]-fluoro-17β-estradiol ([<sup>18</sup>F]-FES) positron emission tomography (PET), may have additional value in these situations. However, the role of this imaging technique in routine clinical practice remains to be further determined. Therefore, we assessed the value of [<sup>18</sup>F]-FES-PET in a large retrospective set of patients, by evaluating if the physicians' clinical dilemma that remained after standard workup was solved by the [<sup>18</sup>F]-FES-PET scan. **Methods:** In this single center study, [<sup>18</sup>F]-FES-PET scans, performed in patients with (suspected) ER+ metastatic BC with remaining clinical dilemma after standard workup (such as computed tomography, [<sup>18</sup>F]-fluorodeoxyglucose ([<sup>18</sup>F]-FDG)-PET, bone scintigraphy, magnetic resonance imaging, or biopsy), performed at the UMCG between November 2009 and January 2019, were included. A whole-body [<sup>18</sup>F]-FES-PET scan was performed 60 min after ~200 MBq of [<sup>18</sup>F]-FES was injected intravenously. ER antagonists had to be discontinued at least 5 weeks before [<sup>18</sup>F]-FES-PET. Primary endpoint was the percentage of cases in which the referring physician's clinical dilemma was solved based on the [<sup>18</sup>F]-FES-PET results. The dilemma was considered solved if 1) the [<sup>18</sup>F]-FES-PET provided a solution for the clinical dilemma (for example an extra metastatic site to biopsy), or 2) a treatment decision (to change or continue) was made based on the [<sup>18</sup>F]-FES-PET result. If the physician had doubts about the diagnosis after the [<sup>18</sup>F]-FES-PET examination, and additional workup was necessary for treatment decision-making, the dilemma was considered not solved. Secondary endpoints were type of clinical dilemma, and rate of [<sup>18</sup>F]-FES positive or negative PET scans (visual interpretation), related to frequency of solved dilemmas. **Results:** One hundred [<sup>18</sup>F]-FES-PET scans were performed in 83 patients. Clinical dilemma types were: 1) inability to determine extent of (suspected) metastatic disease with standard workup ( $n=52$ ), 2) unclear disease ER status ( $n=31$ ), and 3) inability to determine which primary tumor caused metastases ( $n=17$ ). Dilemmas were solved by [<sup>18</sup>F]-FES-PET in 87/100 cases (87%). In these 87 cases, treatment was changed in 52 cases, and continued in 35 cases. The frequency of solved dilemmas was not related to the type of clinical dilemma. In contrast, the frequency of solved dilemmas was related to whether scans were [<sup>18</sup>F]-FES positive or negative. Out of the 63 [<sup>18</sup>F]-FES positive scans, the clinical dilemma was solved in 61 cases (97%); in 26 out of the 37 [<sup>18</sup>F]-FES negative scans (70%) the dilemma was solved ( $p<0.001$ ). **Conclusion:** In this real life study of BC patients with a clinical dilemma after standard workup, we showed that [<sup>18</sup>F]-FES-PET solved the dilemma in the large majority of cases. Relevant treatment decisions were made based on the scan, particularly in ER+ disease. This indicates that the [<sup>18</sup>F]-FES-PET can be of value to solve clinical dilemmas in BC patients. Ultimately, this can support optimal treatment in these patients and potentially improve outcome. Prospective trials are currently ongoing to further assess this.

A phase 2 study of oral paclitaxel and encequidar (oPac+E) in the treatment of cutaneous angiosarcoma: The breast angiosarcoma subgroup

Vinod Ravi<sup>1</sup>, Michael Wagner<sup>2</sup>, Tom Wei-Wu Chen<sup>3</sup>, Herbert H Loong<sup>4</sup>, Robert Menzel<sup>5</sup>, Cheuh-Chuan Yen<sup>6</sup>, Glen Clack<sup>7</sup>, David Cutler<sup>7</sup>, Rudolf Kwan<sup>7</sup> and Wing-Kai Chan<sup>7</sup>. <sup>1</sup>University of Texas MD Anderson Cancer Centre, Houston, TX; <sup>2</sup>University of Washington/Fred Hutchinson Cancer Centre, Seattle, WA; <sup>3</sup>National Taiwan University Hospital, Taipei, Taiwan; <sup>4</sup>The Chinese University Hospital of Hong Kong, Hong Kong, Hong Kong; <sup>5</sup>Texas Oncology, Dallas, TX; <sup>6</sup>Taipei Veterans General Hospital, Taipei, Taiwan; <sup>7</sup>Athenex Inc., Buffalo, NY

**Background** Cutaneous angiosarcomas are highly aggressive malignant tumors with poor prognosis. Currently there is no FDA-approved treatment. oPac+E is a combination of oral paclitaxel and a novel oral P-glycoprotein inhibitor, Encequidar. **Materials and Methods:** This is a phase-2 study evaluating the activity, safety and tolerability of oPac 205mg/m<sup>2</sup> + E 12.9 mg once daily for 3 consecutive days weekly for patients with unresectable cutaneous angiosarcoma. Tumour response was evaluated every 6 weeks using RECIST and photography. **Results:** From Aug-2018 to May-2020, 7 of 26 enrolled patients (pts) had breast cutaneous angiosarcoma. All had previous breast cancer, mastectomy and radiotherapy and/or adjuvant chemotherapy, no prior taxane for angiosarcoma and no metastatic disease. Median age was 66 yrs (range 49-76). Best objective response rates were: complete response (CR) 43% (3/7 pts), partial response (PR) 14% (1/7 pts), stable disease (SD) 43% (3/7 pts), progressive disease (PD) 0%. Furthermore, 3 pts (43%) who had inoperable lesions were deemed operable after Oraxol treatment and received curative intent surgical resection. Median progression free survival (PFS) was 17 weeks. oPac+E was generally well tolerated. Grade-3 treatment related adverse events (AEs) occurred in 5 pts: diarrhea=1, fatigue=2, neutropenia =1, dyspnea=1, dehydration=1, pneumonitis=1. Grade-4 AE were neutropenia in 2 pts. Grade-2 paraesthesia=1. All pts fully recovered. Dose reductions were needed in 3 subjects. No patients discontinued treatment due to AEs. To date no patients died. **Conclusions:** oPac+E may provide an effective oral treatment for radiation-associated breast angiosarcoma, with a high clinical benefit rate (CR + PR+ SD=100%), durable response and enabled resection of unresectable tumors. It is generally well tolerated even in elderly patients; with low incidence of neuropathy. It may allow patients to avoid hospital IV chemotherapy visits and the option of home treatment.

**Background:** Ki67 values >10% 2-4 weeks (wks) after starting neoadjuvant ET (NET) indicates persistent cell proliferation, resistance to ET, and is associated with increased risk of recurrence. The ACOSOG Z1031 trial suggested that these tumors are also relatively chemotherapy (chemo) resistant with a low pathologic complete response (pCR) rate to NCT. The ALTERNATE trial (NCT01953588) is a randomized study of neoadjuvant anastrozole (ANA), fulvestrant (FUL), or ANA + FUL in postmenopausal patients (pt) with newly diagnosed clinical stage II or III ER+ (Allred score 6-8)/HER2- BC. Ki67 >10% at wk 4 or 12 after starting NET triggered triage to NCT of physician choice or weekly paclitaxel. Pts who refused protocol-directed therapy, were not candidates for NCT, or decided to undergo immediate surgery are being followed per protocol. Here we report the rates of pCR and residual cancer burden (RCB) following NCT for pts triaged to NCT due to Ki67 >10% at wk 4 or 12. **Results:** Of the 1,299 eligible pts randomized to receive ANA, FUL, or ANA + FUL, 286 (22%) had Ki67 >10% at wk 4 or 12. 168 of these 286 pts (58.7%) chose to switch to NCT, 32 went to surgery (11.2%), and 86 discontinued further protocol-directed therapy (30.1%). Among the 168 pts who underwent NCT, the presenting clinical T stages were cT2 (n=113; 67.26%), cT3 (n=47; 27.98%) and cT4 (n=8; 4.76%) and N stages were cN0 (n=82; 48.8%), cN1 (n=75; 44.6%), cN2/3 (n=9; 5.4%) and cNx (n=2; 1.2%). Central ER testing was performed on pre-treatment biopsies and confirmed ER Allred score 6-8 in 155 of 168 (92.2%) pts, with the rest being ER Allred score 4-5 (n=5; 3%), ER- (Allred score 0) (n=2; 1.2%), or not tested (n=6; 3.6%). Most (n=139; 82.7%) were ER+/PR+, while 17.3% (n=29) were ER+/PR-, and tumor grades were G1 (n=10; 6%), G2 (n=99; 58.9%), G3 (n=54; 32.1%), not reported (n=5; 3%). Baseline Ki67 levels prior to NET were >10% in 94% (n=158), ≤10% in 3% (n=5), and not done in 3% (n=5). NCT regimens administered included doxorubicin/cyclophosphamide (AC) followed by paclitaxel (T) (n=60; 35.71%); weekly paclitaxel (n=56; 33.33%), docetaxel/cyclophosphamide (TC) (n=33; 19.65%), other doxorubicin and/or taxane containing regimen (n=17; 10.12%), and cyclophosphamide/methotrexate/fluorouracil (CMF) (n=2; 1.19%). 35 (20.8%) pts did not complete planned course of NCT due to toxicity (n=27) or refusal (n=8). 154 NCT pts underwent surgery (mastectomy in 40.3%, and breast conserving surgery in 59.7%). The path ypT stages were Tis/0 (n=10; 6.5%), T1 (n=62; 40.3%), T2 (n=61; 39.6%), and T3/4 (n=21; 13.6%), and the ypN stages were N0 (n=66; 42.9%), N1 (n=57; 37%), N2/3 (n=30; 19.5%), and Nx (n=1; 0.6%). Among the 168 pts who started on NCT (intent to treat population), there were 8 pCRs (no invasive disease in the breast or lymph nodes) (4.8%; 95% CI: 2.1% to 9.2%). Residual Cancer Burden (RCB) categories include RCB 0 (n=8; 4.8%), RCB 1 (n=15; 8.9%), RCB 2 (n=82; 48.8%), RCB 3 (n=42; 25.0%), and not determined (n=21; 12.5%). Correlations of baseline pt and tumor characteristics with pathology response to NCT will also be presented. **Conclusion:** In pts with NET-resistant ER+/HER2- BC, salvage NCT is not likely to induce a complete or near complete response. More effective treatments are needed for this high-risk ER+/HER2- pt population. **Support:** U10CA180821, U10CA180882, U24CA196171, UG1CA189856, U10CA180868 (NRG); NCI BIQSFP, BCRF, Genentech, AstraZeneca. <https://acknowledgments.alliancefound.org>. Genetic profiling for circulating tumor cell clusters to unveil molecular drivers of metastasis

Qiang Zhang<sup>1</sup>, Lorenzo Gerrata<sup>2</sup>, Paolo D'Amico<sup>3</sup>, Andrew A. Davis<sup>1</sup>, Saya Liz Jacob<sup>1</sup>, Xinkun Wang<sup>2</sup>, Zhe Ji<sup>1</sup>, Zheng Cai<sup>4</sup>, Elena Vagia<sup>1</sup>, Wenan Qiang<sup>1</sup>, Ami Shah<sup>1</sup>, Youbin Zhang<sup>1</sup>, Lisa Flaum<sup>1</sup>, Firas Wehbe<sup>1</sup>, Amir Behdad<sup>1</sup>, William Gradishar<sup>1</sup>, Leonidas Platani<sup>1</sup> and Massimo Cristofanilli<sup>1</sup>.  
<sup>1</sup>Northwestern University, Lurie Cancer Center, Chicago, IL; <sup>2</sup>Northwestern University, Chicago, IL; <sup>3</sup>Northwestern University, Istituto Europeo di Oncologia - IEO, Milan, Italy, Chicago, IL; <sup>4</sup>University of Washington, Seattle, WA

**Introduction:** Although CTCs display the same spatial and temporal heterogeneity as the primary tumor, they represent a privileged window to disclose mechanisms of metastases. A portion of CTCs may form clusters that contain two or more CTCs bound together which were reported to have up to 50-fold of potential of forming distant metastasis in MBC as compared to individual CTCs (Aceto N. Cell, 2015). However, genomic characterization of CTCs-clusters compared to single CTCs remain largely unknown. We previously reported single CTC sequencing for HER2<sup>+</sup> CTCs (2020 AACR #3120). Herein, we report a new finding of heterogeneity profiling for CTC-clusters compared to single CTCs, which would be helpful to evaluate the MBC metastasis capability and treatment in clinic. **Methods:** Whole blood sample (7.5ml/each) was collected from stage III/IV MBC patients before therapy. CTC enumeration was performed using the FDA-cleared CellSearch<sup>TM</sup> System (Menarini) targeting the EpCAM antigen for capturing CTCs which were then stained by Anti-CK-PE, DAPI, anti-CD45-APC and anti-HER2-FITC. The CTC-clusters and single CTCs were isolated using DEPArray<sup>TM</sup> System (Menarini). DNA was isolated from CTC-clusters and single CTCs by Arcturus<sup>TM</sup> PicoPure<sup>TM</sup> DNA Extraction kit. The initial library was prepared by SMARTer<sup>®</sup> PicoPLEX<sup>®</sup> Gold Single Cell DNA-Seq Kit, and the exome capture was performed by Twist Human Core Exome EF Multiplex Complete Kit. The sequencing was prepared by NextSeq 500 mid output V2.5 kit and was performed on the NextSeq 500 (Illumina). It was a paired end run, 75×75 bps run with dual indexing. **Results:** We identified 107 CTCs by CellSearch<sup>TM</sup>, including 93 single CTCs, 14 CTC-clusters and 145 WBCs. Autologous CTC-clusters (CK<sup>+</sup>DAPI<sup>+</sup>CD45<sup>-</sup>, Group 1), single CTCs (CK<sup>+</sup>DAPI<sup>+</sup>CD45<sup>-</sup>, Group 2), and leukocytes (CK<sup>-</sup>DAPI<sup>+</sup>CD45<sup>+</sup>, Group 3) were sequenced respectively. The sequencing data was processed following the GATK pipeline and annotated using SnpEff. There were 60,638 counts (6.77%) and 70,334 counts (8.20%) for exon variants in CTC-clusters and single CTCs respectively, 507,595 counts (56.69%) and 486,119 counts (56.69%) for intron variants, 194,026 (21.67%) and 175,819 counts (20.51%) for intergenic variants, 54,174 counts (6.05%) and 50,370 counts (5.87%) for downstream genes, 51,716 counts (5.78%) and 45,915 counts (5.36%) for upstream genes, and 3.04% and 3.37% of others variants in CTC-clusters and single CTCs respectively. Meanwhile, there was 0 count for exon and intron variants found in Group 3. There were 60 and 79 gene variants (SNP and Ins-Del) identified to have the highest impact effect (≥20) on CTC-clusters and single CTC exons respectively, which affect significantly on the functional proteins coding. Among the top 50 high impact gene variants in each group, there were 25 gene alteration sites were similar in Group 1 and 2, including *XYLB*, *RAN*, *QPCT*, *HPGDS*, *HDAC8*, *GABBR2*, *CYP11B2* and *CHKA*. Specific to Group 1, there were 25 gene alterations which were primarily related to cellular proliferation and tumor promotion (*AMD1*), liver drug clearance (*CES1*), tissue remodeling (*CHI3L1*), immune cytokine signaling (*JAK1*) and metabolism (*ASRGL1*). Meanwhile, there are 25 specific gene alterations in Group 2 compared to Group 1, which were associated with nucleotide-excision repair (*DDB1* and *FAN1*) chromosome positioning (*KIF11*), cell growth, differentiation, mitotic cycle, oncogenic transformation (*PTPN3* and *MAPK14*), apoptosis (*CASP1*) and cell growth (*CTNNB1*). **Conclusion:** Genomic characterization of CTC-clusters compared to autologous single CTCs and leukocytes elucidated new specific gene alterations in CTC-clusters associated with most aggressive disease metastasis in MBC, which will help to gain new insights on the molecular mechanisms associated with the metastasis and find new molecularly driven therapies for disease metastasis.

Publication Number: PD6-05

Subtype-specific MRI models to guide selection of candidates for de-escalation of neoadjuvant therapy

Wen Li<sup>1</sup>, David C Newitt<sup>1</sup>, Jessica Gibbs<sup>1</sup>, Lisa J Wilmes<sup>1</sup>, Ella F Jones<sup>1</sup>, Natsuko Onishi<sup>1</sup>, Bonnie N Joe<sup>1</sup>, Elissa Price<sup>1</sup>, John Kornak<sup>1</sup>, Christina Yau<sup>1</sup>, Denise M Wolf<sup>1</sup>, Barbara LeStage<sup>2</sup>, Susan Samson<sup>2</sup>, the I-SPY 2 Imaging Working Group, the I-SPY 2 Consortium, Laura J Esserman<sup>1</sup> and Nola M Hylton<sup>1</sup>. <sup>1</sup>UCSF, San Francisco, CA; <sup>2</sup>I-SPY 2 Advocacy Group, San Francisco, CA

**Background:** MRI measured functional tumor volume (FTV) can predict pathologic complete response (pCR) to neoadjuvant chemotherapy (NAC) as early as 3 weeks after treatment initiation (1), indicating the potential of using MRI to guide treatment de-escalation. We developed MRI based, subtype-specific models for predicting pCR, to be used as part of a de-escalation strategy combining MRI and inter-regimen core biopsy pathology in I-SPY 2. **Methods:** I-SPY 2 patients underwent MRI exams at pre-treatment, early treatment (3 wks), inter-regimen (12 wks), and pre-surgery. pCR was assessed at surgery. FTV was calculated semi-automatically for every MRI (2). Subtype-specific FTV-based MRI prediction models were trained using FTV measurements at baseline, early treatment and inter-regimen timepoints for patients enrolled in I-SPY 2 between May 2010 and November 2016. Breast cancer subtype was defined by hormone receptor (HR) and human epidermal growth factor receptor 2 (HER2) status. The MRI prediction model was then used to predict probability of achieving pCR for each patient at inter-regimen, based on their subtype. The therapy de-escalation strategy focuses on achieving high positive predictive value (PPV, correct identification of patients with pCR) while maximizing sensitivity (proportion of patients with pCR identified by the test). Predicted probability above a specified threshold was considered a positive test for pCR. This study investigated the tradeoff between PPV and sensitivity within subtype groups defined by HR and HER2, and held to constraints set by probability thresholds at the 1<sup>st</sup>, 2<sup>nd</sup> (median) and 3<sup>rd</sup> quartile. **Results:** A total of 814 patients were included in the analysis. Median age was 49 (range: 24 - 77) years. The pCR rate was 36% (289/814). Table 1 shows patient number and pCR rate by HR/HER2 subtype. The subtype-specific MRI models consist of the predictors: change of FTV (dFTV) at inter-regimen for HR+/HER2- and HR-/HER2+; dFTV at early treatment for HR+/HER2+; pre-treatment FTV and dFTV at inter-regimen for triple negatives. The highest probability varied by subtype: 0.24 for HR+/HER2-, 0.61 for HR+/HER2+, 0.73 for HR-/HER2+, 0.68 for triple negatives. The maximum PPV was 67% for HR+/HER2- and 100% for all other subtypes. Table 1 shows the tradeoff between PPV and sensitivity by subtype using the 1<sup>st</sup>, median, and 3<sup>rd</sup> quartile thresholds.

**Conclusions:** Our data demonstrate that PPV and sensitivity vary by breast cancer subtype when the probability threshold generated by MRI model increases from low to high quartile. Results from this study suggest that the probability threshold for recommending treatment de-escalation should be selected carefully based on breast cancer subtype. Imaging results will be combined with core biopsy information obtained at the 12-week timepoint to further improve overall accuracy.

Table 1 Tradeoff between positive predictive value (PPV) and sensitivity at different levels of PPV

Cohort	N	pCR rate	Probability threshold		PPV (%)	Sensitivity (%)
HR+/HER2-	328	20% (64/328)	1 <sup>st</sup> quartile	0.18	24	91

Serum thymidine kinase activity in patients with luminal metastatic breast cancer treated with palbociclib and fulvestrant within the PYTHIA trial

Luca Malorni, Svitlana Tyekucheva, Florentine S Hilbers, Michail Ignatiadis, Patrick Neven, Marco Colleoni, Stephanie Henry, Alberto Ballestrero, Andrea Bonetti, Guy Jerusalem, Konstantinos Papadimitriou, Antonio Bernardo, Francois Duhoux, Iain MacPherson, Alastair Thomson, David Mark Davies, Mattias Bergqvist, Matteo Benelli, Amelia McCartney, Heidi De Swert, Barbara Ruepp, Manuela Rabaglio, Rudolf Maibach, Martine Piccart and Meredith M Regan. PYTHIA collaborators, International Breast Cancer Study Group and Breast International Group, Bern, Switzerland

**Background:** The CDK4/6 inhibitor palbociclib (P) plus fulvestrant (F) is approved for the treatment of patients (pts) with luminal metastatic breast cancer (MBC) progressed on prior endocrine therapy (ET). Despite clinical activity, a significant proportion of pts in this setting show primary resistance to P+F, with treatment failure within 3-6 months of initiation. To date there is no validated biomarker to identify such pts. Thymidine kinase 1 is a cancer proliferation marker downstream of the CDK4/6 pathway, whose activity can be measured in serum as a readout of tumour proliferation. Circulating thymidine kinase activity (TKa) is a potential prognostic and monitoring marker in pts treated with ET alone or in combination with P for MBC. However, the prognostic value of early changes in TKa during P+F treatment and its role in identifying pts with primary resistance are not yet defined. Here we prospectively investigated the role of serum TKa measured at different timepoints in pts treated with P+F within the PYTHIA trial (IBCSG 53-14/BIG 14-04; NCT02536742), a downstream trial of the AURORA platform (BIG 14-01; NCT02102165).

**Methods:** PYTHIA is a biomarker discovery phase II trial including pts (Aug '16 to Jun '19) with ET-resistant luminal MBC who received P+F at standard schedule and dose with 3-monthly imaging. Serum samples were collected at baseline (D0; n=122), on-treatment at day 11-16 of cycle 1 (D15; n=108), and during the one week off P before initiating cycle 2 (D28: Day 24-37 of Cycle 1; n=108). TKa was measured with DiviTum®, a refined ELISA-based assay. Complete TKa response (CTR) was defined as TKa below the limit of detection (LOD; 20 Du/L) at D15. Cox models evaluated association of log-transformed TKa measurements with progression-free survival (PFS; from initiation of therapy until progression by RECIST criteria or death). Kaplan-Meier method estimated median, 3 and 6 months (95% CI) PFS in groups of patients defined by dichotomizing TKa as "high" or "low" at the median or by CTR. A sample size of 120 provided 80% power to detect a hazard ratio of 2.0 for biomarker with 30-50% prevalence (two-sided  $\alpha=0.05$ ) after  $\geq 80$  events.

**Results:** A total of 122 pts were enrolled. About half had received one prior line of ET for MBC, and 18% had received one prior line of chemotherapy. 48% had visceral metastases and 31% had bone-only disease. TKa at D0 was not associated with clinical characteristics. Median TKa (mTKa) at D0 was 87 Du/L. Overall, 82 pts experienced progression, with a median PFS (mPFS) of 11 months (95% CI: 8.6 - 16). P+F dramatically suppressed mTKa levels at D15, with 90/108 (83%) pts achieving CTR. At D28, TKa showed some rebound in most pts. At each timepoint, higher TKa was significantly and consistently associated with shorter PFS (each  $p<0.001$ ). The effect of TKa on PFS remained statistically significant after adjusting for clinical variables. At 6 months, the largest difference between PFS probabilities was observed between patients with CTR versus no CTR at D15.

**Conclusions:** TKa is an independent prognostic biomarker in pts treated with P+F. High baseline TKa and incomplete suppression of TKa during treatment may identify pts with poor prognosis and primary resistance to P+F. TKa may represent a novel biomarker to select pts for alternative treatment modalities. These results warrant further investigation in prospective comparative trials.

	Timepoint		
	Baseline (D0)	D15 <sup>1</sup>	D28
<b>TK median value (Du/L) (range)</b>	87 (<20 - 14,510)	<20 (<20 - 7,060)	52 (<20 - 3,533)

Latest findings from the breast cancer cohort in SUMMIT - a phase 2 'basket' trial of neratinib + trastuzumab + fulvestrant for *HER2*-mutant, hormone receptor-positive, metastatic breast cancer

Komal Jhaveri<sup>1</sup>, Cristina Saura<sup>2</sup>, Angel Guerrero-Zotano<sup>3</sup>, Iben Spanggaard<sup>4</sup>, Francois-Clement Bidard<sup>5</sup>, Jonathan W Goldman<sup>6</sup>, Jose A Garcia-Saenz<sup>7</sup>, Andres Cervantes<sup>8</sup>, Valentina Boni<sup>9</sup>, John Crown<sup>10</sup>, Adam Brufsky<sup>11</sup>, Sherene Loi<sup>12</sup>, Barbara Haley<sup>13</sup>, Ingrid A Mayer<sup>14</sup>, Stephen Chia<sup>15</sup>, Janice Lu<sup>16</sup>, James Waisman<sup>17</sup>, Noa Efrat Ben-Baruch<sup>18</sup>, Mark E Burkard<sup>19</sup>, Jennifer M Suga<sup>20</sup>, Lucia Gonzalez-Cortijo<sup>21</sup>, Bruno Perrucci<sup>22</sup>, Feng Xu<sup>23</sup>, Sofia Wong<sup>23</sup>, Jie Zhang<sup>23</sup>, Lisa D Eli<sup>23</sup>, Alshad S Lalani<sup>23</sup> and Hans Wildiers<sup>24</sup>. <sup>1</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>2</sup>Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology, Barcelona, Spain <sup>3</sup>Fundacion Instituto Valenciano de Oncologia, Valencia, Spain <sup>4</sup>Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark <sup>5</sup>Institut Curie, St Cloud, France <sup>6</sup>UCLA, Santa Monica, CA; <sup>7</sup>Hospital Clinico San Carlos, Madrid, Spain <sup>8</sup>Hospital Clinico Universitario, University of Valencia, Valencia, Spain <sup>9</sup>START Madrid-CIOCC, Hospital Universitario, Madrid Sanchinarro, Madrid, Spain <sup>10</sup>St. Vincent's University Hospital, Dublin, Ireland <sup>11</sup>Magee-Womens Hospital of UPMC, Pittsburgh, PA; <sup>12</sup>Peter MacCallum Cancer Centre, Melbourne, Australia <sup>13</sup>UT Southwestern Medical Center, Dallas, TX; <sup>14</sup>Vanderbilt University Medical Center/Vanderbilt-Ingram Cancer Center, Nashville, TN; <sup>15</sup>British Columbia Cancer Agency, University of British Columbia, Vancouver, BC, Canada <sup>16</sup>USC Norris Comprehensive Cancer Center, Los Angeles, CA; <sup>17</sup>City of Hope Comprehensive Cancer Center, Duarte, CA; <sup>18</sup>Kaplan Medical Center, Rehovot, Israel <sup>19</sup>University of Wisconsin School of Medicine and Public Health, Madison, WI; <sup>20</sup>Kaiser Permanente Cancer Research Center, Vallejo, CA; <sup>21</sup>Hospital Universitario Quironsalud, Madrid, Spain <sup>22</sup>ASST Cremona, Cremona, Italy <sup>23</sup>Puma Biotechnology Inc., South San Francisco, CA; <sup>24</sup>University Hospitals Leuven, Leuven, Belgium

**Background:** *HER2* mutations are oncogenic in hormone receptor positive (HR+) metastatic breast cancer (MBC), and may confer resistance to prior endocrine therapy but retain sensitivity to neratinib. Neratinib is an oral, irreversible, pan-HER tyrosine kinase inhibitor with clinical activity either as a single agent or in combination with fulvestrant in *HER2*-mutated, *HER2*-non-amplified MBC. Genomic analyses suggest that acquired resistance to neratinib can occur via additional *HER2* alterations, which may alter *HER2*-pathway signaling. We investigated whether dual *HER2*-targeted therapy could improve clinical benefit in a cohort of patients with *HER2*-mutant, HR+ MBC treated with neratinib + trastuzumab + fulvestrant (N+T+F) from SUMMIT - a phase 2 basket trial (NCT01953926).

**Methods:** Patients with HR+ MBC with known or suspected pathogenic *HER2* mutation(s) identified by genomic sequencing were eligible to receive N+T+F (oral neratinib 240 mg/day, i.v. trastuzumab 8 mg/kg initially followed by 6 mg/kg every 3 weeks, and i.m. fulvestrant 500 mg on days 1&15 of month 1, then on day 1 every 4 weeks). Loperamide prophylaxis was mandatory during the first 2 treatment cycles. There was no restriction on the number of prior lines of systemic treatment for MBC. Efficacy endpoints: confirmed objective response rate and clinical benefit rate (RECIST v1.1); duration of response; progression-free survival.

**Results:** As of 22-May-2020, 46 patients were enrolled in the N+T+F cohort and received at least 1 dose of study medication (safety population). 14 unique *HER2* allelic variants were identified: 8 kinase domain missense; 1 extracellular domain missense; 2 transmembrane domain missense; 2 exon-20 insertion; 1 exon-19 deletion. The most common *HER2* mutant variant was L755S (n=15, 33%) Median number of prior systemic regimens for metastatic disease was 4 (range 0-10); 34 (74%) patients had received prior fulvestrant, and 31 (67%) patients had received prior cyclin-dependent kinase 4 and 6 (CDK4/6) inhibitor therapy. 16 (35%) patients had ductal histology, 29 (63%) had lobular carcinoma, and 1 (2%) had mixed ductal and lobular carcinoma. At this time, 30/46 patients had RECIST measurable disease and are efficacy evaluable (ongoing patients who did not have the opportunity for their first post-baseline tumor assessment were excluded); clinical activity - see Table. Diarrhea was the most commonly reported adverse event (80% any grade) with 15 (33%) patients reporting grade 3 diarrhea (no grade 4 diarrhea). 10 patients (22%) had a neratinib dose reduction due to diarrhea but no patients discontinued treatment due to diarrhea.

	RECIST measurable and efficacy evaluable patients (n=30)
Confirmed objective response, <sup>a</sup> n (%)	12 (40)
CR	0
PR	12
ORR, % (95% CI)	40 (23-59)
Best overall response, n (%)	18 (60)
CR	0
PR	18
Best overall response rate, % (95% CI)	60 (41-77)
Median <sup>b</sup> DOR, months (95% CI)	8.4 (4.1-NE)
Clinical benefit, <sup>c</sup> n (%)	14 (47)
CR or PR	12
SD ≥24 weeks	2
CBR, % (95% CI)	47 (28-66)
Median <sup>b</sup> PFS, months (95% CI)	8.3 (4.2-12.5)
<sup>a</sup> ORR is defined as either a CR or a PR that is confirmed no less than 4 weeks after the criteria for response are initially met; <sup>b</sup> Kaplan-Meier analysis; <sup>c</sup> CBR is defined as confirmed CR or PR or SD for ≥24 weeks; CR, complete response; CBR, clinical benefit rate; DOR, duration of response; NE, not estimable; ORR, objective response rate; PFS, progression-free survival; PR, partial response; SD, stable disease.	

**Conclusions:** The combination of N+T+F demonstrated encouraging clinical activity in heavily pre-treated *HER2*-mutant, HR+, *HER2*-non-amplified MBC, including patients who had previously received either fulvestrant and/or CDK4/6 inhibitor-based therapies. While the rate of grade 3 diarrhea was higher than that observed with single-agent neratinib in SUMMIT, this was manageable through loperamide prophylaxis, and no patients discontinued study treatment due to diarrhea. SUMMIT has recently been amended to evaluate N+T+F, T+F and F (1:1:1 randomization) and continues to enroll patients.

Concordance between patient-reported and physician-documented comorbidities among stage 4 breast cancer patients

Saumya Umashankar, Michelle E. Melisko, Madeline Matthys, Laura Van't Veer and Amrita Basu. University of California, San Francisco, San Francisco, CA

**Background**

Comorbidities in metastatic breast cancer patients (pts) impact treatment decisions, eligibility for clinical trials, and influence prognosis and quality of life (QoL). The aim of this study was to evaluate the concordance between pt-reported and physician-documented (PD) comorbidities in an electronic medical record to (1) reliably document pts' health histories to establish eligibility for clinical trials and novel therapeutics, and, (2) identify comorbidities that may be more comprehensively reported by pts rather than physicians.

**Patients and Methods**

All new pts at UCSF's Breast Care Center (BCC) are administered an electronic intake survey that includes an assessment of pt-reported health history, comorbidities and symptoms. Between November 2016 and March 2020, 305 pts self-reported metastatic breast cancer (described as "breast cancer spread to sites other than breast or axillary lymph nodes"), and 222 consented to use of their clinical data for research. Chart-reviews were conducted for PD comorbidities at their initial BCC clinic visit. Pt and physician concordance was summarized for 54 comorbidities. Cohen's kappa ( $\kappa$ ) was used to quantify level of agreement. Concordance was classified using Landis and Koch thresholds with agreement as poor or slight ( $\kappa < 0.20$ ), fair ( $\kappa \geq 0.20$  to  $< 0.40$ ), moderate ( $\kappa \geq 0.40$  to  $< 0.60$ ), substantial ( $\kappa \geq 0.60$  to  $< 0.80$ ), or almost perfect ( $\kappa \geq 0.80$ ).

**Results**

Of the 222 pts, 37 pts (17%) incorrectly reported having metastatic breast cancer, 4 (2%) had duplicate surveys, 7 (3%) cancelled appointment and 5 (2%) had metastatic cancer from another primary. Thus, 168 pts with confirmed metastatic disease were included in the analysis (median age, 56 years; age range, 29-86 years; median time from diagnosis of metastatic breast cancer, 0.46 years). Highest PD comorbidities were obesity, hypertension (HTN) and thyroid disease, while highest reported comorbidities by pts were HTN, depression and arthritis. 23 of 54 comorbidities had a moderate to high level of agreement between physician and pt reports ( $\kappa \geq 0.40$ ). As shown in Table 1, agreement was high for diabetes (type 1 or 2), HTN and thyroid disease, moderate for asthma/bronchitis and depression, and low for obesity, anxiety, stomach ulcers/gastroesophageal reflux disease (GERD) and arthritis.

Table 1: Concordance between physician-documented and patient-reported comorbidities

Comorbidity	Physician Reported	Patient Reported	Concordance	$\kappa$
Diabetes	6%	5%	98%	0.83
Hypertension	24%	20%	93%	0.79
Thyroid Disease	20%	18%	92%	0.74
Insulin dependent Diabetes	1%	1%	99%	0.66
Depression	11%	20%	87%	0.51
Asthma/bronchitis	12%	15%	89%	0.51
Stomach ulcers/ GERD	11%	18%	84%	0.36
Obesity	34%	15%	75%	0.36
Heart disease/heart valve disease	7%	4%	93%	0.32
Anxiety	10%	18%	83%	0.30
Non-insulin dependent diabetes	3%	1%	97%	0.27
Arthritis	9%	20%	78%	0.14

**Conclusion**

In this review of data collected as part of routine care at an academic medical center, rates of comorbidities were relatively low, and there is substantial variance in the concordance of comorbidity reporting between pt and physicians. Pt-reported comorbidity data may help physicians more comprehensively document conditions such as depression, anxiety, arthritis and stomach ulcers/GERD, which in some cases may be subjective in nature but may significantly impact a pt's quality of life and performance status. However, pts may underreport conditions such as obesity and heart disease, and inaccurately report other conditions such as non-insulin dependent diabetes. Recognition of depression, anxiety and GERD as comorbidities is important since some medications for these conditions may be contraindicated in some clinical trials.

Understanding this concordance data may inform how we collect pt reported data to optimize understanding of a pt's global health condition.

Trends in breast-conserving surgery in Mexico after the implementation of a public health insurance system

Enrique Bargallo-Rocha, Nancy Reynoso-Noveron, Jaime Corona, Nereida Esparza-Arias, Maria Teresa Ramirez-Ugalde, Carlos Daniel Robles-Vidal, Robin Shaw-Dulin, Armen Stankov, Rafael Vazquez-Romo, Patricia Villarreal-Colin, Sergio Aguilar-Villanueva, Jaime Hidalgo-Bahena, Milagros Perez-Quintanilla, Fernando U Lara-Medina, Juan Alejandro Torres, Enrique Soto-Perez-de-Celis, Paula Cabrera-Galeana, Alejandro Mohar and Abelardo Meneses-Garcia. Instituto Nacional de Cancerologia, Mexico City, Mexico

**Introduction** Although temporal trends in breast conserving surgery (BCS) have been described for developed countries like the United States (US), there is a lack of information regarding the uptake of breast conservation in developing regions of the world. In developing countries, the implementation of breast conservation might be hindered by the availability of radiation therapy, lack of training among surgeons, or concerns regarding compliance with follow-up care and surveillance. In 2006, the Mexican government created *Seguro Popular*, which provided coverage for breast cancer care for all Mexican women, thus potentially mitigating the difficulties with obtaining care after BCS and improving access to multidisciplinary care. We undertook an overview of ten years of breast cancer surgery at our Mexican cancer center following the implementation of *Seguro Popular*, and explored changes in surgical technique over time. **Methods** A retrospective cohort analysis was conducted using the National Cancer Institute of Mexico (INCAN) database from 2006 to 2016. All patients with a diagnosis of breast cancer seen during that period were included. Patients who received surgery for breast cancer were then grouped together based on the type of surgery (mastectomy versus BCS). The effect of the year of diagnosis and of clinical stage at the time of presentation was evaluated. Logistic regression was used to model temporal trends in use of BCS over mastectomy for three 3-year periods (2006-2009, 2010-2012, and 2013-2016). **Results** The patient cohort consisted of 5289 women from the INCAN database, of which 4519 received some form of local surgical treatment. Sixty-one percent ( $n = 2764$ ) had locally advanced disease (stages IIB-IIIC) at the time of presentation, and a quarter ( $n = 1156$ ) had  $\geq 60$  days between diagnosis and receipt of surgical treatment. Eighty percent of the patients in the entire cohort ( $n = 3611$ ) were treated with mastectomy, while 20% ( $n = 908$ ) received BCS. For the 2006-2009 period, out of 1596 total surgeries, 9.9% were BCS ( $n = 158$ ). The proportion of BCS increased for each of the other two studied periods, being 18.5% for the 2010-2012 period ( $n = 276/1490$ ), and 33.1% for the 2013-2016 period ( $n = 474/1433$ ) ( $p < 0.01$  for trend). While the increase in BCS was significant for all stages, it was most pronounced for women with early-stage disease (Stages I-IIA), going from 17% in 2006-2009 to 52% in 2013-2016 ( $p < 0.01$ ), than in those with locally-advanced disease (6.5 to 18%,  $p < 0.01$ ). **Conclusions** In the ten years after the start of the *Seguro Popular* public insurance program, the proportion of BCS at a Mexican cancer center increased significantly, particularly for women with early-stage disease. The rates seen at INCAN for the period between 2013-2016 resemble those reported by the US National Cancer Database, in which approximately 61% of women with stage I-II breast cancer and 20% of women with stage III disease receive BCS. Potential reasons for the increase in the uptake of BCS include improved access to adjuvant radiation therapy, improved access to systemic treatment, and higher adherence to follow-up care after the start of *Seguro Popular*, as well as improvements in surgical training. In addition, changes in BCS may also be related to improvements in the implementation of multidisciplinary teams over time, which may lead to a more homogeneous and comprehensive care. Our results show that improving access to care for patients living in developing countries positively impacts the uptake of BCS for women with breast cancer.

Hypofractionated volumetric modulated arc therapy for breast cancer: A propensity-score-weighted comparison of radiation-related toxicity according to fractionation and modality

Nalee Kim, Jee Suk Chang, Ki Chang Keum, Chang-Ok Suh, Hyejung Shin and Yong Bae Kim. Yonsei Cancer Center, Seoul, Korea, Republic of

**Background:** Recent trials support a shorter, hypofractionated regimen (HF-RT) for breast cancer. Based on START-B trial, 3-week schedules of hypofractionated-RT (HF, 40 Gy/15 fractions) has been adopted as the one of standard of cares. We studied the clinical benefit of combining volumetric modulated arc therapy (VMAT) and HF-RT in the incidence of radiation-related toxicities. **Methods:** We retrospectively reviewed 4209 patients treated with three-dimensional conventional fractionation (CF-3D, mostly 50.4 Gy/28 fractions) and 1540 patients treated with HF-RT (768 received HF-3D and 772 received HF-VMAT, mostly 40 Gy/15 fractions) between 2005 and 2017 at a tertiary academic center. A total of 2229 patients (38.8%) received regional node irradiation (RNI): 1642 (39.0%), 167 (21.7%), and 420 (54.4%) patients received RNI in the CF-3D, HF-3D, and HF-VMAT, respectively. VMAT was used to HF patients either to minimize cardiac dose in regional RT for unfavorable/challenging cardio-thoracic anatomy (n = 420) or to shorten the treatment time by using 3.2 Gy of simultaneous integrated boost (SIB) in 15 fractions for breast conservation (n = 352). Physician-reported events during/within 3 months after RT were defined as acute/subacute toxicity. Late toxicities included radiation pneumonitis, lymphedema, hypothyroidism, and cardiotoxicity. Propensity scores were calculated via logistic regression then inverse probability of treatment weighting analysis was performed for pairwise comparison. **Result:** The rate of grade 2+ acute/subacute toxicities were the highest in patients treated with CF-3D (15.0%, 2.6%, and 1.6% in patients treated with CF-3D, HF-3D, and HF-VMAT, respectively;  $p < 0.001$ ). HF-VMAT significantly reduced grade 2+ acute/subacute toxicities compared to CF-3D (odds ratio [OR] 0.11,  $p < 0.001$ ) and HF-3D (OR 0.45,  $p = 0.010$ ). The 3-year cumulative rate of late toxicities was 18.0% (20.1%, 10.9%, and 13.4% in patients treated with CF-3D, HF-3D, and HF-VMAT, respectively;  $p < 0.001$ ). The sensitivity analysis showed that the benefit of HF-VMAT was greater in the regional RT group. The local recurrence rate did not differ among the groups ( $p > 0.05$ ). **Conclusion:** HF was associated with decreased toxicities than CF in this real-world inverse probability of treatment weighting analysis cohort. HF-VMAT further decreased acute and late toxicity than HF-3D or CF-3D, especially in women underwent RNI, although prospective long-term follow-up is needed. The shortening of overall treatment time by SIB-VMAT in HF may be of value.

Table. Pairwise comparisons of outcomes by treatment group after propensity score weighting

Outcome	CF-3D vs. HF-3D (reference: CF-3D)		CF-3D vs. HF-VMAT (reference: CF-3D)		HF-3D vs. HF-VMAT (reference: HF-3D)	
	OR (95% CI)	P	OR (95% CI)	P	OR (95% CI)	P
Acute or subacute toxicity with any grade $\geq 2$	0.20 (0.15-0.27)	<.0001	0.11 (0.08-0.17)	<.0001	0.45 (0.24- 0.83)	0.0101
	HR (95% CI)	P	HR (95% CI)	P	HR (95% CI)	P
Late toxicity	0.79 (0.69-0.90)	0.0006	0.58 (0.50-0.68)	<.0001	0.79 (0.60-1.03)	0.0838
Radiation pneumonitis	1.54 (1.16-2.04)	0.0029	0.27 (0.15-0.48)	<.0001	0.14 (0.06-0.29)	<.0001

**Background:** Triple negative breast cancers (TNBC) are more aggressive, have a worse prognosis, and few targeted therapies compared to other BC subtypes. TNBC is molecularly heterogeneous, with at least 4 distinct subtypes: basal-like immune-activated (BLIA), basal-like immunosuppressed (BLIS), luminal androgen receptor (LAR), and mesenchymal (MES). The molecular subtyping gene signature, BluePrint (BP), classifies breast tumors into Luminal, HER2, or Basal subtype based on the assessment of downstream signaling pathways and independently of IHC expression. Compared to IHC-defined TNBC, a higher frequency of BLIS or BLIA subtypes and fewer LAR or MES tumors were reported in BP-defined Basal tumors. To advance our understanding of TNBC heterogeneity, we evaluated the relationship between gene expression signatures, TNBC subtype and BluePrint, in IHC-defined TNBC.

**Methods:** The FLEX registry (NCT03053193) is an ongoing, prospective study evaluating primary tumors from stage I-III BC patients who receive the risk of distant recurrence gene signature, MammaPrint (MP), and BP testing and consent to clinically annotated full transcriptome data collection. This analysis includes 204 IHC-defined TNBC patients. TNBC subtypes BLIA, BLIS, LAR, and MES were derived using an adjusted version of the Burstein centroid signature. BP classified patient samples into Luminal, HER2, and Basal subtypes. A proportion of tumors may exhibit a secondary but less pronounced activated pathway or BP subtype. Therefore, each BP subtype was divided into single activated or mixed subtype based on BP indices.

**Results:** Of 204 TNBC tumors, 84% were classified as Basal by BP, most of which were BLIS (65%), followed by BLIA (22%), with a low frequency of MES (8%) and LAR (5%) subtypes (Table). Approximately 14% of TNBCs were reclassified as Luminal by BP, most of which were LAR (76%), whereas 24% were MES. Clustering analysis revealed similar gene expression profiles between Basal-BLIS and Basal-BLIA tumors. Interestingly, the transcriptional profile of Basal-MES and Basal-LAR tumors were similar to Luminal-MES and Luminal-LAR tumors. BP Basal indices distinguished between different TNBC subtypes. The Basal pathway was predominantly activated in 90% of BP Basals (single activated tumors), most of which were either BLIS or BLIA (96%), whereas 10% of BP Basals were mixed subtype and more likely to classify as LAR (53%) or MES (35%). Approximately 25% of the BP Basal gene signature overlapped with the TNBC subtype gene signature. Expression of 18 and 12 genes out of 28 genes that make up the BP basal signature were significantly different in Basal-BLIA/BLIS compared to LAR or MES, respectively ( $P < 0.05$ ). *PRR15* and *CAPN13* were significantly differentially expressed between LAR and MES within Basals.

**Conclusion:** BP reclassified a subgroup of TNBC tumors to Luminal, explaining the discrepancy in the distribution of TNBC subtypes between IHC-defined TNBC and BP Basal tumors. Furthermore, BP indices distinguished between single activated and mixed subtypes, which correlated with different TNBC subtypes. These data suggest that molecular classification by BP adds further precision in classifying TNBC patients and sheds new light on the heterogeneity of these tumors. These findings have clinical implications in stratifying patients and identifying successful targeted treatment options. Future studies are warranted to investigate treatment response and prognosis in these molecular subgroups.

Fertility preservation in young women with breast cancer: Impact on treatment and outcomes

Angelena Crown<sup>1</sup>, Shirin Muhsen<sup>2</sup>, Varadan Sevilimedu<sup>1</sup>, Joanne Kelvin<sup>1</sup>, Shari B Goldfarb<sup>1</sup> and Mary L Gemignani<sup>1</sup>. <sup>1</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>2</sup>Clemenceau Medical Center/Johns Hopkins International, Beirut, Lebanon

**Background.** The American Society of Clinical Oncology guidelines recommend timely referral to reproductive endocrinology and infertility (REI) specialists for young women diagnosed with breast cancer. There is a paucity of data evaluating the impact of FP on oncologic outcomes and timely initiation of chemotherapy.

**Methods.** This retrospective review included all women age  $\leq 45$ y diagnosed with stage I-III unilateral breast cancers at Memorial Sloan Kettering Cancer Center between 2009-2015 who received chemotherapy and consulted with an REI specialist. Factors associated with the decision to undergo FP were analyzed. Survival curves were constructed using the Kaplan-Meier method.

**Results.** A total of 172 women were identified. Median age was 34y (interquartile range 31-37). The majority of women were single (n = 99, 58.1%) and nulliparous (n = 134, 77.9%). Most women underwent FP (n = 121, 70.3%). Tumor characteristics and treatments were similar between women who underwent FP and those who declined (Table 1). While white race was associated with decision to pursue FP, this association did not persist on multivariable analysis (MVA). Young age (p = 0.003), nulliparity (p = 0.001), referral from Breast Surgery (p = 0.009), and private insurance (p < 0.001) were independent predictors of FP on MVA. Timing of chemotherapy (adjuvant vs neoadjuvant) was not associated with decision to undergo FP. FP was not associated with breast cancer treatment delays.

A total of 25.5% (n = 44) of women had a biological child following breast cancer treatment (Table 2). Women who underwent FP were more likely to have a biological child after breast cancer treatment. Race and insurance type were also associated with having a biological child after treatment, with white women and women with private insurance being more likely to have a biological child. MVA revealed that undergoing FP, being married, and being white were independent predictors of having a biological child.

The 5-year overall survival (OS) was 97.5% (95% CI: 93.5-99.1%) and the 5-year recurrence-free survival (RFS) was 91.4% (95% CI: 85.9%-94.8%) with a median follow-up of 70 months (range 4-127). Five-year overall survival (OS) and recurrence-free survival (RFS) were similar between women who underwent FP and those who declined (OS: FP 98.2%, 95% CI 92.9%-99.5% vs 95.9%, 95% CI 84.6-98.9%, p = 0.20 and RFS: FP 92.1%, 95% CI: 85.4-95.8% vs declined 89.7%, 95% CI 76.9-95.6%, p = 0.42). Disease stage, race, and pregnancy were not associated with differences in OS or RFS. Private insurance was associated with improved OS but not with improved RFS.

**Conclusions.** Most women underwent FP. Women pursued FP at high rates independent of the timing of chemotherapy and oncologic factors. These findings indicate that timely consultation with REI specialists is the key factor in completing FP, and highlight opportunities for improved education and counseling regarding FP. They also identify FP as a possible area of racial disparities within breast cancer care, and serve as a reminder of the complex interplay between socioeconomic factors, reproductive choices, and pregnancy outcomes.

Table 1. Factors associated with decision to pursue cryopreservation

Sipa1 effects rock pathway in human breast cancer linking to HGF mediated changes in tight junction functions controlling metastasis

Chang Liu, Fiona Ruge, Lin Ye, Gregory M. Harrison, Wen G. Jiang and Tracey A. Martin. School of Medicine, Cardiff University, Cardiff, United Kingdom

**Background:** SIPA1 (Signal-induced proliferation-associated gene 1) is a mitogen-inducible gene encoding a GTPase-activating protein for Rap1 and Rap2 and has been suggested to be involved in metastatic progression. We have previously shown SIPA1 may regulate barrier function in breast cancer cells as part of hepatocyte growth factor-determined changes and that this may be via a number of regulatory pathways, most likely via the ROCK pathway. Our aim with this current work was to definitively identify which pathway is involved. **Methods:** After knockdown of SIPA1 in MDA-MB-231 cells, they were treated to a number of inhibitors to proteins involved in pathways involved in TJ barrier function (ROCK, N-WASP, ARPs, WAVES, MAPK, ERK, PLC-gamma). Following the identification of suitable inhibitor a large scale *in vivo* study was carried out using a tumour model of SIPA1 knockdown versus WT control was treated with/without inhibitors and immunohistochemistry (IHC) used to assess changes in tumour growth, architecture and protein expression. We also assessed the expression of SIPA-1 in a cohort of human breast cancer tissues using IHC. **Results:** After knockdown of SIPA1 in MDA-MB-231 cells, we subjected cells to a number of inhibitors to proteins involved in pathways involved barrier function (ROCK, N-WASP, ARPs, WAVES, MAPK, ERK, PLC-gamma). Analysis of behaviour showed that knockdown cells no longer responded to the ROCK inhibitor (ROCKi Y-27632,  $p < 0.05$ ,  $n = 10$ ). *In vivo* tumour samples were assessed for expression of ROCKI, expression of phospho-ROCK, and any differences when treated with ROCKi. Control tissues showed good levels of all three proteins (SIPA1, ROCKI and phosphor-ROCK). Knockdown tissues exhibited significantly lower levels of ROCK and phosphor-ROCK ( $p < 0.01$ ,  $n = 12$ ). In control tumours, phosphor-ROCK was increased after treatment with ROCKi; conversely, in SIPA1 knockdown tumours, phosphor-ROCK was decreased after treatment with ROCKi ( $p < 0.05$ ). In SIPA1 knockdown tissues, ROCK and phosphor-ROCK was diffuse in staining pattern when compared to the control where the staining was located at the cell membrane. **Conclusion:** Our results confirm our hypothesis that SIPA1 is involved in the control of TJ in breast cancer and that this is through the ROCK pathway. Moreover, these results demonstrate that this may be due to the effect that SIPA1 has on cellular ratios of ROCK to phosphor-ROCK in breast cancer.

Genome-wide association study identifies *UACA* as a modulator of breast cancer chemoresistance and survival

Lawrence H Kushi<sup>1</sup>, Qianqian Zhu<sup>2</sup>, Emily Schultz<sup>2</sup>, Jirong Long<sup>3</sup>, Janise M Roh<sup>1</sup>, Emily Valice<sup>1</sup>, Cecile A Laurent<sup>1</sup>, Li Yan<sup>2</sup>, Isaac J Ergas<sup>1</sup>, Warren Davis<sup>2</sup>, Dilrini K Ranatunga<sup>1</sup>, Marilyn L Kwan<sup>1</sup>, Ping-Ping Bao<sup>4</sup>, Wei Zheng<sup>3</sup>, Xiao-Ou Shu<sup>3</sup>, Christine B Ambrosone<sup>2</sup> and Song Yao<sup>2</sup>. <sup>1</sup>Kaiser Permanente Northern California, Oakland, CA; <sup>2</sup>Roswell Park Comprehensive Cancer Center, Buffalo, NY; <sup>3</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>4</sup>Shanghai Municipal Center for Disease Prevention and Control, Shanghai, China

Prior studies suggest a strong genetic influence on breast cancer prognosis. Six genome-wide association studies (GWAS) on breast cancer prognosis have been published to date. However, none of the reported loci was replicated across studies and only two passed genome-wide significance ( $P < 5 \times 10^{-8}$ ). In the Pathways Study, a prospective cohort of breast cancer survivors begun in Kaiser Permanente Northern California (KPNC) in 2006, we carried out a GWAS of overall survival (OS) in 3,973 patients. Trans-ethnic meta-GWAS identified an association with OS of a locus on chromosome 15 that almost reached genome-wide significance ( $P = 9.42 \times 10^{-8}$ ). This locus spanned the *UACA* gene, a key regulator of tumor suppressor Par-4. We found that receipt of chemotherapy modified the effect of the *UACA* locus on OS ( $P_{\text{interaction}} = 2.4 \times 10^{-4}$ ). This observation led us to hypothesize that the *UACA* locus effect on OS may be specific to Par-4 dependent chemotherapies, which include anti-HER2 therapy and doxorubicin. We stratified patients into two groups, those who received Par-4 dependent chemotherapy agents versus other patients. In separate trans-ethnic meta-GWAS, the *UACA* locus was significantly associated with OS in patients taking Par-4 dependent chemotherapies ( $P = 1.27 \times 10^{-9}$ ), while no association was observed in the other patients ( $P = 0.21$ ). To evaluate whether the *UACA* gene may be responsible for this association, we performed a transcriptome-wide association study (TWAS) of OS in White patients taking Par-4 dependent chemotherapies. Higher *UACA* gene expression was significantly associated with OS ( $P = 4.68 \times 10^{-7}$ ), the only gene reaching transcriptome-wide significance ( $P < 4.34 \times 10^{-6}$ ). These results suggest that higher *UACA* expression may inhibit Par-4 induced apoptosis and lead to stronger chemoresistance and worse survival. We attempted to validate our findings in the independent KPNC Genetic Epidemiology Research on Aging (GERA) cohort. The GERA cohort included only 168 White patients with incident breast cancer after DNA collection who received Par-4 dependent chemotherapies. We found a non-significant association (hazard ratio (HR) = 1.46,  $P = 0.66$ ) consistent with Pathways Study findings. However, the GERA cohort also included 1,983 prevalent breast cancer patients with biospecimen collection after diagnosis. In this group, the risk allele frequency in breast cancer survivors receiving Par-4 dependent chemotherapies was significantly lower than that in the White population ( $P = 5.50 \times 10^{-3}$ ) while the risk allele frequency in the those not receiving these chemotherapies was similar to the population ( $P = 0.07$ ). This is consistent with Pathways Study observations that the *UACA* locus risk allele significantly increased risk of mortality in patients taking Par-4 dependent chemotherapies. A higher mortality in breast cancer survivors carrying the risk allele would result in decreased risk allele frequency. We further validated our findings in Shanghai Breast Cancer Survival Study (SBCSS) and Shanghai Breast Cancer Study, which were conducted from 1996 to 2006 in urban Shanghai and recruited 5,575 breast cancer patients. In this independent Asian breast cancer population, the *UACA* locus was modestly associated with OS in the overall population (HR = 1.18,  $P = 0.012$ ), and more significantly in 1,289 SBCSS patients who received anthracyclines (HR = 1.66,  $P = 1.55 \times 10^{-4}$ ). This is the first human study suggesting the Par-4 pathway affects breast cancer patient survival with *UACA* a key modulator of treatment outcomes by anti-Her2 therapy and doxorubicin. Our findings suggest a path toward new predictive pharmacogenetic markers for personalized medicine targeting the Par-4 pathway for breast cancer treatment.

Randomized controlled trial of decision support tools for patients and providers to increase breast cancer chemoprevention

Katherine D Crew<sup>1</sup>, Gauri Bhatkhande<sup>1</sup>, Thomas Silverman<sup>1</sup>, Tarsha Jones<sup>2</sup>, Jennie Mata<sup>1</sup>, Ashlee Guzman<sup>1</sup>, Ting He<sup>1</sup>, Jill Dimond<sup>3</sup> and Rita Kukafka<sup>1</sup>. <sup>1</sup>Columbia University Irving Medical Center, New York, NY; <sup>2</sup>Florida Atlantic University, Boca Raton, FL; <sup>3</sup>Sassafras Collective, Ann Arbor, MI

**Background:** Breast cancer chemoprevention with selective estrogen receptor modulators (SERMs) and aromatase inhibitors (AIs) have been shown in randomized controlled trials to reduce breast cancer incidence by 50-65% among high-risk women. However, chemoprevention is still underutilized with fewer than 5% of high-risk women offered chemoprevention agreeing to take the medications. Reasons for low chemoprevention uptake include inadequate knowledge about chemoprevention among patients and healthcare providers, concerns about side effects, competing comorbidities, and time constraints during the clinical encounter. To address these barriers to chemoprevention uptake, we developed decision support tools for patients and providers. **Methods:** We conducted a randomized controlled trial of standard educational materials alone or combined with web-based decision support tools, *RealRisks* and *BNAV*, among 300 high-risk women and 50 healthcare providers, respectively. Patient eligibility criteria included: 1) women, age 35-75 years; 2) high-risk for breast cancer, defined as a 5-year invasive breast cancer risk  $\geq 1.67\%$  according to the Gail model or history of lobular carcinoma *in situ* (LCIS); 3) no prior use of a SERM or AI; 4) No personal history of breast cancer; 5) Access to the internet. Providers included primary care providers, such as internists, family practitioners, gynecologists, and nurse practitioners, and specialists, such as breast surgeons and medical oncologists. The *RealRisks* decision aid (DA) is available in English and Spanish and includes interactive modules to communicate personalized breast cancer risk and the risks and benefits of chemoprevention. The *BNAV* tool includes self-paced learning modules on breast cancer risk factors and chemoprevention and was made available to all providers through the electronic health record (EHR) dashboard. The primary endpoint was chemoprevention uptake at 6 months as assessed via the EHR. Secondary outcomes included validated measures of perceived breast cancer risk, breast cancer worry, chemoprevention knowledge, self-efficacy, decision conflict, chemoprevention attitudes, intention, and informed choice, which were administered to patients at baseline, 1 month, and 6 months after randomization. **Results:** Among 282 evaluable high-risk women enrolled from November 2016 to March 2020, mean age was 57 years (SD, 9.9), including 59% white, 14% black, 21% Hispanic, and 6% other. Mean 5-year invasive breast cancer risk was 2.98% (SD, 1.42), including 67% of women with benign breast disease and 64% with a first-degree family history of breast cancer. Comparing the intervention and control arms at 1 month, there were significant differences among high-risk women in accurate breast cancer risk perceptions (56% vs. 39%,  $p=0.017$ ), adequate chemoprevention knowledge (49% vs. 27%,  $p<0.001$ ), informed choice (41% vs. 23%,  $p=0.003$ ), and mean decision conflict (34.0 vs. 47.0,  $p<0.001$ ). There were no significant differences between the two groups in other patient-reported outcomes. Among patients who completed their 6-month follow-up, only 2.3% of high-risk women in the intervention arm and 3.8% in the control arm initiated a SERM or AI for breast cancer chemoprevention. **Conclusions:** With short-term follow-up, exposure to our decision support tools was associated with improvement in decision antecedents (accurate breast cancer risk perceptions, adequate chemoprevention knowledge) and decision quality (increased informed choice, reduced decision conflict). However, actual chemoprevention uptake in both arms remained low at less than 5%. Future research should focus on targeting high-risk women with LCIS or atypical hyperplasia and better incorporating decision support into clinic workflow through EHRs and patient portals.

Impact of body mass index on pathological complete response after neoadjuvant chemotherapy: Results from the I-SPY 2 trial

Haiyun Wang<sup>1</sup>, Douglas Yee<sup>1</sup>, David Potter<sup>1</sup>, Patricia Jewett<sup>1</sup>, Christina Yau<sup>2</sup>, Heather Beckwith<sup>1</sup>, Allison Watson<sup>1</sup>, Nicholas G O'Grady<sup>2</sup>, Amy Wilson<sup>3</sup>, Susie Brain<sup>2</sup>, I-SPY 2 TRIAL Consortium and Anne Blaes<sup>1</sup>. <sup>1</sup>Division of Hematology, Oncology and Transplantation, University of Minnesota Medical School, Minneapolis, MN; <sup>2</sup>University of California San Francisco, San Francisco, CA; <sup>3</sup>Quantum Leap Healthcare Collaborative, San Francisco, CA

**Purpose:** Increased body mass index (BMI) is a risk factor for breast cancer and has been associated with poor outcomes in both premenopausal and postmenopausal breast cancer patients. Several retrospective studies have demonstrated higher BMI to be associated with inferior pathological complete response (pCR) to neoadjuvant chemotherapy, yet it remains unclear if this difference is related to chemotherapy underdosing among obese breast cancer patients. We evaluated the association between BMI and response to neoadjuvant chemotherapy (defined by pCR) in the I-SPY 2 trial, an adaptive clinical trial platform enrolling biologically high-risk breast cancer patients (triple negative, human epidermal growth factor receptor 2 (HER2) positive and MammaPrint high-risk) that utilizes standard neoadjuvant therapy regimens with treatment based on actual body weight.

**Patients and Methods:** From 3/2010 to 11/2016, 989 patients were enrolled in the I-SPY 2 trial, 978 had a recorded baseline BMI prior to treatment and were included in the analysis. Tumor subtypes were defined by hormone receptor and HER2 status. Pretreatment BMI was categorized as obese (BMI ≥ 30 kg/m<sup>2</sup>), overweight (25 ≤ BMI < 30 kg/m<sup>2</sup>), and normal or underweight (< 25 kg/m<sup>2</sup>) based on World Health Organization criteria. pCR was defined as elimination of detectable invasive cancer in the breast and lymph nodes (ypT0/Tis and ypN0) at the time of surgery. Logistic regression analysis was used to determine associations between BMI and pCR, and we reported odds ratios (OR) and 95% confidence intervals (CI). Event-free survival (EFS) and overall survival (OS) between different BMI categories were examined using Cox proportional hazards regression.

**Results:** The median age in our study population was 49 years. 35% of patients were normal/underweight, 32% overweight, and 33% obese. Black patients were more likely to be obese (P < 0.0001). pCR rates differed significantly by tumor subtype (P < 0.0001) and tumor stage (P = 0.0009). pCR rates were 32.8% in normal/underweight, 31.4% in overweight, and 32.5% in obese patients. In univariable analysis, there was no significant difference in pCR with BMI. In multivariate analysis adjusted for race/ethnicity, age, menopausal status, breast cancer subtype, and clinical stage, there was no significant difference in pCR to neoadjuvant chemotherapy for obese compared with normal/underweight patients (OR = 1.1, 95%CI: 0.68-1.63, p = 0.83), and for overweight compared with normal/underweight (OR = 1, 95%CI: 0.64-1.47, p = 0.88). We tested for potential interaction between BMI and breast cancer subtype, however, the interaction was not significant in the multivariate model (P = 0.09) (Table 1). Multivariate Cox regression showed there was no difference in EFS (p = 0.81) or OS (p = 0.52) between obese, overweight and normal/underweight breast cancer patients with a median follow-up time of 4.0 years.

**Conclusions:** There was no difference in pCR rates by BMI with actual body weight based neoadjuvant chemotherapy in this biologically high-risk breast cancer population. In contrast, breast cancer subtype and stage showed predictive value for pCR in this high-risk operable breast cancer population receiving neoadjuvant chemotherapy in the I-SPY 2 clinical trial.

**Table 1:** pCR rate of different BMI categories by breast cancer subtypes.

Breast Cancer Subtype	pCR	Normal/underweight Frequency (%)	Overweight Frequency (%)	Obese Frequency (%)	P-value
HR+/HER2+	No	39 (61.9)	27 (61.4)	32 (66.7)	0.83
	Yes	24 (38.1)	17 (38.6)	16 (33.3)	
HR+/HER2-	No	105 (80.8)	116 (89.2)	93 (78.8)	0.06
	Yes	25 (19.2)	14 (10.8)	25 (21.2)	
HR-/HER2+	No	7 (25.0)	11 (35.5)	15 (51.7)	0.11

Delivery and activity of SN-38 by sacituzumab govitecan in breast cancer brain metastases

Andrew J Brenner<sup>1</sup>, Renu Pandey<sup>2</sup>, Jennifer Chiou<sup>2</sup>, John Floyd<sup>1</sup>, Prathiba Surapreneni<sup>1</sup>, Virginia Kaklamani<sup>1</sup>, Kate Lathrop<sup>1</sup>, Richard Crownover<sup>1</sup> and Stefano Tiziani<sup>2</sup>. <sup>1</sup>UT Health Mays Cancer Center, San Antonio, TX; <sup>2</sup>UT Austin Livestrong Cancer Center, Austin, TX

**BACKGROUND:** Sacituzumab Govitecan (SG, TRODELVY™) is an FDA approved antibody drug conjugate for treatment of metastatic triple negative breast cancer (TNBC). SG has payload and linker characteristics preferable for CNS delivery including a pH hydrolysable, a payload (SN-38) that is the active 1000-fold more potent than the parent compound CPT-11 and crosses the blood brain barrier. Our preliminary data showed SG activity in intracranial xenografts leading to our hypothesis that SG would achieve concentration of SN-38 within the breast cancer brain metastases (BCBM) that would be therapeutically relevant. **METHODS:** We undertook a single center, prospective, window of opportunity trial (NCT03995706) to examine the concentrations of SG, SN-38, and SN-38G in tumors patients undergoing craniotomy for BCBM (n=20) or recurrent glioblastoma (rGBM, n=10). A single dose of SG was administered at 10mg/kg IV the day prior to craniotomy. Tumor was collected and [SN-38] was analyzed via mass spectrometry (UHPLC-HRMS). following recovery patients resumed SG at 10mg/kg IV days 1 and 8 of 21 day cycle and were assessed for response or progression every third cycle by MRI. **RESULTS:** To date 21 patients have been treated, including 11 BCBM and 10 rGBM. UHPLC-HRMS analysis was performed in the first 10 tumors (n=4 and 6 respectively). For BCBM, total concentration of SN-38 varied from 173nM to 1160nM, with a mean concentration of 626nM. All GBM patients had residual measurable disease and 4 breast patients had measurable disease. With a median follow-up of 12 weeks from the first postoperative cycle in the first 14 patients, 2 partial responses from each group were observed (ORR of 28% and 50% at 12 weeks respectively). Updated results will be presented. **CONCLUSIONS:** SG achieves therapeutically relevant concentrations of SN-38 at 150-fold mean IC50s for BCBM. Early intracranial responses are encouraging and merit further evaluation. A multi-center trial of SG for HER2 negative BCBM (SWOG S2007) will be enrolling soon.

Emerging from COVID-19 pandemic: Provider perspective on use of neoadjuvant endocrine therapy (NET) in early stage hormone receptor positive breast cancer

Ko Un Park<sup>1</sup>, Megan E Gregory<sup>1</sup>, Maryam B Lustberg<sup>1</sup>, Jose G Bazan<sup>1</sup>, Chengli Shen<sup>1</sup>, Shoshana M Rosenberg<sup>2</sup>, Victoria S Blinder<sup>3</sup>, Priyanka Sharma<sup>4</sup>, Lajos Pusztai<sup>5</sup>, Ann H Partridge<sup>2</sup> and Alastair Thompson<sup>6</sup>. <sup>1</sup>The Ohio State University Wexner Medical Center, Columbus, OH; <sup>2</sup>Dana-Farber Cancer Institute, Boston, MA; <sup>3</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>4</sup>University of Kansas Medical Center, Westwood, KS; <sup>5</sup>Yale University, New Haven, CT; <sup>6</sup>Baylor College of Medicine, Houston, TX

**Introduction** During the coronavirus 2019 (COVID-19) pandemic in USA, NET use has been recommended to allow safe deferral of surgical treatment in early stage, estrogen receptor positive breast cancer (ER+BC). In such circumstances, after NET use there is limited guidance on locoregional treatment, especially with management of the axilla. We aimed to evaluate patterns of care in early stage ER+BC during the first several months of the COVID-19 pandemic. **Method** A cross-sectional, 30-item survey was developed using a standardized survey development framework. The survey was administered May 8 - June 12, 2020 to a convenience sample of medical oncologists (MO), radiation oncologists (RO), and surgeons (SO) - breast committee members of two national cooperative groups (Alliance and SWOG) with additional participation through chain referrals. Providers were presented with general questions on NET use before and during the pandemic. They were asked their propensity for omitting axillary lymph node dissection (ALND) after NET if 1 micrometastatic node is found on sentinel lymph node biopsy, based on duration of NET. **Results** 114 providers from 29 US states completed the survey - 42 (37%) MO, 14 (12%) RO, and 58 (51%) SO, the majority (N=73/96, 76%) with practices dedicated  $\geq$  75% to BC, at NCI designated comprehensive cancer centers 52% (N=48/94) and in large cities (N=49/94, 52%). Prior to COVID-19, most rarely (N=49/107, 46%) or sometimes (N=36, 33%) used NET for early stage ER+BC. Nearly half were willing to delay surgery up to 2 months (46%) and 3 months (21%) without use of NET (Table 1,  $p < 0.05$ ). Most providers would perform a genomic assay on the biopsy specimen on all or select patients prior to NET initiation, more frequently by MO compared to RO and SO (90% vs. 75% and 60%,  $p < 0.05$ ). The most preferred regimen was tamoxifen (without ovarian suppression) for premenopausal patients and aromatase inhibitor for postmenopausal patients. Most planned to use NET for as little time as possible until surgery could proceed. When stratified by specialty, more MO stated they would vary the duration of therapy based on patient's risk of cancer progression. Most providers recommended omitting ALND after 1, 2, or 3 months of NET (1 month N=56/93, 60%; 2 months N=54/92, 59%; 3 months N=48/90, 53%). With longer duration of therapy, the propensity for omitting ALND decreased (definitely omit after 6 months N=25/91, 27%; probably omit after 6 months N=38/91, 42%; definitely omit after 1 year N=26/92, 28%; probably omit after 1 year N=29/92, 32%). Omitting ALND was not associated with provider's years in practice, percent of practice dedicated to BC, practice type or setting, participation in multidisciplinary tumor board, or number of COVID-19 cases in the provider's practicing state. **Conclusion** Most providers changed their management of early stage ER+BC during the COVID-19 pandemic by utilizing NET until surgery could proceed. As the duration of NET extended, more providers favored ALND in low volume axillary metastatic disease in early stage ER+BC. Additional data to inform the care on post-NET locoregional management is needed.

Table 1. Management of early stage, node negative, ER+BC during COVID-19 pandemic

	Total (N, %)	Med Onc	Rad Onc	Surgeon
<b>How long are you willing to delay surgery (without use of endocrine therapy)?</b>				
Up to 1 month	25 (23%)	10 (24%)	0	15 (26%)
Up to 2 months	51 (46%)	17 (40%)	7 (64%)	27 (47%)
Up to 3 months	23 (21%)	9 (21%)	2 (18%)	12 (21%)
Up to 4 months	3 (3%)	2 (5%)	1 (9%)	0
Up to 6 months	8 (7%)	4 (10%)	1 (9%)	3 (5%)
<b>Have you changed your practice during the current pandemic?</b>				
Yes - institution mandated change to delay surgery	8 (25%)	4 (36%)	0	4 (29%)
Yes - based on multidisciplinary team discussion (no explicit institutional mandate to delay cancer surgery)	21 (66%)	6 (55%)	7 (100%)	8 (57%)
No - was not allowed by institution to change	0	0	0	0
No - was not necessary	3 (9%)	1 (9%)	0	2 (14%)
<b>If using endocrine therapy before surgery, which regimen are you using??</b>				
Tamoxifen for all patients	0	0	0	0
Tamoxifen for premenopausal patients; aromatase inhibitor for postmenopausal patients	77 (81%)	26 (63%)	0	51 (94%)
Ovarian suppression with aromatase inhibitor for premenopausal patients; aromatase inhibitor for postmenopausal patients	18 (19%)	15 (37%)	0	3 (6%)
<b>How are you staging the axilla prior to starting endocrine therapy?</b>				
Exam only	28 (26%)	8 (19%)	2 (17%)	18 (33%)
Exam + US	77 (71%)	30 (71%)	10 (83%)	37 (67%)
Exam + US + cross sectional image (CT scan)	4 (4%)	4 (10%)	0 (0%)	0 (0%)
SLNB	0	0	0	0
<b>If using endocrine therapy first (before surgery), are you?</b>				
Sending genomic assay on biopsy specimen on all patients	28 (26%)	18 (44%)	1 (8%)	9 (16%)
Sending genomic assay on biopsy specimen on only select patients (ie. high grade, size on imaging/exam, high Ki-67)	51 (48%)	19 (46%)	8 (67%)	24 (44%)
Not sending genomic assay. Using PEPI score instead.	4 (4%)	1 (2%)	1 (8%)	2 (4%)
Not sending genomic assay. Using Magee Equations for Estimating Oncotype DX Recurrence Score instead.	2 (2%)	0	0	2 (4%)
None of above	21 (20%)	3 (7%)	2 (17%)	18 (33%)
<b>If using endocrine therapy first, what duration do you plan to use it for the average patient??</b>				
Minimum 1 year for all patients	0	0	0	0
Minimum 6 months for all patients	7 (6%)	4 (10%)	0 (0%)	3 (5%)

Minimum 3 months for all patients	19 (18%)	7 (17%)	1 (8%)	11 (20%)
As short as possible (less than 3 months), until it is safe to proceed with surgery in light of COVID-19 situation	57 (53%)	14 (34%)	9 (75%)	34 (62%)
Duration of therapy depends on patient"s risk of cancer progression (ie. tumor grade, percent hormone positivity)	25 (23%)	16 (39%)	2 (17%)	7 (13%)
<b>If using endocrine therapy before surgery, do you plan to re-image the breast prior to surgery??</b>				
Yes, re-image all patients	27 (25%)	14 (34%)	1 (8%)	12 (22%)
No	8 (7%)	0 (0%)	2 (17%)	6 (11%)
Case by case basis	72 (67%)	27 (66%)	9 (75%)	36 (67%)

Diabetes decreases overall survival in women with breast cancer in the southern community cohort study

Lucy B. Spalluto, Sonya Reid, Diane Haddad, Tuya Pal, Ingrid A. Mayer, Xiao-ou Shu, Maureen Sanderson, Wei Zheng, William J. Blot and Loren Lipworth. Vanderbilt University Medical Center, Nashville, TN

**Background:** Factors contributing to breast cancer survival disparities in underrepresented racial and ethnic groups and low-income populations are poorly understood as few clinical trials and population based studies have included these underserved populations. The Southern Community Cohort Study (SCCS), a prospective cohort of underserved, low-income adults with high representation of Black participants, provides a unique opportunity to evaluate such disparities in cancer outcomes. A previous study utilizing SCCS data found no evidence of increased *breast cancer risk* among women with diabetes in this population. The purpose of this study was to evaluate the association of diabetes with *overall survival in women with breast cancer* in the SCCS.

**Methods:** The SCCS enrolled approximately 86,000 participants aged 40-79 from 12 southeastern states between 2002-2009, 86% of whom were enrolled at Community Health Centers. This analysis includes women diagnosed with incident localized breast cancers identified through annual cohort linkage with 12 state cancer registries. Demographic data including participant age at breast cancer diagnosis, self-reported history of diabetes (patient answered yes to "has a doctor ever told you that you have diabetes"), body mass index (BMI), race, household income, and insurance coverage were obtained from baseline surveys, cancer type and stage data from state cancer registries, and survival data from death registries. Survival time was defined as the number of months between initial breast cancer diagnosis and death from any cause. Descriptive characteristics including mean (standard deviation) or number (%) were used to summarize demographics. We used Pearson Chi-squared analysis to examine the association between diabetes and overall survival. Multivariable Cox proportional hazards regression was used to evaluate overall survival and diabetes, adjusting for covariates including age (continuous), race, BMI (categorical by WHO classifications), household income (binary – annual income <\$25,000, annual income ≥\$25,000), insurance coverage, cancer subtype, and cancer stage).

**Results:** We identified a total of 1,347 women diagnosed with breast cancer. Of these, 1,016 were diagnosed with localized disease (stage 1-3) and comprised our analytic sample. Difference in denominators reflects missing data. The women were predominantly Black (667/1,016, 65.6%), low income (719/1,016 annual income less than \$25,000, 70.8%), and insured (Private insurance 220/763, 28.8%; Medicare 331/763, 43.4%; Medicaid 178/763, 23.3%). Average age at diagnosis was 60.7 years (SD 9.1, IQR 41-88). Approximately one quarter of the patients (258/994, 26.0%) self-reported diabetes and 59.6% (605/1,016) were obese (BMI ≥30). The breast cancer immunohistochemistry subtypes in this cohort of women included HR+HER2- (392/564, 69.5%), HR+,HER2+ (55/564, 9.8%), HR-,HER2+ (31/564, 5.5%), and HR-HER2- (86/564, 15.3%). Women with diabetes had lower overall survival (174/258, 67.4%) than women without diabetes (587/746, 79.8%) ( $p < 0.0001$ ). In the adjusted multivariate Cox regression model, diabetes significantly decreased overall survival in women with breast cancer, hazard ratio 1.87, 95% Confidence Interval [CI] = 1.12-3.09.

**Conclusion:**

In a low-income, predominantly Black population with incident localized breast cancer, decreased overall survival was observed among women with diabetes compared to those without diabetes. Future studies should explore additional biological, societal, and socio-economic factors affecting survival among women with breast cancer in medically underserved minority populations.

Tan<sup>18</sup>, Shelley E. Ackerman<sup>19</sup>, Heidi LeBlanc<sup>19</sup>, David Dornan<sup>19</sup>, Marcin Kowanetz<sup>19</sup>, Michael N. Alonso<sup>19</sup> and Edith A. Perez<sup>19</sup>. <sup>1</sup>The University of Texas MD Anderson Cancer Center, Houston, TX; <sup>2</sup>START Midwest, Grand Rapids, MI; <sup>3</sup>Columbia University Medical Center, New York, NY; <sup>4</sup>University of Chicago, Chicago, IL; <sup>5</sup>UPMC Hillman Cancer Center, Pittsburgh, PA; <sup>6</sup>Henry Ford Cancer Institute/Henry Ford Hospital, Detroit, MI; <sup>7</sup>Dana-Farber Cancer Institute, Boston, MA; <sup>8</sup>Massachusetts General Hospital, Boston, MA; <sup>9</sup>Asan Medical Center, Seoul, Korea, Republic of; <sup>10</sup>Samsung Medical Center, Seoul, Korea, Republic of; <sup>11</sup>Seoul National University College of Medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of; <sup>12</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>13</sup>Stephenson Cancer Center, Oklahoma City, OK; <sup>14</sup>Stanford University, Stanford, CA; <sup>15</sup>Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC; <sup>16</sup>START, San Antonio, TX; <sup>17</sup>Virginia Cancer Specialists, Fairfax, VA; <sup>18</sup>Levine Cancer Institute, Atrium Health, Charlotte, NC; <sup>19</sup>Bolt Biotherapeutics, Redwood City, CA

**Background:** To date, no immune-based therapies beyond anti-HER2 monoclonal antibodies are approved for treating patients (pts) with HER2-driven or -expressing cancers. However, pts still develop progressive disease, and new treatment options that could achieve durable antitumor efficacy are needed. Recent studies indicate that intratumoral delivery of immunostimulatory adjuvants such as toll-like receptor (TLR) 7/8 agonists can activate tumor resident antigen-presenting cells (APCs), driving uptake, processing, and presentation of tumor neoantigens to T cells that mediate antitumor immunity. To overcome limitations associated with intratumoral delivery while leveraging superior preclinical biology, BDC-1001, a novel, systemically delivered ISAC was developed. BDC-1001 consists of an investigational biosimilar of the humanized monoclonal antibody trastuzumab that is chemically conjugated to a TLR 7/8 agonist (payload) with an intervening non-cleavable linker. BDC-1001 activates human myeloid APCs while retaining antibody-mediated effector functions such as antibody-dependent cellular cytotoxicity/phagocytosis (ADCC/ADCP). Xenograft and syngeneic tumor resistant models indicate that trastuzumab ISACs elicit potent and durable immune-mediated antitumor efficacy including complete tumor regression in a TLR- and Fc receptor-dependent manner (Ackerman et al. Cancer Res. 2019;79 [13 Suppl]; Ackerman et al. J Immunother Cancer. 2019;7:283). Importantly, BDC-1001 did not induce interstitial lung disease, cytokine release syndrome, or thrombocytopenia in non-human primate studies. A four-part phase 1/2, first-in-human study has been initiated that evaluates BDC-1001 with or without (+/-) an immune checkpoint inhibitor targeting PD-1 in pts with HER2-expressing or HER2-amplified advanced/metastatic solid tumors.

**Study Description:** This phase 1/2 dose-escalation and dose-expansion study is enrolling up to 390 pts with advanced solid tumors that are HER2-expressing (IHC2+ or 3+ protein irrespective of gene amplification) or HER2-amplified (by in situ hybridization or next-generation sequencing) and ineligible for approved anti-HER2 treatments. The primary objectives of the dose-escalation phase are to define safety and tolerability and to determine the recommended phase 2 dose of BDC-1001 as monotherapy (Part 1) and in combination with an immune checkpoint inhibitor (Part 2). Primary endpoints of Parts 1 and 2 include incidence of 1) adverse events and severe adverse events graded according to NCI CTCAE v5.0; 2) dose-limiting toxicities within a 3+3 design; and 3) potential immune-related toxicities. BDC-1001 is administered IV over 60 min q3w at increasing doses. Once safety data are available for BDC-1001, initiation of the immune checkpoint inhibitor combination is planned. The dose-expansion phase 2 portion of the trial will evaluate preliminary antitumor activity of BDC-1001 alone (Part 3) and in combination with an immune checkpoint inhibitor (Part 4) using RECIST v1.1 and iRECIST. The primary endpoint of this dose-expansion phase is overall response rate, with secondary endpoints of duration of response, disease control rate, and progression-free survival. Exploratory objectives will evaluate pharmacokinetic parameters and pharmacodynamic biomarkers associated with drug exposure. These exploratory studies will help elucidate the mechanism of action and seek to identify biomarkers to improve selection of pts most likely to benefit from treatment with BDC-1001 +/- immune checkpoint inhibitor. This global study is currently recruiting pts. For further information, visit ClinicalTrials.gov (NCT04278144).

Identification of pathogenic RET alterations in cell-free DNA (cfDNA) from patients with metastatic breast cancer

Mary Love Taylor<sup>1</sup>, Benjamin Mayro<sup>1</sup>, Leylah Drusbosky<sup>2</sup>, Carey Anders<sup>1</sup> and Jeremy Force<sup>1</sup>. <sup>1</sup>Duke University, Durham, NC; <sup>2</sup>Guardant Health, Redwood City, CA

**Background:** *RET* is an important proto-oncogene involved in the development of various cancers for which we have FDA approved therapies. *RET* alterations are a known mechanism of resistance against breast cancer systemic therapies and higher *RET* expression has been demonstrated in breast cancer brain metastases compared to their primary tumors. While the genomic characterization of *RET* alterations has occurred from bulk breast tumors, the frequency and type of *RET* alterations in metastatic breast cancer (MBC) have not been fully characterized from cfDNA. The purpose of this study was to identify the incidence of *RET* genomic alterations occurring in cfDNA from patients with MBC and elucidate which *RET* alterations may increase RET kinase activity or may function as mechanisms of resistance against the FDA approved RET inhibitor, selpercatinib.

**Methods:** We queried 16,053 reports from Guardant Health between June 2015 - October 2019 to identify the incidence of *RET* alterations detected in cfDNA from MBC. We classified each alteration type into the following categories: fusions, single nucleotide variants (SNVs), or indels. Focus was placed on characterizing *RET* SNVs. Amino acid changes occurring at conserved regions across multiple species were identified. We compared known activating mutations in *EGFR* and *ERBB2* with homologous regions in *RET*. *In silico* modeling with PyRx was used to dock selpercatinib onto the *RET* kinase (PDB 6NJA). Three-dimensional *in silico* analyses with ChimeraX was utilized to further determine which alterations may increase RET kinase activity or may induce resistance against selpercatinib.

**Results:** Nonsynonymous *RET* alterations from the Guardant Health breast cancer database were found in 162 samples from a cohort of 16,053 patients indicating an overall incidence of 1.0%. Alterations included: 3 (1.9%) *RET-CCDC6* fusions, 2 (1.2%) *RET-KIF5B* fusions, 6 (3.7%) indels, and 151 (93.2%) SNVs. Of the 151 samples with SNVs, we identified 37 (23%) and 63 (38.9%) point mutations occurring in the transmembrane/juxtamembrane and kinase domains, respectively, and 77 occurred at highly conserved regions across species. The most frequent hotspot mutations occurring in 4 or more unique breast cancers included H594P, 6 (4.0%); S696L, 4 (2.6%); C634Y/G, 5 (3.3%); R813W/Q, 4 (2.6%); and M918T, 8 (5.3%). We aligned *RET* with homologous kinases and found 8 (5.3%) *RET* mutations (R721Q, V804L, M868I, R873Q, G894S) and (A641T, S891L, D925H) that corresponded to known activating mutations in *EGFR* (E709A/K, T790M, R831H, R836C, G857V) and *ERBB2* (V659E, T862A/S, R896C), respectively. Three-dimensional analyses indicate that *RET* alterations occurring within the hinge (E805Q), HRD (H872R, R873Q), and DFG (D892Y, G894S) regions, and regulatory spine (D933N) of the *RET* kinase are postulated to induce resistance against selpercatinib.

**Conclusions:** We found that a modest incidence of *RET* genomic alterations occur in cfDNA from patients with MBC. Novel somatic alterations in *RET* were identified from Guardant Health that were not detected in the public domain. A portion of *RET* SNVs occurred at highly conserved regions across species or at known homologous kinase activating mutations suggesting these specific *RET* mutations may increase RET kinase activity and might be actionable therapeutic targets in breast cancers harboring these mutations. Three dimensional analyses of the RET protein tyrosine kinase further illustrate which specific alterations may increase RET kinase activity or induce resistance against selpercatinib.

Relationship between body mass index and tumor subtype by menopausal status: An analysis in women with lobular carcinoma of the breast

Harriet Rothschild, Laura Esserman, Christopher Benz and Rita Mukhtar. UCSF, San Francisco, CA

**Background:** Invasive lobular carcinoma (ILC) is the second most common type of breast cancer and is primarily estrogen receptor (ER)-positive. Compared to invasive ductal carcinoma, ILC is more strongly associated with risk factors that modulate sex steroid hormones, including obesity and use of hormone replacement therapy. Studies also suggest that body mass index (BMI) and metabolic syndrome may impact the molecular characteristics of ILC. We evaluated the relationship between BMI, metabolic syndrome, and tumor characteristics by menopausal status in a single institution cohort of women with newly diagnosed ILC.

**Methods:** We retrospectively evaluated ILC cases from an institutional database of patients treated between 1996 and 2020. We excluded cases with mixed ILC/IDC histology, and those with triple negative or human epidermal growth factor-2 overexpressing disease. BMI was calculated as (weight kg)/(height m)<sup>2</sup> and was evaluated continuously and categorically with 20-24.9 as normal weight, 25-30 as overweight, and >30 as obese. Metabolic syndrome was defined as having any 3 of the following 5 factors: obesity, hypertension, hypercholesterolemia, hypertriglyceridemia, or diabetes mellitus. Oncotype Dx Recurrence Scores (RS) were recorded in the subset for whom scores had been obtained clinically. Data were analyzed in Stata 14.2.

**Results:** Of the 481 ILC cases studied, 147 (30.5%) were pre-menopausal at diagnosis, while 334 (69.5%) were post-menopausal, with mean ages of 48 and 64.9 years ( $p<0.0001$ ). Most tumors (79.5%) were both ER-positive and progesterone receptor (PR)-positive. Post-menopausal women had significantly more ER-positive/PR-negative ILC than premenopausal women (25.3% vs 9.9%,  $p<0.001$ ), were more likely to have a BMI in the overweight/obese category (53.6% vs 40.1%,  $p=0.016$ ), and were more likely to have metabolic syndrome (21.9% vs 6.8%,  $p<0.001$ ). Of the 143 cases with an Oncotype RS, 69.9% were intermediate, 21.7% were low, and 8.4% were high risk. Post-menopausal women had significantly higher RS than premenopausal women

when RS was treated as a continuous variable (16.9 vs 13.8,  $p=0.007$ ). Among postmenopausal women, overweight/obesity status was associated with lower RS while those with normal weight had a greater proportion of high RS tumors ( $p=0.027$ ). There was no association between BMI and RS in the pre-menopausal population. Similarly, there was no association between metabolic syndrome and tumor subtype in either group.

**Conclusions:** In this cohort of women with ER-positive pure ILC, we found that post-menopausal ILC had higher rates of overweight/obesity, metabolic syndrome, and numerically higher RS than pre-menopausal ILC. However, within the post-menopausal group, higher BMI was anti-correlated with RS whereas BMI had no impact on pre-menopausal ILC RS. Since obesity is associated with worse outcomes for breast cancer, these findings are unexpected and raise the possibility that the hormonal pathogenesis and estrogenic drive behind ILC differs in pre- vs post-menopausal women, consistent with their different PR positivity rates, possibly due to the more local production of estrogen from higher breast adiposity in post-menopausal women relative to the greater systemic ovarian production of estrogen in pre-menopausal women. These findings have potential implications for both ILC prevention and adjuvant therapy strategies.

Estrogen-based hormone replacement therapy [E-HRT] reduces all-cause, breast cancer, and Alzheimer's dementia mortality

Joseph Ragaz<sup>1</sup>, Shayan Shakeraneh<sup>1</sup>, Hong Qian<sup>1</sup>, Hubert Wong<sup>1</sup>, John J. Spinelli<sup>1</sup> and Kenneth S. Wilson<sup>2</sup>. <sup>1</sup>School of Population and Public Health, University of British Columbia, Vancouver, BC, Canada<sup>2</sup>British Columbia Cancer, Victoria, BC, Canada

**OBJECTIVES.** To evaluate the long-term population-level impact of E-HRT on cause-specific and all-cause mortality in postmenopausal women in the USA, using the results of the 2017 Women's Health Initiative HRT Trial 2 update.<sup>1</sup> Of particular interest was the significantly reduced Breast Cancer [BrCa] mortality rates [RR=0.55, 95% C.I.=0.33-0.92].<sup>1</sup>

**METHODOLOGY.** In the WHI HRT Trial 2, women were randomized to receive estrogen (**E**) or placebo (**P**).<sup>1</sup> For our analyses, the Annualized mortality rates (AR) were extracted for women aged 50-59, 60-69, 70-79, for breast cancer, Alzheimer's dementia, and all-cause mortality. The Median follow-up was 18 years. The Annualized Mortality Rate Difference (**ARD**) between the two groups was calculated as a difference of the AR between the **P** vs. **E** ( $AR\ in\ P - [minus]\ AR\ in\ E$ ), expressed per 100,000 person-years. Subsequently, the Number of Avoided Deaths per year (**NAD/year**) was calculated using the number of women in each age group from the 2010 US census data.

**RESULTS.** The annualized number of deaths avoided by the use of E-HRT in the US population was estimated as follows: BrCa, 9,292; Alzheimer's dementia: 18,966; and all cause-mortality: 50,008 (*Table*).

Ages	Age 50 – 59(N=21,506,008)		Age 60 – 69(N=15,323,140)		Age 70 – 79(N=9,169,601)		ALL ages(N=45,998,749)
	ARD / 100,000	NAD / Year	ARD / 100,000	NAD / Year	ARD / 100,000	NAD / Year	NAD / Year
Breast Cancer	20	4,301	23	3,524	16	1,467	9,292
Alzheimer's Dementia	0	0	40	6,129	140	12,837	18,966
All-Cause Mortality	150	32,259	50	7,662	110	10,087	50,008

**CONCLUSIONS.** These data show a major beneficial impact of E-HRT, with over 50,000 deaths/year prevented in the USA alone. While these gains, sustained throughout the follow-up, represent undoubtedly major multi-organ metabolic benefits of estrogen, the most striking and unexpected findings involve BrCa, with over 9,000 BrCa deaths potentially avoided each year, just in the USA alone.

**RECOMMENDATION.** Adoption and implementation of E-based HRT to the current HRT medical guidelines, to extend the health benefits to millions of women, and to prevent thousands of deaths each year in the USA alone.

Functional importance of long-tail mutations in breast cancer

Tao Qing, Hussein Mohsen, Mariya Rozenblit, Michal Marczyk, Julia Foldi, Kim Blenman, Vignesh Gunasekharan and Lajos Pusztai. Yale University, New Haven, CT

**Background:** Cancer driver genes are characterized by frequently recurrent mutations, substantial functional impact on in vitro and in vivo cancer growth, and several of the represent clinically important therapeutic targets. Whole exome and genome sequencing studies identified mutations in at least one cancer driver gene in about 70% breast cancers. These studies also revealed that each cancer also harbors hundreds to thousands of additional non-recurrent mutations which follow a long-tail distribution. Historically, these long tail “passenger” mutations are considered random due to genomic instability and not expected to contribute to the biology of the disease. We hypothesize that “long-tail” mutations could also have functional importance and contribute to the unique biology of a given cancer. The goal of the current analysis was to identify the long-tail mutations in breast cancer, and estimate their overall functional importance. **Methods:** We obtained somatic mutations from the breast cancer TCGA cohort (N=1076) and calculated the somatic mutation frequency for each gene. The dNdScv algorithm was used to estimate significantly mutated genes. A gene was considered to be in the long tail of mutations if its somatic mutation frequency was 1-3%, and the dNdScv p-value was < 0.05. We performed pathway enrichment analysis with 21 cancer pathways assembled by NanoString Technologies (Seattle, WA) for the long-tail genes using Fisher's exact test and obtained gene dependency scores (DS) from The Cancer Dependency Map (DepMap) project which performed genome-wide pooled loss of function screening for 17,634 human genes using and CRISPR-Cas9-mediated (CRISPR) gene editing to estimate tumor cell viability after gene silencing in 563 cell lines. The more negative (i.e. lower) the dependency score the more important the gene is to sustain cell viability. We compared the DS of the long tail genes with known cancer driver genes and other human genes excluding known breast cancer driver genes. We also compared the dependency score of genes with long-tail mutations between breast cancer and other cancer types using the Mann-Whitney U test. We estimated the trend of average dependency score across genesets using the Jonckheere Terpstra test and using Kendall's tau ( $\tau$ ) coefficient to show the increasing (positive value) or decreasing (negative value) trend. **Results:** Seventy percent of breast cancers (n=763) carried long-tail mutations in 115 different genes. The average number of long tail mutations was N=3 (range from 1 to 118). Genes with long-tail mutations were enriched in epithelial-mesenchymal transition, extracellular matrix, angiogenesis, adaptive immunity, MAPK, innate immunity, inflammation, and RAS pathways (FDR<0.035). Genes with long-tail mutations showed the lowest average dependency score in breast cancer cell lines (n=28) with median DS= -0.080, the range of median DS was -0.079 to -0.056 in other cancer cell lines (P=0.70). In the breast cancer cell lines, known breast cancer driver genes (N=11) had the lowest DS (median=-0.352), followed by the long-tail genes (median=-0.0801), followed by all other human genes (median DS=-0.0528). An increasing trend ( $\tau=1.78$ , P=0.024) of dependency score was observed across known cancer driver genes, long-tail genes, and other human genes which indicate that long-tail genes are important in cancer cell viability. **Conclusions:** Long-tail mutations are seen in most breast cancers in unique combinations. They primarily affect genes involved in key cancer pathways. Long tail genes have negative dependency scores across 563 cancer cell lines indicating functional importance in sustaining cancer viability. These results suggest that long-tail genes with mutations could contribute to the biology of breast cancers and might explain the broad range of differences in clinical behavior or morphologically similar cancers.

Genomic profiling and clinical outcomes with first-line atezolizumab and *nab*-paclitaxel in triple-negative breast cancer: An exploratory analysis from the phase 3 IMpassion130 trial

Leisha Emens<sup>1</sup>, Luciana Molinero<sup>2</sup>, Sylvia Adams<sup>3</sup>, Hope S. Rugo<sup>4</sup>, Andreas Schneeweiss<sup>5</sup>, Veronique Dieras<sup>6</sup>, Hiroji Iwata<sup>7</sup>, Carlos Barrios<sup>8</sup>, Eric P. Winer<sup>9</sup>, Ching-Wei Chang<sup>2</sup>, Stephen Y. Chui<sup>2</sup>, Peter Schmid<sup>10</sup> and Sherene Loi<sup>11</sup>. <sup>1</sup>University of Pittsburgh Medical Center Hillman Cancer Center, Pittsburgh, PA; <sup>2</sup>Genentech, Inc., South San Francisco, CA; <sup>3</sup>NYU Langone Medical Center, New York, NY; <sup>4</sup>University of California San Francisco Comprehensive Cancer Center, San Francisco, CA; <sup>5</sup>University Hospital and German Cancer Research Center Heidelberg, Heidelberg, Germany; <sup>6</sup>Department of Medical Oncology, Centre Eugene Marquis, Rennes, France; <sup>7</sup>Aichi Cancer Center Hospital, Nagoya, Japan; <sup>8</sup>Centro de Pesquisa Clinica, HSL, PUCRS, Porto Alegre, Brazil; <sup>9</sup>Dana-Farber Cancer Institute, Boston, MA; <sup>10</sup>Barts Cancer Institute, Queen Mary University London, London, United Kingdom; <sup>11</sup>Peter MacCallum Cancer Centre, Melbourne, Australia

**Background:** The clinical implications of genomic alterations in metastatic triple-negative breast cancer (mTNBC) have not been clearly addressed. In IMpassion130, atezolizumab (A) + *nab*-paclitaxel (nP) showed improved progression-free survival (PFS) and clinically meaningful overall survival (OS) benefit vs placebo (P) + nP in PD-L1+ mTNBC (Schmid, *NEJM* 2018). The goal of this exploratory study was to evaluate the prevalence of genomic alterations and their relationship with PD-L1 status and to determine whether a prognostic or predictive role for these factors exists for A + nP in a randomized dataset. **Methods:** Primary or metastatic tumor samples from patients in the IMpassion130 biomarker-evaluable population (BEP) were centrally evaluated for short variants (SV), copy number alteration (CNA) and rearrangements by using a targeted next-generation sequencing (NGS) panel (FoundationOne). PD-L1 status was evaluated using the VENTANA SP142 assay, with PD-L1 positivity defined by PD-L1-expressing immune cells on ≥1% of tumor area. Prognostic effects of genomic alterations were evaluated in the pooled population from both treatment arms. PFS and OS (co-primary endpoints) were analyzed by Cox proportional hazards models. ClinicalTrials.gov identifier: NCT02425891. **Results:** The BEP comprised 614 patients (68% of intent-to-treat population), 605 of whom received treatment. The most common pathogenic alterations were found in the following genes: *TP53* (SV, 85%), *MYC* (CNA, 21%), *PIK3CA* (SV, 18%), *PTEN* (SV/CNA, 18%), *RB1* (SV, 7%) and *BRCA1* (SV, 9%). Primary tumors (n = 419), compared with metastatic tumors (n = 195), were more likely to bear alterations in *BRCA1* (11.9% vs 5.6%) and less likely to have *PIK3R1* alterations (4.8% vs 9.2%). *TP53* loss-of-function mutations were associated with PD-L1+ status, whereas amplifications in *VEGFA* and *CCND3* genes were significantly less associated; none of these alterations were linked with clinical outcomes favoring A + nP. Loss of *RB1* (frequency 5%) was linked with reduced PFS and OS prognosis independent of treatment (hazard ratio [HR], 2.09 [95% CI: 1.42, 3.07] and HR, 1.98 [1.26, 3.11]), respectively), and CNA in *CDKN2A* (12%) and *CDKN2B* (11%) were associated with improved PFS and OS clinical activity in the A + nP arm vs the P + nP arm (HR PFS, 0.43-0.44 and HR OS, 0.47, respectively). Three of 584 microsatellite-evaluable samples (0.5%) had MSI-H status, which was not associated with PD-L1 status; all 3 MSI-H patients were from the P + nP arm. A total of 220 of 514 evaluable samples (42.8%) had *PIK3CA/AKT1/PTEN*-altered status, which was not significantly associated with PD-L1 status or A + nP clinical outcome. **Conclusions:** In this exploratory analysis using a targeted NGS panel, we show that tumors from patients with previously untreated mTNBC had similar genomic profiles at baseline as those published for early TNBC tumors. The few alterations that were linked to PD-L1 status were not linked to clinical outcome. CNA in cell cycle genes (e.g., *RB1*) had potential prognostic value, whereas *CDKN2A* and *CDKN2B* were potentially predictive of A + nP clinical benefit favoring A + nP. These data are hypothesis generating and require validation in an independent data set.

Ribociclib + letrozole in patients with hormone receptor-positive (HR+), human epidermal growth factor receptor-2-negative (HER2-) advanced breast cancer (ABC): Expanded safety analysis of the phase IIIb ComPLEEment-1 trial

Janice Lu<sup>1</sup>, Paul Cottu<sup>2</sup>, Miguel Martin<sup>3</sup>, Claudio Zamagni<sup>4</sup>, Aleix Prat<sup>5</sup>, Stephen Chia<sup>6</sup>, Guy Jerusalem<sup>7</sup>, Senthil Rajappa<sup>8</sup>, Constanta Timcheva<sup>9</sup>, Lyudmila Zhukova<sup>10</sup>, Katie Zhou<sup>11</sup>, Jiwen Wu<sup>11</sup>, Lakshmi Menon-Singh<sup>11</sup> and Michelino De Laurentiis<sup>12</sup>. <sup>1</sup>USC Norris Comprehensive Cancer Center, Los Angeles, CA; <sup>2</sup>Curie Institute, Paris, France; <sup>3</sup>Gregorio Marañon General University Hospital, Madrid, Spain; <sup>4</sup>Bologna University Hospital, St Orsola-Malpighi Polyclinic, Bologna, Italy; <sup>5</sup>Hospital Clinic, University of Barcelona, Barcelona, Spain; <sup>6</sup>University of British Columbia, Vancouver, BC, Canada; <sup>7</sup>CHU de Liege, University of Liege, Liege, Belgium; <sup>8</sup>Basavata Ramakrishna Indo American Cancer Hospital and Research Institute, Hyderabad, India; <sup>9</sup>MHAT 'Nadezhda', Sofia, Bulgaria; <sup>10</sup>Loginov Moscow Clinical Scientific Center, Moscow, Russian Federation; <sup>11</sup>Novartis Pharmaceuticals Corporation, East Hanover, NJ; <sup>12</sup>National Cancer Institute "Pascale Foundation", Naples, Italy

**Background:** ComPLEEment-1 (NCT02941926) is an ongoing Phase IIIb trial of ribociclib (RIB) in combination with letrozole (LET) in the first-line setting for patients (pts) with HR+, HER2- ABC, reflecting a real-world clinical setting by including a more diverse pt population than those included in the pivotal MONALEESA trials. Here we report further analyses of the primary endpoint of safety from the completed Core Phase of the trial. **Methods:** ComPLEEment-1 included women of any menopausal status and men with HR+, HER2- ABC treated with ≤1 line of prior chemotherapy and no prior hormonal therapy for advanced disease. Pts received RIB (600 mg QD, 3 weeks on/1 week off) in combination with LET (2.5 mg QD, continuous). Premenopausal women and men received a luteinizing hormone-releasing hormone agonist (3.6 mg goserelin or 7.5 mg leuprolide, Q28D). The primary endpoints were safety and tolerability. Updated analyses included dose reduction/interruption or treatment discontinuation due to adverse events (AEs), clinical impact of AEs of special interest (AESI), and exposure-adjusted incidence/occurrence rates (IRs) for AESI. **Results:** At data cutoff (November 8, 2019) 3,246 pts had been evaluated (median follow-up of 25.4 months), and median duration of exposure to RIB was 17.5 months; 1,301 (40.1%) pts completed Core Phase treatment, 415 of whom moved to the Extension Phase. Overall, 1,945 (59.9%) pts permanently discontinued treatment, mostly due to progressive disease (34.2%) and AEs (15.5%). Treatment-related AEs were reported in 3,091 (95.2%) pts, leading to dose modification in 2,235 (68.9%) pts. Dose modification occurred most often in pts with grade ≥3 neutropenia (dose interruption, 1,671 [51.5%] pts; dose reduction, 480 [14.8%] pts); treatment discontinuation occurred most frequently in pts with grade ≥3 increased alanine aminotransferase (ALT; 116 [3.6%] pts) or aspartate aminotransferase (AST; 68 [2.1%] pts). Grade ≥3 neutropenia occurred in 1,856 (57.2%) pts, with the median time to first occurrence of 4.1 weeks and median duration of first occurrence of 1.1 weeks. As measured by laboratory values, grade ≥2 increased ALT and AST occurred in 453 (14.0%) and 380 (11.7%) pts, respectively. Grade ≥2 QTcF prolongation was infrequent, occurring in 101 (3.1%) pts, leading 8 (0.2%) pts to discontinue from treatment. AESI rarely led to hospitalization (0 to 0.3%) and none were fatal. Exposure-adjusted IRs for AESI per 100 patient-years of exposure show that with increasing RIB exposure, the IR and the event rates for AESI decreased by a factor of ×2 to ×8 from 0-1 years compared with 1-2 years (Table 1). **Conclusions:** AEs associated with RIB + LET combination therapy were manageable, consistent with previous Phase III trials of RIB + LET - and adjusted IRs for AESI notably decreased from Year 1 to Year 2 of treatment. These data further support the use of RIB + LET for first-line treatment of HR+, HER2- ABC in both men and women of any menopausal status and in a broader and more diverse patient population.

**Table 1. Exposure-adjusted IRs for selected AESI per 100 patient-years of exposure**

AESI	0-1 years		1-2 years	
	IR per 100 PTY <sup>a</sup>	Events per 100 PTY <sup>b</sup>	IR per 100 PTY <sup>a</sup>	Events per 100 PTY <sup>b</sup>
Neutropenia	276.76	410.22	92.43	200.83
ALT increased	20.37	41.66	3.79	6.32
AST increased	17.51	33.27	2.94	4.61
QTcF prolongation	8.44	10.22	1.08	1.26

<sup>a</sup> IR per 100 PTY: n/100 PTY, number of patients with an event divided by the corresponding sum of the exposure duration for patients, where duration of exposure in patient treatment-years (PTY) is counted up to the first qualifying event (or duration of exposure in time interval for patients without an event).

<sup>b</sup> Events per 100 PTY: n/100 PTY, number of events divided by the corresponding sum of the exposure duration, where duration of exposure in patient treatment-years (PTY) is duration of exposure in time interval.

Publication Number: PD9-05

A tiered algorithm using mid-therapy ultrasound (US) response assessment and a novel gene expression signature (GES) improves the prediction of pathologic complete response (pCR) to neoadjuvant therapy (NAT) in triple-negative breast cancer (TNBC): Results from the ARTEMIS trial (NCT02276443)

Sahil Seth, Gaiane M Rauch, Beatriz Adrada, Helen Piwnica-Worms, Lei Hou, Alastair M Thompson, William F Symmans, Bora Lim, Jason White, Giulio F Draetta, Andrew Futreal, Jeffrey Chang and Stacy Moulder. MD Anderson Cancer Center, Houston, TX

**Background:** The heterogeneity of TNBC results in mixed responses to NAST: 30-60% of patients (pts) have a pCR to standard chemotherapy with an excellent prognosis. Several methods have been used to predict pCR, most yielding a positive predictive value (PPV) of no greater than 70%. To improve prediction of pCR to NAT, we hypothesized that we can integrate mid-treatment US with molecular profiling to generate a GES, thus reducing the need for escalation of therapy (example: immunotherapy) in select patients. We used data from ARTEMIS, a prospective trial that uses molecular profiling and imaging assessment of TNBC response during therapy to personalize NAT. **Methods:** Patients begin a planned 4 cycles of AC. Those with substantial volumetric reduction ( $\geq 70\%$ ) of the primary tumor by US (SVR-US) after AC receive standard taxane-based therapy as the second phase of NAT, while those with resistant disease (including disease progression during AC) are offered therapeutic trials based upon molecular profiling of the pre-treatment biopsy. Pathologic response is assessed at surgical resection. **Results:** 167 patients had RNAseq, US and pCR data. Overall pCR was 36%. TNBCs with SVR-US after AC (n=101) had significantly higher pCR (55 vs 6%,  $p < 0.001$ ). SVR-US had a PPV of 0.55 and NPV of 0.94 for prediction of pCR. Given the strong NPV, we focused on improving the PPV. In the 101 TNBCs that had SVR-US after AC, we performed differential gene expression comparing those with pCR vs residual disease using 74 TNBCs as a training set and 29 as a validation/test set. Differentially expressed genes (N=500-1000) served as a feature set for a series of machine learning models, including GBM (gradient boosting machines), GLM (generalized linear models), SVM (support vector machines) and CNN (convolutional neural networks) (N train=74). CNN and GLM had similar accuracy, NPV and PPV on the validation set (N=29), therefore GLM was selected as the final model because of ease of interpretability. By combining with SVR-US, we were able to increase the PPV of the tiered model from 0.55 (SVR-US after AC) to 0.89 (SVR-US after AC+GES/GLM) (validation set). Our analysis has validated the predictive value of the GES in patients with SVR-US to 4 cycles of AC, but the entire algorithm (including TNBCs without SVR-US) requires a second validation cohort. However, if the PPV and NPV remain consistent, the impact of this strategy to determine which TNBCs require therapy escalation beyond AC $\pm$ T is estimated in Table 1. **Conclusions:** We have created an integrative, tiered model combining two complementary modalities (mid-treatment US assessment of response and GES) that has substantially improved the PPV in assessing pCR to NAST using the ARTEMIS strategy.

Table 1: PPV and NPV used to estimate the impact in escalation of therapy*			
Correct decision: 88% of pts	Incorrect decision: 12% of pts		
Predicted pCR=pCR (True positives) Therapy correctly not escalated	Predicted non-pCR=non-pCR (True negatives) Therapy correctly escalated	Under treatment	Over treatment

First efficacy results of a 2-stage Simon's design randomised phase 2 of darolutamide or capecitabine in patients with triple-negative, androgen receptor positive advanced breast cancer (UCBG06-3)

Herve Bonnefoi<sup>1</sup>, Florence Lerebours<sup>2</sup>, Olivier Tredan<sup>3</sup>, Florence Dalenc<sup>4</sup>, Christelle Levy<sup>5</sup>, Mahasti Saghatian<sup>6</sup>, Marie Ange Mouret Reynier<sup>7</sup>, Delphine Mollon<sup>8</sup>, Severine Guieu<sup>9</sup>, Laurence Venat Bouvet<sup>10</sup>, Elisabeth Carola<sup>11</sup>, Geraldine Martineau<sup>12</sup>, Marina Pulido<sup>1</sup>, Gaetan MacGrogan<sup>1</sup> and Anthony Goncalves<sup>13</sup>. <sup>1</sup>Institut Bergonie, Bordeaux, France<sup>2</sup>Institut CURIE - Hopital R. Huguenin, Saint Cloud, France<sup>3</sup>Centre Leon Berard, Lyon, France<sup>4</sup>Institut Claudius Regaud, Toulouse, France<sup>5</sup>Centre Francois Baclesse, Caen, France<sup>6</sup>Gustave Roussy, Villejuif, France<sup>7</sup>Centre Jean Perrin, Clermont Ferrand, France<sup>8</sup>CHIC Quimper, Quimper, France<sup>9</sup>Institut du Cancer de Montpellier, Montpellier, France<sup>10</sup>CHU Dupuytren, Limoges, France<sup>11</sup>Groupe Hospitalier du Sud de l'Oise, Creil, France<sup>12</sup>unicancer, Paris, France<sup>13</sup>Institut Paoli-Calmettes, Marseille, France

**Background:** Triple negative breast cancer (TNBC) is an heterogeneous disease and encompasses at least 4 subtypes. One of these expresses the androgen receptor (AR). Several prospective trials demonstrated antitumour efficacy with anti-androgen treatment in patients with advanced breast cancer. Darolutamide is an androgen-receptor antagonist with a potent anti-tumour efficacy in metastatic prostate cancer with a favorable safety profile. We conducted a randomized non-comparative phase II trial to study the efficacy and tolerability of darolutamide and capecitabine in AR-positive TNBC (NCT03383679).

**Material and methods:** Patients (Pts) with a metastatic, centrally reviewed, AR-positive ( $\geq 10\%$  by immunohistochemistry) and TNBC who have received a maximum of one line of chemotherapy for advanced disease were eligible. They were randomised in a 2:1 ratio to receive darolutamide (D arm) 600 mg twice daily or capecitabine (C arm) at 1000 mg/m<sup>2</sup> twice daily 2 weeks on and 1-week off, until progression or unacceptable toxicity. The primary endpoint was clinical benefit rate (CBR) defined as the proportion of pts presenting a complete response (CR), partial response (PR), or stable disease (SD) at 16 weeks. Main secondary endpoints included objective response rate, overall survival, progression-free survival and safety. An interim statistical analysis was planned when 19 assessable pts will be available in the D arm. According to an optimal 2-stage Simon's design, if  $<5$  patients experienced a CBR the trial should be stopped for futility; if 5 or more experienced a CBR the trial should continue up to a total of 54 patients in the D arm.

**Results:** Out of 133 pts screened and centrally analyzed, from 37 centres, 54% (72/133) were AR-positive. 45 pts were randomized (29 in D arm and 16 in C arm) from April 2018 to December 2019. In arm D, median age was 60 years (range 47-88). and 13.8 % received a first line of chemotherapy for metastatic disease. A total of 19 pts were eligible and assessable for the primary endpoint in D arm. 5 CBR were confirmed at 16 weeks (26.3%; 95% CI: 9.2%-51.2 %) including 1 confirmed PR and 4 SD. In arm D, fatigue (23.8%), ASAT increased (23.8%), and blood alkaline phosphatase increased (23.8%) were the most common drug-related adverse events; the majority of them being grade 1 or 2. 6 pts presented with drug-related serious adverse events: one in D arm and 5 in C arm.

**Conclusions:** According to the planned interim analysis, the efficacy objective is met (5 CBR) in D arm. Moreover, darolutamide is well tolerated. Thus, patients are now recruited in the second stage.

**Keywords:** Androgen receptor, triple-negative breast cancer, darolutamide, advanced breast cancer

**Background:** AZD9833 is an oral selective estrogen receptor (ER) antagonist and degrader (SERD) in Phase 2 clinical development for the treatment of ER+ HER2- breast cancer. Here we report data from Parts C and D of the ongoing Phase 1 study (SERENA-1) examining AZD9833 in combination with palbociclib, together with updated data from Parts A and B examining AZD9833 monotherapy. **Methods:** SERENA-1 (NCT03616587) is an ongoing open-label Phase 1 study of AZD9833 in pre- and post-menopausal women with ER+, HER2- advanced breast cancer who have previously received  $\geq 1$  endocrine therapy and  $\leq 2$  prior chemotherapies. Prior treatment with fulvestrant and/or CDK4/6 inhibitors was permitted. The primary objective is to determine the safety and tolerability of once daily (QD) AZD9833, with dose-limiting toxicities (DLTs) in the first 28 days defining the maximum tolerated dose. Secondary objectives include anti-tumor response (including circulating tumor [ct] DNA response) and pharmacokinetics. Parts A (escalation) and B (expansion) assess AZD9833 as a monotherapy, and Parts C (escalation) and D (expansion) assess AZD9833 in combination with palbociclib. **Results:** At a data cut-off of March 24 2020, 17 patients had received either 150 mg or 300 mg AZD9833 in combination with palbociclib, given according to its product labeling. Eighty patients had received AZD9833 monotherapy at doses of 25, 75, 150, 300, and 450 mg QD. In patients treated with AZD9833 and palbociclib, treatment-related adverse events (AEs; experienced by  $\geq 10\%$  of patients) included visual disturbances\*, bradycardia\*, asthenia, anemia, QTcF prolongation, nausea, neutropenia, decreased white blood cell count, and vomiting (\*combined terms). All instances of AZD9833-related bradycardia were Grade 1. One DLT was observed in the 150 mg cohort: CTCAE Grade 2 visual disturbances, which began on Cycle 1 Day 8 and resolved by Cycle 1 Day 9 following dose interruption. The patient restarted treatment on Cycle 1 Day 15 at 75 mg and continued this dose until data cut-off. No causally related AEs led to discontinuation of AZD9833. The tolerability of AZD9833 with palbociclib was consistent with the observed tolerability profile of AZD9833 monotherapy, and the known tolerability profile of palbociclib. Pharmacokinetic analysis showed similar AZD9833 exposure for monotherapy and palbociclib combination therapy. Similarly, palbociclib exposure was comparable with simulations using a published population pharmacokinetic model. In Part A, *ESR1* hotspot mutations were detected in ctDNA at baseline in 26/56 (46%) patients; 13/26 (50%) of these patients achieved a partial response or stable disease at 24 weeks, including 5/10 (50%) with a Y537S *ESR1* mutation. Further, in patients with *ESR1* mutations and samples available for longitudinal ctDNA analysis, 17/20 (85%) exhibited a reduction or loss of mutant *ESR1* on treatment with AZD9833. Efficacy data to be presented include objective response rate and clinical benefit rate at 24 weeks. Of note, unconfirmed partial responses have been observed in Part C after the data cut-off for this abstract. **Conclusions:** AZD9833 continues to show an encouraging efficacy and dose-dependent safety profile as a monotherapy or in combination with palbociclib. A Phase 2 study comparing the efficacy and safety of three doses of AZD9833 versus fulvestrant (NCT04214288), and a Phase 2 pre-surgical 'window of opportunity' study (EUDRA-CT; 2019-003706-2) are ongoing.

Neoadjuvant chemotherapy selectively alters spatially-defined immune landscapes in clinical luminal B HR+/HER2- breast cancers: Analysis of the breast cancer genome guided therapy study (BEAUTY)

Jodi M Carter<sup>1</sup>, Judy C Boughey<sup>1</sup>, Jun He<sup>1</sup>, Vera J Suman<sup>1</sup>, Xue Wang<sup>2</sup>, Jennifer M Kachergus<sup>2</sup>, Krishna R Kalari<sup>1</sup>, Liewei Wang<sup>1</sup>, Richard Weinshilboum<sup>1</sup>, Ann M Moyer<sup>1</sup>, Sarah A McLaughlin<sup>2</sup>, Alvaro Moreno-Aspitia<sup>2</sup>, Donald W Northfelt<sup>3</sup>, Richard J Gray<sup>3</sup>, James N Ingle<sup>1</sup>, E. Aubrey Thompson<sup>1</sup> and Matthew P Goetz<sup>1</sup>. <sup>1</sup>Mayo Clinic, Rochester, MN; <sup>2</sup>Mayo Clinic, Jacksonville, FL; <sup>3</sup>Mayo Clinic, Phoenix, AZ

**Introduction:** The immune microenvironment of high-risk HR+ breast cancer (BC) is poorly understood. BEAUTY is a prospective neoadjuvant chemotherapy (NAC) study of stage I-III BC patients treated with neoadjuvant weekly taxane followed by anthracycline-based chemotherapy. Among clinical luminal B BC (St. Gallen criteria) from BEAUTY, we used high-plex digital spatial profiling (DSP) to characterize the intra-epithelial tumor and stromal immune landscapes to 1) assess the impact of NAC on these landscapes and 2) identify immune biomarkers predictive of response to NAC. **Methods:** The tissue set included FFPE sections of resected tumors from 35 patients (median 51y; range: 21-71y) with clinically-defined luminal B BC (ER > 10%/grade 2/Ki67 ≥ 15% or ER > 10%/grade 3), and 16 paired pre-NAC biopsies. Nanostring GeoMX DSP was used to quantitate 58 immune and BC biomarker proteins in intra-epithelial, cytokeratin-positive tumor segments and adjacent stromal (cytokeratin-negative/SYTO13 (nuclear stain)-positive) segments. Data were normalized using the geometric mean of two negative controls (RbIgG and MslgG1). A general linear model with negative binomial identified differentially-expressed (DE) proteins in pre/post-NAC tumors. Based on DE protein data and biologic function, a targeted protein subset (N=19) was evaluated in pre-NAC biopsies for associations between protein abundance and residual cancer burden (RCB) class (0-II vs. III) (Wilcoxon-rank sum test: p-value < 0.025 considered significant) or RCB 'breast only' index (Spearman correlation). **Results:** Comparing tumor segments in pre-NAC specimens, intra-epithelial segments were predictably enriched in cytokeratin, ER, PR and Ki-67, but also CD127 and NY-ESO-1; whereas stromal segments were enriched in proteins associated with T cell subsets (e.g. CD3, CD4, CD8), macrophages (CD68 and CD163), antigen presentation/dendritic cells (CD11c, HLA-DR) and immune checkpoint proteins (PD-L1, PD-L2, B7-H3, TIM-3, VISTA) among others. While NAC did not alter the spatial distribution of proteins (intra-epithelial vs. stromal segments), it markedly attenuated the immune landscape, with decreased abundance of functionally-diverse immune proteins (e.g. CD45, CD3, CD4, CD127, granzyme B, CTLA4; STING, B7-H3, CD11c, and CD68, log2FC: 0.27-1.52 p < 0.05), including low abundance proteins PD-1, PD-L1, PD-L2, CD20, and OX40L (log 2FC: 0.15-1.16, p < 0.05). Both PR and Ki-67 decreased in post-NAC tumors whereas ER was not significantly altered (p < 0.05). CD8, CD14, CD163, HLA-DR, IDO-1 and TIM-3 were not significantly altered by NAC. In the pre-NAC biopsies (which had subsequent residual tumor burdens of RCB class 0 or I (n=1 each), II (n=6), and III (n=8), and median RCB 'breast only' index of 3.39 (range: 0.00-38.02), 19 proteins were used for RCB analysis (CD3, CD4, CD8, CD14, CD34, CD44, CD45, CD68, CD127, CD163, CTLA4, granzyme B, STING, B7-H3, fibronectin, Ki-67, HLA-DR, SMA and TIM3). Among them, stromal CD127 was significantly higher in RCB class III than RCB class 0-II (p=0.021) and RCB 'breast only' index was positively correlated with intra-epithelial granzyme B (rho = 0.61; p=0.012), and negatively correlated with intra-epithelial Ki-67 (rho= -0.71; p=0.0022). **Conclusion:** In this series of clinical luminal B BC, NAC markedly attenuated the tumoral immune landscapes with a small set of "NAC-resistant" immune proteins. Among a targeted set, stromal CD127 was significantly higher in RCB III, and RCB breast-only index was positively correlated with intra-epithelial granzyme B. These data provide insight into the impact of NAC on HR+ BC, and identify potential immune biomarkers to predict response to neoadjuvant chemotherapy.

Universal genetic testing in breast cancer patients: A multi-center prospective study

Brenda Ernst<sup>1</sup>, Natalie Ertz-Archambault<sup>1</sup>, Deborah J Rhodes<sup>2</sup>, Donald W Northfelt<sup>1</sup>, Myra Wick<sup>2</sup>, Douglas L Riegert-Johnson<sup>3</sup>, Scott Okuno<sup>2</sup>, Katie Kunze<sup>1</sup>, Michael Golafshar<sup>1</sup>, Cindy M Azevedo<sup>1</sup>, PLS Uson Junior<sup>1</sup>, ED Esplin<sup>4</sup>, Robert Nussbaum<sup>4</sup>, Margaret Klint<sup>1</sup>, Sarah Mantia<sup>3</sup>, Megan Hager<sup>1</sup>, Keith Stewart<sup>1</sup> and Niloy Jewel Samadder<sup>1</sup>. <sup>1</sup>Mayo Clinic, Phoenix, AZ; <sup>2</sup>Mayo Clinic, Rochester, MN; <sup>3</sup>Mayo Clinic, Jacksonville, FL; <sup>4</sup>Invitae Corporation, San Francisco, CA

**Background:** Hereditary factors play a key role in the risk of developing breast cancers. Identification of a germline predisposition can have important implications for treatment decisions, risk-reducing interventions, cancer screening, and testing for family members. **Aim:** To determine the prevalence of pathogenic or likely pathogenic germline mutations (P/LP) using a “universal” testing approach and uptake of no-cost cascade family testing in patients with breast cancer. **Methods:** We undertook a prospective multi-site study of germline genetic alterations among breast cancer patients receiving care at Mayo Clinic cancer centers in Rochester, MN; Eau Claire, WI; Jacksonville, FL and Phoenix, AZ between April 1, 2018 and March 31, 2020. Patients with a new or active breast cancer diagnosis (all stages) irrespective of cancer family history were tested with a >80-gene next generation sequencing panel. **Results:** Of 390 patients, the median age was 58 years (SD 12.3), 1% were male, 85% were white and 28% had advanced (stage 3-4) disease. P/LP were found in 12.1% (n=47) of patients, including 29 in moderate and high penetrance cancer susceptibility genes. 13 (3.3%) patients had mutations in BRCA1 or 2, while 33 (8.4%) had mutations in BRCAness (ATM, BAP1, BARD1, BLM, BRCA1, BRCA2, BRIP1, CHEK2, NBN, PALB2, RAD50, RAD51C, RAD51D, WRN) associated genes. Of the P/LP findings the most frequent aberrations were in BRCA2 (13.5%), BRCA1 (11.5%), CHEK2 (11.5%), MUTYH (11.5%), and WRN (9.6%). Variants of uncertain significance were found in 209 (53.6%) including 26 (6.6%) with concurrent P/LP and VUS. 37 (9.4%) patients had mutations associated with published management recommendations, precision therapies and/or clinical trial eligibility. 10 (2.6%) patients had P/LP that would not have met current screening guidelines, including 4 with moderate or high penetrance mutations. Patients with younger age of diagnosis were less likely than patients with older age of diagnosis to have a P/LP mutation (OR= 0.47, 95%CI: 0.25-0.90  $p = 0.020$ ). Only 10 (21%) patients with P/LP had family members undergo familial site- specific testing at no cost. **Conclusions:** In this prospective multi-center study of unselected breast cancer patients, universal multi-gene panel testing found that 1 in 8 patients harbor P/LP germline variants. Current guidelines were able to identify the majority of patients with P/LP mutations. Familial site specific testing is greatly under-utilized even when cost is not a barrier. Multigene panels impact cancer patient care by identifying precision medicine treatment interventions, and guiding long-term medical management and preventive surveillance.

Prospective evaluation of the gut microbiome and response to neoadjuvant therapy (NAT) in early-stage triple negative breast cancer (TNBC)

Nour Abuhadra<sup>1</sup>, Chia-Chi Chang<sup>1</sup>, Clinton Yam<sup>1</sup>, Ryan Sun<sup>1</sup>, Lei Huo<sup>1</sup>, Jason White<sup>1</sup>, Elizabeth E Ravenberg<sup>1</sup>, Jennifer Litton<sup>1</sup>, Bora Lim<sup>1</sup>, Naoto T Ueno<sup>1</sup>, Banu Arun<sup>1</sup>, Debu Tripathy<sup>1</sup>, Senthil Damodaran<sup>1</sup>, Rashmi Murthy<sup>1</sup>, Vicente Valero<sup>1</sup>, Gabriel Hortobagyi<sup>1</sup>, Nuhad Ibrahim<sup>1</sup>, Alastair Thompson<sup>2</sup>, Elizabeth Mittendorf<sup>3</sup>, Stacy Moulder<sup>1</sup> and Robert Jenq<sup>1</sup>. <sup>1</sup>University of Texas - MD Anderson Cancer Center, Houston, TX; <sup>2</sup>Baylor College of Medicine, Houston, TX; <sup>3</sup>Dana Farber Cancer Institute, Boston, MA

**Introduction:** Emerging data suggest that the gut microbial composition influences responses to chemotherapy and immunotherapy. However, similar data in patients with TNBC receiving NAT remains limited. Thus, we investigated the association between the gut microbial composition in patients with newly-diagnosed, early-stage TNBC and response to NAT in a cohort of patients enrolled in the ARTEMIS trial (NCT02276443). **Methods:** We performed 16S sequencing on bacterial genomic DNA extracted from pre-NAT fecal samples using the 2x250 bp paired-end read protocol. Quality-filtered sequences were clustered into Operational Taxonomic Units and classified using Mothur method with the Silva database version 128. Associations between abundance and pathologic response to NAT were assessed using the Mann Whitney U Test. A cohort of 32 patients had longitudinal samples collected. Mann-Whitney U Test and Fishers exact were used to compare clinical variables as appropriate between the pCR and non-pCR groups. **Results:** There was no significant difference in age, race or stage between the pCR and non-pCR groups (Table 1). As expected, the pCR group was enriched for high TIL (p=0.026). There was no difference in alpha-diversity of the gut microbiome between patients with NAT-sensitive (pCR) and NAT-resistant disease (non-pCR) (p=0.5). Relative to patients with NAT-sensitive disease (pCR), the gut microbiome in patients with NAT-resistant disease was enriched for *Fusobacterium* (p=0.009), *Intestinimonas* (p=0.01) and *Lachnospiraceae* (p=0.003) at the genus level; the median abundances between pCR and non-pCR are provided in Table 1. Longitudinal samples collected during NAT demonstrated no substantial impact of NAT on the gut microbiome.

Table 1: Median Microbial Abundance and Clinicopathological Variables (N=43)			
	pCR (n=18)	Non-pCR (n=25)	p- value
<b>Microbial Abundance</b>			
<b>Fusobacterium</b>	1 x 10 <sup>-6</sup>	1.02 x 10 <sup>-5</sup>	<b>0.009</b>
<b>Intestinimonas</b>	6.4 x 10 <sup>-5</sup>	4.8 x 10 <sup>-4</sup>	<b>0.01</b>
<b>Lachnospiraceae</b>	6.2 x 10 <sup>-3</sup>	1.0 x 10 <sup>-2</sup>	<b>0.003</b>
<b>Age median, interquartile range (n=44)</b>	45 (38-59)	53 (46-58)	0.61
	n (%)		
<b>Race/Ethnicity</b>			
<b>White, non-Hispanic</b>	11 (61.1)	14 (56.0)	0.53
<b>White, Hispanic</b>	4 (22.2)	3 (12.0)	
<b>Black</b>	2 (11.1)	7 (28.0)	
<b>Asian</b>	1 (5.6)	1 (4.0)	
<b>T category</b>			
<b>T1</b>	5 (27.8)	4 (16.0)	0.15
<b>T2</b>	13 (72.2)	17 (68.0)	
<b>T3</b>	0	4 (16.0)	
<b>T4</b>	0	0	
<b>Nodal status</b>			
<b>Negative</b>	12 (66.7)	14 (56.0)	0.54
<b>Positive</b>	6 (33.3)	11 (44.0)	
<b>Stage</b>			
<b>I</b>	3 (16.7)	3 (12.0)	0.91
<b>II</b>	11 (61.1)	15 (60.0)	
<b>III</b>	4 (22.2)	7 (28.0)	
<b>TIL</b>			
<b>&lt;20%</b>	7 (38.9)	19 (76.0)	<b>0.026</b>
<b>≥20%</b>	11 (61.1)	6 (24.0)	

**Conclusions:** Taken together, these data suggest that response to NAT may be influenced by the gut microbial composition, which remains unaltered during NAT. Research efforts to modulate the gut microbiome should be further explored as a potential therapeutic strategy in TNBC.

Rugo<sup>5</sup>, Monica Arnedos<sup>6</sup>, Hiroji Iwata<sup>7</sup>, Pier Franco Conte<sup>8</sup>, Fabrice Andre<sup>6</sup>, Albert Reising<sup>9</sup>, Chong Ma<sup>10</sup>, Michelle Miller<sup>9</sup>, Naveen Babbar<sup>10</sup> and Dejan Juric<sup>11</sup>. <sup>1</sup>University Hospital 12 de Octubre, Madrid, Spain<sup>2</sup>German Breast Group, Neu-Isenburg, Germany<sup>3</sup>Vanderbilt University School of Medicine, Vanderbilt-Ingram Cancer Center, Nashville, TX;<sup>4</sup>Institut de Cancerologie de l'Ouest, St. Herblain, France<sup>5</sup>University of California, San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA;<sup>6</sup>Institut Gustave Roussy, Villejuif, France<sup>7</sup>Aichi Cancer Center Hospital, Aichi, Japan<sup>8</sup>Istituto Oncologico Veneto, University of Padua, Padua, Italy<sup>9</sup>Novartis Pharmaceuticals Corporation, East Hanover, NJ;<sup>10</sup>Novartis Pharmaceuticals Corporation, Cambridge, MA;<sup>11</sup>Department of Oncology/Hematology, Gillette Center for Women's Cancer, Massachusetts General Hospital Cancer Center, Boston, MA

**Introduction:** The PI3K pathway is often hyperactivated in cancer as a result of an altered PI3K isoform and/or loss of phosphatase and tensin homolog function. Approximately 40% of patients (pts) with hormone receptor-positive (HR+), human epidermal growth factor receptor-2-negative (HER2-) advanced breast cancer (ABC) have tumors with mutations in *PIK3CA*, which encodes the  $\alpha$ -isoform of PI3K, p110 $\alpha$ . These mutations are known to cause hyperactivation of the PI3K pathway, which contributes to cell proliferation, drug resistance, and poor prognoses. Alpelisib (ALP) is an  $\alpha$ -selective PI3K inhibitor that, in combination with fulvestrant (FUL), prolonged median progression-free survival (mPFS) in pts with HR+, HER2-, *PIK3CA*-mutant ABC following progression on/after prior aromatase inhibitor in the phase 3 SOLAR-1 trial. In SOLAR-1, prospective *PIK3CA* mutation testing was performed on tumor tissue using PCR-based assays. Through retrospective analysis, efficacy of ALP was demonstrated in subgroups of pts with *PIK3CA* alteration(s) in tumor tissue and mutation(s) in ctDNA, detected by next-generation sequencing (NGS) and PCR, respectively. In this exploratory biomarker analysis, we assessed clinical outcomes of pts with *PIK3CA* alteration(s), detected in ctDNA by NGS. **Methods:** SOLAR-1 is a phase 3, randomized, double-blind, placebo-controlled study of ALP 300 mg vs placebo taken daily with FUL 500 mg every 28 days + Cycle 1 Day 15 in men and postmenopausal women with HR+, HER2- ABC. Retrospectively, the full exonic region of the *PIK3CA* gene was sequenced using the Foundation Medicine 324-gene ctDNA panel in plasma ctDNA collected at baseline. mPFS was assessed using Kaplan-Meier methodology per investigator assessment. **Results:** Of 572 pts in SOLAR-1, 381 pts (66.6%) across both *PIK3CA*-mutant and nonmutant cohorts had valid plasma ctDNA data. Of these pts, 193 (50.7%) had a *PIK3CA* alteration; 168 (87%) had PCR-detectable mutations and 147 (76%) had a single alteration. A total of 70 (36%) and 102 (53%) pts had alterations in exons 9 and 20, respectively. ALP plus FUL prolonged mPFS in pts with *PIK3CA* alterations detected in plasma ctDNA by NGS (n=101; Table). Clinical benefit was also observed in pts with PCR-detectable mutations (n=88), single mutations (n=83), and pts with mutations in exon 9 (n=34) and exon 20 (n=54). Pt numbers were low, and wide 95% CIs were observed in groups with alterations not detectable by PCR (n=13) and in pts with multiple alterations. Some limitations of this retrospective plasma analysis include that this is a subgroup (66.6%) of the SOLAR-1 pt population and that the subgroup of pts with non-altered *PIK3CA* included pts with a *PIK3CA* mutation in their tumor tissue. **Conclusions:** ALP plus FUL demonstrated clinical benefit in pts with *PIK3CA* mutations detected in plasma ctDNA by NGS, in pts with single alterations, and in pts with alterations in exons 9 and 20. Results were consistent across pt groups, except in those with alterations not detectable by PCR. In conclusion, these data demonstrate a consistent clinical benefit of ALP plus FUL in various groups of pts with *PIK3CA* alterations detected in ctDNA by NGS.

Clinical Outcomes of Patients With <i>PIK3CA</i> Alterations Detected in Plasma ctDNA by NGS in SOLAR-1					
	Alpelisib + fulvestrant		Placebo + fulvestrant		HR (95% CI)
	Events/N (%)	mPFS, mo (95% CI)	Events/N(%)	mPFS, mo (95% CI)	
<i>PIK3CA</i> altered vs non-altered					
Altered	58/101(57.4)	11.04(7.72-16.16)	73/92(79.3)	3.65(2.86-6.80)	0.47(0.33-0.67)

Changes in management of breast cancer patients during first wave of COVID19, throughout the area of Kent, United Kingdom. An audit of ESMO guideline implementation

Simon N Rodney, Charlotte Abson, Russell Burcombe, Rema Jyothirmayi and Catherine Harper-Wynne. Maidstone Hospital, Kent, United Kingdom

**Background:** The global COVID-19 pandemic has placed unprecedented burden on individual oncology patients, oncology departments, hospitals and national health systems. In order to protect individual patients from the risk of COVID-19 infection as well as improve capacity for COVID-19 patient management, a series of national and internationally agreed measures were proposed. During the first wave of infections the virulence and effect on cancer patients was not known. It is vitally important that the measures implemented to combat these risks are assessed and evaluated in order to learn best how to manage potential future waves of known and unknown viral infections. **Methods:** The international ESMO COVID-19 guidelines and national (NICE) guidelines were implemented across Kent, UK. All changes to treatment regimens were audited to assess what were the most frequent changes and in which patient groups could these be implemented. Data was subdivided for both early and advanced breast cancer as well as ER+, HER2+ or triple negative disease. **Results:** We collected full treatment history from 1,718 breast cancer patients currently receiving active oncology treatments. We were able to change treatment regimens due to COVID19 for 32.8% of patients. Of these 27.1% were early breast cancer patients compared with 43.7% were those with advanced metastatic disease. The most common changes for neoadjuvant changes were proceeding to surgery before completion of planned chemotherapy (10.2%), switch to 3 weekly Paclitaxel (10%) and chemotherapy break (8%). For adjuvant patients the most common changes included postponement of bisphosphonates (70.8%), chemotherapy break (13.5%), and curtailment to 6 months of adjuvant Trastuzumab (10.4%). For our palliative patients the most common changes included delay CDK4/6 inhibitor treatment (79.2%), postponement of bisphosphonates (24.8%), break in HER2 antibody (9.6%) and break in chemotherapy (8%). **Conclusions:** A large proportion of breast cancer oncology patients were deemed suitable to have a change in original planned treatment. We are fortunate to have comparatively large number of treatment options that can be customised on a patient basis to individual reduce risk of COVID-19. Further analysis is needed over time to compare the oncological outcomes of those in whom treatment was changes from the current gold standards of care.

Characterization of breast cancer management during the COVID 19 pandemic in a large integrated healthcare delivery system: Stage at diagnosis and timing/modality of first treatment

Sharon B. Chang<sup>1</sup>, Alison C. Savitz<sup>2</sup>, Brooke Vuong<sup>3</sup>, Annie Tang<sup>4</sup>, Margaret Mentakis<sup>3</sup>, Amy M. Miller<sup>2</sup>, Veronica C. Shim<sup>5</sup> and Gillian E. Kuehner<sup>6</sup>.  
<sup>1</sup>Kaiser Permanente, Fremont Medical Center, Fremont, CA; <sup>2</sup>Kaiser Permanente, Walnut Creek Medical Center, Walnut Creek, CA; <sup>3</sup>Kaiser Permanente, South Sacramento Medical Center, Sacramento, CA; <sup>4</sup>University of California, San Francisco, San Francisco, CA; <sup>5</sup>Kaiser Permanente, Oakland Medical Center, Oakland, CA; <sup>6</sup>Kaiser Permanente, Vallejo Medical Center, Vallejo, CA

**Background:** The COVID 19 pandemic has disrupted all aspects of healthcare, including the diagnosis and treatment of breast cancer. In March 2020, the Society of Surgical Oncology, the American College of Surgeons, and the American Society of Breast Surgeons issued guidelines regarding the timing of surgery for cancer patients to preserve hospital resources and minimize exposure of patients and staff to COVID 19. Recommendations included delaying breast cancer surgery if possible, and using neoadjuvant chemotherapy or neoadjuvant endocrine therapy to treat selected patients while waiting for definitive surgery. In California, the “shelter in place” (SiP) order began March 17, 2020, and both screening mammography and elective surgeries were stopped in a large, integrated health care system. We evaluated the impact of these operational changes on the presentation and treatment of breast cancer patients in our system. **Methods:** We performed a retrospective review of patients newly diagnosed between 3/17/20, the starting date of SiP, and 5/18/20, when elective operations resumed in our system. We compared this cohort to patients who were diagnosed between 3/17/19 and 5/18/19. Age, histology, anatomic staging features, grade, receptor status, and initial treatment were compared between the cohorts. For the patients who underwent surgery, we compared the time from biopsy to time to surgery (TTS) and the type of operation. Comparisons involving categorical variables were performed using the chi-square test. Normally-distributed continuous variables were compared using two sample-t-tests. P-values of <0.05 were considered statistically significant. **Results:** There were 790 patients in the 2019 cohort and 279 in the 2020 cohort. There were no significant differences in age at presentation, histologic subtypes, nodal status, or operation type between the two groups. The T-stages at presentation of the 2020 group were higher than those of the 2019 group; 29% presented with T1c tumors in 2020 vs 26% in 2019, and 37% with T2 tumors in 2020 vs 30% in 2019 (p=0.03). A higher percentage of patients presented with distant metastatic disease at the time of diagnosis in 2020 (7% in 2020 vs 2% in 2019, p<0.001), although the absolute numbers of patients were similar (19 patients in 2020 vs 17 patients in 2019). Of patients with invasive breast cancer, a higher percentage of patients presented with grade 3 tumors in 2020 (35% in 2020 vs 24% in 2019, p=0.002), and triple negative tumors (15% vs 10%, p=0.02). Fewer patients underwent surgery first in 2020 (73% in 2020 vs 85% in 2019, p<0.001) and more underwent neoadjuvant chemotherapy (13% in 2020 vs 9% in 2019, p=0.03). Only 4% of the 2020 surgery group had been placed on neoadjuvant endocrine therapy while awaiting definitive surgery. The TTS for patients with surgery as the initial treatment was significantly shorter for the 2020 group (mean 22 days in 2020 vs 31 days in 2019, p<0.001). **Conclusions:** Without screening mammography, newly-diagnosed patients in a large, integrated health care system during the COVID 19 pandemic presented with more advanced and aggressive breast cancers as compared to the equivalent time period in 2019. Fewer patients underwent surgery first, and more underwent neoadjuvant chemotherapy. The TTS for breast cancer patients in 2020 was significantly shorter than in 2019, which we hypothesize was due to the availability of operating rooms since elective operations had been stopped. This study demonstrates the ability of a large, integrated health care system to deliver timely breast cancer care to patients presenting with symptomatic disease during the constraints of the COVID 19 pandemic, and highlights the importance of screening in the early detection of breast cancer.

### Background

Trastuzumab deruxtecan (T-DXd, DS-8201) is an antibody-drug conjugate with a HER2 antibody, tetrapeptide-based cleavable linker, and a novel topoisomerase I inhibitor payload. DESTINY-Breast01 (NCT03248492) is an open-label, international, multicenter, phase 2 study of T-DXd in patients with HER2 positive metastatic breast cancer (MBC) and supported regulatory approval in the US and Japan. Updated longer-term safety and efficacy results are presented here.

### Methods

All patients were required to have MBC that progressed on or after T-DM1. 253 patients were enrolled and 184 received T-DXd 5.4 mg/kg, representing the primary analysis set. The primary endpoint was ORR. Additional endpoints included duration of response, PFS, and OS.

### Results

Patients had received a median of 6 previous lines of treatment for MBC. In this updated data cutoff (8 June 2020) compared to the prior data cutoff (1 Aug 2019), median duration of follow-up has increased from 11.1 to 20.5 mo; 37 patients (20.1%) remain on treatment. Confirmed ORR was 61.4% (12 CRs) with a median duration of response of 20.8 mo; the disease control rate was 97.3% (95% CI, 93.8-99.1). The updated mPFS was 19.4 mo (95% CI, 14.1 mo-NE). Estimated OS was 85% (95% CI, 79%-90%) at 12 months and 74% (95% CI, 67%-80%) at 18 months. The preliminary mOS is 24.6 mo (estimated at 35% maturity with only 17 patients at risk at 24 months). The safety profile of T-DXd was similar as that previously reported; with an additional 9 mo follow-up, only 3 new cases of T-DXd-related interstitial lung disease (ILD) were reported. Results are summarized in the table below.

### Conclusion

Consistent with prior results, T-DXd demonstrated high rates of durable responses in a heavily pretreated population of patients with MBC. From this single-arm, phase 2 study, the PFS and immature OS results are encouraging; these endpoints will be further evaluated in the ongoing randomized controlled studies of T-DXd. For patients who remained on treatment for this longer duration (double that of the previous report), the rate of discontinuation or ILD did not notably increase. Continued attention to pulmonary symptoms and careful monitoring is warranted.

Updated Results for DESTINY-Breast01

	1 Aug 2019 datacut	8 Jun 2020 datacut
Patients remaining on treatment, n/N (%)	79/184 (42.9%)	37/184 (20.1%)

High-risk breast cancer in oldest old: Exploring the effect of different treatments on outcomes

Abdulla Al-Rashdan, Yuan Xu, Lisa Barbera, Jeffrey Cao, Winson Cheung, Antoine Bouchard-Fortier and MayLynn Quan. Tom Baker Cancer Centre, Calgary, AB, Canada

**Background:** Octogenarians and nonagenarians diagnosed with breast cancer have a competing risk of death from other causes and their management is frequently found to be discordant with guidelines in comparison to the younger patients, particularly with low-risk disease. There is limited information about the disease trajectory and outcomes of patients with high-risk disease. Thus, this study was conducted. **Methods:** This is a retrospective, population-based observational study. Women aged 80 years of age or older and diagnosed with non-metastatic, high-risk breast cancer in Alberta, Canada between January 2004 and December 2017 were identified from the Alberta Cancer Registry. High-risk disease was defined as having any of the following; T3/4, any N positive, triple negative, or Her-2 positive disease. A risk scoring system was generated based on the presence of two anatomical and one biological high-risk features to generate 3 risk levels. Patients' characteristics (age, Charlson comorbidity index, residence, education-, and income- quintiles), disease characteristics (stage, grade, receptor status,) treatment patterns (treatment delivered, facility) and survival were determined from linkage with administrative databases (Discharge Abstract Data, National Ambulatory Care Reporting System, and Vital statistics). Treatments were stratified into; none, hormonal treatment only (HT), surgery only (S), and surgery with any adjuvant treatment (S+A). Statistical methods included chi-square and Cox regression models. Association between patient, tumor and treatment variables and survival were assessed with uni- and multivariable analysis. Primary outcome was breast cancer specific survival (BCSS) in patients stratified by different risk levels in relation to the treatment delivered. **Results:** 1369 patients met the inclusion criteria. The median age was 84 years (interquartile range [IQR] 82-88). After a median follow-up of 35 months (m), 873 (64%) patients had died; 405 (46%) of deaths were due to breast cancer. On multivariable analysis, patients had a lower hazard of death from cancer if they were treated with S (HR = 0.51, 95%CI: 0.34, 0.77, p = 0.001) or S+A (HR = 0.41, 95%CI: 0.28, 0.6, p < 0.001) in comparison to HT alone. Patients who did not receive any form of treatment were more likely to die from breast cancer (HR 2.14 95%CI: 1.38, 3.31, p = 0.0006). Patients who had 1 or 2 risk features had higher cancer specific and overall survival if they had S or S+A (49/31m, 92/66m median differences respectively p < .0001). Those with 3 risk features showed longer survival if they received S+A (29/25m median differences p < .0001). **Conclusions and Relevance:** Our findings suggest that a significant proportion of older patients with breast cancer patients with high-risk features may have increased disease-specific mortality risk. Based on a priori risk levels, and in properly selected patients, treatment options including surgery and adjuvant treatment may be associated in longer survival.

The 70-gene signature (MammaPrint) accurately predicts distant breast cancer recurrence risk in patients aged  $\geq 70$  years from the population-based observational FOCUS cohort

Iris Noordhoek<sup>1</sup>, Esther Bastiaannet<sup>1</sup>, Ersan Lujinovic<sup>2</sup>, Laura Esserman<sup>3</sup>, Jelle Wesseling<sup>1</sup>, Astrid Scholten<sup>4</sup>, Carolien P Schroder<sup>5</sup>, Sjoerd Elias<sup>6</sup>, Nienke A de Glas<sup>1</sup>, Judith R Kroep<sup>1</sup>, Johanneke EA Portielje<sup>1</sup>, Miranda Kleijn<sup>2</sup> and Gerrit-Jan J Liefers<sup>1</sup>. <sup>1</sup>Leiden University Medical Center, Leiden, Netherlands<sup>2</sup>Agendia, Inc., Amsterdam, Netherlands<sup>3</sup>University of California, San Francisco, San Francisco, CA; <sup>4</sup>Netherlands Cancer Institute, Amsterdam, Netherlands<sup>5</sup>University Medical Center Groningen, Groningen, Netherlands<sup>6</sup>University Medical Center Utrecht, Utrecht, Netherlands

**Background** Predicting breast cancer recurrence in patients aged  $\geq 70$  years is challenging, as they generally have more indolent tumors and a higher chance of dying of competing causes than younger patients. The 70-gene signature test (MammaPrint) has been shown to accurately predict recurrence in women with early breast cancer and up to 3 positive lymph nodes. **Aim** To study outcome related to MammaPrint result in patients aged  $\geq 70$  years with breast cancer using a population-based cohort. **Methods** The population-based FOCUS cohort included all 2095 consecutive patients with any stage breast cancer, diagnosed between 1997 and 2004, aged  $\geq 65$  years, in the Comprehensive Cancer Center region West, the Netherlands. In the present exploratory sub-study, patients from FOCUS with the following criteria were included:  $\geq 70$  years old, T1-2N0-3M0, hormone receptor positive, HER2 negative, no neo-adjuvant treatment and available tumor specimens. MammaPrint is a genomic risk profile based on microarray gene expression analysis, classifying patients as ultralow risk (M-ULR), low (not UL) risk (M-LR) or high risk (M-HR) of developing a recurrence. Patients were considered clinically low risk (C-LR) with T1-2N0 grade 1-2 tumors and clinically high risk (C-HR) with N+ or T2/grade 3 tumors. Primary endpoint was 10-year distant recurrence free interval (DRFi) in relation to genomic risk, estimated from cumulative incidence and Fine and Gray analyses to take competing mortality into account. **Results** In this study, 422 patients were included. Median age was 78 years, 238 patients (56%) had node negative disease, 235 patients (56%) had T2 tumors and 227 patients (54%) were C-LR. Most patients were treated with endocrine therapy (ET), and 22 patients (5%) were treated with chemotherapy (CT; table 1). Overall, 50 (12%) patients were M-ULR, 226 (53%) were M-LR and 146 (35%) were M-HR. Discrepancies were found between C and M risk groups in 18/50 M-ULR patients with C-HR, and 56/146 M-HR patients with C-LR. Of the 59 patients that experienced a recurrence during 10 years of follow-up, 44 (75%) were distant recurrences. In the M-ULR group, DRFi was 2% (95%CI 0-6) after 10 years of follow-up, this was 8% (95%CI 5-12) in the M-LR group and 17% (95%CI 11-23) in the M-HR group ( $p < 0.001$ ). In the C-HR subgroup, none of the 18 M-ULR patients developed a recurrence, and DRFi was 10% (95%CI 3-16) in M-LR patients and 20% (95%CI 12-28) in M-HR patients ( $p = 0.015$ ). C risk alone was not able to predict distant recurrence risk (C-LR 8%, C-HR 14%, sHR 1.8 [95%CI 0.9-3.2];  $p = 0.060$ ; table 2). **Conclusion** MammaPrint accurately predicts 10-year DRFi in older patients with breast cancer. Patients classified as ultralow risk by MammaPrint had a very low chance of developing metastatic disease. Even in clinically high-risk patients who were M-ULR, recurrent disease did not occur 10 years after diagnosis. These findings are in line with published results of the STO-3 trial (JAMA Oncol, 2017) and provide foundation for de-escalation of treatment in older patients guided by genomic testing.

**Background:** LIV-1 is a highly prevalent transmembrane protein in breast cancer cells. Ladiratuzumab vedotin (LV), SGN-LIV1A, is an investigational antibody-drug conjugate (ADC) that targets LIV-1 via a humanized IgG1 monoclonal antibody conjugated to monomethyl auristatin E (MMAE) by a protease-cleavable linker. LV is internalized when it binds LIV-1 on cell surfaces and MMAE is released, which binds tubulin and induces apoptosis. LV has been shown to be active and tolerable in metastatic breast cancer (mBC) at a recommended dose of 2.5 mg/kg every 21 days (Modi 2017). More frequent, fractionated dosing has improved the activity and/or safety of other ADCs. Thus, this study is actively accruing subjects with metastatic triple negative breast cancer (mTNBC; estrogen receptor (ER)/progesterone receptor (PR)/human epidermal growth factor receptor 2 (HER2) receptor-negative) and endocrine-resistant ER+ or PR+ (hormone receptor [HR+])/HER2-negative mBC to test weekly dosing of LV (Days 1, 8, and 15 of every 3-week cycle). **Methods:** This study is enrolling up to 82 subjects (42 HR+/HER2-negative and 40 mTNBC) into dose escalation and dose expansion cohorts (NCT01969643). Eligible subjects are females ≥18 years old with pathologically and radiologically confirmed metastatic HR+/HER2-negative or mTNBC with at least 1 measurable lesion per RECIST v1.1. Subjects with HR+/HER2-negative disease must have received no more than 1 prior line of cytotoxic chemotherapy in the locally advanced (LA)/mBC setting, either as single agent or combination therapy. Subjects with mTNBC must have received 1 prior line of cytotoxic chemotherapy in the LA/mBC setting. Progression within 6 months of completion of neoadjuvant or adjuvant therapy is considered an LA/mBC regimen. Subjects must have adequate organ function, ECOG status of ≤1, and no ≥ Grade 2 peripheral neuropathy. Subjects with brain lesions must have received definitive treatment of the lesions. Prior therapy with MMAE-containing agents is not allowed. Dose escalation follows the modified toxicity probability interval method (Ji 2010). Dose expansion cohorts will provide data about activity and tolerability. Tumor assessments will be conducted every 2 cycles per RECIST v1.1 and all subjects will be followed for safety. Pharmacokinetics and markers of pharmacodynamics will be assessed. Primary safety endpoint is the incidence of adverse events and dose-limiting toxicities. Key efficacy endpoints include confirmed overall response rate, duration of response, and progression-free survival.

Phase II randomized trial of fulvestrant with or without enzalutamide in ER+/Her2- primary breast cancer (BC)

Anthony D Elias<sup>1</sup>, Monica Fournier<sup>2</sup>, Gregory A Vidal<sup>3</sup>, Sharon Sams<sup>1</sup>, Nicole Spoelsta<sup>1</sup>, Peter Kabos<sup>1</sup>, Jennifer R Diamond<sup>1</sup>, Elena Shagisultanova<sup>1</sup>, Anosheh Afghahi<sup>1</sup>, Jose Mayordomo<sup>1</sup>, Julia Wulfkuhle<sup>4</sup>, Emanuel Petricoin<sup>4</sup>, Lisa Carter<sup>1</sup>, Kathryn Zolman<sup>1</sup>, Stephanie Armstead<sup>1</sup>, Alyse Winchester<sup>1</sup>, Tessa McSpadden<sup>1</sup>, Gloria Crawford<sup>1</sup>, Virginia Borges<sup>1</sup>, Dexiang Gao<sup>1</sup> and Jennifer Richer<sup>1</sup>. <sup>1</sup>University of Colorado, Aurora, CO; <sup>2</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>3</sup>West Cancer Center and Research Institute and Dept of Medicine, University of Tennessee Health Sciences Center, Memphis, TN; <sup>4</sup>George Mason University, Fairfax, VA

**Background:** Almost all ER+ breast cancers express androgen receptor (AR), but its function is uncertain. AR expression is associated with more indolent tumors, however high AR expression relative to ER is associated with endocrine resistance, and in the absence of estradiol or if ER function is blocked, preclinical data would suggest that AR can take over to signal cell survival and proliferation. This non-blinded randomized phase II trial of neoadjuvant fulvestrant with or without enzalutamide was performed in women with T2 or greater ER+/Her2- primary breast cancer. **Methods:** Eligible patients were women with ECOG 0-2, ER+/Her2- primary breast cancer cT2 or greater. A total of 4 months of therapy was given (fulvestrant 500 mg IM weeks 1, 3, 5, 9, and 13). Patients were randomized to receive enzalutamide 160 mg po daily on a continual basis for 16 weeks. Stratification factors were clinical node status (N0 vs N1/2) and T-stage (T2 vs T3/4). Surgery was planned for week 17. Fresh tumor biopsies were required at study entry and at ~4 weeks on therapy. Tissue, both fresh frozen and FFPE, was also obtained at time of surgery. The PEPI score at time of surgery was the primary endpoint for efficacy. The statistical design were parallel phase II trials with the experimental arm designed as a Simon 2-stage. The expectation for the control arm was a PEPI score of 0 in 16% and 32% for the combination arm. Additional enrollment of 12 patients would ensue if 4 or more achieved a PEPI score of 0 within the first 22 patients enrolled onto the combination arm. 27 patients would be enrolled into the fulvestrant alone arm. **Results:** The Simon 2-stage criteria were met and the trial continues to accrue up to 11 more evaluable patients. Thus far, 58 patients were consented of whom 50 were treated. Median age was 61.5 years (45-83); PS 0 (0-2). Among the 46 patients with information on AEs, there are 25 patients with Grade 2 AEs, including 5 with fatigue, 3 with headache, and 2 with hot flashes. There are 5 patients with grade 3 AEs including abdominal pain, gallbladder obstruction, ALT elevation, hyperglycemia, and hypertension. We also have 2 patients with grade 4 AEs, chest pain-cardiac and cardiac disorder-other. There is no grade 5 event. Paired samples at baseline and at 4 weeks are collected so far from 49 patients. 42 patients have completed surgery, while two patients have not undergone surgery. **Conclusions:** The combination of fulvestrant plus enzalutamide had manageable side effects. The trial is now in its extended stage since PEPI score = 0 was achieved in at least 4 of the first 22 patients on the combination arm. Extensive molecular studies of paired fresh biopsies from pretreatment and at 4 weeks are underway. These analyses and correlations with clinical outcome will be described.

The distribution of radiosensitivity index differs by PAM50 subtype in primary breast tumors

Matthew Fahey<sup>1</sup>, Nicholas Russo<sup>1</sup>, Casey Liveringhouse<sup>2</sup>, Matthew Mills<sup>2</sup>, Kamran Ahmed<sup>2</sup> and Roberto Diaz<sup>2</sup>. <sup>1</sup>University of South Florida Morsani College of Medicine, Tampa, FL; <sup>2</sup>Moffitt Cancer Center, Department of Radiation Oncology, Tampa, FL

**Background:** Prior studies identified radiosensitive and radioresistant breast tumor phenotypes and demonstrated that gene-expression signatures such as the radiosensitivity index (RSI) can be used to derive biologically rational radiation dose selection. In this study, we assessed the RSI of primary breast tumor samples and its association with PAM50 subtype. **Materials/Methods:** Primary breast tumor samples were identified from a multi-institutional tissue biorepository. Tumors were excluded if they were treated with neoadjuvant therapy or had distant metastatic disease at the time of sample collection. The RSI gene signature and PAM50 subtype were assessed through transcriptomic profiling performed on Affymetrix microarray chips. Distribution of RSI values across PAM50 subtypes was assessed with the Kruskal-Wallis test. Differences in proportions of radioresistant and radiosensitive tumors among PAM50 subtypes were assessed with the Chi-squared test, where radioresistant was defined as RSI>0.3745 based on prior studies. Clinicopathologic characteristics were obtained through clinical chart review. **Results:** A total of 637 primary breast tumors with available genomic profiling and clinical information were included for analysis. Histologies were predominantly invasive ductal carcinoma (81.5%) and invasive lobular (11.6%). Most tumors were T1-T2 (91.7%) while 35.9% had pathologically positive lymph nodes. The distribution of RSI significantly differed by PAM50 classification (Kruskal-Wallis  $p < 0.001$ ). Proportions of radioresistant vs radiosensitive tumors varied significantly according to PAM50 subtype and are included in the accompanying table (Chi-squared  $p < 0.001$ ). Median follow-up was 89 months.

		PAM50					Total
		Basal	Her2	LumA	LumB	Normal	
RSI Phenotype	Radioresistantn (%)	50 (60.2%)	32 (42.1%)	146 (54.4%)	82 (45.3%)	24 (82.8%)	334 (52.4%)
	Radiosensitive n (%)	33 (39.8%)	44 (57.9%)	122 (45.6%)	99 (54.7%)	5 (17.2%)	303 (47.5%)
Total		83	76	268	181	29	637

**Conclusion:** Breast tumor PAM50 subtypes demonstrate significant variation in radiosensitivity. Further studies are needed to determine if genomic subtyping can refine the ability to predict clinical radiation response and further optimize individual therapy.

Publication Number: PD11-06

Associations between obesity and metastasis in the Carolina breast cancer study

Linnea T Olsson<sup>1</sup>, Andrea Walens<sup>1</sup>, Alina M Hamilton<sup>1</sup>, Halei C Benefield<sup>1</sup>, Kevin P Williams<sup>2</sup>, Jodie M Fleming<sup>2</sup>, Stephen D Hursting<sup>1</sup> and Melissa A Troester<sup>1</sup>. <sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>North Carolina Central University, Durham, NC

**Background.** Metastatic disease accounts for the majority of breast cancer-specific mortality, and identifying women who are most at risk for metastasis remains an important challenge. Genomic risk scores are valuable tools in assessing risk of recurrence but have rarely been applied to assess risk of distant metastasis in large, diverse population-based cohorts. Such cohorts can identify important modifiers of the relationship between tumor genomics and metastasis. In particular, obesity at diagnosis has been implicated as a risk factor for breast cancer metastasis. Waist-to-hip ratio (WHR), as a measure of central adiposity, appears to increase risk of breast cancer mortality. It is important to understand how obesity impacts risk of metastasis and modifies other known prognostic factors. **Methods.** Data from the Carolina Breast Cancer Study, a prospective cohort of women with incident breast cancer that oversampled young women and black women such that each represented 50% of the study population, were used to study metastasis within five years of follow up (n=239 incident metastases in 2767 eligible participants with stage I-III disease). PAM50-derived risk-of-recurrence (ROR-PT) scores were measured using a research version of the 50-gene assay, and represent a multigene classifier incorporating tumor subtype, size, and proliferation score. Women with de novo metastasis (identified at diagnosis, n=109) were excluded, as incident and de novo metastases have different prognosis. Obesity was defined by WHR (> 0.85). Absolute risk within strata and risk differences between strata were calculated using the Kaplan-Meier estimator; models were adjusted with inverse probability weights conditional on grade, stage, age, and race, where appropriate. To examine the association between obesity and site or multiplicity of metastasis, relative frequency differences were estimated using generalized linear models. **Results.** The overall risk of metastasis in CBCS differed significantly by race (11.2% in Black women and 6.8% in non-Black women and was associated with higher ROR-PT score (19.8% in high ROR-PT vs. 6.5% in low or medium ROR-PT). 48.2% of women were classified as obese by WHR. Women with high WHR had a significantly higher absolute risk of metastasis (11.2%, 95% CI: 9.4, 13.0) relative to those with lower WHR (6.9, 95% CI: 5.6, 8.2). However, the effects of WHR on risk seemed to be isolated to those with high risk tumors. Non-obese and obese women with low-to-medium ROR-PT scores had similar risk of metastasis [ $RD_{LowMed}$  (95% CI) = 1.5% (-1.5, 4.4)], while obese women with high ROR-PT scores had substantially higher risk of metastasis than non-obese women [ $RD_{High}$  (95% CI) = 13.1% (4.3, 21.9); 26.2% vs. 13.1%]. Considering site of metastasis, more metastases were observed among women with high WHR at every site except brain. More occurrences of multiple metastases were also observed among obese women. **Conclusions.** Consistent with previous studies, we observed racial disparities in metastasis, with Black women having higher 5-year metastatic risk and with women with high ROR-PT scores also having higher risk. Obesity, herein measured by WHR, is an important predictor of metastatic risk and may modify the relationship between genomic risk scores and risk of metastasis.

Circulating TP53 mutations in TNBC after neoadjuvant chemotherapy is associated with rapid disease recurrence: Correlative analysis from clinical trial BRE12-158

Milan Radovich, Nawal Kassem, Guanglong Jiang, Bradley A. Hancock and Bryan P. Schneider. Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN

**Background:** Neoadjuvant chemotherapy (NAC) is a standard approach for many patients with triple negative breast cancer (TNBC). Our group, and others, have previously reported that the detection of circulating tumor DNA (ctDNA) after NAC and surgery is a surrogate for the presence of minimal residual disease (MRD) leading to inferior survival outcomes. Further, our group has also reported that the emergence of somatic TP53 mutations in tissue samples post-NAC was associated with inferior survival outcomes. In this study, we sought to determine whether TP53 mutations detected in the plasma of patients with ctDNA-positivity after NAC was associated with inferior outcomes compared to non-TP53 mutated patients.

**Methods:** BRE12-158 was a phase II clinical trial which randomized early-stage TNBC patients with residual disease after NAC to post-neoadjuvant genomically-directed therapy vs treatment of physician choice. 196 patients were enrolled. Patients had blood samples collected for ctDNA at the time of post-neoadjuvant treatment assignment. ctDNA was successfully sequenced using the FoundationACT or FoundationOneLiquid Assay in 142 patients. Patients who were ctDNA positive after NAC (N=90, 63%), were selected for this comparison. Median clinical follow-up was 22.9 months. A multivariate cox proportional-hazards model was used to compare DDFS, DFS, and OS of ctDNA-positive patients with and without TP53 mutations found in the ctDNA.

**Results:** 90 patients in BRE12-158 were ctDNA-positive after NAC and surgery. 36/90 (40%) of those patients had TP53 mutations detected in their plasma. Patients with TP53-mutated ctDNA had significantly inferior outcomes and a significantly shorter time to recurrence when compared to those without TP53 mutations. Detection of TP53-mutated ctDNA was significantly associated with an inferior DDFS (median DDFS: 6.99 months vs. 48.69 months; HR=2.78, 95%CI: 1.41-5.49; p=0.0033). At 24 months, the DDFS probability was 36% in TP53-mutated patients as compared to 72% in non-mutated patients. Similarly, detection of TP53-mutated ctDNA was significantly associated with an inferior DFS (median DFS: 4.83 months vs. 48.69 months; HR=3.63, 95%CI: 1.76-7.48; p=0.00047). At 24 months, the DFS probability was 30% in TP53-mutated patients as compared to 72% in non-mutated patients. Lastly, detection of TP53-mutated ctDNA was significantly associated with an inferior OS (median OS: 17.8 months vs. Not Reached; HR=3.48, 95%CI: 1.51-8.01; p=0.0034). At 24 months, the OS probability was 42% in TP53-mutated patients as compared to 80% in non-mutated patients.

**Conclusion:** In patients with ctDNA-positivity after NAC, the presence of TP53 mutations was associated with rapid disease relapse. These data suggest that TP53 mutation status may stratify outcomes among this high-risk group of patients with ctDNA positivity in the post-neoadjuvant setting.

Impact of an online ductal carcinoma *in situ* (DCIS) decision support tool on awareness of treatment options and knowledge of breast cancer risks

Rinaa Sujata Punglia<sup>1</sup>, Ann Partridge<sup>1</sup>, Shelley Hwang<sup>2</sup>, Alastair Thompson<sup>3</sup>, Elizabeth Frank<sup>4</sup>, Donna Pinto<sup>5</sup>, Deborah Collyar<sup>6</sup>, Desiree Basila<sup>7</sup>, Thomas Lynch<sup>2</sup>, Terry Hyslop<sup>2</sup>, Marc Ryser<sup>2</sup> and Elissa Ozanne<sup>8</sup>. <sup>1</sup>Dana-Farber Cancer Institute, Boston, MA; <sup>2</sup>Duke University, Durham, NC; <sup>3</sup>Baylor College of Medicine, Houston, TX; <sup>4</sup>COMET Patient Leadership Team, Boston, MA; <sup>5</sup>COMET Patient Leadership Team, San Diego, CA; <sup>6</sup>COMET Patient Leadership Team, Danville, CA; <sup>7</sup>COMET Patient Leadership Team, San Francisco, CA; <sup>8</sup>University of Utah, Salt Lake City, UT

**Background** An interactive decision support tool (DST) was adapted to support patients diagnosed with DCIS who are making treatment decisions. The DST provides the following risk estimates over 10 years: 1) future DCIS or invasive breast cancer in the same breast, 2) the risk of dying from causes other than breast cancer, and 3) the risk of dying from invasive breast cancer. Estimates are personalized based on patient age and DCIS grade (low/intermediate versus high grade or “don’t know”) and were based on a model incorporating data from clinical trials and life tables. **Methods** The DST was implemented in collaboration with the COMET study on the website DCISoptions.org ([www.dcisoptions.org](http://www.dcisoptions.org)). On the DST, personalized results are displayed separately using a 100-woman icon array and percentages with each outcome (future DCIS/invasive breast cancer, death due to breast cancer, death due to other causes) in a different color for each treatment selected by the patient (lumpectomy only, lumpectomy + radiation therapy, lumpectomy + endocrine therapy, lumpectomy + radiation and endocrine therapy, mastectomy with or without reconstruction, bilateral mastectomy with or without reconstruction). In addition, information regarding active monitoring was provided in descriptive terms without icon array display of personalized outcomes. DST users were defined as those who navigated to the website and entered age and DCIS grade allowing them to access the information about expected outcomes. Users were asked to complete an optional survey both prior to use of the DST and after to assess the impact of the DST on: 1) their awareness of options for DCIS treatment, 2) their willingness to consider these options, 3) their knowledge of mortality risks associated with DCIS, and 4) how helpful the DST was to them (after use only). **Results** As of June 1, 2020, there were 420 users of the DST (total) with 362 completing the pre-tool survey and 58 of whom completed the post-tool survey. Among all DST users, mean age was 54.0 (9.6 years SD) and DCIS was low/intermediate for 72.0%, high for 18.5% and unknown for the remaining 9.5%. Among users who submitted both the pre- and post-tool survey, median time spent on the tool was 10.4 minutes. Awareness of each treatment option was high and did not change with the tool: 90% among both pre-survey and post-survey users except for bilateral mastectomy which remained at 82.9% among pre-survey and post-survey responders. Among those users who completed the pre- and post-tool surveys, the DST increased the percentage of patients who believed the chance of dying from DCIS is very low from 60.3% at baseline to 74.1% ( $p < 0.0001$ ) and reduced the median estimated numerical risk of dying from DCIS in 10 years from 9.0% at baseline to 3.0% ( $p < 0.0001$ ). A large majority of DST users found the tool very helpful or helpful (79.3% of those who responded) in making a treatment decision for DCIS. **Discussion** DCIS patients have been shown to greatly overestimate the risks of dying from breast cancer and this has been associated with increased anxiety and potential overtreatment. Our personalized online DST significantly improved knowledge about DCIS risks. Future studies of the DST should assess patient characteristics associated with knowledge gains and whether improved knowledge translates to improved patient outcomes including more patient preference and values-based treatment decisions.

Adherence to and patient satisfaction with the combination therapy of exemestane and everolimus in postmenopausal women with HR+ HER2-advanced breast cancer: Results from the IPSOC-mamma study

Veerle Foulon<sup>1</sup>, Carrie Visser<sup>1</sup>, Sandra De Coster<sup>1</sup>, Lise-Marie Kinnaer<sup>1</sup>, Ellen Reynders<sup>2</sup>, Anne Deblander<sup>2</sup>, Patrick Berteloot<sup>2</sup>, Kevin Punie<sup>2</sup>, Hans Wildiers<sup>2</sup>, Veronique Cocquyt<sup>3</sup>, Hannelore Denys<sup>3</sup>, Ahmad Awada<sup>4</sup>, Eric Strobbe<sup>5</sup>, Andrea Gombos<sup>4</sup>, Isabelle Spoormans<sup>6</sup>, Ximena Elzo-Kraemer<sup>7</sup>, Christof Vulsteke<sup>7</sup>, Marleen Borms<sup>8</sup>, Philip Debruyne<sup>8</sup>, Wim Wynendaele<sup>9</sup> and Patrick Neven<sup>2</sup>. <sup>1</sup>Klinische Farmacologie en Farmacotherapie, Leuven, Belgium<sup>2</sup>UZ Leuven, Leuven, Belgium<sup>3</sup>UZ Gent, Gent, Belgium<sup>4</sup>Institut Bordet, Brussel, Belgium<sup>5</sup>Novartis, Vilvoorde, Belgium<sup>6</sup>AZ Damiaan, Oostende, Belgium<sup>7</sup>AZ Maria Middelaers, Gent, Belgium<sup>8</sup>AZ Groeninge, Kortrijk, Belgium<sup>9</sup>AZ Imelda, Bonheiden, Belgium

**Background** Everolimus in combination with exemestane is indicated for the treatment of hormone receptor-positive, HER 2-neg endocrine resistant advanced breast cancer in postmenopausal women. This study investigated treatment adherence, tolerability, satisfaction and efficacy.

**Methods** A prospective, non-interventional, non-controlled, multicentric observational study assessed adherence by means of a validated questionnaire ('Morisky Medication Adherence Scale') and 'Medication Event Monitoring System' (MEMS®) data. The level of adherence was calculated per patient as percentage of days on which the medicine was taken as prescribed during the total treatment period, referred to as 'unadjusted adherence rate' (UAR). Second, MEMS® data were adjusted for treatment interruptions according to the CRF and questionnaire data, approved by the treating physician ('adjusted adherence rate' (AAR)). Successful adherence was defined as  $\square$  95% –  $\square$  105%. Validated questionnaires ('Patient Satisfaction with Cancer Treatment Education', 'Cancer Treatment Satisfaction Questionnaire' (CTSQ) and 'Functional Assessment of Cancer Therapy – General' (FACT-G) were used to report patients experience and satisfaction with the treatment and perceived care, questioned at initial visit and after approximately 1, 3, 6 and 12 months. The efficacy was primary analyzed through progression free survival (PFS).

**Results** Between Dec 2015 and Nov 2017, a total of 58 women (median age 65 yrs) from 7 oncology centers were included after a mean of  $34\text{m} \pm 36.9$  (SD) of being diagnosed with stage IV disease; most (62.1%) had  $\geq 3$  organs involved and 84.5% had  $\geq 2$  prior metastatic treatment lines. The mean follow-up duration was  $185.5 \pm 100.0$  days. The mean UAR for exemestane, everolimus and the combination were 92.9 %, 84.8 % and 81.7 % respectively. For everolimus and the combination therapy these rates differ significantly from the mean AAR, with  $p < 0.05$  (see table 1). For the AAR of the combination therapy, 13.8 % of the patients showed optimal adherence (100 %).

Table 1. UAR and AAR for Exemestane, Everolimus and the combination

	Exemestane	Everolimus	Combination therapy
UAR (%) mean $\pm$ SD	92.97 $\pm$ 13.17	84.86 $\pm$ 19.40	81.74 $\pm$ 20.98
AAR (%) mean $\pm$ SD	93.07 $\pm$ 13.14	91.81 $\pm$ 15.04	87.55 $\pm$ 18.17
Significance difference P-value	0.277	< 0.001	< 0.001

Six patients (10.3%) interrupted their treatment with exemestane with a mean time of treatment pause of  $34.3 \pm 19.1$  days. The treatment with everolimus was interrupted by 36 (62.1%), with a mean interruption time of  $24.3 \pm 16.5$  days, which corresponds with a mean of  $19.6 \% \pm 17.6\%$  of the total follow-up duration. Some patients interrupted their treatment multiple times. The most common side effect was mucositis ( $n=26$  at 1 month, of whom 8 patients grade 3 and 15 patients grade 2)). Six (10.4 %) of the 58 patients stopped treatment with everolimus and exemestane due to side effects. The median PFS was 170 days. With regard to quality of life, patients scored lowest on emotional and functional well-being. However, there were no significant differences measured for the mean FACT-G score between Day0, M1 and M3 ( $P = 0.273$ ). Also, patients scored overall low on the 'CTSQ'.

**Conclusion** Despite close monitoring and preventive measures to overcome side effects, adherence to everolimus and exemestane was rather low. Many patients needed to interrupt the treatment due to side effects; treatment is perceived as intensive. Nevertheless, median PFS is 170 days, even when used late in the therapeutic journey of breast cancer patients.

Treatment persistence of residual breast tumors through an embryonic diapause-like cancer cell state with suppressed myc activity

Eugen Dhimolea<sup>1</sup>, Ricardo De Matos Simoes<sup>1</sup>, Dhvanir Kansara<sup>1</sup>, Juliette Bouyssou<sup>1</sup>, Jennifer Roth<sup>2</sup>, Michal Sheffer<sup>1</sup>, Rinath Jeselsohn<sup>1</sup>, Nathanael Gray<sup>1</sup>, Ulrich Steidl<sup>3</sup>, Boris Bartholdy<sup>3</sup>, Myles Brown<sup>1</sup>, Aedin Culhane<sup>1</sup> and Constantine Mitsiades<sup>1</sup>. <sup>1</sup>Dana Farber Cancer Institute, Boston, MA; <sup>2</sup>Broad Institute of MIT and Harvard, Boston, MA; <sup>3</sup>Albert Einstein College of Medicine, New York, NY

Systemic breast cancer treatments often fail to achieve complete and sustained responses due to drug-persistent residual tumor foci, the “seed” for eventual relapse. Recent clinical studies have revealed that the chemo-persistent tumor cells undergo extensive transcriptional reprogramming in response to neo-adjuvant treatment; however, the impact of this acquired molecular signature on the ability of residual cancer cells to survive during therapy is not clear. To further study the molecular hallmarks of chemo-persistent cancer cells, we analyzed the transcriptional signatures of post-treatment residual tumors in a large number of breast cancer patients from several neoadjuvant clinical studies. We observed that the treatment-persistent tumor cells had a distinct cellular state which molecularly resembles that of the embryonic diapause, a dormant stage of transiently suspended development in undifferentiated epiblasts triggered by stress and induced by suppression of Myc activity and overall biosynthesis. Remarkably, the propensity for residual tumors with an embryonic diapause-like (EDL) molecular signature was significantly associated with worse outcome in breast cancer patients. To dissect this distinct cancer cell state, we developed novel *in vitro* models using 3D breast cancer organoids which responded to cytotoxic treatment by generating longitudinally-persistent residual organoid fractions that phenotypically and molecularly simulated the *in vivo* emergence of post-treatment residual tumors in preclinical and clinical settings. The treatment-persistent tumor fractions in cancer organoids and in the respective *in vivo* xenografts did not exhibit significant genetic changes compared to baseline tumor cells, but had reduced apoptotic priming and an EDL transcriptional reprogramming similar to that of residual tumors in patients. Similarly to embryonic diapause, residual persistent fractions in cancer organoids, xenografts and patient tumors had markedly suppressed Myc transcriptional output and biosynthetic levels. Ectopic induction of MYC expression enhanced acute chemotherapeutic cytotoxicity in breast cancer organoids. Conversely, suppression of MYC or pharmacological inhibition of Myc transcriptional co-activators, BET bromodomains, abrogated chemotherapeutic cytotoxicity and induced in breast cancer cells an EDL molecular signature characterized by below-baseline redox stress levels which were maintained during drug exposure. High-throughput interrogation of residual persistent breast cancer organoids indicated broad refractoriness to specific anticancer drug classes thought to operate through induction of cellular stress (e.g. agents targeting DNA or DNA-repair). However, maintaining the residual cells in dormancy after completion of cytotoxic chemotherapy via inhibition of Brd4/Myc axis or pharmacologically interfering with the diapause-like transcriptional reprogramming of treatment-persistent cancer cells represent potential therapeutic strategies to target chemo-persistent tumor cells. Overall, our study shows that breast tumors dynamically co-opt the stress survival mechanism of embryonic diapause to persist during treatment, and reveals an unexpected role of Myc as regulator of cancer cell entry into transient drug-refractory dormancy. The diapause-like persister organoid cancer models provide *ex vivo* tractability for studying the otherwise elusive, dormant, drug-refractory residual tumors, with potential implications in personalized medicine and drug discovery.

Comparative analysis of anti-proliferative effects and gene profiling of lapatinib, neratinib, and tucatinib

Neil T Conlon<sup>1</sup>, Jeffrey J Kooijman<sup>2</sup>, Suzanne JC van Gerwen<sup>2</sup>, Winfried R Mulder<sup>2</sup>, Guido JR Zaman<sup>2</sup>, Irmna Diala<sup>3</sup>, Lisa D Eli<sup>3</sup>, Alshad S Lalani<sup>3</sup>, John Crown<sup>4</sup> and Denis Collins<sup>1</sup>. <sup>1</sup>Dublin City University, Dublin, Ireland<sup>2</sup>Netherlands Translational Research Center B.V., Oss, Netherlands<sup>3</sup>Puma Biotechnology Inc., Los Angeles, CA,<sup>4</sup>St Vincent's University Hospital, Dublin, Ireland

**Introduction:** Human epidermal growth factor 2 (HER2/ERBB2) is frequently amplified or mutated across various cancer types. The tyrosine kinase inhibitors (TKIs) lapatinib, neratinib, and tucatinib are FDA-approved for the treatment of HER2-positive breast cancer. All three TKIs bind and inhibit the kinase domain of HER2 but differ both in the mechanism of binding and in specificity for other HER family members. Direct comparisons to differentiate the pre-clinical efficacy of the three TKIs have been limited to small-scale studies and novel biomarkers of response to further define appropriate patient populations are required. **Methods:** In this study, the anti-proliferative effects of the three TKIs were compared using a 115-cancer cell line panel, including 12 breast cancer cell lines and 22 cell lines harbouring point mutations or amplifications of *EGFR*, *HER2*, or *HER3*. Hierarchical clustering analysis was carried out to compare the IC<sub>50</sub> "fingerprint" of the three TKIs to 168 other anti-cancer agents. Novel markers of TKI sensitivity and resistance were identified through cross-analysis of each drug response profile with mutation, copy number variation, and gene expression data. **Results:** All three TKIs were effective against HER2-positive breast cancer models; neratinib showed the most potent activity, followed by tucatinib and lapatinib respectively (Table 1). Neratinib displayed the greatest anti-proliferative activity in *HER2*-mutant and *EGFR*-mutant cell lines. Clustering analysis revealed that the anti-proliferative profile of tucatinib was most similar to trastuzumab, while neratinib and lapatinib were most like other HER family inhibitors. Mutation and gene expression analysis identified potential markers of response for each TKI. High expression of four genes (*HER2*, *VTCN1*, *CDK12*, and *RAC1*) correlated with response to all three TKIs. DNA damage repair genes were significantly associated with resistance to the HER2-targeted TKIs. *BRCA2* mutation was correlated with neratinib and tucatinib response, and high gene expression of *ATM*, *BRCA2*, and *BRCA1* were all associated with neratinib resistance. **Conclusions:** Neratinib was the most effective HER2-targeted TKI against *HER2*-amplified, -mutant, and *EGFR*-mutant cell lines. This analysis revealed possible mechanisms that may be exploited using combinatorial strategies involving CDK inhibitors, immunotherapies, and targeting DNA repair pathways.

Table: IC50 values for neratinib, lapatinib, and tucatinib in the HER2+ breast cancer cell lines

	IC50 values (nM)		
Cell lines	Neratinib	Lapatinib	Tucatinib

**Background:** Cytotoxic chemotherapy (CT) in combination with trastuzumab and pertuzumab (HP) is standard of care for patients (pts) diagnosed with HER2-positive early breast cancer (EBC). While highly effective, the toxicity associated with CT is challenging. In KRISTINE/TRIO-021, neoadjuvant T-DM1 was combined with pertuzumab (KP) and compared to standard TCHP. Pts. received six cycles of neoadjuvant treatment followed by adjuvant therapy (KP or HP). Pts. in the KP arm were allowed to receive standard adjuvant CT. Pathologic complete response (pCR) rate was significantly lower with KP versus TCHP and more pts. had disease progression prior to surgery with KP, resulting in a meaningfully lower event-free survival rate vs. the control (85.3% vs 94.2%). However, 3-year invasive disease-free survival was numerically similar in both arms. Neoadjuvant KP demonstrated less toxicity than standard CT, although treatment discontinuation was higher post-surgery. Association of KP and TCHP with treatment-related amenorrhea (TRA) in premenopausal EBC pts. has not been ascertained. **Methods:** All pts. with premenopausal status at study entry (those not meeting the menopause definition based on National Comprehensive Cancer Network Guidelines v3, 2012) and with menstrual period documented within 3 months of randomization, were independently evaluated for presence or absence of TRA by two reviewers. TRA, a prespecified exploratory endpoint of KRISTINE, was defined as cessation of menstruation for  $\geq 12$  months in the absence of treatment with ovarian suppression or other interventions that can induce amenorrhea. Pts. were followed from the time of study entry through the 3-year follow up period after surgery. For cases with inconsistent determination between the two reviewers, a third reviewer adjudicated. TRA rates were calculated per arm, hormone-receptor (HR) status, adjuvant CT and age group. Proportions were compared by estimating the odds ratio (OR) and the 95% confidence interval. **Results:** Of 444 pts. enrolled, 205 were excluded based on being post-menopausal per NCCN guidelines. Of 239 pts. remaining, 56 were excluded due to insufficient data. The median age of pts. included was 40 years (range: 22-53) for TCHP and 42.5 (range: 23-52) for KP. TRA was observed in 55% (50/91) of pts. treated with TCHP compared to 30% (28/92) treated with KP (OR=2.79; 95% CI 1.52-5.12). In pts. with HR-positive EBC, TRA occurred in 62% with TCHP vs 35% for KP (OR=2.998; 95% CI 1.44-6.25). In those with HR-negative EBC, TRA was observed in 42% with TCHP vs. 21% with KP (OR=2.77; 95% CI 0.88-8.72). In the KP arm, TRA was observed in 38% (8/21) of pts. treated with standard adjuvant CT vs. 28% (20/71) of those that did not (OR 1.57; 95% CI 0.57-4.36). For women age  $\leq 40$ , the rate of TRA was 38% with TCHP vs. 17% with KP (OR=3.00; 95% CI 1.05-8.60). For those  $> 40$  years, TRA was observed in 74% treated with TCHP vs. 39% of those with KP (OR=4.50; 95% CI 1.88-10.73). **Conclusion:** The rate of TRA with standard TCHP is nearly double that observed with KP, suggesting that targeted CT with an antibody-drug conjugate regimen is associated with less gonadal toxicity. Rates of TRA are higher in women over the age of 40 for each treatment arm however KP is associated with lower rate of TRA in each age group. Association of TRA with efficacy outcomes (pCR, iDFS) will be presented.

**Background:** Whilst Atezolizumab + nab-paclitaxel is the new standard of care in patients with PD-L1+ metastatic triple negative breast cancer (BC), the role of immunotherapy in ER+ BC has yet to be defined. ECLIPSE, an open label, phase II trial, aims to evaluate the effect of short-term pre-operative immune-modulatory agent combinations on ER+ tumour immune-phenotypes (NCT03395899). Here, we examined the first results of the dynamic changes of PD-L1 expression ( $\geq 1\%$  positive immune cell by VENTANA PD-L1 SP142 IHC) and T-cell expansion and activation after 1 cycle of atezolizumab alone or in combination with AKT, MEK or VEGF inhibitors.

**Methods:** Patients with histologically confirmed, untreated, operable ER+/HER2- primary BC received 1 cycle of atezolizumab alone or atezolizumab + ipatasertib, atezolizumab + cobimetinib, or atezolizumab + cobimetinib + bevacizumab 3 weeks prior to surgery or neoadjuvant therapy. Biopsies were obtained pre and on completion of study treatment. Dynamic changes in biomarkers were compared in 48 evaluable patients, including 41 paired samples.

**Results:** PD-L1 IC expression significantly increased after 1 cycle of treatment ( $p < 0.0001$ ). At a 1% IC cutoff, 21/45 patients (47%) were PD-L1 IC-positive (+) at baseline while 34/44 (77%) were PD-L1 IC + post-treatment. Increased tumour cell expression was also found in post-treatment samples ( $p < 0.01$ ). All post-treatment PD-L1 negative patients ( $n = 9$ ) were also negative at baseline. Overall, there was a small but significant increase in CD8 + T-cells post-treatment compared to baseline ( $p = 0.03$ ). In parallel, the number of T-cells that were positive for both CD8 and granzyme B (GZMB) - a T-cell activation marker - increased substantially ( $p < 0.01$ ). Single GZMB+ cells and single FOXP3+ cells did not change with treatment. In 2 cases, no tumour was detected post-treatment, suggesting a major pathological response. Baseline biopsies of both patients stood out as having the largest amount of CD8+GZMB+ T-cells. Post-treatment tumour bed profiling of these patients showed major infiltration of CD8+ and CD8+GZMB+ T-cells. Dynamic gene expression analysis showed upregulation of genes related to innate immunity and a cytotoxic T-cell transcriptional signature (tGE8), ( $p < 0.001$ ). Patients were grouped as immune-responsive or non-responsive based on a dynamic increase of CD8+GZMB+ cells. The immune-response group was characterized by increased IFN response signatures and decreased luminal gene signatures at baseline.

**Conclusions:** Our data indicate that short-term induction treatment with atezolizumab  $\pm$  targeted treatments induce dynamic changes toward inflamed immune phenotypes both at the morphological and transcriptional level, in patients with operable ER+/HER2- primary BC. These findings might help identify novel immunotherapy combination strategies in this setting, alongside the most appropriate biomarkers that can aid in identifying patients most likely to benefit from these treatments.

**Background:** Pathologic complete response (pCR) after neoadjuvant chemotherapy (NAC) in patients with breast cancer is associated with improved survival. Further assessment of the extent of residual disease, using the pathological anatomic American Joint Committee on Cancer staging method (ypStage) or the Residual Cancer Burden (RCB) method, have been shown to add prognostic information for patients with residual disease. Neo-Bioscore, an alternate system to classify response to NAC, includes clinical stage at diagnosis and biology and defines eight prognostic groups. The goal of this study was to compare three scoring systems (anatomic ypStage (7<sup>th</sup> ed), RCB Class and Neo-Bioscore) and assess whether RCB Class and Neo-Bioscore provide additional prognostic value in the context above anatomic ypStage, the most commonly used method for post-neoadjuvant residual disease assessment. **Methods:** Data from 5161 patients treated with NAC was pooled from 12 sites. Patients without clinical and pathological staging were excluded, as were patients with HER2+ breast cancer who did not receive neoadjuvant HER2-targeted therapy, leaving 3730 for analysis. pCR was defined as no residual invasive tumor in breast and nodes, i.e. RCB-0 or ypT0/Tis and ypN0. Patients with discordant pCR status by RCB Class vs ypStage (n=9) were excluded. Associations between each scoring system and event-free survival (EFS) were evaluated using the log rank test. EFS at 5 years was estimated using the Kaplan Meier method. Associations between Neo-Bioscore and EFS were assessed in the pCR group. For patients with residual disease, we assessed RCB and Neo-Bioscore within each ypStage. Analysis was performed overall and within subtype. Subgroups with <5 patients were excluded from the survival analyses. **Results:** ypAJCC staging, RCB class and Neo-Bioscore were all associated with EFS in the overall population and within each subtype (log rank p<0.0001). Of note, 13 patients with a Neo-Bioscore of 7 all recurred or died within 19 months of follow-up. Overall, 34% (1264/3721) of patients achieved a pCR. Their Neo-Bioscore ranges from 0-5, where 3% (37/1264) has a Neo-Bioscore of 5 despite achieving pCR. The Neo-Bioscore was not associated with EFS in case of a pCR, with EFS estimates at 5 years of 95%, 94%, 92%, 93%, 90% and 92% for Neo-Bioscores 0-5 respectively. As HR and HER2 status are components of the score, the range of Neo-Bioscore in the pCR group differs by subtype. However, similar to the overall analysis, the Neo-Bioscore was not prognostic within subtypes in case of pCR. Overall, among the patients who did not achieve pCR, both RCB class and Neo-Bioscore were associated with EFS within ypStages I, II and III. However, the ypStage within which RCB and Neo-Bioscore are prognostic is different for each subtype. RCB class was prognostic in ypStage I in both HR+ subtypes: patients with ypStage-I/RCB-I had significantly improved survival compared to patients with ypStage-I/RCB-II (5-year EFS: 100% vs 83% in HR+HER2- and 95% vs 77% in HR+HER2+). In contrast, for patients with triple negative breast cancer, RCB class was prognostic within ypStage II and III. Analysis by clinical stage and the components of the three systems that contribute most to prognosis will be presented. **Conclusions:** The degree of response to NAC adds important information to pCR versus residual disease. The Neo-Bioscore was not prognostic among patients with pCR, suggesting that clinical stage (including subtype and grade) adds little information in the setting of a pCR. In contrast, both RCB and Neo-Bioscore provide additional prognostic information to the conventional ypAJCC staging among non-pCR patients, suggesting that clinical stage, tumor biology as well as extent of residual disease all contribute to prognosis in the setting of residual disease after NAC.

The detection and enumeration of circulating tumor cells (CTCs) and circulating endothelial cells (CECs) in metastatic breast cancer

Qiang Zhang<sup>1</sup>, Paolo D'Amico<sup>2</sup>, Jeannine Donahue<sup>1</sup>, Lorenzo Gerratana<sup>3</sup>, Andrew A. Davis<sup>1</sup>, Saya Liz Jacob<sup>1</sup>, Zheng Cai<sup>4</sup>, Elena Vagia<sup>1</sup>, Wenan Qiang<sup>1</sup>, Ami N. Shah<sup>1</sup>, Katy Kerby<sup>1</sup>, Lisa Flaum<sup>1</sup>, Youbin Zhang<sup>1</sup>, Firas Wehbe<sup>1</sup>, Amir Behdad<sup>1</sup>, William Gradishar<sup>1</sup>, Leonidas Platanias<sup>1</sup> and Massimo Cristofanilli<sup>1</sup>. <sup>1</sup>Northwestern University, Lurie Cancer Center, Chicago, IL; <sup>2</sup>Northwestern University, Istituto Europeo di Oncologia - IEO, Milan, Italy, Chicago, IL; <sup>3</sup>Northwestern University, University of Udine, Chicago, IL; <sup>4</sup>University of Washington, Seattle, WA

**Introduction:** Circulating tumor cells (CTCs) are the roots of metastasis which is the main cause for death in metastatic breast cancer (MBC). CTCs enumeration is strongly prognostic in advanced disease and can stratify patients in two distinct disease, Stage IV aggressive and Stage IV indolent. In the former disease, the detection of CTC clusters and HER2-expression increase prognostic and predictive value. The metastatic cascade is a complex, regulated process involving immune cells and endothelial cells for progression and neoangiogenesis. Circulating endothelial cells (CECs) from the inner wall of blood vessels are shed into the blood stream during formation of blood vessels which is considered a sensitive marker of endothelial damage in pathological conditions such as cancer. CECs have been also studied as a biomarker for tumor progression and monitoring anti-angiogenic therapeutic effects in MBC. We evaluated the concomitant detection of CTCs and CECs in MBC patients, along with expression of HER2 in CTCs that may offer an interesting clue to elucidate the metastasis mechanisms. **Methods:** Whole blood samples (7.5ml/each) were collected from 14 stage IV MBC patients before systemic therapy. CTCs enumeration was performed in FDA approved CELLTRACKS System (Menarini) by using CTC Kit contains specific antibodies targeting the EpCAM for capturing CTCs, anti-CK-PE (for epithelial cells), DAPI (for nucleus), anti-CD45-APC (for leukocytes), and anti-HER-2/neu-FLU. The CTCs were classified as CK<sup>+</sup>, EpCAM<sup>+</sup>, DAPI<sup>+</sup> and CD45<sup>-</sup>. Meanwhile, the same patients' blood samples (4.0ml/each) were processed for CEC analyzed by using CEC kit which immunomagnetically captures CD146<sup>+</sup> cells, and then stains the cells for CD105-PE (specific for protein endoglin), CD45-APC, nucleus-DAPI. The positive CECs were classified as CD 146<sup>+</sup>, CD105<sup>+</sup>, DAPI<sup>+</sup> and CD45<sup>-</sup>. The associations between CTCs, HER2 expression and CECs were evaluated. **Results:** The average age of patients was 53.1. Subtypes of Luminal, HER2 positive and TNBC were 64.2% 7.2% and 28.6% respectively. Distant metastasis were found in 13 out of 14 patients, including bone (7), liver (5), Lymph nodes (5) and Pleura (2). CTCs were found positive (≥5, Stage IV aggressive) in 5 patients (range: 5-47, mean=24), and HER expression was identified in all 5 of these cases with a range of numbers between 1 and 7 (mean=4.2). The ratios of HER<sup>+</sup> CTC/total ratios were 8.51%, 17.95%, 20%, 30.77%, and 33.33%. HER2 expression were defined officially in our lab according to the percentile of positive HER2 CTCs/Total CTCs and the expression intensity as - (<20%), + (20-39%), ++ (40-59%) and +++ (≥60%) respectively. There were 9 patients (%) were identified as CTCs negative (<5, Stage IV indolent) with the mean=1, and HER<sup>+</sup> CTCs were found in only 2 patients with Stage IV indolent. Meanwhile, CECs were found in all 14 patients with a range of numbers between 4 to 115. There were an average of 33 CECs in Stage IV aggressive disease, compared to 53 CECs in Stage IV indolent. The average of CECs were 53.44, 12 and 37.25 in Luminal, HER2 positive and TNBC groups respectively. On the other hand, patients with HER2<sup>+</sup> CTCs had an average of 50 CECs which is significantly higher than average of 41 CECs in patients without HER2<sup>+</sup> CTCs. Moreover, there were average of 94.5, 56 and 40.22 CECs were found in groups when HER2 expression was ++/+++, above + and - respectively. The results demonstrated that although CTC enumeration have a reverse correlation with CECs numbers, HER2 expression in CTCs was significantly related with high CECs numbers. **Conclusions:** Our data provides the first evidence of potential association between CTCs and CECs in metastatic breast cancer. The association between HER2 expression and CECs offers a potential new insight to mechanism connections between CECs and disease metastasis in MBC.

Exploring the causal role of the human gut microbiome in breast cancer risk using mendelian randomization

Tim Robinson, Grace Edmunds, Bryony Hayes and Kaitlin Wade. University of Bristol, Bristol, United Kingdom

**Background:** Variation in the human gut microbiome may influence cancer progression and therapy response through various mechanisms including modulation of both immune and cell signalling pathways. Whilst observational epidemiological studies have provided evidence that the gut microbiome may play a role in cancer risk, such studies are prone to residual confounding, reverse causation, and other forms of bias. Therefore, the nature of these associations still remains unclear. Mendelian randomization (MR) is a causal methodology that uses genetic variants as instruments ("proxies") for risk factors to eliminate such biases when questioning causality in observational epidemiological associations. The statistical power and precision of MR analyses can be increased by employing a "two-sample MR" (2SMR) framework in which summary data – usually from large, independent, genome-wide association studies (GWASs) reporting associations of genetic variants with exposures (here, the gut microbiome) and outcomes (here, cancer) – are synthesised to estimate causal effects of each exposure on each outcome of interest. In this study, we utilised 2SMR to interrogate causal relationships between the gut microbiome and breast cancer (BC) risk using the largest published GWASs of the gut microbiome and of clinically utilised subtypes of BC.

**Methods:** We performed 2SMR using summary-level data from the GWAS of the host genetic contribution to gut microbiome variation amongst European individuals (the Flemish Gut Flora Project and two German cohorts (n=3890)) combined with summary-level data from the GWAS of BC risk (Breast Cancer Association Consortium (133,384 cases stratified by Luminal A, Luminal B, Human Epidermal Growth Factor 2 (Her2) positive, Her2 negative and triple negative status and 113,789 controls, plus 18,908 BRCA1 mutation carriers (9,414 with BC)). Sensitivity analyses were also conducted to assess pleiotropy of genetic variants on BC risk, independent of gut microbiota. Analyses were conducted in R Studio using the TwoSampleMR and the MR-TRYX packages.

**Results:** Of the 14 microbial traits (MTs) with evidence for a host genetic contribution in the GWAS of the gut microbiome, we found evidence that abundance of a genus within a certain bacterial order decreased the risk of triple negative BC (odds ratio per standard deviation increase: 0.84; 95% CI: 0.71, 0.9; p=0.03). In addition, we demonstrated that the risk of all molecular subtypes of BC may be altered by variation in these MTs, and that these relationships differed according to subtype. Sensitivity analyses demonstrated that pleiotropy was unlikely to explain these relationships.

**Conclusions:** In our study, we utilised two recent and novel GWASs in an MR context to appraise causality in relationships between the gut microbiome and BC risk and found evidence that certain bacteria may alter BC risk, effects of which vary according to molecular subtype. These important results generate hypotheses about mechanisms underlying the causal biology of BC subtypes and potentially facilitate the design of BC risk-reducing interventions and prevention strategies.

How often does retrieval of a clipped lymph node change adjuvant therapy recommendations? A prospective consecutive patient cohort

Anna Weiss, Claire King, Samantha Grossmith, Leah Portnow, Sughra Raza, Faina Nakhlis, Laura Dominici, Elizabeth A. Mittendorf and Tari A. King. Brigham and Women's Hospital, Boston, MA

**Objectives and Rationale:** For breast cancer patients receiving neoadjuvant chemotherapy (NAC) and undergoing pre-NAC axillary lymph node biopsy, NCCN guidelines recommend biopsy marker (clip) placement. This recommendation is based on reports that retrieval of the clipped node after NAC minimizes the false negative rate of sentinel lymph node biopsy (SLNB). Prior studies examining this practice in cN1 patients have reported that the clipped node is a non-SLN 20% of the time. There is limited data regarding if the clipped node needs to be retrieved among cN0 patients, and how often the post-NAC pathologic status of the clipped node has potential to change adjuvant therapy decisions. Here we aim to determine: 1) how often the clipped node is a non-SLN among both cN0 and cN1 patients, and 2) how often the retrieved, clipped node is a non-SLN and is the only positive node after NAC, potentially impacting adjuvant treatment recommendations.

**Methods:** A consecutive cohort of 147 patients treated with NAC and surgery at our institution between January 2019-May 2020 was prospectively examined. Prior to NAC, all patients underwent routine axillary ultrasound (AxUS). For those with an abnormal appearing node, biopsy was performed of the most suspicious lymph node and a clip was placed. All cN0 patients underwent SLNB without localization of the clipped node. Patients who converted from cN1 to cN0 underwent radioactive seed localization of the clipped node and SLNB with dual tracers (radioactive tracer and blue dye). All lymph nodes were analyzed by IHC. Any residual disease, including ITCs, was considered pathologic node positive (ypN+). Patients with DCIS/unknown breast tumor histology (N = 3), those without AxUS (N = 9), those treated with neoadjuvant endocrine therapy (N = 9) and cN1 patients without a clip (N = 2) were excluded. Descriptive analyses were performed to examine the rate of ypN+ disease among cN0 and cN1 patients, and how often the clipped node was a non-SLN containing residual disease. In the cN0 population, if the clipped node was not obtained during SLNB it was considered a non-SLN.

**Results:** Of 124 patients meeting study criteria, 61 were cN0 and 63 cN1. Among cN0 patients, 21 (34%) had suspicious lymph nodes on AxUS which were biopsied (negative) and clipped. All cN0 patients underwent successful SLNB, with a median of 2 SLNs removed (range 1-10). Of these, 5 (8%) were ypN+. Of the 21 patients with clipped nodes, 14 (67%) of the clipped nodes were non-SLN. If <3 SLNs were sampled, the clipped non-SLN rate was 82% (9/11). If ≥3 were sampled, the clipped non-SLN rate was 50% (5/10). Among patients with clipped nodes and ypN+ disease, there were no cases in which the clipped node was the only positive node.

Among 63 cN1 patients with clipped nodes, 55 (87%) converted to cN0 and underwent SLNB. SLNB was successful in 52/55 (95%) and a median of 3 SLNs were removed (range 1-8). Overall, 28/55 (51%) were ypN+. Of the 52 with successful SLNB, 15 (29%) of the clipped nodes were non-SLN. If <3 SLNs were sampled, the clipped non-SLN rate was 46% (6/13). If ≥3 were sampled, the clipped non-SLN rate was 23% (9/39). In one of 52 (2%) patients, the clipped non-SLN was the only positive node.

**Conclusions:** In this prospective study, among cN0 patients with negative pre-NAC lymph node biopsies, the clipped node was frequently a non-SLN and pathologic status of the clipped node alone did not impact management. Among cN1 patients suitable for SLNB after NAC, although the clipped node was a non-SLN 29% of the time, it was the only positive node in only one patient. The finding that the post-NAC pathologic status of the clipped lymph node alone potentially changed adjuvant treatment recommendations in only 2% (1/52) of patients warrants further investigation.

**Introduction:** Mutations in *PIK3CA*, which encodes the  $\alpha$ -isoform of phosphatidylinositol 3-kinase (PI3K $\alpha$ ), occur in ~40% of patients (pts) with HR+, HER2- ABC and can contribute to endocrine resistance. Alpelisib (ALP), a PI3K $\alpha$ -selective inhibitor and degrader, plus fulvestrant (FUL) demonstrated efficacy in the phase 3 SOLAR-1 trial, which included 20 pts who had prior CDK4/6i in the *PIK3CA*-mutant cohort. Limited clinical data are available in the post-CDK4/6i setting for *PIK3CA*-mutated, HR+, HER2- ABC. BYLieve (NCT03056755), an ongoing phase 2, multicenter, open-label, 3-cohort noncomparative study, is the first trial evaluating ALP + endocrine therapy (FUL or letrozole [LET]) in pts with *PIK3CA*-mutated, HR+, HER2- ABC who progressed on/after prior therapy, including CDK4/6i. In the prior CDK4/6i + aromatase inhibitor (AI) cohort (Cohort A), pts received ALP + FUL. With median follow-up of 11.7 months (mo), the primary endpoint in Cohort A was met—50.4% of pts were alive and without disease progression (PD) at 6 mo per local investigator assessment (n=61; 95% CI, 41.2%-59.6%). Median progression-free survival (mPFS) was 7.3 mo (n=72; 95% CI, 5.6-8.3 mo); AEs were consistent with prior observations. Now, we report on the cohort of pts who received a CDK4/6i + FUL as immediate prior therapy before enrollment (Cohort B). **Methods:** Daily oral treatment in Cohort B consisted of ALP 300 mg + LET 2.5 mg. Each cohort planned to enroll at least 112 pts with centrally confirmed *PIK3CA* mutation, based on immediate prior treatment of either a CDK4/6i + AI (Cohort A), a CDK4/6i + FUL (Cohort B), or systemic chemotherapy or endocrine therapy (which may also include prior CDK4/6i + FUL; Cohort C, follow-up ongoing). The primary endpoint, the proportion of pts with centrally confirmed *PIK3CA* mutation alive without PD at 6 mo per local investigator using Response Evaluation Criteria in Solid Tumors (RECIST) 1.1, is assessed for each cohort separately and is met if the lower bound of the 95% CI is >30%. Men and premenopausal women were allowed goserelin 3.6 mg subcutaneously or leuprolide 7.5 mg intramuscularly every 28 days. **Results:** 126 pts whose immediate prior treatment was CDK4/6i + FUL were enrolled into Cohort B: 115 had centrally confirmed *PIK3CA* mutations. Median follow-up was 15.0 mo (range, 1-31 mo); 58 (46.0%) had  $\geq 2$  lines of prior therapy in the metastatic setting, and 103 (81.7%) pts progressed on prior AI therapy. The primary endpoint was met with 46.1% (95% CI, 36.8%-55.6%) of pts alive without PD at 6 mo. mPFS was 5.7 mo (95% CI, 4.5-7.2 mo). The most frequent all-grade AEs ( $\geq 25\%$ ) were diarrhea (67.5%), hyperglycemia (63.5%), nausea (54.8%), decreased appetite (44.4%), stomatitis (34.1%), fatigue (31.0%), rash (31.0%), and vomiting (24.6%). Most frequent grade  $\geq 3$  AEs included hyperglycemia (25.4%), rash (9.5%), and rash maculopapular (7.9%). Incidence of AEs leading to treatment discontinuation was 14.3% (n=18); most frequent AEs leading to discontinuation were rash (4 pts, 3.2%, including rash maculopapular), fatigue, and diarrhea (3 pts, 2.4% each). **Conclusion:** Alpelisib in combination with LET following progression on FUL + CDK4/6i and prior AIs was effective in this noncomparative trial. Consistent with the known safety profile of alpelisib, manageable toxicities were observed. These data suggest that alpelisib in combination with LET may be an effective treatment option for pts with *PIK3CA*-mutated, HR+, HER2- ABC in the post-CDK4/6i setting.

**Background:** Young breast cancer patients (pts) carrying a germline *BRCA* mutation (*mBRCA*) have similar outcomes as non-carriers. However, there is currently lack of evidence regarding the impact of *mBRCA* type and hormone receptor status on clinical behavior and outcomes of *mBRCA* breast cancer. We aim to address these questions in the largest dataset to date of young *mBRCA* breast cancer pts.

**Methods:** This was an international, multicenter, hospital-based, retrospective cohort study. Women harboring deleterious germline *mBRCA1* or *mBRCA2* that received a diagnosis of stage I-III invasive early breast cancer at age ≤40 years between January 2000 and December 2012 were included. Baseline pts, tumor, and treatment characteristics, pattern and risk over time of disease-free survival (DFS) events, and survival outcomes (DFS, distant recurrence-free interval [DRFI] and overall survival [OS]) were compared between *mBRCA1* and *mBRCA2* pts overall and by hormone receptor status. Multivariate Cox proportional hazard models were used to compare hazard rates (HRs).

**Results:** 1,236 young *mBRCA* breast cancer pts were included. Among 808 and 428 pts with *mBRCA1* or *mBRCA2*, respectively, 191 (23.6%) and 356 (83.2%) had hormone receptor-positive tumors while 617 (76.4%) and 72 (16.8%) hormone receptor-negative disease ( $p < 0.001$ ). Compared to *mBRCA2* breast cancer pts, those with *mBRCA1* were younger, more likely to have reported Jewish ancestry, had more grade 3 tumors, less nodal involvement, lobular histology and HER2 positivity, and received more frequently chemotherapy (all  $p < 0.001$ ). More *mBRCA1* pts with hormone receptor-positive tumors did not receive adjuvant endocrine therapy (14.7% vs. 4.2%,  $p < 0.001$ ). No difference between *mBRCA1* and *mBRCA2* pts was observed in risk-reducing mastectomy (43.9% vs. 46.0%;  $p = 0.371$ ) or salpingo-oophorectomy (48.3% vs. 48.8%;  $p = 1.0$ ). Median follow-up was 7.9 years (range 5.6-10.6 years). Second primary breast cancers (17.0% vs. 12.2%,  $p = 0.025$ ) and non-breast primary malignancies (4.3% vs. 1.9%,  $p = 0.033$ ) were more frequent among *mBRCA1* pts compared to *mBRCA2* pts, while distant recurrences were less frequent (10.4% vs. 15.4%,  $p = 0.013$ ). 8-year DFS was 62.8% and 65.9% for *mBRCA1* and *mBRCA2* pts, respectively (adjusted HR 0.76; 95% CI 0.60-0.96). The worse DFS in *mBRCA1* was observed regardless of hormone receptor status ( $p_{\text{interaction}} = 0.848$ ): hormone receptor-positive (adjusted HR 0.77; 95% CI 0.58-1.03) and hormone receptor-negative (adjusted HR 0.73; 95% CI 0.48-1.13). No differences in DRFI and OS were observed between *mBRCA1* and *mBRCA2* pts. Compared to pts with hormone receptor-negative disease, those with hormone receptor-positive breast cancer had higher chances of developing distant ( $\pm$  loco-regional) recurrences (16.1% vs. 9.0%;  $p < 0.001$ ) and less frequent second primary malignancies (BC: 12.1% vs. 17.9%,  $p = 0.005$ ; non-BC: 2.8% vs. 4.0%,  $p = 0.216$ ). No differences in DFS and OS were observed between pts with hormone receptor-positive or negative breast cancer. However, there was a trend towards worse DRFI in women with hormone receptor-positive breast cancer as compared to those with hormone receptor-negative disease (8-year DRFI: 83.4% vs. 90.1%; adjusted HR 1.39; 95% CI 0.94-2.05).

**Conclusions:** In this large unique dataset, young *mBRCA1* breast cancer pts had worse DFS than those with *mBRCA2* mostly due to higher rates of second primary malignancies. Hormone receptor positivity had no positive prognostic value in young *mBRCA* breast cancer pts with a trend towards worse DRFI in those with hormone receptor-negative disease. These results provide important information for counseling young *mBRCA* breast cancer pts regarding treatment, prevention and follow-up care strategies.

**Background** The PI3K/AKT signaling pathway plays a significant role in both HR+ BC and TNBC. IPATunity130 is a double-blind, placebo-controlled, randomized phase 3 trial of ipatasertib in combination with paclitaxel in patients with *PI3K/AKT1/PTEN*-altered HR+ or TNBC. A next-generation sequencing (NGS)-based assay from Foundation Medicine Inc. (FMI) was used to select patients prospectively for enrollment in this trial. **Patients and methods** An investigational clinical trial assay (CTA) of a composite 3-gene biomarker signature [Kim, Lancet Oncol 2017] based on the FoundationOne<sup>®</sup> CDx assay was used to identify patients with PI3K/AKT pathway-activated tumors as eligible for enrollment in IPATunity130 (NCT03337724). Qualifying alterations for the 3-gene signature (referred to as 'biomarker-positive') comprised activating mutations in *PIK3CA* and/or *AKT1*, and/or loss of function (LOF) alterations in *PTEN* represented by homozygous or heterozygous deletions, dominant-negative mutations, or inactivating mutations under loss of heterozygosity. Study sites were required to submit formalin-fixed paraffin-embedded archival or fresh biopsy tissue derived from primary or metastatic tumors for patient screening. IPATunity130 includes three independent cohorts: Cohort A (biomarker-positive TNBC); Cohort B (biomarker-positive HR+/HER2- BC); and Cohort C (biomarker-negative TNBC). **Results** In total, 1736 patients were screened, from whom 1690 samples were tested by FMI. Of these, 1475 (87%) produced a valid NGS result. The remaining 215 (13%) failed quality control for reasons including insufficient tissue, DNA yield, lab error, and computational failure. Alteration status for *PIK3CA* and/or *AKT1* and/or *PTEN* was positive in 703 (49%) of 1440 CTA-evaluable samples. In the HR+/HER2- cohort, the breakdown of CTA-positive samples was 301/356 (85%) *PIK3CA/AKT1* mutations and 86/356 (24%) *PTEN* LOF alterations. In TNBC, 183/347 (53%) had *PIK3CA/AKT1* mutations and 193/347 (56%) had *PTEN* LOF alterations. CTA results according to baseline characteristics are shown overall and by subtype below.

Subgroup		<i>PIK3CA/AKT1/PTEN</i> alteration, n/N (%)		
		Overall	HR+/HER2-	TNBC
All patient samples		703/1440 (49)	356/647 (55)	347/793 (44)
Age, years	≤50	219/475 (46)	99/195 (51)	120/280 (43)
	>50	484/965 (50)	257/452 (57)	227/513 (44)
Sample source	Primary	456/941 (48)	232/414 (56)	224/527 (43)
	Metastatic	222/448 (50)	112/213 (53)	110/235 (47)
Geographic region	North America	60/102 (59)	33/49 (67)	27/53 (51)
	Asia-Pacific	172/330 (52)	81/145 (56)	91/185 (49)
	Europe	301/633 (48)	171/310 (55)	130/323 (40)
	Rest of world	170/375 (45)	71/143 (50)	99/232 (43)

The most common mutations detected outside the 3-gene biomarker signature in the screened population were in the *TP53*, *BRCA1*, *RB1*, *BRCA2*, and *NF1* genes in the TNBC cohort and the *TP53*, *GATA3*, *CDH1*, *MAP3K1*, and *ESR1* genes in the HR+/HER2- cohort. In the HR+/HER2- cohort, 30 (14%) of 213 metastatic tumors had *ESR1* mutations compared with 10/414 (2%) primary tumors. Tumor *BRCA1* mutations were more common in patients aged ≤50 years whereas *MAP3K1* mutations were more common in those aged >50 years. **Conclusions** IPATunity130 is the first reported pivotal trial to utilize the 3-gene biomarker CTA in HR+/HER2- BC and TNBC to screen for patients with PI3K/AKT pathway-activated tumors. The 3-gene biomarker CTA detected alterations in 49% of screened patients, with a higher prevalence of *PIK3CA/AKT1/PTEN* alterations in HR+/HER2- BC than TNBC. Additional analyses are planned to assess correlations between clinical outcomes and tumor characteristics.

Incidence and survival of inflammatory breast cancer between 1973 - 2015 in the surveillance, epidemiology and end results (SEER) database

Hannah Abraham, Yaoxuan Xia, Bhramar Mukherjee and Sofia D Merajver. University of Michigan, Ann Arbor, MI

**Purpose**Inflammatory breast cancer (IBC) is a rare and aggressive variant of breast cancer characterized by erythema, edema, and “peau d’orange” of the breast progressing within six months. We assessed the incidence and survival of IBC in the US currently, compared to historical results.

**Methods**Using SEER\*Stat, a case list of IBC patients diagnosed between 1973-2015 (n = 29,718) was extracted from the SEER 18 registries by defining IBC using a combination of morphology, stage, and extent of disease criteria. Age-adjusted incidence rates, relative survival rates, and mean survival time were calculated. Significance was determined as non-overlapping 95% confidence intervals.

**Results**The overall incidence of IBC from 1973 - 2015 is 2.76 (2.73, 2.79) cases per 100,000 people, with white patients having an incidence rate of 2.63 (2.60, 2.67), black patients 4.52 (4.39, 4.65), and patients of other race 1.84 (1.76, 1.93). The relative rate of 5-year survival for IBC patients as a whole is 40.5% (39.0%, 42.0%), with white patients having a rate of 42.5% (40.7%, 44.3%) and black patients' survival rate 29.9% (26.6%, 33.3%) (**see Table 1**). White patients diagnosed in 1988-1992 have a mean survival time of 81.9 (53.5, 110.3) months, while those diagnosed in 2008-2012 have mean survival time of 101.9 (90.0, 113.7) months. In contrast black patients diagnosed in 1988-1992 have a mean survival time of 48.5 (37.5, 59.4) months, while those diagnosed in 2008-2012 have mean survival time of 84.3 (77.2, 91.4) months (**see Table 2**).

**Conclusions**Our results suggest that IBC survival has moderately increased in recent years. However, despite the overall improvement in survival for all racial groups, there remains a persistent survival disparity between white and black patients that has not narrowed over two decades. Further research is urgently needed to understand and address this disparity.

**Table 1:** Relative Survival Rates for inflammatory breast cancer by race, %(95% CI). “Cohort”: cohort analysis, “Period”: period analysis. Significance relative to black patients, determined by non-overlapping 95% CI calculated via the Greenwood method and demonstrated by \* for cohort and + for period analysis.

**Background:** Cancer cells overexpress CD47 to evade phagocytic programmed cell removal (PrCR) by macrophages of the innate immune system. Blocking CD47 using magrolimab (Hu5F9-G4), an anti-CD47 humanized monoclonal antibody, works via preventing CD47 signaling via macrophage Sirpα to allow PrCR, as well as using an Fc-receptor mechanism to encourage macrophage-mediated phagocytosis. We have previously shown that magrolimab in combination with tumor-targeting antibodies (e.g. rituximab) further enhances magrolimab's anti-cancer effects in preclinical models and in the clinic [Advani R, et al. N Engl J Med 2018; 379:1711-1721]. We therefore hypothesized that magrolimab combined with anti-HER2 monoclonal antibody would synergize to promote ADCP *in vitro*, and HER2+ breast xenograft growth inhibition *in vivo*. **Methods:** To test this hypothesis,  $1 \times 10^5$  CFSE-labeled HER2+ BT474 and SKBR3 cells were plated in 96-well ultra-low attachment plates in serum-free media. Isotype control antibody, trastuzumab, magrolimab, and trastuzumab + magrolimab combination (10μg/ml) were added, and allowed to incubate at 37°C for 30 mins.  $5 \times 10^4$  human macrophages were then added each well, and were co-cultured for 2 hours. Human macrophages were stained with anti-CD11b, and phagocytosis was determined as the percentage of cells that were CD11b+ and CFSE+ using a BD LSR Fortessa Analyzer. For *in vivo* tumor xenograft growth kinetics, GFP+/Luciferase+ BT474 cells ( $1 \times 10^5$ ) were implanted with 25% Matrigel into the mammary fat pads of 4-8 week-old NOD scid gamma (NSG) female mice. Twenty-five days after engraftment, trastuzumab (100ug) was administered via intraperitoneal (IP) injection weekly, magrolimab 250ug IP was administered every other day, and PBS control was administered IP at 100uL once weekly, and tumor growth was monitored for 17 weeks by bioluminescence (IVIS) after D-luciferin injection, and quantified using Image 4.0. **Results:** SKBR3 and BT474 parental and Trastuzumab-resistant lines demonstrated significantly increased susceptibility to ADCP when opsonized with combination treatment of trastuzumab + magrolimab (15.34, 95%CI= 12.2 to 16.6) compared to trastuzumab (9.66, 95%CI=1.861 to 7.7579,  $p = 0.034$ ), or magrolimab alone (10.23, 95%CI=1.254 to 7.037,  $p = 0.0083$ ). Treatment with magrolimab maintained tumor burden within the starting range but further progressed upon treatment cessation ( $2.09 \times 10^9$ , CI95% = 2801531434 to 15343840962,  $p = 0.0006$ ). Trastuzumab treatment resulted in lower starting range tumor burden, but also demonstrated progression once treatment was stopped ( $1.72 \times 10^6$ , CI95% = -695208489 to -86402608,  $p = 0.0052$ ). However, in the combinatorial treatment arm, tumors were significantly below the starting range and did not show signs of tumor progression within the 10-week non-treatment period ( $8.51 \times 10^5$ , CI95% = -311406356 to -66914472,  $p = < 0.0001$ ). **Conclusion:** We conclude magrolimab plus trastuzumab cooperate to inhibit HER2+ xenograft growth *in vivo*, and that treatment effect persists even after treatment is stopped. Our *ex vivo* data suggests one mechanism to explain the observed tumor growth inhibition is increased susceptibility to ADCP when HER2+ tumors are opsonized by the combination of trastuzumab + magrolimab. Future clinical translation of this combination is warranted.

Comparison of liquid biopsy and tissue based detection of *PIK3CA* mutations in HR positive metastatic breast cancer patients

Christoph Suppan<sup>1</sup>, Qing Zhou<sup>2</sup>, Stephan Jahn<sup>3</sup>, Ricarda Graf<sup>4</sup>, Eva Valentina Klocker<sup>1</sup>, Angelika Terbuch<sup>1</sup>, Karl Kashofer<sup>5</sup>, Florian Posch<sup>1</sup>, Hanno Gerritsmann<sup>6</sup>, Nadia Dandachi<sup>1</sup>, Ellen Heitzer<sup>2</sup> and Marija Balic<sup>1</sup>. <sup>1</sup>Medical University Graz, Division of Oncology, Department of Internal Medicine, Graz, Austria<sup>2</sup>Medical University Graz, Institute of Human Genetics, Graz, Austria<sup>3</sup>Medical University Graz, Institute for Pathology, Graz, Austria<sup>4</sup>Medical University Graz, Institute of Human Genetics, Graz, Austria<sup>5</sup>Medical University Graz, Institute for Pathology, Graz, Austria<sup>6</sup>Novartis Pharma GmbH, Vienna, Austria

The treatment of hormone receptor positive metastatic breast cancer patients has changed dramatically over the last few years and combination strategies attempting to overcome resistance of the disease are gaining importance. After introducing CDK 4/6 inhibitors in the treatment one of the subsequent strategies is definitely targeting PI3 kinase pathway. Several drugs have been tested, but only recently, SOLAR-1 phase III trial demonstrated the benefit of adding alpelisib to fulvestrant, with acceptable tolerability. With this trial the importance of *PIK3CA* testing was postulated. In the present study a comparison of liquid biopsy and tissue-based detection of *PIK3CA* mutations in HR positive metastatic breast cancer patients was performed. **Materials and Methods:** Plasma and the most recent tumor tissue were screened for *PIK3CA* hotspot mutations from 58 patients with metastatic hormone-receptor positive breast cancer. For plasma samples, SiMSen-Seq NGS sequencing was used covering 11 frequent *PIK3CA* mutations, which were applied for stratification in SOLAR-1. Only plasma samples with variant allele frequency (VAF) >1% were considered as positive. For tumor tissue samples, targeted Ion Torrent NGS was used. Matched tissue plasma samples were available from 40 patients. **Results:** *PIK3CA* mutations were detected in 25/50 (50.0%) tissue samples and in 18/48 (37.5%) plasma samples. VAF ranged from 4.4 to 72.9% with an average of 28.7% in tissue samples, and from 1.1% to 49.9% with an average of 8.2% in plasma samples. In tumor samples, the most frequent variant was H1047R (11/25, 44.0%), followed by E545K (8/25, 32.0%), E542K (4/25, 16.0) and H1047L (2/25, 8.0%). In plasma samples, the most frequent *PIK3CA* variant was H1047R (12/18, 66.7%), followed by E542K (6/18, 33.3%), and E545K (2/18, 11.1%). Double mutations in plasma samples occurred in two patients (both with H1047R + E542K). In 15/48 (31.3%) plasma samples, 19 low-level mutations (AF between 0.1% and 1.0 %) were detected, with an average of 0.49% (range 0.18-0.98). Matched tissue and plasma samples were available from 40/58 (68.9%) patients with a median time between matched tissue and plasma collection of 285 days (25<sup>th</sup>-75<sup>th</sup> percentile: 24-1833 days). The overall concordance rate between plasma and tissue samples was 62.5% (25/40 patients). In detail, 8/40 patients (20.0%) had the same *PIK3CA* mutation in plasma and tumor tissue, while in 17/40 patients (42.5%) were tested negative in both sample types. Discordant results occurred in 15/40 samples (37.5%). Specifically, nine patients had a *PIK3CA* mutation in the tissue sample only, while four patients had a *PIK3CA* mutation in the plasma sample only. In addition, in two patients a different *PIK3CA* mutation was detected in the plasma sample compared to the tissue sample. **Conclusion:** SiMSen-Seq based detection of *PIK3CA* mutations from plasma demonstrated promising results for selection of candidate patients for Alpelisib treatment. However, these results will be validated in a larger cohort of patients. Our data align with FDA recommendation to initially carry out the mutation testing in ctDNA. Only if the test is negative for *PIK3CA* mutations in plasma, patients should undergo testing for *PIK3CA* mutations in tumor tissue.

Proteomic analysis of breast cancer formalin-fixed paraffin-embedded clinical specimens identifies biologically-important subtypes with distinct clinical outcomes

Karama Asleh<sup>1</sup>, Gian Luca Negri<sup>2</sup>, Sandra E. Spencer Miko<sup>2</sup>, Shane Colborne<sup>2</sup>, Christopher S. Hughes<sup>2</sup>, Xiu Q. Wang<sup>1</sup>, Dongxia Gao<sup>1</sup>, C. Blake Gilks<sup>1</sup>, Stephen K.L. Chia<sup>3</sup>, Torsten O. Nielsen<sup>1</sup> and Gregg B. Morin<sup>2</sup>. <sup>1</sup>Genetic Pathology Evaluation Centre, Vancouver, BC, Canada<sup>2</sup>Canada's Michael Smith Genome Sciences Centre, Vancouver, BC, Canada<sup>3</sup>Department of Medical Oncology, British Columbia Cancer Agency, Vancouver, BC, Canada

**Background:** Genomic classification of breast cancer has advanced breast cancer diagnosis and outcomes. However, extensive heterogeneity still exists beyond their DNA or RNA profiles. Newer classifications based on protein profiling are being developed to investigate the molecular oncology of breast cancers at the level where most drugs act. Using a recently-developed technology, we performed global proteomic profiling of 300 breast cancer specimens linked to outcome data. **Methods:** Sections of 75 samples from each PAM50 intrinsic subtype (Luminal A, Luminal B, Her2-enriched, Basal-like; n = 300) were macrodissected and analyzed using the Single-Pot Solid-Phase enhanced Sample Preparation Clinical Tissue Proteomics, a highly sensitive 11-sample multiplex massspectrometry protocol applicable to formalin-fixed, paraffin embedded (FFPE) specimens. This methodology enables comprehensive quantification of protein expression for classifier and biomarker discovery. Patients were diagnosed during 2008-2013 (n = 178, dataset I) and 1986-1992 (n = 122, dataset II). **Results:** In-depth proteomic analysis measured 9088 proteins in total, including 4214 proteins quantified in every sample. Consensus clustering of 174 evaluable cases in dataset I identified four distinct groups based on expression values for 1054 highly variant proteins. Cluster 3 (n = 47, mostly basal-like with HER2-Enriched) displayed the most favorable recurrence free survival (RFS) when compared to other clusters (HR = 0.22, 95%CI [0.08-0.63], p = 0.005). This cluster was enriched for immune related pathways including antigen processing and presentation and type I & II interferon signaling, and displayed high tumor infiltrating lymphocyte counts, characterizing this cluster as "immune hot". In contrast, cluster 2 (n = 50, mostly basal-like) exhibited the poorest RFS (HR = 2.88, 95%CI [1.45-5.70], p = 0.002) and was enriched for proteins related to stromal and extracellular matrix with few immune related peptides. Cluster 1 (n = 34, luminal B and HER2-Enriched) was associated with lipid metabolism, whereas cluster 4 (n = 43, mostly HER2-Enriched with luminal A and luminal B) had a profile enriched for extracellular matrix, blood coagulation and complement activation. **Conclusions:** Global proteomic analysis on FFPE specimens can characterize the heterogeneity of breast cancer in a reliable and clinically-applicable high throughput manner. Our methodology identifies protein candidates that potentially serve as therapeutic targets and could be adapted to archived clinical specimens from other tumors.

Survival outcomes after chemotherapy in invasive lobular carcinoma compared to estrogen receptor positive invasive ductal carcinoma

Jasmine Timbres, Charlotte Moss, Anca Mera, Anna Haire, Cheryl Gillett, Mieke Van Hemelrijck and Elinor Sawyer. King's College London, London, United Kingdom

### **Introduction**

Invasive lobular breast cancer (ILC) accounts for 10-15% of all invasive breast carcinomas and has distinct clinical and biological characteristics compared with the more common invasive ductal carcinoma (IDC). They are generally ER-positive (ER+) with the exception of a small number of pleomorphic cases and there is some evidence that the 10-year survival rate of women with ILC is lower than that for ER+ IDC. Furthermore, studies have shown that ILC may be less sensitive to chemotherapy than IDC, with lower rates of complete pathological response after neoadjuvant chemotherapy, but it is not clear what effects this has on long term survival. The aim of this study was to investigate whether ER+ ILC patients who received chemotherapy (neoadjuvant or adjuvant) had similar outcomes to ER+ IDC patients who received chemotherapy.

### **Methods**

Patients were diagnosed at Guy's & St Thomas' NHS Foundation Trust between 1971 and 2016 and were eligible for inclusion into the study if they were female, had been diagnosed with either IDC or ILC, if their tumours were ER+, and if they received chemotherapy. They were followed up from date of primary diagnosis until 30<sup>th</sup> June 2019 and were assumed to be alive in the absence of a reported death date. Patients with estrogen receptor negative (ER-) tumours were excluded, due to well-known chemosensitivity in these breast cancer subtypes. Data used was requested from the Guy's & St Thomas' Breast Cancer Database.

### **Results**

Of 5526 patients diagnosed with ILC or IDC between 1971 and 2016, 3945 were ER+ with 3436 IDC and 509 ILC. ER+ IDC and ILC had similar survival for the first 10 years after diagnosis after which outcomes began to diverge with worse outcomes in ILC. The 10-year and 15-year survival of 59.3% and 47.5% respectively were seen in IDC, and 58.6% and 44.6% in ILC. 1327 ER+ patients who received chemotherapy were selected for analysis, of which 161 (12.1%) were ILC and 1166 (87.9%) were IDC. 159 (12.0%) of patients received neo-adjuvant chemotherapy, while 1168 (88.0%) received adjuvant chemotherapy. In chemotherapy patients, 10-year survival was 53.1% in ILC and 54.0% in IDC, and by 15 years this was 35.1% and 44.7% respectively. In ER+ chemotherapy patients, there was no evidence of a crude association between histological subtype and survival (HR: 1.19, 95% CI: 0.97, 1.47) using Cox regression. However, the multivariate Cox regression model estimated a significantly worse outcome in ILC compared to IDC (HR: 1.28, 95% CI: 1.02, 1.60), adjusted for chemotherapy (neo-adjuvant or adjuvant), stage (I-IV), grade, HER2 status, time period of diagnosis, and surgery type (mastectomy or excision). When stratified by chemotherapy, this association was only observed in patients that received adjuvant treatment.

### **Conclusion**

This study suggests that ER+ ILC patients who received adjuvant chemotherapy may have a worse outcome than ER+ IDC when adjusted for stage and grade. This is a potentially important finding but needs to be studied in a larger population treated with modern chemotherapy regimens. Other studies have shown that the outcome for ILC is better in the first 5 years after diagnosis compared to ER+ IDC but worsens after 10 years, as it does in this study. Thus, having long follow up is essential in order to be able to detect any differences in survival between ILC and ER+ IDC. Nonetheless, this study has displayed a significant difference in survival between ER+ ILC and ER+ IDC receiving adjuvant chemotherapy, and thus recommendations for adjuvant chemotherapy may need to be considered separately for the two subtypes. Furthermore, it would be beneficial to develop a tool that could help in identifying cases of ILC that would most benefit from chemotherapy.

**Background and Purpose:** Early and accurate assessment of breast cancer response to NAST is important for patient management. In this study, we investigated the value of radiomic phenotypes derived from semi-quantitative and quantitative DCE-MRI parametric maps for early prediction of NAST response in TNBC patients. **MATERIALS AND METHODS:** This IRB approved study included 74 patients with stage I-III TNBC who were enrolled in the prospective ARTEMIS trial (NCT02276443). Pathologic complete response (pCR) and non-pCR were assessed by surgical histopathology after NAST (pCR=34; non-pCR=40). MRI scans were obtained at 3 time points during the NAST treatment with every 2-week anthracycline-based chemotherapy (AC): at baseline (BSL=74), post-2 cycles of AC (C2= 27) and post-4 cycles of AC (C4= 27). Patients went on to receive taxane-based chemotherapy prior to surgery. Tumor regions of interest (ROIs) were segmented by a breast radiologist at the early-phase subtractions of DCE-MRI scans using in-house developed software, followed by co-registration of the ROIs with quantitative ( $K_{trans}$ ,  $V_e$  and  $K_{ep}$ ), and semi-quantitative DCE parametric maps (Maximum Slope Increase (MSI), Positive Enhancement Integral (PEI) and Peak Signal Enhancement Ratio (SER)). A total of 93 first order radiomic features were extracted from the tumor ROIs of each time point semi-quantitative DCE parametric map, while a total of 390 extracted radiomic features (first order-histogram features and second order grey-level-co-occurrence matrix) were extracted from each quantitative DCE parametric map using an in-house developed Matlab software. Radiomic features at each time point and changes between the 3 time points were compared between pCR and non-pCR using Wilcoxon Rank Sum test and Fisher's exact test. Area under the receiver operating characteristics curve (AUC) was used to determine which features predicted pCR. Logistic regression was performed for feature selection, and used to build the radiomic phenotype model. The model performance was assessed by leave-one-out cross validation and 3-fold cross validation.

**RESULTS:** Thirty-three radiomic features from PEI map were significantly different between pCR and non-pCR. The PEI most significant features were changes between BSL and C4 in skewness, mean and median (AUC=0.87, 0.85 and 0.87,  $p<0.001$ , 0.001 and 0.002 respectively). Additionally, 31 MSI features were significantly different between pCR and non-pCR. The top 2 features were the interscan-change in skewness between BSL and C2 (AUC=0.80,  $P=0.007$ ) and C4 standard deviation (AUC=0.80,  $P=0.006$ ). Four BSL  $V_e$  radiomic features were statistically significant between pCR and non-pCR with the best being range of difference variance (AUC=0.64,  $P=0.03$ ). One BSL  $K_{ep}$  feature (Angular-Variance of Information measure of correlation-2) was able to differentiate pCR from non-pCR (AUC=0.64,  $P=0.04$ ). Five C4- $K_{trans}$  features were able to differentiate pCR and non-pCR, with the most significant being mean value (AUC=0.86,  $P=0.001$ ). BSL- $K_{ep}$  radiomic model built from 24 features (AUC=0.80,  $p=0.003$ ) and combined ( $K_{trans}$ ,  $V_e$  and  $K_{ep}$ ) C2-radiomic model consisting of 20 features (AUC=0.97,  $p=0.01$ ) showed the best performance for prediction of pCR.

**CONCLUSIONS:** Radiomic phenotypes from DCE-MRI parametric maps were useful for differentiation between pCR and non-pCR and showed promise as noninvasive imaging biomarkers for early prediction of NAST response in TNBC. Potentially, DCE-MRI radiomic features may be used for development of diagnostic predictive model for early noninvasive assessment of NAST treatment response in TNBC patients.

Lower rates of neuropathy with oral paclitaxel and encaequidar (oPac+E) compared to IV paclitaxel (IVPac) in treatment of metastatic breast cancer (mBC): Study KX-ORAX-001

H S Rugo<sup>1</sup>, G Umanzor<sup>2</sup>, F J Barrios<sup>3</sup>, R H Vasallo<sup>4</sup>, M A Chivalan<sup>5</sup>, S Bejarano<sup>6</sup>, J R Ramirez<sup>7</sup>, L Fein<sup>8</sup>, R D Kowalyszyn<sup>9</sup>, D L Cutler<sup>10</sup>, D Kramer<sup>10</sup>, J Goldfinch<sup>10</sup>, H Wang<sup>10</sup>, T Moore<sup>10</sup> and R MF Kwan<sup>10</sup>. <sup>1</sup>University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA; <sup>2</sup>Liga Contra el Cancer, San Pedro Sula, Honduras; <sup>3</sup>Instituto Nacional de Cancerologia (INCAN), Guatemala City, Guatemala; <sup>4</sup>Clinical Research RD, Santo Domingo, Dominican Republic; <sup>5</sup>CELAN Clinica Medica, Guatemala City, Guatemala; <sup>6</sup>Excel Medica, San Pedro Sula, Honduras; <sup>7</sup>CRESEM, Quetzaltenango, Guatemala; <sup>8</sup>Instituto de Oncologia de Rosario, Rosario, Argentina; <sup>9</sup>Centro de Investigaciones Clinica, Clinica Viedma, Argentina; <sup>10</sup>Athenex Inc., Buffalo, NY

**Background:** Chemotherapy-induced peripheral neuropathy (CIPN) is a common dose-limiting toxicity associated with IVPac. Primarily sensory, CIPN is an often irreversible condition primarily affecting the hands and feet associated with pain, numbness, tingling, and sensitivity to cold and has a significant impact on quality of life and treatment tolerance. Risk of CIPN increases with age, dose intensity, cumulative dose, and preexisting conditions including diabetes.

**Methods:** Study KX-ORAX-001 was a phase III, randomized, international study in women with mBC for whom treatment with IVPac was recommended. Eligible patients were randomized 2:1 to receive oPac+E or IVPac. Patients continued treatment until discontinuation due to progressive disease or toxicity. oPac 205 mg/m<sup>2</sup> was given once daily for 3 days weekly. E 12.9 mg was given 1 hour before each dose of oPac. IVPac 175 mg/m<sup>2</sup> was infused over 3 hours every 3 weeks. The primary endpoint was efficacy defined as tumor response confirmed by BICR at two consecutive evaluations. Key secondary endpoints included PFS, OS. Safety was monitored throughout the study.

**Results:** A total of 402 mBC patients were enrolled, 265 randomized to oPac+E and 137 to IVPac (ITT population). 399 patients were treated and comprise the safety population. The confirmed response rate was significantly greater in the oPac+E group vs IVPac (35% vs 23%) for the ITT population. Median overall survival was (27.7 vs 16.7 months, ITT) at the time of the analysis. Long-term follow up for final determination of PFS and OS is ongoing. Incidence of neuropathy-related TEAEs were lower in patients receiving oPac+E vs IVPac: Overall (21% vs 64%; all grades), grade ≥3 (2% vs 15%). Cumulative risk for neuropathy with IVPac was >50% by week 8 and was 83% at week 88. In contrast, the cumulative risk of neuropathy with oPac+E rose slowly and plateaued at 34% at week 88. Treatment discontinuations due to neuropathy occurred only in the IVPac arm (8%). Dose reductions due to neuropathy were reported in 8% of IVPac treated patients and in 2% of oPac+E treated patients. In agreement with the lower rates of peripheral neuropathy in patients treated with oPac+E, there was lower use of medications used for the treatment of neuropathic symptoms. Use of gabapentin or pregabalin was 12% for patients receiving oPac+E vs 40% for IVPac treated patients.

**Conclusions:** oPac+E was associated with greater efficacy in the treatment of patients with mBC and a lower incidence of neuropathy, slower onset and lesser severity of neuropathic events compared to IVPac 175mg/m<sup>2</sup> administered every three weeks. Fewer patients receiving oPac+E required dose reduction due to neuropathy and no patients receiving oPac+E discontinued treatment due to neuropathy. Reduction in neuropathy may improve quality of life and allow longer administration of effective therapy while maintaining dose intensity.

Role of the calcium-sensing receptor (CaSR) in invasive lobular breast carcinoma metastasis to the ovary

Ye Qin<sup>1</sup>, Laura Savariau<sup>1</sup>, Ahmed Mohammed Basudan<sup>1</sup>, Osama Shah<sup>1</sup>, Zheqi Li<sup>1</sup>, Tiantong Liu<sup>2</sup>, Nilgun Tasdemir<sup>1</sup>, Lan Coffman<sup>1</sup>, Esther Elishaev<sup>3</sup>, Jennifer M Atkinson<sup>1</sup>, Peter Lucas<sup>1</sup>, Adrian V Lee<sup>1</sup> and Steffi Oesterreich<sup>1</sup>. <sup>1</sup>University of Pittsburgh, Pittsburgh, PA; <sup>2</sup>Tsinghua University, Beijing, China; <sup>3</sup>Magee Women's Hospital, Pittsburgh, PA

Invasive lobular carcinoma (ILC) is the second most common histological subtype of breast cancer, after the more common invasive ductal carcinoma (IDC). ILC accounts for 10 to 15% of all invasive breast carcinomas, affecting approx. 26,000-40,000 women in 2020 in the US alone. Despite 95% of ILC being Luminal A conferring patients a favorable prognosis, patients with ILC have poorer long-term outcomes when compared to patients with Luminal A IDC. ILC spread to common sites of ER+ breast cancer metastasis such as the bones, but are also three times more likely to spread to the ovaries, peritoneum, and gastrointestinal tract compared to IDC, and these unique aspects of metastases remain poorly understood. To better understand metastasis to the ovary we performed DNA and RNA sequencing of 11 pairs of primary breast tumor and ovarian metastasis as well as 13 orphan breast cancer ovarian metastases. Our cohort was enriched for lobular histology, with 13 samples originating from ILC, 6 from IDC and 6 from mixed ILC/IDC. We found mutations in *CDH1* (43%), *PIK3CA* (40%), and *FOXA1* (29%) highlighting the enrichment in ILC cases present in our cohort. Gene expression analysis lead to identification of 874 differentially expressed between primary tumors and ovarian metastases. We identified the calcium-sensing receptor CaSR as one of the top upregulated in ovarian metastases compared to primary tumor in 10 out of the 11 paired samples. Other genes highly expressed in ovarian metastases included TAC3, GLRA2, ALLC, MUC19, CHRNA2, PIP, CST4, and TEX15. Pathways analyses showed an enrichment of signaling through glutamate receptor and glycine receptor families. To assess the contribution of CaSR to breast cancer cell proliferation and metastatic properties, and due to the absence of breast cancer cell lines expressing CaSR, we generated CaSR overexpression models using lentiviral infection in MDA-MB-134, MDA-MB-330, BCK4 and SUM44PE ILC cell lines. While overexpression of CaSR alone did not confer a cell growth advantage or migratory ability to the cell lines, stimulation with calcium or a calcium mimetic resulted in enhanced migration in transwell assays in 3 of the 4 cell lines. Scratch assays further confirmed the stimulation of cell migration in cells with CaSR overexpression in the presence of calcium. Cell migration in CaSR overexpression models could be stimulated with the calcimimetic R568, and inhibited by the calcilytics NPS2143, and F-actin staining confirmed the need to activate the receptor to enhance migratory properties. Our studies further revealed that the induced migratory properties of CaSR overexpressing cells required estradiol and ER signaling, and that migration could be blocked with ER inhibitors such as ICI 182,780 and tamoxifen. Western blotting data revealed that the enhanced cell migratory properties of CaSR overexpressing cells was via activation of the MEK/ERK pathway and migration could be inhibited using specific small molecule pathway inhibitors. Altogether, our study provides insight on the potential mechanism by which upregulation of the CaSR supports breast cancer ovarian metastasis. We hope that these studies will not only deepen our understanding of ILC ovarian metastasis but will eventually lead to the development of more effective therapies and improve the outcome of patients with this understudied type of breast cancer.

Racial disparities in pathological complete response among breast cancer patients receiving neoadjuvant chemotherapy

Fangyuan Zhao, Meghan Steiner, Abiola Ibraheem, Gini Fleming, Nora Jaskowiak, Rita Nanda, Olufunmilayo I. Olopade and Dezheng Huo. University of Chicago, Chicago, IL

**Background:** With the increasing use of neoadjuvant chemotherapy in breast cancer patients, it is important to better understand how host factors interact with tumor characteristics to determine response to neoadjuvant chemotherapy. Pathological complete response (pCR) is a strong surrogate for long term survival in certain subtypes of breast cancer. Racial disparities in breast cancer survival have been well documented, but few studies have been conducted to examine the extent of racial disparities in pCR after neoadjuvant chemotherapy. **Method:** We established a cohort of patients with breast cancer treated at an academic medical center in the ethnically diverse City of Chicago — the Chicago Multiethnic Epidemiologic Breast Cancer cohort (ChiMEC). Among patients who received neoadjuvant chemotherapy, we examined whether racial disparity existed in the rate of pCR, defined as ypT0/isypN0. Multivariable logistic regression models were used to estimate the odds ratios (ORs) of black relative to white patients, adjusting for clinical tumor stage and molecular subtype. We also explored whether there were racial difference in treatment characteristics, including days from diagnosis to the first neoadjuvant chemotherapy and dosage of 7 most commonly used drugs (Carboplatin, Cyclophosphamide, Docetaxel, Doxorubicin, Paclitaxel, Trastuzumab and Pertuzumab) using Wilcoxon rank-sum tests. **Results:** The study consisted of 595 stage I-III breast cancer patients who received neoadjuvant chemotherapy (51% Whites and 40% Blacks). Among them, 32.5% of the White patients achieved pCR while only 23.9% of the Black patients achieved pCR (**Table**). After adjusting for tumor subtype and clinical stage, Black patients still had a significantly lower odds of achieving pCR compared to Whites (OR=0.67, 95% CI: 0.44-1.00). The racial difference in pCR rates existed in all four molecular subtypes, though most pronounced in the HR-/HER2+ subgroup (OR=0.35, 95% CI: 0.13-0.97). Further adjusting for time from diagnosis to first chemotherapy reduced the racial difference (OR=0.76, 95% CI: 0.50-1.15), suggesting that some of this racial disparity could be explained by delay in treatment initiation. This hypothesis is also supported by the observation that the largest racial difference in treatment initiation was in the HR-/HER2+ subgroup, with White patients taking an average of 30.9 days to get their first chemotherapy after diagnosis while Black patients taking an average of 45.4 days ( $P = 0.019$ ). In addition, the study found that Black patients received significantly less cycles of Cyclophosphamide and Doxorubicin (i.e., the AC regimen) than White patients ( $P = 0.024$ ). **Conclusion:** Our study showed that Black patients had a lower pCR rate after neoadjuvant chemotherapy, and this racial disparity was largest among HR-/HER2+ patients. Although delayed initiation of treatment may partially contribute to this racial disparity, treatment differences in this single institution study are relatively small so most of racial disparity in response to neoadjuvant therapy could be due to biological difference beyond subtypes. Host and tumor characteristic that modulate response to therapy in diverse populations deserve further exploration to optimize design of innovative clinical trials and reduce disparities in clinical outcomes.

Racial disparity in pCR stratified by subtype and adjusted for tumor and treatment characteristics

	pCR rate		Odds Ratio (95% CI)	Adjusted Odds Ratio (95% CI)*	Adjusted Odds Ratio (95% CI)+
	White	Black	Black vs. White	Black vs. White	Black vs. White
Overall	32.5%	23.9%	0.66 (0.45-0.96)	0.67 (0.44-1.00)	0.76 (0.50-1.15)
Subtype					
HR+/HER2-	17.5%	12.3%	0.66 (0.27-1.63)	0.69 (0.28-1.72)	0.74 (0.30-1.85)
HR+/HER2+	28.6%	22.9%	0.74 (0.31-1.77)	0.77 (0.32-1.86)	0.86 (0.35-2.09)
HR-/HER2+	70.0%	43.3%	0.33 (0.12-0.88)	0.35 (0.13-0.97)	0.44 (0.16-1.23)
TNBC	35.4%	26.3%	0.65 (0.35-1.21)	0.78 (0.42-1.47)	0.88 (0.47-1.68)
* adjusted for subtype, clinical T stage and clinical N stage					
+ adjusted for subtype, clinical T stage, clinical N stage and days from diagnosis to first chemotherapy

Peripheral blood gene signatures predict response to neoadjuvant chemotherapy in breast cancer patients

Margaret L Axelrod<sup>1</sup>, Paula I Gonzalez-Ericsson<sup>1</sup>, Xiaopeng Sun<sup>1</sup>, Riley E Bergman<sup>1</sup>, Joshua Donaldson<sup>1</sup>, Sara M Tolaney<sup>2</sup>, Ian E Krop<sup>2</sup>, Ana C Garrido-Castro<sup>2</sup>, Melinda E. Sanders<sup>1</sup>, Ingrid A Mayer<sup>1</sup> and Justin M Balko<sup>1</sup>. <sup>1</sup>Vanderbilt University, Nashville, TN; <sup>2</sup>Dana Farber Cancer Institute, Boston, MA

**Purpose:** Neoadjuvant chemotherapy (NAC), the standard of care for a subset of breast cancer patients, is known to have immunologic effects. With emerging data showing improved response rates with anti-PD-1/PD-L1 immunotherapy in combination with chemotherapy, the effects of NAC on systemic and local anti-tumor immunity require further study. Biomarkers of anti-tumor immunity are needed to identify which patients are most likely to respond to immunotherapy. Our previous work has shown that changes in the peripheral blood can be observed over the course of NAC for breast cancer. Peripheral blood biomarkers are attractive because of the relative ease of sampling compared to site of disease. Residual cancer burden (RCB) is a useful surrogate marker of long-term prognosis, as patients who experience a pathologic complete response (pCR) have better outcomes than those with residual disease (RD). **Methods:** We previously identified an 8 gene signature of cytotoxicity, derived from single cell RNA sequencing of PD-1<sup>Hi</sup> CD8<sup>+</sup> T cells, which are enriched for tumor-reactive T cells. Using a custom NanoString panel, we tested expression of this gene signature in whole blood collected prior to definitive surgery in 88 breast cancer patients (TNBC, n=21; HER2+, n=17; ER+, n= 54; PR+, n=53) across two cohorts (VUMC, n=58; DFCI, n=30), 64 of whom had received NAC (pCR, n=11; RD, n=53). We further investigated peripheral blood gene expression using RNA sequencing (n=58; 34 post-NAC, 24 untreated). **Results:** In two cohorts of breast cancer patients, expression of the 8 gene signature (*FGFBP2* + *GNLY* + *GZMB* + *GZMH* + *NKG7* + *LAG3* + *PDCD1* - *HLA-G*) was highest in patients with RD who experienced a recurrence within three years compared to those with pCR (p<0.01) or those with the highest RCB (RCB III) compared to those with RCB 0/II who did not have a recurrence with three years (p<0.05). RNA sequencing showed higher expression of interferon alpha, interferon gamma, and complement gene sets in patients experiencing a pCR compared to those with RD by gene set enrichment analysis (FDR-corrected q-values < 0.05). **Conclusions:** Expression of immune-related genes in the peripheral blood may predict response to NAC in breast cancer patients and be a useful biomarker for those who would benefit from additional therapies. These results will be further tested in a large cohort of longitudinal samples from breast cancer patients receiving NAC alone or in combination with pembrolizumab from the I-SPY-2 trial, to determine whether peripheral blood gene signatures can predict response to immunotherapy in breast cancer.

Identification of pathogenic FGFR1, FGFR2, and FGFR3 alterations in cell-free DNA (cfDNA) from patients with metastatic breast cancer

Mary Love Taylor<sup>1</sup>, Benjamin Mayro<sup>1</sup>, Leylah Drusbosky<sup>2</sup>, Robin Batchelder<sup>1</sup>, P. Kelly Marcom<sup>1</sup>, Carey Anders<sup>1</sup> and Jeremy Force<sup>1</sup>. <sup>1</sup>Duke University, Durham, NC; <sup>2</sup>Guardant Health, Redwood City, CA

**Background:** *FGFR* alterations are a known mechanism of resistance against breast cancer systemic therapies with higher *FGFR* RNA expression in breast cancer brain metastases compared to their primary tumors. While the genomic characterization of *FGFR* alterations has occurred from bulk breast tumors, the frequency and type of *FGFR* alterations in metastatic breast cancer (MBC) have not been fully characterized from cfDNA. The purpose of this study was to identify the incidence of *FGFR1*, *FGFR2*, and *FGFR3* genomic alterations in cfDNA from patients with MBC and elucidate which *FGFR* alterations may increase *FGFR* kinase activity or may function as mechanisms of resistance against the FDA approved *FGFR* inhibitor, erdafitinib.

**Methods:** We queried 16,053 reports from Guardant Health between June 2015 - October 2019 to identify the incidence of *FGFR1*, *FGFR2*, and *FGFR3* alterations detected in cfDNA from MBC. We classified each alteration type into the following categories: copy number variation (CNV), fusion, indel, or single nucleotide variant (SNV). Focus was placed on characterizing *FGFR1*, *FGFR2*, and *FGFR3* SNVs. We compared known activating mutations in *EGFR*, *ERBB2*, and *BRAF* with homologous regions in *FGFR1*, *FGFR2*, and *FGFR3*. *In silico* modeling with PyRx was used to dock erdafitinib onto *FGFR1* (PDB 4V05), *FGFR2* (PDB 5B7V), and *FGFR3* (PDB 6LVM) kinases. Three-dimensional *in silico* analyses with ChimeraX was utilized to further determine which alterations may increase *FGFR1*, *FGFR2*, and *FGFR3* kinase activity or may induce resistance against erdafitinib.

**Results:** The incidence of nonsynonymous alterations occurring in *FGFR1*, 2213 (13.8%); *FGFR2*, 1017 (6.3%); and *FGFR3*, 144 (0.9%) were identified in the Guardant Health MBC database. *FGFR1*, *FGFR2*, and *FGFR3* alterations are detailed in **Table 1**. We identified 40 (9.15%) and 167 (38.2%), 55 (7.2%) and 310 (40.4%), and 31 (27.4%) and 32 (28.3%) mutations occurring in the transmembrane/juxtamembrane and kinase domains of *FGFR1*, *FGFR2*, and *FGFR3*, respectively. Hotspot mutations were observed at R54C/S/G/R and N546K/D/S in *FGFR1*, D304N and N549K/D/S in *FGFR2*, and at S408/F/C/L/Y in *FGFR3*. We aligned *FGFR1*, *FGFR2*, and *FGFR3* with homologous kinases and found 12 unique samples with mutations in our *FGFR1* dataset corresponded to known activating mutations in *EGFR* and *ERBB2*; 18 samples with mutations in our *FGFR2* dataset corresponded to known activating mutations in *EGFR*, *ERBB2*, and *BRAF*; and 1 mutation in our *FGFR3* dataset corresponded to a known activating mutation in *ERBB2*. *FGFR1* mutations C488S, V492M, M535I, L569V and *FGFR2* mutations L550V, E565A, Y566N, S568C, G570R, G685E are postulated to induce resistance against erdafitinib.

**Conclusions:** We found that 21% of MBC in this dataset harbor *FGFR* genomic alterations detected from cfDNA. Novel somatic alterations in *FGFR1*, *FGFR2*, and *FGFR3* were identified from Guardant Health that were not detected in the public domain. A portion of *FGFR* SNVs occurred at known homologous kinase activating mutations in *EGFR*, *ERBB2*, and *BRAF* suggesting these specific *FGFR* mutations may increase *FGFR* kinase activity and might be actionable therapeutic targets in breast cancers harboring these mutations. Three dimensional analyses of the *FGFR* protein tyrosine kinase further illustrate which specific alterations may increase *FGFR* kinase activity or induce resistance against erdafitinib.

Gene	CNV (%)	Fusion (%)	Indel (%)	SNV (%)
FGFR1	1770 (80%)	-	6 (0.3%)	437 (19.7%)
FGFR2	224 (22%)	15 (1.5%)	11 (1.1%)	767 (75.4%)
FGFR3	-	24 (16.7%)	7 (4.9%)	113 (78.4%)

**Table 1.** Incidence and type of *FGFR* alterations in Guardant Health MBC database

Efficacy and safety of larotrectinib in patients with TRK fusion breast cancer

Ezra Y. Rosen<sup>1</sup>, Antoine Italiano<sup>2</sup>, Dejan Juric<sup>3</sup>, John A. Reeves<sup>4</sup>, Laura Dima<sup>5</sup>, Nicoletta Brega<sup>4</sup> and Alexander Drilon<sup>6</sup>. <sup>1</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>2</sup>Early Phase Trials Unit, Institut Bergonie, Bordeaux, France; <sup>3</sup>Massachusetts General Hospital Cancer Center, Boston, MA; <sup>4</sup>Bayer HealthCare Pharmaceuticals, Whippany, NJ; <sup>5</sup>Bayer Consumer Care AG, Basel, Switzerland; <sup>6</sup>Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY

**Introduction:** Larotrectinib is a first-in-class, CNS-active, highly selective tropomyosin receptor kinase (TRK) inhibitor approved by the US Food and Drug Administration and European Medicines Agency for the treatment of adult and pediatric patients with tumor agnostic indication for TRK fusion-positive cancer. Larotrectinib produced an objective response rate (ORR) of 79% in 159 patients with TRK fusion-positive cancer across various tumor types (Hong DS et al. *Lancet Oncol.* 2020). Here we report the efficacy and safety of larotrectinib in the six patients from the NAVIGATE phase II study (NCT02576431) with TRK fusion-positive breast cancer. **Methods:** Data were obtained for patients with breast cancer harboring a neurotrophic tyrosine receptor kinase (*NTRK*) gene fusion and treated with larotrectinib in the NAVIGATE study. All patients received 100 mg twice daily on a continuous 28-day schedule. Responses were investigator-assessed per RECIST v1.1 (data cut-off: July 15, 2019). **Results:** A total of 6 patients with TRK fusion breast cancer were included: 3 with secretory carcinomas, 2 with triple-negative breast cancer (TNBC), and 1 with ER+/HER2- disease. The median age was 49 years (range 32-65). One of the patients with secretory breast cancer was male. All of the secretory cases and 1 TNBC patient harbored an *ETV6-NTRK3* fusion, 1 TNBC patient had an *LMNA-NTRK1* fusion, and the ER+/HER2- patient had a *TPM3-NTRK1* fusion. Four patients had received ≥3 prior systemic therapies. The majority of patients had metastatic disease (n=5); 1 patient had locally advanced disease. The ORR was 83% (95% confidence interval [CI] 36-100) with 5 partial responses, while the ER+/HER2- patient had progressive disease. One of the TNBC patients had brain metastasis with complete resolution of CNS disease while on therapy. The median time to response was 1.7 months (range 0.9-1.9) and the duration of treatment ranged from 0.9 to 12+ months, with 4 patients (3 secretory and 1 TNBC) continuing on therapy at time of data cut. Median duration of response was not reached (95% CI 8.2-NE). Median progression-free survival was 9.1 months (95% CI 1.0-NE). Median overall survival was not reached at a median follow-up of 7.4 months. Four of the 6 patients had worst-grade adverse events (AEs) Grade 1-2; the most common Grade 1-2 AEs were dizziness and nausea. One patient had Grade 3 hepatocellular injury and Grade 4 hepatitis that were related to larotrectinib. There were no discontinuations due to AEs. **Conclusion:** Larotrectinib demonstrated an ORR in breast cancer patients similar to the ORR reported for larotrectinib across all tumor types, which supports the routine testing for *NTRK* gene fusions in patients with breast cancer regardless of histology.

Fluoroestradiol F18 positron emission tomography diagnostic performance to characterize estrogen receptor status in breast cancer

Peter Webner<sup>1</sup>, Brenda F. Kurland<sup>2</sup>, Jay R. Wiggins<sup>3</sup>, Amandine Coche<sup>1</sup>, Charlotte Fontan<sup>1</sup>, Yann Bouvet<sup>1</sup>, Chaitanya Divgi<sup>4</sup> and Hannah M. Linden<sup>5</sup>.  
<sup>1</sup>Zionexa US Corporation, Fishers, IN; <sup>2</sup>University of Pittsburgh, Pittsburgh, PA; <sup>3</sup>Merlin Biomedical Consulting LLC, Hendersonville, NC; <sup>4</sup>Divgi Consulting LLC, Meadowbrook, PA; <sup>5</sup>University of Washington, Seattle, WA

**Background**

Estrogen receptor (ER) status by immunohistochemistry (IHC) of breast cancer tissue is currently used to direct endocrine therapy. Fluoroestradiol F18 (18F-FES) is a noninvasive method to determine the presence and ligand-binding function of the ER in metastatic breast cancer lesions throughout the body. Concordance of imaging and tissue assays should be established for 18F-FES PET to be an alternative or complement to tissue biopsy for metastatic lesions.

**Objective**

We conducted a meta-analysis of published results comparing 18F-FES PET and tissue assays of ER status in patients with breast cancer.

**Method**

PubMed and EMBASE were searched for English-language manuscripts with at least 10 patients and low overall risk of bias. We used hierarchical summary receiver-operating characteristic (HSROC) curve models for four analyses.

-For the first three analyses, IHC was used as the standard for tissue reference assay: i) 18F-FES PET performance for nonbreast lesions in patients with metastatic breast cancer; ii) 18F-FES PET performance for breast tumors; iii) 18F-FES PET performance for all lesions (combined analysis);  
 -The last analysis assesses 18F-FES PET performance with all evaluable studies, which used a variety of standards for the tissue reference.

**Results**

PubMed and EMBASE searches identified 103 breast cancer studies involving 18F-FES PET, and 12 studies met the criteria for inclusion in our meta-analysis. Results are presented in Table 1.

	Number of studies	Pooled number of ER-positive lesions	Sensitivity (95% confidence region)	Pooled number of ER-negative lesions	Specificity (95% confidence region)
Nonbreast lesions, IHC	4	69	0.78 (0.65-0.88)	44	0.98 (0.65-1)
Breast lesions, IHC	3	60	0.86 (0.73-0.94)	18	0.76 (0.52-0.90)
Combined, IHC	7	143	0.83 (0.72-.90)	64	0.83 (0.64-0.93)
Combined, all reference standards	11	211	0.81 (0.73-0.87)	116	0.86 (0.68-0.94)

Table 1: <sup>18</sup>F-FES PET test accuracy results

Tests of homogeneity did not find differences in sensitivity or specificity among the studies in the primary analysis or other analyses with IHC as the tissue reference standard.

Examining all tumor sites and all breast cancer stages, our results are consistent with other published meta-analyses (Table 2).

Study	Van Kruchten 2013 <sup>1</sup>	Evangelista 2016 <sup>2</sup>	Chae 2019 <sup>3</sup>	Combined, IHC
Sensitivity (95% Confidence Region)	0.84 (0.73-0.91)	0.82 (0.74-0.88)	0.83 (0.72-0.91)	0.83 (0.72, 0.90)
Specificity (95% Confidence Region)	0.98 (0.90-1.00)	0.95 (0.86-0.99)	0.93 (0.74-0.99)	0.83 (0.64-0.93)

Table 2: Comparison with other published meta-analyses

**Conclusion**

A strong correlation has been demonstrated between ER status determined by IHC of tissue from a single lesion and 18F-FES PET in this meta-analysis, which validates the accuracy of 18F-FES PET assessment of metastatic ER status. These results suggest that 18F-FES PET is useful for characterization of ER status of metastatic breast cancer lesions. Moreover, 18F-FES has been approved by the FDA in May 2020 as an adjunct to biopsy in recurrent and metastatic breast cancer.

**Background:** Addition of CDK 4/6 inhibitors to endocrine therapy has provided significant improvements in outcomes for patients (pts) with metastatic breast cancer (mBC). However, acquired resistance to front-line therapy remains a challenge, and response to late lines of therapy is poor. H3B-6545 is a selective, orally available, small molecule covalent antagonist of the estrogen receptor (ER $\alpha$ ). H3B-6545 binds covalently to a cysteine residue at position 530 of both wild-type and the constitutively active mutant ER $\alpha$  proteins, including Y537S. H3B-6545 demonstrated significant antitumor activity in multiple PDX breast cancer models, including those with mutated *ESR1* (the gene encoding ER $\alpha$ ). **Methods:** This is a multicenter phase I/II trial. The primary objective of the phase I is to determine the maximum tolerated dose and recommended phase 2 dose (RP2D) in pretreated pts with ER+, HER2- mBC. Secondary objectives include safety and antitumor activity. The primary objective of the phase II is to estimate the objective response rate (ORR) and secondary objectives include clinical benefit rate (CBR), progression-free survival (PFS) and safety. The trial was designed to exclude a lower limit of ORR of 5% at one-sided level of significance of 0.05 and a power of 90%.

**Results:** Between August 2017 and February 2020, 130 pts were enrolled; 47 in the Phase I part and 83 in the Phase II part of the trial. A total of 105 pts, including 73 patients on 450 mg, were response-evaluable. The phase I evaluated once daily doses from 100 to 600 mg. No dose-limiting toxicities (DLT) were observed at doses up to 450 mg and 2 DLTs were observed in 2 (grade 3 fatigue and grade 3 drug eruption) of 7 pts on the 600 mg cohort. Consequently, the dose of 450 mg was selected as the RP2D. Median age was 62 years (range: 31 to 87 years), 82% had liver and/or lung metastases, and the median number of prior therapies for metastatic disease was 3 (range: 1 to 10), with 41% of the pts receiving  $\geq 4$  prior therapies in the metastatic setting. Prior CDK4/6 inhibitors, fulvestrant, and chemotherapy were received by 87%, 71%, and 54% of the pts, respectively. 75 pts (58%) had detectable *ESR1* mutations. As of May 31, 2020, grade 2 or higher adverse events reported in  $\geq 10\%$  were anemia (20%), fatigue (16%), nausea (14%), diarrhea (11%) and AST increase (11%). Three cases of grade 4 AE were reported (serum bilirubin, urinary tract obstruction, and hyponatremia), all considered related to disease progression. Grade 1 sinus bradycardia (asymptomatic) was reported in 35% and grade 2 (symptomatic, no intervention needed) was reported in 4%. Grade 2 and 3. QTcF prolongation were reported in 2 and 3 patients, respectively. There were no treatment-related deaths. In the response-evaluable group, 13 confirmed partial responses (PR, 12%. 90% confidence limits: 7.5%-19%), including 11 PRs (15%, 90% confidence limits: 8.7%-23.7) on 450 mg dose, were observed, thus achieving the primary objective of the trial. Stable disease (SD) and clinical benefit rates ( $\geq 23$  weeks) were 45% and 33% respectively at 450 mg and 46% and 34%, respectively on all doses. Responses were observed in heavily pretreated pts, pts with visceral metastases and in pts who received prior fulvestrant, prior CDK4/6 inhibitor, and/or prior chemotherapy, in the metastatic setting. Three PRs (25%) and 4 SDs were observed in 12 pts in whom clonal *ESR1* Y537S was the main ER $\alpha$  driver. Median PFS, in all pts and in pts with clonal *ESR1* Y537S was 3.7 months and 7.3 months, respectively. **Conclusions:** H3B-6545 has a manageable safety profile and demonstrated single-agent anti-tumor activity in heavily pretreated ER+, HER2- mBC patients including those with a constitutively active clonal *ESR1* Y537S mutation.

Publication Number: PD7-06

Unstable mutational profile and heterogeneity of residual breast tumor following neoadjuvant therapy from comprehensive genomic and transcriptomic sequencing

Minoru Miyashita<sup>1</sup>, Masaya Hattori<sup>1</sup>, Yonglan Zheng<sup>1</sup>, Toshio Yoshimatsu<sup>1</sup>, Joshua SK Bell<sup>2</sup>, Padma Sheila Rajagopal<sup>1</sup>, Anna Woodard<sup>1</sup>, Jean Baptiste Reynier<sup>1</sup>, Elisabeth Sveen<sup>1</sup>, Galina Khramtsova<sup>1</sup>, Fang Liu<sup>1</sup>, Abiola Ibraheem<sup>1</sup>, Gini Fleming<sup>1</sup>, Nora Jaskowiak<sup>1</sup>, Rita Nanda<sup>1</sup>, Benjamin Leibowitz<sup>2</sup>, Nike Beauvier<sup>2</sup>, Kevin White<sup>2</sup>, Dezheng Huo<sup>1</sup> and Olufunmilayo I Olopade<sup>1</sup>. <sup>1</sup>The University of Chicago, Chicago, IL; <sup>2</sup>Tempus Inc, Chicago, IL

**Background:** In patients with early breast cancer, neoadjuvant therapy is widely performed as standard of care. While the molecular targeting strategy makes progress in HER2 positive breast cancer, the optimal regimens for ER+/HER2- breast cancer (BC) and triple negative breast cancer (TNBC) remain undecided. Furthermore, there are few strategies for patients who do not achieve complete pathological response (pCR) who have worse prognosis. To address these unmet clinical needs, there is urgent need to examine the genomic alterations and immune microenvironment of residual tumors after neoadjuvant therapy. Here, we conducted a comprehensive analysis integrating genomic, transcriptomic, and clinical data to investigate the difference between primary breast cancer and residual disease. **Materials and Methods:** Using the large prospectively ascertained ethnically diverse Chicago Multi-Ethnic (ChiMEC) cohort of 562 participants with integrated genomic data, we identified 176 patients with breast cancer who underwent sequencing with Tempus xT next-generation sequencing panel including DNA- and whole-transcriptome RNA-sequencing. These included 131 primary breast tumors and 45 residual tumors after neoadjuvant therapy. We compared mutation rates between primary tumor and residual tumor in ER+/HER2- BC and TNBC. We also investigated homologous recombination deficiency (HRD) scores, tumor mutational burden (TMB), degree of immune infiltration, and microsatellite instability (MSI), and their association with survival. **Results:** Out of the 176 patients, there were 72 ER+/HER2- BC, 42 TNBC, and 44 HER2 positive cases. Among patients with HR+/HER2- BC, residual tumors had higher mutation rates in *PIK3CA* (61% vs 33%), *CDH1* (33% vs 17%), *CCND1* (39% vs 7%), *FGF3* (28% vs 0%), *FGF4* (33% vs 2%), *FGF19* (33% vs 2%), and *GATA3* (44% vs 7%) than primary tumors, but lower rates in *TP53* (28% vs 48%), *MAP3K1* (6% vs 40%), *KMT2D* (0% vs 33%), *MCL1* (0% vs 30%), *SPEN* (6% vs 20%), *ZFHX3* (0% vs 20%), *ARID1A* (11% vs 16%), *KMT2C* (0% vs 19%), *LZTR1* (0% vs 19%), *BCORL1* (6% vs 17%), *NOTCH3* (6% vs 17%), *FAT1* (0% vs 17%) and *LPR1B* (0% vs 17%). Relative to primary TNBC tumors, residual TNBC tumors exhibited higher mutation rates in *PTEN* (10% vs 3%), *CCNE1* (10% vs 3%), *CIC* (10% vs 0%), and *KMT2D* (10% vs 3%). Conversely, residual TNBC tumors had relatively lower rates of *MCL1* (0% vs 21%), *RB1* (0% vs 12%), *CDH1* (0% vs 12%), *KMT2C* (11% vs 18%), and *PIK3CA* (0% vs 15%), *CDKN1B* (0% vs 12%) and *ETV6* (0% vs 12%). There was a significant trend of higher TMB (>5.0 mutations/megabase, m/MB) associated with improved disease-free survival among the 176 patients ( $P=0.031$ ). TMB was not significantly different between primary tumors and residual tumors, or across subtypes. Microsatellite instability (MSI) status was high in 3 patients (1.6%) and equivocal in 5 patients (2.7%). TMB in MSI-high or MSI-equivocal tumors was significantly higher than TMB in tumors with microsatellite stability (37.7m/MB vs 5.3m/MB,  $P<0.001$ ). HRD scores were highest in TNBC, and lowest in ER+/HER2- breast cancers ( $P=0.022$ ). There was no significant association between the HRD scores and survival. To date, tumors from 106 patients have undergone immune profiling, with estimation of immune cell infiltration, macrophages, B cells, CD4, CD8, and NK cells. Initial analysis showed no association between immune profiling and survival. **Conclusion:** These comprehensive analyses demonstrated that mutation status in HR+/HER2- breast cancers and TNBC differs between primary and residual tumors after neoadjuvant therapy. We identified genomic alterations and pathways in residual tumors that could be further explored as potential targets in the adjuvant setting to improve long term outcomes for patients who do not achieve pCR.

Incidence and management of central nervous system metastases in patients with inflammatory breast cancer

Laura Warren, Samuel M Niman, Marie Claire Remolano, Jean Landry, Faina Nakhlis, Jennifer R Bellon, Meredith M Regan and Beth A Overmoyer.  
Dana-Farber Cancer Institute, Boston, MA

**Background:** Patients (pts) with inflammatory breast cancer (IBC) have a high risk of central nervous system (CNS) metastasis (mets) with their associated impact on longevity and quality of life. Given evolving CNS-directed treatments, including focal radiation (RT), we compared the proportion of pts diagnosed with asymptomatic CNS mets before and after 2012 as data from Phase III trials in the preceding years (yr) increasingly supported the use of stereotactic radiosurgery (SRS). Specific attention was paid to pts treated with tri-modality therapy (TMT), defined as preoperative systemic therapy, surgery, and RT to determine whether screening for asymptomatic CNS mets would be beneficial. **Methods:** We retrospectively reviewed the records of pts diagnosed with IBC 1997-2019 and enrolled in an IRB-approved registry at a dedicated IBC center. CNS met-free survival time was defined as the time from IBC diagnosis to date of CNS mets. Alive CNS met-free pts were censored at their latest survival date and death was treated as a competing risk. Cumulative CNS mets incidence was computed. Analyses were stratified based on stage at diagnosis (III vs. de novo IV) and receipt of TMT. For pts completing TMT, the completion date was the starting point for cumulative incidence calculations. Overall survival (OS) was estimated as the time from CNS mets diagnosis to death, with censoring for pts who were still alive. **Results:** A total of 531 pts were identified; 372 (70%) with stage III; 159 (30%) with de novo Stage IV disease. The median follow-up for pts presenting with stage III and stage IV disease at diagnosis was 5.6 yr and 1.8 yr, respectively. 124 pts had CNS mets; 5 of them at diagnosis. CNS was the first site of mets or progression in 50 pts (9.4%). The cumulative incidence of CNS mets stratified by stage at diagnosis and receipt of TMT is seen in Table 1. Among the 50 de novo Stage IV pts who completed TMT, 4 developed CNS mets prior to surgery. The median overall survival (mOS) after CNS mets was 0.6 yr (IQR: 0.2 - 1.4). Results stratified by tumor subtype were: HER2+ disease (n=51) 1.4 yr (IQR: 0.6 - 3.7); hormone receptor+/HER2- (n=27) 0.6 yr (IQR: 0.2 - 1.2); triple negative (n=40) 0.2 yr (IQR: 0.1 - 0.5). Most pts with CNS mets (87/124, 70%) had neurologic symptoms prompting imaging. There was no difference in the proportion of asymptomatic pts diagnosed with CNS mets prior to or after 2012. Management of CNS mets was as follows: 47 pts (38%) received whole brain RT (WBRT) alone, 22 (18%) SRS alone, 15 WBRT + SRS (12%), 6 resection + WBRT (5%), and 5 resection + SRS (4%). The remaining pts received several of these modalities with or without intrathecal chemotherapy (13, 11%) or CNS treatment was not documented (16, 13%). A total of 258/531 pts have died (49%). Of these pts, 103 (40%) had CNS mets. 67/103 (65%) died due to CNS mets. **Conclusions:** Among pts with IBC completing TMT, the incidence of CNS mets is as high as 20% both in de novo Stage IV pts at 1 yr and in Stage III pts within 5 yrs, supporting routine surveillance brain MRI among pt with Stage IV disease. The majority of pts continue to receive WBRT with its resultant toxicities. Efforts should be made to identify CNS mets early to facilitate more focal therapy. Future research on systemic therapy with CNS penetrance for IBC patients should be pursued. These data support an ongoing prospective study of screening brain MRI in pts with Stage III IBC to quantify the incidence of CNS mets, utilization of WBRT and impact on neurologic quality of life (NCT04030507).

Cumulative Incidence of CNS Mets

	No.	1 year (95% CI)	2 year (95% CI)	3 year (95% CI)
Stage III (All)	372	5% (3-7)	9% (6-12)	18% (14-23)
Stage IV (All)	154	17% (12-24)	30% (22-37)	42% (32-51)
Stage III (TMT)	304	5% (3-8)	11% (8-16)	19% (14-24)
Stage IV (TMT)	46	21% (10-34)	28% (16-43)	35% (20-50)

## Background

Trilaciclib is an intravenous (IV) cyclin-dependent kinase 4/6 (CDK4/6) inhibitor. Preliminary data showed that adding trilaciclib prior to gemcitabine plus carboplatin (GCB) significantly increased overall survival (OS) compared with GCB alone among patients with metastatic triple-negative breast cancer (mTNBC) (Tan et al., *Lancet Oncol.* 2019;20:1587-1601). Here, final antitumor efficacy results (objective response rate [ORR], progression-free survival [PFS], and OS) are reported for the whole study population, and in cohorts according to CDK4/6 dependence and level of programmed death ligand-1 (PD-L1) expression.

## Methods

This was a randomized, open-label, phase 2 study of patients with mTNBC who had received  $\leq 2$  previous lines of chemotherapy in the recurrent/metastatic setting (NCT02978716). Patients were randomized (1:1:1) to receive GCB on days 1 and 8 (group 1, n=34), trilaciclib prior to GCB on days 1 and 8 (group 2, n=33), or trilaciclib alone on days 1 and 8 and prior to GCB on days 2 and 9 (group 3, n=35), in 21-day cycles. PFS and OS (prespecified secondary endpoints) were assessed in the intention-to-treat (ITT) population, and ORR in response-evaluable patients. Patient tumors were characterized as CDK4/6 independent (basal-like) or indeterminate (HER2-enriched, normal-like, luminal A/B) according to the established PAM50 signature, or CDK4/6 dependent (luminal androgen receptor) or indeterminate (basal-like 1/2, mesenchymal) according to the established Lehmann signature. PD-L1 expression was scored as negative or positive if  $<1\%$  or  $\geq 1\%$  of the total tumor area contained PD-L1-labelled immune cells, respectively, using the Ventana SP142 assay. Association of CDK4/6 dependence and PD-L1 expression with antitumor efficacy was assessed using proportional hazards regression.

## Results

Median follow-up was 8.4 months (range: 0.1-25.7) for group 1, 14.0 months (1.3-33.6) for group 2, and 15.3 months (3.5-33.7) for group 3. The ORR among response-evaluable patients was 7/24 (29.2%) in group 1, 15/30 (50.0%) in group 2, and 12/31 (38.7%) in group 3. Median PFS (95% confidence interval [CI]) in the ITT population was 5.7 (3.3, 9.9) months in group 1, 9.4 (6.1, 11.9) months in group 2, and 7.3 (6.2, 13.9) months in group 3, with hazard ratios (HRs) of 0.62 ( $P = 0.2099$ ) and 0.63 ( $P = 0.1816$ ), for groups 2 and 3 versus group 1, respectively. Overall, 73.5%, 39.4%, and 57.1% of patients in groups 1, 2, and 3 had died. Median OS (95% CI) was 12.6 (6.3, 15.6) months in group 1, not reached (NR) (10.2, NR) in group 2 (HR = 0.31,  $P = 0.0016$ ), and 17.8 (12.9, 32.7) months in group 3 (HR = 0.40,  $P = 0.0004$ ). For groups 2 and 3 combined, median OS was 19.8 (14.0, NR) months (HR = 0.37,  $P < 0.0001$  vs group 1). ORR, PFS, and OS were comparable in tumors categorized as CDK4/6 dependent, independent, or indeterminate. Antitumor efficacy by PD-L1 status is provided in the **Table**.

	Group 1		Group 2		Group 3	
	PD-L1 +ve	PD-L1 -ve	PD-L1 +ve	PD-L1 -ve	PD-L1 +ve	PD-L1 -ve
Patients, n	17	10	16	10	16	16
ORR, n (%)	4 (23.5)	3 (30.0)	8 (50.0)	4 (40.0)	7 (43.8)	4 (25.0)
Median PFS, months (95% CI)	3.5 (2.2, NR)	9.5 (5.2, NR)	7.9 (4.3, NR)	11.9 (8.8, NR)	9.0 (6.2, NR)	6.9 (6.4, NR)
P value (Wald Test)	-	-	0.347	0.604	0.069	0.766

Median OS, months (95% CI)	10.5 (6.3, 18.8)	13.9 (12.6, NR)	20.1 (10.2, NR)	NR (9.4, NR)	32.7 (15.3, NR)	17.8 (12.9, NR)
P value (Wald Test)	-	-	0.028	0.083	0.02	0.239
HR (95% CI)	-	-	0.35 (0.1, 0.9)	0.34 (0.1, 1.2)	0.33 (0.1, 0.8)	0.57 (0.2, 1.5)
HR and P values are for comparisons between group 2 versus group 1, and group 3 versus group 1. +ve, positive; -ve, negative; CI, confidence interval; HR, hazard ratio; NR, not reached; ORR, objective response rate; OS, overall survival; PD-L1, programmed death ligand-1; PFS, progression-free survival.						

## Conclusions

Mature data from this study confirm that administering trilaciclib prior to GCB enhances antitumor efficacy compared with GCB alone, with statistically significant improvements in OS. Subgroup analyses suggest that adding trilaciclib prior to GCB benefits patients regardless of CDK4/6 dependence status and PD-L1 expression. Additional immune subtyping analyses are ongoing and will be presented.

Plasma exosomal miRNAs: A minimally invasive diagnostic biomarker for inflammatory breast carcinoma

Sarah Hamdy Ahmed<sup>1</sup>, Ahmed El-Damen<sup>2</sup>, Mohamed A. Badawy<sup>3</sup>, Mohamed El-Shinawi<sup>4</sup>, Martin Gotte<sup>5</sup> and Sherif Abdelaziz Ibrahim<sup>2</sup>.<sup>1</sup>Biotechnology/ Biomolecular Chemistry Program, Chemistry Department, Faculty of Science, Cairo University, Giza, Egypt<sup>2</sup>Zoology Department, Faculty of Science, Cairo University, Giza, Egypt<sup>3</sup>Chemistry Department, Faculty of Science, Cairo University, Giza, Egypt<sup>4</sup>General Surgery Department, Faculty of Medicine, Ain Shams University, Cairo, Egypt<sup>5</sup>Department of Gynecology and Obstetrics, Munster University Hospital, Munster, Germany

**Background.** Inflammatory Breast Cancer (IBC) is a rare, but aggressive subtype of breast carcinoma with dermal lymphatic invasion in young females. IBC is poorly diagnosed as it develops vast rapidly relative to other non-IBC and without distinct lumps formation, moreover, it is usually misdiagnosed with mastitis. Nanosized exosomes (20-200nm) circulating in liquid biopsies are a promising minimally invasive diagnostic alternative to standard biopsies. In cancer microenvironment, they modulate cancer progression via shuttling their encapsulated microRNAs (miRNAs) into recipient cells to either trigger signaling or induce malignant transformation of targeted cells. While small non-coding regulatory miRNAs are an already known cancer biomarkers, exosomal miRNAs serve as a novel class of diagnostic biomarkers. The present study aims to evaluate the expression levels of exosomal miRNAs relevant to IBC pathogenesis. **Design/Materials/Methods.** This is a prospective case-control study that includes 77 females; 57 were diagnosed with breast cancer (34 non-IBC and 23 IBC), while 20 were healthy volunteers. All have signed an informed consent to be enrolled in this investigation. Patients included were neither pregnant nor issued with bloodborne or autoimmune disease, while healthy subjects had no oncologic history. Plasma circulating exosomes were isolated using precipitation and ultracentrifugation methods. The successful isolation was verified by dynamic light scattering (DLS), transmission electron microscopy (TEM), Western blot (WB), and Dot blot (DB). The expression level of exosomes-derived miR-181b-5p, miR-222-5p and let-7a was quantified by qPCR. Afterwards, that expression level was verified in the human non-IBC MDA-MB-231 and IBC SUM149 cell lines. **Statistics.** Difference between groups was tested using Student's t-test through IBM SPSS statistics software package, version 24. A  $p < 0.05$  was considered significant. **Results.** DLS and TEM analysis revealed that nanovesicles with 146.65 nm were successfully isolated. Moreover, CD63, HSP70, Alix90 and GM130 antibodies used in DB and WB have further confirmed the successful isolation. Relative to non-IBC, our qPCR showed that plasma exosomes-derived miR-181b-5p and miR-222-5p were significantly ( $p < 0.0001$  and  $p < 0.01$ , respectively) upregulated in IBC, whereas exosomal let-7a was significantly ( $p < 0.0001$ ) downregulated in IBC. Further, the expression levels of miR181-5p and miR-222 were upregulated in SUM-149-derived exosomes relative to those of MDA-MB-231-derived exosomes (Both  $p < 0.001$ ), while the expression levels of let-7a did not significantly change. Diagnostic accuracy of the candidate plasma exosomal miRNAs was assessed via receiver operating characteristic (ROC) curves analysis. Interestingly, Area Under Curve (AUC) was 0.826 for miR-181-5p ( $p < 0.0001$ ), 0.7212 for miR-222-5p ( $p < 0.0001$ ), and 0.9188 for let7a ( $p < 0.01$ ). Additionally, bioinformatical analysis for predicted targets of the identified exosomal miRNAs will be assessed. **Conclusion.** Exosomes derived miR-181-5p, miR-222-5p and let7-7a may act as non-invasive diagnostic biomarkers to discriminate IBC from non-IBC patients.

Predicting breast cancer risk for women veterans

Shiuh-Wen Luoh<sup>1</sup>, Cynthia Brandt<sup>2</sup>, Sally Haskell<sup>2</sup>, Lina Gao<sup>1</sup>, Byung Park<sup>1</sup>, Paul Spellman<sup>1</sup>, Saiju Pyarajan<sup>3</sup>, Million Veteran Program, Nallakkandi Rajeevan<sup>2</sup> and Jessica Minnier<sup>1</sup>. <sup>1</sup>VA Portland Health Care System, Portland, OR; <sup>2</sup>VA Connecticut Health Care System, West Haven, CT; <sup>3</sup>VA Boston Health Care System, Boston, MA

**Background** Accurate breast cancer risk assessment allows personalized approach in breast cancer screening and/or prevention. Breast cancer risk prediction models have been developed. Independent prospective validation however was needed before broad clinical applications. The Department of Veterans Affairs (VA) Million Veteran Program (MVP) is one of the largest biobanks in the world. Important attributes include: large sample size (>830,000, April 20), national coverage, multi-ethnic representation, access to bio-specimens from which multi-omics measurements have been conducted, thousands of biomedical phenotypes derived from our baseline and life style surveys and electronic health records (EHR). About 9% of MVP registrants are women. Breast cancer risk prediction models were evaluated in a prospective cohort of women in MVP.

**Methodology** More than 350,000 MVP participants completed genotyping to date. Breast cancer diagnoses were captured from the EHR. Ethnicity was determined by a supervised learning algorithm, Harmonized Ancestry and Race/Ethnicity (HARE), that used genetically inferred ancestry to refine self-identified race/ethnicity. Clinical breast cancer risk prediction instruments were based on personal health, lifestyle, demographics, family history, and environmental exposure. Polygenic Risk Score used in this study is comprised of 313 single nucleotide polymorphisms (PRS313). Clinical risk models tested were: BPC3, Lit and Breast Cancer Risk Assessment Tool (BCRAT, a version of the Gail's model). The BPC3 and Lit models were tested by deploying the iCARE (Individualized Cancer Absolute Risk Estimator) with or without incorporation of PRS313. The BCRAT was deployed in the R package "BCRA" (Breast Cancer Risk Assessment v. 2.1 by F. Zhang). The performance of the risk prediction models was assessed by Area under the Receiver Operating Characteristic Curve (AUC-ROC). The observed absolute risk over expected absolute risk was compared for each decile.

**Results** 351,333 genetic females were identified without a prior breast cancer diagnosis. By HARE definition, 10,717 were African Americans (AA), 317 non-Hispanic Asians (ASIAN), 19,941 non-Hispanic whites (EU), 1,803 Hispanic (HIS) and 13,555 unassigned. The median age of this cohort at MVP entry was 55. 369 subjects developed incident breast cancers with a median follow up of 4 years. These new cases were identified from Cancer Registry (292 cases) and EHR search for compatible ICD plus CPT codes (77 cases). The breast cancer incidence rate was 2.6/1000/year. iCARE-lit model was tested in 2,731 AA women (38 incident breast cancers), 9,027 EU women (111 incident breast cancers), and 10,254 non-AA women (122 incident breast cancers) that had comprehensive risk factor evaluation (<4 missing). The AUC with the iCARE-lit model alone is 0.569 for AA, 0.563 for EU, and 0.565 for non-AA. Incorporation of PRS313 into the iCARE-lit model improved the AUC to 0.573 for AA, 0.645 for EU and 0.638 for non-AA. Additionally, iCARE-lit plus PRS313 estimated that 15% (AA), 7.3% (EU) and 7.7% (non-AA) of the women would have a lifetime risk of >20%. The iCARE-BPC3 had similar performance as iCARE-lit. The AUC of BCRAT alone was 0.648 for EU (20,550 with 179 incident breast cancers) and 0.661 for AA (10,462 with 96 incident breast cancers). Incorporation of PRS313 to BCRAT improved the AUC to 0.682 (EU) and 0.658 (AA). BCRAT plus PRS313 estimated that 5.6% (AA) and 4.4% (EU) of the women would have a lifetime risk of >20%.

**Discussion** We prospectively evaluated and validated the performance of breast cancer risk prediction models as reported from case control studies. Longer follow up of more women in MVP will provide better assessment esp. for AA women. Prospective validation of these risk prediction models provides strong rationale for further development of these models in the clinical setting.

Association between pathological response and tumor genomic profiling in triple negative breast cancer patients treated with neoadjuvant chemotherapy

Foluso O Ademuyiwa<sup>1</sup>, Jingqin Luo<sup>1</sup>, Bryan Fisk<sup>1</sup>, Gejae Jeffers<sup>1</sup>, Tracy Summa<sup>1</sup>, Isabella Grigsby<sup>1</sup>, Mothaffar Rimawi<sup>2</sup>, Meenakshi Anurag<sup>2</sup>, Matthew Ellis<sup>2</sup>, Obi Griffith<sup>1</sup> and Malachi Griffith<sup>1</sup>. <sup>1</sup>Washington University, Saint Louis, MO; <sup>2</sup>Baylor College of Medicine, Houston, TX

**Background:** Triple negative breast cancer (TNBC) has a marked molecular diversity that promotes clinical heterogeneity. Less than 40% of TNBC patients will achieve a pathological complete response (pCR) to standard neoadjuvant chemotherapy. Patients who do not achieve pCR have a high risk of disease recurrence and subsequent death from breast cancer. Molecular characterization may identify TNBC patients unlikely to achieve pCR and subsequently develop recurrent disease. **Methods:** We are conducting a multicenter prospective study of clinical stages II and III TNBC patients treated with neoadjuvant docetaxel and carboplatin. We performed tumor whole exome sequencing on 56 patients pre-treatment samples to identify somatic mutation associated with pCR. Thirteen matching samples from cycle 1 day 3 (C1D3) were also analyzed to assess changes in somatic mutation profiles. **Results:** In this biomarker study, thirty-seven (66.1%) patients are Caucasians, 17 (30.4%) African American. Nineteen (33.9%) achieved pCR following six cycles of neoadjuvant docetaxel and carboplatin. 9063 variants were detected in 5386 unique genes. The overall mutation burden for patients who achieved pCR was not significantly different from non-pCR patients (median of 80 variants, IQR 51-135 in pCR, vs median 72, IQR 44-102 in non-pCR, Wilcoxon rank sum test  $p=0.78$ ). As expected, *TP53* is the most frequently mutated gene observed in 48 of all 56 patients (85.7%). There was a non-significant trend with lower *TP53* mutations occurring in 78.9% of patients with pCR, versus 89.2% of non-pCR patients (OR 0.46, 95% CI 0.07 - 2.83;  $p$  value 0.42). *BRCA2* somatic mutations were observed in 5.4% and 5.3% of pCR and non-pCR samples, respectively. No *BRCA1* somatic mutations were identified. *EGFR*, *RAD51AP2*, *SDK2*, *L1CAM*, *KPRP*, *CACNA1S*, *CFAP58*, *COL22A1*, and *COL4A5* were differentially mutated and almost exclusively found in pCR samples. *PCDHA1* and *TRMT9B* were observed in 18.9% and 16.2%, respectively, of non-pCR samples only. There was a trend of higher variant counts in the thirteen matched samples at C1D3 (median of 82, IQR 49-157) versus corresponding pre-treatment samples (median of 72, IQR 42-92), Wilcoxon rank sum test  $p=0.29$ , suggesting clone emergence under treatment pressure. Using the Molecular Signatures Database v7.1, several gene families involved in immune related pathways showed differences between pCR and non-pCR samples. Additionally, borderline differences in hedgehog signaling pathway were identified between pCR and non-pCR samples. There were no differences in apoptosis, DNA repair, EMT, inflammatory response, NOTCH signaling pathways. **Conclusion:** Across TNBC tumors analyzed, *TP53* mutation frequency does not differ in pCR versus non-pCR patients. Somatic mutations in *EGFR*, *RAD51AP2*, immune pathways genes, and hedgehog signaling pathway genes may predict pCR to docetaxel and carboplatin chemotherapy.

Molecular imaging of hypoxia and granzyme B alterations during combination treatment with immunotherapy in triple negative breast cancer

Tiara S. Napier, Chanelle L. Hunter, Patrick N. Song, Ben M. Larimer and Anna G. Sorace. University of Alabama at Birmingham, Birmingham, AL

**Background:** Although a portion of triple negative breast cancer (TNBC) is sensitive to chemotherapeutic treatment with agents such as paclitaxel (PTX), patients have a high risk of recurrence and short overall and progression-free survival. Clinical trials for TNBC using immune checkpoint inhibitors such as anti-programmed cell death 1 (PD1) have met some success; however, only a small percentage of patients have a positive response to immunotherapy and there is risk for severe side effects. Therefore, there is a need for improvements in monitoring and predicting patient-specific response. The goal of this study is to use non-invasive visualization of the tumor microenvironment to collect longitudinal information that can be used to study tumor response to immunotherapy. By applying positron emission tomography (PET) imaging techniques to investigate changes in the tumor microenvironment (hypoxia and immune cell activation), we seek to predict early response to immunotherapy and better identify which treatments will be effective for individual tumors in TNBC. **Methods:** A TNBC mouse mammary carcinoma cell line, 4T1, was transduced with CMV-luciferase and  $2 \times 10^5$  cells were injected into the third mammary fat pad of 5-6 week old female Balb/c mice (N=28). Mice in cohort 1 received: PTX (10 mg/kg), anti-PD1 (200  $\mu$ g), both, or vehicle control (saline) (n=4/group). Mice in cohort 2 received: anti-PD1 (n=5), combination PTX/anti-PD1 (n=4), or vehicle control (saline; n=3). Treatments were administered intraperitoneally on days 0, 2, and 5 for cohort 1 (n=16) who underwent granzyme B-PET imaging ( $^{68}\text{Ga}$ ]-NOTA-GZP-PET) and on days 0, 2, 5, and 8 for cohort 2 (n=12) who underwent hypoxia imaging with [ $^{18}\text{F}$ ]-fluoromisonidazole (FMISO)-PET imaging. Bioluminescence (BLI) imaging and caliper measurements were performed to track tumor size changes at multiple timepoints and tumors were collected for histological validation on day 20. Mean standard uptake value ( $\text{SUV}_{\text{mean}}$ ) was calculated as percent of day 0, and statistical analyses were performed with unpaired t-tests and Wilcoxon-rank sum tests. **Results:** Voxel analysis of GZP-PET images revealed an 42.9% increase in T cell activation of TNBC tumors treated with single-agent PTX compared to anti-PD1 alone on day 3 (p=0.08). FMISO-PET revealed that tumors treated with anti-PD1 alone had lower hypoxic fraction compared to control group tumors (p=0.10) and tumors treated with combination PTX/anti-PD1 (p=0.17) on day 3. BLI data showed that treatment with PTX and anti-PD1 significantly decreased viability signal between days 3 and 6 for cohort 1 (p=0.04). Non-responders to treatment had a significantly higher tumor volume compared to responders starting on day 6 (p<0.05).  $\text{SUV}_{\text{mean}}$ , indicating T cell activation, was significantly higher for responders compared to non-responders on days 3 and 6 (p<0.05). There was a significant decrease in hypoxia, as measured through FMISO-PET  $\text{SUV}_{\text{mean}}$  on day 6 for responders compared to non-responders (p=0.04). **Conclusion:** It is known that the tumor microenvironment can impact neovascularization, tumor cell invasion, tumor oxygenation and growth. Results from this study show that noninvasive PET imaging can provide data on changes in T cell activation and hypoxia in response to chemotherapeutic treatment and immunotherapy in TNBC. Utilizing clinically-translatable advanced imaging strategies to understand the biologically distinct features of the TNBC tumor microenvironment can aid in personalizing anti-cancer therapies. **Acknowledgements:** We thank the American Cancer Society for RSG-18-006-01-CCE, NIH NCI R01 CA240589, and NIH P30CA013148.

Neoadjuvant endocrine therapy helps identify HER2 up-regulation in patients with hormone receptor-positive HER2-negative breast cancer

Lubna N Chaudhary, Julie M Jorns, Yee Chung Cheng, Sailaja Kamaraju, Mary Beth Gonyo, Amanda Kong, Caitlin Patten, Tina Yen, Chandler Cortina, Ebony Carson, Nedra Johnson, Carmen Bergom, Anjishnu Banerjee, Yu Wang, Christopher R Chitambar and Hallgeir Rui. Medical College of Wisconsin, Milwaukee, WI

**Background:** Endocrine therapy provides significant improvement in the long-term outcomes of patients with hormone receptor-positive (HR+) breast cancer (BC). However, metastatic recurrences of endocrine resistant disease develop in about 20-25% of patients and remain a major cause of BC mortality. Up-regulation of the HER2 growth factor receptor represents a common escape strategy used by cancer cells to survive and continue to proliferate in an ER-independent manner. Neoadjuvant endocrine therapy (NET) offers a unique opportunity to identify responsiveness of HR+ BCs and detect tumors that display up-regulation of HER2, an early endocrine resistance mechanism. **Methods:** A single arm, interventional, exploratory clinical trial evaluating four weeks of NET in early stage HR+/HER2-negative BC patients was conducted at our institution (NCT03219476). The primary objective was to assess changes in HER protein expression (HER1-4) from diagnostic core biopsies to surgically resected tumors treated with NET. Secondary objectives included assessment of other molecular markers, tumor proliferation and volumetric responses. Optimized protocols for immunohistochemistry (IHC) and fluorescence *in situ* hybridization (FISH) were used to assess HER2 status in the pre- and post-treatment tumor specimens. Chi-square and t-tests were performed. Linear regression multivariate analysis was performed to evaluate association of covariates with the primary outcome with 80% power at a significance level of 0.05. Here we present the changes in HER2 protein expression with NET in this study. Up-regulation was defined as an increase of  $\geq 1$  in IHC scores (ordinal 0,1,2,3) or gene amplification by FISH. **Results:** Thirty-seven patients with cT1-T3, cN0 HR+/HER2-negative BC were enrolled. Median age at diagnosis was 64 yrs (42-81) and median BMI was 28.3 (19.3-55.1). Most patients were post-menopausal (83.8%). Median tumor size clinically was 1.3 cm (0.5-7.7). Most tumors were low (42.1%) or intermediate (47.4%) grade and invasive ductal histology was seen in 70%. Median tumor size at surgery was 1.2 cm (0.09-4). One patient had a complete pathologic response (pCR) at surgery. Seven patients had pN1 disease at surgery (six with 1 lymph node involved, one with pN1mi). There was no significant change in ER-positivity between pre and post-treatment specimens. However, a trend towards decrease in PR-positivity was seen in post-treatment tumors consistent with functional ER pathway disruption ( $p=0.08$ ). On HER2 protein assessment by IHC, most patients had IHC 0 (37.8%) or IHC 1+ (54%) at diagnosis. Significant up-regulation in HER2 protein was seen in 46% (17/37) of patients ( $p=0.0004$ ), whereas down-regulation was detected in only 5% (2/37) and no change in the remaining 49% (18/37). Three patients converted to HER2-positive status (IHC 3+ or FISH amplified) at surgery and received adjuvant trastuzumab-based treatment. No significant associations were identified between any clinicopathologic covariates and change in HER2 protein expression. **Conclusions:** HER2 was up regulated in 46% of tumors after short-term NET in patients diagnosed with early stage HR+/HER2-negative BC. Short-term NET is a promising strategy to identify HR+ tumors that up-regulate HER2 as an early escape pathway and endocrine resistance mechanism. Patients with such HER2 up-regulated tumors after NET may benefit from HER2-directed therapies upon disease recurrence or as adjuvant combination therapy. These findings need to be further explored in larger randomized clinical trials.

Genomic landscape of metastatic breast cancer (MBC): Comprehensive cell-free DNA analysis from over 10,000 patients and comparison with primary breast cancer

Aditya Bardia<sup>1</sup>, Massimo Cristofanilli<sup>2</sup>, Justin Cha<sup>3</sup>, Lesli Kiedrowski<sup>4</sup>, Dejan Juric<sup>1</sup>, Ben H Park<sup>5</sup>, Adam Brufsky<sup>6</sup>, Joyce O'Shaughnessy<sup>7</sup>, Becky Nagy<sup>4</sup>, Leif Ellisen<sup>1</sup>, Ignaty Leshchiner<sup>3</sup> and Gaddy Getz<sup>3</sup>. <sup>1</sup>Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA; <sup>2</sup>Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL; <sup>3</sup>Broad Institute, Cambridge, MA; <sup>4</sup>Guardant Health, Redwood City, CA; <sup>5</sup>Vanderbilt-Ingram Cancer Center, Nashville, MA; <sup>6</sup>UPMC Hillman Cancer Center, University of Pittsburgh, Pittsburgh, PA; <sup>7</sup>Baylor University Medical Center, Dallas, TX

**Background:** Current tissue-based genomic sequencing datasets typically reflect early stage, mostly treatment-naïve cohorts, and fail to capture the genomic landscape of advanced disease, including mutations conferring acquired resistance to therapy. Plasma cell-free DNA (cfDNA) can provide information on somatic alterations non-invasively and can capture spatial tumor heterogeneity. Here, we studied cfDNA from 15,564 blood samples from 12,827 patients (11.5% of patients had serial samples) with MBC, and analyzed the differences in mutational landscape between cohorts of heavily pre-treated and primary untreated breast cancers. **Materials and methods:** Deidentified aggregate genomic data from stage III/IV breast cancer clinical samples submitted for cfDNA next-generation sequencing (NGS) analysis with Guardant360 (Guardant Health, Inc; Redwood City, CA, USA) assay between 11/25/16 and 5/26/20. This clinical assay detects somatic single nucleotide variants (SNVs), indels, copy number gains, and fusions in either all or a subset of exons in up to 74 genes. We compare the observed alterations to events detected from whole-exome sequencing data representing ~1,000 untreated primary breast cancers from The Cancer Genome Atlas (TCGA) project. **Results:** In the overall cohort (N = 12,827), the average patient age was 61 (range 18-100); 99% were female. Of the 11,290 pts with at least one sample with a non-synonymous alteration, the most frequently mutated genes were *TP53* (53%), *PIK3CA* (38%), *ESR1* (28%), *ATM* (13%), *GATA3* (10%), and *ARID1A* (10%) at varying allelic frequencies with dynamic changes over time (in pts with serial specimens) highlighting clonal heterogeneity and temporal evolution. Copy-number gains were most frequent in *FGFR1* (13%), *CCND1* (11%), *EGFR* (9%) and *PIK3CA* (9%), but fusions were infrequent (below 1%), with fusions involving *FGFR3* (n=22), *FGFR2* (n=12), *ALK* (n=7), *NTRK1* (n=6), *RET* (n=4), and *ROS1* (n=1). Overall, patients had significantly higher frequency of actionable alterations based on ctDNA analysis, as compared to that observed in TCGA. Similarly, non-synonymous mutations were identified in genes associated with acquired resistance, including *ESR1* (28%), *ERBB2* (9%), *PTEN* (8.1%), *RB1* (7.7%), *NF1* (6.2%), and *AKT1* (4%), mutated at frequencies significantly exceeding those observed in TCGA. Finally, we developed a novel classifier to identify the breast cancer receptor subtypes based on differential genomic profile, which was further validated in an independent genomic dataset. **Conclusions:** In the largest dataset to date, we provide the comparative genomic landscape of the various SNVs, indels, copy-number gains, and fusions identified by next generation sequencing of cfDNA in patients with MBC, compared to primary breast cancer. Interestingly, both targetable genomic alterations and resistance mutations occur at frequencies much higher than observed in primary breast cancer, highlighting the genomic complexity of MBC and potential need for combinatorial therapy. Finally, we describe a novel classifier for detection of HR+ and HER2+ tumors, which could be particularly valuable clinically given the receptor switch with tumor evolution and practical difficulty with serial tissue biopsies in MBC. Comparison of genomic signature profiles between MBC and primary breast cancer will be presented at the meeting.

Myc regulates alternative splicing through a network of RNA binding proteins in breast cancer

Laura Urbanski<sup>1</sup>, Brittany Angarola<sup>2</sup>, Mattia Brugiolo<sup>2</sup>, Marina Yurieva<sup>2</sup>, Sunghee Park<sup>2</sup> and Olga Anczukow<sup>1</sup>. <sup>1</sup>University of Connecticut/Jackson Laboratory, Farmington, CT; <sup>2</sup>Jackson Laboratory, Farmington, CT

The oncogenic transcription factor MYC is one of the most frequently altered genes in cancer and is highly dysregulated in aggressive tumor types, including triple negative breast cancer (TNBC). Although direct targeting of MYC or its regulators in human tumors has proved difficult, the undisputed clinical relevance of this transcription factor warrants continued study for therapeutic targeting of MYC-driven processes in tumors. Recently, we and others have shown the tumorigenic capacity of MYC is critically dependent on the RNA splicing machinery and on several splicing factor RNA-binding proteins (RBPs). Dysregulation of alternative mRNA splicing, a key step in gene expression regulation, is a hallmark of cancer, and can lead to the expression of isoforms driving tumor initiation, progression or drug resistance. Understanding which component(s) of the RNA machinery are regulated by MYC, and the functions of MYC-induced spliced isoforms, may reveal new targets that circumvent prior failures of directly targeting MYC. Here, we examine MYC-induced changes in gene expression and alternative splicing through RNA-sequencing of breast cell lines and tumors. Using a mammary epithelial cell line with an inducible MYC system, we identified over 4,000 MYC-induced alternative splicing events as well as 378 MYC-induced RBPs. Co-expression network analysis of these RBPs in TCGA breast tumor RNA-seq data uncovered 8 RBP modules, four of which are highly correlated with MYC activity and highly expressed in TNBC. One of these modules is preserved across almost all other TCGA tumor types and remains highly correlated with MYC activity, suggesting a pan-cancer role of this co-expression module. We are now defining the functional role of these RBP modules in MYC-driven tumorigenesis in breast cancer models, as well as identifying their downstream oncogenic splicing targets. Our research project will define the role and regulation of alternative splicing in breast cancer, and more specifically in aggressive tumor types such as TNBC. Our findings will provide mechanistic insight into the role of MYC-driven splicing in tumor maintenance and will uncover novel therapeutic targets for MYC-active tumors.

Rna genetic testing improves detection of patients with hereditary breast cancer

Holly LaDuca, Lily Hoang, Carolyn Horton, Jessica Profato, Tameron Harvell, Jill S Dolinsky, Tina Pesaran and Rachid Karam. Ambry Genetics, Aliso Viejo, CA

Background: DNA genetic testing is commonly used to inform treatment decisions for breast cancer patients. In recent years, RNA genetic testing has shown promise for increasing the detection of disease-causing variants and decreasing inconclusive results. Here we describe the impact of concurrent DNA and RNA genetic testing on identifying breast cancer patients with germline cancer predisposition who may have been missed by DNA-only testing. Methods: We performed a retrospective review of breast cancer patients who received concurrent DNA and RNA hereditary cancer panel testing between March 2019 and February 2020 at Ambry Genetics. Patients underwent DNA and RNA genetic testing of up to 18 hereditary cancer genes at the discretion of the ordering healthcare provider (*APC*, *ATM*, *BRCA1*, *BRCA2*, *BRIP1*, *CDH1*, *CHEK2*, *MLH1*, *MSH2*, *MSH6*, *MUTYH*, *NF1*, *PALB2*, *PMS2* exons 1-10, *PTEN*, *RAD51C*, *RAD51D*, and *TP53*). Breast cancer patients with positive results, defined as the presence of a pathogenic or likely pathogenic variant in any of these 18 genes, were selected for inclusion in this study (n=946). Results: Concurrent DNA and RNA genetic testing led to the identification of 23 breast cancer patients with positive results who would have otherwise received inconclusive or negative results with DNA-only testing. These cases represented 2.4% of all positive results reported in the 18 genes studied (n=23/946). The majority of RNA-related positive results occurred in either *ATM* (n=14) or *BRCA1/2* (n=7). The remaining two cases involved alterations in *NF1* and *PMS2*. Guidelines for risk-reducing breast surgery (*BRCA1/2*) and breast imaging surveillance (*ATM*, *BRCA1/2*, *NF1*) were relevant for 30.4% and 95.7% of patients with RNA-dependent positive results, respectively. In addition, treatment options such as PARP inhibitors or clinical trial eligibility were potentially implicated for 91.3% of RNA-dependent positives (*BRCA1/2*, *ATM*). In 16 of the 23 cases, variants would have been detected by DNA-only testing but would have remained inconclusive without supporting RNA data. In the remaining 7 cases, abnormal RNA results led to the identification of pathogenic/likely pathogenic intronic variants beyond the analytical range of DNA testing. Thus, these seven patients would have received negative results from DNA-only testing. Four of these cases involved pathogenic/likely pathogenic intronic variants in *ATM* and three involved pathogenic intronic variants in *BRCA1*. Conclusions: One in 41 breast cancer patients who test positive on concurrent DNA and RNA genetic testing would have received negative or inconclusive results from DNA-only testing. These findings demonstrate the impact of a comprehensive diagnostic testing approach that includes concurrent DNA and RNA analysis and highlights the important implications for the personalized management of these breast cancer patients including potential missed opportunities for early detection and prevention of additional cancer and familial testing in the absence of RGT.

Lenvatinib plus pembrolizumab for previously treated, advanced triple-negative breast cancer: Early results from the multicohort phase 2 LEAP-005 study

Hyun Cheol Chung<sup>1</sup>, Esma Saada-Bouzi<sup>2</sup>, Federico Longo Munoz<sup>3</sup>, Eduardo Yanez<sup>4</sup>, Seock-Ah Im<sup>5</sup>, Eduardo Castanon<sup>6</sup>, Donna M. Graham<sup>7</sup>, Javier Garcia-Corbacho<sup>8</sup>, Juanita Lopez<sup>9</sup>, Razi Ghori<sup>10</sup>, Corina Dutcus<sup>11</sup>, Alan Smith<sup>12</sup>, Kevin Norwood<sup>13</sup> and Carlos Gomez-Roca<sup>14</sup>. <sup>1</sup>Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of; <sup>2</sup>Early Phase Trial Unit, Centre Antoine Lacassagne, Nice, France; <sup>3</sup>Hospital Universitario Ramon y Cajal, IRYCIS, CIBERONC, Madrid, Spain; <sup>4</sup>Instituto Clinico Oncologico del Sur, Temuco, Chile; <sup>5</sup>Seoul National University Hospital, Seoul, Korea, Republic of; <sup>6</sup>Clinica Universitaria de Navarra, Pamplona, Spain; <sup>7</sup>The Christie NHS Foundation Trust, Manchester, United Kingdom; <sup>8</sup>Hospital Clinic i Provincial de Barcelona, Barcelona, Spain; <sup>9</sup>The Royal Marsden Foundation Trust and the Institute of Cancer Research, London, United Kingdom; <sup>10</sup>Merck & Co., Inc., Kenilworth, NJ; <sup>11</sup>Eisai Inc., Woodcliff Lake, NJ; <sup>12</sup>Eisai Ltd, Hatfield, United Kingdom; <sup>13</sup>Merck & Co., Inc., Kenilworth, NJ; <sup>14</sup>Institut Claudius Regaud, Toulouse, France

**Background:** Triple-negative breast cancer (TNBC) is associated with poor survival outcomes and treatment options are limited. These tumors lack therapeutic targets and become rapidly resistant to chemotherapy. The anti-PD-1 antibody pembrolizumab showed durable antitumor activity and manageable safety in patients with TNBC in the KEYNOTE-012, KEYNOTE-086, and KEYNOTE-119 studies. The combination of lenvatinib, an antiangiogenic multiple receptor tyrosine kinase inhibitor, with pembrolizumab has shown promising clinical outcomes in early-phase clinical trials across several cancer types. LEAP-005 (ClinicalTrials.gov, NCT03797326) is an ongoing study evaluating the efficacy and safety of lenvatinib combined with pembrolizumab in patients with previously treated advanced solid tumors. Here, we report the first results from the TNBC cohort of LEAP-005. **Methods:** This ongoing, multicohort, open-label, phase 2 study enrolled patients aged ≥18 y with previously treated, histologically or cytologically confirmed advanced TNBC. PD-L1 expression was assessed at a central laboratory using the PD-L1 IHC 22C3 pharmDx assay and measured using the combined positive score (CPS; number of PD-L1-positive tumor cells, lymphocytes, and macrophages divided by total number of tumor cells x 100). Patients received lenvatinib 20 mg once daily orally plus pembrolizumab 200 mg every 3 weeks intravenously for a maximum of 35 pembrolizumab doses, then lenvatinib alone until progressive disease or unacceptable toxicity. Primary endpoints were objective response rate (ORR) by blinded independent central review per RECIST version 1.1 and safety. Key secondary endpoints were disease control rate (DCR; defined as best overall response of complete response [CR], partial response [PR], or stable disease [SD] per RECIST v1.1), duration of response (DOR), progression-free survival (PFS), and overall survival (OS). Safety was monitored through 30 days after the last dose of study drug (90 days for serious AEs), with AEs graded using NCI CTCAE v4.0. **Results:** 31 patients have been enrolled in the TNBC cohort of LEAP-005. Median age was 56 y (range, 37 to 85), 58% had received ≥2 prior lines of therapy, and 26% had CPS ≥10 tumors. As of the April 10, 2020 data cutoff, median follow-up was 7 mo (range, 4 to 13). ORR was 29% (95% CI: 14–48), with 1 CR and 8 PRs. 9 pts had SD, and the DCR (CR + PR + SD) was 58% (95% CI: 39–76). 4 responses (1 CR and 3 PRs) were in patients with CPS ≥10 tumors (n=8) for an ORR of 50% (95% CI: 16–84), and 5 responses (all PRs) were in patients with CPS <10 tumors (n=22) for an ORR of 23% (95% CI: 8–45). Median DOR was not reached (range, 0+ to 8+ mo); 7 (78%) responses were ongoing at data cutoff. Median PFS was 4 mo (95% CI: 2–NR), with a 6-mo rate of 49%. Treatment-related AEs (TRAEs) occurred in 97% of pts; 10% discontinued due to TRAEs. 55% of pts had grade 3-5 TRAEs (1 death due to subarachnoid hemorrhage). **Conclusions:** Lenvatinib in combination with pembrolizumab showed promising antitumor activity with manageable toxicity in patients with previously treated advanced TNBC. Based on these early data, the cohort will be expanded to include 100 patients.

**Publication Number:** PD12-07

Incidences of endometrial events and frequencies of endometrial invasive diagnostic procedures in breast cancer survivors on tamoxifen: A nationwide study

Soojeong Choi<sup>1</sup>, Jae ho Jeong<sup>1</sup>, Jinhong Jung<sup>1</sup>, Young Jae Lee<sup>2</sup>, Jong Won Lee<sup>1</sup>, Beom Seok Ko<sup>1</sup>, Byung Ho Son<sup>1</sup>, Sei Hyun Ahn<sup>1</sup>, Yura Lee<sup>1</sup>, Hee jeong Kim<sup>1</sup> and Il Yong Chung<sup>1</sup>. <sup>1</sup>Asan Medical Center, Seoul, Korea, Republic of<sup>2</sup>Asan Medical Center, Gangneung, Korea, Republic of

**Background**Breast cancer survivors who taking tamoxifen as adjuvant therapy have been reported to have more endometrial lesions. According to guidelines, a gynecological assessment is recommended for postmenopausal women, but there is no mention of premenopausal women. The purpose of this study is to compare the risk of endometrial cancer by age at diagnosis, and to investigate frequencies of gynecological exam in breast cancer patients taking tamoxifen in South Korea.

**Methods**A nationwide retrospective cohort study was conducted using South Korea Health Insurance Review and Assessment Service claims data. Between 2010 and 2015, a total of 60,545 (mean follow-up, 66.0 months) newly diagnosed female breast cancer survivors were included. Endometrial evaluation and Dilatation & Curettage (D&C) proportion were analyzed by age at diagnosis. The incidence of endometrial cancer and benign lesions were calculated as incident cases per person-year and analyzed with the Kaplan-Meier method. **Results**The 26,374 patients who taking tamoxifen were divided into four groups by age at diagnosis. The incidence rate of endometrial cancer per 1,000 person-years was 1.13 and 1.45 for age range 50-59 and over 60 and 0.62 and 0.82 for in age under 40 and range 40-49. However, D&C proportion did not all differ from 10 to 11% in each subgroup.

**Conclusions**This nationwide cohort study showed that the risk of endometrial cancer in premenopausal breast cancer women taking tamoxifen was lower than that of postmenopausal women. However, the invasive diagnostic procedure such as aspiration, biopsy, polypectomy and D&C was proceeding at a level that makes no difference with those in postmenopausal women.

## Background

T-DXd is a novel antibody-drug conjugate composed of an anti-HER2 antibody, cleavable tetrapeptide-based linker, and membrane-permeable topoisomerase I inhibitor payload. In a phase 2 study in patients (pts) with HER2+ (IHC 3+ or IHC 2+/ISH+), unresectable or metastatic breast cancer (MBC) previously treated with trastuzumab emtansine (T-DM1), the confirmed ORR (cORR) with T-DXd was 60.9% and median PFS (mPFS) was 16.4 mo (Modi *NEJM* 2020). In pts with HER2-low (IHC 2+/ISH-, IHC 1+) advanced BC, cORR was 37.0% and mPFS 11.1 mo in a phase 1 study (Modi *J Clin Oncol* 2020). Recently, T-DXd was approved for the treatment of adult pts with HER2+, unresectable or MBC who have received ≥ 2 prior anti-HER2-based regimens (US) or had prior chemotherapy and are refractory to or intolerant of standard treatments (Japan). In preclinical models, T-DXd combined with an anti-PD-1 antibody had greater efficacy than either agent alone (Iwata *Mol Cancer Ther* 2018). We conducted a phase 1b, open-label, multicenter, 2-part study of T-DXd in combination with nivolumab (Nivo) in pts with HER2-expressing (by centrally testing) MBC or advanced urothelial cancer (DS8201-A-U105; NCT03523572); interim results for the BC cohorts are presented.

## Methods

Pts were aged ≥18 y and immune checkpoint inhibitor naive. Pts were enrolled in the United States and Europe. In part 1 (dose escalation), pts received T-DXd 3.2 or 5.4 mg/kg intravenously (IV) every 3 weeks (q3w) and Nivo 360 mg IV q3w to determine the recommended dose for expansion (RDE). In part 2, the RDE was given to 2 MBC cohorts: HER2+ (IHC 3+ or IHC 2+/ISH+) disease that progressed on prior T-DM1 or HER2 low (IHC 1+ or IHC 2+/ISH-) disease that progressed on prior standard treatments. The primary efficacy endpoint is cORR by independent central review (ICR) per RECIST version 1.1 in part 2. Additional endpoints include duration of response (DOR), disease control rate (DCR), PFS, OS, safety, and pharmacokinetics.

## Results

52 pts with MBC were enrolled. In part 1, 4 pts received T-DXd 3.2 mg/kg (HER2+, n=3; HER2 low, n=1), 3 pts received 5.4 mg/kg (all HER2+). In part 2, 45 pts received the RDE of T-DXd 5.4 mg/kg and Nivo 360 mg (HER2+, n=29; HER2 low, n=16 [13 HR+]); median follow-up time was 7.0 and 6.9 mo, respectively.

All pts (n=48) who received RDE were female; median duration of follow-up was 6.9 mo. HER2+ pts had a median age of 55 y and median of 5 prior lines of metastatic/locally advanced therapy. At data cutoff (June 8, 2020), 56.3% of pts remained on treatment (median treatment duration: T-DXd, 6.5 mo; Nivo, 5.2 mo). HER2 low pts had a median age of 47 y, median of 4 prior lines, and 50.0% remained on treatment (median: T-DXd, 6.3 mo; Nivo, 4.9 mo).

In pts treated at RDE, the cORR by ICR in the HER2+ cohort was 59.4% (19/32, 18 PR) and for the HER2 low cohort was 37.5% (6/16, all PR). The DCR was 90.6% and 75.0% in the HER2+ and HER2-low cohorts, respectively. Median DOR was not reached in either cohort; median PFS was 8.6 mo (95% CI, 5.4-NE) for the HER2+ cohort and 6.3 mo (95% CI, 2.3-NE) for the HER2 low cohort.

Adverse events (AEs) grade ≥3 occurred in 43.8% (18.8% related to T-DXd, 18.8% to Nivo) of pts treated at RDE (n=48); anemia (16.7%) and transaminase increase (6.3%) were most common. Nausea (54.2%), fatigue (45.8%), and alopecia (41.7%) were the most common any-grade AEs. 5 pts (10.4%, all HER2+) had treatment-related interstitial lung disease (ILD) as adjudicated by an independent committee (grade 5, n=1; grade 2, n=4). No other deaths associated with a drug-related AE occurred.

## Conclusions

In pts with HER2-expressing MBC, T-DXd plus Nivo demonstrated antitumor activity consistent with prior studies of T-DXd and had an acceptable safety profile in this interim analysis; whether adding IO therapy to T-DXd benefits pts requires longer follow-up and additional studies.

**Publication Number:** PD1-07

A Phase 2 study of poziotinib in patients with HER2-positive metastatic breast cancer heavily pre-treated with HER2-targeted therapy

Adam Brufsky<sup>1</sup>, Malik Zulfikar<sup>2</sup>, Julio Peguero<sup>3</sup>, Kate Lathrop<sup>4</sup>, Gajanan Bhat<sup>5</sup> and Francois Lebel<sup>5</sup>. <sup>1</sup>University of Pittsburgh Medical Center, Pittsburgh, PA; <sup>2</sup>New York Cancer Associates, New York, NY; <sup>3</sup>Oncology Consultant PA, San Antonio, TX; <sup>4</sup>University of Texas Health Science Center, San Antonio, TX; <sup>5</sup>Spectrum Pharmaceuticals, Irvine, CA

**Background:** Poziotinib is a novel pan-HER inhibitor that irreversibly blocks the EGFR family of tyrosine-kinase receptors and inhibits the proliferation of tumor cells. This study evaluates the safety and clinical activity of poziotinib in patients with HER2-positive metastatic breast cancer (MBC) who received at least 2 therapies (trastuzumab and TDM-1) in dose-schedule ranging study. **Methods:** Patients were treated with oral poziotinib in 2 dose cohorts: 24mg daily 2 weeks/1 week off and 16mg daily continuously in a 21-day cycle. Dose reduction was allowed if toxicity observed. Patients continued treatment until disease progression, death, intolerable AE, or for a maximum of 24 months. The primary endpoint was the objective response rate (ORR), evaluated using RECIST 1.1. Secondary endpoints included disease control rate (DCR), duration of response (DOR), progression-free survival (PFS) and safety.

**Results:** Sixty-seven patients (33 in 24mg; 34 in 16mg) were enrolled (57 evaluable) in 2 cohorts; all patients either completed or discontinued (36 PD, 5 deaths due to PD, 16 AEs) the study with 1 completed 25 months of treatment. The median (range) age was 57 (29-94) years. Patients were heavily pretreated and the median (range) lines of previous therapy were 7 (2-13) and 4 (2-16) in 2 cohorts respectively [unique drugs 3 (2-5) and 3 (1-9)]; 75% received pertuzumab in addition to trastuzumab and TDM-1 and 37% received at least one tyrosine kinase inhibitor (TKI). The mean relative dose intensity was 57% and 51% with 67% and 47% had dose reductions in 2 cohorts respectively. Common Grade ≥3 treatment-related AEs were similar to other 2<sup>nd</sup> generation TKIs and include diarrhea (30%), rash (28%) and stomatitis (7%). The ORRs were 27% and 26% with the corresponding median DORs of 5.6 and 13 months respectively. 3 patients in 16mg dose had a CR and another 2 patients had an unconfirmed CR. The DCRs were 50% and 70% in 2 cohorts along with median PFS of 4.1 and 5.8 months respectively. The ORRs were 25% each in 2 cohorts in 24 and 20 heavily pre-treated patients with ≥4 lines of therapy that included trastuzumab, TDM1 and pertuzumab. The ORRs were 23% and 0% in 2 cohorts with 13 and 10 patients received at least one tyrosine kinase inhibitor (TKI) as the sample sizes were small to make any meaningful evaluation.

**Conclusion:** Poziotinib has demonstrated clinical activity in this dose-ranging study with tumor reduction shown in the majority of patients along with durable responses in this heavily pre-treated MBC patients. Safety profile was mechanism related and was similar to other 2nd generation TKIs.

Glycemic index, glycemic load and breast cancer risk: Results from the prospective NutriNet-Santé cohort

Charlotte Debras<sup>1</sup>, Eloi Chazelas<sup>1</sup>, Bernard Srour<sup>1</sup>, Chantal Julia<sup>1</sup>, Emmanuelle Kesse-Guyot<sup>1</sup>, Laurent Zelek<sup>2</sup>, Cedric Agaesse<sup>1</sup>, Nathalie Druet-Pecollo<sup>1</sup>, Pilar Galan<sup>1</sup>, Serge Hercberg<sup>1</sup>, Paule Latino-Martel<sup>1</sup>, Melanie Deschasaux<sup>1</sup> and Mathilde Touvier<sup>1</sup>. <sup>1</sup>Nutritional Epidemiology Research Team (Inserm, Inra, Cnam, Paris 13 University), Bobigny, France<sup>2</sup>Oncology Department, Avicenne Hospital, AP-HP, Bobigny, France

**Background:** Evidence is accumulating that high dietary glycemic index (GI) and glycemic load (GL) are risk factors for several metabolic disorders, e.g. diabetes or cardiovascular diseases, but evidence on GI/GL and cancer is less consistent. However, mechanistic data suggest that food with high-GI may contribute to carcinogenesis through the insulin resistance pathway. **Objective:** The objective was to study the associations between dietary GI/GL and breast cancer risk. **Design:** Population based prospective cohort study. **Setting and Participants:** 81,526 women aged  $\geq 18$ y (mean age:  $40.8 \pm 14.0$ y), free of cancer at baseline and with no prevalence or incidence of diabetes, from the French NutriNet-Santé cohort (2009-2019) were included in the analyses. 24-hour dietary records linked with a nutritional composition table for >3,500 food/beverage items containing GI values and carbohydrate content enabled us to compute average dietary GI and GL. **Main outcome measures:** Associations between GI; GL; proportion of energy and proportion of carbohydrates from low-GI ( $GI \leq 55$ ) and from medium/high-GI ( $GI > 55$ ) foods and risk of breast cancer were assessed by Cox proportional hazard models adjusted for known risk factors (sociodemographic, anthropometric, lifestyle, medical history, and nutritional factors). **Results:** A higher dietary GL was associated with higher postmenopausal breast cancer risk ( $n=572$ , hazard ratio for quintile 5 versus quintile 1: 1.64 confidence interval 1.06-2.55  $P_{trend}=0.03$ ). Percentage of energy intake from medium/high-GI foods was associated with higher breast cancer risk ( $HR_{Q5vs.Q1}=1.34$  (1.05-1.71),  $P_{trend}=0.04$ ), more specifically postmenopausal breast cancer ( $HR_{Q5vs.Q1}=1.36$  (1.00-1.84),  $P_{trend}=0.02$ ). Carbohydrates intake from medium/high-GI foods was also associated with higher breast cancer risk ( $HR_{Q5vs.Q1}=1.34$  (1.05-1.71),  $P_{trend}=0.04$ ) in both premenopausal ( $HR_{Q5vs.Q1}=1.49$  (1.03-2.17),  $P_{trend}=0.04$ ) and postmenopausal ( $HR_{Q5vs.Q1}=1.44$  (1.08-1.93),  $P_{trend}=0.03$ ) women, whereas carbohydrates from low-GI foods was associated with lower breast cancer risk ( $HR_{Q5vs.Q1}=0.74$  (0.59-0.92),  $P_{trend}=0.04$ ), only among postmenopausal women ( $HR_{Q5vs.Q1}=0.69$  (0.52-0.92),  $P_{trend}=0.03$ ).

**Conclusion:** The consumption of foods with high-GI was associated increased breast cancer risk. If these results are confirmed dietary GI and GL should be considered as modifiable risk factor for primary breast cancer prevention.

Use of low-dose tamoxifen to increase screening sensitivity in mammography of premenopausal women

Mikael Eriksson, Kamila Czene and Per Hall. Karolinska Institutet, Stockholm, Sweden

**Background.** High mammographic density decreases sensitivity of both 2D and 3D mammography. Tamoxifen reduces mammographic density thereby potentially increasing screening sensitivity. We tested if low-dose tamoxifen could be used to increase sensitivity of mammography in premenopausal women.

**Methods.** Mammography screening sensitivity was calculated using the Swedish KARMA prospective screening cohort including 28,282 premenopausal women. Two models were fitted to estimate screening sensitivity and tumor size based on density level at baseline. BI-RADS dependent sensitivity was estimated in each of the four categories (A, B, C, D). The 2.5 mg tamoxifen arm of the KARISMA tamoxifen trial was used to define the change of mammographic density after exposure to low-dose tamoxifen. The models predicted screening sensitivity and tumor size in the KARMA cohort assuming that all women were exposed to 2.5 mg of tamoxifen. Reduction in interval and advanced cancers were estimated in women with mammographic density decrease of 10%, 20%, 30% and 50%. Mammographic density was measured as percent density and a computerized BI-RADS score was estimated using the STRATUS tool.

**Results.** During 8 years of follow-up, 287 (56%) screening detected and 230 (44%) interval cancers were diagnosed in the KARMA cohort. The screening sensitivities, before exposure to tamoxifen, were 77%, 69%, 53%, 46% for BI-RADS categories A, B, C and D, respectively. The mean density decrease after exposure to 2.5 mg of tamoxifen was 17.4% and the BI-RADS category dependent change in sensitivity was 0% ( $p=0.95$ ), 2% ( $p=0.01$ ), 4% ( $p<0.001$ ), and 5% ( $p<0.001$ ), respectively. A density decrease of  $\geq 20\%$  would reduce the number of interval cancers with 24% ( $p<0.01$ ) and the probability of identifying  $>20$  mm tumors with 4% ( $p<0.01$ ).

**Conclusion.** Low-dose tamoxifen has the potential to increase the sensitivity of a screening mammogram and thereby reduce the proportion of interval and advanced cancers.

**Table.** Number of interval cancers per 100,000 age standardized screened women, change in number of interval cancers after tamoxifen exposure, by percentage mammographic density decrease. Density response is presented using density responder cut-offs and is stratified by computer-generated BI-RADS categories A+B, C, D. The normal (unexposed) group is included as the reference.

Number of interval cancers (N)	Normal group	Density responder cut-off (%)			
		$\geq 10$	$\geq 20$	$\geq 30$	$\geq 50$
BI-RADS A+B	155	107	102	100	88
BI-RADS C	382	356	339	299	253
BI-RADS D	276	197	180	160	129
BI-RADS A to D combined	813	660	621	559	470
<i>Difference compared to normal group, N (%)</i>					
BI-RADS A+B	ref.	-48 (-31)	-53 (-34)	-55 (-35)	-67 (-43)
BI-RADS C	ref.	-26 (-7)	-43 (-11)	-83 (-22)	-129 (-34)
BI-RADS D	ref.	-79 (-29)	-96 (-35)	-116 (-42)	-147 (-53)
BI-RADS A to D combined	ref.	-153 (-19)	-192 (-24)	-254 (-31)	-343 (-42)

Number of interval cancers were significantly reduced in each density decrease group,  $p<0.01$ .

Tan<sup>12</sup>, Roberto Salgado<sup>1</sup>, Vassiliki Karantza<sup>13</sup>, Petar Jelinic<sup>13</sup>, Anran Wang<sup>13</sup>, Linggang Huang<sup>13</sup>, Razvan Cristescu<sup>13</sup>, Lakshman Annamalai<sup>13</sup>, Jennifer Yearley<sup>13</sup>, Jennifer Yearley<sup>13</sup> and Sylvia Adams<sup>14</sup>. <sup>1</sup>Peter MacCallum Cancer Institute, Melbourne, Australia<sup>2</sup>Barts ECOMC, Barts Cancer Institute, Queen Mary University of London, and Barts Health NHS Trust, London, United Kingdom<sup>3</sup>IOB Institute of Oncology, Quiron Group, Madrid & Barcelona, and Vall d'Hebron Institute of Oncology, Barcelona, Spain<sup>4</sup>UHN Princess Margaret Cancer Centre, Toronto, ON, Canada<sup>5</sup>Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA; <sup>6</sup>Rutgers Cancer Institute of New Jersey, New Brunswick, NJ, Canada<sup>7</sup>UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA; <sup>8</sup>Istituto Nazionale Tumori IRCCS Fondazione G. Pascale, Naples, Italy<sup>9</sup>University of Chicago, Chicago, IL; <sup>10</sup>Aichi Cancer Center Hospital, Nagoya, Japan<sup>11</sup>Medical Oncology Clinic, Institut Jules Bordet, Brussels, Belgium<sup>12</sup>Levine Cancer Institute - Atrium Health, Charlotte, NC; <sup>13</sup>Merck & Co., Inc., Kenilworth, NJ; <sup>14</sup>Perlmutter Cancer Center, NYU Langone Health, New York, NY

**Background:** In the phase 2 KEYNOTE-086 study (NCT02447003), pembrolizumab monotherapy had durable antitumor activity in a subset of patients with previously treated mTNBC (cohort A; n = 170) and in patients with previously untreated PD-L1-positive mTNBC (cohort B; n = 84). In this exploratory analysis of KEYNOTE-086, we evaluated the association between several biomarkers and response to pembrolizumab. **Methods:** Cohort A enrolled patients regardless of PD-L1 expression who had documented disease progression following  $\geq 1$  systemic therapy for metastatic disease. Cohort B enrolled patients with PD-L1-positive (combined positive score [CPS]  $\geq 1$ ) tumors who had not received prior systemic therapy for metastatic disease. Immunohistochemistry was used to measure PD-L1 CPS and CD8 density; H&E staining for percentage of stromal tumor infiltrating lymphocytes (sTILs); RNA-sequencing for 18-gene T-cell-inflamed gene expression profile (GEP), angiogenesis, and glycolysis signatures; and whole exome sequencing (paired tumor and germline) for TMB (TMB-H defined as  $\geq 175$  mut/exome), HRD-LOH (DNA damage), Signature 3, and APOBEC. Biomarkers were analyzed as continuous variables in cohorts A and B combined and individually. Area under the receiver operating characteristic curve was estimated between each biomarker and overall response rate (ORR). Wald test *P*-values were calculated using logistic regression adjusted for cohort and Eastern Cooperative Oncology Group performance status. Germline and somatic *BRCA1/2* mutations were pooled; one-sided *P*-value was calculated using Fisher's exact test. Spearman's correlation was used for correlations. **Results:** Biomarker data were available in the following number of patients: 253 (99.6%; PD-L1), 204 (80.3%; CD8), 187 (73.6%; GEP), 171 (67.3%; TMB/HRD), 228 (89.8%; sTILs), 163 (64.2%; Signature 3/APOBEC), and 132 (52.0%; angiogenesis/glycolysis). When data from cohorts A and B were combined, PD-L1 CPS (median 2; IQR 0-10), CD8 (median 159; IQR 62-319), GEP (median -0.34; IQR -0.57 to -0.11), TMB (median 82 mut/exome; IQR 50-139), and sTILs (median 5; IQR 2-20) were significantly associated with ORR (**Table**). There were moderate correlations between PD-L1 and GEP ( $r = 0.532$ ), PD-L1 and sTILs ( $r = 0.451$ ), and GEP and sTILs ( $r = 0.490$ ). No correlation was observed between TMB and PD-L1 ( $r = 0.038$ ), GEP ( $r = -0.035$ ), and sTILs ( $r = -0.031$ ). When cohorts were combined, TMB was significantly associated with ORR, PFS, and OS after adjustment for PD-L1, GEP, CD8, or sTILs. HRD-LOH score, Signature 3, and APOBEC were not significantly associated with ORR (**Table**); *P* for *BRCA1/2* was 0.2385. The angiogenesis signature was associated with lack of response while the glycolysis signature was associated with response to pembrolizumab (**Table**). **Conclusions:** In this exploratory biomarker analysis from KEYNOTE-086, higher levels of PD-L1, GEP, TMB, CD8 IHC, sTILs, and the glycolysis signature were associated with increased response to pembrolizumab monotherapy. These findings may help identify patients with mTNBC who are most likely to respond to pembrolizumab.

Table. Association of Biomarkers as Continuous Variables With Pembrolizumab Objective Response

Biomarker	Combined Cohorts AUC	Combined Cohorts <i>P</i> *	Combined Cohorts Multitest corrected <i>P</i>	Cohort A AUC	Cohort B AUC
PD-L1	0.674	0.040	-	0.544	0.654

Identification of novel molecules that enhance neratinib efficacy in triple-negative breast cancer by high-throughput RNA interference

Jangsoon Lee<sup>1</sup>, Troy Pearson<sup>1</sup>, Huey Liu<sup>1</sup>, Jon A. Fuson<sup>1</sup>, Toshiaki Iwase<sup>1</sup>, Irmina Diala<sup>2</sup>, Alshad S. Lalani<sup>2</sup>, Lisa D. Eli<sup>2</sup>, Debu Tripathy<sup>1</sup>, Bora Lim<sup>1</sup> and Naoto T. Ueno<sup>1</sup>. <sup>1</sup>UT MD Anderson Cancer Center, Houston, TX; <sup>2</sup>Puma Biotechnology, Inc., Los Angeles, CA

**Background:** Neratinib is a potent, irreversible pan-HER inhibitor that inhibits the ErbB family members EGFR, HER2, and HER4 and downstream signal transduction of these receptors. Triple-negative breast cancer (TNBC) is a heterogeneous disease that lacks druggable levels of receptors for estrogen, progesterone and HER2 and therefore challenging to treat. There is evidence that some cases of TNBC have activated signaling pathways mediated by ErbB family members that may contribute to aggressive behavior. The purpose of this preclinical study was to identify and validate kinases whose targeting may enhance the antitumor activity of neratinib in TNBC cell lines. **Methods:** *In vitro* proliferation assays were used to evaluate the efficacy of neratinib in TNBC cell lines. Baseline and post-neratinib-treatment expression of EGFR and phosphorylated EGFR (phospho-EGFR) were assessed via Western blot analysis in 18 TNBC cell lines. Reverse-phase protein array (RPPA) was used to profile and validate the signaling networks induced by neratinib. To identify potential targets or pathways that may synergize with neratinib treatment, we performed high-throughput RNA interference (HT RNAi) screening using a 709-kinome library. CellTiter-Blue, sulforhodamine B, and soft-agar assays were performed to evaluate the antiproliferative effect of neratinib alone and with target inhibitor. Mammary fat pad xenograft models were used to evaluate the efficacy of neratinib alone or with inhibitor *in vivo*. **Results:** *In vitro* proliferation assays showed that the half-maximal inhibitory concentration (IC<sub>50</sub>) of neratinib in tested TNBC cell lines ranged from 0.16  $\mu$ M to 1.25  $\mu$ M. RPPA and Western blot analyses revealed that the efficacy of neratinib correlated with phospho-EGFR expression levels across the TNBC cell lines tested ( $R^2 = 0.3245$ ). Among the tested TNBC cell lines, SUM149 cells (*PIK3CA* wild-type) were selected for high throughput RNAi screening because this cell line has high EGFR expression and is moderately sensitive to neratinib (IC<sub>50</sub> = 0.35  $\mu$ M). We identified the 40 most relevant kinase targets by the sensitivity index analysis, and further pathway analysis identified PI3K/AKT/mTOR (drug: everolimus) and MAPK (drug: trametinib) as major canonical pathways whose targeting enhanced the cytotoxic effect of neratinib. Everolimus (mTOR inhibitor) produced a strong antiproliferative effect when combined with neratinib in most tested TNBC cell lines (12 of 15 cell lines; combination index [CI] values, 0.1-0.5) and was more effective in *PIK3CA*-mutated compared to wildtype cell lines. Trametinib (MEK inhibitor) showed a moderate antiproliferative effect (effective in 10 of 15 cell lines; CI values, 0.2-0.9). Synergistic antitumor effects of neratinib combined with everolimus or with trametinib were also observed in anchorage-independent growth conditions ( $P < 0.05$ ). *In vivo* experiments demonstrated that neratinib plus everolimus and neratinib plus trametinib combinations inhibited tumor growth in the SUM149 xenograft model for than single drug (neratinib, 42.3% growth inhibition; everolimus, 29.7%; trametinib, 47.1%; neratinib plus everolimus, 69.7%; neratinib plus trametinib, 77.7%;  $P < 0.0001$ ). **Conclusion:** Combining neratinib with everolimus or with trametinib enhanced the antitumor effects of these drugs in TNBC regardless of *PIK3CA* mutation status, and clinical investigations evaluating these combination regimens for the treatment of TNBC are warranted.

Publication Number: PD2-08

Endocrine therapy non-persistence and recurrence in young women with early stage breast cancer

Shoshana M Rosenberg<sup>1</sup>, Yue Zheng<sup>1</sup>, Philip Poorvu<sup>1</sup>, Kathryn Ruddy<sup>2</sup>, Rachel Gaither<sup>1</sup>, Rulla Tamimi<sup>3</sup>, Lidia Schapira<sup>4</sup>, Jeffrey Peppercorn<sup>5</sup>, Steven Come<sup>6</sup>, Virginia Borges<sup>7</sup> and Ann Partridge<sup>1</sup>. <sup>1</sup>Dana-Farber Cancer Institute, Boston, MA; <sup>2</sup>Mayo Clinic, Rochester, MN; <sup>3</sup>Weill Cornell Medicine, New York, NY; <sup>4</sup>Stanford Cancer Institute, Stanford, CA; <sup>5</sup>Massachusetts General Hospital, Boston, MA; <sup>6</sup>Beth Israel Deaconess Medical Center, Boston, MA; <sup>7</sup>University of Colorado Cancer Center, Aurora, CO

**Background:** Young age at diagnosis is an independent risk factor for recurrence and death from breast cancer (BC), with the greatest impact of young age demonstrated in hormone receptor positive (HR+) disease. Younger women are less likely to be adherent to endocrine therapy (ET), which may contribute to disparate outcomes. **Methods:** As part of a prospective cohort that enrolled women with BC diagnosed at age  $\leq 40$  between 2006-2016, we identified women with HR+, Stage I-III BC. Serial surveys with items assessing socio-demographic and treatment information including medication use are administered 1-2 times per year. Medical record review was used to ascertain stage and HR status and to confirm recurrent disease (locoregional, distant, or new primary breast cancer). Women who initiated ET but discontinued it  $< 5$ -years post-diagnosis without resumption were classified as non-persistent. Univariable and multivariable regression models were fit to identify predictors of non-persistence and recurrence. **Results:** Among 607 women who initiated ET (median age at diagnosis: 36, range: 17-40; 38%, 45%, 17% were Stage 1, 2, and 3, respectively). 16% (99/607) were non-persistent, of whom 30% (30/99) discontinued ET  $\leq 2$  years post-diagnosis and over half had discontinued (54%, 54/99) by 3 years. In multivariable regression, those who were younger at diagnosis (age  $\leq 30$  vs. 36-40: OR: 3.39, 95% CI: 1.84-6.24; age 31-36 vs. 36-40: OR: 2.81 95% CI: 1.70-4.64) were more likely to discontinue ET while those with a higher stage at diagnosis were less likely to discontinue ET (Stage 2 vs. 1: OR: 0.46, 95% CI: 0.29-0.74; Stage 3 vs 1: OR: 0.32, 95% CI: 0.15-0.68). At a median follow-up time from diagnosis of 7.8 years (range 1-13 years), 15% of women (88/607) recurred or developed a new primary BC at a median time from diagnosis of 3.5 years (range 1-12 years). Of these, 66% (58/88) were distant recurrences, 32% (28/88) loco-regional, and 2% (2/88) new primary BCs. Rates of recurrence were higher among women who were persistent (81/508, 16%) vs. non-persistent (7/99, 7%,  $p=0.02$ ). In multivariable regression, those who were non-persistent were less likely to recur (OR: 0.43, 95% CI: 0.19-0.98) while those with a higher stage were more likely to recur (Stage 3 vs. 1: OR: 2.36, 95% CI: 1.03-5.41). Sociodemographic, patient, and other treatment factors did not predict recurrence. **Conclusions:** Approximately 16% of young women with HR+ BC stop ET earlier than indicated, however non-persistence was not a risk factor for BC recurrence a median of 8 years following diagnosis in our cohort. Importantly, women with higher risk disease who are likely to benefit most from adherence to ET were less likely to discontinue treatment. Extended follow-up will further inform the impact of non-persistence on the incidence of late recurrences for which women with HR+ BC are at increased risk.

Publication Number: PS10-07

Pathologic complete response and 3-year survival with or without pertuzumab using real-world data of stage II and III HER2-positive breast cancer

Anna van der Voort<sup>1</sup>, Marte Liefwaard<sup>1</sup>, Mette van Ramshorst<sup>2</sup>, Erik van Werkhoven<sup>1</sup>, Astrid Scholten<sup>1</sup>, Jelle Wesseling<sup>3</sup>, Marie-Jeanne Vrancken Peeters<sup>1</sup>, Linda de Munck<sup>4</sup> and Gabe Sonke<sup>1</sup>. <sup>1</sup>Netherlands Cancer Institute, Amsterdam, Netherlands<sup>2</sup>Onze Lieve Vrouwe Gasthuis, Amsterdam, Netherlands<sup>3</sup>Leiden University Medical Center, Leiden, Netherlands<sup>4</sup>the Netherlands Comprehensive Cancer Organisation, Utrecht, Netherlands

**Background** Pertuzumab greatly improves pathologic complete response (pCR) rates in early stage HER2-positive breast cancer. Long-term benefit of pertuzumab, however, is less well established, as follow-up of the NEOSPHERE and APHINITY trials did not show clear improvement in overall survival, although patients with high risk of recurrence (e.g. node positive) appeared to benefit. Since its long-term benefit remains uncertain, we compared outcome of patients treated with or without pertuzumab in a quasi-random experiment using real-world data.

**Methods** We identified all patients with stage II-III HER2-positive breast cancer in the Netherlands treated with neoadjuvant trastuzumab containing chemotherapy between November 2013 and January 2016 from the nationwide Netherlands Cancer Registry. During this period, reimbursement of pertuzumab in the Netherlands was pending and pertuzumab was only available as trial medication for patients in 37 hospitals that participated in the TRAIN-2 study. This setting created a unique opportunity to compare two quasi-random cohorts of patients treated with or without pertuzumab. We used logistic regression analysis to evaluate the association between pertuzumab use and pCR (ypT0/is, ypN0) and Kaplan-Meier estimates and Cox regression analysis for the association with overall survival (OS). Multivariate analyses included age, cT-status, cN-status, hormone receptor (HR) status and grade. Multiple imputation was used to impute missing data for multivariate analysis.

**Results** We identified 1,124 eligible patients of whom 453 (40%) had received pertuzumab. Baseline characteristics were comparable with and without pertuzumab: 61% of tumors were cT2, 22% cT3, 66% were node positive and 62% ER and/or PR-positive. Grade was missing for 17% in patients treated with and 46% in patients treated without pertuzumab and therefore imputed. PCR in breast and axilla could be determined in 1,091 patients. Pertuzumab use improved pCR rates (65% vs 41%, adjusted odds ratio [aOR] 3.01; 95% confidence interval [CI] 2.29-3.97; p<0.001). At a median follow-up of 59 months (IQR 53-66) 23 deaths had occurred in the pertuzumab group and 68 in the non-pertuzumab group (3-year OS 98% vs 95%; adjusted hazard ratio [aHR]: 0.61; 95% CI:0.38-1.00, p=0.048). Pertuzumab benefit appeared largest in ER/PR negative and cN+ tumors, although the number of events in each subgroup was too small for formal comparisons. Complete-case analysis showed similar aHRs, but with broader 95% confident intervals.

	pCR (%)		3-yr OS (%)		aHR (95%CI)
	Ptz	no Ptz	Ptz	no Ptz	
Overall	65%	41%	98%	95%	0.61 (0.38-1.00)
HR-positive	51%	32%	98%	97%	0.70 (0.36-1.33)
HR-negative	86%	55%	97%	92%	0.54 (0.26-1.13)
cN0	71%	46%	99%	100%	0.54 (0.14-2.00)
cN+	62%	38%	97%	93%	0.65 (0.39-1.09)

**Conclusion** This real-world quasi-experiment confirms the efficacy of pertuzumab to achieve a pCR in stage II and III HER2-positive breast cancer. In addition, these data suggest a small absolute overall survival benefit with pertuzumab, most prominently in hormone receptor negative and node positive tumors. Despite the unique setting of two quasi-random cohorts treated with or without pertuzumab and very similar baseline characteristics, residual confounding cannot be fully excluded. Breast cancer specific evaluation and translational work including central revision of tumor grade for missing cases is pending.

Predictors of 10-year overall survival in patients with breast cancer

Nadeem Bilani, Leah Elson, Hong Liang, Elizabeth Elimimian and Zeina Nahleh. Cleveland Clinic Florida, Weston, FL

**Background:** The combination of mass screening programs and improved, targeted therapies have led to a substantial increase in the number of breast cancer (BC) survivors. Despite a growing majority of patients surviving beyond 5 years, few studies have examined prognostic factors associated with 10-year overall survival (OS) in breast cancer.

**Methods:** We conducted a retrospective analysis of patients with BC using the *National Cancer Database* (NCDB). Our dataset documents survival leading up to and including the year 2016. Thus, to evaluate factors associated with 10-year OS, we included patients diagnosed between 2004-2006. We described sociodemographic and clinicopathologic characteristics of this cohort using frequencies/percentages. Variables were included in a multiple logistic regression model predicting 10-year OS, and considered statistically significant to a p-value <0.001, due to the large sample size.

**Results:** A total of n=515,610 patients with BC were analyzed. The age distribution included n=125,657 (24.4%) <50 years, n=256,003 (49.7%) between 50-70 years, and n=133,950 (26.0%) >70 years. N=440,048 (87.6%) were White, n=52,220 (10.4%) were Black, and n=9872 (2.0%) were Asian. 10-year OS by AJCC clinical stage was: 54.5% for patients diagnosed at stage 0, 50.0% at stage I, 42.4% at stage II, 29.7% at stage III, and 6.1% at stage IV. Sociodemographic variables significantly associated with 10-year OS were: age, race, income, insurance status, and facility type (Table 1). Black patients were less likely to exhibit 10-year OS compared to White patients (40.7% compared to 48.0%, OR 0.821, 95% CI 0.786-0.858, p<0.001). Patients with an estimated annual income >\$46,000 were more likely to experience 10-year OS compared to those with an annual income <\$30,000 (50.5% compared to 41.8%, OR 1.126, 95% CI 1.076-1.178, p<0.001). Compared to patients treated at community cancer programs (CPs), those treated at comprehensive community CPs were more likely to experience long-term survival (47.7% versus 43.8%, OR 1.125, 95% CI 1.077-1.175, p<0.001). Clinicopathologic factors significantly associated with 10-year OS were: Charlson/Deyo comorbidity index, AJCC clinical staging, tumor grade, estrogen receptor (ER) status, progesterone receptor (PR) status, the use of surgery, radiation, chemotherapy, hormonal therapy, and immunotherapy (Table 1). Compared to patients with well-differentiated tumors, those with moderately-differentiated (OR 0.889, 95% CI 0.860-0.919, p<0.001) and poorly-differentiated tumors (OR 0.782, 95% CI 0.752-0.812, p<0.001) had lower long-term survival. ER positivity was associated with a lower likelihood of 10-year OS, while PR positivity was associated with a higher likelihood of 10-year OS. However, effect sizes for receptor status are small (ORs between 0.90-1.10), and thus may not have clinical relevance despite statistical significance. HER2 status was not documented in the NCDB before 2010, so its prognostic value could not be evaluated. Tumor histology was not significantly associated with 10-year OS.

**Conclusions:** 10-year OS data for BC is scarce. We found high rates of 10-year OS, particularly in patients diagnosed at early stages. This is welcomed news; emphasizing the real-world impact of population screening. As anticipated, racial disparities and social determinants of health remain relevant prognosticators of long-term survival.

Trastuzumab deruxtecan (T-DXd; DS-8201) combinations in patients with HER2-positive advanced or metastatic breast cancer: A phase 1b/2 open-label, multicenter, dose-finding and dose-expansion study (DESTINY-Breast07)

### Background

HER2-targeted therapies have substantially improved survival in patients with HER2-positive (immunohistochemistry [IHC] 3+ or IHC2+/in situ hybridization-positive) advanced or metastatic breast cancer. Despite significant advancements, patients ultimately develop resistance to standard-of-care HER2-targeted therapies. Therefore, a need remains for regimens that prolong disease control and survival in these patients. T-DXd is a HER2-targeted antibody-drug conjugate containing a linker selectively cleaved in tumor cells and a topoisomerase I inhibitor payload with high cell-membrane permeability. T-DXd has been approved by the FDA for use in adult patients with unresectable or metastatic HER2-positive breast cancer who have received  $\geq 2$  prior anti-HER2-based regimens in the metastatic setting and by Japan's Ministry of Health, Labour and Welfare for use in patients with HER2-positive unresectable or recurrent breast cancer after prior chemotherapy (use limited to patients refractory to or intolerant of standard treatments). Results from the phase 2 DESTINY-Breast01 trial demonstrated an objective response rate (ORR) of 60.9% per independent central review and a median progression-free survival (PFS) of 16.4 months in a heavily pretreated population (median of 6 prior lines of therapy) of patients with HER2-positive advanced or metastatic breast cancer treated with T-DXd (Modi S, et al. *N Engl J Med*. 2020;382:610-621). Here, we describe a phase 1b/2 trial evaluating the safety and preliminary antitumor activity of T-DXd combinations in patients with HER2-positive advanced or metastatic breast cancer.

### Study Description

DESTINY-Breast07 is a global, multicenter, open-label, phase 1b/2 dose-finding and dose-expansion trial designed to evaluate the safety, tolerability, and preliminary antitumor activity of T-DXd in combination with other therapies in patients with HER2-positive advanced or metastatic breast cancer. Patients will be enrolled globally at  $\approx 110$  sites in  $\approx 10$  countries. The study will initially consist of 4 combination modules, each with 2 parts: dose finding (part 1) and dose expansion (part 2), and a T-DXd monotherapy module (part 2 only). The 4 combination modules will enroll patients for treatment with (1) T-DXd + durvalumab, (2) T-DXd + pertuzumab, (3) T-DXd + paclitaxel, or (4) T-DXd + durvalumab + paclitaxel. New combination treatment modules may be added via protocol amendment. Part 1 of each combination module will enroll patients who have had disease progression on  $\geq 1$  prior line of therapy in the metastatic setting. In part 2, patients who have received no prior therapy for metastatic disease will be randomized to receive a combination regimen or T-DXd monotherapy. Antitumor activity will be evaluated based on investigator assessment according to RECIST 1.1. The primary endpoint is to assess the safety and tolerability of T-DXd combinations and determine the recommended phase 2 doses. Secondary endpoints include ORR, PFS, duration of response, overall survival, pharmacokinetics, and immunogenicity.

Metastatic breast cancer patients' preferences and expectations for oral chemotherapy

Alyssa Jaisle<sup>1</sup>, Erica E. Fortune<sup>1</sup>, Jamie Jacobs<sup>2</sup>, Claire Saxton<sup>3</sup>, Jemeille Ackourey<sup>1</sup> and Alexandra K. Zaleta<sup>1</sup>. <sup>1</sup>Cancer Support Community, Philadelphia, PA; <sup>2</sup>Harvard Medical School, Boston, MA; <sup>3</sup>Cancer Support Community, Washington, DC

**Introduction:** As options for cancer treatment continue to expand, there is a growing need to understand patients' preferences for treatment options and their tolerance for related side effects. The aims of the present analysis were to 1) describe metastatic breast cancer (MBC) patient and survivor perceptions of intravenous (IV) and oral chemotherapy modalities, and 2) explore the relationship between modality perceptions, tolerance for side effects, and current levels of physical and social functioning.

**Methods:** 129 MBC patients were recruited to participate in an online research survey about expectations and preferences for oral and IV chemotherapy treatments. Respondents were also asked to report their willingness to tolerate various chemotherapy side effects using multi-item Likert scales. Quality of life was assessed using two Patient-Reported Outcomes Measurement Information System (PROMIS-29v2.0) subscales, Physical Function and Ability to Participate in Social Roles and Activities, with transformed T scores used for purposes of interpretation.

**Results:** Respondents were 91% White and 6% Black with ages ranging from 28 to 77 years old ( $M=58.0$ ,  $SD=10.1$ ). Time since diagnosis ranged from <1 to 32 years ( $M=11.2$ ,  $SD=6.4$ ). Almost half of respondents (46%) reported having received both oral and IV chemotherapy at some point during their treatment history, while 36% reported having received only IV and 11% reported having received only oral chemotherapy. When assuming equal effectiveness of the two treatments, the majority of respondents stated a preference for oral chemotherapy (72%) versus IV chemotherapy (11%), while 17% stated no preference. The most frequently expected benefits of oral chemotherapy included ease of managing medication at home (76%), less need to travel to treatment center (81%), and freedom to travel or work while on treatment (73%). The severe (grade III/IV) side effects participants were least willing to tolerate (*not at all or not very willing*) included hand-foot syndrome (58%), diarrhea (58%), neuropathy (61%), and nausea (57%).

Controlling for treatment history, participants who indicated a preference for oral chemotherapy were more likely to have higher expectations for oral chemo ( $t=-2.69$ ,  $p<.01$ ) and better physical ( $t=-2.06$ ,  $p<.05$ ) and social functioning ( $t=-2.27$ ,  $p<.05$ ). Additionally, they reported less willingness to tolerate key side effects: nausea ( $t=2.40$ ,  $p<.05$ ) and neuropathy ( $t=2.10$ ,  $p<.05$ ).

**Conclusion:** Many MBC patients report a preference for oral chemotherapy and believe it will confer benefits including fewer disruptions to work and life. Those who prefer oral chemotherapy are less willing to tolerate side effects and report better social and physical functioning. As options for treatment continue to expand, it is important to understand the shifting perceptions of available treatments among patients. Patients' attitudes, beliefs, and behaviors can and do influence treatment decision-making and adherence. Additionally, when patients have a better understanding of the treatments they are being offered, they are more likely to have a proactive role in the treatment decision-making process and are less likely to experience decision regret. Therefore, it is key to not only ensure patients are involved in treatment decision-making, it is imperative to ensure that they are prepared with the tools to engage in shared decision-making.

Elderly breast cancer patients benefit from surgery according to guidelines

Mathias Kvist Mejdahl, Mette Haulund Christensen, Birgitte Paaschburg Nielsen and Tove Holst-Filtenborg Tvedskov. Herlev and Gentofte University Hospital, Denmark, Copenhagen, Denmark

**Background:** With a globally increasing population of otherwise healthy people above 70 years, more knowledge on treatment and prognosis of breast cancer patients in this group is needed. In Denmark, the Danish Breast Cancer Group describes national treatment guidelines for diagnostic work-up and surgical and oncological treatment of all patients with primary invasive breast cancer with no upper age limit. Still, many patients  $\geq 70$  years, regardless of comorbidity, do not adhere to treatment guidelines, often receiving less imaging and less treatment than recommended. The aims of the present study were to examine, among patients  $\geq 70$  years with primary invasive breast cancer, whether endocrine treatment only, resulted in an inferior breast cancer related survival compared to standard surgical and oncological treatment, to examine whether patients treated with breast conserving surgery (BCS) with no preoperative imaging had a higher risk of local recurrence than patients receiving preoperative imaging, and finally to examine whether clinically node negative patients had a higher risk of regional recurrence if they did not receive axillary staging. **Methods:** All women,  $\geq 70$  years, diagnosed with primary invasive breast cancer and treated at the Department of Breast Surgery at Herlev Hospital, Denmark, from 2000-2007 were included. Patients were prospectively registered in a hospital-based database. Differences in standardized mortality ratios (SMR) between patients treated by surgery, endocrine therapy only, or endocrine therapy followed by surgery were estimated by Poisson regression and evaluated by rate ratios. Differences in local recurrence between patients with and without preoperative imaging before BCS, and in regional recurrence between surgically treated patients with and without a sentinel lymph node biopsy, with axillary clearance in case of a positive sentinel node, excluding clinically node positive patients directly treated with an axillary clearance, were estimated by Cause Specific Hazards Models and evaluated by cause specific hazard ratios (HR). Adjustments were made for age, comorbidity, adjuvant radiotherapy, tumor size, time since diagnosis, and time period. **Results:** In total 1,142 patients were included in the study. The median age was 77 years. For overall mortality, median follow-up was 7.80 years, with 795 (69.6%) dying during follow-up, and for recurrence 6.25 years. 52 were registered with local recurrence and 39 with regional recurrence. Patients who received only endocrine therapy had a significantly higher SMR than patients treated with primary surgery (adj. RR=2.57; 95% CI: 2.01-3.30), while patients who received endocrine therapy followed by later surgery did not (RR=1.23; 95% CI: 0.91-1.66). 253 out of 580 patients with BCS (43.6%) did not have preoperative imaging. Patients without imaging did not have a higher risk of local recurrence compared to patients with preoperative imaging (adj. HR=1.14; 95% CI: 0.36-3.67). 13 out of 197 surgically treated patients without axillary surgery (6.8%) had regional recurrence, while only 7 out of 428 patients (1.6%) with axillary staging by sentinel node biopsy had regional recurrence. This difference was significant (adj. HR 4.68 95% CI=1.53-14.37).

**Conclusions:** In the present study we have shown that women  $\geq 70$  years, diagnosed with primary invasive breast cancer, have a higher mortality if they are not surgically treated, and they have a higher risk of regional recurrence if they are not offered axillary staging. The study emphasizes that unless elderly patients have comorbidity contraindicating surgery, they should be treated according to guidelines.

Jo Chien<sup>1</sup>, Judy Boughey<sup>3</sup>, Heather Han<sup>4</sup>, Anne Wallace<sup>5</sup>, Heather Beckwith<sup>6</sup>, Minetta Liu<sup>3</sup>, Christina Yau<sup>1</sup>, E. Paul Wileyto<sup>7</sup>, Lamorna Brown Swigart<sup>1</sup>, Jane Perlmutter<sup>1</sup>, Lauren Bayne<sup>2</sup>, Shannon Deluca<sup>2</sup>, Stephanie Yee<sup>7</sup>, Erica Carpenter<sup>2</sup>, Laura Esserman<sup>1</sup>, John Park<sup>1</sup>, Lewis Chodosh<sup>8</sup> and Angela DeMichele<sup>7</sup>. <sup>1</sup>University of California San Francisco, San Francisco, CA; <sup>2</sup>University of Pennsylvania, Philadelphia, PA; <sup>3</sup>Mayo Clinic, Rochester, MN; <sup>4</sup>Moffitt Cancer Center, Tampa, FL; <sup>5</sup>University of California San Diego, San Diego, CA; <sup>6</sup>University of Minnesota, Minneapolis, MN; <sup>7</sup>University of Pennsylvania, Philadelphia, PA; <sup>8</sup>University of Pennsylvania, Philadelphia, CA

**Background:** Disseminated tumor cells (DTCs) in bone marrow detected after treatment may represent occult residual disease. We enumerated DTCs after neoadjuvant chemotherapy (NACT) in patients (pts) diagnosed with high-risk early stage breast cancer and examined the relationship of these cells with response and survival. **Methods:** I-SPY SURMOUNT is a sub-study of the I-SPY 2 TRIAL (NCT01042379). Pts enrolled on I-SPY 2, who signed consent for this sub-study, had bone marrow aspirates (BMA) collected after NACT at the time of surgery. DTCs were isolated and enumerated from BMA using immunomagnetic enrichment/flow cytometry (IE/FC). DTCs were defined as EPCAM-positive and CD45-negative nucleated cells. Samples were considered positive using a predetermined threshold of >4 DTCs per mL (Magbanua et al, unpublished data). Pathologic response was assessed using the residual cancer burden (RCB) method at local sites, and pts underwent standard adjuvant therapy if indicated and follow up for recurrence events and death. Relationship of DTCs with clinicopathologic variables was examined using Chi-squared test. Group means were compared using t tests. The log-rank test was used to compare survival curves. **Results:** A total of 73 patients were enrolled, 51 of whom had successful DTC assessment. The median DTC per mL was 4 (interquartile range 1.2-11.6). 24/51 (47%) were DTC-positive. Clinical characteristics by DTC status are shown in the table. DTC-positive pts were significantly younger (p=0.02) and had larger pretreatment tumors (longest diameter by magnetic resonance imaging) compared to DTC-negative pts (p=0.032). DTCs were not associated with receptor subtype. Thirty pts (41%) achieved a pathologic complete response (pCR). DTCs were not associated with pCR (p= 0.166); however, DTC-positive patients were significantly more likely to have residual cancer (RCB-II/III) after NACT compared to DTC-negative patients (OR 3.3, p=0.037). Median follow up of this cohort was 2.8 years (range: 0.9-4.8). Interim survival analysis showed that DTCs were not significantly correlated with EFS (p=0.6) or DRFS (p=0.41). **Conclusions:** Detection of DTCs at surgery after NACT is significantly more common in young patients, those with larger tumors, and those with residual disease at surgery. While these associations suggest higher risk for later recurrence, larger studies and longer follow up are necessary to determine if DTCs add prognostic value over pathologic evaluation alone for pts receiving NACT.

**Background:** Rintodestrant is an orally bioavailable, potent and selective estrogen receptor degrader (SERD) that inhibits estrogen receptor (ER) gene transcription, degrades the ER, and delays tumor proliferation in preclinical models. Preliminary results from Part 1 dose escalation (200-1000 mg once daily) demonstrated that rintodestrant has a favorable safety profile and encouraging antitumor activity in patients (pts) with heavily pretreated ER+/HER2- advanced breast cancer (ABC) (Dees et al., ESMO 2019 [abstract #3587]). Here, we report the pharmacodynamic (PD) analysis in peripheral blood and tumor biopsies from pts who received rintodestrant in Part 1 and 2 (600 and 1000 mg dose expansion) to characterize the pt population and mechanisms of response. **Methods:** This Phase 1, first-in-human, open-label study evaluated rintodestrant in women with ER+/HER-ABC after progression on endocrine therapy. PD analysis included inhibition of ER target engagement with <sup>18</sup>F-fluoroestradiol positron emission tomography (FES-PET), mutational profiling (cell-free DNA [cfDNA]), and circulating tumor cell (CTC) enumeration. Tumor biopsies sampled at baseline and 6 weeks on treatment were evaluated for ER degradation (immunohistochemistry [IHC]) and proliferation (Ki67, IHC) to understand the on-target effects of rintodestrant. **Results:** As of May 13, 2020, 67 pts had been treated. FES-PET data were obtained in 14 pts and showed a decrease in all pts, with maximum standard uptake values (SUVmax) ranging from 70% to 98% after 4 weeks of rintodestrant monotherapy across all doses. Fifty-nine pts were tested for cfDNA at baseline; 95% (n = 56) harbored ≥1 somatic variant (median = 3 mutations per pt). Among pts with somatic variants, 41% had *ESR1* mutations, with *D538G* being the most common (58%). Additionally, 46% and 42% of pts harbored mutations in *TP53* and *PIK3CA*, respectively, and 10% had mutations in both *ESR1* and *PIK3CA*. Similar clinical benefit rates were observed in wild-type vs *ESR1* and/or *PIK3CA* mutant tumors. An analysis of change of variant allele fraction (VAF) in 55 pts between baseline and 2 weeks of treatment revealed that 58% had a decrease in mean VAF, with a decrease in *ESR1* VAF in 16/20 pts that had *ESR1* mutations at baseline. Furthermore, of 24 pts who had samples collected at baseline and progression, 16 (67%) developed additional variants (median [range]: 2 [1, 15]), including *EGFR*, *ERBB2*, *TP53*, and *ESR1*. CTC analysis (n = 45) showed the mean value of Epi+CD45- CTCs decreased from 2.8 cells/mL to 1.8 cells/mL after 8 weeks of treatment. Tumor biopsies were collected in 9 pts (5 received 600 mg and 4 received 1000 mg) at baseline and 6 weeks on treatment. Of the 7/9 pts that had a decrease in the ER H-score (median [range]: -27.8% [-33.8%, -3.4%]), 4 had ≥1 variant in *ESR1* at baseline. Overall, 4 pts had a decrease in Ki67, with reductions mostly observed in pts who received 600 mg rintodestrant. Additional analyses, including correlations with clinical response, are ongoing and will be presented. **Conclusions:** Rintodestrant demonstrated robust ER target engagement on FES-PET, as well as substantial decreases in ER H-score, cfDNA VAF, and Epi+CD45- CTCs. These data, along with promising clinical benefit in pts with heavily pretreated ER+/HER2- ABC, regardless of *ESR1* or *PIK3CA* mutation status, warrant additional investigation of rintodestrant (NCT03455270).

Ribociclib + letrozole in patients with hormone receptor-positive (HR+), human epidermal growth factor receptor-2-negative (HER2-) advanced breast cancer (ABC) and central nervous system metastases: Subgroup analysis of the phase IIIb CompLEEment-1 trial

Paul Cottu<sup>1</sup>, Michelino De Laurentiis<sup>2</sup>, Paolo Marchetti<sup>3</sup>, Luigi Coltelli<sup>4</sup>, Nadia Califaretti<sup>5</sup>, Marc Debled<sup>6</sup>, Shekar Pati<sup>7</sup>, Ella Evron<sup>8</sup>, Francois Duhoux<sup>9</sup>, Lakshmi Menon-Singh<sup>10</sup>, Jiwen Wu<sup>10</sup>, Katie Zhou<sup>10</sup> and Javier Salvador Bofill<sup>11</sup>. <sup>1</sup>Curie Institute, Paris, France<sup>2</sup>National Cancer Institute "Pascale Foundation", Naples, Italy<sup>3</sup>Sapienza University of Rome, Rome, Italy<sup>4</sup>Felice Lotti Hospital, Pontedera, Italy<sup>5</sup>Grand River Hospital, Kitchener, ON, Canada<sup>6</sup>Bergonie Institute, Bordeaux, France<sup>7</sup>Bangalore Institute of Oncology, Bangalore, India<sup>8</sup>Oncology Institute, Kaplan Medical Center, Rehovot, Israel<sup>9</sup>Saint-Luc University Clinics, Brussels, Belgium<sup>10</sup>Novartis Pharmaceuticals, East Hanover, NJ;<sup>11</sup>Virgen Del Rocio University Hospital, Institute of Biomedicine of Seville, Seville, Spain

**Background:** Approximately 10-30% of patients (pts) with metastatic breast cancer (BC) are diagnosed with central nervous system (CNS) metastases, which are a major cause of morbidity and mortality, and are associated with a poor prognosis. Due to improving diagnostics and treatments in BC, and therefore longer pt survival, more CNS metastases in breast cancer pts are readily detected. However, pts with CNS metastases are often excluded from clinical trials. Ribociclib (RIB), an oral, selective cyclin-dependent kinase 4/6 inhibitor, is approved for use in combination with endocrine therapy (ET) in women with HR+, HER2- ABC. Here, we present a subgroup analysis of pts with CNS metastases at baseline from the Core Phase of CompLEEment-1 (NCT02941926), a Phase IIIb trial of RIB in combination with letrozole (LET) in pts with HR+, HER2- ABC. The eligibility criteria for this study allowed a broader and more diverse pt population than those of previous Phase III trials of RIB + LET, to reflect a typical real-world clinical setting. **Methods:** CompLEEment-1 included women of any menopausal status and men with HR+, HER2- ABC treated with ≤1 line of prior chemotherapy and no prior hormonal therapy for advanced disease. Pts received RIB (600 mg QD, 3 weeks on/1 week off) in combination with LET (2.5 mg QD, continuous). Men and premenopausal women received a luteinizing hormone-releasing hormone agonist (3.6 mg goserelin or 7.5 mg leuprolide, Q28D). This subgroup analysis assessed the primary outcomes (safety and tolerability) and secondary outcomes of time to progression (TTP), overall response rate (ORR), and clinical benefit rate (CBR) in pts with CNS metastases. **Results:** At the data cutoff date (November 8, 2019), 51 pts with CNS metastases (1.57%; total pt population N = 3,246) had been evaluated: median age was 56.0 years, 30 (58.8%) pts were postmenopausal, and ECOG PS <2 was observed in 49 (96.1%) pts. Median duration of exposure to RIB was 16.8 months. Adverse events (AEs) were reported in 49 (96.1%) pts; with all but one experiencing a treatment-related AE. Grade ≥ 3 AEs were reported in 38 (74.5%) pts; serious AEs were reported in 8 pts. There was 1 treatment-related fatal AE (sepsis). The most common all-grade AEs were neutropenia (66.7%), nausea (39.2%), and vomiting (29.4%). The most common grade ≥ 3 AEs were neutropenia (51.0%), leukopenia (13.7%), and increased alanine aminotransferase (5.9%), aspartate aminotransferase (5.9%), and gamma-glutamyltransferase (5.9%). Overall, 19 pts (37.3%) had ≥ 1 dose reduction of RIB, 12 (23.5%) due to AEs, and 32 pts (62.7%) permanently discontinued treatment, 6 (11.8%) due to AEs. Median TTP was not estimable (NE) (95% CI, 15.5-NE) in this subgroup analysis; with an event-free probability of 56.1% (95% CI, 39.3-69.8) at 30 months. For the 35 pts with measurable disease and CNS metastases at baseline, ORR was 42.9% (95% CI, 26.3-60.6%) and CBR was 62.9% (95% CI, 44.9-78.5). **Conclusions:** This subgroup analysis from CompLEEment-1 supports the use of RIB + LET in pts with CNS metastases, who typically have poor outcomes and are frequently excluded from clinical trials. Efficacy results support the use of RIB + LET in HR+, HER2- ABC in a close to real-world setting. The safety profile associated with RIB + LET was manageable, with few pts discontinuing treatment due to AEs, consistent with previous Phase III trials of RIB + LET.

Blocking H3K27me3 methyltransferase or demethylase activity impacts epithelial-mesenchymal plasticity, suppressing tumor growth and metastasis

Joseph Taube<sup>1</sup>, Provas Das<sup>1</sup>, Kelsey Johnson<sup>1</sup>, John Landua<sup>2</sup>, Lacey Dobrolecki<sup>2</sup> and Michael Lewis<sup>2</sup>. <sup>1</sup>Baylor University, Waco, TX; <sup>2</sup>Baylor College of Medicine, Houston, TX

**Background:** Epithelial-mesenchymal plasticity (EMP) is key feature driving breast cancer metastasis. Induction of epithelial-mesenchymal transition (EMT) increases the migratory and invasive capabilities associated with metastatic competence and endows tumors with stem cell properties necessary for initiating tumor growth in the metastatic site. Mesenchymal-epithelial transition (MET) has been increasingly recognized as an integral part of the latter stages of the metastatic cascade as it is required for re-epithelialization, proliferation, and expansion of micro-metastases into macro-metastases with a histopathology similar to that of the primary tumor. Interconversion between epithelial and mesenchymal states requires remodeling of the epigenome—including addition and erasure of H3K27me3, especially near gene promoter and enhancers. Deposited by EZH1 or EZH2, members of the PRC2 complex, H3K27me3 is associated with gene silencing. However, gene activation occurs upon H3K27me3 demethylation to H3K27me1, mediated by KDM6A or KDM6B, members of the Compass-like complex. **Results:** Based upon our prior work, which showed EMT-driven re-distribution of H3K27me3 onto and off of genes that are critical regulators of cell fate and differentiation, we asked whether inhibition of H3K27me3-directed methyltransferases and demethylases could impact breast cancer. We found that the EZH2 inhibitor, EPZ011989, reduced EMP by preventing recovery of epithelial traits in cells exposed to TGFβ, but did not, on its own, induce EMT. However, we found that either inhibition of the H3K27me3-directed demethylases, KDM6A and KDM6B, using GSK-J4 or shRNA knockdown, induced EMT and promoted cellular migration. Thus, manipulation of either EZH2 or KDM6A/B affected the capacity of cells to repress or activate expression of genes known to exhibit dynamic gain or loss of H3K27me3 during EMT. Given the effects of inhibitors of H3K27-targeted enzymes on EMP, we sought to ascertain their impact on tumor growth and metastasis. Using a GFP-expressing patient-derived xenograft (PDX) model of ER-positive breast cancer, we observed a dose-dependent suppression of primary tumor growth and fewer disseminated tumor cells (DTCs) in response to small molecules targeting H3K27me3 regulators. **Conclusions:** These results indicate that addition and removal of H3K27me3 is critical for maintenance of cell fate and plasticity. Furthermore, targeting this pathway suppresses breast cancer growth and metastasis in a mouse model of ER-positive breast cancer.

Neoadjuvant adriamycin plus cyclophosphamide followed by docetaxel (AC4-D4) vs 5-fluorouracil, epirubicin plus cyclophosphamide followed by docetaxel (FEC3-D3) in stage II or III operable breast cancer : Randomized phase III neo-shorter trial (NCT02001506)

Inhwan Hwang<sup>1</sup>, Jeong Eun Kim<sup>2</sup>, Jae Ho Jeong<sup>2</sup>, Jin-Hee Ahn<sup>2</sup>, Kyung Hae Jung<sup>2</sup>, Byung Ho Son<sup>3</sup>, Sei-Hyun Ahn<sup>3</sup>, Hee Jin Lee<sup>4</sup>, Gyungyub Gong<sup>4</sup> and Sung-Bae Kim<sup>2</sup>. <sup>1</sup>Department of Oncology, Veterans Health Service Medical Center, Seoul, Korea, Republic of <sup>2</sup>Department Oncology, Asan Medical Center, Seoul, Korea, Republic of <sup>3</sup>Department of Surgery, Asan Medical Center, Seoul, Korea, Republic of <sup>4</sup>Department of Pathology, Asan Medical Center, Seoul, Korea, Republic of

**Background:** Two neoadjuvant anthracycline and taxane containing chemotherapy regimens have been widely used. The objective of the study was shorter duration of 6 cycles of FEC3-D3 is comparable to 8 cycles of AC4-D4. **Method:** Enrolled patients (pts) were diagnosed clinically stage II or III breast cancer between November 2012 and December 2015 at Asan Medical Center, Seoul, Korea. Pts were stratified according to hormone receptor and HER2 expression status and randomized 1:1 to AC4-D4 and FEC3-D3 arm. The primary endpoint was pathologic complete response (pCR) and the secondary end points were 3 year disease-free survival (3Y DFS) and toxicities. **Result:** Among 252 pts enrolled, 1pt ineligible for screening; 10 pts discontinued treatment due to progressive disease (7 pts in AC4-D4 arm and 3 pts in FEC3-D3), 17 pts dropped out due to withdrawal of written consent and 2 pts unable to complete study. Two hundred twenty two pts receiving surgery were included for this analysis. Baseline characteristics are well balanced between two arms- median age (47 vs 48), % of TNBC (24% vs 26%) in AC4-D4 (N=126) vs FEC3-D3 arm (N=125) respectively. Baseline median Ki-67 labeling index was 50% (range, 10%-90%). By ITT analysis, pCR was achieved in 18/126 (14.3%) pts of AC4-D4 arm and 15/125 (12.0%) pts in FEC3-D3 arm, respectively ( $p=0.17$ ). According to per protocol, in AC4-D4 arm, 95/103 pts achieved clinical response (6 complete response [CR] and 89 partial response [PR]) and among them 18 pts (17.5%) achieved pCR. In FEC3-D3 arm, 97/119 pts achieved clinical response (4 CR and 93 PR) and among them 15 pts (12.6%) achieved pCR. With a median follow up of 64.1 months, 3Y DFS (77.0% in AC4-D4 vs. 74.9% in FEC3-D3) was comparable between two arms ( $p=0.79$ ). The most common adverse event (AE) was Grade 3/4 neutropenia. 44/126 (34.9%) pts in AC4-D4 arm vs 39/125 (31.2%) pts in FEC3-D3 arm. The most common Grade 3/4 non-hematologic AE was hyperglycemia (3.2%). Dose modification was done in 37/126 (29.4%) pts in AC4-D4 arm and 25/125 (20.0%) pts in FEC3-D3 arm, respectively ( $p=0.09$ ). Multivariate analyses showed that  $\geq 50\%$  of baseline Ki-67 labeling index [hazard ratio (HR) 2.1 (95% confidence interval (CI), 1.20-3.72;  $p=0.009$ )],  $\geq 40\%$  of pre-treatment Ki-67 labeling index reduction after neoadjuvant chemotherapy (NACT) [HR 2.1 (95% CI, 1.20-3.66;  $p=0.01$ )], and  $\geq 4$  lymph node metastases at surgery [HR 2.2 (95% CI, 1.24-3.80;  $p=0.07$ )] were independent predictive factors for 3Y DFS. Of note, in patients with non-pCR,  $\geq 40\%$  reduction of Ki-67 after NACT was associated with better 3Y DFS in luminal type [HR 2.9 (95% CI, 1.51-5.65;  $p=0.001$ )]. **Conclusion:** Both NACT AC4-D4 and FEC3-D3 showed comparable outcomes in terms of pCR, 3 year DFS and toxicities.  $\geq 50\%$  of baseline Ki-67 labeling index and  $\geq 40\%$  reduction of Ki-67 labeling index after NACT were independent for 3Y DFS. Shorter neo-adjuvant FEC3-D3 could be an alternative to AC4-D4 in stage II or III operable breast cancer. **Keywords:** Neoadjuvant, AC followed by docetaxel, FEC followed by docetaxel, operable breast cancer

**Background:** Loss-of-function mutations in genes encoding components of the homologous recombination DNA damage response (DDR) machinery, notably *BRCA1/2*, are associated with tumor sensitivity to poly(ADP-ribose) polymerase inhibitors (PARPi). Little is known about the potential contribution of tumor alterations in non-DDR genes to modulating sensitivity to PARP inhibitors in the clinic. In EMBRACA, the PARPi TALA improved progression-free survival (PFS) (HR [95% CI] 0.54 [0.41-0.71],  $P < 0.001$ ) vs chemotherapy (CT) in germline *BRCA1/2*-mutated HER2-negative locally advanced/metastatic breast cancer.

**Methods:** Baseline tumor tissue from 308 pts (71%; intent-to-treat) was tested by FoundationOne®. To support exploratory identification of tumor gene alterations associated with best vs worst outcomes, pts were mapped into 2 groups: [1] BEST: Pts in TALA arm with OS  $\geq 30$  mo and duration of treatment  $\geq 24$  mo, Pts in CT arm with OS  $\geq 30$  mo; [2] WORST: Pts in TALA or CT arm with a PFS event (PD by Independent Radiological Facility or death)  $\leq 12$  wks. 2 pts had short PFS but long OS and were initially mapped to both groups but then assigned to BEST and excluded from WORST.

**Results:** Exploratory heat map visualizations of known/likely pathogenic genetic alterations defined by the FoundationOne® gene panel were used to assess differences in genetic alterations between BEST and WORST in TNBC and non-TNBC subpopulations, leading to the identification of *MYC* and *RAD21* as commonly altered genes of high interest. Based on these results showing imbalances in tumor amplification events between BEST and WORST outcome pts, Cox regression analysis was used to explore potential associations of *MYC* or *RAD21* amplification with OS across the evaluable ITT population. In TNBC pts receiving TALA, OS was shorter with *MYC* amplification than without [HR (95% CI) 1.877 (1.102, 3.196)]. No such association was evident in TNBC pts receiving CT [HR (95% CI) 0.706 (0.303, 1.643)]. In contrast, for non-TNBC pts receiving TALA, no association with OS was evident for *MYC* amplification versus without [HR (95% CI) 0.603 (0.310, 1.173)], while for pts receiving CT OS was shorter with *MYC* amplification than without [HR (95% CI) 1.917 (1.037, 3.544)]. *RAD21* amplification status was not associated with OS in either TNBC or non-TNBC patients for either treatment arm, although it should be noted that two *RAD21* subgroups were very small ( $n=7$  and  $11$ ; others had  $n \geq 21$ ).

**Conclusions:** Based on these exploratory, retrospective analyses *MYC* amplification was associated with shorter OS in TNBC pts receiving TALA. This may reflect the role of *MYC* in positive regulation of genes involved in homologous recombination such as *RAD51* (Carey et al, Cancer Res 2018;78(3):742-757). *MYC* and *RAD21* are both located at 8q24 and frequently coamplified in breast cancer (eg, Annunziato et al, Nat Commun. 2019;10(1):397), hence the lack of association of *RAD21* amplification with outcome in TNBC suggests that the association of *MYC* amplification with shorter OS seen in pts receiving TALA may be gene-specific. Further investigation is warranted.

Gene expression profiles of Ghanaian and Ethiopian triple-negative breast tumors

Rachel Martini<sup>1</sup>, Endale Gebregzabher<sup>1</sup>, Princesca Dorsaint<sup>1</sup>, Timothy Chu<sup>2</sup>, Kanika Arora<sup>2</sup>, Lee Gibbs<sup>3</sup>, Zarko Manojlovic<sup>3</sup>, Nicolas Robine<sup>2</sup>, Andrea Sboner<sup>1</sup>, Olivier Elemento<sup>1</sup>, John Carpten<sup>3</sup>, Lisa Newman<sup>1</sup> and Melissa Davis<sup>1</sup>. <sup>1</sup>Weill Cornell Medical College, New York City, NY; <sup>2</sup>New York Genome Center, New York City, NY; <sup>3</sup>University of Southern California, Los Angeles, CA

**Background:** Triple-negative breast cancer (TNBC) remains the most aggressive molecular subtype of breast cancer, with worse survival outcomes compared to other breast cancer subtypes. TNBC prevalence is highest among women of African descent worldwide, and through our previous work we have established a connection between West African ancestry (WAa) and higher rates of TNBC. Specifically, we have shown that prevalence rates of TNBC among West African and African American women are similar and higher than that of East African and White American women. We have also shown that quantified African ancestry is higher among TNBC cases compared to non-TNBC cases. To determine the influence African ancestry on the TNBC tumor environment, we sought to determine any differences in gene expression profiles of Ghanaian (West African) compared to Ethiopian (East African) women. **Methods:** RNA was extracted and sequenced from a pilot cohort of archival FFPE tumor tissue among Ghanaian ( $n = 19$ ) and Ethiopian ( $n = 20$ ) women. RNAseq reads were aligned, and quality of alignments were assessed, where de-duplicated samples with counts above 10M reads were included in the final analysis. Genetic ancestry was quantified by obtaining SNVs called from the RNAseq alignments, using GATK best practices. Differentially expressed genes lists were determined comparing Ghanaian vs. Ethiopian TNBC tumors, and also by identifying genes that were associated with increasing African ancestry. These gene lists, and log-fold change between comparison groups, were used as input for Ingenuity Pathway Analysis (IPA), to identify canonical pathways and *de novo* networks that are specific to Ghanaian or Ethiopian TNBC tumors. **Results:** Using 1KG populations as our reference to quantify genetic ancestry, we show that Ghanaian samples have >94% AFR ancestry, specifically matching population groups representative of WAa. The Ethiopian samples showed between 37-48% AFR ancestry, primarily represented by East African groups. Interestingly, there seems to be a significant proportion of EUR ancestry among the Ethiopians samples (30-49%), primarily represented by Italian ancestry. We have conducted the differential gene expression analysis in two ways. First, we have compared gene expression profiles between Ghanaian and Ethiopian tumors. In our preliminary analysis, we identified >600 genes ( $p < 0.01$ ) that were differentially expressed between Ghanaian and Ethiopian TNBC tumors. Second, we used AFR ancestry as a continuous variable, where we conducted a linear regression analysis to identify genes associated with AFR ancestry. We identified >900 genes associated with AFR ancestry ( $p < 0.01$ ), and this gene signature distinguished Ghanaian from Ethiopian tumors in an unsupervised hierarchical clustering. In comparing the differentially expressed gene lists from these two approaches, approximately 200 genes were shared, indicating the distinct value of both analyses. Using these gene lists as input for IPA analysis, we have begun to identify canonical pathways that have been altered by our differentially expressed genes, alongside *de novo* networks that differ between our Ghanaian and Ethiopian tumors. In our overlapping gene list, we see predicted differences in functions such as quantity of T lymphocytes, where genes downregulated in Ethiopian tumors may indicated reduced presence of these immune cells. Using CIBERSORT and xCell deconvolution methods, validation of these findings are ongoing. **Conclusions and Ongoing work:** This work highlights how ancestry-specific gene regulation can delineate differences in the tumor microenvironment among a cohort of African tumors. We are currently evaluating distribution of TNBC subtypes and estimation of immune cell populations in these tumors, to determine ancestry-specific differences in tumor heterogeneity and immune response.

Deep inspiration breath-hold in right-sided breast irradiation: Quantifying the benefit

Revathy Krishnamurthy, Grace Lee, Zhihui (Amy) Liu, Tyler Pittman, Anthony Fyles and Christine Anne Koch. Princess Margaret Cancer Centre, Toronto, ON, Canada

**Background:** Deep inspiration breath-hold (DIBH) in left-sided breast radiation therapy (RT) is proven to reduce ipsilateral lung and heart doses. The potential benefit of this technique in right-sided breast RT has not been fully explored. We describe the differences in organs at risk (OAR) dosimetry between DIBH and free-breathing (FB) plans in 15 patients who received right-sided breast RT.

**Materials and methods:** Fifteen consecutive patients with right-sided breast cancer who received RT with DIBH between January 1, 2016 and August 31, 2019 were enrolled in this study. All patients initially underwent RT planning with FB scans, and subsequently required DIBH rescanning due to concerns related to exposure of OAR. Dose volume histograms (DVH) for the target volume and OAR coverage were compared between both plans on RayStation Treatment Planning System to quantify the benefit of DIBH. The median value of relative reduction (MRR) and interquartile range in dosimetric parameters were calculated when comparing DIBH to FB. Two-sided Wilcoxon signed-rank test was performed, and a p-value < 0.05 was considered statistically significant.

**Results:** The median age of patients was 64 (38-78). None of the patients had cardiac, respiratory or hepatic comorbidities. The majority of patients (10/15) received locoregional RT (50 Gy in 25 fractions); the remaining 5 patients received breast RT (42.4 Gy in 16 fractions). Tumor bed boost was delivered in 9 of 15 patients. DIBH was delivered throughout RT to 14/15 patients and the clinical goal(s) for which DIBH was introduced was achieved in all cases. DIBH was most commonly used to minimize liver exposure (11/15 patients); in 3 of these 11 patients, reduction in heart or lung exposure was also required. Statistically significant reductions in the imaged liver V5Gy [MRR 89.8% (99 to 71.6, p<0.001)], V10Gy [MRR 94.7% (100 to 77.9, p<0.001)], V20Gy [MRR 97.2% (100 to 84.7, p<0.001)], maximum dose [MRR 15.5% (73.2 to 8, p<0.001)] and average dose [MRR 68.7% (79.4 to 58.6, p<0.001)] were observed with DIBH. Compared to FB, the use of DIBH led to statistically significant reductions in right lung V20 [Median Relative Reduction 20.8% (27.1 to 15.9, p<0.001)], as well as the maximum dose received by the heart and left lung. The target volume coverage was not compromised by DIBH, with at least 99% of the target volume receiving 95% dose in all 15 cases.

**Conclusion:** DIBH for right-sided breast irradiation effectively reduces exposure to liver, lung and heart while maintaining target volume coverage. It can be employed to achieve specific dosimetric goals in the clinical setting.

**Background:** Patients (pts) with metastatic triple-negative breast cancer (mTNBC) who have brain metastases represent a poor prognosis cohort with a high unmet clinical need. Sacituzumab govitecan (SG) is an antibody-drug conjugate composed of an anti-Trop-2 antibody coupled to SN-38, an active metabolite of irinotecan, via a unique hydrolyzable linker that allows for SN-38 release intracellularly and in the tumor microenvironment (bystander effect). SN-38 can cross the blood-brain barrier and is a drug partner in central nervous system (CNS) disease regimens (PMID: 18784279; PMID: 26080460). Although antibody-based therapy raises concerns regarding CNS penetration, activity with SG has been seen in intracranial xenograft models (Brenner *Neurooncol Adv* 2019). In a subgroup analysis from ASCENT, the efficacy and safety of SG were evaluated in pts with stable brain metastases.

**Methods:** In the phase 3 ASCENT study (NCT02574455), 529 pts with mTNBC refractory to or relapsing after at least 2 prior chemotherapies were randomized 1:1 to receive SG (10 mg/kg IV on days 1 and 8 every 21 days) or single-agent treatment of physician's choice (TPC; capecitabine, eribulin, vinorelbine, or gemcitabine) until disease progression or unacceptable toxicity. Brain MRIs were required in pts with known brain metastases who were eligible if they had stable CNS disease for  $\geq 4$  wk by MRI. Per protocol, stable disease was defined as  $\geq 2$  wk from discontinuation of antiepileptic medication and corticosteroid dose ( $\leq 20$  mg prednisone equivalent) that was stable or decreasing for  $\geq 2$  wk before randomization. In these pts, brain MRIs were required throughout the study. The primary endpoint was progression-free survival (PFS) per independent central review (RECIST v1.1) in brain metastases-negative pts. Secondary endpoints included PFS per investigator assessment, PFS in the full population (in pts with/without brain metastases) by central review, objective response rate (ORR), overall survival (OS), and safety.

**Results:** Overall, 61 of 529 (12%) enrolled pts had stable brain metastases at screening and were randomized to SG (n=32) or TPC (n=29). Median age was 53 y for SG and 51 y for TPC; all pts were female and had a median of 5 prior anticancer regimens. In this subset, median PFS was 2.8 mo (95% CI, 1.5-3.9) for SG vs 1.6 mo (95% CI, 1.3-2.9) for TPC by central review, and median OS was 6.8 mo (95% CI, 4.7-14.1) for SG vs 7.5 mo (95% CI, 4.7-11.1) for TPC. ORR for SG vs TPC, respectively, was 3% (1/32) vs 0% by central review, with a clinical benefit rate of 9.4% vs. 3.4%. Stable disease was achieved in 15 (47%) pts with SG vs 9 (31%) pts with TPC. In 53 pts who received at least 1 dose of treatment (SG, n=30; TPC, n=23), any-grade treatment-emergent adverse events ( $>20\%$  with SG) for SG vs TPC were fatigue (63% vs 52%), diarrhea (50% vs 13%), neutropenia (43% vs 35%), nausea (43% vs 26%), decreased appetite (30% vs 17%), decreased neutrophil count (33% vs 22%), anemia (23% vs 35%), alopecia (23% vs 13%), and constipation (23% vs 22%). There were no treatment-related deaths. Two pts treated with SG are continuing study treatment for 16.2 and 6.3 mo as of the data cutoff date.

**Conclusions:** Data interpretation in this population with poor prognosis is limited by the small sample size. In this exploratory analysis of pts with brain metastases from the phase 3 ASCENT study, SG was numerically better than TPC for tumor response and PFS but not OS. The safety profile was similar to that of the population without brain metastases for both study arms. SG is currently under clinical investigation for pts undergoing elective craniotomy for breast cancer with brain metastases or recurrent glioblastoma (NCT03995706) based on promising preclinical and intracranial clinical data.

**Background:** Probod<sup>®</sup> therapeutics (Pb-Tx) are masked antibodies designed to be selectively activated in the tumor microenvironment by tumor-associated proteases, while remaining largely inactive in normal tissue and in circulation. This allows Pb-Tx to address previously undruggable targets that are highly expressed in both tumor and normal tissue, such as the adhesion molecule CD166 (ALCAM). CX-2009, an investigational PDC consisting of an anti-CD166 monoclonal antibody conjugated to the microtubule inhibitor DM4, is being evaluated in a Phase 1/2 clinical trial for patients with advanced solid tumors (NCT03149549). Clinical data have been previously presented (Boni V, et al. *J Clin Oncol.* 2020; 38 [15 suppl]: abstract 526); here we present translation data assessing tumoral CX-2009 activation and DM4 accumulation in patients receiving  $\geq 4$  mg/kg every 2 or 3 weeks (Q2W or Q3W), alongside clinical results from breast cancer (BC) patients.

**Methods:** Eligible patients with metastatic cancer after  $\geq 2$  prior standard treatments were required to submit tumor tissue for CD166 IHC analysis. CX-2009 was administered at escalating doses Q3W (0.25-10 mg/kg) or Q2W (4 or 6 mg/kg) until discontinuation criteria were met. Tumor response was assessed Q8W. On-treatment tumor biopsies in consenting patients were collected 3-5 days after the first dose. Levels of CD166 and of intact and activated CX-2009 in patient biopsies were measured by capillary immunoelectrophoresis; levels of DM4 were evaluated by a competitive ELISA, following depletion of the majority of CX-2009 from the sample.

**Results:** 99 patients, including 45 with HR+/Her2- BC, HER2+ BC, or TNBC, were enrolled from 27 sites. The median number of prior therapies was 5.5 (range, 1-10) in all patients and 7 (3-16) in BC patients. Patients received a median of 2 (range, 1-16) CX-2009 doses. 92 patients discontinued treatment; the majority for disease progression/symptomatic deterioration (n=65) or adverse events (n=11). In 26 evaluable BC patients treated at  $\geq 4$  mg/kg, ORR was 11% (HR+/HER2-; n=18) and 38% (TNBC; n=8) including confirmed and unconfirmed responses, with a Clinical Benefit Rate at 24 weeks (CBR24) of 35%. CX-2009 remained predominantly (median >95%) in the inactive form in circulation (Stroh M, et al. *J Clin Oncol.* 2020; 38 [15 suppl]: abstract 3599). Over the dose range of 4-10 mg/kg, activated CX-2009 was quantifiable in 18 out of 22 biopsy samples, including 6 of 7 samples from the BC subset. The intratumoral concentrations of activated CX-2009 and CD166 were significantly correlated ( $r^2=0.59$ ,  $p=0.004$ ). DM4 was measured in 12 evaluable biopsy samples. Levels of normalized intratumoral DM4 were significantly correlated with the relative change in target lesions ( $r^2=0.34$ ,  $p=0.045$ ).

**Conclusions:** CX-2009 behaved as designed, with activated drug in tumor and predominantly intact drug in plasma, leading to clinically meaningful disease control in patients with advanced BC. The relationship between normalized intratumoral DM4 and tumor volume changes support the premise that accumulation of payload toxin is related to anti-tumor activity. The correlation between activated CX-2009 and target expression suggests a role for CD166 in intratumoral accumulation of activated CX-2009. Taken together, the data support continued development of CX-2009 in patients with HR+/HER2- BC and TNBC.

Contemporary practice patterns for the use of regional nodal irradiation during post-lumpectomy radiotherapy for patients with N0/N1 breast cancer

Derek Bergsma<sup>1</sup>, Kent Griffith<sup>2</sup>, Reshma Jaggi<sup>2</sup>, Michael Dominello<sup>3</sup>, Thomas Boike<sup>4</sup>, Joshua Dilworth<sup>5</sup>, Amit Bhatt<sup>6</sup>, Frank Vicini<sup>7</sup>, Maggie Grubb<sup>2</sup>, Jean Moran<sup>2</sup>, James Hayman<sup>2</sup>, Lori Pierce<sup>2</sup>, on behalf of MROQC, the Michigan Radiation Oncology Quality Consortium. <sup>1</sup>Mercy Health Saint Mary's, Grand Rapids, MI; <sup>2</sup>University of Michigan, Ann Arbor, MI; <sup>3</sup>Karmanos, Detroit, MI; <sup>4</sup>MHP Radiation Oncology, Troy, MI; <sup>5</sup>Beaumont Health System, Royal Oak, MI; <sup>6</sup>McLaren Greater Lansing, Lansing, MI; <sup>7</sup>MHP Radiation Oncology, Pontiac, MI

**BACKGROUND:** Current national guidelines encourage consideration for treating the at-risk regional nodes (axillary, supraclavicular, and/or internal mammary) with directed regional nodal irradiation (RNI) during post-lumpectomy radiotherapy for high risk N0 (node negative) and N1 (1-3 nodes positive) breast cancer patients. This recommendation is based on the results of several randomized trials published over the last decade. Evidence regarding translation of these trials into clinical practice in the United States has been limited to date. In this study, we sought to characterize the temporal changes in and clinical factors associated with the utilization of RNI during post-lumpectomy radiotherapy for N0-N1 breast cancer across a contemporary, statewide consortium of radiation oncology practices.

**METHODS:** Within a statewide radiation oncology quality consortium, 12,170 breast cancer patients were consecutively enrolled between 1/1/2013 and 10/31/2019 in both academic (teaching) and community (non-teaching) facilities. Data on receptor status, adjuvant systemic therapy, age, TNM stage, extent of axillary surgery, race, body mass index (BMI), type of treating facility, and year completing radiotherapy (RT) were collected. Eligibility for the present analysis was limited to patients with N0 and N1 disease not receiving neoadjuvant systemic therapy and receiving adjuvant radiotherapy after lumpectomy for non-metastatic breast cancer. Multiple variable logistic regression models were separately fit to explain the use of directed RNI (to the axilla, supraclavicular region, and/or internal mammary region) for the N0 and N1 populations separately and described using odds ratios (OR), with significant ORs ( $p < 0.05$ ) reported.

**RESULTS:** A total of 8,468 patients from 29 treating facilities met the inclusion criteria: 6,929 (81.8%) with N0 and 1,539 (18.2%) N1 disease. RNI was performed in addition to whole breast radiation in 95 (1.4%) and 908 (59%) patients in the N0 and N1 cohorts respectively. For the N0 cohort, significant correlates of RNI on multivariable analysis (MVA) were receipt of adjuvant chemotherapy (OR 2.7), higher T-stage (OR 1.9 for T2 vs T1 and 27.3 for T3/T4 vs T1), axillary surgery [compared to sentinel node biopsy (SLN) alone : no axillary surgery (OR 14.5), axillary lymph node dissection (ALND) with 10+ nodes removed (OR 15.1) ALND after SLN (OR 2.7)], and underweight BMI (OR 4.9 compared to overweight, which was the reference as the largest BMI category). For the N1 cohort, MVA suggested adjuvant chemotherapy (OR 1.8) and larger tumors (OR 1.6 [T2 vs T1]) were significantly associated with use of RNI. The year completing RT was also significantly associated with RNI use, with 22% and 15% increases per year from 2013 to 2019 in the N0 and N1 cohorts, respectively. Lastly, receiving treatment in an academic facility compared to a community facility was significantly associated with receipt of RNI in both the N0 (OR 1.8) and N1 (OR 2.2) cohorts.

**CONCLUSION:** In this large cohort, selective use of RNI added to post-lumpectomy whole breast radiotherapy is estimated to have increased over time, suggesting growing implementation of recent trial data and current clinical practice guidelines. Patient, treatment, and tumor characteristics appear to factor into the decision to treat with RNI, but differences in use between academic and community practices suggest opportunities for improving the consistency of care across care delivery settings. Ongoing trials seeking to identify subgroups of N1 patients in whom RNI can safely be omitted may be especially important to inform decisions, given the almost even split (59% receiving, 41% not) in practice observed in this large American cohort.

Mapping the tumor and microenvironmental evolution underlying DCIS progression through multiplexed ion beam imaging

Michael Angelo. Stanford University, Palo Alto, CA

Ductal Carcinoma in Situ (DCIS) is a pre-invasive lesion that accounts for nearly 20% of new breast cancer diagnoses. Of these cases, about half will progress to invasive breast cancer (IBC) within ten years. However, because diagnostic criteria for delineating low risk lesions from those likely to progress to IBC have not been identified, many patients are receiving unnecessary chemotherapy and surgery that can result in therapy-related morbidity and death. With this in mind, we used Multiplexed Ion Beam Imaging by time of flight (MIBI-TOF) and RNA-seq laser-capture microdissection (SMART-3SEQ) to construct a comprehensive spatial atlas describing the structure, function, and cellular composition of DCIS. MIBI-TOF and SMART-3SEQ were used to compare lesions from patients that later developed IBC with those from age- and history matched DCIS controls without recurrence. Using a 37-marker staining panel to interrogate 137 lesions, we identified 17 distinct cell populations of epithelial, stromal, and immune cells that were arranged in recurrent cellular microenvironments specific for DCIS or invasive disease. We observe a coordinated shift in the immune and stromal compartments as invasive disease arises, including a robust influx of lymphocytes and expansion reactive stromal phenotypes in synchronous DCIS + IBC, which was distinct from the macrophage-dominant, highly vascularized microenvironment of recurrent IBC. Further, single cell segmentation using a deep learning model was combined with pixel-level coexpression analysis to extensively evaluate how the thickness, continuity, and phenotype of ductal myoepithelium changes as tumors progress from a pre-invasive state. These data were incorporated into a comprehensive model which was subsequently used to identify a subset of features that correlate with disease-free survival following DCIS tumor resection. Taken together, these features represent important prognostic metrics that can be used to separate pre-invasive from indolent DCIS tumors, and allow for tailored therapy that improves patient outcomes and quality of life in this disease.

**Background and Purpose:** There is currently a lack of recognized imaging criteria for prediction of treatment response to NAST in breast cancer patients with recent reports showing that breast MRI is the most accurate modality for evaluation of NAST response. DCE-MRI evaluates tumor perfusion that influences tumor enhancement at the post-contrast subtraction images and allows for more accurate measurement of changes in tumor volume during NAST. In this study, we evaluated the ability of tumor volumetric changes after 2 and 4 cycles of NAST by longitudinal ultrafast DCE-MRI to predict pathologic complete response (pCR) in TNBC undergoing NAST. **Materials and Methods:** Stage I-III TNBC patients enrolled in an IRB approved prospective clinical trial (ARTEMIS, NCT02276433) who had ultrafast DCE-MRI at baseline (BL, N=103), post 2 cycles (C2, N=59), and post 4 cycles (C4, N=103) of anthracycline-based NAST, and had surgery, were included in this analysis. Tumor volume was calculated using 3D measurements of the index lesion at BL, C2, and C4. Percent change of tumor volume (%TV) between BL, C2, and C4 was calculated at early (9-12 sec) and delayed (360-480 sec) phases of DCE-MRI. The largest lesion was used for analysis in patients with multicentric or multifocal disease. Demographic, clinical, and pathologic data and treatment response at surgery (pCR versus non-pCR) were documented. Receiver operating characteristics curve (ROC) analysis was performed for prediction of pCR status. Positive predictive value (PPV), negative predictive value (NPV) and Youden Index were used to select %TV cut-off thresholds for pCR prediction. **Results:** 103 patients (median age, 53 years; range, 24-79 years) were included, 48 (47%) had pCR, and 55 (53%) had non-pCR at surgical pathology. The %TV reduction at C2 DCE-MRI was predictive of pCR on both early phase DCE MRI (AUC, 0.873; CI:0.779-0.968,  $p < .0001$ ) and delayed phase DCE MRI (AUC, 0.844; CI:0.742-0.947,  $p < .0001$ ). Optimal thresholds were as follows: 70% TV reduction on early phase DCE MRI with Youden's index of 1.58 was able to predict pCR correctly for 79% of patients with PPV of 81%; 75% TV reduction on delayed phase with Youden's Index of 1.44 was able to predict pCR correctly for 71% of patients with PPV of 85%. %TV reduction was also predictive of pCR at the C4 time point on both early phase DCE MRI (AUC, 0.761; CI:0.665-0.856,  $p < .0001$ ) and delayed phase DCE MRI (AUC, 0.737; CI:0.641-0.833,  $p < .0001$ ). Optimal thresholds were as follows: 90% TV reduction on early phase DCE MRI with Youden's index of 1.43 was able to correctly predict pCR in 72% of patients with PPV of 70%; and 90% TV reduction on delayed phase with Youden's Index of 1.34 was able to predict pCR correctly in 68% of patients with PPV of 71%. **Conclusion:** Our data shows that percent tumor volume reduction by DCE-MRI after 2 and 4 cycles of NAST was able to predict pCR in TNBC with high accuracy and can be used as an early imaging biomarker of NAST response prediction. Volumetric changes by longitudinal DCE-MRI can be used to differentiate chemoresistant and chemosensitive TNBC patients as early as after 2 cycles of NAST, and can help to triage patients for treatment de-escalation or targeted therapy.

The MYC oncogene suppresses tumor immune infiltration and function which is reversible with combinatorial immunotherapies

Joyce V Lee<sup>1</sup>, Filomena Housley<sup>1</sup>, Christina Yau<sup>1</sup>, Golzar Hemmati<sup>1</sup>, Yibing Zhang<sup>1</sup>, Susan Samson<sup>1</sup>, Carole Baas<sup>2</sup>, Hope Rugo<sup>1</sup>, Mehrdad Matloubian<sup>1</sup> and Andrei Goga<sup>1</sup>. <sup>1</sup>UCSF, San Francisco, CA; <sup>2</sup>National Cancer Institute, Bethesda, MD

Immunotherapy has great potential to improve outcomes for breast cancer patients. Yet, deciding on how to rationally combine therapeutic agents and predict patient populations who would benefit remains challenging. Less than 20% of patients with metastatic breast cancer respond to current immunotherapy regimens, further demonstrating the need for research in this area. We postulate that oncogene activation leads to immune-related vulnerabilities which can be exploited to discover new immunotherapy combinations with improved efficacy. MYC is an oncogene that is frequently overexpressed in the majority of triple negative breast cancers (TNBCs), and is frequently found in disease recurrence, metastasis, and chemotherapy resistance. Despite the association of MYC with poor patient outcome, little is known about how MYC facilitates immune evasion in TNBC. Using TNBC patient datasets from the TCGA, we discovered that the MYC gene signature is anti-correlated with T-cell activation signatures and a subset of genes that regulate antigen processing and presentation with MHC-I. We further examined the effects of MYC using a MYC-driven mammary tumor mouse model (MTB-TOM). MYC activation leads to downregulation of MHC-I expression on tumor cells, poor CD8+ T cell infiltration and consequently poor response to anti-PD-L1 monotherapy. We demonstrate three methods to improve response to immunotherapy—by inactivation of MYC, by inducing an interferon response within the breast tumor, or by inducing MYC tumor synthetic lethality with a small molecule inhibitor of PIM kinases. Using these combination immunotherapy strategies, we observed that a majority of animals eradicated their breast tumors and demonstrated a durable anti-tumor response following subsequent tumor re-challenge. Our data suggest MYC is an indicator of whether a breast cancer patient will respond to immunotherapy. Analysis of the MYC gene signature as a predictor of patient response to pembrolizumab in combination with paclitaxel followed by AC in the neoadjuvant I-SPY 2 trial is on-going and will be presented. Our study is the first to describe oncogenic MYC downregulation of MHC-I in a TNBC model of breast cancer and to demonstrate translatable approaches to overcome MYC orchestrated immune evasion.

Comparison of breast cancer staging models in patients after neoadjuvant chemotherapy

Olga Kantor<sup>1</sup>, Alison Laws<sup>1</sup>, Ricardo G Pastorello<sup>1</sup>, Stephanie Wong<sup>2</sup>, Tanujit Dey<sup>1</sup>, Stuart Schnitt<sup>1</sup>, Tari A King<sup>1</sup> and Elizabeth A Mittendorf<sup>1</sup>.<sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>McGill University, Montreal, QC, Canada

**Background:** Neoadjuvant chemotherapy (NAC) is commonly utilized for breast cancer, however no consensus exists on the best way to stage these patients following treatment. Importantly, the American Joint Commission on Cancer (AJCC) 8<sup>th</sup> edition staging system did not specifically address staging after NAC. However, previous work by our group has shown that the pathologic prognostic stage does stratify patients with respect to outcomes. Our objective was to compare performance of the AJCC pathologic prognostic staging system to a second staging model, the Residual Cancer Burden (RCB) Index which takes into account residual tumor size, cellularity, lymph node status and size of any lymph node metastases.

**Methods:** A retrospective review identified patients with stage I-III invasive breast cancer treated with NAC from 2004-2014 at Dana-Farber Cancer Institute. Patients were excluded if they did not have RCB reported on final pathology. Disease-free survival (DFS) was defined as any recurrence or death from any cause, and overall survival (OS) as death from any cause. DFS and OS were calculated using the Kaplan-Meier method for each staging model. Receiver operator characteristic (ROC) curves were used to assess model fit using the c-statistic and the Hanley method to compare c-statistics.

**Results:** A total of 802 patients underwent NAC for stage I-III breast cancer. The median age was 48 years (range 22-86). Most patients presented with cT2 (n=470, 58.6%) or cT3 (n=188, 23.4%) and cN1 (n=422, 52.6%) disease. The majority (n=563, 70.2%) presented with grade 3 disease. In terms of subtype, 296 (36.9%) patients had hormone receptor-positive, HER2 negative, 261 (32.5%) HER2+, and 245 (30.5%) triple negative disease. Median follow up was 79.5 months (range 4-169). There were 176 recurrences including 32 local, 25 regional, and 145 distant recurrences. 676 (76.8%) patients were alive at last follow-up. The **Table** depicts the 7-year DFS and OS estimates for each of the staging models. The ROC c-statistics for DFS model fit were statistically similar, 0.72 for AJCC pathologic prognostic stage and 0.71 for RCB (p=NS). The c-statistics for OS were 0.74 and 0.71 respectively (p=NS).

**Conclusions:** Our results provide additional external validation of the AJCC pathologic prognostic stage and RCB's ability to stratify patients after NAC with respect to survival outcomes. These data can be used to inform subsequent revisions of the AJCC breast cancer staging system.

Estimated 7-year DFS and OS in Potential Staging Models for Breast Cancer Patients after NAC (n=802)

	7yr-DFS	7yr-OS
Pathologic Prognostic Stage		
Stage 0 (n=228)	92.9%	94.8%
Stage IA (n=193)	81.7%	90.2%
Stage IB (n=173)	74.5%	86.6%
Stage IIA (n=105)	62.2%	71.5%
Stage IIB (n=11)	70.2%	57.3%
Stage IIIA (n=40)	62.2%	75.4%
Stage IIIB (n=27)	56.7%	83.0%
Stage IIIC (n=25)	27.8%	28.2%
C-statistic (95% CI)	0.72 (0.68-0.76)	0.74 (0.69-0.79)
RCB		
0 (n=226)	93.5%	94.8%
I (n=118)	83.0%	90.0%
II (n=278)	75.9%	85.0%
III (n=180)	55.1%	69.9%
C-statistic (95% CI)	0.71 (0.67-0.75)	0.71 (0.66-0.75)

**Background** Adaptive immunity is initiated by T-cell receptor (TCR) engagement with cognate tumor antigen, leading to T-cell maturation (i.e. conversion from naïve to effector state), clonal proliferation, and potentially tumor elimination. Therefore, broad T-cell repertoire diversity could be an important determinant of anti-tumor immunity. In breast cancer, chemo may facilitate adaptive immunity, but conversely may also be lymphotoxic. We characterize the impacts of curative-intent chemo and palliative combination chemo/immune checkpoint inhibition (ICI) on lymphocyte quantity, maturation, and clonal proliferation. **Methods** Peripheral blood mononuclear cells (PBMCs) were collected at baseline and serially in stage I-III subjects receiving curative-intent chemo (dose-dense doxorubicin, cyclophosphamide, paclitaxel, n=20), and in stage IV subjects receiving palliative ICI (pembrolizumab) plus chemo (paclitaxel, n=15; or capecitabine, n=14). Flow cytometry was conducted on fresh PBMCs to minimize cellular losses related to cryopreservation. DNA was extracted for T-cell clonality analysis using the immunoSEQ Assay (Adaptive Biotechnologies) at deep resolution. T-cell richness, calculated using the iChao1 richness estimator was used to assess overall T-cell diversity. **Results** Both dose-dense chemo and palliative chemo/ICI were lymphodepleting, however dose-dense chemo was associated with greater reductions in CD4+ naïve T cell count (week 8 counts 34% vs. 96% of baseline, p<.001) and T-cell richness (week 8 richness 57% vs 90% of baseline, p<.001). These effects were durable, with reductions in lymphocyte subsets (ALC, CD4, CD8, naïve, effector, and central memory subsets) and T-cell richness (estimated rearrangements 4.37 vs 3.29 x 10<sup>5</sup>/sample) sustained at metastatic relapse. T-cell richness correlated with CD4+ naïve cell proportion (R<sup>2</sup>=0.52), suggesting a major contribution of CD4+ naïve cells to overall T-cell diversity. In this dataset, acute memory T-cell expansions were observed following initiation of chemo, but only among younger patients (age<60). **Conclusions** Curative-intent cytotoxic chemotherapy durably alters the quantity and diversity of peripheral T-cells, particularly of naïve cells, contributing to lymphopenia and reduced T-cell richness at metastatic relapse. Acute expansions of EM subsets were also observed but only in younger individuals. These contrasting immunologic effects highlight the potential importance of sequencing of ICI relative to chemo, and raise concerns regarding age-related thymic involution and immunosenescence. Ongoing research is warranted to investigate the predictive/prognostic utility of T-cell diversity/quantity in breast cancer, and whether thymic T-cell regeneration can be targeted therapeutically to enhance immunotherapy response, for example with cytokine therapies (IL-12 or IL-7, NCT04095689) or sex steroid inhibition (NCT03650894).

**Background** The outbreak of COVID-19 pandemic in China has greatly impacted the radiotherapy (RT) strategy for breast cancer (BC) patients, which might lead to an increased distressing psychological symptom. Thus, we perform a multi-center cross-section survey aiming to investigate the prevalence of fears of cancer recurrence (FCR) and explore predictors for FCR in BC patients referred for RT during pandemic. **Methods:** 542 BC patients who referred for RT between 24<sup>th</sup> Jan and 30<sup>th</sup> April 2020 during pandemic were consecutively enrolled from 14 hospitals around China including Yangtze Delta River Region, Guangdong and Shanxi province. Patients' sociodemographic, treatment information as well as psychological characteristics were collected using an information sheet, Fear of progression questionnaire-short form (FoP-Q-SF), Hospital Anxiety and Depression Scale (HADS) and EORTC QLQ-C30. The influence of pandemic on RT schedule was divided into four categories: "delay" was defined as >12 weeks from surgery to RT in patients without chemotherapy or >8 weeks from last time of anti-tumor therapy (including chemotherapy and surgery) to RT in patients with chemotherapy; "Special normal" was defined that patients themselves believed to have delayed RT initiation but actually not; "Interruption" was defined as any unplanned gaps in original RT regime and all other would be classified into "normal". Another type of influence on RT strategy was that patients had to shift planned RT hospital from Grade-A tertiary hospital to local hospitals. Univariable analyses of FCR were performed in a one-way analysis of variance (ANOVA) or student t-test or Pearson correlation analyses and candidate variables with  $P < 0.2$  were included Hierarchical multiple regression models to investigate predictors for FCR. Guangdong province was chosen as reference in models. **Results** 488 patients with complete data were eligible for the present analysis and none of patients and their family members had been diagnosed as COVID-19. The RT strategy was affected in 265 (54.3%) patients, including 143 with delayed RT initiation, 66 with "special normal" schedule, 24 (4.9%) with RT interruptions, 19 shifting to local hospitals for RT, and the remaining 13 being influenced on both RT schedule and planned RT hospitals. Most of patients with affected RT strategy occurred in late January and February, when was peak of COVID-19 pandemic in China. The mean FCR scores was 24.83 (SD=8.554) and 84 patients (17.3%) were classified as dysfunctional level of FCR (sum score  $\geq 34$ ). In univariable analyses, FCR were significantly higher in patients who received RT in Guangdong province and in hospitals with < 100 BC cases per year. In term of during pandemic, a significant difference in FCR was observed in terms of influence on RT schedule ( $p < 0.001$ ), and changes of hospital levels ( $p = 0.009$ ). There were significant correlations between FCR and anxiety/depressive in HADS or all five function scales (physical, role, emotional, cognitive and social) and global QoL in QLQ-C30 ( $p < 0.001$ ). Finally, the model explained 59.7% of observed variances in FCR and showed that influence of RT strategy during pandemic had significantly impacted on FCR ( $\Delta R^2 = 0.01$ ,  $\Delta F = 2.966$ ,  $p = 0.019$ ). Hospitals in Shanxi province ( $\beta = -0.117$ ,  $p = 0.001$ ), emotional function ( $\beta = -0.19$ ,  $p < 0.001$ ), social function ( $\beta = -0.111$ ,  $p = 0.006$ ), anxiety ( $\beta = 0.434$ ,  $p < 0.001$ ) and RT interruption ( $\beta = 0.071$ ,  $p = 0.035$ ) were independent predictors for FCR. **Conclusions** RT strategy for BC patients was greatly influenced during pandemic. RT interruption is an independent predictor for high FCR. Our findings emphasize the necessity to ensure the continuum of RT in BC patients, and efforts should be taken to alleviate the FCR through psychological interventions.

Patient perception of telehealth services for breast and gynecologic cancer care during the SARS-CoV-2 (COVID-19) pandemic in NYC: A single center survey-based study

Brittney S Zimmerman, Danielle Seidman, Natalie Berger, Krystal P Cascetta, Michelle Nezoslosky, Kara Trlica, Alisa Ryncarz, Caitlin Keeton, Erin Moshier and Amy Tiersten. Icahn School of Medicine at Mount Sinai, New York, NY

**Background:** Prior to the COVID-19 pandemic, telehealth was rarely utilized in providing oncologic care. At our large NYC based outpatient clinic, telehealth services were quickly adapted for utilization for visits that could be completed outside of the clinic, in order to limit patient exposure to the novel coronavirus. This survey-based study aimed to assess patient perceptions of the utility of telehealth in their oncologic care during a time of national crisis. **Methods:** A 34-question survey was administered to all patients receiving care at our outpatient center between March 1, 2020 and June 30, 2020 including those who had visits delayed or cancelled during this time period. Of the 622 patients who received the survey via RedCap online or physical copy in clinic, 211 (34%) completed the survey. For evaluation of the Telehealth provided during the pandemic, we have adapted the validated SUTAQ (Service User Technology Acceptability Questionnaire) which assesses patient acceptability of telehealth via measures of accessibility, comfort, usability, privacy and security, confidentiality, satisfaction, convenience and health benefits with in-home telemonitoring. **Results:** All patients who completed the survey had a history of DCIS/ADH/LCIS, invasive breast cancer or gynecologic malignancy. Of the total survey respondents, 72 (35%) participated in a telehealth visit during the four month evaluation period. For all survey questions, "agreement" was considered if the patient selected mildly, moderately or strongly agreed on the SUTAQ scale. Of patients who participated in telehealth visits, 66 (92%) felt that the telehealth saved them time, 52 (72%) felt it increased their access to care and 56 (81%) felt it helped improve their health. Only 8 (12%) of patients felt that telehealth made them feel uncomfortable and 4 (6%) worried about confidentiality related to telehealth usage. Overall, 65 (92%) of patients were satisfied with the telehealth services they received and 64 (89%) would recommend these services to people with similar health conditions. Twenty-five (35%) felt that telehealth can be a replacement for their normal health care and 67 (93%) reported it could be a good addition to their care. Fifty-four (76%) would be interested in participating in telehealth visits in the future. **Conclusions:** Overall, patients expressed satisfaction with the use of telehealth services for oncologic care during the COVID pandemic. Although most patients do not feel that this is a suitable replacement for their in person care, they expressed that it was certainly a good addition to their care. A large majority of patients expressed interest in continuing to participate in telehealth visits in the future. Telehealth services should be carefully adapted as a long term addition to the in person clinical care of patients with cancer. These services should be utilized to optimize patient satisfaction, save time and increase access to care, especially among high risk patients.

DCE-MRI derived imaging features for characterizing invasive lobular breast cancer and predicting recurrence-free survival after neoadjuvant therapy

Geraldine Tran<sup>1</sup>, Ella Jones<sup>2</sup>, Wen Li<sup>2</sup>, Kelly Fahrner-Scott<sup>2</sup>, David Newitt<sup>2</sup>, Bonnie Joe<sup>2</sup>, Laura Esserman<sup>2</sup>, Nola Hylton<sup>2</sup> and Rita Mukhtar<sup>2</sup>. <sup>1</sup>Boston Medical Center, Boston, MA; <sup>2</sup>UCSF, San Francisco, CA

**Background** With current imaging technologies, assessing response to neoadjuvant chemotherapy (NAC) or neoadjuvant endocrine therapy (NET) remains a challenge for patients with invasive lobular carcinoma (ILC). Therefore, we evaluated imaging features from dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) before and after neoadjuvant therapy in a cohort of patients with ILC, including the longest tumor diameter (LD), functional tumor volume (FTV), and peak signal enhancement ratio (SER). FTV is the sum of all image voxels enhancing above a set threshold within a defined region, and has been validated as a predictor of recurrence-free survival (RFS) for breast cancer. SER is a measure of contrast wash-in and wash-out and reflects neovascularity of tumors. We determined whether baseline and post-treatment imaging features differed by type of neoadjuvant therapy and if they were associated with RFS in neoadjuvantly treated ILC regardless of treatment type.

**Methods** With institutional review board approval, a retrospective analysis of pre- and post-treatment breast DCE-MRI was performed on a cohort of ILC patients receiving neoadjuvant therapy between 1998 and 2017. We compared pre-treatment, post-treatment, and percent reduction ( $\alpha$ ) in LD, FTV, and peak SER by neoadjuvant treatment type (i.e. NAC or NET) using the Wilcoxon rank-sum test. Univariate t-tests, Chi-squared tests, analysis of variance, and Spearman's correlation were used to evaluate associations of clinicopathologic features and treatment type. Univariate and multivariate associations with RFS in the entire neoadjuvantly treated cohort adjusting for treatment type were evaluated using the log-rank test and Cox proportional hazards models.

**Results** A cohort of 76 patients with pre- and post-treatment MRI were included in this study, of whom 42 (55.3%) received NAC and 34 (44.7%) received NET. The NAC group was significantly younger (55 vs. 60 years,  $p=0.013$ ), less likely to have stage 1 disease (26.2% vs. 73.5%,  $p<0.001$ ), and showed a trend of having more human epidermal growth factor 2 receptor-positive (HER2) tumors. The mean follow up time was 4.9 years with no difference between treatment groups. Patients in the NAC group had significantly larger pre-treatment LD and FTV but no difference was found in pre-treatment peak SER between groups. Post-treatment LD, FTV, and peak SER did not differ between treatment groups (**Table 1**). Those receiving NAC had significantly greater reduction in FTV compared to those receiving NET;  $\alpha$ LD and  $\alpha$  peak SER did not differ. In a multivariate Cox proportional hazards model including all patients in the cohort, higher pre-treatment peak SER was significantly associated with worse RFS regardless of neoadjuvant treatment type when adjusting for age, stage, receptor subtype, and tumor grade (hazard ratio 1.3,  $p=0.005$ , 95% CI 1.1-1.6). Neither LD nor FTV were associated with RFS on multivariate analysis.

**Conclusion** Pre-treatment peak SER measured by MRI may provide prognostic information beyond standard clinicopathologic variables in patients with ILC receiving either neoadjuvant chemotherapy or endocrine therapy. Further evaluation in a larger ILC cohort is needed to validate our initial findings.

**Table 1.** Comparison of MR imaging features of ILC patients receiving neoadjuvant chemotherapy and neoadjuvant endocrine therapy.

The role of CYP2D6 mediated tamoxifen metabolism in the suppression of ovarian function trial (SOFT)

Matthew P. Goetz<sup>1</sup>, Gini F. Fleming<sup>2</sup>, Mary Kuffel<sup>1</sup>, John R. Hawse<sup>1</sup>, John L. Black<sup>1</sup>, Richard Weinshilboum<sup>1</sup>, James N. Ingle<sup>1</sup>, Patrizia dell'Orto<sup>3</sup>, Olivia Biasi<sup>3</sup>, Roswitha Kammler<sup>4</sup>, Sherene Loi<sup>5</sup>, Marco Colleoni<sup>3</sup>, Giuseppe Viale<sup>3</sup>, Prudence A Francis<sup>5</sup> and Meredith M Regan<sup>6</sup>. <sup>1</sup>Mayo Clinic, Rochester, MN; <sup>2</sup>University of Chicago, Chicago, IL; <sup>3</sup>European Institute of Oncology IRCCS, Milan, Italy; <sup>4</sup>IBCSG Coordinating Center, Bern, Switzerland; <sup>5</sup>Peter MacCallum Cancer Centre, University of Melbourne, Melbourne, Australia; <sup>6</sup>Dana-Farber Cancer Institute, Boston, MA

Tamoxifen (T) is a pro-drug that undergoes CYP2D6-mediated metabolic activation to metabolites that more potently inhibit estrogen stimulated growth compared to the parent drug. While many studies have examined the role of CYP2D6 genotype in T-treated postmenopausal women, the role of CYP2D6 metabolism in premenopausal women (pre-MW) receiving T, with or without ovarian function suppression (OFS) or exemestane (E) and OFS is unknown. Methods: SOFT randomized 3066 (pre-MW) from 2003-2011 in 27 countries, stratified according to prior receipt or nonreceipt of chemotherapy and nodal status, to receive 5 years of T, T+OFS, or E+OFS. We designed a pharmacogenetics substudy (activated October 2010) to collect blood DNA from North American (NA) patients (pts) or to extract non-tumor DNA from available formalin fixed paraffin embedded (FFPE) tissue blocks. For pts with a blood sample, CYP2D6 was genotyped beginning with the Luminex Tag-It Mutation Detection Kit and when needed, with a copy number variation assay and/or sequencing assays. For pts with FFPE-derived DNA, CYP2D6 genotyping for \*3, \*4, \*6, \*9, \*10, \*17 and \*41 was performed using a Taqman Allelic Discrimination Assay. CYP2D6 phenotypes were called by classifying pts on the basis of a combination of poor (PM: \*3, \*4, \*5, \*6, \*7, \*8), slow (SM: \*10), intermediate (IM: \*9, \*17, \*29, \*41) and extensive metabolizer alleles (EM; all others). Activity scores (AS) from phenotypes assigned for each allele: 0 if PM, 0.25 if SM, 0.5 if IM and 1 if EM allele, and multiplied x2 or x3 if duplicate or triplicate. With concomitant use of potent CYP2D6 inhibitor, AS=0; use of weak inhibitor subtracted 0.5. Metabolizer status was defined by CYP2D6 genotype alone or in combination with CYP2D6 inhibitor use at randomization from the AS: extensive (AS 1.25 to 3), intermediate (AS >0.5 to <1.25), slow/poor (AS 0 to 0.5) metabolizer status. The laboratory was blinded to all clinical data. The substudy primary objective was to assess the association between disease-free survival (DFS) and CYP2D6 metabolizer status in the T arm, and secondarily in the T + OFS, and E + OFS arms. A Cox model estimated hazard ratios comparing status according to treatment assignment, with prespecified prognostic factors. Results: 1200/3047 (39%) randomized pts in the intention-to-treat (ITT) population had successful CYP2D6 genotyping and 50% received prior chemotherapy. Following randomization, 435/1023 (42%) NA pts provided a blood sample and CYP2D6 genotypes were derived in 435/435. Non-tumor tissue was macrodissected from 1277 available FFPE blocks, resulting in DNA concentrations of > 0.3 ng/ml in 1053, and successfully derived CYP2D6 genotypes for 765/3047 pts (25%). 182 (15%) pts had DFS events after 8 yrs median follow-up. Metabolizer status from genotype was 57% extensive, 29% intermediate, 15% slow/poor. Metabolizer status was not associated with DFS in pts assigned T alone (P=0.60; Table), nor in pts assigned T+OFS (P=0.41) or E+OFS (P=0.30). 11% of pts used CYP2D6 inhibitors concomitantly at randomization; for 8% it changed the metabolizer status. The results using this definition were consistent. Conclusion: This retrospective-prospective SOFT pharmacogenetics substudy found no relation of CYP2D6 metabolizer status with DFS in premenopausal pts receiving T, T + OFS, or E + OFS. Given that 50% were pretreated with chemotherapy, further study is needed regarding the role of CYP2D6 metabolism in patients treated with T monotherapy.

Table

Treatment Group	N pts (N events)	Comparison (N pts)	Hazard Ratio	95% CI
Tamoxifen	324 (56)	Intermediate (114) vs Extensive (210)	0.78	0.43-1.39
Tamoxifen	265 (52)	Slow/Poor (55) vs Extensive (210)	1.11	0.58-2.13
Tamoxifen + OFS	357 (46)	Intermediate (122) vs Extensive (235)	0.73	0.38-1.40
Tamoxifen + OFS	299 (45)	Slow/Poor (64) vs Extensive (235)	1.25	0.64-2.43
Exemestane + OFS	344 (46)	Intermediate (107) vs Extensive (237)	0.59	0.28-1.22
Exemestane + OFS	293 (47)	Slow/Poor (56) vs Extensive (237)	1.13	0.56-2.27

Germline mutation landscape in Chinese breast cancer patients

Nan Wang<sup>1</sup>, Jiayang Zhang<sup>1</sup>, Lu Tan<sup>2</sup>, Hao Liao<sup>1</sup>, Yaxin Liu<sup>1</sup>, Xinyu Gui<sup>1</sup>, Jiaxin Niu<sup>2</sup>, Feng Xie<sup>2</sup>, Yue Zhang<sup>2</sup>, Yong Huang<sup>2</sup>, Jianjun Yu<sup>2</sup> and Huiping Li<sup>1</sup>. <sup>1</sup>Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Department of Breast Oncology, Peking University Cancer Hospital and Institute, Beijing, China<sup>2</sup>Huidu (Shanghai) Medical Sciences, Ltd, Shanghai, China

**Background:** Genetic testing for patients with breast cancer (BCa) patients may change the routine patient care and shift the paradigm towards more personalized managing and treatment strategies. In particular, testing germline mutations in BRCA1/2 has become a part of the standard clinical practice for patients with BCa. However, our understanding of genetic epidemiology of BCa is mainly driven by data from Caucasian populations and it has been evident that gene alterations may be ethnic specific in breast cancer.

**Methods:** Aiming to delineate the landscape of germline mutations in Chinese patients with BCa to breast cancer, we collected blood samples from in 356 BCa patients at stage I-IV in Beijing Cancer Hospital between Jan. 2013 to Dec. 2019. Peripheral blood mononuclear cells were isolated from blood samples and genomic DNA were extracted for capture-based NGS sequencing. A large comprehensive 600 gene panel (PredicineATLAS, Huidu Medical Science Technology, Inc.) was used to detect germline mutations in the covered genes with average 300x sequencing depth.

**Results:** A total of 356 BCa patients were included in our study, with the median age at first diagnosis of 49 years (Range: 21-87). Among all cases, 21.9% (78/356, 95% confidence interval [CI]: 17.7-26.6%) carried pathogenic or likely pathogenic mutations in 48 cancer related genes. Twenty-seven patients (7.6%, 95% CI: 5.1-10.8%) harbored BRCA1/2 mutations, followed by 5 patients carrying ATM mutations and RAD50 mutations respectively. Other commonly mutated genes include BARD1 (1.1%), FANCD2 (1.1%), CHEK2 (0.6%), FANCC (0.6%), FANCM (0.6%), PMS2 (0.6%), and TP53 (0.6%), most of which are related to DNA damage repair pathway. Moreover, BRCA1/2 carriers were more likely to appear among those with breast or ovarian cancer family history than those without (OR=3.41, 95% CI: 1.14-9.12, P=0.01). Compared with patients that aged older than 50 years at first diagnosis, those aged 30 years or younger were 6 times more likely to detect germline mutations in BRCA1/2 (95% CI: 1.18-26.1, P=0.02). In addition, mutations in BRCA1/2 were differentially associated with breast cancer subtypes. BRCA1 mutations were strongly enriched in triple-negative breast cancer (TNBC) (OR=6.7, 95% CI: 1.54-33.13, P=0.005). There is no strong significant survival difference observed between BRCA1/2 carriers and non-carriers, however, patients carrying ATM or RAD50 mutations tend to have lower disease-free survival.

**Conclusions:** This is a comprehensive analysis of germline mutation spectrum in a large Chinese patient cohort with breast cancer. Collectively, a substantial proportion of patients with breast cancer had hereditary risk factors. Distinct distribution of pathogenic mutations in breast cancer subtypes and differential associations between mutation status and clinical features were further observed. All these findings will advance our understanding regarding the pathologies and heterogeneity of breast cancer.

**Rationale and research objective:** As a result of neoadjuvant chemotherapy (NAC), approximately 1/3 of clinically node positive (cN+) breast cancer patients convert to a pathologic complete response (pCR) of the axilla. Targeted Axillary Dissection appears to be most accurate to evaluate axillary treatment-response, but evidence to support this is limited. The RISAS trial was set up to determine the accuracy of sentinel lymph node biopsy (SLNB) combined with excision of the pretreatment marked positive lymph node for axillary staging after NAC in cN+ patients.

**Methods:** This prospective, multicenter trial included cT1-4N1,2,3b patients treated with NAC. Prior to NAC, an iodine seed was placed in the pathologically confirmed positive lymph node. After NAC, all patients underwent SLNB together with excision of the marked lymph node (RISAS-procedure) followed by axillary lymph node dissection (ALND). The identification rate and the accuracy (i.e. false negative rate (FNR) and negative predictive value (NPV)) were calculated for the RISAS procedure. Assuming an FNR of 2%, a prevalence of a positive ALND of 64% and a 10% drop-out rate, a sample size of 248 patients was needed to determine non-inferiority. The NULL hypothesis of inferiority would be rejected at a significance level of 5% if the upper bound of the two-sided 90% Clopper-Pearson confidence interval of the observed FNR would be below the non-inferiority margin of 6.25%. Secondary objectives included the accuracy of the SLNB and excision of the marked lymph node separately.

**Results:** A total of 252 pathologically proven cN+ patients provided informed consent of whom 227 underwent the RISAS procedure/Targeted Axillary Dissection (SLNB combined with excision of the marked positive lymph node). The identification rate of the RISAS procedure is 98% (223/227). Preliminary analysis shows a false negative rate of approximately 5% and a negative predictive value of approximately 91%. Furthermore, by combining SLNB with excision of the marked lymph node, both the identification rate and the accuracy are improved compared to either the SLNB alone or the excision of the marked lymph node alone.

**Conclusion:** This prospective multicenter validation trial shows that the RISAS procedure/Targeted Axillary Dissection is most suitable in terms of identification rate and accuracy to replace ALND for axillary staging after NAC in cN+ patients. The trial was funded by the Dutch Cancer Society (KWF, grant number 2015-8023).

Definition of a high risk cardiac zone on non-contrast computed tomography (CT) scans for indirect optimization of left anterior descending coronary artery (LADCA) dosimetry for breast radiotherapy

Pierre Loap, Nicolas Tkatchenko, Eliot Nicolas and Youlia Kirova. Institut Curie, Paris, France

**Background :** Breast radiotherapy is associated with a cardiotoxicity risk which could be decreased by optimizing radiation dose to the left anterior descending coronary artery (LADCA). However, precise delineation of the LADCA on non-contrast computed tomography (CT) scans is complex and poorly reproducible.

**Purpose :** This study aimed to define a reproducible "high risk cardiac zone" (HRCZ) which could straightforwardly replace LADCA delineation on non-contrast CT scans for treatment planning optimization. Additionally, we compared standard dosimetric parameters (mean and maximum doses) of the proposed HRCZ and of the LADCA.

**Materials/methods :** Forty breast cancer patients treated with intensity-modulated radiation therapy (IMRT) were randomly selected from our institutional database. The LADCA was manually delineated on the non-contrast simulation CT scans according to ESTRO guidelines (Duane et al., 2017), to ensure reproducibility, and each contour was validated by a staff of three radiation oncologists. "High risk cardiac zones" (HRCZ) were defined as segments of the anterior cardiac wall, geometrically centered around the inter-ventricular groove where the LADCA anatomically lies (from top to bottom) with a constant 1cm-thickness and a symmetrical lateral expansion on both sides of the groove (HRCZ width). For each patient, eight "high risk cardiac zones" (HRCZ) were delineated differing by their width, ranging between 1 cm and 8 cm (by steps of 1cm). Mean and maximum doses to the LADCA and to the HRCZ were retrieved, and relative variations were calculated as follows, as a function of the HRCZ width:

*Mean dose relative variation* =  $[mean\ dose\ (HRCZ) - mean\ dose\ (LADCA)] / mean\ dose\ (LADCA)$

*Max. dose relative variation* =  $[max.\ dose\ (HRCZ) - max.\ dose\ (LADCA)] / max.\ dose\ (LADCA)$

**Results :** Mean and maximum dose relative variations between HRCZ and LADCA are reported in **table 1** as a function of HRCZ width, for left-sided and right-sided irradiation. For a given HRCZ width, LADCA radiation exposure can be straightforwardly deducted from HRCZ dosimetric parameters, by applying the corresponding dose adjustments. HRCZ had higher maximum doses than LADCA, independently of the width. However, for a HRCZ width larger than 4 cm, dosimetric adjustments for the maximum doses drastically increased for right-sided irradiation with a potential risk of non-representativeness.

Table 1: maximum and mean dose relative variation between the LADCA and the proposed HRCZ

HRCZ width (cm)	Max. dose var. (left-sided RT)	Mean dose var. (left-sided RT)	Max. dose var.(right-sided RT)	Mean dose var. (right-sided RT)
1	5.3%	-13.0%	7.8%	-1.4%
2	12.6%	-19.1%	16.3%	-2.4%
3	19.1%	-22.6%	26.4%	-2.8%
4	24.8%	-26.0%	38.6%	-2.8%
5	29.0%	-28.5%	52.2%	-2.2%
6	29.0%	-32.3%	71.3%	-1.1%
7	29.9%	-36.0%	92.4%	0.5%
8	29.9%	-38.8%	118.3%	2.8%

Table 1: maximum and mean dose relative variation between the LADCA and the proposed HRCZ, as a function of the HRCZ width. HRCZ: "high risk cardiac zone". LADCA: Left anterior descending coronary artery.

**Conclusion :** When planning breast radiotherapy on non-contrast CT scans, delineating a segment of the anterior cardiac wall centered on the inter-ventricular groove from top to bottom, with a 1cm thickness and a 3-4cm width, can replace LADCA uncertain contouring and can be conveniently used for indirect coronary sparing.

The psychosocial impact of caregiving on partners of young women with breast cancer in treatment

Tamryn F Gray<sup>1</sup>, Nancy Borstelmann<sup>1</sup>, Shoshana Rosenberg<sup>1</sup>, Shari Gelber<sup>1</sup>, Meghan E Meyer<sup>1</sup>, Kathryn J. Ruddy<sup>2</sup>, Lidia Schapira<sup>3</sup>, Steven Come<sup>4</sup>, Virginia Borges<sup>5</sup>, Tamara Cadet<sup>6</sup>, Peter Maramaldi<sup>6</sup> and Ann H. Partridge<sup>1</sup>. <sup>1</sup>Dana-Farber Cancer Institute, Boston, MA; <sup>2</sup>Mayo Clinic, Rochester, MN; <sup>3</sup>Stanford University School of Medicine, Palo Alto, CA; <sup>4</sup>Beth Israel Deaconess Medical Center, Boston, MA; <sup>5</sup>University of Colorado, Aurora, CO; <sup>6</sup>Simmons College School of Social Work, Boston, MA

**Background** Cancer diagnosis and early treatment may have wide-ranging consequences for a woman's partner (ie. spouse or significant other). In general, younger caregivers have been found to have greater unmet needs and higher levels of distress compared to those who are older. To date, there is little known about the unmet needs and experiences of partners who care for young women with breast cancer during active treatment. **Trial Design:** Cross-sectional survey of partners of young women with breast cancer. **Eligibility Criteria:** The current analysis focuses on a subset of respondent partners of women with breast cancer participating in the Young Womens Breast Cancer Study (NCT01468246) who met the following criteria: diagnosed at age < 40 years; time since diagnosis < 12 months; and/or Stage IV disease (at diagnosis or in metastatic setting); and/or local recurrent disease < 12 months. **Specific Aims:** To explore the experience of partners of women in active treatment or having very recently completed treatment for breast cancer. **Statistical Methods:** We employed descriptive statistics to present sample characteristics, including means or medians for continuous variables and proportions for categorical variables. We assessed partners' responses re: sociodemographics, perceived social support (MOS-Social Support Survey, Cancer Perceived Agents of Social Support), quality of life (QOL) (Caregiver QOL Index-Cancer), coping (Brief COPE), perceived financial security, perceived parenting concerns (Parenting Concerns Questionnaire), anxiety and depression symptoms (Hospital Anxiety and Depression Scale), sexual satisfaction (Global Measure of Sexual Satisfaction), posttraumatic growth (Posttraumatic Growth Inventory-Short Form), and an open-ended question to explore their experiences and needs. **Accrual:** 25 participants were included. **Results:** All partners were male (25/25; 100%), and most were white (n=23/25; 92%), working full-time (n=21/25; 91%); and college educated (n=19/25; 86%). Eighteen partners (n=18/25; 72%) were parenting children < 18 years old and 40% (n=10/25) were partnered with women with Stage 4 breast cancer. At the time of the survey, the median age of partners was 44 years (range, 28-69) and of patients was 38 years (range, 25-40). Many partners (57%) reported symptoms of anxiety (>8 on the HADS anxiety subscale), fewer (22%) were categorized as having symptoms of depression (>8 on the HADS depression subscale). Additionally, 39% reported not being sexually active; 41% reported maladaptive coping; 30% reported financial strain; 30% reported relationship strain. Reported caregiver QOL ranged from 22-116, with a mean score of 52.5 (SD, 23.9), similar to population norms, with higher scores indicating lower quality of life. Parenting concerns scores were generally low indicating less concern, with a range of 12-35, and mean of 20.5 (SD, 7.6). Post-traumatic growth ranged from 4-33, with a mean score of 20.7 (SD, 7.4), with higher scores indicating greater personal growth experienced. 44% (11/25) responded to the open-ended experiences and needs question. Common responses included feeling a lack of support, need for tailored and titrated information, and desire to connect with other men who faced similar experiences. Partners also reported their struggles with uncertainty about the future.

**Discussion:** A subset of partners of young women in active treatment for breast cancer expressed concerns related to relationship strain, sexuality, need for support, and finances. Future work designed to meet the needs of partners of breast cancer patients including informational and psychosocial supports may benefit them and the patients as they manage the process of ongoing treatment and challenges about the future.

Primary efficacy results from AIPAC: A double-blinded, placebo controlled, randomized multinational phase IIb trial comparing weekly paclitaxel plus eftilagimod alpha (soluble LAG-3 protein) vs. weekly paclitaxel plus placebo in HR-positive metastatic breast cancer patients

Hans Wildiers<sup>1</sup>, Anne Armstrong<sup>2</sup>, Eveline Cuypere<sup>3</sup>, Florence Dalenc<sup>4</sup>, Luc Dirix<sup>5</sup>, Steve Chan<sup>6</sup>, Frederik Marme<sup>7</sup>, Carolina Pia Schroder<sup>8</sup>, Jens Huober<sup>9</sup>, Jill Wagemans<sup>10</sup>, Peter Vuylsteke<sup>11</sup>, Jean-Philippe Jacquin<sup>12</sup>, Etienne Brain<sup>13</sup>, Sherko Kummel<sup>14</sup>, Zsuzsanna Papai<sup>15</sup>, Luca Perjesi<sup>16</sup>, Christian Mueller<sup>17</sup>, Chrystelle Brignone<sup>18</sup> and Frederic Triebel<sup>18</sup>. <sup>1</sup>Department of General Medical Oncology and Multidisciplinary Breast Centre, Leuven, Belgium<sup>2</sup>The Christie NHS Foundation Trust, Manchester, United Kingdom<sup>3</sup>AZ Sint-Jan Burgge-Oostende AV, Ruddershove, Belgium<sup>4</sup>Institut Claudius Regaud, Toulouse, France<sup>5</sup>GZA Ziekenhuizen Campus Sint-Augustinus, Oosterveldlaan, Belgium<sup>6</sup>Nottingham Cancer Clinical Trials Team (NCCTT), Nottingham, United Kingdom<sup>7</sup>National Center for Tumor Diseases (NCT) Heidelberg, Heidelberg, Germany<sup>8</sup>University Medical Center Groningen, Groningen, Netherlands<sup>9</sup>Universitätsfrauenklinik Ulm, Ulm, Germany<sup>10</sup>AZ Sint-Maarten, Mechelen, Belgium<sup>11</sup>CHU UCL Namur, St Elisabeth, Belgium<sup>12</sup>Institut de Cancerologie de la Loire (ICO) Lucien Neuwirth, Saint Priest en Jarez, France<sup>13</sup>Institut Curie - Hopital Rene Huguenin, Saint-Cloud, France<sup>14</sup>KEM | Evang. Kliniken Essen-Mitte, Essen, Germany<sup>15</sup>MH Egeszegugyi Kozpont Onkologiai Osztaly, Budapest, Hungary<sup>16</sup>Immutep, Budapest, Hungary<sup>17</sup>Clinical Development, Immutep, Berlin, Germany<sup>18</sup>Research & Development, Immutep, Paris, France

**Background:**Eftilagimod alpha (efti, IMP321), a soluble LAG-3 protein (LAG-3Ig) that binds to a subset of MHC class II molecules, mediates antigen-presenting cell (APC) activation followed by CD8 T-cell activation. AIPAC (Active Immunotherapy PAClitaxel; NCT02614833) investigated combinations of the APC activator efti + weekly paclitaxel compared to paclitaxel + placebo in metastatic breast carcinoma (MBC) patients (pts).

**Methods:**The placebo-controlled, double-blinded, 1:1 randomized, multinational, phase IIb trial enrolled pts with measurable disease, hormone receptor-positive (HR+) MBC with indications for first line weekly paclitaxel without indication for HER2/neu targeted therapy. Pts received paclitaxel (80 mg/m<sup>2</sup> IV at D1, D8, D15 plus efti (30 mg) or placebo at D2, D16 (injected SC every 2 weeks) for 6 cycles (1 cycle = 4 weeks). Maintenance phase followed in which pts benefitting from treatment received efti or placebo for an additional 52 weeks. Primary endpoint was progression-free survival (PFS) (RECIST1.1) determined by blinded independent central read (BICR). Secondary endpoints included local read PFS, RECIST 1.1 tumor response, pharmacodynamic effects, quality of life and overall survival. The study was powered (80 %) to detect 0.667 hazard ratio (HR) based on 5% one-sided alpha and planned to enroll 226 pts.

**Results:** From Jan 2017-Jul 2019, 227 pts were randomized. All except 1 received ≥ 1 treatment and were included in the full analysis set [(efti (n = 114); placebo (n = 112)]. Data cut-off was 10<sup>th</sup> Jan 2020 with 12 month median follow-up. HR for PFS assessed by BICR was 0.93 [95 % CI 0.67-1.30], p = 0.341. In the efti group 63 % (95% CI 52- 71%) were progression free at 6 months compared to 54 % (95% CI 43-63%) in the placebo group. ORR was 48.3 % in the efti group compared to 38.4 % in the placebo group as assessed by BICR (p=0.118). Efti increased numbers of PBMCs and T cells (CD4 and CD8) significantly compared to placebo. In predefined subgroups such as pts with low monocytes at baseline, luminal B subtype or age <65 years, clinically meaningful improvement in PFS was observed. TEAE rates leading to death (or discontinuation) in the two groups were similar, at 1.8 % (5.3 %) and 2.7 % (6.3 %) for the efti and placebo groups, respectively. Three pts (1.3 %) were withdrawn from treatment due to grade 3-4 immediate hypersensitivity reactions to efti, while 4 pts (1 in efti group vs. 3 in placebo group) were withdrawn from the study due to grade 2-3 hypersensitivity to paclitaxel. The most frequent (≥10%) TEAEs ≥ grade 3 were gamma-glutamyl transferase increase (19.3% vs 29.5%), aspartate aminotransferase increase (8.8% vs 10.7%) and neutropenia (15.8% vs 14.3%) reported in the efti and placebo group, respectively. Injection site reaction (34.2% vs 3.6%) and injection site erythema (30.7% vs 1.8%) were more frequent in efti versus placebo arms.

	BICR		Investigator	
	Efti+paclitaxel(N= 114)	Placebo+paclitaxel(N= 112)	Efti+paclitaxel(N= 114)	Placebo+paclitaxel(N= 112)
Median PFS, months (95% CI)	7.29 (6.64-7.46)	7.29 (5.52-7.46)	7.16 (5.65-7.39)	6.70 (5.52-7.33)
HR (95% CI)	0.93 (0.67-1.30)		0.92 (0.69-1.23)	
P value	0.341		0.305	
Mean PFS [SE], months	7.12 [0.37]	6.64 [0.38]	6.81 [0.33]	6.30 [0.31]

**Conclusion:** Efti did not prolong overall median PFS in women with HR+ MBC receiving first line chemotherapy. Tested in a randomized setting against placebo in pts receiving paclitaxel, efti is well tolerated and did not add clinically significant toxicity while inducing a sustained, significant increase in CD8 T cells in blood and clinical benefits in some predefined subgroups. Relevant subgroups and overall survival will be investigated.

Igf1r mediates cdk4/6 inhibitor (cdk4/6i) resistance in tumor samples and in cellular models

Seth A. Wander<sup>1</sup>, Pingping Mao<sup>2</sup>, Maxwell R. Lloyd<sup>2</sup>, Gabriela N. Johnson<sup>2</sup>, Kailey Kowalski<sup>2</sup>, Uttara Nayar<sup>2</sup>, Lillian M. Guenther<sup>2</sup>, Kimberly Stegmaier<sup>2</sup>, Eric P. Winer<sup>2</sup>, Nancy U. Lin<sup>2</sup> and Nikhil Waghe<sup>2</sup>. <sup>1</sup>Massachusetts General Hospital Cancer Center, Boston, MA; <sup>2</sup>Dana-Farber Cancer Institute, Boston, MA

**Background:** Deciphering the molecular landscape of resistance to the CDK4/6 inhibitors represents a critically important question for patients with hormone-receptor positive (HR+) metastatic breast cancer (MBC). Emerging insights from sequencing efforts suggest that inactivating alterations in the RB1 tumor suppressor occur in a small minority of patients and that a variety of heterogeneous mediators provoke resistance in patient samples. Proteins implicated in CDK4/6i resistance include cell cycle regulators such as cyclin E1/2, CDK6, and aurora kinase as well as known oncogenic signal transduction mediators involved in activation of the RAS-MEK and AKT-mTOR pathways. The insulin-like growth factor 1 receptor (IGF1R) has been implicated in modulating anti-estrogen resistance, and IGF1R inhibitors are currently in various stages of pre-clinical and clinical development.

**Methods:** We identified patients with amplification events in IGF1R from a database containing targeted sequencing of solid tumor samples obtained from patients with HR+ MBC enrolled on a research biopsy protocol. Tumor biopsies may have been obtained at various points during each patient's clinical treatment course. HR+ T47D cells were modified to over-express IGF1R via lentiviral infection and selection. Derivative cell lines were treated with IGF-1 ligand and downstream activation of the PI3K/AKT and RAS/MEK pathways were assessed via western blotting. Control cells (expressing GFP) were mixed with IGF1R-expressing cells 1:1 and cultured in the presence of IGF-1 ligand and palbociclib or other drugs, for 1-3 weeks. At the timepoint of interest, cells were harvested and the relative proportion of GFP or IGF1R-expressing cells were interrogated via flow cytometry.

**Results:** We identified seven patients with HR+ MBC and IGF1R amplifications via targeted sequencing of tumor biopsies. Five of these patients had exposure to CDK4/6i-based therapy in the metastatic setting. Three patients demonstrated intrinsic resistance to CDK4/6i treatment (with duration <6 months) and biopsies were obtained prior to CDK4/6i exposure or, in one case, while on treatment. In an additional patient, after nine months of CDK4/6i-based therapy, an IGF1R amplification was present at the time of progression. In one counter-example, a baseline biopsy revealed IGF1R amplification and subsequent clinical benefit with CDK4/6i, exceeding 10 months, was noted. T47D cells over-expressing IGF1R demonstrated increased pERK and pAKT activation following introduction of IGF-1 ligand. Control GFP and IGF1R-expressing cells were plated 1:1 and cultured in the presence of IGF-1 ligand and palbociclib. In a flow cytometry-based competition assay, an IGF-1 dose-dependent increase in the relative proportion of IGF1R-expressing cells was noted after one, two, and three weeks of palbociclib treatment. The extent of IGF1R-expressing cell enrichment was attenuated in the presence of either a MEK inhibitor or an IGF1R inhibitor.

**Conclusions:** IGF1R amplification events were identified in tumor biopsy samples that reflect either intrinsic or acquired resistance to CDK4/6i-based therapy. HR+ breast cancer cells which over-express IGF1R demonstrate enrichment under palbociclib drug selection in a flow cytometry-based competition assay, which was abrogated by concurrent use of a MEK or IGF1R inhibitor. These results suggest that IGF1R may join the increasingly heterogeneous landscape of CDK4/6i resistance mediators. Further exploration of this possibility is warranted. A subset of patients with IGF1R-mediated CDK4/6i resistance could benefit from therapeutic strategies designed to downregulate MEK or IGF1R activity.

The role of purinergic signaling in the chemotherapy response of triple negative breast cancer

Jasmine Manouchehri, Jharna Datta and Mathew Cherian. The Ohio State University, Columbus, OH

Triple negative breast cancer (TNBC) affects women worldwide with a higher incidence in minority populations. Patients with TNBCs often have poorer prognoses in comparison to other breast cancer sub-types due to a lack of effective therapeutic options. Chemotherapy and immunotherapy are the only effective treatments, but these modalities generally result in short-term response. Therefore, there is a need to identify additional therapies to intensify the chemotherapeutic response in TNBC. When cancer cells are exposed to chemotherapy, they release adenosine triphosphate (ATP) into the extracellular space. Extracellular ATP is degraded by CD39 (E-NTPDase) to adenosine diphosphate (ADP) and then adenosine monophosphate (AMP), and AMP is broken down to adenosine by CD73. We examined the potential role of extracellular ATP in chemotherapy-induced cancer cell death. We hypothesized that extracellular ATP sensitizes TNBC cells to chemotherapy and that ATP degrading enzymes such as CD39 and CD73 attenuate this effect. TNBC MDA-MB 231, MDA-MB 468, and Hs 578t cell lines were treated with the chemotherapeutic agent paclitaxel for different time courses. Extracellular ATP was measured via the ATPlite 1step luminescence assay, and cell viability was assessed by applying PrestoBlue HS cell viability reagent. Paclitaxel-treated TNBC cell lines revealed a dose-dependent increase in extracellular ATP release in the presence of an inhibitor of CD39 (POM-1), accompanied by a dose-dependent decrease in cell viability. In addition, the general P2X receptor (P2RX) inhibitor iso-PPADS and the P2RX7 specific inhibitor (A438079) were added separately to observe if the P2X receptors are necessary for the release of ATP upon paclitaxel treatment. After paclitaxel treatment, TNBC cell lines showed a decline in the amount of ATP released with the addition of the inhibitors iso-PPADS and A438079. Treatment of non-tumorigenic immortalized MCF-10A mammary epithelial cells with paclitaxel in the presence and absence of the inhibitors iso-PPADS and A438079 did not result in a significant increase in extracellular ATP or a decrease in cell viability. These results indicate that P2RX7 is necessary for ATP release in TNBC cell lines exposed to chemotherapy. Furthermore, when TNBC cell lines were treated with increasing concentrations of ATP, there was a dose-dependent decrease in cell viability. Overall, these findings suggest that extracellular ATP may impact the chemotherapeutic response in TNBC cell lines through the activation of the ATP-gated channel P2RX7.

**Introduction.** As nonobligate precursors of invasive disease, pre-cancers provide a unique vantage point from which to study the molecular pathways and evolutionary dynamics that lead to the development of life-threatening cancers. Ductal carcinoma *in situ* (DCIS) is the most commonly diagnosed precursor of breast cancer, with variable propensity for invasive progression. In order to address the problems of over- and under-treatment, we performed a multimodal, integrated profile of DCIS with clinical outcomes with which to develop and validate predictors of invasive progression.

**Methods.** We present observations on DNA, RNA, and protein expression on two independent patient cohorts of DCIS, diagnosed from 1981 to 2014, from the Translational Breast Cancer Research Consortium (TBCRC 038) and the Washington University Repository of Archival Human Breast Tissue (RAHBT). Patients initially diagnosed with DCIS, with either DCIS or invasive recurrence (cases; mean follow up 5.8 years) were matched to those without recurrence (controls; mean follow up 10.3 years), based upon age at diagnosis and year of diagnosis. **Results.** We present genomic and cellular changes that correlate with both disease states and patient outcomes in DCIS. DCIS can be clustered by classification systems developed for IBC. Specific immune cell types and pathways correlate with longitudinal outcome. Luminal cell adhesion and metabolism pathways are upregulated in controls and cases, respectively. Highly multiplexed ion beam imaging (MIBI) was used to validate RNA seq findings, and to provide single cell-level spatial context for molecular alterations. **Conclusion.** We have performed an integrated multi-omic analysis of DCIS and associated tumor microenvironment. Our multi-scale approach employs in situ methods to generate a spatially resolved atlas of breast precancers where different modalities can be directly compared to each other, and correlated with conventional pathology findings and clinical outcome. The PreCancer Atlas represents a complex multi-modal database for DCIS study, whose design allows for future discovery and hypothesis generation.

**Table 1. Breast Pre-cancer Atlas Multi-scale Characterization Assays**

Assay	Scale	Type of Data	Integration and validation with other assays
RNA-seq (Single duct, single cell, TME)	Cell, duct, organ, normal tissue	1. Whole transcriptome gene expression profiling per single duct (also enabling CNV and cell type prediction)2. Whole transcriptome gene expression profiling per single duct	1. Prediction of CNV confirmed by DNA-seq (single duct) and FISH (single cell)2. Prediction of cell type composition (Cibersort) confirmed by multiplex IHC and multicolor flow cytometry
Low-pass whole genome DNA-seq	Duct and adjacent normal	CNV profiling per single duct	Analysis of CNV supported by RNA-seq (single duct) and MIBI (single cell)
Whole genome sequencing	Duct and adjacent normal	Mutation status per single duct	Mutational analysis confirmed by RNA-seq
Multiplex IHC (MIBI & Cyclic multicolor)	Cell	1. Cell type2. Proteomic analysis	Analysis of cell type supported by RNA-seq of ducts (Cibersort) and single cells
H&E Morphometrics	Cell, duct, organ	Spatial location of cell types, organization of ducts	Analysis of H&E images correlated with FISH data

A phase 1/2 study of SAR439859, an oral selective estrogen receptor (ER) degrader (SERD), as monotherapy and in combination with other anti-cancer therapies in postmenopausal women with ER-positive (ER+)/human epidermal growth factor receptor 2-negative (HER2-) metastatic breast cancer (mBC): AMEERA-1

Hannah M Linden<sup>1</sup>, Mario Campone<sup>2</sup>, Aditya Bardia<sup>3</sup>, Gary A Ulaner<sup>4</sup>, Alice Gosselin<sup>5</sup>, Severine Doroumian<sup>6</sup>, Vasiliki Pelekanou<sup>7</sup>, Marina Celanovic<sup>7</sup> and Sarat Chandarlapaty<sup>4</sup>. <sup>1</sup>University of Washington Medical Center, Seattle Cancer Care Alliance, Seattle, WA; <sup>2</sup>Institut de Cancerologie de l'Ouest, Rene Gauducheau, St Herblain, France <sup>3</sup>Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA; <sup>4</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>5</sup>Sanofi, Paris, France <sup>6</sup>Sanofi, Montpellier, France <sup>7</sup>Sanofi, Cambridge, MA

**Background** SERDs belong to a class of ER-targeted therapies that antagonize and degrade ERs, including in ER-dependent tumors resistant to other endocrine therapies (ET). This study (AMEERA-1; NCT03284957) investigates SAR439859, an oral SERD, as monotherapy and (in ongoing cohorts) in combination with targeted therapies in patients (pts) with ER+/HER2- mBC. Here we report updated safety and antitumor activity with SAR439859 monotherapy, including exploratory analyses by prior therapy and *ESR1* status. **Methods** This open-label, phase 1/2, first-in-human study assessed SAR439859 as monotherapy in Parts A (dose escalation 20-600 mg once daily [QD]) and B (dose expansion with recommended dose at 400 mg QD). Eligible pts were heavily pre-treated, postmenopausal women with ER+/HER2- mBC and measurable disease who received ≥6 months of prior ET in the advanced setting. Prior chemotherapy, mammalian target of rapamycin inhibitors (mTORi) and cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) for advanced disease were allowed. This analysis pooled data from pts receiving SAR439859 ≥150 mg (Part A) and 400 mg (Part B), administered in 28-day cycles. Antitumor activity was assessed by the objective response rate and clinical benefit rate (CBR: complete response [CR], partial response [PR] and stable disease [SD] ≥24 weeks) per RECIST v1.1, determined by investigators. Analyses by prior therapy and baseline *ESR1* mutation status were performed. Safety was also evaluated. **Results** Pts (n = 62; Part A: 13; Part B: 49) had a median age of 63 (range 37-88) years and ECOG PS 0 (59.7%) or 1 (40.3%); 93.5% had visceral metastases. Pts had a median of 2 (range 1-8) prior lines of therapy in the advanced setting (48.4% had ≥3 prior lines): all had prior ET and 72.6% had prior targeted therapy. SAR439859 monotherapy showed antitumor activity in the response-evaluable population (n = 59) and in subset populations with ≤3 prior lines (n = 33) or without prior mTORi, CDK4/6i, or SERD (n = 14) (Table 1). For pts with *ESR1* status (n = 58), CBR with SAR439859 was comparable in *ESR1* wild-type (36.7%) and mutant mBC (32.1%), with similar results in subpopulations. Treatment-related adverse events (TRAEs) occurred in 62.9% of pts (all grade 1-2); none resulted in SAR439859 discontinuation. Most frequent TRAEs were hot flush (16.1%); constipation and arthralgia (each 9.7%); decreased appetite, vomiting, diarrhea and nausea (each 8.1%); and fatigue (6.5%). **Conclusions** Among heavily pre-treated pts, SAR439859 demonstrated antitumor activity, similar to historical single-agent fulvestrant activity in less heavily pre-treated pts with advanced/mBC (2L+ setting; no prior targeted agents) (indirect comparison). In both subsets of pts with fewer prior advanced lines of therapy, SAR439859 showed trends of greater clinical activity versus historical fulvestrant activity. SAR439859 had a favorable safety profile with limited TRAEs. No safety signals of cardiac or ocular toxicities were observed. Ongoing parts of the study are investigating SAR439859 in combination with targeted therapies. Based on the monotherapy results, a randomized phase 2 study is investigating SAR439859 compared with physician's choice in a 2L+ setting (AMEERA-3; NCT04059484). Funding: Sanofi.

Antitumor activity overall and in subpopulations by prior lines of therapy (Parts A+B)

	Overall population (A+B) (n = 59) <sup>a</sup>	≤3 Prior advanced lines (n = 33) <sup>b</sup>	Without prior targeted therapy (n = 14) <sup>c</sup>

I-SPY2 is a neoadjuvant trial evaluating experimental therapies in combination with cytotoxic chemotherapy compared to chemotherapy alone with the primary endpoint of pathologic complete response (pCR). Abundant preclinical evidence suggested the type I insulin-like growth factor receptor (IGF-1R) regulated breast cancer growth, although multiple clinical trials did not show benefit. We were the first to report the results of a monoclonal IGF-1R antibody ganitumab (G) in combination with chemotherapy. PGM followed by doxorubicin/cyclophosphamide (AC) did not result in substantial increases in pCR when compared to P followed by AC. In this report, we examined several potential predictive biomarkers.

IGF-1R inhibitors induce hyperglycemia and we examined hemoglobin A1C (HgbA1c) as a measure of glucose control in patients before and after PGM therapy. 106 patients received PGM and 104 patients had baseline HgbA1c with a median of 5.4%. However, 27% (28/104) had levels greater than 5.7% the upper limit of normal as defined by the NIDDK. 4 of 104 had HgbA1c greater than 6.5%, a level associated with type 2 diabetes. pCR rates are similar between patients with baseline HgbA1c ≤5.7% (21%) vs. >5.7% (25%) (Fisher test p=0.79). 72 of these patients had an additional HgbA1c during the course of PGM therapy. For patients with HgbA1c ≤5.7%, 27% (14/52) had subsequent elevation above 5.7% after PGM. For patients with a baseline HgbA1c >5.7%, all 20 patients continued to have elevated levels through PGM.

We also examined pre-treatment tumor gene expression profiles derived from custom Agilent 44K full-genome microarrays. We studied 11 genes associated with the IGF-1R signaling (IGF1, IGF2, IGF1R, INSR, IGFBP2, IRS1, IRS2, IGFBP3, IGFBP4, IGFBP5, CDH1), the IGFBP5/IGFBP4 ratio, and two IGFR expression signatures (Creighton, et al. J Clin Oncol 26:4078 2008 PMID: 18757322; Mu, et al. Breast Cancer Res Treat 133:321 2012 PMID: 22297468). The 2 signatures evaluated: the IGF1 ligand score and the IGF1-R signature are anti-correlated (Rp= - 0.79). In the population as a whole, lower levels of IRS1 and IGFBP5 significantly associated with response to PGM (likelihood ratio test (LR) p< 0.05), as do lower levels of the IGF1 ligand score and higher levels of the IGF-1R signature. However, levels of IRS1 and the two expression signatures also trend toward or are significantly associated with response in the control arm; and treatment interactions for all four biomarkers are non-significant (LR p>0.05). Therefore, none of these biomarkers qualify as specific predictors of response to PGM. Similarly, high MammaPrint scores (MP2) were associated with higher pCR scores in both PGM and Control arms. Previous gene expression profiles were divided into tertiles (low, intermediate, high). Similar to the continuous case, IGF1Rsig-class associates with pCR in both the PGM and control arms (Fisher test p=0.033 and 0.044, respectively), and thus also fails as a specific predictor of response to PGM.

We conclude that PGM therapy results in worsening of glucose control and likely increases serum insulin levels. While IGF gene expression profiling associated with treatment response, they were not specific for PGM. Further, biomarker analysis and strategies to control glucose will be needed to optimize anti-IGF-1R therapies.

Young, empowered & strong (YES): A web-based education and supportive care intervention for young women with breast cancer across the care continuum

Tal Sella, Craig Snow, Hannah Freeman, Phillip D Poorvu, Shoshana M Rosenberg and Ann H Partridge. Dana Farber Cancer Institute, Boston, MA

**Background:** Young women diagnosed with breast cancer have unique physical and psycho-social needs that are often unaddressed. Patient-centered models of care, including eHealth strategies, can help empower young women to self-manage symptoms and psychosocial concerns, as well as support informational needs throughout the cancer care trajectory. **Methods:** YES (Young, Empowered and Strong) is an interactive web-based portal designed with patient-reported outcome questionnaires (PROs) that trigger delivery of young breast cancer patient-specific education and symptom management materials. Personal journal and messaging components are also available. We piloted the YES portal among young women (<45 years) with newly diagnosed early breast cancer (EBC), breast cancer survivors (BC-S) and women living with metastatic breast cancer (MBC), for whom PROs were deployed weekly (EBC, MBC) or every 4 weeks (BC-S) over 12-weeks. At study completion, the use, feasibility and acceptability of the YES portal was assessed via a survey and a structured interview. **Results:** Thirty women were enrolled between April and June 2019: 10 EBC, 10 BC-S and 10 MBC. Mean age at diagnosis and enrollment was 36 (range 25-44) and 39 (range 31-44) years respectively and 13% (4/30) were non-white. Nearly all participants were receiving treatment (96%, 27/28) including 54% (15/28), endocrine therapy and 43% (12/28), chemotherapy. Overall, 61% (180/296) of PROs deployed were completed, with completion rates highest for EBC patients (EBC: 70%, BC-S: 63%, MBC: 52%). Of 37 PROs domains, the most frequently triggered were sexual health (EBC: 90%, BC-S: 90%, MBC: 90%), anxiety (EBC: 80%, BC-S: 90%, MBC: 90%) and fatigue (EBC: 90%, BC-S: 80%, MBC: 90%). Physical domains and young breast cancer specific domains commonly addressed in clinic (i.e., fertility, genetic testing) were less frequently triggered. The post-pilot survey was answered by 15 participants: 8/15 reported the information shared through YES was helpful, 6/14 felt the portal helped monitor side effects and 8/14 felt the portal helped manage side-effects. Nineteen women completed post-pilot interviews: most women with EBC and MBC said the portal increased symptom awareness and complemented information communicated by providers; the BC-S group more frequently commented that features of the YES portal focusing on symptom monitoring/management would have been more useful when they were earlier in their care (newly diagnosed or undergoing more active treatment). **Conclusions:** YES, a novel eHealth intervention designed to support young women with breast cancer, is feasible and acceptable to young women across the breast cancer care continuum. The nearly universal triggering of information and support for sexual and mental health suggests sub-optimal management of these issues in the clinical setting and the potential role for self-management through an eHealth platform for this population. Future efforts will aim to evaluate whether provision of information through the YES portal reduces symptom burden and unaddressed needs and concerns in young women with breast cancer.

Modeling clonal structure over narrow time frames via circulating tumor DNA in metastatic breast cancer

Daniel G Stover<sup>1</sup>, Katharine A Collier<sup>1</sup>, David Tallman<sup>1</sup>, Juliet Forman<sup>2</sup>, Sachet Shukla<sup>2</sup>, Sarah Asad<sup>1</sup>, Justin Rhoades<sup>2</sup>, Samuel Freeman<sup>2</sup>, Mathew Cherian<sup>1</sup>, Sagar Sardesai<sup>1</sup>, Romualdo Barroso-Sousa<sup>3</sup>, Carrie Cibulskis<sup>2</sup>, Niall Lennon<sup>2</sup>, Gavin Ha<sup>4</sup>, Sara M Tolaney<sup>5</sup>, Viktor A Adalsteinsson<sup>2</sup> and Zachary Weber<sup>1</sup>. <sup>1</sup>Ohio State University Comprehensive Cancer Center, Columbus, OH; <sup>2</sup>Broad Institute of Harvard and MIT, Cambridge, MA; <sup>3</sup>Hospital Sirio-Libanês, Brasília, Brazil; <sup>4</sup>Fred Hutchinson Cancer Research Center, Seattle, WA; <sup>5</sup>Dana-Farber Cancer Institute, Boston, MA

**Introduction:** Circulating tumor DNA (ctDNA) offers the ability to repeatedly interrogate tumor genomic information, providing an opportunity for real-time monitoring of tumor genomic dynamics. In this study, we deeply analyzed multiple ctDNA samples collected over narrow time frames (days-to-weeks) from seven patients with metastatic triple-negative breast cancer (mTNBC), a cancer type known to have high ctDNA content. **Methods:** Patients with mTNBC were enrolled in a clinical trial of multi-kinase inhibitor cabozantinib, providing uniform and targeted treatment, and samples were collected day 1, day 8, then every 21 to 42 days on study. ctDNA was extracted from each plasma sample and underwent ultra-low pass whole genome sequencing (ULP-WGS; average depth 0.1x; n=42 samples), deep targeted panel sequencing (TPS) of 402 cancer-related genes with unique molecular identifier indexing (depth 10,000x; n=42 samples), and samples with tumor fraction (TFx) >10% underwent whole exome sequencing (WES; depth 200x; n=31 samples), with whole blood germline sequencing of both TPS and WES for subsequent analyses. Somatic copy number alterations (SCNAs) were identified from ULP-WGS and WES. PyClone with TPS was employed for clonal dynamic analyses. Predicted neoantigens were determined from WES using HLathena. **Results:** A total of 42 total plasma samples from 7 patients (range 4-8 samples per patient) were collected at narrow time intervals, median 21 days (range 6 to 42 days) between samples. The median TFx across all samples was 18.1% (range 2.5% to 44.3%). TFx estimates were concordant when comparing orthogonal sequencing approaches (ULP-WGS, WES) and tumor fraction estimation algorithms (ichorCNA, FACETS). Despite all seven patients having 'stable disease' as best objective response, TFx dynamics were widely variable with TFx declining to lower limit of detection in three of seven patients. Of all samples, 31/42 (73.8%) had tumor fraction >10% and underwent WES; each patient had at least 3 samples that underwent both WES and TPS. There was strong agreement between TPS and WES: across all 31 shared samples, mutation recall in TPS versus WES (gold standard) was 95.5%. Variant allele frequency across all mutations detected in both TPS and WES was highly concordant (Pearson's  $r=0.949$ ). Clonal mutations were consistently detected across multiple samples within patients. When comparing genome-wide copy number from last to first available sample within each patient, copy number log ratios were largely stable within patients (union Pearson's  $r=0.924$ ) and there were not recurrent shifts in SCNAs across patients. Through statistical modeling of TPS data, we tracked distinct clonal populations for each patient over their sampling windows. Modeled clonal architecture in most patients revealed stable, polyclonal profiles, with important breast cancer driver alterations (e.g. TP53 and PIK3CA) recurrently presenting at high prevalence. Infrequently, we also detected emergence and expansion of clones over narrow time frames (weeks) containing acquired alterations poorly annotated in the breast cancer literature. We successfully predicted neoantigens from ctDNA WES at multiple time points in each patient, with evidence that patients acquired new mutations predicted to be 'strong binder' neoantigens over time on therapy. **Conclusions:** Analysis of serial ctDNA samples collected at narrow time intervals (days-to-weeks) provides unique insight into the dynamics of ctDNA. We demonstrate strong concordance across ctDNA sequencing approaches. Evolving genomic features of tumor populations can be identified via ctDNA while on treatment, potentially providing real time insight for clinical decision-making.

Population pharmacokinetic and exposure-response modeling of the oral selective estrogen receptor degrader, rintodestrant (G1T48), in patients with ER+/HER2- advanced breast cancer

Andrew P Beelen<sup>1</sup>, Chao Li<sup>1</sup>, Praneeth Jarugula<sup>2</sup>, Mathangi Gopalakrishnan<sup>2</sup>, Jessica A Sorrentino<sup>1</sup>, Curt D Wolfgang<sup>1</sup>, Sarika Jain<sup>1</sup> and Wenli Tao<sup>1</sup>.  
<sup>1</sup>G1 Therapeutics, Inc., Research Triangle Park, NC; <sup>2</sup>University of Maryland, School of Pharmacy, Baltimore, MD

**Background:** Rintodestrant is an orally bioavailable, potent and selective estrogen receptor degrader (SERD) that competitively binds to the estrogen receptor (ER) and blocks ER signaling in tumors resistant to other endocrine therapies. Clinical trials have been conducted to evaluate the safety and efficacy of rintodestrant in healthy volunteers and patients with ER+/HER2- locally advanced or metastatic breast cancer (ABC). Population pharmacokinetic (PK) and exposure-response (Ex/Re) analyses were performed to further characterize the PK profile of rintodestrant and identify potential Ex/Re relationships. **Methods:** The present analyses include data from two studies: (1) G1T48-01, a Phase 1 first-in-human study of rintodestrant monotherapy (200-1000 mg once daily [QD]) in women with ER+/HER2- ABC after progression on endocrine therapy (NCT03455270), and (2) G1T48-10, a study in healthy volunteers investigating potential drug-drug interactions between rintodestrant (200 mg QD) and palbociclib (125 mg QD). A PK model was developed using nonlinear mixed effects methodology to estimate PK parameters for individual patients. A tumor dynamic model was built to characterize the relationship between rintodestrant concentrations and the longitudinal tumor sizes according to RECIST v1.1.

Ex/Re for key pharmacodynamic markers, including ER target engagement (<sup>18</sup>F-fluoroestradiol positron emission tomography [FES-PET]), dynamics of cell-free DNA mutational burden, ER degradation and proliferation (Ki67) in tumors, and enumeration of circulating tumor cells are being evaluated. Relationships between model-predicted exposures and study endpoints (objective response rate, clinical benefit rate) are also being evaluated.

**Results:** Rintodestrant PK was best described using a linear two-compartment model with a mixed absorption model. The predicted population mean trough concentration of rintodestrant at the recommended Phase 2 dose (800 mg QD) exceeded the IC<sub>90</sub> value for ER degradation established *in vitro*. A positive Ex/Re relationship was identified between total exposure and target ER engagement as measured by FES-PET. A clear Ex/Re relationship was not identified between any PK parameters and ER degradation or proliferation, potentially due to confounding effects from covariates in the model (eg, prior SERD treatment, *ESR1* mutations, etc). Additional exploration of these covariates is ongoing. The final PK, Ex/Re and PK/tumor dynamics model results will be presented. **Conclusions:** A population PK model was developed and Ex/Re relationship analyses were performed to support the development of rintodestrant for the treatment of patients with ER+ breast cancer. Initial results identified an Ex/Re relationship with target ER engagement via FES-PET analysis.

Tucatinib potentiates the activity of the antibody-drug conjugate T-DM1 in preclinical models of HER2-positive breast cancer

Anita Kulukian, Janelle Taylor, Nishi Jain, Devra Olson, Margo Zaval, Robert Thurman, Shawna Hengel, Lauren Farr, Thomas Pires and Scott R. Peterson. Seattle Genetics, Bothell, WA

**Background:** Tucatinib is an orally administered, reversible, highly specific HER2 tyrosine kinase inhibitor recently approved by the FDA in combination with trastuzumab and capecitabine for adult patients with advanced unresectable or metastatic HER2-positive breast cancer (mBC), including patients with brain metastases, that have failed at least one anti-HER2 regimen in the metastatic setting. In a phase IB clinical trial, tucatinib in combination with the HER2-targeted antibody-drug conjugate (ADC) ado-trastuzumab emtansine (T-DM1) was well tolerated and demonstrated activity in heavily pre-pretreated patients with HER2-positive mBC (NCT01983501; Borges VF et al., 2018). We previously presented preclinical data that tucatinib increases the activity of trastuzumab-derived ADCs in HER2-positive breast cancer models. Here, we provide mechanistic insight that tucatinib potentiates the activity of T-DM1 by modulating HER2 protein dynamics and facilitating increased cytotoxic maytansinoid drug delivery.

**Methods:** To assess changes to HER2 protein levels upon treatment with tucatinib, HER2-amplified breast cancer cell lines were analyzed by Western blot and quantitative FACS (qFACS). To probe the dynamics of HER2 at the cell surface upon binding to antibody therapeutics, SK-BR-3 cells were incubated with fluorescently labeled trastuzumab to mark HER2 at the cell surface. Cells were imaged over 72 hours to observe the internalization of surface-bound antibody. Concurrent experiments were conducted with trastuzumab labeled with QF01, a quenched fluor which fluoresces only upon lysosomal processing and can serve as a proxy for antibody catabolism. To directly measure the rates of ADC catabolism, lysates were generated from BT-474 cells treated with T-DM1 in the presence or absence of tucatinib over a 72 hour time course, and were analyzed by mass spectrometry for the T-DM1 adduct, Lys-MCC-DM1. **Results:** In HER2-amplified breast cancer cell lines, treatment with tucatinib increased overall and cell membrane-localized HER2 levels. As demonstrated by internalization assays, tucatinib had an initial effect that increased the dwell time of HER2 at the cell surface of SK-BR-3 cells. At later timepoints, HER2 bound to trastuzumab was internalized and directed towards lysosomes. These data were supported by parallel intracellular Lys-MCC-DM1 measurements, which demonstrated increased concentration of the adduct when TDM-1 was administered in combination with tucatinib. These data provide a mechanistic rationale as to why the co-administration of tucatinib with T-DM1 in vitro was synergistic by isobologram analysis, and why the combination of tucatinib with T-DM1 was more effective in vivo than either single agent alone in BT-474 xenografts and in PDX models tested, producing a higher proportion of partial or complete tumor regressions. **Conclusions:** The described preclinical in vitro and in vivo data of simultaneous dual HER2 inhibition with tucatinib and T-DM1, along with the results of the phase IB/2 clinical trial demonstrating preliminary safety and efficacy of the combination, warrant further clinical development of tucatinib in combination with T-DM1. These results also support the evaluation of tucatinib in combination with other HER2-targeted ADCs in patients with HER2-positive mBC.

## Outcomes of germline BRCA carriers versus non-carriers in the french national metastatic breast cancer ESME cohort 2008-2016

**BACKGROUND:** Approximately 5% of breast cancer (BC) patients (pts) carry a deleterious germline BRCA mutation (gBRCAm). Retrospective studies suggest that overall survival (OS) is equivalent between gBRCAm carriers and non-carriers with metastatic BC (MBC). We aimed to use the large ESME multicentre national MBC database to compare outcomes of gBRCAm carriers, gBRCA wild-type (WT) and not tested (NT) pts. **METHODS:** We used the large ESME MBC database (NCT03275311), a unique national cohort of all consecutive pts who initiated a first-line treatment for MBC between 2008 and 2016 in one of the 18 French Comprehensive Cancer Centers. All pts with data available regarding gBRCA testing were selected for the present analysis. 26 pts with non-BRCA germline mutations were classified in the WT group. The primary endpoint was OS from date of treatment initiation in the 3 groups of patients: gBRCAm, gBRCA WT and gBRCA NT. Secondary endpoints were progression-free survival under first line treatment (PFS1), clinical and biological characteristics of the 3 groups and prognostic factors for OS. Multivariable analyses included the main known prognostic factors (age at MBC, MBC subtype, disease-free interval, presence of visceral disease, number of metastatic sites). They were conducted using Cox proportional analyses. **RESULTS:** 20624 pts were included in this analysis (414 gBRCAm, 1710 WT, 18500 gBRCA NT). Pts and disease characteristics are summarized in table 1. As expected, patients with gBRCAm were younger and had a higher rate of TNBC and G3 tumors.

	gBRCAm. N = 414	gBRCA WT. N = 1710	gBRCA NT N = 18500	Pvalue (chi-2)
<b>Age (years) median [range]</b>	45 [23-82]	48 [20- 88]	61 [22-103]	<b>p&lt;0.0001</b>

<b>De novo MBC N (%)</b>	74 (17.9)	359 (21)	5914 (32)	<b>p&lt;0.0001</b>
<b>Disease-free interval (months) median [range]</b>	39.0 [-1.5- 425.7]	36.3 [-2.1- 549.6]	31.8 [-2.9- 657.8]	<b>p&lt;0.0001</b>
<b>Metastatic sites ≥3 N (%)</b>	113 (27.3)	349 (20.4)	3943 (21.3)	<b>p=0.008</b>
<b>Visceral metastases N (%)</b>	279 (67.4)	964 (56.4)	10659(57.6)	<b>p=0.0002</b>
<b>Central Nervous System Metastases N (%)</b>	66 (15.9)	132 (7.7)	1145 (6.2)	<b>p&lt;0.0001</b>

**Table 1: characteristics of patients and disease**

Median follow-up was 50.5 months (95%CI 49.7-51.5). Non-adjusted median OS was 30.6 months [21.9-34.3] in the gBRCAm group, 35.8 [32.2-37.8] in the WT and 39.3 [38.3-40.3] in NT groups. Median PFS1 was 7.9 months [6.6-9.3] in the gBRCAm group, 7.8 [7.3-8.5] in the WT and 9.7 months [9.5-10.0] in the NT groups. In multivariable analyses, OS and PFS were not significantly different between MBC patients with gBRCA and others (respective HRs 1.01 [0.88;1.17], p=0.87 and 0.94 [0.84;1.06], p=0.31). **CONCLUSION:** In this large scale real-life ESME MBC database analysis, outcomes of gBRCAm carriers with MBC do not differ from non carriers or not tested subgroups, when adjusted for other prognostic factors.

An ENT2-dependent, cell-penetrating, and DNA-damaging lupus autoantibody crosses the blood-brain barrier to target breast cancer brain metastases

James E Hansen<sup>1</sup>, Shenqi Zhang<sup>1</sup>, Anupama Shirali<sup>1</sup>, Christopher May<sup>1</sup>, Benedette Cuffari<sup>1</sup>, Valentina Dubljevic<sup>2</sup>, James A Campbell<sup>2</sup> and Jiangbing Zhou<sup>1</sup>. <sup>1</sup>Yale School of Medicine, New Haven, CT; <sup>2</sup>Patrys Ltd, Melbourne, Australia

**Introduction:** Antibody-based immunotherapy has potential to change paradigms in the management of breast cancer brain metastases, if the blood-brain barrier (BBB) can be overcome. The autoimmune disease systemic lupus erythematosus offers an unexpected new approach to this problem. 3E10 is a lupus anti-DNA autoantibody that localizes to DNA at tumors, penetrates cells via the ENT2 nucleoside transporter, inhibits DNA repair, and is synthetically lethal to BRCA1/2 or PTEN-deficient cancer cells with impaired homologous recombination (HR). Breast cancer brain metastases exhibit increased HR defects and PTEN loss compared to primary breast tumors, and ENT2 expressed in brain endothelial cells (BECs) regulates nucleoside flux at the BBB. Further, 3E10 has previously delivered cargo protein to ischemic brain. We hypothesized that ENT2 may facilitate transport of 3E10 across the BBB, and that 3E10 could be used to treat breast cancer brain metastases. Deoxymab-1 (also known as PAT-DX1 or DX1) is a re-engineered and optimized fragment of 3E10 in pre-clinical development for use against HR-deficient tumors. In the present study we examined the ability of DX1 to cross the BBB and suppress breast cancer brain metastases.

**BBB study results:** ENT2-dependent transport of DX1 across the BBB was evaluated in vitro and in vivo. DX1 penetrated hCMEC/D3 BECs and crossed from apical to basolateral chambers in an hCMEC/D3 transwell model of the BBB. Integrity of the model was confirmed by measuring transendothelial electrical resistance and demonstrating the barrier prevented movement of control protein into the basolateral chamber. Expression of ENT2 in hCMEC/D3 cells was confirmed by immunostaining, and the ENT2 inhibitor dipyrindamole (DP) inhibited both penetration by DX1 into the cells and its transport across the BBB transwell model. Immunodeficient mice with orthotopic GBM tumors were treated with IV and IP control buffer (n=2), IV DX1 (20 mg/kg) and IP control buffer (n=4), or IV DX1 (20 mg/kg) and IP DP (ENT2 inhibitor, 70 mg/kg) (n=4). DX1 was labeled with Alexa Fluor 750 (AF750) to allow detection by IVIS. Twenty-four hours after treatment, mice treated with DX1 in the absence of DP exhibited strong AF750 signal in the brain correlating to tumor. Co-treatment with DP reduced uptake of DX1 into the brain tumors by ~78% (P<0.001). These findings are consistent with DX1 crossing the BBB and localizing into brain tumors in an ENT2-dependent manner.

**Efficacy study results:** The 231-BR brain-seeking subclone of the MDA-MB-231 triple negative breast cancer cell line exhibits PTEN loss relative to parental cells. DX1 penetrated and killed 231-BR cells in vitro. For in vivo testing, brain metastases were generated in immunodeficient mice by intracardiac injection of 231-BR cells engineered for expression of luciferase. Brain metastases were confirmed by IVIS one week later, and then mice were treated with IV control buffer (PBS, n=7) or DX1 (20 mg/kg, n=7). In separate studies DX1 was delivered as a single cycle or as four consecutive cycles, with one cycle defined as control or DX1 3X/week. DX1 significantly suppressed tumor growth, evidenced by weekly IVIS. At week 5 brain radiance efficiencies (x10<sup>5</sup>) in the single cycle study in control and DX1-treated mice were 264.8±72.0 and 71.9±31.3 (P<0.04), and 320±66 and 20.2±8.5 (P≤0.01) in the four-cycle study. One cycle of DX1 yielded a non-significant increase in median survival from 30 to 35 days (P=0.42). Four cycles of DX1 had greater impact, with median survival increased by 14 days (from 31 to 45) (P<0.002). DX1 was not associated with nonspecific toxicity.

**Conclusion:** Our findings support an ENT2-mediated mechanism of BBB penetration by DX1 and establish proof of concept for use of a DNA-targeting autoantibody against breast cancer brain metastases.

Operational standardization and quality assurance yield high acceptance rate for breast MRI in the I-SPY 2 TRIAL

Jessica Gibbs<sup>1</sup>, David C Newitt<sup>1</sup>, Margarita Watkins<sup>1</sup>, Wen Li<sup>1</sup>, Lisa Cimino<sup>2</sup>, Clifton Li<sup>1</sup>, Natsuko Onishi<sup>1</sup>, Lisa J Wilmes<sup>1</sup>, Teffany Joy Bareng<sup>1</sup>, Evelyn Proctor<sup>1</sup>, Barbara LeStage<sup>3</sup>, Bev Parker<sup>4</sup>, the I-SPY 2 Coordinators, the I-SPY 2 Imaging Working Group and Nola M Hylton<sup>1</sup>. <sup>1</sup>University of California, San Francisco, San Francisco, CA; <sup>2</sup>American College of Radiology, Philadelphia, PA; <sup>3</sup>Dana-Farber Cancer Institute, Boston, MA; <sup>4</sup>University of Chicago Medicine, Chicago, IL

**Background:** The I-SPY 2 TRIAL is a multi-site response adaptive clinical trial evaluating novel drug combinations for neoadjuvant treatment of breast cancer. Patients receive four or more MRI studies during treatment, and serial measurement of functional tumor volume (FTV) is used to assess response. Under FDA IDE approval, FTV plays an integral role in adjusting patient randomization and evaluating treatment efficacy. FTV is a quantitative measure that requires stringent standards for image quality and protocol adherence. The I-SPY 2 TRIAL consistently reports a high level of data quality and data acceptance for FTV measurements. We present an overview of MRI operational performance and share lessons learned about maintaining high quality MRI data in a multi-site clinical trial.

**Methods:** Over the 10-year course of the I-SPY 2 TRIAL, workflow has been improved to optimize communication between the Imaging Core Lab (ICL) and sites and to collect details about the MRI that are needed for accurate FTV measurement. A standardized imaging acquisition protocol is distributed to all sites, and new sites submit two test cases for review at site initiation. A scan verification form is required for each MRI study completed at sites to document critical information. Sites submit studies using TRIAD image transfer and de-identification software (American College of Radiology), and data is archived and processed at the ICL. All MRI studies are reviewed by the ICL for protocol adherence as soon as they are submitted, and feedback is provided to sites. Image quality factors including motion, fat suppression, and signal-to-noise ratio are qualitatively assessed. The ICL communicates with sites through a centralized email account, regular Coordinator Calls, and Imaging Working Group meetings to discuss emerging issues and offer ongoing training. The ICL contributes to revisions of study protocols and standard operating procedures.

**Results:** As of June 2020, 3020 patients had been registered in I-SPY 2, 1741 patients randomized to treatment with one of 18 experimental drugs or standard therapy (controls), and a total of 7527 MRI studies were performed. FTV could be calculated for 97% (7317/7527) of MRI studies. Of the 7317 studies where FTV could be calculated, relatively minor issues with image quality or imaging protocol adherence were documented for 28% (2030/7317). These issues included motion artifacts (32%, 659/2030), off-protocol scan duration (21%, 433/2030), off-protocol contrast injection rate (14%, 281/2030), and off-protocol imaging field of view (9%, 191/2030).

**Conclusion:** Breast MRI studies using a variety of scan protocols are well-suited for diagnostic evaluation, including BIRADS categorization, measurement of longest diameter, and assessment of lesion washout. The quantitative measures used in the I-SPY 2 trial require adherence to a specific imaging protocol that is kept consistent for all MRI studies for a single patient. Operational standardization, clear communication with sites, and streamlined workflow yield high quality MRI data across multiple sites and scanners. As a result, FTV is a robust biomarker of response to treatment, and is being used to predict patient response and guide treatment planning. We are actively investigating strategies that will improve FTV accuracy for predicting response and informing guidelines for treatment de-escalation. This will allow the ICL to further standardize and improve image quality and will provide the foundation for testing a variety of imaging biomarkers in the I-SPY 2 TRIAL.

Identification of incidental putative germline variants in circulating tumor DNA

Andrew A Davis, Michael C Burns, Lorenzo Gerratana, Paolo D'Amico, Saya Jacob, Ami Shah, Neelima Katam, Firas Wehbe, Qiang Zhang, Elena Vagia, Lisa Flaum, Kalliopi P. Siziopikou, Leonidas C Plataniias, Amir Behdad, William J Gradishar and Massimo Cristofanilli. Robert H. Lurie Comprehensive Cancer Center, Feinberg School of Medicine, Northwestern University, Chicago, IL

**Background:** Circulating tumor DNA (ctDNA) has emerged as a potential tool for detecting disease recurrence, monitoring response to therapy, and identifying resistance mutations in the peripheral blood. With increased frequency of testing, there is an unmet need to recognize putative germline variants in ctDNA, and the probability that these variants are associated with inherited conditions. Here, we evaluated a large cohort of breast cancer patients who underwent ctDNA evaluation to determine the type and frequency of ctDNA mutations identified with confirmed germline testing.

**Methods:** We reviewed ctDNA testing from a single institution (Northwestern University). All breast cancer patients who had next-generation sequencing (NGS) performed by Guardant Health (Redwood City, CA) from 2015-2020 were included in this retrospective study. An allele frequency cutoff of 30% was pre-established as a threshold to review patient charts to determine whether genetic counseling and germline testing were performed, along with the timeframe of this testing (e.g. before or after ctDNA evaluation). Clinical information including demographics, pathology, tissue NGS testing, and germline testing were collected. Descriptive analyses and statistical associations were performed using STATA.

**Results:** The initial cohort consisted of 520 patients with breast cancer who underwent ctDNA testing. From this, we identified 84 patients (16.2%) who had at least one variant with allele frequency  $\geq 30\%$ . The most common variants identified were the following: *TP53* (34%), *PIK3CA* (27%), *BRCA1* (9%), *BRCA2* (8%), and *AKT1* (4%). Guardant360 classified 99% of these variants as pathogenic and 1% as a variant of unknown significance. Germline positivity using a separate CLIA-approved test for this indication was confirmed at the following frequencies: *BRCA1* (2 of 8 positive, 25%), *BRCA2* (2 of 5 positive, 40%), *PIK3CA* (0 of 5 positive), and *TP53* (0 of 26 positive). In total, 14% of patients with ctDNA allele frequency  $\geq 30\%$  had a confirmed germline mutation. Lower age at breast cancer diagnosis was significantly associated with the probability of germline testing prior to ctDNA evaluation ( $P=0.0001$ ). For patients who had a variant with allele frequency  $\geq 30\%$ , 24.3% never received genetic counseling or germline testing.

**Conclusion:** High allele frequency ctDNA variants ( $\geq 30\%$ ) were present in 16% of patients who underwent ctDNA evaluation with 14% of these variants confirmed as true germline variants. Consenting patients for ctDNA testing should include the possibility of identifying putative germline variants, and criteria should be established to refer patients for subsequent genetic counseling and germline testing, given the potential implications for patients and their family members.

Publication Number: PS13-08

Predictors and long-term outcome of pathologic complete response in patients receiving neoadjuvant chemotherapy for breast cancer - an NCDB analysis

Lauren Mikesell Panebianco<sup>1</sup>, Prashanth Ashok Kumar<sup>1</sup>, Shreya Sinha<sup>2</sup>, Dongliang Wang<sup>1</sup>, Danning Huang<sup>1</sup> and Abirami Sivapiragasam<sup>1</sup>. <sup>1</sup>SUNY Upstate, Syracuse, NY; <sup>2</sup>Geisinger, Scranton, PA

**Background:**

Among women with high-risk early stage breast cancer, neoadjuvant chemotherapy (NCT) is increasingly utilized. The Collaborative Trials in Neoadjuvant Breast Cancer working group studied 13,000 patients from 12 large trials involving NCT and concluded that pathologic complete response (pCR) resulted in significantly better outcomes with respect to both disease recurrence and mortality. This National Cancer Database (NCDB) study aims to gather patient and tumor characteristics to further identify prognosticators of pCR, and determine which subgroups achieving pCR have the greatest survival benefit.

**Methods:**

Retrospective analysis using NCDB data from 2004-2015 identified 46,836 women ≥18 years with stage I to III breast cancer who received NCT. Achievement of pCR was defined as ypT0 ypN0 or ypT0/is ypN0. Tumor and patient characteristics were evaluated, and multivariate logistic regression was used to calculate odds ratio (OR) of pCR. Kaplan-Meier curves were constructed for calculation of overall survival (OS) at 5 years. Hazard ratios (HR) were estimated from Cox models. Propensity score weighting was used to adjust for confounding effects of various factors on survival via Cox regression.

**Results:**

Patients were more likely to achieve pCR with ductal vs. lobular histology (OR 1.62 [95% CI 1.414-1.872]), grade 3 vs. 1 (OR 1.606 [95% CI 1.394-1.849]), stage 3 vs. 1 (OR 1.76 [95% CI 1.623-1.908]), ER+PR- vs. ER+PR+ (OR 2.004 [95% CI 1.855-2.165]), ER-PR- vs. ER+PR+ (OR 2.572 [95% CI 2.425-2.729]), age <60 (OR 1.43 [95% CI 1.32-1.55]), Charlson-Deyo combined comorbidity (CDCC) score of 0 vs. 2 (OR 1.27 [95% CI 1.04-1.54]), and private insurance vs. uninsured (OR 1.24 [95% CI 1.09-1.41]). HR for death adjusted by propensity score in patients attaining pCR vs. non-pCR was 0.346 (95% CI 0.325-0.368) for the overall cohort, 0.591 (95% CI 0.513-0.681) for ER+PR+ patients, 0.373 (95% CI 0.315-0.442) in the ER+PR- group, and 0.307 (95% CI 0.284-0.332) for ER-PR- patients. Achieving pCR conferred better OS in all subgroups with higher magnitude in hormone negative patients (table 1).

**Conclusions:**

This study not only highlights factors associated with achieving pCR after neoadjuvant chemotherapy for breast cancer, but also demonstrates that attaining pCR reduces the risk of death by 65.4% in all patients regardless of receptor subtype. Furthermore, the survival curve increasingly separates with time. Our study reveals an intriguing observation that ER+PR+ patients who attain pCR have 40.9% decreased mortality compared to non-pCR. Limitations of this analysis include the lack of HER2 status and that conclusions are made from non-population based observational data. Despite utilization of propensity score weighting, there may have been confounders that were not adjusted for by the multivariate model. Future analysis is needed to identify HER2 status, as HER2-positive patients may have contributed to the OS benefit in the subgroups. Nonetheless, these data are among the first to suggest that hormone-positive patients derive long-term survival benefit from achievement of pCR, albeit to a lesser extent than hormone-negative subtypes.

Table 1. 5-year survival estimates from Kaplan-Meier analysis

	pCR	Non-pCR	Survival difference	p (95% CI)

Comparison of PD-L1 protein expression between primary tumors and metastatic lesions in triple negative breast cancers

Mariya Rozenblit<sup>1</sup>, Richard Huang<sup>2</sup>, Natalie Danziger<sup>2</sup>, Brian Alexander<sup>2</sup>, Shakti Ramkissoon<sup>2</sup>, Kim Blenman<sup>1</sup>, Jeffrey Ross<sup>2</sup>, David Rimm<sup>1</sup> and Lajos Pusztai<sup>1</sup>. <sup>1</sup>Yale, New Haven, CT; <sup>2</sup>Foundation Medicine Inc, Cambridge, MA

**Background:** Several recent studies that compared small cohorts of metastatic and primary lesions, suggested substantial heterogeneity in tumor infiltrating lymphocyte count, immune gene expression and PD-L1 protein expression across different metastatic sites and between primary breast cancers and metastasis. Understanding the frequency of PD-L1 positivity rates across different tissue sites can indicate differences in the immune microenvironment and may also guide biopsy site selection. We compared PD-L1 positivity on immune cells and tumor cells in primary and metastatic triple negative breast cancer tumors (TNBC). **Methods:** A retrospective data analysis of the Foundation Medicine PD-L1 IHC database was conducted on 340 cases of TNBC. PD-L1 positivity was determined by IHC using SP142CDx. Results are reported as percent of PD-L1 stained immune cells (IC) in the tumor area. A tumor was considered PD-L1 positive if  $\geq 1\%$  IC stained positive with PD-L1. As an exploratory analysis, PD-L1 positivity of tumor cells (TC) was also assessed. PD-L1 percent positive staining results are reported as means with 95% CI. The proportion of PD-L1 positive and negative IC and TC in primary tumors vs metastatic sites was compared using Chi-Square test. Prism 8 was used for all data analysis. **Results:** All patients were female, with median age 56 years (range 26-89); 179 samples were from primary tumors and 161 from metastatic lesions, representing 15 different tissue sites. Overall, PD-L1 expression on immune cells was statistically significantly more frequent in primary tumors compared to metastatic sites (63.7% [n=114] vs 42.9% [n=69]),  $p < 0.0001$ . This was driven by the lower PD-L1 positivity rates in skin (23.8%, 95% CI: 8.22% - 47.2%), liver (17.4%, 95% CI: 5.00% - 38.8%) and bone (16.7%, 95% CI: 2.10% - 48.4%) metastases. Lung (68.8%, 95% CI: 41.3 - 90.0), soft tissues (65.2%, 95% CI: 42.7 - 83.6) and lymph nodes 51.1%, 95% CI (35.8 - 66.3) had PD-L1 % positivity rates similar to primary tumors. PD-L1 expression was rare on tumor cells in both the breast and metastatic sites (8.3% vs 4.3%,  $p=0.13$ ). **Conclusion:** We observed substantial heterogeneity in PD-L1 positivity rates across metastatic sites. Lung, soft tissues and lymph node metastases had PD-L1 % positivity rates that were similar to that of primary tumors whereas skin, liver and bone metastases had significantly lower PD-L1 % positivity rates. These results raise the possibility that response to immune therapy could depend on the location and the PD-L1 positivity of the metastatic site. Limited current experience in breast cancer is not sufficient to correlate tumor response with PD-L1 expression in metastases, but as more patients receive treatment, this could be examined in the future.

1

Table 1: Sample Characteristics and % PD-L1 positivity on immune cells

Sample type	Total N (%)	N PD-L1 positive (% , 95% CI)
Primary Tumor	179 (52.6)	114 (63.7%, 56.2% - 70.7%)
Metastatic Lesion	161 (47.4)	69 (42.9%, 35.1% - 50.9%)
Sites of Metastases	N (% of metastatic samples)	N PD-L1 positive (% , 95% CI)
Lung	16 (10.0)	11 (68.8%, 41.3% - 90.0%)
Soft Tissues	23 (14.3)	15 (65.2%, 42.7% - 83.6%)

Low dose endoxifen represses mouse mammary tumorigenesis: A preclinical study of monotherapy and combination with ulipristal acetate

Oukseub Lee<sup>1</sup>, Minhua Wang<sup>1</sup>, Maarten C. Bosland<sup>2</sup>, Omid Hosseini<sup>1</sup>, Irene Helenowski<sup>1</sup> and Seema A. Khan<sup>1</sup>. <sup>1</sup>Northwestern University, Chicago, IL; <sup>2</sup>University of Illinois at Chicago, Chicago, IL

**Background:** Endoxifen (ENX), a major active metabolite of the selective estrogen receptor (ER) modulator tamoxifen (TAM), has been shown to inhibit the growth of ER+ cancer. However, it has not been evaluated for prevention of mammary cancer. We report here the cancer prevention efficacy of ENX as monotherapy and in combination with ulipristal acetate (UPA), a selective progesterone receptor (PR) modulator. We compare these to TAM using the SV40 C3 T-antigen (C3-TAg) mouse, a well-documented mammary cancer prevention model. **Methods:** C3-TAg female virgin mice aged 7-8 weeks were randomized to no-treatment control or to drug treatment groups (TAM, ENX, UPA and ENX+UPA). Drug pellets were subcutaneously implanted on backside of mice. The doses of drug pellet were 12.5mg/30d for TAM, 9mg/90d for ENX, 10mg/30d for UPA, and combination of ENX (9mg/90d) + UPA (10mg/30d). The dose of ENX was equivalent to the exposure resulting from 20 mg/day, the lowest dose used in a recent Phase I human trial. Pellets were replaced every 30 days or 90 days. Mammary tumor formation was monitored twice weekly by palpation. Tumor latency, multiplicity, and tumor volume were recorded; animals are euthanized at 23 weeks of age, or earlier if tumors reach > 1 cm<sup>2</sup>. Tumors and mammary glands were formalin fixed and paraffin embedded for histology evaluation by a rodent pathologist. The primary endpoint was a reduction in tumor incidence in drug treated versus control groups. Secondary endpoints included prolongation of latency, reduction in tumor multiplicity, and tumor burden. Statistical significance between groups was calculated with Wilcoxon log-rank test for % tumor-free survival and Mann Whitney test for tumor multiplicity and burden. **Results:** All mice in the control group developed tumors by 18 weeks of age. Tumor-free survival % of ENX, UPA, and ENX+UPA treated groups were significantly higher than control animals, with the greatest increase in the ENX group (p=0.02). TAM had no effect on tumor-free survival (p=0.32). Median tumor latencies were similar in three treated groups: ENX (112 days), UPA (114 days), and ENX+UPA (111 days) groups, and were significantly delayed compared to the control or TAM group (100 days in both) (p<0.05). Median tumor multiplicity (invasive adenocarcinoma) per animal was significantly lower in ENX group compared to control group (3 vs. 7, p=0.02). UPA and TAM did not significantly reduce tumor multiplicity (4 for TAM and 6 for UPA). We observed non-significant 32% and 23% reduction in median tumor weight of ENX+UPA group and ENX group, respectively compared to control group. Histology evaluation for ENX+UPA group and pathologic size of invasive carcinoma is ongoing, along with the expression of Ki67, ER $\alpha$  and PR of mammary tumors and mammary gland by immunohistochemistry. **Conclusions:** TAM showed no significant effect on delaying tumorigenesis, consistent with a previous study. However, low dose of ENX (equivalent to 24 mg/day in human) effectively repressed tumor development and growth than TAM or UPA treatment. Our data suggest that ENX is promising for prevention of ER+ mammary tumorigenesis and warrant a dose optimization study for improving efficacy.

Diabetes risk reduction diet and survival following breast cancer

Tengteng Wang<sup>1</sup>, Maryam Farvid<sup>2</sup>, Jae Hee Kang<sup>3</sup>, Michelle Holmes<sup>1</sup>, Bernard Rosner<sup>1</sup>, Rulla Tamimi<sup>4</sup>, Walter Willett<sup>2</sup> and A. Heather Eliassen<sup>1</sup>.<sup>1</sup>Brigham & Women's Hospital, Harvard Medical School, and Harvard T. H. Chan School of Public Health, Boston, MA; <sup>2</sup>Harvard T. H. Chan School of Public Health, Boston, MA; <sup>3</sup>Brigham & Women's Hospital and Harvard Medical School, Boston, MA; <sup>4</sup>Weill Cornell Medicine and Harvard T. H. Chan School of Public Health, New York, NY**Importance:** Type 2 diabetes (T2D) is associated with poor breast cancer prognosis. Adherence to a dietary pattern associated with lower T2D risk may improve breast cancer outcomes.**Objective:** To evaluate the association between adherence to a diabetes risk reduction diet (DRRD) after diagnosis and survival outcomes following breast cancer.**Method:** We followed 8,320 women diagnosed with stage I-III breast cancer from two large prospective cohort studies, the Nurses' Health Study (NHS; 1980-2014) and the NHSII (1991-2015). Information on diet and other covariates was repeatedly measured in validated follow-up questionnaires every two to four years. The DRRD adherence score includes 9 dietary components: higher intakes of cereal fiber, coffee, nuts, whole fruits and polyunsaturated:saturated fat ratio; and lower glycemic index of diet, lower intakes of trans fat, sugar-sweetened beverages/fruit juices, and red meat. Cumulative average DRRD score was calculated using repeated measures of diet after breast cancer diagnosis. Deaths were reported by family members or via the search of National Death Index, and cause of death was assigned by reviewing death certificates/medical records. Multivariable-adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) for the association between DRRD score and breast cancer-specific and all-cause mortality were estimated using Cox proportional hazards models.**Results:** During a median of 16 years of follow-up after diagnosis, we ascertained 2,146 deaths, of which 948 were due to breast cancer. In the multivariable-adjusted models, women with higher post-diagnostic DRRD scores had a 17% lower risk of breast cancer-specific mortality (top vs. bottom quintile HR =0.83; 95%CI=0.67-1.02; p-trend=0.03) and 33% lower risk of all-cause mortality (HR =0.67; 95%CI=0.58-0.78; p-trend <0.0001). Associations were slightly attenuated after further adjusting for neighborhood socioeconomic status index (breast cancer mortality: HR =0.86; 95%CI=0.70-1.07; p-trend=0.06; overall mortality: HR =0.69; 95%CI=0.60-0.80; p-trend <0.0001). Compared with women who consistently had lower DRRD score ( $\leq$ median) before and after diagnosis, those who improved their score from low to high had a significantly lower risk of breast cancer mortality (HR =0.81; 95%CI=0.65-1.00).**Conclusion:** We found that greater adherence to the DRRD after breast cancer diagnosis was associated with better survival, suggesting dietary modification after diagnosis consistent with T2D prevention may be important to breast cancer survivors.**Table 1.** Multivariable HRs and 95% CIs for the association between post-diagnostic diabetes risk reduction diet score and mortality among breast cancer survivors using pooled data from NHS and NHSII (N=8,320)

Intratumoral heterogeneity of second-harmonic generation scattering from tumor collagen and its effects on metastatic risk prediction

Edward Brown<sup>1</sup>, Danielle Desa<sup>1</sup>, Wencheng Wu<sup>1</sup>, Robert Hill<sup>2</sup>, John Martens<sup>3</sup>, Robert Strawderman<sup>1</sup> and Bradley Turner<sup>1</sup>. <sup>1</sup>University of Rochester, Rochester, NY; <sup>2</sup>Harmonigenic Corporation, Rochester, NY; <sup>3</sup>Erasmus University Medical Center, Rotterdam, Netherlands

Second harmonic generation (SHG) is an intrinsic optical signal that can be generated from fibrillar collagen. The directionality of SHG emission is influenced by the diameter and spacing of collagen fibrils, and the disorder in their packing within collagen fibers. One measure of SHG directionality is the ratio of forward- to backward-scattered SHG, or "F/B". F/B has been used to assess healthy vs diseased tissue in breast, ovarian, and lung cancer, and is an independent prognostic indicator of metastasis free survival time in ER+, lymph node-negative (N0), invasive ductal carcinoma (IDC). Here we assess the heterogeneity in F/B within tumor sections from ER+ N0 IDC, and its effect on the use of F/B for metastatic risk prediction. We find that F/B of tumor collagen varies between the tumor/host interface and the more cellular tumor bulk ( $p < 0.0001$ , Student's t-test), and that F/B from the tumor/host interface, but not tumor bulk, is prognostic of metastasis free survival in 95 IDC ER+ N0 patients ( $p = 0.0020$  and  $0.10$ , respectively, log rank test for trend). This result was repeated with two additional image analysis procedures to generate F/B with reduced user input and hence reduced possibility of bias. Using Random Survival Forests to generate a data-driven predictive model, we find that F/B from the tumor/host interface, but not bulk, as well as a 21-gene prognostic score inferred from Affymetrix data, both contribute to predicting metastasis-free survival in this cohort. Any tool to help predict metastasis and assist with treatment decisions is likely to be applied in combination with the now well-established genomic scores. To understand how F/B can support genomic methods for guiding treatment decisions we divided our patient samples into two cohorts based upon the value of their 21-gene score relative to the TAILORx cutoff of 26 (separating low-intermediate and high-risk groups). The F/B value from tumor-host interface identifies a subgroup of patients in the low-intermediate risk group with poor clinical outcome ( $p = 0.045$ , log rank test for trend). Overall, this data reveals that intratumor heterogeneity can impact the ability of F/B to predict patient outcome, and that F/B specifically from the tumor-host interface may provide a tool to better identify patients in need of adjuvant treatment or enrollment in clinical trials.

**Background:** A previous phase 2 study in metastatic breast cancer compared treatment with intravenously delivered oncolytic reovirus, pelareorep (pela), in combination with paclitaxel (PTX) versus PTX alone. This study demonstrated a statistically significant improvement in overall survival (OS), without differences in objective response or progression-free survival. We hypothesized that the OS benefit from pela + PTX may be attributed to an adaptive immune response triggered by pela. To test this hypothesis, and examine if pela can mediate the priming of an anti-tumor immune response, we designed a study called AWARE-1 (A window-of-opportunity study of pela in Early Breast Cancer), which is currently enrolling and for which initial translational research results are presented.

**Methods:** AWARE-1 is evaluating the safety and effect of pela ± atezolizumab on the tumor microenvironment (TME) in 38 women with early breast cancer. Patients are treated with pela on days 1, 2, 8, and 9, while atezolizumab is administered on day 3. Tumor biopsies are collected at diagnosis, day 3, and day ~21. Five cohorts will be examined: Cohort 1: Hormone Receptor-positive/HER2-negative (HR+/HER2-neg) (10 patients), pelareorep + letrozole. Cohort 2: HR+/HER2-neg (10 patients), pelareorep + letrozole + atezolizumab. Cohort 3: Triple Negative Breast Cancer (TNBC) (6 patients), pelareorep + atezolizumab. Cohort 4: Hormone Receptor-positive/HER2-positive (HR+/HER2+) (6 patients), pelareorep + trastuzumab + atezolizumab. Cohort 5: Hormone Receptor-negative/HER2-positive (HR-/HER2+) (6 patients), pelareorep + trastuzumab + atezolizumab. The primary endpoint of the study is CeITIL score, a metric for quantifying the changes in tumor cellularity and infiltration of TILs, where an increase in CeITIL is associated with a favorable response to treatment. Tumor tissue was examined for pela replication, and changes to the TME were assessed by imaging mass cytometry (IMC), immunohistochemistry, and T cell receptor sequencing (TCR-seq). Peripheral blood was also examined by TCR-seq.

**Results:** Detailed translational research results will be presented from patients in cohort 1, who received just pelareorep and letrozole. CeITIL score increased in 5/10 patients at day 3 biopsies and 6/10 patients at day 21 biopsies. Preliminary results show high levels of viral replication (>50% of tumor cells) while immunohistochemistry and IMC analysis revealed changes to the TME, with increases in CD8+ T cells and upregulation of PD-L1 at both day 3 and day 21 biopsies. Overall, preliminary data from cohort 1 of AWARE-1 demonstrate pela-mediated priming of an adaptive immune response. (NCT04102618)

Did Medicaid expansion under the Affordable Care Act narrow the gap between American Indians and Whites on breast cancer management and prognosis?

Anu G Gaba<sup>1</sup>, Li Cao<sup>2</sup>, Rebecca Renfrew<sup>3</sup>, Kristi A Egland<sup>4</sup>, DeAnn L Witte<sup>3</sup>, Janet Wernisch<sup>5</sup> and Ross Crosby<sup>6</sup>. <sup>1</sup>Sanford Roger Maris Cancer Center, Fargo, ND; <sup>2</sup>Sanford Research, Fargo, ND; <sup>3</sup>Sanford Health, Fargo, ND; <sup>4</sup>SAb Biotherapeutics, Sioux Falls, SD; <sup>5</sup>Sanford Research, Sioux Falls, SD; <sup>6</sup>Sanford Center for Biobehavioral Research, Fargo, ND

Prior studies have shown that over a span of 20 years (1990-2009), breast cancer death rates in the U.S. have not significantly declined for American Indians (AIs) in comparison to the White population. Health insurance coverage contributes independently and positively to the health of individuals through the receipt of adequate preventive services and care for diseases such as breast cancer. To this end, the 2010 Medicaid Expansion as part of the Affordable Care Act (ACA) has extended the health insurance coverage eligibility to adults with incomes up to 133 percent of the federal poverty level. In this study, we examined whether Medicaid expansion resulted in the improvement of breast cancer management and prognosis for AIs relative to the White population. Methods: We abstracted information from the National Cancer Data Base (NCDB) for AI and White breast cancer patients diagnosed between the years 2004-2016 who lived in states that expanded Medicaid in January 2014, and those that did not expand Medicaid. Data on age, race, stage at diagnosis, insurance status, definitive treatment initiation within 30 days of diagnosis, and 3-year mortality was analyzed. Odds ratios (OR) and 95% confidence intervals (CI) were estimated using multiple logistic regression to determine the impact of race (White vs. AI), Medicaid expansion status, and pre- vs. post-expansion periods on breast cancer management and prognosis. All p-values are two-sided. Analyses were performed using SPSS software V25. Results: There were 1,465,103 newly diagnosed White and AI breast cancers between the years 2004-2016; 99.7% were Whites and 0.3% were AIs. Of these, 46.9% resided in states that expanded Medicaid in January 2014 and 53.1% in states that did not expand Medicaid; 73.8% were diagnosed in the pre-expansion period (January 2004-December 2013) and 26.2% were diagnosed in the post-expansion period (January 2014-December 2016). There was an increase in the proportion of early stage (0, 1) breast cancer diagnosis in the period 2014-2016 as compared to the period 2004-2013 (OR=1.434, 95% CI: 1.159- 1.775; p = 0.001), and this increase was significantly greater for AIs than for Whites (6% vs 3%; p=0.027) in both expansion and non-expansion states. An independent chi-square analysis of AIs found that there was a significant increase of the early stage diagnosis in the expansion states during the post-expansion period (p=0.001). The proportion of uninsured declined in the period 2014-2016 as compared to the period prior (OR=0.331, 95% CI: 0.129- 0.850; p=0.022), more so in the expansion states (decrease from 1.4% to 0.8%), vs. non expansion states (decrease from 2.3% to 2.2%) (p=0.019); no difference in decline was found between Whites and AIs. The probability of getting first definitive treatment within 30 days of diagnosis declined more in states without Medicaid expansion (decrease from 54% to 43%) than in states with Medicaid expansion (decrease from 50% to 43%) (p=0.028) for both AIs and Whites; and the decline was more in Whites ( decrease from 55% to 44%) than in AIs (decrease from 49% to 42%) from pre-expansion period to post-expansion period (p=0.018). The 3-year mortality rates did not show any significant relationship to race, expansion status, or the pre- or post-expansion periods. Conclusion: In patients newly diagnosed with breast cancer, the proportion of uninsured declined significantly with Medicaid expansion and the proportion of patients who received first definitive treatment within 30 days of diagnosis decreased significantly less in AIs and in states that expanded Medicaid under the Affordable Care Act. Medicaid expansion increased early breast cancer diagnosis in AIs; this effect was not seen in non-expansion states. Medicaid expansion did not affect 3-year mortality rate.

Impact of genetic testing for hereditary breast cancer on screening and risk-reducing surgeries among multi-ethnic breast cancer survivors

Vicky Ro<sup>1</sup>, Tarsha Jones<sup>2</sup>, Meghna S Trivedi<sup>1</sup>, Julia E McGuinness<sup>1</sup>, Thomas Silverman<sup>1</sup>, Wendy K Chung<sup>1</sup>, Rita Kukafka<sup>1</sup> and Katherine D Crew<sup>1</sup>.<sup>1</sup>Columbia University Irving Medical Center, New York, NY; <sup>2</sup>Florida Atlantic University, Boca Raton, FL

**Introduction** Current guidelines for cancer risk management for hereditary breast cancer focus on individuals with pathogenic/likely pathogenic variants (P/LP) in high penetrance genes. There is little consensus on prophylactic mastectomy for low/moderate penetrance genes or variants of uncertain significance (VUS). Furthermore, many guidelines for enhanced breast cancer screening are targeted to unaffected carriers, but not breast cancer survivors. Given the increasing use of multigene panel testing, more patients are receiving results of P/LP in low/moderate penetrance genes or VUSs. We aimed to investigate how multigene panel results impacted surgical and screening decisions among breast cancer patients. **Methods** We conducted a retrospective analysis of women diagnosed with stage 0-III breast cancer at Columbia University Irving Medical Center in 2013 or later, who received germline genetic testing. Clinical data were extracted from the electronic health record (EHR), tumor registry, and genetic testing portals. Patients were excluded if they had stage IV disease at diagnosis, had bilateral mastectomy before 2013, or had missing genetic test results or surgical reports. For the screening analysis, patients were excluded if they had bilateral mastectomy or did not have breast imaging in the EHR. Surgery type was defined by the most advanced breast surgery received. Enhanced screening was defined as use of breast ultrasound or MRI in the absence of breast symptoms and in the setting of a normal mammogram. Univariable and multivariable analyses were performed to assess the association between clinical factors and receipt of bilateral mastectomy or enhanced screening. **Results** Among 715 evaluable women, about two-thirds were 50 years or younger, with 45% white, 12% black, 27% Hispanic, 11% Asian, and 4% other. Most patients (69.5%) had benign/likely benign (B/LB) genetic test results, while 91 (12.7%) had P/LP and 127 (17.8%) had VUS. VUS rates were higher among racial/ethnic minorities (27% Asian, 25% Hispanic, 19% black) compared to white women (10%). About 31% of women underwent bilateral mastectomy, 25% unilateral mastectomy, and 45% lumpectomy. Bilateral mastectomy rates among patients with P/LP variants were higher compared to those with VUS or B/LB results (66% vs. 27% vs. 26%), particularly P/LP in high-penetrance genes (76%) compared to other genes (45%). On multivariable analysis, compared to patients with B/LB genetic results, P/LP was significantly associated with bilateral mastectomy (odds ratio [OR]=5.72, 95% confidence interval [CI]=3.43-9.53). Younger age at diagnosis and family history of breast cancer were also associated with bilateral mastectomy. Among patients with breast cancer screening data, almost half (43%) received enhanced screening (59% ultrasound, 25% MRI, 16% both). On multivariable analysis, patients with P/LP variants and age of diagnosis under 50 were more likely to receive enhanced screening (OR=4.43, 95% CI=1.59-12.33 and OR=1.92, 95% CI=1.09-3.38, respectively). Hispanic women compared to non-Hispanic whites and those with Medicaid rather than private health insurance were less likely to undergo enhanced screening. **Conclusions** We demonstrated that detection of P/LP variants on multigene panel testing influences surgical and screening decisions among breast cancer patients. Patients with VUS, a group enriched for racial/ethnic minorities, appropriately have similar surgical and screening decisions as those with B/LB results. Our findings suggest adequate genetic counseling and communication of cancer risk to multi-ethnic breast cancer survivors.

Correlative studies of the breast cancer index (HOXB13/IL17BR) and ER, PR, AR, AR/ER ratio and Ki67 for prediction of extended endocrine benefit: A trans-aTTom study

Dennis C Sgroi<sup>1</sup>, Kai Treuner<sup>2</sup>, Yi Zhang<sup>2</sup>, Tammy Piper<sup>3</sup>, Ranelle Salunga<sup>2</sup>, Ikhlal Ahmed<sup>4</sup>, Lucy Doos<sup>4</sup>, Sarah Thornber<sup>4</sup>, Karen J Taylor<sup>3</sup>, Elena F Brachtel<sup>1</sup>, Sarah Pirrie<sup>4</sup>, Catherine A Schnabel<sup>2</sup>, Daniel W Rea<sup>4</sup> and John MS Bartlett<sup>5</sup>. <sup>1</sup>Massachusetts General Hospital, Boston, MA; <sup>2</sup>Biotheranostics, Inc., San Diego, CA; <sup>3</sup>University of Edinburgh, Edinburgh, United Kingdom; <sup>4</sup>University of Birmingham, Cancer Research UK Clinical Trials Unit, Birmingham, United Kingdom; <sup>5</sup>Ontario Institute of Cancer Research, Ontario, ON, Canada

**Background:** Several biomarkers such as estrogen receptor (ER), progesterone receptor (PR), androgen receptor (AR) and Ki67 have been implicated in the pathogenesis and/or as prognostic biomarkers of breast cancer, and are utilized to determine treatment. Given the heterogeneity of response to endocrine therapy, however, predictive biomarkers are critical to better individualize patient care. Previous results from the Trans-aTTom study demonstrated that the Breast Cancer Index HOXB13/IL17BR [BCI (H/I)] biomarker significantly predicts extended endocrine benefit from 10 vs 5y of tamoxifen. In this correlative study, the predictive activity of BCI (H/I) was compared with ER, PR, AR and Ki67 protein expression in node positive patients treated in the aTTom trial. **Methods:** Patients with available tumor tissue and biomarker analyses were included. ER, PR, AR and Ki67 were centrally assessed by immunohistochemistry (IHC) utilizing tissue microarrays. BCI gene expression analysis by RT-PCR was performed blinded to clinical outcome. Multivariate Cox models adjusting for age, tumor size, tumor grade and HER2 status were used to assess the significance of the interaction between treatment and each biomarker as continuous variables. 17-year risk of recurrence, as a function of each continuous biomarker, was estimated from Cox models in each of the 2 treatment arms. **Results:** Analysis of 789 HR+, N+ patients showed a weak negative correlation between BCI (H/I) and ER, PR, and AR expression whereas Ki67 and the AR/ER ratio showed no correlation (ER,  $\text{cor} = -0.18$ ; PR,  $\text{cor} = -0.25$ ; AR,  $\text{cor} = -0.14$ ; Ki67,  $\text{cor} = 0.04$ ; AR/ER ratio,  $\text{cor} = 0.02$ ). The interaction between BCI (H/I) and extended tamoxifen treatment was significant ( $p = 0.014$ ). In addition, analysis of risk of recurrence as a function of continuous BCI (H/I) demonstrated that the magnitude in the reduction in recurrence risk with extended tamoxifen correlated with increasing H/I levels. In contrast, interaction P values were nonsignificant (ER,  $p = 0.829$ ; PR,  $p = 0.659$ ; AR,  $p = 0.783$ ; Ki67,  $p = 0.865$ ; AR/ER ratio,  $p = 0.835$ ) and the magnitude of endocrine benefit did not correlate with expression levels of any of other biomarkers.

**Conclusion:** Results from this post-hoc analysis of the Trans-aTTom study demonstrated that whereas BCI(H/I) is a significant predictive biomarker of endocrine response, analysis of ER, PR, AR, Ki67 and AR/ER expression showed no interaction with treatment, and lacked the ability to predict benefit of extended tamoxifen in HR+ early stage breast cancer. These results add to the growing body of evidence that BCI (H/I) is distinct in its ability to predict benefit from therapy and interrogates distinct tumor biology that is not captured by other traditional biomarkers.

**Introduction** CEST MRI permits quantitation of macromolecules such as amide proteins that are of interest in cancer metabolism. However, optimal CEST acquisition and analysis methods remain undetermined. In this study, we investigated CEST MRI as an imaging biomarker for early treatment response in 51 TNBC patients receiving NAST and compared the performance with two different CEST saturation power levels and two analysis methods.

**Methods** A total of 51 stage I-III TNBC patients enrolled in the prospective ARTEMIS trial (NCT02276443) had CEST imaging performed on a 3T MRI scanner at baseline before NAST (BL, N = 51), after 2 cycles (C2, N = 37), and 4 cycles (C4, N = 44) of NAST. 33 of the 51 patients had imaging at all 3 time points. 29 of the 33 patients had pathological findings, with N = 16 with pathological complete response (pCR) and N = 13 with non-pCR. Two sets of CEST images using 0.9 and 2.0  $\mu$ T saturation power levels were acquired and analyzed using the magnetization transfer ratio asymmetry ( $MTR_{asym}$ ) and the Lorentzian line fitting (Mag3.5) methods, for a total of 4 acquisition/analysis combinations. The group averaged CEST signals,  $MTR_{asym}$  at 0.9 and 2.0  $\mu$ T and Mag3.5 at 0.9 and 2.0  $\mu$ T, at BL, C2 and C4 were determined and evaluated using unpaired (51 patients) and paired (33 patients) Kruskal-Wallis tests. The Mag3.5 at 0.9  $\mu$ T and the  $MTR_{asym}$  at 2.0  $\mu$ T were further compared between pCR and non-pCR. The group averaged CEST signals at BL, C2, and C4 were evaluated using the Friedman test for the pCR and the non-pCR groups. Separately, the change in the CEST signal from BL to C2 and C4 was determined for each patient and evaluated using the Mann-Whitney test for both groups.  $P < 0.05$  was considered statistically significant.

**Results** The  $MTR_{asym}$  at BL was higher at 2.0  $\mu$ T than at 0.9  $\mu$ T. In contrast, the Mag3.5 at BL was higher at 0.9  $\mu$ T than at 2.0  $\mu$ T. The  $MTR_{asym}$  at 2.0  $\mu$ T and the Mag3.5 at 0.9  $\mu$ T decreased during treatment while the  $MTR_{asym}$  at 0.9  $\mu$ T and the Mag3.5 at 2.0  $\mu$ T were similar. Both the unpaired and the paired Mag3.5 at 0.9  $\mu$ T showed a significant decrease at C2 and C4 vs. BL ( $p < 0.01$ ). The unpaired and paired  $MTR_{asym}$  at 2.0  $\mu$ T showed a decrease, although the change was not significant except for the unpaired data at C4. The decrease in the group averaged Mag3.5 at 0.9  $\mu$ T was significant at C2 vs. BL for the pCR group ( $p = 0.04$ ), while it was not significant for the pCR group at C4 vs. BL and for the non-pCR group at either C2 or C4 vs. BL. The group averaged  $MTR_{asym}$  at 2.0  $\mu$ T changes were not significant for either the pCR or the non-pCR groups. None of the CEST signal changes on a per patient basis at C2-BL, C4-BL and C4-C2 were significantly different between the pCR and the non-pCR groups. Further, none of the group averaged CEST signals at BL, C2 and C4 were significantly different between the pCR and the non-pCR groups.

**Conclusion** Our study demonstrates that the CEST quantitation in TNBC patients undergoing NAST depends on acquisition and analysis. For a maximum change in the CEST effect, Lorentzian line fitting is better paired with acquisition at a low saturation power (0.9  $\mu$ T) and  $MTR_{asym}$  is better paired with acquisition at a high saturation power (2.0  $\mu$ T). Further, a significant CEST signal decrease was observed in TNBC patients with pCR after NAST when a 0.9  $\mu$ T saturation power and the Lorentzian line fitting were used. In comparison, the decrease was not significant in non-pCR patients using the same saturation power and analysis method. The results suggest that the CEST signal acquired at 0.9  $\mu$ T saturation power and analyzed using Lorentzian line fitting may be able to differentiate between pCR and non-pCR among TNBC patients undergoing NAST. Additional studies with a larger patient population are ongoing to further validate our findings and their potential for determining pCR.

**Background:** There is limited prospective data for advanced breast cancer (ABC) patients (pts), unresectable locally or metastatic, treated as per clinical practice. RegistEM, an academic study conducted by a non-profit collaborative group, will provide epidemiological, pathological and clinical data as per routine practice, including treatments for different disease settings, collected from pts' medical records. Understanding the real distribution of BC subtypes is the primary objective. This is a non-interventional cohort study that will enroll approximately 1,867 pts with advanced disease diagnosed from January 2016 to December 2019, either after recurrence or as first diagnosis (*de novo*), in 38 Spanish sites representative of the whole country geography and whose investigators are GEICAM members. Biological samples (primary and/or metastatic tumor tissue, and blood) collection is part of study procedures. **Methods:** In this analysis we describe the characteristics of 229 pts with HR+/HER2- BC documented in a metastatic tumor lesion after disease recurrence and who received adjuvant endocrine therapy (ET). This subpopulation has been identified as an interesting group from a clinical perspective for detailed analysis. Three subgroups of pts have been considered for this analysis based on their disease-free interval (DFI) since the diagnosis of early disease: <36 months (mo), ≥36 mo to <60 mo, and ≥60 mo. **Results:** This subset of pts makes up 13.7% (n=229) of the whole population currently registered (n=1,672). The distribution of pts on <36 mo, ≥36 mo to <60 mo, and ≥60 mo DFI subgroups was 15.3%, 16.6% and 68.1%, respectively, with >50% pts recurring at ≥84 mo and only 1.3% pts at ≤12 mo. Most pts were Caucasian (99.1%) and female (99.6%), and at ABC diagnosis, 75.5% were postmenopausal and their median age was 59 years (33-88); median age was higher in pts with DFI ≥60 mo. Family history of BC and/or ovarian cancer was reported in 31.4% pts, with a slightly higher percentage in pts with DFI <36 mo; an hereditary-risk genetic test was performed in 11.4% pts in total and BRCA2 gene mutation (n=6) was the only one reported. Bone (59%), liver (33.2%), lung (23.1%) and lymph nodes (21.8%) were the most frequent sites of metastases. Visceral disease was present in 63.3% pts and 76% pts had ≤2 locations. Liver involvement was more frequent in pts with DFI <36. The most frequent 1<sup>st</sup>-line therapies were ET/biological therapy (BT) (46.7%) and ET (28.8%). The most common ET/BT regimens were aromatase inhibitor (AI)/cyclin-dependent kinase 4/6 inhibitor (CDKi) (48.6%) and fulvestrant (FUL)/CDKi (28.0%); AIs (67.3%) and FUL (31.0%) were also the most common drugs for ET (as monotherapy). A 2<sup>nd</sup>-line therapy was reported in 52.4% pts. The median time to progression (TTP) to 1<sup>st</sup>-line therapy was 11.4 mo (1.2-37.0), being similar in pts with DFI <36 mo and ≥36 mo to <60 mo (around 7 mo), and higher in pts with DFI ≥60 mo (13.2 mo). The most frequent 2<sup>nd</sup>-line therapies were ET/BT (33.3%) (FUL/CDKi 42.5%, AI/CDKi 30%), chemotherapy as monotherapy (29.2%) (capecitabine 51.7%, taxanes 20.7%, eribulin 13.8%) and ET (19.2%) (FUL 54.5%, AI 36.4%). Median duration of 2<sup>nd</sup>-line therapy was 5.7 mo (0.03-37.2) and disease progression was reported in 56.7% pts. Most frequent 1<sup>st</sup>-/2<sup>nd</sup>-line therapies between DFI subgroups were similar in type but not in frequency. 3<sup>rd</sup>-line therapy has been reported in 25.8% of 229 pts. **Conclusions:** In pts with HR+/HER2- ABC due to disease recurrence, >50% pts recurred at ≥84 mo. Bone is the most frequent metastatic location in all DFI subgroups. The most common 1<sup>st</sup>- and 2<sup>nd</sup>-line therapies were the ET/BT combination, with AI/CDKi and FUL/CDKi, respectively. The median TTP to 1<sup>st</sup>-line therapy was superior in pts with DFI ≥60 mo.

**Background** Tucatinib (TUC) is a highly selective oral tyrosine kinase inhibitor of HER2 with minimal inhibition of EGFR. It was recently approved by the FDA for patients (pts) with HER2+ metastatic breast cancer (MBC), including pts with brain metastases (BM) whose cancers have progressed on at least 1 prior anti-HER2 regimen in the metastatic setting. In the HER2CLIMB (NCT02614794) pivotal trial, pts with HER2+ MBC previously treated with trastuzumab (T), pertuzumab, and trastuzumab emtansine (T-DM1) were randomized to receive TUC or placebo in combination with T and capecitabine (C). The addition of TUC resulted in clinically meaningful and statistically significant improvements in overall survival (OS), progression-free survival (PFS), and objective response rate (ORR) in HER2+ MBC pts. Primary methods and outcomes have been reported previously (Murthy, NEJM 2019). Here we present an exploratory analysis describing the outcomes in the HER2CLIMB trial based on hormone receptor (HR) status.

**Methods** Pts were randomized 2:1 to receive TUC or placebo in combination with T and C. All pts had a baseline brain MRI and randomization was stratified by presence of BM, ECOG status, and geographic region. All pts with HER2+ MBC who were positive for either or both estrogen receptor and progesterone receptor ( $\geq 1\%$ ) were assigned to the HR "positive" subgroup. Pts not meeting the above criteria were assigned to the HR "negative" subgroup. For the exploratory HR+/HR- efficacy analysis presented here, PFS per RECIST 1.1 by blinded independent central review was evaluated in the first 480 pts enrolled. OS, PFS in pts with baseline BM, and confirmed ORR in pts with measurable disease were evaluated in the total study population. P values presented for PFS are nominal.

**Results** Overall, 612 pts were enrolled to HER2CLIMB; 370 pts (60%) had HR+ and 242 (40%) had HR- tumors. Baseline demographics and disease characteristics in HR+/HR- subgroups were generally balanced between treatment arms. In the HR+ group, there was a 42% reduction in the risk of progression or death in the TUC arm (hazard ratio: 0.58; 95% CI: 0.42, 0.80; P=0.0008); median (95% CI) PFS was 7.6 mo (7.4, 9.5) in the TUC arm vs 5.6 mo (4.3, 7.4) in the control arm. In the HR- group, there was a 46% reduction in the risk of progression or death in the TUC arm (hazard ratio: 0.54; 95% CI: 0.34, 0.86; P=0.008); median (95% CI) PFS was 8.1 mo (7.0, 11.6) in the TUC arm vs 4.2 mo (3.1, 8.6) in the control arm. In the total population, median OS was 21.7 mo vs 18.2 mo in HR+ in the TUC arm vs control arm, respectively; median OS in HR- was 31.1 mo in the TUC arm vs 14.1 mo in the control arm. In pts with BM in the HR+ group (n=166 [45%]), there was a 52% reduction in the risk of progression or death (hazard ratio: 0.48; 95% CI: 0.31, 0.75; P=0.0008); median (95% CI) PFS was 7.5 mo (5.6, 9.5) in the TUC arm vs 5.1 mo (4.1, 5.7) in the control arm, and median OS was 18.1 mo vs 12.8 mo, respectively. In pts with BM in the HR- group (n=125 [52%]), there was a 50% reduction in the risk of progression or death (hazard ratio: 0.50; 95% CI: 0.27, 0.95; P=0.03); median (95% CI) PFS was 7.8 mo (6.1, 11.6) in the TUC arm vs 5.4 mo (2.9, 8.6) in the control arm, and median OS was 18.5 mo vs 11.5 mo, respectively. In the total population, ORR was numerically higher in the TUC arm vs the control arm regardless of HR status (HR+: 37.4% [95% CI: 30.8, 44.5] vs 27.1% [95% CI: 19.0, 36.6], respectively and HR-: 45.3% [95% CI: 36.7, 54.0] vs 15.6% [95% CI: 7.8, 26.9], respectively).

**Conclusions** Among pts with HER2+ MBC previously treated with T, pertuzumab, and T-DM1, the addition of TUC to T and C showed clinically meaningful improvements of PFS, OS, and ORR independent of HR status. Furthermore, pts with HR+ and HR- MBC with BM derived similar benefit from the addition of TUC to T and C.

### Background

In patients (pts) with HER2+ (immunohistochemistry [IHC] 3+ or IHC 2+/in situ hybridization [ISH]+) metastatic breast cancer (mBC), HER2-targeted therapies have greatly improved survival. However, for pts with HER2-low mBC (IHC 1+ or IHC 2+/ISH-), there are no approved HER2-directed therapies. In pts with hormone receptor (HR)+, HER2-low mBC whose disease progresses on standard first-line treatment (endocrine therapy [ET] and CDK4/6 inhibitors), median progression-free survival (PFS) with continued ET alone is  $\approx$  2 months, and with mTOR or PI3K inhibitors (in *PIK3CA*-mutant tumors) in the second-line setting, PFS ranges from 3.5 to 7.3 months, respectively (André F, et al. ESMO 2018; Dhakal A, et al. ASCO 2018; Rugo R, et al. ASCO 2020). For ET-refractory pts, chemotherapy (CTX) is the standard of care and has a poor benefit-risk ratio. The treatment landscape for pts with HR-, HER2-low mBC is even more limited, consisting largely of CTX (with or without PD-1/PD-L1 inhibitors in the first-line setting). T-DXd is an antibody-drug conjugate composed of a humanized HER2 antibody attached to a membrane-permeable topoisomerase I inhibitor payload via a cleavable tetrapeptide-based linker at a drug to antibody ratio of  $\approx$  8. In a recent phase 1b study, pts with heavily pretreated (median, 7.5 prior therapies) HER2-low advanced or metastatic breast cancer treated with T-DXd 5.4 or 6.4 mg/kg had a confirmed objective response rate (ORR) of 37.0% (20/54) by independent central review and a median PFS of 11.1 months, and the safety profile was generally manageable (Modi S, et al. *J Clin Oncol.* 2020;38:1887-1896). Here, we describe a phase 1b trial evaluating the safety, tolerability, and pharmacokinetics (PK) of T-DXd in combination with other anticancer agents in pts with HER2-low, HR+ or HR- mBC.

### Study Description

DESTINY-Breast08 is a multicenter, open-label, 2-part study evaluating T-DXd combinations in pts with HER2-low mBC. The 5 treatment modules comprise T-DXd in combination with (1) capecitabine, (2) durvalumab + paclitaxel, (3) capivasertib, (4) anastrozole, and (5) fulvestrant.

**Part 1 (dose finding):** Each treatment module will enroll 3 to 12 pts per dose level to determine the recommended phase 2 dose (RP2D) in combination; modules 1 through 3 will enroll irrespective of HR status, whereas modules 4 and 5 will be restricted to only HR+ pts. HR+ pts should have received  $\geq$  1 prior line of ET and  $\geq$  1 prior line of CTX; HR- pts should have received  $\geq$  1 prior line of CTX.

**Part 2 (dose expansion):** Modules 1, 4, and 5 will enroll 20 pts, and modules 2 and 3 will enroll 40 pts using the RP2D determined in part 1 of each module. Patient eligibility per module in part 2 is as follows:

- Module 1 (HR+ or HR-): HR-, only 1 prior line of CTX for mBC; HR+, only 1 prior line of ET but no prior CTX for mBC
- Module 2 (HR-): no prior CTX for mBC
- Module 3 (HR-): only 1 prior line of CTX for mBC
- Modules 4 and 5 (HR+): only 1 prior line of ET but no prior CTX for mBC

The primary endpoint in part 1 is safety and tolerability and determination of RP2Ds. In part 2, the primary endpoint is safety and tolerability, and secondary endpoints include ORR, duration of response, and PFS (all by investigator assessment according to RECIST 1.1) as well as overall survival, PK, and immunogenicity.

Long-term results of prepectoral implant-based reconstruction using braxon®acellular dermal matrix - national audit from United Kingdom

Mihir Chandarana<sup>1</sup>, Sankaran Narayanan<sup>2</sup> and Rishikesh Parmeshwar<sup>3</sup>. <sup>1</sup>Royal Victoria Hospital, Kirkcaldy, United Kingdom<sup>2</sup>University Hospitals of North Midlands NHS Trust, Stoke-on-Trent, United Kingdom<sup>3</sup>University Hospital of Morecambe Bay, Lancaster, United Kingdom

**Background** Single stage direct-to-implant reconstruction is the most common method of reconstruction in the United Kingdom (UK) after a mastectomy. Prepectoral implant placement with full implant coverage using acellular dermal matrix (ADM) is a relatively new technique with paucity of data on surgical outcomes. We report on long term outcomes of prepectoral breast reconstruction (PBR) using Braxon® ADM from a multicentre audit across the UK. **Methods** A retrospective multicentre audit of all direct-to-implant post-mastectomy PBR using Braxon® was conducted. The demographic details, treatment details, 90-day complication rates and implant loss rates for the entire study period were evaluated. Factors affecting major complication rates and implant loss rates were analysed using univariable and multivariable analysis. **Results** Eight hundred and twenty two patients underwent 1020 post-mastectomy PBR across 29 centres in the UK from January 2014 to 2019. Median age of the cohort was 49 years with a median BMI of 25 kg/m<sup>2</sup>. The median and mean follow-up periods were 14 and 17.54 months respectively. The overall 90-day complication rate was 26.47% with major complications in 13.04% of patients. The 90-day readmission rate was 11.18% and return to theatre rate was 12.25%, with a 90-day implant loss rate of 5.1 percent. The implant loss rate was 6.28% for the entire study period. On multivariable analysis, therapeutic mastectomy (p = 0.008) and a higher breast specimen weight (p = 0.000) were the only factors to significantly impact major complications. Implant loss rates were significantly higher in current smokers (p = 0.000) and patients with previous breast radiation therapy (p = 0.010), axillary nodal clearance (p = 0.007), high breast specimen weight (p = 0.034) and a higher implant volume (p = 0.044) on multivariable analysis. **Conclusion** Implant-based prepectoral breast reconstruction with Braxon® acellular dermal matrix has satisfactory short-term and long-term operative outcomes, comparable to National data from the United Kingdom. Smoking, previous breast radiation therapy, axillary nodal clearance, high breast specimen weight and implant volume could negatively impact complications and implant loss rates. Patient-reported outcomes need to be evaluated.

Characteristics	Number of patients or procedures

The PORTRET-tool: A prediction tool for older patients with breast cancer that predicts recurrence, survival and other-cause mortality

Willeke van der Plas-Krijgsman<sup>1</sup>, Daniele Giardiello<sup>2</sup>, Hein Putter<sup>2</sup>, Ewout W Steyerberg<sup>2</sup>, Esther Bastiaannet<sup>3</sup>, Anne M Stiggelbout<sup>4</sup>, Simon P Mooijjaart<sup>5</sup>, Johanneke EA Portielje<sup>1</sup>, Gerrit J Liefers<sup>3</sup> and Nienke A de Glas<sup>1</sup>. <sup>1</sup>Department of Medical Oncology, Leiden University Medical Center, Leiden, Netherlands<sup>2</sup>Department of Biomedical Data Sciences, Leiden University Medical Center, Leiden, Netherlands<sup>3</sup>Department of Surgery, Leiden University Medical Center, Leiden, Netherlands<sup>4</sup>Department of Medical Decision Making, Biomedical Data Sciences, Leiden University Medical Center, Leiden, Netherlands<sup>5</sup>Department of Gerontology and Geriatrics, Leiden University Medical Center, Leiden, Netherlands

**Introduction** Previous studies have shown that available tools such as 'Adjuvant Online!' are not able to accurately predict the prognosis of patients aged 65 years or older with breast cancer. Furthermore, all available tools predict prognosis in terms of recurrence-free survival or overall survival, whilst the risk of other-cause mortality is often high in the older patient with breast cancer. This is highly relevant as it may influence treatment decisions. Patient characteristics such as comorbidity and various geriatric variables have shown to be predictive for these outcomes and could enhance the precision of prognostic tools for this target population. The objective of this study was to develop a prediction tool for recurrence, survival and other-cause mortality for older patients with breast cancer who received locoregional treatment, with incorporation of patient-, tumor- and geriatric variables. The tool additionally predicts expected benefits of systemic treatment. **Methods** Data from the large population-based FOCUS cohort was used, consisting of consecutive breast cancer patients in the South-Western part of the Netherlands, diagnosed between 1997 and 2004, aged 65 years and older. It contains detailed information on tumor characteristics, treatment, comorbidity and geriatric parameters. We developed a risk prediction model using a Cox proportional hazards regression model for overall survival and cause-specific Cox proportional hazards models for recurrence and other-cause mortality (defined as mortality without recurrence). The included predictors were derived from the PREDICT tool (consisting of age and various tumor variables), since this tool was previously shown to have the best performance in older adults so far. Predictors were complemented with comorbidity and geriatric variables. Discrimination accuracy was evaluated using time-dependent area under the curve (AUC). The potential annual benefit of chemotherapy was calculated assuming a relative risk of chemotherapy on recurrence of 0.7, derived from data from the most recent updates of the Early Breast Cancer Trialists' Collaborative Group (EBCTCG). Additional benefit of endocrine treatment will be included in further development of the tool. **Results** A total of 2,744 patients were included for the initial development. For all patients, 5-year follow-up was complete with a high event-rate including 343 recurrences and 831 total deaths of which 586 without recurrence. The strongest predictors for overall survival and non-recurrence mortality were age (HR = 2.14, 95% CI: 1.89 - 2.43 and HR = 2.87, 95% CI: 2.46 - 3.35, respectively) and dementia (HR = 1.52, 95% CI: 1.16 - 1.99 and HR = 1.9, 95% CI: 1.49 - 2.65, respectively), and for recurrence, nodal status (HR = 1.80, 95% CI: 1.45 - 2.24) and tumor grade (HR = 2.96, 95% CI: 1.88 - 4.66). The time-dependent AUC at 5 years for recurrence-specific and other-cause mortality were 0.78 (95% CI: 0.76 - 0.81), and 0.75 (95% CI: 0.72 - 0.78), respectively. The AUC for overall survival was 0.75 (95% CI: 0.72 - 0.78). External validation is currently being performed in a large dataset retrieved from the national cancer registry (N= 13,631). These results will be presented during the symposium. **Conclusion** We have developed a model for predicting 5-year recurrence, other-cause mortality and overall survival, including expected benefits of adjuvant treatment, for older patients with breast cancer, with a good discrimination performance within a large-population based cohort. To our knowledge, this is the first model specifically designed for the older population, including competing risk as a predicted outcome and with incorporation of geriatric variables.

Does genomic recurrence score predict for ipsilateral breast tumor recurrence after breast conservation therapy?

Adam H Richman, Ankur K Patel, Atilla Soran, Emilia J Diego, Priscilla F McAuliffe, Ronald R Johnson, Adam Brufsky, Vikram Gorantla, Jennifer Steiman, Joanna S Lee and Sushil Beriwal. UPMC, Pittsburgh, PA

**Purpose/Objectives** Gene profiling Recurrence Score (RS) assays are commonly used to identify patients with hormone receptor (HR) positive, HER-2 negative invasive breast cancer (IBC) who might benefit from systemic chemotherapy. More recently, the 21-gene recurrence score assay has been found to correlate with locoregional recurrence (LRR) after mastectomy (SWOG) or lumpectomy (NSABP). In the NSABP analysis, risk of ipsilateral breast tumor recurrence (IBTR) was not correlated with RS and was high in patients younger than 50 years of age irrespective of genomic score. However, tumor bed radiotherapy (RT) boost was not utilized in these protocols. The purpose of this study is to determine if RS predicts for IBTR or LRR in women treated with modern breast conserving therapy (BCT) using RT boost and optimal systemic treatment.

**Materials/Methods** We performed a retrospective review of patients with HR positive, HER-2 negative IBC who underwent gene profile testing and were treated at our institution with BCT and sentinel lymph node biopsy (SLNB) from 2013 to 2017. Both node negative and node positive patients were included. The Oncotype® 21-gene recurrence score assay was used in 84%, Mammprint® in 12%, and Prosigna® in 4%. 97% received hormonal therapy (HT), 18% chemotherapy (CHT), 58% hypofractionated RT, and 96% a surgical bed RT boost. IBTR and LRR were measured from the end of local treatment to IBTR or LRR, with death or last follow up date as censoring events. The Kaplan-Meier method was used to estimate event-time probabilities for the above endpoints. Predictors of IBTR/LRR were analyzed using log rank tests between groups and with Cox regression for continuous variables. P-values <0.05 were considered significant.

**Results** 686 evaluable patients were identified with median follow-up of 50 months (Interquartile range [IQR] 36-64 months). Median age was 61 years (IQR 53-68 years). 76% had invasive ductal carcinoma, 64% grade 2 disease, and 18% positive SLNB. RS of any type was low in 60% of patients and intermediate or high in 40%. Four-year IBTR was 0.2% (95% Confidence Interval [CI] 0.0-0.6%) for any low risk RS and 1.6% (95% CI 0.0 - 3.2%) for intermediate or high-risk RS ( $p = 0.01$ ). Tumor grade was also predictive for IBTR ( $p < 0.01$ ), but age < 50 was not ( $p = 0.4$ ). For patients younger than 50, four-year IBTR was 0.9% (95% CI 0.0 - 2.6%) and not affected by RS ( $p = 0.231$ ). On multivariate analysis, grade remained a significant predictor for IBTR ( $p = 0.04$ ), but RS did not ( $p = 0.08$ ). Four-year LRR was 0.5% (95% CI 0.0-1.3%) in patients with a low risk RS and 3.8% (95% CI 1.3-6.3%) in those with intermediate or high risk ( $p < 0.01$ ). Grade ( $p < 0.01$ ) and pathologic tumor size ( $p < 0.01$ ) were also correlated with LRR, although only RS (HR 5.14, 95% CI 1.02-25.9,  $p = 0.047$ ) and pathologic tumor size on (HR 1.05, 95% CI 1.01- 1.09,  $p = 0.02$ ) remained significant on multivariate analysis. Of the 125 patients with positive SLNB, 47% were treated with high tangents and 42% with comprehensive regional nodal irradiation. For node positive patients, LRR was not correlated with low versus intermediate or high RS ( $p = 0.07$ ). However, if intermediate risk Oncotype scores were grouped with low risk Oncotype and Mammprint scores, then LRR was 0.0% for low and intermediate risk and 9.1% for high risk ( $p < 0.01$ ).

**Conclusions** In this large single institution study, RS did not predict for IBTR in patients with HR positive, HER-2 negative invasive breast cancer in any age group treated with BCT utilizing a surgical bed RT boost and optimal systemic treatment. High RS did predict for high LRR because of higher regional recurrences and can be used as a guide to add comprehensive RT for node positive patients after BCT.

Oral paclitaxel and encaequidar (oPac+E) versus IV paclitaxel (IVPac) in the treatment of metastatic breast cancer (mBC) patients (study KX-ORAX-001): Progression free survival (PFS) and overall survival (OS) updates

G Umanzor<sup>1</sup>, H S Rugo<sup>2</sup>, F J Barrios<sup>3</sup>, R H Vasallo<sup>4</sup>, M A Chivalan<sup>5</sup>, S Bejarano<sup>6</sup>, J R Ramirez<sup>7</sup>, L Fein<sup>8</sup>, R D Kowalyszyn<sup>9</sup>, D L Cutler<sup>10</sup>, D Kramer<sup>10</sup>, J Goldfinch<sup>10</sup>, H Wang<sup>10</sup>, T Moore<sup>10</sup> and R MF Kwan<sup>10</sup>. <sup>1</sup>Liga Contra el Cancer, San Pedro Sula, Honduras<sup>2</sup>University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA;<sup>3</sup>Instituto Nacional de Cancerologia (INCAN), Guatemala City, Guatemala<sup>4</sup>Clinical Research RD, Santo Domingo, Dominican Republic<sup>5</sup>CELAN Clinica Medica, Guatemala City, Guatemala<sup>6</sup>Excel Medica, San Pedro Sula, Honduras<sup>7</sup>CRESEM, Quetzaltenango, Guatemala<sup>8</sup>Instituto de Oncologia de Rosario, Rosario, Argentina<sup>9</sup>Centro de Investigaciones Clinica, Clinica Viedma, Argentina<sup>10</sup>Athenex Inc., Buffalo, NY

**Background:** IVPac is widely used to treat patients with breast cancer. oPac+E is oral paclitaxel in combination with Encaequidar, an oral, minimally absorbed, specific p-glycoprotein inhibitor that enables the absorption of oral paclitaxel. Results of the phase III trial, KX-ORAX-001, were presented at SABCs, 2019, Abstract # GS6-01. At the time of the database lock for the final analysis of the primary endpoint of confirmed tumor response rate, analyses of PFS and OS were performed. The confirmed tumor response rate was significantly higher in the oPac+E group vs IVPac (35.8% vs 23.4%, p=0.011 ITT, population). The median overall survival was 27.7 months vs 16.7 months, respectively favoring oPac. An update of the duration of response, PFS and OS data comprising an additional 14 months follow-up will be presented. At the time of the update it is projected that approximately 60% of subjects will have had a survival event.

**Methods:** Study KX-ORAX-001 was a phase III, randomized, international study in women with mBC for whom treatment with IVPac was recommended. Eligible patients were randomized 2:1 to receive oPac+E or IVPac. Patients continued treatment until discontinuation due to progressive disease or toxicity. oPac 205 mg/m<sup>2</sup> was given once daily for 3 days weekly. E 12.9 mg was given 1 hour before each dose of oPac. IVPac 175 mg/m<sup>2</sup> was infused over 3 hours every 3 weeks. The primary endpoint was efficacy defined as tumor response confirmed by BICR at two consecutive evaluations. Key secondary endpoints included PFS, OS. Safety was monitored throughout the study.

**Results:** A total of 402 mBC patients were randomized (oPac+E 265: IVPac 137) and represent the ITT population of which 399 subjects were dosed. Updated data for duration of response, PFS and OS for the ITT and prespecified mITT populations will be presented. (NCT 02594371)

Clinical factors and association with treatment modalities in patients with breast cancer and brain metastases who develop leptomeningeal disease

Akshjot Puri, Charisma Mylavarapu, Jiagiong Xu, Tejal A Patel, Bin S Teh, Ivo Tremont-Lukats, Jenny C Chang and Polly Niravath. Houston Methodist, Houston, TX

**BACKGROUND** Improvements in systemic therapies have led to significantly improved survival in patients with breast cancer and have created a challenge with regards to management of brain metastases (BM) and leptomeningeal disease (LMD). LMD is a highly aggressive condition, resulting in rapid neurological decline and a short survival of weeks to months. The purpose of this study is to identify clinical factors that can predict for LMD when a patient is diagnosed with BM, and to assess outcomes with various treatment modalities. **METHODS** A retrospective analysis was conducted using a clinical database at a single institution and included 178 patients with breast cancer and treated BM between 2007-2020. Demographic, clinical, radiographic, and dosimetric data were collected. LMD was diagnosed by cytology or neuroimaging. Chi-square and t-test were used. **RESULTS** Out of 178 patients with breast cancer and treated BM, 41 (23%) developed LMD. Median age for the study cohort was 51.3  $\pm$  13.4 years; those with LMD was 47.9  $\pm$  12.3 ( $p=0.057$ ) years. One of the 178 patients was a male and all 41 with LMD were females. There were 58.5% Caucasian women in the LMD group followed by African-American being 24.4% ( $p=0.31$ ). Characteristics like number of brain lesions ( $p=0.57$ ), median size of the largest brain lesion ( $p=0.70$ ), hemorrhagic/cystic lesions ( $p=0.68$ ), systemic disease being progressive in 42.6%, stable in 19.3% and 26.1% with no evidence of systemic disease at the time of diagnosis of BM ( $p=0.34$ ) did not pose a higher risk in developing LMD. For 29% patients the brain lesions were supratentorial, 23.7% were infratentorial and 47.4% patients had both and had a higher risk for LMD ( $p=0.025$ ). Patients with liver ( $p=0.45$ ) and bone ( $p=0.48$ ) lesions did not have higher risk for LMD which was seen in those without lung metastases ( $p=0.03$ ). In the LMD group, 39% had HR+, 31.7% HER2+, and 41.4% had triple negative breast cancer (TNBC). The higher incidence of HR+ patients could be attributed to the fact that the more aggressive HER2+ and TNBC patients may have not gotten treatment for their BM as they pursued comfort care status. In the LMD group, 13.1% received prior stereotactic radiation, 39.5% whole brain radiation, 10.5% had surgery alone and 36.8% had surgery with pre/post-op radiation. Patients who had any surgery did not have a higher risk for LMD ( $p=0.26$ ). Surgery did not pose a higher risk for local recurrence, seen in 28% patients ( $p=0.42$ ) and occurrence of BM at another site, seen in 36.5% patients ( $p=0.16$ ). **CONCLUSIONS** Among breast cancer patients with brain metastases those who develop LMD tend to be younger, with higher risk in Caucasians and African-American women; however, this was not statistically significant. The number, size, hemorrhagic/cystic character of brain lesions did not pose a higher risk whereas occurrence of synchronous lesions in supratentorial and infratentorial locations increased risk of LMD. There was no statistically significant difference in the rates of LMD, local recurrence, CNS recurrence at another site with surgery and/or radiation.

Ethnicity	Brain metastases (N=178)	LMD group (N=41) ( $p=0.31$ )
Caucasian	58.4%	58.5%
Hispanic	12.4%	4.9%
African-American	19.1%	24.2%
Others	10.1%	12.2%

Clinical characteristics	Brain metastases	LMD group	P value
Number of brain lesions (Median interquartile range)	3 (1-8)	2.5 (1-9)	$P=0.57$
Median size of the largest brain lesion (cm)	2.4 1.4	2.53 1.69	$p=0.70$
Hemorrhagic lesions	22	3	$P=0.68$
Cystic lesions	16	3

Development of a potent mutant-ESR1 targeted agent, ERX-245, for treating metastatic therapy-resistant breast cancer

Ganesh V Raj<sup>1</sup>, Suryavathi Viswanadhapalli<sup>2</sup>, Karla Parra<sup>1</sup>, Shihong Ma<sup>1</sup>, Tae-Kyung Lee<sup>3</sup>, Xihui Liu<sup>1</sup>, Kara Kassees<sup>3</sup>, Weiwei Tang<sup>2</sup>, Junhao Liu<sup>2</sup>, Zexuan Liu<sup>2</sup>, Uday P Pratap<sup>2</sup>, Behnam Ebrahimi<sup>2</sup>, Rajeshwar Rao Tekmal<sup>2</sup>, Jung-Mo Ann<sup>3</sup> and Ratna K Vadlamudi<sup>2</sup>. <sup>1</sup>UT Southwestern, Dallas, TX; <sup>2</sup>UT Health San Antonio, San Antonio, TX; <sup>3</sup>UT Dallas, Dallas, TX

**Background:** *ESR1* mutations are acquired following ERα targeted therapies and are a major determinant of therapy-resistance. These *ESR1* mutations maintain *ESR1* signaling, albeit in a ligand-independent manner. Effective drugs targeting these mutant (MT) ERα proteins represent a significant unmet clinical need. We had previously shown that ERX-11, an *ESR1*-coregulator binding inhibitor, could block the function of these MT ERα proteins. In this study, we sought to leverage recently published structures of MT ERα to develop more potent analogues of ERX-11. **Methods:** Virtual screening of >250,000 derivatives of ERX-11 was performed with simulated docking on the MT ERα to identify and design analogues of ERX-11. Several hundred analogues were synthesized and tested *in vitro* using multiple BC model cells that express wild type (WT) *ESR1* or mutant (MT) *ESR1* (Y537S or D538G). Mechanistic studies were performed using RNA-Seq, Western blotting, qRT-PCR and reporter gene assays. The *in vivo* efficacy of the most potent ERX-11 analogue ERX-245 was examined using xenograft, PDX and metastatic models of MT-ER driven BC. **Results:** From our virtual and functional screen, we identified an ERX-11 analogue, ERX-245 as the most potent hit to target MT-ERα. Docking studies modeled a better fit of ERX-245 into the ligand binding domain of both the Y537S and D538G MT-ERα. ERX-245 potently reduced (IC<sub>50</sub> ~250 nM) the cell viability of both WT-ERα and MT-ERα driven BC cells but not ERα negative BC cells. ERX-245 significantly reduced the growth (colony formation, clonogenic and mammosphere assays) of MT-ERα BC cells. ERX-245 exhibited synergistic activity in combination with CDK4/6 inhibitors. In distinction to classic SERDs like fulvestrant (which degrade ERα within 4h), ERX-245 treatment decreased MT-ERα protein levels over 24 hours. PK studies indicated that ERX-245 is more polar and has better solubility and pharmacokinetic properties than ERX-11. ERX-245 reduced tumor growth of subcutaneous xenograft and PDX models driven by MT-ERα as well as the proliferation of xenograft derived MT-ERα explant models. ERX-245 significantly reduced the invasive capability of MT-ERα BC cells *in vitro* and inhibited both the metastatic capability and growth of metastatic tumors derived from MT-ERα BC cells injected by intracardiac or intratibial routes. **Conclusions:** Taken together, these results indicate that ERX-245 is a potent and pharmacologically translatable analog of ERX-11, with activity against both primary and metastatic tumors driven by MT-ERα.

Nci 10013 - A randomized phase 2 study of neoadjuvant carboplatin and paclitaxel, with or without atezolizumab in triple negative breast cancer (TNBC)

Foluso O Ademuyiwa<sup>1</sup>, Feng Gao<sup>1</sup>, Ina Chen<sup>1</sup>, Donald W Northfelt<sup>2</sup>, Robert Wesolowski<sup>3</sup>, Mili Arora<sup>4</sup>, Adam Brufsky<sup>5</sup>, Claire Dees<sup>6</sup>, Cesar A Santa-Maria<sup>7</sup>, Roisin M Connolly<sup>8</sup>, Jeremy Force<sup>9</sup>, Alvaro Moreno-Aspitia<sup>10</sup>, Sarah Larson<sup>1</sup>, Elad Sharon<sup>11</sup> and William Gillanders<sup>1</sup>. <sup>1</sup>Washington University, Saint Louis, MO; <sup>2</sup>Mayo Clinic, Phoenix, AZ; <sup>3</sup>Ohio State University, Columbus, OH; <sup>4</sup>UC Davis, Sacramento, CA; <sup>5</sup>University of Pittsburgh, Pittsburgh, PA; <sup>6</sup>University of North Carolina, Chapel Hill, NC; <sup>7</sup>Johns Hopkins University, Baltimore, MD; <sup>8</sup>University College Cork, Cork, Ireland; <sup>9</sup>Duke University, Durham, NC; <sup>10</sup>Mayo Clinic, Jacksonville, FL; <sup>11</sup>National Cancer Institute, Bethesda, MD

**Background** Inhibition of PD-L1 with atezolizumab combined with chemotherapy has shown acceptable safety and improved survival in patients with metastatic PD-L1 positive triple negative breast cancer (TNBC). Patients with TNBC who do not achieve a pathological complete response (pCR) to neoadjuvant chemotherapy have a high risk of disease recurrence and death. This randomized, open-label, phase 2 trial evaluates neoadjuvant carboplatin and paclitaxel with or without atezolizumab in patients with previously untreated clinical stages II and III TNBC. **Methods** Women aged ≥18 years with clinical stage T2-T4c, any N, M0 primary tumor by AJCC 7th edition staging TNBC; ECOG PS 0-2; and no prior systemic therapy for the indexed breast cancer were eligible. Patients were randomized in a 1:2 ratio to carboplatin AUC5 q 3 weeks x 4 + paclitaxel 80 mg/m<sup>2</sup> q week x 12 (Arm A), or carboplatin AUC5 q 3 weeks x 4 + paclitaxel 80 mg/m<sup>2</sup> q week x 12 + atezolizumab 1200 mg q3 weeks x 4 (Arm B). Surgery was 3-6 weeks following neoadjuvant chemotherapy. Adjuvant dose-dense doxorubicin and cyclophosphamide was administered q2 weeks with growth factor support to all patients as per routine care. pCR and tumor infiltrating lymphocyte (TIL) percentages are the co-primary endpoints. pCR-evaluable population includes all eligible women who have been randomized and received at least one dose of combination therapy, while the TIL-evaluable population includes all eligible women who have evaluable TIL percentage after one cycle of therapy. A sample size of 67 (22 in Arm A, and 45 in Arm B) provided 80% power at 1-sided alpha = 0.10 to detect a minimum of 15% difference in TIL and 29% improvement (40% vs. 69%) in pCR, respectively. Herein, we report pCR results in the per protocol modified intent-to-treat population (mITT), which includes all eligible patients who were randomized and received at least one dose of combination therapy. **Results** Sixty-seven patients were randomized between 8/2017 and 9/2019. Six patients randomized to Arm A withdrew consent; 2 of these received protocol therapy but are excluded from the mITT analyses as they are not evaluable because definitive pathology reports are not available. Median follow up is 6 months (range 0.3 - 12.6 months). Median age is 52 years (range 25 - 78). Forty-three (64.2%) were Caucasian and thirteen (19.4%) were African American. Twenty-five (37.3%) were pre-menopausal. 67.2% and 32.8% had stages II and III disease respectively. Nine (13.4%) had a germline mutation in either *BRCA1* or *BRCA2*. In the mITT population, 3 of 16 patients achieved pCR in Arm A - 18.8% (95% CI 4.0%- 45.6%), versus 25 of 45 patients in Arm B - 55.6% (95% CI 40.0%-70.4%); p value 0.018. pCR in those with *BRCA* mutations was 50% and 80% in Arm A and Arm B, respectively. Treatment delays were observed in 9 patients (40.9%) in Arm A, and 20 (44.4%) in Arm B; dose reductions occurred in 4 patients (18.1%) in Arm A, and in 6 (13.3%) in Arm B. There were 4 SAEs in Arm A and 10 in Arm B. One patient in Arm B had grade 3 adrenal insufficiency. One patient in Arm B died from recurrent disease during the follow-up period. **Conclusions:** The addition of atezolizumab to neoadjuvant carboplatin and paclitaxel resulted in an increased pCR rate in patients with clinical stages II and III TNBC. However, the pCR in the control Arm A was lower than expected, possibly due to the absence of neoadjuvant anthracyclines. The high pCR rate observed in the experimental arm of this study is similar to that observed in other neoadjuvant trials utilizing anthracyclines, taxanes, and carboplatin in TNBC. Clinical trial information: NCT02883062.

Phase 2 study of response-guided neoadjuvant sacituzumab govitecan (IMMU-132) in patients with localized triple-negative breast cancer (NeoSTAR)

Laura M. Spring<sup>1</sup>, Sara M. Tolane<sup>2</sup>, Neelam Desai<sup>3</sup>, Amy Comander<sup>1</sup>, Therese Mulvey<sup>1</sup>, Ian E. Krop<sup>2</sup>, Eric P. Winer<sup>2</sup>, Elizabeth A. Mittendorf<sup>2</sup>, Leif W. Ellisen<sup>1</sup> and Aditya Bardia<sup>1</sup>. <sup>1</sup>Massachusetts General Hospital, Boston, MA; <sup>2</sup>Dana-Farber Cancer Institute, Boston, MA; <sup>3</sup>Beth Israel Deaconess Medical Center, Boston, MA

**Background:** Optimizing treatments for triple negative breast cancer (TNBC) in the localized breast cancer setting is key to preventing metastatic recurrences and reducing mortality from this devastating disease. Sacituzumab Govitecan (SG), a novel antibody-drug conjugate in which the topoisomerase 1 inhibitor SN-38 (the active metabolite of irinotecan) is coupled to a humanized monoclonal antibody targeting the tumor antigen Trop-2, was granted FDA accelerated approval in April 2020 for treatment of patients with metastatic TNBC. The NeoSTAR clinical trial is evaluating SG in the neoadjuvant setting for patients with localized TNBC. **Trial design:** This is a single arm phase II study of neoadjuvant SG in patients with localized TNBC. SG will be administered via an IV infusion on Days 1, 8 of each 21-day cycle at a starting dose of 10 mg/kg for 4 cycles. After 4 cycles, patients who have biopsy-proven residual disease will have the option to receive additional standard neoadjuvant therapy at the discretion of the treating physician and subsequently proceed to surgery. Those with a complete response on imaging may proceed directly to surgery. A baseline research biopsy prior to initiation of study therapy is required as well as tissue collection following treatment with SG (either at surgery or via biopsy prior to additional neoadjuvant therapy). **Eligibility criteria:** Patients  $\geq 18$  years of age with previously untreated primary TNBC as determined by the local institution according to ASCO/CAP criteria will be enrolled. Patients must either have a primary tumor  $>1$  cm measured by imaging (cT1c-T4), or be node positive. An ECOG performance score of 0 or 1, and adequate bone marrow, hepatic, and renal function is required. **Specific aims:** The primary objective is to assess the pathological complete response (pCR) rate in breast and lymph nodes (ypT0/isN0) with SG. Secondary objectives include assessment of radiological response rate, evaluation of the safety and tolerability of SG (CTCAE v5.0), disease-free survival (DFS), and quality of life (EORTC QLQ-C30). Exploratory objectives include assessment of potential predictive biomarkers, including Trop-2 expression, DNA damage response markers and immunological markers, as well as changes in cell free DNA with SG. **Statistical methods:** The primary analysis is based on the estimated pCR rate with SG and will be provided as a proportion (with two-sided 95% confidence interval). Accounting for up to a 14% drop out rate, a sample size of 43 patients will provide 80% power to exclude a lower limit of pCR of 20% (alpha 0.05, two-sided test). DFS will be analyzed using Kaplan-Meier methods and descriptive statistics. **Target Accrual:** 50 patients. **Contact:** Dr. Laura Spring (LSpring@mgh.harvard.edu)

High infiltration of adipocytes is associated with inflammation, metastasis as well as favorable tumor immune microenvironment whereas low infiltration is associated with highly proliferative tumor in ER positive breast cancer patients

Yoshihisa Tokumaru<sup>1</sup>, Masanori Oshi<sup>1</sup>, Eriko Katsuta<sup>1</sup>, Nobuhisa Matsushashi<sup>2</sup>, Manabu Futamura<sup>2</sup>, Kazuhiro Yoshida<sup>2</sup> and Kazuaki Takabe<sup>1</sup>.

<sup>1</sup>Roswell Park Comprehensive Cancer Institute, Buffalo, NY; <sup>2</sup>Gifu University School of Medicine, Gifu, Japan

**Background:** Cancer associated adipocytes are known to cause inflammation and leads to the cancer progression, and metastasis. In the current study, we defined intra-tumoral adipocytes transcriptionally utilizing a computational algorithm, xCell, which allowed us to quantify infiltrating adipocytes. We hypothesized that high amount of intra-tumoral adipocytes is associated with aggressive cancer characteristics and poor survival outcome.

**Material and Methods:** The clinicopathological data and survival information of 1090 breast cancer patients were obtained from The Cancer Genome Atlas (TCGA), GSE25066 and study by Yau et al. Survival analysis, gene set enrichment analysis (GSEA) were conducted comparing the intra-tumoral adipocyte high and low groups. The association between the amount of intra-tumoral adipocytes and Nottingham pathological grade or AJCC stage were evaluated. CYT score and xCell were utilized to evaluate intratumoral immune cell composition within breast cancer.

**Results:** Our transcriptomically defined intra-tumoral adipocyte appropriately reflected mature adipocytes in a bulk tumor. Surprisingly, intra-tumoral adipocytes high tumors did not demonstrate worse survival, neither OS or DFS, in the whole cohort or any of the subtypes. Less aggressive Stage 1 even trended toward increased intra-tumoral adipocytes although statistically insignificant. Further, less proliferative grade 1 was associated with increased intra-tumoral adipocytes compared with other grades in whole and ER positive/HER2 negative (ER+/HER2-) subtype of TCGA cohort ( $p < 0.001$ ). This result was consistent in GSE25066 cohort ( $p < 0.001$ ). An amount of intra-tumoral adipocytes was weakly inversely correlated with MKI67 expression in three cohorts; TCGA, GSE25066 and the study by Yau et al ( $r = -0.235$ ,  $r = -2.09$  and  $r = -0.355$ , respectively). In agreement with the previous in vitro studies, adipocyte high tumors enriched the gene sets associated with inflammation, such as TNF- $\alpha$  and Inflammatory response. Further, intra-tumoral adipocyte high tumors enriched the gene sets related to metastasis, such as EMT, TGF- $\beta$  signaling, and Notch signaling. On the other hand, adipocyte high tumors enriched the gene sets related to immune response such as IL2 signaling and IFN- $\gamma$  especially in ER+/HER2- subtype. The analysis of tumor immune microenvironment revealed that intra-tumoral adipocyte high tumors were associated with favorable tumor immune microenvironment in ER+/HER2- subtype, but not in triple negative (TN). Consistent with the association with pathological grade and MKI67, intra-tumoral adipocyte low tumors enriched the cell cycle and cell proliferation gene sets, such as G2M checkpoint, in both TCGA and GSE25066 cohorts. These results force us to speculate that intra-tumoral adipocytes does cause inflammation and evoke metastatic pathways as previously reported in in vitro studies, but also associate with immune response, whereas adipocyte low tumors are highly proliferative cancers, thus, there are no difference in clinical outcome between them.

**Conclusion:** High infiltration of adipocyte was associated with inflammation, metastatic pathways and favorable tumor immune microenvironment, whereas low infiltration of adipocytes was associated with highly proliferative tumor in ER-positive breast cancer. These cancer biologies may explain the reason why adipocyte infiltration high tumors did not demonstrate worse survival.

Outcomes after sentinel lymph node biopsy and radiation therapy in women over 70 years old with ER+, HER2-, clinically node negative breast cancer

Priscilla F McAuliffe, Neil M Carleton, Jian Zou, Yusi Fang, Stephen E Koscumb, Osama Shah, Fangyuan Chen, Sushil Beriwal, Emilia J Diego, Adam M Brufsky, Steffi Oesterreich, Steve D Shapiro, Robert Ferris, Leisha A Emens, George Tseng, Oscar C Marroquin and Adrian V Lee. University of Pittsburgh Medical Center, Pittsburgh, PA

Overtreatment of early-stage breast cancer with favorable tumor biology in elderly patients can result in higher rates of complications and morbidities without impacting survival. Guidelines directed towards deimplementation of sentinel lymph node biopsy (SLNB) (Choosing Wisely) and radiation therapy (RT) (National Comprehensive Cancer Network) have been recommended. We sought to describe rates and impact on disease recurrence and survival of SLNB and RT in elderly patients with early breast cancer. Patient data were obtained from the cancer registry and electronic health record from University of Pittsburgh Medical Center, multicenter, single health care system. Consecutive female patients aged  $\geq 70$  with ER+, HER2- clinically node-negative breast cancer within a health care system from 2010 to 2018 were identified. Rates and patient characteristics associated with receipt of SLNB and RT, as well as local recurrence free survival (LRFS) and disease-free survival (DFS) were compared for patients that were diagnosed between 2010 and 2014 to allow for adequate follow up time. Cox proportional hazards regression was used to estimate hazard ratios (HRs) of mortality. Among 3,361 identified women, 2,195 (65.3%) received SLNB and 1,828 (54.4%) received RT. Rates of SLNB steadily increased (1.0% per year); this trend persisted in 2017 and 2018, even after the Society of Surgical Oncology adopted the Choosing Wisely Guidelines in 2016. During the same time period, rates of RT declined (3.4% per year). To examine outcomes, we limited the analysis to 2109 cases from 2010-2014; median (IQR) follow up time was 4.1 (2.5-5.7) years. Median (IQR) age was 77 (73-82) years. 1373 (65.1%) received SLNB and 1,219 (57.8%) received RT. Patients receiving SLNB were younger ( $P < 0.001$ ) with smaller ( $P < 0.0001$ ) and lower stage ( $P < 0.0001$ ) tumors. They had fewer comorbidities ( $P < 0.001$ ), longer follow-up times ( $P < 0.001$ ), were less likely on Medicaid/Medicare ( $P = 0.0091$ ), and were more often seen at an academic center ( $P < 0.0001$ ). There was no difference in grade between those that did and did not receive SLNB ( $P = 0.31$ ) and those that did and did not receive RT ( $P = 0.13$ ). Multivariate cox proportional hazard analysis showed no effect of SLNB on LRFS (HR = 1.17, 95% CI 0.29-4.75,  $P = 0.83$ ) or DFS (HR = 0.90, 95% CI 0.44-1.83,  $P = 0.77$ ). Log rank test showed no difference in 5-year LRFS ( $P = 0.78$ ) between patients who received (98.5%, 95% CI 97.7%-99.7%) and did not receive (98.1%, 95% CI 96.7%-99.5%) SLNB, but an increase was seen with 5-year DFS ( $P = 0.023$ ), with 96.2% (95% CI 95.0%-97.4%) of patients disease-free among those who did receive SLNB vs. 93.0% (95% CI 90.6%-95.4%) with no SLNB. Multivariate cox proportional hazard analysis showed that RT was associated with improved LRFS (HR = 0.13, 95% CI 0.03-0.51,  $P < 0.01$ ) and DFS (HR = 0.32, 95% CI 0.15-0.68,  $P < 0.01$ ). Log rank test showed a difference in 5-year LRFS ( $P < 0.0001$ ) for those who received RT (99.4%, 95% CI 98.8%-100%) against those who did not (96.5%, 95% CI 95.0%-98.1%), and a similar difference in 5-year DFS ( $P < 0.0001$ ) in patients who did (97.0%, 95% CI 95.8%-98.1%) and did not (92.4%, 95% CI 90.2%-94.7%) receive RT. Lower age (OR = 0.89, 95% CI 0.87-0.92) and comorbidities (OR = 0.79, 95% CI 0.66-0.94) were associated with receipt of SLNB, while only age (OR = 0.91, 95% CI 0.88-0.94) was associated with receipt of RT. We conclude that receipt of SLNB has no impact upon DFS or LRFS. This data supports deimplementation of SLNB for this patient population. Receipt of RT is important for controlling locoregional recurrence, supporting use of RT in this patient cohort.

**Introduction:** U3-1402 is a novel, investigational ADC directed against HER3, which is widely expressed in breast cancer. Safety and preliminary antitumor activity of U3-1402 was previously reported in this ongoing, phase 1/2 clinical trial (NCT02980341/JapicCTI-163401). Here we report updated safety data from the dose escalation/dose finding (DE/DF) and phase 2 dose expansion parts, and we present for the first time efficacy data for patients in the expansion part with HR+/HER2- MBC with high or low levels of HER3 expression. **Methods:** In DE/DF, U3-1402 was administered intravenously (IV) Q2W or Q3W at doses ranging from 1.6 to 8.0 mg/kg. Patients had HER3-expressing advanced/unresectable disease refractory/intolerant to standard treatment or for which no standard treatment was available. In the expansion part, U3-1402 was administered IV Q3W to patients with HER3-high (4.8 or 6.4 mg/kg) or HER3-low (6.4 mg/kg) HR+/HER2- MBC or with HER3-high triple-negative breast cancer (TNBC; 6.4 mg/kg). Primary objectives included safety and efficacy of U3-1402; secondary objectives included correlative biomarker and pharmacokinetics analyses. Archival or pretreatment tissue obtained in the 6 months prior to U3-1402 treatment was analyzed by IHC for HER3 expression. **Results:** As of March 2020, all 4 expansion cohorts had completed enrollment. In the DE/DF and expansion parts combined, 172 patients received ≥1 dose of U3-1402 (114 [66%] had HR+/HER2- MBC). Median age was 56 y (range, 30-83 y); 123 (72%) and 49 (28%) patients had an ECOG PS of 0 or 1, respectively. Patients received a median of 6 (range, 1-14) prior systemic therapies. Median treatment duration of U3-1402 was 5 mo (range, 1-30 mo). 101 patients (59%) discontinued because of progressive disease, and 15 (9%) discontinued because of an AE. The most common grade ≥3 treatment-emergent AEs reported were decreased neutrophil count (43 patients [25%]), decreased platelet count (39 patients [23%]), decreased white blood cell count (28 patients [16%]), and anemia (31 patients [18%]). Nine patients (5%) experienced treatment-related interstitial lung disease according to central adjudication, including one grade 5 event. At data cutoff, 85 patients in the HR+/HER2- expansion part were evaluable for efficacy by blinded independent central review. Among 33 patients with HR+/HER2- HER3-high MBC treated with 4.8 mg/kg, 10 (30%) had a response (all partial responses [PRs]), with a clinical benefit rate (CBR; complete response + PR + stable disease for ≥6 mo) of 45% (15/33). Among 31 patients with HER3-high MBC treated with 6.4 mg/kg, 3 (10%) had a response (all PR) with a CBR of 16% (5/31). Among 21 patients with HER3-low MBC treated with 6.4 mg/kg, 6 (29%) had a response (all PRs) with a CBR of 33% (7/21). TNBC data are immature at the time of abstract data cutoff; efficacy by HR status will be provided in the presentation. Membrane HER3 expression levels were dynamic; they varied between archival and pretreatment biopsies and decreased on treatment with U3-1402. Across the doses evaluated, the U3-1402 AUC and C<sub>max</sub> of the total antibody, intact ADC, and released payload were approximately dose proportional, with minimal accumulation after multiple doses; the released payload C<sub>max</sub> was highest in cycle 1 and decreased in later cycles. **Conclusions:** In this heavily pretreated MBC population, U3-1402 demonstrated clinically meaningful antitumor activity in HR+/HER2- MBC with high or low levels of HER3 expression. The safety profile of U3-1402 was consistent with that previously reported, with 9% of patients discontinuing because of AEs. Clinical data pertaining to patients with TNBC and correlative analyses (including association of HER3 expression with response) will be presented.

Alternative splicing events from progesterone exposure differ based on BRCA1 mutation status

Gannon Cottone<sup>1</sup>, Batzaya Davaadelger<sup>2</sup>, Shivangi Yadav<sup>1</sup>, J Julie Kim<sup>2</sup>, Seema A. Khan<sup>1</sup> and Susan Clare<sup>1</sup>. <sup>1</sup>Department of Surgery, Lurie Cancer Center, Northwestern University, Feinberg School of Medicine, Chicago, IL; <sup>2</sup>Department of Obstetrics and Gynecology, Lurie Cancer Center, Northwestern University, Feinberg School of Medicine, Chicago, IL

**Background:** Progesterone (P) and progestin are instrumental in the breast cancer risk associated with reproductive hormones. Progesterone receptor (PR) signaling has been shown to be inhibited by the wild-type BRCA1 protein and it is hypothesized that if this inhibition is lost, due to gene mutation, potentially tumorigenic consequences may result. Our efforts are focused on understanding the role PR and P play in *BRCA1* mutation carriers. The purpose of this study was to determine if the presence of a *BRCA1* mutation effects alternative splicing (AS) events.

**Methods:** Mammary organoids from 12 patients, six with a *BRCA1* mutation and six without (WT, control), were cultured *in vitro*. The organoids from each patient were divided into two groups and treated over the course of 28 days to mimic a normal menstrual cycle. One group was treated with estradiol and progesterone (EP) while the other was treated with EP and the PR antagonist telapristone acetate (TPA) to identify PR-mediated effects. After treatment, RNA was extracted from both groups and RNA-sequencing performed. A statistical model, "replicate Multivariate Analysis of Transcript Splicing" (rMATS) was employed to identify AS events. Output from rMATS was then entered into "RNA Map Analysis And Plotting Server" (rMAPS) to identify RNA-binding proteins (RBP) motifs in the region of the splices. Droplet digital PCR (ddPCR) from Bio-Rad was employed, with the use of Evagreen intercalating dye, to validate a subset of the AS events identified by the RNA-Seq data. RNA from eight of the EP treated samples was reverse transcribed and ddPCR performed. The data was analyzed using QuantaSoft Analysis Pro (Bio-Rad). The identified AS events were validated additionally using data generated from solid tissue normals (STN) from premenopausal, *BRCA1*<sup>mut</sup> and *BRCA1*<sup>WT</sup> patients, who developed breast cancer, which was available for download from The Cancer Genome Atlas (TCGA).

**Results:** Genes involved in the epithelial-mesenchymal-transition (EMT), progesterone metabolism, and cellular proliferation are significantly differentially spliced in the EP treated *BRCA1*<sup>mut</sup> tissue (p-value < 0.01 and FDR < 5%) and absent in those with TPA treatment, suggesting the AS is a PR-mediated effect. *CD44*, associated with cellular proliferation and migration, *NCOR2* associated with tamoxifen resistance, and *AKR1C2* associated with progesterone metabolism all showed significant skipped exon (SE) events. Exon 11 in *CD44* and exon 45 in *NCOR2* were skipped in both the *BRCA1* organoids as well as in *BRCA1* STN from TCGA. Skipping of Exon 4 in *AKR1C2* was validated using the ddPCR: the *BRCA1*<sup>mut</sup> organoids displayed two isoforms, indicative of a skipped exon.

**Conclusions:** PR-mediated alternative splicing events differ in mammary organoids of *BRCA1* carriers compared to non-carriers. We hypothesize that the skipping of Exon 4 of *AKR1C2* in *BRCA1*<sup>mut</sup> results in a structural alteration that decreases protein activity, leading to increased concentrations of P4 and 5 $\alpha$ -pregnane-3,20-dione. This may explain the previously reported high median luteal phase serum P levels (p=0.00034) in *BRCA1*<sup>mut</sup>/*BRCA2*<sup>mut</sup> (PMID: 24140203).

Vadis trial: Phase II trial of nelipecimut-s peptide vaccine in women with DCIS of the breast

Anne E O'Shea<sup>1</sup>, Guy T Clifton<sup>1</sup>, Na Qiao<sup>2</sup>, Brandy Heckman-Stoddard<sup>3</sup>, Malgorzata Wojtowicz<sup>3</sup>, Eileen Dimond<sup>3</sup>, Isabelle Bedrosian<sup>2</sup>, Diane Weber<sup>2</sup>, Alex Husband<sup>4</sup>, Ricardo Pastorello<sup>4</sup>, Lana Vornik<sup>2</sup>, George Peoples<sup>5</sup> and Elizabeth A Mittendorf<sup>4</sup>. <sup>1</sup>Brooke Army Medical Center, Ft. Sam Houston, TX; <sup>2</sup>The University of Texas MD Anderson Cancer Center, Houston, TX; <sup>3</sup>National Cancer Institute, Bethesda, MD; <sup>4</sup>Dana-Farber Cancer Institute, Boston, MA; <sup>5</sup>Cancer Vaccine Development Program, San Antonio, TX

**Background:** Peptide cancer vaccines may be most effective when used in earlier stage cancers or pre-cancers where systemic and tumor microenvironmental immune suppression are less profound. Nelipecimut-S (NPS) plus granulocyte-macrophage colony-stimulating factor (GM-CSF) is a vaccine comprised of a human leukocyte antigen (HLA) restricted peptide from the extracellular domain of the HER2 protein (E75) combined with GM-CSF. We have completed a randomized phase II trial of preoperative vaccination with NPS+GM-CSF vs. GM-CSF alone with the primary outcome being NPS-specific cytotoxic T lymphocyte (CTL) responses.

**Methods:** HLA-A2 positive, DCIS patients were enrolled and randomized to either NPS+GM-CSF vs GM-CSF alone. The patients received two vaccinations prior to surgery at 2-week intervals. The number of NPS-specific CTL was measured at specified intervals (pre-vaccination, time of surgery, 1 month (+/- 7 days) post-op, and 3 months (+/- 7 days) post-op) using a flow cytometry-based dextramer assay. Differences in NPS-specific CTL responses between the two groups and between baseline pre-vaccination and 1-month post-op were analyzed using either a two-sample t-test or Wilcoxon rank sum test, when appropriate. The incidence and severity of adverse events, graded according to Common Terminology Criteria for Adverse Events (CTCAE) version (v) 4.03, were recorded and compared between treatment groups.

**Results:** 45 patients were registered; 7 withdrew consent, 1 opted for surgery at an external facility, 20 were ineligible due to negative HLA-A2, and 4 failed screening for other reasons, leaving 13 patients enrolled. The 13 patients were randomized (2:1) into treatment groups, with nine patients receiving NPS+GM-CSF and four patients receiving GM-CSF alone. The two groups were well-matched for age; however, the GM-CSF alone group had higher percentages of African American (50% vs. 22%) and Hispanic (25% vs. 11%) patients as compared to the NPS+GM-CSF group. In general, vaccination was well-tolerated with similar treatment-related toxicity profiles in the NPS+GM-CSF vs GM-CSF groups (Grade 1 - 93.3% vs. 89.3%, Grade 2 - 6.7% vs. 10.7%, respectively). The mean NPS-specific CTL% in the NPS+GM-CSF group at 1-month post-op was double that of the GM-CSF alone group (0.10 +/- 0.12% vs. 0.05 +/- 0.08, p=0.70). In addition, between baseline pre-vaccination and 1-month post-op, the NPS+GM-CSF group experienced an 11-fold increase in percentage of NPS-specific CTL (0.01 +/- 0.02% vs. 0.11 +/- 0.12%) as compared to only a 2.25-fold increase of NPS-specific CTL in the GM-CSF alone group (0.04 +/- 0.07% vs. 0.09 +/- 0.15%).

**Conclusions:** NPS+GM-CSF is safe and well-tolerated when given preoperatively to patients with DCIS. In HLA-A2 positive patients with DCIS, a single inoculation with NPS+GM-CSF can induce in vivo immunity and a continued antigen-specific T-cell response one month post-surgery. This data provides support for further testing of NPS+GM-CSF in the neoadjuvant and adjuvant settings in an attempt to prevent invasive recurrence in DCIS.

**Introduction.** Due to advances in imaging technology and an increase in mammographic screening, there has been a significant increase in the diagnosis rate of ductal carcinoma *in situ* (DCIS). At the present time, nearly all women undergo surgical removal of DCIS, often followed by adjuvant radiation and in some cases anti-hormonal therapy. Currently, there are no means by which to diagnose DCIS accurately, or to predict which patients benefit from aggressive therapy. Thus, the recommendation for surgery persists, despite studies which support that not all DCIS will subsequently progress to invasive disease. In this context, animal models can be particularly useful in studying DCIS progression. Here, we present the first *in vivo* model of DCIS, referred to as Mouse-INtraDuctal (MIND), in which patient-derived DCIS epithelial cells are injected intraductally and allowed to progress naturally in mice. **Methods.** We performed intraductal injection of DCIS epithelial cells derived from 30 patient samples into 194 total glands. Of the 194, 146 xenografts showed *in vivo* growth, for a 75% take rate). Among the DCIS samples injected into mice, 18 (103 mouse mammary glands) were followed for a median of 9 months. Among those, 50% (9) showed invasive progression while 50% (9) remained non-invasive. DCIS invasive progression was evaluated by performing immunofluorescence staining using anti-smooth muscle actin (SMA) antibody and confirmed by the loss of SMA around the xenografted DCIS like lesions on 3 consecutive sections of FFPE tissues. **Results.** Progressed xenografts exhibited invasive progression, evident by the loss of SMA, as early as 6 months following transplantation. Similar to human DCIS, the cancer cells initially formed *in situ* lesions inside the mouse mammary ducts and mimicked all histologic subtypes including micropapillary, papillary, cribriform, solid and comedo. Among the biomarkers tested, including ER, PR, Ki67, HER2, p53, histology, nuclear and tumor grade, only low ER & PR expression and extent of DCIS growth in xenografts significantly correlated with invasive progression. A high depth targeted sequencing platform (T200) on DNA isolated from LCM captured DCIS of patient and xenograft pairs identified shared (i.e., EGFR) as well as unique (STK11, RUNX1, PIK3CA) mutations in patient/xenograft pairs. Notably, we also observed private mutations that were not shared within the same patient/xenograft pairs. These results indicate the presence of DCIS clonal heterogeneity and that DCIS xenografts may represent one or more clonal subpopulations of patient DCIS. **Conclusion.** The MIND model represents the first realistic *in vivo* model that recapitulates human DCIS progression in a manner that represents the inter- and intra-tumoral heterogeneity of human disease. These innovative mouse models will be invaluable for the discovery of molecular signatures of invasive DCIS by allowing comparison of xenografts with variable propensity for invasive progression. These models will enable the discovery of extrinsic factors that regulate DCIS malignancy as well as testing of pharmaceutical and natural compounds for prevention of DCIS progression to invasive disease.

An AI-digital breast cancer risk discrimination platform (PreciseDx) using a representative H&E image and selected clinical variables accurately categorized patients with oncotype Dx low risk recurrence scores (RS)

Michael Joseph Donovan, Nina Shpalensky, Marcel Prastawa, SM Abishek, Richard Scott, Mary Sawyer, Jack Zeineh and Gerardo Fernandez. Icahn School of Medicine at Mt. Sinai, New York City, NY

**Background:** Clinical practice guidelines emphasize the critical importance of grading and stage in breast cancer treatment. Although histologic grade is subjective, non-quantitative, skill-dependent, and oftentimes inaccurate it remains an independent prognostic feature and therefore plays a direct role in patient management including neoadjuvant therapy vs surgery, and interpretation of genomic studies. We developed an AI-based platform which combines digital H&E features with select clinical variables to assess risk of breast cancer recurrence and evaluated ability to predict Oncotype low risk RS categorization. **Methods:** Retrospective study to identify a subset of Mt. Sinai, NY invasive ductal breast cancer (IDC) patients from 2010-2016 with H&E stained slides, clinical features and OncotypeDx recurrence scores (RS). Recurrence endpoint(s): local- regional, distant-recurrence free and overall survival. Digital images generated with Philips scanning system; reviewed by two pathologist for tumor content and quality prior to image analysis and feature extraction. Support vector machine learning models were used for initial feature performance and final models generated. Positive predictive value (PPV), sensitivity (S) and likelihood ratios (LR) were used for performance. **Results:** 391 patients: mean age 57 years, 100% Stage I/II, 59% Grade 2, and 6% LN+ve 0-3; 97% IDC, 100% ER+ve, 94% PR+ve, 0% Her2 amplified; median follow-up 61 months; 323 (83%) low risk ( $\leq 25$ ) RS and 68 (17%) high risk RS ( $> 25$ ). There were 23 events (6%) and 13 (56%) were locoregional recurrence. PreciseDx model with age, and PR levels combined with imaging features reflective of mitotic activity and nuclear characteristics (clinical grade not selected) correctly identified LR RS categorization: PPV of 91%, [95CI 0.87-0.94], Se 92% [0.86-0.95] and positive / negative likelihood ratio : 6.8, and 0.5, respectively. **Conclusions:** Application of an AI-digital breast cancer risk assessment platform using only the H&E image and limited clinical data successfully classified low risk RS patients with high accuracy. Future models will extend outcome to 10 years and evaluate treatment selection and duration

Herpet study- PET imaging of HER2 expression in breast cancer using the novel Affibody tracer [18F]GE-226, a first in patient study

Laura M. Kenny<sup>1</sup>, Gosala S. Gopalakrishnan<sup>1</sup>, Tara D. Barwick<sup>2</sup>, Vijay Vaja<sup>1</sup>, S. Hope McDevitt<sup>1</sup>, Robert Punjani<sup>1</sup>, Neva H. Patel<sup>2</sup>, Rathi Ramakrishnan<sup>2</sup>, Naina R. Patel<sup>1</sup>, Stephen Johnston<sup>3</sup>, Janine Mansi<sup>4</sup>, Gary J. Cook<sup>5</sup>, Fiona J. Gilbert<sup>6</sup>, Franklin I. Aigbirhio<sup>6</sup>, Duncan Hiscock<sup>7</sup> and Eric O. Aboagye<sup>1</sup>. <sup>1</sup>Imperial College London, London, United Kingdom<sup>2</sup>Imperial College Healthcare NHS Trust, London, United Kingdom<sup>3</sup>Royal Marsden NHS Foundation Trust, London, United Kingdom<sup>4</sup>Guys and St Thomas' Hospital NHS Foundation Trust, London, United Kingdom<sup>5</sup>Kings College London, London, United Kingdom<sup>6</sup>University of Cambridge, Cambridge, United Kingdom<sup>7</sup>GE Healthcare, Buckinghamshire, United Kingdom

**Background** 20% of breast cancers have over-expression of the human epidermal growth factor receptor-2 (HER2), which is an adverse prognostic factor and used to guide therapy selection. At present HER2 expression can only be determined using biopsy material which is then analysed using immunohistochemistry or fluorescence in situ hybridisation. GE-226 is a radiolabelled Affibody® tracer which binds to the HER2 receptor with high affinity at a different epitope than trastuzumab. Heterogeneous expression does exist but the impact this has on treatment response has not been well assessed. A non-invasive method for determining HER2 expression could have several advantages and help select appropriate therapy for patients.

**Trial Design** Patients with locally advanced or metastatic breast cancer were recruited and scanned for 65 mins after iv injection of 200MBq (mean activity injected for each patient 198 MBq (range 164-219MBq), mean radiochemical purity 94.6%) of tracer, with one dynamic bed position, and then a half-body scan was performed. Blood sampling was used to measure metabolism of the tracer. Safety was recorded. HER2-extracellular domain (ECD) domain was measured in blood. The original accrual target was 16 patients. Tumoural uptake was quantified by semi-quantitative and fully quantitative parameters in HER2 positive and HER2 negative tumours.

**Results** Thirteen patients were recruited. Scans were well tolerated. There were no serious adverse events. GE-226 was metabolised into a single metabolite in the liver. 96.8 % parent remained at 60 minutes post injection. There was a significant difference between HER2 positive and HER2 negative tumoural uptake of tracer as measured by  $SUV_{mean}$  and  $SUV_{max}$  ( $p < 0.05$ ). Comparing HER2 positive to HER2 negative cases, there was also a significant difference between tumour to normal tissue uptake ratios ( $p < 0.05$ ). Heterogeneous uptake was observed in the same patient. Tumoural uptake increased over time. Uptake in salivary glands and the thyroid gland was noted. In one patient GE-226 was able to differentiate between lymphadenopathy due to sarcoidosis and cancer and was superior to FDG which had shown widespread uptake in the same patient.

**Conclusions** [18F]GE-226 imaging is well tolerated and shows promise for imaging of HER2 positive breast cancer. Further studies with this agent are now planned.

Patient-reported outcomes of adolescents and young adults with breast cancer treated with curative intent

Revathy Krishnamurthy, Tulin Cil, Philippe Bedard, Robin Forbes, Madeline Li, Zhihui (Amy) Liu and Jennifer Croke. Princess Margaret Cancer Centre, Toronto, ON, Canada

**Purpose:** To evaluate patient-reported outcomes of adolescents and young adults (AYAs) with breast cancer treated with curative intent.

**Methods:** AYA breast cancer patients (defined as diagnosed between 18 to 39 years of age) treated at a large tertiary cancer centre between January 2014 and December 2016 were identified. Patients routinely complete the validated symptom screening tool, the Edmonton Symptom Assessment System-revised (ESAS-r) prior to their clinical encounter. Scores from diagnosis up to 24 months post-diagnosis were obtained from our internal database, with elevated scores defined as  $\geq 4$  for each individual symptom (rated 0-10). Patient, clinical and treatment characteristics were extracted from medical records. Descriptive statistics were used to describe patient, clinical and treatment characteristics, and ESAS-r scores. Time to recurrence was calculated from diagnosis to local or regional recurrence, distant metastasis or death (whichever occurred first). Kaplan-Meier survival analysis and log-rank tests were used to compare time to recurrence between women with vs. without elevated symptom scores. Chi-squared test was used to test the change in number of patients with elevated symptom scores over time. Univariable and multivariable logistic regression models were carried out to assess association between various factors and ESAS-r symptoms of depression, anxiety and well-being within 24 months of diagnosis.

**Results:** Among 258 patients identified, 211 (82%) had accompanying ESAS-r and were eligible for analysis. Median follow-up was 3.9 years. Median age at diagnosis was 35 (20-39), most were clinical stage 2/3 at diagnosis (63%), 20% had triple negative disease, 76% received chemotherapy and 81% received radiotherapy. Overall, symptom burden was the highest (scores  $\geq 4$ ) for decreased well-being (52%), tiredness (48%) and anxiety (44%). Although symptom burden significantly improved over time, 43%, 38% and 33% of patients, respectively, reported elevated symptoms 24 months post-diagnosis. Multivariable analysis found that elevated anxiety was significantly associated with younger age at diagnosis ( $p=0.036$ ), receipt of chemotherapy ( $p=0.01$ ) and presence of long-term toxicity ( $p=0.0032$ ). Elevated depression, anxiety and well-being were significantly associated with referral to Psychosocial Oncology ( $p=0.024$ ,  $p=0.036$  and  $p=0.019$ , respectively), whereas well-being was also associated with referral to Survivorship Clinic ( $p=0.043$ ). However, overall rates of referral (24-36%) were much lower than symptom prevalence. There was no association between elevated symptoms and time to recurrence.

**Conclusion:** AYAs diagnosed with breast cancer report high symptom burden that continues to persist up to 24-months post-diagnosis. Patients with elevated psychosocial distress are more likely to be referred to Psychosocial Oncology and Survivorship clinics, indicating that the ESAS-r is a useful screening tool in a real-world setting. However, a gap between symptom burden and intervention exists, providing opportunities for future research.

High tumor mutational burden ( $\geq 10$  mut/Mb) is enriched in specific breast cancer pathological subtypes

Mason A Israel, Marni Tierno, Richard SP Huang, Kimberly McGregor, Ethan S Sokol, Prasanth Reddy and Jeffrey S Ross. Foundation Medicine Inc., Cambridge, MA

**Background:** Pembrolizumab recently received pan-tumor FDA approval for the treatment of patients with unresectable or metastatic solid tumors with tumor mutational burden (TMB)  $\geq 10$  mutations per megabase (mut/Mb) and who have no satisfactory alternative treatment options. The KEYNOTE-119 and TAPUR trials have validated TMB as a predictive biomarker using TMB cutoffs of  $\geq 10$  mut/Mb and 9 mut/Mb, respectively, for benefit from single-agent pembrolizumab in subsets of patients with clinically advanced breast cancer (aBC). Limited data exist on which pathological subtypes of aBC are most likely to be TMB  $\geq 10$  mut/Mb (TMB-High). This study analyzed the frequency of TMB-High tumors in aBC subtypes to evaluate variations between subtypes and correlation with additional immunotherapy biomarkers. **Methods:** Utilizing the Foundation Medicine breast cancer database, 5,475 samples with aBC and pathological subtype information were identified. Pathological subtypes included in this study were ER+/HER2-negative invasive ductal carcinoma (IDC), ER-negative/HER2+ IDC (HER2+), triple negative IDC (TNBC), invasive lobular, inflammatory, metaplastic, mucinous and papillary. TMB was determined on 0.8-1.1 Mb of sequenced DNA, and microsatellite instability (MSI) was assessed across 114 loci in 564 cases. PD-L1 was determined in a subset of cases by immunohistochemistry (Ventana SP142). **Results:** TMB-High ( $\geq 10$  mut/Mb) was common in all breast cancer pathological subtypes except papillary carcinoma (Table 1). TMB-High was most often found in lobular, inflammatory and HER2+ carcinomas (16%, 14% and 12% of cases, respectively). Metaplastic, mucinous and papillary subtypes were least likely to be TMB-High (7%, 7% and 0% of cases, respectively). TMB-High was more common than MSI-High in all subtypes, excluding papillary. Emerging biomarkers that may play a role in mitigating immunotherapy response, such as *MDM2* amplifications and *STK11* alterations, were observed in most subtypes. The frequencies of these alterations, as well as alterations associated with FDA-approved therapies in breast cancer, are provided in Table 1 and will be further discussed. **Conclusions:** TMB-High ( $\geq 10$  mut/Mb) is common in most pathological subtypes of clinically advanced breast cancer and can identify patients not identified by MSI or PD-L1 testing who may benefit from immunotherapy. Based on the high percentage of advanced breast cancer patients who are TMB-High or have genomic alterations in other biomarkers associated with FDA-approved targeted therapies, comprehensive genomic profiling including TMB and MSI should be considered for all pathological subtypes.

Table 1

Pathological subtype	Invasive ductal carcinoma (IDC)							
	ER+, HER2-negative	ER-negative, HER2+	Triple-negative (TNBC)	Invasive Lobular Carcinoma	Inflammatory	Metaplastic	Mucinous	Papillary

Novel chimeric small molecule AC682 potentially degrades estrogen receptor with oral anti-tumor efficacy superior to fulvestrant

Wei He, Hui Zhang, Lorena Perkins, Lissette Bouza, Ke Liu, Yimin Qian and Jie Fan. Accutar Biotechnology Inc., Brooklyn, NY

Modulation of estrogen activity and/or synthesis has been the mainstay therapeutic strategy for estrogen receptor (ER)-positive breast cancer. Fulvestrant, which provides superior clinical benefit over aromatase inhibitors and selective ER modulators, achieves its potent ER signaling inhibition through unique ER degradation activity beyond direct antagonism. Despite this superiority, the efficacy of fulvestrant appears limited by poor drug exposure through intramuscular injection. Up to 50% of ER baseline levels remained after 6 months of fulvestrant treatment. Therefore, an oral ER degrader with optimal pharmacokinetic profile may lead to better convenience and efficacy than fulvestrant. Here we report preclinical characterization of our novel oral ER degrader development candidate, AC682, a chimeric small molecule containing both ligands of ER and E3 ligase discovered with our ACCU-Degron technology. Through engaging E3 ligase and ER simultaneously, AC682 induced potent ER degradation with a sub-nanomolar half-maximal degradation concentration (DC<sub>50</sub>) in multiple ER-positive breast cancer cell lines tested, including a tamoxifen-resistant long-term estrogen deprived (LTED) cell line and cell lines expressing clinically-relevant ESR1 variants (Y537S and D538G). Proteasome-dependent ER degradation by AC682 peaked after a few hours of treatment, resulting in diminished expression of ER-regulated genes and subsequent cell growth inhibition. In the *in vivo* setting, oral dosing of AC682 achieved substantial drug exposure and oral bioavailability, with well tolerance in multiple animal species. In estradiol-dependent MCF7 xenograft tumors, oral daily dosing of AC682 led to dose-dependent tumor growth inhibition/regression and concomitant tumor ER protein reduction more than 90% at study termination. In particular, 3 mg/kg oral daily dosing achieved tumor stasis. When administrated in combination with CDK4/6 inhibitor Palbociclib, AC682 showed clear synergy in both the estradiol-dependent MCF7 model and a tamoxifen-resistant MCF7 model. In a patient-derived xenograft model, which bears ESR1 Y537S mutation and is hormone-independent, AC682 significantly inhibited tumor growth whereas fulvestrant only showed weak efficacy. In conclusion, oral chimeric ER degrader AC682 demonstrated robust ER degradation and anti-tumor efficacy in preclinical models, supporting its continued investigation in the clinic.

Targeting depressive symptoms in younger breast cancer survivors: A randomized controlled trial of mindfulness meditation and survivorship education

Patty Ganz<sup>1</sup>, Julianne E Bower<sup>2</sup>, Ann H Partridge<sup>3</sup>, Antonio C Wolff<sup>4</sup>, Elissa D Thorner<sup>4</sup>, Hadine Joffe<sup>5</sup>, Michael R Irwin<sup>2</sup>, Laura Petersen<sup>2</sup>, Laura Petersen<sup>2</sup> and Catherine M Crespi<sup>2</sup>. <sup>1</sup>Department of Health Policy & Management, UCLA Fielding School of Public Health, Los Angeles, CA; <sup>2</sup>UCLA Jonsson Comprehensive Cancer Center, Los Angeles, CA; <sup>3</sup>Medical Oncology, Dana-Farber Cancer Institute, Boston, MA; <sup>4</sup>The Johns Hopkins University School of Medicine and Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD; <sup>5</sup>Connors Center for Women's Health and Gender Biology, Brigham and Women's Hospital, and Harvard Medical School, Boston, MA

**Purpose** Breast cancer before age 50 comprises 25% of incident breast cancer cases in women. Younger breast cancer survivors (YBCS) are at increased risk for the negative effects of cancer diagnosis and treatment, including elevated levels of depression and related symptoms (i.e., anxiety, stress, fatigue, sleep disturbance, vasomotor symptoms), leading to significantly diminished quality of life. **Patients and Methods** This Phase III, randomized, multi-institution trial was designed to examine the efficacy of two brief interventions- mindfulness meditation and survivorship education - for YBCS (ClinicalTrials.gov NCT03025139). We recruited women diagnosed at age 50 or younger with early-stage breast cancer who had completed cancer treatment between 6 months and 5 years earlier and endorsed at least mild depressive symptoms. Participants were randomly assigned to Mindful Awareness Practices (MAPs), Survivorship Education (SE), or wait-list control (WL). Both intervention programs were tailored for YBCS and included 6 weeks of structured content delivered in a group format. Assessments were conducted at baseline, post-intervention, and at 3- and 6-month post-intervention follow-ups. The primary outcome was depressive symptoms (Center for Epidemiologic Studies Depression scale; CESD) at post-intervention; secondary outcomes included anxiety (Generalized Anxiety Disorder-7), fatigue severity (Fatigue Symptom Inventory), sleep disturbance (Insomnia Severity Index), and hot flashes (BCPT symptom checklist). **Results** We enrolled and randomized 247 women (85 MAPs, 81 SE, 81 WL). On average, participants were 45.4 years old at study entry and had been diagnosed 2.6 years earlier. Linear mixed models were conducted to compare each intervention group to WL on primary and secondary outcomes, controlling for baseline differences across groups in study site, race, and marital status. MAPs led to significant reductions in depressive symptoms at post-intervention and at 3- and 6-month follow-up relative to WL ( $P$ s < .01); see Table 1. SE also led to significant reductions in the CESD at post-intervention and 3-month follow-up ( $P$ s < .01). Both MAPs and SE produced reductions in anxiety at post-intervention relative to WL ( $P$ s < .05), though effects did not persist over follow-up. MAPs also had beneficial effects on other secondary outcomes, yielding significant decreases in fatigue severity, sleep disturbance, and hot flashes that persisted over the 6-month follow-up ( $P$ s < .05). In contrast, there was minimal evidence that SE impacted these outcomes. **Conclusion** Two brief behavioral intervention programs specially designed for YBCS were effective in reducing depressive symptoms and, in the case of mindfulness, improving related symptoms (fatigue, sleep disturbance) that pose serious threats to younger women's health and well-being after cancer. These interventions are standardized, manualized, and have the potential for wide dissemination over virtual platforms. **Table 1** Adjusted means and standard error (SE) for CESD depressive symptoms by group and time, controlling for study site, race, marital status. A CESD score of 16 or greater indicates moderately severe depressive symptoms. P-values are for differences between intervention and waitlist control groups in change over time between Baseline and Post-Intervention (1-2), Baseline to 3-month Follow-up (1-3), and Baseline to 6-month Follow-up (P 1-4).

	Baseline	Post-intv	P (1-2)	3 mo FU	P (1-3)	6 mo FU	P (1-4)
Group	CESD	CESD		CESD	P	CESD	
Mindful Awareness Practices (MAPs)	18.4 (1.0)	13.6 (1.1)	.001	13.4 (1.1)	<.001	12.9 (1.1)	.013
Survivorship Education (SE)	17.4 (1.1)	13.3 (1.1)	.007	13.6 (1.2)	.003	12.7 (1.2)	.063

**Background:** The development of central nervous system (CNS) metastases presents a considerable challenge in metastatic breast cancer (MBC) due to the limited availability of evidence-based treatments. Up to 50% of patients with HER2-positive (HER2+) MBC develop CNS metastases during the course of their disease. Neratinib, an irreversible pan-HER tyrosine kinase inhibitor, has demonstrated activity against CNS metastases in HER2+ MBC in two phase 2 studies (NEFERT-T, TBCRC 022) and one phase 3 study (NALA); significant benefits for predefined CNS endpoints were reported in NEFERT-T and confirmed in NALA. Here we present an exploratory analysis of patients from NALA with CNS involvement at enrollment.

**Methods:** NALA was an international, randomized, open-label, active-controlled, phase 3 study in patients with HER2+ MBC who had received ≥2 lines of HER2-directed therapy in the metastatic setting (ClinicalTrials.gov: NCT01808573). Patients with asymptomatic metastatic brain disease managed with stable doses of corticosteroids for ≥14 days prior to randomization were eligible, whereas patients with symptomatic or unstable brain metastases were excluded. Patients were randomized (1:1 ratio) to neratinib (N; 240 mg qd po) + capecitabine (C; 750 mg/m<sup>2</sup> bid po) or lapatinib (L; 1250 mg qd po) + C (1000 mg/m<sup>2</sup> bid po). Co-primary endpoints were centrally assessed progression-free survival (PFS) and overall survival (OS). Intervention for symptomatic metastatic CNS disease was a secondary endpoint. CNS disease at baseline was defined as patients with treated or untreated disease in the 'brain' assessed by investigator at enrollment. CNS imaging was not mandatory at screening.

**Results:** Of the 621 patients enrolled in NALA, 101 (16%) had documented baseline CNS disease and 520 (74%) had no CNS disease at baseline. Patients with CNS disease had a lower performance status and were more likely to have hormone receptor-negative disease than those with no CNS disease; no major imbalances of baseline characteristics were noted between treatment arms. Overall, 78 (77%) patients had previously received CNS radiation [whole brain, n=59 (58%); stereotactic, n=17 (17%); unknown, n=2 (2%)], and 5 (5%) patients had undergone CNS surgery. Median treatment duration was 5.7 (IQR 2.8-8.5) months for N, and 3.5 (IQR 2.1-6.9) months for L. PFS, OS, and cumulative incidence of interventions for symptomatic CNS disease are summarized in the table. No new safety signals were detected.

**Table.** Efficacy outcomes in patients with and without CNS disease at baseline

	Intention-to-treat (n=621)		CNS metastases at baseline - Yes (n=101)		CNS metastases at baseline - No (n=520)	
	N+C (n=307)	L+C (n=314)	N+C (n=51)	L+C (n=50)	N+C (n=256)	L+C (n=264)
PFS <sup>a</sup>						
Hazard ratio (95% CI)	0.76 (0.63-0.93)		0.66 (0.41-1.05)		0.76 (0.62-0.94)	
P-value	0.0059		0.0741		0.0099	
Restricted mean PFS <sup>b</sup> , months	8.8	6.6	7.8	5.5	9.0	6.9
Difference, months	2.2		2.3		2.1	
OS						
Hazard ratio (95% CI)	0.88 (0.72-1.07)		0.90 (0.59-1.38)		0.85 (0.68-1.06)	
P-value	0.2086		0.6352		0.1517	
Restricted mean OS <sup>b</sup> , months	24.0	22.2	16.4	15.4	25.6	23.6
Difference, months	1.7		1.0		2.0	
Incidence of CNS intervention						
Overall cumulative incidence <sup>c</sup> , %	22.76	29.19	40.13	47.79	19.16	24.65
P-value	0.043		0.430		0.067	
<sup>a</sup> Centrally confirmed; <sup>b</sup> Restriction prespecified as 24 months for PFS, and 48 months for OS; <sup>c</sup> % requiring intervention for CNS disease (competing risk model)						

**Conclusions:** Regardless of the status of CNS metastases at baseline, patients appeared to have better outcomes in the N+C arm compared with the L+C arm.

Telemedicine usability for cancer care during the COVID-19 pandemic

Andrea Leon, Rebecca Kaltman, Hannah Arem, Richard Amdur, Andrea Gesteira, Samuel Duffy, Christian Miller, Brooke Burgess and Christiane Morecock. GW Cancer Center, Washington, DC

**Background** Healthcare delivery via telemedicine has increased substantially amid COVID-19. The George Washington Cancer Center (GWCC) now provides cancer care services via tele-visits for patients at high risk of morbidity and mortality secondary to COVID-19. This study was performed to assess usability of virtual cancer care delivery for patients and providers across specialties.

**Methods** Participants included patients and providers surveyed to assess baseline usability after initiating tele-visits. Surveys included demographics, Telehealth Usability Questionnaire (TUQ), and questions on perceived safety and preferences around telemedicine. Subjects also provided open-ended feedback for quality improvement.

**Results** For patients (n=133), 93% of surveys sent were completed and analyzed. Most patients were between ages 60-69 (26%), 70-79 (24%), 50-59 (22%). Breast cancer (41%) was the most commonly reported cancer type. Mean patient TUQ scores based on a 5-point scale (1-strongly disagree, 5 - strongly agree) were: 4.4 for Interface Quality (IfQ), 4.3 for Ease of Use (EU), 4.2 for Usefulness (U) and Satisfaction (S), 4.1 for Interaction Quality (ItQ), 3.4 for Reliability (R). No association was found between mean TUQ scores and age groups ( $p=0.33$ ), sex ( $p=0.79$ ), timing of diagnosis in relation to telemedicine visit ( $p=0.67$ ), stage of diagnosis ( $p=0.98$ ), or treatment type ( $p=0.65$ ). However, patients with more telemedicine visits did score significantly higher in Reliability ( $P=0.018$ ) and Satisfaction ( $P=0.039$ ), compared to those with fewer telemedicine visits. Compared to in-person visits, 77% of patients agreed/strongly agreed that telemedicine made them feel safer, 75% agreed/strongly agreed that it reduced stress, and 72% expressed interest in using it with other medical specialties.

For providers (n=109), 84% of surveys sent were completed and analyzed. Most providers were between ages 30-39 (33%) or 40-49 (21%), and 41% had 50 or more experiences with telemedicine. The predominant specialty participating was Internal Medicine (27%). Mean provider TUQ scores were 4.3 for U, 4.1 for S, 3.8 for EU, 3.7 for ItQ, 3.6 for IfQ, and 2.7 for R. No association was found between mean TUQ scores and experience with telemedicine ( $p=0.31$ ), age groups ( $p=0.06$ ), or specialty ( $p=0.53$ ). However, providers with more experiences with telemedicine scored significantly higher in Satisfaction ( $p=0.01$ ) and Usefulness ( $p=0.02$ ).

The majority of providers (97%) agreed/strongly agreed that telemedicine improves access to care, yet 59% expressed concern about missing something they may have caught in person. Furthermore, older providers generally had lower reliability scores compared to younger providers ( $p=0.03$ ), and also showed generally greater concern about losing personal interface with patients with the use of telemedicine than younger providers ( $p=0.006$ ).

#### **Conclusion**

The utility of telemedicine in cancer care during the COVID-19 pandemic was perceived favorably by both patients and providers. All patient groups scored highly on perceived safety, reduced stress and improved access, independently of subject characteristics. Older providers were more wary of the reliability of telemedicine and its effects on patient-provider relationships. These findings provide a useful benchmark for advancement of virtual care delivery in cancer care, beyond the COVID-19 pandemic.

Tumour infiltrating lymphocytes of prognostic value in different molecular breast cancer subgroups and as a suggestive predictive factor for adjuvant tamoxifen benefit in premenopausal patients after 30 years follow-up

Christine Lundgren<sup>1</sup>, Par-Ola Bendahl<sup>2</sup>, Maria Ekholm<sup>1</sup>, Marten Ferno<sup>2</sup>, Carina Forsare<sup>2</sup>, Ute Kruger<sup>2</sup>, Bo Nordenskjöld<sup>3</sup>, Olle Stål<sup>3</sup> and Lisa Ryden<sup>4</sup>.

<sup>1</sup>Department of Oncology, Jonköping, Region Jonköping County, and Department of Biomedical and Clinical Sciences, Linköping University and Department of Clinical Sciences Lund, Division of Oncology, Lund University, Lund, Sweden<sup>2</sup>Department of Clinical Sciences Lund, Division of Oncology, Lund University, Lund, Sweden<sup>3</sup>Department of Biomedical and Clinical Sciences, Linköping University, Linköping, Sweden<sup>4</sup>Department of Clinical Sciences Lund, Division of Surgery, Lund University, Lund, Sweden

**BACKGROUND** The molecular breast cancer subgroups comprise diverse immune biology; for human epidermal growth factor receptor 2-positive (HER2+) breast cancer (BC) and triple-negative breast cancer (TNBC) abundance of tumour infiltrating lymphocytes (TILs) have been shown to indicate good prognosis and could predict pathological complete response after neoadjuvant chemotherapy. In contrast, the clinical relevance of TILs in estrogen receptor-positive/HER2-negative (ER+/HER2-) tumours is not settled. We primary aimed to analyse the prognostic effect of TILs on BC-free interval (BCFI) in premenopausal patients, stratified by molecular subgroups. The secondary aim was to investigate the predictive value of TILs on tamoxifen benefit.

**METHODS** Archival tissue from primary tumours was collected from patients included in the SBII:2pre trial. In this study, 564 premenopausal women were randomised between two years of adjuvant tamoxifen or no systemic treatment regardless of hormone-receptor status. TILs were scored on whole tissue sections and the tumours were divided into ER+/HER2- (n = 255), HER2+ (n = 65) and TNBC (n = 95) molecular subgroups by immunohistochemistry and *in situ* hybridisation (ISH). The prognostic value of TILs was evaluated in patients allocated to no systemic therapy, whose tumours were successfully scored for TILs and had IHC/ISH data for generating molecular subgroups (n = 221). All patients with ER+ tumours and successfully annotated TILs were considered for prediction of tamoxifen benefit (n = 321). The median follow-up was 28 years and the prognostic and predictive analyses were performed by cumulative incidence curves and Cox regression analyses.

**RESULTS** TILs were successfully scored in 477 tumours with available ER status and the proportion of low (<10%), intermediate (10-49%) and high (≥50%) TILs were 52% (n = 248), 33% (n = 157) and 15% (n = 72), respectively. High infiltration of TILs was a favourable prognostic factor (univariable analysis: hazard ratio<sub>BCFI</sub> (HR<sub>BCFI</sub>) 0.40; 95% confidence interval (CI) 0.22-0.71; P = 0.002) (Table 1). The results were essentially the same in the ER+/HER2- molecular subgroup (HR<sub>BCFI</sub> 0.40; 95% CI 0.14-1.09; P = 0.07). Adjuvant tamoxifen improved prognosis in patients with ER+ tumours and TILs levels <50%, (univariable analysis HR<sub>BCFI</sub> 0.63; 95% CI 0.47-0.84; P = 0.002), which was not observed in patients displaying high immune infiltration (≥50%) (HR<sub>BCFI</sub> 0.84; 95% CI 0.24-2.86; P = 0.77). However, evidence for differential effect of tamoxifen in categories of TILs, i.e. interaction, was weak.

**CONCLUSIONS** We demonstrate a long-term favorable prognostic value of levels of TILs in a cohort of premenopausal BC patients. This effect seems to be extended to the ER+/HER2- subgroup. A beneficial effect of tamoxifen in ER+ patients was observed in patients with tumours of low TILs infiltration as compared to patients with tumours of high immune infiltration, but we could not confirm a treatment predictive effect.

Androgen and ESR1 mutant receptors mechanistically collaborate for overexpression of genes associated with poor outcomes in ER-positive metastatic breast cancer

Suzanne Fuqua<sup>1</sup>, Thomas L Gonzalez<sup>1</sup>, Guowei Gu<sup>1</sup>, Sarah Herzog<sup>1</sup>, Yassine Rechoum<sup>1</sup>, Amanda Beyer<sup>1</sup>, David Edwards<sup>1</sup>, Hangqing Lin<sup>1</sup>, Basil Paul<sup>1</sup>, Ralf Kittler<sup>2</sup>, Nancy Weigel<sup>1</sup>, Sandra Grimm<sup>1</sup>, Cristian Coarfa<sup>1</sup> and Tasneem Bawa-Khalfe<sup>3</sup>. <sup>1</sup>Baylor College of Medicine, Houston, TX; <sup>2</sup>UT Southwestern, Dallas, TX; <sup>3</sup>University of Houston, Houston, TX

**Background:** Recurrences are delayed for years with endocrine therapy (ET), but resistance ultimately evolves with the development of ER+ metastatic breast cancer (MBC). ESR1 mutations are acquired in MBC undergoing ET in about 20-40% of patients. We have previously demonstrated that AR overexpression confers resistance to both tamoxifen and aromatase inhibitor treatments. We discovered that AR protein is up-regulated in tumors expressing ESR1 mutations, and herein explore the functional consequences of AR-ESR1 mutant co-expression on metastatic progression of breast cancer. **Objective:** We hypothesize that ET resistance mechanisms driven by AR overexpression and acquisition of ESR1 mutations co-evolve under the selective pressure of therapy to drive distant metastasis. We investigated whether AR engages in novel genomic binding interactions with mutant ER to promote tumor progression. **Methods:** Expression profiling of CRISPR-Cas9 engineered cell lines was integrated with chromatin immunoprecipitation-sequencing (ChIP-Seq) to define the genomic distribution of ER and AR binding sites. Genomic distribution of AR-ER co-occupied binding sites from MBC patient tumors, and a gene expression signature associated with patient outcomes was generated using Cox Regression analysis to calculate Hazard Ratios for recurrence free survival from gene expression in the KMPlotter Breast Cancer Dataset and signature validation by Kaplan Meier analysis in the ER+ METABRIC patient cohort. **Results:** AR protein was post-transcriptionally elevated in ESR1 mutant cells, including distant metastatic tumors from ESR1 mutant xenograft models. Transcriptome data showed significant elevation of Cancer Hallmark pathways, including epithelial-mesenchymal transition (EMT) and estrogen response, but down-regulation of androgen response genes. However, both ER and AR functions were constitutively activated, independent of their respective ligands in ESR1 mutant-expressing models. AR was disproportionately re-distributed to selected enhancer genomic regions, but also heterochromatin in ESR1 mutant compared to cells with WT ER in the presence of estrogen. In addition, AR-ER co-occupied sites were increased in enhancer regions in ESR1 mutant cells, and these sites best discriminated distal ER enhancer regions in non-responder patients and MBC. . The expression of genes co-bound by AR and ER were significantly associated with shorter recurrence-free and overall survival in ER+ breast cancer. Treatment with AR agonists blocked distant metastasis of ESR1 mutant PDX models *in vivo*, in part due to reduction in ER protein and ER binding to select genomic sites. **Conclusions:** Our results demonstrate that unliganded AR collaborates with ESR1 mutations to regulate genes associated with the metastasis of ER+ breast cancer. We hypothesize that in an ESR1 mutant genomic background, AR acquires ER co-activator functions that are blocked with AR agonists, suggesting a unique hormonal therapeutic vulnerability in tumors with ESR1 mutations.

Sox4 and smarca4 upregulate glycolysis-driven tumor proliferation through hexokinase 2 in tnbc

Pooja Khanna<sup>1</sup>, Gaurav Mehta<sup>2</sup> and Michael L. Gatz<sup>2</sup>. <sup>1</sup>Rutgers University/Robert Wood Johnson Medical School, Lawrence Township, NJ; <sup>2</sup>Rutgers University/Robert Wood Johnson Medical School, New Brunswick, NJ

**Background** Triple-negative breast cancer (TNBC) accounts for nearly 1-in-4 breast cancer related deaths in the United States each year despite representing 10-12% of newly diagnosed cases. This aggressive disease, which is largely synonymous with the basal-like molecular subtype, predominantly affects younger women and women of African American descent. Despite a number of recent advances, overall survival has not drastically improved, highlighting the need to better understand mechanisms regulating tumor growth and progression as a means to identify novel therapeutic opportunities in these patients.

**Methods** In order to identify the functional impact of overexpression of the oncogenic transcription factor SOX4 and its co-factor SMARCA4 in TNBC, RNAseq and ChIPseq analyses were used to identify SMARCA4-dependent and -independent SOX4 gene expression programs. Analyses of more than 3,000 tumor samples from the METABRIC and TCGA cohorts was used to investigate the functional implications and clinical association of these gene expression programs in human tumors. Mass spectrometry (MS)-based metabolomic profiling in conjunction with genetic and pharmacological-based *in vitro* studies were used to demonstrate the impact of these programs on tumor cell metabolism, cell viability and proliferation.

**Results** We, and others, have previously demonstrated that the oncogenic transcription factor SOX4 is overexpressed in basal-like tumors. In order to identify mechanisms by which this protein mediates breast cancer tumorigenesis, we first identified SOX4 co-factors. Immunoprecipitation followed by MS was used to identify the SWI/SNF ATPase SMARCA4 as a prominent SOX4 cofactor that is concurrently overexpressed in basal-like tumors.

Mechanistic studies showed that this complex is required to maintain an active open chromatin conformation at regulatory regions upstream of SOX4-regulated genes. ChIPseq and RNAseq-based analyses were next used to investigate the role of this complex in TNBC signaling and tumorigenesis. Our analyses identified SMARCA4-dependent and -independent SOX4 gene expression programs and demonstrated that SMARCA4-dependent SOX4 signaling is associated with poor clinical outcome. Further *in silico* analyses of human tumors indicate that each program mediates distinct down-stream signaling; SMARCA4-dependent signaling is associated with altered tumor metabolism and increased proliferative signaling. Consistent with this premise, *in vitro* studies showed that SOX4 and SMARCA4 are essential for breast tumor cell proliferation, survival and colony formation. Metabolomic profiling of breast cancer cell lines demonstrated that SOX4 overexpression resulted in increased glycolysis. The effect of SOX4 and SMARCA4 on cell metabolism was validated by demonstrating that this complex can mediate intracellular glucose consumption. Finally, we determined that SOX4 and SMARCA4 cooperatively regulate mRNA expression of hexokinase 2 (HK2), which catalyzes for the first step in glucose metabolism, and demonstrated that HK2 activity is essential for SOX4/SMARCA4-regulation of glycolysis. Importantly, *in vitro* genetic and pharmacological studies identified a link between HK2 activity, glycolysis and SOX4/SMARCA4-mediated cell proliferation and viability in TNBC.

**Conclusions** Our studies have identified SOX4 and its transcriptional cofactor SMARCA4 as being uniformly overexpressed in basal-like or TNBC tumors. These analyses demonstrate that SOX4 and SMARCA4 cooperatively promote tumorigenesis in TNBC cells, in part, by modulating glycolysis and cell proliferation through transcriptional regulation of HK2. Given the drug-ability of the glycolysis pathway, these results have potential clinical implications for treatment of TNBC patients.

**Background:** NET is offered to postmenopausal patients (pts) with clinical stage 2/3 ER+/HER2- BC to promote breast-conserving surgery. Also limited surgical accessibility during the COVID19 pandemic has increased NET utility. Inability to identify ET-resistant disease at diagnosis risks disease progression (PD) and delays more effective treatments. Dowsett *et al.* recently demonstrated that baseline levels of ER, progesterone receptor (PR), Ki67 (>15% vs ≤15%), and Ki67 (>10% vs ≤10%) 2-4 weeks (wks) after starting NET may improve appropriate patient (pt) selection for NET (PMC7280290). The ER, PR and Ki67-based prediction model divides pts with primary ER+/HER2- BC into 3 groups for appropriateness for NET: (Group 1) NET is likely to be *inappropriate* (Allred ER <6 or ER 6 and PgR <6), (Group 2) NET *may be appropriate* and a biopsy for on-treatment Ki67 analysis may be considered after 2-4 wks of NET (2A: ER 7 or 8 and PgR <6 and 2B: ER 6 or 7 and PgR ≥6) given that on-treatment Ki67 >10% has been associated with worse outcome (PMC5455353), or (Group 3) NET is *appropriate* (ER 8 and PgR ≥6). The ALTERNATE trial (NCT01953588) randomized postmenopausal women with clinical stage II or III, ER+ (Allred score 6-8)/HER2- BC to receive anastrozole (ANA), fulvestrant (FUL), or ANA + FUL for 6 months, unless Ki67 was >10% on wk 4 or 12 biopsy, in which case pts were triaged to receive neoadjuvant chemotherapy (NCT) or surgery. As previously reported, the ET-sensitive disease (mPEPI 0 plus pCR) rates were similar across the treatment arms and overall 22% (286 of 1,299) pts had Ki67 >10% at wk 4 or 12. The ALTERNATE trial therefore provides a large independent data set to evaluate the NET appropriateness model.

**Results:** Among 1,299 eligible pts randomized to receive 6 months of NET, 214 were excluded due to absent HR Allred score (n=41) or absence of pre-treatment and wk 4 Ki67 determinations (n=173). The proportions of the remaining 1,085 pts in Group 1, 2 and 3 were 1% (n=10), 43% (n= 468), and 56% (n=607), respectively. On-study Ki67 >10% prompting conversion from NET to NCT/Surgery occurred in: Group 1 90% (9 of 10), Group 2 30% (141 of 468), and Group 3 17% (104 of 607) (Table 1). Among the 1,075 pts in Groups 2 and 3, 260 (24%) pts had Ki67 ≤15% at baseline (BL), among whom only 14 (5.4%) had Ki67 >10% at wk 4, compared to 231 of the 815 (28.3%) who had BL Ki67 >15% and subsequent Ki67 >10% at wk 4. 2% of pts who remained on NET due to on-treatment Ki67 <10% had PD. Response and PEPI-0 rates by group will be reported. **Table 1 Baseline levels of ER, PR, and Ki67 in Relation to Wk 4 Ki67 (N=1,085)**

		Baseline			Week 4		
Group	N	ERAllred Score	PRAllred Score	Ki67	Ki67 ≤10%N (%)	Ki67 >10%N (%)	
1	N=2	6	<6	≤15%	0 (0%)	2 (100%)	9 (90)
	N=8	6	<6	>15%	1 (12.5%)	7 (87.5%)	
2A	N=64	7 or 8	<6	≤15%	61 (95.3%)	3 (4.7%)	90 (30.1)
	N=235	7 or 8	<6	>15%	148 (63%)	87 (37%)	
2B	N=46	6 or 7	≥6	≤15%	42 (91.3%)	4 (8.7%)	51 (30.2)
	N=123	6 or 7	≥6	>15%	76 (61.8%)	47 (38.2%)	
3	N=150	8	≥6	≤15%	143 (95.3%)	7 (4.7%)	104 (17.1)
	N=457	8	≥6	>15%	360 (78.8%)	97 (21.2%)	

**Conclusion:** ALTERNATE trial data support a model whereby levels of ER, PR and Ki67 at diagnosis can be used for the identification of postmenopausal pts with primary ER+/HER2- BC who are appropriate for NET. When baseline ER Allred scores are >6 and Ki67 ≤15%, there is a low likelihood of ET-resistant disease. When BL Ki67 is >15%, ET sensitivity is variable, and on-treatment biopsy for Ki67 may assist in triaging regarding NET appropriateness, particularly given the extremely low local PD rates seen in ALTERNATE when on-treatment Ki67 was <10%. **Support:** U10CA180821, U10CA180882, U24CA196171, UG1CA189856, U10CA180868 (NRG); NCI BIQSFP, BCRF, Genentech, AstraZeneca. <https://acknowledgments.alliancefound.org>; Clinical Trials.gov Identifier: NCT01953588

Dietary supplement use in a healthy eating and exercise lifestyle intervention in breast cancer survivors: The lifestyle exercise and nutrition (LEAN) study

ThaiHien Nguyen<sup>1</sup>, Maura Harrigan<sup>1</sup>, Courtney McGowan<sup>1</sup>, Annette Hood<sup>2</sup>, Fangyong Li<sup>1</sup>, Brenda Cartmel<sup>1</sup>, Leah Ferrucci<sup>1</sup>, Melinda L Irwin<sup>1</sup> and Tara Sanft<sup>3</sup>. <sup>1</sup>Yale School of Public Health, New Haven, CT; <sup>2</sup>Yale Cancer Center, New Haven, CT; <sup>3</sup>Yale School of Medicine, New Haven, CT

**Background:** Dietary supplements (DS), defined as herbal preparations, vitamins and minerals (DSHEA Act 1994), are used by 70% of cancer survivors. The World Cancer Research Fund/American Institute for Cancer Research 2018 Cancer Prevention Recommendations specify not to use DS to protect against cancer. There is some evidence that DS are linked to harmful outcomes, including increased mortality and breast cancer recurrence. DS have potential pharmacokinetic interactions via cytochrome P450 enzyme and pharmacodynamic interactions via estrogenic or hepatotoxic activity, which may increase or reduce clinical efficacy or potentiate adverse effects of Tamoxifen and Aromatase Inhibitors (AIs). This analysis examines baseline usage of DS and potential interactions with Tamoxifen and AIs among breast cancer survivors enrolled in the Lifestyle, Exercise, and Nutrition (LEAN) study, a randomized healthy eating and exercise lifestyle intervention. **Methods:** We examined the use of DS in 151 breast cancer survivors enrolled in the LEAN Study. Women with a body mass index (BMI)  $\geq 25$  kg/m<sup>2</sup> were randomly assigned to a 6-month healthy eating and exercise lifestyle intervention (n=93) or to usual care (n=58). At baseline and 6 months, we asked participants to self-report regular DS use, defined as at least 3 times a week for at least one month. The intervention group received evaluation and counseling of DS use by a Registered Dietitian (RD) with a Certified Specialty in Oncology Nutrition (CSO). Potential interactions of moderate and major ratings between DS with Tamoxifen and AIs (Letrozole, Exemestane and Anastrozole) were identified through the Natural Medicines Database by both a pharmacist specializing in oncology and a RD, CSO. **Results:** Out of 151 women, at baseline 120 (80%) reported using DS. Fifty-four different formulations were enumerated. The majority of women (72, 60%) were taking  $\geq 3$  formulations. One quarter of women (29, 24%) were taking  $\geq 5$  formulations (range = 1 - 20). Of the 54 formulations, 33% had potential interactions with Tamoxifen and/or AIs according to the Natural Medicines Database. Total interactions by medication were: 18 Tamoxifen, 14 Letrozole, 14 Exemestane, 9 Anastrozole. The majority of these interactions (87%) were associated with herbal preparations. **Conclusions:** Our findings are indicative of the high prevalence of DS use among breast cancer survivors and the potential risk of interactions with prescribed hormonal therapy. More research is needed to test if counseling from a RD, CSO can reduce DS use and ultimately lead to better outcomes due to fewer interactions with breast cancer treatments.

**Background:** Trophoblast cell-surface antigen-2 (Trop-2) is highly expressed in many epithelial tumors, including triple-negative breast cancer (TNBC). Sacituzumab govitecan (SG) is an antibody-drug conjugate composed of an anti-Trop-2 antibody coupled to SN-38, the active metabolite of irinotecan, via a unique hydrolyzable linker that allows SN-38 release intracellularly and in the tumor microenvironment (bystander effect). SG received accelerated approval in April 2020 for the treatment of patients with metastatic TNBC (mTNBC) who received at least 2 prior therapies for metastatic disease. The most common adverse events (AEs) observed with SG are neutropenia and gastrointestinal toxicity, also seen with irinotecan. To provide further information on SG, additional safety analyses from ASCENT, a randomized, phase 3 confirmatory study of SG versus standard-of-care chemotherapy in patients with mTNBC, will be reported. **Methods:** In the global, multicenter, open-label, phase 3 ASCENT study (NCT02574455), 529 patients with mTNBC refractory to or relapsing after at least 2 prior chemotherapies were randomized 1:1 to receive SG (10 mg/kg intravenously on days 1 and 8 every 21 days) or single-agent treatment of physician's choice (capecitabine, eribulin, vinorelbine, or gemcitabine) until disease progression or unacceptable toxicity. The primary endpoint was progression-free survival measured by central independent review per RECIST v1.1. Secondary endpoints included objective response rate, duration of response, overall survival, and safety. An exploratory analysis of incidence of grade 3-5 AEs by *UGT1A1* genotype was also performed. Post-hoc analysis of the time to onset and duration of key AEs will be performed, and descriptive analyses on alopecia, nausea and vomiting will also be provided. **Results:** Exploratory safety analyses by *UGT1A1* allele status will be shown as well as time to onset and duration of neutropenia and diarrhea. Further descriptive analyses on alopecia, nausea, and vomiting will be provided along with AE management strategies. **Conclusions:** These analyses will provide further insights into the safety profile of SG and appropriate AE management strategies for patients with previously treated mTNBC to allow optimal therapeutic exposure.

*HER2 L755S* mutation is acquired upon resistance to lapatinib and neratinib and confers cross-resistance to tucatinib and trastuzumab in HER2-positive breast cancer cell models

Jamunarani Veeraraghavan, Ragini Mistry, Sarmistha Nanda, Vidyalakshmi Sethunath, Martin Shea, Tamika Mitchell, Meenakshi Anurag, Michael A. Mancini, Fabio Stossi, C. Kent Osborne, Mothaffar F. Rimawi and Rachel Schiff. Baylor College of Medicine, Houston, TX

**Background:** The role of HER2 mutations in anti-HER2 resistance is gaining more importance in HER2-positive (+) breast cancer (BC). The common *HER2 L755S* mutation is further enriched in metastatic lesions compared to primary tumors. Despite their mounting significance, effective therapies for HER2-amplified/mutant tumors are lacking. We recently reported that acquired resistance to lapatinib (Lap)-containing regimens is mediated by *HER2 L755S*, which could be overcome by the irreversible pan-HER tyrosine kinase inhibitor (TKI) neratinib (Nrb). However, less is known about the role of *L755S* in resistance to new generation TKIs, and the clinically implementable therapeutic strategies to overcome it. **Materials and Methods:** Our recently developed HER2+ BT474 cell models with acquired resistance to Lap (LapR) or Nrb (NrbR), developed through long-term exposure to increasing doses of the respective drug, and their naïve parental (P) counterparts were used. The resistant derivatives and their cognate P cells were subjected to proteomic (Reverse phase protein array (RPPA) and western blot) and transcriptomic (RNA-seq) characterization. For drug efficacy studies, change in cell growth was assessed using the *in situ* imaging-based high-throughput IncuCyte system. **Results:** Proteomic profiling of the resistant models and their P equivalents revealed partial restoration of HER2 phosphorylation and downstream signaling in the LapR and NrbR derivatives. Consistent with activated mTOR signaling observed in the resistant cells, we detected reduced levels of phospho (p)-RAPTOR S792, which is otherwise essential to inhibit the mTOR complex 1 (mTORC1). In addition, p-P38MAPK T180/Y182 levels were reduced. RNA-seq analysis revealed the presence of *HER2 L755S* mutation in the LapR and NrbR derivatives, but not in P cells, suggesting that the HER signaling reactivation could be attributed to acquisition of *HER2 L755S*. Interestingly, the NrbR cells co-harbor other pathogenic mutations in key BC related genes, the therapeutic and functional significance of which is being investigated. Importantly, the NrbR derivatives were cross-resistant to Lap and the monoclonal antibody trastuzumab (T). Next, we determined the efficacy of Nrb and the HER2-selective TKI tucatinib (Tuca), both recently approved for metastatic HER2+ BC, either alone or in combination with T. Nrb effectively inhibited the growth of LapR cells, although a higher dose (IC50: ~50nM) was required to inhibit the growth compared to that needed for naïve P cells (~IC50: ~2nM). When combined with T, Nrb was effective in inhibiting the LapR cell growth, though the inhibitory effect may very well be driven entirely by Nrb. On the other hand, the resistant derivatives were cross-resistant to Tuca, both as a single-agent and in combination with T. We then evaluated the efficacy of the antibody drug conjugate TDM1 and the irreversible pan-HER TKI poziotinib. In contrast to the high sensitivity of P cells to both these agents, a spectrum of effect was observed in the NrbR derivatives, with responses ranging from partial growth inhibition by poziotinib to complete response with TDM1, suggesting their therapeutic potential against tumors harboring HER2 mutations. **Conclusions:** Our findings suggest that *HER2* mutations, particularly *HER2 L755S*, that emerge under the pressure of potent HER2-targeted therapy may confer cross-resistance to other single agent or combination HER2-targeted therapy. This holds important therapeutic implications in light of current treatment landscape. An in-depth molecular characterization of our resistant models to determine the differential gene expression and mutational profile is ongoing to gain additional mechanistic insights and to guide discovery of other actionable targets.

Web-based intervention to improve knowledge, intent to screen and uptake of breast cancer screening among long-term, high-risk Hodgkin lymphoma survivors who received chest radiation

Smitha Sagaram<sup>1</sup>, Patricia Jewett<sup>1</sup>, Rachel I. Vogel<sup>1</sup>, Lucie Turcotte<sup>1</sup>, Karim Sadak<sup>1</sup>, Heather Beckwith<sup>1</sup>, David Potter<sup>1</sup>, Douglas Yee<sup>1</sup>, Hee Yun Lee<sup>2</sup> and Anne Blaes<sup>1</sup>. <sup>1</sup>University of Minnesota, Minneapolis, MN; <sup>2</sup>University of Alabama, Tuscaloosa, AL

**Background** Many cancer survivors experience late effects from their cancer treatment including second cancers. Breast cancer risk in Hodgkin lymphoma (HL) survivors is estimated at 35% by age 50 years<sup>1</sup> with a 40-fold increase when treated with chest radiation prior to age 20 years<sup>2</sup>. For patients who received chest radiation between ages 10 and 30 years, NCCN recommends annual screening mammogram and breast MRI 10 years after chest wall radiation or after age 30 and 25 years respectively<sup>3</sup>. We designed a web-based intervention to improve knowledge, intent to screen and uptake of breast cancer screening among long-term, high-risk HL survivors. **Methods** We invited 263 long-term HL survivors treated with chest radiation, of which 60 women were enrolled. Participants were randomized 1:1 to web-based intervention or control groups. The web-based intervention consisted of daily, interactive, highly tailored learning modules over the course of one week. Both groups received handouts on potential complications from cancer treatment and screening recommendations. All participants were invited to a baseline survey, first follow-up survey 1-2 weeks post intervention, and a final survey 3 months post intervention. In total, 53 participants completed the baseline survey, and to-date 41 the first follow-up survey. The last 3-month follow-up surveys are due in fall 2020. We compared frequencies of who correctly answered questions regarding potential complications from prior treatment and breast cancer screening recommendations at baseline vs. first follow-up in the intervention and control groups using Chi-squared and Fisher's exact tests. P value < 0.05 was considered significant. **Results** At baseline, participants were on average 49 years old, and 22.4 years out from their HL diagnosis. Baseline self-reported adherence to annual mammography and breast MRI screening was low: 55% of all participants reported receiving annual mammograms, and only 6% reported annual MRIs. At baseline, 79% of participants reported awareness of complications from previous treatments however, only 27% correctly identified national guidelines on breast cancer screening for HL survivors who received chest radiation. At one week after the intervention, individuals assigned to the intervention (compared with controls) more often 1) reported knowing how to reduce the risk from prior treatments (89.5% vs. 50%, p = 0.009), 2) correctly identified national guidelines on screening (63.2% vs. 27.3%, p=0.007) at first follow-up. Our preliminary data did not show an increase in intent to screen or uptake of screening shortly after intervention.

	Intervention N=30 (%)	Control N=30 (%)	p-value
Identified national guidelines on breast cancer screening for HL survivors who received chest radiation	12 (63.2)	6 (27.3)	0.007
Reported knowing what to do to reduce risk of complications from prior cancer treatment	17 (89.5)	11(50.0)	0.009

**Conclusions** Adherence to breast cancer screening recommendations is low among long-term, high-risk HL survivors. Preliminary analysis of an RCT comparing a web-based intervention to paper handouts identified improved knowledge regarding current national guidelines on breast cancer screening and how to reduce the risk of complications from prior HL treatments. Further research should address barriers to screening and interventions to address them. **References**1. Moskowitz CS et al. Medicaid expansion associated with earlier stage and improved reconstruction rates in low income breast cancer patients

Johnie Rose<sup>1</sup>, Weichuan Dong<sup>1</sup>, Uriel Kim<sup>1</sup>, Samilia Obeng-Gyasi<sup>2</sup> and Siran Koroukian<sup>1</sup>. <sup>1</sup>Case Western Reserve University, Cleveland, OH; <sup>2</sup>Ohio State University Medical Center, Columbus, OH

**Introduction:** Substantial delays in time to initiation of treatment (TTT) following diagnosis of breast cancer (BC) can inflict a toll on quality of life and can decrease cancer-specific survival. Among low-income, non-elderly Ohio women having newly-diagnosed breast cancer with local or regional spread, we examined TTT and other measures where income-related disparities have been documented, comparing 2011-2013 (pre-Medicaid-expansion) vs. 2014-2016 (post-expansion). Our primary hypothesis was that TTT would decrease following 2014 Medicaid expansion. **Methods:** Using data from the Northeast Ohio Cancer Assessment and Surveillance Engine (NEO-CASE), a multilevel data infrastructure linking Ohio cancer registry data with community data, we identified 30-64 year-old women with new diagnosis of invasive, non-metastatic BC who were uninsured or on Medicaid when diagnosed. TTT was defined as days from diagnosis to first BC treatment with any modality. We excluded women with TTT=0 (likely coding error). The main exposure was pre- or post-Medicaid expansion period defined as 2011-2013 or 2014-2016, respectively. We examined additional key demographic and treatment variables before and after expansion and in multivariate analysis of TTT. We used a previously-described probability-weighting approach based on neighborhood median income to approximate excluding women with incomes above 138% of Federal Poverty Level. As a control analysis, we compared pre- and post-expansion TTT among privately insured women, probability weighted to select for higher income individuals. **Results:** Our study population included 1177 and 1143 women diagnosed with BC pre- and post-expansion, respectively. Demographic characteristics were similar, though mean age increased by 1.2 years ( $p<0.01$ ) post-expansion. Mean TTT increased by 2 days post-expansion, from 41.1 to 43.1 ( $p=0.18$ ). The control analysis showed a similar small post-expansion increase. Though no significant change in TTT was observed, the percent uninsured in the low-income group fell by more than half (from 32.9% to 14.1%;  $p<0.01$ ), and the percent of women diagnosed with regional stage disease decreased from 38.1% to 30.9% ( $p<0.01$ ). The percent of women undergoing reconstructive surgery increased from 12.1% to 16.7% ( $p<0.01$ ) from the pre- to the post-Medicaid expansion period, a change not observed in the privately-insured control group. Cox proportional hazards regression models controlling for the effect on TTT of covariates shown in the table revealed an adjusted hazard rate (AHR) of 0.950 (95% CI 0.855 to 1.056) associated with Medicaid expansion. Stage-stratified Cox models showed a similar lack of effect among women with local and regional disease. **Discussion:** TTT increased by 2 days post-expansion; however, this increase was neither statistically significant nor clinically meaningful. Despite the lack of improvements in TTT, we note the dramatic drop in the percent uninsured among BC patients post-expansion, as well as a marked decrease in the percent of women diagnosed with regional-stage disease, and an increase in BC patients undergoing reconstruction. Taken together, these trends show an overall positive impact of Medicaid expansion on BC process of care and outcome measures.

	Pre-expansion	Post-expansion	p
N	1177	1143

Adverse events in breast cancer patients treated with concurrent or sequential radiation therapy and CDK 4/6 inhibitors in metastatic setting

Marcin Kubeczko, Agnieszka Badora-Rybicka, Anna Polakiewicz-Gilowska, Aleksandra Leśniak, Katarzyna Świdorska, Marta Mianowska-Malec, Barbara Grandys, Barbara Łanoszka, Magdalena Stankiewicz, Marzena Gawkowska, Elżbieta Nowicka, Grzegorz Woźniak, Dorota Gabryś, Rafał Tarnawski, Leszek Miszczyk and Michał Jarząb. Maria Skłodowska-Curie National Research Institute of Oncology, Gliwice, Poland

**Background.** Radiation therapy (RT) is important modality in MBC patients, however, there is paucity of data on safety and feasibility in combining radiation and a cyclin-dependent kinase 4 and 6 inhibitors (CDK 4/6i). No sufficient data were gathered in clinical trials and a few small retrospective series were published; it is important to extend these data. Theoretically, concerns pertain both the augmentation of effect (toxicity) or decrease of treatment effectiveness. **Methods.** 116 patients with MBC were treated in our center with CDK 4/6i (ribociclib n=59, palbociclib n=57) between 2018-2020. 26 patients were also treated with RT and were included into further analysis. 10 patients were treated with concurrent RT and 16 patients with sequential RT. Median age of patients was 55 years (range 23-78). 11 patients (42%) were diagnosed with de novo MBC, whereas 15 patients (57%) with recurrent breast cancer. 16 patients received prior chemotherapy, 6 of them less than 1 year before CDK 4/6i treatment. 73% of patients received CDK 4/6i in first line setting. Bones were the main metastatic site in the majority of patients, whereas visceral metastasis were diagnosed in 9 patients (35%). Overall 32 RT treatments in 26 patients were performed. Various RT regimens were used, including 8 Gy in 1 fraction (n=10), 20 Gy in 5 fractions (n=9), 30 Gy in 10 fractions (n=3). SBRT was performed in 5 patients and chest wall irradiation in 3 patients. The majority of patients received palliative radiotherapy to the bones, including 6 patients (23%) with RT to the pelvic area. **Results.** Nineteen patients (73%) experienced G2 and G3 neutropenia, with no G4 case. Neutropenia G $\geq$ 2 occurred during first cycle of CDK 4/6i treatment in 50% of patients (n=8) after sequential RT and significantly more often in patients after concurrent RT (all treated, n=10; p= 0.0095). No neutropenia was observed in 7 patients after sequential RT (27%). 4 patients (15%) had CDK 4/6i dose reduction, including 1 patient treated with concurrent RT and 3 patients treated with sequential RT. In all 4 patients the cause of dose reduction was prolonged G3 neutropenia. Patients were treated as follows: 60yo patient received RT 8 Gy in 1 fraction for bone metastases in lumbar and thoracic spine and ribs; 31yo patient received RT 20 Gy in 5 fractions for central nervous system, then 20 Gy in 5 fractions for bone metastases in thoracic, lumbar and sacral spine (all of these treatments were performed during 4 weeks before CDK 4/6i first dose). The following two patients received additionally doxorubicin-based chemotherapy shortly before CDK 4/6i treatment. At median follow up of 17 months (range 9-20 months) none of these patients discontinued treatment because of toxicity: one patient continue ribociclib at first dose reduction level, two patients continue ribociclib at second dose reduction level and one patient continued ribociclib treatment for 11 consecutive months and then CDK 4/6i treatment was ended because of disease progression. There was no difference in neutropenia rate in patients treated previously with chemotherapy (n=16) and chemo-naïve patients (n=10; p=0.6680). No cases of acute radiation-induced enterocolitis or enhanced dermatologic toxicity were found. No other serious adverse events were observed. **Conclusions.** We found that concurrent RT leads to more frequent neutropenia than sequential RT, although it did not change treatment course in the majority of patients and appeared well-tolerated. Potential risk factors for radiation-induced CDK4/6i dose reduction might be extensive radiation fields and previous chemotherapy in metastatic setting. Until now, combined RT is not a part of adjuvant CDK 4/6i clinical trials protocols. Excellent tolerance of this combination supports future consideration of this scenario in clinical trial setting.

The use of magnetic resonance imaging (MRI) in predicting pathological complete response(pCR) in the breast and axilla after the addition of immunotherapy to neoadjuvant systemic therapy (NST)

Noeline Rajarajan<sup>1</sup>, Daniel Segarra<sup>2</sup>, Robert J Weinfurter<sup>1</sup>, Adrian A Lopez<sup>1</sup>, M Catherine Lee<sup>1</sup>, John Kiluk<sup>1</sup>, Hatem Soliman<sup>1</sup>, Hung Khong<sup>1</sup>, Han S Hyo<sup>1</sup>, Marilyn Rosa<sup>1</sup>, Brian J Czerniecki<sup>1</sup> and Nazanin Khakpour<sup>1</sup>. <sup>1</sup>H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL;<sup>2</sup>USF Health Morsani College of Medicine, Tampa, FL

**Introduction:** Immunotherapy use is increasing as an adjunct to current NST for breast cancer treatment with the goals of increasing pCR and down staging tumors. In this study, we assessed the effectiveness of MRI in the evaluation of tumor response after neoadjuvant immunotherapy in combination with NST. **Methods:** We retrospectively reviewed the clinicopathological data of 105 women undergoing Immunotherapy in conjunction with NST at a single institution. All patients had been enrolled in IRB approved protocols and had undergone definitive surgery. Patients were excluded for: failure to complete at least two thirds of treatment, no pre or post treatment MRI, or surgery in an outside institution. We analyzed 73 patients from 5 distinct treatment protocols including: (1) 24 Triple negative breast cancer (TNBC) patients (pts) treated with Intratumoral Talimogene laherparepvec (TVEC) in combination with weekly paclitaxel followed by dose dense Adriamycin and Cytosin (ddAC); (2) 19 HER2/Neu positive (HER2+) pts treated with subcutaneous interferon gamma (IFN-γ) in combination with weekly paclitaxel with trastuzumab and pertuzumab (HP); (3), 7 HER2+ pts treated with 3 weeks of HER2 pulsed dendritic cell vaccines (DC1) followed by Taxotere, Carboplatin, and HP; (4), 14 pts on the ISPY2 trial: 8 TNBC and 4 Hormone receptor positive, HER2/Neu negative (HR+) pts randomized to treatment with pembrolizumab with weekly paclitaxel followed by ddAC (2 also received additional SD101), and 2 TNBC pts treated with Durvalumab, Olaparib and Paclitaxel, followed by ddAC and (5) 9 HR+ pts on neoadjuvant Durvalumab and an Aromatase Inhibitor for 6 cycles. **Results:** A total of 73 patients were included in the study. Median age was 51 years (range 27-76); 46.6% of patients had TNBC, 35.6% had HER2+ and the remaining 17.8% were HR+ HER2-. The median clinical tumor size was 3.4cm (range 1.3-10.6) pre therapy and 1cm (range 0-10.1) post therapy. The pCR was 38.2%, 57.7%, and 0% respectively for TNBC, HER2+, HR+ tumors. Complete radiological response (rCR) of both the axilla and breast was 41.2%, 61.5% and 7.7%, for TNBC, HER2+ and HR+ tumors. The sensitivity of MRI to detect in breast pCR was 65.6% with a specificity of 81%, NPV and PPV of 75% and 73.3% respectively. MRI identified 37 pts with suspicious axillary nodes on pretreatment MRI; of these 30 had fine needle aspiration (FNA) confirmed metastatic disease. Post treatment, 70.3% (26/37) had normalized axillary nodes. Of those with normalized nodes, 26.9% (7/26) had residual cancer on final pathology. Of the patients with confirmed FNA lymph node metastasis, axillary pCR of 63.3% was achieved. The sensitivity and specificity of MRI to detect pCR within the axilla was 87% and 50% and NPV and PPV 70% and 74.1%, respectively. 3 patients had axillary disease on final pathology but no suspicious imaging and a benign FNA. **Conclusion:** The addition of immunotherapy to current NST strategies can improve pCR and decrease residual cancer burden. The PPV and NPV of MRI to predict pCR in patients undergoing immunotherapy in combination with NST remains within the ranges described in patients undergoing NST alone. MRI remains a useful tool to guide surgical management but is not accurate enough to replace pathological evaluation.

Pathologic features of the inter-regimen biopsy predict response to neoadjuvant therapy in the I-SPY 2 TRIAL

Jodi M Carter<sup>1</sup>, Molly E Klein<sup>2</sup>, Sara J Venters<sup>3</sup>, Kimmie Rabe<sup>2</sup>, I Tolgay Ocal<sup>4</sup>, Kamaljeet Singh<sup>5</sup>, Denise M Wolf<sup>3</sup>, Sunati Sahoo<sup>6</sup>, Shuko Harada<sup>7</sup>, Laila Khazai<sup>8</sup>, Malini Harigopal<sup>9</sup>, Alexander D Borowsky<sup>10</sup>, Gregor Krings<sup>3</sup>, Ronald Balassanian<sup>3</sup>, Yunn-Yi Chen<sup>3</sup>, Kimberley Cole<sup>9</sup>, Sonal Shad<sup>3</sup>, Amy Delson<sup>3</sup>, Lamorna Brown-Swigart<sup>3</sup>, I-SPY 2 TRIAL Consortium, Laura Esserman<sup>3</sup>, Laura van 't Veer<sup>3</sup> and W Fraser Symmans<sup>8</sup>. <sup>1</sup>Mayo, Rochester, MN; <sup>2</sup>U. Minnesota, Minneapolis, MN; <sup>3</sup>UCSF, San Francisco, CA; <sup>4</sup>Mayo, Scottsdale, AZ; <sup>5</sup>Brown University, Providence, RI; <sup>6</sup>UTSW, Dallas, TX; <sup>7</sup>UAB, Birmingham, AL; <sup>8</sup>MDACC, Houston, TX; <sup>9</sup>Yale, New Haven, CT; <sup>10</sup>UC Davis, Sacramento, CA

**Background:** I-SPY 2 is a neoadjuvant platform trial open to patients with locally advanced, molecular high-risk breast cancer. In a concerted pursuit of mid-therapy response biomarkers, we evaluated inter-regimen biopsies, to identify patients who may be candidates for treatment de-escalation. In a pilot study, we observed that absence of carcinoma in an inter-regimen biopsy may predict pathologic complete response (pCR). In this expanded study of 100 participants, we sought to confirm that finding and assess pathologic features of the inter-regimen biopsy as predictors of tumor response to neoadjuvant therapy.

**Methods:** Digital H&E images of 100 inter-regimen (12 week) image-guided breast biopsies +/- ancillary immunohistochemistry (p63 and/or cytokeratin) were reviewed by 9 I-SPY affiliated pathologists to record 1) tumor bed and 2) presence/absence of residual invasive carcinoma (IC) (with tumor cellularity scored as 0-100%). The data set included 393 cores (mean 3.9 (2-4) cores/biopsy). Fisher's exact t-test was used for association of presence/absence of IC with pCR, and tumoral hormone receptor (HR) and HER2 status. Association between biopsy tumor cellularity and residual cancer burden (RCB) indices used Pearson's correlation.

**Results:** In the biopsy set, 84 (84%) had ≥80% inter-observer diagnostic agreement on both 1) presence of tumor bed and 2) presence/absence of IC (53 IC+ /31 IC-). IC+/IC- biopsies had equal numbers of evaluable tissue cores. The primary tumors were 63% HR+/37% HR-. The presence of IC in the biopsy correlated with tumoral HR/HER2 status (p=0.0014: 74%: HR+HER2-; 62%: TN; 60%: HR+HER2+; 10%: HR-HER2+). Of 31 patients with IC- biopsies, 25 (80%) went on to pCR, whereas only 7/53 (13%) of patients with IC+ biopsies had pCR, conferring an odds ratio for pCR of 26, Fisher p=7.5E-10. Overall, IC- biopsies had a positive predictive value (PPV) for pCR of 81%, with a PPV for HR- tumors of 94% vs. 67% for HR+ tumors (Table 1). In the 6 IC- biopsies from patients with non-pCR ("false-negatives"), most were HR+ (5/6, Table 1), and tumor bed size in the resection specimen was smaller than for IC+ biopsies with non-pCR: 276 mm<sup>2</sup> (0.4-1000 mm<sup>2</sup>) vs. 1166 mm<sup>2</sup> (1-11960 mm<sup>2</sup>). In contrast, the 46/53 IC+ biopsies in patients with non-pCR had a PPV for predicting non-pCR of 86%, (PPV for HR+ tumors: 94% vs. PPV for HR- tumors: 66%. Tumor cellularity in the biopsy (mean 37%, [2.5-93%]) did not correlate with RCB index (p=0.57) or RCB breast-only index (p = 0.17) at resection.

Table 1: PPV for pCR/non-pCR by Inter-regimen Biopsy Status

Inter-regimen biopsy with or without Invasive carcinoma (IC+/-)	pCR	non-pCR	PPV (Sensitivity) for pCR(IC- Biopsies)	PPV (Sensitivity) for non-pCR(IC+ biopsies)
IC- biopsies				
All	25	6	81% (78%)	-
HR+	10	5	67% (83%)	-
HR-	15	1	94% (75%)	-
IC+ biopsies				
All	7	46	-	86% (88%)
HR+	2	36	-	94% (88%)
HR-	5	10	-	66% (91%)

**Conclusion:** In this 100 biopsy set from the I-SPY2 trial, the absence of residual carcinoma in inter-regimen biopsies was highly predictive of pCR, particularly for HR- tumors. The "false-negative" biopsies (IC-/non-pCR) were predominantly HR+ tumors with small residual tumor beds at resection. Conversely, the presence of carcinoma in inter-regimen biopsies was highly predictive of non-pCR, particularly for HR+ tumors. These data demonstrate the utility, and the limitations, of the inter-regimen biopsy as one tool to identify patients who may benefit from therapeutic de-escalation.

Achievability of 2030 sustainable development goals in breast cancer control

Gizem Sultan Nemutlu<sup>1</sup>, Ethan Thayumanavan<sup>2</sup>, Barri Blauvelt<sup>2</sup> and Jagpreet Chhatwal<sup>1</sup>. <sup>1</sup>Harvard Medical School-MGH, Boston, MA; <sup>2</sup>Innovara, Hadley, MA

### **Background**

The United Nations Sustainable Development Goals (SDGs) target a one-third reduction in non-communicable disease (NCD) mortality between the years 2015 and 2030. Cancer accounts for 22% of NCD deaths, and breast cancer is the leading global cause of female cancer mortality, despite its high survivability. Therefore, reducing female breast cancer mortality is critical to any nation's achievement of this goal. However, sex-based disparities in healthcare are evident in lower-resource settings, and lack of infrastructure for breast cancer control leads to greater underdiagnosis in low- and lower middle-income countries (LICs & LMICs). Mortality may be a biased indicator due to the impact of differing incidence rates. Therefore, the mortality-to-incidence ratio (MIR) was examined as a practical indicator of breast cancer control. We projected mortality and MIR for women with breast cancer in 195 countries to quantify progress in breast cancer control and assess the feasibility of achieving the 2030 NCD mortality target of the SDGs.

### **Methods**

We used data on incidence and mortality rates for female breast cancer reported by The Global Burden of Disease Study 2017 for the years between 2000-2017. For each country, we projected mortality rate and MIR for female breast cancer by national income level from 2018-2030 using generalized linear mixed-effects models. We stratified our results by country's Gross National Income per Capita (GNI/capita) and income group as defined by the World Bank.

### **Findings**

Between 2017 and 2030, global breast cancer mortality is projected to increase by 12.4% from 19.02 (95% confidence interval [CI]: 17.36-20.64) to 21.38 (95% prediction interval [PI]: 19.03-23.93), while MIR is projected to decrease by 10.3% from 0.404 (95% CI: 0.385-0.425) to 0.362 (95% PI: 0.342-0.383). In 2017, MIR was 2.22 times higher in low-income countries (LICs) and 1.71 times higher in lower-middle income countries (LMICs) than in high income countries (HICs). Although MIR is projected to decrease between 2017 and 2030 across all income groups (15.9% in HICs, 10.61% in UMICs, 3.66% in LMICs, 10.2% in LICs), 2030 MIR is projected to be 2.37 times higher in LICs and 1.96 times higher in LMICs when compared to HICs.

### **Interpretation**

Use of mortality to measure progress towards SDGs can be misleading in the context of breast cancer control. Simultaneously increasing mortality and incidence may still imply improvement, if mortality is increasing at a slower rate than incidence. Therefore, MIR is a better indicator of progress in breast cancer control. The decreasing global breast cancer MIR from 2015 to 2030, despite increasing mortality, indicates that global progress is being made in breast cancer. Despite globally decreasing MIR, the disparity between HICs and LICs may increase between now and 2030 in the absence of significant resource-stratified policy reform.

Next generation sequencing (NGS) in older adults with breast cancer using tissue-based and circulating tumor DNA (ctDNA) assays

Katherine K Clifton<sup>1</sup>, Jingqin Luo<sup>1</sup>, Yu Tao<sup>1</sup>, Jennifer Saam<sup>2</sup>, Thereasa Rich<sup>1</sup>, Timothy Rearden<sup>1</sup>, Anna Roshal<sup>1</sup>, Ashley Frith<sup>1</sup>, Caron Rigden<sup>1</sup>, Foluso Ademuyiwa<sup>1</sup>, Katherine Weilbaeher<sup>1</sup>, Leonel Hernandez Aya<sup>1</sup>, Lindsay Peterson<sup>1</sup>, Nusayba Bagegni<sup>1</sup>, Rama Suresh<sup>1</sup>, Ron Bose<sup>1</sup>, Tanya Wildes<sup>1</sup>, Mateusz Opyrchal<sup>1</sup> and Cynthia Ma<sup>1</sup>. <sup>1</sup>Washington University in Saint Louis, Saint Louis, MO; <sup>2</sup>Guardant Health, Redwood City, CA

**Background:** With advances in next generation sequencing (NGS) and now approved targeted therapy in breast cancer, genomic testing to identify potentially actionable mutations has become a common practice in patients (pts) with advanced breast cancer using both ctDNA and traditional tissue-based assays. Less is known regarding physician practice patterns in obtaining NGS testing and the practical implications of testing in older adults with breast cancer. **Methods:** Pts with advanced breast cancer underwent molecular profiling using a plasma-based ctDNA NGS assay (Guardant360® or Tempus®) between 5/2015 and 5/2020 at Siteman Cancer Center. Pts with advanced breast cancer who underwent genomic profiling using a tissue-based NGS assay (Tempus®) between 12/2017 and 5/2020 at this institution were also included. Clinicopathological histories were obtained from the medical record. Correlations were examined using a Fisher's exact test. **Results:** During 5/15-5/20, 244 pts underwent ctDNA testing and 147 pts had a tissue-based NGS assay performed. There was no significant difference between the number of pts ≥ 65 years-old who underwent ctDNA testing (n=78, 32.0%) and tissue testing (n=37, 25.2%). There was no statistically significant difference between date of metastatic diagnosis and date of NGS testing between the older and younger cohorts. In pts who underwent tissue-based NGS testing, there was no significant difference between site of tissue tested (distant recurrence vs local) in the older and younger cohorts. The most common clinical managements following both ctDNA and tissue-based testing are presented in Table 1. Out of the 391 pts who underwent testing, 27 pts had both ctDNA and tissue-based NGS performed. Pts ≥ 65 were less likely to have both assays performed (n=3, 11.1%; p<0.05). In pts undergoing both assays, there were high concordance rates of *ESR1* (81.5%) and *PIK3CA* (81.5%) mutations. Mean time between tissue and plasma collection for NGS testing in pts undergoing both assays was 356.4 days.

Table 1

clinical management following NGS testing	≥65 years-old	<65 years-old	p value
no actionable mutations	41 (35.7%)	123 (44.6%)	p=0.1
testing results saved for potential future use	27 (23.5%)	45 (16.3%)	p=0.1
change in management	15 (13.0%)	41 (14.9%)	p=0.6

**Conclusion:** Older adults, who are typically less likely to be included in clinical trials, may still benefit from NGS to reveal potentially targetable mutations. It is reassuring in our cohort that older adults had ctDNA and tissue-based NGS performed at similar rates as part of standard of care treatment. The clinical management following NGS testing was also not significantly different in the older adult cohort. Older adults were less likely to have both tissue and ctDNA testing performed however, given the high concordance rates between tests, this may be less clinically relevant.

Chemotherapy-induced nausea and vomiting (CINV) risk after prior breakthrough CINV: Unmasking the false average

Rudolph M Navari<sup>1</sup>, Gary Binder<sup>2</sup>, Alexander Molassiotis<sup>3</sup>, Eric Roeland<sup>4</sup>, Kathryn J. Ruddy<sup>5</sup>, Thomas W. LeBlanc<sup>6</sup>, Dwight D. Kloth<sup>7</sup>, Silvia Sebastiani<sup>8</sup>, Lina Y. Dimberg<sup>2</sup>, Luke M. Schmerold<sup>9</sup>, Xing Liu<sup>9</sup> and Lee Schwartzberg<sup>10</sup>. <sup>1</sup>World Health Organization, Cancer Care Program, Atlanta, GA; <sup>2</sup>Helsinn Therapeutics US, Inc., Iselin, NJ; <sup>3</sup>School of Nursing, The Hong Kong Polytechnic University, Hung Hom, Hong Kong; <sup>4</sup>Massachusetts General Hospital Cancer Center, Boston, MA; <sup>5</sup>Mayo Clinic, Rochester, MN; <sup>6</sup>Duke University School of Medicine; Duke Cancer Institute, Durham, NC; <sup>7</sup>Fox Chase Cancer Center, Philadelphia, PA; <sup>8</sup>Helsinn Healthcare SA, Lugano, Switzerland; <sup>9</sup>SmartAnalyst, Inc., New York, NY; <sup>10</sup>Division of Hematology/Oncology, University of Tennessee Health Sciences Center and West Cancer Center, Germantown, TN

**Background:** Although many studies have demonstrated consistent levels of effectiveness of CINV prophylaxis for the entire study population across multiple chemotherapy cycles, rarely have studies reported how each patient's risk of subsequent CINV differs based on prior cycle breakthrough CINV with the same prophylaxis. We lack data on whether prophylaxis continues to fail in the same group of patients each cycle, or whether failure is random with each subsequent cycle. We sought to evaluate individual patients' risk of repeat CINV in each subsequent chemotherapy cycle. **Methods:** In a prospective, 4-cycle CINV prophylaxis trial of oral or intravenous combination netupitant/palonosetron (NEPA) + dexamethasone (day 1) for patients with breast cancer receiving anthracycline + cyclophosphamide (AC), we defined CINV as vomiting or use of rescue medication during days 1-5 after chemotherapy. Patients without CINV were classified as complete response (CR); the rest as treatment failure (TF). We analyzed patients' sequences of CR and TF, and compared CR or TF for cycles 2-4 based on cycle 1 outcomes, using chi-square statistics. To provide context, we performed a post-hoc similar analysis of results reported by Herrstedt et al [2005] from a clinical trial of ondansetron + aprepitant (APR) for patients with breast cancer receiving 4 cycles of AC. **Results:** The 402 female patients in the NEPA trial received a total of 1,299 cycles. In cycle 1, 99 (24.6%) patients experienced TF (TF1); over all 4 cycles, TF occurred 253 times (19.5%). Patients with CR in cycle 1 (CR1) had a ≥92% rate of CR in cycle 2; their rates of repeat CR were similar in each subsequent cycle. Patients with TF1 had nearly equal risk of CR or TF in cycle 2 (45:55); thereafter 85% of this TF1 subgroup repeated their cycle 2 outcome (CR or TF) in cycles 3 and 4. Over all cycles of NEPA, patients with CR1 subsequently had CR in >90% of cycles 2-4; those with TF1 subsequently had TF in 49.8% of cycles 2-4 ( $p < 0.0001$ ) (see Table). We separately examined Herrstedt's evaluation of 433 patients across 1537 cycles with APR. In cycle 1, TF was seen 213 times (49.2%), with TF reported in 46.7% of cycles 1-4. We found that patients with CR1 had an 80.5% rate of CR in cycle 2 and repeat CR rates were higher in subsequent cycles. Patients with TF1 had TF in cycle 2 (TF2) at a rate of 78.4%, with 76.6% TF3 and 72.7% TF4. For APR, CR1 resulted in subsequent CR in 78.6% of cycles 2-4 while patients with TF1 again had TF in 74.8% of cycles 2-4 ( $p < 0.0001$ ). Patients with TF1 were more likely to later drop from the study (see Table). Notably, among those with CR1 after APR, the few patients who later had TF in any cycle, had a subsequent repeat failure rate similar to those with TF1. **Conclusions:** When patients receiving guideline-recommended triple antiemetic prophylaxis successfully avoided CINV in their first cycle of HEC, they had 80-95% likelihood of repeating that success in later cycles. After NEPA, those whose prophylaxis failed in cycle 1 did not face a similar high risk of repeat failure in cycle 2. The pattern of repeat failure after aprepitant was different, with a high repeat failure risk starting in cycle 2. These findings strongly suggest that consistent population average CR rates reported across cycles may mask a higher repeat failure rate for individual patients that experience cycle 1 CINV, particularly for aprepitant. Further study of this phenomenon is needed for other HEC regimens, and to confirm the lack of high repeat failure seen in cycle 2 for NEPA.

Repeat CINV in Later Cycles, Based on Cycle 1 Results

	NEPA			Aprepitant + Ondansetron		
Initial Cycle Result (n/total initial cycles)	CR1 (303/402)	TF1 (99/402)	CR1 vs TF1 (P value)	CR1 (220/433)	TF1 (213/433)	CR1 vs TF1 (P value)
Subsequent CR cycles (n, % of total subseq. cycles)	636 (93.0%)	107 (50.2%)	<0.0001	464 (78.6%)	124 (25.2%)	<0.0001
Subsequent TF cycles (n, % of total subseq. cycles)	48 (7.0%)	106 (49.8%)		126 (21.4%)	370 (74.8%)	
Total subsequent cycles (n, % of total subseq. cycles)	684 (100%)	213 (100%)		590 (100%)	494 (100%)	
Dropped vs ITT* (n, % ITT cycles)	225 (24.8%)	84 (28.3%)	0.2263	70 (10.6%)	145 (22.7%)	<0.0001

\* The NEPA trial was closed when the last patient completed the first cycle, resulting in an artificially high proportion of patients that did not complete 4 cycles.

Development and validation of a tool integrating the 21-gene recurrence score and clinicopathologic features to individualize prognosis for distant recurrence and prediction of absolute chemotherapy benefit in early breast cancer

Joseph A Sparano<sup>1</sup>, Michael R Crager<sup>2</sup>, Gong Tang<sup>3</sup>, Robert J Gray<sup>4</sup>, Salomon M Stemmer<sup>5</sup> and Steve Shak<sup>2</sup>. <sup>1</sup>Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY; <sup>2</sup>Exact Sciences, Redwood City, CA; <sup>3</sup>University of Pittsburgh, NRG Statistics and Data Management Center, Pittsburgh, PA; <sup>4</sup>ECOG-ACRIN Statistical Center, Dana Farber Cancer Institute, Boston, MA; <sup>5</sup>Davidoff Center, Rabin Medical Center, Sackler Faculty of Medicine, Tel Aviv, Israel, Israel

**Background:** The 21-gene recurrence score (RS) provides prognostic information for distant recurrence (DR) and predictive information for chemotherapy (CT) benefit in early breast cancer, whereas clinicopathologic features provide only prognostic information. We used patient-specific meta-analysis (PSMA) methods (Crager et al, J Appl Stat 2014 [PMID: 26664111]; Tang et al. J Clin Oncol 2011 [PMID: 22010013]) to develop an online tool that assesses individualized estimates of DR risk and absolute CT benefit. We also externally validated this new tool for estimating DR risk in an independent cohort. **Methods:** The PSMA included 10,004 women with hormone-receptor positive, HER2-negative, node-negative breast cancer from the NSABP B-14 (n=577) trial receiving endocrine therapy (ET) alone and TAILORx trial receiving ET alone (n=4854) or CT plus ET (n=4573). The baseline risk used TAILORx event rates with ET alone. A patient-specific estimator of absolute CT benefit was computed by combining PSMA of the individualized relative CT effect from the TAILORx and NSABP B-20 (n=550 HER2-negative) trials and risk estimates with ET alone. External validation of DR risk estimation was performed in an independent cohort of 1098 women enrolled in the Clalit Health Service registry who had a 21-gene RS performed, of whom 222 (20%) received CT in addition to ET as per the recommendation of their treating physician guided by the RS. **Results:** The new tool is more informative for DR risk than RS or clinicopathologic factors alone (p<0.001, likelihood ratio test). The risk estimate was significantly associated with DR risk in the independent Clalit cohort (p<0.001), and closely approximated the observed 10-year DR risk (Lin concordance 0.962). Since the RS strongly influenced CT use, propensity score matching could not appropriately be used for evaluation of CT benefit in Clalit. Using this tool for a 55-year-old woman with a low clinical risk 1.5 cm intermediate grade tumor, the absolute CT benefit estimate ranges from 0% to 15% as RS ranges from 11 to 50; this compares to a range of 2% to 8% if the relative CT benefit were held constant. Over the same RS range for a 55-year-old woman with high clinical risk 2.5 cm poor grade tumor, the tool's absolute CT benefit estimate ranges from 1% to 33% compared to 4% to 17% if the relative CT benefit were held constant. This indicates that incremental CT benefit observed with higher RS is driven not only by a higher underlying recurrence risk, but also by prediction of relative CT benefit. **Conclusions:** We describe a validated clinical tool integrating clinicopathologic and genomic features to guide adjuvant chemotherapy of hormone-receptor positive, HER2-negative, axillary node-negative breast cancer with greater precision than using clinicopathologic or genomic data alone. The individualized CT effect prediction provided by the RS, based on contemporary treatments, contributes substantially to the estimate of absolute CT benefit. **Support:** This study was conducted by the ECOG-ACRIN Cancer Research Group (Peter J. O'Dwyer, MD and Mitchell D. Schnall, MD, PhD, Group Co-Chairs) and supported by the National Cancer Institute of the National Institutes of Health under the following award numbers: U10CA180794, U10CA180820, U10CA180822, U10CA180868, and UG1CA189859. **Background:** Germline pathogenic variants (PVs) in the moderate penetrance *ATM* gene confer a roughly 2-fold increased risk for breast cancer. Currently, any woman with an *ATM* PV meets the >20% lifetime risk threshold for consideration of relatively aggressive screening recommendations, which include initiating screening at younger ages and consideration of breast MRI. We and others have previously shown that breast cancer risks for women with inherited PVs in many hereditary breast cancer genes can be adjusted using PRS data, breast cancer family history, and other clinical information. Herein we show the development of a comprehensive breast cancer risk model for *ATM* PV carriers incorporating a previously described 86-variant PRS along with family history/clinical information captured by Tyrer-Cuzick V7.02. **Methods:** This IRB-approved study included de-identified clinical records from 353,809 women of European ancestry who were tested clinically for hereditary cancer risk with a multi-gene panel. Model development analyzed *ATM* PV carriers ( $N=2,666$ ) and women negative for breast cancer gene PVs ( $N=351,143$ ) who were tested between September 2013 and November 2019 (July 2019 for non-carriers). Women with the unusually high risk *ATM* c.7271 allele were excluded from analysis. Risk estimates incorporating *ATM*, PRS, and Tyrer-Cuzick were calculated using a fixed-stratified method that accounted for correlations between risk factors in a manner equivalent to multivariable co-estimation. Risk stratification was assessed in an independent cohort of *ATM* carriers ( $N=272$ ) who were tested after November 2019 and were not included in model development. **Results:** We detected significant positive correlation of *ATM* status with breast cancer family history ( $p=1.6 \times 10^{-7}$ ). Within *ATM* PV carriers, we observed positive yet non-significant (at  $\alpha < 0.05$ ) correlation between PRS and breast cancer family history ( $p=0.10$ ); joint effects were co-estimated using the fixed-stratified method. After adjusting for multiple testing, we found no evidence of interaction of *ATM* status with clinical factors, or PRS with clinical factors within *ATM* carriers. In an independent cohort, 30.1% of *ATM* carriers were categorized as having low breast cancer risk (<20%), 58.5% as moderate risk (20-50%), and 11.4% as high risk (>50%). **Conclusions:** In *ATM* PV carriers, our comprehensive model allowed for differentiation of *ATM* PV carriers into low, moderate, and high breast cancer risk categories. Precision breast cancer risk estimation may inform individualized clinical screening and prevention strategies.

The impact of non-classic LCIS on the natural history of DCIS

Faina Nakhli<sup>1</sup>, Fisher Katlin<sup>1</sup>, Samantha Grossmith<sup>1</sup>, Ashley DiPasquale<sup>1</sup>, Beth Harrison<sup>2</sup> and Tari King<sup>1</sup>. <sup>1</sup>Dana-Farber Cancer Institute/Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Brigham and Women's Hospital, Boston, MA

**Background:** Classic lobular carcinoma in situ (C-LCIS) and non-classic LCIS (NC-LCIS) are histologically and biologically distinct types of lobular neoplasia. Little is known about the impact of NC-LCIS on risk of recurrence when found in association with concomitant malignancy. We sought to assess oncologic outcomes in patients with DCIS and concomitant NC-LCIS as compared to DCIS with concomitant C-LCIS treated with breast conservation.

**Methods:** Upon IRB approval, an institutional database was accessed to identify patients with a diagnosis of C-LCIS + DCIS or NC-LCIS+DCIS in the same core biopsy and/or excisional biopsy specimen. All pathology slides relevant to the diagnosis were confirmed by internal review. Patients with prior or concurrent ipsilateral invasive breast cancer and/or prior ipsilateral DCIS were excluded. Use of adjuvant therapies and the incidence of ipsilateral and contralateral DCIS and invasive breast cancer were compared in the 2 groups. Statistical analysis was performed using the chi-square test.

**Results:** Among patients diagnosed with DCIS between 1996 and 2015 and treated with breast conserving surgery, 69 also had C-LCIS and 13 also had NC-LCIS (the diagnosis of NC-LCIS was not encountered until 2000). Median patient age was 55 years (range 40-88), 42 (51%) had a family history of breast cancer and 5 (6%) had a prior diagnosis of atypical proliferative breast lesions; these factors did not differ between patients with C-LCIS+DCIS and NC-LCIS+DCIS. Patients with NC-LCIS+DCIS were more likely to present with mammographic distortion (25% vs 6%,  $p=0.03$ ), to have been diagnosed by core biopsy, and less likely to have ER positive (67% vs 91%,  $p=0.03$ ) or PR positive (50% vs 78%,  $p=0.014$ ) DCIS. In 78% of the patient cohort, final excision margins were negative, and these proportions were not different between the 2 groups. The median number of surgeries performed to obtain clear surgical margins which was 2 (range 1-4) for the entire cohort and for C-LCIS+DCIS and NC-LCIS+DCIS, individually. 78% of C-LCIS+DCIS patients and 54% of NC-LCIS+DCIS patients received adjuvant radiation ( $p=0.064$ ), and 45% of C-LCIS+DCIS patients took adjuvant hormonal therapy, while none of the NC-LCIS+DCIS patients did ( $p=0.002$ ). At median follow-up of 78 (1-260) months for C-LCIS+DCIS and 60 (1-197) months for NC-LCIS+DCIS, there were no differences observed in the incidence of ipsilateral and contralateral breast cancer (10.1% vs 7.7%,  $p=0.19$ , and 10.1% vs 0%, respectively,  $p=0.78$ ). One of 13 patients (7.7%) with NC-LCIS+DCIS, who developed an ipsilateral invasive carcinoma, was subsequently diagnosed with bone metastasis.

**Conclusions:** Patients with NC-LCIS+DCIS were more likely to have ER and/or PR negative DCIS and only 54% of this cohort received radiation, yet local-regional recurrence rates were low and not different between NC-LCIS +DCIS and C-LCIS+DCIS patients. Despite the more aggressive histologic features of NC-LCIS, these data do not suggest that NC-LCIS associated with DCIS portends a different prognosis that C-LCIS associated with DCIS. Larger studies are needed to confirm these findings.

## Partitioning of cancer therapeutics in nuclear condensates

Isaac Klein<sup>1</sup>, Ann Boija<sup>2</sup>, Lena Afeyan<sup>2</sup>, Susana Wilson Hawken<sup>2</sup>, Mengyang Fan<sup>1</sup>, Alessandra Dall'Agnese<sup>2</sup>, Ozgur Oksuz<sup>2</sup>, Jonathan Henninger<sup>2</sup>, Krishna Shrinivas<sup>3</sup>, Benjamin Sabari<sup>2</sup>, Ido Sagi<sup>2</sup>, Victoria Clark<sup>4</sup>, Jesse Platt<sup>4</sup>, Mrityunjay Kar<sup>5</sup>, Patrick McCall<sup>5</sup>, Alicia Zamudio<sup>2</sup>, John Mantiega<sup>2</sup>, Eliot Coffey<sup>2</sup>, Charles Li<sup>2</sup>, Nancy Hannett<sup>2</sup>, Yang Guo<sup>2</sup>, Tim-Michael Decker<sup>6</sup>, Tong Lee<sup>2</sup>, Tinghu Zhang<sup>1</sup>, Jing-Ke Weng<sup>2</sup>, Dylan Taatjes<sup>6</sup>, Arup Chakraborty<sup>3</sup>, Phillip Sharp<sup>3</sup>, Young Tae Chang<sup>7</sup>, Anthony Hyman<sup>5</sup>, Nathanael Gray<sup>1</sup> and Richard Young<sup>2</sup>. <sup>1</sup>Dana Farber Cancer Institute, Boston, MA; <sup>2</sup>Whitehead Institute, Cambridge, MA; <sup>3</sup>Massachusetts Institute of Technology, Cambridge, MA; <sup>4</sup>Massachusetts General Hospital, Boston, MA; <sup>5</sup>Max Plank Institute, Dresden, Germany; <sup>6</sup>University of Colorado, Boulder, CO; <sup>7</sup>POSTECH, Pohang, Korea, Republic of

The molecules of the cell are compartmentalized into membrane- and non-membrane-bound organelles. Many non-membrane-bound organelles are phase-separated biomolecular condensates with distinct physicochemical properties that can absorb and concentrate specific proteins and nucleic acids involved in discrete biochemical processes. We reasoned that selective condensate partitioning might also occur with small molecule drugs whose targets occur within condensates, and that the therapeutic index and efficacy of such compounds might therefore relate to their ability to partition into condensates. To test this idea, we focused our study on nuclear condensates reported in cell lines, demonstrated they occur in normal human and malignant breast cancer, and developed assays to test clinically active antineoplastic small molecule drugs relative to these condensates. To study the behavior of drugs within condensates, these were modeled in vitro with purified proteins and visualized by fluorescent confocal microscopy. We found that cisplatin, tamoxifen, JQ1, THZ1, and mitoxantrone are concentrated in specific protein condensates in vitro, and that this occurs through physicochemical properties independent of the drug target. For each drug, the small molecule partitioned into the same condensate in vitro in which its established target resides in vivo. A screen of a chemically diverse fluorescent probes and mutant-protein condensates demonstrated that pi-system interactions between aromatic moieties in the protein and small molecule govern concentration in condensates. These results show that clinically important drugs partition into specific protein condensates in vitro by virtue of defined chemical properties, thereby altering their local concentration. Alkylating agents are a class of commonly used antineoplastic compounds, of which cisplatin is a prominent example. In vitro droplet assays revealed that cisplatin is selectively concentrated in transcriptional condensates, and that this ability is required for efficient platination of target DNA. In cell studies revealed that cisplatin preferentially targets DNA contained within MED1 condensates, and disrupts the genetic regulatory elements that compose phase-separated transcriptional condensates. Live cell imaging demonstrated that transcriptional condensates are dissolved by cisplatin, whereas other condensates remain intact. Thus, we conclude that cisplatin preferentially modifies transcriptional condensate-associated DNA in cells, and that this causes selective condensate disruption. The mechanisms that produce drug resistance can provide clues to drug activity in the clinical setting. Investigating the behavior of tamoxifen within ER transcriptional condensates demonstrated that it disrupts these condensates in vitro and on oncogenes in cells; hormonal therapy resistant ESR1 mutations render these condensates resistant. MED1 overexpression, a poorly understood mechanism of tamoxifen resistance, increased the size of ER-MED1 condensates, thereby rendering tamoxifen more dilute and ineffective when concentrated therein. This suggest that altering the size and nature of transcription condensates in breast cancer can mediate drug resistance in the clinical setting. Our results show that antineoplastic drugs partition selectively into condensates, that this can occur through physicochemical properties independent of their molecular targets, and that resistance to drugs may occur through condensate altering mechanisms. These results have implications for development of efficacious cancer therapeutics; effective target engagement will depend on factors such as drug partitioning in condensates. Assays of the type described here may thus help optimize condensate partitioning, target engagement, and the therapeutic index of drugs for cancer treatment.

Pre-operative pembrolizumab (Pembro) with radiation therapy (RT) in patients with operable triple-negative breast cancer (TNBC)

Heather McArthur<sup>1</sup>, Stephen Shiao<sup>1</sup>, Scott Karlan<sup>1</sup>, Reva Basho<sup>1</sup>, Farin Amersi<sup>1</sup>, Brittany Arnold<sup>2</sup>, Michele Burnison<sup>1</sup>, Alice Chung<sup>1</sup>, Cathie Chung<sup>3</sup>, Catherine Dang<sup>1</sup>, Armando Giuliano<sup>1</sup>, Nimmi Kapoor<sup>1</sup>, Negin Habibi Khameneh<sup>1</sup>, Simon Knott<sup>1</sup>, Cynthia Martin<sup>1</sup>, Philomena McAndrew<sup>1</sup>, Monica Mita<sup>1</sup>, Dorothy Park<sup>1</sup>, Christina DiLauro Abaya<sup>1</sup> and Alice Ho<sup>2</sup>. <sup>1</sup>Cedars-Sinai Medical Center, Los Angeles, CA; <sup>2</sup>MGH, Boston, MA; <sup>3</sup>The Angeles Clinic, Los Angeles, CA

**Background:** Pembrolizumab (pembro)-mediated checkpoint blockade has shown only modest efficacy in triple negative breast cancer (TNBC). Pathologic complete response (pCR) rates in TNBC are 34-55% with neoadjuvant chemotherapy and 26% with neoadjuvant stereotactic radiation therapy (RT) alone. However, because RT induces immune-mediated cell death that can generate a rich supply of tumor antigens and trigger anti-tumor immunity, the addition of pembro to RT can generate robust anti-tumor immune responses as demonstrated in metastatic TNBC. If administered in the pre-operative setting, immune therapy plus RT could induce long-term tumor-specific memory, and ultimately, improve cure rates. This study aimed to establish the safety of pre-operative pembro plus RT in 20 TNBC patients for whom lumpectomy and adjuvant RT were planned and to explore predictive biomarkers (NCT03366844).

**Methods:** Women planning breast conserving surgery for operable, stage II/III, TNBC were enrolled in this single-institution pilot study. Study treatment consisted of pre-operative pembro (200mg IV) followed 3 weeks later by pembro (200mg IV) plus RT (24 Gy/3 fractions) to the primary breast tumor followed 3-5 weeks later by standard-of-care (SOC) neoadjuvant chemotherapy. Adjuvant RT was administered per SOC after surgery, but without a boost dose. Research blood and tumor biopsies were obtained at baseline, at week 4 prior to pembro/RT, and at week 6-8 prior to chemotherapy initiation. Co-primary endpoints were: safety/tolerability (defined by the number of patients who do not necessitate a delay in SOC chemotherapy or surgery) and change in tumor infiltrating lymphocyte (TIL) score. Secondary endpoints include safety/toxicity up to 19 weeks after study enrollment and pathologic complete response (pCR) rate.

**Results:** 20 patients were enrolled and completed all treatment (pembro, RT, chemotherapy and surgery) as of July 2020. The median age is 55y (range 33-70y). The stage distribution is IIA (11), IIB (6), IIIA (2) and IIIC (1) with biopsy proven nodal involvement in 55%. All patients received a taxane containing regimen, 12/20 (60%) received carboplatin and 15/20 (75%) received an anthracycline. Three patients did not complete the planned course of chemotherapy, two of whom had residual disease. None of the patients experienced significant delay (>2 weeks) in receiving SOC treatment. There were no observed grade 3 or 4 toxicities observed during the pembro +/- RT treatment. Grade 4 colitis in 2/20 was reported during SOC chemotherapy and was attributed to pembro. The most frequent grade 1/2 toxicities were nausea (4/20), arthralgia (15/20), fatigue (16/20), maculopapular rash (1/20), diarrhea (1/20) and mucositis (1/20). At the time of surgery, 12/20 (60%) were ypT0N0 and 13/20 (65%) were ypT0Tis. 15/20 (75%) achieved an RCB 0/1, 4/20 (20%) were RCB 2 and 1/20 (5%) was RCB 3. Of the 11 patients with node-positive disease at diagnosis, 9/11 (82%) became ypN0, 1/11 (9%) became ypN1mic and 1/11 (9%) became ypN1a. No patients progressed during treatment. Change in TILs after pembro or pembro-RT did not correlate with treatment response, however baseline TIL count ≥10% in the initial biopsy was associated with pCR (p = 0.005). Further profiling of the immune cells in the biopsies revealed that RCB 0/1 patients were strongly associated with increased numbers of CD8+ T cells and lower numbers of CD11b+ myeloid cells following the combination of pembro and RT.

**Conclusions:** Neoadjuvant pembro plus RT prior to SOC chemotherapy is safe/feasible and may increase pCR rates and clearance of nodal metastases beyond chemotherapy alone. A phase 2 study of checkpoint blockade + RT expansion of this trial (n=50) is currently accruing.

Real-world analysis of concomitant medication use with potential drug-drug interactions (DDI) in patients with metastatic breast cancer (MBC) treated with cyclin dependent kinase (CDK) 4/6 inhibitors

Hope S. Rugo<sup>1</sup>, Sanjeev Balu<sup>2</sup>, Yunfeng Li<sup>2</sup>, Guifang Chen<sup>3</sup>, Xin Li<sup>3</sup>, Stuart Turner<sup>2</sup> and Roxana Sin<sup>2</sup>. <sup>1</sup>University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA; <sup>2</sup>Novartis Pharmaceuticals, East Hanover, NJ; <sup>3</sup>KMK Consulting Inc., Morristown, NJ

**Background:** In combination with endocrine therapy, the CDK4/6 inhibitors (CDK4/6i) ribociclib, palbociclib, and abemaciclib have improved progression free survival and in some cases overall survival in women with hormone receptor positive (HR+)/HER2 negative MBC. Use of concomitant medications and the potential for drug-drug interactions (DDI) is an important issue in clinical oncology, particularly among patients with MBC treated for long durations of time with CDK4/6i, and could lead to sub-optimal medication adherence or subsequent dose reductions/discontinuations.

**Objective:** To describe concomitant medication use that could lead to DDI with CDK4/6i as well as CDK4/6i dosing, adherence, and discontinuation patterns in real-world clinical practice. **Methods:** Adult women with HR+/HER2- MBC initiating treatment with ribociclib, palbociclib, or abemaciclib as the first CDK4/6i (index therapy) were retrospectively identified from the Optum Clinformatics Data Mart (1/1/2017 - 9/30/2019), a large US healthcare claims database. Eligibility included 3 months of baseline (pre-index date) and at least 3 months of follow-up (post-index date) data. Concomitant medications (identified from the literature) evaluated at baseline included CYP3A inhibitors and inducers, P-glycoprotein (P-gp) inhibitors and inducers, and medications associated with risk of torsades de pointes (TdP). Treatment persistence was analyzed using Kaplan-Meier (KM) as time from index date to discontinuation, defined as an interruption of at least 90 consecutive days of the index treatment or end of patient enrollment or switch to another medication. Adherence was measured by proportion of days covered (PDC), using the recommended administration schedule of 21 days of treatment followed by 7 days off. **Results:** A total of 2,994 women were included: 184 initiated ribociclib as first CDK4/6i; 2,550 palbociclib; and 260 abemaciclib. Median duration of follow-up was 13.7 [Interquartile range (IQR)] 11.8; 13.1 (IQR 13.5); and 9.3 (IQR 9.2) months. The majority in each cohort were postmenopausal (ribociclib: 89.1%; palbociclib: 92.8%; abemaciclib: 90%) and received the index CDK4/6i as > 2nd line of therapy (ribociclib: 81.5%; palbociclib: 87.6%; abemaciclib: 88.9%). Mean age (66.4; 66.8; and 65.3 yrs) and National Cancer Institute comorbidity index [mean/SD: 1.2 (1.6); 1.2 (1.7); 1.1 (1.6)] were similar for the ribociclib, palbociclib, and abemaciclib cohorts, respectively. Patients with ≥ one concomitant medication (60.3%; 64.2%; 65.8%) and those with > one medication associated with TdP (57.1%; 59.4%; 61.9%) were similar for the 3 cohorts. The CDK4/6i discontinuation rates, starting dose, dose reduction, and adherence results are listed below (Table). **Conclusions:** Use of concomitant medications that could lead to a DDI with a CDK4/6i, especially those with risk of TdP, CDK4/6i treatment discontinuation, and adherence was similar between ribociclib, palbociclib, and abemaciclib in this real-world retrospective descriptive study. More patients in the ribociclib cohort maintained starting dose and less decreased to <50% of the starting dose compared to palbociclib and abemaciclib, although the cohort is small. Results are limited by the relatively smaller number in the ribociclib and abemaciclib cohorts.

Descriptive analysis on characteristics in follow up period by index drug group

	Ribociclib (N = 184)	Palbociclib (N = 2550)	Abemaciclib (N = 260)
Discontinuation of Index Treatment, n (%)	96 (52.2)	1266 (49.7)	123 (47.3)
Starting dose, mean (SD)	532.6 (141.1)	118.5 (13.4)	287.7 (56.6)
Patients with first time dose change			
No change during the entire follow up period, n (%)	148 (80.4)	1740 (68.2)	176 (67.7)
Decrease > 50%, n (%)	7 (3.8)	0 (0)	5 (1.9)
Decrease ≤ 50%, n (%)	20 (10.9)	773 (30.3)	68 (26.2)
Adherence (PDC), mean (SD)	0.85 (0.2)	0.87 (0.2)	0.87 (0.2)

Breast cancer index is a molecular signature of endocrine responsiveness that determines extended endocrine benefit independent of prognostic risk

Gerrit-Jan Liefers<sup>1</sup>, Iris Noordhoek<sup>1</sup>, Kai Treuner<sup>2</sup>, Hein Putter<sup>1</sup>, Yi Zhang<sup>2</sup>, Jenna Wong<sup>2</sup>, Elma Meershoek-Klein Kranenbarg<sup>1</sup>, Marjolijn Duijm-de Carpentier<sup>1</sup>, Cornelis JH Van De Velde<sup>1</sup> and Catherine A Schnabel<sup>2</sup>. <sup>1</sup>Leiden University Medical Center, Leiden, Netherlands<sup>2</sup>Biotheranostics, Inc., San Diego, CA

**Background:** For patients with early stage, hormone receptor positive (HR+) breast cancer, extension of endocrine therapy beyond 5 years reduces the ongoing risk of late distant recurrence and new primary breast cancer but is associated with potentially serious toxicities and side effects that can impair quality of life. While risk stratification by clinicopathological factors and prognostic biomarkers is recommended to guide patient selection, predictive biomarkers that are directly informative of therapeutic response are critical for clinical utility. Breast Cancer Index (BCI) is a gene expression-based signature that reports: 1) BCI Prognostic (BCI Score), which combines the Molecular Grade Index (MGI) with the HOXB13/IL17BR (H/I) ratio to provide individualized risk of late (post-5y) distant recurrence, and 2) BCI Predictive (BCI H/I), which predicts benefit from extended endocrine therapy. In this study, BCI and endocrine benefit from 5 vs 2.5y of extended letrozole were examined by comparing the deterministic effects of prognostic risk vs endocrine response in patients treated in the IDEAL trial. **Methods:** 908 patients with available tumor tissue were included in this pre-specified and blinded analysis, with recurrence-free interval (RFI) as the primary endpoint. Kaplan-Meier and Cox proportional hazards regression were performed using pre-defined assay cut-points. Clinically high prognostic risk was defined as pN+ and ≥pT2; low prognostic risk was defined as pN0 or pN1 and pT1 or G1. Genomic risk was defined by BCI prognostic categories (High vs Low risk). **Results:** Patients classified with endocrine responsive disease by BCI (H/I)-High status showed a statistically significant benefit from 5 vs 2.5y of letrozole irrespective of clinical risk, whereas those classified as BCI (H/I)-Low did not show benefit in either clinical risk category. Both clinically High and Low risk patients derived a similar magnitude of benefit when stratified as BCI (H/I)-High (12.5% and 15.1%, respectively).

Prognostic Risk	BCI Predictive	N	HR (95% CI)	P value
<b>Clinical Risk</b>				
High Risk: N+ / T2+ (N=353)	High BCI(H/I)	162	0.32 (0.10-0.98)	0.035
	Low BCI(H/I)	191	1.13 (0.55-2.31)	0.742
Low Risk: N0 or N1 & T1 or grade 1 (N=404)	High BCI(H/I)	191	0.15 (0.03-0.66)	0.004
	Low BCI(H/I)	213	0.75 (0.33-1.70)	0.484
<b>Genomic Risk</b>				
High BCI Score(N=621)	High BCI(H/I)	341	0.42 (0.20-0.89)	0.020
	Low BCI(H/I)	280	1.05 (0.58-1.88)	0.880
Low BCI Score(N=227)	High BCI(H/I)	60	0.35 (0.04-3.38)	0.344
	Low BCI(H/I)	167	0.64 (0.22-1.92)	0.425

Evaluation of BCI (H/I) predictive performance in the context of BCI prognostic risk categories showed similar results. In particular, patients with High Risk/High Likelihood to benefit showed significantly improved outcomes with extended therapy (HR 0.42 [0.20-0.89]; absolute benefit 10.7%; P=0.020), whereas those with High Risk but Low Likelihood to benefit did not show response to extended endocrine therapy (HR 1.05 [0.58-1.88]; absolute benefit -0.7%; P=0.880), despite considerable risk of late distant recurrence (~20%). **Conclusion:** Results from this study highlight distinct tumor biology underlying recurrence risk vs endocrine responsiveness in HR+ early stage breast cancer. BCI (H/I) as a molecular signature to identify patients with endocrine responsive disease is a key determinant of benefit and improved outcome with extended endocrine therapy. Prediction of endocrine benefit with BCI (H/I) is a more actionable approach vs risk assessment to individualize discontinuation of or continued treatment with prolonged durations of endocrine therapy.

*Esr1* mutation as a potential predictor of abemaciclib benefit following prior cdk4/6 inhibitor (cdk4/6i) progression in hormone receptor-positive (hr+) metastatic breast cancer (mbc): A translational investigation

Seth A. Wander<sup>1</sup>, Hyo S. Han<sup>2</sup>, Gabriela N. Johnson<sup>3</sup>, Maxwell R. Lloyd<sup>1</sup>, Pingping Mao<sup>3</sup>, Utthara Nayar<sup>3</sup>, Kailey Kowalski<sup>3</sup>, Casey R. Stein<sup>1</sup>, Veronica Mariotti<sup>2</sup>, Leslie SL Kim<sup>4</sup>, Maren Levin<sup>4</sup>, Jing Xi<sup>5</sup>, Apurva Pandey<sup>6</sup>, Siobhan Dunne<sup>4</sup>, Azadeh Nasrazadani<sup>6</sup>, Adam Brufsky<sup>6</sup>, Kevin Kalinsky<sup>7</sup>, Cynthia X Ma<sup>5</sup>, Joyce O'Shaughnessy<sup>4</sup>, Nikhil Wagle<sup>3</sup> and Aditya Bardia<sup>1</sup>. <sup>1</sup>Massachusetts General Hospital Cancer Center, Boston, MA; <sup>2</sup>Moffitt Cancer Center, Tampa, FL; <sup>3</sup>Dana-Farber Cancer Institute, Boston, MA; <sup>4</sup>Texas Oncology, Dallas, TX; <sup>5</sup>Washington University, Saint Louis, MO; <sup>6</sup>University of Pittsburgh, Pittsburgh, PA; <sup>7</sup>Columbia University, New York, NY

**Background:** CDK4/6 inhibitors have emerged as the standard of care for HR+ MBC. However, there is limited insight into the potential benefit of abemaciclib following prior progression on palbociclib or ribociclib. Based on a multi-center cohort of patients with HR+ MBC who had received abemaciclib after prior palbociclib progression (Wander SA et al ASCO 2019), we have previously reported that abemaciclib after prior CDK4/6i progression was well tolerated and that a subset of patients derived durable clinical benefit. Identifying molecular predictors of sensitivity to abemaciclib after prior CDK4/6i progression constitutes an important area of research. Given the high frequency of *ESR1* mutations in HR+ MBC with antiestrogen resistance, we evaluated the translational impact of *ESR1* mutations in mediating response to abemaciclib in this setting.

**Methods:** To evaluate abemaciclib sensitivity in *ESR1* mutant cell lines, T47D HR+ breast cancer cells were modified to over-express multiple mutant *ESR1* isoforms via lentiviral infection and antibiotic selection. These isoforms included *ESR1* Y537S, Y537N, and D538G. In an additional T47D cell line, RB1 expression was knocked down via CRISPR. The resulting derivative cell lines were grown in the absence of estrogen (via charcoal-stripped serum, CSS) or in escalating doses of abemaciclib. Cell viability was measured via cell-titer-glo assay. For clinical validation, we identified patients with MBC who had *ESR1* mutations detected by targeted sequencing of cell-free DNA (cfDNA), via CLIA certified Guardant assay, and had abemaciclib exposure following prior progression on palbociclib or ribociclib in the existing multi-center cohort from six US institutions.

**Results:** All *ESR1* mutant derivative cells demonstrated enhanced growth in estrogen deprivation compared to GFP controls, as expected, and were similarly sensitive to escalating doses of abemaciclib monotherapy *in vitro*, suggesting that *ESR1* mutations do not confer resistance to abemaciclib. Interestingly, two patients with *ESR1* mutations (in the absence of concurrent driver alterations in *RB1*, *FGFR*, *CCNE2*, and *ERBB2*) demonstrated progression on palbociclib and sensitivity to abemaciclib. In one patient, cfDNA obtained prior to palbociclib and fulvestrant exposure failed to reveal any *ESR1* alteration. Following progression on palbociclib, and prior to sequential exposure to abemaciclib, an *ESR1* Y537N alteration was identified. The patient went on to receive 16 months of abemaciclib monotherapy. In a second patient, an *ESR1* D538G alteration was identified following progression on palbociclib and fulvestrant. The patient had several intervening regimens, and subsequently went on to receive abemaciclib and fulvestrant for 16 months. RB1-null T47D cells were resistant to abemaciclib monotherapy *in vitro*, as expected and, in the clinical dataset, the presence of alterations in previously identified genomic mediators of CDK4/6i resistance, such as *RB1*, were associated with progression on both palbociclib and abemaciclib.

**Conclusions:** HR+ breast cancer cells expressing mutant *ESR1* isoforms were resistant to estrogen deprivation but retained sensitivity to abemaciclib *in vitro*. Furthermore, patients harboring *ESR1* mutations via targeted sequencing of cfDNA, in the absence of other known mediators of CDK4/6i resistance, were shown to derive clinical benefit from abemaciclib following prior progression on palbociclib. These results suggest that patients with HR+ MBC, *ESR1* mutation, and clinical resistance to anti-estrogen treatment and palbociclib may be candidates for abemaciclib treatment. Further research is warranted to confirm these novel translational observations.

Mutational burden of the normal breast during age and pregnancy

Biancastella Cereser, Neha Tabassum, Lisa Del Bel Belluz, Sladjana Zagorac, Angela Yiu, Philip Carter, Cristian Miere, Alicia R Jeffries-Jones and Justin Stebbing. Imperial College London, London, United Kingdom

**Background:** The potential for accumulation of somatic mutations in the healthy breast throughout life and pregnancy is poorly understood. In particular, the unique mutational landscape of both epithelial and stromal components of the mammary gland has not been investigated in depth. As cancer risk correlates with both age, age of first-time pregnancy and other factors including pregnancy itself, we wished to study mutational rate over time, using these landmarks. **Methods:** Here, using whole genome sequencing, we determined how the rate of mutations in both cancer drivers and passenger mutations are affected by both age and pregnancy. We aimed to describe for the first time how the mammary epithelium and stroma differ in their mutational burden. **Results:** Our analysis of epithelial and stromal laser-capture micro-dissected DNA from 25 normal breast samples of nulliparous and age-matched early- and late-parous women collected from Komen Tissue Bank, University of Indiana, shows that the mammary gland is characterised by known COSMIC signatures SBS1 and SBS5, both of which correlate with age ( $p < 0.05$ ). Using a non-negative matrix factorization approach, we identified a novel signature HB1 for a subset of samples which could not be fitted into the known signature database. Differences between the two cellular compartments were observed mostly in the enrichment pathway of mutated genes, notably a significant enrichment in mutations in the PI3K-Akt signalling pathway in the epithelium. We found that parous stroma is associated with a significant enrichment in mutations in the 3'UTR of genes, suggesting that regulation of the environment in the post-partum breast could preferably occur via these pathways. Alike other normal tissue, the mutational burden of the mammary gland significantly increases with age ( $P < 0.05$ ) and we observed parity-associated patterns of mutational burden, particularly evident in the epithelial compartment. The nulliparous epithelium is characterised by a significant increase of mutations ( $p < 0.05$ ), but mutated clones are maintained at a consistently small size. Conversely, the number of somatic mutations in the parous epithelium is not significantly affected by age, but age is positively correlated with bigger clone sizes ( $P < 0.05$ ) in this group. This trend suggests that possible cancer-associated mutations may have a lower probability of occurring but higher chance of expanding within the parous breast with age, compared to the nulliparous breast. To confirm this, we detected mutations in known driver genes in all the healthy samples, with some occurrence of known individual pathogenic variants. **Conclusions:** We show the mutational landscape of the healthy breast and highlight differences in the epithelial and stromal cellular compartments. We show how mutated cells, including mutations in driver genes for breast cancer, and genetic alterations change in the context of pregnancy and age, provide a possible explanation for pregnancy-associated breast cancer risk.

Serial MRI and pathology combined to select candidates for therapy de-escalation in the I-SPY 2 TRIAL

Sara J Venters<sup>1</sup>, Wen Li<sup>1</sup>, Denise M Wolf<sup>1</sup>, Jodi M Carter<sup>2</sup>, Molly E Klein<sup>3</sup>, Kamaljeet Singh<sup>4</sup>, Kimmie Rabe<sup>3</sup>, I Tolgay Ocal<sup>5</sup>, David Newitt<sup>1</sup>, Christina Yau<sup>1</sup>, Natsuko Onishi<sup>1</sup>, Jessica Gibbs<sup>1</sup>, Sunati Sahoo<sup>6</sup>, Shuko Harada<sup>7</sup>, Laila Khazai<sup>8</sup>, Malini Harigopal<sup>9</sup>, Alexander D Borowsky<sup>10</sup>, Gregor Krings<sup>1</sup>, Ronald Balassanian<sup>1</sup>, Yunn-Yi Chen<sup>1</sup>, Kimberley Cole<sup>9</sup>, Sonal Shad<sup>1</sup>, Barbara LeStage<sup>1</sup>, Amy Delson<sup>1</sup>, Sandra Finestone<sup>11</sup>, Lamorna Brown-Swigart<sup>1</sup>, I-SPY 2 Imaging Working Group., I-SPY 2 TRIAL Consortium, Laura Esserman<sup>1</sup>, Laura van 't Veer<sup>1</sup>, W Fraser Symmans<sup>9</sup> and Nola M Hylton<sup>1</sup>. <sup>1</sup>UCSF, San Francisco, CA; <sup>2</sup>Mayo, Rochester, MN; <sup>3</sup>U. Minnesota, Minneapolis, MN; <sup>4</sup>Brown University, Providence, RI; <sup>5</sup>Mayo, Scottsdale, AZ; <sup>6</sup>UTSW, Dallas, TX; <sup>7</sup>UAB, Birmingham, AL; <sup>8</sup>MDACC, Houston, TX; <sup>9</sup>Yale, New Haven, CT; <sup>10</sup>UC Davis, Sacramento, CA; <sup>11</sup>UC Irvine, Irvine, CA

**Background:** The I-SPY 2 TRIAL, open to patients with locally advanced, molecular high-risk breast cancer, aims to bring each patient to pathologic complete response (pCR) with a minimum of toxicity. Here we test the hypothesis that imaging (MR volume predictors) combined with core biopsy may be used to accurately select candidates who show early response and provide an option of treatment de-escalation at mid-therapy (12 weeks).

**Methods:** Of 100 I-SPY 2 patients with pathologist-assessed core biopsies at the inter-regimen time point (~12 weeks through treatment) and pCR data, 87 also had serial MR images and were considered in this study. Eleven I-SPY 2 TRIAL pathologists independently provided a digital assessment of the presence or absence of residual invasive cancer from H&E stained, and any requested ancillary IHC, images from imaging-guided core biopsies. Pathology predicts pCR if there is a consensus of no invasive residual disease. We generated predictions for all (55) unique pairs over the 11 pathologists, where pCR is predicted if both pathologists find no invasive cells. MRI pCR prediction models were previously developed on an independent dataset of ~990 I-SPY 2 patients, and applied to this cohort. Volume-based prediction models were previously optimized within each subtype and predicted probability thresholds were selected over a range of positive predictive value (PPV). In this study, MR predicts pCR (positive test) if the predicted probability is above a threshold that yields a given PPV value. For each pathologist pair, we combined pathology-based and MR-based predictors into a predictive-RCB (pre-RCB); and pre-RCB predicts a patient as pCR (RCB0) if both MR and pathology predicts pCR. Predictive performance is assessed by calculating the mean and range of PPV and sensitivity. **Results:** 39% (34/87) of the patients in this study achieved pCR. Over all pairs of pathologists, on average 80% of pathology-only predicted pCRs were true pCRs (mean PPV = 80% [range: 69-92%]), and 74% of patients who achieved pCR were predicted pCR by pathology alone (mean sensitivity = 74% [65-82%]). We assessed combinations with MR probability thresholds at PPV levels 50%-70%; and observed the best balance of PPV and sensitivity for the pre-RCB when MR thresholds were set at 50% PPV level. At this threshold setting, the pre-RCB achieved a PPV = 92% [83-100%], meaning on average 92% of predicted pCRs were true pCRs, and this improvement in positive predictive performance over pathology alone is achieved with a lower but still-reasonable 53% sensitivity [33-62%].

**Conclusion:** Pre-RCB, which predicts a patient as pCR if both MR and inter-regimen pathology predicts pCR, provides clinically actionable accuracy for treatment de-escalation for early responders (PPV>90%). Adding a final MR review at the time of early surgery may further improve performance. Resulting from data presented in this abstract, the pre-RCB algorithm, including the final MR review, has been operationalized and will be used prospectively to identify patients who are highly likely to have already achieved pCR by the inter-regimen timepoint.

**Background:** Overexpression of human epidermal growth factor receptor 2 (HER2) occurs in 15-20% of breast cancers (BC). At the same time, HER2-low tumors (immunohistochemistry 1+ or 2+ with no gene amplification) comprise ~50% of all BC. DS-8201a is an anti-HER2 antibody drug conjugate that has shown very promising response rates both in HER2+ and HER2low BC. However, not all patients respond or benefit to the same extent. Thus, there is a need to identify predictive biomarkers. Here, we hypothesize that by performing several molecular studies in both tissue and plasma samples of those patients participating in the pivotal DESTINY-Breast trials, we will shed more light about the molecular features of HER2+ BC and better characterized the patient population according to their benefit from this promising new anti-HER2 agent. **Methods:** HER2-PREDICT is a multi-center, observational study within the biomarker program of SOLTI group, which will include patients who will participate, are participating or previously participated in the Daiichi Sankyo INC sponsored phase III trials: DS8201-A-U301 (NCT03523585), -U302 (NCT03529110) and -U303 (NCT03734029). Patients with HER2-positive or HER2-low unresectable and/or metastatic breast cancer may be included in SOLTI-1804 HER2-PREDICT study if randomized to the DS-8201a arm. All patients need to consent for obtaining a fresh tumor biopsy or donating an archival metastatic biopsy. Primary tumors are allowed under SOLTI acceptance. Additionally, patients included before initiating DS-8201a therapy will provide blood samples for biomarker analyses on Cycle 1 Day 1 (C1D1), C2D1 and end of treatment. The primary objectives are (1) to identify an optimal *ERBB2* mRNA cut-off point predictive of Ds-8201a response and (2) to evaluate the correlation of baseline *ERBB2* mRNA levels (as a continuous variable) with overall response rate (ORR) in the Ds-8201a-treated cohorts. Secondary objectives includes: to evaluate the association of *ERBB2* mRNA levels, PAM50 intrinsic subtypes and immune-related genes with ORR, progression-free survival and overall survival; to design a new gene expression signature predictive of Ds-8201a benefit; to correlate early changes in ctDNA with Ds-8201a benefit and to identify acquired somatic mutations of resistance to DS8201a upon progression in plasma samples. Collection of tumor biopsies is an essential part of this study. Pathological analysis includes hematoxylin and eosin (H&E) staining, identification of areas with greater amount of tumor cells and determination of their tumor cell percentage. RNA will be isolated and analyzed at the nCounter (Nanostring Technologies). Molecular intrinsic subtypes will be identified by a research-based version of PAM50. Furthermore, we aim to evaluate 771 additional genes (+5 housekeeping genes) that encompass important genomic signatures and individual genes of importance for breast cancer by means of the nCounter®Breast Cancer 360 Panel. Somatic mutations in *PIK3CA*, *TP53*, and additional genes (e.g., *GATA3* and *ERBB2*) will be identified using next-generation sequencing (NGS). Also, a comprehensive NGS gene panel will be performed under the Ion Torrent or Illumina platforms to DNA extracted from FFPE tumor blocks and to circulating tumor DNA (ctDNA) in plasma samples. **Current status:** Since December 13<sup>th</sup>, 2019, a total of 10 patients have been included, 5 of them with blood samples. As of today, 13 out of 15 Spanish sites are recruiting patients. Clinical trial identification: NCT04257162

Investigating the clinical utility of tumor mutational burden in predicting rapid progression and death in patients with metastatic breast cancer

Igor Makhlin, Amy S Clark, Paul Wileyto, Noah Goodman, John Ndicu, Shannon DeLuca, Candace Clark, S. William Stavropoulos, Natalie Shih, Michael D Feldman, Susan M Domchek, Jennifer M Matro, Payal D Shah, Hayley M Knollman, Kevin R Fox, Kara N Maxwell, Lewis A Chodosh and Angela DeMichele. University of Pennsylvania, Philadelphia, PA

**Background** Up to 30% of breast cancer patients will eventually relapse with metastatic disease. With an increasing array of therapeutic options, there is an ongoing need for predictive biomarkers to help guide treatment strategies including sequencing of therapies in the metastatic setting. We sought to evaluate the prognostic and predictive potential of a panel-specific tumor mutational burden (TMB) in metastatic breast cancer patients.

**Methods** METAMORPH is a prospective, longitudinal cohort study. Eligible patients (pts) had newly diagnosed or progressive metastatic breast cancer and enrolled prior to starting a new line of therapy (physician's choice) at the University of Pennsylvania. Pts underwent tissue biopsy of a suspected metastatic site. Tumor samples were analyzed for mutations and copy number alterations (CNA's) using our institution's CLIA-certified Center for Personalized Diagnostics (CPD) targeted gene panel, which evolved over the course of the study from 20 genes to 152 genes. TMB-high (TMB-H) was defined as  $\geq 3$  mutations and/or copy-number gains (CNG) among 18 genes shared across all panel versions. Pts were followed for time to progression (TTP), progression-free survival (PFS), and overall survival (OS). The frequency of rapid progressors and rapid death (defined as having progressed or died within 3 months of enrollment, respectively) was assessed.

**Results** Three hundred pts enrolled from 2013-2020, of whom 200 pts had CPD reports generated. Of these, 12 pts were excluded due to either no treatment change on enrollment (n=11) or different primary cancer on biopsy (n=1). Thus 188 pts were included in this analysis. The median age was 55 years (range 28-79). 77% of pts identified as white, 18% as Black or African American, and 3.2% as Asian. Pts had a median of 1 line (range 0-12) of prior systemic therapy in the metastatic setting. 46.8% had no prior therapies for MBC, while 31% had  $\geq 3$  prior lines of therapy. 74.4% were HR+, 22.8% TNBC, and 2.7% HR-/HER2+. 6.9% of the cohort were classified as TMB-H. The average mutation/CNG rate was 2.2/sample, and 22.5% had no mutations or CNA's. The most common mutations were TP53 (35%) and PIK3CA (26%).

While TMB-H patients showed a statistically non-significant trend towards shorter median TTP and PFS compared with TMB-L, they comprised a significantly greater proportion of rapid progressors (54.5% vs 24.1%,  $p=0.027$ ), with an odds ratio for rapid progression of 3.8 (95% CI 1.08-13.2). In a multivariate logistic regression analysis, TMB-H remained independently associated with rapid progression when adjusted for receptor subtype and next line of therapy. Receptor subtype analysis revealed that ER- (including ER-/PR+) patients with TMB-H had a shorter median TTP compared to ER- TMB-L (147 vs 68 days,  $p=0.03$ ). TMB-H was also associated with significantly shorter OS compared with TMB-L (587 vs 648 days,  $p=0.02$ ; HR 2.2 [95% CI 1.11-4.41]). 44.4% of TMB-H pts died within 3 months of enrollment, as compared to 11.0% of TMB-L pts ( $p=0.005$ ), with an odds ratio for rapid death, adjusted for number of previous lines of therapy and receptor subtype, of 6.7 (95% CI 1.5-31.0).

**Conclusion** MBC pts who are TMB-H represent a population who are highly resistant to standard therapies, progress rapidly, and have significantly shorter overall survival with more rapid time to death. Our data support further studies investigating the utility of TMB as a predictive biomarker in directing patients away from standard treatment options and towards novel approaches e.g. immunotherapy.

Impact of BRCA mutation status on immune infiltration, chemosensitivity, and prognosis of breast cancer patients treated with neoadjuvant chemotherapy

Beatriz Grandal<sup>1</sup>, Clemence Evrein<sup>1</sup>, Eric Daoud<sup>1</sup>, Elise Dumas<sup>1</sup>, Nadir Sella<sup>1</sup>, Clara Sebbag<sup>1</sup>, Sonia Rozette<sup>1</sup>, Isabelle Jardin<sup>1</sup>, Lucie Laot<sup>1</sup>, Florence Coussy<sup>1</sup>, Claire Saule<sup>1</sup>, Dominique Stoppa-Lyonnet<sup>1</sup>, Sophie Franck<sup>1</sup>, Claire Senechal<sup>2</sup>, Enora Laas<sup>1</sup>, Marick Lae<sup>3</sup>, Diane De Croze<sup>4</sup>, Fabien Rey<sup>1</sup> and Anne-Sophie Hamy<sup>1</sup>. <sup>1</sup>Institut Curie, Paris, France<sup>2</sup>Institut Bergonie, Bordeaux, France<sup>3</sup>Centre Rene Huguenin - Institut Curie, St Cloud, France<sup>4</sup>Centre Rene Huguenin - Institut Curie, St Cloud, France

**Context:** The majority of BRCA mutation carriers diagnosed with breast cancer (BC) are treated with chemotherapy. The effectiveness of standard neoadjuvant chemotherapy (NAC) in BRCA associated BC compared to noncarriers has been poorly explored. **Objectives:** To assess whether the BRCA mutation status modifies the immune infiltration, chemosensitivity, and prognosis of breast cancer. **Methods:** We retrospectively identified in our institutional database all consecutive patients with BRCA germline mutation status available treated with NAC between 2002 and 2012. Microbiopsy specimens and paired surgical samples were evaluated for pre-NAC and post-NAC immune infiltration (stromal TILs, str TILs; intratumoral TILs, IT TILs). Response to chemotherapy was assessed by pathological complete response (pCR) rates. Association of clinical and pathological factors with pCR, overall survival (OS), and relapse free survival (RFS) was assessed by univariate and multivariate analyses. **Results:** Overall, 267 patients were included in this study (46 BRCA carriers and 221 BRCA noncarriers). The median age at BC diagnosis was 40 years old, and most of the patients (n=227, 85%) were premenopausal. Patients repartition by subtype was as follows: luminal (n=90, 33.7%), TNBC (n=110, 41.2%), HER2-positive (n=67, 25.1%). BRCA mutation carriers were likely to have familial history of BC (73.9% vs. 52.3%, p = 0.012), and be diagnosed with TNBC (58.7% vs 37.6%; p = 0.006), than noncarriers. No pattern was significantly different between BRCA mutation subgroups regarding age, body mass index, histology, tumor size, grade or Ki67. TIL levels were available in 192 patients. Neither pre-NAC stromal TIL levels nor IT TILs were significantly different by BRCA status in the whole population, nor in each BC subtype. PCR rates were significantly higher in BRCA mutation carriers (p= 0.035), and this association remained statistically significant only in the luminal BC subtype (p=0.006) after stratification by BC subtype (Pinteraction= 0.056). After multivariate analysis, only BC subtype and pre-NAC str TILs were independent predictors of pCR. Post-NAC stromal and intra-tumoral TIL levels were significantly higher luminal subtype (p=0.009 and p=0.019, respectively). After a median follow-up of 90 months, RFS and OS were not different between BRCA carriers and noncarriers, neither in the whole population nor after stratification by BC subtype. **Discussion:** In our study, BRCA status was associated with an enhanced response to standard NAC, particularly in luminal BC patients, in addition to higher post-NAC TIL levels. Whether patients with luminal BC and BRCA mutation derive benefit from second line immunotherapy after NAC completion remains to determine.

Patient reported outcomes and health care utilization of UPMC breast cancer survivorship clinic patients

Kristine Gade, Stefanie C. Altieri Dunn, Ellen Ormond, Andrew Bilderback, Jill W Brufsky, Emily M. Geramita and G J van Londen. UPMC, Pittsburgh, PA

**Background.** The number and longevity of cancer survivors is growing due to aging of the population, improving cancer treatments, and earlier detection. The Institute of Medicine has recommended creation of guideline-concordant models of cancer survivorship care and clinics for this growing population with unique needs. There is currently little data on how cancer survivors seen at a survivorship clinic fare compared to those seen in routine oncology clinics in terms of quality of life and health care utilization. At the University of Pittsburgh Medical Center (UPMC), we performed a descriptive analysis of healthcare utilization and patient reported outcomes (PROs) of cancer survivors seen at survivorship clinic compared to at oncology clinics.

**Methods.** The population consisted of breast cancer patients who received care at UPMC survivorship or oncology clinics (control) between January 2012 and December 2018. PROs were collected at each clinic visit and included the SF-12, the Edmonton Symptom Assessment Scale (ESAS), Patient Health Questionnaire (PHQ-9) and Generalized Anxiety Disorder (GAD-7) scales. Cancer diagnoses and staging were obtained from the UPMC Network Cancer Registry. Patient demographics, mortality, ED visits and inpatient stays were extracted from the electronic medical record. ED utilization and inpatient admissions were examined one-year prior to survivorship care compared to 90-days after the start of survivorship care. Categorical and continuous data were examined by Wilcoxon rank sum tests and likelihood-ratio chi-squared tests, respectively. A p-value <0.05 was considered statistically significant.

**Results.** Data from 680 cancer survivors were included, of which 285 patients received their follow-up care in survivorship clinic and 395 patients received their follow up care in oncology clinics. Baseline demographics were comparable between the two groups, except survivorship clinic patients (SCPs) had higher 1-year mortality (3.5% vs. 0.5%, p=0.003) and cancer stage (62% vs. 48% ≥ stage II, p=0.044). SCPs had significantly more ED visits at baseline and their number of ED visits remained higher than control once enrolled in survivorship clinic, although this trended down after 90 days in survivorship clinic (table 1). Inpatient visits were significantly increased for SCPs as compared to controls at 90 days after enrollment in survivorship clinic (6.4% with ≥ 1 inpatient admission vs. 1.8%, p=0.003). SCPs had consistently worse PROs compared to controls. Prior to enrolling in survivorship clinic, SCPs had higher rates of moderate to severe depression (22.4% with PHQ-9 score of 10-24 vs. 7.8%, p=0.002) and anxiety (20.6% with GAD-7 scores of 10 - 21 vs. 9.2 %, p<0.001) and this remained elevated at all time points compared to controls, although these rates appeared to decrease over time. SCPs also rate their overall health lower than controls on the SF-12 and they have higher symptom severity across most ESAS symptoms.

**Conclusions.** Cancer survivors who are referred to and receive care in survivorship clinic have poorer quality of life and higher health care utilization at baseline and over time when compared to patients who receive care in oncology clinics. This observation suggests that survivorship clinics may be seeing cancer survivors with higher symptom burden and health care needs. This warrants future efforts to better understand, support, and prevent morbidity of survivorship clinic patients.

Table 1. ED and Hospital Utilization Among Survivorship Clinic Patients and Controls.

	Pre-Survivorship Clinic			After Enrollment in Survivorship Clinic		
	1 Year			90 Days		
# ED Visits	Control (%)	Survivorship (%)	P	Control (%)	Survivorship (%)	P
0	345 (87.3)	199 (69.8)	<0.001	382 (96.7)	250 (87.7)	<0.001
1+	50 (12.7)	86 (30.2)		13 (3.3)	35 (12.3)	
# Inpatient Admissions						
0	319 (80.8)	225 (79.0)	0.341	388 (98.2)	267 (93.7)	0.003

Natural transition targeted surgery

Peter Kern<sup>1</sup>, Oliver Hoffmann<sup>2</sup>, Ann-Kathrin Bittner<sup>2</sup>, Rainer Kimmig<sup>2</sup>, Mahdi Rezai<sup>3</sup>, Ines Bucker<sup>1</sup> and Alina Kessel<sup>4</sup>. <sup>1</sup>Ruhr-University of Bochum & University Hospital of Essen, Bochum & Essen, Germany<sup>2</sup>University Hospital of Essen, Essen, Germany<sup>3</sup>Malteser Hospital of Duisburg, Duisburg, Germany<sup>4</sup>Ruhr-University of Bochum, Bochum, Germany

**Background:** Breast conserving surgery is the standard in T1-T3 primary breast cancer. The cosmetic result is very much depending on the surgeon's experience, the tumor-size/breast ratio and the technique applied. To improve cosmetic outcome and reduce repeated surgery, we have proposed a nomogram earlier (1) which has been cited by the American Society of Breast Surgeons Consensus Conference (2). In this nomogram, we proposed 5 simple oncoplastic techniques to handle the vast majority of breast cancer cases with a good cosmetic result. However, these techniques used direct access to the mammary gland, leaving scars in the visible skin of the breast. To avoid this, we chose a more natural access to the mammary gland at the natural transitions. **Methods:** We conducted a prospective open-arm study including all primary invasive and non-invasive breast cancer cases of tumor stages AJCC 0-III A (Version 8.0). Access to the tumor was chosen according to the proximity of the tumor to one of the following natural transitions (Areola, Lateral Insertion of the breast, inframammary fold): Non-palpable tumors and those undergoing neoadjuvant chemotherapy had to be marked by a wire and clips before. Intraoperative ultrasound was applied before skin incision and after removal of the tumour (ultrasound of the specimen to confirm clear margins). Resection was performed as a segmentectomy and SLN biopsy and axillary clearance was done according to current guidelines. **Results:** 84 patients with breast conserving NTT-surgery have been enrolled so far. 76 patients had primary surgery with stage distribution as follows: Tis (1), T1a (3), T1b (8), T1c (30), T2 (30), T3 (4) and T4b(1). 8 patients had neoadjuvant chemotherapy with stage distribution as follows: ypT0 (3), ypT1a(2), ypT1c(1) and ypT2 (2). Histopathology was predominantly invasive-ductal breast cancer (70), followed by invasive-lobular (6), ductulo-lobular (5), invasive-ductal and DCIS (1), invasive-ductal and mucinous (1) and mucinous only (1). After first surgery 77 patients had a tumor resection according to the nomogram of NTT-surgery with free margins and 7 with involved margins, thus 91,6 % tumors were resected with free margins at first surgery. The remaining 8,4 % were margin-free after second surgery. **Conclusion:** Scars were not visible on the surface of the breast outside of natural transitions and rate of free margins was high at 91,6 % without impairment due to the remote access to the mammary gland. We report a high patient satisfaction. Patient-reported outcome in detail has been evaluated by validated questionnaires and will be presented onsite. **References:**1. **Background:** I-SPY 2 is a multicenter, phase 2 trial using response-adaptive randomization within molecular subtypes defined by receptor status and MammaPrint (MP) risk to evaluate novel agents as neoadjuvant therapy for women with high-risk stage II/III breast cancer. The primary endpoint is pathologic complete response (pCR, ypT0/Tis ypN0). SGN-LIV1A is an investigational antibody drug conjugate consisting of an antibody to LIV1A, a zinc transporter highly prevalent in breast cancer, and a highly potent microtubule inhibitor, monomethyl auristatin E. Retrospective IHC analysis of LIV1A expression levels amongst tumor samples from 100 previous I-SPY-2 patients showed 88% of breast tumor samples with moderate to high expression of LIV1A (Yau, C. et al SABCS 2018). **Methods:** Women with tumors  $\geq 2.5$ cm were eligible for screening. Only HER2 negative (HER2-) patients were eligible for this treatment, hormone-receptor positive (HR+) patients had to have MP high molecular profile. Treatment included SGN-LIV1A 2.5 mg/kg (max dose 250 mg) every 3 weeks x 4, followed by doxorubicin/cyclophosphamide (AC) every 2-3 weeks x 4. The control arm was weekly paclitaxel x 12 followed by AC every 2-3 weeks x 4. All patients undergo serial MR imaging where response at 3 & 12 weeks combined with accumulating pCR data are used to estimate, and continuously update, predicted pCR rate for the trial arm. Analysis set was modified intention to treat with patients who switched to non-protocol therapy counted as non-pCR and not as their pCR status at time of surgery. The goal is to identify/graduate regimens with  $\geq 85\%$  Bayesian predictive probability of success (i.e. demonstrating superiority to control) in a future 300-patient phase 3 neoadjuvant trial with a pCR endpoint within signatures defined by HR & HER2 status & MP result. This investigational arm was eligible for graduation in 3 of 10 pre-defined signatures: HER2-, HR+HER2- and HR-HER2-. Regimens may also leave the trial for futility ( $< 10\%$  probability of success), maximum sample size accrual ( $10\% \leq$  probability of success  $< 85\%$ ), maximum time in trial (2 years) or for safety as recommended by the independent DSMB. **Results:** Sixty patients were randomized and evaluable to SGN-LIV1A. The study arm was stopped due to reaching the predetermined time limit for patient accrual of 2 yrs. Final estimated pCR rates are below. The estimated pCR rates were similar between the SGN-LIV1A and control arms for any tumor subtype. Preliminary safety events for SGN-LIV1A include increased rates of transaminitis and hyperglycemia and reduced rates of peripheral neuropathy compared to control. One patient was removed from the analysis as she was determined to have angiosarcoma of the breast. Notably, this patient had a dramatic early response and subsequent pCR to SGN-LIV1A treatment. **Conclusion:** The value of I-SPY 2 is to give insight about the performance of an investigational agent's likelihood of achieving pCR. SGN-LIV1A delivered every 3 weeks was comparable to paclitaxel for the primary endpoint of pCR in I-SPY2 and may have a similar side effect profile, however, with less peripheral neuropathy. Clinical trials evaluating weekly dosing of SGN-LIV1A are ongoing. A trial of SGN-LIV1A in the treatment of angiosarcoma is under consideration at this time.

Final Estimated pCR Rates and Predictive Probabilities

	Estimated pCR rate(95% prob interval)

Circulating tumor DNA (ctDNA) as a diagnostic tool to identify putative germline *BRCA* mutations

Saya Jacob, Andrew Davis, Paolo D'Amico, Lorenzo Gerratana, Michael Burns, Ami Shah, Neelima Katam, Firas Wehbe, Qiang Zhang, Elena Vagia, Lisa Flaum, Kalliopi Siziopikou, Leonidas Platanias, Amir Behdad, William Gradishar and Massimo Cristofanilli. Northwestern University, Chicago, IL

**Background:** As the role of precision medicine in metastatic breast cancer (MBC) expands, there is an increasing emphasis on diagnostic tools to characterize both somatic and germline alterations that drive carcinogenesis. Circulating tumor DNA (ctDNA) has provided an important means for *real-time*, non-invasive detection and monitoring of tumor somatic alterations without standard paired white blood cell testing. However, its application for the detection of germline mutations remains relatively understudied. Here, we characterize the role of *BRCA1&2* ctDNA mutant allele frequency (MAF) to identify underlying putative germline *BRCA1&2* mutations.

**Methods:** Patient data were retrospectively obtained under an IRB-approved protocol to review ctDNA data at Northwestern University between 2015 and 2020. All ctDNA samples were analyzed using the Guardant360 next-generation sequencing (NGS) assay (Guardant Health). Patients with ctDNA alterations in the *BRCA* genes were identified at all mutant allele frequencies (MAF). Clinical data were collected including breast cancer subtype, prior lines of therapy, tissue-based NGS and germline testing information. Separate CLIA-approved testing performed per standard of care was used as the gold standard for germline testing. Statistical analysis was used to test the association of MAF cut-offs with the presence or absence of a germline alteration. Receiver operating characteristic (ROC) analysis was performed.

**Results:** We identified 127 patients with breast cancer who underwent ctDNA collection. There were 69 HR+ HER2-, 24 HER2+, and 34 triple negative breast cancer (TN) patients. Of these, 8 patients had known *BRCA1* germline mutations, as confirmed with separate germline testing, and 9 patients had known *BRCA2* germline mutations. *BRCA1* germline mutations were significantly associated with age < 40 ( $p=0.016$ ) and triple negative subtype ( $p=0.042$ ). Mean ctDNA *BRCA1* MAF was 2.27% (Standard Deviation {SD} 10.19%) and mean *BRCA2* MAF was 2.04% (SD 9.51%). *BRCA1/2* MAF was analyzed with respect to germline mutations through ROC analysis. For *BRCA1* ctDNA MAF cut-off 32.4% was associated with confirmed putative germline mutation. This cutoff demonstrated sensitivity of 1 and specificity of 0.99. Area under the curve (AUC) was 1.00 at this cut-off. For *BRCA2*, ctDNA MAF cutoff of 28.5% was associated with confirmed putative germline mutations. This cutoff demonstrated sensitivity of 0.86, specificity of 0.99 and AUC of 0.93.

**Discussion:** ctDNA alterations of *BRCA1* with MAF>32.4% and *BRCA2* with MAF>28.5% in clinical ctDNA testing were useful criterion to identify germline *BRCA* mutations. The data suggest the potential to utilize ctDNA as a diagnostic tool to predict germline mutations based on MAF thresholds. Future prospective studies are needed to determine how ctDNA testing may be incorporated into existing clinical algorithms to refer patients for germline testing.

<sup>18</sup>F-fluoroestradiol (fes) and <sup>18</sup>f-fluorodeoxyglucose (fdg) pet imaging in metastatic lobular breast cancer

Poorani Manohar<sup>1</sup>, Lanell Peterson<sup>1</sup>, Vicky Wu<sup>2</sup>, Isaac Jenkins<sup>2</sup>, Mark Muzi<sup>1</sup>, Jennifer Specht<sup>1</sup>, Delphine Chen<sup>1</sup>, Jeanne Link<sup>3</sup>, Kenneth Krohn<sup>4</sup>, Paul Kinahan<sup>1</sup>, David Mankoff<sup>5</sup> and Hannah Linden<sup>1</sup>. <sup>1</sup>University of Washington/Seattle Cancer Care Alliance, Seattle, WA;<sup>2</sup>Fred Hutchinson Cancer Research Center, Seattle, WA;<sup>3</sup>Oregon Health Sciences University, Portland, OR;<sup>4</sup>Oregon Health Sciences University, Portland, Portland, OR;<sup>5</sup>University of Pennsylvania, Philadelphia, PA

Background: The histology and pattern of spread in lobular breast cancer has presented challenges in estimating extent of disease by traditional imaging methods. <sup>18</sup>F-FES is an estrogen analogue PET imaging tracer which measures tumor ER expression at multiple tumor sites simultaneously. It is FDA approved in the US and will be available in 2021, pressing clinicians to define the role of FES in patients with breast cancer before use in practice. We compared quantitative FES-PET and clinical FDG-PET SUV uptake between patients with metastatic lobular carcinoma.

Methods: Metastatic lesions in patients with primary ER+ lobular breast cancer were retrospectively evaluated with FES- and FDG-PET. SUV uptake was calculated in 38 patients enrolled in various studies at our institution. Up to ten matched lesions in each patient were assessed for a total of 192 lesions. Pairwise t-tests were performed to measure the difference between paired FES and FDG lesions.

Results: Among metastatic breast cancer patients with lobular histology, 87% of patients had a positive FES scan. The majority of positive scans demonstrated uptake in all sites, with only a small percentage (6%) lacking FES uptake in at least one lesion. Uptake was noted in various metastatic tumor sites including bone (78%), soft tissue/lymph node (17%), breast (8%) and lung (1%). Mean (range) SUVmax in FES and FDG respectively was 3.38 (0.88, 9.08) and 4.14 (1.25, 9.49). Paired lesion analysis showed concordance between the two imaging modalities in lesions with low SUV uptake. FES and FDG uptake, however, could be discordant in both directions (FES > FDG, and FDG > FES) when there is higher level of uptake in at least one of the tracers. This was specifically seen in the 150 bone lesions, possibly indicating differences in lesion phenotype or response to therapy.

Conclusions: FES and FDG scans demonstrate similar average SUV uptake in metastatic lobular breast cancer, suggesting that both scans have utility in detecting lobular histology. Our data suggests that at higher SUV values, FES may provide additional information to FDG. Discordance between FES and FDG SUV uptake in the same lesions, especially in bone, has important implications for staging and assessing response to therapy. Large prospective trials are needed to define the clinical utility of FES-PET in metastatic lobular breast cancer.

Inhibition of estrogen biosynthesis by hops, licorice species, and their bioactive compounds

Atieh Hajirahimkhan<sup>1</sup>, Caitlin Howell<sup>2</sup>, Tareisha Dunlap<sup>2</sup>, Shao-Nong Chen<sup>2</sup>, Susan E. Clare<sup>1</sup>, Guido F. Pauli<sup>2</sup>, Judy L. Bolton<sup>2</sup>, Birgit M. Dietz<sup>1</sup> and Seema A. Khan<sup>1</sup>. <sup>1</sup>Northwestern University, Chicago, IL; <sup>2</sup>University of Illinois at Chicago, Chicago, IL

**Introduction:** Breast cancer risk continues to rise following menopause, despite the cessation of ovarian estrogen synthesis. Pathways involving increased aromatase activity and inflammation in the breast microenvironment are implicated. Their concerted disruption could be protective against breast cancer. Popular botanicals for menopausal health, such as hops (*Humulus lupulus*), three licorice species (*Glycyrrhiza glabra*, *Glycyrrhiza inflata*, *Glycyrrhiza uralensis*) extracts, and their bioactive compounds have shown estrogenic and chemopreventive properties *in vitro* and *in vivo*. Their effects on aromatase expression and activity, and on inflammatory responses in the breast are not well characterized. **Methods:** Inhibition of aromatase activity by hops extract, its compounds (8-prenylnaringenin, 6-prenylnaringenin, and xanthohumol); three licorice extracts, and their bioactive compounds, (liquiritigenin, isoliquiritigenin, 8-prenylapigenin, and licochalcone A) were evaluated fluorometrically, using aromatase supersomes. Computational docking was performed to assess the binding of the bioactive compounds to the binding pocket of aromatase crystal structure compared to the known aromatase inhibitors, letrozole (non-steroidal) and exemestane (steroidal). Using qPCR, the effect of treatments on aromatase mRNA expression in breast microstructures of menopausal women was evaluated. The effects of hops and licorice on transactivation of NF- $\kappa$ B in MCF-7 breast cancer cells were studied, using a luciferase assay. **Results:** Among the extracts, one of the licorice species, *Glycyrrhiza inflata* showed the highest aromatase inhibitory potency (IC<sub>50</sub>  $\approx$  1  $\mu$ g/mL). Among the compounds, the phytoestrogens 8-prenylnaringenin (IC<sub>50</sub> = 50 nM or 17 ng/mL) from hops, liquiritigenin (400 nM or 0.1  $\mu$ g/mL), and 8-prenylapigenin (IC<sub>50</sub>  $\approx$  590 nM or 0.2  $\mu$ g/mL) from licorice exhibited the highest potency. Computational docking suggested that these phytoestrogens bind to the aromatase binding pocket like the aromatase inhibitor, letrozole. This effect was not observed with non-estrogenic bioactive compounds including 6-prenylnaringenin and xanthohumol from hops as well as isoliquiritigenin and licochalcone A from licorice. Hops and 8-prenylnaringenin reduced aromatase expression in breast microstructures by 60% ( $P < 0.05$ ). Moreover, hops and licorice extracts suppressed NF- $\kappa$ B-luciferase activity by 70% in MCF-7 cells ( $P < 0.01$ ). **Conclusions:** Hops, licorice species, and their phytoestrogens inhibit aromatase activity and expression. The extracts suppress NF- $\kappa$ B transactivation in MCF-7 cells, suggesting inhibition of inflammatory response. Further studies will better elucidate the potential of these popular botanicals and their bioactive compounds for preventing breast cancer in menopausal women.

Monitoring neoadjuvant chemotherapy using diffuse optical tomography breast imaging system

Mirella L Altoe, Kevin Kalinsky, Hua Guo, Hanina Hibshoosh, Mariella Tejada, Katherine D Crew, Melissa K Accordino, Meghna Trivedi, Alessandro Marone, Hyun K Kim, Andreas H Hielscher and Dawn L Hershman. Columbia University, New York, NY

**Background:** Optical based imaging modalities have shown promise for monitoring tumor response to neoadjuvant chemotherapy (NAC) in patients with breast cancer. In this study, we evaluate whether changes in deoxy-hemoglobin concentration values acquired by a Diffuse Optical Tomography Breast Imaging System (DOTBIS) over different time points are associated with tumor response.

**Methods:** This is a retrospective evaluation of 55 stage II-III BC patients in the neoadjuvant setting who received weekly paclitaxel x 12, followed by dose-dense adriamycin/cyclophosphamide every 2 weeks x 4. The patients were enrolled in this cohort study between 2011 and 2019, and DOTBIS images were acquired from the patient whole breast volume at 6 different time points: at baseline (TP0); two weeks after the first taxane infusion (TP1); after four infusions of taxane (TP2); at the end of the taxane regimen and before starting AC cycle (TP3); after two AC infusions (TP4); and at the end of NAC and before surgery (TP5). ctHHb tumor concentration was measured using low-intensity near-infrared light and normalized by the non-tumor region ctHHb mean value ( $ctHHb_N$ ). In order to evaluate whether pCR status, menopausal status, and molecular subtype classification influence the change of  $ctHHb_N$  over time, we designed a multilevel mixed-effect statistical model. pCR was defined as no invasive tumor cells from the breast and axillary tissue at surgery (ypT0 ypN0).

**Results:** 20 patients had pCR and 35 were classified as non-pCR. The estimate average  $ctHHb_N$  for pCR tumors at baseline was 4.02. There was a significant reduction in  $ctHHb_N$  levels for pCR group at TP1 (-1.31,  $p = .0001$ ) and TP2 (-1.36,  $p = .0416$ ). Changes in  $ctHHb_N$  levels compared to baseline (TP0) values were statistically significant different between pCR and non-pCR at all time points except at the end of the taxane cycle (TP3), Table 1. No significant changes over time were identified between molecular subtypes groups, or between pre- and post-menopausal status. Table 1 - Changes in  $ctHHb_N$  levels compared to baseline (TP0) values between pCR and non-pCR at all imaging time points. Bold values indicate statistical significance at  $p < .05$  level.

Time Point	Mean Difference $\pm$ Std. Error	p-value
TP1	1.92 $\pm$ 0.40	<b>0.0000</b>
TP2	2.04 $\pm$ 0.82	<b>0.0145</b>
TP3	0.83 $\pm$ 1.03	0.4198
TP4	2.71 $\pm$ 0.87	<b>0.0021</b>
TP5	2.63 $\pm$ 0.90	<b>0.0037</b>

**Conclusions:** Our study adds to the body of evidence reported for diffuse optical imaging methods applied to breast cancer treatment response. These results show that DOTBIS measured features, such as  $ctHHb_N$ , change in accordance with pCR status after 2 weeks under NAC, and there are differences in time evolution between the pCR groups. Reduction in  $ctHHb_N$  levels represents the chemotherapeutic-induced changes in the tumor microvasculature: lower  $ctHHb_N$  values associate with the reduction in tumor cell proliferation, and consequently in oxygen consumption. Future studies are warranted to evaluate whether early response prediction might determine if earlier treatment changes alter patient outcome.

**Background** With 8.7 years follow-up, the prospective phase III randomized MINDACT trial (EORTC 10041/BIG3-04) continues to meet its primary objective, i.e. 95.1% (95%CI 93.1-96.6), 5-year distant metastasis-free survival (DMFS) in clinical high (C-High)/genomic low (G-Low) risk patients who did not receive adjuvant chemotherapy (ACT) (Cardoso et al., ASCO 2020). In addition, about half of the MINDACT patients had a low clinical risk (C-Low) defined by pre-specified clinical-pathological characteristics. Here, we evaluated the outcome of this C-Low population stratified by the 70-gene signature (MammaPrint®) (G-Low or G-High) for outcome considering age, and present data on the total G-low population (C-Low and C-High combined). **Methods** Of 6693 patients enrolled in the MINDACT trial between 2007 and 2011, 3337 were C-Low, characterized as mainly T1, grade 1 or 2, and node negative. We evaluated the pre-specified DMFS, distant metastasis free interval (DMFI), and overall survival (OS) rates at 5 and 8 years in the C-Low population: i) in patients with genomic low risk (C-Low/G-Low, n=2744) who were recommended to receive endocrine therapy only (for 99% HR+), and ii) in C-Low/G-High who received ACT or not following randomization (ITT, n=690, 81% HR+). Exploratory analyses by age, ≤50 and >50, were conducted for ACT vs no ACT received in C-Low/G-High. In parallel we estimated survival rates for all G-low patients if all would have followed the genomic low risk assignment and received no ACT (C-Low/G-Low, and C-High/G-Low randomized to no ACT double weighted, n=4130). We used Kaplan-Meier estimates for time to event endpoints and hazard ratios with 95%CI from Cox-regression models adjusted for stratification factors used for the randomization. **Results** C-low/G-low patients who were recommended endocrine therapy only (compliance > 79%, based on local guidelines) have excellent 5 and 8 year survival rates for all endpoints (Table 1). The estimated survival rates for all G-Low patients, if all would have followed the genomic low risk assignment and received no ACT, is excellent as well (Table 1), albeit this population includes both C-Low and C-High patients. The survival estimates for C-Low/G-High patients are for all endpoints a few percentage points lower than for the C-Low/G-Low group (Table 1). At 8 years of follow-up, in the relatively small subset of 690 patients with C-Low/G-High tumors assigned to ACT or not by randomization (ITT), a 1.5% (SE ±2.3%) higher DMFS is seen in the ACT group, and a 2.9% (SE ±2.0%) higher DMFI. This suggested benefit is mostly seen in patients under 50 years of age (absolute Δ in DMFS for ACT vs no ACT at 8 years: 5.4% for age ≤50 vs -0.3% for age >50). **Conclusion** Patients with a 70-gene G-Low risk tumor have an excellent 8 year outcome in the context of C-Low characteristics when recommended for endocrine therapy only, very close to the outcome in the larger group of all G-Low patients regardless of clinical risk. Stratification of C-Low patients in to G-Low and G-high provides meaningful information. The benefit of ACT in C-Low patients with a 70-gene G-High risk tumor needs further confirmation, especially relevant in younger women.

**Introduction:** Hormonal agents remain the most effective therapies for estrogen receptor positive (ER+) HER2- breast cancer. The androgen receptor (AR) is the most highly expressed steroid receptor found in up to 95% of ER+ breast cancer patients. Androgen agonists have antiproliferative activity in ER+ breast cancer and have been used in treatment, however their lack of availability and virilizing side effects have limited their use. Enobosarm is a non-steroidal tissue-selective AR modulator that is being developed for AR targeted treatment of ER+/AR+ breast cancer.

**Methods:** An international, Phase 2, open label, parallel design, randomized study was conducted in 136 patients (pts) to investigate the efficacy and safety of enobosarm in postmenopausal women with metastatic ER+/AR+ breast cancer that progressed on previous endocrine therapy. Pts were randomized to receive 9 mg (n=72) or 18 mg (n=64) of oral daily enobosarm. The primary endpoint was clinical benefit rate (CBR) at 24 weeks (defined as CR, PR or SD) by RECIST 1.1. Secondary endpoints included objective response rate, best overall response rate (BOR), progression free survival (PFS), duration of clinical benefit.

**Results:** The study population consisted of heavily pre-treated pts with a mean of 4 (range 1-6) prior hormone therapies and >90% receiving one prior course of chemotherapy. Median age was 60.8 years (35-83) for 9 mg and 62.1 (42-81) for the 18 mg cohort. AR positivity was centrally confirmed in 73.6% and 81.2% in the 9 and 18 mg cohorts, respectively. Efficacy: In the evaluable pts, 50 in the 9 mg arm and 52 in the 18 mg arm (AR confirmed), 32% of the 9mg cohort met the primary endpoint of CBR at 24 weeks (95% CI, 19.5%; 46.7%) and 29% (95% CI, 17.1%; 43.1%) in the 18 mg cohort. The BOR was 2 CRs, 10 PRs in the 9 mg and 3 CRs, 7 PRs in the 18 mg group by central review. Median PFS was 5.6 (2.9 to 27.5) and 4.2 (2.8 to 11) months (mo) in the 9 mg and 18 mg groups. The median duration of treatment was 4.0 months (0.23-30.3 months) in the 9 mg group and 3.8 months (0.5-16.7 months) in the 18 mg group. At the time the study was terminated, the median duration of clinical benefit was not reached (NR) in the 9 mg group (range 8.2 mo to NR) and 14.1 mo (range 11.0 to 16.5) in the 18 mg group.

**QOL:** Using a standardized instrument of generic health status (EQ-5D), a significant percentage of pts reported improvement in measurements including mobility (40%, 50%), anxiety/depression (50%, 29%) and pain discomfort (50%, 31%) for the 9 and 18 mg groups, respectively. Drug related severe adverse events (SAEs) (Grades 3-4) were observed in 6 (8.0%) at the 9 mg and 10 (16.4%) at the 18 mg dose. The SAEs (Grade 3-4) attributed to the study drug by the site investigator were for the 9 mg group: fatigue (1), elevated transaminases (2), headache (1), hypercalcemia (2) and anemia (1). For the 18 mg group the drug attributable SAEs (Grade 3-4) were: dry mouth (1), increased aminotransferase (2), decreased white blood cell count (1), fatigue (2), hypercalcemia (1), decreased appetite (1), headache (1), tumor flare (2), agitation (1), lymphadenopathy (1) and acute kidney injury (1).

**Conclusions:** In this Phase 2 parallel design study, enobosarm (9 mg and 18 mg) has significant clinical activity and was well tolerated in heavily pretreated patients with ER+/AR+ metastatic breast cancer. Given the limited options of hormonal therapy for metastatic ER+ breast cancer, enobosarm merits further clinical development in a Phase 3 clinical program as an AR targeted treatment for metastatic ER+AR+ breast cancer.

Triple-negative breast cancer (TNBC), which accounts for 15-20% of breast cancers, causes the highest mortality rate among all breast cancer subtypes. Due to its heterogeneity and lack of estrogen and progesterone receptor or human epidermal growth factor receptor 2 expression, valuable targeted therapy is limited. Therefore, it is critical to identify novel therapeutic targets in TNBC. 2-oxoglutarate (2-OG)-dependent enzymes, including prolyl hydroxylases (Egln1-3), histone demethylases (for example, KDM5A) and DNA hydroxylases (such as TET1-3), are associated with cancer progression. However, the role of these enzymes in TNBC has never been systematically studied. Here, by performing a functional siRNA screening for 2-OG-dependent enzymes, we identified gamma-butyrobetaine hydroxylase 1 (BBOX1) as an essential gene for TNBC tumorigenesis. BBOX1 depletion inhibits TNBC cell growth, while not affecting normal breast cells. Mechanistically, BBOX1 binds with the calcium channel inositol-1,4,5-trisphosphate receptor type 3 (IP3R3) in an enzymatic-dependent manner and prevents its ubiquitination and proteasomal degradation. BBOX1 depletion suppresses IP3R3 mediated endoplasmic reticulum calcium release, therefore impairing calcium-dependent energy-generating processes including mitochondrial respiration and mTORC1 mediated glycolysis, which leads to apoptosis and impaired cell cycle progression in TNBC cells. Therapeutically, genetic depletion or pharmacological inhibition of BBOX1 inhibits TNBC tumor growth in vitro and in vivo. Our study highlights the importance of targeting previously uncharacterized BBOX1-IP3R3-calcium oncogenic signaling axis in TNBC.

Survival outcomes and prognosis for patients with triple negative breast cancer who received stereotactic radiosurgery for brain metastases

Ran An<sup>1</sup>, Yan Wang<sup>1</sup>, Fuchenchu Wang<sup>2</sup>, Chao Gao<sup>3</sup>, Akshara Singareeka Raghavendra<sup>4</sup>, Diana Amaya<sup>1</sup>, Nuhad K Ibrahim<sup>4</sup> and Jing Li<sup>1</sup>. <sup>1</sup>MD Anderson Cancer Center-University of Texas, Department of Radiation Oncology, Houston, TX; <sup>2</sup>MD Anderson Cancer Center-University of Texas, Department of Biostatistics, Houston, TX; <sup>3</sup>The Fourth Hospital of Hebei Medical University, Shijiazhuang, China <sup>4</sup>MD Anderson Cancer Center-University of Texas, Department of Breast Medical Oncology, Houston, TX

**Background:** Triple-negative breast cancer (TNBC) has a high propensity for brain metastasis (BM) with poor prognosis. Stereotactic radiosurgery (SRS) has emerged as an effective treatment option for BM. However, clinical outcomes after SRS for BM from TNBC have not been well defined. We evaluated survival outcomes and prognostic factors among TNBC patients who received SRS for BMs. **Methods:** We retrospectively reviewed 99 patients with TNBC and BM who had received SRS at a single large-volume cancer center from May 2008 through April 2018. For the initial treatment of BM, 73 patients received SRS, 25 received whole-brain radiotherapy (WBRT), and 1 patient received surgery. Endpoints were overall survival (OS) from BM diagnosis, BM progression-free survival (BMPFS) from start of BM treatment, and times to intracranial local and distant failure from start of BM treatment. Both intracranial local and distant failure were considered BM progression. Local failure was defined as an increase in size of any treated lesions on imaging or assessment of treating physicians; enlargement attributable to radiation necrosis or post-radiation change was not counted as local failure. Kaplan-Meier analysis and Cox proportional hazard regression models were used to estimate survival curves and identify prognostic factors. **Results:** The median follow-up time from BM diagnosis was 12.7 months (95% confidence interval [CI] 1.3–52.1). The median age at BM diagnosis was 52 (range 24–82). The median interval between the diagnosis of primary breast cancer and BM was 25.8 months (95% CI 8.7–120.3). Of the 99 patients, 81 (81.8%) had 1–3 BMs and 18 (18.2%) had >3 BMs at diagnosis. The median OS time for all patients was 13.3 months (95% CI 10.3–16.4), and the cumulative survival rates were 55.1% at 1 year and 29.2% at 2 years. Factors independently associated with increased risk of death in multivariate analysis were Karnofsky performance score (KPS)  $\leq 70$  ( $p=0.01$ ) and uncontrolled extracranial metastasis at BM diagnosis ( $p=0.05$ ). No difference was found in OS according to type of initial treatment for BMs. Of the initial 99 patients, 12 were excluded from the evaluation of BMPFS, local and distant failure for missing follow-up imaging after initial treatment. The median BMPFS time was 7.2 months (95% CI 5.1–9.3). Of the 87 evaluable patients, 23 (26.4%) developed local recurrence after initial treatment, and among these 10 of 61 patients (16.4%) had received SRS and 13 of 25 patients (52%) had received WBRT. Patients initially treated with SRS had longer time to local failure than WBRT (50<sup>th</sup> percentile not reached vs. median 14.0 months,  $p=0.001$ ). Multivariate analysis showed higher risk of local failure for patients who initially received WBRT versus SRS (hazard ratio [HR] 3.4,  $p=0.005$ ). Forty-nine of 87 patients (56.3%) developed distant brain recurrence after initial treatment, and among these 35 of 61 patients (57.4%) had received SRS and 14 of 25 patients (56%) had received WBRT. No difference in risk of distant brain failure was found for patients initially treated with SRS versus WBRT ( $p=0.24$ ). No difference was found in time to develop distant failure after initial treatment with SRS (median 18.4 months) versus WBRT (median 12.8 months,  $p=0.24$ ). **Conclusion:** Patients with BM from TNBC had a median OS time of 13.3 months and a BMPFS time of 7.2 months. KPS  $\leq 70$  and uncontrolled extracranial disease at the time of BM diagnosis were independent prognostic factors that increase risk of death. Patients initially treated with SRS had a longer time to develop intracranial local failure than those initially given WBRT, and this may be related to patient selection. Further prospective studies of larger numbers of patients with BM from TNBC are needed for a more accurate comparison of treatment modalities

Impact of COVID-19 on study sites: Survey analysis from the noninterventional POLARIS study

Debu Tripathy<sup>1</sup>, Joanne L Blum<sup>2</sup>, Gabrielle Rocque<sup>3</sup>, J. Daniel Cuevas<sup>4</sup>, Jennifer Specht<sup>5</sup>, Steven Corso<sup>6</sup>, Jawad E Francis<sup>7</sup>, Stephanie Mendez<sup>8</sup>, Veneta Pope<sup>9</sup>, Joseph Cappelleri<sup>9</sup> and Yao Wang<sup>9</sup>. <sup>1</sup>The University of Texas MD Anderson Cancer Center, Houston, TX; <sup>2</sup>Texas Oncology Sammons Cancer Center, US Oncology, Dallas, TX; <sup>3</sup>University of Alabama at Birmingham, Birmingham, AL; <sup>4</sup>St. Louis Cancer Care, St. Louis, MO; <sup>5</sup>University of Washington, Seattle, WA; <sup>6</sup>Gibbs Cancer Center, Spartanburg, SC; <sup>7</sup>Mercy Health Youngstown, Youngstown, OH; <sup>8</sup>ICON plc, North Wales, PA; <sup>9</sup>Pfizer Inc, New York, NY

**Background:** The COVID-19 pandemic is negatively affecting patient enrollment, therapy administration, and patient visits in breast cancer clinical trials worldwide. COVID-19 may have a lasting impact on how clinical trials are conducted, and guidelines are necessary to inform trial design and patient safety. While many groups and journals have recently published guidelines, including NCCN, ESMO, IQVIA, and *Lancet Oncology*, there is no consensus on how to treat patients in the current environment. Understanding and quantifying the impact of the pandemic on clinical study sites will help inform the rational development of a consensus approach. The goal of this survey was to gather site-level data on the impact of COVID-19 from clinical sites participating in the POLARIS study (NCT03280303), an ongoing, prospective, real-world, noninterventional study in patients with hormone receptor-positive/human epidermal growth factor receptor 2-negative advanced breast cancer receiving palbociclib plus endocrine therapy. **Methods:** Two rounds of questionnaires were sent to investigators at POLARIS study sites: 1 via email March 26-27, 2020, and 1 via telephone from April 30-May 20, 2020. The questions on COVID-19 impact and management are shown in the **Table**. **Results:** Eighty of 122 POLARIS study sites contacted responded to the March questionnaire, and 86 responded to the April-May questionnaire. In March, 33% (26/80) of the surveyed population were working predominantly remotely, 26% (21/80) were working both onsite and remotely, and 31% (25/80) were working onsite. Approximately 24% of sites reported delayed data entry. The option of telemedicine or office visits was offered to subjects at approximately 73% (58/80) of sites, and 11% (9/80) of sites were restricted to telemedicine visits. In April-May, 36% (31/86) of respondents reported an impact on study management and 64% (55/86) reported no impact. Approximately 94% (81/86) of surveyed sites felt they were able to maintain clinical studies despite the challenges due to COVID-19, and 79% (68/86) of sites had the option for telemedicine and/or office visits, while 18% (16/86) had no telemedicine alternative. In April-May, 38% of sites reported an impact on patient visits. **Conclusion:** Although these findings must be interpreted with caution due to the limitations of survey studies, the results suggest that approximately 1/3 of the study sites will experience an impact on their responsiveness to correspondence, timely data entry, and subject management due to the COVID-19 pandemic. Telemedicine may be used to mitigate the effect of the pandemic on clinical trial execution. Pfizer (NCT03280303)

Table. Survey Questions

March Questionnaire (March 26-27, 2020)	
Question	Responses
Working onsite or remotely?	26 sites are predominately working remotely 21 sites are working a combination of onsite and remotely 25 sites are working onsite 7 sites provided inconclusive responses
Subject visits in office, by phone, by video, or a combination of 3 options?	50 sites are using a combination of onsite and telemedicine 8 sites have onsite visits 9 sites have telemedicine visits only 8 sites provided inconclusive responses 4 instances where question was inapplicable due to no active subjects
Is data entry delayed?	19 sites responded Yes 54 sites responded No 6 sites provided inconclusive responses
Is collection of biomarker blood samples impacted?	11 sites indicated there will be impact to biomarker collection 28 sites indicated there will be no impact to biomarker collection 40 instances where question was inapplicable due to no subjects participating in collection
What other study areas are impacted?	20 sites indicated impact due to financial challenges or limited abilities while working remotely Remaining sites did not note any additional areas of impact
Patient-reported outcome questionnaire issues?	Most sites had not experienced any issues, but an overwhelming majority inquired about the ability to do them via phone or mail. Many sites and subjects expressed preference for the paper questionnaire instead of the electronic version.
May Questionnaire (April 30-May 20, 2020)	
Question	Responses
Has COVID-19 impacted your site's ability to execute a study? • Clarify impact on your site	55 sites responded No 31 sites responded Yes • Subject visits impacted (limited onsite visits): 24 • Institutional restrictions/limited staff: 7
Is there any impact on scheduled onsite standard of care patient visits?	53 sites responded No 33 sites responded Yes
Please indicate which if any of the following apply to your site: Process in place for remote patient study visits Process is used for remote patient study visits Alternative methods are available to deliver drug Other	67 sites responded that telemedicine is in place for subject visits 16 sites responded that there is no alternative for telemedicine 1 site noted that they have no active subjects 1 site noted that subjects are attending on site visits 1 site did not respond to question
How able are you to maintain ongoing studies at this time? Extremely able to do so Very able to do so Moderately able to do so A little able to do so Not at all able to do so	27 sites are extremely able to do so 42 sites are very able to do so 12 sites are moderately able to do so 5 sites are able to do so only a little • COVID impact is felt more profoundly at 4 sites • Financial barrier has limited one site's time on study 0 Sites unable to do so at all

Can composite risk model help clinicians make adjuvant ovary function suppression decision for breast cancer patients

Yue Liang, Xiaosong Chen, Weiqi Gao, Siji Zhu, Jin Hong, Jiayi Wu, Ou Huang, Jianrong He, Li Zhu, Yafen Li, Weiguo Chen and Kunwei Shen. Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China

**Background:** Composite measure of recurrence risk with certain clinicopathologic characteristics provided prognostic and adjuvant ovarian function suppression (OFS) therapeutic effect information for patients in the TEXT and SOFT trials, but the role of this composite risk score (CRS) in OFS treatment decision-making has not been established. We carry out this study to evaluate the association of CRS with OFS treatment recommendation in our multidisciplinary team (MDT) treated patient cohort. **Methods:** Premenopausal patients with hormone receptor (HR) positive, human epidermal growth factor receptor 2 (HER2) negative breast cancer who received surgery between April 2013 and December 2018 and had OFS decision-making made by MDT were included. The association of CRS with OFS recommendation and survival outcome were analyzed. **Results:** Totally 887 patients were identified, amongst which 239 (26.94%) were recommended to receive OFS. The median CRS was 1.92, 455 (51.3%) patients were categorized as low-risk and 432 (48.7%) as high-risk. Age < 35 years (OR = 24.68, 95% CI 12.97-46.95,  $P < 0.001$ ),  $\geq 4$  ALNs metastasis (OR = 3.95, 95% CI 2.08-7.48,  $P < 0.001$ ), ER  $\geq 50\%$  (OR = 5.45, 95% CI 2.16-13.75,  $P < 0.001$ ) and CRS high-risk (OR = 2.82, 95% CI 1.62-4.91,  $P < 0.001$ ) were independently predictive of OFS recommendation. CRS also served as an effective predictor of OFS recommendation in receiver operating characteristics (ROC) curve analysis (AUC = 0.775,  $P < 0.001$ ). CRS high-risk was related to worse breast cancer-free interval (BCFI) (89% vs. 97.6%, HR 8.98, 95% CI 2.73-29.51,  $P < 0.001$ ), no significant differences in overall survival (OS) were found between patients with CRS high and low-risk (96.5% vs. 99.8%, HR 5.5, 95% CI 0.66-45.73,  $P = 0.076$ ). **Conclusions:** CRS was associated with OFS recommendation and BCFI in premenopausal patients with HR positive/HER2 negative breast cancer, which may be integral to their individualized OFS treatment decision-making.

Trends in incidence and stage of male breast cancer, 2004-2016: An analysis from the national cancer database

Lifen Cao, Rashi Singh, Anuja L Sarode, Michael Kharouta, Robert Shenk and Megan E Miller. University Hospitals Cleveland Medical Center, Cleveland, OH

**Background:** Male breast cancer has been less well studied due to the rarity of this condition compared with female breast cancer. Men have traditionally presented at later stages than women, leading to disparities in outcomes. Our aim was to identify the incidence of male breast cancer in recent years and determine trends in clinical and pathologic stage that could be utilized to improve breast cancer care. **Methods:** Patients diagnosed with primary breast cancer between 2004 and 2016 were identified using the National Cancer Database (NCDB), which collects hospital registry data from over 1,500 Commission on Cancer (CoC)-accredited facilities and represents more than 70% of newly diagnosed cancer cases in the United States. Patient, tumor, treatment, and facility data was compared between male and female patients. Incidence of male and female breast cancer was stratified by both AJCC clinical stage and pathologic stage (I-IV) and evaluated over the study period. **Results:** 17,814 male breast cancer patients and 2,001,551 female patients with breast cancer were identified. The incidence of male breast cancer increased by 1.5-fold from 1044 cases per year in 2004 to 1565 cases per year in 2016. The number of female breast cancer cases was 123,799 in 2004 and reached the highest annual volume of 184,718 in 2015. In 2010 incident male breast cancer cases rose by nearly 100% compared with the prior year, the majority of which represented early stage disease. In that year alone, for males there was a 99.6% increase (276 vs. 556 cases) in pathologic stage I disease, 89% increase (200 vs. 378 cases) in pathologic stage II disease and 94.7% increase (68 vs. 132 cases) in patients diagnosed with in situ disease. After 2010, incidence patterns for male breast cancer stabilized with ratio changes for Stage I or II at the level of only 1% to 7.3% per year. Interestingly, the proportion of male to female breast cancer incident cases remained constant over the study period, with males representing 0.8-0.9% of the total cases. Overall, a minority of patients presented with Stage III (6.6%) and Stage IV (4.6%) disease, though a greater proportion of males than females had advanced stage disease at diagnosis (16.88% of males vs. 11.14% females,  $p < 0.001$ ). The incidence of clinical Stage I and II disease increased over time for both genders, though a greater proportion of female breast cancer was Stage I (43.2% female vs. 35.93% male,  $p < 0.001$ ), and Stage II disease was more common in men (33.83% male vs 24.22% female,  $p < 0.001$ ). When pathologic stage was considered, Stage I and II represented the majority of male breast cancer cases, 74.7% to 80% per year, and was slightly higher than the combination of Stage I and II at clinical diagnosis, 65.7% to 78.7% per year. **Conclusions:** Over past 15 years, the incidence of male breast cancer has increased substantially, yet remains a stable proportion of total breast cancer cases. The greater frequency of Stage II, III and IV disease in men likely reflects the difference in diagnosis by clinical exam or symptoms in men vs. screening programs in women. Education to increase awareness of male breast cancer, promote symptom recognition, and encourage appropriate use of genetic testing should be emphasized to improve early diagnosis of breast cancer in men.

Patient perspectives on chemotherapy de-escalation: "Don't de-escalate! I don't want to die!"

Gabrielle Rocque<sup>1</sup>, Courtney P. Williams<sup>2</sup>, Courtney J. Andrews<sup>1</sup>, Kathleen Gallagher<sup>3</sup>, Timothy C. Childers<sup>1</sup>, Kimberly D. Wiseman<sup>4</sup>, Alan Balch<sup>3</sup>, Stacey A. Ingram<sup>1</sup>, Thelma Brown<sup>1</sup>, Tara Kaufman<sup>5</sup>, Nadine Tung<sup>6</sup>, Mary Lou Smith<sup>7</sup>, Antonio C. Wolff<sup>8</sup>, Angela DeMichele<sup>5</sup> and Lynn Wagner<sup>4</sup>.  
<sup>1</sup>UAB, Birmingham, AL; <sup>2</sup>National Cancer Institute, Rockville, MD; <sup>3</sup>Patient Advocate Foundation, Hampton, VA; <sup>4</sup>Wake Forest, Winston-Salem, NC; <sup>5</sup>University of Pennsylvania, Philadelphia, PA; <sup>6</sup>Beth Israel Deaconess Medical Center | Harvard Medical School, Boston, MA; <sup>7</sup>Research Advocacy Network, Plano, TX; <sup>8</sup>Johns Hopkins, Baltimore, MD

**Introduction:** Given excellent survival outcomes in breast cancer and new methods to predict treatment response, oncologists are interested in de-escalating the amount of chemotherapy delivered to patients. This is particularly important in the setting of COVID-19, where patient perspectives of de-escalation may be altered by perception of COVID-19 risk. **Methods:** This concurrent mixed methods study included (1) semi-structured interview data from patients with breast cancer treated at the University of Alabama at Birmingham and patient advocates from nationally representative advocacy organizations (10/2019-5/2020) and (2) cross-sectional survey data from a nationwide sample of women with breast cancer (11/19-12/2019). Questions evaluated interest in de-escalation study participation, perceived barriers/facilitators to participation, and language describing de-escalation. Participant perspectives surrounding COVID-19 impact on de-escalation were elicited in interviews post 3/2020. **Results:** Quantitative and qualitative findings were synergistic. Interviews were conducted with 40 female participants (24 patients, 16 patient advocates). Participant ages ranged from 33-79 years old; 30% were minorities; 35% didn't have a college degree. Common barriers to acceptance of de-escalation included fear of recurrence, worry about decision regret, lack of clinical trial interest, and dislike for the focus on less treatment. Fear of recurrence was the most commonly expressed barrier, with one participant stating, "I'm just afraid it wouldn't get it all". Common facilitators included trust in the physician, toxicity avoidance, monitoring with the option of increasing treatment intensity, perception of good prognosis, and impact on daily life. Participants interviewed during the COVID-19 pandemic (n=16) expressed substantial virus-related fear, including fear of exposure, fear of infecting their personal contacts or health care team, fear of cancer-related complications, and fear about their immunocompromised state. These fears contributed to participants perspective on de-escalation, as highlighted by participants stating, "I wouldn't worry about getting the chemo as much as I would worry about getting the virus" and "Less is more for me right now". Of 91 survey respondents (69% response rate), median age was 58 years (interquartile range [IQR] 48-69), 86% had early stage breast cancer. Many (43%) patients were not interested in participation in a study testing lower doses of chemotherapy than standard of care. Patients not interested in participating were more often unmarried (55% vs. 32%, V=.23), disabled (56% vs. 40%, V=.17), or diagnosed with early stage cancer (45% vs. 22%, V=.14). Barriers to participation included fear of cancer recurrence (85%) and regret about the decision to receive less chemotherapy if the cancer were to recur (79%). Few patients (19%) considered clinical trials themselves as a barrier. Patients were interested in participation due to lessened physical side effects of treatment (82%), lessened long-term problems related to treatment (76%), and lessened impact on daily life (72%). The most popular terminology describing chemotherapy de-escalation was "lowest effective chemotherapy dose" (53%); no patients preferred the term "de-escalation." **Conclusion:** Fear of recurrence is a common barrier to de-escalation clinical trial participation in patients with breast cancer. Fears may be altered for patients considering treatment during the COVID-19 pandemic. Trust in the physician and use of patient-generated language, such as "customized" instead of "de-escalation", are potential areas for future interventions engaging patients in trials.

Ribociclib + letrozole in premenopausal patients with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-) advanced breast cancer (ABC): Subgroup analysis of the phase IIIb ComPLEEment-1 trial

Hikmat Abdel Razeq<sup>1</sup>, Paul Cottu<sup>2</sup>, Alistair Ring<sup>3</sup>, Michelino De Laurentiis<sup>4</sup>, Janice Lu<sup>5</sup>, Hamdy Azim<sup>6</sup>, Claudio Zamagni<sup>7</sup>, Katie Zhou<sup>8</sup>, Jiwen Wu<sup>8</sup>, Lakshmi Menon-Singh<sup>8</sup> and Miguel Martin<sup>9</sup>. <sup>1</sup>King Hussein Cancer Center, Amman, Jordan<sup>2</sup>Curie Institute, Paris, France<sup>3</sup>Royal Marsden NHS Foundation Trust, Surrey, United Kingdom<sup>4</sup>National Cancer Institute "Pascale Foundation", Naples, Italy<sup>5</sup>USC Norris Comprehensive Cancer Center, Los Angeles, CA<sup>6</sup>Cairo University, Cairo, Egypt<sup>7</sup>Bologna University Hospital, St Orsola-Malpighi Polyclinic, Bologna, Italy<sup>8</sup>Novartis Pharmaceuticals, East Hanover, NJ<sup>9</sup>Gregorio Maranon General University Hospital, Madrid, Spain

**Background:** The oral, selective cyclin-dependent kinase 4/6 inhibitor, ribociclib (RIB), has demonstrated significant overall survival benefit in combination with endocrine therapy (ET) in premenopausal patients with HR+, HER2- ABC. Here, we present a subgroup analysis of premenopausal patients from the Core Phase of ComPLEEment-1 (NCT02941926), a Phase IIIb trial of RIB in combination with letrozole (LET) in patients with HR+, HER2- ABC, which included a more diverse and broader patient population, reflecting a real-world clinical setting. **Methods:** ComPLEEment-1 included women of any menopausal status and men with HR+, HER2- ABC treated with ≤1 line of prior chemotherapy and no prior hormonal therapy for advanced disease. Pts received RIB (600 mg QD, 3 weeks on/1 week off) in combination with LET (2.5 mg QD, continuous). Men and premenopausal women received a luteinizing hormone-releasing hormone agonist (3.6 mg goserelin or 7.5 mg leuprolide, Q28D). This subgroup analysis assessed the primary outcomes (safety and tolerability) and secondary outcomes of time to progression (TTP), overall response rate (ORR), and clinical benefit rate (CBR) in premenopausal women. Baseline and end-of-treatment patient quality of life (QoL) was also measured in patients from selected countries as a secondary endpoint using the FACT-B questionnaire. **Results:** At the data cutoff date (November 8, 2019), 722 premenopausal patients (22.2%; N = 3,246) had been evaluated, with a median duration of exposure to RIB of 18.3 months. Adverse events (AEs) were reported in 710 (98.3%) patients; 681 (94.3%) patients had treatment-related AEs. Grade ≥ 3 AEs were reported in 519 (71.9%) patients; severe treatment-related AEs were reported in 26 (3.6%) patients. There were no treatment-related fatal AEs. The most common all-grade AEs were neutropenia (76.9%), nausea (36.0%), and leukopenia (27.6%). The most common grade 3/4 AEs were neutropenia (57.9%), leukopenia (10.4%), and increased alanine aminotransferase (5.7%). Overall, 242 (33.5%) patients had ≥ 1 dose reduction of RIB, 170 (23.5%) due to AEs. 413 (57.2%) patients permanently discontinued treatment, 67 (9.3%) due to AEs. In this subgroup analysis, median TTP was 25.1 months (95% confidence interval [CI], 22.1-not estimable). For the 458 patients with measurable disease, ORR was 49.3% (95% CI, 44.7-54.0%) and CBR was 69.7% (95% CI, 65.2-73.8). FACT-B questionnaire assessments showed a trend that patient QoL was maintained while on treatment (n = 290). **Conclusions:** This subgroup analysis from ComPLEEment-1 supports the use of RIB + LET in premenopausal patients. ORR was similar to that seen in the Phase III MONALEESA-7 trial which studied RIB + ET in a premenopausal patient population, validating the efficacy of RIB in a close-to-real-world setting. The safety profile associated with RIB + LET was manageable and consistent with previous Phase III trials of RIB + LET.

Phase II study of nivolumab in combination with abemaciclib plus endocrine therapy in patients with HR+, HER2- metastatic breast cancer: WJOG11418B NEWFLAME trial

Jun Masuda<sup>1</sup>, Junji Tsurutani<sup>2</sup>, Norikazu Masuda<sup>3</sup>, Yuko Tanabe<sup>4</sup>, Tsutomu Iwasa<sup>5</sup>, Masato Takahashi<sup>6</sup>, Manabu Futamura<sup>7</sup>, Koji Matsumoto<sup>8</sup>, Kenjiro Aogi<sup>9</sup>, Hiroji Iwata<sup>10</sup>, Mari Hosonaga<sup>11</sup>, Toru Mukohara<sup>12</sup>, Kenichi Yoshimura<sup>13</sup> and Toshimi Takano<sup>1</sup>. <sup>1</sup>The Cancer Institute Hospital of JFCR, Toranomon Hospital, Tokyo, Japan<sup>2</sup>Showa University, Tokyo, Japan<sup>3</sup>National Hospital Organization Osaka National Hospital, Osaka, Japan<sup>4</sup>Toranomon Hospital, Tokyo, Japan<sup>5</sup>Kindai University Faculty of Medicine, Osaka, Japan<sup>6</sup>NHO Hokkaido Cancer Center, Hokkaido, Japan<sup>7</sup>Gifu University, Gifu, Japan<sup>8</sup>Hyogo Cancer Center, Hyogo, Japan<sup>9</sup>NHO Shikoku Cancer Center, Ehime, Japan<sup>10</sup>Aichi Cancer Center, Nagoya, Japan<sup>11</sup>The Cancer Institute Hospital of JFCR, Tokyo, Japan<sup>12</sup>National Cancer Center Hospital East, Kashiwa, Japan<sup>13</sup>Hiroshima University Hospital, Hiroshima, Japan

**Background:** Currently, the standard immunotherapy treatment for anti-programmed death-ligand 1 (PD-L1)-positive triple-negative breast cancer is a combination of PD-L1 antibody and nab-paclitaxel. PD-1/PD-L1 antibody was investigated as a treatment for hormone receptor positive (HR+) breast cancer; however, the efficacy of single agents is poor. In pre-clinical studies, anti-PD-1/PD-L1 antibody, CDK4/6 inhibitors, and endocrine therapy (ET) have synergistic effects. We initiated this investigator-initiated trial to evaluate the efficacy and safety of the combination of nivolumab, abemaciclib, and ET (fulvestrant [FUL] or letrozole [LET]) as a first- or second-line treatment for patients (pts) with HR+, human epidermal growth factor receptor 2 negative (HER2-) metastatic breast cancer (MBC). **Methods:** This multicenter, multi-cohort, nonrandomized, open-label phase II study evaluated the efficacy and safety of nivolumab, abemaciclib, and ET (FUL or LET) in pts with HR+, HER2- MBC. Key eligibility criteria for the FUL cohort were: HR+, HER2- MBC with ECOG PS  $\leq$  1; measurable disease; no more than one ET; no prior chemotherapy for MBC; and had exhibited disease progression while receiving ET, adjuvant ET, or  $\leq$  12 months after adjuvant ET. Key eligibility criteria for the LET cohort were: postmenopausal HR+, HER2- MBC with ECOG PS  $\leq$  1; measurable disease; and no prior systemic therapy. ET as an adjuvant was permitted if the patient had a disease-free interval  $>$  12 months after the completion of ET. Patients received 240 mg nivolumab on days 1 and 15, 150 mg abemaciclib twice daily, and either 500 mg FUL on days 1, 15, 29, and every 4 weeks thereafter (FUL cohort) or 2.5 mg LET once daily (LET cohort) until disease progression or unacceptable toxicity. The primary endpoint was the objective response rate (ORR). Key secondary endpoints included toxicity, disease control rate (DCR: CR+PR+SD), progression-free survival (PFS), and the overall survival (OS). The threshold and expected ORR of the FUL cohort were 45% and 60%, respectively; and 32 pts would ensure a statistical power of 80% ( $\alpha = 0.20$ ). The threshold and expected ORR of the LET cohort were 55% and 75%, respectively; and 16 pts would ensure a statistical power of 80% ( $\alpha = 0.20$ ). **Results:** Between June and December 2019, 17 pts were enrolled (FUL cohort: n = 12, LET cohort: n = 5). One patient in the FUL cohort was excluded due to prior treatment history. Enrollment was closed and combination treatment was discontinued mid-study due to safety concerns. All pts had  $\geq$  1 adverse event (AE). AEs  $\geq$  Grade 3 were observed in 91.7% and 100% of pts in the FUL and LET cohorts, respectively. Immune-related AEs  $\geq$  Grade 3 were observed in 66.7% and 60.0% of pts in the FUL and LET cohorts, respectively. The most frequent AEs  $\geq$  Grade 3 were elevated liver function tests (LFT; FUL cohort: 50.0%, LET cohort: 60.0%). Immune-related (elevated LFT) AEs  $\geq$  Grade 3 were observed in 50.0% and 40.0% of pts in the FUL and LET cohorts, respectively. Severe AEs (SAEs) were observed in 50.0% and 60.0% of pts in the FUL and LET cohorts, respectively. One treatment-related patient death occurred in the LET cohort due to interstitial lung disease (ILD). ORR was 54.5% (6/11) and 20% (1/5) in the FUL and LET cohorts, respectively. DCR was 90.9% (10/11) in the FUL cohort and 80.0% (4/5) in the LET cohort. Due to the discontinuation, PFS and OS were undetermined. **Conclusions:** Although nivolumab + abemaciclib + FUL appeared to have activity, our findings do not support further investigation of this combination therapy due to toxicity. Toxicity profiles vary with CDK4/6 inhibitors; therefore, a different inhibitor may improve tolerability. Results of the ongoing nivolumab, palbociclib, and ET trial are awaited (CheckMate 7A8, NCT04075604). Clinical trial information: JapicCTI-194782.

Tao kinase 3 augment the resistance to microtubule-disrupting agents in breast cancer cells

Chih-Yeu Fang<sup>1</sup>, Tsung-Ching Lai<sup>2</sup> and Michael Hsiao<sup>1</sup>. <sup>1</sup>Genomics Research Center, Academia Sinica, Taipei, Taiwan<sup>2</sup>Department of Pulmonary Medicine, WanFan Hospital, Taipei Medical University, Taipei, Taiwan

Breast cancer is the leading type of cancer in women worldwide. It is a heterogeneous disease that contains several subtypes with substantial differences in pathology and clinical outcome. With the advancements in imaging and targeted therapy, many patients with early stages of this disease have a great opportunity to be cured. However, recurrence or metastasis of tumor still occurs in patients even after successful primary treatment. Chemotherapy remains one of the most important treatment for advanced breast cancer. Anti-microtubule agents including taxanes, eribulin and vinca-alkaloids constitutes the major anti-breast cancer chemotherapeutic category, while chemoresistance remains a thorny issue for advanced disease. We aimed to discover novel candidate regulators for chemoresistance in breast cancer. A lentiviral-based, high-throughput shRNA platform was developed for screening the variation of global kinome to find new therapeutic targets in paclitaxel-resistant breast cancer cells. The underlying molecular mechanisms was further explored by global phosphoprotein array and expression microarray. The serine/threonine kinase, TAO Kinase 3 (TAOK3), was identified from 724 kinase genes. Knockdown of TAOK3 exhibited the most profound reduction of IC50 values in response to paclitaxel treatment in breast cancer cells. High expression of TAOK3 was related to poor prognosis in breast cancer patients after adjuvant chemotherapy. Furthermore, the expression of TAOK3 also decreased the sensitivity to other anti-microtubule drugs, including eribulin and vinorelbine. Expression microarray analysis revealed that NF- $\kappa$ B signaling plays the major regulation roles in TAOK3-associated resistance. Taken together, our results showed that TAOK3 increases resistance to anti-microtubule drug through upregulating the NF- $\kappa$ B signaling in breast cancer. Inhibitors that disrupt TAOK3 and NF- $\kappa$ B signaling pathway may overcome the drug resistance for patients treated with anti-microtubule agents.

Risk estimation of locoregional recurrence, distant metastasis and second primary breast cancer in early stage breast cancer patients: The INFLUENCE 2.0 nomogram

Sabine Siesling<sup>1</sup>, Vinzenz Volkel<sup>2</sup>, Tom Hueting<sup>3</sup>, Teresa Draeger<sup>4</sup>, Marissa C van Maaren<sup>1</sup>, Luc JA Strobbe<sup>5</sup>, Marjanka K Schmidt<sup>6</sup>, Gabe S Sonke<sup>6</sup>, Marjan van Hezewijk<sup>7</sup> and Catharina GM Groothuis-Oudshoorn<sup>8</sup>. <sup>1</sup>Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, Netherlands<sup>2</sup>Tumor Center Regensburg, Regensburg, Germany<sup>3</sup>Evidencio Medical Decision Support, Haaksbergen, Netherlands<sup>4</sup>Tumor Center Regensburg, Regensburg, Netherlands<sup>5</sup>Canisius Wilhelmina Hospital, Nijmegen, Netherlands<sup>6</sup>Netherlands Cancer Institute, Amsterdam, Netherlands<sup>7</sup>Radiotherapy Group, Arnhem, Netherlands<sup>8</sup>University of Twente, Enschede, Netherlands

**Background** Breast cancer follow-up aims at early detection of locoregional recurrences (LRR) and second primary breast cancer (SP). Predicting a patient's time-dependent risk for such an event may improve follow-up strategies. Furthermore, many clinicians and patients are interested in the risk of distant metastasis (DM) as well, as it provides additional information on prognosis. The existing INFLUENCE nomogram predicts the yearly risk of LRR up to five years from diagnosis using logistic regression analyses. However, this model was based on patients diagnosed between 2003 and 2006 and lacked information on HER2 status, which is nowadays an important prognostic variable. In this population-based study, we aimed to improve the INFLUENCE model with more flexible predictions over time, more recent information and additional outcomes - risk of LRR, distant metastasis (DM) and SP - using different underlying models.

**Methods** Patient-, tumor- and treatment-related characteristics of all female patients diagnosed with invasive adenocarcinoma of the breast in 2007, 2008 and 2012, of who active 5-year follow-up was performed, were selected from the Netherlands Cancer Registry. Models were developed for LRR, DM and SP as a first event separately, and for each three-monthly time interval to predict time-dependent risks as accurately as possible. Follow-up was calculated from date of definite surgery to date of event or last observation. We compared three different models to estimate the three outcomes: a Cox regression model, a flexible parametric spline model and a random survival forest (RF) model. To assess calibration of each outcome, three-monthly risk predictions during the 5-year follow-up period were compared to corresponding observed event rates. To assess discrimination, the areas under the curves (AUC) were calculated for each timeframe in the 5-year period and averaged to one combined measure (average 5-year AUC). To correct for optimism we performed bootstrapping on the entire cohort with 200 replicates and updated the calibration measures and AUCs accordingly.

**Results** In total, 13,494 patients were included. LRR, DM and SP within five years were experienced by 2.8%, 6.3% and 3.1% of the patients, respectively. The following variables were included in the final models: age, tumor grade, tumor stage, nodal stage, multifocality, HER2 status, hormonal receptor status, type of surgery, chemotherapy, radiotherapy, hormonal therapy, anti-HER2 therapy. The optimism-corrected mean time-dependent prediction errors for individual risk predictions ranged between 0.12% and 0.46% for all three models and all three month timeframes. The average 5-year AUCs for LRR, SP and DM using the Cox model were 0.71, 0.63 and 0.77, respectively. The average 5-year AUCs for LRR, SP and DM using the parametric spline model were 0.71, 0.63 and 0.78, respectively. When using the RF model, the average 5-year AUCs were 0.74, 0.68 and 0.77 for LRR, SP and DM, respectively (Table).

**Conclusion** Although differences were very small, the RF model had the best performance overall. This INFLUENCE 2.0 model provides us with updated information on the individual time-dependent risks of LRR, DM and SP within five years following surgery. This model is freely accessible at <https://tinyurl.com/influence-2> and can be used as an instrument to improve follow-up strategies and to give patients better insights in their prognosis.

Table. Optimism-corrected average AUCs over the 5-year follow-up period

Model type	LR	DM	SP
Cox regression	0.71	0.77	0.63
Flexible parametric spline	0.71	0.78	0.63
Random survival forest	0.74	0.77	0.68

Epithelial proliferation score as an independent breast cancer risk predictor in benign breast disease

Jodi M Carter<sup>1</sup>, Matthew R Jensen<sup>1</sup>, Robert A Vierkant<sup>1</sup>, Stacey J Winham<sup>1</sup>, Tanya L Hoskin<sup>1</sup>, Marlene Frost<sup>1</sup>, Karthik Ghosh<sup>1</sup>, Derek C Radisky<sup>2</sup>, Amy C Degnim<sup>1</sup> and Mark E Sherman<sup>2</sup>. <sup>1</sup>Mayo Clinic, Rochester, MN; <sup>2</sup>Mayo Clinic, Jacksonville, FL

**Background:** Women with benign breast disease (BBD) experience an increased risk of breast cancer (BC). Histologic classification of BBD, as non-proliferative disease (NP), proliferative disease without atypia (PDWA) or atypical hyperplasia (AH), stratifies groups of patients into progressively higher categories of BC risk. However, this classification does not comprehensively assess the proliferative state of the epithelium throughout the biopsy. In addition, while AH is considered the most high-risk class of BBD, it is not always a highly proliferative lesion; atypical ductal lesions may reflect focal cytologic and architectural changes. We evaluated the association of an alternative classification of BBD severity and BC risk based on subjective grading of: 1) the maximal degree of epithelial proliferation and 2) multifocality of epithelial proliferation. **Methods:** Pathologists reviewed biopsies from participants aged 18 to 85 years in the Mayo BBD cohort (2002-2013), masked to BC outcomes, ascertained via questionnaires, tumor registry data and medical record review. Biopsies were classified as NP, PDWA or AH and semi-quantitatively scored for: 1) maximal degree of epithelial proliferation within a focus (DP) (0-3; none to severe) and 2) multifocality of proliferation (MP) (0-3; none to multiple foci). DP and MP scores were also summed to give a DP+MP score (0-6). Associations of DP and MP with BC risk were examined using Cox proportional hazards regression analyses, adjusting for age at BBD biopsy. Women were followed from date of initial biopsy to date of BC, death or last follow-up. **Results:** Of the 1529 assessable biopsies, 544 (35.6%) were classified as NP, 708 (46.3%) as PDWA and 277 (18.1%) as AH. Both DP and MP scores had significant positive correlation with increasing BBD severity (DP:  $r=0.51$ ,  $p<0.001$ ; MP:  $r=0.52$ ,  $p<0.001$ ). Mean (SD) DP scores were 0.6 (0.6) for NP, 1.6 (0.9) for PDWA, and 1.8 (0.7) for AH (ANOVA  $p<0.001$ ). Mean (SD) for MP scores were 0.6 (0.6) for NP, 1.4 (0.8) for PDWA, and 1.8 (0.8) for AH (ANOVA  $p<0.001$ ). Mean (SD) for DP+MP scores were 1.2 (1.2) for NP, 2.9 (1.5) for PDWA, and 3.6 (1.2) for AH (ANOVA  $p<0.001$ ). With median follow-up of 8.8 years for controls and 5.3 years for cases, 10.6% of the women in the cohort developed BC. Compared to those with DP scores of 0, women with DP scores of 3 had significantly increased BC risk (HR 1.42, 95% CI: 1.16, 1.74,  $p=0.003$ ). MP was associated with a non-significant increase in BC risk for scores of 3 versus 0 (HR: 1.20, 95% CI: 0.97, 1.49,  $p=0.11$ ). DP+MP scores of 6 conferred the highest BC risk (HR (score 6 vs. 0): 1.62, 95% CI 1.18, 2.21,  $p=0.02$ ). Results did not substantively differ after adjusting for BBD severity as NP, PDWA or AH. **Conclusions:** In this preliminary analysis within the Mayo BBD cohort, both proliferative degree (DP) and multifocality (MP) scores were correlated with histologic severity of BBD. DP and DP+MP scores were each associated with increased BC risk. We conclude that improved characterization of epithelial proliferation in BBD biopsies may enable refined prediction of individual BC risk.

Preclinical head-to-head comparison of CDK4/6 inhibitor activity toward CDK4 vs CDK6

Scott Delach and Giordano Caponigro. Novartis Institutes for Biomedical Research, Cambridge, MA

**Background:** The cyclin-dependent kinase (CDK) 4/6 inhibitors ribociclib, abemaciclib, and palbociclib have been established as effective treatment options for hormone receptor–positive (HR+) human epidermal growth factor receptor 2–negative (HER2–) breast cancer. While these agents have not been evaluated head-to-head in clinical studies, they have all demonstrated significant progression-free survival improvements; however, only two of these, abemaciclib plus endocrine therapy (ET; MONARCH 2) and ribociclib plus ET (MONALEESA-3 and MONALEESA-7), achieved significant overall survival (OS) to date prompting closer examination of how these CDK4/6 inhibitors are distinct. Preclinical studies revealed differences in how these molecules interact with various kinases. These studies indicated that ribociclib and palbociclib exhibited greater selectivity for CDK4 and CDK6 relative to other human kinases than abemaciclib. In addition, studies suggested that these molecules displayed different relative activity against their primary targets CDK4 and CDK6. Although intriguing, these latter studies either used purified proteins without the accompanying cellular context or used proliferation as a proxy for target engagement. Here, we sought to extend the body of evidence created by the prior analyses by constructing cellular model systems where the effects of each CDK4/6 inhibitor on CDK4 or CDK6 could be studied in isolation. **Methods:** MEL-JUSO (an *NRAS* mutant melanoma cell line) and MIA PaCa-2 (a *KRAS* mutant pancreatic ductal adenocarcinoma cell line) cells were selected for this analysis after being identified as lacking dependence on either CDK4 or CDK6, as indicated by short hairpin RNA knockdown. Isogenic variants of each cell line lacking either CDK4 or CDK6 expression were generated by ablating CDK4 or CDK6 expression using CRISPR/CAS9 genome editing techniques and single-cell clonal selection. Levels of phosphorylated RB (phospho-RB) protein were used as a readout for target inhibition and were measured by Fast Scan phospho-RB (ppRB807/811) enzyme-linked immunosorbent assay (ELISA). Half-maximal inhibitory concentrations (IC<sub>50</sub>) for each CDK4/6 inhibitor were calculated in parental cells, as well as variant cell lines expressing only CDK4 or CDK6. Additionally, measurement of phospho-RB was performed in T47-D cells (an estrogen receptor–positive breast cancer cell line) to confirm results of prior analyses. **Results:** The level of phospho-RB inhibition in T47-D cells was similar to what has been described previously (Chen P, et al. *Mol Cancer Ther.* 2016). In MEL-JUSO cells, ribociclib, abemaciclib, and palbociclib inhibited CDK4 at 11-, 22-, and 2-fold lower drug concentrations than CDK6, respectively. In MIA PaCa-2 cells, ribociclib, abemaciclib, and palbociclib inhibited CDK4 at 9-, >47-, and 2-fold lower drug concentrations than CDK6, respectively. **Conclusions:** Consistent with prior biochemical studies and cell proliferation assays, our findings indicate that both ribociclib and abemaciclib more potently inhibit CDK4 than CDK6, whereas palbociclib has similar activity against both targets in cells. Understanding the importance of CDK4 relative to CDK6 in the etiology of breast cancer and possible implications for increased CDK4 target engagement is an emerging topic of discussion in the field. Given that CDK4 has been shown to be expressed at higher levels in breast tumor samples, and many breast cancer cell lines have demonstrated greater dependence on CDK4 vs CDK6, the differential inhibition of the CDK4/6 inhibitors may have important implications.

Targeting insulin receptor in estrogen receptor positive breast cancer

Lynsey M. Fetting<sup>1</sup>, Jingran Cao<sup>1</sup>, Kelly LaPara<sup>1</sup>, Sylaja Murikipudi<sup>2</sup>, Andrea R. Delpero<sup>2</sup>, Thomas M. Lancaster<sup>2</sup>, Todd C. Zion<sup>2</sup> and Douglas Yee<sup>1</sup>.

<sup>1</sup>University of Minnesota, Minneapolis, MN; <sup>2</sup>Akston Biosciences, Beverly, MA

Obesity and metabolic dysfunction are on the rise in the United States. Hyperinsulinemia, frequently seen in these conditions, correlates with an increased risk of development of and mortality from estrogen receptor (ER) positive breast cancer. Expression of components of the insulin and insulin-like growth factor (IGF) family of proteins promote cancer cell growth *in vitro*, is linked to shorter progression-free survival, and is associated with an increased risk of metastatic disease and death in breast cancer patients. Previously our lab found that development of resistance to the commonly used ER-targeting drug tamoxifen (Tam) *in vitro* is associated with a loss of the type I IGF receptor expression with an increased dependence on the homologous insulin receptor (IR). These data argue for targeting IR in breast cancer, but concern has been raised due to the potential of disrupting glucose homeostasis in patients with or without existing metabolic disease. To address this concern, a novel insulin-Fc fusion protein (AKS-130) was developed to lower blood glucose levels without causing clinical hypoglycemia with a potential to target tumor IR. AKS-130 was found to downregulate IR expression in models of colorectal cancer (HCT-116) and malignant melanoma (WM266.4). Further, AKS-130 suppressed xenograft growth in fed and fasted states.

We examined if AKS-130 had similar effects on ER positive breast cancer cells. To test the hypothesis that resistance to endocrine therapy increases the reliance of ER positive breast cancer cells on IR signaling, we utilized the ER positive breast cancer cell lines (MCF-7, T47D) and their Tam resistant derivatives (MCF-7 TamR, T47D TamR). Similar to in HCT-116 and WM266.4 cells, we found that AKS-130 is a modest agonist of IR in ER+ breast cancer cells. Exposure to AKS-130 led to a marked reduction in IR expression in both parental and TamR cell lines, and was associated with partially suppressed downstream signaling to Akt. Interestingly, AKS-130 induced proliferation at similar levels to insulin treatment in parental and TamR cells at 3 and 5 days post treatment, however AKS-130 prevented further insulin-stimulated proliferation. *In vivo*, AKS-130 treatment by itself did affect MCF7 parental xenograft growth however AKS-130 in combination with Tam trended toward extending time to a tumor size of 500mm<sup>3</sup>. In MCF7 TamR xenografts, addition of AKS-130 to Tam treatment also trended toward delaying xenograft growth. Importantly, prolonged treatment with AKS-130 did not lead to significant changes in weight or blood glucose.

Taken together these data show that novel agents, such as AKS-130, may serve as way to disrupt IR signaling in cancer cells without affecting host glucose metabolism. Addition of AKS-130 to Tam treatment trended toward delaying xenograft growth though further studies are needed. These data indicate that IR signaling may represent a target to overcome or delay endocrine therapy resistance in breast cancer.

Impact of Medicaid expansion on racial disparities in time to adjuvant chemotherapy administration among breast cancer (BC) patients

Mariana Chavez-MacGregor, Xiudong Lei, Hui Zhao, Tina Shih and Sharon H Giordano. The University of Texas MD Anderson Cancer Center, Houston, TX

**BACKGROUND:** Delays in adjuvant chemotherapy initiation have a detrimental effect in outcomes and are more frequently seen among racial/ethnic minorities, uninsured patients and those with low socioeconomic status. A provision in the Affordable Care Act called for expansion of Medicaid eligibility in order to cover more low-income Americans. In this study we evaluate the impact of Medicaid expansion on racial disparities in time to adjuvant chemotherapy administration in a large cohort of BC patients. **METHODS:** Women (aged 40-64) diagnosed with primary invasive BC (stage I-III) between 01/01/2007 and 12/31/2016 were identified in the National Cancer Database. All patients underwent surgery as initial treatment modality and received adjuvant chemotherapy within 6 months of surgery. Chemotherapy delay was defined as >60 days from surgery to the first dose of chemotherapy. The cohort was limited to those residing in states that underwent Medicaid expansion in 2014 (KY, NV, CO, OR, NM, WV, AR, RI, AZ, MD, MA, ND, OH, IA, IL, VT, HI, NY, DE). For comparison purposes, 2007-2013 was considered the pre-expansion period and 2014-2016 the post-expansion period. We calculated difference-in-difference (DID) estimates using multivariable linear regression models. Results are presented as adjusted differences (in % points) between race/ethnicity groups in the pre and post-expansion periods, and as adjusted DID with 95% CI. A negative DID estimate indicates that Medicaid expansion reduces the racial/ethnic disparity in chemotherapy administration delay. The parallel trend assumption was tested. Variables in the final model included age, comorbidities, BC subtype, insurance status, distance to treatment facility, region, education, household income, facility type and facility case volume. **RESULTS:** 105,385 patients were included (median age 53), of them 75,663 (71.8%) were diagnosed in the pre- and 29,722 (28.2%) in the post-expansion period. 77.5% of the patients were White, 11.7% Black and 4.9% Hispanic. The proportion of patients experiencing chemotherapy initiation delays was greater among Blacks and Hispanics in both study periods compared to Whites. The proportion of chemotherapy delays decreased for all races between the pre and the post-expansion period. We observed a statistically significant decrease in the chemotherapy initiation racial disparity. The adjusted DID was -2% (95%CI -3.8 to -0.3, P=0.02) between Whites and Blacks and -3% (95%CI -5.5 to -0.5, P=0.02) between Whites and Hispanics. In a subgroup analysis among 10,777 Medicaid patients the parallel trend assumption was not valid, therefore we estimated the DID between Whites and Blacks using a propensity-score based weight sample, identifying a reduction in the racial disparity of even greater magnitude (DID -9.1% [-14.4 to -3.8, P<0.001]).

Race	Pre-Expansion			Post-Expansion			Adjusted DID (95% CI), Percentage Points	P
	N	Adjusted Rate of Delayed Chemo > 60 days	Adjusted Difference Between White Race (% points)	N	Adjusted Rate of Delayed Chemo > 60 days	Adjusted Difference Between White Race, (%points)		
White	59305	27.2	0	22325	24.2	0	Ref	Ref
Black	8560	36.1	8.9	3720	31.1	6.9	-2.0 (-3.8 to -0.3)	0.02
Hispanic	3432	32.3	5.1	1704	26.3	2.1	-3.0 (-5.5 to -0.5)	0.02

**CONCLUSIONS:** We demonstrate that Medicaid expansion reduced racial disparities by decreasing the proportion of Blacks and Hispanics experiencing delays in adjuvant chemotherapy initiation and decreasing the gap that exists when compared to Whites. These important results highlight the positive impact of policies aimed at improving equity and increasing access to health care.

Intratumoural heterogeneity in PgR expression: Molecular and prognostic significance

Lila Zabaglo<sup>1</sup>, Richard Buus<sup>2</sup>, Eugene Schuster<sup>2</sup>, Belinda Yeo<sup>3</sup>, Marie Klintman<sup>4</sup>, Ivana Sestak<sup>5</sup>, Jack Cuzick<sup>5</sup>, Ian Smith<sup>6</sup> and Mitch Dowsett<sup>1</sup>.

<sup>1</sup>Ralph Lauren Centre for Breast Cancer Research, Royal Marsden Hospital, London, United Kingdom<sup>2</sup>Breast Cancer Now Toby Robins Research Centre, The Institute of Cancer Research, London, United Kingdom<sup>3</sup>Olivia Newton-John Cancer Research Institute, Austin Hospital, Melbourne, Australia<sup>4</sup>Lund University Cancer Centre, Lund, Sweden<sup>5</sup>Centre for Cancer Prevention, Wolfson Institute of Preventive Medicine, Queen Mary University of London, London, United Kingdom<sup>6</sup>Breast Unit, Royal Marsden Hospital, London, United Kingdom

**Background:** PgR is only expressed significantly in ER+ breast cancers and is generally considered a classical estrogen-sensitive protein, however, while ER+ cells are almost always expressed in a non-clustered pattern across the tumour bed, PgR+ cells form clusters or clumps with surrounding areas of PgR- cells when assessed by IHC in about 20-25% of PgR+ tumours. This is an ill-described and unexplained feature of intratumoural heterogeneity of a widely measured biomarker. The prognostic significance of the PgR clumpiness is also unknown.

**Aims:** to determine the (i) biologic and (ii) prognostic significance of PgR clumpiness in ER+ primary breast cancer.

**Methods:** (i) Biologic study: 40 primary ER+PgR+ tumours were identified with distinct PgR clumpiness by IHC. Areas of PgR+ and PgR- cells (PgR-rich and PgR-poor areas, respectively) were needle microdissected from unstained sections by juxtaposing them with PgR-stained sections from the same tumour. Areas were also dissected from 8 homogeneous PgR+ and 8 PgR- tumours for reference. NanoString gene expression analysis using a 50-gene code set (45 oestrogen-responsive or proliferation genes + 5 housekeeping genes) was performed on RNA extracts from the samples. (ii) Prognostic study: we developed a PgR heterogeneity score (PgR Het-score, range 0-18) as the product of (A) the number of PgR+ clumps/cm<sup>2</sup> of tumour area (range 0 to 6) and (B) the level of overall PgR-positivity (0-4% or 96-100%, score 0; 5-19% or 80-95%, score 1; 20-39 or 60-79%, score 2; 40-59%, score 3). PgR Het-scores were derived from images (Hamamatsu NanoZoomer-XR) of PgR-stained sections from two sets of tumour biopsies taken at diagnosis after which all patients received adjuvant endocrine therapy: 322 tumours from the Royal Marsden and from Southern Sweden collected for a case:control study of risk of recurrence (recurrence:no recurrence, 1:1) and 591 patients from the TransATAC cohort study with time to recurrence as the end-point.

**Results:** (i) Biologic study: In unsupervised hierarchical clustering of RNA expression from all samples, 33/40 pairs of PgR-rich and PgR-poor areas from a single tumour paired together and all 8 positive and negative control samples were grouped separately. Eight genes were differentially expressed between the PgR-rich and -poor areas (FDR<0.05: PGR, SERPINA3, AURKA, MSMB, PDZK1, IGSF1, FKBP5, SLC2A3). PGR had a 35-fold difference indicating that transcriptional differences explained the PgR IHC differences. The progesterone-regulated genes FKBP3 and SERPINA3 both showed significantly higher expression in PgR-rich areas consistent with the PgR differences having functional impact. AURKA was also more highly expressed in the PgR-rich areas indicating that the PgR-rich areas may also be more proliferative. ER and most of known estrogen-regulated genes were not differentially expressed and therefore show an unexpected divergence from PgR expression and regulation downstream of ER. (ii) Prognostic study: The PgR Het-score showed no consistent association with clinical factors including tumour size, nodal status, grade, age. Each of the individual components as well as the composite PgR Het score were significantly associated with risk of recurrence in POLAR: (A) p=0.02; (B) p=0.002; (PgR Het score) p=0.008. However, there was no association of the PgR Het score with risk of recurrence in TransATAC.

**Conclusion:** Major, functionally significant differences in PgR expression occur within some ER+ tumours that are not explained by differences in ER expression and are not associated with differences in expression of most other estrogen-dependent genes. Further work is on-going to provide a mechanistic explanation for the PgR heterogeneity. Given the discordance in results from the two clinical studies its prognostic significance is uncertain.

Hormone receptor positive breast cancers and Black race: Does gender matter?

Mariam Eskander<sup>1</sup>, Yaming Li<sup>1</sup>, Bridget Oppong<sup>1</sup>, Oindrila Bhattacharyya<sup>2</sup>, Allan Tsung<sup>1</sup> and Samilia Obeng-Gyasi<sup>1</sup>. <sup>1</sup>The Ohio State University, Columbus, OH; <sup>2</sup>Indiana University Purdue University, Indianapolis, IN

**Introduction:** Male breast cancer (MBC) patients present with later disease stages and have higher mortality rates than female breast cancer (FBC) patients. Additionally, black breast cancer patients, regardless of gender, consistently have worse clinical outcomes than their white counterparts. To date, there are few studies exclusively comparing clinical outcomes between black MBC and black FBC patients. The objective of this study is to understand the differences in presentation, treatment and mortality between black MBC and black FBC patients with hormone receptor positive breast cancer using the National Cancer Database (NCDB).

**Methods:** The NCDB was queried for all black MBC and FBC patients, ages 18-90, with hormone receptor positive breast cancer diagnosed between 2010-2016. Hormone receptor positivity was defined as estrogen receptor positive, progesterone positive and HER 2-negative cancer. Sociodemographic and clinical variables were compared between MBC and FBC patients on univariate analysis. For stages I-III patients, a propensity score (PS) was generated by a logistic regression model including the following covariates: age at diagnosis, tumor size, nodes removed, node positivity, resection margin status, hormonal treatment, chemotherapy treatment, and radiation treatment. MBC patients were matched to FBC patients using PS 2:1 nearest-neighbor matching. A log rank test was used to determine differences in survival between the matched cohort.

**Results:** There were 994 black MBC and 65,931 black FBC patients that met study criteria. MBC patients were older at diagnosis than women (age, MBC 63 ± 12.5, FBC 60.6 ± 13.3). Compared to FBC patients, more MBC patients had lower oncotype scores (RS 0-10, MBC 39.7%, FBC 24%, p<0.001). Additionally, MBC patients were more likely to present with metastatic disease (stage 4, MBC 4.4%, FBC 2.6%, p<0.001), had fewer smaller tumors (tumor size <2cm, MBC 32.1, FBC 49.1%, p<0.001) and a higher percentage of poorly differentiated tumors (grade 3, MBC 28.5%, FBC 21.4%, p<0.001). Notably, MBC patients had lower rates of hormone therapy (MBC 66.4%, FBC 80.7%, p<0.001) and neoadjuvant chemotherapy (MBC 5.8%, FBC 7.5%, p=0.05) utilization than their female counterparts. On propensity score matched analysis black MBC patients had a higher overall mortality compared to FBC patients (p=0.026).

**Conclusion:** Hormone receptor positive black MBC patients in the NCDB present with more advanced stages of disease, are less likely to receive endocrine therapy and have worse overall mortality compared to their black FBC counterparts. These results indicate that significant gender-based disparities exist in presentation, treatment and mortality among black breast cancer patients. Future studies should evaluate how biologic sex and tumor biology intersect to affect these intra-racial differences in clinical outcomes.

A Phase 1b/2 Study of the BET inhibitor ZEN003694 in combination with talazoparib for treatment of patients with TNBC without gBRCA1/2 mutations

Philippe Aftimos<sup>1</sup>, Mafalda Oliveira<sup>2</sup>, Kevin Punie<sup>3</sup>, Valentina Boni<sup>4</sup>, Erika Hamilton<sup>5</sup>, Ayca Gucalp<sup>6</sup>, Payal Shah<sup>7</sup>, Lida Mina<sup>8</sup>, Priyanka Sharma<sup>9</sup>, Lisa Bauman<sup>10</sup>, Eric Campeau<sup>11</sup>, Sarah Attwell<sup>11</sup>, Margo Snyder<sup>10</sup>, Karen Norek<sup>11</sup>, Akos Czibere<sup>12</sup>, Yanke Yu<sup>13</sup>, Michael H Silverman<sup>10</sup>, Sanjay Lakhota<sup>10</sup>, Susan Domchek<sup>7</sup>, Jennifer Litton<sup>14</sup> and Mark Robson<sup>6</sup>. <sup>1</sup>Institut Jules Bordet - Universite Libre de Bruxelles, Brussels, Belgium<sup>2</sup>Vall d'Hebron Institute of Oncology, Barcelona, Spain<sup>3</sup>UZ Leuven, Leuven, Belgium<sup>4</sup>START, Madrid, Spain<sup>5</sup>Sarah Cannon Research Institute, Nashville, TN;<sup>6</sup>Memorial Sloan Kettering Cancer Center, New York City, NY;<sup>7</sup>Abramson Cancer Center University of Pennsylvania, Philadelphia, PA;<sup>8</sup>Banner MD Anderson Cancer Center, Gilbert, AZ;<sup>9</sup>University of Kansas Cancer Center, Westwood, KS;<sup>10</sup>Zenith Epigenetics, San Francisco, CA;<sup>11</sup>Zenith Epigenetics, Calgary, AB, Canada<sup>12</sup>Pfizer, Cambridge, MA;<sup>13</sup>Pfizer, La Jolla, CA;<sup>14</sup>University of Texas MD Anderson, Houston, TX

**Background:** Metastatic triple-negative breast cancer (TNBC) is an aggressive and heterogeneous cancer with limited therapeutic options. PARP inhibitors (PARPi) are approved to treat breast cancer harboring germline BRCA1/2 (*gBRCA1/2*) mutations and have not shown efficacy in homologous recombination DNA repair (HRR) proficient tumors. In pre-clinical models, the BET inhibitor (BETi) ZEN003694 sensitizes wild-type *BRCA1/2* tumors to PARPi through downregulation of HRR gene expression, providing a rationale for combination therapy. We report initial results from a Ph 1b/2 trial evaluating the combination of ZEN003694 and the PARPi, talazoparib, in TNBC patients without *gBRCA1/2* mutations.

**Methods:** A Ph 1b dose-finding segment will be followed by a single-arm Ph 2 Simon 2-stage segment. Ph 1b evaluated several dose combinations of ZEN003694 and talazoparib, with safety and recommended Ph 2 dose (RP2D) as primary endpoints and pharmacokinetics (PK), pharmacodynamics (PD), and clinical benefit rate (CBR = Objective response rate (ORR) + stable disease ≥ 4 months) as secondary endpoints. The Ph 2 segment has CBR as the primary endpoint and progression free survival (PFS) and duration of response as secondary endpoints. Eligibility criteria included TNBC (ER/PR < 10% and not a candidate for endocrine therapy), HER2-, wild-type *gBRCA1/2*, and ≥ 1 prior chemotherapy regimen for metastatic disease. Patients were dosed daily in continuous 28-day cycles until disease progression or unacceptable toxicity. Dose limiting toxicity (DLT) period was one cycle. Adverse events (AE), PK, and PD in whole blood and tissue biopsies were assessed. Response endpoints were assessed per RECIST 1.1 every 2 cycles.

**Results:** Findings of the Ph 1b are reported. 15 patients with a median 3 lines of prior therapy in the metastatic setting were enrolled in 3 dose-finding cohorts. RP2D was determined to be 48mg ZEN003694 plus 0.75mg talazoparib. Across the cohorts, the most common AE was thrombocytopenia (TCP) (73%) with 53% G3/4 (Table 1). G4 TCP was the DLT and 1 DLT patient required a platelet transfusion. TCP could be managed to G1/2 levels with intermittent dose holds and reductions. Other G1/2 AEs included fatigue, anorexia, neutropenia, nausea, dysgeusia, and photophobia. Dose intensity analysis showed average daily doses of ZEN003694 and talazoparib could be maintained above 40mg and 0.5mg, respectively, over 4 cycles. Exposures of ZEN003694 and talazoparib were dose proportional with no drug-drug PK interactions. At RP2D, PD assessment by a whole blood mRNA assay for BET-dependent genes demonstrated robust down-regulation of *CCR1*, *IL1RN*, and *IL8* to < 50% of baseline for > 8 h. Expression of HRR genes, *RAD51* and *BRCA1*, in whole blood also decreased for > 8 h. Analysis of an on-treatment biopsy showed robust and durable BET target modulation assessed by comparing RNA sequence data with a reference BET dependent signature. Across the 3 cohorts, ORR by Investigator was 38% (5/13), including 1 CR and 4 PRs, and CBR was 57% (8/14). 6 of the 15 patients are ongoing as of data analysis date (2-9 cycles), with 1 patient responding for > 6 months.

**Conclusions:** Combination of ZEN003694 and talazoparib demonstrated anti-cancer activity in pretreated metastatic TNBC patients without *gBRCA1/2* mutations. TCP is frequent but manageable with dose adjustments. PK is predictable, and PD data show meaningful target engagement. The Ph 2 part of the trial is currently ongoing.

Grade 3/4 Adverse Events	Cohort 1(1mg talazoparib + 48mg ZEN003694)N=6	Cohort 2(0.75 mg talazoparib + 48mg ZEN003694)N=6	Cohort 3(1mg talazoparib + 36mg ZEN003694)N=3

Molecular characterization of advanced breast cancer according to site of metastasis

Fara Braso-Maristany<sup>1</sup>, Laia Pare<sup>2</sup>, Nuria Chic<sup>1</sup>, Olga Martinez-Saez<sup>1</sup>, Tomas Pascual<sup>2</sup>, Meritxell Mallafre<sup>1</sup>, Blanca Gonzalez-Farre<sup>3</sup>, Esther Sanfeliu<sup>3</sup>, Debora Martinez<sup>1</sup>, Patricia Galvan<sup>1</sup>, Belinda Salinas<sup>3</sup>, Barbara Adamo<sup>3</sup>, Reinaldo Moreno<sup>3</sup>, Maria Vidal<sup>3</sup>, Montserrat Munoz<sup>3</sup> and Aleix Prat<sup>1</sup>. <sup>1</sup>August Pi i Sunyer Biomedical Research Institute, Barcelona, Spain<sup>2</sup>SOLTI Breast Cancer Cooperative Group, Barcelona, Spain<sup>3</sup>Hospital Clinic Barcelona, Barcelona, Spain

**Background:** There is an increasing need in the clinic to biopsy metastatic disease in patients with advanced breast cancer (ABC). However, the microenvironment and tumor cell biology of breast cancer metastasis is largely unknown. Here, we report a molecular characterization of ABC according to the site of metastasis. **Methods:** RNA from 184 FFPE metastatic samples were evaluated using the nCounter BC 360 Panel, which includes the expression of 689 BC-related genes and 82 immune-related genes. PAM50 subtypes (Basal-like, HER2-enriched [HER2-E], Luminal A, Luminal B and Normal-like) were also determined. HER2 protein expression was assessed by immunohistochemistry (IHC) in 115 tumor samples, and HER2-low tumors (i.e. 1+ or 2+ and ISH-negative) were identified. Descriptive statistics, significance analysis of microarrays (using False Discovery Rate [FDR]) and logistic regressions were used to identify organ-specific gene expression profiles. Finally, we derived an organ-specific predictor of 209-genes from our cohort, and applied it to the RNAseq-based TCGA PanCancer dataset, which includes 174 glioblastomas multiforme, 424 liver hepatocellular carcinomas and 576 lung adenocarcinomas, among other cancer-types. **Results:** A single metastatic tumor sample from 184 individual patients with ABC was obtained from bone (18%), liver (17%), skin (15%), brain (12%), breast (13%), lymph nodes (9%), lung (7%), pleura (5%), ovary (2%), muscle (1%) and peritoneum (1%). All PAM50 subtypes were identified across the main organ sites; however, significant differences in subtype distribution were observed ( $p < 0.001$ ). Basal-like subtype was more prevalent in brain, lung and skin metastasis (FDR=0.3%). Unsupervised analysis and principal component analysis revealed brain and liver metastasis as the most distinct. Supervised analysis identified organ-specific genes independently of PAM50 subtype, i.e.: bone-specific genes (*WIF1*, *IBSP*, *MMP9* and *ITGB3*); brain-specific genes (*CRYAB*, *SOX10*, *FGF1* and *CHI3L1*); liver-specific genes (*ALDH1A1*, *CYP4F3*, *PCK1*, and *SFRP2*); lung-specific genes (*CAV1*, *WNT5A*, *PTGS2* and *IL6*); skin-specific genes (*KRT14*, *KRT5*, *S100A7* and *SERPINB5*). Among the organ-specific gene list, 15 (30%) of the 50 PAM50 genes were identified, including up-regulation of *FGFR4* in liver, *ESR1* in bone, *ERBB2* in lung and *KRT5* and *KRT14* in skin. Regarding *ERBB2*, a high correlation between *ERBB2* mRNA and HER2 IHC expression (0, 1+, 2+ and 3+) was observed ( $p < 0.001$ ). Interestingly, HER2-low disease was identified across all PAM50 subtypes and organ sites, including bone metastasis. Regarding immune-genes, all were found differentially expressed across the main organ sites (FDR<5%) with lung metastasis showing the highest expression (i.e. *PDCD1*, *CD8A*, *GMZA*, *IL1B*) and liver and brain metastasis the lowest. Finally, the 209-gene organ-specific predictor in PanCancer TCGA identified 96% of glioblastomas multiforme as brain, 98.6% of liver hepatocellular carcinomas as liver and 57.1% of lung adenocarcinoma as lung. **Conclusions:** The main sites of metastasis in ABC have unique biological features independently of tumor molecular subtype. Our results suggest that treatment strategies based on the site(s) of metastasis should be explored.

Phase 1b clinical trial of HX008, a novel anti-PD-1 monoclonal antibody, Combined with gemcitabine and cisplatin in the first-line treatment of metastatic triple-negative breast cancer

Xichun Hu, Jun Cao, Biyun Wang, Jian Zhang, Leiping Wang, Zhonghua Tao and Ting Li. Fudan University Shanghai Cancer Center, Shanghai, China

**Background** HX008 is a humanized IgG4S228P anti-PD-1 monoclonal antibody with an engineered Fc domain. Gemcitabine plus cisplatin (GP) has shown satisfying antitumor activity as first-line therapy for metastatic triple-negative breast cancer (mTNBC) in CBCSG 006 trial (ClinicalTrials.gov, NCT01287624). The phase 1b study was conducted to assess the safety and preliminary antitumor activity of HX008, combined with GP in patients with mTNBC in first-line setting. **Methods** Eligible patients are mTNBC with  $\geq 6$  months DFI who never receive antitumor therapy for metastatic disease. Participants received HX008 at 3mg/kg (d1, q3w) plus gemcitabine at 1250mg/m<sup>2</sup> (d1, 8, q3w) and cisplatin 75mg/m<sup>2</sup> (d1, q3w). At most 6 cycles of GP chemotherapy were given, while HX 008 could be maintained until disease progression or unacceptable toxicity occurred. **Results** Between July 2019 and March 2020, a total of 31 patients were enrolled in this study. Median (range) age was 50 (29-69) years. Among 31 patients who were evaluated, 25 (80.6%) experienced objective response and the other 6 (19.4%) experienced stable disease (SD). The median progression free survival (PFS) was 9.07 months (95%CI, 7.29m-13.01m). The PFS data was not yet mature, for nearly half of the intent-to-treat population has not progressed by October 9, 2020. The most common treatment-related adverse events of grade 3 or 4 included neutropenia (71.0%), anemia (55.5%), thrombocytopenia (32.3%), hypocalcemia (9.68%), hypokalemia (6.45%), and Alanine aminotransferase increased (6.45%). There were no treatment-related deaths. **Conclusion** HX008 plus GP demonstrated promising activity and manageable safety in patients with mTNBC in first-line setting. Clinical trial information: CHINADRUGTRIALS.ORG, CTR 20191353.

Correlation of pathological complete response and radiological response with Contrast-enhanced mammography in breast cancer patients after neoadjuvant chemotherapy

Elisenda Llabres Valenti, Jose Carlos Antela Lopez, Monica Cejuela Solis, Alfonso Gomez de Liano, Victor Vega Benitez, Marta Pavcovich, Concepcion Jimenez Medina, Joel Joselito Aranda Sanchez, Isabel Reyes Rodriguez, Manuel Cazorla Betancor, Maria Eugenia Galan Garcia, Ana Alicia Tejera Hernandez, Pedro Perez Correa, Paula Junquera Rionda, Avinash Ramchandani Vaswani and Elena Vicente Rubio. Complejo Hospitalario Universitario Insular-Materno Infantil de Gran Canaria, Las Palmas de Gran Canaria, Spain

**Background:** Pathological complete response (pCR) after neoadjuvant chemotherapy (NAC) has been reported as a surrogate endpoint for prediction of disease-free survival (DFS) and overall survival (OS) particularly in HER2-positive and triple-negative (TN) breast cancer. NAC requires imaging techniques to accurately predict pathological response and subsequently surgical planning. Magnetic resonance imaging (MRI) has been the most sensitive technique to assess response to NAC, although it is expensive and time consuming. In our hospital we use Contrast-enhanced mammography (CEM) that is easy to perform, fast, reproducible and its signs are superimposable to the MRI, with the advantages of lower cost. It allows diagnosing multifocal, multicenter and bilateral involvement, and monitoring the response to treatment with NAC. **Aims:** Analyze the correlation between complete radiological response (rRC) with CEM and pCR in patients treated with NAC. Analyze this correlation based on the different immunophenotypes (IF). **Methods:** Retrospective analysis of 112 patients with stage II-III breast cancer treated with NAC, from January 2018 to April 2020, in the Complejo Hospitalario Universitario Insular-Materno Infantil de Gran Canaria, with CEM performed before and after NAC. pCR categorization using the Miller and Payne system, defined pCR as a non-invasive tumor in the breast and axilla (ypT0/is N0). **Results:** Of 112 analyzed patients, 8 did not undergo surgery (6 patients with T4d tumors received radical radiotherapy, 1 progressed during NAC and 1 did not undergo surgery for liver failure). Median age 53 years (range 31-89). Stages: IIA 26%, IIB 47%, IIIA 16%, IIIB 10%, IIIC 1%. IF: Luminal A: 11%, Luminal B Her2+: 33%, Luminal B Her2-: 23%, pure HER2: 21%, TN: 12%. NAC received: doxorubicin-cyclophosphamide (AC)-weekly paclitaxel 53%, Taxanes + pertuzumab + trastuzumab (PT) 39%, AC-paclitaxel + PT 4%, other 4%. 99 patients obtained radiological response: 60 (54%) rRC and 39 (35%) partial response. In 14 patients (12%) there was no response. 36% pCR (N = 37). The sensitivity (S) and specificity (E) of CEM for the evaluation of pCR were 67% and 95% respectively. S was 100% in pure HER2 and 78% in TN. The positive and negative predictive values (PPV and NPV) were 96% and 61% respectively. After a median follow-up of 19 months, 6 patients have relapsed and 2 have died. **Conclusion:** CSEM has an S and E to detect pCR after NAC of 67 and 95% respectively; rates higher than those offered in other series by the MRI. S and E are higher in pure HER2 and TN tumors.

Oral paclitaxel and encequidar (oPac+E) in the treatment of metastatic breast cancer (mBC): Management of gastrointestinal adverse events (GI AE). Study KX-ORAX-001

H S Rugo<sup>1</sup>, G Umanzor<sup>2</sup>, F J Barrios<sup>3</sup>, R H Vasallo<sup>4</sup>, M A Chivalan<sup>5</sup>, S Bejarano<sup>6</sup>, J R Ramirez<sup>7</sup>, L Fein<sup>8</sup>, R D Kowalyszyn<sup>9</sup>, D L Cutler<sup>10</sup>, D Kramer<sup>10</sup>, J Goldfinch<sup>10</sup>, H Wang<sup>10</sup>, T Moore<sup>10</sup> and R MF Kwan<sup>10</sup>. <sup>1</sup>University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA; <sup>2</sup>Liga Contra el Cancer, San Pedro Sula, Honduras; <sup>3</sup>Instituto Nacional de Cancerologia (INCAN), Guatemala City, Guatemala; <sup>4</sup>Clinical Research RD, Santo Domingo, Dominican Republic; <sup>5</sup>CELAN Clinica Medica, Guatemala City, Guatemala; <sup>6</sup>Excel Medica, San Pedro Sula, Honduras; <sup>7</sup>CRESEM, Quetzaltenango, Guatemala; <sup>8</sup>Instituto de Oncologia de Rosario, Rosario, Argentina; <sup>9</sup>Centro de Investigaciones Clinica, Clinica Viedma, Argentina; <sup>10</sup>Athenex Inc., Buffalo, NY

**Background:** There is a need for more effective and less toxic treatments for patients with mBC. Patients may prefer oral vs IV cytotoxic therapies to avoid frequent hospital visits. In addition, oral therapies allow frequent or metronomic dosing regimens which may alter the toxicity or activity profile of agents vs infrequent IV administration. oPac+E is oral paclitaxel combination with Encequidar, a specific, minimally absorbed, oral p-glycoprotein inhibitor that facilitates the absorption of oral paclitaxel. mBC patients who received oPac+E had significantly greater confirmed tumor response and longer survival with lower rates and severity of neuropathy but increased GI AE compared to IV paclitaxel (IVPac) (Study KX-ORAX-001 presented at SABCS, 2019, Abstract # GS6-01).

**Methods:** Study KX-ORAX-001 was a phase III, randomized, study in women with mBC for whom treatment with IVPac was recommended. Patients were randomized 2:1 to receive oPac+E or IVPac. Patients continued treatment until discontinuation due to progressive disease or toxicity. oPac 205 mg/m<sup>2</sup> was given once daily for 3 days weekly. E 12.9 mg was given 1 hour before each dose of oPac. IVPac 175 mg/m<sup>2</sup> was infused over 3 hours every 3 weeks. The primary endpoint was efficacy defined as tumor response confirmed by BICR at two consecutive evaluations. Key secondary endpoints included PFS, OS. Safety was monitored throughout the study.

**Results:** All IVPac patients received high-dose dexamethasone and antihistamine premedication, which have significant anti-emetic activity and may have received additional anti-emetic agents as needed. The protocol did not allow any prophylaxis for GI AE for oPac+E patients nor were they to receive predose corticosteroids, nor antihistamines.

The protocol was amended after approximately 30% of patients were enrolled to allow prophylactic anti-emetic medications for patients randomized to oPac+E. Patients were also given loperamide to take at home and were instructed to initiate loperamide with the onset of diarrhea. The rates of Grade ≥2, vomiting and diarrhea for patients treated with IVPac, the patients treated with oPac+E prior to after the amendment are summarized in the table below.

	IVPac			oPac+E Pre-Amendment			oPac+E Post Amendment		
	Grade 2	Grade 3	Grade 4	Grade 2	Grade 3	Grade 4	Grade 2	Grade 3	Grade 4
Vomiting	4%	1%	0%	24%	7%	0%	7%	4%	0%
Diarrhea	7%	1%	0%	27%	9%	0%	16%	3%	0.5%

Prophylactic anti-emetic therapy and early use of loperamide markedly decreased the incidence of ≥Grade 2 vomiting and diarrhea although there was a greater incidence than IVPac.

The most frequently prescribed anti-emetic agents for oPac+E treated patients were ondansetron (54%), metoclopramide (21%), domperidone (4%) and aprepitant (3%). For patients randomized to IVPac, the most frequently prescribed agents were ondansetron (59%), granisetron (24%), palonosetron (7%) and aprepitant (2%). Oral administration of the oral NK1 inhibitor aprepitant appeared to be associated with increased incidence of oral paclitaxel systemic toxicity, potentially due to inhibition of metabolism of oPac by cytochrome P450 3A4.

**Conclusions:** oPac+E was associated with greater efficacy in the treatment of mBC and lower rates and severity of peripheral neuropathy, but increased GI AE compared to IVPac 175mg/m<sup>2</sup>. GI AE in oPac+E treated patients can be managed by prophylactic use of anti-emetics, primarily 5-HT<sub>3</sub> inhibitors and early intervention with the anti-diarrhea agent loperamide. The use of the oral NK1 inhibitor aprepitant in combination with oPac+E is not recommended.(NTC02594371)

Recruitment strategies for enrollment of high-risk women to a randomized controlled trial of web-based decision support tools to increase breast cancer chemoprevention

Gauri Bhatkhande, Thomas Silverman, Jennie Mata, Ashlee Guzman, Ting He, Jill Dimond, Tarsha Jones, Rita Kukafka and Katherine Crew.  
Columbia University, New York, NY

**Background:** Less than 10 % of those identified as eligible for clinical trials are recruited. Recruitment for chemoprevention trials poses challenges as it is often difficult to identify unaffected patients at high risk for cancer. Barriers to recruitment include personal perceptions of the benefits, fear of trials, low recruitment of minorities, language barriers, transportation costs, and complex study designs. In this study, we identified five potential sources of recruitment that could be collectively leveraged to identify women at high risk for breast cancer to improve recruitment yield.

**Methods:** A total of 300 high-risk women and 50 healthcare providers were recruited and randomized to access web-based decision support tools in combination with standard educational materials or standard educational materials alone. Patient inclusion criteria included: 1) women, age 35-75 years; 2) English or Spanish-speaking; 3) no previous breast cancer diagnosis; 4) no prior use of selective estrogen receptor modulators (SERMs) or aromatase inhibitors (AIs). Five broad strategies were considered for identification and recruitment of women at high risk for breast cancer: 1) in-person recruitment during routine screening mammography with survey administration for breast cancer risk assessment according to the Gail model; 2) collection of breast cancer risk factors from the electronic health record (EHR) for risk assessment according to the Breast Cancer Surveillance Consortium (BCSC) risk calculator; 3) identification of women with atypical hyperplasia (AH) or lobular carcinoma *in situ* (LCIS) using ICD-9/10 diagnostic codes from the EHR; 4) high-risk women with clinic appointments and referred by enrolled providers; 5) women who responded to recruitment flyers and online recruitment distributed throughout the medical center and community.

**Results:** A total of 6229 high-risk women were identified using these recruitment sources, of which 3663 were contacted by email, mailed letter, and/or phone for participation in our clinical trial. Of these contacted women, 16.4% were identified through in-person recruitment during screening mammography, 35.8% through breast cancer risk factors in the EHR, 14.5% had a diagnosis of AH or LCIS identified in the EHR, 28.7% had appointments with enrolled providers, and 4.5% responded to recruitment flyers or online recruitment. Women from the different recruitment sources varied by mean age (64.7 years for mammography and 44.9 years for recruitment flyers), race/ethnicity (73.7% non-white from mammography and 45.5% from breast cancer risk factors in the EHR), and mean 5-year breast cancer risk (2.56% identified from the EHR and 1.34% from recruitment flyers). Of 300 consented patients, 44.7% came from provider referrals (12.7% recruitment yield [number consented/number contacted]) and 27.3% from mammography (13.6% recruitment yield). Comparing enrolled to unenrolled patients, there were significant differences in mean age (57.3 vs. 58.7 years,  $p=0.027$ ), proportion of non-whites (41.5% vs. 54.7%,  $p<0.001$ ), and mean 5-year breast cancer risk (3.0% vs. 2.2%,  $p<0.001$ ).

**Conclusions:** We were able to identify a large cohort of women at high risk from breast cancer from multiple different recruitment sources. Our recruitment yield was highest among direct referrals from healthcare providers and in-person recruitment from mammography. Consented patients tended to be younger, include more non-Hispanic whites, and have a higher risk of breast cancer compared to the overall pool of high-risk women identified. We were able to successfully recruit a racially-ethnically diverse study population to a randomized controlled trial of decision support for breast cancer chemoprevention.

Intraoperative radiation therapy (IORT) for 1200 early breast tumors

Melinda Epstein, Melvin Silverstein, Peter Chen, Kevin Lin, Brian Kim, Sadia Khan, Lincoln Snyder, Lisa E. Guerra and Colleen Coleman. Hoag Memorial Hospital Presbyterian, Newport Beach, CA

**Introduction:** Two prospective randomized trials, TARGIT-A and ELIOT, have shown intraoperative radiation therapy (IORT) to be a safe alternative with a low-risk of local recurrence compared to whole breast radiation therapy following breast conserving surgery for selected low-risk patients. We report the first 1200 tumors treated with this modality at our facility. **Methods:** 1200 distinct breast cancers in 1169 patients (31 bilateral) were treated with breast conserving surgery and X-ray IORT, using the Xofig Accent System from June 2010 to November 2018. Patients were enrolled in an IORT registry trial and data were collected at 1 week, 1 month, 6 months, 1 year, and yearly thereafter. The primary endpoint was local recurrence. **Results:** To date, there have been 61 events in 54 patients: 50 ipsilateral local recurrences (14 DCIS and 36 invasive), 7 regional nodal recurrences and 4 distant recurrences. Of local recurrences, 9 were within the IORT field, 21 outside of the IORT field but within the same quadrant as the index cancer, and 20 were new cancers in different quadrants. There has been no breast cancer related deaths and 27 non-breast cancer deaths. Currently, with a median follow-up of 52 months, Kaplan Meier analysis projects 5.2 % local recurrence rate at 5 years. In the table below, the five-year probability of local recurrence is analyzed by quadrant and/or type of recurrence (all recurrences or just invasive). Using the 2017, ASTRO Categories, 520 patients (43%) were suitable for IORT, 415 (35%) were cautionary, and 265 (22%) were unsuitable for IORT after final histopathology was evaluated. **Conclusion:** IORT is profoundly convenient. When used as the only adjuvant breast irradiation, it eliminates approximately 15-35 outpatient visits. This has become increasingly important during the current COVID-19 pandemic. In the group of patients described here, more than 100,000 patient-hours were saved. The local, regional, and distant recurrence rates observed in this trial were slightly higher than those of the prospective randomized TARGIT-A and ELIOT Trials. This may be explained by 22% of our patients being considered unsuitable for IORT by ASTRO Criteria. The low complication rates previously reported by our group as well as the low recurrence rates reported in this study support the cautious use and continued study of X-ray IORT in women with low-risk breast cancer.

Factors associated with chronic breast lymphedema after adjuvant radiation in women undergoing breast conservation therapy

Sanjay Rama<sup>1</sup>, Cara Canella<sup>1</sup>, Jenna Luker<sup>1</sup>, Kelley Park<sup>2</sup>, Renee Barry<sup>1</sup>, Saheli Ghosh<sup>3</sup>, Simeng Zhu<sup>1</sup>, Yalei Chen<sup>1</sup>, Jessica Bensenhaver<sup>1</sup>, Eleanor Walker<sup>1</sup>, Kenneth Levin<sup>1</sup>, Dunya Atisha<sup>1</sup> and Maristella Evangelista<sup>1</sup>. <sup>1</sup>Henry Ford Hospital, Detroit, MI; <sup>2</sup>Wayne State University School of Medicine, Detroit, MI; <sup>3</sup>Michigan State University College of Osteopathic Medicine, East Lansing, MI

**Purpose/Objective(s):** Unlike temporary breast edema caused by post-lumpectomy radiation therapy (RT), the edema that persists beyond one year is not well defined and difficult to treat. The aim of this study is to define the incidence and risk factors for the development of chronic breast lymphedema in women undergoing lumpectomy with RT at a large metropolitan cancer center.

**Materials/Methods:** A retrospective chart review was performed on all patients who underwent lumpectomy from 2014 to 2018. Women who did not undergo RT at our institution and those with stage IV disease were excluded from the analysis. Patient demographics, comorbidities, operative data, RT data and postoperative complications were obtained. Chronic breast lymphedema (CBL) was defined as edema that persisted beyond one year post completion of radiation therapy. Breast volumes were determined by contoured breast volumes or, if unavailable, estimated by the 95% isodose volumes from the RT treatment planning system. Using a density curve, the distribution of breast volumes was plotted for patients with and patients without CBL. Univariate analysis was used to evaluate factors associated with CBL. Multivariate regression analysis was used to evaluate factors associated with the risk of CBL while accounting for potential confounding variables as defined by the univariate analysis.

**Results:** A total of 1173 patients were included for analysis. Seventy-four (6.3%) patients developed breast lymphedema beyond one year. For the entire cohort, mean age was 63 years old (SD=11.17), mean BMI was 31.15 kg/m<sup>2</sup> (SD=7.17), mean breast volume was 1198.54 cm<sup>3</sup> (SD=645.82 cm<sup>3</sup>), mean total radiation was 59.18 Gy (SD=16.76), and 139 (11.8%) patients underwent ALND. Compared to the cohort that did not develop CBL (n=1099), the CBL cohort (n=74) had a higher median BMI (33.23 kg/m<sup>2</sup> vs. 29.81 kg/m<sup>2</sup>, P<0.001), higher percentage of African Americans (56.8% vs. 37.9%, P=0.004), larger median breast volume (1502.33 cm<sup>3</sup> vs. 1083.59 cm<sup>3</sup>, P<0.001), higher percentage that underwent ALND (23% vs. 11.1%, P=0.005), and larger median size of lumpectomy specimen (128.00 cm<sup>3</sup> vs. 94.57 cm<sup>3</sup>, P=0.002). When accounting for potential confounding variables, multivariate regression analysis revealed when breast volume was evaluated as a continuous variable, for every 1 cm<sup>3</sup> increase in breast volume, the risk of breast lymphedema increases by 0.1% (OR=1.001, P<0.001). When breast volume was analyzed as a categorical variable using 1300 cm<sup>3</sup> as the optimal cutoff (based on density curve evaluations), patients whose breast volume was greater than 1300 cm<sup>3</sup> had nearly 3 times the risk of developing CBL (OR=2.976, P<0.001) compared to those with less than 1300 cm<sup>3</sup> breast volume. The multivariate regression also demonstrated that CBL was associated with total radiation dose (OR=1.02, P=0.015) and African American race (OR=1.705, P=0.037).

**Conclusion:** Chronic breast lymphedema presents a clinical concern for women undergoing lumpectomy with postoperative radiation, particularly in women with larger breasts. Further studies should focus on preventative strategies, as well as the psychosocial and economic impact of this morbidity.

Patient-reported outcomes from the Phase III IMpassion031 trial of neoadjuvant atezolizumab + chemotherapy in early triple-negative breast cancer

Elizabeth Mittendorf<sup>1</sup>, Nadia Harbeck<sup>2</sup>, Hong (Amy) Zhang<sup>3</sup>, Shigehira Saji<sup>4</sup>, Kyung Hae Jung<sup>5</sup>, Sheetal Patel<sup>6</sup>, Shilpen Patel<sup>6</sup>, Anh Nguyen Duc<sup>7</sup>, Mario Liste-Hermoso<sup>7</sup>, Stephen Y Chui<sup>6</sup> and Carlos H Barrios<sup>8</sup>. <sup>1</sup>Dana-Farber/ Brigham and Womens Cancer Center, Boston, MA; <sup>2</sup>Breast Center, Ludwig-Maximilians-University (LMU), Munich, Germany; <sup>3</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>4</sup>Fukushima Medical University, Fukushima, Japan; <sup>5</sup>University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic of; <sup>6</sup>Genentech, Inc., South San Francisco, CA; <sup>7</sup>F. Hoffmann-La Roche, Ltd., Basel, Switzerland; <sup>8</sup>Oncology Research Center, HSL, PUCRS, Porto Alegre, RS, Brazil

**Background:** In the IMpassion031 study (NCT03197935) of patients (N = 333) with invasive stage II or III early triple-negative breast cancer (eTNBC), neoadjuvant treatment with atezolizumab vs placebo, each combined with nab-paclitaxel followed by doxorubicin + cyclophosphamide, significantly improved pathologic complete response in the intent-to-treat population. Patient-reported outcomes (PROs) were collected to document patient perspectives on overall treatment burden and clinical benefit of atezolizumab + chemotherapy for neoadjuvant treatment of eTNBC. **Methods:** Patients received either atezolizumab 840 mg or placebo every 2 weeks (q2w) with nab-paclitaxel 125 mg/m<sup>2</sup> every week for 12 weeks followed by atezolizumab 840 mg or placebo q2w with doxorubicin 60 mg/m<sup>2</sup> + cyclophosphamide 600 mg/m<sup>2</sup> q2w for 4 cycles. After surgery, patients in the atezolizumab arm were unblinded and continued to receive atezolizumab 1200 mg every 3 weeks for 11 doses, while patients in the control arm did not receive any study treatment. Patients completed the EORTC Quality of Life Questionnaire Core 30 (QLQ-C30) and single-item GP5 from the Functional Assessment of Cancer Therapy-General (FACT-G) questionnaire at baseline and day 1 of each cycle of neoadjuvant and adjuvant treatment, at end of treatment and during follow-up every 3 months during year 1, every 6 months during years 2-3, and then annually. Mean and mean change from baseline scores (with changes ≥ 10 considered clinically meaningful) in function (role and physical) and global health status/health-related quality of life (GHS/HRQoL) were predefined secondary endpoints. Mean and mean change from baseline scores in disease and treatment-related symptoms, as well as an assessment of overall side-effect bother, were exploratory endpoints. **Expected results:** The PROs will be compared between the atezolizumab and placebo arms to assess overall treatment burden and the effect of adding atezolizumab to neoadjuvant chemotherapy for the treatment of eTNBC.

**Background:** Margetuximab (M), an investigational Fc-engineered, immune-activating, HER2-targeted monoclonal antibody, shares specificity with trastuzumab (T) and is being studied in HER2 overexpressing tumors including MBC. The randomized phase 3 SOPHIA trial (NCT02492711) in pretreated HER2+ MBC demonstrated PFS superiority by blinded analysis of M + chemotherapy over T + chemotherapy. M demonstrated a tolerable safety profile. Here, patient-reported health-related quality of life (HRQOL) is reported. **Methods:** In SOPHIA, 536 patients with HER2+ MBC and ≥ 2 prior HER2+ directed therapies, including pertuzumab, were randomized 1:1 to M (15mg/kg IV q3w) or T (6 [8 for loading dose] mg/kg IV q 3wk). Each antibody was given with physician's choice chemotherapy (standard dose capecitabine, eribulin, gemcitabine, or vinorelbine). HRQOL was measured at baseline and on D1 of each odd cycle using the Network-Functional Assessment of Cancer Therapy-Breast Cancer Symptom Index (NFB SI) - 16 and EuroQol 5-Dimension 5 level (EQ-5D-5L) questionnaires. Descriptive statistics were performed on NFB SI-16 total score (possible score range: 0 [most symptomatic] - 64 [least symptomatic]), EQ-5D-5L overall score (possible score range: 0 [most symptomatic] - 100 [least symptomatic]), and subscales of each measures. Lower scores reflect a higher impact on HRQOL domains. Changes from baseline in NFB SI-16 total score and in EQ-5D-5L utility score were assessed using mixed model repeated measures analysis (MMRM) with treatment group, stratification factors, time, and treatment group by time interaction as covariates. Each analysis used an unstructured covariance matrix, and least square mean estimates were calculated at each time point. A Cox proportional hazard model was used to assess time to symptom progression, defined as a ≥ 5-point decrease from baseline in NFB SI-16, using the same covariates as in MMRM analyses. **Results:** HRQOL questionnaire completion rates were comparable between M and T treatment groups. Mean NFB SI-16 total scores and EQ-5D-5L overall scores were similar between treatment arms at baseline and at end of treatment. During cycles 11-17, a greater proportion of patients in the M group reported being bothered by side effects and fatigue "quite a bit" or "very much" on the NFB SI-16. However, adverse event assessments at corresponding time points were largely attributed to concomitant chemotherapy. Also, a smaller proportion of patients on T completed these measures at these times. Overall, least mean square estimates (95% CIs) of change from baseline NFB SI-16 total scores were -1.99 (-3.395, -0.594) in the M group, and -2.13 (-3.794, -0.469) in the T group. A slightly higher proportion of patients in the M group had ≥ 5-point decrease from baseline NFB SI-16 total score compared to those in the T group (M: 105 [39.5%]; T: 100 [37%]). However, this difference was neither prespecified nor statistically significant (Cox model HR: 0.88, 95% CI: 0.672, 1.164; p=0.382). Overall least square mean estimates (95% CIs) of change from baseline in EQ-5D-5L total scores were -0.93 (-4.493, 2.637) in the M group, and -3.93 (-8.253, 0.387) in the T group, suggesting that patients on M had less signs of deterioration compared to the T group; statistical significance testing was not prespecified. **Conclusions:** Overall, HRQOL domains, including symptoms and functioning, were maintained. Changes from baseline were similar between the 2 treatment groups. Treatment-specific symptoms were consistent with side effects associated with chemotherapy, not antibody study therapy. Findings support similar, acceptable safety profiles demonstrated previously for margetuximab and trastuzumab.

Her2-xpat, a novel protease-activatable prodrug t-cell engager (tce), exhibits potent t-cell activation and efficacy in her2 tumors, yielding large predicted safety margins based on non-human primate (nhp)

Fiore Cattaruzza, Ayesha Nazeer, Zachary Lange, Caitlin Koski, Mikhail Hammond, Angela Henkensiefken, Trang Dao-Pick, Mika K Derynck, Bryan Irving and Volker Schellenberger. Amunix, Mountain View, CA

#### Background

TCEs are effective at inducing remissions in hematologic cancers but have been challenging in solid tumors due to *on*-target, *off*-tumor toxicity. Attempts to circumvent CRS include fractionated or step-up dosing and/or complex molecular designs, but these have been unsuccessful due to toxicity and/or enhanced immunogenicity. Amunix has developed a conditionally active TCE, XPAT or XTENylated Protease-Activated bispecific T-Cell Engager, that exploits the protease activity present in tumors vs. healthy tissue to expand the therapeutic index (TI). The core of the HER2-XPAT (PAT) consists of 2 tandem scFVs targeting CD3 and HER2. Two unstructured polypeptide masks (XTEN) are attached to the core that sterically reduce target engagement and extend T1/2. Protease cleavage sites at the base of the XTEN masks enable proteolytic activation of XPATs in the tumor microenvironment, unleashing a highly potent TCE with a short T1/2 and further improving the TI. Although checkpoint inhibitors have been ineffective in HER2+ or HR+ breast cancer, TCEs can co-opt T-cells regardless of their antigenic specificity, providing the potential to introduce effective T-cell immunity against tumors expressing HER2. HER2-XPAT, as a tumor protease-activatable prodrug with a wide safety margin, offers the potential to induce effective T-cell cytotoxicity against HER2<sup>hi</sup> tumors and HR+/HER2 1-2+ tumors.

#### Methods

Preclinical studies were conducted to characterize the activity of HER2-XPAT, HER2-PAT (cleaved XPAT), and HER2-NonClv (a non-cleavable XPAT) for cytolytic activity *in vitro*, for anti-tumor efficacy in xenograft models, and for stability and safety in NHPs.

#### Results

HER2-PAT (cleaved XPAT) demonstrated potent *in vitro* tumor-directed T-cell cytotoxicity (EC50 1-2pM) and target-dependent T-cell activation and production of cytokines by PBMCs. HER2-PAT also exhibited cytotoxicity in HR+, HER2 1+ MCF7s at higher doses (EC50 0.13nM). HER2-XPAT provided up to 14,000-fold protection against killing of HER2 tumor cells and exhibited no cytotoxicity against cardiomyocytes at concentrations up to 1uM. *In vivo*, HER2-XPAT induced complete tumor regressions in BT-474 tumor models with equimolar dosing to HER2-PAT, whereas non-cleavable HER2-NonClv had no efficacy, supporting tumor protease cleavage requirement for T-cell activity. In NHP, HER2-XPAT has been dose-escalated safely up to 42mg/kg (MTD) but was not tolerated at 50mg/kg. HER2-XPAT demonstrated early T-cell margination at 2mg/kg but largely spared CRS, cytokine production, and tissue toxicity at doses up to 42mg/kg. PK profiles of HER2-XPAT and HER2-NonClv were comparable in NHP, indicating minimal systemic cleavage of XPAT, consistent with its *ex vivo* stability when incubated in the plasma of cancer pts for 7 days at 37°C. Given by continuous infusion, HER2-PAT induced lethal CRS and cytokine spikes at 0.3mg/kg/d, but was tolerated at 0.2mg/kg/d, providing HER2-XPAT with >3000-fold protection in tolerated Cmax versus HER2-PAT, >4 logs over cytotoxicity EC50s for HER2 and HR+ cell lines, and a 20-fold margin of safety over the dose required for pharmacodynamic activity.

#### Conclusions

HER2-XPAT is a potent prodrug T-cell engager with promising evidence of activity at low doses while exhibiting minimal CRS and a potentially wide TI based on NHP tolerability at doses up to 42mg/kg. With XTEN's prior clinical data demonstrating low immunogenicity, the XPAT TCEs provide a promising solution. IND studies are currently ongoing. Additional PK, PD, cytokines, safety, and efficacy data will be presented.

Differential gene expression analysis and clinical utility of MammaPrint and Blueprint in male breast cancer patients

Jennifer Crozier<sup>1</sup>, Julie Barone<sup>2</sup>, Kalyan Banda<sup>3</sup>, Beth Lesnikowski<sup>1</sup>, Robert Maganini<sup>4</sup>, Sami Diab<sup>5</sup>, Ian Grady<sup>6</sup>, Thomas Lomis<sup>7</sup>, Charles Cox<sup>8</sup>, Amy Truitt<sup>9</sup>, Benjamin Nota<sup>10</sup>, Andrea Menicucci<sup>9</sup>, Erin Yoder<sup>9</sup>, William Audeh<sup>9</sup>, FLEX Investigators Group. <sup>1</sup>Baptist MD Anderson Cancer Center, Jacksonville, FL; <sup>2</sup>Vail Health The Shaw Cancer Center, Edwards, CO; <sup>3</sup>University of Washington, Seattle Cancer Care Alliance, Seattle, WA; <sup>4</sup>AMITA Health, Saint Alexis Medical Center, Barlett, IL; <sup>5</sup>Rocky Mountain Cancer Center-Aurora, US Oncology, Aurora, CA; <sup>6</sup>North Valley Breast Clinic, Redding, CA; <sup>7</sup>Valley Comprehensive Surgical Center, Van Nuys, CA; <sup>8</sup>University of South Florida, Tampa, FL; <sup>9</sup>Agendia Medical Affairs, Irvine, CA; <sup>10</sup>Research and Development, Agendia NV, Amsterdam, Netherlands

**Background:** Male breast cancer (MaBC) is rare, comprising <1% of all breast cancers in the United States. The low incidence of MaBC limits the ability to conduct clinical trials specifically for this population. Due to the paucity of research on MaBC, current understanding regarding MaBC biology, pathology, and treatment strategies has been primarily based on evidence extrapolated from research on female breast cancer (FBC) patients. Traditional diagnostic biomarkers such as ER, PR, and HER2, as well as newer multi-gene prognostic signatures, are employed when making treatment decisions for both MaBC and FBC. However, limited empirical data is available to support the use of identical laboratory biomarkers and molecular signatures in both MaBC and FBC. The 70-gene risk of distant recurrence signature, MammaPrint (MP), and the 80-gene molecular subtyping signature, Blueprint (BP), are commonly used to help make treatment decisions for both MaBC and FBC patients. To support the clinical utility of MP and BP in MaBC, this study aims to elucidate whether significant molecular biological differences exist between MaBC and FBC. To address this knowledge gap, we evaluated and compared 1) MP index results within Low Risk (LR) and High Risk (HR) groups, 2) MP and BP gene expression, and 3) differentially expressed genes within the full genome and their associated biological pathways between tumors from MaBC and FBC.

**Methods:** This analysis included a total of 817 breast tumor samples sent to Agendia, Inc. (Irvine, CA) for MP and BP testing. Full-transcriptome microarray data were available for 1) a subset of 400 post-menopausal FBC patients enrolled in the FLEX Registry (NCT03053193) and 2) 80 MaBC patients, 32 of whom enrolled in the FLEX registry and 48 non-study patients for whom data were limited to metadata and quality metrics routinely captured for diagnostic testing. Data from all patients were de-identified.

Differences in mean MP indices between FBC (N=400) and MaBC (N=417) according to MP Risk classification (LR or HR) were analyzed using a Z-test. Differential gene expression analysis was performed using the R-limma package in which gene expression data were quantile normalized. Pathway analyses were performed using GSeq. Differentially expressed genes (DEGs) were identified between FBC (N=400) and MaBC (N=80) for whom full transcriptome microarray data were available. DEGs were defined as those with a fold change of > 2 and an adjusted *P* value of < 0.05.

**Results:** All patients in this study had hormone positive, HER2 negative early-stage breast cancer. There was no statistical difference in the average MP index between MaBC and FBC classified as MP LR (*P*=0.273) or those classified as MP HR (*P*=0.692). Gene expression comparison revealed 166 DEGs between MaBC (N=80) and FBC (N=400), 99 DEGs between MP HR MaBC (N=42) and MP HR FBC (N=200), and 290 DEGs between MP LR MaBC (N=38) and MP LR FBC (N=200). Pathway analyses revealed that downregulated genes in MaBC compared to FBC enriched to immune-related functions, including B-cell mediated immunity, whereas upregulated genes were associated with hormone metabolic processes. In all comparisons, expression of MP or BP genes was not significantly different.

**Conclusions:** We found similar MP index distributions between MaBC and FBC. Importantly, differential gene expression between MaBC and FBC provides novel insight into the mechanisms underlying MaBC. Although these data reveal biological distinctions between male and female breast cancer, MP and BP assay performance is preserved across both groups. Further studies are needed to assess clinical outcomes; however, these findings support the use of MP risk of recurrence assay and BP molecular subtyping assay for prognosis and informing treatment decisions in MaBC.

**Background:** Platinum-based chemotherapy regimens (PtCT) have been shown to increase treatment efficacy when combined to neoadjuvant standard of care treatment of triple negative breast cancers (TNBC). In the metastatic breast cancer (MBC) setting, preclinical and clinical data suggest that PtCT could be more efficient than non-platinum based ones (non-PtCT) among patients (pts) with germline BRCA1/2 mutations (gBRCAm). However, published data remain controversial on this topic, particularly for MBC. We evaluated the progression-free (PFS) and overall survival (OS) under first-line PtCT and non-PtCT among gBRCAm carriers in ESME, a nationwide real-life MBC database. **Methods:** ESME MBC database (NCT03275311), is a unique national cohort of all consecutive pts who initiated a first-line treatment for MBC between 2008 and 2016 in one of the 18 French Comprehensive Cancer Centers. Women with HER2- MBC and known hormone receptors (HR) and gBRCA1/2 (before or in the 6 first months of metastatic disease, gBRCAm / wild type / not tested) status, who received a first-line MBC CT were selected. Patients with other germinal mutations were considered as wild type. Primary objectives were OS and PFS under first-line CT (PtCT vs. non-PtCT) in the TNBC gBRCA1/2m population. Secondary objectives were OS and PFS during first-line CT (PtCT vs. non-PtCT) in the TNBC wild-type and "not tested" population, as well as among the HR+/HER2- pts. To avoid guarantee time bias related to oncogenetic testing, analyses were performed at baseline (CT initiation) and different landmark time points (3-month or 6-month after CT initiation). Thus, BRCA status was defined according to oncogenetic testings performed before the landmark time, and patients who progressed or censored before the landmark time were excluded. **Results:** 10,164 pts (2,794 TNBC; 7,370 HR+/HER2-) were included in this analysis. Pts who received PtCT were significantly younger, affected by a gBRCA1/2m, had a high histological grade and/or TNBC tumor, with more frequent visceral and central nervous system spreading than non PtCT ones. Median follow-up was 51.1 months [95%CI 49.6; 52.6]. All reported results were based on the gBRCA status defined at CT initiation and on multivariable analysis adjusted on age at MBC diagnosis, de novo MBC status, type and number of metastases. In the gBRCA1/2m TNBC population (N=132), PtCT was independently associated with a better PFS compared to non-PtCT (HR=0.56, 95%CI 0.38-0.84, p=0.005), without significant difference in OS (HR=0.79, 95%CI 0.51-1.23, p=0.29). No difference was seen in wild-type BRCA1/2 TNBC pts (N=269) according to the CT regimen, while, in the larger population of untested TNBC (N=2,393), PtCT was associated with worse OS (HR=1.18, 95%CI 1.03-1.34, p=0.016) compared to non-PtCT regimens, without significant difference in PFS (HR=1.07, 95%CI 0.95-1.22, p=0.26). No significant difference was seen regarding PFS nor OS in gBRCA1/2m HR+/HER2- pts (N=124) and in the wild-type BRCA1/2 HR+/HER2- population. However, in the larger population of untested HR+/HER2- pts (N=6,836), PtCT was independently associated with worse OS (HR=2.15, 95%CI 1.79-2.59, p<0.001) and PFS (HR=1.57, 95%CI 1.33-1.86, p<0.001) compared to non-PtCT regimens. Results were similar in landmark analyses at 3-month or 6-month after CT initiation. **Conclusions:** This large-scale real-life analysis suggests higher efficacy of PtCT in term of PFS in gBRCA1/2m TNBC pts. The small sample size and post-1<sup>st</sup> line treatments may preclude observing a significant OS difference. PtCT appeared however associated with worse outcomes in untested TNBC and HR+/HER2- pts. These results emphasize the need for BRCA1/2 characterization before considering these regimens in the MBC setting.

Comprehensive analysis of health services, sociodemographic, clinical, and genomic factors driving locally advanced breast cancer mortality via a first-in-kind linkage of SEER-Medicare data with physical tumor samples

Timothy J Robinson<sup>1</sup>, Lauren Wilson<sup>2</sup>, Paul K Marcom<sup>3</sup>, Melissa Troester<sup>4</sup>, Charles F Lynch<sup>5</sup>, Brenda Hernandez<sup>6</sup>, Edgardo P Castellar<sup>2</sup>, Heather Ann Brauer<sup>7</sup>, Lindsey Enewold<sup>8</sup> and Michaela Dinan<sup>2</sup>. <sup>1</sup>H. Lee Moffitt Cancer Center, Tampa, FL; <sup>2</sup>Duke University Medical Center, Durham, NC; <sup>3</sup>Duke University Medical Center, Durham, NC; <sup>4</sup>University North Carolina Chapel Hill, Chapel Hill, NC; <sup>5</sup>University of Iowa, Des Moines, IA; <sup>6</sup>University of Hawaii Cancer Center, Honolulu, HI; <sup>7</sup>Gates Foundation, Seattle, WA; <sup>8</sup>NIH, Bethesda, MD

**Background:** There continues to be an active debate as to the relative contribution of health services, sociodemographic, clinical, and genomic factors in breast cancer disparities. Efforts to understand the contributions of each of these factors have historically focused on separate investigations of socioeconomic, demographic, and genomic elements. However, true multidisciplinary investigation of these factors requires the existence of datasets that combine each of these elements together into population-level, real world cohorts. To this end we created the first-in-kind linkage of SEER-Medicare data to physical tumor samples to combine clinical, health services, and genomic data into a single cohort and used it to investigate the impact of screening and socioeconomic status on early stage breast cancer biology and mortality. **Methods:** This retrospective study used formalin-fixed, paraffin-embedded (FFPE) breast cancer (BC) tissue collected between 1992-2006 within the Iowa and Hawaii SEER Residual Tissue Repositories (SEER-RTR). Medicare fee-for-service claims data were linked for participating patients age 65 and older. Molecular subtyping and exploratory genomic analyses were completed using the NanoString Breast Cancer 360 (BC360) gene expression panel containing the PAM50 classifier. Screening status was assessed by validated claims-based algorithms. Factors associated with overall (OS) & breast cancer-specific (BCS) survival were analyzed in women aged 66-75 with clinically high risk ER+ disease (M0, T1b+, LN+) using Cox proportional hazards models combining sociodemographic, clinical, and genomic data. **Results:** SEER-Medicare data were available for 1,232 women, of which 379 (30.7%) were diagnosed by screening mammogram. Screen-detected disease was associated with lower T stage, N stage, and improved OS (HR 0.72) & BCS (HR 0.68) in multivariable analysis. Molecular analysis of 130 luminal A/B cases revealed superior outcomes of luminal A and luminal B tumors compared to symptom detected tumors of the same molecular subtype ( $p = 0.02$ ). In multivariable cox proportional hazards models increased overall mortality was associated with impoverished neighborhoods, PR- receptor status, upregulation of TGF-beta and p53 dysregulation, whereas protective factors included upregulation of androgen receptor (AR), stromal, and cytotoxicity signaling (all  $P < 0.05$ ; **Table 1**). T2 vs. T1 tumor stage was associated with the largest observed differences in gene expression, and was associated with distinct changes in gene expression in luminal A vs. B disease including down regulation of interferon gamma signaling and MHCII expression in luminal B, but not luminal A, tumors. **Conclusions and Relevance:** Linkage of SEER, Medicare, and physical tumor specimen data is feasible and allows the combination of genomic analyses with clinical and health services data within population-level cohorts and may provide a novel means to elucidate links between biology, access, and disparities in breast cancer outcomes. Future research is warranted to conduct analogous prospective investigations of cancer disparities.

Table – Cox multivariable survival model	
Parameter	All-cause mortality HR (95% CI)
Symptomatic tumor	1.59 (0.70 - 3.64)
Stage N2+ vs N1	2.67 (0.48 -14.83)
Stage T2 vs T1	<b>3.49 (1.42 - 8.58)</b>

Identification and validation of stromal immunotype predict survival and benefit from neoadjuvant chemotherapy in patients of breast cancer

Fei Ji, Ciqiu Yang, Liulu Zhang, Mei Yang, Jieqing Li, Hongfei Gao, Teng Zhu, Minyi Cheng and Kun Wang. Guangdong Provincial People's Hospital, Guanzhou, China

**Background** Immune infiltration of breast cancer is associated with clinical outcome. A growing number of research suggests the immune response were composed by variously functionally distinct immune cell. But it's not clear which kinds of cell play the important role. The aim of this study was to determine whether differences in the cellular composition of the immune infiltrate in breast cancer influence survival and treatment response, and construct a stromal immunotype which could predict the response of neoadjuvant therapy and survival. **Patients and Methods** A total of 1502 ER negative breast cancers from TCGA and METABRIC cohort were used to infer the proportions of 22 subsets of immune cells, Another 320 ER negative breast cancer patients from Guangdong Provincial People's Hospital in the validation cohort were also included in the study. Immune cell infiltration was evaluated by immunohistochemical staining or CIBERSORT method, Five immune features were selected out of 22 immune features to construct immunotype based on LASSO Cox regression model.

**Result** Of the cell subsets investigated, CD8+ T cells (hazard ratio [HR] = 0.064, 95% CI 0.018-0.234;  $p < 0.001$ ), CD4+ T cells (HR 0.072, 95% CI 0.013-0.382;  $p = 0.002$ ), B cells (HR 0.04, 95% CI 0.005-0.340;  $p = 0.003$ ), M1 macrophages (HR 0.09, 95% CI 0.016-0.502;  $p = 0.006$ ) were associated with favourable outcome. T regulatory cells (HR 10.791, 95% CI 2.059-58.444;  $p = 0.005$ ) emerged as the most strongly associated with poor outcome. Using the LASSO model, we classified ER negative breast cancer patients into stromal immunotype A subgroup (CD8+T cells<sup>high</sup> CD4+T cells<sup>high</sup> B cell<sup>high</sup> M1 macrophages<sup>high</sup> Treg<sup>low</sup>) and stromal immunotype B subgroup (CD8+T cells<sup>low</sup> CD4+T cells<sup>low</sup> B cell<sup>low</sup> M1 macrophages<sup>low</sup> Treg<sup>high</sup>). Significant differences were found between immunotype A and immunotype B in the combined cohort with 10-year overall survival (66.2% vs. 49.8%;  $P < 0.001$ ) and 10-year disease-free survival (63.8% vs. 44.4%;  $P < 0.001$ ). Stromal immunotype was revealed to be an independent prognostic indicator in multivariate analysis in all cohorts separately, and also showed to be related to pCR in neoadjuvant chemotherapy. Finally, stromal immunotype A showed higher immune checkpoint molecules (PD-L1, PD-1, CTLA-4) expression and three important cytokines expression profiles (IL-2, INF- $\gamma$  and TGF- $\beta$ ). **Conclusion** The stromal immunotypes could predict survival and recurrence of ER negative breast cancer patients effectively. Furthermore, the immunotypes might be a practical predictive tool for immunotherapy and neoadjuvant chemotherapy.

Associations with response to poly(ADP-ribose) polymerase (PARP) inhibitors in patients with BRCA mutated metastatic breast cancer: Results of a meta-regression analysis

Alexandra Desnoyers, Brooke E. Wilson, Michelle B. Nadler and Eitan Amir. Princess Margaret Cancer Center, Toronto, ON, Canada

**Background:** PARP inhibitors (PARPi), when given as single agents, have modest antitumor activity in patients with advanced breast cancer and mutation in BRCA1 or BRCA2. It is unclear whether some subgroups derive greater benefit from treatment. **Methods:** Two electronic databases (MEDLINE, CENTRAL) and one registry (Clinicaltrials.gov) were searched from inception to June 2020 to identify trials of PARPi in patients with metastatic breast cancer. Objective response rate (ORR) and disease control rate (DCR) to PARPi were extracted and pooled in a meta-analysis using the Mantel Haenszel random effects model. Analyses were performed for patients with a BRCA mutation exclusively. Meta-regression explored the influence of patient and tumor characteristics and previous chemotherapy on ORR and DCR as reported in individual studies. Analysis comprised of a linear regression weighted by individual study sample size using the weighted least squares (mixed effect) method. Quantitative significance was defined using methods described by Burnand et al.

**Results:** Twenty-two studies comprising 1627 patients were identified and among these 1466 (90%) patients had a germline (n=1451) or a somatic (n=15) BRCA mutation and were included in the analysis. In 7 of these studies (32%; n=680 patients), the PARPi was given in combination with a platinum-based chemotherapy.; 54% of breast cancers were triple-negative. 81% of patients had received at least 1 prior line of chemotherapy in the metastatic setting and 28% were previously exposed to a platinum-based chemotherapy in the metastatic setting. Pooled ORR was 46%; 66% when combined with platinum vs 36% with PARPi alone (OR 3.44, 2.77-4.29, p0.001). Meta-regression results are shown in the Table. Previous chemotherapy in the metastatic setting, especially platinum-based chemotherapy, was associated with highly significantly lower ORR as defined by by Burnand et al. Age and hormone receptor status were not associated with response. Quantitatively similar results were observed for DCR.

**Conclusion:** PARPi therapy is associated with lesser response in patients with prior chemotherapy exposure, especially platinum-based treatment. There was no association between ORR and hormone receptor status or age.

Dependent variable	Variable	Coefficients Bêta	Significance
ORR BRCA1/2n = 146645.67 %	Age	-0.32	0.34

## Background

Activating mutations in *PIK3CA*, encoding the p110α subunit of phosphatidylinositol 3-kinase (PI3K) occur in ~40% of HR+/HER2- BCs. GDC-0077, a PI3Kα-selective inhibitor and mutant PI3Kα degrader, is being developed as an anticancer agent. A phase I/Ib study of GDC-0077 alone and combined with other therapies is ongoing in pts with locally advanced or metastatic *PIK3CA*mut, HR+/HER2- mBC (NCT03006172). Targeted safety events are presented here.

## Methods

Safety was assessed via NCI-CTCAE v4 for GDC-0077 administered alone (Arm A), with letrozole and palbo (Arm B), with letrozole (Arm C), with fulvestrant (Arm D), or with fulvestrant and palbo (Arm E, plus metformin in Arm F for pts with body mass index ≥ 30 and/or HbA1c ≥ 5.7%), in 28-day cycles until intolerable toxicity or disease progression. GDC-0077 was administered orally daily at 3, 6, 9, or 12 mg; letrozole, at 2.5 mg orally daily; palbo, at 125 mg orally 21/28 days; and fulvestrant, at 500 mg intramuscularly every 4 weeks. Targeted adverse events (AEs) included hyperglycemia, diarrhea, stomatitis (includes stomatitis, mucosal inflammation, mouth ulceration, glossitis, lip ulceration, palatal ulcer, and tongue ulceration), rash (includes rash, maculopapular rash, dermatitis acneiform, erythema, and erythematous rash), neutropenia (includes neutropenia and neutrophil count decreased), thrombocytopenia, and pneumonitis.

## Results

As of clinical data cutoff (03/20/2020), 157 pts were enrolled and treated (Arm A: 20; Arm B: 33; Arm C: 37; Arm D: 39; Arm E: 13; Arm F: 15). Median cumulative dose intensity was 97.2% for GDC-0077, 90.6% for palbo, 99.9% for letrozole, and 100% for fulvestrant.

Pts, n (%)	Treatment-related AEs	Treatment-related grade ≥ 3 AEs
	<b>All arms; N = 157</b>	<b>All arms; N = 157</b>
Hyperglycemia	98 (62)	36 (23)
Stomatitis (grouped terms)	69 (44)	2 (1)
Diarrhea	68 (43)	0
Rash (grouped terms)	19 (12)	1 (1)
	<b>Palbo arms (B/E/F); N = 61</b>	<b>Palbo arms (B/E/F); N = 61</b>
Neutropenia	45 (74)	36 (59)
Stomatitis (grouped terms)	41 (66)	2 (3)
Thrombocytopenia	19 (31)	4 (7)

Pneumonitis was reported in 2 pts, both in palbo-containing arms (grade 1 in Arm B; grade 2 in Arm F). Hyperglycemia required antihyperglycemic treatment in 69 pts (44%), and the most frequent agents used were metformin (39%; except Arm F where this was required as part of study treatment), empagliflozin (16%), and sitagliptin (15%). Fifteen pts (10%) required GDC-0077 dose reductions due to hyperglycemia. Stomatitis treatment was administered in 51 pts (32%), with dexamethasone mouthwash used most frequently (22%). Neutropenia and thrombocytopenia were managed with palbo dose reduction in 13 pts (21%) and 1 pt (2%), respectively. Overall, treatment-related AEs led to GDC-0077 discontinuation in 2 pts (1%) (grade 3 hyperglycemia in Arm B; grade 2 panniculitis in Arm F).

## Conclusion

Targeted safety events with GDC-0077 alone and in combination ET ± palbo were manageable and required minimal GDC-0077 dose modifications or discontinuations. No unexpected safety events were reported in combination with palbo. A phase III study of GDC-0077 in combination with palbo and fulvestrant is enrolling currently (NCT04191499).

Identifying breast cancer survivors with dormant disseminated tumor cells: The PENN-SURMOUNT screening study

Lauren Bayne, Isoris Nivar, Brooke Goodspeed, Shannon Deluca, E. Paul Wileyto, Natalie Shih, Anupma Nayak, Michael D Feldman, Joshua Edwards, Kevin Fox, Jennifer M. Matro, Susan Domchek, Hayley Knollman, Rachel Jankowitz, Angela Bradbury, Payal D. Shah, Jewell Graves, George Woodfield, Elizabeth Chislock, Jianping Wang, George Belka, Lewis A. Chodosh, Amy S. Clark and Angela DeMichele. University of Pennsylvania, Philadelphia, PA

**Background:** Patients (pts) treated for early stage breast cancer have a 30% lifetime risk of developing incurable, distant metastatic disease. Current models suggest that this occurs through escape of cells from the primary tumor into the circulation and subsequent sequestration of “disseminated tumor cells” (DTCs), in the bone marrow and other sequestration sites, where they enter dormancy. DTCs identified by immunohistochemistry (IHC) are associated with poor prognosis in longitudinal studies and meta-analyses, increasing odds of recurrence by approximately 2 to 5-fold. However, little is known about the test characteristics of the DTC-IHC assay, clinical DTC detection rates over time, and patient and disease risk factors that can identify pts harboring these cells.

**Methods:** The PENN-SURMOUNT Screening Study (NCT 02732171) is a prospective, longitudinal study examining bone marrow and blood biomarkers of recurrence among pts within 5 years of diagnosis who have completed therapy for primary breast cancer (with the exception of endocrine therapy). Pts with positive lymph nodes, triple negative receptors, ER-positivity with RS  $\geq$  25 and/or high-risk MammaPrint (MP), or residual disease after neoadjuvant chemotherapy were screened with bone marrow aspirate (BMA) for presence of DTCs. A positive DTC-IHC result is defined by the presence of at least one pancytokeratin-DAB positive cell utilizing the methods of Naume et al. Cytospin slides prepared from the BMA are independently reviewed by two pathologists with adjudication for the presence of DTCs; Pts who screen negative for DTCs are offered repeat screening annually. Pts who screen positive are referred to an interventional clinical trial (CLEVER, NCT 03032406).

**Results:** A total of 194 pts screened eligible for enrollment on PENN-SURMOUNT between 6/2016 and 3/2020. Of these, 158 consented and 151 underwent BMA with successful IHC analysis on 100%. Pts came from 22 U.S. states;  $\geq$  1/3 traveled over 50 miles to the study center. At baseline BMA, 36/151 (24%) had at least 1 measurable DTC by IHC. Patient characteristics and DTC distribution among subpopulations are shown in Table 1. Of the 78/115 who were initially DTC negative and continued to be eligible for repeat screening, as of 3/2020, 46 (59%) returned for at least one repeat BMA. 13/46 (28%) had at least 1 detectable DTC on 1 of up to 3 subsequent follow up assessments for a total DTC positivity rate of 32.5% (49/151). 48 (98%) DTC+ pts have subsequently enrolled on the CLEVER trial.

**Conclusions:** BMA assessment for DTCs is feasible in pts with high risk, early stage breast cancer. DTCs are detected in up to a third of breast cancer survivors with repeat assessment during the surveillance period. DTC positivity rates are relatively similar across all receptor subtypes, and after both neoadjuvant and adjuvant chemotherapy. Pts harboring DTCs are highly likely to enroll on interventional trials designed to reduce recurrence risk.

Benign breast disease: Temporal trends from 1967 to 2013

Amy Degnim, Karthik Ghosh, Jodi M Carter, Robert A Vierkant, Matthew R Jensen, Stacey J Winham, Tanya L Hoskin, Marlene Frost, Teresa M Allers, Denise L Gehling, Mindy J Kern, Laura M Pacheco-Spann, Celine M Vachon, Derek C Radisky, Daniel W Visscher and Mark E Sherman. Mayo Clinic, Rochester, MN

**Background:** Women with benign breast disease (BBD) are at increased risk of breast cancer (BC). Classic studies based on film-based mammographic screening and pathology diagnosis of surgical biopsies conducted in the 1980s established a hierarchy of increasing BC risk: non-proliferative (NP) BBD, proliferative BBD without atypia (PDWA) and atypical hyperplasia (AH). Given changes in epidemiological BC risk factors and introduction of percutaneous core needle biopsy (CNB) in mid-1990s, and later, digital mammography, we hypothesized that the patient characteristics and relative frequency of BBD diagnoses have changed over time. Accordingly, we performed a longitudinal analysis of the frequency of patient characteristics and BBD diagnoses in the Mayo BBD cohort.

**Methods:** Utilizing the Mayo Clinic Surgical and Pathology Indices, women ages 18 to 85 who had a BBD biopsy between 1/1/67 and 12/31/13 were identified. Breast pathologists reviewed biopsies masked to diagnoses of incident BC diagnosed in follow-up. Demographic characteristics and BC events were obtained by query of institutional data sources and participant surveys. Trends were evaluated for the following eras: 1: pre-mammogram (1967-1981), 2: pre-CNB (1982-1992), 3: CNB Transition (1993-2001), and 4: CNB (2002-2013). Demographics were formally compared across eras using chi-square tests for categorical variables and analyses of variance (ANOVAs) for continuous variables.

**Results:** From 1967-2013, the cohort includes 19,582 unique women with BBD. The frequency of CNB increased from eras 1-4: 0.04%, 0.6%, 51.3 %, and 88.9%, respectively. Mean age at BBD diagnosis was younger in era 1 (48.0 years) vs eras 2-4 (53.2, 52.0, and 51.8, respectively,  $p<0.001$ ). The percentage of biopsies diagnosed as PDWA increased from era 1-4 (25.7%, 34.3%, 35.2%, 46.2%,  $p<0.001$ ), as did the percentage with AH (2.4%, 5.1%, 8.6%, 12.3%,  $p<0.001$ ). Over eras 1-4, the percentages of women with a strong family history of BC increased (9.9%, 12.7%, 17.1%, and 29.0%,  $p<0.001$ ) as did mean BMI (24.8, 26.4, 27.4, and 28.6,  $p<0.001$ ). With a median follow-up of 10.9 years, 1,719 breast cancers have developed, with increasing proportion of noninvasive (DCIS-only) disease across eras 1-4: 15.0%, 21.1%, 21.2%, and 33.2%,  $p<0.001$ .

**Conclusions:** Analysis of this large, single institution BBD cohort for the 46 year period 1967-2013 demonstrates that BC risk factors among BBD patients has changed over time, with subjects demonstrating increasing age, BMI, and family history, and that the percentages of BBD classified as PDWA and AH have increased. Impact on BC risk will be further investigated.

Potential therapeutic effects of HDACi FK228 on TNBC using various models

Madlin Alzoubi, Khoa Nguyen, Katherine Hebert, Margarite Matossian, Hope Burks, Bridgette Collins-Burow and Matthew Burow. Tulane University School of Medicine, New Orleans, LA

Breast cancer is the most prevalent type of cancer among women. Most breast cancers are hormone sensitive, however triple negative breast cancer (TNBC), a more aggressive subtype of breast cancer is characterized by its negative expression of estrogen and progesterone receptors, and lack of Her2/NEU amplification. Because of its receptor status, hormone receptor targeted treatments are ineffective against TNBC making it difficult to treat. FK228, known as Romidepsin, is a histone deacetylase inhibitor (HDACi) that specifically targets the enzymes HDACs 1 and 2, tumor suppressor and other proteins exerting epigenetic changes on tumor cells resulting in anticancer activity. FK228 has not been studied in TNBC, but has been approved by the FDA for the treatment of peripheral T-cell lymphoma (PTCL), where the mechanism of action has demonstrated cell cycle arrest and apoptosis [1,2]. To assess the preliminary role of FK228 in breast cancer, a number of TNBC cell lines were treated with the drug and analyzed for suppression of cell cycle genes. Similar to PTCL, TNBC cell lines showed an increase in cell cycle arrest genes such as p21 and others subsequent to treatment. Moving forward, to recapitulate the tumor microenvironment we have utilized 2D and 3D culture, while PDXs (patient derived xenografts), an excellent translational tool. We first identified changes in morphology and migration in 2k1, MDA-MB 231 and HS-578t cell lines treated with FK228 under in-vitro conditions. Additional molecular studies also show a reversal of the epithelial to mesenchymal transition (EMT) in FK228 treated BC cell lines; specifically in relation to EMT genes CDH1 and ZEB2, both directly connected to HDAC1/2 activity. To further study the effects of FK228, PDXs are implanted into mice to study growth patterns, recurrence, metastatic potential and response to FK228 in different patient tumor models. FK228 showed a drastic suppression in tumorigenesis in model TU-BCX-2O0, prompting the study of several other models in tumorigenesis including TU-BX-4IC, 4M4 and 4QX. Metastasis was also monitored by H&E staining lung and liver tissue for analysis for each model, and using an in vivo model consisting of GFP/luciferase transfected breast cancer cells MDA-MB-231 and SUM-159 to monitor both the proliferation and spread of disease in mice. Ultimately this study aims to characterize the FK228 alteration of pathways involved in tumorigenesis, metastasis and resistance within TNBC.

Ctc-her2+ a novel subset in stage IV<sub>aggressive</sub>: Molecular correlations, outcome and clinical characteristics in metastatic breast cancer

Paolo D'Amico<sup>1</sup>, Qiang Zhang<sup>1</sup>, Lorenzo Gerratana<sup>1</sup>, Youbin Zhang<sup>1</sup>, Ami Shah<sup>1</sup>, Carolina Reduzzi<sup>1</sup>, Andrew Davis<sup>1</sup>, Saya Jacob<sup>1</sup>, Firas Wehbe<sup>1</sup>, Amir Behdad<sup>1</sup>, Giuseppe Curigliano<sup>2</sup> and Massimo Cristofanilli<sup>1</sup>. <sup>1</sup>Northwestern University, Chicago, IL; <sup>2</sup>Istituto Europeo di Oncologia, Milano, Italy

**Background** The enumeration of Circulating Tumor Cells (CTCs) in the peripheral blood of patients (pts) with metastatic breast cancer (MBC) showed prognostic value independent of clinic-pathological characteristics and proposed as a new tool for Stage IV stratification. Molecular characterization of CTCs with analysis of standard HER2 and estrogen-receptor (ER) status provides additional predictive value. The presence of HER2 positive CTCs (CTCs-HER2+) has been documented in pts with HER2 negative MBC and suggestive of tumor heterogeneity. The molecular features associated with the detection of these cells and the clinical significance of CTCs-HER2+ remains of unclear clinical significance. The lack of validated prospective trials limits the use of this immunophenotypic characterization as a prognostic and predictive factor. We conducted an analysis of a large cohort of patients with MBC evaluated for CTCs enumeration (CTCs+), molecular analysis of CTCs (CTCs-HER2+) and ctDNA. **Methods** The IRB-approved study prospectively analyzed blood samples of pts with MBC enrolled before starting a new line of therapy. Samples were collected from pts treated at Northwestern University (Chicago, IL) between 2016 and 2020. ctDNA was analyzed using the Guardant360 NGS assay (Guardant Health) with a specific focus on the detection of *ERBB2* mutations. CTCs were enumerated through CellSearch™ (Menarini Silicon Biosystems, Bologna, Italy), and characterized for HER2 expression using the CellSearch CXC Kit. HER2+ CTCs were divided in 4 different categories (0,1+,2+,3+), leaning on fluorescence intensity, as previously reported by Riethdorf et al. Pts with <5 CTCs (stage IV<sub>indolent</sub>) were excluded from the analysis. The cHER2 ratio, defined as the sum of 2+ CTCs and 3+ CTCs divided by the total number of HER2+ CTCs was used to split the remaining pts in 2 different subgroups: cHER2 ratio > 0.75 (cHER2<sub>high</sub>), cHER2 ratio < 0.75 (cHER2<sub>low</sub>). Pts' characteristics and genomic alterations were compared between these two subgroups and a long-rank test was performed to analyze the outcome (progression-free survival, PFS). **Results** A total of 247 pts with MBC about to start new therapy were enrolled. 136 patients (55%) demonstrated CTCs count ≥ 5 (stage IV<sub>aggressive</sub>). Of these, 111 pts had a blood sample bearing HER2+ CTCs. 88 pts were classified as cHER2<sub>low</sub>, while 32 were allocated in the second subgroup (cHER2<sub>high</sub>). The clinic subtype distribution of the two groups was as follows: 65% ER+, 19% HER2+ and 16% TNBC among cHER2<sub>low</sub>, compared to 55% ER+, 38% HER2+ and 7% TNBC among cHER2<sub>high</sub> pts. The HER2+ subtype was significantly more represented in the cHER2<sub>high</sub> group (p<0.05), along with *ERBB2* mutations (p<0.05). We observed a total of 89 events (progression to treatment), 67 and 22 respectively. The median PFS was 87 days in the cHER2<sub>low</sub> and 209 days among cHER2<sub>high</sub> pts (log Rank test, p<0.001). **Conclusion** This study shows a significant association between the cHER2 ratio and outcome in pts with Stage IV<sub>aggressive</sub> disease, suggesting a potential predictive/prognostic role of this biomarker among MBC pts bearing CTC-HER2+. cHER2<sub>high</sub> pts, in which blood was collected a prevalent number of CTC-HER2+ 2+ and 3+, were more likely to have a HER2 FISH amplification by tissue biopsy and *ERBB2* gene alteration by ctDNA. These findings, taken together, suggest a potential role of these subsets of CTC-HER2+ in the characterization of the HER2+ metastatic disease. The cHER2<sub>low</sub> is intrinsically characterized by a higher percentage of CTC-HER2+ 1+. This CTC-HER2+ subset of cells is commonly detected among all subtypes but, more frequently in ER+ disease and their significance remains unclear. Exploring the underlying biological nature of the CTC-HER2+ 1+ could allow to better understand the role these cells in the natural evolution of the MBC.

Targetable *ERBB2* mutation status is an independent marker of adverse prognosis in estrogen receptor positive, *ERBB2* non-amplified primary lobular breast carcinoma: Validation using a novel gene signature of HER2 activation

Mansour Alsaleem<sup>1</sup>, Sasagu Kurozumi<sup>2</sup>, Kartikeya Bhardwaj<sup>1</sup>, Cintia Monteiro<sup>1</sup>, Stacey EP Joosten<sup>3</sup>, Andrew R Green<sup>1</sup>, Takaaki Fujii<sup>2</sup>, Ken Shirabe<sup>2</sup>, Ian O Ellis<sup>1</sup>, Emad A Rakha<sup>1</sup>, Nigel P Mongan<sup>1</sup>, David M Heery<sup>1</sup>, Wilbert Zwart<sup>3</sup>, Steffi Oesterreich<sup>4</sup> and Simon J Johnston<sup>5</sup>. <sup>1</sup>University of Nottingham, Nottingham, United Kingdom<sup>2</sup>Gunma University Graduate School of Medicine, Gunma, Japan<sup>3</sup>Netherlands Cancer Institute, Amsterdam, Netherlands<sup>4</sup>Womens Cancer Research Center, UPMC Hillman Cancer Center and Magee-Women Research Institute, Pittsburgh, PA;<sup>5</sup>AstraZeneca, Cambridge, United Kingdom

Invasive lobular carcinoma (ILC) accounts for 10-15% of primary breast cancer and is typically ER+ and *ERBB2* non-amplified. There is preclinical evidence that somatic *ERBB2* mutation may provide an alternative and tractable mechanism for upregulation of HER2 activity in tumors that do not express HER2 by current clinical criteria. Using large public datasets, we previously demonstrated that targetable *ERBB2* mutations are enriched in ILC *versus* invasive ductal carcinoma (IDC) and are an independent prognostic factor in ILC (HR=3.7, 95% CI 1.2-11.0;  $p=0.021$ )\*. We next hypothesized that a gene expression signature incorporating HER2 activity due to *ERBB2* mutation and / or amplification would validate the prognostic signal we found in ILC.

To derive a novel gene expression signature of HER2 activity that accounted for the effect of potentially targetable *ERBB2* mutations in *ERBB2* non-amplified tumors, we applied a weighted average difference method to gene expression data in cases from the METABRIC 2012 (N=1,980) and TCGA 2015 (N=817) cohorts. To compare our novel gene expression signature with an established signature of HER2 activity, we performed multivariate regression modeling of response to neratinib, a small molecule tyrosine kinase inhibitor of HER1, 2 and 4, using pharmacogenomic data accessed via the CellMinerCDB online portal.

We show that our novel HER2 pathway signature score uniquely enriches for *ERBB2* mutated tumors. Using a Cox regression model and stratifying gene expression scores into upper *versus* lower quartiles, we were able to validate the prognostic signal of *ERBB2* mutations in ILC tumors (HR for 10-year OS in ILC=2.3, 95% CI 1.04-5.05;  $p=0.040$ ). In contrast, no relationship was found between *ERBB2* mutation status or novel HER2 pathway enrichment score and patient outcome in cases of IDC.

We conclude that *ERBB2* mutations that are enriched in ILC provide a robust biomarker of HER2 pathway activation and can be detected via gene expression signature. Novel clinical trials of HER2-targeted therapy in *ERBB2* non-amplified primary ILC are warranted.

A randomized, open-label, phase III trial of pertuzumab re-treatment in HER2-positive, locally advanced/metastatic breast cancer patients previously treated with pertuzumab, trastuzumab, and chemotherapy: The Japan Breast Cancer Research Group-M05 (PRECIOUS) study

Yutaka Yamamoto<sup>1</sup>, Hiroji Iwata<sup>2</sup>, Taira Naruto<sup>3</sup>, Norikazu Masuda<sup>4</sup>, Masato Takahashi<sup>5</sup>, Tetsuhiro Yoshinami<sup>6</sup>, Takayuki Ueno<sup>7</sup>, Tatsuya Toyama<sup>8</sup>, Takashi Yamanaka<sup>9</sup>, Toshimi Takano<sup>7</sup>, Masahiro Kashiwaba<sup>10</sup>, Koichiro Tsugawa<sup>11</sup>, Yoshie Hasegawa<sup>12</sup>, Kenji Tamura<sup>13</sup>, Hiroshi Tada<sup>14</sup>, Fumikata Hara<sup>7</sup>, Shigehira Saji<sup>15</sup>, Satoshi Morita<sup>16</sup>, Masakazu Toi<sup>16</sup>, Shinji Ohno<sup>7</sup>, Japan Breast Cancer Research Group. <sup>1</sup>Graduate School of Medical Sciences, Kumamoto University, Kumamoto, Japan<sup>2</sup>Aichi Cancer Center, Nagoya, Japan<sup>3</sup>Okayama University Hospital, Okayama, Japan<sup>4</sup>National Hospital Organization Osaka National Hospital, Osaka, Japan<sup>5</sup>National Hospital Organization Hokkaido Cancer Center, Sapporo, Japan<sup>6</sup>Osaka International Cancer Institute, Osaka, Japan<sup>7</sup>The Cancer Institute Hospital of JFCR, Tokyo, Japan<sup>8</sup>Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan<sup>9</sup>Kanagawa Cancer Center, Yokohama, Japan<sup>10</sup>Adachi Breast Clinic, Kyoto, Japan<sup>11</sup>St. Marianna University School of Medicine Hospital, Kawasaki, Japan<sup>12</sup>Hiroaki Municipal Hospital, Hiroaki, Japan<sup>13</sup>Shimane University Hospital, Izumo, Japan<sup>14</sup>Graduate School of Medicine, Tohoku University, Sendai, Japan<sup>15</sup>Fukushima Medical University, Fukushima, Japan<sup>16</sup>Graduate School of Medicine Kyoto University, Kyoto, Japan

**Background:** Patients (pts) with HER2-positive locally advanced/metastatic breast cancer (LA/MBC) previously treated with pertuzumab (P)-containing regimens have few therapeutic options. The efficacy of Pre-treatment combined with trastuzumab (T)+chemotherapy as 3 or 4 -line chemotherapy was examined in such pts. **Methods:** Pts previously treated with P-containing regimens as 1st/2nd-line treatment for LA/MBC were randomly assigned 1:1 to two groups (P+T+chemotherapy based on physicians' choice (C) (PTC), and T+C (TC)), stratified by estrogen receptor status, previous P treatment duration, number of previous chemotherapy regimens, and presence or absence of visceral metastasis. The primary endpoint was investigator-assessed progression-free survival (PFS). Superiority of PTC to TC will be tested using a stratified log-rank test that accounts for all stratification factors, and a one-sided P-value of less than 0.05 will be considered an indicator of superiority. The distribution of PFS will be estimated using the Kaplan-Meier method. In addition, the hazard ratio and one-sided 95% CI of the therapeutic effect between the groups will be calculated using the Cox proportional hazard model. Secondary endpoints included independent reviewer assessed PFS, PFS in pts treated with T-DM1 as the latest regimen (PFS after T-DM1), objective response rate (ORR), overall survival (OS), safety, and health-related quality of life (HR-QoL). **Results:** Of the 219 pts enrolled, 217 (108 PTC, 109 TC) were included in the intent-to-treat analysis. At the data cutoff (July 31, 2019), PFS and OS events were 184 (84.8%) and 84 (38.7%), respectively. Median follow-up time was 14.2 months (mo). Investigator-assessed PFS was significantly better in the PTC group (median PFS 5.3 vs. 4.2 mo; HR = 0.755 [One-sided 95% CI upper limit, 0.967]; One-sided stratified log-rank test p = 0.0217). Median PFS after T-DM1 (5.3 vs. 4.2 mo; HR = 0.801 [One-sided 95% CI upper limit, 1.061]; One-sided log-rank test p = 0.0952) and OS (28.8 vs. 23.4 mo; HR = 0.713, [One-sided 95% CI upper limit, 1.026], One-sided log-rank test p = 0.062) tended to be longer in the PTC group, though further follow-up is needed. The ORR with measurable disease (PTC (n = 90) 18.9% vs. TC (n = 92) 19.6%) did not differ between the groups. The serious adverse event rate did not differ between the groups (17.9% vs. 21.3%). There were no new safety signals included cardiac events in the groups. In the comparison of HR-QoL by time to deterioration analysis, there was no significant difference between the groups in FACT-B trial outcome index (PTC 2.8 mo vs. TC 4.3 mo; HR = 1.274, log-rank test p = 0.2289). **Conclusions:** P re-treatment as 3 or 4 -line chemotherapy was active and feasible. P re-treatment can be a standard treatment option for patients with HER2-positive LA/MBC previously treated with P. (ClinicalTrials.gov number: NCT02514681)

Prospective HER-2 testing using simultaneous immunohistochemistry (IHC) and chromogenic *in situ* hybridization (CISH): Experience of dual testing in a single academic institution

Kara K Landry, Abiy B Ambaye, Donald L Weaver and Peter A Kaufman. University of Vermont Medical Center, Burlington, VT

Background: HER-2 testing informs prognosis and critically guides therapy in breast cancer. Current guidelines for immunohistochemistry (IHC) testing define 3+ as positive, 0 and 1+ as negative, and 2+ as equivocal with additional testing recommended. Guidelines for *in situ* hybridization (ISH) testing are more complex and generally define a HER-2/CEP17 ratio of  $\geq 2.0$  with average HER-2 copy number of  $\geq 4.0$  copies/cell as HER-2 positive. Further, HER-2 copy number between 4 and 6 per cell, with a ratio of  $< 2.0$ , is considered equivocal while  $\geq 6$  per cell is frequently confirmed positive. Limited data suggest that an elevated HER-2 copy number alone has clinical relevance, however most clinical trials addressing HER-2 targeted therapeutics define HER-2 positive based on HER-2/CEP17  $\geq 2.0$ .

Design: From 2013-2016, all new invasive breast cancer cases diagnosed at the University of Vermont Medical Center were prospectively tested for HER-2 using both IHC and chromogenic *in situ* hybridization (CISH) simultaneously. All testing was performed on formalin-fixed paraffin-embedded tissue, using the 4B5 Rabbit Monoclonal Antibody (Ventana) for IHC and the INFORM dual ISH DNA probe (Ventana) for CISH. Interpretation was performed using published criteria, and all cases were independently analyzed by two experienced reviewers.

Results: 1906 patients underwent HER-2 testing by both IHC and CISH. 1671 (87.7%) patients had a HER-2/CEP17 ratio of  $< 2.0$ . Of patients considered to be non-amplified by the CISH ratio, 55 (3.2%) had a HER-2 copy number  $\geq 4$ . In IHC 0 and 1+ cases with HER-2/CEP17 ratio of  $< 2$ , 0.4% and 2.3% have equivocal and excess HER-2 copies/cell, respectively, compared to 10.8% for IHC 2+. Additionally, 17 (8.6%) of the IHC 3+ cases had a CISH ratio of  $< 2$ , of which 41.2% had  $\geq 4$  HER-2 copies/cell (see table).

Table. Simultaneously tested IHC and CISH data for new invasive breast cancer cases

	IHC	CISH ratio $\geq 2.0$	CISH ratio $< 2.0$	HER-2 copies/cell (CISH ratio $< 2.0$ cohort)			CISH ratio $< 2.0$ with $\geq 4$ HER-2 copies/cell
IHC	n	n (%)	n (%)	$< 4$ (n)	4-6 (n)	$> 6$ (n)	
0	501	0 (0.0)	501 (100.0)	499	2	0	0.4%
1+	942	21 (2.2)	921 (97.8)	899	20	1	2.3%
2+	265	33 (12.5)	232 (87.5)	206	25	0	10.8%
3+	198	181 (91.4)	17 (8.6)	10	6	1	41.2%
Total	1906	235 (12.3)	1671 (87.7)	1614	53	2	3.2%

Conclusion: To our knowledge, this is the largest study to date that has examined the concurrent use of both IHC and ISH HER-2 assays prospectively in a real-time clinical setting. In the IHC 2+ cohort, only 12.5% were amplified by ISH testing. Interestingly, of those in the IHC 2+ cohort not amplified by CISH, 10.8% had an equivocal or excess HER-2 copy number. Further, while based on a very small sample size, 41.2% of IHC 3+ patients with a CISH ratio of  $< 2.0$  had an equivocal or excess HER-2 average copy number. Finally, data on the clinical outcome and therapeutic benefit of HER-2 targeted therapy in patients with non-amplified ISH testing and equivocal or excess HER-2 copy number remains limited, and warrants further evaluation.

Altered regional cerebral blood flow in adjuvant-treated breast cancer survivors after chemo- and endocrine therapy

Claire L Vandenberg, Patricia A Ganz, Stephen S Liu and Daniel HS Silverman. University of California, Los Angeles, CA

**Objectives:** In the first published observation of altered brain metabolism in patients exposed to chemotherapy (*Breast Cancer Res Treat.* 2007; 103:303-311), we described diminished metabolism in prefrontal cortex in proportion to magnitude of diminishment of short-term memory performance, 5-10 years following patients' last chemotherapy dose. Subsequently, at least 7 other groups of investigators have independently demonstrated altered cerebral metabolism of frontal cortex as assessed by FDG-PET (*J Nucl Med.* 2019; 60:16821690). We now offer the first report of regional cerebral blood flow (rCBF) changes assessed by [O-15]water PET in prospectively recruited subjects with newly diagnosed breast cancer, longitudinally followed from time of initial therapy for one year.

**Methods:** A total of 204 brain [O-15]water PET scans were obtained of 17 right-handed female subjects newly diagnosed with breast cancer, with near-equal portions of 10 chemo-exposed (**C**) and 7 unexposed (**U**) subjects undergoing endocrine therapy in the ensuing year (5/10, 3/7). For each subject, 12 scans were obtained -- 6 during short-term memory, long-term memory, and control tasks presented in counterbalanced order soon after completion of any adjuvant chemotherapy but prior to initiation of any endocrine therapy (baseline), and repeating one year later. PET data were assessed through paired t statistical tests at the voxel level, after Family Wise Error (FWE)-based corrections for multiple comparisons.

**Results:** Across all subjects, scans at baseline during short-term recall revealed most marked activation of bilateral temporal-occipital cortex (peak voxel  $t=7.20$ ; size 4,649 voxels,  $p<.0005$  FWE<sub>corr.</sub>) and similar activation occurred during long-term recall ( $t=6.48$ ; 6,446 voxels,  $p<.0005$  FWE<sub>corr.</sub>). One year later, left prefrontal cortex, including Broca's area, activated during short-term recall ( $t=5.74$ ; 227 voxels,  $p=.02$  FWE<sub>corr.</sub>), as did bilateral medial occipital cortex ( $t=5.45$ ; 908 voxels,  $p<.0005$  FWE<sub>corr.</sub>); during long-term recall, prefrontal cortex activated with greater bilaterality, but with an extent in left frontal lobe (1031 voxels,  $p=.008$  FWE<sub>corr.</sub>) about double the size of right (452 voxels), and with less occipital activation. In therapy-stratified analyses, baseline short-term recall of left prefrontal cortex, including Broca's area, activated more extensively (3253 voxels,  $p<.0005$  FWE<sub>corr.</sub>) in **U**, while **C** showed more extensive activation in medial occipital cortex (5670 voxels,  $p<.0005$  FWE<sub>corr.</sub> vs. 423 voxels,  $p=.001$ ). One year later, short-term recall in **U** continued to activate left prefrontal cortex including Broca's area (4035 voxels,  $p<.0005$  FWE<sub>corr.</sub>), while **C** still primarily activated medial occipital cortex (976 voxels,  $p=.008$  FWE<sub>corr.</sub>), though demonstrating a shift of activation away from this region relative to one year prior, with more voxels of activation tending to appear in left prefrontal cortex over that interval. Similar, though less striking, differences were observed during long-term recall.

**Conclusions:** Activation of rCBF during recall of verbal associative memories was diminished in left prefrontal brain areas critical to verbal memory performance in **C** relative to **U**. Concomitantly, **C** demonstrated apparent compensatory activation of primary visual cortex, involved in perceiving the visually presented verbal memory cues, in lieu of specific activation of the prefrontal cortical regions in the dominant hemisphere involved in processing language information. The strengths of these therapy-associated differences were generally diminished one year later, consistent with partial interim recovery in **C** of cerebral processing by language-specialized areas.

A Phase 2, open-label study to evaluate the safety and efficacy of the proboddy therapeutic (Pb-Tx) CX-2009 in metastatic HR-Positive/HER2-negative breast cancer (mHR+/HER2- BC) and of CX-2009 as monotherapy and in combination therapy with CX-072 in metastatic triple-negative breast cancer (TNBC)

Kathy D. Miller<sup>1</sup>, Leisha A. Emens<sup>2</sup>, Sara Tolaney<sup>3</sup>, Sara A. Hurvitz<sup>4</sup>, Erika Hamilton<sup>5</sup>, Virginia Paton<sup>6</sup>, Alison Hannah<sup>6</sup> and Valentina Boni<sup>7</sup>. <sup>1</sup>Indiana University Simon Cancer Center Indianapolis, Indianapolis, IN; <sup>2</sup>University of Pittsburgh Medical Center, Hillman Cancer Center, Pittsburgh, PA; <sup>3</sup>Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA; <sup>4</sup>University of California, Los Angeles/ Jonsson Comprehensive Cancer Center, Los Angeles, CA; <sup>5</sup>Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN; <sup>6</sup>CytomX Therapeutics, Inc., South San Francisco, CA; <sup>7</sup>South Texas Accelerated Research Therapeutics (START) Madrid, Centro Integral Oncologico Clara Campal, Madrid, Spain

**Background:** Proboddy® therapeutics (Pb-Tx) are masked antibodies designed to be selectively activated in the tumor microenvironment by tumor-associated proteases, while remaining largely inactive in normal tissue and in circulation. This allows Pb-Tx to address previously undruggable targets that are highly expressed in both tumor and normal tissue, such as the activated leukocyte cell adhesion molecule (ALCAM) CD166. CX-2009 is an investigational Proboddy drug conjugate consisting of an anti-CD166 monoclonal antibody conjugated to the microtubule inhibitor DM4. A Phase 1 study demonstrated safety and durable clinical activity in patients with mHR+/HER2- BC and in mTNBC patients who had received a median of 7 prior regimens. In the efficacy evaluable subgroup receiving doses of at least 4 mg/kg Q3W, the overall response rate (ORR; includes confirmed and unconfirmed responses) was 11% (HR+/HER2-; n=18) and 38% (TNBC; n=8), with a clinical benefit rate at 24 weeks (CBR24) of 35% in all breast cancer patients. Gr ≥3 DM4-associated ocular toxicities related to CX-2009 ≤7mg/kg were reported in 2%. In this Phase 2 study, CX-2009 monotherapy will be evaluated in patients with mHR+/HER2- BC and mTNBC. In addition, CX-2009 will be combined with CX-072, a Proboddy therapeutic directed against PD-L1, to evaluate the safety of the combination and whether the cytotoxic activity of the DM4 payload is additive with PD-L1 blockade via CX-072 in patients with mTNBC. CD166 expression in patients with HR+/HER2- BC was high (>90%) in the Phase 1 study; this cohort will enroll without screening for CD166. CD166 expression in patients with TNBC was variable and, as such, patients will undergo screening for CD166 positivity.

**Methods:** This Phase 2, open-label noncomparative study with 3 parallel arms (n≈40/arm) is investigating the safety and activity of CX-2009 monotherapy (7 mg/kg Q3W) and the combination of CX-2009 (7 mg/kg Q3W) + CX-072 (1200 mg Q3W) in patients with previously treated locally advanced or metastatic HER2- BC. All patients will be adults with an ECOG status of 0-1, acceptable end-organ function, measurable disease, and willingness to receive ocular prophylaxis for DM4 related toxicities. Tumor tissue is required for CD166 expression analysis. Key eligibility criteria for the mHR+/HER2- BC cohort include 2-4 prior regimens (not including single-agent hormonal therapy). Patients with mTNBC must be CD166 positive by IHC and have received 1-3 regimens. For mTNBC patients who receive the doublet, key exclusion criteria include known PD-L1-negative tumor status, history of or active autoimmune disease, and progression within 120 days of first dose of an IO agent. Patients with active or chronic corneal disorders will be excluded from the study. All treatments will be given until disease progression or unacceptable toxicity. Radiology assessments will be done Q6W. The primary endpoint will be ORR assessed by an independent radiology committee per RECIST v1.1. Secondary endpoints will include ORR, DoR, CBR16 and CBR24, and PFS by investigator, OS will also be assessed. This study will also evaluate tolerability, pharmacokinetics, and antidrug antibodies with CX-2009 as monotherapy and in combination with CX-072. Exploratory endpoints will include potential predictive markers of response or toxicity. This trial is actively enrolling.

**Background** Margetuximab (M) is an investigational Fc-engineered anti-HER2 monoclonal antibody that targets the same epitope as trastuzumab (T). Compared with T, M has higher affinity for both the 158V (high-binding) and 158F (low-binding) allotypes of the activating Fc receptor CD16A. M enhances innate immunity more effectively than T in vitro, including CD16A-mediated antibody-dependent cellular cytotoxicity. Samples collected from patients (pts) before and after single-agent treatment also demonstrate that M induces HER2-specific adaptive immune responses, including both T- and B-cell responses. The SOPHIA trial (NCT02492711) in pts with pretreated HER2+ MBC showed that M+chemotherapy (chemo) improved progression-free survival vs T+chemo, with comparable safety. A pooled analysis of M safety across 3 clinical trials is presented. **Methods** Study 01 (NCT01148849), an ongoing Phase 1 dose-finding/safety study of M monotherapy, enrolled 66 pts with advanced HER2+ carcinomas, including 27 with MBC. Study 02 (NCT01828021), a completed Phase 2 study of M monotherapy in low-expressing HER2+ MBC, enrolled 25 pts. Study 04 (NCT02492711), an ongoing Phase 3 study in pts with pretreated HER2+ MBC to compare M + chemo vs T + chemo, randomized 536 pts, of whom 264 and 265 received M and T, respectively. The pooled safety population includes all pts who received any M in Study 01 (cutoff 01Oct2015), Study 02 (cutoff 02Aug2017), and Study 04 (cutoff 10OCT2018). Treatment-emergent adverse events (AEs), defined as AEs that began or worsened in severity on or after first dose of study drug through an End of Treatment Visit or 28 days after last study treatment, are reported. **Results** Of 355 pts that received at least 1 dose of M, 295 received 15 mg/kg Q3W, and 60 received other doses from 0.1 - 18 mg/kg. Median (mean, range) number of cycles for all dose levels was 5.0 (6.6, 1-43), higher on Study 04 (6.0) than Study 01 (1-3 across dose groups) or Study 02 (2.0). Most pts (347 [97.7%]) experienced at least 1 AE, and about half (173 [48.7%]) had at least 1 Grade  $\geq$  3 AE. Serious AE (SAE) incidence across studies was low (58 [16.3%]), and 21 pts (5.9%) discontinued M due to AEs. Most frequently reported AEs ( $\geq$  20%) were fatigue (124 [34.9%]), nausea (103 [29.0%]), diarrhea (75 [21.1%]), and neutropenia (75 [21.1%]). Blood/lymphatic system disorders were the most frequent events by SOC, and largely restricted to Study 04. Increased neutropenia on M (26.1%), relative to T (20.4%), was observed in Study 04 yet both febrile neutropenia (M 3.0%, T 4.5%) and infections (M 36.4%, T 39.6%) were higher on T. By contrast, Study 01 and Study 02 revealed no tendency of M monotherapy to cause neutropenia. Overall, infusion related reactions (IRRs) were observed in 51 pts (14.4%), primarily at first infusion, including serious IRRs in 5 (1.4%). Also, 34 pts (9.6%) had  $>$  15% reduction in LVEF with a median time to  $>$  15% reduction of 49 days. In all pts with complete follow-up, these LVEF reductions were asymptomatic and reversible. No M-induced cardiac conduction abnormalities were noted. In Study 04, similar proportions in both groups experienced AEs (M 97.7%, T 96.2%), including Grade  $\geq$  3 AEs (M 52.3%, T 48.3%), SAEs (M 14.8%, T 17.4%), discontinuations due to AEs (M 3.0%, T 2.6%), and deaths due to AEs (M 0.8%, T 0.8%). As of the 23Feb2020 safety update, 2 pts remain on M in Study 01, after 116 and 109 cycles (6.7 and 6.3 years), respectively. In Study 04, 16 pts (6%) continued on M, and 7 (2.6%) remained on T. **Discussion** M has demonstrated an acceptable safety profile across Phase 1, 2, and 3 studies. It has been administered for over 6 years without long-term cumulative safety issues. Combined M plus chemotherapy Q3W demonstrated acceptable safety and tolerability, similar to that for T plus chemotherapy Q3W in Study 04.

Trastuzumab deruxtecan (T-DXd; DS-8201) vs investigator's choice of chemotherapy in patients with hormone receptor-positive (HR+), HER2 low metastatic breast cancer whose disease has progressed on endocrine therapy in the metastatic setting: A randomized, global phase 3 trial (DESTINY-Breast06)

Aditya Bardia<sup>1</sup>, Carlos Barrios<sup>2</sup>, Rebecca Dent<sup>3</sup>, Xichun Hu<sup>4</sup>, Joyce O'Shaughnessy<sup>5</sup>, Kan Yonemori<sup>6</sup>, Annie Darilay<sup>7</sup>, Sarice Boston<sup>7</sup>, Yufan Liu<sup>7</sup>, Gargi Patel<sup>8</sup> and Giuseppe Curigliano<sup>9</sup>. <sup>1</sup>Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA; <sup>2</sup>Centro de Pesquisa Clinica, Hospital Sao Lucas, Porto Alegre, Brazil <sup>3</sup>National Cancer Centre Singapore, Singapore, Singapore <sup>4</sup>Shanghai Cancer Center, Fudan University, Shanghai, China <sup>5</sup>Baylor University Medical Center, Dallas, TX; <sup>6</sup>National Cancer Center Hospital, Tokyo, Japan <sup>7</sup>AstraZeneca Pharmaceuticals LP, Gaithersburg, MD; <sup>8</sup>AstraZeneca Pharmaceuticals LP, Cambridge, United Kingdom <sup>9</sup>European Institute of Oncology, IRCCS and University of Milan, Milan, Italy

**Background:** HER2 directed therapies have substantially improved clinical outcomes in patients with HER2 positive (immunohistochemistry [IHC] 3+ or in situ hybridization [ISH] positive) metastatic breast cancer. However, no HER2 directed therapies are currently available for breast cancer with lower HER2 expression (IHC 2+/ISH- or IHC 1+). Patients with HER2 low and HR+ breast cancer typically receive initial treatment with endocrine therapy ± targeted therapies (CDK4/6, PI3K, or mTOR inhibitors). After disease progression, patients are treated with chemotherapy, which has shown limited clinical benefit. There is an unmet need for treatments that provide a superior risk-benefit profile compared with standard chemotherapy. T-DXd is an antibody-drug conjugate consisting of an anti-HER2 antibody, a cleavable tetrapeptide-based linker, and a membrane permeable topoisomerase I inhibitor payload. Results from a phase 1 study demonstrated promising antitumor activity with a confirmed objective response rate (ORR) of 37.0% (20 of 54) per independent central review (ICR) and a median progression-free survival (PFS) of 11.1 months in patients with heavily pretreated (median 7.5 prior regimens) HER2 low metastatic breast cancer. Among patients with HR+ disease, the ORR was 40.4% (19 of 47) per ICR (Modi S, et al. *J Clin Oncol*. 2020;38:1887-1896). Here, we describe a phase 3 trial evaluating the efficacy and safety of T-DXd vs chemotherapy in patients with HR+, HER2 low metastatic breast cancer that has progressed on prior endocrine therapy. In addition to the primary population of patients with HER2 low disease being studied, this trial will also study the efficacy and safety of T-DXd in an IHC > 0 < 1+ (detectable HER2 staining < 1+) population.

**Study Description:** DESTINY-Breast06 is a global, randomized, multicenter, open-label, phase 3 trial designed to demonstrate superiority of T-DXd vs investigator's choice of chemotherapy in patients with HR+, HER2 low metastatic breast cancer who had prior progression on endocrine therapy. Approximately 850 patients (HER2 low, n = 700; IHC > 0 < 1+, n = 150) from ≈ 300 centers globally will be randomized 1:1 to receive T-DXd 5.4 mg/kg every 3 weeks or investigator's choice of chemotherapy (paclitaxel, nab-paclitaxel, or capecitabine) until disease progression, discontinuation due to intolerable toxicity, or death. Patients must have progression on ≥ 2 prior lines of endocrine therapy and cannot have received prior chemotherapy or any anti-HER2 therapy for metastatic disease. Randomization will be stratified by prior CDK4/6 inhibitor use (yes vs no), HER2 IHC expression (IHC 2+/ISH- vs IHC 1+ vs IHC > 0 < 1+), and prior taxane use in the non-metastatic setting (yes vs no). The primary endpoint is PFS per blinded ICR (BICR) in the HER2 low population. Key secondary endpoints are overall survival in the HER2 low and intent-to-treat (ITT; HER2 low and HER2 IHC > 0 < 1+) populations and PFS by BICR in the ITT population. Primary and key secondary endpoints will be tested in a hierarchical order. Other secondary endpoints are ORR by BICR and investigator assessment (according to RECIST 1.1), duration of response by BICR and investigator, time to second progression or death per investigator, time to first subsequent treatment or death, and time to second subsequent treatment or death (all in the HER2 low and ITT populations); PFS per investigator assessment in the HER2 low population; and safety, pharmacokinetics, patient-reported outcomes, and immunogenicity.

Impact of race/ethnicity on triple negative breast cancer molecular features, treatment response and clinical outcomes in patients receiving neoadjuvant therapy

Mediget Teshome, Ryan Sun, Elizabeth E. Ravenberg, Abenaa Brewster, Mariana Chavez-MacGregor, Jason B. White and Stacy Moulder. University of Texas MD Anderson Cancer Center, Houston, TX

**Background:** Triple negative breast cancer (TNBC) disproportionately impacts Black and Hispanic women and is suggested to be partly responsible for disparities observed in breast cancer mortality. We sought to evaluate the impact of race/ethnicity on TNBC molecular subtype, immune profile, pathologic complete response (pCR) and recurrence free survival (RFS).

**Methods:** The ARTEMIS trial (NCT02276443) uses imaging response and molecular profiling to personalize neoadjuvant chemotherapy in early stage TNBC. After 4 cycles of AC, patients with chemo-sensitive disease receive standard taxane-based therapy, while those with chemo-resistant disease are offered therapeutic trials based upon molecular profiling. Pathologic response was assessed at surgery. Patients self-reported race/ethnicity was categorized as Asian, Black/African-American, Hispanic/Latino and White (non-Hispanic). Patients were excluded if no race or ethnicity was reported. Clinical and pathologic factors were recorded and compared. Gene expression profiling was performed by RNAseq to determine Vanderbilt signature. PD-L1 and Androgen Receptor (AR) were determined by immunohistochemistry. Frequencies at which various factors were observed by race/ethnicity were calculated and Fisher's exact test performed to determine statistical significance. Kaplan-Meier analysis was used to estimate survival stratified by pCR status and race/ethnicity.

**Results:** Among 321 women enrolled in ARTEMIS, 26 (8.1%) were classified as Asian, 50 (15.6%) as Black, 59 (18.4%) as Hispanic and 186 (57.9%) as White. Demographic and clinical features were similar, except Black women were more likely to have BMI  $\geq 30$  (70.0%,  $p < 0.001$ ). Comparing by race/ethnicity, there was no statistically significant difference in tumor histology, tumor size, nodal status, clinical stage, chemo-resistant disease, type of surgery or receipt of radiation. A trend toward higher proportion of N3 disease was observed in Black women (24.0%) compared to other groups ( $p = 0.054$ ). Tumor profiling results are listed in Table 1. No statistically significant difference was observed by race/ethnicity in Vanderbilt signature, presence of PD-L1 or stromal tumor infiltrating lymphocytes (sTIL) status. More AR-positive tumors were identified in Asian women (64%,  $p = 0.007$ ). pCR and RCB status did not significantly vary by race/ethnicity however, higher proportion of RCB-III disease was identified in Black (14%) and Hispanic women (16.9%) as compared to Asian (3.8%) and White (8.6%) women ( $p = 0.164$ ). At median follow up of 23.8 months (range 3.4-51.1), there was no statistically significant difference in RFS by race/ethnicity.

**Conclusion:** Among this population of patients with TNBC treated with neoadjuvant chemotherapy there was no statistically significant difference observed in TNBC Vanderbilt signature, PD-L1 staining, sTIL, pCR or RFS by race/ethnicity. Asian women were found to have a higher incidence of AR-positive subtype. Numerically higher rates of N3 stage in Black women and RCB-III classification in Black and Hispanic women were identified, however not statistically significant. Larger cohorts of patients are needed to further investigate these findings.

### Background

Mutations in p110 $\alpha$ , encoded by *PIK3CA*, are present in ~40% of HR+/HER2- BCs. GDC-0077, a PI3K $\alpha$ -selective inhibitor and mutant PI3K $\alpha$  degrader, elicits antitumor activity in *PIK3CA*mut preclinical models as a single agent and when combined with endocrine therapy (ET). New evidence suggests BCs harboring multiple *PIK3CA*mut exhibit increased signaling through the PI3K/AKT pathway and are more sensitive to PI3K $\alpha$  inhibitors compared with BCs with a single *PIK3CA*mut. We report a preliminary analysis of *PIK3CA*mut status with clinical outcomes from an ongoing study of GDC-0077 alone or with ET (letrozole/fulvestrant)  $\pm$  palbociclib (palbo) in pts with *PIK3CA*mut HR+/HER2- mBC (NCT03006172).

### Methods

Detectable *PIK3CA*mut from local tumor tissue/blood-based assay or tumor tissue by cobas *PIK3CA* assay were required to enroll. Plasma-derived circulating tumor (ct) DNA was collected at baseline (BL), cycle 1 day 15 (C1D15), and C2D1 (in the cohort where GDC-0077 starts at C1D15) to detect *PIK3CA*mut. Paired tumor samples were analyzed for Ki67 and pAKT/pS6 expression by immunohistochemistry. Single vs multiple *PIK3CA*mut was correlated with the percentage of pharmacodynamic (PD) inhibition of Ki67/pAKT/pS6 expression; with the *PIK3CA*mut allele frequency ratio between BL and C1D15 or C2D1 (MAFr15); with best overall response (BOR, RECIST v1.1); and with time on treatment (TOT) in days. Statistical analyses: Kruskal-Wallis and Mann-Whitney-Wilcoxon for group and pairwise comparisons, respectively, and two-sample proportion testing for categorical comparisons.

### Results

Data cutoff was 03/20/2020. *PIK3CA*mut were detected in 87/103 (84.5%) pts with BL ctDNA available for sequencing. Multiple *PIK3CA*mut were detected in 21/87 (24.1%) BL ctDNA samples: 9 from pts treated with single-agent GDC-0077; 8 from pts treated with GDC-0077 + letrozole/fulvestrant; and 4 from pts treated with GDC-0077 + letrozole/fulvestrant + palbo. The median number of lines of prior therapy for metastatic disease was not different between pts with multiple (3.0 lines) vs single (2.5 lines) *PIK3CA*mut detected at BL ( $p = 0.205$ ). Median percentage inhibition of Ki67/pAKT/pS6 expression was greater in pts with multiple (-65.8, -70.3, -66.8%, respectively) vs single (-42.1, -34.1, -29.5%) *PIK3CA*mut detected at BL ( $p = 0.095, 0.002, 0.056$ ). Median MAFr15 was lower in pts with multiple (MAFr15 0.01) vs single *PIK3CA*mut (MAFr15 0.15) detected at BL ( $p = 0.004$ ). Of 73 pts with both BL ctDNA-detected *PIK3CA*mut and BOR data, 16/16 (100%) with multiple *PIK3CA*mut experienced BOR of partial response (PR) or stable disease (SD) while 42/57 (73.7%) with single *PIK3CA*mut experienced BOR of PR or SD ( $p = 0.051$ ). No pts with multiple *PIK3CA*mut detected experienced a BOR of progressive disease. Median TOT was greater in pts with multiple *PIK3CA*mut (196 days) vs single *PIK3CA*mut (140.5 days) detected at BL, but this was not significant ( $p = 0.1804$ ).

### Conclusions

The fraction of pts in which multiple *PIK3CA*mut were identified from BL ctDNA in this HR+/HER2- mBC dataset (24.1%) was slightly higher than reported elsewhere. This may be due to the method of detection (blood vs tissue) and/or the definition of multiple *PIK3CA*mut used. Pts in which multiple *PIK3CA*mut were detected by ctDNA exhibited greater depth of PD biomarker inhibition in tumors and experienced PR/SD more often compared with pts in which only one *PIK3CA*mut was detected. However, no significant associations were observed with the number of prior lines of therapy for metastatic disease or TOT. The dataset is currently too small to assess the impact of different treatment regimens in this study but will be re-evaluated as the data mature.

Can oncotype Dx risk categories be predicted in invasive lobular carcinoma?

Akisha Glasgow<sup>1</sup>, Haley Sechrist<sup>2</sup>, Phillip Bomeisl<sup>1</sup>, Hannah Gilmore<sup>1</sup> and Aparna Harbhajanka<sup>1</sup>. <sup>1</sup>University Hospitals Cleveland Medical Center, Cleveland, OH; <sup>2</sup>Case Western Reserve University, Cleveland, OH

**Background** Oncotype Dx Recurrence Score (ODX-RS) is a 21-gene assay used to predict recurrence in early stage breast cancer and guide chemotherapy decisions. Invasive lobular carcinomas (ILC) represent approximately 10-15% of all breast cancers. Many prior studies have shown that they have unique clinicopathologic features when compared to other histological subtypes. Therefore, the aim of this study was to first assess whether ODX-RS can be predicted using clinicopathologic factors in ILC and secondly, to compare these factors in invasive ductal carcinoma (IDC) and invasive carcinoma with mixed ductal and lobular features (IMC). **Materials and Methods** With IRB approval, the CoPath pathology database was queried for patients who were newly diagnosed with either IDC, ILC or IMC from 2010-2018 and had available Oncotype scores. For ILC cases, the subtype and presence or absence of LCIS was documented. The original pathology report was reviewed, and a chart review was performed to assess treatment decisions, locoregional and or distant recurrences and duration of follow-up. Patients with hormone receptor negative, HER2 positive or lymph node macrometastatic disease were excluded. **Results** A total of 582 patients were identified. The mean age was 60.1 years (range, 25-80 years). The median follow-up was 49 months (range, 0-145 months). There were 414 (71%), 102 (18%) and 66 (11%) cases of IDC, ILC and IMC, respectively. For ILC, there was a statistically significant relationship between ODX-RS and tumor grade, tubule formation, nuclear pleomorphism, mitotic count, modified Magee score (MME) and associated LCIS (Table 1). When compared to IDC and IMC, ILC had the lowest percentage of Grade 3 tumors, PR expression and high-risk patients by ODX. Factors predictive of high-risk ODX-RS in ILC were nuclear pleomorphism, mitotic count, ER H-score, PR H-score and MME, while for IDC, predictive factors included tumor grade, PR H-score, and MME using TAILORx cutoffs (Table 2). The rate of locoregional recurrences was similar between ILC and IDC (Table 1). No statistically significant correlation was found between ILC variants and RS. Disease free survival (DFS) was best in patients with IMC compared to IDC and ILC. DFS was also significantly better in patients with classic variant of ILC compared to pleomorphic variant. **Conclusion** We found that although ILC was similar to IDC and IMC based on tumor stage, tumor grade, risk category distribution, they demonstrated different predictors of high-risk ODX. Overall DFS was best in patients with IMC and patients with ILC, classic variant, however, when stratified based on RS scores the results were variable. Table 1. Clinicopathologic features of patients with ILC based on risk categories.

Vitamin and supplement use and documentation in a breast cancer survivorship clinic

Anne Moore, Julia Silver and Alyson Goldenberg. Weill Cornell Medicine, New York, NY

**Introduction:** Breast cancer survivors take vitamins and supplements to bolster their general health and to try to decrease the risk of cancer recurrence. Healthcare professionals are frequently unaware of the specific type and dose of vitamins and dietary supplements taken by their patients. This information is often poorly documented in the electronic medical record (EMR). The aim of this study was to document accurately patients' dietary supplements and vitamins in the EMR and to inform patients' medical teams of this important information. **Methods:** All patients seen between May 5th and June 24th, 2020, with a history of nonmetastatic breast cancer (mean years since diagnosis=13.9) were invited to participate in the study prior to their routine visits at the Weill Cornell Breast Cancer Survivorship Clinic. 50/51 women consented (ages 46 to 87, mean age=70). The nurse practitioner called each patient the day before their visit to obtain informed consent and to document their use of supplements and vitamins. The labels for each vitamin and supplement were reviewed and patients were asked the reason why they were taking each supplement. Study data were collected and managed using REDCap electronic data capture tools hosted at Weill Cornell Medicine. Due to COVID-19, 48/50 patient visits were conducted through telemedicine. **Results:** Of the 50 patients enrolled in the study, 72% were taking two or more vitamins and/or supplements (mean=2.4, range= 0-9). 82% were taking a Vitamin D supplement, 42% were taking a calcium supplement, and 24% were taking a vitamin C supplement. 16% were taking a daily multivitamin and 8% were taking no supplements or vitamins. Some of the rare supplements patients were taking included ginseng root tea, shiitake extract, and kamwo tea (one patient each). Patients reported a variety of reasons for their vitamin and supplement use. Some patients stated the supplement was recommended by their physician or a friend, some did not know why they were taking a specific supplement, some reported that they had "always taken it", and many stated that the supplement was a preventative measure against bone loss or catching a cold. Five patients mentioned immunity or prevention of COVID-19. We compared the patient reported list with the medication list in the EMR. The majority of the participants had multiple providers who entered medications in the EMR. Of the 50 participants in our study, none had an accurate list of the vitamins and supplements in the EMR. **Conclusion:** 46 of the 50 breast cancer survivors in our study were taking vitamins and/or supplements. No study participant had a complete list of their vitamins and supplements in the EMR. Accurate vitamin and supplement documentation is important for optimal patient care. For example, vitamins and supplements may interfere with prescription medications taken by patients with a history of breast cancer. The inaccurate EMR documentation also precludes the investigation of vitamin and supplement use in future retrospective analyses. As a result of this study, we strongly recommend more attention to accurate vitamin and supplement recording by providers and the development of a more tailored and convenient method for documentation of vitamins and supplements in the EMR.

Efficacy of the tyrosine kinase inhibitor lapatinib in the treatment of patients with HER2-negative metastatic breast cancer and HER2-positive circulating tumor cells - results from the randomized phase III DETECT III trial

Tanja Fehm<sup>1</sup>, Volkmar Mueller<sup>2</sup>, Maggie Banys-Paluchowski<sup>3</sup>, Peter A Fasching<sup>4</sup>, Thomas WP Friedl<sup>5</sup>, Andreas Hartkopf<sup>6</sup>, Jens Huober<sup>5</sup>, Christian Loehberg<sup>7</sup>, Brigitte Rack<sup>5</sup>, Sabine Riethdorf<sup>8</sup>, Andreas Schneeweiss<sup>9</sup>, Diethelm Wallwiener<sup>6</sup>, Franziska Meier-Stiegen<sup>1</sup>, Oliver Hoffmann<sup>10</sup>, Lothar Muller<sup>11</sup>, Pauline Wimberger<sup>12</sup>, Eugen Ruckhaeberle<sup>1</sup>, Jens Blohmer<sup>13</sup> and Wolfgang Janni<sup>5</sup>. <sup>1</sup>Department of Gynecology and Obstetrics, Heinrich Heine University Dusseldorf, Dusseldorf, Germany<sup>2</sup>Department of Gynecology and Obstetrics, University Hospital Hamburg-Eppendorf, Hamburg, Germany<sup>3</sup>Department of Gynecology and Obstetrics, Asklepios Hospital Barmbek, Hamburg, Germany<sup>4</sup>Department of Gynecology and Obstetrics, University Hospital Erlangen, Erlangen, Germany<sup>5</sup>Department of Gynecology and Obstetrics, University Hospital Ulm, Ulm, Germany<sup>6</sup>Department of Gynecology and Obstetrics, University Hospital Tübingen, Tübingen, Germany<sup>7</sup>Department of Gynecology and Obstetrics, University Hospital Erlangen, Comprehensive Cancer Center Erlangen-EMN, Friedrich-Alexander University Erlangen-Nuremberg, Erlangen, Germany<sup>8</sup>Department of Tumor Biology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany<sup>9</sup>National Center for Tumor Diseases and Department of Gynecology and Obstetrics, University Hospital Heidelberg, Heidelberg, Germany<sup>10</sup>Department of Gynecology and Obstetrics, University Hospital Essen-Duisburg, Essen, Germany<sup>11</sup>Onkologische Schwerpunktpraxis Leer, Leer, Germany<sup>12</sup>Department of Gynecology and Obstetrics, University Hospital Dresden, TU Dresden, Dresden, Germany<sup>13</sup>Department of Gynecology and Obstetrics, University Hospital Charite, Berlin, Germany

**Background:** It is well-known that tumor biology may change during the course of the disease due to clonal evolution, and such changes might have important implications for response to targeted treatments. Circulating tumor cells (CTCs) could serve as a real-time liquid biopsy to detect changes in tumor biology. It has been demonstrated that patients with HER2-negative metastatic breast cancer (MBC) may have discordant, HER2-positive CTCs in the peripheral blood. However, up to now there is no randomized clinical trial investigating whether treatment decisions based on CTC phenotype provide benefits in terms of improved outcome. The aim of the DETECT III study is to investigate whether patients with initially HER2-negative MBC and HER2-positive CTCs benefit from HER2-targeted therapy with the tyrosine kinase inhibitor lapatinib. In addition, the significance of CTCs as an early predictive marker for response to therapy will be analyzed. **Methods:** The randomized phase III DETECT III trial (NCT01619111) compares lapatinib in combination with standard therapy versus standard therapy alone in patients with initially HER2-negative MBC and HER2-positive CTCs. Efficacy of lapatinib treatment is evaluated by CTC clearance rate, progression-free survival (PFS) and overall survival (OS). In addition, we investigate the association between CTC results and both PFS and OS to assess the utility of CTCs as an early predictive marker for treatment response. CTC enumeration and phenotyping was performed using the CellSearch® technology (Menarini Silicon Biosystems; Bologna, Italy). Survival data are analyzed using log rank tests, univariable and adjusted multivariable cox regressions. **Results:** First results on CTC clearance rates, PFS and OS of 105 prospectively randomized patients will be presented. **Conclusion:** This first randomized clinical trial in breast cancer patients with treatment decisions being based on the phenotype of CTCs will show whether patients with HER2 negative MBC and HER2 positive CTCs benefit from additional HER2-targeted therapy with lapatinib. This finding might be increasingly important as novel HER2-targeted drugs become available.

Concordance and use patterns of tissue and cell-free based genomic testing in metastatic breast cancer

Minetta Liu<sup>1</sup>, Jeff Schaffer<sup>2</sup>, Aneta Piwowarczyk<sup>2</sup>, Nike Beaubier<sup>2</sup>, Kimberly Blackwell<sup>2</sup> and Ben Park<sup>3</sup>. <sup>1</sup>Mayo Clinic, Rochester, MN; <sup>2</sup>Tempus Labs, Chicago, IL; <sup>3</sup>Vanderbilt University Medical Center, Nashville, TN

Genomic testing has transformed clinical care in metastatic breast cancer. Cell-free DNA (cfDNA) has made sequential testing feasible, however, concordance between tissue and cfDNA, sensitivity of cfDNA, and optimal sampling frequency have not been examined on large data sets with clinical annotation. Of the 648 genes in the tissue NGS Tempus xT assay, 105 genes are also included in the Tempus xF cfDNA plasma-based test. Both platforms are run on Illumina and detect SNVs, indels, CNVs, and rearrangements/fusions with high sensitivity and specificity (>90%). This study used the Tempus Labs LENS™ tool to identify the most recent ~3,300 metastatic breast cancer patients who underwent clinical testing and had either tissue-based testing, cfDNA testing or both. Of the 212 patients with xF and xT testing, 87 had xT before xF, 135 had xF before xT, and 7 had the testing performed at the same time. The most common pathogenic germline versus somatic alterations on tissue-based testing and their concordance will also be reported. In summary, this data suggests a variable amount of concordance between tissue-based and plasma-based assays. Timing of assay performance and inclusion of germline DNA might play an important role in contributing to these differences which need further exploration.

**Table: Count of Reported Variants and xT/xF Concordance by Gene**

Somatic Genes	xF frequency (n)	xT frequency(n)	Concordance Between xF and xT
<i>TP53</i>	139	110	43%

Prognostic significance of age, histologic subtype, tumor size and nodal status on breast cancer specific survival of "clinical low risk" grade 1 ER+/HER2- breast carcinoma patients - SEER analysis 2010-2012

Amila Orucevic and John L Bell. The University of Tennessee Medical Center, Knoxville, TN

**Introduction:** TAILORx and MINDACT clinical trials on ER+/HER2-/lymph node (LN) 0 or LN 1-3 positive breast carcinoma (BC) patients (pts) revealed that breast-cancer-specific-survival (BCSS) of pts with low Oncotype DX or MammaPrint genomic assay scores did not improve with addition of adjuvant chemotherapy (CTH) to endocrine therapy. Furthermore, pts from MINDACT trial with "clinical low risk" (CLOW) BC had no benefit from the use of CTH regardless of the MammaPrint score (low or high), underscoring the importance of identifying these CLOW patients who might not obtain value from genomic testing. CLOW is defined as the 10-year probability of BCSS >88% without CTH among women with ER+ tumors. MINDACT trial algorithm based on grade, tumor size and lymph node status is used to classify patients into CLOW vs. "clinical high-risk" group. We investigated the significance of age, histologic subtype, tumor size, nodal and PR status on BCSS in a subgroup of CLOW pts with grade 1 tumors ≤30 mm in size and N0-1 LN, utilizing Surveillance Epidemiology and End Results (SEER) database.

**Methods:** "Incidence, SEER research, 18 registries, Nov 2019 sub (2000-2017)" database was used to select female BC pts with ER(+)/HER2(-) BC diagnosed between 2010-2012 to allow for at least a 5-year follow-up (2010-2017). A subgroup of clinical low-risk pts was selected based on MINDACT trial algorithm: grade 1/N0/≤30 mm tumor size, or grade 1/N1/≤20 mm tumor size. Five invasive BC histologic types were selected: ductal (IDC), lobular (ILC), cribriform (ICC), tubular (ITC) and mucinous (IMC). Frequency statistics and a multivariate Cox regression were used for analyses of patient's characteristics and BCSS using SPSS Version 25 (Armonk, NY: IBM Corp).

**Results:** From 132,822 female pts diagnosed with BC from 2010-2012, 20,677 pts (age range 19-85+) fulfilled above selection criteria. Age, tumor size, nodal status and ILC were significant (p<0.05) predictors for BC death in a multivariate Cox regression analysis: pts ≥50, tumor size 21-30 mm, 1-3 LN positive, and ILC histologic type were respectively 2.9 (95% CI=1.8-4.7), 2.6 (95% CI=1.8-3.6), 2.7 (95% CI=2.1-3.6) and 1.4 (95% CI=1.1-1.9) times more likely to die from BC than pts <50, tumor size 1-20 mm and negative LN (Table). IDC and IMC histologic types and PR status did not significantly influence BCSS, although PR status was borderline significant (0.05) in ILC histologic type. Cox regression analysis did not include ICC and ITC pts due to low number of BC caused death. A 5-year BCSS was the best for ITC and the worst for ILC pts, with 3/608 (0.5%) and 52/2047 (2.5%) pts dying from BC, respectively (Table), confirming ITC as an indolent, "good prognosis carcinoma".

**Conclusions:** Our results show that 5-year breast cancer specific survival is significantly influenced by patient's age, ILC histologic type, tumor size and nodal status even in the lowest risk of "clinical low risk" ER(+)/HER2(-), grade 1 BC pts. Since addition of CTH to endocrine therapy is not beneficial in these patients, further studies/clinical trials are needed to evaluate different endocrine therapy regimens for this subgroup of "clinical low-risk" patients in order to improve their BCSS.

**Table:**

Clinicopathologic characteristics of a grade 1 subgroup of "clinical low-risk" ER+/HER2(-) patients						
Histologic subtypes	N=20,677 (100%)	IDC	ILC	ICC	ITC	IMC
Variables	N=20,677 (100%)	N (%)	N (%)	N (%)	N (%)	N (%)

Genomic analysis from the talazoparib beyond BRCA clinical trial: Homologous recombination (HR) deficiency scores, loss-of-heterozygosity and mutations in non-BRCA1/2 mutant tumors with other HR mutations

Joshua J Gruber<sup>1</sup>, Anosheh Afghahi<sup>2</sup>, Alyssa Hatton<sup>1</sup>, Wyatt Gross<sup>1</sup>, Jessica Foran<sup>1</sup>, Alex McMillan<sup>1</sup>, James M Ford<sup>1</sup> and Melinda L Telli<sup>1</sup>. <sup>1</sup>Stanford University, Palo Alto, CA; <sup>2</sup>University of Colorado, Aurora, CO

**Background:** Talazoparib, a PARP1 inhibitor, is active in germline BRCA1/2 mutant advanced HER2-negative breast cancer, but its activity beyond BRCA1/2 less well understood. The Talazoparib Beyond BRCA clinical trial treated 20 patients with germline (g) or somatic (s) mutations in HR pathways genes other than BRCA1/2, which included PALB2, CHEK2, ATM, BRIP1, RAD50, ATR, PTEN, and FANCA. Talazoparib treatment was associated with a 31% overall response rate in patients with breast cancer, including tumor regression from baseline as best response in 6 out of 6 patients treated gPALB2 mutations. We now present the results of additional genomic studies to further characterize treatment responses and resistance mechanisms. **Methods:** Primary and metastatic tumor biopsies were assessed using the commercially-available next-generation sequencing HRD assay (Myriad). Panel gene sequencing of tumors was performed for 108 genes associated with genomic instability. Loss-of-heterozygosity (LOH) was assessed in tumors. Tumor/normal exome sequencing identified pre-treatment somatic variants. Circulating-tumor DNA at baseline and disease progression was assessed by targeted panel sequencing and plasma whole exome sequencing. **Results:** Of the 18 HRD assays performed, 3 failed and were thus excluded. Seven patients had HRD analysis performed on both primary and metastatic tumors. For these patients the HRD score was significantly higher in the metastasis versus the primary (means 46.2 versus 36.5,  $p = 0.018$  by paired t-test). By panel sequencing of tumors (n=18) the most common alterations detected included mutations in PIK3CA (n=8), PALB2 (n=6), ATM (n=5), KRAS (n=4), PTEN (n=5) and TP53 (n=4). In all cases except one, the HR-associated mutation used as entry criteria were detected. LOH analysis showed that of tumors with gPALB2 mutations, 3 of the 6 had LOH for PALB2, and an additional two tumors had 2 independent PALB2 mutations suggesting bi-allelic inactivation. The one remaining tumor had an uncertain LOH result due to test failure. Thus, it is likely that most, if not all, of the tumors in our cohort with gPALB2 mutations had complete inactivation of PALB2 gene function. Other detected mutations that were associated with LOH included all sTP53 mutations (n=4), all gCHEK2 mutations (n=3), gFANCA (n=1), all sRB1 mutations (n=3) and NF1 (n=1). Of the three gATM mutations one had LOH, while the others had two independent mutations, suggestive of bi-allelic inactivation. sATM mutations were associated with LOH in a breast cancer and with 2 independent (possibly bi-allelic) mutations in a non-breast cancer. Additional results from ctDNA targeted sequencing and plasma whole exome sequencing of baseline and progression samples will be presented. **Conclusions:** In this proof-of-concept phase II study, talazoparib demonstrated activity in HER2-negative advanced breast cancer patients with a HR pathway mutation beyond BRCA1/2, especially in patients with gPALB2 mutations and high HRD scores. These additional genomic analyses provide evidence that HRD scores may be significantly higher in metastatic samples compared to primary tumors. Also, we detected either LOH or bi-allelic inactivation for most HR-associated mutations used to determine eligibility. These findings may inform selection of patients for PARP inhibitor monotherapy beyond BRCA1/2.

Comparative analysis of differential gene expression by ancestry using primary breast cancers from Nigeria and the cancer genome atlas (TCGA)

Padma Sheila Rajagopal<sup>1</sup>, Yi-Hsuan S Tsai<sup>2</sup>, Ashley Hardeman<sup>3</sup>, Ian Hurley<sup>4</sup>, Aminah Sallam<sup>5</sup>, Yonglan Zheng<sup>4</sup>, Toshio Yoshimatsu<sup>4</sup>, Anna Woodard<sup>4</sup>, Dezheng Huo<sup>6</sup>, Guimin Gao<sup>6</sup>, Charles M Perou<sup>7</sup>, Joel S Parker<sup>7</sup>, Mengjie Chen<sup>8</sup> and Olufunmilayo I Olopade<sup>4</sup>. <sup>1</sup>Section of Hematology/Oncology, Department of Medicine, The University of Chicago, Chicago, IL; <sup>2</sup>Bioinformatics Core, Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>3</sup>Baylor College of Medicine, Houston, TX; <sup>4</sup>Center for Clinical Cancer Genetics & Global Health, Department of Medicine, The University of Chicago, Chicago, IL; <sup>5</sup>Yale University School of Medicine, New Haven, CT; <sup>6</sup>Department of Public Health Sciences, The University of Chicago, Chicago, IL; <sup>7</sup>Department of Genetics, Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>8</sup>Section of Genetic Medicine, Department of Medicine, The University of Chicago, Chicago, IL

**Introduction:** Breast cancers differ between genomic and transcriptomic features by ancestry within the TCGA, but current understanding of how gene expression differs across global ancestral populations is extremely limited. We hypothesized that differential expression performed by ancestry and geography may provide insight into population-specific, clinically relevant expression patterns.

**Objective:** To compare differentially expressed protein-coding genes and pathways among primary breast tumors of Nigerian origin versus African- and European-American ancestry in TCGA

**Methods:** We analyzed an integrated dataset of RNA-seq from 93 women in Nigeria, 31 African-ancestry women (TCGA AA), and 39 European-ancestry women from TCGA (TCGA EA) with whole-genome data. Ancestry within TCGA was classified by principal component analysis, with African ancestry as >50% contribution and European ancestry as >90% contribution. RNA was obtained from tumors in Nigeria using Qiagen PAXgene kits. A *STAR/HTSeq* pipeline generated read counts. To optimize assay-associated batch effects, we performed differential expression within each PAM50 subtype using *limma-voom* with quantile normalization. Significance was defined as a  $\geq 1.5$ -fold change in gene expression (log2 scale) with a false-discovery-rate-adjusted p-value of 0.05. Pathway analysis was performed via Gene Ontology and the Web-Based Gene Set Analysis Toolkit. We also compared gene expression, claudin-low (30 genes) and VEGF (13 genes) signatures to an additional set of 189 primary breast cancers from Nigeria assayed on the NanoString nCounter System using a custom Nano110 probe set (PAM50 + claudin-low & VEGF genes). RNA for these cancers was isolated from paraffin-embedded tumor using the Roche High Pure paraffin kit.

**Results:** Differential expression was performed pairwise across ancestry groups within PAM50 subtypes (see Table). Fewer genes were differentially expressed, and fold change smaller across shared genes, when comparing Nigerian vs. TCGA AA versus Nigerian vs. TCGA EA comparisons, supporting quantile normalization. The strongest gene ontology pathway associations, seen for all subtypes, were intracellular protein targeting and viral gene expression. The epigenetic regulation pathway was significantly associated with comparisons in Basal-like tumors ( $p_{adj}=1.54e-7$  for TCGA EA,  $p_{adj}=0.001$  for TCGA AA). The PI3K-Akt pathway was significantly associated with Nigerian vs. TCGA-EA within Luminal A ( $p_{adj}=0.006$ ). The Nanostring cohort shared a similar distribution of PAM50 subtypes (see Table,  $\chi^2 p=0.21$ ). We found concordance in both Nigerian cohorts of relative claudin-low and VEGF expression signature patterns across subtypes. Of 17 genes with significant differential expression by ancestry in the Nanostring dataset, 9 (*ADM*, *ACTB*, *BIRC5*, *CDC6*, *CENPF*, *MKI67*, *MPP1*, *RAD17*, and *VEGFA*) showed significant differential expression by ancestry in the PAXgene dataset.

**Discussion:** This is one of the first analyses of differential gene expression across tumors from a global population. We identified differential pathways in breast tumors between African and European ancestry populations to target for future work. We also validated several ancestry-specific genes across platforms with potential clinical relevance. Understanding how molecular features differ across global populations will improve precision oncology for all patients.

Double heterozygous pathogenic variants prevalence in a cohort of hereditary breast cancer patients

Thais Megid, Maria Isabel Achatz, Janina Pontes Pisani and Mariana Cartaxo. Hospital Sirio Libanes, Sao Paulo, Brazil

Significant progress has been made in the identification of inherited genetic factors underlying hereditary cancers. Inherited pathogenic variants in cancer predisposition genes that confer moderate to high risk of breast cancer (BC) are found in 10% of BC cases. Pathogenic variants in BRCA1 and BRCA2 genes are the underlying alterations in hereditary BC. Women with a pathogenic variant in BRCA1 or BRCA2 are at substantially higher risk of developing breast, ovarian and pancreatic cancers and represent 25-28% of hereditary BC cases. The gold standard for molecular diagnosis of a hereditary cancer syndrome is a Next Generation Sequencing (NGS) panel that includes all genes known to confer moderate to high-risk for BC (TP53, PTEN, CHEK2, ATM, PALB2, STK11, RAD51C and BRIP1). Identifying who is eligible to perform genetic testing remains a challenge but presently age at the time of tumor diagnosis, family history and disease stage are still the best predictors. The identification of a germline pathogenic variant enables appropriate genetic counseling, risk-reducing interventions. The detection of variants in BRCA1, BRCA2 and PALB2 may also determine treatment options in patients with advanced or metastatic disease. The known non-BRCA1/2-associated hereditary BC comprise a heterogeneous group of tumors, for most of which the prevalence of histologic and immunohistochemical (IHC) phenotypes are yet to be identified while triple-negative BC is the most prevalent in BRCA1 carriers. The co-occurrence of more than one germline pathogenic variant in BC genes is a rare event and it may affect cancer risk and penetrance is still unknown. Only a few reports on cases and series of double mutation carriers have been described in BRCA1, BRCA2, PALB2, CHEK2, BLM or NBN. In this series case we report patients with double heterozygous (DH) mutation in BC, their age at diagnosis, presence of second neoplasia and cancer phenotype in moderate and high penetrance genes on germline panels. Considering this scenario, we performed an active search among the 2651 women from the Hereditary Cancer Registry at Hospital Sirio-Libanes, São Paulo, Brazil, between January 2013 and June 2020. We have included 229 patients with a histopathological confirmation of a BC who have tested positive for pathogenic/likely pathogenic variant. Of these, 4.3% (10/229) women were identified with DH mutation in high and moderate penetrance genes in BC (table 1). All patients carried a germline pathogenic variant in at least one high-penetrance gene. A total of 7 cases (7/10) carried at least one BRCA1/2 pathogenic variant. Two women (2/10) included had developed bilateral BC. The occurrence of a second primary cancer was described in three patients (3/10). The median age at first BC diagnosis was 36.7 years old. Two BC were found to be triple negative, five cases were of Luminal subtype and one was HER2+. The age at diagnosis is similar to most hereditary BC related to those developed by BRCA1 and TP53 germline variant carriers. In this case series there is no evidence of additive effect on the risk of tumor development. Larger series of DH mutation carriers are needed to estimate the risk in double heterozygous populations and to determine whether the presence of DH have a synergistic interaction or additive effect on cancer risk.

Table1 - Breast Cancer double variants

Statin use significantly improves outcome in luminal B relative to luminal A breast cancers

Andrew David Redfern<sup>1</sup>, Lisa J Spalding<sup>2</sup>, Robin L Anderson<sup>3</sup> and Hilary Martin<sup>4</sup>. <sup>1</sup>University of Western Australia, Perth, Australia<sup>2</sup>Harry Perkins Institute of Medical Research, Perth, Australia<sup>3</sup>Olivia Newton-John Cancer Research Institute, Melbourne, Australia<sup>4</sup>Fiona Stanley Hospital, Perth, Australia

Cholesterol and statins may have a role in breast cancer progression where statins have been found to associate with reduced breast cancer recurrence risk in early breast cancer patients. Links between breast cancer progression and intra-tumoural cholesterol metabolism have been described, indicating possible underlying cancer biology. Here we set out to explore whether statin use correlated with differences in baseline tumour characteristics including biological tumour sub-type and whether outcomes were impacted by statin use, both overall and within sub-types. Two cohorts of invasive breast cancer patients from a single institution in Western Australia were studied; one comprised of cases across all sub-types (n=417) and one of hormone receptor positive cases only (n=1766), with available data on tumour biology, statin use, and relapse. Statin prescription data was available on 2183 patients, of whom 454 were taking a statin at some point from diagnosis through the end of the follow-up period. Of the patients where statin type was known, 38% were taking a hydrophilic and 62% a lipophilic statin. Although tumour stage did not vary by statin usage, those on a statin had less frequent high grade tumours (12.7 v 18.7%, p=0.025), and were more frequently estrogen receptor positive (96.1 v 93.1, p=0.022) although other receptor expressions did not differ. Finally, luminal A tumours were more common in statin users, at the expense of luminal B and HER2-enriched cancers (81.4 v 74.0, p=0.018) (Table 1).

Overall breast cancer events were more common in statin non-users compared to users (16.7 v 9.3%, HR 1.80, p<0.0001). Due to the influence of the larger hormone receptor positive cohort, the majority of patients had luminal tumours. Looking to the influence of statins on events within sub-types, users compared to non-users experienced substantially less breast cancer events in luminal B cancers (8.8% v 22.3%, p=0.012) and modestly reduced events in luminal A cancers (8.3 v 12.6%, p=0.0326). Considering HER2 positive luminal B cancers relative to those afforded luminal B status by virtue of being high grade, the former group showed significantly less events in statin users v non-users (0 v 19.9%, p=0.0047) whereas no significant protection was observed in the latter (18.2 v 24.6%, p=0.294). Low numbers of HER2 positive hormone receptor negative cases precluded analyzing whether protection extended to all HER2 positive tumours, although none of these patients relapsed. No significant differential effect was found by statin type.

In conclusion, statin usage after early breast cancer afforded substantial protection to HER2 positive hormone receptor positive patients, an effect that may extend to all HER2 positive cases. Further validation is warranted. Such patients could be considered for trials exploring statins as agents protecting against relapse.

Table 1: Breast tumour demographics comparing statin users to non-users.

Interim analysis of a phase I dose escalation study of topical bexarotene in women at high risk for breast cancer

Parijatham S Thomas<sup>1</sup>, Anisha B Patel<sup>1</sup>, Diane Liu<sup>1</sup>, J. Jack Lee<sup>1</sup>, Seema Khan<sup>2</sup>, Miguel Muzzio<sup>3</sup>, Alejandro Contreras<sup>1</sup>, Lana Vornik<sup>1</sup>, Eileen P Dimond<sup>4</sup>, Marjorie Perloff<sup>4</sup>, Brandy Heckman-Stoddard<sup>4</sup> and Powel H Brown<sup>1</sup>. <sup>1</sup>University of Texas MD Anderson Cancer Center, Houston, TX; <sup>2</sup>Northwestern University, Chicago, IL; <sup>3</sup>IIT Research Institute, Chicago, IL; <sup>4</sup>National Cancer Institute, Bethesda, MD

**Background:** Breast cancer prevention with anti-estrogens, including tamoxifen, raloxifene, and exemestane, has been shown to reduce the incidence of hormone receptor-positive breast cancer. However, agents that can reduce the incidence of hormone receptor negative breast cancer are currently lacking. Retinoids such as bexarotene are vitamin A analogues that have been shown to be involved in cell differentiation, growth, and apoptosis. In preclinical mouse models that develop ER-negative breast cancers, bexarotene showed a significant reduction in mammary tumor development. Oral bexarotene has been evaluated in BRCA mutation carriers and significant decreases in cyclin D1 were noted in breast cells suggesting biological activity of bexarotene on breast tissue. Systemic side effects of hyperlipidemia and hypothyroidism were also found. Data from chemoprevention studies with topical 4-hydroxytamoxifen support the concept of topical agents penetrating into the breast tissue and exhibiting biological activity. We hypothesize that topical bexarotene can be applied to the breast as a prevention agent with penetration into the breast tissue and without subsequent systemic side effects as seen with oral bexarotene. **Methods:** Women at high risk for breast cancer were recruited and assigned to escalating doses of 1% topical bexarotene: 10mg (1ml) every other day, 10mg (1ml) daily and 20mg (2ml) daily for 4 weeks. Cohorts of 3-4 participants were enrolled and fully evaluated through 4 weeks prior to enrolling the next cohort. Each dose level enrolled a maximum of 10 participants. The primary endpoint of the study was to determine the recommended phase II dose of topical bexarotene 1% gel for evaluation in healthy at-risk women. Dose Limiting Toxicity (DLT) was defined as a grade 2 skin adverse event that persists for at least 6 days or any grade 3 or greater adverse event related to the study drug. A grade 2 skin adverse event that recurs and persists for at least 3 days is also a DLT. The Maximum Tolerated Dose (MTD) was defined as the highest dose level at which no more than 2 participants experience a DLT among 10 participants treated. Once the MTD was determined, interim biomarker analysis will be completed to assess bexarotene levels in serum and tissue samples. An expansion cohort of an additional 10 patients will be recruited at the MTD to further evaluate safety and toxicity. Secondary endpoints include serum bexarotene level, tissue bexarotene levels, and changes in thyroid function tests, lipid profile, and calcium. **Results:** Ten women were enrolled at the dose level of 10mg every other day and 9/10 participants experienced Grade 1 skin related events at the application site. Two participants reported Grade 2 skin related events at the application site but did not last long enough to be considered DLTs. Four women were enrolled at the second dose level of 10mg daily and 3/4 experience Grade 2 skin related events including 2 DLTs which stopped accrual to the study. Therefore, the MTD was determined to be 10mg every other day. No laboratory abnormalities were noted across either dose level and no grade 3 or 4 adverse events were reported. **Conclusion:** Maculopapular rash at treatment site was the most common adverse event related to study drug and resolved with discontinuation. Analysis is ongoing to assess bexarotene drug levels in serum and breast tissue samples.

Efficacy and safety of AB928 plus pegylated liposomal doxorubicin (PLD) with or without IPI-549 in participants with metastatic ovarian and triple negative breast cancer

Jasjit C. Sachdev<sup>1</sup>, Amy Prawira<sup>2</sup>, Arvind Chaudhry<sup>3</sup>, Vinod Ganju<sup>4</sup>, Caroline Trudeau<sup>5</sup>, Jennifer Scott<sup>5</sup>, Rachel Woloski<sup>5</sup>, Melissa Paoloni<sup>6</sup>, Halle Zhang<sup>7</sup> and Olivia Gardner<sup>5</sup>. <sup>1</sup>HonorHealth Research Institute/TGEN, Scottsdale, AZ; <sup>2</sup>Kinghorn Cancer Centre/St Vincent's Hospital Sydney, Sydney, Australia; <sup>3</sup>Cancer Centers, Spokane, WA; <sup>4</sup>PASO Medical, Frankston, Australia; <sup>5</sup>Arcus Biosciences, Hayward, CA; <sup>6</sup>Arcus Biosciences, Hayward, AZ; <sup>7</sup>Infinity Pharmaceuticals, Cambridge, MA

**Background:** Adenosine, derived from ATP released by dying cancer cells in response to chemotherapy, activates the A<sub>2a</sub> and A<sub>2b</sub> receptors (R) on immune cells, resulting in an ineffective anti-tumor immune response. Adenosine receptor blockade may improve the efficacy of chemotherapy, notably anthracycline regimens, by enhancing immunogenicity within the tumor microenvironment. AB928, the first clinical-stage small molecule dual A<sub>2a</sub>R/A<sub>2b</sub>R antagonist, is highly potent and well tolerated in combination with chemo/immunotherapy. Novel combinations of AB928 with PLD +/- IPI-549, a PI3Kgamma inhibitor believed to shift tumor associated macrophages toward an anti-tumor phenotype, may offer potential clinical benefit for tumors previously considered immunotherapy-resistant. **Methods:** ARC-2 (NCT03719326) is an ongoing Phase (Ph) 1/1b, open-label study in patients (pts) with metastatic or locally advanced, unresectable ovarian or triple negative breast (TNBC) cancer. Eligible pts must have ECOG performance status 0-1 and at least one measurable lesion. In dose escalation, AB928 (75 or 150 mg) administered orally once daily was given with standard PLD in a 3+3 design. Once a tolerable doublet regimen was established, escalating doses of oral IPI-549 (30 or 40 mg once daily) were added. Two expansion cohorts, the doublet of AB928 150 mg + standard PLD and the triplet (+ IPI549 40 mg), are ongoing in pts with TNBC. **Results:** As of 19Jun2020, 29 pts received AB928 as part of the doublet or triplet regimen (Table 1). The number of prior therapies for escalation and expansion range from 0-11 (median=2) and 0-5 (median=1), respectively. Across both regimens, most treatment emergent AEs (TEAEs) were Grade (Gr) 1 or 2. The most common TEAEs (>6 pts) were fatigue, anemia, constipation, stomatitis, cough, and nausea. Four pts reported 6 Gr ≥3 SAEs; none were related to AB928 or IPI-549 and one event (pleural effusion) was at least possibly related to PLD. One pt discontinued study treatment for an AE (Gr 3 peripheral neuropathy) related to the triplet regimen; this pt had a complete response (CR) at the time of discontinuation. Of those pts treated with AB928 + PLD, 16 pts had at least one on-study disease evaluation, 2 pts (1 TNBC, 1 ovarian) achieved a partial response (PR), 8 stable disease (SD) and 6 progressive disease (PD) as best response. The addition of IPI-549 (n=11) resulted in 1 complete response (CR; ovarian), 3 PR (2 ovarian, 1 TNBC), 4 SD, and 3 PD. Nine pts received prior immunotherapy as part of an anticancer regimen; 2/9 achieved a PR on study treatment (1 confirmed, 1 pending). Thirteen pts had prior anthracycline; 6/13 achieved SD as best overall response, including 1 pt who received doublet therapy >1 year. **Conclusions:** AB928 and PLD +/- IPI-549 is tolerable in pts with advanced ovarian cancer and TNBC. Doublet and triplet combination treatment were associated with clinical benefit, including responses in those with progression after prior immunotherapy. The promising observation that late-line pts, including those previously treated with an anthracycline and/or immunotherapy, can experience clinical benefit with AB928 combination therapy warrants further investigation.

The study of Jag1-notch in the extravasation of triple negative breast cancer cells in metastasis

Benjamin Gordon<sup>1</sup>, Reyhaan A Chaudhri<sup>2</sup>, Tim Sargis<sup>1</sup>, LA Naiche<sup>1</sup> and Jan K Kitajewski<sup>1</sup>. <sup>1</sup>University of Illinois at Chicago, Chicago, IL; <sup>2</sup>NuVasive, Atlanta, GA

In breast cancer, the primary tumor is usually not lethal, while metastatic spread to other organs is a frequent cause of death. Up to 20% of breast cancer diagnoses are triple negative breast cancer (TNBC) and late stage metastatic TNBC can have a 5-year survival as low as 11%. TNBC is unresponsive to hormonal and targeted therapies of other types of breast cancer. Surgery and adjuvant chemotherapy are effective treatment options for early stage disease, but there are very few therapeutic options for advanced metastatic TNBC spread. For metastasis to occur, circulating tumor cells (CTCs) must cross the endothelial barrier twice: first to migrate away from the primary tumor and enter systemic circulation (intravasation), and then to exit circulation to colonize other tissues (extravasation).

We are currently exploring the role of Jagged-1 (Jag1), a Serrate class Notch ligand, in the metastatic process. Jag1 is expressed in many human TNBC cell lines and its expression is associated with a worse prognosis in the clinic. Our data suggest that Jag1 presented on tumor cells promotes extravasation behavior, particularly TNBC binding to endothelium and subsequent transendothelial migration (TEM).

Our preliminary studies have blocked Jag1 function with the Notch decoy N1<sub>10-24</sub>, which utilizes EGF-like repeats of the Notch1 receptor that unproductively bind Jag1. Treatment with N1<sub>10-24</sub> reduces the ability of D3H2LN cells, a Jag1<sup>high</sup> derivative of the MDA-MB-231, to attach endothelial cells *in vitro*. Treatment with N1<sub>10-24</sub> also impedes the ability of these highly metastatic human TNBC cells to migrate across a monolayer of human primary endothelial cells. We therefore conclude that Jag1-Notch signaling inhibition via N1<sub>10-24</sub> suppresses activities required for TEM of TNBC cells. However, the mechanistic role of Jag1, however, is not understood in TEM. Both TNBC and endothelial cells express Jag1, and the aforementioned secreted decoys may target Jag1 signaling either within TNBC cells, within endothelial cells, or between cell types. We hypothesize that tumor expression of Jag1 is critical for metastasis. In order to explore the effects of tumor-derived Jag1 on tumor-intrinsic signaling, we have knocked out Jag1 in D3H2LN cells and generated multiple Jag1<sup>KO</sup> clonal lines, which have been interrogated for downstream transcriptional changes related to TEM. To explore the effects of tumor-derived Jag1 on neighboring endothelium, we are studying the extravasation capabilities of Jag1<sup>KO</sup> clonal lines using dynamic systems that will track TNBC adhesion, rolling, and TEM under dynamic flow *in vitro* as well as characterizing their metastatic potential *in vivo*. Our studies are elucidating a mechanism of Jag1-mediated metastasis via endothelial interactions.

Apatinib combined with taxanes and platinum neoadjuvant chemotherapy for patients with triple-negative and HER2-positive breast cancer: A multicenter, randomized, open-label, phase II trial

Yunjiang Liu<sup>1</sup>, Xiangmei Zhang<sup>1</sup>, Li Wang<sup>2</sup>, Miao Cao<sup>1</sup>, Shuo Zhang<sup>1</sup>, Hui Zhang<sup>1</sup>, Yarong Zhou<sup>1</sup> and Jintian Wang<sup>1</sup>. <sup>1</sup>The Fourth Hospital of Hebei Medical University, Shijiazhuang City, Hebei Province, China<sup>2</sup>Xingtai People's Hospital, Xingtai City, Hebei Province, China

**Background:** Apatinib, a tyrosine kinase inhibitor targeting vascular endothelial growth factor receptor 2 (VEGFR2), has demonstrated a promising efficacy in patients with metastatic breast cancer. For triple-negative and HER2-positive subtypes, increasing the pathological complete response (pCR) of neoadjuvant therapy may benefit their clinical outcomes. Here, we assessed whether the combination of Apatinib with neoadjuvant chemotherapy elevate the pCR rate in locally advanced breast cancer. **Method:** In this multicenter, open-label trial, we randomized 53 patients into TP neoadjuvant chemotherapy (docetaxel 75 mg/m<sup>2</sup> or nab-paclitaxel 260 mg/m<sup>2</sup> or paclitaxel liposome 175 mg/m<sup>2</sup> day 1, and carboplatin AUC=6 or cisplatin 75 mg/m<sup>2</sup> or lobaplatin 30 mg/m<sup>2</sup> day 1), or combined with apatinib (500mg day 1-21). Trastuzumab was added to neoadjuvant therapy in HER2-positive subtype. Six cycles were repeated every 3 weeks. **Results:** In total patients with stage IIb-IIIc triple-negative and HER2-positive breast cancer, the addition of apatinib to TP neoadjuvant chemotherapy (Apa+TP) significantly increased the pCR rate (70.8%, 17/24), compared with TP alone (41.4%, 12/29),  $P=0.032$ . When separating patients into triple-negative (Apa+TP 66.7% (8/12) vs. TP 42.9% (3/7)) and HER2-positive (Apa+TP 75% (9/12) vs. TP 40.9% (9/22)) subtypes, the effect of apatinib on pCR was also improved though no significant differences were found ( $P=0.377$ ;  $P=0.080$  separately) compared with control group. The most common Grade 3-4 adverse events (AE) included hypertension (Apa+TP 12.5% vs. TP 0%,  $P=0.173$ ), hand-foot syndrome (Apa+TP 8.3% vs. TP 0%,  $P=0.389$ ) and erythra (Apa+TP 4.2% vs. TP 0%,  $P=0.924$ ). No significant differences of toxic effects were found between Apa+TP and control group. **Conclusion:** Apatinib combined with TP neoadjuvant chemotherapy significantly increased the pCR rate in patients with locally advanced triple-negative and HER2-positive breast cancer, indicating an applicable strategy in the future.

Initial outcomes of adjuvant proton pencil beam scanning radiation for patients with breast cancer requiring comprehensive nodal irradiation within a single institution

Cristina DeCesaris<sup>1</sup>, Ariel Pollock<sup>1</sup>, Emily Kowalski<sup>2</sup>, Kayla Paulosky<sup>2</sup>, Sung Choi<sup>2</sup>, Mark Mishra<sup>2</sup> and Elizabeth Nichols<sup>2</sup>. <sup>1</sup>University of Maryland Medical Center, Baltimore, MD; <sup>2</sup>University of Maryland School of Medicine, Baltimore, MD

**Background:** Following lumpectomy or mastectomy, locally advanced breast cancer (LABC) requires adjuvant radiation (RT) to the chest wall (CW) and comprehensive regional nodal basins (CNI). Proton therapy (PBT) has demonstrated dosimetric advantages in heart, lung, and esophageal exposures compared to photon RT, but little is published regarding oncologic outcomes of PBT for LABC. **Methods:** Consecutive patients treated from 2016-2019 were retrospectively reviewed. Men and women over the age of 18 requiring adjuvant RT with CNI were included; all patients had at least 6 months of follow up from RT completion. Initial treatment volumes, excluding boosts to scars or gross disease, (CTV\_init) included CW-CNI per the RADCOMP atlas. CTV\_init coverage was prescribed as 95% CTV\_init at 100% Rx dose. All patients were treated with proton pencil-beam scanning RT (PBS-PBT), typically with a two-field anterior SFO technique. Patient, tumor, and dosimetric characteristics were analyzed. Tumoral control and survival rates were estimated by the Kaplan Meier method. Toxicities were recorded prospectively by treating physicians and reviewed retrospectively. Local recurrence was defined as in-breast, or skin/chestwall; regional recurrence was defined as a nodal failure. **Results:** One hundred patients were included with a median follow up of 15.4 months (6-42). Ninety-eight percent were female, and 61% were white. Median age was 52 years, and 94% of patients had an ECOG PS ≤1. AJCC 8<sup>th</sup> edition anatomic staging was predominantly stage II (49%) or III (48%). Sixty-five percent of patients were treated for left-sided disease; 7% of patients received bilateral RT; 87% received cytotoxic chemotherapy (63% neoadjuvant, 37% adjuvant). Twenty-six patients received concurrent systemic therapy with trastuzumab (H)/pertuzumab (P) (38%), capecitabine (29%), H-emetansine (21%), or H (12%). The median initial RT dose was 50.4 (45-50.4) while median total RT dose was 50.4 Gy (45-70.2). Forty-two percent of patients underwent an RT boost to nodal areas and/or the scar. All patients were treated in 1.8 or 2.0 Gy fractions. Eighty-seven percent of lesions were invasive ductal carcinomas; 52% were ER+/Her2-, 17% were triple-negative (TNBC), and 31% were Her2+. Nine (9%) of patients experienced a ≥G3 acute toxicity, all in the form of radiation dermatitis. There was one acute G4 incidence of skin necrosis. There were no ≥G3 late toxicities or documented major cardiac events at the time of last follow up. Median doses to critical organs at risk (OARs) were as follows: mean heart 0.9 Gy (<0.1 - 3.9), V25 heart 0.9% (0 - 6.6) ipsilateral lung V20 15% (4.6 - 29.2) ipsilateral lung V5 41.1% (17.5 - 62.2), volume of the esophagus receiving 70% Rx dose 0.1 cc (0 - 5.3). For bilateral plans, the median total lung V20 was 15.6% (6.6 - 23.5) and V5 was 41.5% (18.5 - 45.0). Overall, there were 3 local, 3 regional, and 8 distant failures. All local failures were TNBC; regional and distant failures were equally distributed between histologies. All distant failures occurred in patients with at least AJCC 8<sup>th</sup> Edition anatomic stage IIIA. Actuarial rates of 2-year local, regional, locoregional, and distant failures were 4% (±3), 2% (±2), 6% (±3%), and 11% (±4). Two-year actuarial survival was 94% (±3). **Conclusions:** We present a large series of patients with high-risk or LABC treated with adjuvant PBS-PBT and CNI. Our series includes significant percentages of TNBC, non-white patients, and patients requiring dose-escalated RT boosts overall demonstrating promising initial oncologic outcomes and very favorable acute toxicity and dosimetric profiles. Continued follow up is warranted to confirm long-term oncologic outcomes.

Trends in breast and axillary surgery for T1-T2 male breast cancer: A study from the national cancer database

Rashi Singh, Lifan Cao, Anuja L Sarode, Michael Kharouta, Robert Shenk and Megan E Miller. University Hospitals, Cleveland, OH

**Introduction:** Due to the low incidence of male breast cancer, large scale prospective trials to guide therapy are lacking. Historically males with breast cancer present at more advanced stages than females and have been surgically treated with modified radical mastectomy. Recent studies suggest that breast-conserving therapy for early-stage male breast cancer yields similar outcomes as for female patients, and that sentinel lymph node biopsy (SLNB) can be used in place of axillary lymph node dissection (ALND) for appropriate clinically node-negative patients. Our study investigates trends in breast and axillary surgery for male breast cancer patients, focusing specifically on the treatment of early-stage disease. **Methods:** The National Cancer Database (NCDB) was utilized to identify male and female patients diagnosed with clinical T1-2 breast cancer from 2004-2016. Patient, tumor, facility, and surgical treatment factors were examined. Patients were stratified by surgery type: partial, unilateral, and bilateral mastectomy; simple versus modified radical mastectomy; SLNB (removal of  $\leq 5$  lymph nodes) and ALND ( $>5$  lymph nodes). Trends in surgery type were compared between male and female patients and over the study period for each gender. **Results:** 9,782 males and 1,078,105 females with T1-2 breast cancer were identified. Men were significantly older at diagnosis than women (31.4% vs. 23.6% age  $>70$ ,  $p<0.0001$ ), were more often insured by Medicare (44.5% vs. 35.3%,  $p<0.0001$ ), and had greater co-morbidity (21.9% vs. 15.6% Charlson Deyo Score  $>0$ ). ER/PR+ disease (94.2% vs. 84.1%,  $p<0.0001$ ), moderate/high grade histology (85.4% vs. 77.8%,  $p<0.0001$ ) and lymphovascular invasion (24% vs. 15.3%,  $p<0.0001$ ) were also more common in males vs. females. The majority of all patients were clinically node negative (80.4% of males, 85% of females) and had AJCC clinical stage I or II disease (92.3% men, 95.2% women). Unilateral mastectomy was performed most commonly for men (67.1% men vs. 24.1% women,  $p<0.001$ ), while women more frequently underwent partial mastectomy (64.7% women vs. 26.4% men,  $p<0.001$ ). The rates of each surgery type remained disparate by gender and stable over the study period: male unilateral mastectomy rate 59.8% in 2004 and 66.1% in 2016; female partial mastectomy rate 65.9% in 2004, 68.4% in 2016. Modified radical mastectomy rates decreased in favor of simple mastectomy for both genders, 61.8% to 24.1% in males and 58.7% to 20.2% in females, 2004 to 2016. There was a similar overall increase in SLNB vs. ALND for all patients, though SLNB was not adopted as the more common procedure in male patients until 2009. In 2016, 78.2% of females and 65.3% of males underwent SLNB vs. 51.1% and 39.8% in 2004, respectively. **Conclusions:** Although breast-conserving therapy is the treatment of choice for female patients with early-stage breast cancer and could be similarly used to treat men with T1-T2 disease, the majority of male breast cancer patients continue to undergo unilateral mastectomy for early-stage disease. In more recent years, SLNB has surpassed ALND for men, mirroring the trend for women, though in a more delayed and gradual fashion. Partial mastectomy and SLNB warrant consideration for men with T1 and T2 breast cancer, in particular since male breast cancer patients present at older ages and with more co-morbidity than their female counterparts, and may benefit from de-escalation of surgical treatment.

The impact of corona virus disease-2019 on breast services at university hospitals of North Midlands, United Kingdom

Manoj Gowda S, Kirti Kabeer, Fatima Mansour, Ammara Hasan, Eisa Nael, Vallipuram Gopalan, Daljit Gahir, Apurna Jegannathen, Sekhar Marla, Soni Soumian, Sankaran Narayanan and Sadaf JafferBhoy. University Hospitals of North Midlands, Stoke-on-Trent, United Kingdom

**Introduction:** The COVID-19 pandemic has disrupted routine cancer care and training globally. Breast units adopted modified national guidelines in the UK, and significant changes were implemented to ensure the safety of patients and staff. The national breast screening services were temporarily suspended from March 2020. Patients underwent surgery in COVID-19 free zones. Complex oncoplastic procedures and immediate reconstructions were not offered. Adjuvant treatments were modified to reduce the risk of complications and hospital readmission. The objective of our study is to assess the impact of COVID-19 on breast cancer management and surgical training. **Methods:** The resource reallocation was implemented for 100 days, commencing from the 16th of March, 2020. Patients diagnosed with breast cancer during this period were identified from the cancer database, and a comparison was made with patients diagnosed last year within the same time frame. We assessed the time taken from the decision to treatment and modifications made to cancer management due to the pandemic. The impact on resident training was evaluated by comparing the number of cases performed or assisted during this period. **Results:** During the pandemic period, out of 1064 patients seen in the Breast one-stop clinic, 64 patients (6.0%) were diagnosed with breast cancer. During the same time frame in 2019, out of 1881 new symptomatic patients, 90 (4.8%) were diagnosed with cancer. In 2019, sixty-three patients were treated for screen-detected cancer, whereas only 23 patients entered the screening pathway before the services were suspended. Majority of patients underwent surgery in 2019 as compared to 2020 (80% versus 36%). Fifty-six percent of patients received endocrine treatment as primary or bridging therapy; whereas, in 2019, only 12% received primary endocrine therapy. In 2020, time from decision to surgical treatment has decreased by half as compared to 2019 (8.6 versus 19.1 days). One patient who underwent surgery developed COVID-19 infection after two weeks, and no postoperative mortality was reported. On average, each trainee was involved in 35 procedures during 2020; whereas in 2019, 54 procedures were assisted or performed by a trainee. **Conclusion:** Our study shows that COVID-19 has made a significant impact on patients' management and surgical training. Majority of the patients were commenced on neoadjuvant endocrine therapy instead of surgery. The conversion rate to cancers in one-stop clinic improved possibly due to a smaller number of benign referrals during the pandemic. The impact on surgical training is due to the reduction in the number of patients operated during this period, and constraints of performing complex oncoplastic procedures and breast reconstruction.

	2019 (16.03.2019 to 22.06.2019)	2020COVID period (16.03.2020 to 22.06.2020)

Potential value of FOXA1 expression as genomic predictor of response to docetaxel and carboplatin neoadjuvant (NA) chemotherapy in patients with triple negative breast cancer (TNBC)

Sara Lopez-Tarruella<sup>1</sup>, Maria del Monte-Millan<sup>1</sup>, Enrique Alvarez<sup>2</sup>, Yolanda Jerez<sup>1</sup>, Jose Angel Garcia Saenz<sup>3</sup>, Isabel Echavarria<sup>2</sup>, Fernando Moreno<sup>3</sup>, Ivan Marquez-Rodas<sup>1</sup>, Coralía Bueno-Muino<sup>4</sup>, Blanca Herrero<sup>2</sup>, Maria Cebollero<sup>5</sup>, Rocio Ramos-Medina<sup>1</sup>, Nerea Lobato<sup>2</sup>, Ricardo Gonzalez del Val<sup>2</sup>, Maria Isabel Palomero<sup>2</sup>, Santiago Lizarraga<sup>6</sup>, Uriel Bohn<sup>7</sup>, Ana Isabel Ballesteros<sup>8</sup>, Patricia Rincon<sup>6</sup>, Tatiana Massarrah<sup>1</sup>, Inmaculada Ocana<sup>2</sup>, Lucia Villarejo<sup>2</sup>, Charles M Perou<sup>9</sup> and Miguel Martin<sup>1</sup>. <sup>1</sup>Department of Medical Oncology, Hospital General Universitario Gregorio Marañon Instituto de Investigacion Sanitaria Gregorio Marañon, CiberOnc, Madrid, Spain<sup>2</sup>Department of Medical Oncology, Hospital General Universitario Gregorio Marañon Instituto de Investigacion Sanitaria Gregorio Marañon, Madrid, Spain<sup>3</sup>Department of Medical Oncology, Hospital Clinico San Carlos, CIBERONC, Madrid, Spain<sup>4</sup>Medical Oncology Department, Hospital Infanta Cristina, Parla, Madrid, Spain<sup>5</sup>Pathology Service, Hospital General Universitario Gregorio Marañon, Madrid, Spain<sup>6</sup>Gynecology Service, Hospital General Universitario Gregorio Marañon, IISGM, Universidad Complutense, Madrid, Spain<sup>7</sup>Gynecology Service, Hospital General Universitario Gregorio Marañon, IISGM, Universidad Complutense, Madrid, Spain<sup>8</sup>Department of Medical Oncology, Hospital Universitario Dr Negrin, Las Palmas de Gran Canaria, Spain<sup>9</sup>Department of Medical Oncology, Hospital Universitario de La Princesa, Madrid, Spain<sup>9</sup>Department of Pathology and Laboratory Medicine, University of North Carolina, Chapel Hill, NC

**Background:** TNBC is a particularly aggressive subtype with high recurrence rates and poor long-term survival. Anthracycline-free regimens based on docetaxel plus carboplatin (TCb) achieve around 50-55% pathologic complete responses (pCR) which correlates with better survival outcomes. Identification of genomic predictors of response is key to individualize therapies for this heterogeneous breast cancer (BC) subgroup. FOXA1 is a pioneer factor for androgen (AR) and estrogen receptors (ER). Its under-expression has been linked to cancer stemness in TNBC and better prognosis in ER-positive BC. The differential expression of AR, FOXA1 and BRCA1 is associated with sensitivity to chemotherapy in TNBC patients. Data support the plasticity role of FOXA1 driving basal to luminal BC cells by inducing luminal genes but also by repressing the basal phenotype and thus, tumor aggressiveness, although its role as a biomarker in TNBC is still controversial. We have analyzed RNAseq data of FOXA1 and AR in a series of TNBC tumors homogeneously treated with neoadjuvant TCb to study their correlation with survival and response. **Methodology:** 300 TNBC patients have been included in a multicenter, prospective, non-randomized trial aimed to identify predictors of response to TCb in the neoadjuvant setting (NCT01560663). 278/300 patients were evaluable. PAM50 subtypes (NanoString nCounter) and RNAseq (HiSeq2500) were analyzed for those patients with both available samples and evaluable pathological response (n=208). Correlations were studied by the Kendall method. Linear or logistic regressions were adjusted for univariate analysis depending on numerical or categorical response variables, respectively. **Results:** FOXA1 and AR were differentially expressed between basal and non-basal tumor subtypes (PAM50), being overexpressed in non-basal (p<0.001 for both FOXA1 and AR). FOXA1 and AR were significantly overexpressed in non-basal subtypes from the Vanderbilt TNBC-type classification (36/208) as well. Both genes expression showed a significant correlation with several luminal marker genes. AR was significantly associated with ANXA9 (p=0.008), GATA3 (p=0.00002) and XBP1 (p<0.001), while FOXA1 expression was positively associated with ANXA9 (p=0.03), ESR1 (p<0.001), GATA3 (p<0.001) and XBP1 (p<0.001). In terms of response, significant differences in FOXA1 expression levels were found between responders and non-responders by Residual Disease Burden (RCB) classification taking response as binary variable of PCR vs RCB-I/II/III (p=0.003) as well as pCR/RCB-I vs RCB-II/III (p=0.008) with responders showing a lower FOXA1 expression level. The same analysis for AR expression did not show statistically significant differences. Within the PAM50 basal subgroup, neither AR nor FOXA1 individual gene expression (172/208) showed association with response. For survival, with a median follow-up of 36 months, neither FOXA1 nor AR showed significant impact on EFS or OS per univariate Cox regression analysis (EFS: HR<sub>FOXA1</sub> 1.076; p=0.307; HR<sub>AR</sub> 1.156, p=0.084 and OS: HR<sub>FOXA1</sub> 1.120, p=0.140; HR<sub>AR</sub> 1.152, p=0.121). **Conclusions:** Within our cohort, FOXA1 expression is a better predictor of response to NA chemotherapy than AR. FOXA1 is overexpressed in TNBC tumors who do not achieve pCR with neoadjuvant TCb chemotherapy, correlating with non-basal tumor subtypes. This suggests that measuring FOXA1 expression levels in patients with TNBC could be useful to predict response to TCb regimen enabling physicians to select more effective alternative NA schemes in this population.

Floor and ceiling effects in the EORTC QLQ-C30 physical functioning subscale among patients with breast cancer enrolled in commercial clinical trials vs. a community trial

Meena N Murugappan<sup>1</sup>, Bellinda King-Kallimanis<sup>2</sup>, Christina Mangir<sup>3</sup>, Lynn Howie<sup>4</sup>, Vishal Bhatnagar<sup>2</sup>, Julia A Beaver<sup>2</sup>, Ethan Basch<sup>5</sup> and Paul G Kluetz<sup>2</sup>. <sup>1</sup>ORISE Fellow, Office of Oncologic Diseases, Center for Drug Evaluation and Research (CDER), U.S. Food and Drug Administration, White Oak, MD; <sup>2</sup>Oncology Center for Excellence, U.S. FDA, White Oak, MD; <sup>3</sup>Association of Community Cancer Centers, Rockville, MD; <sup>4</sup>Pardee Hospital, University of North Carolina Health, Hendersonville, NC; <sup>5</sup>Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC

**Background:** The EORTC QLQ-C30 Physical Functioning (PF) subscale is a widely used patient-reported outcome (PRO) measure that quantifies cancer patients' physical function. Responsiveness, the degree to which a scale can assess clinical deterioration and improvement, is an important measurement characteristic that can be assessed by looking at floor and ceiling effects. A floor effect is defined as a high proportion of study participants reporting the lowest possible score in the variable of interest, while a ceiling effect is the opposite. We characterized floor and ceiling effects of the PF subscale in patients with breast cancer enrolled in commercial clinical trials vs. a community-based trial. **Objectives:** (1) Determine floor/ceiling effects of the QLQ-C30 PF items and subscale among patients receiving treatment for breast cancer (2) Compare floor/ceiling effects among patients enrolled in randomized clinical trials vs. those treated in a community care trial. **Methods:** PF data from 5 breast cancer commercial clinical trials submitted to the FDA for review were pooled (Clinical Trial or CT Cohort). A subgroup of breast cancer patients from the Alliance PRO-TECT trial was also analyzed (Community Cohort). Descriptive statistics were used to assess floor/ceiling effects, distributions of PF items, and the summed PF score at baseline and follow-up, for both cohorts. **Results:** The CT Cohort and Community Cohort consisted of 5,975 and 178 patients, respectively. Most patients in both cohorts were female, over the age of 50, and White. They were from varied treatment settings (adjuvant, 1<sup>st</sup> line, and 2<sup>nd</sup> line). 78% of CT patients had a baseline ECOG score of 0 (fully active), vs. only 44% in the Community Cohort. Baseline and follow-up floor effects (i.e. % of patients with the lowest response option - "not at all") are presented in Table 1. Floor effects were more pronounced in the CT Cohort, with 43 to 94% of CT patients responding "not at all" to items in the PF subscale at baseline vs. 24 to 89% in the Community Cohort. Additionally, smaller proportions of CT patients responded "not at all" at Cycle 3 follow up compared to baseline. Meanwhile, floor effects in the Community Cohort were similar at baseline and month 3 follow up. Ceiling effects (i.e. % of patients with the highest domain response) were also observed in both cohorts. Over 54% of CT patients scored  $\geq 93/100$  on the 100-point PF subscale, at baseline. This proportion decreased to 30% at Cycle 3 follow up. On the other hand, 26% of community patients scored  $\geq 93/100$  on the PF subscale, at baseline. This proportion increased to 30% at Month 3.

Table 1: Baseline and Follow Up Floor Effects - % of patients responding "not at all"

Item	Question	Clinical Trial Cohort		Community Cohort	
		Baseline	Cycle 3	Baseline	Month 3
		% (n)	% (n)	% (n)	% (n)
1	Do you have any trouble doing strenuous activities, like carrying a heavy shopping bag or a suitcase?	43% (2,540)	27% (573)	24% (42)	27% (43)
2	Do you have any trouble taking a long walk?	60% (3,554)	28% (585)	24% (42)	30% (47)
3	Do you have any trouble taking a short walk outside of the house?	88% (5,256)	68% (1,395)	58% (104)	64% (101)
4	Do you need to stay in bed or a chair during the day?	73% (4,364)	57% (1,181)	46% (82)	51% (81)
5	Do you need help with eating?	94% (5,599)	93% (1,904)	89% (159)	91% (145)

**Conclusion:** We observed high floor/ceiling effects in the PF domain of the QLQ-C30 among patients in commercial clinical trials, more so than in the community. Inclusion of patient advocacy groups in the item selection process may increase the relevancy and sensitivity of the PF domain to the population being studied. Stakeholders in clinical trial and clinical practice settings may consider adding additional high functioning items from the EORTC's item library, to more accurately determine the impact of anti-cancer treatment on patients' physical functioning.

Prediction of pathological complete response to neoadjuvant chemotherapy in early triple negative breast cancer patients by serial breast ultrasound examination

Bernardo Rapoport<sup>1</sup>, Teresa Smit<sup>1</sup>, Liezl Heyman<sup>1</sup>, Farhana Moosa<sup>1</sup> and Carol Ann Benn<sup>2</sup>. <sup>1</sup>The Medical Oncology Centre of Rosebank, Johannesburg, South Africa<sup>2</sup>Netcare Breast Care Centre, Johannesburg, South Africa

**Background.** Pathological complete response (pCR) following neoadjuvant chemotherapy is associated with a good prognosis and long-term survival in patients with triple negative breast cancer (TNBC). Imaging offers significant information in monitoring response to neoadjuvant chemotherapy as a complement to conventional tumor assessment by physical examination. **Methods.** This is a single institution, retrospective cohort study. The primary objective was to determine whether volumetric measurement by ultrasound examination, of the pre-treatment breast tumor size, post-cycle two, post-cycle four and at completion of neoadjuvant chemotherapy predicted pCR. Tri-dimensional measurements were used to calculate the volume index. The percentage change between pre-treatment and cycle 2, pre-treatment and cycle 4, and pre-treatment and completion of treatment was calculated. Patients were treated with taxane, anthracycline, and alkylating agents based neoadjuvant chemotherapy. A pCR was defined as the complete disappearance of the invasive cancer in the breast and absence of tumor in the axillary lymph nodes. A radiological complete response (rCR) was defined as no malignant lesions detected by ultrasound (0mm). Receiving operating characteristics (ROC) analysis was used to determine the association between pCR and percentage of tumor shrinkage. Specificity was defined as the proportion of patients with a non-pCR that were correctly classified as non-responders by ultrasound measurement. Sensitivity was defined as the proportion of patients with a pCR that were correctly classified as complete responders by ultrasound assessment. Statistical analysis was performed using NCSS version 11 and statistical tests used the significance level of 0.05. **Results.** Seventy-eight TNBC patients with a median age of 48 years (range 27-85 years). The population's tumor sizes were classified as T1 = 18 (23%), T2 = 54 (69%), T3 = 6 (8%). Positive glands in 33 (43%) patients and negative glands in 45 (57%) patients. Stage I = 11 (23%) patients, Stage IIA = 40 (51%) patients, stage IIB = 22 (28%) patients and stage III = 5 (6%) patients. The median volume pre-treatment was 18624mm<sup>3</sup> (SD = 41284mm<sup>3</sup>). A pCR rate of 57% was documented. A 80% shrinkage of tumor, following the second cycle of chemotherapy, was associated with a pCR in 74% of responders (specificity 71%, sensitivity 70%). A 93% shrinkage following four cycles of chemotherapy was associated with a pCR in 73% of responders (specificity 62%, sensitivity 81%). A 97% shrinkage upon completion of chemotherapy was associated with a pCR in 70% of responders (specificity 45%, sensitivity 93%). A shrinkage of more than 90% was associated with a pCR in 93% pts (specificity 79%, sensitivity 66%). Radiological CR was associated with a pCR in 84% pts (specificity 70%, sensitivity 68%). Patients attaining a pCR had a mean volume of 877mm compared to patient not attaining a pCR with a mean volume of 833mm ( $p < 0.97088$ ). **Conclusion.** The breast ultrasound is a useful, non-expensive, non-invasive test to monitor TNBC pts undergoing neoadjuvant chemotherapy. Measurement of the tumor by serial ultrasound is a useful predictor of pCR in these patients. Percentage shrinkage of more than 90% of the tumor at the completion of treatment, is more accurate in predicting pCR compared to radiological CR.

Palmitate exacerbates breast tumorigenesis in vitro via induction of a senescent-like phenotype in fibroblasts

Brittany Susanne Harlow<sup>1</sup>, Albert Davalos<sup>2</sup>, Andrew Brenner<sup>3</sup>, Christopher Jolly<sup>1</sup>, Stefano Tiziani<sup>1</sup>, Steve Hursting<sup>4</sup> and Linda deGraffenried<sup>1</sup>.

<sup>1</sup>University of Texas at Austin, Austin, TX; <sup>2</sup>Buck Institute for Research on Aging, Novato, CA; <sup>3</sup>UT Health Science Center at San Antonio, San Antonio, TX; <sup>4</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC

**Background:** Obesity is associated with a worse breast cancer prognosis, conferring an increased risk of recurrence and mortality. At the same time, recent evidence suggests that obesity is also correlated with development of cellular senescence, an inflammatory state associated with exacerbation of breast tumorigenesis in preclinical models. As obese individuals present greater levels of inflammation at baseline, research efforts are warranted to examine the means by which obesity promotes the development of a senescent phenotype, which may further exacerbate inflammation. Additionally, studies have yet to determine whether obesity-induced senescence modulates the tumorigenic process in the context of breast cancer specifically.

**Methods:** To this end, we exposed fibroblasts to the obesity-associated circulating factor palmitate and used qPCR and western immunoblotting to assess the expression of genes and proteins involved in the senescent state, including interleukin (IL)-1a, IL-6, IL-8, senescence-associated beta-galactosidase (SA-beta-gal), and matrix metalloproteinase (MMP)-9. As a mechanistic investigation, we next assessed the impact of palmitate on activation of NF-κB signaling using western immunoblotting, immunofluorescence, and NF-κB luciferase reporter assays. Finally, we utilized cell counting, MTT, wound healing, and colony formation assays to examine the impact of these palmitate-exposed fibroblasts on breast cancer cell proliferation, viability, motility, and survival, respectively. **Results:** We found that palmitate induced fibroblast gene expression of IL-1a, IL-6, and IL-8, major components of the senescent secretome, as well as expression of the senescent markers SA-beta-gal and MMP-9. The mechanism at least partially involved activation of NF-κB, responsible for production of about 75% of senescent secretome components. More importantly, these palmitate-exposed fibroblasts were of pathological impact, exacerbating in vitro measures of breast cancer cell aggressiveness. **Conclusions:** These findings contribute to our understanding of the impact of obesity-associated factors on breast tumorigenesis, demonstrating a mechanistic link between palmitate and the pro-tumorigenic effects of senescent cells. Our studies will ultimately aid in the identification of a therapeutic target that can be used to improve the comparably worse outcomes of the obese breast cancer patient.

**Background:** Balixafortide (B) is a potent, selective antagonist of the chemokine receptor CXCR4. High CXCR4 levels correlate with aggressive metastatic phenotypes and poor prognosis in metastatic breast cancer (MBC). Efficacy and safety data were published recently from the Phase 1 trial investigating B + eribulin (E) in patients with HER2 negative MBC<sup>1</sup>. We report the final safety and efficacy analyses from this trial, including an assessment of dose-response and adverse events of particular interest (AEPIs) (e.g. neutropenia, peripheral neuropathy).

**Methods:** In this single-arm, dose escalation trial, patients (pts) received E + increasing doses of B using a 3+3 design in 3 parts: *Part I* cohorts received low B doses (0.5–1mg/kg) + increasing E doses (1.1–1.4mg/m<sup>2</sup>); *Part II* dose-escalation cohort for B (1–5.5mg/kg) + 1.4mg/m<sup>2</sup> E; *Expanded Cohort* (EC) to confirm safety and efficacy of B 5.5mg/kg + 1.4mg/m<sup>2</sup> E. Most cohorts received E on days 2 and 9, and B on days 1–3 and 8–10 of 21-day cycles.

**Results:** At entry, all 56 women (age range 33–82 years) were HER2 negative, CXCR4 positive. Most pts were Caucasian and heavily pretreated in the metastatic setting (line of chemotherapy on study: 29% 2<sup>nd</sup> line, 50% 3<sup>rd</sup> line, 21% 4<sup>th</sup> line). 75% were hormone receptor positive and 23% had triple negative breast cancer.

A linear dose-exposure was observed over the entire dose range tested for B. C<sub>max</sub> and AUC for E were within published ranges.

Safety findings (including AEPIs) remained similar to those reported previously<sup>1</sup>.

No dose-limiting toxicities were confirmed; therefore, the maximum tolerated dose of B was not reached. The highest B dose evaluated was 5.5mg/kg; pharmacokinetic evaluation showed that further protocolled dose increments of B would not have provided a sufficient increase in plasma levels. In addition, the objective response rate in Part II was 3-fold greater than published for eribulin alone which suggested that the anti-tumor activity of B was worthy of further exploration at 5.5mg/kg in the EC. Efficacy data for the trial are shown in the table.

	Part II(N=21)	Expanded Cohort(N=24)	Overall Efficacy Population(N=54)
<b>Objective Response Rate (95% CI)</b>	33% (15–57)	38% (19–59)	30% (18–44)
<b>median duration in months (IQR)</b>	2.8 (1.4–3.3)	4.4 (3.1–5.3)	3.2 (2.2–4.5)
<b>Clinical Benefit Rate (95% CI)</b>	43% (22–66)	63% (41–81)	44% (31–59)
<b>median duration in months (IQR)</b>	5.4 (4.2–6.7)	8.1 (6.3–10.8)	6.9 (5.4–10.3)
<b>median PFS in months (95% CI)</b>	4.2 (3–5.4)	6.2 (2.9–8.1)	4.6 (3.2–5.7)
<b>median OS in months (95% CI)</b>	10.4 (7.7–18.4)	18 (12.2–27.2)	16.8 (10.6–18.4)
<b>Landmark OS estimate</b>			
<b>12 months (95% CI)</b>	40% (19–60)	75% (53–88)	60% (45–72)
<b>18 months (95% CI)</b>	30% (12–50)	50% (29–68)	42% (29–55)
<b>24 months (95% CI)</b>	20% (6–39)	33% (16–52)	25% (14–37)

CI: confidence interval; IQR: interquartile range; OS: overall survival; PFS: progression free survival

These data suggest a potential dose-response relationship for B across all efficacy endpoints, with efficacy being numerically greatest in the EC. While PFS and OS should be interpreted with caution in single arm trials, these data suggest potential benefit for this combination. Further analyses will be presented.

Responses were observed regardless of line of chemotherapy on study or extent of CXCR4 expression and were numerically higher in hormone receptor positive patients.

**Conclusions:** A consistent dose response effect for B + E was suggested across all efficacy endpoints for heavily pretreated pts with HER2 negative MBC. When these results are compared with published data for E monotherapy in similar populations, the EC consistently shows numerically greater benefit for all efficacy endpoints<sup>2, 3</sup>.

The safety and tolerability of B + E appear comparable to published data on E or B alone, particularly for neutropenia and peripheral neuropathy<sup>1</sup>.

These results suggest that B + E could potentially provide a new treatment option in heavily pretreated patients with HER2 negative MBC. A Phase 3 trial exploring efficacy and safety of B 5.5mg/kg + E is ongoing.

National comprehensive cancer network (NCCN) recommendations for drugs without US food and drug administration (FDA) approval in metastatic breast cancer: A cross-sectional study

Tal Etan<sup>1</sup>, Eitan Amir<sup>2</sup>, Adriana Tibau<sup>3</sup>, Rinat Yerushalmi<sup>4</sup>, Assaf Moore<sup>4</sup>, Daniel Shepshelovich<sup>1</sup> and Hadar Goldvaser<sup>4</sup>. <sup>1</sup>Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel<sup>2</sup>Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada<sup>3</sup>Hospital de la Santa Creu i Sant Pau, Universitat Autònoma de Barcelona, Barcelona, Spain<sup>4</sup>Rabin Medical Center, Petah- Tikva, Israel

**Background:** NCCN guidelines include recommendations not approved by the FDA. We aimed to compare the NCCN recommendations for metastatic breast cancer (MBC) with the FDA approved indications and to identify characteristics that are associated with NCCN recommendations for off-label treatment. **Methods:** All NCCN recommendations for MBC and their supporting data were identified. Drug labels were reviewed to determine whether recommendations are FDA approved indications. Odds ratio (OR) and 95% confidence interval (CI) were calculated to compare between FDA approved and off-label recommendations for pre-specified categories including drug type, tumor subtype, level of recommendation and line of therapy. **Results:** Of 124 recommendations identified, 68 (55%) were off-label. Chemotherapy and human epidermal growth factor receptor 2 (HER2) targeted drugs were associated with less frequent approved indications (OR=0.28, 95% CI 0.12-0.62, p=0.001 and OR=0.29, 95% CI 0.12-0.70, p=0.005, respectively). Recommendations for endocrine therapy (OR=3.44, 95% CI 1.32-9.09, p=0.009) and non-HER2 targeted treatment (OR=10.0, 95% CI 3.03-33.33, p<0.001) were associated with FDA approved indications. Compared to combination therapies, monotherapies were more likely to be FDA approved (OR=3.45, 95% CI 1.64-7.23, p=0.001). Category 1 (OR=7.63, 95% CI 2.19-26.55, p=0.001) and preferred NCCN recommendations (OR=5.49, 95% CI 2.36-12.77, p<0.001) were more likely to be FDA-approved indications. Compared to off-label recommendations, NCCN recommendations of approved drugs were based on significantly higher sample size (mean 477 vs. 342 patients, p=0.017) and were non-significantly associated with availability of randomized data (OR=1.92, 95% CI 0.87-4.24, p=0.10). **Conclusion:** More than half of all NCCN recommendations for MBC are off-label, mostly involving chemotherapy containing regimens for HER2 negative disease and combinations which include HER2 targeting drugs. The clarity of the NCCN guidelines can be improved by underlining the strength of the evidence supporting various recommendations for MBC and the hierarchy between various treatment options.

Impact of axillary dissection and patterns of care in patients with ypN1 triple negative breast cancer receiving regional nodal irradiation

Michael Kharouta, Nicholas Damico, Megan Miller, Eleanor Harris and Janice Lyons. University Hospitals Cleveland Medical Center, Cleveland, OH

**Background:** The benefit of axillary lymph node dissection (ALND) in patients with pN1 disease on sentinel lymph node biopsy (SLNB) following neoadjuvant chemotherapy for invasive breast cancer in patients receiving regional nodal irradiation (RNI) is unclear, even in patients with high risk histologic features such as triple negative disease. We sought to determine any association of ALND with improved survival, as well as patterns of care in this cohort using the National Cancer Database (NCDB).

**Methods:** The NCDB was queried for women ages 18-75 with cT1-3N1 and ypT0-T3N1M0 breast cancer that underwent definitive surgical resection with axillary staging followed by adjuvant regional nodal irradiation, with triple negative receptor status. Only patients who were treated from 2012 - 2015 were included for appropriate coding of the extent of axillary surgery. Overall survival was estimated using the Kaplan-Meier method and Cox proportional hazards models. An analysis of the number of lymph nodes removed, rate of RNI utilization, and rate of ALND was performed using the Wilcoxon rank-sum test, proportions of RNI utilization compared using the Chi-squared test, and correlation of these to year of diagnosis was evaluated with the Pearson correlation coefficient.

**Results:** A total of 572 women were identified that met inclusion criteria. The median age was 53 (range 24-75) years. 67 (11.7%) of women had SLNB alone and 505 (88.3%) had ALND with or without SLNB. Four year OS was 66.7% in patients undergoing ALND compared to 70.6% in those that had SLNB alone ( $p = 0.47$ ). Charlson-Deyo comorbidity index (CDCC) ( $p = 0.01$ ) and clinical T3 stage ( $p = 0.03$ ) were significantly associated with survival. After adjusting for age, histology, clinical and pathologic T-stage, and CDCC, there was no significant relationship between receipt of ALND and overall survival (OS), however CDCC ( $p = 0.01$ ) and cT3 or pT3 ( $p = 0.02$  and  $p = 0.01$ ) remained significantly associated with OS. The mean number of lymph nodes sampled from 2012 to 2015 increased from 11.68 to 13.46 ( $p = 0.07$ ). The rate of RNI increased from 55.6% in 2012 of patients to 58.4% in 2015 ( $p = 0.6$ ). The rate of ALND increased from 83.9% in 2012 to 90.8% in 2015 ( $p = 0.2$ ). Pearson correlation coefficients between mean number of lymph nodes sampled, rate of RNI, and rate of ALND were 0.83, 0.13, and 0.95 respectively.

**Conclusions:** There was no difference in overall survival between patients with cT1-3N1M0 and ypT0-3N1M0 triple negative breast cancer receiving SLNB compared to ALND with adjuvant RNI, even when adjusting for tumor size and comorbidities, which remained significant risk factors. There was a trend towards an increase in the mean number of lymph nodes sampled and increased utilization of ALND, though these failed to reach statistical significance. We await the results of the Alliance 011202 randomized trial to provide prospective guidance of the utility of ALND in this high risk subgroup.

Multidimensional molecular profiling of repeated metastatic TNBC biopsies in the intensive trial of omics &ITOMIC&; safely guides treatment decisions

Kimberly A Burton<sup>1</sup>, Eric Q Konnick<sup>2</sup>, Sibel Blau<sup>1</sup>, Michael O Dorschner<sup>2</sup>, Julie Gralow<sup>3</sup>, Rahul Parulkar<sup>4</sup>, Elisabeth Mahen<sup>2</sup>, Patricia Spilman<sup>4</sup>, Stephanie Parker<sup>1</sup>, Francis M Senecal<sup>1</sup>, Colin Pritchard<sup>2</sup>, Christopher Szeto<sup>4</sup>, Jing Zhu<sup>5</sup>, Vijayakrishna K Gadi<sup>2</sup>, Stephen C Benz<sup>4</sup>, Shahrooz Rabizadeh<sup>4</sup>, Patrick Soon-Shiong<sup>6</sup> and Carl Anthony Blau<sup>2</sup>. <sup>1</sup>Northwest Medical Specialties, Tacoma, WA; <sup>2</sup>University of Washington, Seattle, WA; <sup>3</sup>Seattle Cancer Care Alliance, Seattle, WA; <sup>4</sup>ImmunityBio, Santa Cruz, CA; <sup>5</sup>University of California at Santa Cruz, Santa Cruz, CA; <sup>6</sup>Nantomics/ImmunityBio, Culver City, CA

**Background** Metastatic triple negative breast cancer (mTNBC) is an inherently diverse disease and while molecular classification of mTNBC has assisted in treatment decisions, if based on only an initial biopsy, it does not take into account the evolution of metastatic cancer. Characterization of emerging metastases is needed to reveal both new resistance or sensitivity to available therapeutics. The goal of “Intensive Trial of OMics in Cancer (ITOMIC) - Intensive Longitudinal Monitoring in Subjects With Triple-Negative Breast Cancer” (NCT01957514) - was to determine the feasibility of longitudinal collection of patient biopsies that would be subjected to molecular analysis to provide actionable, relevant and timely information to guide treatment decisions. **Methods** Multiple biopsies were collected longitudinally, including pre- and post-treatment, from 29 mTNBC patients enrolled in the ITOMIC study and subjected to multi-dimensional molecular profiling including WES, WGS, cancer gene panel sequencing, RNA-seq, and proteomics and/or IHC for tumor biomarkers. This information was used to guide iterative, patient- and tumor- individualized treatment recommendations made by a multi-institutional ITOMIC Tumor Board (ITB) and conveyed to each subject's oncologist. **Results** Longitudinal biopsy collection was found to be safe. Molecular profiling revealed that 2 of an original 31 enrolled subjects likely had lung cancer rather than mTNBC, supporting the merit of repeated tissue analysis. While the other 29 subjects had all been given a diagnosis of mTNBC before entering the trial, estrogen receptor, progesterone receptor, and/or HER2 were found to be over-expressed in at least one sample for 12 subjects; appearance of receptor positivity suggests targeted therapy may be effective. Tumor evolution in response to the first on-study treatment for most subjects (cisplatin) was revealed by copy number alterations, changes in single nucleotide variants, and insertions/deletions in pre-/post-treatment biopsies. Over the course of the study, the ITB convened 54 times and 39 of 182 recommended treatments were evaluated and accessed through either an existing clinical trial, a single patient IND, approved off label or label indication. While not all ITB treatment recommendations were followed, 24 subjects did receive at least one ITB-recommended drug, frequently as part of a clinical trial. Currently, for 27 subjects (2 withdrew) median survival is ~31 months. There are 4 surviving patients in treatment with a remarkable median survival of >51 months. **Conclusion** Collection and molecular analysis of multiple biopsies during the course of patient's disease, shown here to be safe and feasible, provides information vital to appropriate treatment choice and reveals new targets for and resistance to therapy in metastatic TNBC.

Non-invasive screening for breast cancer risk based on circulating ensembles of tumor associated cells

Dadasaheb Akolkar<sup>1</sup>, Darshana Patil<sup>1</sup>, Pradip Fulmali<sup>1</sup>, Pooja Fulmali<sup>1</sup>, Revati Patil<sup>1</sup>, Archana Adhav<sup>1</sup>, Shoeb Patel<sup>1</sup>, Sachin Apurwa<sup>1</sup>, Sushant Pawar<sup>1</sup>, Harshal Bodke<sup>1</sup>, Vishal Ranjan<sup>1</sup>, Rohit Chougule<sup>1</sup>, Pradyumna Shejwalkar<sup>1</sup>, Shabista Khan<sup>1</sup>, Raja Dhasarathan<sup>1</sup>, Pradip Devhare<sup>1</sup>, Sanket Patil<sup>1</sup>, Vineet Datta<sup>1</sup>, Cynthe Sims<sup>1</sup>, Stefan Schuster<sup>2</sup>, Jatinder Bhatia<sup>1</sup>, Chirantan Bose<sup>1</sup>, Ajay Srinivasan<sup>1</sup> and Rajan Datar<sup>1</sup>. <sup>1</sup>Datar Cancer Genetics, Nasik, India<sup>2</sup>Datar Cancer Genetics Europe GmbH, Bayreuth, Germany

**Background:** Common modalities for breast cancer screening include self-breast examination (SBE) for detection of palpable lumps as well as Mammography scans for detection of suspicious nodules or masses. While both approaches have low specificity, SBE has lower sensitivity for early stage cancers while mammography is associated with radiation exposure risks. A blood-based non-invasive approach for determination of breast cancer risk in asymptomatic individuals can facilitate early detection and improve prognosis and survival. Circulating Ensembles of Tumor Associated Cells (C-ETACs) are heterotypic clusters of malignant cells which originate in a tumor and are ubiquitously detected in peripheral blood of individuals with solid organ cancers. We present findings from two large-cohort prospective observational studies showing the suitability of C-ETACs for non-invasive, non-radiological screening for breast cancer. **Methods:** 15 ml of peripheral blood was collected from 14,962 female volunteers among whom 832 were suspected cases of breast cancer and 14,962 were asymptomatic individuals with age-associated risk of breast cancer. The 832 suspected cases underwent a foundational (first diagnostic) biopsy following collection of blood while the 14,962 asymptomatic individuals underwent a mammography scan following collection of blood. Peripheral blood mononuclear cells (PBMCs) were isolated from all blood samples and treated with an epigenetically activating treatment medium which exerts selective cytotoxicity towards non-malignant hematolymphoid cells and allows survival of apoptosis resistant malignant cells and their clusters (C-ETACs). C-ETACs were defined as clusters of 3 or more cells which were EpCAM+, PanCK+ and CD45+/- . **Results:** Among the 832 suspected cases, 779 were eventually diagnosed with breast cancer and 53 with benign breast conditions. C-ETACs were detected in 701 / 779 cases of breast cancer (90.0% sensitivity) with comparable detection rates in metastatic (365/408 = 89.5%) as well as non-metastatic (336/371 = 90.6%). C-ETACs were also detected in 1 / 53 (1.9%) cases of benign breast tumor. Among the asymptomatic cohort of 14,130, C-ETACs were detected in 657 cases (4.7%), which included 509 / 10,859 (4.7%) individuals with BIRADS 1 and in 148 / 3,271 (4.5%) of individuals with BIRADS ≥2. These individuals have been advised clinical follow-up. **Conclusions:** We show that C-ETACs are ubiquitous in breast cancers and rare in individuals with benign conditions as well as asymptomatic individuals. Being derived from the tumor mass, C-ETACs are specific for cancer and thus provide direct visual evidence of malignancy in cancer cases and risk of malignancy in asymptomatic cases. The non-invasive nature of the approach is well suited for screening of large asymptomatic populations for breast cancer.

Safe margins for delineation of left anterior descending artery (LAD) using cardiac-gated CT-scan (CG-CT) in left side breast cancer patients

Eliot Nicolas<sup>1</sup>, Nadjoua Khalifa<sup>2</sup>, Sabrina Bouhroum<sup>3</sup>, Cyril Laporte<sup>4</sup> and Youlia Kirova<sup>1</sup>. <sup>1</sup>Institut Curie, Paris, France<sup>2</sup>Institut Cancerologie Paris Nord, Sarcelles, France<sup>3</sup>Groupement de Cooperation Sanitaire Recherche & Innovation Sante, Sarcelles, France<sup>4</sup>Institut de Cancerologie Paris Nord, Sarcelles, France

**Background:** Cardiac toxicity after breast cancer (BC) radiotherapy (RT) is partly due to the large radiation doses to coronary arteries. The left anterior descending artery (LAD) is particularly exposed. A first step in achieving robustly proven dose constraints to the LAD during treatment planning is homogeneous delineation based on guidelines. LAD delineation can be problematic due to heart movements. **Purpose/Objective(s):** The aim of the study was to establish a safety margin for delineation of the LAD in BC patients. **Materials/Methods:** We studied 45 left-sided BC patients who had an indication for adjuvant radiotherapy between 2015 and 2018. They all underwent cardiac-gated computed tomography scan (CG-CT), as well as planning CT scans (P-CT) with or without contrast agents, to assess LAD diameter and movements. CG-CT was performed while monitoring the cardiac cycle. Acquisition was launched immediately after contrast injection (arterial sequence), with deep inspiration breath hold and use of a beta-receptor blocking agent. By manually reviewing each scan, the LAD positions and diameter were defined at 20 different phases of the cardiac cycle at 5 different sites: ostium, circumflex (Cx) bifurcation (bfc), first diagonal (D1) bfc, second diagonal (D2) bfc and apex (right coronary anastomosis). Next step is to introduce it in software of automatic delineation to improve the atlas of cardiac structures. **Results:** Movement of the LAD is maximal at the ostium, then constant overall even when far from its origin. The diameter decreases with the distance from ostium: 4.9 mm (OS), 3.9 mm (Cx), 3.5 mm (D2) and 3.1 mm (D2). **Conclusion:** We suggest using a safety delineation margin consisting of a cylinder with a diameter of 10 mm surrounding the LAD. These findings must be validated in independent series of patients treated for BC.

Population-based tool to estimate residual risks of breast cancer specific mortality (BCSM) and non-BCSM

Jose P Leone<sup>1</sup>, Sara M Tolane<sup>1</sup>, Bernardo A Leone<sup>2</sup>, Rachel A Freedman<sup>1</sup>, Michael J Hassett<sup>1</sup>, Julieta Leone<sup>2</sup>, Carlos T Vallejo<sup>2</sup>, Eric P Winer<sup>1</sup>, Nancy U Lin<sup>1</sup> and Nabihah Tayob<sup>1</sup>. <sup>1</sup>Dana-Farber Cancer Institute, Boston, MA; <sup>2</sup>Grupo Oncologico Cooperativo del Sur, Neuquen, Argentina

**Background:** The risk of breast cancer death persists for at least 20 years from diagnosis. Most reports describing this risk have been based on selected patients (pts) enrolled into clinical trials. These studies report absolute risks at fixed timepoints (i.e. 10 or 20 years) and do not consider the dynamic changes in risks over time. The aim of this study was to develop a tool to calculate residual risks of BCSM and non-BCSM based on individual pt and tumor characteristics, at any given time after breast cancer diagnosis. **Methods:** Using data from the Surveillance, Epidemiology, and End Results (SEER) program, we identified women diagnosed with non-metastatic invasive breast cancer between 1990-2005, with one primary cancer in their lifetime, and known hormone receptor (HR) status. We estimated the effect of baseline clinical and pathologic variables known to be prognostic, including pt age, HR status, tumor size (T), nodal status (N), and tumor grade, on residual cumulative risks of BCSM and non-BCSM over time. The tool generates the residual death risk (RDR), which is a nonparametric estimate of the cumulative risk of BCSM and non-BCSM by year 20 after any given time from initial diagnosis, among patients defined by baseline clinical and pathologic variables using the method of Gray (1988) implemented in the cmprsk package in R. **Results:** We included 235,015 pts (median follow-up = 14 years). Among all breast cancer deaths, the proportion occurring after 5 years was 60% for HR+ vs 24% for HR- (p<0.001). The table shows risks of BCSM and non-BCSM by HR and N status. The cumulative risk of BCSM in year 5-20 ranged from 4.2% in HR+ T1a N0 to 50.1% in HR+ N3. Using the RDR tool, a 54 year-old pt, diagnosed 7 years prior with a HR+, T1c, N1, grade 2 breast cancer, has a 16.6% residual cumulative risk of BCSM over the following 13 years, and a residual cumulative risk of non-BCSM over the same period of 4.0%. For a 66 year-old pt, diagnosed 10 years prior with a HR+, T1c, N0, grade 1 breast cancer, her residual cumulative risk of BCSM over the following 10 years is 2.9%, and her residual cumulative risk of non-BCSM over the same period is 10.0%. For a 45 year-old pt, diagnosed 8 years prior with a HR-, T2, N1, grade 3 breast cancer, her residual cumulative risks of BCSM and non-BCSM over the following 12 years are 4.4% and 4.9%, respectively. **Conclusions:** For HR+ breast cancer, risks of BCSM remain high beyond 5 years from diagnosis. For HR- breast cancer, the risk of BCSM is highest within 5 years from diagnosis; however, risks beyond 5 years are still considerable. The RDR tool provides population-based long-term estimates of cumulative risk of BCSM and non-BCSM over time, based on individual pt and tumor characteristics.

Impact of trastuzumab on Ipsilateral breast tumor recurrence after breast conserving surgery

Jong Ho Cheun, Han-Byoel Lee, Hyeong-Gon Moon, Dong-Young Noh and Wonshink Han. Seoul National University Hospital, Seoul, Korea, Republic of

**Background:** Trastuzumab is well known to be effective to control locoregional recurrence and distant metastasis of human epidermal growth factor receptor 2 (HER2)-overexpressing breast tumor. However, few studies have reported the effect of ipsilateral breast tumor recurrence (IBTR) in spite of higher incidence of IBTR for HER2 overexpressing subtype than other subtypes. The purpose of this study is to investigate the difference in the incidence of IBTR of HER2-overexpressing breast tumor according to adjuvant trastuzumab.

**Methods:** We retrospectively reviewed 996 patients who had done surgery for HER2-overexpressing breast cancer between January 2000 and December 2017 in our institution. Patients with tumors smaller than 0.5cm without axillar node metastasis were excluded. As regarding IBTR as recurrence "in" the ipsilateral breast, only patients who had done breast conserving surgery were included.

**Results:** There were 735 patients who had finished adjuvant trastuzumab as first planned and 555 patients with hormone receptor positive. Median follow-up period for all patients was 70.7 months (range 12.7-239.6 months). The 10-year IBTR-free survival rate showed a significant benefit for the group treatment with trastuzumab than the group without trastuzumab (97.0% versus 91.9%;  $p=0.007$ ). In a multivariate analysis, presence of lymphovascular invasion (Hazard ratio [HR], 2.53; 95% Confidence interval [CI], 1.19 - 5.41), closed or involved resection margin (HR, 2.62; 95% CI, 1.20 - 5.74), positive hormone receptor (HR, 3.70; 95% CI, 1.69 - 8.08), positive axillar lymph node (HR, 5.21; 95% CI, 1.75 - 15.57), and omitted or uncompleted adjuvant trastuzumab (HR, 2.72; 95% CI, 1.11 - 6.67) were independent predictors of IBTR. However, subgroup analysis of the patients with hormone receptor negative tumor showed no benefit of adjuvant trastuzumab (98.1% versus 96.6%,  $p=0.669$ ) while it controlled IBTR for hormone receptor positive tumor (95.7% versus 86.2%;  $p=0.002$ ). When additionally analyzed, trastuzumab showed benefit for 10-year locoregional recurrence-free survival (95.5% versus 89.7%,  $p=0.012$ ) and distant metastasis-free survival (93.5% versus 77.8%,  $p<0.001$ ).

**Conclusions:** Trastuzumab has a clinical benefit in not only locoregional recurrence but also IBTR among HER2-overexpression breast cancer, especially with negative hormone receptor.

Irreversible inhibition of HER2 activating mutations with neratinib enhances the pre-clinical efficacy of trastuzumab emtansine and trastuzumab deruxtecan

Ron Bose<sup>1</sup>, Shunqiang Li<sup>1</sup>, Tina M. Primeau<sup>1</sup>, Maureen K. Highkin<sup>1</sup>, Ashley R. Tipton<sup>1</sup>, Nagalaxmi Vemalapally<sup>1</sup>, Xuefeng Gao<sup>1</sup>, Gail Sudlow<sup>1</sup>, Irmina Dila<sup>2</sup>, Yu Tao<sup>1</sup>, Jingqin Luo<sup>1</sup>, Ian Hagemann<sup>1</sup>, Chieh-Yu Lin<sup>1</sup>, Richard P. Bryce<sup>2</sup>, Alshad S. Lalani<sup>2</sup>, Samuel Achilefu<sup>1</sup> and Cynthia X. Ma<sup>1</sup>.

<sup>1</sup>Washington University School of Medicine, St. Louis, MO; <sup>2</sup>Puma Biotechnology Inc., Los Angeles, CA

**Background:** HER2 activating mutations occur in 2-5% of metastatic breast cancer (MBC) patients, and three phase II or basket clinical trials have shown that the irreversible pan-HER tyrosine kinase inhibitor, neratinib, has good single agent efficacy for HER2 mutated MBC patients. Current trials are combining neratinib with other targeted therapies to increase response rate and progression free survival for these patients. **Methods:** We established patient derived xenografts (PDX) and organoids from two patients with HER2 mutated, non-amplified MBC and used them to test neratinib with the antibody drug conjugates (ADC's), trastuzumab emtansine (T-DM1) and trastuzumab deruxtecan (T-DXd), both in 3D culture and in vivo. Real time, in vivo uptake of these ADC's was visualized with a near infrared fluorophore. **Results:** PDX lines WHIM51 and WHIM64 were established from ER+, HER2 non-amplified MBC patients that had HER2 activating mutations. WHIM51 has HER2 exon 20 insertion mutation at amino acid 776 (ERBB2 A775\_G776insYVMA) and WHIM64 has a HER2 L869R missense mutation, both of which are located in the HER2 tyrosine kinase domain. Both of these HER2 mutations have been previously characterized and are known activating mutations. Organoids were established from both PDX's and were grown in 3D culture. Drug combination testing of neratinib with T-DM1 in 3D culture showed strong synergy and the mechanism was explored. We demonstrate that neratinib and other irreversible HER2 inhibitors increase the endocytic uptake of T-DM1, but this effect does not occur with the reversible HER2 inhibitors, tucatinib and lapatinib. Real time, in vivo uptake of T-DM1 was measured by labeling the ADC with a near infrared fluorophore and we observed statistically significant increase in T-DM1 uptake with neratinib pre-treatment. Combining neratinib with T-DM1 increased apoptosis at day 3 post-treatment and enhanced tumor shrinkage. With the FDA approval of T-DXd at the end of 2019, we hypothesized that this same mechanism may apply to neratinib combined with T-DXd. We have tested both the combinations of neratinib + T-DXd and neratinib + T-DM1 in vivo in both HER2 mutant PDX's and observed statistically significant tumor regression with the neratinib + ADC combinations as compared to either T-DXd or T-DM1 on its own. **Conclusions:** Neratinib increases the endocytosis of trastuzumab emtansine (T-DM1) and trastuzumab deruxtecan (T-DXd), thereby increasing tumor cell kill and causing greater tumor regression in HER2 mutated MBC. These data provide preclinical justification for trials of neratinib plus HER2 ADCs including T-DXd or T-DM1 in HER2 mutant or HER2+ MBC. Further, this mechanism of neratinib stimulated HER2 endocytosis may also apply to HER2 low MBC.

Silicone implant based sustained localized drug delivery of fulvestrant to prevent breast cancer

Pamela N Munster, Pujan K Desai, Nela Pawlowska, Elysia Roche, Romain Pacaud, Maxim A Daud, Emily Hsu, David Gingrich, Amelia Deitchman, Fran Aweeka, Scott Thomas. University of California, San Francisco, San Francisco, CA

**Background:** Hereditary breast cancer is common. With enhanced awareness and the recent introduction in affordable multi-gene germ line testing, an estimated 0.5-1 million women will learn that they carry a considerable risk to develop breast cancer. Thus, a rapidly increasing number of women, many of them very young, will be in need of effective strategies for breast cancer prevention. Current options to prevent breast cancer in women at high risk include bilateral mastectomies or systemic anti-estrogen therapy. Both options, while effective, may have a detrimental impact on the physical and emotional well-being of the patient. Localized delivery of an established anti-estrogen to breast tissue only may thus offer an attractive alternative for cancer prevention and may replace systemic therapy for ductal carcinoma *in situ* and early stage breast cancer with minimal risk for metastases.

**Methods:** As such, we have sought to develop a silastic-silicone device, which when placed under breast tissue, will deliver the anti-estrogen fulvestrant directly to the target tissue. Sustained slow release of fulvestrant from a silastic-silicone device directly into the mammary tissue will provide the risk reducing benefits of systemic hormonal therapy while minimizing systemic exposure and the resulting poor compliance due to adverse effects.

**Results:** Using a combination of *in vitro* and *in vivo* studies, we show that fulvestrant can be delivered through a silastic-silicone device. Implanted adjacent to mammary tissue, this drug delivery device provides sustained high levels of fulvestrant to inhibit estrogen receptor signaling and breast cancer cell proliferation. In a MCF-7 breast cancer xenograft model we have shown that silastic-silicone delivers fulvestrant selectively to mouse mammary tissue for more than 1 year with anti-tumor effects similar to those achieved with systemic fulvestrant exposure. Using the Sprague-Dawley rat DMBA spontaneous breast cancer induction model, we further demonstrate that fulvestrant delivered by silastic-silicone devices implanted adjacent to mammary tissue significantly delays time to first tumor compared to control animals (n=90, HR = 0.42, 95% CI 0.21-0.83) with minimal systemic exposure (plasma average 1.1 ng/mL, SD  $\pm$ 1.5 ng/mL). Initial large animal safety and toxicity studies in female sheep (ewes, n=2) support the surgical strategy to place the device between breast tissue (*i.e.* udder) and the chest wall (abdominal wall in ewes). Following 1 month of fulvestrant release, gross and histopathological analysis found no adverse effects or implant related toxicity. Bioanalytical analysis of mammary tissues suggested that drug was found highest near the implant (max 341 ng/g, udder average 58.4 ng/g, SD  $\pm$ 17.1 ng/g), with diminishing levels distal from the implant. Systemic exposure was low, with plasma levels 1.2 ng/mL, SD  $\pm$ 0.22 ng/mL, comparing favorably to clinical plasma levels achieved by intramuscular fulvestrant of 500 mg: 28.0 ng/mL, SD  $\pm$ 27.9 ng/mL (FDA package insert). Subsequent large animal studies will focus on the safety and pharmacokinetics of device delivered fulvestrant in longer studies (*e.g.* 3 to 6 months).

**Conclusions:** The greater awareness and genetic identification of individuals at risk for breast cancer brings about an increased need for novel approaches to breast cancer prevention. The development of a silastic-silicone based device for sustained and localized drug delivery with an approved and effective anti-estrogen should allow rapid transition into clinical testing. This strategy will provide an alternative option to mastectomies and allow breast conservation for women identified to have a more than 40% lifetime chance of developing breast cancer, as well as provide an alternative to systemic hormonal therapy in women with ductal carcinoma *in situ* or stage I breast cancer.

The value of shear-wave elastography for prediction of treatment response to neoadjuvant chemotherapy in patients with breast cancer

Soong June Bae, Min Ji Kim, Yoon Jin Cha, Na Lae Eun, Dooreh Kim, Janghee Lee, Sung Gwe Ahn, Eon Ju Son and Joon Jeong. Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of

**Introduction** Recently, Shear-wave elastography (SWE) has been known to be useful for the diagnosis of breast cancer and lymph node metastasis. However, little is known about whether SWE can predict the response to neoadjuvant chemotherapy in patients with breast cancer. This study aimed to investigate the relationship between treatment response and elasticity values. **Method** Pre-treatment shear-wave elastography was performed in 394 patients who underwent neoadjuvant chemotherapy followed by surgery at Gangnam Severance Hospital from January 2012 to May 2020. We evaluated the pathologic complete response (pCR, defined as ypTis/T0, No) according to elasticity values such as 'Mean stiffness', 'Minimum stiffness', 'Maximum stiffness', and 'Ratio'. **Results** A total of 394 patients, 147 (37.3%) achieved pCR. All elasticity values were significantly lower in patients with pCR after neoadjuvant chemotherapy than those with the residual invasive tumor. In the multivariable analysis, the mean stiffness (OR 0.995; 95% CIs, 0.989-1.000; P=0.039) and the maximum stiffness (OR 0.995; 95% CIs, 0.990-0.999; P=0.024) were independent predictive factors for pCR after adjusting clinic-pathologic factors. Besides, the tumor-infiltrating lymphocytes (TILs) evaluated in biopsy samples were inversely correlated with pre-treatment mean stiffness (CC -0.053, P=0.044), and elasticity ratio (CC-0.288, P=0.033). **Conclusion** In this study, pre-treatment elasticity values measured by SWE were significantly associated with pCR in breast cancer. Our results suggest that SWE can be a useful diagnostic tool for predicting treatment response in patients with breast cancer who will receive neoadjuvant chemotherapy.

**Background:** Neoadjuvant chemotherapy (NACT) results in eradication of cancer in the axillary lymph nodes in 40% to 70% of patients. This has raised questions about the benefit of further axillary treatment in these patients with no evidence of residual disease in the lymph nodes. **Trial design:** A multi-centre phase III randomised controlled trial with embedded economic evaluation in which participants will be randomised in a 1:1 ratio. **Study participants:** T1-3N1M0 breast cancer patients aged 18 years or older, with needle biopsy proven nodal metastases, who after NACT have no residual cancer in the lymph nodes on dual tracer sentinel node biopsy and removal of at least 3 lymph nodes (sentinel nodes and marked involved node). **Intervention:** Participants in the experimental group will not receive further axillary treatment (axillary lymph node dissection [ALND] or axillary radiotherapy [ART]), after NACT and surgery. Participants in the control group will receive further axillary treatment (ALND or ART) after NACT and surgery, as per local guidelines. **Stratification:** Institution, type of breast surgery (breast conserving surgery (BCS) vs mastectomy), receptor status (triple negative vs HER2 positive vs ER status positive and/or PR status positive and HER2 negative) **Eligible participants will be/should have:** •Age ≥ 18 •Male or female •T1-3N1M0 breast cancer at diagnosis (prior to NACT) •FNA or core biopsy confirmed axillary nodal metastases at presentation •Oestrogen receptor and HER2 status evaluated on primary tumour •Received standard NACT as per local guidelines (Patients undergoing neoadjuvant endocrine therapy as part of another clinical trial are eligible) •Ultrasound of the axilla at completion of NACT •Undergo dual tracer sentinel node biopsy after NACT and at least 3 nodes removed (sentinel nodes and marked node). If axillary node sampling is performed following failed localisation of sentinel nodes, patient will be eligible if at least 3 nodes removed (including the marked node) •No evidence of nodal metastases post NACT (isolated tumour cells, micro or macro metastasis) **Participants will be excluded if they have any one of the following:** •Bilateral invasive breast cancer •Sentinel node biopsy prior to NACT •Marked node not removed *except* where at least one node removed shows evidence of down-staging with complete pathological response e.g. fibrosis or scarring and at least 3 nodes removed •Previous axillary surgery on the same body side as the scheduled targeted sampling •Any previous cancer within last 5 years or concomitant malignancy *except* basal or squamous cell carcinoma of the skin, in situ carcinoma of the cervix or in situ or stage 1 melanoma, contra- or ipsilateral in situ breast cancer **Specific aims:** To assess whether, omitting further axillary treatment (ALND and ART) for patients with early stage breast cancer and axillary nodal metastases on needle biopsy, who after NACT have no residual cancer in the lymph nodes on sentinel node biopsy, is non-inferior to axillary treatment in terms of disease free survival (DFS), and reduces the risk of lymphoedema at 5 years. Statistical methods: All analyses will be carried out on an intention-to-treat basis to preserve randomisation, avoid bias from exclusions and preserve statistical power.

The prognostic role of tumor-infiltrating lymphocytes after treatment with neo-adjuvant chemotherapy in inflammatory breast cancer patients

Christophe Van Berckelaer<sup>1</sup>, Leonie Vercauteren<sup>2</sup>, Iris Vermeiren<sup>2</sup>, Glenn Broeckx<sup>3</sup>, Steven Van Laere<sup>1</sup>, Luc Dirix<sup>1</sup>, Cecile Colpaert<sup>3</sup> and Peter Van Dam<sup>2</sup>. <sup>1</sup>Translational Cancer Research Unit, GZA Hospitals & CORE, University of Antwerp, Antwerpen, Belgium<sup>2</sup>Multidisciplinary Breast Clinic, Unit Gynaecologic Oncology, Antwerp University Hospital (UZA), Edegem, Belgium<sup>3</sup>Department of Pathology, Antwerp University Hospital (UZA), Edegem, Belgium

**Introduction:** Inflammatory breast cancer (IBC) is a rare, but aggressive form of breast cancer. Increasing evidence indicates that immune cells in the tumor micro-environment play an important role in IBC progression: infiltration with stromal Tumor Infiltrating Lymphocytes (sTIL) is associated with a better response to neo-adjuvant chemotherapy (NACT) and longer overall survival in IBC patients. However, the prognostic role of sTIL in patients without a complete pathological response (pCR) after NACT remains unclear. In this study we evaluated the effect of NACT on sTIL in IBC and locally advanced non-inflammatory breast cancer (LABC) and the prognostic impact of sTIL in IBC.

**Methodology:** In this retrospective case-control study we evaluated sTIL in patients with IBC (n=60) and LABC (n= 134) that received anthracyclin-taxane based NACT. Tumor tissue was sampled as part of the routine work-up, before (diagnostic biopsy) and after (resection specimen) NACT. sTIL scoring was performed on Haematoxylin & Eosin stained 5-µm sections of formalin-fixed paraffin-embedded tumor tissue by two different researchers according to the recommendations by the International TILs Working Group. In case of discrepancy, the sample was scored by a third observer in order to obtain a consensus score. sTIL difference between pre-treatment and post-treatment specimen was called  $\delta$ sTIL. Cellularity of the residual cancer after NACT was evaluated according to the MD Anderson Residual Cancer Burden (RCB) method.

**Results:** Most of the IBC patients presented with a hormone receptor (HR) positive carcinoma (n=35/60, 58.3%) and 25 patients had pCR after NACT (42%); the latter patients had less than 1% sTIL in the tumor bed area. Besides having histologically more poorly differentiated tumors ( $P=0.033$ ), no significant clinicopathological differences between the IBC and LABC cohort were observed. There was no significant difference in the pre-treatment median sTIL score between IBC (12.5%, range: 1% - 80%) and LABC (10%, range: 1% - 85%). Furthermore, both in the IBC (median  $\delta$ sTIL: -4.5%,  $P=0.01$ ) and in the LABC (median  $\delta$ sTIL: -1%,  $P=0.06$ ) cohort the number of sTIL was lower after NACT. This decrease was significantly greater in the IBC cohort ( $P=0.04$ ). In a multivariate model - including HR and HER2 status, histological differentiation grade, nodal status and IBC/LABC phenotype - IBC disease correlated with a stronger decrease of sTILs after NACT (OR: 0.31, 95% CI 0.10 - 0.89,  $P=0.04$ ).

As we previously demonstrated, higher sTIL score before NACT was associated with better overall survival (OS) ( $P=0.006$ ) in IBC. IBC patients without pCR, but with a stronger decrease ( $>4.5\%$ ) of the number of sTIL after NACT had a better OS ( $P=0.04$ ) and disease-free survival (DFS) ( $P=0.04$ ). There was a significant correlation between  $\delta$ sTIL and both higher sTIL score before NACT ( $P<.001$ ) and lower residual cancer cellularity ( $P=0.02$ ). However, in a multivariate model - including sTIL before NACT,  $\delta$ sTIL and residual cancer cellularity - both a strong decrease of sTIL (HR: 0.32; 95% CI 0.10 - 1.00;  $P=0.05$ ) and a low residual cancer cellularity (HR: 0.22; 95% CI 0.07 - 0.68;  $P=0.009$ ) were independent predictors of a better DFS.

**Conclusion:** Both the IBC and LABC cohort had the same number of sTIL before NACT. However, the IBC phenotype was associated with a stronger decrease of sTIL after NACT independent of molecular subtype and nodal stage. Furthermore, a strong decrease in sTIL was an independent predictor of better prognosis in IBC.

MEN1611 is a p13K  $\alpha/\beta$  selective and  $\delta$  sparing inhibitor with long-lasting antitumor activity in different genetic backgrounds of p13K mutant breast cancer models

Alessio Fiascarelli<sup>1</sup>, Corrado Carrisi<sup>1</sup>, Giuseppe Merlino<sup>1</sup>, Stefania Capano<sup>1</sup>, Diego Bisignano<sup>1</sup>, Simone Talucci<sup>1</sup>, Alessandro Bressan<sup>1</sup>, Daniele Bellarosa<sup>1</sup>, Mario Bigioni<sup>1</sup>, Maurizio Scaltriti<sup>2</sup>, Joaquin Arribas<sup>3</sup>, Andrea Pellacani<sup>4</sup>, Massimiliano Salerno<sup>1</sup> and Monica Binaschi<sup>1</sup>. <sup>1</sup>Menarini Ricerche, Pomezia, Italy<sup>2</sup>Department of Pathology, Memorial Sloan Kettering Cancer Center, New York, WA;<sup>3</sup>Vall d'Hebron Institute of Oncology, Barcelona, Spain<sup>4</sup>Menarini Ricerche, Firenze, Italy

Dysregulation of the PI3K/AKT/mTOR pathway has the potential to trigger the activation of class I phosphoinositide 3-kinases (PI3Ks) and eventually lead to cancer. Class I PI3Ks are heterodimers composed of the regulatory subunit p85 and the catalytic subunit p110. There are four isoforms of p110,  $\alpha$  and  $\beta$ , important in solid tumors, and  $\delta$  and  $\gamma$ , preferentially expressed in leukocytes, and drivers in hematological malignancies. While activation of PI3K p110 $\alpha$  is the most frequent oncogenic event in solid tumors, p110 $\beta$  plays an important role in PTEN deficient cancers and in mediating resistance to p110 $\alpha$  selective PI3K inhibitors. MEN1611 is a PI3K inhibitor active on p110 $\alpha$  (both mutants and wt),  $\beta$  and  $\gamma$  (8.6- and 2.2- fold less potent compared to the  $\alpha$ , respectively), while sparing the  $\delta$  isoform (36-fold less potent compared to the  $\alpha$ ). Thus, MEN1611 differs from other selective PI3K inhibitors such as alpelisib (p110 $\alpha$  selective) and taselisib (p110 $\beta$  sparing). MEN1611 is currently in clinical development for patients with HER2 positive advanced or metastatic breast cancer in combination with trastuzumab with/without fulvestrant (B-PRECISE-01).

Patient-derived xenograft (PDX) models and breast cancer cell lines with different genetic background were used to assess the antitumor activity of MEN1611 in p110  $\alpha$ - and  $\beta$ - dependent tumors. Healthy-donors derived CD69+ B-cells, which are primarily dependent on p110  $\delta$  for proliferation and survival were used to test the activity of the compound against the p110 $\delta$ .

According to the biochemical selectivity, MEN1611 demonstrated a lower cytotoxic potential in a p110 $\delta$ -driven cellular model (CD19+ B-cells), when compared to taselisib (>150-fold) and an improved cytotoxic activity in the p110 $\beta$ -driven cellular model (PTEN-null breast cancer cells) when compared to alpelisib. Moreover, MEN1611 selectively decreases the p110 $\alpha$  protein levels in PIK3CA mutated breast cancer cells in a concentration-dependent manner, with a corresponding reduction in pAKT. *In vivo*, MEN1611 monotherapy showed significant and long-lasting anti-tumor activity, reflected in tumor-stasis or tumor regression in several trastuzumab-resistant PIK3CA-mutant HER2 positive PDXs with different concomitant genomic aberrations. The combination of trastuzumab and MEN1611 significantly improved the efficacy compared to single agent treatment. Interestingly, MEN1611 monotherapy showed a significant tumor volume inhibition in a PTEN-null breast cancer PDX model. Overall, our data provide evidence that MEN1611 is active against HER2 positive and PTEN-null breast tumors. Moreover, its  $\delta$ -sparing profile may have potential implications on MEN1611 tolerability and ability to overcome resistance to p110 $\alpha$  selective inhibitors.

Decision making process and contralateral prophylactic mastectomy

Hala Farouk Alameddine<sup>1</sup>, Akshara Singareeka<sup>2</sup>, Clark Andersen<sup>2</sup>, Jesse Selber<sup>2</sup>, Abena Brewster<sup>2</sup>, Carlos H. Barcenas<sup>2</sup>, Abigail Caudle<sup>2</sup>, Baru Arun<sup>2</sup> and Nuhad Ibrahim<sup>2</sup>. <sup>1</sup>Kindred Hospital, Sugar Land, TX; <sup>2</sup>MD Anderson Cancer Center, Houston, TX

**BACKGROUND** The relatively high rate of contralateral prophylactic mastectomy (CPM) among women with early stage unilateral breast cancer has raised concerns particularly with the lack of evidence for a survival benefit related to the CPM and with the low risk of developing contralateral breast cancer among women with early stage breast cancer. Women might be choosing this procedure to ease their fear of recurrence, and by believing that CPM may improve their quality of life; others might be influenced by their partner, physician or media. The purpose of this study was to assess the influence of the partner, physician, or media on the decision making process of women with unilateral breast cancer who decided to undergo CPM.

**METHODS** This is a retrospective study, conducted under MD Anderson Institutional Review Board. Women were identified from an existing cohort of breast cancer patients, age 20-60 years old, who were diagnosed with unilateral breast cancer stage 0 to III, who had no clinical or radiographic evidence of contralateral breast cancer, and who underwent CPM between January of 2010 and December of 2017 at MD Anderson Cancer Center; participants received a link to the quantitative cross-sectional survey using the Red Cap platform, 1341 patients were eligible to participate in the study, of which 397 completed the survey. The survey consisted of 16 questions that were adopted and modified from the Prophylactic Mastectomy Outcomes Study Survey. The survey design provided a numeric description of the factors that are affecting the women decision to undergo CPM; as well as the influence of the partner, physician, or media on the woman's decision-making process. Exclusion included women who had bilateral breast cancer before undergoing CPM, women who had received any treatment for breast cancer before their initial visit to MD Anderson, women who had bilateral breast cancer before undergoing CPM and patients with incomplete documentation of diagnosis of breast cancer, hormone receptor status or metastatic disease. Incidence of doctor, partner, and media influence were each modeled by logistic regression with adjustment for family history of breast cancer and pathology stage.

**RESULTS** 203/343 (59%) patients reported some doctor influence on the CPM decision. The logistic regression model of the incidence of doctor-influence demonstrated significantly higher overall influence on the CPM decision due to doctors compared to self-determination alone ( $p=.0006$ ), suggesting that 59% of patients' decisions were influenced by doctors. 53/189 (28%) patients with partners reported some partner influence on the CPM decision. The logistic regression model of the incidence of partner-influence demonstrated significantly lower overall influence on the CPM decision due to partners compared with self-determination alone ( $p<.0001$ ), suggesting that 28% of patients' decisions were influenced by partners. 36/213 (16%) patients reported some level of media influence on the CPM decision. The logistic regression model of the incidence of media-influence demonstrated significantly lower overall influence on the CPM decision due to media compared with self-determination alone ( $p<.0001$ ), suggesting that 16% of patients' decisions were influenced by media.

**CONCLUSION** Partners, physicians, and media all had significant influence ( $p < 0.05$ ) on the decision-making process of women with unilateral breast cancer to undergo CPM. It is important for women with unilateral breast cancer to fully understand the benefits versus the adverse effect of CPM and make an informed decision regarding the irreversible surgical procedure. The findings of this study may inform policy by highlighting the need for educational aids, programs, or tools that help women with unilateral breast cancer make informed decisions that are evidence-based regarding the efficacy of CPM.
