Title: Analysis of molecular prognostic factors associated with tumor immune and stromal microenvironment in BEATRICE, an open-label phase 3 trial in early triple-negative breast cancer (eTNBC)

Molinero L, Yu J, Li C, Deurloo R, Dent RA A, Bell R, Brown J, Parmar M, Toi M, Suter T, Steger G, Pivot X, Mackey J, Jackisch C, Hall P, Hegde P, Bais C and Cameron D. Genentech Inc., South San Francisco, CA; F Hoffmann-La Roche Ltd, Basel, Switzerland; National Cancer Center, Singapore, Singapore; Sunnybrook Health Sciences Center, University of Toronto, Toronto, Canada; Deakin University, Geelong, Australia; Clinical Trials Research Unit, University of Leeds, Leeds, United Kingdom; Medical Research Council Clinical Trials Unit, London, United Kingdom; Kyoto University, Kyoto, Japan; Swiss Cardiovascular Center, Bern University Hospital, Bern, Switzerland; Medical University of Vienna, Vienna, Austria; University Hospital Jean Minjoz, Besançon, France; Cross Center Institute, Edmonton, Canada; Klinikum Offenbach, Offenbach, Germany; Leeds Institute of Health Sciences, University of Leeds, Leeds, United Kingdom and University of Edinburgh and Cancer Services, NHS Lothian, Edinburgh, United Kingdom.

Body: Background: TNBC is a mutationaly complex heterogeneous breast cancer subtype. In BEATRICE, adding bevacizumab to standard adjuvant chemotherapy for eTNBC improved neither invasive disease-free survival (IDFS; primary endpoint) nor overall survival (OS) [Cameron 2013; Bell SABCS 2014]. We explored prognostic effects of tumor-associated immune and stromal gene signatures.

Methods: Gene expression (RNA) was assessed in pretreatment archival tumor tissue using an 800-gene nanostring platform. Given the low event rates and lack of bevacizumab effect in BEATRICE, treatment arms were pooled. The biomarker-evaluable population (BEP; all patients with an evaluable biomarker sample and ≥1 postbaseline efficacy assessment) was dichotomized using median gene expression level as the cutoff. Prognostic associations between IDFS/OS and prespecified candidate gene sets/de novo identified clusters were assessed using univariate Cox proportional hazards models.

Results: Baseline characteristics and efficacy were similar in the BEP (988/2591 randomized pts; 38%) and the overall study population. In hierarchical cluster analysis based exclusively on immune gene expression, immune genes were enriched in 33% of samples, intermediate in 38%, and weak in 28%. Further characterization suggested differential prognostic value of distinct immune and stromal cell gene sets (Table). A significant prognostic effect for IDFS and OS was seen for CD8 effector T cell (T_{eff}) and regulatory T cell (T_{reg}) gene signatures, but not for the T_{eff}:T_{reg} ratio. A less pronounced positive prognostic effect was seen for other gene sets representing immune cells, including macrophages, CD4 T cells, and B cells (data not shown). Activated T helper (Th)-1 cell-derived chemokines and negative immune modulators of T cell activity (eg PD-L1) were highly prognostic for IDFS and OS. Both the cytokine IL-8 and ESM1 (target of VEGF-A pathway activation) were associated with worse IDFS and OS. No association was seen between outcome and markers for classic microvasculature (CD31, CD34), cancer-associated fibroblasts (FAP, BGN, DCN), VEGF-A, or VEGF-C.

Conclusions: These molecular gene signature analyses in eTNBC confirm that markers of cytotoxic CD8 T cells are associated with good prognosis. This is the first report of a positive prognostic effect of regulatory T cell markers, immune checkpoint modulators, and macrophage-associated markers in the adjuvant TNBC setting. High VEGF-A activity, but not its expression, was associated with worse prognosis. The strong prognostic effect of immune checkpoint modulators suggests equilibrium between cytotoxic T cells and their inhibitors in eTNBC, supporting further exploration of immune checkpoint inhibitors in this therapeutic context.
Title: Lymphocytic infiltration in invasive lobular breast cancer

Body: Background: The presence and prognostic value of tumor infiltrating lymphocytes (TILs) in invasive breast carcinoma has been demonstrated in several studies, especially in the triple-negative and HER2-positive subtypes. So far, TILs have not been investigated with sufficient detail in invasive lobular breast cancer (ILBC). Here we therefore aimed at: first, assessing the distribution of stromal TILs in ILBC; second, correlating the presence of TILs with standard clinical and pathological markers; third, exploring associations of TILs with recurrent genomic alterations; and, fourth, comparing the lymphocytic composition of ER-positive/HER2-negative lobular to ER-positive/HER2-negative ductal tumors.

Material and methods: The percentage of stromal TILs was independently assessed according to Salgado et al. (Ann Oncol 2015) by three pathologists on full-face hematoxylin and eosin slides in a well-annotated retrospective series of 614 primary ILBCs previously characterized at the genomic level. The median value of TILs was used for the analyses. For the association analyses, we focused on the more homogeneous group of ER-positive/HER2-negative ILBC (555/614). Breast cancer-free interval was used as survival endpoint and the analyses were censored at 12 years of follow-up. The comparison of the lymphocytic composition (relative percentage of CD45+ TILs which are CD4+, CD8+ or CD19+) was assessed by FACS in a separate prospective cohort of 51 ER-positive/HER2-negative lobular and 112 ER-positive/HER2-negative ductal tumors.

Results: The intraclass correlation coefficient between the three pathologists was 0.71 (95%CI:0.65-0.76). The median percentage of stromal TILs was 5% and the interquartile range 5-10%, with only 9% of the samples having ≥20%. Greater numbers of TILs were significantly associated with younger age at diagnosis, axillary lymph node involvement, high proliferative tumors as assessed by Ki67, and with the mixed non-classic ILBC subtypes. Greater numbers of TILs were associated with worse prognosis (HR=1.22; 95%CI:1.07-1.38, p=0.003) only in the unadjusted analysis, as it lost significance after adjustment for standard clinical and pathological variables. Greater numbers of TILs were observed in tumors harboring ARID1A, BRCA2, KMT2C and TP53 mutations, as well as chr3p21.31 and chr8q24.23 (PTK2) loss; whereas lower numbers were observed in tumors with ERBB3 mutations as well as chr7p and chr11q14.1 (PAK1) gains. There were no significant differences in the relative proportion of CD4+, CD8+ or CD19+ lymphocytes between ER-positive/HER2-negative lobular and ductal tumors.

Conclusion: In this work, which reports to our knowledge on the largest series of ILBC ever assessed for TILs, we showed that most ILBCs were characterized by low lymphocytic infiltration. Besides the association of TILs with clinical and pathological features of ILBC patients, we found that higher TIL levels were observed in the presence of specific mutations and copy number alterations. Higher numbers of TILs were associated with worse prognosis at the univariate analysis. Finally, based on the assessed markers, we have no evidence of differential lymphocytic composition between ER-positive/HER2-negative lobular and ductal tumors.
Title: Pooled individual patient data analysis of stromal tumor infiltrating lymphocytes in primary triple negative breast cancer treated with anthracycline-based chemotherapy

Loi S, Drubay D, Adams S, Francis PA A, Joensuu H, Dieci MV Vittoria, Badve S, Demaria S, Gray R, Piccart MJ J, Kellokumpa-Lehtinen P-L, Andre F, Dufaure-Gare I, Denkert C, Salgado R and Michiels S. Peter MacCallum Cancer Centre, East Melbourne, VIC, Australia; Gustave Roussy, Villejuif, France; New York University School of Medicine, NY; Helsinki University Central Hospital, Helsinki, Finland; University of Padova, Padova, Italy; Indiana University, Indianapolis, IN; Dana-Farber Cancer Institute, Boston, MA; Institut Jules Bordet, Brussels, Belgium; Tampere University Hospital, Tampere, Finland and Charite Universite Hospital, Berlin, Germany.

Body: Background:
Retrospective analyses from individual clinical trials have suggested that host anti-tumor immunity as measured by stromal tumor infiltrating lymphocytes (TILs) is important for the outcomes of the primary triple negative breast cancer (TNBC) subgroup, but the clinical utility of TILs in day-to-day management of primary TNBC is still limited. Our objective was to conduct a pooled analysis of the clinical trials that have investigated TILs in TNBC patients treated by anthracyclines-based (A) chemotherapy regimens in order to gain a robust understanding of the prognostic value of TILs in this setting.

Material and methods:
Methods were predefined in a protocol. Eligible studies were randomized clinical trials that have evaluated the prognostic associations of TILs (evaluated in the same manner) in patients diagnosed with early stage TNBC treated with A or A plus taxanes (A+T). Cox regression models stratified by trial for invasive disease-free survival (IDFS, primary endpoint) and overall survival (OS), fitting stromal TILs as a continuous variable.

Results:
We collected individual data from 991 TNBC patients included in 6 randomized clinical trials (ECOG2197, ECOG1199, BIG2-98, FinHER, 2 from Gustave Roussy): 62% of patients were treated by A+T and 38% by A alone; 32% of patients had no nodal involvement, 43% of patients had 1-3 nodes and 25% patients more than 3 nodes involved. The average age was 49 years (range 22.6-85 yrs) and the average tumor size 3.0 cm (sd 1.7).

Across the entire data set, the average value of stromal TILs was 20% (sd 17%); 90% of patients had at least 1% stromal TILs. After adjusting for trial, stromal TILs were significantly lower with increasing tumor size (linear model, p<0.0001) but not significantly associated with nodal status categories (p=0.52 and p=0.37) nor age (p=0.25). With a median follow-up of 6.6 years for IDFS and 7.3 years for OS, a total of 363 IDFS events and 273 deaths were observed. Each 10% increase in stromal TILs was associated with a 14% relative reduction in IDFS events (HR=0.86, 95% CI 0.80 to 0.93, p<0.0001) and a 17% relative reduction in deaths (HR=0.83, 95% CI 0.76 to 0.91, p=0.0001). There was no significant evidence for heterogeneity between trials for IDFS (chi2=4.55, p=0.34) nor for OS (chi2=4.45, p=0.34).

In a multivariable analysis adjusted for age, nodal status, tumor size and chemotherapy regimen, stromal TILs added significant independent prognostic information for both IDFS and OS (likelihood chi2=17.9 for IDFS, p<0.0001 and chi2=16.7 for OS, p<0.0001). The adjusted hazard ratio for each 10% increase in stromal TILs was HR=0.86 (0.76-0.92) for IDFS events and HR=0.84 (0.76-0.92) for death.

Conclusion:
This large pooled individual patient data analysis confirms the strong prognostic role of stromal TILS in primary TNBC treated with A or A+T. TILs should now be strongly considered for incorporation as a stratification factor in future clinical trials enrolling TNBC patients. Given the important prognostic role of pre-existing immunity, patients with TNBC are rational candidates for immunotherapy clinical trials.

Title: Avelumab (MSB0010718C), an anti-PD-L1 antibody, in patients with locally advanced or metastatic breast cancer: A phase Ib JAVELIN solid tumor trial

Dirix LY Y, Takacs I, Nikolinakos P, Jerusalem G, Arkenau H-T, Hamilton EP P, von Heydebreck A, Grote H-J, Chin K and Lippman ME E. Sint Augustinus - University of Antwerp, Antwerp, Belgium; Semmelweis University, Budapest, Hungary; University Cancer & Blood Center, LLC, Athens, GA; CHU Sart Tilman Liege and Liege University, Liege, Belgium; Sarah Cannon Research Institute, London, United Kingdom; Sarah Cannon Research Institute, North Nashville, TN; Merck KGaA, Darmstadt, Germany; EMD Serono, Billerica, MA and University of Miami Miller School of Medicine, Miami, FL.

Body: Background: The programmed death-1 receptor (PD-1) and its ligand (PD-L1) are key therapeutic targets in the reactivation of the immune response against cancer. Avelumab* (MSB0010718C) is a fully human anti-PD-L1 IgG1 antibody being investigated in clinical trials. We report clinical activity of avelumab in a cohort of patients (pts) with locally advanced (LA) or metastatic breast cancer (MBC) refractory to or progressing after standard-of-care therapy (NCT01772004).

Methods: Pts received avelumab at 10 mg/kg Q2W until confirmed progression, unacceptable toxicity, or any criterion for withdrawal occurred. Tumors were assessed every 6 wks (RECIST 1.1). Unconfirmed best overall response was evaluated. Adverse events (AEs) were graded by NCI-CTCAE v4.0. Biopsy or surgical specimens were collected within 90 days prior to 1st dose of avelumab for biomarker analyses. Tumor PD-L1 expression was assessed by immunohistochemistry using various cutoff criteria.

Results: As of 27 Feb 2015, 168 pts (167 female, 1 male) with MBC, including ductal (56.5%), carcinoma NOS (9.5%), lobular (3.6%), or other (30.4%), were treated with avelumab and followed for a median of 10 mo (range 6-15). Median age was 55y (range 31-81), ECOG performance status was 0 (49.4%) or 1 (50.6%), and pts had received a median of 3 prior therapies for LA/M disease (range 0-10; pts must have received prior treatment with taxane and anthracycline, unless contraindicated). Pts were HER2–/ER+ or PR+ (69 [41.1%]), triple negative (TNBC = HER2–/ER–/PR–; 57 [33.9%]), HER2+ (26 [15.5%]), or had unknown biomarker status (16 [9.5%]). Median duration of treatment was 8 wks (range 2-50), and 9 pts (5.4%) remained on avelumab. Any grade treatment-related treatment-emergent AEs (TEAEs) occurred in 120 pts (71.4%); the most common (>10%) were fatigue (33 [19.6%]), nausea (24 [14.3%]), and infusion-related reactions (20 [11.9%]). Treatment-related grade ≥3 TEAEs occurred in 24 pts (14.3%) and included (≥1%) fatigue, anemia, increased GGT, and autoimmune hepatitis (each 3 [1.8%]), and arthralgia (2 [1.2%]). There were 2 treatment-related deaths (acute liver failure, respiratory distress). Unconfirmed objective response rate (ORR) in the entire cohort was 5.4% (9 pts; 95% CI: 2.5, 9.9), with 1 CR and 8 PRs. Five of 9 responses were ongoing at time of cutoff. Stable disease was observed in additional 40 pts (23.8%), for an overall disease control rate of 29.2%. Evidence of tumor reduction by ≥30% was seen in 15 pts (8.9%). There were responders in all biomarker subgroups, including 5 PRs in TNBC (n=57 [8.8%]; 95% CI: 2.9, 19.3). PD-L1 expression was evaluable in 136 pts. Among all pts with PD-L1 expressing immune cells within the tumor, 33.3% (4 of 12) had PRs. In pts with TNBC who had PD-L1+ immune cells within the tumor, 44.4% (4 of 9) had PRs, compared with 2.6% (1 of 39) for TNBC and PD-L1− immune cells.

Conclusions: Avelumab showed an acceptable safety profile and had clinical activity in a subset of pts with MBC. In pts with TNBC, presence of PD-L1 expressing immune cells within the tumor may be associated with clinical responses to avelumab. Further analyses of PD-L1 expression and clinical activity of avelumab in MBC are ongoing. *Proposed INN.

Title: Abstract Withdrawn

Body:
The miR-424/503 cluster is a breast cancer tumor suppressor with a role in chemoresistance

Silva J, Llobet-Navas D, Rodriguez-Barrueco R, Sanchez-Garcia F and Pe’er D. Mount Sinai School of Medicine, NYC, NY and Columbia University, NYC, NY.

Body: Recently, we have identified the miR-424(322)/503 cluster as an important regulator of mammary epithelial homeostasis. The miR-424(322)/503 cluster was identified as one of the few miRNAs significantly upregulated during involution after pregnancy. By generating a knock-out mouse model, we found that regression of the mammary epithelium after pregnancy was compromised in the absence of miR-424(322)/503. Mechanistically, our studies unveiled that miR-424(322)/503 is induced by the canonical TGF-β-SMAD pathway, and that it orchestrates changes in the mammary epithelium by downregulating the expression of key components of signal transduction (IGF1R) and apoptosis (BCL2) (Llobet et al. Genes & Development 2014).

Remarkably, our new studies have revealed that miR-424(322)/503-/- female mice develop hyperplasia and mammary tumors that are promoted by pregnancy. Thus, we investigated the status of this cluster in human breast cancers. For this we analyzed the METABRIC dataset. These studies revealed that the miR-424(322)/503 cluster was heterozygously deleted in ~16% of breast cancers and that its deletion correlates with lower expression levels of the mature miRNA forms. Importantly, miR-424(322)/503 is located on the X-chromosome and we have confirmed that is monoallelically expressed due to X-chromosome inactivation. Thus, the mutation of the active allele strongly impacts the expression of the miR-cluster. Deletions of the miR-424(322)/503 locus were more frequent in molecular subtypes with aggressive behavior (Luminal B, HER2+ and Basal) and both deletions and low expression of the cluster were associated with poor prognosis and reduced survival.

Some of the miR-424(322)/503 targets that we have previously validated (BCL2 and IGF1R) are involved in resistance to chemotherapy. Thus, we investigated in vivo, utilizing our knock-out mouse model, if loss of miR-424(322)/503 induces resistance to chemotherapeutic drugs. For this we crossed our miR-424(322)/503-/- animals with the HER2+ model FVB/N-Tg(MMTVneu)202Mul/J. Tumors emerging in HER2+/miR-424(322)/503-/- animals presented higher levels of BCL2 and hyperactivation of the IGF1R-AKT signaling compared to HER2+/miR-424(322)/503+/+ counterparts. Furthermore, these tumors were resistant to standard chemotherapy. Importantly, inhibition of BCL2 with ABT-199 and IGF1R with BMS-754807, two compounds currently in clinical trial, completely reverted chemotherapy resistance.

Overall, our data present evidence supporting a tumor suppressor role for miR-424(322)/503 cluster and its implication in resistance to chemotherapy.

WITHELD PENDING PRESS CONFERENCE
Title: A comparison of the diagnostic performance of 2D synthetic mammography versus digital breast tomosynthesis in 2500 patients

Holt SD D, Sharaiha YM M, Moalla A, Williams HR R, Thomas D and Huws AM M. Prince Philip Hospital, Llanelli, Carmarthenshire, United Kingdom.

Body: Introduction: A synthetic 2D mammogram (C-view) can be created by combining the individual optimally enhanced 1mm slices of a digital breast tomosynthesis (DBT). Studies show that screening with 2D mammography and DBT increases the cancer detection rate by about 40% and reduces the recall rate by about 25% but it doubles the x-ray exposure to the patient and reading time for the radiologist compared to standard 2D screening. The use of a synthetic 2D instead of a standard 2D film may theoretically overcome these problems by avoiding a second exposure and presenting the detail normally available in DBT in one picture. The hypothesis we wished to test is, "if the synthetic 2D is normal/benign, is there any advantage in also viewing the DBTs?"

Method: We prospectively collected data on 2500 unselected cases presenting symptomatically or at follow up, all of whom underwent DBT on a Hologic® Dimensions machine. From the 3D data sets synthetic 2D mammograms were constructed (Hologic® C-view). One breast radiologist with 13 years experience of interpreting mammograms and 5 years with DBTs was asked to review the 2D synthetic mammograms (CC and MLO) and report them before then reviewing the DBTs and issuing a final report. The mammograms were reported M1 to M5 using the standard BIRADs criteria. The BIRADs scores for each breast were recorded prospectively. Similarly the breast density as assessed by eye was recorded (fatty/average density/dense).

Results: 2500 patients were studied between October 2013 and October 2014. The average age of the women was 58.4 years (range 28-95). Of these some were under follow up after mastectomies so in total there were 4589 individual mammogram sets reported. Table 1 summarises the correlation between the synthetic 2D and DBT reports.

</tbody>
</table>

The correlation is very close, but there were 11 patients in whom the synthetic 2D was reported normal or benign (M1 or M2) but the DBT was reported as M3. Of these 10 were benign on assessment and one malignant. There was one patient reported as M2 on synthetic 2D but M4 on DBT. Assessment confirmed malignancy. Sixteen cases reported as suspicious of malignancy (M3/4) by synthetic 2D were subsequently downgraded to benign after review of the DBT. We estimate that 2D mammography alone would have detected only 68 of the 94 detected by synthetic 2D.

Of the 4589 examinations, 1131 (25%) were assessed as fatty, 1851 (40%) as average density and 1607 (35%) as dense. One cancer was missed in an averagely dense and one in a dense breast.

Conclusion: In a symptomatic and follow up clinic, our study suggests that much radiologist's time and x-ray exposure to the patient could be saved by using synthetic 2D mammograms rather than using 2D/3D combinations. Only if the synthetic 2D is reported M3, 4 or 5 is it necessary to review the DBT. Whilst a similar trial is required to confirm these findings in a screening population, this trial suggests that synthetic 2D mammography could be cost effective compared to combination 2D/3D.
Title: Importance of margin width and re-excision in breast conserving treatment of early breast cancer; a Danish breast cancer cooperative group study of 11,900 women

Bodilsen A, Bjerre K, Offersen BV V, Vahl P, Mele M, Dixon MJ J, Ejlertsen B, Overgaard J and Christiansen P. Aarhus University Hospital, Aarhus, Denmark; Danish Breast Cancer Cooperative Group, Copenhagen, Denmark; Aarhus University Hospital, Aarhus, Denmark; Aarhus University Hospital, Aarhus, Denmark and Breakthrough Research Unit Edinburgh Breast Unit, Western General Hospital, Edinburgh, United Kingdom.

Body: Background: The majority of women with invasive breast cancer are treated surgically by breast conserving surgery (BCS). A significant proportion subsequently undergo re-excision to obtain clear margins. However what constitutes a sufficient negative margin continues to be subject of controversy. The purpose of the study was to investigate the association between margin width and ipsilateral breast tumour recurrence (IBTR) as well as identifying factors associated with residual disease after repeat surgery, and to determine the effect of re-excision on IBTR in a population-based nationwide cohort.

Method: 11,900 patients treated with breast conserving therapy for unilateral invasive cancer in Denmark between 2000 and 2009 were included. All patients received whole breast irradiation and were offered systemic adjuvant treatment according to the guidelines of the Danish Breast Cancer Cooperative Group.

Results: The median follow-up was 4.9 years. The cumulative incidence of IBTR at 5 and 9 year was 2.4% and 5.9%, respectively. No decrease in IBTR with a wider negative margin compared to a narrow but negative margin was seen in adjusted analysis (>0-1 mm vs. 2-4 mm vs. ≥5 mm (reference): HR 1.54 (CI 95% 0.81-2.93) vs 0.95 (CI 95% 0.56-1.62) vs. 1). A final positive margin did however increase the risk of IBTR (HR 2.51; 95% CI 1.02-6.23). Other factors associated with increased IBTR were young age (HR 3.10; 95% CI 1.89-5.10), more than 4 positive lymph nodes (HR 1.80; 95% CI 1.24-2.62), and re-excision (HR 1.53; 95% CI 1.16-2.02). Receiving chemotherapy (HR 0.45; 95% CI 0.33-0.61) or boost (HR 0.43; 95% CI 0.31-0.60) reduced risk of IBTR as did being oestrogen receptor positive treated with (HR 0.35; 95% CI 0.25-0.49) or without (HR 0.43; 95% CI 0.31-0.60) adjuvant endocrine therapy.

Within two months of initial BCS 1342 women (11%) had a re-excision. Residual disease was found in 20% of re-excisions. In adjusted analysis DCIS outside the invasive tumour (OR 2.69; 95% CI 1.99-3.63), positive initial margin (OR 2.26, 95% CI 1.70-2.99, p<0.001), and age <50 years (OR 1.53; 95% CI 1.00-2.31) was associated with increased risk of residual disease. Patients with residual disease after re-excision had in the adjusted analysis an increased risk of ipsilateral breast tumour recurrence (IBTR), regardless of whether residual findings were invasive carcinoma (HR 2.97, CI 95% 1.57-5.62) or DCIS (HR 2.58, CI 95% 1.50-4.45). However no difference was seen for overall survival comparing one procedure with repeat surgery with or without residual disease (p=0.96).

Conclusion: An overall low rate of IBTR was seen. While a final positive margin was associated with a more than two-fold risk of IBTR, no evidence of improved local control was found with wider negative margins compared to narrow. However the finding of residual disease at re-excision was associated with an increased risk of IBTR.

Persistence of circulating tumor cells in high risk early breast cancer patients during follow-up care suggests poor prognosis – Results from the adjuvant SUCCESS A trial

Janni W, Rack B, Fasching P, Haaberle L, Friedl T, Tesch H, Lorenz R, Neugebauer J, Koch J, Jaeger B, Fehm T, Mueller V, Schneeweiß A, Lichtenegger W, Beckmann M, Scholz C, Pantel K and Trapp E. University Hospital Ulm, University of Ulm, Ulm, Germany; University Hospital Ludwig-Maximilians University, Ludwig-Maximilians University, Munich, Germany; University Hospital, Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany; Medical Center Hamburg-Eppendorf, University Hospital Hamburg-Eppendorf, Hamburg, Germany; University Hospital Heidelberg, Ruprecht-Karls-University, Heidelberg, Germany; University Hospital Nuremberg-Erlangen, Friedrich-Alexander University Erlangen-Nuremberg, Erlangen, Germany; Haemato-Oncology Practice, Bethanien Hospital, Frankfurt, Germany; Gynaecology Practice Lorenz/Hecker, Braunschweig, Germany; Charité University Hospital Campus Virchow, Berlin, Germany and University Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Background: Recent data suggest that circulating tumor cells (CTCs) are of prognostic relevance in early as well as metastatic breast cancer (BC). While persisting CTCs immediately after chemotherapy are known to indicate poor prognosis, there is a lack of data regarding the prognostic role of CTCs assessed during long-term follow-up care. Hence the prognostic value of CTCs two years after chemotherapy was analyzed.

Methods: The SUCCESS A trial is a randomized, open-label, 2x2 factorial design Phase III study in high-risk breast cancer patients (N0 or T2–T4 or grade 3 or age ≤ 35 or hormone-receptor negative). Patients were first randomized to adjuvant chemotherapy treatment with 3 cycles of epirubicin-fluorouracil-cyclophosphamide followed by either 3 cycles of docetaxel or 3 cycles of gemcitabine-docetaxel. In addition, patients were randomized to 2 vs. 5 years of zoledronate treatment. Presence of CTCs was assessed using the FDA-approved CellSearch System (Janssen Diagnostics, LLC). CTC positivity was defined as ≥ 1 CTC in 7.5 ml whole blood. To investigate if CTC status 2 years after chemotherapy is of prognostic relevance independent from CTC status before chemotherapy and to evaluate the prognostic relevance of changed CTC status, only patients with data on CTC status before and 2 years after chemotherapy were included. Patient outcomes in terms of overall survival (OS) and disease-free survival (DFS) were analyzed by univariate log-rank tests and multivariate Cox regressions adjusted for age, menopausal status, tumor stage, nodal stage, grading, histological type, hormone receptor status and HER2 status. Survival time was measured beginning with the date of follow-up CTC assessment two years after chemotherapy.

Results: Data on CTC status before and 2 years after chemotherapy were available for 1103 (29.4%) of 3754 randomized patients. The CTC status 2 years after chemotherapy was positive in 204 (18.5%) patients. The median follow-up time was 37 months. Multivariate Cox regressions including CTC status before chemotherapy showed significant independent prognostic role for CTC status 2 years after chemotherapy on OS (hazard ratio (HR) 3.95, 95% confidence interval (CI) 2.13 – 7.32, p < 0.001) and DFS (HR 2.28, 95% CI 1.48 – 3.50, p < 0.001). The prognostic value of CTC status 2 years after chemotherapy was independent from hormone- and HER2-receptor status. Overall, 719 (65.2%) patients were CTC negative before and 2 years after chemotherapy, while 157 (14.2%) had a negative CTC status before and a positive CTC status 2 years after chemotherapy. 180 (16.3%) patients converted from positive to negative CTC status and 47 (4.3%) patients were persistently positive for CTCs. There were significant differences in OS and DFS among the four patient groups (log rank tests, both p < 0.001) and persistently CTC positive patients had the worst outcome in terms of OS and DFS.

Conclusion: The presence of CTCs two years after chemotherapy analyzed during routine breast cancer follow-up care was associated with decreased survival. According to these results, persisting CTCs during long term follow-up independently predict patients’ outcome and may serve as surveillance marker.

Title: Early survival analysis of the randomized phase II trial investigating the addition of carboplatin to neoadjuvant therapy for triple-negative and HER2-positive early breast cancer (GeparSixto)

von Minckwitz G, Loibl S, Schneeweiss A, Salat CT T, Rezai M, Zahm D-M, Klare P, Blohmer J-U, Tesch H, Khandan F, Fasching PA A, Jakisch C, Nekljudova V and Untch M. German Breast Group, Neu-Isenburg, Germany; University Hospital Heidelberg, Heidelberg, Germany; Hämatothologisch-Onkologische Schwerpunktpraxis Salat/Stoetzer, München, Germany; Luisenkrankenhaus, Düsseldorf, Germany; SRH Wald-Klinikum Gera, Gera, Germany; Praxisklinik Berlin, Berlin, Germany; Charité Breast Centre, Berlin, Germany; Onkologische Gemeinschaftspraxis am Bethanien-Krankenhaus, Frankfurt, Germany; St. Markus Krankenhaus, Frankfurt, Germany; University Hospital Erlangen, Erlangen, Germany; Sana Klinikumk Offenbach, Offenbach, Germany and Helios Klinikum Berlin-Buch, Berlin, Germany.

Body: Introduction
Addition of carboplatin to anthracycline/taxane-based neoadjuvant chemotherapy has shown to improve pathological complete response (pCR; ypT0 ypN0) rates in patients with triple-negative breast cancer in two large phase II studies (GeparSixto: von Minckwitz et al. Lancet Oncol 2014; CALGB 40603: Sikov et al. J Clin Oncol 2015). Participants of the GeparSixto study with triple-negative tumors showed an improvement of pCR rate from 36.9 to 53.2% by the addition of carboplatin (p=0.005); however, no statistically significant difference in pCR rate was observed in the HER2-positive subgroup (36.8 vs 32.8%, respectively). A greater benefit with carboplatin was observed in patients with BRCA mutations or a high homologous recombination deficiency (HRD score) in the tumor (pCR rate of 30% compared to 10% for patients without HRD). So far, it is unknown whether these effects on pCR translate into a survival benefit for the patients. We here report an early survival analysis of the GeparSixto study.

Patients and Methods
In the GeparSixto trial (NCT01426880), patients were treated for 18 weeks with paclitaxel 80mg/m² q1w and non-pegylated-liposomal doxorubicin (NPLD) 20mg/m² q1w. Patients with TNBC (N=315) received concurrently bevacizumab 15mg/kg i.v. q2w until surgery. Patients with HER2+ disease (N=273) received concurrently trastuzumab 6(8)mg/kg q3w and lapatinib 750mg daily. All patients were randomized 1:1 to receive concurrently carboplatin AUC 1.5-2.0 q1w vs no carboplatin, stratified by subtype (HER2+ vs TNBC). Carboplatin dose was reduced from AUC 2.0 to 1.5 by an amendment after 330 patients. Primary objective was pCR rate (ypT0 ypN0). Loco-regional invasive recurrence free survival (LRRFS), distant-disease-free survival (DDFS), invasive disease-free survival (IDFS), and overall survival (OS) were secondary objectives.

Results
595 patients were recruited (8/2011 - 12/2012) in 51 German centers. 296 patients were randomly assigned to receive carboplatin and 299 to no additional carboplatin, of whom 295 and 293 started treatment, respectively. So far, 82 events have been reported after a median of 28 months follow-up. Analysis of updated events by treatment arm in the full study population as well as in the TNBC and HRD subgroups will be presented.

Conclusion
Even if the GeparSixto study was not powered to show carboplatin effects on survival, the expected results will help to assess the overall benefit of carboplatin in TNBC and the power of pCR to predict for DFS and OS.
Title: Event-free and overall survival following neoadjuvant weekly paclitaxel and dose-dense AC +/- carboplatin and/or bevacizumab in triple-negative breast cancer: Outcomes from CALGB 40603 (Alliance)

Title: A phase I trial of the safety and immunogenicity of a multiple antigen vaccine (STEMVAC) in HER2 negative advanced stage breast cancer patients

Higgins DM M, Childs JS S, Salazar LG G and Disis ML L. University of Washington-Tumor Vaccine Group, Seattle, WA.

Body: Background: Biologically relevant epithelial to mesenchymal transformation (EMT) associated proteins, a subpopulation of tumor cells with stem like properties, have been identified and are responsible for tumor initiation, metastasis formation and resistance to cancer therapies involved in breast cancer (BC) initiation. It is hypothesized that the acquisition of stem cell properties is driven by EMT induction and that BC stem cells express EMT-associated proteins. A vaccine which would educate the immune system to recognize and eliminate cells that have up-regulated proteins associated with BC stem cells/EMT could eradicate BC at the time of initiation or relapse. We have identified 5 stem cell/EMT proteins that are immunogenic in BC patients and created a vaccine, STEMVAC, composed of extended Th1 epitopes derived from these proteins. STEMVAC is safe and inhibits tumor growth in preclinical murine studies.

Trial design: Phase I dose escalation study evaluating 3 doses of STEMVAC admixed with 100 mcg of GMCSF. Patients enrolled sequentially into 1 of 3 dose arms (10 patients/arm): Arm 1=150 mcg, Arm 2=300 mcg, and Arm 3=600 mcg. 3 patients must complete 3 monthly vaccines and month 4 evaluation with no dose limiting toxicity before further accrual to that arm. Patients may receive 2 boosters, 3 and 9 months after their 3rd vaccine. Toxicity is assessed at baseline through end of study. Serial blood draws for immunologic monitoring is done.

Eligibility criteria: Stage III-IV HER2 negative BC patients treated with standard therapy who: (1) are without evidence of disease or have stable bone-only disease, (2) are 28 days from last chemotherapy, radiotherapy, systemic steroids, (3) have adequate blood counts, (4) have no active autoimmune disease. Endocrine therapy and bisphosphonates are allowed.

Specific aims: (1) Determine the safety of 3 escalating doses of STEMVAC, (2) Determine the most immunogenic dose, (3) Determine whether a STEMVAC Th1 polyepitope plasmid based vaccine elicits persistent T cell memory, and (4) Evaluate if STEMVAC modulates T regulatory and myeloid derived suppressor cells.

Statistical methods: Safety will be determined by laboratory and clinical parameters. Descriptive statistics will be used to summarize changes from baseline. Safety benchmarks to move to the next arm will be grade 3 toxicity rate of ≤ 15% and grade 4 toxicity rate of ≤ 5% in the first 3 vaccinations. Immunogenicity evaluated by generation of antigen specific Th1 immunity via ELISPOT. Immunologic efficacy is defined as achievement of significant increase in Th1 immunity for ≥50% of the immunizing antigens compared to baseline; and a greater proportion of patients developing T-cell immunity to a greater number of the antigens included in the vaccine. Exploratory analysis will be used to assess memory Th1 dominant immune response to all 5 antigens. Treg and MDSC will be defined as present or absent, and the probability of each will be estimated as a simple proportion.

Target accrual: 30 patients-no patients accrued to date.
2015 San Antonio Breast Cancer Symposium

Title: Pilot trial of a type I polarized autologous dendritic cell vaccine incorporating tumor blood vessel antigen-derived peptides in patients with metastatic breast cancer

Baar J, Storkus W, Finke J, Butterfield L, Lazarus H, Reese J, Brufsky A, Downes K, Budd GT and Fu P.  Case Comprehensive Cancer Center - Seidman Cancer Center, Cleveland, OH; Case Comprehensive Cancer Center - Taussig Cancer Center, Cleveland, OH and University of Pittsburgh Medical Center, Pittsburgh, PA.

Body: BACKGROUND. Cancer vaccines based on tumor-associated antigens are rarely curative in advanced cancer. This limitation relates to the heterogeneity of cancer due to defects in antigen presentation and altered immunophenotypes. Therefore, another method to promote anti-tumor immunity is to prime T cells against tumor-associated stromal cells. We have reported that IL-12 gene-therapy of established HLA-A2neg B16 melanomas in HLA-A2 transgenic (Tg) mice resulted in CD8+ T cell-mediated immunity against the host HLA-A2+ stromal cells within the tumor microenvironment (TME). We have also shown that vaccines based on a subset of tumor blood vessel antigen (TBVA)-derived peptides (DLK1310-318, EphA2883-891, HBB31-39, NRP1433-441, RGS55-13 and TEM1691-700) prevented HLA-A2neg MC38 tumor establishment and promoted the regression of melanomas in HLA-A2 Tg mice by CD8+ T cell targeting of HLA-A2+ pericytes and vascular endothelial cells in the TME.

TRIAL DESIGN. Based on this pre-clinical data, we are undertaking a Susan G. Komen-funded (IIR13261822; IND 15722) IRB-approved clinical trial of chemo-immunotherapy using the immunomodulatory drug gemcitabine (GEM) to suppress tumor infiltrating suppressor cells such as myeloid-derived suppressor cells (MDSC) and regulatory T cells (Tregs) with a dendritic cell (DC) vaccine pulsed with the above six HLA-A2-presented TBVA-derived peptides (DC-TBVA) in 30 HLA-A2+ patients with metastatic breast cancer (MBC). Eligible patients will first undergo leukapheresis for the generation of the DC-TBVA vaccine. Patients will then receive 3 cycles of GEM, 1000 mg/m2 IV on days 1 and 8 of a 21-day cycle for 3 cycles. Patients will then receive the DC-TBVA vaccine administered twice intradermally 7 days apart.

ELIGIBILITY CRITERIA. Patients must be HLA-A2+ and have radiologically measurable MBC, an ECOG performance status of 0-1 and not have any active immune disorders. Prior GEM therapy is acceptable as long as the last dose was ≥ 3 months from registration on this study. Patients may not be on steroids.

SPECIFIC AIMS. The 4 specific aims are to 1) assess the safety of GEM + αDC1-TBVA vaccination, 2) assess the clinical response of MBC to GEM + αDC1-TBVA vaccination, 3) determine the clinical efficacy of GEM + αDC1-TBVA vaccination in generating Tc1 immunity, and 4) correlate changes in MDSC and Tregs with the generation of anti-TBVA Tc1-cell immunity.

STATISTICAL METHODS. Clinical response: if the response rate is less than 10%, then there is probability 0.05 or less of accepting the vaccine therapy; if the response rate is bigger than 32%, then the probability of rejecting the combination is less than 0.2. While the secondary goals of the study are exploratory, there is sufficient statistical power to identify moderate to large effects (i.e., there will be statistical power >.80 to detect changes from baseline in the different immune function parameters that are >0.6 standard deviations of the parameter.)

TARGET ACCRUAL. We will enroll 30 patients over 3 years, with the first patient expected to be enrolled in July 2015.

CONTACT INFORMATION. Joseph Baar, MD, PhD. Seidman Cancer Center. E-mail: joseph.baar@uhhospitals.org.
Title: Adoptive cell transfer (ACT) using tumor infiltrating lymphocytes to target neoantigens in patients with metastatic breast cancer

Goff SL L, Feldman SA A, Somerville R and Rosenberg SA A. Surgery Branch, National Cancer Institute, Bethesda, MD.

Body: Background: Adoptive transfer of tumor infiltrating lymphocytes (TIL) can cure patients with metastatic melanoma, likely based on the recognition of mutated neoantigens (Robbins et al Nature Medicine 2013). Although immunogenic cancer antigens have been found in gastrointestinal cancers (Tran et al Science 2014), this has not been widely studied in patients with breast cancer. The presence of TIL on pathologic examination of triple-negative breast cancers is a positive prognostic marker for disease-free survival and overall survival. This pilot study investigates the ability to grow TIL from breast cancer metastases, to identify personalized non-synonymous mutations and potential neoantigens, and to adoptively transfer TIL into patients with breast cancer.

Trial Design: This is a single-arm, non-randomized pilot study of adoptive immunotherapy in patients with metastatic epithelial cancers with a cohort designated for those patients with breast cancer. Once screened for eligibility, patients undergo metastectomy to obtain tissue for culture of TIL and extensive in vitro studies will be performed to identify TIL cultures reactive to neoantigens. Once robust TIL have been identified, the patient is admitted to the National Institutes of Health Clinical Center for conditioning chemotherapy, TIL infusion and interleukin-2. Treatment and recovery generally entails about three weeks as an inpatient.

Eligibility Criteria: Patients between the ages of 18 and 70 with metastatic breast cancer who have measurable metastatic disease with at least one lesion resectable with minimal morbidity. Patients must be refractory to standard systemic therapy and must have shown progression on at least two lines of chemotherapy prior to infusion of TIL. Patients must be of good performance status (ECOG 0-1) and have three or fewer brain metastases. In addition, patients must meet common hematologic and chemistry lab criteria. Given the nature of immunotherapy and the rigorous treatment, patients are ineligible for the following reasons: dependence on steroids, cardiac dysfunction, active infection, active major medical illness of the respiratory, cardiovascular or immune system.

Specific Aims: The aims are both clinical and research oriented. Of greatest interest is to determine the ability of autologous TIL to mediate tumor regression in patients with metastatic breast cancer. We will also be examining the phenotypic and functional characteristics of TIL derived from breast cancer metastases. We will be attempting to identify non-synonymous immunogenic mutations within resected tumors.

Statistical Methods and Trial Accrual: Twenty-one patients will be initially enrolled in the treatment phase of this cohort to assess toxicity and tumor responses. If two or more of the first 21 patients per groups shows a clinical response (PR or CR), accrual will continue to 41 patients, targeting a 20% goal for objective response. We have currently enrolled three patients on the screening phase of this trial and one patient on the treatment phase.

2015 San Antonio Breast Cancer Symposium

Publication Number: OT1-01-04

Title: A multicenter, phase 1b, first-in-human dose-escalation study of ADXS31-164, a *Listeria monocytogenes*-LLO immunotherapy, in patients with HER2-expressing solid tumors

Tan AR R, Olszanski A, Golan T, Mauro D and Rugo H. Levine Cancer Institute, Charlotte, NC; Fox Chase Cancer Center, Philadelphia, PA; Sheba Medical Center, Tel HaShomer, Ramat Gan, Israel; Advaxis Inc., Princeton, NJ and UCSF, Helen Diller Family Comprehensive Cancer Center, San Francisco, CA.

Body: Background: Wild type *Listeria monocytogenes* (*Lm*) is taken up by antigen-presenting cells (APCs) and has the capability to escape destruction in the phagolysosome and proliferate in the cytosol of the APC. ADXS31-164 is a live attenuated *Lm*-listeriolysin O (LLO) immunotherapy bioengineered to express the intracellular domain 1 and extracellular domains 1 and 2 of chimeric human epidermal growth factor receptor 2 (cHER2) as a fusion protein to a truncated form of the LLO (tLLO) in the cytoplasm of APCs. The resultant immunologic response generates tumor antigen-specific cytotoxic T lymphocytes while also inhibiting regulatory T cells and myeloid-derived suppressor cells in the tumor microenvironment. Preclinical studies have shown ADXS31-164 can delay the progression of tumors in both transplantable and autochthonous HER2-expressing mouse tumor models.

Trial Design: This is an open-label, multicenter Phase 1b trial (NCT02386501). Patients will receive ADXS31-164 every 3 weeks until progression of disease or unacceptable toxicity. Dose escalations will be performed according to a standard 3+3 design starting at $1 \times 10^9$ colony forming units (CFU) to a maximum dose level of $1 \times 10^{10}$ CFU. The maximum tolerated dose (MTD) will be identified as the dose level in which a dose-limiting toxicity is seen in 2 of 6 patients; the previous dose level will be selected as the recommended Phase 2 dose (RP2D). Once the MTD and RP2D have been identified, up to 4 HER2-overexpressing tumor-specific expansion cohorts will be evaluated. Treatment cycles can be repeated at the RP2D (or less) for each patient until a study discontinuation criterion is met or the subject completes 1 cycle of treatment post-observation of complete response. Blood samples will be evaluated for immunologic effects in cycle 1 only. Descriptive statistics will be used to evaluate the safety and tolerability of ADXS31-164.

Objectives: The primary aim of this trial is to evaluate safety and tolerability of ADXS31-164 in patients with solid tumors that express HER2, and to select the RP2D. Secondary objectives include tumor response rates and progression-free survival (measured by Response Evaluation Criteria In Solid Tumors [RECIST] 1.1 and immune-related RECIST criteria). Exploratory analyses will describe and evaluate data from correlative immunologic studies. Key Eligibility Criteria: Patients aged ≥18 years with HER2-positive tumors determined by fluorescence in situ hybridization (FISH) or immunohistochemistry (IHC, at least 1 positive in 1% of the evaluable tumor cells) and an Eastern Cooperative Oncology Group performance status of 0–1 are eligible. Additional criteria include a diagnosis of locally advanced/metastatic solid tumor that has progressed or become intolerant to standard therapy or for which no standard therapy is available, measurable and/or evaluable disease per RECIST 1.1, and a left ventricular ejection fraction within normal limits.
Body: Background: Immune-based strategies involving T-cell activation have recently shown significant activity in multiple tumor types. The presence of immune elements in breast cancers has prognostic and predictive impact. Thus, strategies that optimize the interplay between a breast cancer and the effected individual's immune system may be therapeutic. Interleukin-12 (IL-12), a pro-inflammatory cytokine, reverses immune escape mechanisms induced by myeloid derived suppressor and dendritic cells which, in turn, improves the function of activated CD8+ T cells and promotes tumor stroma collapse. Because tumor neoantigens may be generated in response to chemotherapy, IL12-mediated immune modulation may be optimal in patients with chemotherapy-sensitive metastatic breast cancer. Ad-RTS-hIL-12 (Ad) is a novel gene therapy candidate expressing IL-12 under the control of an orally-administered activator ligand, veledimex (V) through the proprietary RheoSwitch Therapeutic System® (RTS).

Trial Design: Open-label, phase 1b/2, single-arm, single-center study of Ad+V in women with stable or responsive disease after \( \geq 12 \) weeks of 1st or 2nd-line chemotherapy. Eligible patients will be placed on chemotherapy-holiday and enter the immunotherapy phase, consisting of a single cycle of Ad administered intratumorally (Day 1), along with V (80 mg QDx7). HER2-directed antibody therapy may be continued during the immunotherapy phase for women with HER2- disease.

Key Eligibility Criteria: Women \( \geq 18 \) years with histologically-confirmed locally advanced or metastatic breast cancer of any subtype who have achieved a partial response (PR) or stable disease (SD) to 1st or 2nd-line chemotherapy are eligible. Exclusion criteria include use of immunosuppressive drugs, compromised immune function, autoimmune disorder, or brain metastases.

Specific Aims: To evaluate the safety and tolerability of Ad+V immunotherapy in eligible women. Secondary endpoints include 12 week overall response rate, 12 week disease control rate and the impact of treatment on exploratory immune biomarkers.

Statistical Methods: Safety and efficacy will be evaluated separately for HER2-/HER2+ patients. Tumor response will be evaluated by RECIST v1.1 at 6 and 12 weeks. To ensure safety, stopping rules defined by grade 3/4 adverse events and 12-week progression rate were adopted.

Target Accrual: Up to 40 patients, including up to 8 patients (20%) with HER2+ disease.

Summary: Ad+V is a novel gene therapy which controls local expression of IL-12 and may induce tumor stroma collapse and stimulation of an anti-cancer T cell immune response. The ability to regulate the production of IL-12 by modulating V dosing may result in an improved therapeutic index in combination with standard of care. The data from this study will directly inform future studies.

Study Contact (Clinical Trials.gov: NCT02423902).
Title: A phase III randomized trial of atezolizumab in combination with nab-paclitaxel as first line therapy for patients with metastatic triple-negative breast cancer (mTNBC)

Emens L, Adams S, Loi S, Schmid P, Schneeweiss A, Rugo H, Chui S and Winer E. Johns Hopkins University School of Medicine, Baltimore, MD; New York University School of Medicine, NY, NY; Peter MacCallum Cancer Centre, East Melbourne, VIC, Australia; Barts Cancer Institute, Queen Mary University London, London, United Kingdom; Heidelberg University Hospital, Heidelberg, Germany; University of California San Francisco Comprehensive Cancer Center, San Francisco, CA; Genentech, Inc., South San Francisco, CA and Dana-Farber Cancer Institute, Boston, MA.

Body: Background: The management of mTNBC is a therapeutic challenge, and chemotherapy remains the mainstay of treatment. Atezolizumab (atezo; MPDL3280A) is a humanized anti-PDL1 antibody that inhibits PD-L1 binding to PD-1 and B7.1 but leaves PD-L2/PD-1 binding intact. mTNBC has high levels of tumor-infiltrating immune cells (IC), increased PD-L1 expression and high mutation rates that may generate immunogenic neoantigens, making it an attractive candidate for PD-L1–targeted therapy with atezo. Accordingly, atezo monotherapy has demonstrated durable responses in mTNBC (Emens et al, AACR 2015). In addition, atezo combined with nab-paclitaxel has shown promising tolerability and activity in mTNBC (Adams et al, SABCS 2015; pending). Nab-paclitaxel has high anti-tumor activity that may favorably alter the immune microenvironment. Based on these preliminary results, a Phase III multicenter, randomized, double-blind, placebo-controlled trial (IMpassion130) was designed to evaluate the efficacy and safety of nab-paclitaxel combined with atezo as first-line therapy for mTNBC.

Methods: Patients are randomized 1:1 to receive atezo (840 mg) or placebo on days 1 and 15 plus nab-paclitaxel (100 mg/m²) on days 1, 8, and 15; all treatments are given on a 28-day cycle. Patients are stratified by the presence of liver metastases, prior taxane therapy and the PD-L1 status of IC (IC0 vs IC1/2/3). PD-L1 expression is centrally evaluated by immunohistochemistry using the SP142 assay. To capture pseudoprogression and delayed responses to atezo, patients with radiographic progression may continue to receive open-label atezo alone or with nab-paclitaxel until unacceptable toxicity or loss of clinical benefit.

Eligibility criteria: This study will enroll patients with histologically documented locally advanced or metastatic TNBC, no prior systemic therapy for advanced TNBC, ECOG PS 0-1 and measurable disease per RECIST v1.1. Patients with significant cardiovascular or CNS disease (except asymptomatic treated CNS metastases), autoimmune disease or prior immune checkpoint blockade therapy are excluded.

Endpoints: The co-primary efficacy endpoints are progression-free survival (PFS) in all patients and in PD-L1–selected patients. Secondary endpoints include overall survival, objective response rate, response duration, safety/tolerability, pharmacokinetics and health-related quality of life. Tumor biopsies are obtained at baseline and at progression to evaluate potential biomarkers associated with therapeutic response and resistance.

Statistical methods/target accrual: PFS will be compared between treatment arms (nab-paclitaxel vs. nab-paclitaxel plus atezo) using the stratified log-rank test. The hazard ratio for disease progression or death will be estimated using a stratified Cox proportional hazards model. Kaplan-Meier methodology will be used to estimate the median PFS for each treatment arm. About 350 patients will be enrolled at ≈ 120 sites globally.

Sponsor: Genentech, Inc. ClinicalTrials.gov identifier NCT02425891.

Title: nab-paclitaxel (nab-P) plus nivolumab (Nivo) in human epidermal growth factor receptor 2 (HER2)–negative recurrent metastatic breast cancer (MBC)

Waterhouse D, Gutierrez M, Bekaii-Saab T, DeRosa W, Wainberg Z, George B, Duval Fraser C, Ko A, Pierce DW W, Stergiopoulos S and Soliman H.  Oncology Hematology Care Inc, Cincinnati, OH; John Theurer Cancer Center, Hackensack, NJ; Ohio State University Comprehensive Cancer Center, Columbus, OH; Regional Cancer Care Associates LLC, Morristown, NJ; UCLA Hematology/Oncology, Santa Monica, CA; Medical College of Wisconsin, Milwaukee, WI; Celgene Corporation, Summit, NJ; Celgene Corporation, Summit, NJ; Celgene Corporation, Summit, NJ; Celgene Corporation, Summit, NJ and Moffitt Cancer Center, Tampa, FL.

Body: Background: Nivo is an inhibitory antibody against programmed death receptor-1 (PD-1), a regulator of antitumor immunity. Nivo is approved for treatment of unresectable or metastatic melanoma and disease progression (PD) following ipilimumab or, in BRAF V600 mutation–positive melanoma, following a BRAF inhibitor, and for metastatic squamous non-small cell lung cancer (NSCLC) following PD during or after platinum-based chemotherapy. Nivo and other immune checkpoint inhibitors are also being investigated in other tumor-types. nab-P is a novel taxane formulation and does not require prophylaxis with immunosuppressive steroids. It has demonstrated superior efficacy over control regimens in phase III studies of MBC, pancreatic cancer, and NSCLC. This open-label, 6-arm, multicenter phase I trial will evaluate the safety of Nivo with nab-P in 3 cancer types (2 arms/disease): MBC, advanced NSCLC (+ carboplatin), and advanced pancreatic cancer (+ gemcitabine). The study design for the MBC portion is described below.

Methods: Eligibility criteria include histologically/cytologically confirmed HER2-negative MBC; 1 prior chemotherapy for MBC, including an anthracycline unless clinically contraindicated; no relapse < 12 months after taxane adjuvant therapy; measurable disease by RECIST v1.1; ECOG performance status 0-1; adequate organ function; and preexisting peripheral neuropathy grade < 2. Patients (pts) with MBC will be treated in 2 arms: nab-P 100 mg/m2 on days 1, 8, and 15 of each 28-day cycle plus Nivo 3 mg/kg on days 1 and 15 starting at cycle 3 or nab-P 260 mg/m2 on day 1 of each 21-day cycle plus Nivo 5 mg/kg on day 15 starting at cycle 3. Pts will be treated until PD or allowed to continue treatment beyond RECIST v1.1–defined PD if they continue to meet study eligibility; do not have rapid PD or clinical deterioration or unacceptable toxicities; and can benefit from continuation of study treatment in the treating physician's opinion and will not delay an imminent intervention to prevent serious complications of PD. The primary endpoints of the study are the number of pts with dose-limiting toxicities (DLTs) in each treatment arm (part 1) and the percentage of pts with grade 3/4 treatment-emergent adverse events (TEAEs) or treatment discontinuation due to a TEAE (parts 1 and 2). Part 1 of the study will assess whether the starting dose of Nivo is deemed safe (≤ 1 DLT in 6 pts); otherwise, the Nivo dose will be de-escalated and assessed in a new cohort at the next lower dose level. The Nivo dose in combination with nab-P deemed safe in a treatment arm may be further assessed in part 2 of the study, with enrollment expanded to an additional ~ 14 pts/arm (total of 20 Nivo-treated pts/arm). Secondary study endpoints include TEAEs leading to dose reduction, delay, interruption, or treatment discontinuation; progression-free survival; overall survival; disease control rate; overall response rate; and duration of response (per RECIST v1.1). Exploratory endpoints include tumor-associated PD-L1 expression, modulation of immune activation in the tumor and peripheral blood in response to Nivo treatment, Nivo serum levels, and development of anti-globulin antibodies. ClinicalTrials.gov identifier NCT02309177.

Title: Pilot study of prognostic utility of circulating tumor cells (CTCs) assessed by AdnaGen technology and clinical outcome of patients with stage III breast cancer who completed locoregional and systemic treatment

Body: Background: Detection of high number of CTCs (>5) before initiation of first-line therapy in patients with metastatic breast cancer is associated with shorter progression free survival and overall survival. The most widely used method is CellSearch (Veridex, Raritan, NJ). It relies on immunomagnetic capture of CTCs, using antibodies against the epithelial cell adhesion molecule (EpCAM). Although the US Food and Drug Administration approved CellSearch assay for clinical use. In addition to isolation and enumeration, a promising area of research is genomic CTCs characterization which entails phenotyping and molecular expression profiling of CTC subsets consisting of those of epithelial origin (CTC-Epi), others undergoing epithelial to mesenchymal transition (CTC-EMT), or expressing cancer stem cell-like phenotype (CTC-CSC; CD44+ CD24low, ALDH+), respectively. EMT is a molecular process to acquire the traits needed to execute the multiple steps of metastasis. Through the EMT process, epithelial cells lose cell-cell contacts and cell polarity, downregulate epithelial-associated genes, acquire mesenchymal gene expression and undergo major changes in their cytoskeleton. Currently, a CTC detection kit is available to detect CTCs expressing EMT-associated genes by semiquantitative RT-PCR (Adna EMT2/Stem Cell test). EMT will be detected by measuring EMT-inducing transcription factors such as TWIST1, SNAIL1, SLUG, ZEB1 and FOXC2) by RT-PCR

Objectives. Primary objective: To investigate if activated pathways in CTCs are correlated with clinical outcome of patient with stage III breast cancer. Secondary objective: To prospectively determine if assessment of the pathways profiling in CTCs can be used to stratify NED breast cancer patients

Patients Eligibility: Inclusion: histologically confirmed invasive breast cancer (any subtype), clinical stage III, no evidence of distant metastasis by PET-CT or CT scan of chest and abdomen, and body scan, age 18 years or older, pts must be scheduled to start neoadjuvant/adjuvant therapy, ECOG PS 0-2. Pts must sign a written informed consent. Exclusion: distant metastasis, investigational therapy, prior history of other malignancies within the last 2 years, except non-melanoma skin cancer. This study (PA12-0097) was approved by IRB of UT MD Anderson Cancer Center.

Trial Design. This is a pilot, international, multicenter, prospective, blood sample collection from 200 patients with clinical or pathologic stage III breast cancer.

Statistical Analysis: This study is a 7-year study (84 months). Pts will be classified as to the presence [negative (neg) vs. positive (pos)] of CTC and as to the expression of a biomarker (neg vs. pos). The primary endpoint of the study is breast cancer recurrence. Time to recurrence curves for the four breast cancer patient groups (neg/neg, neg/pos, pos/neg, or pos/pos) will be estimated using the Kaplan-Meier method and differences in the recurrence rates will be evaluated by the log-rank test at the end of the study (84 months). The confidence intervals for the quantiles of the recurrence distribution will be based on the sign test as described by Brookmeyer and Crowley.
Title: The DETECT study program – Personalized treatment in metastatic breast cancer based on circulating tumor cells

Schramm A, Friedl TWP WP, Huober J, Jäger B, Rack B, Trapp E, Fasching PA A, Taran F-A, Hartkopf A, Schneeweiss A, Müller V, Aktas B, Pantel K, Meier-Stiegen F, Wimberger P, Kümmel S, Gebauer G, Müller L, Janni W and Fehm T. University Hospital Ulm, Ulm, Germany; Gynecology and Obstetrics, Klinikum der Ludwig-Maximilians-Universität, Munich, Germany; Gynecology and Obstetrics, University Hospital Erlangen, Erlangen, Germany; Gynecology and Obstetrics, University Hospital Tübingen, Tuebingen, Germany; University Hospital Heidelberg, Heidelberg, Germany; Gynecology and Obstetrics, University Hospital Hamburg-Eppendorf, Hamburg, Germany; Gynecology and Obstetrics, University Hospital Essen, Essen, Germany; University Hospital Hamburg-Eppendorf, Hamburg, Germany; Gynecology and Obstetrics, Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany; Gynecology and Obstetrics, University Hospital Hamburg-Eppendorf, Hamburg, Germany; Gynecology and Obstetrics, University Hospital Essen, Essen, Germany; University Hospital Hamburg-Eppendorf, Hamburg, Germany; Gynecology and Obstetrics, Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany; Gynecology and Obstetrics, University Hospital Hamburg-Eppendorf, Hamburg, Germany; Gynecology and Obstetrics, University Hospital Dresden, Technische Universität Dresden, Dresden, Germany; Interdisciplinary Breast Center Unit Kliniken-Essen-Mitte, Essen, Germany; Gynecology Marienhospital Hamburg, Hamburg, Germany and Private Practice Onkologie UnterEms, Leer Ostfriesland Leer, Leer, Germany.

Body: Circulating tumor cells (CTCs) are found in patients with primary and metastatic breast cancer (MBC), respectively, and discordance in HER2 and hormone-receptor status between primary tumor, metastases and CTCs is well described. Treatment decisions are still based on the expression profile of solid tumor samples whereas CTCs are thought to cause tumor progression by blood-derived metastases. Nevertheless, targeted therapy based on expression profile of CTCs is not established in clinical routine. Individualized treatment decisions based on presence and phenotype of CTCs will be analyzed within the DETECT study program.

Metastatic breast cancer patients with HER2-negative MBC are screened in DETECT III and IV for presence of CTCs by using the CellSearch System (Janssen Diagnostics) which is FDA approved for enumeration of CTCs. Patients are enrolled into the different cohorts according to HER2-phenotype of CTCs. Since February 2012, women with HER2-negative MBC and HER2-positive CTCs are treated in the multicenter randomized Phase III study DETECT III with standard therapy with or without additional HER2-targeted therapy with Lapatinib. For standard therapy, physicians can choose between exemestane, letrozole and anastrozole for endocrine therapy, or docetaxel, paclitaxel, capecitabine, vinorelbine and non-pegylated liposomal doxorubicin for chemotherapy. Efficacy of CTC-based anti-HER2 treatment is evaluated by analyzing CTC-clearance rate after treatment.

Patients with only HER2-negative CTCs are recruited for the multicenter open-label phase II study DETECT IV. Since December 2013, women with hormone-receptor positive MBC receive endocrine therapy (tamoxifen, exemestane, letrozole or anastrozole) plus everolimus in DETECT IVa. In February 2015, DETECT IV was extended by the eribulin-cohort which offers a cytotoxic treatment with eribulin for women with triple-negative or hormone-receptor positive, chemotherapy demanding MBC (DETECT IVb). Progression free survival is used for assessment of clinical efficacy with overall survival and disease control rate as secondary objectives.

DETECT V, a multicenter open-label phase III study starting in summer 2015, randomizes patients with hormone-receptor positive, HER2-positive MBC to a dual HER2 targeted therapy (Trastuzumab and Pertuzumab) combined with either endocrine therapy or cytotoxic treatment. Quality of life determined by occurrence of adverse events is compared between both treatment arms. For prediction of endocrine treatment response, an “Endocrine Responsiveness Score” is calculated based on expression of estrogen-receptor and HER2 on detected CTCs.

More than 1200 patients are already screened in the DETECT study concept. Thus, it is the worldwide largest study concept with therapy decisions resulting from CTC-testing and CTC-phenotypization. The accompanying translational research programs evaluates further markers for molecular characterization of CTCs and prediction of therapy response.

Conclusion and Contact
The value of CTC phenotypes for making decisions on therapy interventions and predicting treatment responses in patients with MBC is tested in the DETECT study concept. The findings will help to move a step forward towards a more personalized anti-cancer therapy.
**Title:** A phase II study of single-agent PF-03084014 in patients with advanced triple-negative breast cancer with or without activating genomic alterations in NOTCH receptors

**Body:** Background: PF-03084014 is a reversible, noncompetitive, selective gamma-secretase inhibitor that blocks the NOTCH signaling pathway. Pre-clinical studies have demonstrated that PF-03084014 has strong anti-tumor activity in a subset of breast cancer models that harbor NOTCH receptor activating genomic alterations (NA+). Genomic data from the Cancer Genome Atlas have also shown that the NOTCH pathway is altered via multiple mechanisms in about 13% of patients (pts) with triple-negative breast cancer (TNBC). These results, together with the need for more effective therapies for TNBC, support the evaluation of PF-03084014 as single-agent treatment in pts with NA+ TNBC.

Study design: A8641020 is a multi-center, open-label, single-arm phase II study investigating the administration of PF-03084014 as a single-agent for the treatment of pts with NA+ TNBC. In addition, the study includes a subset of pts whose tumors test negative for activating genomic alterations in NOTCH receptors (NA-), to evaluate in pts the antitumor activity of PF-03084014 previously observed in pre-clinical animal models of NA- TNBC. Other eligibility criteria include ECOG PS ≤2, measurable disease, and availability of tumor tissue for central profiling of NOTCH genomic alterations (archival or de-novo specimens). For NA- TNBC pts, at least 1 prior line of therapy for advanced disease is required to enter the study. Pts will be enrolled in 2 parallel cohorts: cohort 1, n = 15 pts with NA+ TNBC and cohort 2, n = 15 pts with NA- TNBC. All pts will receive PF-03084014 at the starting dose of 150 mg BID given orally and continuously in 21-day cycles. Treatment will continue until disease progression, patient refusal, or unacceptable toxicity.

Endpoints: The primary endpoint is objective response (OR) in pts with NA+ TNBC, as assessed using RECIST version 1.1. Secondary endpoints include OR in pts with NA- TNBC, progression-free survival, duration of response, one-year survival, overall survival, and pharmacodynamic effects of PF-03084014 in tumor specimens and peripheral blood.

Statistical methods: The final analysis of the primary endpoint is planned after 15 response-evaluable pts with NA+ TNBC have been treated.

Accrual: Approximately 30 pts will be enrolled across Europe and North America. As of April 2015, 8 pts were accrued. Reference Study ID Numbers: NCT02299635; 2014-002286-30.
Title: Evaluation of the use of oral care to prevent oral mucositis in estrogen receptor positive metastatic breast cancer patients treated with everolimus: Phase III randomized control trial

Niikura N, Ohta Y, Hayashi N, Naito M, Kashiwabara K, Watanabe K, Yamashita T, Mukai H and Umeda M. Tokai University School of Medicine; St. Luke's International Hospital; Nagoya University Graduate School of Medicine; University of Tokyo; Hokkaido Cancer Center; Cancer and Infectious Diseases Center Tokyo Metropolitan Komagome Hospital; National Cancer Center Hospital East and Nagasaki University Graduate School of Biomedical Sciences.

Body: Background:
In patients with estrogen receptor (ER)-positive advanced breast cancer, everolimus plus exemestane prolongs progression-free survival compared to exemestane monotherapy. However, as an adverse event from everolimus, oral mucositis (all grades) has been reported in 58% of all patients and 81% of Asian patients. Although no established prevention method is available, a previous study reported that professional oral care might prevent oral mucositis, and dentists have hypothesized that such care can reduce the occurrence of oral mucositis induced by everolimus. To evaluate this hypothesis, we compare the incidence of oral mucositis with and without professional oral care.

Method:
This is a randomized, multi-center, open-label, phase III study to evaluate the efficacy of professional oral care in preventing oral mucositis induced by everolimus in postmenopausal ER-positive metastatic breast cancer (MBC). Patients will be randomized into professional oral care and control groups (1:1 ratio). All patients will receive everolimus (10 mg daily) with exemestane (25 mg daily) and will continue everolimus until disease progression. Before the initiation of everolimus, instruction on a professional brushing method will be provided to both groups by specialists. In the professional oral care group, patients will receive teeth surface cleaning, scaling, and tongue cleaning before starting everolimus, and will continue to receive professional oral care weekly from oral surgeons throughout the 8 week treatment. In the control group, patients will brush their own teeth and gargle with 0.9% sodium chloride solution or water. The primary endpoint is the incidence of all grades of oral mucositis. The secondary endpoints are the incidence of over grade 2 and over 3 oral mucositis as determined by an oncologist and oral surgeons. The endpoints include onset and duration of oral mucositis. Major eligibility criteria include: 1) Postmenopausal women with ER positive MBC, and 2) No more than one prior chemotherapy treatment for MBC. Target accrual is 200 patients with a two-sided type I error rate of 5% and 80% power to detect 25% risk reduction. This study has just begun, and 5 of a planned 200 patients have been enrolled. (This study was registered with the UMIN 000016109).
Title: FINESSE - An open, 3-cohort, phase II trial testing oral administration of lucitanib in patients with FGFR1-amplified or non-amplified oestrogen receptor positive metastatic breast cancer

Andre F, Daly F, Azim Jr HA A, Agrapart V, Fumagalli D, Gingras I, Guitart M, Lange A, Turner NC C, Pierrat M-J, Loibl S, Poiret C, Curigliano G, Loi S, Pallis A, Piccart M and Cortes J. Institut Gustave Roussy, Villejuif Cedex, France; Frontier Science (Scotland) Ltd, Kincraig, United Kingdom; Breast Data Centre, Institut Jules Bordet, Brussels, Belgium; Laboratoires Servier, Surennes, France; Breast International Group, Brussels, Belgium; The Royal Marsden NHS Foundation Trust, London, United Kingdom; German Breast Group/Sana Klinikum Offenbach, Neu-Isenburg, Germany; Istituto Europeo di Oncologia, Milan, Italy; Translational Breast Cancer Genomics Lab Peter MacCallum Cancer Centre, Melbourne, Australia and Vall d’Hebron University Hospital, Barcelona, Spain.

Body: Background: Lucitanib is a potent, oral inhibitor of the tyrosine kinase activity of Fibroblast Growth Factor Receptors 1-3 (FGFR1-3), Vascular Endothelial Growth Factor Receptors 1-3 (VEGFR1-3) and Platelet-Derived Growth Factor Receptors α/β (PDGFRα/β). FGF aberrancy, as defined by amplification of either FGFR1, or 11q (containing FGF ligands 3, 4, CCND1, and 19), or both, is a hallmark genomic alteration that can be observed in up to 25% of patients with breast cancer. In a phase I clinical trial of lucitanib at daily doses of 5 to 20 mg, heavily pretreated patients with advanced breast cancer patients and FGF aberrancy experienced an objective response rate (ORR) of 50% and a median progression-free survival (PFS) over 9 months (Soria et al, 2014). This compelling clinical activity has led to the initiation of a global clinical development program for lucitanib in breast cancer.

Trial design: this is a phase II trial testing the efficacy of lucitanib at the dose of 15 mg daily in patients with ER+/HER2- metastatic breast cancer who have received at least one first-line systemic anticancer therapy in the metastatic setting. After informed consent, metastatic tissue (fresh biopsy or archival) is centrally evaluated by FISH for FGFR1- and/or 11q- amplification. Based on FISH results, patients are allocated to cohort 1 (FGFR1-amp), cohort 2 (11q-amp) or cohort 3 (neither). Patients with dual amplification are allocated to cohort 1. The primary objective is to evaluate the ORR of single agent lucitanib in the three cohorts. Secondary objectives include clinical benefit rate, PFS, safety and pharmacokinetics in addition to exploratory biomarker analyses. A Simon two-stage design will be used for each of the cohorts to test the null hypothesis that the ORR is 5% or less versus 20% using a one-sided test with 5% level of significance and 90% power. In each cohort separately, an initial 21 patients with measurable disease at baseline will be assessed at the end of stage 1. If at least 2 patients respond per the pre-specified criteria, this cohort will accrue additional 20 patients. The null hypothesis will be rejected if there are at least 5 responders among all 41 patients.

Eligibility Criteria: ER+/HER2- metastatic breast cancer who have received at least a first line of systemic anticancer therapy and no more than 2 line of chemotherapy with or without targeted therapy in the metastatic setting and have ECOG performance status ≤ 2. Patients with uncontrolled hypertension and at risk of developing hypertension related complications are not eligible.

Conclusion: FINESSE is a phase II trial testing lucitanib, a multikinase inhibitor, in three selected populations in order to investigate the ORR in FGFR1 or 11q amplified or non-amplified populations and to explore the role of FGFR1 or 11q amplifications through correlative translational analyses. As of May 21st 2015, 40 patients have been enrolled, 19 of them in the FGFR1-amplified arm.
Title: A phase 2 study of abemaciclib in patients with brain metastases secondary to hormone receptor positive breast cancer

Background:
Abemaciclib, an oral drug administered twice daily on a continuous schedule, is an inhibitor of both CDK4 and CDK6. In study JPBA, abemaciclib demonstrated evidence of single-agent activity in a cohort of patients with heavily pretreated metastatic breast cancer (MBC, median of 7 prior therapies); all responses were observed in women with hormone receptor positive (HR+) disease. Preclinical results demonstrating that abemaciclib crosses the blood-brain barrier coupled with the clinical responses observed in study JPBA support further investigation of abemaciclib in the current phase 2 trial (JPBO) of patients with brain metastases secondary to HR+ breast cancer.

Trial design:
Study JPBO (NCT02308020) is an open-label, phase 2 trial that will evaluate the safety and efficacy of abemaciclib 200 mg administered orally every 12 hours in patients with HR+ MBC and brain metastases. The study will consist of 3 parts; 2 of these parts will each accrue from 23 to 56 patients. These 2 parts will include patients with HER2+ breast cancer (Part A) and HER2- breast cancer (Part B). Part C will include approximately 8 MBC patients with either HER2+ or HER2- disease who have 1 to 3 intracranial lesions and for whom surgical resection is clinically indicated, with the goal of assessing drug concentrations in plasma, CSF, and brain tumor tissue. These patients may resume abemaciclib post-operatively.

Eligibility criteria:
Eligible patients include women with HR+ MBC who have completed local therapy ≥14 days prior to abemaciclib treatment, a life expectancy ≥12 weeks, and a Karnofsky performance status of ≥70. Part A includes MBC with confirmed HER2 overexpression and/or amplification (HER2+) status. Part B includes MBC that does not demonstrate HER2 overexpression and/or amplification (HER2-). For Parts A and B, patients will have ≥1 new or not previously irradiated measurable metastatic brain lesion ≥10 mm in the longest diameter or a progressive previously irradiated metastatic brain lesion identified by gadolinium-enhanced MRI. For Part C (surgical), patients have either HER2+ or HER2- MBC with brain lesion(s) for which surgical resection is clinically indicated and agree to provide post-treatment brain tumor tissue.

Specific aims:
The primary efficacy measure is objective intracranial response rate (complete response + partial response) as defined by Response Assessment in Neuro-Oncology brain metastases response criteria. Secondary intracranial objectives include best overall response, duration of response, disease control rate, and clinical benefit rate. The following overall objectives (intracranial + extracranial) include: overall survival, objective response rate, and progression-free survival. Change in neurologic symptoms will also be assessed.

Statistical methods:
Two separate Simon 2-stage designs will be employed for Part A and Part B. Each design assumes a 1-sided type-I error of 0.05 and 80% power. All tests will be conducted at a 2-sided alpha level of 0.05, unless otherwise stated. All confidence intervals will be given at a 2-sided 95% level.

Target accrual:
Approximately 120 patients.

Contact information:
For further information, please contact 1-877-CTLILLY (1-877-285-4559).
A phase III, randomized, open label, multicenter, controlled trial of niraparib versus physician’s choice in previously-treated, HER2 negative, germline BRCA mutation-positive breast cancer patients. An EORTC-BIG intergroup study (BRAVO study)

Balmana J, Tryfonidis K, Audeh W, Goulioti T, Slaets L, Agarwal S, Lema N, Cameron D and Turner N. Val d’Hebron, University Hospital, Barcelona, Spain; EORTC Headquarters, Brussels, Belgium; Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles; Breast International Group, Brussels, Belgium; TESARO, Inc, Waltham, MA; University of Edinburgh, Edinburgh, United Kingdom and The Royal Marsden NHS Foundation Trust, London, United Kingdom.

**Background**
Germline BRCA mutations (gBRCAmut) amongst breast cancer (BC) patients ranges between 5% - 25% depending on family history of BC or ovarian cancer (OC). Cells treated with PARP inhibitors (PARPi) accumulate defects that lead to their death in the absence of homologous recombination (HR) repair (e.g. gBRCAmut). Niraparib is a PARPi in development. As the TNT study showed better results of 1st line carboplatin vs docetaxel in gBRCAmut patients, a rise of a platinum-exposed population is expected. Due to prior experience in OC where platinum sensitivity of HR deficient cells is linked with PARPi sensitivity, it seems that patients who progress on or soon after platinum should be excluded from PARPi therapy, without sparing from PARPi those who may retain sensitivity. The protocol was amended to include platinum-exposed patients.

**Trial Design**
Bravo is a multicenter (North America, Europe & Israel) EORTC & BIG phase III trial sponsored by TESARO. Patients with gBRCAmut will be randomized (2:1) to niraparib (per os) vs physician’s choice (PC) (eribulin or capecitabine or gemcitabine or vinorelbine)-NCT01905592.

**Eligibility Criteria**
- Patients with deleterious/suspected deleterious gBRCAmut locally or centrally. Central confirmation will be done. If post inclusion, based on a previous test, mutation is not centrally confirmed, they can participate based on their physician/own preference.
- Up to 2 prior chemotherapy lines for metastatic disease (MD).
- Previously untreated for MD are allowed if they relapse during/within 12 months of (neo-) adjuvant chemotherapy.
- Prior therapy must include a taxane and/or anthracycline. Previously received platinum in the MD can be enrolled if they did not progress while on or within 8 weeks from the last day of the platinum administration. Those who received (neo-) adjuvant platinum are eligible, if relapsed 12 or > months after the last platinum dose.

**Specific aims**
Primary endpoint is PFS assessed by blinded central review. Secondary are OS, safety, PFS on local investigator assessment, time to treatment failure, response & duration of response, health-related quality assessments & tests for companion diagnostic test development.

**Statistical methods**
The PFS analysis will be done after 232 PFS events in the population of centrally confirmed gBRCAmut randomized patients. Assuming that median PFS is 3 months for PC & 6 months for niraparib (hazard ratio=0.5), there is 99.6 % power (1-sided alpha=0.025) to detect a difference from 3 - 6 months. Sample size ensure power for an OS comparison. Assuming an increase in OS from 9 -13 months, with a hazard ratio of 0.69, there is 80% power at 1- sided alpha of 0.025 when 265 deaths are observed. Assuming 40% of patients will be randomized based on local test and 15% won't be mutated centrally, an over-enrollment of 18 patients is needed to obtain the 306 in the efficacy population. A futility interim analysis will happen at 40% of PFS events.

**Present accrual and target accrual**
1200 patients will be registered & 306 randomized. Accrual will finish in 2 years.
Title: LORELEI: A phase II randomized, double-blind study of neoadjuvant letrozole plus taselisib (GDC-0032) versus letrozole plus placebo in postmenopausal women with ER-positive/HER2-negative, early-stage breast cancer

Oliveira M, de Azambuja E, Saura C, Dubsky P, Zardavas D, Fesl C, Bardia A, Soberino J, Ciruelos Gil E, Ng V, Fredrickson J, Stout TJ, Singel SM, Hsu JY, Piccart M, Grant M and Baselga J. Vall d’Hebron University Hospital, Vall d’Hebron Institute of Oncology (VHIO), Barcelona, Spain; SOLTI Breast Cancer Research Group, Barcelona, Spain; Jules Bordet Institute, Brussels, Belgium; Breast Data Centre at the Jules Bordet Institute, Brussels, Belgium; Medical University of Vienna, Vienna, Austria; ABCSG Austrian Breast and Colorectal Cancer Study Group, Vienna, Austria; Breast International Group (BIG aisbl), Brussels, Belgium; Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA; 12 de Octubre University Hospital, Madrid, Spain; Genentech, Inc., South San Francisco, CA and Memorial Sloan-Kettering Cancer Center, NY, NY.

Body: Background: Taselisib is an orally bioavailable, potent, selective inhibitor of Class I PI3-kinase (PI3K) alpha, gamma, and delta isoforms, with 30-fold less inhibition of the PI3K beta isoform relative to the alpha isoform showing enhanced activity against PIK3CA mutant cancer cell lines. Clinical data have demonstrated confirmed partial responses in patients with PIK3CA mutant breast cancer (BC) treated with single-agent taselisib. Enhanced antitumor activity has been noted when taselisib is combined with either letrozole or fulvestrant in preclinical and Phase Ib clinical studies.

Methods: LORELEI is a Phase II, two-arm, randomized, double-blind, multicenter, study of neoadjuvant letrozole and taselisib versus letrozole and placebo in postmenopausal women with newly diagnosed ER+/HER2-, untreated, Stage I-III operable BC. Other eligibility criteria include tumor size ≤2 cm by magnetic resonance imaging (MRI), ECOG PS 0-1, and evaluable tumor tissue for PIK3CA genotyping. Patients treated with anti-diabetic drugs are not eligible. Patients are randomized (1:1) to receive continuous letrozole (2.5 mg) with either taselisib (4 mg on a 5 days on/2 days off schedule) or placebo for 16 weeks, followed by surgery. Stratification is based on tumor size and nodal status. The co-primary endpoints are overall objective response rate (ORR) by centrally assessed breast MRI via modified RECIST criteria and pathologic complete response (pCR) rate in breast and axilla at time of surgery in all randomized patients and PIK3CA mutant patients. Secondary endpoints include ORR by centrally-assessed MRI and pCR rate in PIK3CA wild-type patients. The sample size was calculated to detect an absolute percentage increase of 24% in ORR with 80% power and an absolute percentage increase of 18% in pCR rate. An interim safety analysis will be conducted by an Independent Data Monitoring Committee. As of 1st Jun 2015, 54 of the 330 patients have been enrolled, and global enrollment is ongoing (clinicaltrials.gov NCT02273973).

Phone: 888-662-6728 (US Only)
Email Address: global.rochegenentechtrials@roche.com
Body: Background: Breast cancer stem cells (BCSC) have the ability to self renew and generate the full range of cells that make up a bulk tumor. Experimental models and retrospective clinical observations point to BCSC as responsible for tumor recurrence and metastasis. CXCR1, one of the receptors for CXCL8, has been identified on BCSC. Reparixin, an allosteric inhibitor of CXCR1, reduced BCSC in breast cancer xenografts (Ginestier C et al., JCI 2010) both as single agent and in combination with taxane chemotherapy. In a phase Ib trial in women with metastatic HER2-negative BC, the combination of escalating doses (400 to 1200 mg three times per day) of reparixin with weekly paclitaxel resulted in a low incidence and severity of adverse reactions, a sizeable response rate and time-to-progression, with some long-term responders (Schott AF et al., SABC 2014).

Trial Design: In this randomized, double-blind phase 2 trial patients will be randomized (1:1) to paclitaxel 80 mg/m2 on days 1, 8 and 15 of 28-day cycles in combination with reparixin or placebo oral tablets 1200 mg three times daily on days 1-21. Treatment continues until disease progression, unacceptable toxicity or withdrawal of consent. An independent Data Monitoring Committee has been appointed to oversee the trial. An independent Radiology Review will be performed for analysis of primary and secondary endpoints. Disease response will be assessed every 8 weeks. Patients will be followed up to 12 months after last enrolled patient completes treatment.

Eligibility Criteria: Patients must be female aged ≥18 years with untreated metastatic TNBC who have relapsed >12 and >6 months after the end of a taxane- or non taxane-based (neo)adjuvant chemotherapy regimen, respectively. They must have measurable disease, ECOG PS of 0-1, adequate organ function, and no history or evidence of brain metastases (brain CT or MRI required). Tumor tissue must be available from a metastatic site or from primary tumor for confirmation of diagnosis and correlative studies. Key exclusion criteria are pre-existing peripheral neuropathy G>1 and any disease significantly affecting gastrointestinal function.

Specific Aims: Primary: to evaluate progression-free survival (PFS) rate by independent assessment. Secondary: to determine median PFS, overall survival (OS), objective response rates and safety of the combination treatment. Exploratory: to determine median time to new tumor metastasis (TTM), proportion of patients progressing with new metastatic lesions, incidence and severity of peripheral neuropathy, and to evaluate BCSC in metastatic tissue

Statistical Methods: The trial design provides 80% power to detect an increase in 6 month PFS from 30% to 50% with a 2-sided 5% significance level (Chi-square test). Kaplan-Meier curves will be produced for median PFS, OS outcomes and exploratory median TTM. Appropriate descriptive statistics will be provided for safety variables.

Present Accrual and Target Accrual: Target accrual is 190 patients. Patients will be enrolled internationally in US and Europe.

**Title:** DESIREE - A multicenter, randomized, double-blind, phase II study to evaluate the tolerability of an induction dose escalation of everolimus in patients with metastatic breast cancer

Loibl S, Furlanetto J, Barinoff J, Bauerschlag D, Herr D, Lübbe K, Maass N, Müller V, Mundhenke C, Schmidt M, Schwedler K, Thill M, Gkantrigas I, Burchardi N and von Minckwitz G. German Breast Group, Neu-Isenburg, Germany; Sana Klinikum Offenbach, Offenbach, Germany; Agaplesion Markus Krankenhaus, Frankfurt am Main, Germany; Universitätsklinikum Schleswig-Holstein, Kiel, Germany; University Hospital Würzburg, Würzburg, Germany; Diakoniekrankenhaus Henriettenstiftung, Hannover, Germany; University Hospital Hamburg-Eppendorf, Hamburg, Germany; University Hospital Schleswig-Holstein, Kiel, Germany; University Hospital Mainz, Mainz, Germany and Kantonspital Luzern, Luzern, Germany.

**Body:**

**Background:** The BOLERO-2 study demonstrated a relevant benefit for patients who received everolimus in addition to exemestane in patients who progressed during/after a non steroidal aromatase inhibitor (NSAI), which led to approval of everolimus in this indication. However, in routine use a high rate of intolerability due to side effects is reported. The most common side effect of everolimus is mucositis with a reported high rate of intolerability especially during the first 12 weeks of treatment. Mucositis is also considered to be the leading cause for treatment discontinuation not related to tumor progression. In the neoadjuvant GeparQuinto study, a dose-escalation schema was successfully used to improve tolerability of everolimus together with cytotoxic agents.

**Methods:** DESIREE (NCT02387099) is a randomized, double-blind, phase II study of everolimus in addition to exemestane in patients who progressed during or after NSAI. Patients will be randomized in a 1:1 ratio to receive either everolimus 10 mg/day (week 1-3: 4x2.5 mg/day, blinded; week 4-24: 10mg/day, open according to label) or an escalating dose of everolimus as follows: week 1: 1x2.5 mg verum + 3x placebo/day; week 2: 2x2.5 mg verum + 2x placebo/day; week 3: 3x2.5 mg verum + 1x placebo/day; week 4-24: 10 mg/day (open according to label).

The primary aim of the study is to evaluate the incidence of the first episode of mucositis grade 2-4 (WHO's oral toxicity scale) any time during a 12 week period after start of everolimus treatment. Secondary objectives are to compare the cumulative rate of mucositis grade 2-4 at 24 weeks after start of treatment, the cumulative rate of mucositis grade 1 and any grade at 12 and 24 weeks after start of treatment, the rate of patients on 10 mg daily at 12 weeks and 24 weeks after start of treatment, the clinical benefit rate after 24 weeks, safety, time to onset of grade ≥2 mucositis, the cumulative everolimus dose at 4 weeks, the relative dose intensity for everolimus, and quality of life using the FACT-B and the QSDQ questionnaire. Biomaterial (whole blood, serum, plasma and optional primary tumor/metastasis tissue) will be collected to evaluate potential biomarkers predicting safety and compliance. Overall, 156 evaluable patients (78 in each arm) are required to detect a clinically relevant difference of 20% in the mucositis rate between treatment arms using a continuity-corrected χ²-test on a significance two sided level alpha of 0.2 and a power of 90%. The rate was estimated to be 40% and 20% in the control arm and the treatment arm, respectively.

**Results:** The study will be conducted in up to 60 German centers. Recruitment will start in June 2015. Enrollment is planned to be completed within 24 months.

**Conclusion:** The combination of everolimus and exemestane has shown to improve the outcome of patients with metastatic breast cancer. In the DESIREE trial a dose-escalating schema will be employed to enhance patient compliance and tolerability necessary to achieve an adequate dose-intensity.
Title: FAIRLANE: A phase II randomized, double-blind, study of the Akt inhibitor ipatasertib (Ipat, GDC-0068) in combination with paclitaxel (Pac) as neoadjuvant treatment for early stage triple-negative breast cancer (TNBC)

Saura C, Isakoff SJ J, Calvo I, Patt D, Andersen J, Gonzalez-Martin A, Fisher J, Ciruelos E, Gil-Gil M, De la Peña L, Choi Y, Jia S, Singel S, Patel PH H, Baselga J and Oliveira M. Vall d'Hebron Institute of Oncology (VHIO); SOLTI Breast Cancer Research Group; Massachusetts General Hospital Cancer Center; Centro Integral Oncológico Clara Campal; Texas Oncology Center; Compass Oncology; MD Anderson Cancer Center; Carolinas Healthcare System; Hospital Universitario 12 de Octubre; ICO L'Hospitalet, Barcelona; Genentech and Memorial Sloan-Kettering Cancer Center.

Body: Background: TNBC often exhibits activation of PI3K/Akt signaling, associated with loss of PTEN expression, low INPP4B expression, and/or increased AKT3 amplification. Inhibition of the PI3K/Akt pathway in diverse cancers leads to radiosensitization and/or chemosensitization. Ipat is an oral, potent ATP-competitive small molecule inhibitor of all three isoforms of Akt. The combination of Ipat with taxanes in preclinical models resulted in enhanced efficacy relative to either Ipat or chemotherapy alone. In a Phase Ib clinical study, the combination of Ipat with diverse chemotherapy regimens was well-tolerated and resulted in RECIST responses, particularly pts with tumors having PI3K/Akt activation.

Methods: FAIRLANE is a randomized, double-blind, placebo controlled, multicenter, neoadjuvant Phase II study designed to estimate the efficacy of Ipat combined with pac versus placebo combined with pac in women with Stage Ia /Ila TNBC. Approximately 150 pts (Pts) will be enrolled, randomized in a 1:1 ratio, and stratified by PTEN status, node involvement, and tumor size. Pts will receive 3 cycles of Ipat 400 mg or placebo orally once daily on Days 1 to 21 of each 28-day cycle, along with pac 80 mg/m2 every 7 days for a total of 12 doses. All pts will undergo pretreatment and Day 8 tumor tissue acquisition to evaluate pathway biomarkers. Following three cycles of treatment, pts will undergo surgery. The primary efficacy endpoint, pCR within the breast and axilla (ypT0/Tis ypN0) in all pts and in pts with PTEN low tumors, will be assessed by local pathology evaluation following completion of neoadjuvant therapy and surgery. Additional endpoints include objective response rate, safety, BCS rate, pharmacokinetics, and pathway biomarkers. Following surgical resection of primary tumor, pts are expected to continue post-operative treatment with a standard adjuvant chemotherapy regimen at physician's discretion. The study is open for accrual. Clinical trial information: NCT02301988.
Title: A phase I followed by a randomized phase II trial of two cycles carboplatin-olaparib followed by olaparib monotherapy versus capecitabine in BRCA-1 or -2 mutated Her2 negative advanced breast cancer as first line treatment (REVIVAL study)

Body: Background
Preclinical studies revealed that the combination of platinum compounds and olaparib is additive and possibly even synergistic in cell models with BRCA1 or -2 mutations. Early clinical trials suggested high benefit of olaparib with induction carboplatin in BRCA1 and -2 mutation carrier enriched populations. However, there is no evidence yet that carboplatin-olaparib has a superior benefit-risk compared to current standard therapy in advanced breast cancer in BRCA1 and -2 mutation carriers.

Trial design
We initiated a phase-I/II study due to an olaparib formulation change from capsule to tablet. During phase-I a traditional 3+3 dose escalation study is performed. Carboplatin will be dose escalated in 1 step from AUC 3 to AUC 4 with a constant olaparib dose of 25 mg BID. Olaparib is then dose escalated in 3 steps to 50, 75 and 100 mg BID until > 1/6 patients develop a DLT, the previous safe dose-level will be determined the MTD. After the MTD is established a randomised phase-II trial will be initiated where patients are randomised between standard capecitabine 1250 mg/m2 BID day 1-14, q day 22 or 2 cycles carboplatin-olaparib followed by olaparib monotherapy 300mg BID. After progression, patients in the experimental arm receive capecitabine, all other patients receive physicians choice of paclitaxel, vinorelbine or eribulin at standard dose. A compassionate use program with olaparib is available for patients in the standard arm after progression on second line treatment.

Eligibility criteria
In phase-II patients with histological or cytological proof of advanced BRCA1 or -2 mutated HER2 negative breast cancer are eligible if they are ≥18 years, have measurable disease according to RECIST 1.1 criteria, a WHO performance status of 0–2, a life expectancy ≥ 3 months and a negative pregnancy test. Pretreatment should contain an anthracycline and/or taxane in the (neo)adjuvant setting, unless not indicated. In the advanced setting only hormonal pre-treatment is allowed. Minimal laboratory values ANC ≥ 1.5 x 10^9 /L, Hb ≥ 6.2 mM (no transfusions in the last 28 days), platelet count ≥ 100 x 10^9 /L, serum bilirubin ≤ 1.5 x ULN, ASAT and ALAT < 2.5 x ULN and a serum creatinine ≤ 1.5 x ULN or creatinine clearance ≥ 50 mL/min.

Aims
In phase-1 we establish the MTD for treatment in phase-II where we study progression free survival on first line treatment(PFS1) compared with standard of care capecitabine.

Statistical methods
Toxicity analysis in phase-I can take place after all patients completed their 28 day DLT period.
A total of 104 events in 110 patients on first line treatment need to be observed in phase-II to detect a clinical meaningful improvement in median PFS1 in the experimental arm from 4 to 7 months, assuming an accrual of 2 years and a follow-up of ≥6 months, providing a power of 80% (two-sided significance level of 5%). An interim analysis for futility and efficacy will be performed when 52 events have been observed.

Accrual
It is expected that 15-20 patients are needed in phase-I, inclusion is due around November 2015. Phase-II will be multicentre and is expected to start accrual December 2015.
**Title:** Phase III randomized, placebo-controlled clinical trial evaluating the use of adjuvant endocrine therapy +/- one year of everolimus in patients with high-risk, hormone receptor (HR) positive and HER2-negative breast cancer (BC): SWOG/NRG/Alliance S1207 (NCT01674140)

Chavez-MacGregor M, Barlow WE E, Pusztai L, Goetz MP P, Rastogi P, Ganz PA A, Mamounas EP P, Paik S, Bandos H, Gralow J, Lew DL L and Hortobagyi GN N. The University of Texas MD Anderson Cancer Center; Cancer Research and Biostatistics, SWOG Statistical Center; Yale Cancer Center, Yale School of Medicine; Mayo Clinic; NRG Oncology/NSABP and UPMC Cancer Center; UCLA Jonsson Comprehensive Cancer Center; NRG Oncology/NSABP and UF Health Cancer Center; NRG Oncology/NSABP, and the Severance BioMedical Science Institute and Yonsei University College of Medicine; NRG Oncology, and the University of Pittsburgh, Graduate School of Public Health; University of Washington/Seattle Cancer Care Alliance and SWOG Statistical Center.

**Body:** Background: Abnormalities of the PI3kinase/AKT/mTOR signaling network are common in BC. This pathway is associated with resistance to endocrine therapies among HR+ tumors. Everolimus, an mTOR-inhibitor, increases the biological activity of endocrine therapy. S1207 evaluates the role of everolimus in combination with endocrine therapy in the adjuvant setting.

Methods: Specific aims/ design: Randomized phase III double-blinded, placebo-controlled trial. Primary objective is to assess whether the addition of everolimus to standard adjuvant endocrine therapy improves invasive disease-free survival (DFS) among patients with high risk, HR+ BC. Secondary objectives include overall survival, distant recurrence-free survival, safety, adherence and QoL. Patients are randomized to receive standard adjuvant endocrine therapy in combination with one year of everolimus (10 mg PO daily) or placebo. Submission of tissue specimens/blood samples is required for translational studies Eligibility criteria: Patients with histologically confirmed HER2-negative and HR+ invasive BC treated with surgery, adjuvant chemotherapy and radiation therapy (if indicated) are eligible if they have: node-negative disease and tumors >2cm and a recurrence score (RS) >25; 1-3 positive nodes and RS >25 or grade 3 in the absence of RS; >4 positive lymph nodes regardless of RS. Patients >1 positive lymph node after completing neoadjuvant chemotherapy are eligible. Statistics/Target accrual:Parallel randomization design with equal allocation to the two treatment groups, the study will randomize 3,500 patients. All analyses are intent-to-treat with the primary analysis conducted 3 years after the last patient is randomized. The study has 90% power (with 2-sided $\alpha$=0.05) to detect an effective hazard ratio of 0.75 for everolimus versus placebo, corresponding to a gain in DFS of approximately 4.3% at 5 years. All patients will be followed for 10 years. Support: NIH/NCI NCTN Grants CA180888, 180819, 180868, 180821, 180822 189867, and in part by Novartis Clinical trial information: NCT01674140.
Title: MANTA: A randomized phase II study of fulvestrant in combination with the dual mTOR inhibitor AZD2014 or everolimus or fulvestrant alone in estrogen receptor-positive advanced or metastatic breast cancer

Schmid P, Ferreira M, Dubey S, Zaiss M, Harper-Wynne C, Makris A, Brown V, Kristeleit H, Patel G, Perelló A, Jones A, Mithal N, Ruiz I, Kümmel S, Brunt AM, Guerra JA, Gonzalez Cao M, Saura C, Mousa K, Sarker S-J, Coetzee C, Swann R and Cortes J. Queen Mary University London, London, United Kingdom; Instituto Portugues De Oncologia Porto, Porto, Portugal; Derriford Hospital, Plymouth, United Kingdom; Praxis Fuer Interdisziplinaere Onkologie und Haematologie, Freiburg, Germany; Kent Oncology Centre, Maidstone, United Kingdom; Mount Vernon Cancer Centre, Northwood, United Kingdom; Nottingham City Hospital, Nottingham, United Kingdom; Queen Elizabeth Hospital, Woolwich, United Kingdom; Royal Sussex County Hospital, Brighton, United Kingdom; Hospital Son Espases, Palma, Spain; Royal Free Hospital, London, United Kingdom; Kent and Canterbury Hospital, Canterbury, United Kingdom; Hospital Sant Joan de Reus, Tarragona, Spain; Kliniken Essen-Mitte, Essen, Germany; Royal Stoke University Hospital, Stoke-on-Trent, United Kingdom; Hospital Universitario De Fuenlabrada, Madrid, Spain; Instituto Dexeus, Barcelona, Spain and Hospital Universitari Vall d'Hebron, Barcelona, Spain.

Body: Background: Resistance to endocrine therapy remains a major clinical challenge in ER+ breast cancer. Aberrant PI3K/AKT/mTOR pathway activation frequently occurs in ER+ breast cancer and is associated with resistance to endocrine therapy. However, there is increasing evidence that inhibition of only mTORC1 with rapalogues such as everolimus sets off a negative feedback mechanism that leads to increased AKT signalling and is linked with treatment resistance. AZD2014 is a dual inhibitor of both mTORC1 (rapamycin-sensitive) and mTORC2 (rapamycin insensitive); compared to rapalogues, AZD2014 has a broader range of growth inhibitory activity in preclinical models based on a more profound mTORC1 inhibition and the additional inhibition of mTORC2. AZD2014 is especially effective in ER+ breast cancer models, showing superior activity to everolimus both in hormone-sensitive and resistant models.

Trial objectives: The main aims of this trial are (i) to determine whether dual inhibition of mTORC1 and mTORC2 with AZD2014 will increase the activity of endocrine therapy with fulvestrant in ER+ breast cancer, (ii) whether inhibition of mTORC1 and mTORC2 using AZD2014 will have superior anti-tumour activity compared to inhibition of mTORC1 alone with everolimus, and (iii) to compare the safety and efficacy of two schedules of AZD2014.

Methods: MANTA is an international investigator led, sponsored, open-label, randomised phase II trial. Patients are randomised in a 2:3:3:2 ratio to receive either fulvestrant (500mg) alone, fulvestrant and AZD2014 at a continuous daily schedule (50mg BD), fulvestrant and AZD2014 at an intermittent schedule (2 days on, 5 days off; 125mg BD) or fulvestrant and everolimus (10mg OD). Patients are stratified by disease measurability and response to prior endocrine therapy. Treatment is given until disease progression (RECIST 1.1), intolerable toxicity or elective withdrawal.

Eligibility criteria: This study enrols post-menopausal women with ER+, HER2-negative, advanced or metastatic, hormone refractory breast cancer. Patients must have at least one measurable lesion and no life-threatening visceral disease. Patients with significant pulmonary dysfunction, cardiovascular disease or uncontrolled diabetes are excluded. Patients must not have had previous treatment with fulvestrant, PI3K/Akt or mTOR inhibitors or no more than one line of chemotherapy for metastatic breast cancer.

Endpoints: The primary endpoint is progression-free survival . Secondary endpoints include objective response rate, change in tumour size, clinical benefit rate, overall survival, duration of response, patient reported outcomes and pharmacokinetic parameters of AZD2014 and fulvestrant. Archival tumour tissue must be available to evaluate biomarkers associated with therapeutic response and resistance.

Target accrual: Approximately 316 patients will be enrolled at ~90 sites in the UK, Germany, Spain, Portugal, France, Hungary, Romania, Georgia, and South Korea. Recruitment opened in 2014 and 121 patients have been recruited to date. NCT02216786.
Title: A phase II, double blind, randomised, placebo-controlled study of the AKT Inhibitor AZD5363 in combination with paclitaxel in triple-negative advanced or metastatic breast cancer (TNBC)(NCT02423603)

Schmid P, Wheatley D, Baird R, Chan S, Abraham J, Tutt A, Kristeleit H, Patel G, Bathakur U, Bishop J, Harper-Wynne C, Sims E, Copson E, Perren T, Stein R, Poole C, Cartwright H, Sarker S-J, Mousa K and Turner N. Queen Mary University of London, London, United Kingdom; Royal Cornwall Hospital, Truro, Cornwall, United Kingdom; Addenbrookes Hospital, Cambridge, United Kingdom; Nottingham City Hospital, Nottingham, United Kingdom; Velindre Cancer Centre, Cardiff, United Kingdom; Guy's & St Thomas' Hospital, London, United Kingdom; Queen Elizabeth Hospital, London, United Kingdom; The Royal Sussex County Hospital, Brighton, United Kingdom; Yeovil District Hospital, Somerset, United Kingdom; Glan Clwyd Hospital, Denbighshire, United Kingdom; Maidstone Hospital, Kent, United Kingdom; Queens Hospital, Essex, United Kingdom; Southampton General Hospital, Southampton, United Kingdom; St James' University Hospital, Leeds, United Kingdom; University College London Hospitals, London, United Kingdom; University Hospital Coventry, Coventry, United Kingdom and Royal Marsden Hospitals, London, United Kingdom.

Body: Management of metastatic TNBC remains a challenge. Chemotherapy is the mainstay of treatment but benefits are frequently short-lived with rapid development of resistance. The PI3K/AKT/mTOR pathway has been implicated in many ways in TNBC, making inhibition of AKT an attractive therapeutic target. Based on downstream pathway activation signatures, PI3K pathway activation appears higher in TNBC compared to other molecular subtypes, despite a relatively low percentage of activating PI3K mutations. Alternative means of activating the PI3K pathway have been identified in TNBC, including loss or mutation of PTEN (up to 35%) and INPP4B (up to 30%) and/or amplification of PIK3CA, AKT2 or AKT3, resulting in increased activation of AKT. Induction of AKT by chemotherapy can be an early compensatory mechanism that can be exploited therapeutically to increase the efficacy of chemotherapy. Preclinical TNBC models with activated AKT signalling have been shown to be highly sensitive to AKT inhibitors. AZD5363 is a potent pan-AKT inhibitor with good oral bioavailability. Multiple lines of investigation have demonstrated strong synergistic effects between AKT inhibition and taxane chemotherapy in models of TNBC both in vitro and in vivo, providing rationale for the combination of AZD5363 and paclitaxel in TNBC. PAKT is designed to test the hypothesis that inhibition of AKT will increase the anti-tumour activity of paclitaxel chemotherapy in TNBC. The study will try to characterize those patients who may benefit from this treatment to identify potential predictors of sensitivity.

PAKT is an international investigator led and sponsored, double-blind, placebo controlled, randomised phase II trial. Patients are randomised 1:1 to receive paclitaxel weekly (90mg/m²) on days 1, 8, and 15 plus AZD5363 (400mgBD) or placebo (400mgBD) on days 2-5, 9-12, 15-19 (28 day treatment cycles). Patients are stratified by the number of metastatic sites and the interval from the end of adjuvant chemotherapy. Treatment is given until disease progression (RECIST 1.1), intolerable toxicity or elective withdrawal. Tumour assessments are carried out every 8 weeks. PAKT enrols patients with histologically documented locally advanced/metastatic TNBC (ER≤Allred2, PR≤Allred2, HER2=0,1+or2+), no prior systemic therapy for advanced TNBC, ECOG PS 0-2 and measurable disease per RECIST v1.1. Patients with brain metastases, significant cardiovascular disease, motor polyneuropathy are excluded. The primary endpoint is progression-free survival. Secondary endpoints are objective response rate, change in tumour size, clinical benefit rate, overall survival, duration of response, and patient reported outcomes. Archival tumour tissue must be available to evaluate potential biomarkers associated with therapeutic response and resistance. PFS will be compared between treatment arms by the stratified log-rank test. HR for disease progression/death will be estimated using a stratified Cox proportional hazards model. Kaplan-Meier methodology will be used to estimate the median PFS for each arm. Approximately 140 patients will be enrolled at ≈65 sites in the UK, France, Hungary, Romania, Georgia & South Korea.
Title: SANDPIPER: Phase III study of the PI3-kinase inhibitor taselisib (GDC-0032) plus fulvestrant in patients with estrogen receptor-positive, HER2-negative locally advanced or metastatic breast cancer enriched for patients with PIK3CA-mutant tumors

Baselga J, Cortés J, De Laurentiis M, Diéras V, Harbeck N, Hsu J, Jin H, Schimmoller F, Wilson TR R, Im Y-H, Jacot W, Krop IE E and Verma S. Memorial Sloan-Kettering Cancer Center, Memorial Hospital, NY, NY; Vall d'Hebron University Hospital, Barcelona, Spain; Istituto Nazionale Tumori Fondazione G. Pascale, Naples, Italy; Institut Curie, Paris, France; Brustzentrum der Universität München, Munich, Germany; Genentech Inc., South San Francisco, CA; Samsung Medical Center, Seoul, Korea; Institut du Cancer de Montpellier, Montpellier, France; Dana-Farber Cancer Institute, Boston, MA and Division of Medical Oncology, Sunnybrook Odette Cancer Centre, Toronto, ON, Canada.

Body: Background: PIK3CA mutations are one of the most frequent genomic alterations in breast cancer (BC), being present in ~40% of estrogen receptor (ER)-positive, HER2-negative breast tumors. PIK3CA mutations promote growth and proliferation of tumors and mediate resistance to endocrine therapies in BC. Taselisib is a potent and selective PI3-kinase (PI3K) inhibitor that displays greater selectivity for mutant PI3Kα than wild-type PI3Kα. Taselisib has enhanced activity against PIK3CA-mutant BC cell lines, and clinical data include confirmed partial responses in patients with PIK3CA-mutant BC treated with taselisib either as a single agent or in combination with fulvestrant.

Trial design: SANDPIPER is a double-blind, placebo-controlled, randomized, phase III study, designed to evaluate efficacy and safety of taselisib plus fulvestrant in patients with ER-positive, HER2-negative locally advanced or metastatic BC. Patients will be randomized 2:1 to receive either taselisib (4 mg daily) or placebo in combination with fulvestrant (500 mg intramuscular on Days 1 and 15 of Cycle 1, and on Day 1 of each subsequent 28-day cycle). Randomization will be stratified by visceral disease, endocrine sensitivity, and geographical region. The study enriches for patients with PIK3CA-mutant tumors who will be randomized separately from patients with non-mutant tumors.

Eligibility: Postmenopausal women with ER-positive, HER2-negative, locally advanced or metastatic BC are eligible if they have disease recurrence or progression during or after aromatase inhibitor treatment. A valid PIK3CA-mutation result via central assessment is required prior to enrollment.

Aims: The primary efficacy endpoint is investigator-assessed progression-free survival (PFS) in patients with PIK3CA-mutant tumors. Other endpoints include overall survival (OS), objective response rate (ORR), clinical benefit rate (CBR), duration of objective response, safety, pharmacokinetics, and patient-reported outcomes. Efficacy in patients without PIK3CA-mutant tumors will be an exploratory endpoint.

Statistical methods: The primary efficacy analysis population will include all randomized patients with PIK3CA-mutant tumors. Patients will be grouped according to treatment arm assigned at randomization. Median PFS and OS will be estimated using Kaplan-Meier methodology in each treatment arm. Cox proportional-hazards models will be used to estimate the hazard ratio with 95% confidence intervals (CIs). ORR, CBR, and their 95% CIs will be estimated by treatment arms. Duration of objective response will be estimated by treatment arms using the Kaplan-Meier methodology. Quality of life will be analyzed and summarized by treatment arms. Safety will be analyzed for all treated patients according to actual treatment received.

Accrual: Target enrollment is 600 pts from ~165 sites and ~23 countries. The study is open for enrollment and 11 patients have been enrolled as of May 31, 2015. Clinicaltrials.gov ID: NCT02340221.

Contact information: For more information or to refer a patient, email global.rochegenentechtrials@roche.com or call 1-888-662-6728 (USA only).
The METRIC trial: A randomized international study of the antibody-drug conjugate glembatumumab vedotin (GV or CDX-011) in patients with metastatic gpNMB-overexpressing triple-negative breast cancer (TNBC)

Melisko M, Yardley DA, Blackwell K, Forero A, Ma C, Monetero A, Daniel BR, Wright G, Fehrenbacher L, Chew H, Ferrario C, Nanda R, Seller Jr M, Guthrie T, Vance K, Ouellette G, He Y, Bagley RG, Zhang J and Vahdat LT. University of California, San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA; Sarah Cannon Research Institute/Tennessee Oncology, PLLC; Duke University Medical Center; University of Alabama; Washington University; Cleveland Clinic; Chattanooga Oncology Hematology Associates; Florida Cancer Specialists; Kaiser Permanente; University of California Davis Comprehensive Cancer Center; Segal Cancer Center-Jewish General Hospital; University of Chicago; Crescent City Research Consortium, LLC; Baptist Cancer Institute; Alabama Oncology; Celldex Therapeutics, Inc. and Weill Cornell Medical College.

Body: Background
Glycoprotein NMB (gpNMB) is an internalizable transmembrane protein overexpressed in approximately 20% of breast cancer (BC), including approximately 40% of TNBC. gpNMB is a poor prognostic marker in BC (Rose CCR 2010) and preclinically has been implicated in tumor invasion, metastasis, and angiogenesis. GV is a novel antibody-drug conjugate targeting the potent cytotoxin monomethylauristatin E (MMAE) to gpNMB overexpressing cancer cells.

In a Phase I/II study and the Phase II "EMERGE" study, GV demonstrated promising activity with TNBC patients (pts) deriving the greatest benefit and exhibiting the highest degree of gpNMB overexpression. GV was well-tolerated with the most frequent treatment-related toxicities consisting of rash, neutropenia, and neuropathy. In subset analyses of the EMERGE trial, objective response rate (ORR) was 30% (7/23) for GV vs. 9% (1/11) for investigator's choice in tumors with gpNMB overexpression (>25% of tumor epithelium); 18% (5/28) vs. 0% (0/11) in TNBC; and 40% (4/10) vs. 0% (0/6) in gpNMB-overexpressing TNBC for GV and IC respectively, with apparent improvements in progression-free survival (PFS; hazard ratio (HR) = 0.11) and overall survival (OS; HR = 0.14).

Trial design
The METRIC Trial (NCT#01997333) is an international (USA, CA, Aus), two-arm phase II study. Pts are randomized 2:1 to GV (1.88 mg/kg IV q 21 days) or capecitabine, a current standard of care for this population (2,500 mg/m² daily for d1-14, q21 days) until progression or intolerance. Crossover is not permitted.

Eligibility criteria
Key eligibility criteria include: ≥25% of tumor epithelium gpNMB+ by central immunohistochemistry (IHC) screening of archival tissue; estrogen receptor and progesterone receptor <10% and HER2 negative [0-1+ IHC, or ISH copy number <4.0/ratio <2.0] by local assessment; ECOG 0-1; taxane resistance; anthracycline exposure (if indicated); ≤2 chemotherapy regimens for advanced BC; measurable disease; no persistent Grade ≥2 toxicity.

Specific aims
The primary endpoint is PFS per independent, blinded central review committee according to RECIST 1.1. Secondary endpoints are ORR, duration of response, OS, safety, pharmacokinetics and pharmacodynamics. Exploratory endpoints are quality of life and/or cancer-related pain.

Statistical methods and target accrual
The trial has 85% power to detect a PFS HR of 0.64 with two sided α = 0.05. The hypothesized median PFS is 4.0 months for capecitabine and 6.25 months for GV. Target accrual is open for 300 pts.
EMBRACA: A phase 3, open-label, randomized, parallel, 2-arm international study of the oral PARP inhibitor talazoparib (BMN 673) versus physician's choice in BRCA mutation subjects with locally advanced and/or metastatic breast cancer

Litton JK K, Blum JL L, Im Y-H, Martin M, Mina L, Roché H, Visco F, Yang X, Lokker NA A, Lounsbury DL L and Eiermann W. The University of Texas MD Anderson Cancer Center, Houston, TX; Baylor Sammons Cancer Center, Texas Oncology, US Oncology, Dallas, TX; Samsung Medical Center, Seoul, Republic of Korea; Hospital General Universitario Gregorio Marañón, Madrid, Spain; Indiana University School of Medicine, Indianapolis, IN; Institut Universitaire du Cancer Toulouse, Toulouse, France; National Breast Cancer Coalition, Washington, DC; BioMarin Pharmaceutical Inc., Novato, CA and Interdisziplinäres Onkologisches Zentrum München, München, Germany.

Background: Cancer cells with deleterious mutations in breast cancer susceptibility genes 1 and 2 (BRCA1/2) are deficient in the DNA double-strand break repair mechanism, rendering them highly dependent on the single-strand break repair pathway, which is initiated by poly-(ADP-ribose) polymerase (PARP) [1-3]. In cells with deleterious BRCA1/2 mutations, PARP inhibition is synthetically lethal because of accumulation of irreparable DNA damage [1-3]. Talazoparib (BMN 673) exhibits a novel two-pronged approach in treating BRCA1/2-mutant tumors: 1) potent catalytic inhibition of the PARP enzyme; and 2) trapping of PARP at sites of DNA damage [4-7]. The capacity to trap PARP-DNA complexes varies widely across PARP inhibitors and is not correlated with catalytic inhibition potency [4-7]. In preclinical models, trapping PARP on DNA is more potent at inducing cancer cell death than enzymatic inhibition of PARP alone [4,7]. Talazoparib is the most potent clinical-stage PARP inhibitor tested to date with the highest efficacy at trapping PARP-DNA complexes [7]. Talazoparib has shown single-agent antitumor efficacy in several solid tumor types and was generally well tolerated in a phase 1/2 clinical study [8].

Methods: This open-label, randomized, parallel, 2-arm, phase 3 international trial (EMBRACA) compares the safety and efficacy of talazoparib with physician's choice treatment (capecitabine, eribulin, gemcitabine, or vinorelbine) in patients with advanced breast cancer. The primary objective is progression free survival (PFS). Secondary objectives include objective response rate (ORR), overall survival (OS), and safety. Exploratory objectives include duration of response (DOR) for objective responders and health-related quality of life measurements. Subject eligibility includes age ≥ 18 years with histologically/cytologically confirmed breast carcinoma, locally advanced and/or metastatic disease, germline BRCA1/2 mutations, ≤ 2 prior chemotherapy-inclusive regimens for locally advanced and/or metastatic disease, prior treatment with a taxane and/or anthracycline, and Eastern Cooperative Oncology Group (ECOG) performance status ≤ 1. Subjects (n=429) will be randomized 2:1 to receive either talazoparib oral capsules (1 mg/day, 21-day cycles) or physician's choice treatment. This trial is currently enrolling patients from the United States, Asia/Pacific, Europe, Israel, and South America (NCT01945775).

This study is funded by BioMarin Pharmaceutical Inc.

**Title:** ABRAZO: An international phase 2 (2-stage, 2-cohort) study of the oral PARP inhibitor talazoparib (BMN 673) in BRCA mutation subjects with locally advanced and/or metastatic breast cancer

**Body:**

Background: Cancer cells with deleterious mutations in breast cancer susceptibility genes 1 and 2 (BRCA1/2) are deficient in the DNA double-strand break repair mechanism, rendering them highly dependent on the single-strand break repair pathway, which is initiated by poly-(ADP-ribose) polymerase (PARP) [1-3]. In cells with deleterious BRCA1/2 mutations, PARP inhibition is synthetically lethal because of accumulation of irreparable DNA damage [1-3]. Talazoparib (BMN 673) exhibits a novel two-pronged approach in treating BRCA1/2-mutant tumors: 1) potent catalytic inhibition of the PARP enzyme; and 2) trapping of PARP at sites of DNA damage [4-7]. The capacity to trap PARP-DNA complexes varies widely across PARP inhibitors and is not correlated with catalytic inhibition potency [4-7]. In preclinical models, trapping PARP on DNA is more potent at inducing cancer cell death than enzymatic inhibition of PARP alone [4,7]. Talazoparib is the most potent clinical-stage PARP inhibitor tested to date with the highest efficacy at trapping PARP-DNA complexes [7]. Talazoparib has shown single-agent antitumor efficacy in several solid tumor types and was generally well tolerated in a phase 1/2 clinical study [8].

Methods: This 2-stage, 2-cohort, phase 2 international study (ABRAZO) evaluates the safety and efficacy of talazoparib in patients with a deleterious germline BRCA1 or BRCA2 mutation with locally advanced and/or metastatic breast cancer. Eligible subjects will be assigned to one of two cohorts based on prior chemotherapy for metastatic disease. Cohort 1 (n=70) includes patients with a complete response (CR) or partial response (PR) to platinum-containing regimens for metastatic disease. Cohort 2 (n=70) includes patients who have received >2 prior chemotherapy regimens in the metastatic setting but have not had prior platinum therapy for locally advanced or metastatic disease (prior adjuvant or neoadjuvant therapy with a platinum is allowed). The primary objective is objective response rate (ORR). Secondary objectives include clinical benefit response (CBR) rate, duration of response (DOR), progression-free survival (PFS), and overall survival (OS). Health-related quality of life (QoL) assessments are an exploratory objective. Eligible subjects will receive oral talazoparib (1 mg/day, 21-day cycles) until disease progression or unacceptable toxicity. This trial is currently enrolling patients from the United States and Europe (NCT02034916). This study is funded by BioMarin Pharmaceutical Inc.

Title: COLET: A multistage, phase 2 study evaluating the safety and efficacy of cobimetinib in combination with paclitaxel as first-line treatment for patients with metastatic triple-negative breast cancer

Kim S-B, Miles D, Rhee J, Yan Y, Hsu J and Brufsky A. Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; Mount Vernon Cancer Centre, London, United Kingdom; Genentech, Inc., South San Francisco, CA and University of Pittsburgh, Pittsburgh, PA.

Body: Background: Cobimetinib (cobi) is a potent, highly selective inhibitor of MEK that has shown benefit when administered in combination with the BRAF inhibitor vemurafenib in BRAFV600-mutated metastatic melanoma. Preclinical data suggest that up-regulation of the MAPK pathway is a potential resistance mechanism against taxane chemotherapy. Clinically, the combination of MEK inhibition and taxane chemotherapy in non–small cell lung cancer patients (pts) has improved response rate (RR) and progression-free survival (PFS). Because most triple-negative breast cancer (TNBC) pts develop resistance to taxane chemotherapy and because genetic alterations (including mutations and gene amplifications) in the MAPK pathway are present in many TNBC tumors, the combination of taxane chemotherapy and MEK inhibition could be an effective treatment option.

Study design: COLET (WO29497) is a multistage study designed to evaluate the safety of and to estimate the efficacy of cobi /paclitaxel in pts with metastatic or locally advanced TNBC who have not previously received systemic therapy for metastatic disease. The study will be conducted in 2 stages: an initial safety run-in stage of approximately 12 pts, followed by a randomized stage in which approximately 100 pts will be randomly assigned in a 1:1 ratio to receive either cobi + paclitaxel or placebo + paclitaxel. Pts will receive paclitaxel 80 mg/m2 on Days 1, 8, and 15 of each 28-day cycle and cobi/placebo 60 mg/day on Days 3-23 of each 28-day cycle until progression of disease or toxicity occurs.

Key eligibility criteria:

• Metastatic or locally advanced (not amenable to curative resection) TNBC
• No prior systemic therapy for metastatic or unresectable locally advanced TNBC
• Neoadjuvant or adjuvant chemotherapy or radiation therapy is allowed if completed >6 months before the start of study treatment
• Measureable disease using Response Evaluation Criteria In Solid Tumors, version 1.1 (RECIST v1.1)
• History of or active untreated or unstable brain metastases or requiring corticosteroids for brain metastases precludes eligibility
• Left ventricular ejection fraction (LVEF) greater than the institutional lower limit of normal or above 50%

Specific aims of the safety run-in stage: Determine the safety and tolerability of cobi when administered in combination with paclitaxel.

Specific aims of the randomized stage: Investigator-assessed PFS (primary end point); safety; pharmacokinetics; the effect of intrinsic subtypes and genetic alterations in PFS; mechanisms of resistance; and health-related quality of life.

Statistical methods: In the randomized stage, pts will be followed up until a total of 60 PFS events occur across the 2 arms. This provides 77% power to detect a hazard ratio of 0.5 at a two-sided significance level of 0.05.

Contact information: Registered with ClinicalTrials.gov, identifier NCT02322814. For more information, please contact Roche/Genentech trials, 888-662-6728 (US only) or reference study ID WO29479 at www.roche.com/about_roche/roche_worldwide.htm.
Title: Design of a phase 1b/2 study to evaluate the efficacy and safety of eribulin mesylate in combination with pembrolizumab in patients with metastatic triple-negative breast cancer

Body: Eribulin mesylate, a microtubule inhibitor, is indicated for treatment of patients (pts) with metastatic breast cancer (MBC) with ≥2 prior chemotherapies for metastatic disease, including an anthracycline or taxane. Pembrolizumab is a human programmed death receptor-1 (PD-1)-blocking antibody indicated for treatment of pts with unresectable or metastatic melanoma and disease progression following ipilimumab and, if BRAFV600-mutation positive, a BRAF inhibitor. Pembrolizumab is also being evaluated for treatment of metastatic triple-negative breast cancer (mTNBC) and multiple tumor types. We report the design of an open-label, single-arm, multicenter, phase 1b/2 study to evaluate safety and efficacy of the eribulin and pembrolizumab combination in pts with mTNBC previously treated with 0 to 2 lines of therapy in the metastatic setting.

From August 2015 to February 2017, approximately 95 pts (aged ≥18 yrs) will be enrolled (n=12 phase 1b; n=83 phase 2) to reach 80 evaluable pts. Accrual has not yet commenced. Pts with measurable disease of ≥1 lesion >10 mm in long-axis diameter (nonlymph nodes) or >15 mm in short-axis diameter (lymph nodes) and an ECOG status of 0 or 1 will be included. Exclusion criteria include pts who received adjuvant chemotherapy within the past 6 months, chemotherapy/biological therapy within the past 3 wks, or radiation or small molecule targeted therapy within the past 2 wks. Pts will also be excluded if they have an autoimmune disease requiring immunosuppression or were previously treated with eribulin or any anti-PD-1, PD-ligand (L) 1, or PD-L2 agent.

Phase 1b includes a safety run-in cohort in which ≥6 pts will receive intravenous (IV) eribulin 1.4 mg/m2 (equivalent to 1.23 mg/m2 eribulin [expressed as free base]) on day (d) 1 and d8 and IV pembrolizumab 200 mg on d1 of a 21d cycle. Dose-limiting toxicity (DLT) will be assessed in the first cycle. This dose will be selected as the recommended phase 2 dose (RP2D) if ≤1 pt has a DLT or, if necessary, alternative doses may be explored. Pts will be stratified by prior chemotherapy for MBC (0, ∼70%; 1–2, ∼30%) and will receive RP2D combination treatment. Pts can remain on 1 or both study drugs with clinical benefit until intercurrent illness, unacceptable toxicity, or disease progression. Bayesian predictive probability of response rate, based on the goal of claiming combination superiority at study end, will be used to monitor response rate after postbaseline tumor assessments for ≥38 pts. The study can be stopped early for efficacy or futility.

Primary objectives include determination of safety and tolerability (phase 1b) and evaluation of objective response rate of the drug combination; secondary endpoints include evaluation of progression-free survival (PFS), overall survival (OS), and duration of response (DOR). PFS, OS, and DOR will be analyzed using Kaplan–Meier product-limit estimates. Median PFS, OS, and cumulative probability of PFS, OS, and DOR at 6 and 12 months will be presented with 2-sided 95% confidence intervals. Relationship between PD-L1 tumor status and efficacy endpoints will also be evaluated.

For further information please contact Erhan Berrak (erhan_berrak@eisai.com).
Title: A phase 2 study of pembrolizumab (MK-3475) monotherapy for metastatic triple-negative breast cancer (mTNBC): KEYNOTE-086

Body: Background: TNBC is defined by a lack of ER and PR expression and the absence of HER2 overexpression. As such, the only approved systemic treatment option approved for mTNBC is chemotherapy, which is associated with median survival of <1 year. The programmed death receptor 1 (PD-1) pathway is frequently altered in cancer and used by tumors to evade an immune response. Pembrolizumab, an anti–PD-1 monoclonal antibody that prevents PD-1 from binding to its ligands, PD-L1 and PD-L2, has shown durable antitumor activity and a manageable toxicity profile in many advanced cancers, including mTNBC. In the phase 1b KEYNOTE-012 study, pembrolizumab 10 mg/kg given every 2 weeks (Q2W) provided an ORR of 18.5% and a 6-month PFS rate of 24.4% (RECIST v1.1, central review) in a cohort of 32 heavily pretreated patients with PD-L1–positive mTNBC.

Trial Design: KEYNOTE-086 is a 2-part, multicohort, nonrandomized, phase 2 trial of pembrolizumab monotherapy for women and men with mTNBC (ClinicalTrials.gov, NCT02447003). Key eligibility for all cohorts include age ≥18 years, centrally determined mTNBC, ECOG PS 0 or 1, measurable disease per RECIST v1.1 by central review, and provision of a tumor sample for assessment of ER, PR, HER2, and PD-L1 status at a central laboratory. PD-L1 expression will be assessed by immunohistochemistry using the 22C3 antibody (Merck), with positivity defined as PD-L1 expression in the stroma or in ≥1% of tumor cells. Part 1 includes 2 cohorts that will enroll simultaneously. In cohort A, up to 160 pts with any PD-L1 status who have received ≥1 systemic treatment for metastatic breast cancer, were treated with an anthracycline and a taxane in the (neo)adjuvant and/or metastatic setting, and had documented disease progression on their most recent therapy will be enrolled. In cohort B, up to 40 pts with PD-L1–positive tumors who have received no prior systemic therapy for metastatic breast cancer will be enrolled. Part 2 is an expansion cohort of cohort A that will enroll up to 45 pts with tumors strongly positive for PD-L1 expression; part 2 will be initiated only if ≥1 response is observed in the cohort A PD-L1-strong-positive population. The definition of strongly positive PD-L1 expression will be determined in part 1. In all cohorts, pts will receive pembrolizumab 200 mg Q3W for 24 mo or until disease progression, intolerable toxicity, or patient or investigator decision. Clinically stable pts may continue pembrolizumab beyond initial RECIST-defined progression. Response will be assessed per RECIST v1.1 by central review every 9 wk for the first 12 mo and every 12 wk thereafter. AEs will be monitored throughout treatment and for 30 days thereafter (90 days for serious AEs and events of clinical interest). Primary end point is ORR. Secondary end points include duration of response (DOR), disease control rate, PFS, and OS. Efficacy and safety will be evaluated in all patients who receive ≥1 pembrolizumab dose. The Kaplan-Meier method will be used to estimate DOR, PFS, and OS.

Current Status: Enrollment in KEYNOTE-086 will begin in June 2015 and continue until up to 245 patients are accrued. For additional information on KEYNOTE-086, contact MerckClinTrialfSupport@merck.com.
Title: PALLAS: PAlbociclib Collaborative Adjuvant Study: A randomized phase 3 trial of palbociclib with adjuvant endocrine therapy versus endocrine therapy alone for HR+/HER2- early breast cancer

Mayer E, DeMichele A, Dubsky P, Barry W, Metzger O, Symmans WF, Burstein H, Miller K, Wolff A, Rastogi P, Loibl S, von Minckwitz G, Goulioti T, Zardavas D, Fesl C, Koehler M, Huang Bartlett C, Chen L, Piccart M, Winer E and Gnant M. Dana-Farber Cancer Institute, Boston, MA; Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA; Alliance for Clinical Trials in Oncology Foundation, Chicago, IL; PrECOG, Philadelphia, PA; Austrian Breast and Colorectal Cancer Study Group, Vienna, Austria; MD Anderson Cancer Center, Houston, TX; Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD; Simon Cancer Center, Indiana University, Indianapolis, IN; University of Pittsburgh Medical Center, Pittsburgh, PA; NSABP Foundation, Pittsburgh, PA; German Breast Group, Neu-Isenburg, Germany; Pfizer, Inc, NY, NY; Breast International Group, Brussels, Belgium and Institute Jules Bordet, Brussels, Belgium.

Body: Background:
Cell cycle inhibition is a target of interest for novel cancer therapeutics. Palbociclib (P) is an orally active inhibitor of CDK4/6 which arrests the cell cycle at the G1-S transition. P has demonstrated efficacy in phase II and III randomized trials for first-line and pre-treated hormone receptor positive/HER2 negative (HR+/HER2-) metastatic breast cancer (MBC), with hazard ratios 0.42-0.49 (Finn et al, Lancet Oncol 2015, Turner et al, NEJM 2015), and is approved in combination with letrozole as first-line therapy for HR+/HER2- MBC. Given confirmed benefits of P and endocrine therapy for MBC, the PALLAS study was designed to determine if the addition of P to adjuvant endocrine therapy (ET) improves outcomes over ET alone in HR+/HER2- early breast cancer.

Trial Design: PALLAS is an international open label phase III trial randomizing patients to 2 years of P (125 mg daily, 21 days on 7 days off in a 28-day cycle) combined with at least 5 years of provider choice ET (AI, tamoxifen, +/- LHRH agonist), versus ET alone. The primary objective of the study is to compare invasive disease-free survival (iDFS) for the combination of P and ET versus ET alone. Secondary objectives include comparing iDFS excluding cancer of non-breast origin, DRFS, LRRFS, OS, as well as safety. The principal translational science objective is to determine the predictive or prognostic utility of defined genomic subgroups with respect to iDFS and OS. Additional translation objectives include evaluation of tissue and blood biomarkers predictive of benefit or resistance, cfDNA, pharmacogenomics, adherence, BMI, and patient-reported QOL. Eligible patients (pts) may be pre- or post-menopausal, have stage II-III breast cancer, HR+/HER2- by ASCO CAP guidelines, and have recovered from prior therapies. Pts may have already initiated ET, but randomization must occur within 12 months of diagnosis and 6 months of initiation of ET. An FFPE block must be received at the central sample repository for eligibility. Total planned accrual to the trial is 4600 pts, providing 85% power to detect a 25% risk reduction in iDFS from ET alone using a stratified logrank test with an overall one-sided alpha = 0.025. Pts will be randomized 1:1 stratified by stage, receipt of prior chemotherapy, age, and geographic location. Interim analyses for safety, futility/efficacy and sample size re-estimation are planned. PALLAS will open in 9/2015; current accrual will be updated at time of presentation.
Title: Analytical validation of a standardized scoring protocol for Ki67: Phase-3 of an international multicenter collaboration

Body: Aims: (i) To determine if between-pathologist agreement for Ki67 is adequate for clinical application, following a standardised scoring protocol. (ii) To compare between-pathologist agreement of scoring hot-spots vs a global method averaging Ki67 across each section.

Background: The nuclear proliferation biomarker Ki67 has multiple potential roles in breast cancer, including aiding decisions based on prognosis, but has unacceptable between-laboratory variability. The International Ki67 Working Group has undertaken a systematic program to determine whether Ki67 measurement can be analytically validated and standardized across labs. In phase 1 variability in visual interpretation was the most important source of variability. Phase 2 showed that significant improvements in agreement could be achieved when scoring the same tumors on tissue microarrays by following clearly defined scoring methods. We now assess whether acceptable performance can be achieved on core-cut biopsies using a standardised method.

Methods: Three adjacent sections from each of 30 primary ER+ breast cancers were centrally stained for Ki67 to assemble three sets of 30 stained tumor sections, circulated around 22 laboratories in 11 countries. Ki67 was scored by 2 methods by all labs: (a) global: 4 fields of 100 cells each were selected to represent any heterogeneity (b) hotspot: the field with highest Ki67 staining percentage was selected and 500 cells scored. Ki67 scores were log2-transformed for statistical analyses and back-transformed for presentation. The primary objective was to assess if either method could achieve an intraclass correlation coefficient (ICC) significantly greater than 0.8, considered substantial to almost-perfect agreement. Secondary objectives were to assess which method had highest observed ICC and to assess whether pathologists identified the same “hotspots”.

Results: The ICC for the global method was 0.88 (95%CI: 0.81-0.93) and therefore met the prespecified success criterion. The ICC for the hotspot method was 0.84 (95%CI: 0.77-0.92) and therefore had a CI which extended below the success criterion. Across the 22 labs, geometric mean value of the 30 scores ranged from 14.4 to 27.9 for the global method and from 17.4 to 40.2 for the hotspot method. The overall mean (95% CI) of these values was 19.8 (18.5-21.3) and 26.4 (24.6-28.3), respectively. Visually, there was moderately strong agreement in location of selected hotspot in the core-cuts across laboratories. The impact of variability of the Ki67 scores for estimating prognosis using the integrated IHC4 + clinical treatment score will be assessed. After selection of the areas to score, the median times for cell counting were 3 and 4 minutes for the global and hotspot methods, respectively.

Conclusions: The global method met the prespecified criterion of success; it should now be evaluated for clinical validity in appropriate cohorts of samples. The hotspot method showed slightly less agreement between labs. The time taken for scoring is practical using counting software we are making publicly available. Establishment of external quality assessment schemes is
likely to improve the agreement between labs further.
(Supported by a grant from the Breast Cancer Research Foundation).
Title: Ki-67 proliferation index supported by digital quantitation in breast cancer: A comparative study

Body: Introduction: In cases of breast cancer, in addition to hormone receptor and Her2 status, proliferation markers (mitotic index, Ki-67 proliferation index = KIPI) also have therapeutic implications. The 2013 St. Gallen consensus guideline includes 14% cut-off point (20% by many experts) for KIPI to distinguish luminal A-like and luminal B-like subtypes, that might be associated with remarkable intra-/interobserver variability applied in daily pathological routine utilizing semiquantitative (SQ) "eye-balling" method.

Objective: The comparison of conventional SQ method and digital image-analysis (DIA) processes for the detection of KIPI.

Methods: Three hundred and forty-seven breast cancer patients' samples with 99.24 months median follow-up data were included in our study (ethical approval: IKEB #7/2008 and 7-1/2008). Tissue microarrays (TMA) were prepared from the representative paraffin-embedded tumor blocks. After performing Ki-67 (MIB1 clone, #0505 by iOT on Ventana Benchmark XT autostainer by Roche) immunoreaction, conventional evaluation of KIPI was performed by 3 breast pathologists independently (SQ1-3). Digital image analysis was supported by PatternQuant (Pannoramic Viewer v15.3 and QuantCenter 2.0, 3DHistech Ltd.) applying a fully automatic tumor tissue recognition module with KIPI detection (DIA-1), and an adjustable module (DIA-2) with the possibility of manual corrections to exclude false detections. Interobserver variability was estimated with intra-class correlation coefficient (ICC). Digital pathological methods were compared to the - currently gold standard - SQ determination of KIPI using SPSS 22 statistical program.

Results: The three pathologists' SQ evaluations demonstrated a remarkable concordance (ICC=0.889; 95% CI= 0.834-0.922). A reference KIPI value (KIPI-RV) was derived from mean values of SQ2 and SQ3, since no significant difference was found between them (p=0.617). KIPI-RV and DIA-2 showed no significant difference (p=0.754), and excellent concordance (ICC=0.979; 95% CI=0.975-0.982). Significant difference has occurred between KIPI-RV and results of DIA-1 (p=0.001). Upon dichotomizing KIPI value at 14%, no significant difference was found between KIPI-RV and DIA-2 (p=0.262), while KIPI-RV and DIA-1 differed (p=0.006). For prognosis prediction, all three methods were able to perform statistically significant division of our patients into 2 cohorts with distinct DFS at 14% (p<0.017-0.038). At 20% threshold of KIPI, DIA-1 failed (p=0.053), while KIPI-RV and DIA-2 were able to separate good and unfavorable prognosis patients' cohorts (p=0.01; p=0.004).

Conclusion: The DIA processes are objective methods in the evaluation of KIPI. The fully automated DIA-1 method differed most from SQ results. Digital image analysis adjusted by a pathologist (our DIA-2 method) reached high concordance with results of SQ. Further refinement and validation are needed to verify applicability of automatic tumor pattern recognition software in diagnostic practice. Our results confirm that SQ evaluation of KIPI is reliable.

Title: Variability of Ki67 labeling index depending on different measurements in luminal type breast cancers

Kim S, Moon B-I and Sung SH. Ewha Womans University School of Medicine, Seoul, Korea; Ewha Womans University School of Medicine, Seoul and Ewha Womans University School of Medicine, Seoul, Korea.

Body: Background: Hormone receptor-positive and HER2-negative breast cancers are divided into luminal A (LA) and luminal B (LB) types using a cutoff of 14% Ki67 labeling index (LI). LB type breast cancer is associated with poor prognosis compared with LA, and considered as an indication of adjuvant chemotherapy. The main obstacles in classification of luminal type breast cancers are non-standardized measurement and Ki67 heterogeneity. We aimed to assess Ki67 variability depending on different methods of measurement and spot selection, and to assess Ki67 heterogeneity in luminal type breast cancers.

Design: We retrospectively retrieved 174 Ki67 stained slides of surgically excised invasive breast cancers with ER+ and/or PR+, HER2-, and Ki67 LI of 10-20% range. On each slide, 3 spots of low, intermediate, and high Ki67 labeling densities were captured via camera snapshot. And then, Ki67 LI was measured by digital image analysis (DIA) and manual count (MC) on 3 captured spots. Each case was classified into LA and LB types based on Ki67 LI measured by 4 methods; hot spot index by DIA; average index by DIA; hot spot index by MC; average index by MC. Ki67 heterogeneity was defined by the tumor with Ki67 KI <5% in low labeled spot, and ≥14% in high labeled spot by DIA. Correlation between the Ki67 heterogeneity and pathological parameters were analyzed.

Result: Ki67 LI measured by DIA was higher than by MC in 3 spots (low: 4.95 vs. 3.39, p<0.001; intermediate: 10.07 vs.9.26, p=0.058; high: 14.88 vs. 14.03, p=0.025) with the biggest difference in low labeled spot. The 4 methods showed poor agreement on classification of LA/LB types. The proportion of LB type ranged from 3.4% to 60.9% depending on methods.

</table>
Conclusion: Ki67 LI is markedly variable depending on different measurements and spot selections. Ki67 heterogeneity exists in 24.1% of luminal breast cancers in this series. Therefore, whole section slides should be preferred for Ki67 LI measurement, rather than tissue microarray or biopsy specimen which may not entirely reflect the proliferation index of the tumor.

Title: Early stage breast cancer prognostication using whole tumor or Ki67 heterogeneity-based digital imaging

Barnes M, Srinivas C, Xu C, Dean S, Singh S, Henricksen LA, Wik N, Morris D, Magliocco A and LaFleur B. Roche Diagnostics, Mountain View, CA; Tom Baker Cancer Centre, Calgary, AB, Canada and Moffitt Cancer Center, Tampa, FL.

Body: Introduction:
Accurate prognosis of hormone-positive early stage breast cancer patients offers the opportunity to make more informed follow-up choices, for example the addition of adjuvant chemotherapy. More recently patient prognostication based on immunohistochemistry-scored protein expression (ER, PR, Her2 and Ki67) in the ATAC trial has been described as IHC4 (C-index of 0.78). However, IHC4 clinical translation has not occurred and may be hindered by the need for a clinically-validated standardized assay as well as pathologist scoring reproducibility. To address this idea, we employed a standardized assay system and automated scoring using digital image analysis to assess either whole tumor (WT) IHC expression values or Ki67 heterogeneity (Ki67H) quantification. The goals were to 1) establish a prognostic model based on and potentially improving the IHC4 concept and 2) improve pathologist scoring reproducibility.

Material and Methods:
A paraffin-embedded whole tissue cohort consisting of 120 cases of hormone-positive, HER2-negative, stage I and II, breast cancer patient samples were re-stained with standardized ER, PR, HER2, and Ki67 IHC assays. Three pathologists independently scored conventional glass slides microscopically (CM) and annotated WT on H&E and Ki67 heterogeneous regions on whole slide scanned images (WSI) for each case separately. The annotations were separately registered across serial stained slides and also scored via the digital pathology algorithm.

Results:
The mean patient age at the time of diagnosis is 63 years with a maximum follow-up of 18 years. Patients with regional and/or distal recurrence compose 26% of the cohort with a median recurrence free survival of 8.5 years. Clinical variables (CV) plus WT (C-index 0.74, r² 0.38) or Ki67H (C-index 0.77, r² 0.39) models improved on patient prognostication each as compared to the IHC4 plus CV (C-index 0.70, r² 0.19) in this cohort. High inter-pathologist reproducibility for the IHC score, as measured by concordance correlation coefficient was noted for Ki67H (0.90).

Conclusions:
Novel algorithmic scoring methodologies such as WT and Ki67H may improve on the IHC4 concept with high inter-pathology reproducibility. We are currently validating in a larger 600 patient cohort.
Agreement rates of pathologist-derived manual and digital read and image analysis quantitation for membrane and nuclear-based immunohistochemistry biomarkers in breast cancer clinical studies

Body: Introduction: Over the past 18 years, pathologists have had an increasing responsibility of quantitating immunohistochemistry (IHC) markers with the expectation of high intra- and inter-reader reproducibility. These markers are related to treatment prediction or patient prognosis and are predominately represented by estrogen receptor (ER), progesterone receptor (PR), human epithelial growth factor receptor 2 (HER2), and Ki-67. Many agencies have instituted quality programs to increase these metrics with dramatic effect; however, improvement is still needed. Digital imaging-based quantitation of IHC offers the potential for increasing intra- and inter-reader reproducibility. In this study, we culminate digital and imaging analysis data across multiple regulatory submissions to understand intra- and inter-reproducibility metrics in the context of five breast cancer biomarkers.

Materials and Methods: For each IHC marker (ER, PR, HER2, Ki-67, and p53), 120 invasive whole tissue breast cancer cases were included from retrospective clinical archives and restained. Cases were represented by binning into three IHC staining categories (ER, PR, Ki-67, and p53: 0 to 0.99%, 1 to <10%, and >=10%; HER2: 0/1+, 2+, 3+) representing 33% of samples for each binned category. Three pathologists (9 total) scored each case per marker as positive/negative around a cut-point (ER and PR: 1%; Ki-67 and p53: 10%, and HER2: 2+) utilizing three scoring modes (manual read [MR], digital read [DR], and imaging analysis [IA]) with a 1-2 week washout. Primary end-point of DR and IA was non-inferiority to MR. Statistical analyses were performed using pair-wise analyses of MR vs DR or IA.

Results: IA inter-reader reproducibility overall percent agreements (OPA) were at least similar to manual read OPAs for ER, PR, HER2, and Ki-67. HER2 IA OPA showed an improvement over MR. DR inter-reader reproducibility OPAs were similar to manual reads for ER, PR, HER2, and p53. Ki-67 DR inter-reader reproducibility underperformed MR (Table 1). Intra-reader reproducibility OPAs across scoring modalities with respect to any single scorer were similar for ER, PR, HER2 and Ki-67 (>88% 95%CI 81.3-99.1%), while p53 was lower (82.9% 95%CI 75.1-91.6%).

Table 1: Inter-reader reproducibility OPAs across MR, DR, and IA for each breast cancer marker

Conclusions: Overall, DR and IA IHC-based quantitation across these biomarkers showed at least similar results to MR. Some markers over or underperform from this MR baseline most likely related to analysis approach and/or marker heterogeneity.
Title: Digital image analysis outperforms manual scoring for breast cancer subclassification and prognostication

Stålhammar G, Rosin G, Kis L, Lippert M, Moelholm I, Grunkin M, Bergh J and Hartman J. Karolinska Institutet, Stockholm, Sweden; St. Erik Eye Hospital, Stockholm, Sweden; Karolinska University Hospital, Stockholm, Sweden; Visiopharm A/S, Hoersholm, Denmark; Cancer Center Karolinska, Stockholm, Sweden and Karolinska University Hospital, Stockholm, Sweden.

Body: Introduction
Categorization according to the four gene expression-based 'intrinsic' subtypes "Luminal A", "Luminal B", "HER2-enriched" and "Basal-like" is the method of choice for practical prognostic and predictive value in the heterogeneous spectrum of Breast Cancers. Gene expression tests are however not yet universally available, which has created an opportunity for routine immunohistochemical stains to act as surrogate markers (biomarkers) for the gene expression-based subtypes. As recommended by international expert consensus, the expressions of Estrogen receptor α (ER), Progesterone receptor (PR), Human Epidermal Growth factor Receptor 2 (HER2) and the proliferation-associated protein Ki67 are scored during the routine pathological work-up of breast cancer specimens. Thus, congruence of these biomarker tests to the gene expression tests are of utmost importance as discrepancies in classification induces dissimilar treatment decisions. In this study, we compare a novel system for Digital Image Analysis (DIA) with the manual scoring of biomarkers used in current clinicopathological routine and suggest methods to improve their congruence to gene expression assays, provide more robust prognoses for survival as well as reduce time consumption for pathologists.

Methods
1 tissue micro array (TMA) cohort and 2 cohorts of primary breast cancer specimens (total n = 436) with >20 years survival data, were sectioned into physical glass slides and digitally scanned at ×20 and then reviewed for manual vs. DIA test congruence to PAM50 gene expression assays in terms of classification into the four intrinsic subtypes, and their prognostic power. This included the evaluation of 6 different methods for DIA biomarker testing. The DIA system used was the Visiopharm Integrator System (VIS) by Visiopharm A/S, Hoersholm, Denmark. In short, this system facilitates ER, PR and Ki67-testing by a 'sandwich' technology, in which each biomarker slide is aligned with an adjacent 3 µm slide stained with a pancytokeratin marker. Thus, non-tumor tissue is to a large extent automatically excluded from analysis and only cells that express cytokeratin are eligible for automatic detection of positivity or negativity of the respective biomarker.

Results
60.8 % of the cases in the TMA cohort was classified in concordance with PAM50 (κ = 0.46) using DIA. Classification with regard to HER2-enriched, Basal-like and Luminal tumors without dichotomization of A and B subtype (thereby avoiding the impact of Ki67-scoring) was 80.9 % (κ = 0.63). In the whole slide cohorts, DIA performed with 95 % of the cases classified in concordance with PAM50 (κ = 0.90), compared to 67 % (κ = 0.59) for the manual method recommended by international consensus. In addition to this DIA produced better prognostication vs. the manual method in terms of hazard of all-cause death for each subtype.

Conclusion
The system for DIA evaluated here outperforms manual scoring in both predictive and prognostic value. It also has the potential to reduce time consumption for pathologists, as many of the steps in the workflow is either automatic or feasible to manage without pathological expertise. Based on the findings in this study however, TMA cannot be recommended for DIA scoring of Ki67.
Title: Distribution pattern of Ki67 immunoreactivity in ductal intraepithelial neoplasia (DIN): Correlation with lesion grade and potential utility

Ozerdem U and Tavassoli FA A. Yale University School of Medicine, New Haven, CT.

Body: INTRODUCTION: Ki67 labeling index has been proposed as an independent predictive and prognostic factor in patients with ductal intraepithelial neoplasia (DIN). Ki-67 labeling index of 14% has been suggested as a useful cut-off for stratifying DIN patients for adjuvant radiotherapy and hormonal therapy. No data is available regarding either the distribution pattern of Ki67 immunoreactivity within the ducts involved by DIN or potential correlation of these patterns with lesion grade. In this study, the pattern of distribution of the nuclei immunoreactive with Ki67 was examined in DIN1C (DCIS, grade 1), DIN2 (DCIS, grade 2), and DIN3 (DCIS, grade 3) to determine if distinctive patterns could be identified and if these patterns would correlate with lesion grade.

METHODS: 47 consecutive DIN cases were retrieved from our departmental files. Of these, 5 qualified as DIN1C, 28 as DIN2 and 14 as DIN3. H&E and Ki67 immunostains were evaluated on each case to elucidate the distribution of Ki67 positive proliferating epithelial cells within the ducts. The DIN cases were evaluated and the patterns of distribution recorded for each case as either basal or haphazard within the epithelial proliferation. Statistical analysis was performed using Chi-square test with Graphpad PRISM statistical analysis software.

RESULTS: There was a statistically significant difference between the 3 groups in terms of basal vs haphazard Ki67 immunostaining (Chi –square test, P=0.0001). Basal staining pattern was dominant (100%) among the DIN1c cases, while haphazard staining pattern was the dominant (100%) distribution among the DIN3 cases. One half of the DIN2 cases showed basal staining pattern, while the other half showed a haphazard staining pattern. This feature could be useful in separating DIN lesions into low grade and high grade eliminating grade 2. We also quantified necrosis on a scale of 0 to 2; 0 indicating absence of necrosis and 2 reflecting comedo type necrosis. Necrosis was more common in the ducts with haphazard Ki67 distribution. The extent of necrosis varied significantly between DIN1c, DIN2 and DIN3 (Chi –square test, P<0.0001) CONCLUSIONS: Two distinct patterns of Ki67 immunoreactivity are seen in DIN lesions; the basal pattern is characteristic of DIN1 (low grade DIN), whereas a haphazard pattern is dominant in DIN3 (high grade DIN). These patterns could be used to divide grade 2 DIN into low grade and high grade. This approach is easier and potentially more reproducible than counting the percentage of Ki67 positive cells. The information could be useful from a prognostic standpoint and may well be predictive of potential response to radiation, hormonal and targeted therapies.
Title: An impending avalanche-breast cancer among women ≥ 90 years of age

Ozerdem U and Tavassoli FA A. Yale University School of Medicine, New Haven, CT.

Body: INTRODUCTION: Pubmed database shows no study on pathological features of breast carcinoma in extremely old women (≥90 years). The data post 1980s is limited due to the definition of such age limit as "older than 75". This study redefines age extreme in breast pathology to better correlate with current patient demographics, and provides characteristics of breast cancer in this population. Little information exists about the breast cancer in extremely old women. This investigation elucidates the growing number of breast cancer diagnoses in extremely old women (≥90 years) in a single institution in 2000s.

MATERIALS AND METHODS: The database of Yale University Department of Pathology was searched for the terms: "breast carcinoma," "age ≥90" for the past 15 years. Clinicopathologic features of the cases that fit the criteria were studied.

RESULTS: A total of 135 patients (134 female; 1 male) aged ≥90 years were identified with a diagnosis of infiltrating carcinoma. A surge in breast cancer diagnoses among elderly patients was noted in 2000s compared to the earlier decade. Only 10 cases were diagnosed between 1990 and 1999 (one case/year) compared to 125 cases diagnosed between 2000 and 2015 (8.3 cases/year). Of these 135 patients, 117 had infiltrating ductal carcinoma (IDC); 16 had infiltrating lobular carcinoma (ILC),1 had pure squamous cell carcinoma. One patient had IDC and ILC ipsilaterally, while another had bilateral IDC. The median age was 92 (range: 90-107), median tumor size was 2.0 cm (range: 0.2-13.0), and the median modified Bloom & Richardson score was 6 (range: 3-9). Among the 117 IDCs, 11 had mucinous, 6 had apocrine, 1 had medullary, 1 had cribriform differentiation. Ductal intraepithelial neoplasia (DCIS) was present in 46% of the cases, while lobular intraepithelial neoplasia (LCIS) was identified in 8% of the cases.

CONCLUSIONS: Our data shows an increasing number of breast carcinomas diagnosed among patients ≥90 years of age with a morphological distribution similar to other age groups. This increased frequency is particularly notable in the last 15 years compared to 1990s. While increased life expectancy is a factor, better delivery of screening to elderly patients and patient awareness are important additional contributors to this increase. Extremely old women particularly those in good health may potentially benefit from breast cancer screening. As the number of substantially older patients with breast cancer increases, we have to be prepared to manage the disease in this population. Further studies are warranted to elucidate the frequency of breast cancer in extremely old women and the optimal management that would probably have to be individualized to the patients' health status.
Title: Ductal carcinoma in situ: A comparative study between histopathological characteristics and imaging findings

Tang X, Yamashita T, Kumaki N, Tokuda Y and Masuda S. Nihon-University School of Medicine, Tokyo, Japan; Tokai University, School of Medicine, Isehara, Kanagawa, Japan; Tokai University School of Medicine, Isehara, Kanagawa, Japan and Tokai University School of Medicine, Isehara, Kanagawa, Japan.

Body: Background: The treatment policy for ductal cancer in situ (DCIS) of the breast greatly depends on the spreading diagnosis. However, a problem is that we cannot compare imaging findings with the histopathology of DCIS. The purpose of this study was to investigate the histopathological characteristics of DCIS and the association with imaging findings.

Methods: Subjects were 128 patients from Tokai University Hospital, diagnosed with DCIS. A positive finding on ultrasonography (USG) was defined as Breast Imaging Reporting and Data System (BI-RADS) of US category 3 or above, in mammography (MMG) it was Japan Breast Cancer Society category 2 or above, and in MRI it was BI-RADS-MRI category 3 or above. Histopathologically, we re-classified DCIS into 3 subtypes.

</tbody>
</table>

The microscopic examination items included the nuclear grade, necrosis and calcification, stromal reactions surrounding DCIS, distribution of DCIS, and with or without adenosis or other benign changes in the background breast. The automated image analysis using figures captured from virtual system are planned to evaluate concentration of DCIS distribution.

Results: 1) The clinical characteristics and association between imaging findings and histopathological classification of the 3 subtypes of DCIS are summarized as: a) Histopathologically, in type 3, there was a higher frequency of necrosis and calcification in the ducts of DCIS ($\chi^2, p<0.001$), the number of dilated peri-ductal capillaries was greater than in type 1 ($p=0.023$), and the distribution of DCIS was concentrated in type 3 ($p=0.020$); b) In imaging findings, type 3 was easier to detect than type 1 on USG ($p=0.008$), but there were no significant differences in MMG and MRI. 2) The 14 DCIS cases that could not be detected by USG, showed slight edematous or myxoid change in the stroma histopathologically ($p<0.001$), and were less likely to be detected by MRI ($p=0.004$). 3) The 6 MRI un-detected cases were less likely to be detected by USG ($p=0.004$), and the occurrence of adenosis or other benign changes in the background breast interfered with MRI ($p=0.010$). Peri-ductal capillaries seemed to be an important factor for MRI detection ($p=0.007$). 4) The results of automated image analysis will be presented.

Conclusion: USG imaging reflected the histopathological subtypes of DCIS, myxoid changes of the stroma, and the concentration of DCIS ducts. MRI was correlated with the peri-ductal capillaries of DCIS and the changes in the background breast, while MMG can make up for the shortcomings of USG and MRI. It is important for us to keep the histopathological type in mind and interpret the imaging findings comprehensively, when we do a spreading diagnosis of DCIS.
Title: Pleomorphic lobular carcinoma in situ (PLCIS)-presentation, associated lesions and outcome

Shaaban AM M, Smith S, Bradley S, McMahon M and Sharma N. Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom and St James's University Hospital, Leeds, United Kingdom.

Body: Pleomorphic lobular carcinoma in situ (PLCIS) is an uncommon lesion characterised by dyscohesive lobular cells showing high grade nuclei. It is commonly associated with comedo necrosis and luminal calcifications and hence diagnosed on mammographic screening. Data on the presentation, focality, associated lesions, optimal treatment and outcome of PLCIS is patchy.

Methods
Cases diagnosed as PLCIS between 2005 and 2015 were identified from the imaging and pathology databases of two UK large breast screening units. Cases diagnosed on diagnostic core biopsy/VAB or surgical excisions were included. Comprehensive data was collected on age, mode of presentation (screening vs symptomatic), imaging (mammography, ultrasound and MRI), surgical management, histological features on core biopsy and excision including type, grade and immunohistochemical profile of associated ductal carcinoma in situ (DCIS) and invasive carcinoma.

Results
86 cases with the diagnosis of PLCIS (confirmed by review and e-cadherin negativity) were identified. The mean patient age at diagnosis was 61.04 years, range: 39-84 years. 32 cases were treated with wide local excision with/without axillary procedure. A total of 38 patients were screen detected & 36 cases were diagnosed in the symptomatic setting. Others presented as incidental calcifications on family history screening, incidental histological findings in breast reductions and risk reducing mastectomy.

On mammography, 6 patients presented with an asymmetrical density, with or without calcifications, 25 with calcifications, 44 as a mass and 2 as stromal deformity. No mammographic abnormality was found in 9 cases. PLCIS was multifocal in 19.7% of cases, diffuse in 9.9%, focal in 69% and multi-centric in 1.4% on imaging.

Histologically, PLCIS was the most advanced lesion on core biopsy without associated DCIS or invasive disease (pure PLCIS) in 23 patients. Of these, surgical excision revealed an invasive carcinoma in 7 cases (upgrade rate = 30.4%). Six more patients presented as DCIS and PLCIS on core biopsy; three of whom (50%) had invasive disease on excision.

Classical LCIS was associated with PLCIS in 27/86 cases (31.3%). The most common type of associated invasive carcinoma on surgical excision was invasive classical lobular carcinoma (ILC, 40 cases), followed by invasive pleomorphic lobular carcinoma (IPLC, 27 cases). Ductal no special type carcinoma, solid papillary and tubulo-lobular carcinoma were also identified. The size of PLCIS on excision ranged from 1-80mm. DCIS was associated in 26.7% of cases. The majority of invasive cancers were of grade 2 (53.5%) and 3 (19%). The tumors were ER positive (53 cases), PR positive (43 cases) and HER2 negative (52 cases).

Conclusion
PLCIS is an uncommon in situ carcinoma presenting via mammographic and also in the symptomatic setting. Unlike classical LCIS, PLCIS is a disease of postmenopausal women. It is multifocal in approximately one fifth of the cases.

PLCIS is commonly associated with classical LCIS and both ILC and IPLC. When identified in core biopsy, the upgrade rate in this series was 30.4% which increased to 50% if the lesion co-existed with DCIS. The associated cancers are often ER positive, HER2 negative. These findings support managing those lesions surgically as per DCIS.
Title: Nuclear immunohistochemical IKK-ε expression in flat epithelial atypia (FEA) of the breast: A predictor of ipsilateral ADH, in-situ or invasive malignancy?

Williams PA A, Parra-Herran CE E, Ayroud Y, Islam S, Gravel DH H, Robertson SJ J and Pratt C. University of Ottawa, Ottawa, ON, Canada and EORLA, Ottawa, ON, Canada.

Body: Background: Flat Epithelial Atypia of the breast (FEA) is associated with in situ and invasive low grade neoplasia. However, the role of excision after FEA on biopsy is controversial as rates of upgrading to atypical ductal hyperplasia (ADH), ductal carcinoma in situ (DCIS) or invasive carcinoma in subsequent excision are relatively low. Problems include difficulties in inter-observer reproducibility and lack of morphologic or immunohistochemistry (IHC) tools that better identify cases at risk for concurrent ADH/Carcinoma. Nuclear image analysis may be useful, but is not widely available. IKK-ε, part of the NF-κB activating pathway, is absent in normal breast epithelium and non atypical (usual) ductal hyperplasia, but is over-expressed in >30% of breast cancers. In addition, in our experience ADH/DCIS shows IKK-ε staining, mostly cytoplasmic. Of note, in prostate cancer, nuclear accumulation of IKK-ε has been described in hormone sensitive prostate disease while cytoplasmic accumulation is associated with metastatic progression. No previous studies of IKK-ε levels in FEA are reported. Here we report IKK-ε status in FEA and correlation with ipsilateral, synchronous ADH, DCIS or invasive carcinoma.

Method: Resection specimens from 61 patients with diagnosis of FEA were retrieved. Presence of ADH/carcinoma and laterality (ipsi or contralateral) was recorded. Synchronous neoplasia was defined as ADH, DCIS or invasive carcinoma diagnosed within 6 months of the diagnosis of FEA. Presence of FEA was confirmed by three observers using strict morphologic criteria. IHC for IKK-ε was performed using ABCAM, rabbit anti-IKK-ε (ab7891) and pH 6 citrate buffer heat-induced epitope retrieval for 20 minutes. IHC slides were scanned and FEA regions captured for blind scoring of nuclear and cytoplasmic staining. Cut off for positive nuclear staining was 10% and cytoplasmic staining was graded as negative, weak, moderate or strong positive.

Results: 40 patients had ipsilateral synchronous ADH/carcinoma, and 21 did not. Within these groups, 6 patients had contralateral ADH/carcinoma (2 with and 4 without ipsilateral neoplasia). While cytoplasmic staining showed no difference between the groups, nuclear positivity was more frequent in cases with ipsilateral synchronous ADH/carcinoma, \( \chi^2(1, N = 61) = 5.1, p = .025 \) (Table 1). In contrast, there was no correlation between IKK-ε staining and ADH/carcinoma in the opposite breast (p=.25).

Table 1

<table>

<tr>
<td>Positive</td>
<td>10 (25)</td>
</tr>
</tbody>
</table>

Conclusion: Nuclear IKK-ε staining may prove useful in predicting synchronous ipsilateral ADH or malignancy in cases of FEA in biopsy material. Given its more frequent association with ipsilateral synchronous ADH/carcinoma, IKK-ε nuclear expression in FEA may represent a step in continuous local oncogenesis rather than a general marker of risk. Given the pleiotropic role of IKK-ε in growth and survival, the significance of the shift from nuclear staining in FEA to cytoplasmic staining in ADH/DCIS may reflect different signaling pathways and requires further investigation. Further validation of our findings in larger cohorts is necessary.
**Title:** Comparison of local clinical subtyping to central molecular classification using microarray-based expression test in breast cancer patients

**Body:**

**Background:**
Measurement of estrogen receptor (ER), progesteron receptor (PR) and human epidermal growth factor receptor 2 (HER2) status in early breast cancer is critical for informing treatment recommendations. Targetprint®, a commercially available microarray-based test, measures mRNA levels of ER, PR and HER2 genes. The aim of this study was to investigate the concordance and accuracy of local clinical subtyping by immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH) with TargetPrint®.

**Material and Methods:**
We collected data retrospectively from 109 early breast cancer patients from 17/5/2012 to 17/4/2015. All of them underwent surgery. ER, PR and HER2 status were assessed by IHC in tumor samples. For HER2 IHC 2+ cases, additional FISH was used. These results were compared with microarray mRNA quantifications. Microarrays were all performed in formalin-fixed paraffin-embedded (FFPE) tumor samples. Accuracy of TargetPrint® was evaluated with positive (PPV) and negative (NPV) predictive value considering IHC as "Gold Standard". Concordance between techniques was evaluated with percentage of concordance and Cohen's κ coefficient. The interpretation of κ Coefficient is done by correlating its value with a qualitative scale (Landis and Koch, 1977): 0 is considered poor; 0,01-0.20 is slight; 0,21-0.40 is fair; 0,41-0.60 is moderate; 0,61-0.80 is substantial; 0.81-1 is almost perfect.

**Results:**
100% of tumor samples were RE positive for both IHC and TargetPrint®. All 109 patients resulted HER2 IHC negative, 3 of them were HER2 TargetPrint® positive. Regarding RP, 80% of tumor samples were IHC and TargetPrint® positive, 11% IHC and TargetPrint® negative, 5% negative by IHC and positive by TargetPrint® and 4% positive by IHC and negative by TargetPrint®. For ER, concordance was 100%, κ=1. For PR, concordance was 90.83%, κ=0.65 (95%CI 0.45-0.85). In the case of HER2, percentage of concordance was 97.25%, κ=0 (kappa paradox). TargetPrint had PPV 1 and NPV 0 assessing ER. For PR, TargetPrint PPV is 0.93 and NPV is 0.75. For HER2, TargetPrint PPV is 0 and NPV is 0.97.

**Conclusions:**
To the best of our knowledge, this is the first study exploring concordance between IHC/FISH and Targetprint® in FFPE tumor samples. According to previous data in fresh tissue, almost perfect concordance for ER and HER2 as well as substantial concordance for PR were seen. We suggest lack of accuracy in IHC technique, in microarray test or intra-tumor heterogeneity as possible reasons for the less consistent accordance in PR. It would be interesting to further design a prospective study to address this question.
Title: Does HER2 immunohistochemistry-guided targeted FISH analysis help identify intratumoral heterogeneity in breast cancer?

Gulbahce HE, Factor RE E, Geiersbach KB B and Downs-Kelly E. University of Utah School of Medicine, Salt Lake City, UT and ARUP Institute for Clinical and Experimental Pathology, Salt Lake City, UT.

Body: Introduction: The updated 2013 ASCO/CAP HER2 guidelines proposed revised scoring with the aim of capturing all patients eligible for targeted therapy. The current guidelines also address intratumoral heterogeneity using immunohistochemistry (IHC) as a platform to identify and target heterogeneously staining areas for FISH analysis. We wanted to determine if identifying the most intense areas of staining in IHC equivocal / 2+ cases would help identify genetic heterogeneity and potentially more FISH amplified patients.

Materials and Methods: Our lab offers HER2 immunohistochemistry by HercepTest™ (Dako) or 4B5 (Ventana), and dual probe FISH (Abbott Molecular or Dako IQ). We offer HER2 testing as IHC or FISH only, and also as a reflex FISH following equivocal (2+) IHC. HER2 tests performed and interpreted after 10/2013, following the implementation of the ASCO/CAP 2013 guidelines, to 5/2015 were included in this study. Both IHC and FISH were manually read following ASCO/CAP 2013 guidelines by one and two observers respectively. Equivocal (2+) cases with heterogeneous staining showing areas with \( \geq 10\% \) weak or moderate circumferential membrane staining were circled by a pathologist and reflexed to HER2 FISH. In those cases where samples were received for FISH testing only, the pathologist circled the entire area of invasive tumor on H&E slides. All circled tumor areas were evaluated before signal enumeration of the FISH probes.

Results: 1805 HER2 FISH test requests received in our laboratory during the study period had interpretable FISH results. 1210 of these cases did not have prior HER2 IHC testing performed in our laboratory (“FISH only”), 595 had reflex FISH testing following equivocal (2+) IHC (“IHC2+/reflex FISH”). Amplification rates between the “IHC2+/reflex FISH” group of patients with targeted areas for FISH and the “FISH only” group where the entire invasive carcinoma was marked on H&E slide and scored were similar (16.3% and 20% respectively). 10/595 (1.7%) “IHC2+/reflex FISH”, and 15/1210 (1.4%) “FISH only” groups showed genetic heterogeneity by FISH with discrete population of amplified tumor cells respectively (p=0.4).

<table>
<thead>
<tr>

<tr>
<td>Amplified</td>
<td>242 (20.0%)</td>
<td>97 (16.3%)</td>
</tr>
</tbody>
</table>

*includes equivocal IHC, and FISH as first line of testing

Conclusion: The updated HER2 ASCO/CAP guidelines recommend that intratumoral heterogeneity for HER2 may be easier to detect with IHC which can be used to guide FISH enumeration. In our study, identifying areas of more intense staining on IHC slides for targeting FISH analysis did not result in a difference in identification of genetic heterogeneity.
Do estrogen receptor negative and progesterone receptor positive breast tumors really exist? Attitude for not making them real

Molly D, Bertaut A, Blanchet C, Beltjens F, Charon-Barra C, Loustalot C, Desmoulins I and Arnould L. GF Leclerc Cancer Center, Dijon, France.

Body: Background: Breast tumors with negative estrogen receptor (ER-) and positive progesterone receptor (PR+) are rare (from 0 to 3.4 % according to the studies), and their existence is contested. These markers determine cancer molecular subtypes which play a determinant role for both the management and the prognosis of breast cancers. It is then essential to document the real existence of ER-/PR+ tumors. The present study aimed at determining if ER-/PR+ tumors share more basal or luminal characteristics.

Methods: Between 2000 and 2015, 50 patients with ER-/PR+ breast tumors, representing 0.6 % of all breast cancers diagnosed in our institution, were included in this study. Their clinical (age, node status), morphological (size, histological type, Elston and Ellis (EE) grade, necrosis, inflammation, pushing margins, central scar, mitotic index) and immunohistochemical characteristics (ER, PR, HER2, CK5/6 and EGFR status) were compared with those of 50 luminal and 50 triple negative (TN) tumors randomly selected in our lab database. At the time this abstract is written, the Ki67 index determination is still in progress. Five of these ER-/PR+ tumors were also given a molecular test (Nanostring). Qualitative variables were compared using Chi2 or Fisher test, quantitative variables were compared using Student or Mann & Whitney tests. To take into account for multiple comparisons, p-values less than 0.025 were considered as significant.

Results: The results are summarized in table 1. For almost all the analyzed criteria, ER-/PR+ tumors present statistical difference with luminal ones. On the contrary, they share most of TN tumors characteristics. The 5 molecular analyzes performed on ER-/PR+ samples showed the following phenotypes: 3 basal, 1 HER2 enriched and 1 luminal. For this last one, new immunohistological analyzes reveal in fact an ER+ staining.

Conclusion: This study tends to support that ER-/PR+ tumors may not exist and are likely to be TN cancers or less frequently false negative ER+ tumors. In a practical point of view, we think that 1) when a tumor shows ER-/PR+ and TN characteristics, it is probably a false positive PR staining, and the tumor has to be considered as a TN one, 2) when an ER-/PR+ tumor don't fit the triple negative tumors characteristics, ER must be retested in order to exclude a true luminal tumor.

Title: Breast cancer biomarkers: Global tumor biomarker quality assurance study of intratumor heterogeneity

Dabbs DJ J and Clark B. Magee-Women's Hospital of UPMC, Pittsburgh, PA.

Body: Introduction
Biomarkers (BM) are often performed on core biopsies (CB) of breast tumors for treatment purposes, yet comprehensive information on BM heterogeneity is lacking. This quality assurance study is to survey BM intra-tumor heterogeneity (ITH) by comparing BM from CB and the examination of entire breast tumors from surgical excisions (SE). This interim report supplies data on 45/100 collected cases to date.

Methods:
Whole tumor cases, 3.0 cm or less were collected in years 2013-2014, excluding neoadjuvant cases and were examined with CB by two pathologists. All tissues were processed using 2013 ASCO/CAP guidelines. Immunohistochemistry (IHC) for ER/PR/Her2/Ki67 was performed on breast core biopsies and each block of a tumor surgical excision (1-13 blocks per case). IHC was performed using the Ultra Ventana-Roche device with FDA IVD clones ER (SP1), PR (1E2) Her2 (4B5) Ki67 (30-9). Whole slides were semi-quantitated for ER/PR using HScore (0-300), Her2 was interpreted with 2013 ASCO/CAP guidelines and Ki67 proliferation index (PI) as estimated whole slide percent of tumor cell nuclear stain. Mean HScores and PI were calculated for all BM on SE, and CB deviations from the SE mean were calculated for ER/PR/Ki67. ITH of BM was assessed by comparing results among all tissue blocks for each case. Her2 results were descriptive. Eight cases lacked CB Ki67 PI.

Results
There were no cases in which categorical hormone receptors results (positive/negative) differed between CB and SE. 2/45 (4%) cases were Her2 positive, and 13/45 (28%) were equivocal by IHC with one case amplified by in situ hybridization. Comparing ER between CB/SE, 3/45 differed in HScores by 30% or more. 10/45 SE ER had ITH of 25% or more among different tissue blocks. 14/45 cases had CB/SE PR difference in HScore of 30% or more. 18/45 cases had SE PR with ITH HScore of 25% or more between tissue blocks.

Ki67 PI differed between CB/SE by more than 25% in 18/37 cases, with ITH among tissue blocks of more than 25% in 23/37 cases. The variability of CB-SE results and ITH among tissue blocks are summarized in table 1.

CB-SE: core biopsy vs surgical excision; ER PR as H Score

Conclusions
In this interim report of 45/100 cases, (1) ITH of 25% or more occurred for ER content in 22 % of cases (2) similar ITH exists for PR content in 40% of cases. (3) Ki67 PI tissue block ITH was expressed with variation of 25% or more in 23/37 cases. (4) While this degree of variability of BM may not affect treatment decisions, the tissues show sufficient BM variability that should stimulate concern for accuracy of results of prognostic gene expression profiles and genomic testing of breast tumors.
Body: Background: The expression of estrogen receptor alpha (ERα) and progesterone receptor (PR) in breast carcinomas is a strong predictor of the efficacy of hormonal therapy for breast cancer patients as well as providing a degree of prognostic information. Anti-ERα (clone EP1) and anti-PR (clone PgR 1294) configured as FLEX ready-to-use antibodies have been tested on the Dako Omnis automated staining platform. These products are in performance evaluation and are not commercially available. A series of concordance studies were performed to evaluate the performance characteristics of these monoclonal antibodies on breast cancer tissue specimens: anti-ERα clone EP1/Dako Omnis was compared to (a) anti-ERα clone EP1/Autostainer Link 48 (238 specimens) and to (b) anti-ERα clone SP1/Autostainer (116 specimens), and anti-PR clone PgR 1294/Dako Omnis was compared to (a) anti-PR clone PgR 636/Autostainer Link 48 (289 specimens) and to (b) anti-PR clone 16 (Leica Biosystems, Newcastle, UK) (144 specimens). In addition, the specificity of the ER and PR antibodies for Dako Omnis was evaluated on a set of normal tissue specimens.

Methods: Formalin-fixed, paraffin-embedded (FFPE) human breast carcinoma specimens and normal tissues were obtained from commercial providers or local hospitals. The specimens had no associated personal information and were not traceable back to the tissue donors. Tissue pretreatment and immunohistochemical staining were performed using the recommended protocol for each antibody and staining platform. The stained slides were evaluated for nuclear ER or PR expression according to ASCO/CAP guidelines (≥1% cut-off for positive) by pathologists who were blinded from the staining method and specimen ID. The concordance studies included breast cancer specimens covering the clinical range of ER or PR expression with approximately half the specimens in the negative (<1%) category, and at least 10% of the specimens in the weakly positive (≥1 ≤10%) category in each study. Two-sided Wilson Score 95% Confidence Intervals were calculated using JMP software (SAS Institute, USA). For the analytical specificity studies the presence or absence of specific staining in the various normal tissue types was recorded.

Results: High concordance rates were observed with both anti-ERα clone EP1/Dako Omnis and anti-PR clone PgR 1294/Dako Omnis compared to the other ER/PR antibodies, with overall agreement rates exceeding 95% in all of the comparative studies. On a set of normal tissues, specific positive nuclear staining was observed only in tissue types known to express ERα or PR.

Conclusions: Monoclonal antibodies anti-ERα clone EP1 and anti-PR clone PgR 1294 configured as FLEX ready-to-use on Dako Omnis are sensitive and specific assays for detecting estrogen receptor and progesterone receptor in FFPE tissues. In comparison testing for assessment of hormonal receptor status on breast carcinoma specimens, anti-ERα clone EP1/Dako Omnis and anti-PR clone PgR 1294/Dako Omnis were highly concordant with commercially-available ER or PR antibodies.
Title: Integrative pathology: Analysis of cellular multiplex technology to detect proteomic, genomic and DNA data from fine needle aspiration biopsy specimens

Mittendorf EA A, Dogan B, Morgan R, Chargin A, Wu Y, Cornett-Risher S and Shults K. The University of Texas MD Anderson Cancer Center, Houston, TX and Penfold-Patterson Research Institute, Frankfort, MI.

Body: Background: An integrative system capable of detecting proteomic, genomic and DNA content from cell isolates obtained by fine needle aspiration (FNA) biopsy may offer distinct advantages in diagnosing breast cancer and monitoring response to therapy. Cellular Multiplex™ is such a system. An initial pilot study evaluating this technology established a series of variables that could separate normal from cancerous elements using cells obtained from an FNA performed on excised tumors and reduction mammoplasty specimens. In order for the technology to be clinically relevant, it must perform robustly on intact tumors. The current study was therefore undertaken to validate Cellular Multiplex™ on cells obtained by FNA performed on intact tumor at the time of diagnosis.

Methods: Patients undergoing lumpectomy requiring either needle or 125I seed localization were identified. FNA was performed on intact tumor (A samples) at the time of radiographic localization prior to lumpectomy and repeated on the excised tumor (B samples). Cells obtained by FNA were placed in a proprietary fixative then hybridized and stained to detect multiple mRNA and protein targets along with DNA content. Estrogen receptor, progesterone receptor and HER2 were included in the panel of targets and compared to the routine clinical pathology report. Cell morphology was assessed by mean corpuscular volume. Samples were analyzed using an EC800 (Sony Biotechnology, San Jose, CA) and the results from matched A and B samples were compared using the Mann-Whitney Wilcoxon Rank Sum test. The study is designed to enroll 50 patients. Here we report an analysis of the first 9 cases.

Results: The cell number obtained from the excised tumors were 3-4 times greater (median to median) than obtained from the intact tumor. There was no statistical difference in the expression of the 2 mRNA targets, 8 protein targets, DNA content and cell morphology between the A and B samples. The parameters derived from Cellular Multiplex matched the standard pathologic features reported on the clinical pathology report in 8 of 9 cases. In the one discrepant case, Cellular Multiplexing detected ER positive cells in a case where standard pathologic evaluation with immunohistochemistry reported the tumor to be estrogen receptor negative.

Conclusions: This interim analysis demonstrates that the Cellular Multiplex technology is working well using cells obtained by FNA performed on intact tumors with readouts matching those obtained from excised specimens. If confirmed in the remaining patients, these data suggest that this technology will be applicable for the evaluation of intact tumors thereby making it relevant for multiple clinical indications including diagnosis and monitoring response to neoadjuvant therapy.
**Title:** Impact of routine subspecialty pathology review on the care of women age $\leq 65$ years with lymph node negative breast cancer

Lupichuk S, Yang H, Ibnshamsah F and Roldan Urgoiti G. Tom Baker Cancer Centre, Alberta Health Services, Calgary, AB, Canada; Calgary Laboratory Services, Alberta Health Services, Calgary, AB, Canada and King Fahad Specialist Hospital, Dammam.

**Body:** **Purpose:** Changes in pathological features of lymph node negative breast cancer (BC) can have a profound impact on local-regional and systemic therapy recommendations. The impact of routine subspecialty pathology review on the care of women with node negative BC has not been well described.

**Methods:** All women diagnosed with node negative BC from January 1, 2012 through December 31, 2012 who had been referred to the Tom Baker Cancer Centre were identified. As per routine institutional practice, patients $\leq 65$ years at the time of referral whose pathology had originally been reported by a general pathologist, had their pathology automatically sent for subspecialty review by a breast pathologist. For the cohort who had their pathology sent for subspecialty review, medical records were examined to determine if original pathology was changed and if treatment recommendations were altered.

**Results:** Of 468 patients diagnosed with node negative BC, 187 patients had their pathology initially reported by a general pathologist and hence their pathology was sent for routine subspecialty review. Of these 187 patients, 82 had at least one change on pathology. The most common pathology change type was an increase in tumour grade (35), followed by increase in tumour size (18), and documentation of LVI (14). Lymph node involvement, was identified in only 3 cases. There was at least one change in treatment recommendation for 21 of the 187 patients (11.2%). The most common change in treatment recommendation was inclusion of adjuvant chemotherapy (10). Had Oncotype DX funding been in place during the study period, 14 cases would have become eligible for testing and 8 would have become ineligible for testing according to our current institutional testing guideline (ER-positive, HER2-negative, grade 2 or 3, and node negative). Nine of 26 treatment recommendation changes occurred in Oncotype DX eligible patients.

**Conclusions**: Routine subspecialty pathology review of lymph node negative BC yielded substantial changes in pathological features and subsequent alterations in treatment recommendations. Optimal practice with the availability of gene signature testing requires further investigation.
Title: Genomic analysis of single cells isolated by a pulse laser retrieval system

Lee H-B, Kim S, Lee K-M, Jung Y, Lee AC, Kim J, Bae S, Ryu HS, Yoo T-K, Moon H-G, Noh D-Y, Kwon S and Han W. Seoul National University College of Medicine, Seoul, Republic of Korea; Interdisciplinary Program of Bioengineering, Seoul National University, Seoul, Republic of Korea; Cancer Research Institute, Seoul National University College of Medicine, Seoul, Republic of Korea; Department of Electrical Engineering and Computer Science, Seoul, Republic of Korea; Seoul National University College of Medicine, Seoul, Republic of Korea and Institutes of Entrepreneurial BioConvergence, Seoul National University, Seoul, Republic of Korea.

Body: Background: Isolating tumor cells of interest and harvesting histologically pure samples is important for genomic studies. Laser capture microdissection (LCM) is an established method to obtain such purified cell populations for various applications including DNA, gene expression, and single cell analyses. However, LCM possesses problems such as limited optical resolution, cell fragmentation from dissection, and adherence of adjacent tissue to the cells which interrupts with single cell isolation from tissue sections. To overcome these obstacles, we developed a high-throughput pulse laser retrieval system which uses a wavelength that minimizes damage to the cellular content and is processed with a sacrificial layer that provides applicable optical resolution. The aim of this study was to evaluate the performance of the pulse laser retrieval system to provide appropriate samples for genomic analysis using breast cancer tissue.

Methods: An indium tin oxide (ITO) coated glass slide was prepared using fresh frozen breast cancer tissue sections of 4 thickness and stained by hematoxylin and eosin. The slide was mounted on the cell isolation machine and imaging was performed with a charge-coupled device camera using a 20× lens. Following identification of the target cells by a pathologist, nano-second pulsed laser (wavelength= 1064nm) was irradiated on the target. Isolated cells were collected in a polymerase chain reaction tube and whole genome amplification (WGA) was carried out using Illustra GenomiPhi V2 DNA Amplification Kit (GE Healthcare Life Sciences, Pittsburgh, PA, USA). Amplified genomic DNA was fragmented and Illumina sequencing libraries were constructed. Sequencing was carried out to generate data with 0.1–0.2× depth throughout the whole genome for each sample. Copy number variation (CNV) was analyzed by the Variable binning algorithm.

Results: Whole genome amplification was performed using bulk tissue and 10 captured single cells from the same specimen. No difference in amplification coverage was observed between the two samples. A CNV analysis of captured single cells revealed similar CNV profiles with those in a matched bulk tumor. Whole exome sequencing (WES) of captured single cells yielded a variant frequency of 15% at a read depth of 15× and 50M base coverage, compared to 0% at 100× and 50M for WES using bulk tumor and 0.5% at 1200× and 100K for targeted sequencing using bulk tumor. Laser capture was performed for DCIS and stromal cells from the same slide. CNV analysis of the two samples showed minimal CNV in normal stromal cells in contrast to DCIS where multiple CNVs were observed.

Conclusions: Newly developed pulse laser retrieval system is suitable for capturing single cells for genomic analysis of breast cancer. WGA, WES, and CNV analysis was successfully carried out using the captured single cells and showed no difference in profile compared to those performed with bulk tissue. This method may have the potential to replace LCM for certain applications such as single cell analyses.
Title: A review of 66 consecutive patients investigated for mammographic abnormalities by digital tomosynthesis guided vacuum assisted breast biopsy

Munir A, Moalla A, Williams HR R, Thomas D, Huws AM M and Holt SD D. Prince Philip Hospital, Llanelli, Carmarthenshire, United Kingdom.

Body: OBJECTIVE: Vacuum-assisted breast biopsy (VABB) has replaced surgical biopsy for the assessment of mammographic abnormalities that are not evident clinically and or on ultrasound examination. The aim of this study was to determine the indications for, and accuracy of, vacuum-assisted breast biopsy (VABB) performed using digital breast tomosynthesis (DBT) guidance. (Hologic® Dimensions, Affirm guidance and Eviva handsets).

MATERIALS AND METHODS:
Design: Retrospective medical record and histopathologic review.

Patients and method: We introduced DBT guided VABB in June 2014 having previously investigated such patients using the prone table technique. This is a review of the first 66 consecutive patients investigated using this technique up to April 2105. The following information was reviewed: Indication for VABB, (mammographic classification M1-5, type of abnormality – calcifications/mass/distortion), complications of the procedure itself, (failure to complete, infection, haematoma), the result of the multidisciplinary team (MDT) review of imaging/pathologic correlation and the outcome for the patient.

RESULTS: In one case it proved impossible to locate the lesion and this patient has been excluded from further analysis. The mean age of the patients was 57 years (30-80years). VABB was proposed for patients with lesions initially reported as highly suspicious (M5) 4 patients (6%), suspicious (M4) in 18 patients (28%), intermediate (M3) in 37 patients (57%) or benign (M2) in 6 patients (9%). Mean size of the lesion was 13mm (range 3-100mm). Forty-four patients (68%) presented with micro calcifications, 14 (21%) with distortions in and 7 (11%) with masses.

There were no complications (infection or haematoma) that required further management following the procedure. Review by the MDT agreed that all biopsies were adequate and removed representative tissue from the lesion (No B1s). Review showed that the histology was benign and consistent in 30 (46%) patients all of whom were discharged to routine screening. 19 (29%) cases were reported as B3 (ADH, flat atypia, LCIS or ALH) in whom all the calcifications had been removed in 13 (20%) and the patients discharged and 6 (9%) went to open biopsy for residual calcifications all of whom were benign on final analysis. There was one (1.5%) radial scar reported as B4 that went to open excision and proved benign. 15 (23%) proved malignant (B5a, B5b) and went on to definitive treatment (with one patient entered into the LORIS low risk DCIS trial).

The procedure is quicker, more accurate (related to the higher resolution and larger window of the receptor plate) and involves less radiation exposure (often involving only one DBT exposure) when compared to performing the same procedure on the Hologic Platinum prone table.

CONCLUSION: DBT-guided VABB is an accurate, convenient and safe procedure.
2015 San Antonio Breast Cancer Symposium

Title: Retrospective analysis of the accuracy of ultrasound-guided core needle biopsy in the diagnosis of breast invasive ductal carcinoma: Experience in Chinese population

Wang W, Guo Y, Xing H, Wang K and Zhai X. China-Japan Union Hospital, Jilin University, Changchun, China and China-Japan Union Hospital, Jilin University, Changchun, China.

Body: Background: Percutaneous imaging-guided core needle biopsy is a reliable alternative to surgical biopsy for a histological diagnosis. Nowadays, core needle biopsy is considered to be the standard technique for histological diagnosis of breast lesions. However, the accuracy of ultrasound-guided core needle biopsy in predicting tumor grade, which is scored according to mitotic index, tubular differentiation, and nuclear atypia, is not well established. The aim of this study is to evaluate the concordance of histological diagnosis between ultrasound-guided core needle biopsies and subsequent excision specimens of breast invasive ductal carcinomas.

Methods: We retrospectively reviewed the medical records of 875 consecutive female patients diagnosed with surgically proven breast invasive ductal carcinomas those were biopsied under sonographic guidance preoperatively, using 14-gauge core needles exclusively, from June 2011 to May 2015. A minimum of four cores were taken per lesion. Tumor grade was assigned using the standard modified Scarff-Bloom-Richardson system. Core biopsy pathological diagnosis and grades were compared with final surgical excision specimens. The diagnostic coincidence rate and the agreement rate were expressed in percentages and in kappa statistics; the rates of overestimation and underestimation were also assessed. The correlation among tumor size, diagnostic coincidence rate, and agreement rate was also evaluated.

Results: Compared with the postoperative pathological diagnosis, the diagnostic coincidence rate of ultrasound-guided core needle biopsy was 95.54% (836/875). 39 cases were diagnosed with ductal carcinoma in situ or intraductal carcinoma by core needle biopsy. The overall agreement rate between core needle biopsy and surgical pathology grade was 69.26%. Agreement rate by biopsy grade was 78.40% (225/287) for grade 3, 74.76% (308/412) for grade 2, and 53.28% (73/137) for grade 1. Core needle biopsy underestimated 22.51% (197/875) and overestimated 8.23% (72/875) of the lesions. Small tumors were inclined to be more easily misdiagnosed as ductal carcinoma in situ or intraductal carcinoma, and large tumors were more likely to show underestimation rather than overestimation when discordant (p=0.002). For mass lesions with a diameter less than 10 mm, the agreement rate (62.33%) was lower (p=0.003).

Conclusion: Ultrasound-guided core needle biopsy accurately predicts high-grade breast tumors but is moderately accurate for lower-grade lesions. Large tumor size negatively impacts the accuracy of tumor grade found on biopsy and is associated with underestimation. Our finding indicates that ultrasound-guided core needle biopsy has proven to be a reliable technique for performing a biopsy for breast invasive ductal carcinoma, and has important significance in estimating breast carcinoma grade.
Lipoproteins regulate the effects of macrophages and mesenchymal stem cells on radiation response of inflammatory breast cancer cells

Rahal OM M, Wolfe AR R, Larson RA A, Ueno NT T, Reuben JM M and Woodward WW W. MD Anderson Morgan Welch Inflammatory Breast Cancer Research Program and Clinic, University of Texas MD Anderson Cancer Center, Houston, TX.

Body: Inflammatory breast cancer (IBC) represents the most aggressive manifestation of breast cancer and results in up to 10% of all breast cancer-related deaths. Lack of IBC-specific targetable drivers suggests involvement of other cell types besides breast tumor epithelial cells. The multidisciplinary treatment of IBC consists of pre-operative neoadjuvant chemotherapy (with targeted agents for Her2- and ER-positive cases), radical mastectomy, followed by radiotherapy. Given that: 1) radiation therapy is a main component in treatment of IBC, 2) we have previously shown that high-density lipoproteins (HDL) mediates outcomes after radiation for IBC, and 3) the possible involvement of tumor micro-environment, it is critically important to understand the role of microenvironment such as tumor-associated macrophages and mesenchymal stem cells (MSC) on radiation response of IBC cells and how this stroma-epithelial crosstalk is regulated by lipoproteins. Here, we used in vitro co-culture system and 2D clonogenic assays of radiation resistance to examine the impact of both polarized human THP1 macrophages and MSCs on radiation response of human IBC cell lines. Further, we determined the effect of MSC-educated THP1 and THP1-educated MSCs, when co-cultured with IBC cells, on radiation response. We also determined the effect of HDL on radiation response of IBC cells co-cultured with M2-polarized (TLR3) MSCs. Our findings demonstrate that while LPS-treated, M1-polarized MSC (TLR4) co-cultured with IBC cell lines SUM149 and IBC3 leads to radio-sensitization, co-culture of IBC cells with Poly(I:C)-treated, M2-polarized MSC (TLR3) leads to radio-resistance of IBC cells. In a similar manner, co-culture of IBC cells with THP1 macrophages polarized to either M1 phenotype (LPS and IFN-γ treated) or M2 phenotype (IL4 and IL13 treated), mediate radio-sensitivity and radio-resistance, respectively, of SUM149 IBC cells. In order to provide a more comprehensive model of macrophage-MSC-IBC crosstalk, we co-cultured IBC cells with THP1 macrophages that have been previously co-cultured (i.e. "educated") with MSC and compared the effect of MSC-educated THP1 versus non-educated on radiation response of IBC cells. Our data show that MSC-education of THP1 enhances radioresistance of IBC SUM149 and KPL4 cells co-cultured with THP1 cells. In a recent publication, we showed that HDL radiosensitize IBC cells and decrease their self-renewal potential. To expand our recently published findings, here we tested whether HDL co-treatment has any effect on MSC-M2 (TLR3)-mediated radioresistance of IBC cells. Our current findings, show that co-treatment of HDL inhibits MSC-M2-mediated radioresistance of SUM149 IBC cells. In sum, these data suggest that cells within tumor micro-environment such as macrophages and MSCs regulate radiation response of IBC cells and this can be altered by lipoproteins.
Title: Estrogens contribute to cytokine upregulation and cancer stem cell recruitment upon breast cancer contact with mature human mammary adipocytes: Effects of estrogen type and adipocyte donor weight

Body: Consequences of the obesity epidemic on cancer morbidity and mortality are not fully appreciated. While obesity confers increased cancer risk and worse outcome, mechanisms thereof are not fully known. We show prolonged co-culture of fat cells (human adipocyte stem cells, differentiated adipocytes or mature adipocytes) from breast tissue together with breast cancer lines or cultured primary dissociated human breast tumor cells increases secretion of six different pro-inflammatory cytokines, each of which contributes to tumor progression through cancer stem cell recruitment. Prolonged exposure to fat cells or to each cytokine increases the proportion of cells that form mammosphere and express ALDH1 activity in vitro and that can initiate primary orthotopic tumors and metastasis in vivo. Adipocyte and cytokine exposures activate Src, and Src family kinase activity leads to induction of embryonic transcription factors that upregulate miR302b. miR302b induction is Sox2-dependent, promotes cytokine-driven sphere formation, and in turn, stimulates cMYC and SOX2 expression. Src is not only activated by adipocyte or cytokine exposures, it is also required to sustain cytokine induction, since Src inhibitors decrease cytokine production after co-culture. Cytokine upregulation was much greater after co-culture of ER+ breast cancer cells with mature, aromatase positive, adipocytes than with adipocyte stem cells. Cytokine induction was estrogen regulated. The mechanisms of cytokine induction, ER-coactivation and effects of different estrogenic ligands will be presented. Present data illuminate the increased risk of breast cancer after menopause, particularly in obese women and the increased breast cancer mortality with obesity: cancer cell invasion into local fat, in the presence of high local aromatase and intracellular estrogen would establish feed-forward loops to activate Src, maintain pro-inflammatory cytokine production and increase tumor initiating cell abundance, tumor growth and metastasis. These data link obesity related pro-inflammatory cytokines to Src activation and cancer initiating cell abundance, and provide a novel rationale for Src inhibitors together with endocrine therapy for breast cancer.
Title: Obesity increases the lipid mediator, sphingosine-1-phosphate in the tumor and tumor microenvironment, and promotes tumor progression

Tsuchida J, Nagahashi M, Moro K, Tatsuda K, Koyama Y, Takabe K and Wakai T. Division of Digestive and General Surgery, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan and Division of Surgical Oncology, Virginia Commonwealth University School of Medicine and the Massey Cancer Center, West Hospital, Richmond, VA.

Body: INTRODUCTION: While obesity is an established independent prognostic factor for breast cancer patients, the underlying mechanisms how obesity promotes breast cancer progression are not well understood. Sphingosine-1-phosphate (S1P) is a pleiotropic bioactive lipid mediator produced by sphingosine kinases (SphKs) that plays critical roles in inflammation and cancer progression. Our hypothesis is that obesity increases levels of S1P in both tumor and its microenvironment, which promotes obesity-induced inflammation and breast cancer progression. The aim of this study is to test the hypothesis.

METHODS: A high fat diet (HFD) was fed C57Bl/6 mice, which is the most commonly used murine diet-induced obesity model. E0771 cells derived from C57Bl/6 mice were implanted into mammary fat pads of mice that were fed with HFD or normal diet (ND) for 12 weeks prior to the implantation. Western blot, immunofluorescent staining, RT-qPCR and LC-ESI-MS/MS assays were used.

RESULTS: Mice fed with HFD for 20 weeks developed severe obesity with an almost 2 fold increase of body weight compared with ND fed mice. E0771 mouse breast cancer cells were implanted into mammary fat pad of C57Bl/6 mice, and the mice fed with HFD developed significantly larger tumors within 30 days than those fed with ND. Expression of pro-inflammatory cytokines, IL-6 and TNF-α, was increased in the tumors of HFD fed mice, compared to those fed with ND. Furthermore, immunofluorescent analysis with anti-F4/80 antibody showed that tumors from HFD fed animals recruited significantly more tumor associated macrophages than those from ND fed animals. Expression of SphK1 and S1PR1, but not SphK2, was increased in the tumors from mice fed HFD. Mass spectrometry analysis revealed that while S1P levels in the normal breast mammary fat pad were increased with HFD feeding, S1P levels were even higher in breast tumors. Consistent with increased SphK1 and S1P in tumors, S1P was also significantly increased in the tumor interstitial fluid, which is a component of the tumor microenvironment and bathes cancer cells in the tumor. S1P levels were also increased in the serum of the tumor-implanted animals fed with HFD compared with those fed with ND, while minimal changes in S1P were evident in the serum of non-tumor bearing mice fed with HFD. Furthermore, S1P levels in the lungs of tumor-implanted animals fed with HFD were significantly higher than those fed with ND.

CONCLUSION: S1P is increased not only in tumor, but also in tumor microenvironment such as tumor interstitial fluid by obesity. Our results suggest that S1P has a role in obesity-induced inflammation and the cancer progression. Response to cyclooxygenase-2 inhibition is regulated by collagen dense stroma

Ebona K, Inman DR R, Saha S, Wilke LG G and Keely PJ J. Univeristy of Wisconsin, Madison, WI; UW Institute for Clinical and Translational Research (ICTR), Madison, WI and UW School of Medicine and Public Health, Madison, WI.

Body: Women with dense breast have over four-fold risk for breast cancer and high breast density is correlated to increased collagen. In our previously characterized mouse model of MMTV-PyVT x Col1a1tm1jae, increased collagen levels in mammary tumors lead to enhanced tumor formation and progression. Additionally, high collagen density in vitro elevated expression of PTGS2, the gene for cyclooxygenase-2 (COX-2), by over four-fold. Because COX-2 over-expression is observed in 40% of invasive breast carcinoma cases and correlates with poor prognosis, we hypothesized that inhibition of COX-2 may be an effective target in the context of mammary tumors arising in dense tissue. Col1a1tm1jae (HD) or wild-type (wt) tumor mice were randomly assigned at 11 weeks of age to daily treatment with vehicle or celecoxib for 21 days. Tumors in HD mice were larger (p < 0.05) and expressed higher levels of COX-2 (p < 0.05) and PGE2 (p < 0.01). COX-2 and PGE2 expression levels were both decreased with COX-2 inhibition (wt and HD = p < 0.0001, for both markers). Cell proliferation decreased in both wt and HD tumors when COX-2 was inhibited (Epithelium wt and HD p < 0.0001; stroma wt = p < 0.05 and HD = p < 0.01). Notably, several cytokines, immune and stromal cell counts were elevated in HD tumors alone, and COX-2 inhibition reversed this effect. These findings indicate that COX-2 has a direct role in modulating tumor progression in dense matrices and it may be an effective therapeutic target for women with dense breast tissue.
Title: SPARC expression in primary metastatic breast cancer

Barinoff J, Brandi C, Thill M, Heinrichs C, Mensah J, Weikel W, Fisseler-Eckhoff A, Sinn P, Meyer A-S, Traut A and Schneeweiss A. Agaplesion Markus Krankenhaus, Frankfurt am Main, Germany; Gemeinschaftspraxis für Pathologie, Frankfurt am Main, Germany; Dr. Horst-Schmidt-Klinik, Wiesbaden, Germany; Heidelberg University Hospital, Heidelberg, Germany and Kliniken Essen Mitte, Essen, Germany.

Body: Aim: To evaluate the prognostic value of the expression of secreted protein acidic and rich in cysteine (SPARC) in primary metastatic breast cancer (PMBC).

Patients and Methods: Fifty-two patients with PMBC diagnosed between 2005 and 2012 at x German centers were retrospectively analyzed for expression of SPARC in tumor cells using an immunoreactive score (IRS) integrating staining intensity and percentage of positive cells (IRS 0-12), and in stroma based on immunohistochemical (IHC) staining intensity only (IHC 0-3+). Association between SPARC expression, tumor characteristics and progression-free survival (PFS) and overall survival (OS) was analyzed.

Results: Only Her2 expression was associated with expression of SPARC in stroma (p 0.028, OR 13.9 95% 1.3-145.5) but not in tumor cells. SPARC expression in stroma was associated with shorter PFS (hazard ratio (HR) 2.6; 95% confidence interval (CI) 1.2-5.4; p 0.014), but not in tumor cells and shorter OS (HR 4.1; 95% CI 1.04-16; p 0.041) for SPARC expression in stroma of breast tumor. No clear association between expression of SPARC in tumor cells and outcome could be detected.

Conclusion: Only SPARC expression in stroma might be associated with shorter PFS and OS in patients with PMBC. This finding is in line with the known key role of expression of SPARC in the metastastatic process. Confirmation in prospective clinical trials is warranted.
Leptin as a mediator of tumor-stromal interactions promotes breast cancer stem cell activity

Giordano C, Panza S, Chemi F, Barone I, Bonofiglio D, Cordella A, Hashim A, Györfy B, Simões BM M, Clarke RB B, Weisz A, Catalano S and Andò S. University of Calabria, Rende, Italy; IRCCS SDN, Napoli, Italy; Laboratorio di Medicina Molecolare e Genomica Università degli Studi di Salerno, Salerno, Italy; MTA TTK Lendület Cancer Biomarker Research Group and Institute Cancer Sciences, University Manchester, United Kingdom.

Body: Breast cancer stem cells (BCSCs) play crucial roles in tumor initiation, metastasis and resistance to anticancer therapies. These cells rely for their properties on complex interactions with the tumor microenvironment through networks of cytokines and growth factors. In this study, we investigated how leptin, as a mediator of tumor-stromal interactions, may affect BCSC activity using breast cancer cell lines and patient-derived samples. We found that conditioned media (CM) from cancer associated fibroblasts and breast adipocytes significantly increase mammosphere formation in breast cancer cells. Depletion of leptin from stromal cell-CM as well as inhibition of leptin signaling by using a full leptin receptor antagonist peptide LDFI completely abrogated this effect. Accordingly, mammosphere cultures exhibited increased leptin receptor expression and leptin exposure enhanced mammosphere formation. Microarray analyses revealed a similar expression profile of genes involved in stem cell biology in mammosphere cells treated with stromal cell-CM and leptin. Interestingly, leptin is able to increase the mammosphere formation in metastatic breast cancer cells isolated from patients (n = 10) and this can be blocked by using peptide LDFI. In addition, leptin receptor (OBR) mRNA expression, analyzed in cells from metastatic fluids, directly correlated with mammosphere formation activity \( r=0.68, \ p=0.05; \ n=8 \). Finally, Kaplan–Meier survival curves indicated that OBR expression correlated with reduced overall survival in breast carcinomas \( HR=1.9, \ p=0.022 \). Together, our results suggest that leptin/leptin receptor may represent a potential therapeutic target that can block the stromal-tumor interactions that drive BCSC-mediated disease progression.
The "panta rhei" of breast cancer: Gene expression timeline analysis during progression of microinvasive breast cancer microenvironment

Body:

Background. Tumors develop by progression through a series of stages. It is now widely accepted that cancer is attributed to the accumulation of genetic alterations in cells. Every cell of the tumor microenvironment is constantly changing in the flow of the cancer progression. A number of genes have been identified as having functions in various stages of progression in promoting cancer progression in experimental models. However, the association between gene expression alterations and resulting phenotypic alterations with respect to the aggressiveness and migration potential of cancer cells is not fully understood. Therefore, elucidation of genotype–phenotype correlation will be required to further understand the complex process of progression and invasion. All tumors require at least some stroma to meet their needs of nutrition, waste removal, and structure. It has become clear in recent years that stroma is essential for tumor maintenance and growth and has potential as a therapeutic target. Here, we aimed to give a chronological order of gene expression changes given in the dynamical framework of microinvasive breast cancer microenvironment.

Materials and Methods. RNA-seq (Ion Proton technology) was performed on three microinvasive breast cancers, applying new modifications to the usual protocol. For each of them we microdissected 7 different portions of the tumor (around 200 cells), 4 related to the breast epithelium and 3 to the stroma. The regions were selected on the basis of their grade of progression. Breast epithelium was chronologically subdivided in normal breast epithelium (NBE), carcinoma in situ (CIS), emerging invasive fingers (EIF) and invasive breast cancer (IBC). For each of the breast epithelium subdivisions we collected the adjacent stroma (S) except for the in situ portion: S-NBE, S-EIF and S-IBC.

Results: Whole transcriptome analysis performed on each microdissected regions reveals a series of gene expression changes occurring during cancer progression in the breast epithelium along with the adjacent stroma. The dendogram analysis, based on the whole gene expression data of each patient revealed a perfect group organization of the various microdissected portions of stroma and mammary epithelium. Within the dendogram, the organization of Normal, In Situ, EIF and Invasive tissue respected perfectly the biological assumptions.

Conclusions: More thorough analyses are needed to give a clear view of the flow of molecular events starting from the normal breast epithelium to the microinvasive stage, as well as to give a better understanding of the stroma-epithelium molecular means of communication. The analysis of all the molecular changes occurring in the breast epithelium and in the stroma of microinvasive cancer could lead to the development of new therapeutic targets.
Tartrate-resistant acid phosphatase (TRAcP) dependent polarization of breast cancer-promoting macrophages

Dai M-S, Janckila A, Lo H-C, Wu C-C, Chao T-Y and Yu J-C. Hematology/Oncology, Tri-Service General Hospital, Taipei, Taiwan; Special Hematology Laboratory, Robley Rex Veterans Administration Medical Center, Louisville, KY; Hematology/Oncology, Shuang-Ho Hospital, Taipei Medical University, New Taipei, Taiwan and Breast Surgery, Tri-Service General Hospital, Taipei, Taiwan.

Background: Breast cancer associated macrophages often promote tumor growth and metastasis by conditioning the tumor microenvironment and suppressing adaptive immune responses. Tartrate-resistant acid phosphatase (TRACP) is a novel serum biomarker associated with systemic macrophage burden in a variety of chronic inflammatory diseases and is strongly expressed by tumor-associated macrophages. We tested the hypothesis that TRACP is required for M2 macrophage polarization.

Methods: Macrophage cell lines were polarized in vitro and tested for TRACP, iNOS and Arg-1 expression and their ability to promote or repress breast cancer cell growth and invasion in vitro and in vivo. A novel TRACP deficient, Acp5 mutant mouse was used as a macrophage source and as a breast cancer host to confirm a role for TRACP for macrophages to support cancer growth.

Results: TRACP was up-regulated in concert with M2 polarization and down-regulated in M1 polarized cells. TRACP expression correlated with macrophage promotion of tumor growth and invasion in vitro. Although TRACP-deficient macrophages could be induced to express Arg-1 when stimulated with IL-4 plus IL-13 (M2 phenotype), the TRACP deficient macrophages behaved like M1 cells suppressing tumor growth and invasion compared to than WT cells. Tumor xenografts grew slower in primary subcutaneous grafts and metastasized less extensively in intravenous grafts in TRACP deficient mice compared to WT. Furthermore, the tumor metastatic patterns could be reversed in WT animals by co-grafting TRACP-deficient macrophages and in TRACP deficient hosts by co-grafting WT macrophages.

Conclusions: TRACP expression is normally a phenotypic marker for alternatively activated macrophages, but not necessary for expression of Arg-1. In a host environment of TRACP deficiency, Arg-1 positive macrophages can be generated by cytokine stimulation in vitro and by tumor in vivo, however, TRACP deficiency still conveyed a tumor suppressive phenotype in cell based studies and in intact animals. TRACP plays a role in functional polarization of M2 macrophages and their ability to promote breast cancer growth and metastasis.
Title: Pegylated recombinant human hyaluronidase PH20 (PEGPH20) enhances efficacy of eribulin mesylate (HALAVEN®) in triple negative breast cancer xenografts

Body: Hyaluronan (hyaluronic acid, HA), a glycosaminoglycan found in tissue throughout the body, overaccumulates in the tumor microenvironment (TME) of many non-hematologic malignancies, including breast cancer. HA overaccumulation in breast cancer patients correlates with tumor progression and decreased survival (Tammi 2008). Pegylated recombinant human hyaluronidase PH20 (PEGPH20), an investigational therapeutic agent entering Phase 3 clinical development in pancreatic cancer, enzymatically removes HA from the TME. In preclinical animal models, PEGPH20-mediated HA degradation is associated with remodeling of the tumor stroma, reduction of tumor pressure, expansion of tumor blood vessels and facilitated delivery of chemotherapy (Thompson 2010, Provenzano 2012, Jacobetz 2013). Accordingly, preclinical studies investigated the combination of PEGPH20 with eribulin mesylate (ERI, HALAVEN®), a microtubule dynamics inhibitor with a novel mechanism of action (Towle 2001, Jordan 2005), currently approved for treatment of certain patients with advanced breast cancer. NCr nu/nu mice were inoculated subcutaneously with human triple-negative breast cancer (TNBC) HCC1806 or HCC1806/HAS3 cells; the latter subline was engineered to accumulate high HA levels, confirmed by immunohistochemistry, via overexpression of hyaluronan synthase 3 (HAS3). When tumors reached 350 mm³, animals were randomly assigned to four treatments groups: vehicle, ERI (0.7 mg/kg, IV, QW), PEGPH20 (37.5 µg/kg, IV, BIW), or ERI plus PEGPH20. In the parental HCC1806 model, addition of PEGPH20 did not significantly change the antitumor effects of ERI. In contrast, combining PEGPH20 with ERI in the HCC1806/HAS3 model increased the antitumor effects of ERI by 27% (94.5% vs. 119.7% TGI, ERI alone vs. ERI+PEGPH20, respectively; p=0.05) and resulted in 6 of 7 complete tumor regressions.

In a complementary study in HCC1806/HAS3 tumors evaluating ERI pharmacokinetics with and without PEGPH20, mice were assigned to three treatments groups: ERI (0.5 mg/kg, IV), simultaneous ERI plus PEGPH20 (37.5 µg/kg, IV); or ERI plus PEGPH20 predosed 24 h prior to ERI. Animals were sacrificed at 0.5, 1, 4, 24, 48, 72 and 96 h post ERI dose, and ERI levels in tumor, muscle, plasma and liver were subsequently analyzed by liquid/liquid extraction and LC-MS/MS chromatography. Simultaneous administration of ERI and PEGPH20 increased ERI maximum tumor concentration (Cmax) slightly and approximately doubled ERI tumor exposure (AUC); whereas the 24 h pretreatment with PEGPH20 approximately doubled ERI Cmax and increased ERI AUC more than two-fold. No significant differences in plasma ERI levels were observed between groups, and no significant differences in ERI levels in liver or muscle tissue were observed between groups. Taken together, these data suggest that PEGPH20-mediated HA removal significantly increases both ERI tumor concentrations and antitumor effectiveness in an HA-high TNBC model. A clinical phase 1b/2 clinical trial is planned to evaluate PEGPH20 plus ERI in first-line HER2-negative metastatic breast cancer.
Title: Breast milk exosomes promote breast cancer progression

Sauter ER, Qin W and Dasgupta S. University of Texas Health Science Center, Tyler, TX.

Body: Background: The stimulation of extant neoplastic cells vs. their inhibition during breast involution is a key concept in whether pregnancy and lactation decrease or increase breast cancer risk. The time of weaning, a period of breast involution and remodeling, appears critical to future breast cancer risk, as during involution the breast microenvironment becomes tumor promotional. Both matrix metalloproteinases (MMPs) and transforming growth factor (TGF)β isoforms have been implicated in this process. We previously reported that TGFβ2 (but not TGFβ1) expression was significantly higher in milk collected from the cancer containing (vs. matched clinically normal) breast of women diagnosed with cancer during lactation.

Hypothesis: TGFβ2 in milk exosomes from healthy lactating women modulates the development and progression of breast cancer.

Methods: Matched (early, mature and wean-early involution) milk samples were collected from 13 lactating women, exosomes isolated and the levels of five (MMP2, 3, 9; TGFβ1, 2) proteins measured. Based on the results, additional wean samples were analyzed for TGFβ2 expression and samples divided based on their TGFβ2 expression. The highest and lowest TGFβ2 expressing milk exosome samples were co-cultured with MCF-7 breast cancer cells grown in exosome-depleted media. Cell proliferation was measured after 24h. Confocal microscopy was performed after 72h to evaluate epithelial to mesenchymal transition (EMT) in the cells. A TGFβ2 neutralizing blocking antibody was applied after 72 h co-culture.

Results: The greatest increase in expression (four-fold) at the time of involution was in TGFβ2. Confocal microscopy performed 24h after co-culture confirmed the uptake of the exosomes (both those expressing hi and lo TGFβ2) in the MCF-7 cells. There was a significant increase in cell proliferation compared to control (p<0.001) in cells treated with hi TGFβ2 milk exosomes. 72h after co-culture, bright field microscopy demonstrated that MCF-7 cells treated with hi TGFβ2 underwent EMT including the formation of filopodia, whereas those treated with low TGFβ2 did not. A TGFβ2 blocking antibody reversed the EMT phenotype and filopodia formation.

Impact: Pregnancy has a lasting influence on breast cancer risk, and pregnancy associated breast cancers (PABCs) diagnosed after delivery are generally aggressive, with a poor prognosis. Part of the reason for the development of PABCs, and the aggressive nature of PABCs may be the influence of high-expressing TGFβ2 exosomes in the milk on the breast ductal epithelium.
The epithelial to mesenchymal transition: Identifying a signature of recurrence in ductal carcinoma in situ

Felipe Lima J, Yao CQ Q, Yan F, Dion D, Quintayo MA, Lungu I, Nofech-Mozes S, Pruneri G, Viale G, Boutros PC C, Bartlett JMS MS and Bayani J. Ontario Institute of Cancer Research, Toronto, ON, Canada; Sunnybrook Health Centre, Toronto, ON, Canada and Istituto Europeu di Oncologia, Milan, Italy.

Background: The epithelial to mesenchymal transition (EMT) plays a critical role in the progression from non-invasive to invasive breast carcinomas (IBC). It is characterized by alterations in gene expression, changes in cellular polarity, the disruption of tight junctions; production of metalloproteinases, transforming growth factor-β (TGFβ) induction, expression of cancer stem cell markers, hypoxia, decrease in e-cadherin expression, along with other molecular biological events. Several transcription factors including ZEB1/2, TWIST1, SNAIL1/2, FOX family, GATA4/6 are involved in the process. There is a need to identify the molecular events driving the progression of ductal carcinoma in situ (DCIS); and to derive a signature that differentiates DCIS lesions that have the potential to recur as a subsequent DCIS, an IBC, or to not recur. To catalog the changes associated with EMT that may reveal a clinically relevant signature of progression from DCIS to DCIS or IBC recurrences using a panel of 200 genes related to EMT.

Methodology: RNA was extracted from formalin-fixed paraffin embedded (FFPE) sections of pure primary DCIS lesions representing three categories of outcome: those that did not recur; those that recurred with a subsequent DCIS; and those that recurred with invasive cancer. RNA abundance profiling was performed using Nanostring platform and data processing using an R statistical environment. Levels of mRNA abundance were modelled as a function of recurrence status. Coefficients were fit to terms representing the effect and the standard errors of the coefficient were adjusted with an empirical Bayes moderation. Model-based t-tests were then used to test if the coefficients were significantly different from zero.

Results: Using a technical control sample, pairwise comparisons across three replicates showed high correlation (ρ=0.99, P<2.2x10-16 for all 3 comparisons), suggesting the robustness of the assay. In our preliminary survey of 45 patients across the three groups, we have identified a number of genes that showed differential mRNA abundance levels between patients who recurred (either DCIS or invasive recurrence) vs. those who did not recur. Using Random Forest analysis in a leave-one-out cross-validation approach, we were able to obtain a classifier with a sensitivity of 82% and specificity of 58%. Based on these initial findings, an additional 200 samples have been processed to support these initial findings.

Conclusion: The current literature provided increasing evidence that transcriptomic patterns reflecting the EMT may reveal novel biomarkers and elucidate molecular mechanisms leading to improved prognosis. Among breast carcinomas, differential expression of the EMT genes has been associated with a worse outcome, among estrogen receptor-negative and basal-like carcinomas. However, the understanding of the role of EMT genes in DCIS is limited; therefore, to elucidate whether the EMT plays a role in the progression of DCIS, we have designed an EMT gene panel that also includes genes that are significant prognosticators for IBC, including ER, PgR, Ki67 and HER2. In an exploratory analysis of cases trained based on clinical outcome, the sensitivity for predicting recurrence (whether DCIS or invasive) was 82%.
Title: The N-terminus of Twist1 is responsible for interacting with transcriptional repressors to promote EMT and metastasis of breast cancer cells

Yu X, He T and Xu J. Baylor College of Medicine, Houston, TX.

Body: Twist1, a basic helix-loop-helix transcription factor, plays a key role to mediate epithelial-mesenchymal transition (EMT) and promote breast cancer metastasis. However, knowledge about Twist1 structure-function relationships to cancer-related phenotypes is limited. Therefore, we studied the requirement of Twist1 N-terminus in Twist1-dependent breast cancer metastasis. We showed that the amino-terminus of Twist1 was the dominant negative mutant of Twist1. Overexpression of Twist1 N-terminus exhibited different cell morphology and motility in vitro. Inoculation of Twist1 N-terminus overexpression cells into SCID mice showed delayed tumor formation and reduced lung metastasis. Furthermore, Twist1 N-terminus overexpression induced expression change of EMT markers, including E-cadherin, β-catenin, vimentin and Twist1 both in vivo and in vitro. Co-immunoprecipitation and mass spectrometry revealed that Twist1 N-terminus interacted with several members of the Mi2/nucleosome remodeling and deacetylase (Mi2/NuRD) complex, HDAC2, 3 and 7, MTA1 and 2, RbAp46/48, and many corepressors including NCoR1 and 2, which released them from the proximal region of E-cadherin promoter for transcriptional activation. These data suggest that Twist1 N-terminus is required for Twist1-mediated transcriptional programs and breast cancer metastasis.
Title: Predictive value of de novo and induced epithelial-mesenchymal transition in locally advanced breast cancer treated with neoadjuvant chemotherapy

Redfern AD D, McLaren SA A, Dissanayake V, Chan A, Zeps N, Dobrovic A, Soon L, Thompson EW W and Christobel SM M. University of Western Australia, Perth, Western Australia, Australia; Saint Vincents Institute, Melbourne, Victoria, Australia; The Mount Hospital, Perth, Western Australia, Australia; Saint John of God Hospital Subiaco, Perth, Western Australia, Australia; Olivia Newton-John Cancer Research Institute, Melbourne, Victoria, Australia; University of Sydney, Sydney, New Sout Wales, Australia and Queensland University of Technology, Brisbane, Queensland, Australia.

Body: The dynamic transformation of an adherent proliferative epithelial cell to a migratory and invasive mesenchymal state that can drive tumour metastasis has been widely acknowledged in in vitro models as epithelial-mesenchymal transition (EMT). We have characterized EMT status in tissues from 35 locally advanced breast cancer (LABC) patients before and after receiving anthracycline and taxane-based neoadjuvant chemotherapy (NAC). Routine analyses for ER, PR, HER2, lymphovascular invasion (LVI) and tumour staging parameters were available for all patients and five year recurrence and survival data was available for 34. Six patients (17%) had a pathological complete response (pCR), five of whom were hormone receptor (HR) negative and one HR positive. 11 patients (43%) had had disease recurrence and 10 (40%) had died from breast cancer at five years follow up.

Core biopsy tissue specimens were available prior to NAC from all 35 patients. Resected tissue following NAC was available from 17 cases with residual disease. Tissue sections were stained for the epithelial marker cytokeratin 19 (CK19) and the mesenchymal marker vimentin (VIM). Fluorescent, multi-channel microscopy identified co-localization of CK19 and VIM within tumour cells, indicating the presence of EMT.

Evidence of EMT prior to NAC was seen in 14/35 (40%) of LABC cases. There was no association between EMT status pre-NAC and pCR which was observed in 2/14 EMT positive and 4/21 EMT negative patients. However, in patients with detectable EMT pre-NAC there was significantly improved five year disease-free survival (86 vs. 52%, p=0.04) and a trend to improved five year overall survival (86 vs. 62%, p=0.12) compared to cases that were EMT negative pre-NAC.

Of the 17 cases without a pCR with tissue available for assessment of pre- and post-NAC EMT status, seven had disease recurrence and six died by five years. Four cases that were EMT negative pre-NAC developed EMT positive tumour cells following NAC, and all have subsequently developed metastatic disease and died from breast cancer. Two cases lost detectable EMT after chemotherapy, both of whom remain alive. In contrast to pre-NAC EMT, induction of EMT following NAC was associated with trends to worse five year disease-free and overall survival (45 v 75%, p=0.20) and (56 v 75%, p=0.40). Additionally, when events past five years are included in analysis, detectable EMT in the post-NAC tissue sample (induced and retained) correlated with a trend to increased recurrence (p=0.09) and to a statistically significant increase in overall mortality (p=0.04).

This is the first study to explore EMT induction and loss during NAC in the clinical setting. Although patient numbers are few, the data show EMT induction during chemotherapy in a moderate proportion of cases. Observations of significantly superior five year disease free survival in patients without detectable EMT pre-NAC and significantly inferior overall survival in those with visible EMT post-NAC need to be interpreted with caution. Larger studies are needed to further examine this potential prognostic differential between EMT detectable either before or after NAC, and to explore how this may guide therapy.
Title: A novel mechanism of epithelial-mesenchymal transition in breast cancer metastasis: Involvement of prostanoid receptor

Kwong A, Siu MT T, Cheuk I, Ho JC C, Chen J and Shin VY Y. The University of Hong Kong, Hong Kong; Hong Kong Sanatorium & Hospital, Hong Kong; Hong Kong Hereditary Breast Cancer Family Registry, Hong Kong and Stanford University School of Medicine.

Body: Background: Triple-negative breast cancer is associated with higher metastatic rate and poor prognosis than other subtypes of breast cancer due to lack of targeted therapy. Epithelial-mesenchymal transition (EMT) is linked with metastasis with phenotypic conversion of epithelial cells. However, the regulation of EMT in breast cancer metastasis remains largely unstudied. Recent attention has focused on targeting the downstream of COX-2 pathway, understanding the role of prostanoid receptors in breast cancer metastasis may help the development of effective therapeutic interventions for patients with metastasis.

Methods: A stable EP2-expression cell line (MB-231-EP2) was used to study tumorigenesis and distant metastasis in human breast cancer metastatic model. Localization of EP2 and EMT markers were examined by immunostaining and immunofluorescence. Profiles of drug transporters genes were compared between siEP2 and siControl cells. Functional role of EP2 on cell proliferation, invasion and apoptosis were assessed. Alteration of EMT markers were examined by real-time PCR and Western blot analysis.

Results: Expression of EP2 receptor were higher in human primary tumors than non-tumor tissues. EP2 receptor was predominantly expressed in metastatic tumors than primary tumors in human breast cancer metastatic mice model. The metastatic tumors showed a higher Ki67 (cell proliferation) and CD31 (angiogenesis) than primary tumors in the xenograft tissues. Larger tumors and poor survival were seen in MD-231-EP2 bearing mice when compared with control. Silencing of EP2 by siRNA markedly reduced cell proliferation and invasion, but increased apoptosis and expression of solute carrier family 19 member A3 (SLC19A3) gene. Interestingly, SLC19A3 had a lower expression in primary tumors and was inversely correlated with EP2 expression. Ectopic expression of SLC19A3 suppressed cell proliferation and invasion through the restoration of E-cadherin and other EMT markers (Twist, Zeb1 and Snai2). Immunofluorescence staining showed that the localization of Twist and E-cadherin were altered in siEP2 cells.

Conclusion: Our results showed that EP2 promoted EMT and breast cancer metastasis through the downregulation of SLC19A3 expression. Taken together, targeting EP2/SLC19A3 signaling pathway maybe a potential treatment for metastasis and adjuvant chemotherapy to reduce the metastatic risk.
Title: Inflammatory breast cancer cells show a particular pattern of canonical and non-canonical TGFβ signalling, possibly affecting cancer cell motility

Body: Introduction
Inflammatory breast cancer (IBC) is an aggressive form of breast cancer with an elevated metastatic potential. Recent evidence suggests that TGFβ signalling may be an important driver of the disease. Here, we describe data from patient samples and preclinical models that corroborate this hypothesis.

Materials and Methods
The xCELLigence system was used to profile a series of 3 IBC and 3 subtype-matched non-IBC cell lines for the cell motility inducing capacity of a panel of chemokines: TGFα, TGFβ, EGF, FGF, HGF, IGF, PDGF, CCL2, CCL5, CCL12 and CXCL21. Significant results were confirmed using classical wound healing assays (WHA). A series of 79 IBC and 133 non-IBC patient samples was evaluated for nuclear SMAD2, -3 and -4 protein expression using immunohistochemistry (IHC). In a subseries of 14 IBC and 21 non-IBC patient samples, protein expression and Affymetrix gene expression data were integrated and Expression2Kinases was used to identify key components of TGFβ signalling in IBC.

Results
Whereas TGFβ-induced cell motility in all non-IBC cells, we noted a 18-fold reduction of cell motility in IBC cells. Classical WHA showed a near complete wound closure (90% reduction of the wound area) after 24hrs of TGFβ treatment in non-IBC cells. Under similar conditions in IBC cells, the reduction of the wound area was less than 10%. IHC on patient samples revealed increased nuclear SMAD2 protein expression in combination with attenuated nuclear SMAD3 protein expression in IBC, independent of classical clinicopathological variables. Integration of protein and gene expression data demonstrated that nuclear SMAD2 expression in IBC is mediated through the canonical TGFβ signalling pathway, whereas the absence of nuclear SMAD3 expression is due to impaired non-canonical, p38MAPK/ATF2-dependent TGFβ signalling. Of note, ATF2 expression is specifically attenuated in IBC.

Discussion
This study provides the basis for continued research into the role of TGFβ in IBC. We show that, unlike non-IBC cells, IBC cells do not induce cell motility in response to TGFβ stimulation. This observation can be explained by impaired non-canonical p38MAPK/ATF2-dependent TGFβ signalling in IBC, which is essential for SMAD3-driven epithelial to mesenchymal transition (EMT). SMAD2 on the other hand is a proven driver of EMT-independent modes of cell motility. Our results strengthen the vision that EMT is not required for IBC cell invasion.
Title: Essential role of notch-4/STAT3 signaling in epithelial-mesenchymal transition of tamoxifen-resistant human breast cancer

Bui QT Thu and Kang KW. College of Pharmacy and Research Institute of Pharmaceutical Sciences, Seoul National University, Seoul, Korea.

Body: Epithelial-mesenchymal transition (EMT) is process in which epithelial cells undergo unique morphologic changes characterized by a transition from epithelial cobblestone phenotype to elongated fibroblastic phenotype (mesenchymal phenotype) leading to increased motility and invasion. Our previous study demonstrated that tamoxifen (TAM)-resistant human breast cancer (TAMR-MCF-7) cells showed the increased expression of mesenchymal marker proteins compared to the parent MCF-7 cells. Notch plays a crucial role in the promotion of EMT during both development and tumor progression. Especially, Notch-1 and Notch-4 were reported as prognostic markers in human breast cancer. Here, we found that the basal expression and activity of Notch-4 were significantly increased in TAMR-MCF-7 cells compared to control MCF-7 cells. Suppression of Notch-4 by either Notch inhibitors or Notch-4 siRNA significantly attenuated the EMT signaling. Interestingly, long-term treatment with DAPT, a Notch inhibitor, eventually led to partial reversal of EMT by up-regulating E-cadherin expression. Activated or tyrosine-phosphorylated STAT3 (pYSTAT3) protein is supposed as a critical signaling molecule in the regulation of tumorigenesis and metastasis of cancer cells. We further found that TAMR-MCF-7 cells exhibited constitutive STAT3 phosphorylation. Suppression of Notch-4 activation attenuated the activated STAT3 elevation in TAMR-MCF-7 cells. We hypothesized that Notch-4 regulated EMT in TAMR-MCF-7 cells via STAT3 signaling. Intrasplicenic injection model of liver metastases was performed using TAMR-MCF-7 cells. Mice were received subcutaneous injections daily with DAPT (10 mg/kg) formed smaller tumor size in spleens and showed less micrometastatic tumor burden in livers compared to group treated with vehicle. In conclusion, inhibition of Notch signaling may have efficacy in the treatment of breast cancer metastasis.

Title: A force-sensitive organoid assay to quantify regenerative potential of single primary human mammary cells

Scheel CH H, Linnemann JR R, Miura H, Meixner LK K, Irmler M, Kloos UJ J, Hirschi B, Bartsch HS S, Sass S, Beckers J, Theis FJ J, Gabka C and Sotlar K. Institute of Stem Cell Research, Helmholtz Center Munich, Neuherberg, Germany; Institute of Experimental Genetics, Helmholtz Center Munich, Neuherberg, Germany; Institute of Pathology, Medical School, Ludwig Maximilian University Munich, Munich, Germany; Institute of Computational Biology, Helmholtz Center Munich, Neuherberg, Germany; Technical University Munich, Freising, Germany; Technical University Munich, Garching, Germany and Nymphenburg Clinic for Plastic and Aesthetic Surgery, Munich, Germany.

Body: We have developed an organoid regeneration assay to quantify the ability of freshly isolated, single human mammary epithelial cells to generate complex branched ductal structures with basal and luminal features. For this purpose, cells are cultured in adherent or floating collagen gels, corresponding to a rigid or compliant matrix. In both conditions, single luminal progenitors form spheres, whereas basal cells generate branched ductal structures. In compliant but not rigid collagen gels, branching ducts in multicellular structures generated by basal cells develop a lumen and alveoli at their tips. Importantly, branched structures generated by single basal cells express basal and luminal markers at correct positions, thereby demonstrating bi-potential. Functionally, basal cells in branched structures display cellular contractility, which we reveal to be required for alveologenesis. In conclusion, branched structures generated by single basal cells in compliant collagen gels resemble terminal ductal-lobular units (TDLU), the functional units of the mammary gland.

To prospectively isolate basal cells with regenerative potential, we added the membrane metallo-endopeptidase CD10 as a cell surface marker to existing sorting protocols, thereby enriching for TDLU-formation and enabling rigorous quantification of regenerative potential by extreme limiting dilution assay (ELDA). Moreover, the use of CD10 as a cell surface marker reveals the presence of stromal cells with endothelial qualities within the CD49fhi/EpCAM– population, previously labeled basal. In summary, we describe a defined in vitro assay system to quantify primary human mammary epithelial cells with regenerative potential and systematically investigate their interaction with the physical environment at distinct steps of morphogenesis.

Title: Epithelial to mesenchymal transition (EMT) regulates the spontaneous generation of GD2+ breast cancer stem-like cells through NFκB activation

Battula VL, Sun J, Nguyen K, Hortobagyi G and Andreeff M. UT MD Anderson Cancer Center, Houston, TX.

Body: Breast cancer recurrence may be a consequence of persistent breast cancer stem-like cells (BCSCs) that survive chemotherapeutic or hormonal therapy. Therefore, targeting BCSCs could complement standard chemotherapy. We discovered that the ganglioside GD2 is expressed on and defines BCSCs (Battula et al., JCI, 2012), as consequence of activation of the enzyme GD3 synthase (GD3S). Inhibition of GD3S expression inhibited breast cancer metastasis to lung. We also observed that GD2- breast cancer cells spontaneously generate GD2+ cells in vitro. As induction of EMT generates a stem cell–like phenotype, we hypothesized that EMT regulates the generation of GD2+ breast cancer cells. To test this hypothesis, MDA-MB-231 and SUM159 cells were cultured in vitro and the percentage of GD2+ cells was measured over time. Interestingly, the percentage and absolute number of GD2+ cells increased in a time-dependent manner, suggesting the spontaneous generation of GD2+ cells. Concomitantly, mesenchymal-related markers including vimentin, N-cadherin, and twist increased 3 to 6-fold. To further investigate whether this process is operational in vivo, GFP+ MDA-MB-231 cells were transplanted into mammary fat pads of NOD/SCID mice. Each week, a group of mice was sacrificed, tumors were extracted and the number of GFP+GD2+ cells was determined by flow cytometry. In line with our in vitro results, we observed significant increases in GD2+ BCSCs with increasing tumor volume from 15.1%±4.6% to 37%±8.7% over a 6 week period, suggesting that breast cancer cells spontaneously undergo EMT during tumor progression and generate GD2+ BCSCs.

To identify possible targets to inhibit EMT in breast cancer cells, proteomic analysis using Kinexus® antibody arrays revealed activation of NFκB and focal adhesion kinase (FAK) signaling in GD2+ breast cancer cells. The activation of NFκB (phospho p65) in GD2+ cells was validated by CyTOF mass cytometry using metal tagged antibodies. These data suggest that inhibition of NFκB signaling may inhibit GD2+ BCSC growth. Indeed, the IKK inhibitor BMS345541 reduced GD2+ cells by >95% and inhibited GD3S expression (determined by qRT-PCR) in a dose- and time-dependent fashion. In contrast, treatment with doxorubicin increased the percentage of GD2+ cells, from 13.5±2.5% to 21±2.6% in MDA-MB-231 cells, suggesting that GD2+ cells are resistant to doxorubicin. In addition, treatment with BMS345541 inhibited the ability of breast cancer cells to form mammospheres by >90% in vitro. In-vivo tumorigenesis assay demonstrated that BMS345541 induced a significant decrease (p <0.01) in tumor volume, and increased survival of tumor bearing mice: median survival was 78 days for BMS345541-treated mice vs. 58 days for controls (p<0.002).

Conclusion: GD2+ BCSCs are spontaneously produced during tumor progression by EMT and NFκB and FAK mediated signaling might regulate this process. Inhibition of NFκB and FAK signaling pathways may inhibit the spread of BCSCs and reduce breast cancer metastases.
Title: Bisphenol A treatment induces hyperplasia in primary and stem cell-generated mammary glands from pregnant mice

Bouamar H, Zhang F, Gu X, Dong Q and Sun L-Z. University of Texas Health Science Center, San Antonio, TX and School of Environmental Sciences and Public Health, Wenzhou Medical College, Wenzhou, Zhejiang Province, China.

Body: Breast cancer is a commonly diagnosed cancer of pregnancy. However, how endogenous and exogenous endocrine factors may contribute to the development of pregnancy-associated mammary tumorigenesis is not clear. There is growing evidence that mammary stem cells (MaSCs) may initiate neoplastic transformation when dysregulated in mouse models. We investigated the effect of the environmental endocrine disruptor bisphenol A (BPA) on mouse mammary gland morphology, epithelial cell composition, pre-neoplastic lesions, and the regenerative function of MaSCs. Pregnant FVB mice with GFP transgene on Day E8.5 were implanted with osmotic pumps that constantly release BPA at 0, 25 or 250 ng/kg/day for 28 days and the mice were euthanized one month after weaning. In agreement with the literature, we observed an abnormality of the morphology of the mammary gland after BPA treatment characterized by higher duct density and abnormal secondary and tertiary branching. Quantification of percent hyperplastic mammary ducts in H&E-stained tissue slides revealed a significant increase of ducts with hyperplastic lesions after BPA treatment, particularly with the low dose. To investigate the effects of BPA treatment on MaSCs, we used enzyme digestion to isolate the CD24hi/CD49f+ luminal epithelial cells (also termed as colony forming cell or CFC) and the CD24+/CD49fhi basal epithelial cells (also termed as mammary repopulating unit or MRU) from mammary gland tissues by FACS and found no significant difference in percent of luminal or basal cell population after BPA treatment. Because the basal cells are enriched with MaSCs that can form mammospheres in suspension culture and subsequently form solid 3D organoids when cultured in Matrigel, we transplanted the solid 3D organoids into cleared mammary fat pads of syngeneic FVB mice and immune-compromised nude mice to examine how BPA treatment might alter MaSC function. Significantly, similar to the results from the primary mammary glands, the regenerated mammary glands by MaSCs from mice treated with the low dose of BPA showed increased duct density, secondary and tertiary branching, and a significantly greater number of hyperplastic lesions. Taken together, our study demonstrated that BPA exposure at very low dose could induce pre-neoplastic lesions in the mammary gland of pregnant mice, apparently by directly targeting MaSCs and implicates BPA as an exogenous endocrine factor that may promote pregnancy-associated mammary tumorigenesis.
The incidence of/mortality from the most aggressive triple negative breast cancer (TNBC) is higher in African American-(AA) than Caucasian (CA)-women. In contrast, breast cancer in Hispanic-women is generally less aggressive. There is an ongoing debate as to whether AA-women have an increased incidence of TNBCs that have poor outcome or there are unique biological factors in AA-women that promote aggressive biology. Through unique approaches, we provide evidence for distinct biology in the normal breasts of CA-women, AA-women, and Hispanic-women. Using resources from the Komen Normal Tissue Bank and a primary cell culturing system that enabled propagation of normal epithelial cells of different lineages including mature-luminal, luminal-progenitor, and stem cells from different ethnic groups, we have identified a subpopulation of CD44high/CD24- cells that are unique to AA-women (p=0.0001). This AA-women-specific subpopulation expressed higher levels of Collagen 3A1, Collagen 5A2, CTNNB1 (β-Catenin of Wnt), FOXC2, and ZEB1 compared to common CD44+/CD24+ subpopulation in every breast. Gene expression pattern in the AA-specific CD44high/CD24- population showed marked similarity to gene expression pattern in the recently described PROCR+ multi-potent mammary stem cells. Indeed, the breast epithelial cells of AA-women were enriched for PROCR-positive stem cells compared to CA-women or Hispanic-women (p=0.015). In contrast to cells from CA- and AA-women, cells isolated from the healthy breast of Hispanic-women displayed mostly differentiated features as they were enriched for CD49f-/EpCAM+ and CD271-/EpCAM+ mature cells. Cells from CA-women, AA-women and Hispanic-women are currently being immortalized to determine the cell types that are preferentially immortalized in each of these ethnic groups. These results suggest ethnicity-dependent differences in Wnt, extracellular matrix, and epithelial to mesenchymal transition (EMT) signaling in normal breast epithelial cells and differences in the proportion of cells that are susceptible to immortalization/transformation.

Title: Mammary stem cell modulation of wildtype and Trp53 null stem cells by CAPE (caffeic acid phenethyl ester), a potential therapeutic agent

Omene C, Patel M, Kannan K, Heguy A and Barcellos-Hoff MH. NYU Langone Medical Center, NYU School of Medicine, NY, NY.

Body: CAPE is the major active component of propolis, a widely available, non-toxic, honeybee natural product with anti-inflammatory, antioxidant, and antitumor properties. We have previously shown that CAPE inhibits growth of breast cancer cells and the tumorigenic potential of breast cancer stem cells. We have identified inhibition of histone deacetylase (HDAC) as one mechanism of action, which suggests that it mediates its effects through epigenetic modifications. We postulated that CAPE may be useful in chemoprevention for women at high risk for triple-negative breast cancers since the cell-of-origin hypothesis states that these cancers likely arise from transformation of mammary stem or progenitor cells, whose self-renewal is maintained via epigenetic states.

We tested the effect of CAPE on wildtype (WT) and Trp53 null mammary stem cell (MaSC) self-renewal from BALB/c mice cultured as mammospheres (MMS). Primary mammary epithelial cells were cultured as MMS for 7 days, dissociated into single cells, re-cultured in the presence of CAPE for 7 days and passaged in secondary and tertiary passages without CAPE. MMS frequency and differentiation potential was analyzed using immunofluorescence detection of luminal marker, cytokeratin 18, basal marker, cytokeratin 14, and progesterone receptor (PR). Chromatin states were identified using ATAC-seq and open chromatin areas unique to CAPE treated murine MMS were used for pathway analysis performed by Ingenuity Pathway Analysis, Gene Set Enrichment Analysis and confirmed by Integrative Genome Viewer.

CAPE treatment resulted in a dose dependent decrease in both WT and p53 null mammosphere forming efficiency that persisted in secondary and tertiary passages, suggesting reduced self-renewal. CAPE treatment also shifted differentiation from predominantly basal K14 to luminal K18-positive in both WT and p53 null MMS and increased PR expression in WT MMS. ATAC-seq of CAPE treated WT MMS showed significant pathway enrichment for p53 signaling, SOX2 signaling, and enrichment of open chromatin for several genes including the SMARCA4 gene, which regulates transcription of genes involved in stem cell renewal. ATAC-seq of CAPE treated Trp53 null MMS showed that genes defining early and late response to estrogen were particularly important. Significant canonical pathways included Aryl hydrocarbon receptor signaling, whose upregulation results in inhibition of self renewal and has been targeted as a potential drug target for estrogen receptor negative breast cancer. The integrin signaling pathway was also highly enriched.

These data suggest that CAPE both inhibits MaSC self-renewal and shifts the lineage commitment to a luminal, ER + lineage. ATAC-seq demonstrated genomic effects that are important in differentiation, SC renewal and adhesion. These data suggest that CAPE may have an effect on lineage commitment in support of our chemoprevention strategy to reduce triple-negative breast cancer.
Title: Msi1 in maintaining breast cancer stem cell involves the AKT/PI3K pathway

Nahas GR R, Sinha GA A, Sherman LS S, Walker ND D and Rameshwar P. Rutgers University-Graduate School of Biomedical Sciences, Newark, NJ.

Body: Musashi1 (Msi1) was originally described in neural stem cells in a role influencing neural differentiation in the Numb/Notch pathway. Due to its role in neural stem cells, there has been much interest in the role of Msi1 in the breast cancer (BC) stem cell population. In this vein, with we have demonstrated a possible feedback loop between the stem cell marker OCT4 and Msi1, in addition to other stem cell-associated genes. Flow cytometry analyses demonstrated that the subset of BC cells (BCCs) that we previously identified as those with high Oct4 was also enriched for Msi1. Msi1 knockdown BCCs showed decreased doubling time and with limited ability to be passaged, indicating the loss of the self-renewal subset needed for cell passaging. These in vitro findings were consistent with the inability of the Msi1 knockdown BCCs to undergo serial passages in vivo. We therefore examined the Msi1 knockdown BCCs for intracellular proteins that could explain the reduced cell growth and the reduced initiating cells. We selected the AKT/PI3K pathway due to its recent connection to the maintenance of BC stem cells. Msi1 knockdown repressed several molecules within the AKT/PI3K pathway: PTEN, AKT, and PI3K. There were no significant differences found however, in the apoptotic factors, BCL-2 and Caspase-3. Upon further investigation, we observed increases in molecules that are linked to decreased cell proliferation and senescence, p16, p53 and p21. Since Msi1 is an RNA binding protein, it is possible that its loss could leave RNAs for binding to miRNAs and this might be partly responsible for the decrease in key intracellular molecules needed for the survival and proliferation of the Msi1 knockdown BCCs. Further studies are needed to investigate how miRNAs and Msi1 interact to maintain the survival of BCCs. Finally, Msi1 KD positively affects the expression of the immune checkpoint inhibitor PD-1L, suggesting increased PD-1L expression in cells that are not of the CSC phenotype. The studies may identify Msi1 or its associated molecules as a potential therapeutic intervention for BC.
Title: Stem cell markers CD44+CD24- and ALDH1 in primary breast cancers and metastatic sentinel and non-sentinel lymph nodes

Kim W, Kim Y-M, Kim W and Lee J-S. Haeundae Paik Hospital, Inje Medical University, Busan, Korea; Haeundae Paik Hospital, Inje Medical University, Busan, Korea and Haeundae Paik Hospital, Inje Medical University, Busan, Korea.

Body: Background and Aim
Studies of Aldehyde dehydrogenase 1 (ALDH-1) and CD44+/CD24- have suggested them as cancer stem cell (CSC) markers in breast cancers and the clinicopathologic and prognostic significance of these CSC markers have been widely investigated. However, expressions of CSC in metastatic axillary lymph nodes (ALN) of breast cancers have not yet been the center of interest. Therefore, the object of this study is to explore breast CSC markers CD44+/CD24- and ALDH-1 in the primary breast tumor and metastatic ALNs by retrospectively analyzing the CSC expressions on metastatic tumor cells within ALN.

Method
180 surgically resected breast cancers were selected and among them 165 cases had undergone sentinel lymph node (SLN) with or without non-sentinel lymph node (NSLN) dissections. 50 SLNs (30.3%) and 43 NSLNs (30.9%) had metastatic tumor cells and total of 74 cases were involved with axillary lymph node metastasis. Double immunohistochemistry of CD44/CD24 and single immunohistochemical staining of ALDH-1 were applied on paraffin embedded breast tissue specimens and lymph node specimens to evaluate the CSC phenotypes of primary tumor and metastatic lymph nodes.

Results
The prevalence of CD44+/CD24- and ALDH-1(+) tumor cells in primary breast cancer was 76.7% and 45.0%. In triple negative breast cancers (TNBC) contained significantly higher percentage (49.2%) of ALDH-1 positive tumor cells (p=0.001). CD44+/CD24- phenotype was present in 65.2% and 40.0% in metastatic SLNs and NSLNs, respectively. The analysis of metastatic sentinel lymph nodes and breast cancers with CSCs indicated that there are significant relationships with ALDH-1(+) (p<0.001) and CD44+/CD24- (p<0.001) phenotypes. CSC expression in metastatic NSLNs and breast tumors also showed significant association (p=0.001). However, CSCs in metastatic SLNs and NSLNs did not show any significant relationships to the intrinsic molecular subtypes.

Conclusions
This study investigated the impact of the stem/progenitor phenotype defined by CD44 positivity/CD24 negativity and ALDH-1 positivity in sentinel lymph nodes (SLN) on non-sentinel lymph node (NSLN) metastases. CSC phenotypes expressed in metastatic SLNs and NSLNs, independently showed significant association with the primary breast tumors. However, in future, the authors recommend that the exploration of a much larger study including a vast amount of pool will provide a more reliable result.
Title: Proto-oncogene PELP1 signaling regulates breast cancer stem cells via G9a/EHMT2

Viswanadhapalli S, Mann M, Sareddy GR R, Xaionan L, Vankayalapati H, Brann D and Vadlamudi RK K. UT Health Sciences Center at San Antonio, San Antonio, TX; Oncolexis Therapeutics, Inc., Dallas, TX and Medical College of Georgia, Augusta, GA.

BACKGROUND: Evolving evidence suggests that cancer stem cells (CSCs) evade hormonal therapy and therapy resistance occurs due to regrowth of tumor cells from cancer stem cells that escaped hormonal therapy or remained in the body after tumor resection. Recent studies suggest that estrogen stimulates breast cancer stem-cells and G9a/EHMT2 plays a critical role in stem cell maintenance. Proline, glutamic acid, and leucine rich protein (PELP1) is a proto-oncogene that functions as a critical coregulator of several nuclear receptors and other transcription factors. PELP1 is commonly overexpressed in hormone-related cancers, and is prognostically linked to shorter breast cancer survival. Recent studies from our lab discovered PELP1 interacts with G9a/EHMT2. However, it remains unknown whether PELP1-G9a signaling plays a role in breast cancer stem cell proliferation. The objective of this study is to develop small molecular inhibitors that block G9a/EHMT2 interactions and to test their utility.

METHODS: We isolated CD44high/CD24low CSCs from three breast cancer cell lines (ZR75, MCF7, T47D) using FACS. To test the effect of PELP1 inhibitors on CSCs, we cultured CSCs in SFM in the presence or absence of PELP1 inhibitors for a period of 7-10 days. Cells were analyzed for spheroid formation, morphological changes, immunofluorescence for differentiation markers, protein (Western) and RNA (RT-qPCR) analysis. Expression of differentiation markers K19 and K14 and stem cell markers CD133, CD44, Id1, Nestin, Musashi-1, SOX2, Notch2, and OCT1 was determined.

RESULTS: Using mapping studies, we identified a small peptide inhibitor (PIP1) that interferes PELP1 interaction with G9/EHMT2. Utilizing Hit-Ligand interaction site with the PELP1 hot spot residues based on 3D alignment and shape, we have identified 61 potential hits from Ligand-Based screening using a 10,000 Diverse Set. Screening of these 61 potential hits using MTT based cell viability assays identified three small organic molecule inhibitors (peptidomimetics) as leads. All three peptidomimetics (#20, #29, #34) showed activity similar to PELP1 peptide inhibitor 1 (PIP1) in assays using three different breast cancer cell lines. Further, PELP1 targeting peptidomimetic disrupted PELP1 interaction with G9a/EHMT2. Peptidomimetic treatment inhibited the proliferation of tamoxifen therapy resistant cells. In mechanistic studies, we found that knockdown of PELP1 inhibited stem cell maintenance. In FACS analysis of ZR75, ZR75-PELP1 and ZR75-PELP1KD cells, the percentage of CD44high/CD24low cells correlated with PELP1 status. Accordingly, in mammosphere formation assays, PELP1 targeting peptidomimetic significantly inhibited the formation of mammospheres and the size of the mammospheres was also substantially decreased. Further, in self-renewal assays, peptidomimetic-treated cells had decreased self-renewal capacity.

CONCLUSIONS: Collectively, our studies have discovered an essential role for PELP1 in breast cancer stem cell maintenance and identified the PELP1- G9a/EHMT2 axis as a potential therapeutic target for reducing stemness. Further, the novel small molecule inhibitors of PELP1 could be used for therapeutic targeting of breast cancer stem cells and therapy resistance.
Characteristics, treatment and outcomes of breast cancer diagnosed during pregnancy and the year after delivery

Body: Background:
Pregnancy associated breast cancer (PABC) is defined as breast cancer (BC) diagnosed during pregnancy or during the year after delivery. Whether PABC is associated with inferior outcomes compared to non-PABC is uncertain. Data suggests characteristics and outcomes of BC diagnosed during pregnancy and BC diagnosed within the year after delivery may differ. However, most previous research has not separated BC cases diagnosed during pregnancy from those diagnosed within the year after delivery.

Methods:
We performed a single institution retrospective cohort study of women diagnosed at the Johns Hopkins Hospital with PABC between 1985-2014 and matched controls. Women with BC diagnosed during pregnancy and BC diagnosed during the year after delivery formed two separate case groups. Controls were matched 2:1 to each of the cases by time period of diagnosis, age (+/- 5 years) and extent of disease at diagnosis. Clinicopathologic features, treatment and outcomes were compared between each case group and its respective controls. Univariate Cox modeling stratified by matching set was used to compare time to relapse between cases and their matched controls.

Results:
Of 140 PABC cases identified, BC was diagnosed during pregnancy in 65 and during the year after delivery in 75. 135 controls were matched to the cases diagnosed during pregnancy and 145 controls were matched to the cases diagnosed during the year after delivery. Compared to their controls, cases diagnosed after delivery were more likely to have grade 3 tumors (81% versus 60%) and less likely to be hormone receptor (HR)-positive (62% versus 82%). Similarly, compared to their controls, cases who were pregnant at diagnosis were more likely to have grade 3 tumors (77% versus 57%) and less likely to be HR-positive (54% versus 75%). The frequency of HER2-positivity between cases diagnosed during pregnancy or during the year after delivery was similar to their respective control groups. A higher proportion of cases diagnosed during pregnancy underwent mastectomy than their controls, but this was not statistically significant (74% versus 67%). Most patients in both case groups and both control groups received chemotherapy. The proportions of patients in both case groups compared to their controls who received radiation were similar. Rates of relapse were high in the entire study population. There was a non-significant increased risk of relapse for both the cases diagnosed during pregnancy compared to their controls (HR 1.77, 95% CI 0.844-3.73, p 0.13) and for the cases diagnosed after delivery compared to their controls (HR 1.51, 95% CI 0.70-3.24, p 0.30).

Conclusions:
In our study population, women diagnosed with BC during pregnancy or within the year after delivery were more likely to have high grade and HR-negative disease than controls matched for age, extent of disease and time period of diagnosis. Rates of recurrence were high among our young study population. Findings must be interpreted with caution due to small sample size, but suggest that rates of relapse were not significantly higher among the cases diagnosed during pregnancy or within the year after delivery compared to their controls.
Title: 5-year overall survival of early breast cancer during pregnancy: A multicenter French case control study

Vanlemmens L, Ploquin A, Delaloge S, Rouzier R, Lesur A, Frenel J-S, Loustalot C, Bachelot T, Provansal M, Ferrero J-M, Coussy F, Debled M, Kerbrat P, Vinceneux A, Djelila A, Baron M, Jebert S, Decoupigny E, Tresch E and Bonneterre J. Centre Oscar Lambret, Lille, France; Institut Gustave Roussy, Villejuif, France; Institut Curie, Paris, France; Institut de Cancérologie de Lorraine, Vandoeuvre les Nancy, France; Institut de Cancérologie de l'Ouest - Centre René Gauducheau, St Herblain, France; Centre Georges Francois Leclerc, Dijon, France; Centre Léon Bérard, Lyon, France; Institut Paoli Calmettes, Marseille, France; Centre Antoine Lacassagne, Nice, France; Hopital Saint Louis, Paris, France; Institut Bergonié, Bordeaux, France; Centre Eugene Marquis, Rennes, France; Hopital Universitaire Bretonneau de Tours, Tours, France; Centre Francois Baclesse, Caen, France and Centre Henri Becquerel, Rouen, France.

Body: Background: Breast cancer (BC) during pregnancy (BCP) is a rare situation that requires collaboration between oncologists, surgeons and obstetricians. The main objectives of this study were to compare the overall survival (OS) and disease free survival (DFS) of a multicenter cohort of pregnant patients (pts) with those of matched control pts.

Methods: Patients from 27 centers and diagnosed between 2000 and 2006 with histological confirmed M0 invasive BC were included in this retrospective study. For the cohort of BCP, pts whose pregnancy was interrupted were not eligible. Controls were matched to BCP pts on 5 criteria: clinical T (of TNM), hormonal receptor (HR) status, HER2 status, administration of neo-adjuvant chemotherapy and pathological nodal status in the absence of neo-adjuvant chemotherapy. Survival times were estimated from the date of diagnosis using Kaplan-Meier method. OS was calculated until death from every cause, DFS was calculated until relapse or death from every cause; patients alive were censored at the date of last news.

Results: 100 BCP pts were identified. Their clinical and pathological characteristics were described on a previous presentation (SABCS 2013 P6-06-07). Matched controls could not be found for 12 BCP pts. 88 BCP pts were matched with 204 controls. The only differences between the 2 populations in terms of characteristics or treatment were more radical mastectomy (p=0.036) and fewer taxane administrations in the BCP group (p=0.06). The median duration of follow-up was 8.2 years for cases and 7.7 years for controls. There were no differences between BCP pts and controls in 5-year OS: 83.4%, IC 95% (73.5-89.8) vs 83.8%, IC 95% (77.9-88.3) nor 7-year OS: 76.5% (65.5-84.4) vs 78.1% (71.5-83.3) (p=0.52). The 5-year DFS was 58.6% IC 95% (47.3-68.3) vs 67.2% IC 95% (60.2-73.2) (p= 0.16). However, 5-year DFS was lower in HR+ BCP pts subgroup than in HR+ control group (56.7% IC 95% (40.7-69.8) vs 70.9% IC 95% (61.4-78.5) (p=0.023).

Conclusion: This multicenter French large study confirmed that there are no differences on OS and DFS between pregnant and no pregnant pts, though this might not be true for HR subgroup.
Reproductive factors and subtype specific breast cancer risk

Anderson WF F, Pfeiffer RM M, Wohlfahrt J, Ejlertsen B, Jensen M-B and Kroman NT T. National Cancer Institute, Bethesda, MD; Statens Serum Institut, Copenhagen; Danish Breast Cancer Group, Copenhagen and Righopitalet, Copenhagen, Denmark.

Introduction: Reproductive history and breast cancer risk reportedly differ by the estrogen receptor (ER±) and by the joint expression of ER and the human epidermal growth factor-2 receptor (ER±/HER2±). However, large sample sizes are needed to identify risk factor associations for the relatively less common ER- subtypes.

Material and Methods: We, therefore, linked two large-scale and population-based Danish registries to assess the associations for parity, number of live births, and age at first live birth (AFLB) with receptor-specific breast cancer risk. Relative risks (RRs) and 95% confidence intervals (CIs) for associations were estimated with Poisson regression models.

Results: With nearly 31 million women-years of follow-up, there were 45786 Danish women between the ages 20-84 years who developed an invasive breast cancer during the study period 1992-2011. Parity significantly reduced risk for ER+ and ER+/HER2- subtypes (RR for ER+/HER2- = 0.92; 0.87, 0.98) and suggestively increased risk for ER- and ER-/HER2- subtypes (RR for ER-/HER2- = 1.16; 0.99, 1.36). RRs increased with advancing AFLB for ER+ cancers, especially among premenopausal women; and were elevated for ER- cancers among age groups 12-19 years and 30-34 years compared to the reference age group 20-24 years.

Conclusion: Associations of breast cancer risk and reproductive history varied among Danish women by ER± and by ER±/HER2±, consistent with receptor-specific etiological heterogeneity. Risk estimates for ER+ and ER+/HER2- cancers were similar to the well-established associations for breast cancer overall, whereas relative risks for ER- and ER/HER2- cancers tended to be null or the inverse of ER+ associations.
Introduction: The clinical classification of breast cancer into at least four intrinsic subtypes has advanced targeted therapy and improved prognosis. However, for etiological classification, it has been proposed that breast cancer is comprised of just two main subtypes: basal-like and non-basal-like. Evidence for these two etiologic subtypes emerges strongly from bimodal age frequency distributions at diagnosis. In the absence of RNA-based intrinsic subtyping, estrogen receptor (ER) expression is a useful surrogate for these two distinct etiologic classes. Using data from the population-based Carolina Breast Cancer Study (CBCS), we examined evidence for a two-component (ER-positive vs. ER-negative) mixture model for breast cancer biologic/etiologic heterogeneity.

Methods: Automated digital scoring of ER expression was performed on immunohistochemistry-stained tissue microarrays comprising 1,920 invasive breast cancer cases from CBCS. Clinical classification of ER status has changed over time as new data have emerged regarding optimal treatment-relevant thresholds, but optimal etiologic thresholds have not been established. Therefore, we considered ER status as a quantitative, categorical variable with cut points of <1% (ER-negative) vs. ≥1% (ER-positive), with ER-positive cases further categorized as highly positive (≥80-100%), intermediate (≥40-<80%), low (≥10-<40%) or borderline (≥1-<10%). Smoothed age frequency distributions at diagnosis (i.e., density plots) were constructed and logistic regression adjusted for age and race was conducted to assess associations between patient and tumor characteristics and level of ER positivity.

Results: As expected for etiologically-distinct entities, ER-negative and highly ER-positive tumors showed predominantly unimodal early-onset and late-onset age distributions at diagnosis with peak frequencies near ages 50 and 70 years, respectively. However, tumors with low and intermediate positivity showed bimodal patterns, consistent with a mixture of two main subtypes. Consistent with these age distribution patterns, young age (<40 years) at diagnosis was associated with an elevated odds ratio (OR) for low positive (OR 1.8; 95% CI 1.1-2.9), borderline (OR 1.9; 95% CI 1.1-3.3) and ER-negative disease (OR 2.2; 95% CI 1.5-3.2). Relative to highly ER-positive tumors, low ER-positive tumors were more likely to be node-positive (OR 1.4; 95% CI 1.0-1.9), higher grade (combined grade III; OR 1.9; 95% CI 1.3-2.9), and were more likely to harbor a p53 mutation (OR 2.0; 95% CI 1.2-3.5).

Conclusions: While etiologic differences between dichotomized ER-negative and ER-positive breast cancer categories have been well described in many epidemiologic studies, differences in breast cancer etiology across quantitative levels of ER expression have not been so well-characterized. In this study, we report that ER-positive tumors with low positivity share etiologic features of ER-negative tumors, including young age at diagnosis and aggressive tumor characteristics. These data provide additional support for a two-component breast cancer mixture model, with quantitative level of ER positivity reflecting the relative distributions of ER-positive and ER-negative tumor populations.

Title: Weight change across the life-course and breast cancer risk among pre and postmenopausal women

Colditz G, Eliassen H, Toriola A, Hankinson S, Willett W and Rosner B. Brigham and Womens Hospital, Boston, MA; Washington University School of Medicine, St Louis, MO and University of Massachusetts, Amherst, MA.

Body: Obesity is well established as a cause of postmenopausal breast cancer incidence and mortality. In contrast, adiposity in early life is inversely related to breast cancer incidence. To better integrate understanding of these relations, we assess adiposity in childhood, in late adolescence, and in adult years, as well as change in weight in relation to total invasive breast cancer and subtype defined by receptor status.

The Nurses' Health Study cohort was established in 1976 when 121,701 female US registered nurses ages 30-55 responded to a mailed questionnaire about risk factors for breast cancer including reproductive factors, hormone use, anthropometric variables, benign breast disease (BBD), and family history of breast cancer. The risk factors have been updated by repeat questionnaires every 2 years. We followed a cohort of 77,232 women from 1980 to 2006 (1,408,188 person-years), with routinely updated risk factor information, documenting 4,254 incident cases of invasive breast cancer. ER and PR status were obtained from pathology reports and medical records. A total of 2,065 ER+/PR+ tumors, 604 ER-/PR- tumors, 520 ER+/PR- tumors were identified among women with complete information on breast cancer risk factors.

Weight at age 18 was inversely related to incidence of pre and postmenopausal breast cancer. The relative risk (RR) per 50lb weight difference at age 18 was 0.80 (95% CI = 0.73, 0.88). However, the inverse association is completely explained by weight at age 10. Weight at age 10 was more strongly inversely related to ER-PR- breast cancer, RR per 50lb difference in weight at age 10 = 0.48; 95% CI 0.32 – 0.74. Weight gain from 10 to 18 was not related to risk. After controlling for weight at age 18, weight loss of 10lb or more was significantly related to lower risk of breast cancer (RR=0.80; 0.66, 0.95) overall. The association was stronger for premenopausal breast cancer (RR=0.51; 0.30, 0.88). Long-term weight change was positively related to total incident breast cancer risk and most clearly to postmenopausal cancer (RR per 50lb weight gain since age 18 =1.26; 1.19-1.34). Weight gain during premenopausal years (weight at menopause minus weight at age 18), and after menopause, were both directly related to increased risk. Weight gain of 30 or more pounds during premenopause increased risk of postmenopausal breast cancer compared to less than 10lb weight change (RR=1.25; 1.14-1.38) and weight gain of 30 or more pounds after menopause carried similar increase in relative risk (RR=1.24; 1.10-1.41). These results were unchanged after control for weight at age 10, and were stronger for ER+PR+ breast cancer. The associations for long-term weight gain and postmenopausal breast cancer are stronger for never vs. ever users of hormone therapy, but are significantly positively associated in both groups.

In conclusion, adiposity in childhood has a protective lifelong relation to breast cancer risk most clearly seen for ER-PR- disease. There are deleterious effects of long-term weight gain both pre- and post-menopause. Weight loss in premenopausal years significantly reduces risk of breast cancer. Weight change can importantly modify breast cancer risk.

Title: Weight gain during pre- and postmenopausal years results in earlier onset of breast cancer. The Tromsø cohort study

Lofterød T, Frydenberg H, Flote VG G, Risberg T, Eggen AE E, McTiernan A, Mortensen E, Wist EA A, Akslen LA A, Reitan JB B, Wilsgaard T and Thune I. Oslo University Hospital, Oslo, Norway; Tromsø University Hospital of Northern Norway, Tromsø, Norway; The Arctic University of Norway, UiT, Tromsø, Norway; Fred Hutchinson Cancer Research Center, Seattle, WA and Haukeland University Hospital, Bergen, Norway.

Body: Background: Obesity is both an independent risk factor, and a prognostic factor of postmenopausal breast cancer. In contrast, the association between premenopausal obesity/leanness, and subsequent weight gain and breast cancer outcomes, is still unclear. Furthermore, the association between adult weight gain, weight and age at diagnosis, and tumor characteristics is less studied.

Methods: During 1979-2007, a total of 18 990 women, aged 18-87 years, answered questionnaires and underwent clinical examination at a total of five repeated health surveys (attendance rate 68-82%). Height and weight were measured at each survey, and before surgery, among those women diagnosed with breast cancer during follow-up. Careful review of the respective medical records, including histopathological workup, was performed. Multivariate Cox Proportional Hazard models were used to study the importance of Body Mass Index (BMI kg/m^2) and weight change on breast cancer risk, and to evaluate variation in breast tumor characteristics.

Results: During a median follow-up of 23.3 years, 579 women with invasive breast cancer were identified, and the cases were histologically verified. These breast cancer cases had a mean age at diagnosis of 56.3 years, and mean BMI at diagnosis of 25.3 kg/m^2. Most (67 %) of the breast cancer patients had estrogen receptor (ER) positive tumors, 48 % had progesterone receptor (PgR) positive tumors, and 41 % had lymph node positive disease. We divided all participating women in three groups of weight change (< 5kg, 5-15 kg, >15 kg). When we compared women with less than 5 kg weight gain, to women with weight gain 5-15 kg, and to women with weight gain above >15kg, we observed a RR of 1.43 (95% CI 1.07-1.90) and a RR of 1.86 (95% CI 1.30-2.68), respectively, for postmenopausal breast cancer. We divided women by quartiles of BMI (kg/m^2) at entry, and observed that women in the lowest quartile of BMI (≤ 21.45 kg/m^2), who had a subsequent weight gain >15 kg, had a RR of 2.40 (95% CI 1.07-5.38) for postmenopausal breast cancer compared to women with the same BMI at entry, but who remained stable in weight. We observed a 6 year difference in age at diagnosis for women diagnosed with breast cancer, who at study entry were in the same BMI group (< 25kg/m^2), but subsequently either experienced a large weight gain (>15 kg), or remained stable in weight (59.5 years vs. 64.4 years, p=0.007). Furthermore, we observed a 15 year difference in age at diagnosis for women diagnosed with breast cancer, who at study entry were in the same BMI group (≥ 25kg m^2), but subsequently either experienced a large weight gain (> 15 kg), or remained stable in weight (60.3 years vs. 74.9 years, p=0.007).

Conclusion: Avoiding large weight gain during pre- and postmenopausal years may both protect against, and delay onset of postmenopausal breast cancer. Our findings support the importance of weight gain as a modifiable lifestyle factor for early onset of breast cancer.
Title: The incidence of and survival after breast cancer recurrence

Body: Background: Patients who complete definitive therapy for primary, stage I-III breast cancer may develop recurrent disease. However, little is known about the outcomes patients experience after recurrence when treated outside of a clinical trial because population-based datasets usually do not capture recurrence status. We describe the overall survival of patients after developing recurrent breast cancer, identify factors independently associated with improved survival, and compare survival for patients with recurrent versus de novo stage IV metastatic disease.

Methods: The cancer registries from two Kaiser Permanente (KP) sites participating in the Cancer Research Network, KP Colorado and KP Northwest, provided data on adult women diagnosed 2000-2011 with primary breast cancer and followed through death, disenrollment or study end (12/31/2012). Among patients with stage I-III disease who completed definitive therapy, recurrence was captured via manual chart abstraction. Survival time was calculated from the date of recurrence or the date of de novo stage IV disease. Multivariable modeling identified factors independently associated with restricted mean survival time (RMST) through 7 years, controlling for age, race, income, co-morbidity, year of recurrence, time from primary diagnosis to recurrence, type of recurrence (local vs. regional/distant), use of chemotherapy or radiation at recurrence, and characteristics of the primary cancer that pre-dated recurrence (i.e., primary stage, grade, hormone-receptor status, and use of chemotherapy or radiation therapy for the primary diagnosis). We compared overall survival after developing recurrent versus de novo stage IV disease after matching for age, race, income, co-morbidity and year.

Results: From 7,216 breast cancer diagnoses we identified 506 cases of recurrent disease and 219 cases of de novo stage IV disease (7% and 3%, respectively). Most recurrences were regional or distant (81%). From the time of recurrence, median survival was 21 months and 2-year survival was 47%. Factors significantly associated with inferior RMST included regional/distant vs. local recurrence (-35.6 months; P<.01), primary stage III vs. stage I disease (-13.6 months; P<.01), and chemotherapy for the primary diagnosis (-9.6 months; P=.02), but not race, income, grade, or primary cancer hormone-receptor status. Patients for whom the interval from diagnosis to recurrence was >4 years vs. <1 year had a longer RMST (+18.9 months; P<.01). Receipt of chemotherapy at the time of recurrence was associated with inferior RMST; the magnitude of this association was higher among patients with local (-18.5 months) versus regional/distant disease (-3.2 months). Women with regional/distant recurrence had significantly worse RMST than those with de novo stage IV disease (-10.3 months; P<.01).

Conclusions: Recurrent breast cancer is at least two-fold more common than de novo stage IV disease. Among patients who develop recurrence, characteristics of the primary cancer and its treatment are associated with survival after recurrence. Survival differences between patients with recurrent and de novo stage IV disease suggest that prognostic estimates and treatment paradigms should be tailored.
**Title:** Time trends in incidence rates and survival for women with de novo metastatic lobular vs. ductal carcinoma, a population-based study

Di Meglio A, Freedman RA A, Lin NU U, Barry WT T, Metzger-Filho O, Keating NL L, Winer EP P and Vaz-Luis I. Dana Farber Cancer Institute, Boston, MA; IRCCS San Martino University Hospital - IST National Cancer Research Institute, Genova, Italy; Harvard Medical School, Boston, MA and Brigham and Women's Hospital, Boston, MA.

**Body:** Background: Survival for metastatic breast cancer (MBC) patients (pts) has modestly improved over time. Until the early 2000’s, incidence rates for invasive lobular carcinoma (ILC) had steadily risen, in contrast to the stable rates observed for invasive ductal carcinoma (IDC). Historically, ILC was deemed to have a more favorable prognosis than IDC. Nevertheless, data on recent time trends in incidence and survival of lobular vs. ductal histology among newly diagnosed MBC pts are limited.

Pts and Methods: Using the Surveillance, Epidemiology, and End Results (SEER) 9 registries, we included 10,767 pts diagnosed with de novo lobular or ductal MBC from 1990-2011, and followed through 2012. Time trends in annual age-adjusted incidence rates were analyzed, stratified by histology. Multivariable Cox regression models were fit to investigate the association of year of diagnosis and overall survival (OS) by stratum, adjusting for features presented in Table 1. We examined interactions between year of diagnosis and histology. In sensitivity analyses, we modeled year of diagnosis as categorical, and restricted the cohort to hormone-receptor positive pts.

Results: 9,376 (87%) pts had IDC and 1,391 (13%) had ILC. Overall, we found a 1.4 fold increase in incidence rates for de novo MBC over the study period, (with a 1.3- and 2.6-fold increase for IDC and ILC, respectively). OS improved over the study period for the overall cohort (Hazard ratio (HR) of death=0.99; 95% confidence interval (CI)=0.98-0.99; 1% decrease/year; 5% decrease/5 years; p=.0059 for the interaction year of diagnosis-histology on OS). ILC pts had better outcomes than IDC pts (median OS=28 vs. 21 months; adjusted HR of death= 0.93; 95%CI=0.87-0.99). For IDC pts, we found a statistically significant improvement in OS over time (HR of death=0.98; 95%CI=0.98-0.99; 2% decrease/year; 6% decrease/5 years). However, we observed no significant change in survival outcomes for ILC pts (HR of death=1.01; 95%CI=0.99-1.02) (Table 1). Results from sensitivity analyses were similar.

Conclusions: From 1990-2011, incidence rates for de novo MBC increased. In this cohort, ILC pts had a better prognosis than IDC pts. Nevertheless, although we found an expected overall improvement in OS for MBC pts, this effect was restricted to IDC pts, with no significant improvement among ILC pts. Dedicated studies are warranted to understand whether our results can be confirmed in other datasets and to investigate the reasons driving this discrepancy, such as the impact of patterns of care, new drug approvals, and tumor molecular subtype.

p<.01 for differences between groups

*Adjusted for: cohort characteristics, SEER registry, and marital status
Body: Background
Young women (<40 yrs) with breast cancer (YWBC) account for 7-12% of BC diagnoses. BC is the leading cause of cancer death in this group (G). Age-specific data on outcome and appropriate treatment (Rx) are lacking. YWBC appear to have more biologically aggressive subtypes and a higher risk of relapse and death. We studied the clinico-pathological (ClinPath) characteristics in YWBC, examining how outcomes/Rx have evolved.

Methods
YWBC were identified from pathology databases at 2 tertiary centers. Pts were divided into 2 cohorts: BC diagnoses from 2000-2007 (G1) and 2008-2015 (G2). ClinPath and Rx data were retrieved from clinical, radiology and histology databases. Statistical analysis was performed using SPSS.

Results
We identified 347 pts. Tumor features are shown in Table I. Median age is 36 (23-39). By histology, 90.8% (n=315) had invasive ductal carcinoma, 53.1% (n=181) had Grade III BC and 56.3% (n=171) had lymphovascular invasion. Pregnancy-associated BC occurred in 10.7% (n=34). Mastectomy (MX) was performed in 53% (n=176) and axillary lymph node clearance (ALNC) in 63.8% (n=192 [G1: 84.3% vs. G2: 48.6%, p<0.001]).

Rx characteristics are shown in Table 2. 85 pts received neo-adjuvant therapy (NAT); 48.3% (n=41) ER+/HER2-, 27% (n=23) HER2+ and 24.7% (n=21) TNBC. Pts receiving NAT in G2 trended towards improved pCR rate (G2: 24.6% vs G1: 8.3%, p=0.057). Endocrine Rx alone was received by 9.8% (n=22); 13.6% (n=18) in G2 vs 4.3% (n=4) in G1. OncotypeDx(ODx) was used in 23 pts (14.9%) (median score 17), 1 had a DR (ODx Score = 18).

| Local relapse | 1 (6.2%) | 1 (1.5%) |
| Distant relapse (DR) | 0 | 22 (33.8%) |

*Data incomplete n=4

DR occurred in 50 pts (16%), including 13 (20.3%) HER2+ pts. Of note, 92.3% (n=12) of these were in G1. Relapse rates (RR) in TN and ER+/HER- pts were 19.6% (n=11) and 13.7% (n=26) respectively. There was a higher RR in G1 (34.8% vs 11.4%, p<0.001). Overall survival in pts with stage IV dx was 32 mos in G1 and 48 mos in G2.

Conclusion
In line with existing data, locally advanced dx is more prevalent in YWBC. MX and ALNC rates were high and most received multimodal Rx. The extent of axillary surgery declined. Pts in G2 had lower volume BC at diagnosis suggesting increasing awareness. TN and HER2+ subtypes accounted for a slightly higher proportion of BC cases. Pts with PCR had better outcomes. Only 16% relapsed with metastatic dx. The impact of HER2 Rx is highlighted by reduced RR in HER2+ G2 pts. Outcomes were unchanged in pts with ER+/HER2- and TNBC. These remain a priority for future research.

**Title:** Increasing population rates of in-situ breast cancer [DCIS] are associated with reduced breast cancer (BrCa) mortality. A case for screening mammography and "overdiagnosis" linked to outcome benefits

Ragaz J, Qian H, Shakeraneh S, Fox J, Wilson KS S., Simpson JS S., Yoon J-Y and Wong H. School of Population and Public Health [SPPH], University of British Columbia [BC], Vancouver, BC, Canada; Centre for Health Evaluation and Outcome Sciences, Providence Health Care Research Institute, St. Paul’s Hospital, University of B.C., Vancouver, BC, Canada; BC Cancer Agency [BCCA], Victoria, BC, Canada; UBC Medical School, Vancouver, BC, Canada and St. Michael Hospital, University of Toronto, Toronto, ON, Canada.

**Body: INTRODUCTION:**
Following the first phase of this project [Ref 1], we correlate here the rates of DCIS with BrCaMOR, in two regions of Canada - British Columbia [BC] and Atlantic Provinces [Atl.P].

We previously reported higher compliance in screening mammography [ScreenMam] and therapeutic [TH*] guidelines [GUIDELINES] for both DCIS and invasive BrCa in BC compared with Atl.P [Ref. 2].

**METHODS:** Annual age-specific rates [cases / 100,000 population] of DCIS, and BrCaMOR between BC vs Atl.P, were obtained for 17 age groups of 5 years (years 0-4 to 85+) and averaged each 5-year period from 1975-1979 up to 2005-2009. To compare age distribution, DCIS rates and BrCaMOR between the two regions, we selected four birth cohorts, age 30-34, 35-39, 40-44 and 45-49 in 1975-1979. From those, we tabulated the DCIS incidence and BrCaMOR for each birth cohort when they reached ages 50-54 and 60-64. We assumed that the rates of DCIS reflect annual ScreenMam practices.

Data were obtained from the Public Health Agency of Canada based on the Canadian Cancer Registry database at Statistics Canada.

**CONCLUSIONS:**
1. Our study shows across all age cohorts higher rates of DCIS and lower BrCaMOR in BC compared to Atl.P - results consistent with higher ScreenMam rates in BC than Atl.P.
2. These data are compatible with the concept that a higher diagnostic rate for early lesions such as DCIS [i.e. frequently designated as "Overdiagnosis"] by ScreenMam, and subsequent earlier Guideline TH*, contributes to lower BrCaMOR.

*TH Guidelines: surgery, radiation, Tamoxifen for DCIS; and the same + chemotherapy for early invasive disease.

Title: Improved long term survival from breast cancer over three decades: Persistent disparities with age, but not socioeconomic status, in a socialized health care system

Malin A, Ashfield AM M, Purdie CA A, Jordan LB B and Thompson AM M. Ninewells Hospital and Medical School, Dundee, Tayside, United Kingdom and MD Anderson Cancer Center, Houston, TX.

Body: Background
Socioeconomic status and patient age have been associated with disparities in survival for breast cancer. We previously reported breast cancer diagnosed in a geographically defined population treated in a single cancer center in a socialized health care system (free health care) with a 5 year survival of 70% (95% CI 67-74%) (reported in 1998) and, in the same cohort, a 10 year survival of 52.7% (95% CI 50.03-55.1%) (reported in 2001). Since that time, multidisciplinary team discussion of every patient at diagnosis, before and after surgery, together with improved drug therapy and radiotherapy techniques have been implemented using national guideline, evidence-based protocols. This study examined survival for the population based cohort of women from the same geographical region treated over 5 years from 2000 to seek evidence of improved outcomes and persistent disparities compared with historical practice.

Methods
Between 2000-2004, a cohort of 1851 women were treated at a single cancer center, representing 98% of the incident breast cancer patients in the geographic region. Prospective electronic clinical data collection was retrospectively manually cross checked with patient records and death certification. While breast screening practice changed little over that time, multidisciplinary team discussion of every patient, second and third generation chemotherapy regimens and hypofractionation of radiotherapy were introduced when compared with pre-2000.

Results
At a median 8.8 years follow-up, amongst 1851 women there were 768 deaths, 342 from breast cancer, and 405 women diagnosed with recurrent disease. The 5 year breast cancer specific survival was 82% and disease free survival 80% (87% and 84% respectively for operable disease) and at 10 years 76% breast cancer specific survival and 75% disease free survival (82% and 78% respectively for operable disease). There were the expected associations between tumor size, grade, node status, estrogen receptor, progesterone receptor, HER2 and disease free or overall survival. Breast cancer specific mortality was significantly better in the <50 years (HR 0.60; 95% CI 0.42-0.85) and 50-69 years (HR 0.69; 95% CI 0.51-0.95) age groups compared with women >70 years. While deprivation was an independent risk factor for all-cause mortality, after adjustment for age, tumor size, grade and node status, breast cancer specific survival was not significantly associated with socioeconomic status.

Conclusions
Over a 30 year period, survival from breast cancer has dramatically improved, likely due to multidisciplinary evidence based practice, including new drugs and enhanced delivery of radiotherapy. While disparities by socioeconomic status have declined, women >70 years age continue to have a worse breast cancer specific survival.
Title: Prognosis of clinico-pathological breast cancer subtypes in routine clinical care

Hennigs A, Heil J, Gondos A, Riedel F, Marme F, Sinn H-P, Schirmacher P, Kauczor H-U, Debus J, Golatta M, Schtz F, Sohn C and Schneeweiss A. Department of Obstetrics and Gynecology, University of Heidelberg, Heidelberg, Germany; Division of Clinical Epidemiology and Aging Research, German Cancer Research Center, Heidelberg, Germany; Department of Pathology, University of Heidelberg, Heidelberg; Department of Radiology, University of Heidelberg, Heidelberg, Germany; Department of Radio-Oncology, University of Heidelberg, Heidelberg, Germany and National Center for Tumor Diseases, University of Heidelberg, Heidelberg, Germany.

Body: Background / Aim: To analyze oncological outcome of breast cancer (BC) subtypes in routine clinical care in specialized breast care units (BCU).

Patients and methods: A prospectively followed cohort of 4110 female cases with primary, non-bilateral, non-metastatic BC treated between 01.01.2003 and 31.12.2012 has been analyzed for the whole cohort and separately for the five routinely used clinico-pathological subtypes (i.e. Luminal A, Luminal B (=Her2 neg.), Luminal B (=Her2 pos.), HER-2, triple negative). The median follow-up of the cohort was 51 month. We calculated estimates for local control rate (LCR), disease-free survival (DFS), distant disease-free survival (DDFS), overall survival (OS) and relative overall survival (ROS).

5 year outcome results referred to 5 different endpoints (using Kaplan-Meier method) of all patients with primary, non-metastatic, non-bilateral breast cancer treated at Heidelberg Breast Care Unit between 01.01.2003 and 31.12.2012

Results: LCR, DFS, DDFS, OS and ROS over 5 years for the whole cohort of invasive cases were 96.1%, 83.7%, 85.7%, 90.5% and 94.7%, respectively. Luminal A tumors were the most frequent (44.7%) and showed the best outcome with LCR, OS and ROS over 5 years at 99.1%, 95.1% and 100.0%, respectively; while triple negative tumors presented the poorest outcome with LCR, OS and ROS over 5 years at 89.6%, 78.5% and 80.1%, respectively.

Conclusions: This outcome analysis of a large cohort of patients with primary BC diagnosed, treated and prospectively followed on a routine basis at a specialized BCU in Germany confirmed general and detailed clinico-pathological subtype outcome data of clinical trials.
Title: Abstract Withdrawn
Title: A statewide, population-based study of molecular subtypes of female breast cancer: Treatment and associated factors

Loch MM M, Zhang L, Hsieh M-C, Wu X-C and Chen VW W. Louisiana State University Health Sciences Center, New Orleans, LA.

Body: Background: Breast cancer is now recognized as a heterogeneous disease with distinct biological molecular subtypes which have different prognoses and treatment options. We conducted the first statewide, population-based study to examine systemic treatment among invasive breast cancer (IBC) patients by subtype and determined their associated factors with treatment.

Methods: We analyzed data from the Louisiana Tumor Registry (LTR) and a Centers of Disease Control and Prevention (CDC)-funded special project of Enhancing Cancer Registry Data for Comparative Effectiveness Research (CER), which included Louisiana women diagnosed with microscopically-confirmed invasive breast cancer in 2011. Patient's socio-demographics, tumor characteristics and detailed information on the treatment, including chemotherapy, hormone, radiation and targeted therapy received within 12 months of diagnosis were collected from hospitals, radiation facilities, and medical oncology clinics. Systemic treatments received by each subtype were examined. Univariate and multivariate logistic regression analyses were used to identify factors associated with not receiving systemic treatment. Analyses were carried out using SAS version 9.4.

Results: About 70% of patients were hormone receptor (HR)+/ human epidermal growth factor receptor 2 (HER2)-, 15% triple negative (HR-/HER2-), 10 % HR+/HER2+ and only 5% HR-/HER2+. Among IBC patients with known HR and HER2 status, 72-78% with HR+ had hormonal therapy, 61-75% with HER2+ had Herceptin. About 0.5-6.1% of patients were given therapies which are contradictory to HR/HER2 status and 11-23% of IBC patients with known molecular subtypes did not receive any systemic treatment. Factors associated with not receiving systemic therapy include triple negative subtype and age ≥65 years. Patients younger than 50 years and with more advanced stages were more likely to receive systemic treatment. Race/ethnicity, grade, lymph node involvement, and comorbidity were not associated with receiving systemic treatment, adjusting for other covariates.

Conclusions: About 12-29% of breast cancer patients in our data set were not receiving treatment consistent with their HR/HER2 status or treatment guidelines. Some possible explanations may be advancing age, death prior to therapy and refusal by patients and/or family. Race, lymph node status and comorbidity were not associated with receiving systemic therapy after adjusting for other covariates. Further studies are needed to explore reasons why patients are not receiving therapy that is concordant with the guidelines and the access to care.
Title: The outcomes for super elderly patients over 80 years old after breast cancer surgery

Nakamura R, Matsuzaki H, Sakamoto M, Suda K, Hayama S and Sangai T. Chiba Cancer Center Hospital, Chiba, Japan; Funabashi Municipal Medical Center; Kameda Medical Center; Juntendou University Urayasu Hospital and Chiba University.

Body: (Purpose)
Considering the dramatic increase in average life expectancy throughout the world, the management of super-elderly patients over 80 years old (SEP) with breast cancer has become a global issue. However, there have been few clinical trials for SEP until now. The reasons for this were a small population, unpredictable prognosis, a large number of non-cancer-related deaths and a lower function of multiple organs in SEP. Surgical treatment or post-operative treatment based on evidence of clinical trials for SEP has also not been unclear. We hypothesized that the outcome of SEP with breast cancer compared with other ages were similarly depended on the breast cancer subtypes.

The aim of this study was to clarify the breast cancer related survival (BRS) rate and overall survival (OS) rate at 5 years for SEP according to breast cancer subtype.

(Methods)
We retrospectively analyzed 407 patients over 80 years old at initial operation between April, 1994 and April 2015 from 4 institutions of Chiba Youth Breast Oncology Research Group. Overall, 366 patients with stage I to Stage IIIc were included. 41 patients with Stage 0 or IV were excluded in this study.

We compared the clinical characteristics, OS and BRS rates among the breast cancer subtype: such as ER positive HER2 negative (ER group), ER negative HER2 negative (TN group), ER negative HER2 positive (HER2 group) and ER positive HER2 positive (ER/HER2 group).

Univariate and multivariate analyses were performed to identify the factors of Tumor size, Lymph node, Ly, ER, HER2 and characteristics, associated with the OS and BRS.

(Results)
The median age of the 366 patients was 83 years (range 80-96 years). The median follow-up duration was 32 months (range, 2-120).

During the follow-up period, 25 (9.4%) patients in the ER group, 19 (27.5%) in TN group, 4 (22.2%) in HER2 group and 2 (20.0%) patients in ER-HER2 group died.

The 5 year OS and BRS rates were 89.2%, 97.1% in ER group, 64.6%, 81.2% in TN group, 61.5%, 33.3% in HER2 group and 83.3%, 100% in ER-HER2 group, respectively.

Univariate and multivariate analyses revealed that ER was one prognostic factor to OS and BRS.

ER positive patients treatment with Aromatase inhibitor had significantly longer survival rates than treatment with Tamoxifen or no treatment (p=0.05).

There were no significant differences in OS or BRS of TN patients according to the use of chemotherapy (n=7) versus non treatment (n=61).

(Conclusions)
The prognosis and clinical course of super elderly patients with breast cancer depended on subtype. Adjuvant therapy for ER group was one prognostic factor to OS and BRS.
Title: Triple-negative breast cancer: A single-centre retrospective cohort study of 408 TNBC cases with a focus on elderly patients

Body: Background: TNBC represents a heterogeneous group of breast cancers that do not express ER-α, PgR and Her-2 receptors. Generally, these tumors are aggressive and more common in younger women. The aim of our study was to create a representative set of patients with TNBC, which could be analyzed and the data gathered to build basic epidemiological, molecular and clinical characteristics of Czech patients with TNBC. In particular, we focused on older patients (≥70 and ≥75 y.o.).

Methods: We retrospectively studied a consecutive cohort of 408 patients diagnosed and/or treated for TNBC at the Masaryk Memorial Cancer Institute between 2004 and 2010. Some clinical-pathologic/molecular correlations were performed to identify prognostically different groups of patients.

Results: The median age of patients was 56 years (25–88). A total of 9.3% of TNBC cases were diagnosed in patients under the age of 34, another 15.2% and 15.0% of cases were in the age group of 35 to 44 years and ≥70 years, respectively. In the group of patients aged ≥70 years (61), 59 % (36) were ≥75 y.o. Incidence of CK5/6+ and BRCA1 mutated tumors decreased with increasing age of patients, while the number of AR+ tumors increased (Chi-square test for trends: p=0.0245, p=0.0049 and p=0.0047, respectively). We confirmed the aggressive nature of this disease: in the follow-up period (median 77.2 months) we observed a relapse in 27.2 % (111) of patients: 71 % of deaths due to disease progression occurred within 2 years after diagnosis of the disease. Patients ≥70 and especially ≥75 years of age had, together with patients ≤30 y.o., the highest risk of death due to tumor progression. DFS and OS of patients ≥75 y.o. was significantly worse in comparison with other patients (OS: p=0.035, HR 0.515; DFS: p=0.0077, HR 0.475). Simultaneously, adjuvant chemotherapy and anthracyclines were much less frequently administered in this age group (p<0.0001), despite the fact that the distribution of clinical stages did not differ among the age groups. In the whole cohort, the most important negative prognostic factors in relation to disease specific OS were: higher clinical stage and pT (both p<0.0001), pN-positive status (p<0.0001), absence or early withholding of chemotherapy (p<0.0001) and minimal disease response to neoadjuvant treatment (TRG4-TRG5) (p=0.005). High levels of BCL2 expression predicted poor OS in basal-like TNBC patients treated with adjuvant anthracycline-based regimens (p=0.033, HR 3.04). Contrariwise, longer OS was associated with the presence of tumor infiltrating lymphocytes (p=0.0004, HR 2.40).

Conclusion: TNBC is an aggressive form of breast cancer, which may occur in patients of all ages, but more frequently in younger patients. Early detection and intensive treatment of these tumors gives a high chance of cure. Patients ≥70 and especially ≥75 years of age, together with patients ≤30 y.o., are at the highest risk of death due to tumor progression. While in younger patients it is likely due to the aggressiveness of disease, in older patients, in particular, because of an absence of adjuvant systemic therapy. The introduction of targeted therapies could potentially improve prognosis in both groups of patients (eg. PARP inhibitors, antiandrogens).

Supported by IGA MZ CR: NT14599-3.
Title: Breast cancer presentation in the over 70s

Murray J, Smith L and Lannigan A. Wishaw General Hospital, Wishaw, Lanarkshire, United Kingdom.

Body: Aims:
Life expectancy of the population is rising, and the risk of breast cancer increases with age. Older patients with breast cancer generally present later with more advanced disease for a variety of factors. We aimed to explore the presentation of the over 70s with breast cancer, along with their attitudes towards screening.

Methods:
A questionnaire was sent to patients aged over 70 at the time of their breast cancer surgery within the three hospitals across NHS Lanarkshire. This detailed reasons and timing of presentation, in addition to thoughts about screening.

Results:
Three hundred and fifty-two questionnaires were sent to women with a mean age of 76 years, 230 were returned (65%). Sixty-four percent routinely examined their breasts with more identifying a lump themselves (70%). Knowledge of signs and symptoms beyond a lump was explored, explicitly asking about nipple inversion, nipple discharge and skin changes with all three having similar degrees of awareness (40%, 35%, 25% respectively). Distressingly only 36% of our patients were aware of any of these signs, with only 9% being aware of all three. The majority of women sought medical attention early after identifying a problem, with 39% seeing someone within days and only 6% waiting over 6 months. Personal concern was the greatest prompt for women to see a doctor (68%) followed by family or friend concern (10%). With regard to screening, 83% routinely attended screening when they were invited. Ninety percent also said they would attend if the service was routinely offered to the over 70s. Although the majority (60%) were not aware that they could opt into the screening service once over 70.

Conclusions:
Despite the belief that most older women are felt to be less breast aware than younger most of our patients routinely examined themselves and identified the pathology, before promptly seeking medical advice (70% within weeks). This is the case despite most women having no knowledge of other signs and symptoms of breast cancer. Our cohort have also shown that they are keen to continue screening over the age of 70 if it was routinely offered.
Title: Breast cancer in young patients, twelve years of experience in a single institution

Body: Breast cancer is very rare in young women and has a more aggressive biological behavior and a worse prognosis than in older premenopausal women. This study was designed to determine and evaluate the features of breast cancer in young patients less than 35 years old at the Instituto Nacional de Enfermedades Neoplásicas, Lima - Perú.

Medical records of 115 patients less than 35 years old with breast cancer, whom were diagnosed and received a kind of treatment, even surgery, chemotherapy, radiotherapy or all of them at the Instituto Nacional de Enfermedades Neoplásicas Lima-Perú, between January 2000 and December 2012, were reviewed.

Triple negative breast cancer (38.3%) is the most common subtype cancer and its presentation is in a lower age compared with the others subtypes (27.1 years vs 28.5 years p: 0.047). The high histological grade was more frequent in triple negative and HER2 subtypes (80% both vs 30% and 48% for luminal A and luminal B p: 0.001). The 2 yr and 5 yr overall survival was 75.0% and 59.3% for luminal A, 71.4% and 55.1% luminal B, 67.7% and 54.9% triple negative, 58.3% and 41.7% HER2 (p: 0.434). The 2 yr progression free survival was 81.6%, 72.6%, 61.5% and 59.4% for each group respectively (p: 0.522).

As conclusion, the breast cancer in 35 yr old or less women is uncommon; the triple negative subtype is more common, also in relation with high histological grade and in lower age. The overall survival and the progression free survival are worse in patients with lower age.
Title: Spatial analyses of breast cancer in women 15-49 years-old in Rio Grande do Sul, southern Brazil

Body: Breast cancer (BC) rates under 50 years have been increasing over time in several countries. Although the exact impact of BC is not know in low and middle income countries, it's estimated that at least 20% of deaths caused by BC affect women under the age of 50 years. In Porto Alegre, the capital of Rio Grande do Sul (RS), Brazil's southernmost state, the incidence of BC in women aged 40-49 years is 165 cases per 100,000, while the mortality rate reaches 25 in 100,000 women. In order to understand BC profile in this age group in the entire state of RS, we established incidence, morbidity and mortality between 2002-2011 through crude and smoothed rates for each municipality. Furthermore, we perform the spatial analysis of these indicators. Incidence data were only available for the state capital, where the rate incidence was 19 and 160 cases per 100,000 women in the age groups of 15-39 and 40-49, respectively. Statewide mortality was 2 and 21 per 100,000 women in the age groups of 15-39 and 40-49, respectively. Hospitalar morbidity associated with BC was 0.6% and 2% in women 15-39 and 40-49 years, respectively. The distribution of morbidity and mortality showed regions with continuously high rates throughout this period with result above 3% and 20 deaths per 100,000 women. In the same areas we did not identify centers specialized in cancer treatment and care. Although there is specific epidemiological surveillance for cancer in Brazil, the coverage is insufficient, especially when it comes to incidence. Morbidity and mortality data showed regions continually affected by high rates suggesting that specific measures as well as specialized care for women in these regions are necessary. This result is particularly important since current guidelines of the Ministry of Health in Brazil recommend mammographic screening starting at the age of 50 years. The expansion of coverage and access to appropriate treatment is essential for the recognition of risk factors, adoption of effective strategies and reduction of cases and deaths in this group of women. Knowledge of the age distribution of BC cases and BC related deaths is important for the definition of health care policies, which will likely be different in different regions of the world.
**Title:** The smoking related risk of breast cancer and proportion of avoidable breast cancer cases due to passive and active smoking in middle-aged women in Norway in 2012: The Norwegian women and cancer study 1991-2012

Gram IT T, Little MA A, Lund E and Braaten T. UiT The Arctic University of Norway, Tromsø, Norway and University of Tennessee Health Science Center, Memphis, TN.

**Body:** Background: The burden of smoking on society may be underestimated as previous estimates of cancer due to smoking have generally not included breast cancer. We utilized the Norwegian Women and Cancer Study, a nationally representative prospective cohort study to examine the risk of breast cancer due to passive and active smoking. We also estimated the proportion of breast cancer attributable to passive and active smoking.

Material and methods: Our study included 130053 women, aged 34 to 70 years, who completed a baseline questionnaire between 1991 and 2007. We followed the women through linkages to the Cancer Registry of Norway and the Norwegian Central Population Register, to identify all cancer cases, emigrations, and deaths, respectively, using the unique national 11-digit personal identification number. Person-years were calculated from the start of follow-up to the date of any incident cancer diagnosis, emigration, death, or the end of follow-up December 31, 2012, whichever came first. Breast cancer cases were classified according to the original codes in the International Classification of Diseases, Seventh Revision including estrogen and progesterone hormone tumor receptor status. We used Cox proportional hazards models, adjusting for relevant confounders, to estimate multivariate adjusted hazard ratios (HRs) with 95% confidence intervals (CIs). Never smokers, excluding passive, served as the reference group. We estimated attributable fractions in smokers and in the population with 95% CIs.

Results: Ever compared with passive and never smokers were younger at breast cancer diagnosis, at first childbirth and at menopause; they were less likely to have higher education, more likely to have used hormonal contraceptives and postmenopausal hormone therapy and to consume alcohol. The alcohol drinkers were consuming more alcohol. During follow-up 4293 women developed invasive breast cancer confirmed by histology. Compared with never smokers, the multivariate adjusted breast cancer HR was for ever smokers 1.21 (1.08-1.34). Compared with parous never smokers, the HR estimate for breast cancer for ever smokers who had smoked five or more years before giving birth was 1.29 (1.14-1.46) after adjustment. A trend test for number of pack-years and breast cancer risk was significant (ptrend= 0.007). We found similar HR estimates when we stratified by menopausal and parous status at entry. The attributable fraction for breast cancer was 17.3 (7.4-25.4) for active smokers. The population attributable fraction of breast cancer for active smoking was 11.9 (5.3-18.1).

Conclusion: In smokers, one in six, and in the population almost one in eight breast cancer cases could have been avoided in the absence of smoking.
Title: Use of serum tumor markers and high cost imaging in women with metastatic breast cancer

Body: Background: Despite data on the sensitivity and specificity of serum tumor marker (STM) tests, there is no evidence to suggest that early changes in therapy related to rising tumor markers have an effect on survival. In fact, the limited data suggests no benefit to early change in therapy. The National Comprehensive Cancer Network recommends monitoring cancer burden in women with metastatic breast cancer (MBC) undergoing therapy; however, they do not provide specific recommendations regarding optimal frequency of STMs or of tumor imaging. We performed a population based analysis to evaluate serum tumor marker usage in patients with hormone sensitive MBC.

Methods: The Surveillance, Epidemiology, and End Results-Medicare database was used to identify female patients with hormone receptor positive MBC diagnosed between 2002 and 2011. For each patient, the dates of STMs (CEA and/or CA 15-3/CA 27.29) were recorded; if either or both CEA and CA 15-3/CA 27.29 were ordered on the same day they were counted as one test. We categorized regular STM use as the percentage of patients who had >4 tests in any year, amounting to tests less than 3 months apart; and very frequent STM use as the percentage of patients who had >12 tests in a year, amounting to tests less than 4 weeks apart. Multivariable analysis was performed to further examine patient characteristics associated with frequent STM use. Odds ratios were calculated comparing positron emission tomography (PET) scan use versus computed tomography (CT) use in women with frequent STM testing.

Results: We identified 3,251 eligible patients. Of these, 2,034 (62.6%) had ≥1 STM test in a given year. On average, patients who underwent STM testing were tested 4 times per year (SD 2.9) for an average of 3 years (SD 2.0). Over half of patients with STM testing had regular testing; 1,065 (52.2%) had STM less than every 3 months, 498 (24.5%) less than every 6 weeks, and 146 (7.2%) less than every 4 weeks apart in any given year. Regular STM evaluation was associated with younger age (65-74 vs 75-84) (OR 1.51, 95% CI 1.25-1.83), later year of diagnosis (OR 1.3, 95% CI 1.04-1.69), and high socioeconomic status compared to low socioeconomic status (OR 1.37, 95% CI 1.08-1.73). Similar factors were associated with very frequent STM use (>12 tests/year). Use of PET scan for tumor imaging compared to CT scan use was higher in women with regular STM evaluation (OR=1.97, 95% CI 1.65-2.35) and in women with very frequent STM evaluation (OR=3.77, 95% CI 2.51-5.66).

Conclusion: Regular use of STMs is common in women with hormone receptor positive MBC. Women who had very frequent STMs were almost 4 times more likely to have expensive tumor imaging. Given the rising costs of cancer care, and the increasing survival time in women with metastatic breast cancer, efforts should be made to determine the optimal timing and modality for evaluating response to treatment.
Title: Infectious disease hospitalization in breast cancer patients: Risk and impact on prognosis

Body: Background: Infection-related hospitalizations are a serious complication in breast cancer patients, resulting in treatment delay, prolonged hospitalization and future morbidity and mortality. Little, however, is known about the actual risk, clinical characteristics and outcomes of infection-related hospitalizations in this patient population.

Methods: We conducted a prospective population-based study including 7071 women diagnosed with primary invasive non-metastatic breast cancer between 2001 and 2008 in the Stockholm-Gotland region (Sweden), with complete follow-up until 2010. Standardized incidence ratios (SIRs) for infection-related hospitalizations (overall and by site) were estimated using background rates from the general female population, matched on age and calendar period. Associations with clinical characteristics and breast cancer outcomes (breast cancer death, distant metastasis and locoregional recurrence) were analysed using flexible parametric survival models.

Results: During a medium follow-up of 5.3 years, 657 hospital admissions with infections were observed and 1, 2 and 5-year cumulative risks were 3.4, 4.7 and 8.1% respectively. Rates of infection-related hospitalizations were increased compared to the general female population (SIR = 2.12; 95% CI = 1.96-2.29) and site-specific SIRs were most pronounced for sepsis (SIR = 3.65; 95% CI = 3.13-4.26) and skin infections (SIR = 2.93; 95% CI = 2.35-3.64). The overall risk of infections was highest during the first year (SIR = 5.06; 95% CI, 4.46-5.74), and recurrent disease contributed to the long-term risk observed. Older age at diagnosis, chemotherapy, axillary radiotherapy, comorbidities and markers of tumor aggressiveness (large tumors, estrogen receptor negative tumors and lymph node positive tumors) were independent predictors of infectious disease risk. Analyses evaluating the prognostic impact of infections revealed an independent effect on breast cancer death and distant metastasis, associations that were mainly driven by sepsis (HR = 4.53; 95% CI, 3.25-6.33 and 1.69; 95% CI, 1.04-2.79 respectively). No association was found with future risk of locoregional recurrence.

Conclusions: Physicians and patients should be aware of the risk of serious infections which persists beyond the initial treatment period. Infection-related hospitalizations are an independent marker of poor prognosis. Further research is needed to elucidate the role of sepsis in breast cancer progression.
Title: Prognostic impact of HER2 overexpression/amplification in women with pT1aN0M0 breast cancer with known screening status: Results from a multicenter population-based cancer registry study

Musolino A, Michiara M, Boggiani D, Sikokis A, Rimanti A, Pellegrino B, Silini EM M, Campanini N, Barbieri E, Sgargi P, Falcini F and Pinto C. Medical Oncology Unit and Cancer Registry of Parma Province, University Hospital of Parma, Parma, Italy; Section of Anatomy and Pathology, University Hospital of Parma, Parma, Italy; SSD Oncologia Medica Addarii, Policlinico S.Orsola-Malpighi, Bologna, Italy and Romagna Tumor Registry, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori, IRCCS, Meldola, Italy.

Body: Introduction: Outcomes for women with pT1aN0M0 breast cancers (BC) may vary by biologic subtype. A higher proportion of HER2-positive BCs diagnosed in the interval between scheduled screening rounds has been proposed to account for the more aggressive behaviour of interval cancers (IC) compared with screen-detected (SD) tumors. No data are available on the prognostic role of HER2-positive status in a general population of pT1aN0M0 breast tumors with known screening status.

Methods: All incident pT1aN0M0 BCs (n=874), systematically collected by the Cancer Registries of Emilia Romagna Region (northern Italy) and diagnosed in women aged 50-69 from 2003 to 2009 were evaluated. Screening status was ascertained by reference to the Emilia Romagna Breast Cancer Screening Program (ERBSP) database. Patients unexposed to screening, with HER2 unknown primary tumor and/or who received adjuvant chemotherapy or trastuzumab were excluded from analysis.

Results: Twenty percent of patients had HER2-positive tumors. Fifty-three percent of the entire study population were SD cancers, while 18% were ICs. Tumors with high histologic grade, high proliferative rate, negative estrogen receptor status, or HER2-positive status were more likely to be diagnosed in the interval between screening. At a median follow-up of 84 months, the 5-year invasive disease-free survival (IDFS) rates were 89% and 95% in patients with HER2-positive and HER2-negative tumors, respectively (P = 0.025). Notably, HER2-positive ICs showed poorer IDFS than HER2-positive SD tumors (84% vs. 95%, respectively; P = 0.04). No difference in IDFS rates were observed between HER2-positive SD cancers and HER2-negative SD cancers. Multivariable analysis of candidate prognostic factors for IDFS will be reported.

Conclusions: In a general population of pT1aN0M0 early BCs with known screening status, IC detection may identify patients with HER2-positive pT1aN0M0 tumors in whom the rate of recurrence justifies consideration for systemic, anti-HER2, adjuvant therapy.
Increased risk of contralateral breast cancer after diagnosis of microscopically invasive breast cancer: SEER 1998-2012

Thomas A, Weigel RJ J, Leone JP P, Spanheimer PM M and Schroeder MC C. Carver College of Medicine, University of Iowa, Iowa City, IA and College of Pharmacy, University of Iowa, Iowa City, IA.

Body: Node negative microscopically invasive breast cancer (BC) is frequently associated with ductal carcinoma in situ (DCIS) and considered to have a similar prognosis. We evaluated women with T1micN0M0 (T1mic), DCIS and Stage I BC and report clinical characteristics, risk for subsequent contralateral breast cancer (CBC) and overall survival (OS).

Methods:
The study cohort included women diagnosed 1998-2012 and reported to Surveillance, Epidemiology, and End Result (SEER) data with DCIS, T1mic, or Stage I BC (not including T1mic). Subsequent CBCs were identified in patients with known laterality without contralateral mastectomy. Kaplan Meier models were used to estimate survival and time to CBC. Log-rank tests assessed differences in survival across groups.

Results:
During the study period, 9,785 women were diagnosed with T1mic. Clinical features and risk of CBC are shown in the Table 1. Women with DCIS and T1mic were younger than those with Stage I BC. T1mic was more likely to be hormone receptor (HR) negative. Women with T1mic underwent mastectomy significantly more often than women with DCIS or Stage 1 BC. T1mic occurred more frequently in non-white women. Women with T1mic were significantly more likely to develop subsequent CBC than women with Stage 1 BC with a trend for increased CBC compared to women presenting initially with DCIS. Of those who develop CBCs 5.9% (DCIS), 11.2% (T1mic), and 14.6% (Stage 1) developed within 1 year (YR) of diagnosis of the index cancer. At 10 YRS these numbers were 73.7%(DCIS), 82.7%(T1mic) and 83.2% (Stage 1) (DCIS vs T1mic, p<0.001 T1mic vs Stage 1, P=0.048). At 10 YRS OS for women with CBC after initial BC was 89.5%(DCIS), 86.6%(T1mic) and 84.3%(Stage1) (DCIS vs T1mic, p=0.077, T1mic vs Stage1 p=0.293), Table 2.

Conclusion:
Women with T1mic were at increased risk for subsequent CBC relative to women with Stage I BC. When subsequent CBC occurred it developed earlier in women with T1mic than those with DCIS. Time course for this second event and survival with CBC at 10 years matched more closely with women diagnosed with Stage 1 BC. These findings offer suggestions about the biology of T1mic and may have implications for counseling these women on risk reducing strategies.

Title: Patterns of multidisciplinary care in the management of nonmetastatic invasive breast cancer in the United States Medicare patient

Churilla TM M, Egleston BL L, Murphy CT T, Sigurdson ER R, Hayes SB B, Goldstein LJ J and Bleicher RJ J. Fox Chase Cancer Center, Philadelphia, PA.

Body: Background: Multidisciplinary care (MDC) in managing localized breast cancer is a resource-intensive treatment strategy that is anecdotally growing in prevalence, but is poorly characterized and thus cannot yet be defined as "standard care." We sought to determine the patterns of MDC care in the United States Medicare patient and assess if survival advantages exist for this paradigm.

Methods: Using the Survival, Epidemiology, and End Results (SEER)-Medicare linked dataset, we evaluated patients with non-metastatic breast cancer from 1992 to 2009. MDC was defined as a preoperative visit after breast cancer diagnosis with a surgeon, medical oncologist and radiation oncologist. Two separate analyses were performed: The first evaluated all MDC patients, and the second characterized the subset of patients who saw all three specialties on the same day. We tested for associations between MDC and clinical/demographic variables using logistic regression and evaluated outcomes using propensity score matching.

Results: A total of 87,984 invasive nonmetastatic breast cancer patients were included. MDC was utilized in 2.8% of patients, while 13% of these saw all three oncologic specialists on the same date. MDC use did not vary significantly according to AJCC stage. Patients receiving MDC overall were significantly more likely to be younger (continuous variable; OR [95% CI] = 0.99 [0.98-0.99]), black race (1.75 [1.50-2.05]), receive lumpectomy (1.15 [1.03-1.28], have fewer nodes examined (0.98 [0.98-0.99], and receive radiation therapy (1.37 [1.25-1.51]). MDC patients receiving care all on the same date were significantly more likely than non-MDC patients to have lobular histology (OR [95% CI] = 1.48 [1.06-2.06]), black race (3.09 [2.19-4.35], receive mastectomy (1.75 [1.34-2.30]) and receive radiation therapy (1.98 [1.52-2.60]). The use of MDC overall and on the same date increased over time (p < 0.001) and varied widely according to geographic region. There was a 20.8 odds increase in the use of same-date MDC in the Midwest compared to the South (p < 0.001). Patients in rural settings were less likely to receive MDC overall: OR [95% CI] = 0.57 [0.48-0.68] and on the same date (0.27 [0.16-0.48]). Survival data suggest improved outcomes for women undergoing MDC (Table 1). There were 117 breast cancer deaths in the MDC overall group but only 15 such events in the smaller MDC same-day subgroup (limiting its power).

Conclusions: The vast majority of Medicare patients having breast cancer did not undergo MDC during the period of study. MDC rates have increased over time, with widely varied MDC utilization across regions. Employing same-day MDC should be considered for patient convenience and may improve outcomes. While not yet widespread, efforts should be made to integrate MDC as standard care across the United States.

Title: Marital status and overall mortality in breast cancer patients: Differences by socioeconomic status and race/ethnicity

Martinez ME Elena, Anderson K, Schwab R, Hurley S, Canchola AJ J, Keegan THM HM, Cheng I, Clarke C, Glaser S and Gomez SL L. Moores Cancer Center, University of California, San Diego, La Jolla, CA; University of California, San Diego, La Jolla, CA; Cancer Prevention Institute of California, Fremont, CA; School of Medicine, Stanford, CA and Stanford Cancer Institute, Palo Alto, CA.

Body: Background: Results of several studies show that married cancer patients have lower mortality than unmarried patients. However, data on differences by race/ethnicity are lacking. We assessed the risk of overall mortality associated with marital status among patients with breast cancer according to neighborhood socioeconomic status (SES) and race/ethnicity.

Methods: We used data from the population-based California Cancer Registry to include breast cancer cases diagnosed between 2000 and 2009 with follow-up through December 31, 2012 and identified 175,154 women with invasive breast cancer. We estimated hazard rate ratios (HR) and 95% confidence intervals (CI) for overall mortality by neighborhood SES and race/ethnicity.

Results: Among all cases, 42.6% were unmarried at the time of diagnosis. In adjusted models, the HR for all-cause mortality (95% CI) for unmarried compared to married women was 1.20 (1.17-1.22). There was no significant difference by SES. However, significant variation was observed by race/ethnicity. The HRs (95% CI) were 1.23 (1.20-1.26), 1.20 (1.11-1.30), 1.12 (1.04-1.21), and 1.05 (0.99-1.11) for NH Whites, NH Asians/Pacific Islanders (API), NH Blacks, and Hispanics, respectively. Among API subgroups, Chinese (HR=1.35; 95% CI, 1.12-1.62) and Filipinas (HR=1.25; 95% CI, 1.09-1.44) were the only groups with significantly higher risk of total mortality associated with unmarried status.

Conclusions: Our results show that not being married at the time of breast cancer diagnosis is associated with worse overall survival compared to being married. Significant variation in risk of mortality was shown by race/ethnicity but not by neighborhood SES. Targeted, culturally-appropriate interventions to support unmarried breast cancer patients through their cancer treatment and survivorship need to be developed to improve their survival.
Title: Systematic review of brain metastases in breast cancer in the United States, European Union, and Japan

Fenske DC, Price GL L, Nyhuis AW W and Hess LM M. Eli Lilly and Company, Indianapolis, IN; Eli Lilly and Company, Indianapolis, IN; Eli Lilly and Company, Indianapolis, IN and Eli Lilly and Company, Indianapolis, IN.

Body: Background: Prevalence of brain metastases (BRM) in breast cancer is increasing due to better detection methods and improved patient survival, presenting an unmet need. The exact prevalence is unknown due to a lack of national cancer registries that track BRM cases. Additionally, preceding research presents inconsistent results on survival outcomes, treatment regimens are not well-defined, and there is very limited data on the cost of treating breast cancer BRM. This study was designed to better understand the epidemiology, treatment patterns, cost, and overall survival (OS) of breast cancer patients with BRM in the US, EU, and Japan. Methods: A systematic review following PRISMA guidelines was conducted by searching PubMed, Ovid, and Embase from January 2003 to December 2013. Keywords, MeSH, and Emtree terms were used to define the search strategy. Studies of patients with breast cancer and BRM met eligibility criteria if peer-reviewed, observational, and published in English. Demographic, clinical, and outcomes data were extracted from the publications and entered into Excel. Descriptive statistics were generated with SAS version 9.2. Demographics were summarized, and treatment patterns and median OS were assessed by country. Results: The literature search identified 8,257 articles, of which 245 (n=105,871 breast cancer patients) met eligibility criteria. In these studies, 18,690 breast cancer patients from the US (58.9%), EU (29.5%), and Japan (11.6%) were reported with BRM. Median age of breast cancer patients with BRM was 51.5 years. Patient characteristics are summarized in Table 1. Median OS of breast cancer patients from the time of BRM diagnosis are presented in Table 2. The rate, by country, of radiation therapy among breast cancer patients with BRM ranged from 38.2% to 90.2%, systemic therapy ranged from 5.3% to 46.8%, and surgery was used in 0.8% to 16.2% of studies.

\textsuperscript{1}Reported in months as the median of medians. \textsuperscript{2}NR=not reported

**Conclusions:** Reported median OS and treatment patterns were highly variable across countries. Exposure to risk factors associated with BRM may help explain some of the geographic variability in survival. The lack of published cost data underscores the need to quantify the economic burden of BRM on patients and society.

Title: CYP2D6 gene variants and effectiveness of adjuvant tamoxifen in breast cancer: A population-based case-control study

Weinmann S, Richert–Boe K, Goddard K, Chen C, Punj S, Schwarzkopf D, Kalter M and Richards CS.  Center for Health Research Northwest, Kaiser Permanente, Portland, OR and  Oregon Health Sciences University, Portland, OR.

Body: Tamoxifen, a cornerstone of adjuvant therapy for hormone-receptor-positive breast cancer, is metabolized to the active metabolite endoxifen through enzymatic activity of cytochrome P450 2D6. CYP2D6 has numerous alleles that affect metabolizing phenotype. Among women who take tamoxifen, those homozygous for inactive alleles (poor metabolizers) have lower levels of serum endoxifen than those with two functional alleles (extensive metabolizers). Several studies have reported increased risk of breast cancer recurrence or death in women homozygous for CYP2D6 inactive alleles, but others have found no association between CYP2D6 function and outcome. We explored this question in the large member population of the Kaiser Permanente Northwest (KPNW) integrated health plan. We conducted a population-based case-control study to evaluate the hypothesis that, after adjuvant tamoxifen treatment for breast cancer, women with CYP2D6 genotypes associated with poor metabolism of tamoxifen have an elevated risk of breast cancer recurrence compared to women with CYP2D6 genotypes associated with extensive metabolism of tamoxifen. We further hypothesized that women with CYP2D6 genotypes associated with intermediate metabolism of tamoxifen are at intermediate risk of recurrence. Study subjects were women who were diagnosed from 1980 to 2011 with hormone-receptor positive breast cancer, who received at least 180 days of adjuvant tamoxifen treatment, and for whom stored formalin-fixed paraffin-embedded (FFPE) normal tissue was available for laboratory analysis. Cases (358) were women with breast cancer recurrence recorded in the KPNW Tumor Registry and validated by medical record review. Randomly selected controls (833), without recurrent breast cancer, were matched to cases on tumor stage, diagnosis year, diagnosis age, race/ethnicity, and patterns of health plan membership. We collected data from medical records and from pharmacy, laboratory, tumor registry, and membership health plan databases. The Oregon Health & Science University Molecular Genetics Laboratory extracted genomic DNA from stored FFPE tissue blocks and performed allelic discrimination assays and pyrosequencing to accurately determine CYP2D6 variant status for the alleles, *3, *4, *5, *10, *17, and *41. All assays have been completed and study subjects have been categorized according to CYP2D6 metabolizer phenotype (poor, intermediate, extensive) and activity score (0-2). Based on the ethnicities in our study population, the CYP2D6 allele frequencies are in Hardy-Weinberg equilibrium, and the frequencies of the predicted metabolizer phenotypes also fall within the expected range. Using multivariable logistic regression analysis, we will assess CYP2D6 functional status and activity score in relation to breast cancer recurrence, taking into account factors that may alter the association, including tamoxifen dose and duration of use, as well as concomitant medications that alter the activity of the CYP2D6 enzyme. Results will be available by 12/1/2015.

Title: Association analysis of single-nucleotide polymorphisms in FANCD2–DNA damage repair pathway genes with breast cancer risk

Chen F, Tang L and Huang J. Xiangya Hospital of Central South University, Changsha, Hunan, China.

Body: Purpose: The aim of the study was to estimate breast cancer risk conferred by individual single-nucleotide polymorphisms (SNPs) of breast cancer susceptibility genes in the monoubiquitinated FANCD2–DNA damage repair pathway.

Methods: We selected 48 tagging SNPs (tSNPs) from eight breast cancer susceptibility genes (TP53, PTEN, NBS1, BRIP1, PALB2, ATM, CHEK2 and RAD50) involved in the monoubiquitinated FANCD2–DNA damage repair pathway. The 48 tSNPs were genotyped by SNPscan in 734 women with breast cancer (534 sporadic cases and 200 early-onset and familial cases) and 672 sex- and age-matched healthy controls from Hunan and Sichuan Province of China. The odds ratio were calculated by logistic regression analysis under co-dominant model, dominant model and recessive model respectively.

Results: Forty-five tSNPs were successfully genotyped by SNPscan, and the call rates for each tSNP were above 98.9%. We found that 13 tSNPs of five genes (PALB2, TP53, NBS1, PTEN, and BRIP1) were significantly associated with breast cancer risk. A total of five tSNPs (rs2299941 of PTEN, rs2735385, rs6999227, rs1805812, and rs1061302 of NBS1) were tightly associated with breast cancer risk in sporadic cases, and five other tSNPs (rs1042522 of TP53, rs2735343 of PTEN, rs7220719, rs16945628, and rs11871753 of BRIP1) were tightly associated with breast cancer risk in early-onset and familial cases. We have not found significant tSNPs in the other three genes (ATM, RAD50, and CHEK2). Three tSNPs of TP53 (rs12951053, rs1042522 and rs8064946), three tSNPs of BRIP1 (rs16945628, rs7220719 and rs11871753) and rs2735343 of PTEN can significantly increase the risk of breast cancer, and most of these were under the analysis of early-onset and familial cases. Four tSNPs of NBS1 (rs2735385, rs6999227, rs1805812 and rs1061302), rs2299941 of PTEN and rs513313 of PALB2 can significantly decrease the risk of breast cancer, and most of these were under the analysis of sporadic cases.

Conclusions: Some of the tSNPs of five breast cancer susceptibility genes (PALB2, TP53, NBS1, PTEN, and BRIP1) involved in the monoubiquitinated FANCD2–DNA damage repair pathway were significantly associated with breast cancer risk in women from Hunan and Sichuan Province of China. Some locuses can increase breast cancer risk, and others can decrease breast cancer risk. But the majority of the tSNPs are located in the intron domain and their functions are unknown, so larger studies are needed to research the functions of these genes further.

Title: Sources of polycyclic aromatic hydrocarbons associated with gene-specific promoter methylation in women with breast cancer

White AJ J, Chen J, McCullough LE E, Xu X, Cho YH, Conway K, Beyea J, Stellman SD D, Steck SE E, Mordukhovich I, Eng SM M, Terry MB, Engel LS S, Hatch M, Neugut AI I, Hibshoosh H, Santella RM M and Gammon MD D. University of North Carolina at Chapel Hill; Ichan School of Medicine at Mt. Sinai; Roche Product Development in Asia-Pacific; University of Montana; Consulting in the Public Interest; Columbia University; University of South Carolina and National Cancer Institute.

Body: Tobacco smoke, diet, and indoor and outdoor air pollution, all major sources of polycyclic aromatic hydrocarbons (PAHs), have been associated with breast cancer incidence. Aberrant methylation may be an early event in carcinogenesis, but whether PAHs influence the epigenome is unclear. Few studies have evaluated whether PAHs are associated with methylation, particularly in breast tumors where methylation changes are particularly relevant. In a population-based case-control study, we measured promoter methylation of 13 breast cancer-related genes in breast tumor tissue (n=765-851 cases) and global methylation in peripheral blood (1,055 cases/1,101 controls). PAH sources (current active smoking, residential environmental tobacco smoke (ETS), vehicular traffic, synthetic log burning, and grilled/smoked meat intake) were evaluated separately. Logistic regression was used to estimate adjusted odds ratios (ORs) and 95% confidence intervals (CIs). When comparing methylated versus unmethylated genes, synthetic log use was associated with increased ORs for CDH1 (OR=2.28, 95%CI=1.07-4.83), HIN1 (OR=2.11, 95%CI=1.32-3.38) and RARβ methylation (OR=1.82, 95%CI=1.18-2.83) and decreased ORs for BRCA1 methylation (OR=0.44, 95%CI=0.30-0.65). Residential ETS was associated with decreased ORs for ESR1 (OR=0.74, 95%CI=0.56-0.99) and CCND2 methylation (OR=0.65, 95%CI=0.44-0.96). Current smoking and vehicular traffic were associated with decreased ORs for DAPK (OR=0.53, 95%CI=0.28-0.99) and increased ORs for TWIST1 methylation (OR=2.79, 95%CI=1.24-6.30), respectively. In controls, synthetic log use was inversely associated with LINE-1 methylation (OR=0.60, 95%CI=0.42-0.87). PAH sources were associated with hypo- and hypermethylation at multiple promoter regions in breast tumors and LINE-1 hypomethylation in blood of controls. Methylation may be a potential biologic mechanism for the association between PAHs and breast cancer incidence.
Expression levels of sialyl transferases and fucosyl transferases in breast cancer and their prognostic significance

Aberrant expression of fucose or sialic acid containing glycans is prevalent in various cancers, including breast cancer. The addition of fucose and sialic acid to glycans is mediated by fucosyl transferases (FUTs) and sialyl transferases (STs), respectively. To explore the roles of these FUTs and STs in breast cancer, we collected 123 paired breast cancer specimens (tumor tissue and non-tumor tissue) and determined the RNA expression levels of 13 FUTs (FUT1-13) and 13 STs (ST3Gal1-6, ST6Gal1, ST6GalNAc1-4, ST6GalNAc6, ST8Sia1 and ST8Sia4) by q-PCR. The expression of 10 FUTs and 10 STs is significantly higher in tumor tissue than in non-tumor tissue by 1.2-4.09 folds. Notably, expression of FUT1 and ST3Gal1 appeared to be highest in triple negative subtype. Further multivariate Cox regression analysis showed a significant correlation between higher hazard ratios (HRs) for five-year relapse-free survival (RFS) and higher ST3Gal1 expression (N = 16, HR = 2.54, p = 0.02) or lower ST3Gal3 expression (N = 88, HR = 3.44, p < 0.001). As to the joint effects of high expression of ST3Gal1 and low expression of ST3Gal3 (N = 10) compared with low expression of ST3Gal1 and high expression of ST3Gal3 (N = 82), the HR was 5.5 (95% CI = 2.16-14.02, p = 0.0004) for RFS. The two gene additive model displayed a statistically significant HR of 2.33 for RFS (95% CI = 1.48-3.69, p = 0.0003). These results suggest that FUTs and STs play important roles in tumor progression.
Body: Background: Due to better molecular classification and new treatment options, epidemiology and prognosis of mBC is rapidly changing. Clinical data extracted from randomized studies are only relevant to specific subpopulations and retrospective studies are prone to selection bias. SToRM is a prospective clinical trial that aims to create a cohort of 1500 mBC patients, with the ultimate goal of identifying germ line polymorphisms associated with prognosis of breast cancer (BC) and response to treatment in the metastatic phase.

Material and methods: Any newly (within 1 year) diagnosed mBC patients were eligible. Whole blood samples were drawn and germline DNA extracted for genetic analysis. Extensive epidemiologic data, disease history from primary diagnosis to metastatic spread, pathological characteristics and ER, PR and HER2 status were collected. Patients are prospectively followed until death. Genotyping using the HumanCoreExome chipset from Illumina is currently underway and will be completed in early summer 2015.

Results: 1502 patients were included from March 2012 to May 2014 from 71 French institutions. Median age at metastatic relapse was 60 years (range 26-93). Median time from primary diagnosis to metastatic relapse was 30 months (range 0-473) with 24% of patients already metastatic at initial diagnosis. 78% of patients were ER+, 18% were HER2+ and only 16% were triple negative. Molecular subtype classification derived from pathological data following St Gallen consensus recommendations is presented below:

<table>
<thead>

</tbody>
</table>

64% of the patients had received previous adjuvant treatment, among which 81% received adjuvant chemotherapy and 9% trastuzumab.

At metastatic relapse, loco-regional progression, liver, lung and bone metastasis were documented in 301 (20%), 494 (33%), 410 (27%) and 1017 (68%) patients respectively. 313 patients (21%) had bone only metastatic disease. First line treatment included:
chemotherapy (71%), endocrine therapy (50%) and anti-HER2 treatments (17%). Survival data will be presented at the meeting. **Conclusion:** Despite a theoretically better prognosis and widespread use of adjuvant hormonal treatment, ER+/HER2- breast cancer still account for more than 60% of mBC. The proportion of patients with HER2+ disease (18%) and triple negative disease (16%) is consistent with percentages observed in early BC populations. In comparison with a cohort of "cured", localized cancer, such as the SIGNAL/PHARE study, GWAS analysis will allow for the identification of genetic polymorphisms correlated with treatment resistance. Fundamentally, such variants will provide insight into the molecular mechanisms responsible for host-genetic influence on BC progression. From a clinical perspective, genetic variants that predispose to metastatic disease can serve as stratification variables in future clinical trials, particularly as the development of new treatment options for resistant BC is needed.
Body: Background: Evaluation of women with BC for germline mutations associated with hereditary breast and ovarian cancer (HBOC) has become increasingly common due to its impact on management. Guidelines for genetic evaluation indicate testing for cases with early onset, triple negative disease or family cancer history. However, the majority of breast cancer occurs in patients without these high risk characteristics. The prevalence of mutations associated with HBOC has not been well characterized in this population.

Methods: We performed a cross sectional study using DNA from blood samples from consecutive new invasive BC patients seen at the Dana-Farber Cancer Institute (01/01/2010 to 07/31/2012) who consented to research. Subjects were otherwise unselected. Mutations in 25 cancer genes were identified using a next generation sequencing based panel. Germline sequence variations and large rearrangements were classified for pathogenicity.

Results: 456 samples from eligible subjects were included. The mean age of BC diagnosis was 50 years. Mutations were found in 51 women, 49 of which were associated with breast cancer (10.8%, 95% CI 8.1-14.0). BRCA1/2 mutations were found in 6.6% [95% CI 4.5-9.2%] while mutations in other BC-associated genes were found in 4.4% [95% CI 2.7-6.7%], particularly CHEK2 (2.2%, 95% CI 1.1, 4.0). Of the 49 women with BC-related mutations, 21 (43%) had BC diagnosed after age 45. In univariate analyses, age at diagnosis, Ashkenazi Jewish ancestry, triple negative histology and family BC/ovarian cancer (OC) history were associated with BRCA1/2 mutations, but no factors were significantly associated with mutations in other genes. Among 261 women with no FDR/SDR with BC/OC, 26 (10.0%) had a mutation. Nineteen mutations (10 BRCA1/2) were found in the 256 women (7.4%) who had not had previous genetic testing.

Conclusions: In a single academic institution, 11% of new breast cancer patients had a germline mutation in a breast cancer predisposition gene: 6.6% were in BRCA1/2. The elevated prevalence compared to population-based series may reflect the practice composition of academic centers, which often attract women younger at BC diagnosis. In an academic practice with an active cancer genetics program, 10 women with BRCA1/2 and 9 with other mutations had not had genetic testing. Expanded testing identifies additional predisposing mutations, the utility of which are being defined for the care of breast cancer patients and their families.
Title: Heterozygous germline mutations in RAD50 among Korean patients with high-risk breast cancer negative for BRCA1/2 mutation

Kim H, Cho D-Y, Choi DH, Jung GH, Shin I, Park W, Huh SJ, Nam SJ, Lee JE, Gil WH and Kim SW. Hallym University Dongtan Sacred Heart Hospital, Hwaseong, Republic of Korea; LabGenomics Clinical Research Institute, LabGenomics, Seongnam, Republic of Korea; Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea and Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.

Body: Background: The MRE11-RAD50-nibrin (MRN) complex participates in pathways of double-strand break induced DNA repair and cell cycle checkpoint control. RAD50 interacts with the MRE11 and NBS proteins, is involved in the maintenance of genomic integrity. The association of RAD50 mutation and breast cancer susceptibility has been reported in European patients. However, the impact of RAD50 mutation on a breast cancer predisposition among Koreans remains uncertain. In the current analysis, we evaluated the incidence of RAD50 mutations among Korean patients with non-BRCA1/2 high-risk breast cancer.

Materials and Methods: A total of 247 Korean patients with high-risk breast cancer who tested negative for BRCA1/2 mutation were enrolled. The criteria for high-risk breast cancer were as follows: having a family history of breast or ovarian cancer in any relative; diagnosed at age 40 years or younger; bilateral breast cancer; and male breast cancer. All participants were screened for BRCA1/2 mutations using fluorescent-conformation sensitive capillary electrophoresis (F-CSCE) and traditional sequencing. The entire RAD50 gene of each patient was sequenced using F-CSCE. In silico analyses of the RAD50 variants was performed using PolyPhen-2 and SIFT.

Results: There were two novel deleterious mutations in RAD50 (p.Q426X, p.E1271del). These mutations were found in two patients, including one with p.Q426X and the other with p.E1271del. Besides, five sequence variants in RAD50 were identified: four exonic variants (p.I118T, p.R486C, p.L1264F, and p.R1279H) and one intronic variant (c.1246-11T>C). Among the four missense variants, p.R486C and p.L1264F were variants predicted to be deleterious by in silico analyses.

Conclusions: We found protein-truncating mutations in RAD50 gene in a small proportion of Korean patients with high-risk breast cancer. The contribution of the mutation to the development of breast cancer should be clarified in further researches.
Increased prevalence of luminal B subtype in Colombian women with breast cancer

Serrano-Gomez SJ J, Sanabria MC C, Hernández-Suarez GA A, Garcia O, Silva C, Romero A, Mejía JC C, Fejerman L, Antonia T, Miele L and Zabaleta J.  Instituto Nacional de Cancerologia, Bogota, Cundinamarca, Colombia;  Pontificia Universidad Javeriana, Bogota, Cundinamarca, Colombia;  Stanley S. Scott Cancer Center, New Orleans, LA;  UCSF, San Francisco, CA;  Moffitt Cancer Center, Tampa, FL; Department of Genetics, New Orleans, LA and  Department of Pediatrics, New Orleans, LA.

Body: Background: Breast cancer is the most frequent malignancy in women worldwide. Distinct intrinsic subtypes of breast cancer have different prognoses, and their relative prevalence varies significantly among ethnic groups. Hispanic/Latino (H/L) populations are a genetically admixed and heterogeneous group, with variable levels of European, Native American and African ancestries. Breast cancer in H/L patients is understudied from a molecular standpoint, and most studies reported so far include limited numbers of H/L patients and assign ethnicity based on self-reported data rather than ancestry. This is the first study to explore the prevalence of breast cancer intrinsic subtypes in Colombia and their association with clinicopathological data and genetic ancestry.

Methods: Immunohistochemistry surrogates from the 2013 St. Gallen International Expert Consensus were applied to classify breast cancer into intrinsic subtypes in 301 patients diagnosed between 2008 and 2012 at the Colombian National Cancer Institute. We analyzed the distribution of subtypes by age, histologic type, node status, margins at surgery, AJCC stage, tumor size, Bloom-Richardson grade, histologic features, administration and response to neoadjuvant therapy, adjuvant therapy and recurrence. Genetic ancestry was estimated from a panel of 80 ancestry-informative markers (AIM).

Results: Luminal B breast cancer subtype was the most prevalent in our population (47.5%), followed by luminal A (23.9%), non-basal triple negative (9.3%), basal-like (8.6%), HER2-enriched (8%), and unknown (2.6%). The average of age at diagnosis was 55 and the average tumor size was 4.08 cm. We found statistical significant differences in age at diagnosis, Bloom-Richardson grade, histologic features, adjuvant chemotherapy and recurrence according to intrinsic subtype. Consistent with North American and European observations, basal-like and non-basal triple negative were poorly differentiated tumors and more likely to be diagnosed at younger ages compared to luminal tumors. Patients diagnosed with HER2-enriched, basal and non-basal triple negative breast cancer had the highest African ancestry.

Conclusions: Luminal B tumors, a high risk subset of ER-positive breast cancer, occur with remarkably higher prevalence in Colombian women with breast cancer compared to North American and European populations. Triple-negative subtypes and HER2-enriched tumors appeared to be more frequent among patients with African ancestry, as observed in North American cohorts. Future studies analyzing the molecular profiles of breast cancer in Colombian women will help us understand the molecular basis of this subtype distribution and compare the molecular characteristics of the different intrinsic subtypes in Colombian Hispanic/Latina patients.
Title: Clinicopathological characteristics and clinical outcome in Egyptian female breast cancer patients with and without BRCA1/2 mutations

AbdelHamid SG G, El-Mesallamy HO O, AbdelAziz HM M and Zekri A-RN N. Faculty of Pharmacy, Ain Shams University, Cairo, Egypt; Faculty of Medicine, Ain Shams University, Cairo, Egypt and National Cancer Institute, Cairo University, Giza, Egypt.

Body: Background: Germline mutations in BRCA1 and BRCA2 genes confer high risk of developing breast cancer. We sought to examine for the first time in the Egyptian population, which has witnessed the world's oldest recorded breast cancer case, whether the clinicopathological characteristics and the clinical outcome differ in patients with and without BRCA mutations.

Patients and Methods: A series of 103 Egyptian female patients diagnosed with breast cancer before 2008 were recruited from Breast Cancer Unit, Clinical Oncology Department, Ain Shams University, Egypt. The enrolled patients, unselected for age of onset or family history, were tested for BRCA1/2 mutations using HRM analysis and direct sequencing. The clinical and pathological features of the patients were retrospectively assessed and comparisons were made between BRCA mutation carriers and non-carriers, respectively, using Chi-square. Disease free survival (DFS) was estimated by Kaplan–Meier method and compared in the two groups with log-rank. Survival Cox proportional hazards models were fit to determine the independent association of mutation status with outcome.

Results: The overall rate of BRCA1/2 mutations was 44% (46/103). Novel deleterious mutations were detected and submitted to NCBI Clinvar database. Deleterious mutations were identified in 29 cases and unclassified variants in 32 cases, 15 of which had a co-occurring deleterious mutation. Patients with BRCA mutations tended to have early onset breast cancer compared to non-carriers (P=0.002), more often premenopausal (P=0.006), with a familial history of breast cancer as well as other cancers (P=0.005). BRCA-related breast cancers were more likely to have T3-T4 stage than wild type (41% versus 28%, P=0.02), positive lymph node involvement (78 versus 53%, P=0.007) and develop bilateral breast cancers (24% versus 9%, P =0.007). Grade and histology were not associated with mutation status. The incidence of ER negative and PR negative tumors was higher in BRCA carriers, but not statistically significant (P=0.17 and 0.15, respectively). No difference in HER-2/neu status was observed (P=0.25). Multivariate logistic regression model showed that early age at onset, positive lymph node involvement, family history of any cancer (P=0.047, 0.05 and 0.05, respectively) are independent predictive factors for occurrence of BRCA1/2 mutations. Carriers of BRCA2 deleterious mutations were more likely to report positive family history of cancer other than breast compared to non-carriers (P=0.001). The median follow-up time for the cohort was 5.53 years (ranged from 4.7 to 20.4 years). Patients with BRCA mutations had poorer 5-year DFS compared to non-carriers (47.7% versus 67.4%, P=0.041); but Cox regression analysis failed to demonstrate a significant independent influence of BRCA mutation status on DFS.

Conclusion: This is the first study in the Middle East to show that BRCA-related breast cancers in the Egyptian population have distinctive clinical and tumor features as well as outcome. Early onset breast cancer, family history of cancer and positive lymph node involvement are predictors for BRCA mutation in this Egyptian cohort. This data has important health implications for guiding cancer control policies.
African American women have lower pathologic complete response rates to neoadjuvant chemotherapy compared to white women for triple negative and HER 2 positive breast cancer

Killelea BK, Chagpar AB, Horowitz NR, Pusztai L, Wang S, Mougalian S and Lannin DR. Yale University School of Medicine, New Haven, CT and Yale University School of Public Health, New Haven, CT.

**Body:**

**Introduction**

Although racial disparities in breast cancer treatment have been well documented, data regarding differences in response to neoadjuvant chemotherapy are few. In 2010 the National Cancer Database (NCDB) included a new variable, documenting pathologic complete response (pCR) after neoadjuvant chemotherapy. The purpose of this study was to explore racial differences in the rates of pCR by molecular subtype.

**Methods**

The NCDB was queried to identify women diagnosed with invasive, stage 1-3 breast cancer in 2010-2011 who received neoadjuvant chemotherapy. Univariate and multivariate logistic regression was performed to determine factors associated with likelihood of pCR.

**Results**

Out of 278,815 patients with known race and ethnicity, 27,300 (10%) received neoadjuvant chemotherapy. Of 17,970 where the outcome was known, 5,944 (33%) had a pCR. As seen in the table, there were no differences in response rate for ER/PR+ tumors, but compared to whites, non-hispanic black women had a lower rate of pCR for ER/PR- Her2+ and triple negative tumors. This difference persisted when adjusted for patient age, clinical T stage, clinical N stage, histology, grade, comorbidity index, facility type, geographic region, insurance status, and census-derived median income and education for the patient’s zip code (OR 0.84, 95% CI: 0.77-0.93).

**pCR rate by race and molecular subtype**

Conclusions
Non-hispanic black women have a lower likelihood of pCR after neoadjuvant chemotherapy compared to white women for triple negative and Her 2 positive breast cancer. It is unknown whether this is due to biologic differences in chemosensitivity or whether it represents treatment or socioeconomic differences that cannot be adjusted for in the current analysis.
Higher incidence of second cancers in African American (AA) patients compared to Caucasian patients with a primary breast cancer

Diab N, Clark G, Hamlington B, Brzeskiewicz L, Langer L and Diab S. Vanderbilt University, Nashville, TN; Arry BioPharma, Boulder, CO; Rocky Mountain Cancer Centers, Aurora and Denver, CO and Compass Oncology, Portland, OR.

**Body:** Background: AA women with breast cancer have lower survival rates compared to Caucasian women. Since this lower survival rate may be related to genetic mutations, and environmental/socioeconomically factors, we hypothesize that the same factors may lead to a higher risk of secondary cancers after an initial diagnosis of breast cancer.

**Method:** Analysis of the Surveillance, Epidemiology, and End Results (SEER) Program data using Multiple Primary - Standardized Incidence Ratio parameters. The incidence of second cancer diagnoses in AA and Caucasian women previously diagnosed with breast was compared to the incidence of cancer in the general population matched by age, race, and year of diagnosis. Results are reported as the observed risk divided by the expected risk (O/E).

**Results:** For the 43,688 AA pts, the overall O/E and excess risks were 1.48 and 51.2 compared to 1.11 and 14.7 for the 428,103 Caucasian patients. The mean ages of diagnoses of initial breast cancer diagnosis and second cancer were 57.2 and 65 years for AA patients compared to 61.8 and 70.2 years for Caucasian patients. The following is a summary of statically significant (p <0.05) selected O/E by the site of second cancer:

This higher risk of second cancers occurred despite the lower relative survival rate for AA compared to Caucasian patients with a 5-year relative survival rate of 68.6% for AA and 78.3% for Caucasian patients.

**Conclusions:** To our knowledge, this is the first report of the incidence of second cancers in AA patients with breast cancer compared to caucasian. More research to understand the biological, genetic, therapeutic, and environmental factors leading to this higher risk of second cancers is warranted.
Socioeconomic characteristics of African American women with breast cancer

Winter A, Raska P, Ornstein M, Moore H, Montero A, Budd GT Thomas, Tullio K, Bailey J and Abraham J. Cleveland Clinic, Cleveland, OH.

Background: Breast cancer is the most common cancer among African American (AA) women. Despite having a lower incidence of breast cancer compared to white women (124.4 compared to 127.9 per 100,000), AAs have a higher death rate (30.2 compared to 21.3 per 100,000). One explanation for this discrepancy is that breast cancer in AAs is often detected at a later stage compared to white women. We conducted this retrospective study to examine socioeconomic characteristics among AA women with breast cancer to see if there were factors associated with stage of diagnosis which may contribute to the known disparities.

Methods: We identified all AA women diagnosed with any stage breast cancer from 2006-2014 within the Cleveland Clinic Cancer Data Warehouse and classified them into either early or late stage disease at time of diagnosis. Stages 0-II were classified as early and stages III-IV as late. We examined several variables at diagnosis including age, marital status, tobacco use, alcohol use, Medicaid insurance status, and breast cancer subtype which included HER-2 positive (HER+), hormone receptor positive/HER2 negative (HR+/HER-), and triple negative(TN). AA median income was obtained from US census data according to the zip code at diagnosis. We conducted univariate logistic regression for individual estimates and confidence intervals and multiple logistic regression and model selection to determine significant predictors of stage of diagnosis.

Results: Of the 771 AA women identified, 108 (14%) were diagnosed at a late stage of disease with a median age of 59 years. Receptor status distribution was 12.4%, 31%, and 16.6% for HER+, HR+/HER-, and TN respectively for early stage, and 15.7%, 27%, and 25% for late stage. Among early stage 50% were current or previous smokers and 2.6% had Medicaid insurance compared to late stage patients where 63% were current or previous smokers and 9.2% had Medicaid insurance. Multiplicative effect estimates and 95% confidence intervals from univariate logistic regressions identified the following significant factors: tobacco use 1.48 [1.11-1.96] and Medicaid 3.73 [1.56-8.51] (p-values<0.01), and TNBC 1.67 [1.02-2.68] (p-value<0.05). In a stepwise model selection, only tobacco use and Medicaid were retained in the model, as well as age at diagnosis. Conclusions: There are socioeconomic differences among AA women with breast cancer. Only tobacco use, Medicaid insurance, and age at diagnosis were predictive of late stage in this study.
Title: New Orleans has the highest incidence rates of triple negative breast cancer

Loch MM M, Li X, Hsieh M-C, Chen VW W and Wu X-C. Louisiana State University Health Sciences Center, New Orleans, LA and Louisiana State University School of Public Health, New Orleans, LA.

Body: Background: We previously demonstrated increased incidence rates of triple negative breast cancer (TNBC) in Black women (BW) in New Orleans (NO) and Louisiana (LA) compared with SEER 17. We explored the hypothesis that BW in NO had a higher incidence of TNBC than in BW other metro areas in the SEER Program.

Methods: We analyzed tumor characteristics of invasive female breast cancers diagnosed 2010-12 from SEER, focusing on racial disparities. We compared LA data with SEER 17 and metropolitan areas (Atlanta, Detroit, Los Angeles and San Francisco). Predictors of TNBC were identified in multivariate logistic regression.

Results: Overall incidence rate of TNBC in BW was significantly higher in NO (32 per 100,000) than in the rest of LA (24 per 100,000) and the SEER metro areas combined (23 per100,000). Detroit had the 2nd highest rates (27.3 per 100,000) followed by Los Angeles, San Francisco and Atlanta (23.2, 23, 22.4 respectively). Compared with SEER 17, the rate ratio of TNBC was 38\% higher for BW in NO (CI: 1.17-1.61) and 17\% higher for BW in Detroit (CI: 1.06-1.29). Compared with other LA metro areas, the rate ratio of TNBC was 44\% higher for BW in NO (CI: 1.10-1.91). Young age (<65) and black race predicted TNBC after adjusting for insurance status, tumor size, lymph node status, grade and derived AJCC stage.

Conclusions: The incidence rates and rate ratios of TNBC in BW in NO and LA are not only significantly higher than in SEER 17 but also higher than any other SEER metro area. We will explore this dataset further by analyzing BMI, comorbidities and SES. This disparity in BW in NO has clinical implications and translational research potential as it enables us to broaden the understanding and treatment of this aggressive disease.
Title: Survival disparities: Quality of care apparently not the answer

Friend SC C, Royce ME E, Kang H, Lomo L, Barry M, Wiggins C, Prossnitz E and Hill DA A. Cancer Research and Treatment Center and School of Medicine, University of New Mexico, Albuquerque, NM and University of New Mexico, Albuquerque, NM.

Body: Introduction: In New Mexico (NM), Hispanic women have a 1.6-fold increased risk of breast cancer-specific death compared to non-Hispanic white women. In previous studies, race/ethnic minority women have been less likely to receive recommended adjuvant treatments, including radiation in women undergoing breast conservation, and hormonal therapy.

Objective: To determine whether non-receipt of recommended therapies contributed to disparate survival.

Methods: We conducted a case-cohort study of breast-cancer-specific survival within a population-based cohort of first invasive breast cancer diagnosed in white females from 1997-2009 in six NM counties, identified through Surveillance Epidemiology End Results (SEER). We selected fifteen percent of all women diagnosed with breast cancer and all breast cancer deaths. After IRB approval, data were collected from comprehensive medical chart reviews, supplemented by SEER information. Receipt of standard of care, vs. not, was defined based on age, diagnosis year and tumor characteristics, according to changes in treatment guidelines. Women who had a reported contraindication or refused therapy were omitted from assessment of quality of care for that therapy. Cox proportional hazards models for case-cohort were conducted using weighted estimates, with calculation of robust variance and hazard ratios (HR) and 95% confidence intervals (CI), using an alpha level of .05. Analyses were restricted to women of age 70 or less who survived at least 12 months. The proportional hazards assumption was verified by Schoenfeld residuals. All analyses were adjusted for age.

Results: Comprehensive medical records reviews were completed for 91% of eligible women (674 cohort members, 519 breast cancer deaths; median follow up 7.8 years). All others were omitted from analysis. Of women eligible for guideline-based treatment, receipt of guideline-appropriate therapy did not differ by Hispanic ethnicity for any treatment, and Hispanic women were slightly more likely overall to receive appropriate therapy (difference not significant). Among guideline-eligible women, at least 91% received radiotherapy, 78% received chemotherapy, 82% received endocrine therapy, and 89% received anti-HER2 targeted agents. After adjustment for other treatment, lack of receipt of guideline-appropriate therapy was related to an increased risk of breast cancer death for endocrine (HR 1.76; 95% CI 1.09-2.84) and radiation therapy (HR 2.05; 95% CI 1.14-3.69). The few HER2-positive women not treated precluded further assessment. After accounting for endocrine and radiation therapy the survival disparity HR of 1.6 in Hispanic women was reduced to 1.57 suggesting only 2% of the disparity was due to differences in receipt of these treatments.

Conclusion: Limitations include likely undercounts of appropriate therapy, thus proportions cited are minimal estimates. Appropriate therapy includes only documented receipt as therapy completion could not always be assessed. Hispanic women have a disproportionately higher breast cancer mortality despite apparently receiving adjuvant therapies to a similar degree as non-Hispanic white women. Equalizing standard of care and attempting to reduce treatment disparities may not be sufficient to address the disproportionate mortality in Hispanic women.
Body: Introduction
Although Hispanic women have lower rates of breast cancer compared to non-Hispanic whites (NHW), breast cancer remains the leading cause of cancer death among Hispanic women. Some studies suggest that Hispanic women have lower rates of breast cancer screening compared to NHW women, primarily due to lack of health insurance and socioeconomic disadvantages. This study aims to understand the demographic characteristics of Hispanic women in the U.S. who access and utilize the Avon Breast Health Outreach Program (BHOP), and how Hispanic women's mammography history differs by nativity. Avon BHOP supports community-based organizations to conduct education and outreach to over 50,000 low-income and uninsured women each year, linking them to routine breast cancer screening and care.

Methods
This study analyzed 2014 Client Intake Forms (CIF) for all women aged 40 and older, who were served by BHOP for the first time (~16,000 women). Descriptive analysis was conducted to summarize their demographic and breast health information, comparing Hispanics with NHW. Multivariate logistic regression was performed to examine the relationship between ethnicity and nativity and having a mammogram in the last two years. Lastly, a sub-analysis among foreign-born (FB) Hispanics only was conducted to assess how the length of time living in the U.S. (number of years) impacts the likelihood of having a mammogram in the last two years.

Results
Of the first time clients served through BHOP in 2014, 10.4% were US-born Hispanics, 45.2% were FB-Hispanics, and 44.4% were NHW. The majority of FB-Hispanic women were from Mexico (66.2%). FB-Hispanics are less likely to have insurance as compared to US-born Hispanic women (19.7% vs. 39.3%), and less likely to have a high school degree (34.3% vs. 44.8%). After controlling for demographic and socioeconomic variables, FB-Hispanics had significantly greater odds of having a mammogram in the past two years compared to US-born Hispanics (OR=1.6, 95% CI, 1.3-1.9), and NHW women (OR=1.4, 95% CI, 1.2-1.6). FB-Hispanics living in the U.S. for 5+ years had a 1.7 greater odds of having a mammogram in the past 2 years, as compared to recent immigrants living in the U.S. for less than one year (OR=1.7, 95% CI, 1.1 – 2.7).

Discussion
In 2014, the percentage of BHOP Hispanic women aged 40+, reporting a mammogram in the last two years (41.1%) was lower than the overall U.S. Hispanic rate (61.4%), suggesting confirmation that BHOP serves vulnerable and underserved populations, as it aims to do. This study also demonstrates how screening behaviors differ among Hispanic women served through BHOP, with FB-Hispanics having higher mammography utilization rates as compared to their US-born counterparts, with variation seen by the number of years living in the U.S. In conclusion, it is critical to view Hispanics as a heterogeneous group in order to best address their clinical needs. Specifically, the results point to how U.S.-born Hispanic BHOP clients may be at particularly high risk for low breast cancer screening.
Title: Effects of breast cancer treatment on markers of metabolic syndrome in a predominantly hispanic patient population

Gaur S, Ochoa C, Sanchez L and Nahleh Z. Texas Tech University Paul L Foster School of Medicine, EL Paso, TX.

Body: Background: Adjuvant chemotherapy improves survival in early breast cancer, however has been reported to contribute to weight gain and insulin resistance. Hispanics are reported to have higher levels of insulin resistance and features of metabolic syndrome as compared to caucasians and as such may be at higher risk of metabolic decompensation during treatment of their cancer. We sought to evaluate the effects of adjuvant/neo-adjuvant breast cancer treatment on markers of metabolic syndrome in a predominantly hispanic population. Study was funded by the institutions department of medicine seed grant funds.

Methods: We enrolled 35 consecutive patients who were about to commence adjuvant or neo-adjuvant chemotherapy for breast cancer. Patients with diabetes mellitus or hyperlipidemia were excluded. Fasting glucose, HBA1C, insulin levels, HDL cholesterol, triglyceride levels, waist circumference and blood pressure were measured before starting chemotherapy and then every 3 months for 1 year. Results were analyzed using repeated measures ANOVA for normally distributed data. For data that was not normally distributed, Friedmans non parametric test was utilized.

A survey of dietary habits, exercise frequency and life style factors was administered before initiating treatment and at completion of the study.

Results:

Baseline characteristics: Of the 35 patients enrolled 31 were hispanics (89%). Median age was 47 years (33-68). 31 (82.8%) were over weight or obese. 13 (37%) had insulin resistance as assessed by HOMA (homeostatic model assessment)-IR, and 12 (34%) met the international diabetic federation (IDF) criteria for metabolic syndrome. 17% had stage 1, 52% had stage 2 and 31% had stage 3 disease. Most common chemotherapy regimen used was dose dense doxorubicin, cyclophosphamide and weekly paclitaxel.

No significant change was noted in the fasting glucose, HBA1C levels, insulin levels, HOMA-IR, weight or waist circumference at any point during the 1 year follow up. Triglyceride levels increased from a mean of 162.2mg/dl prior to therapy to 202.8mg/dl by 3 months, p=0.014. HDL-cholesterol fell from a mean of 50.6 mg/dl to 44mg/dl by 3 months, p=0.04.

Both triglyceride levels and HDL levels returned to baseline by 9 months and there was no change noted by 12 months. Overall 12 patients (34%) met the IDF criteria for metabolic syndrome before initiating adjuvant therapy as compared to 14 (40%) at 1 year.

Subgroup analysis of patients with preexisting metabolic syndrome, obesity or insulin resistance (HOMA-IR >3.8) showed similar results.

Analysis of the survey data showed 22 of the 35 patients (62%) had improved their dietary and exercise habits over the course of the study.

Conclusions: Contrary to other studies, we did not find a significant difference in most of the parameters of metabolic syndrome in a predominantly hispanic patient population. A transient increase in triglyceride levels and a decline in HDL cholesterol level was noted at 3 months, however resolved by the 9th month of treatment. Our data suggests that life style modification may mitigate most of the metabolic adverse effects of therapy and women, at the time of diagnosis, may be particularly motivated to make such changes.
Title: Does adverse tumour biology contribute to inferior outcomes for Indigenous Australians diagnosed with breast cancer?

Redfern A, Lee E, Bulsara M, Threlfall T, Harvey J and Cordell D. University of Western Australia, Perth, Western Australia, Australia; Royal Perth Hospital, Perth, Western Australia, Australia; University of Notre Dame, Perth, Western Australia, Australia and Department of Health, Perth, Western Australia, Australia.

Body: Background: Analyses across multiple Australian states have consistently demonstrated significantly inferior breast cancer survival for Indigenous patients (IPs). Studies compensating for increased remoteness, socioeconomic disadvantage and later presentation demonstrate a residual unexplained detriment. This survival disadvantage is confined to the first five years, akin to the inferior outcomes demonstrated by higher risk biological breast cancer subtypes. We postulated that a preponderance of such higher risk subtypes could explain the disparate mortalities.

Methods: The distribution of breast cancer subtypes in Western Australian IPs diagnosed between 2001 and 2010 was assessed to explore the contribution of adverse prognostic subtypes to poorer outcome. This was a retrospective cohort study of Indigenous women (n=114) and 3:1 age and remoteness matched non-Indigenous women (n=310) diagnosed with invasive, non-metastatic, unilateral breast cancer, who underwent definitive local treatment. Subtypes were assigned as luminal A, B, HER2 enriched and triple negative by ER, PR, HER2 and tumour grade comparisons. Differences in basic tumour demographics and biological sub-types were analysed and racial survival discrepancies explored within biological subtype cohorts.

Results: Hazards for overall and breast cancer-specific mortality in IPs were 4.07 (95% CI 2.55-6.49) and 4.19 (95% CI 2.42-7.25). IPs were significantly more likely to have grade 3 tumours (41 v 25%, p<0.001), LN positive disease (39 v 27%, p<0.001) and larger tumours (median 20 v 10 mm, p<0.001). No significant differences in proportions of classical histological sub-types (ductal v lobular) or in tumours showing ER, PR or HER2 positivity were observed. There were no significant differences in biological sub-type proportions although IPs were diagnosed with numerically more non-Luminal A subtypes (56 v 44%, p=0.08), accounted for by increased Luminal B (21 v 15%) and HER2 enriched (10 v 5%) sub-types. The significant relative five-year survival deficit for IPs noted overall (94 v73%, p<0.0001) was observed for each sub-type with the exception of HER2 positive patients. This extended from the relatively low risk luminal A sub-type where oral anti-estrogens are the mainstay of treatment (98 v 82%, p=0.0002) to the high risk triple negative sub-type where intravenous chemotherapy is the standard adjuvant therapy (94 v 50%, p=0.0014).

Conclusions: The contribution of adverse tumour biological subtype to poorer outcomes for Indigenous women is modest. Indigenous women with almost all biological subtypes fare significantly worse than their non-Indigenous contemporaries. Ongoing work includes more detailed biological comparisons of RNA expression and DNA mutation between groups as well as an exploration of potentially disparate treatment patterns.

Title: Role of endocrine therapy in premenopausal patients with hormone receptor-positive metastatic breast cancer, compared with postmenopausal patients: Diachronic analyses from nationwide cohort in Korea (KCSG BR 14-07)

Kim T-Y, Ahn J-H, Sohn JH, Kim GM, Lee KH, Park YH, Koh S-J, Lee SE, Chae Y, Lee KS, Lee KE, Won HS, Kim JH, Jeong J, Park KH, Cho EK, Im Y-H, Im S-A and Jung KH. Seoul National University Hospital, Seoul, Republic of Korea; Division of Breast-Endocrine Surgery, Chonnam National Univ. Hwasun Hospital, Republic of Korea; Yonsei University College of Medicine, Kwangju, Republic of Korea; Chungbuk National University Hospital, Cheongju, Republic of Korea; Samsung Medical Center, Seoul; Ulsan University Hospital, Ulsan; Dong-A University Hospital, Pusan, Republic of Korea; Kyungpook National University Hospital, Daegu, Republic of Korea; Center for Breast Cancer, National Cancer Center, Goyang, Republic of Korea; Ewha Womans University Hospital, Seoul, Republic of Korea; Uijeongbu St. Mary's Hospital, Uijeongbu, Republic of Korea; Seoul National University Bundang Hospital, Sungnam, Republic of Korea; Gangnam Severance Hospital, Seoul, Republic of Korea; Korea University Anam Hospital, Seoul, Republic of Korea; Gachon University Gil Medical Center, Incheon, Republic of Korea and Asan Medical Center, Seoul, Republic of Korea.

Body: Background

Endocrine therapy (E) has a major role in treatment of hormone receptor (HR)-positive metastatic breast cancer (MBC). However, in contrast to western countries, premenopausal patients (PRE) more prevalent (50% of all breast cancer patients) and have less options of E than postmenopausal patients (POST) in Korea where the use of LHRH agonist in combination aromatase inhibitors (AIs) in PRE is restricted. Recently we have been successfully established nationwide cohort for the patients MBC (575 patients from 26 institutes). This study was designed to evaluate the role of E especially in PRE.

Methods

The patients with MBC were prospectively or retrospectively enrolled between September 2014 and May 2015. Only menopausal status-confirmed patients (296) were analyzed. Postmenopause was defined, based on NCCN guideline. Total duration of treatment was defined as the time from start day of any first treatment to end of any last treatment. Total duration of E was defined as the sum of time duration of each E. Overall survival was calculated from the start day of any treatment for MBC to any causes of death. This work is supported by National Strategic Coordinating Center for Clinical Research (H110C2020).

Results

A total of 296 patients with HR-positive MBC were analyzed [PRE, 169 (57.1%) and POST, 127 (42.9%)]. Except age (mean 44 and 60 years), baseline characteristics including in pathology, HER2 status, initial pathologic stage, de novo metastasis versus recurrence, surgery and adjuvant treatment (chemotherapy, endocrine therapy and radiotherapy) were well balanced. 92 (54.4%) of PRE and 77 (60.6%) of POST received at least one or more E through all treatment course. 41 (24.2%) of PRE and 44 (34.6%) received E as 1st-line treatment (p=0.034). Among PRE who received 1st-line of E, 30 (71.4%) and 9 (21.4%) of PRE received 2nd- and 3rd-line E. 20 (45.4%) and 10 (22.7%) of POST received 2nd- and 3rd- or more line of E. Most of PRE (54%) received tamoxifen+/-goserelin and 32% of PRE received AIs along with ovarian suppression. 71% of POST received AIs. As initial treatment, E was more frequently used in POST than in PRE (34.6% and 24.3%, p=0.053). Overall survival (OS) of all patients was 18.2 months (95% CI, 14.8-21.5). There was no difference in OS between PRE (17.8 months, 10.9-24.8) and POST (18.5 months, 95% CI, 13.2-23.9) (P=0.337). No difference of OS was observed (E, 18.1 moths, 95% CI, 13.0-23.3; chemotherapy 21.2 moths, 95% CI, 16.8-25.5), regardless of initial treatment. Total duration of treatment of PRE and POST were 15.2 and 13.6 months, respectively with no significant difference (p=0.389). PRE (8.3 moths, 95% CI,5.7-10.8) showed the trend toward longer duration of E in comparison with POST (5.5 moths, 95% CI,4.4-6.7), however the difference did not reach statistical significance (p=0.051).

Conclusion

E was more commonly used as 1st-line therapy in POST than in PRE. Although PRE had limited options of E, E was used in long duration of treatment especially in PRE. These findings suggested that E had a role in treatment for PRE with HR-positive MBC and could be used in treatment for PRE with good efficacy.
Title: Mammographic density: Its inherent epidemiology in 12000 women from 22 diverse countries

McCormack VA A. International Pooling Project on Mammographic Density Consortium.

Body: The International Pooling Project on Mammographic Density Consortium

Background: Over the past 25 years, the epidemiologic knowledge for mammographic density (MD), as a strong marker of breast cancer risk, has expanded greatly, aided by the availability of mammograms in countries with wide-scale mammography-based breast cancer screening programs. The known epidemiology of this breast-tissue specific marker is thus that of women in high incidence countries, and not of that in countries with lifestyles that are characterized by very different life-long hormonal influences, especially during the reproductive years. The International Pooling Project on Mammography Density (IPPMD) aimed to examine the epidemiology of MD internationally, to benefit from breast cancer risk and breast cancer risk factor heterogeneity.

Methods: From diverse breast cancer risk populations, IPPMD sought to include samples of 200 premenopausal and 200 postmenopausal general population women for which risk factor data and mammograms, not taken for symptomatic reasons, were available. To date we have included 11447 women from 22 countries, consisting of 40 ethnicity and location-specific population groups. 5 to 6 countries were included in each of Europe, Africa and the Middle East, Asia and the Americas. Populations not previously studied in terms of MD include South Africa, Kenya, Turkey, Egypt and Brazil.

Digitized/digital films for every woman were anonymised, transferred to the study and read using Cumulus 6 by 3 readers, to obtain standardized quantitative and comparable MD estimates across the entire sample. Readers were blind to all woman and study/country identifiers. Normal errors regression models were used to analyse square root percent density and absolute dense area, after standardizing reader-specific values to a single reader’s distribution.

Results: All risk factor data and MD readings have recently been pooled. Initial findings are as follows. Mean percent MD and absolute dense area varied over 2-fold between the 40 population groups, after adjusting for age and BMI. There is striking consistency in several epidemiologic features of MD across all population groups, including the rate of decline of density at both pre and post-menopausal ages and the decline associated with the menopausal transition. We are exploring to what extent these and other factors such as menarche, parity, age at first birth and breastfeeding, account for between population-group differences in MD.

Conclusions: This international perspective provides a valuable insight to the epidemiology of MD worldwide.
Title: A randomized, double-blind trial to compare the efficacy and safety of proposed biosimilar pegfilgrastim (LA-EP2006) with reference pegfilgrastim in patients with breast cancer (PROTECT1)

Harbeck N, Zbarskaya I, Lipatov O, Frolova M, Udovitsa D, Topuzov E, Ganea-Motan DE, Nakov R, Singh P, Rudy A and Blackwell K. Breast Center, University of Munich, Munich, Germany; Leningrad Regional Oncological Dispensary, Leningrad, Russian Federation; Republican Clinical Oncology Dispensary of the Ministry of Public Health of Bashkortostan Republic, Ufa, Russian Federation; Russian Oncology Research Center n.a. N.N. Blochin of RAMS, Moscow, Russian Federation; Oncological Dispensary #2 of Healthcare Department of Krasnodar Territory, Krasnodar, Russian Federation; Northwest State Medical University n.a. I.I. Mechnikov, Saint Petersburg, Russian Federation; Spitalul Judetean de Urgenta, Suceava, Romania; Hexal AG, Holzkirchen/Oberhaching, Germany and Duke University, DUMC, Durham, NC.

Body: Background: An abbreviated pathway for biological products shown to be biosimilar to the reference product exists in Europe and the US. The randomized PROTECT1 trial compared the efficacy and safety of the proposed biosimilar pegfilgrastim with reference pegfilgrastim.

Methods: In this multinational, prospective, double-blind trial, chemotherapy-naïve women aged ≥18 years with histologically proven breast cancer received up to 6 cycles of (neo)-adjuvant TAC chemotherapy (docetaxel 75 mg/m², doxorubicin 50 mg/m², cyclophosphamide 500 mg/m²). Patients were randomized to a single 6 mg SC injection of the proposed biosimilar pegfilgrastim (LA-EP2006) or the reference (Neulasta®) on day 2 of each cycle. Primary endpoint was duration of severe neutropenia (DSN) during Cycle 1, defined as number of consecutive days with an absolute neutrophil count (ANC) <0.5 x 10⁹/L. The study was powered at 90% and had a hierarchical testing procedure utilizing a ±1 day margin to test for equivalence (2-sided 95% confidence interval [CI]) and a subsequent −0.6 day non-inferiority margin (1-sided 97.5% CI) for DSN during Cycle 1. DSN was analyzed with an ANCOVA model adjusted for treatment, chemotherapy, region and baseline ANC. Secondary efficacy assessments were: time to ANC recovery, ANC nadir, incidence of febrile neutropenia, number of days of fever, frequency of infections and mortality due to infection. Safety was assessed at 4 weeks and 6 months after the last pegfilgrastim administration. Immunogenicity was assessed by testing for neutralizing anti-pegfilgrastim antibodies.

Results: A total of 316 patients were randomized and included in the full analysis set (LA-EP2006: n=159; reference: n=157). Baseline demographics were similar in both groups (mean±SD age: LA-EP2006 49.9±9.53, reference 50.5±10.87 years; breast cancer stage II-III: LA-EP2006 n=155 [97.5%], reference n=151 [96.2%]). Mean±SD DSN in Cycle 1 was 0.75±0.88 days with LA-EP2006 and 0.83±0.90 days with reference, with a treatment difference of 0.07 days (95% CI: −0.12, 0.26); LA-EP2006 was both equivalent and non-inferior to the reference. There were no clinically meaningful differences between LA-EP2006 and reference in incidence of febrile neutropenia (3.8% vs 7.0% in Cycle 1, 5.7% vs 7.6% across all cycles), days with fever, depth of ANC nadir in Cycle 1, time to ANC recovery in Cycle 1, or frequency of infections in Cycle 1 and across all cycles. Treatment-emergent adverse events (TEAEs) were similar across groups and consistent with the known safety profile of pegfilgrastim. Most frequently reported TEAEs related to treatment were musculoskeletal and connective tissue disorders (LA-EP2006 4.4%, reference 5.7%). Serious TEAEs were reported in 10.1% of LA-EP2006 and 13.4% of reference patients. No neutralizing anti-pegfilgrastim antibodies were detected.

Conclusions: Proposed biosimilar pegfilgrastim (LA-EP2006) met the primary endpoint demonstrating both equivalence and non-inferiority to the reference. LA-EP2006 and the reference are similar with no clinically meaningful differences regarding efficacy and safety in breast cancer patients receiving (neo)-adjuvant myelosuppressive chemotherapy.
Title: Usage of epoetin alfa biosimilars in the management of chemotherapy-induced anemia in patients with breast cancer: A subanalysis of the ORHEO study

Albrand H, Luporsi E, Michallet M and Soubeyran P. Laboratoire HOSPIRA France, Meudon La Foret, France; Institut de Cancérologie de Lorraine Alexis Vautrin, Vandoeuvre-Les-Nancy, France; Lyon Sud Hospital, Lyon, France and Institut Bergonie, Bordeaux, France.

Body: Introduction
Chemotherapy-induced anemia (CIA) is a frequent complication of breast cancer patients that is associated with fatigue and impaired quality of life. Biosimilars of erythropoietin-stimulating agents have now been approved to treat CIA in Europe. The ORHEO (biOsimilaRs in the management of anaemia secondary to chemotherapy in HaEmatology and Oncology) study was an observational study conducted in France to evaluate the efficacy and safety of a biosimilar epoetin alfa in an oncology setting. The large number of patients who enrolled in the study permitted indication-specific subanalyses to be undertaken. Herein we report the results of the subanalysis that focuses on the subpopulation of breast cancer patients.

Methods
The ORHEO study was a prospective, observational, longitudinal, multicenter postmarketing study. Patients ≥18 years with CIA (hemoglobin [Hb] <11 g/dL)-associated solid tumors, lymphomas, or myelomas who were eligible for treatment with an epoetin alfa biosimilar were enrolled. The primary endpoint was Hb response (defined as Hb reaching ≥10 g/dL, an increase of Hb ≥1 g/dL since inclusion, or reaching target Hb) measured at 3 and 6 months (M3 and M6, respectively). Secondary endpoints included safety and tolerability. Only breast cancer patients with CIA were included in this subanalysis.

Results
The ORHEO study enrolled 2333 patients; of these, 266 patients presented with CIA associated with breast cancer and were included in this subanalysis. The mean age was 61 years, the majority had ECOG PS 1 (51.5%) and metastatic disease (56.0%), and 99.6% received an epoetin alfa biosimilar. At baseline, the mean Hb level was 9.9 g/dL. At the M3 and M6 time points, an Hb response was observed in 86.8% and 91.7% of patients, respectively; average Hb levels increased by 1.3 g/dL (M3) and 1.8 g/dL (M6). By M3, 44% of patients reached their target Hb level; this increased to 53.7% at M6. At M3 and M6, of those patients who definitively or temporarily discontinued treatment, over half did so because the target Hb had been reached (M3: 55.6% [n = 74/133]; M6: 53.2% [n = 81/152]). Clinically significant adverse events (AEs) were observed in 9.9% of patients; the most common AE was infection (7.9%), while thrombotic events were only reported in 0.8% of patients. High baseline systolic blood pressure, high hematocrit levels at M3, and clinical improvement by M3 were identified as potential indicators of a positive response to an epoetin alfa biosimilar.

Conclusion
This subanalysis of the large ORHEO observational study has demonstrated the utility of biosimilar epoetin alfa in a real-world setting. Biosimilar epoetin alfa was seen to be efficacious and well tolerated in patients with breast cancer who presented with CIA, and no new safety signals were identified in this subpopulation. These data support the results observed in the parent ORHEO study, and confirm that biosimilar epoetin alfa (Hospira) is a therapeutic alternative for treating CIA in patients with breast cancer. Several potential prognostic indicators were identified that may warrant further study.
Biosimilar filgrastim in the treatment of patients with breast cancer undergoing neutropenia-inducing chemotherapy: A subanalysis of the NEXT study

Albrand H, Kamioner D and Leprêtre S. Laboratoire HOSPIRA France, Meudon La Forêt, France; Hôpital Privé de l'Ouest Parisien, Trappes, France and Henri Becquerel Hospital, Rouen, France.

Body: Introduction
Febrile neutropenia (FN) is a frequent and serious complication in breast cancer patients undergoing chemotherapy. In addition to being a major risk factor for infection-related morbidity/mortality and disease progression, FN can lead to dose delays and reduction. Nivestim™ (Hospira Inc), a biosimilar filgrastim, is a granulocyte colony-stimulating factor licensed for the treatment of neutropenia and FN induced by myelosuppressive chemotherapy.

The NEXT (Nivestim safety profile in patiEnts treated with cytotoXic CT in real-life clinical practIce) study was a prospective real-world trial assessing the safety of curative or prophylactic biosimilar filgrastim in the treatment of patients undergoing chemotherapy. The large size of this study enabled a subanalysis to be performed in breast cancer patients; the results are presented herein.

Methods
NEXT was a prospective, noninterventional, longitudinal, multicenter French study (NCT01574235). Patients with a solid tumor or a malignant hemopathy (excepting chronic myeloproliferative and myelodysplastic syndromes) undergoing or starting neutropenia-inducing chemotherapy were enrolled. Objectives were to evaluate safety and incidence of FN and infection. Patients received biosimilar filgrastim (Hospira) and were monitored for 1–6 chemotherapy cycles, with 3 visits at inclusion, during, and following treatment.

Results
A total of 2114 patients were enrolled in this study; of these, 463 patients had breast cancer and were included in this analysis. Mean age was 58.4 years, 97% were female, 95.8% had an ECOG PS of 0–1, and 19.4% had metastatic disease. The majority of patients (n = 454; 98.1%) received biosimilar filgrastim as prophylaxis (primary, 94.1%; secondary, 5.9%); 9 (1.9%) patients received curative biosimilar filgrastim. Median time to initiation of biosimilar filgrastim was 7.5 days for curative patients and 4 days for prophylactic patients. Mean treatment duration was: 6.0±1.7 days (curative) and 5.6±2.6 days (prophylactic). Biosimilar filgrastim-related adverse events (AEs) were reported in 119 patients (curative, n = 1; primary prophylaxis, n = 111; secondary prophylaxis, n = 7). The rate of AEs was higher in breast cancer patients (26.1%) compared with the entire NEXT study population with solid tumors (21.1%); similar rates of FN were reported but breast cancer patients had higher rates of AEs and bone and muscle pain compared with the total study population. Considering the prophylactic group only, 4.7% experienced FN and 1.6% reported an infection. The incidence of FN and/or infection resulted in hospitalization in 4.7% of patients (mean duration: 4.6±2.5 days), chemotherapy dose reduction in 2.7% of patients, and a delay of chemotherapy in 5.2% of patients.

Conclusion
These data demonstrate the safety and efficacy of biosimilar filgrastim in a real-world setting. The subanalysis illustrated that biosimilar filgrastim was effective and well tolerated in breast cancer patients in the curative and prophylactic setting. These results mirror those of the parent NEXT study, and show that biosimilar filgrastim is a valid alternative therapeutic option for chemotherapy-induced neutropenia in breast cancer patients.

Title: A prospective study of patterns of chemotherapy, colony-stimulating factor use, and burden of colony-stimulating factor injections in patients with early-stage breast cancer

Body: Background: Febrile neutropenia (FN) is a common side effect of myelosuppressive chemotherapy. Primary prophylaxis with colony-stimulating factors (CSFs) can reduce FN incidence and is recommended when a patient has a high risk of FN (>20%). In the prophylactic setting, CSFs should be administered at least 24 hours after chemotherapy completion. Patient burden associated with CSF administration is not well understood. Here we describe current patterns of chemotherapy use and burden of CSF injections for patients with early-stage breast cancer (ESBC) in US clinical practice.

Methods: This was a prospective cohort study of adult ESBC patients receiving their first chemotherapy course who had a high risk of FN based on high- or intermediate-risk chemotherapy regimen and individual FN risk factors. The burden associated with CSF injections was assessed via questionnaires among patients who received CSF, and a subset analysis of patient burden in the first cycle of chemotherapy is reported.

Results: 598 patients completed the "burden of CSF injections" questionnaire following the first cycle of chemotherapy. Most patients were < 65 years old (76.8%), had a BMI < 30 kg/m² (54.9%), and had few comorbidities (see table for additional characteristics and comorbidities). The three most common chemotherapy regimens received were ddAC-T (34.4%), TC (23.4%), and TCH (15.6%). 98.3% of patients received prophylaxis with CSF in the first chemotherapy cycle: 94.6% of these received pegfilgrastim, and 5.4% received filgrastim. Among all patients who received CSF, mean (SD) one-way travel time for a single CSF injection was 31 (25) minutes; mean (SD) time in office to receive a CSF injection was 41 (68) minutes. Across the first chemotherapy cycle, mean (SD) time missed from work for CSF administration was 3.1 (9.3) hours, and mean (SD) time missed from non-work activities was 5.5 (14.4) hours. 66.3% of patients had someone else assist them with travel to the clinic to receive CSF, of which 98.8% were helped by an unpaid caregiver. When patients were questioned about the subjective burden of CSF injections, 25.4% reported some degree of bother, and 15.9% reported at least moderate inconvenience.

Conclusions: Among the high- and intermediate-risk regimens investigated here, dose-dense and taxane-based chemotherapy regimens were common. As many high-risk patients with ESBC receive primary prophylaxis with CSF, travel and time needed to receive CSF can contribute to patient and caregiver burden.

Title: Randomized phase 2, open-label, dose-ranging study of a novel, long-acting G-CSF (SPI-2012) or pegfilgrastim for the management of neutropenia in patients with breast cancer (BC) treated with (Neo) adjuvant chemotherapy with docetaxel + cyclophosphamide (TC)

Body: Background: SPI-2012 is a distinct biologic that uses the innovative proprietary long-acting protein/peptide discovery technology (LAPSCOVERY™) to enhance the activity of G-CSF. SPI-2012 consists of a novel, modified recombinant human G-CSF conjugated to the Fc fragment of IgG4 via a polyethylene glycol linker to produce a new, more potent, longer-acting G-CSF with a potentially unique distribution to areas rich in Fc receptors. To assess the effect of SPI-2012 in supporting patients with breast cancer receiving myelosuppressive chemotherapy with TC, we conducted a randomized Phase 2 study of 3 SPI-2012 doses versus pegfilgrastim.

Methods: This was an open-label, global, multicenter, dose-ranging study designed to compare the safety and efficacy of SPI-2012 relative to a fixed, standard dose of pegfilgrastim as a concurrent active control. The study included 4 treatment arms: 3 dose levels of SPI-2012 (45 µg/kg, 135 µg/kg, and 270 µg/kg) vs pegfilgrastim (6 mg.). The primary objective of the study was the Duration of Severe Neutropenia (DSN) in patients treated with SPI-2012 compared to pegfilgrastim.

Results: A total of 147 evaluable patients were enrolled. Patient and tumor characteristics were comparable across all 4 treatment arms. Mean age was 58.2 years (range 32 to 77 years); most patients were <65 years (68%), female (98%) and white (95%). The study met its primary endpoint with DSN in patients treated in the 135 µg/kg and 270 µg/kg SPI-2012 treatment arms showing non-inferiority to pegfilgrastim (p=0.002 and p<0.001, respectively). In addition, superiority was demonstrated in patients treated with 270 µg/kg SPI-2012 compared to pegfilgrastim (p=0.023). Non-inferiority in DSN was also observed in Cycles 2 to 4 in both the 135 µg/kg and 270 µg/kg SPI-2012 treatment arms compared to pegfilgrastim.

The common treatment-emergent adverse events observed in ≥20% of patients were similar across all 4 study arms with similar or lower incidence in the SPI-2012 treatment arms, and included fatigue, nausea, alopecia, diarrhea, and bone pain.

**Conclusions:** All doses of SPI-2012 administered in this Phase 2 study were well tolerated, and no new or significant dose-related toxicities were observed. Most reported adverse events were mild and similar to those previously reported in clinical trials with filgrastim and pegfilgrastim in patients receiving myelosuppressive chemotherapy. In Cycle 1, the 135 µg/kg dose of SPI-2012 was non-inferior compared to pegfilgrastim, and the 270 µg/kg dose was superior in terms of DSN. Additional efficacy and safety data for SPI-2012 will be collected in planned Phase 3 clinical trials.
Title: Nausea control and quality-of-life benefit with NEPA, the first combination antiemetic agent, in patients with breast cancer receiving anthracycline/cyclophosphamide (AC) chemotherapy

Rugo HS S, Aapro M and Rizzi G. University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA; Clinique de Genolier, Genolier, Switzerland and Helsinn Healthcare, SA, Lugano, Switzerland.

Body: Background: Patients (pts) with breast cancer (BC) are at high risk for developing chemotherapy-induced nausea and vomiting (CINV) due to the emetogenicity of chemotherapy (often AC-based) and predisposing risk factors including young age and female gender. For pts receiving AC, antiemetic guidelines recommend prophylactic administration of an NK₁ receptor antagonist (RA), a 5-HT₃ RA, and dexamethasone (DEX). NEPA is the first fixed combination agent approved in oncology; comprised of a highly selective NK₁ receptor antagonist (RA), netupitant (300 mg), and the pharmacologically/clinically distinct 5-HT₃ RA, palonosetron (PALO 0.50 mg). NEPA has shown superior complete response (no emesis/no rescue use) rates compared with oral PALO in a Phase 3 trial in pts receiving AC (Aapro, Ann Oncol 2014) and in that study's BC subset. Despite progress in prevention of vomiting, nausea control remains suboptimal, particularly in the delayed phase (days 2-5), and debate exists whether NK₁ RAs improve nausea control. The objective of this post-hoc analysis was to evaluate whether NEPA showed nausea and associated quality-of-life (QOL) benefits in the subset of patients with BC in this trial.

Methods: The subset of chemotherapy-naïve BC pts from this multinational, randomized, double-blind Phase 3 study were included in this analysis. Patients received either a single dose of NEPA or oral PALO prior to AC along with oral DEX 12 mg (NEPA) or 20 mg (PALO). No significant nausea (NSN: max <25 mm on 100 mm visual analog scale) rates in the acute (0-24h), delayed (25-120h) and overall (0-120h) phases following chemotherapy during cycles 1-4 were calculated. QOL was assessed by the Functional Living Index—Emesis (FLIE) during cycle 1 overall phase; the percentage of pts with "no impact on daily life" (NIDL) was calculated. Comparisons between groups were performed using a Cochran-Maentel-Haenszel test.

Results: 1412 patients with BC were included for a total of 5839 AC cycles. NSN rates were similar for both groups in the acute phase, superior for NEPA during cycles 1, 2 and 4 in the delayed phase, and superior for NEPA during cycles 1-4 in the overall phase.

</tbody>
</table>

This corresponded with a significantly greater proportion of NEPA patients reporting NIDL compared with PALO due to nausea (71% vs 65%; p=0.007) in cycle 1.

Conclusions: While other NK₁ RAs have not consistently shown benefit in improving nausea control over 5-HT₃ RA + DEX, in this study NEPA significantly improved prevention of nausea over oral PALO in BC patients receiving AC. In addition, NEPA was superior to PALO in reducing the negative impact of nausea on patients’ daily functioning. As the first fixed antiemetic drug combination, NEPA is highly effective and offers the convenience of a single dose administered with DEX on Day 1 only.
**Title:** Phase 3 comparison of APF530 versus ondansetron, each in a guideline-recommended 3-drug regimen for prevention of chemotherapy-induced nausea and vomiting due to anthracycline + cyclophosphamide (AC)–based highly emetogenic chemotherapy (HEC) regimens: A post hoc subgroup analysis of the MAGIC trial

Schnadig I, Agajanian R, Dakhil S, Taylor C, Wilks S, Cooper W, Mosier M, Payne Y, Klepper M and Vacirca J. Compass Oncology, US Oncology Network, Tualatin, OR; The Oncology Institute of Hope and Innovation, Whittier, CA; Cancer Center of Kansas, Wichita, KS; Tulsa Cancer Institute, Tulsa, OK; Cancer Care Centers of South Texas, San Antonio, TX; TFS International, Flemington, NJ; EMB Statistical Solutions, LLC, Overland Park, KS; Heron Therapeutics, Redwood City, CA; Drug Safety Navigator, LLC, Durham, NC and North Shore Hematology Oncology, East Setauket, NY.

**Body:**

**Background:** Managing delayed chemotherapy-induced nausea and vomiting (CINV) associated with HEC is an unmet need. AC-based HEC is often administered to breast cancer patients (pts), a mostly female, high-CINV-risk population. APF530, an extended-release formulation of granisetron, demonstrated superior complete response (CR; no emesis [vomiting, retching] + no rescue medication use) in delayed-phase (>24-120 h) CINV with HEC (ASCO criteria) vs ondansetron (Ond) (65% vs 57%, \( P=0.014 \)), each combined with a neurokinin-1 antagonist and dexamethasone (Dex) (NCT02106494). This post hoc analysis evaluated efficacy and safety of APF530 in pts receiving AC-based therapy.

**Methods:** In this randomized, double-blind, multicenter trial, pts scheduled to receive single-day HEC were stratified by cisplatin \( \geq 50 \text{ mg/m}^2 \) yes/no and randomized 1:1 to APF530 500 mg SC (granisetron 10 mg) or Ond 0.15 mg/kg IV. Pts received concomitant Dex 12 mg IV and fosaprepitant 150 mg IV on day 1 and oral Dex on days 2-4. The primary end point was CR in the delayed phase. Secondary and other end points included CR in acute (0-24 h) and overall (0-120 h) phases, and complete control (CC; CR and no more than mild nausea) and total response (TR; CR and no nausea) in acute, delayed, and overall phases. Rates were compared using 95% confidence intervals (CIs) for treatment differences; post hoc analysis was not powered to detect treatment differences in the AC subgroup. Safety assessments included adverse events (AEs), injection-site reactions (ISRs), laboratory parameters, and vital signs.

**Results:** A total of 589/902 pts (65%) in the modified intent-to-treat population received AC-based HEC (APF530 291, Ond 298). Baseline demographics were balanced between treatment arms. The majority of pts in the AC subgroup were female (APF530 99%, Ond 98%). Delayed-phase CR was higher with APF530 vs Ond, approaching statistical significance (APF530 64%, Ond 56%; \( P=0.062 \)) in the AC subgroup, similar to the benefit seen in the larger study. No appreciable benefit of APF530 vs Ond was observed in the acute phase, and trends favorable to APF530 were observed in the overall phase (Table). APF530 was well tolerated. Most AEs were ISRs, generally mild or moderate, and resolved by end of study.

</tbody>
</table>
**Conclusions:** APF530 demonstrated an apparent clinical benefit in delayed-phase CR in pts receiving AC-based HEC, concordant with the statistically significant benefit seen in the overall study population. Prevention of CINV in this patient population continues to be a treatment challenge and further investigation is needed.
Title: Effect of a structured group intervention on obesity in breast cancer survivors

Kitagawa H, Hosaka T, Takeda N, Matsumoto N, Tomita M, Takahashi M and Yamauchi H. St. Luke's International Hospital, Chuo-ku, Tokyo, Japan; St. Luke's International Hospital, Chuo-ku, Tokyo, Japan; Breast Center/Oncology Center, St. Luke's International Hospital, Chuo-ku, Tokyo, Japan; St. Luke's International Hospital, Chuo-ku, Tokyo, Japan and Division of Cancer Survivorship Research, National Cancer Center, Chuo-ku, Tokyo, Japan.

Body: Background: Obesity is associated with an increased risk of breast cancer and poor outcomes. Endocrine therapy, including aromatase inhibitors (AI) is a key part of adjuvant treatment. However, it may produce some side effects, including musculoskeletal pain and weight gain. This study aimed to examine the effect of a structured group intervention for breast cancer patients with obesity and abnormal lipid metabolism during adjuvant endocrine therapy.

Methods: The subjects were 32 breast cancer survivors with obesity who were undergoing endocrine therapy (AI or tamoxifen) and had undergone surgery at least 12 months before enrollment. Median age was 51 years (range 37-67). We performed a single-arm pre-post study of combined interventions. The intervention consisted of 15 minutes of nutrition education delivered by a registered dietitian, a 30-minute group health coaching program by a coaching staff, and a 45-minute group aerobic exercise. Before and after the intervention, body weight (BW), body mass index (BMI), mid-upper arm circumference, triceps skinfold, liver enzyme levels (alanine aminotransferase [ALT], aspartate aminotransferase [AST]), total cholesterol (CHO) level, and triglyceride (TG) level were determined and compared. We also compared the results of the Japanese version of K6, Cancer Fatigue Scale (CFS), and Self-efficacy Scale for Cancer Patients (SES) before and after intervention. These weekly structured interventions were held in 3 consecutive weeks. Participants were asked to practice to exercise at home with a DVD, performing the same activities. Pre- and post-intervention data were compared by using paired t tests with IBM SPSS version 21.

Results: Significant decreases were found in BW (p < 0.01), BMI (p < 0.01), TG level (p < 0.05), CHO level (p < 0.01), K6 result (p < 0.05), and CFS result (p < 0.01). In contrast, no statistically significant change at the 5% level was observed in the mid-upper arm circumference, triceps skinfold, AST level, ALT level, and SES result.

Conclusion: This study showed that a short-term, three-session, structured intervention is effective for behavioral changes to promote health among breast cancer survivors, resulting in favorable changes in not only obesity but also in TG/CHO levels. These results suggest its potential as an effective intervention for cancer-related fatigue and mental health of survivors. Further studies with more participants and with a control group are needed to demonstrate the long-term effects of the structured intervention, particularly its possible impact on breast cancer prognosis.
Title: Are patients with breast cancer undergoing adjuvant treatment able to follow an exercise program with a moderate to high intensity?

May AM M, Boer JH H, Velthuis M, Steins Bisschop CN N, Los M, Erdkamp F, ten Bokkel Huinink D, Bloemendal HJ J, Rodenhuis C, de Roos MAJ AJ, Verhaar M, van der Wall E and Peeters PHM HM. University Medical Center Utrecht, Utrecht, Netherlands; Comprehensive Cancer Organisation (IKNL), Utrecht, Netherlands; St. Antonius Hospital, Nieuwegein, Netherlands; Orbis Medisch Centrum, Sittard, Netherlands; Diakonessenhuis, Utrecht, Netherlands; Meander Medical Center, Amersfoort, Netherlands; Hospital Rivierenland, Tiel, Netherlands and Holpoort Hospital, Woerden, Netherlands.

Body: PURPOSE: We recently showed in a randomized trial, the Physical Activity during Cancer Treatment (PACT) study, that an 18-week exercise program reduced complaints of fatigue and improved physical fitness in newly diagnosed breast cancer patients undergoing adjuvant treatment. The beneficial effects were probably underestimated due to high levels of physical activity in the control group that received usual care only. Another possibility for dilution of the effect might be limited participation of the intervention group in the supervised exercise program or low compliance, i.e., an adjustment of the prescribed exercise protocol. We set out to study participation and compliance and to find determinants of reduced compliance.

METHODS: 102 patients in the PACT study were randomized into the intervention group that received a supervised exercise program 2 times a week for 18 weeks (36 sessions in total). Each session had a duration of 60 minutes and included a pre-specified period of aerobic interval exercises of specific intensities as well as muscle strength exercises. Sessions were supervised by physiotherapists, intensity was based on individual fitness characteristics and results were kept in a log. We computed attendance (percentage of total sessions attended) and compliance (adherence to the prescribed duration and intensity of the aerobic part and to the muscle strength part of each attended session). We computed for each woman the percentage of sessions the women complied with the protocol, and report median percentages for compliance with the aerobic exercises, duration and intensity, and with the muscle strength exercises separately. Determinants of low compliance that were included in linear regression models were: age, behavioral, physical and psychosocial factors.

RESULTS: For 92 patients exercise logs were available. Patients were, on average, 50.2±7.8 years of age, all patients received chemotherapy and 70% received radiotherapy. Participation was high: patients participated in 83% (interquartile range 69-91%) of the sessions offered. Overall, also compliance was high: in 88% (63-97%) and 84% (65-94%) of all attended sessions patients were able to complete the aerobic (duration) and muscle strength program, respectively, as prescribed in the protocol. Compliance to the high-intensity part of the aerobic program was lower: in 50% (22-82%) of the sessions the intensity of the aerobic exercises was adjusted. Especially patients who received radiotherapy in addition to chemotherapy and patients who were more physically fatigued at baseline had a lower compliance to the high-intensity part of the aerobic exercises (β=-5.3 (confidence interval -9.4;-1.2) and β=-0.6 (-1.0;-0.1), respectively).

CONCLUSIONS: Participation in and compliance to an 18-week aerobic and muscle strength exercise program was high. Thus, patients are well capable to exercise during adjuvant treatment for breast cancer. This study shows that preferably high intensity aerobic exercises were adjusted in a significant number of participants rather than the duration or the strength exercises. This has to be taken into account when developing training programs, especially in those patients who receive both, radiotherapy and chemotherapy.
Title: An integrative intervention to change breast cancer patients' lifestyle: A medical challenge. A randomize controlled trial

Body: Background. Physical exercise increases breast cancer (BC) patients' survival. However, only about two thirds of them follow the American Guidelines of Exercise to cancer survivors. The aim of this study was to examine the effect of an exercise intervention in breast cancer patients' lifestyle.

Methods. A randomized clinical trial evaluated an intervention (EXE) vs. a control (CON) group in early stage BC patients who recently finished the chemo and radio (neo) adjuvant. Intervention consists on exercise group classes combining aerobic and resistance activities designed specially for the necessities of these patients. Intensity was increasing gradually and intervention was controlled by a qualified in oncologic exercise specialist. CON group maintained their lifestyle without changes. Leisure-time exercise levels (LTEL), quality of life (QoL), grip strength index (GSI), physical capacity (VO2max) and fatigue, were assessed at baseline and after 3 months in both groups. Women who had been participated in the intervention group were followed up after six months to know if lifestyle levels were maintained.

ANOVA and Pearson Test were used to analyze the continuous variables of baseline and final data and ANOVA test was used to analyze the follow-up data. A 95% of CI was calculated and p < 0.05 was determined as statistically significant.

Results 89 women, aged 49.06±8.75, completed the study, 44 in EXE group and 45 in CON group. Adherence rate was on average of 89%. Main results are presented in the Table.

BL=baseline; F= Final; FU= Follow-Up. *Significant differences between EXE and CON. + Significant differences between BL and FU.

There was a significant improvement in LTEL (p=0.0001) and in QoL (p=0.0001) comparing EXE vs. CON group. In addition, results showed a correlation between these two variables in EXE group (r=0.22; p=0.013). These significant improvements, as well as the mentioned correlation, were maintained in the 6-months follow-up assessment in EXE group.

Significant differences between groups were observed in GSI (p=0.004), and in VO2max levels (p=0.001). EXE group showed a significant improvement in fatigue levels compared with CON group (p=0.0001). All these significant improvements were maintained in the 6-months follow-up assessment in EXE group, as well as previous variables.

Conclusion. These results suggest that an exercise intervention increases LTEL correlated to a better QoL, improving patients' lifestyle that could be long lasting. These changes may ameliorate psychological and physical BC treatments side effects, such as fatigue, in patients with early breast cancer that has recently finished adjuvant treatments.
**Title:** Prognostic value of non-alcoholic fatty liver disease in stage II/III breast cancer patients who received neoadjuvant chemotherapy

Yang Y, Lee K-H, Kim T-Y, Han S-W, Oh D-Y, Kim T-Y, Han W, Moon H-G, Park IA, Noh D-Y and Im S-A. Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea; Cancer Research Institute, Seoul National University, Seoul, Korea; Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea and Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea.

**Body: Background**
Metabolic syndrome is associated with various malignancies, including breast cancer. Non-alcoholic fatty liver disease (NAFLD) is a hepatic manifestation of metabolic syndrome. NAFLD is frequently observed during chemotherapy, but its clinical implication is unclear. The purpose of this study is to evaluate the prognostic value of NAFLD in patients with stage II/III breast cancer who received neoadjuvant chemotherapy (NAC Tx).

**Methods**
The patients with clinical stage II/III breast cancer who received NAC Tx with docetaxel and doxorubicin were enrolled. Treatment sequences were: 3 cycles of NAC Tx → surgery → 3 cycles of adjuvant chemotherapy (AC Tx), or 6 cycles of NAC Tx → surgery, allowing AC Tx at the physician's discretion. NAFLD was determined by ultrasonography (radiologists' decision), non-constrast computed tomography [CT] (the attenuation of liver is less than that of spleen or <49 hounsfield unit [HU]) or contrast CT (the difference between liver and spleen attenuation < -18.5 HU). The presence of NAFLD was evaluated 3 times, at diagnosis, after NAC Tx and after the completion of AC Tx. Improvement of NAFLD during NAC Tx was defined as the disappearance of NAFLD after NAC Tx.

**Results**
Between 2002 and 2008, 269 patients were enrolled. The median age was 45 (range 18-69), and 51.7% and 28.6% were with hormone receptor and HER2 positive tumors, respectively. The median number of NAC Tx was 3 cycles (range 1-6). NAFLD was observed in 33 (12.4%) patients at diagnosis, 52 (19.3%) after NAC Tx and 71 (26.4%) at the completion of AC Tx. The patients with NAFLD at diagnosis showed shorter overall survival than those without NAFLD (HR=2.688, 95% CI 1.259-5.747, \( P = 0.011 \)). The improvement of NAFLD during NAC Tx was observed in 28 (10.4%, group A) and persistence of NAFLD observed in 24 (8.9%, group B). Group A showed better prognosis in both PFS (HR 0.125, 95% CI 0.016-0.962) and OS (no event), whereas group B showed worse PFS (HR 2.329, 95% CI 1.280-4.237) and OS (HR 3.721, 95% CI 1.727-8.015) compared to the patients without NAFLD at diagnosis.

**Conclusions**
NAFLD at diagnosis was a poor prognostic marker of OS in patients who received NAC Tx. Improvement of NAFLD during NAC TX was associated with good prognosis in terms of PFS and OS.
Title: Biopsychosocial concerns of adolescent young adults (AYA) with breast cancer

Smith R, Mortimer J, Loscalzo M and Clark K. City of Hope National Medical Center, Duarte, CA.

Body: Background: The natural history of breast cancer in the AYAs with breast cancer is reported to be more aggressing than that observed in older women. We wanted to determine the level of biopsychological distress in this population compared with women in other age groups.

Methods: All new patients seen at City of Hope complete a tablet-based self report biopsychosocial screening questionnaire (SupportScreen®). Patients are asked to score a series of problems on a 5-point Likert scale ("not a problem" to "very severe problem") and are asked if they are interested in obtaining help for that problem. Results: To date 1,159 women have undergone screening; 79 pts (6.9%) were age 18-39 yrs (AYA), 807 (69.6%) age 40-64 yrs, and 273 (23.6%) > 65 yrs. The concerns that were unique to the AYA population included: Ability to have children (p=0.001) and physical appearance (p=0.047 for 40-64 yrs and p=0.018 for age > 65 yrs). Older women were more concerned that AYAs or middle aged women about transportation (p=0.008), walking, climbing stairs (p=0.000). Compared to older women, those age 40-64 yrs were more likely to identify feeling anxious or fearful (p=0.032) and managing work, school or home life (p=0.018). In comparison to AYAs, those age 40-64 yrs had more distress related to recent weight change (p=0.034) and difficulty sleeping (p=0.006).

Conclusions: Biopsychosocial concerns change over the continuum of age. Compared to other age groups, the AYA population was more concerned about their ability to have children and their physical appearance. In other domains of distress, they were comparable to women age 40-65 yrs.
Ethnic differences in quality of life, anxiety and depression and fatigue in breast cancer survivors

Ho PJ, Verkooijen HM M, Gernaat S and Hartman M. Saw Swee Hock School of Public Health, National University of Singapore, Singapore; Imaging Division, University Medical Center Utrecht, Netherlands and Julius Center, University Medical Center Utrecht, Netherlands.

Introduction: With the sharp increase in incidence and improving survival of breast cancer in Asia, survivorship issues, like fatigue, anxiety and depression and health related quality of life are becoming increasingly important. In the multi-ethnic setting of South East Asia, these items have been understudied.

Methods: This cross-sectional study included a random sample of 377 breast cancer patients visiting the breast care clinic of the National University Hospital for routine follow-up between April 2014 - April 2015. Patients were at least 12 months post diagnosis. Patient characteristics were collected from medical records. Malay (n=72) and Chinese (n=305) breast cancer patients were compared in terms of physical function, fatigue, and financial difficulties (as reported in the EORTC-QLQ-C30), and anxiety and depression (Hospital Anxiety and Depression Scale, HADS). Clinically relevant fatigue (CRF) was defined as a score ≥40, and clinically relevant anxiety and depression were defined as scores of ≥8. Mann-Whitney U test and Fisher's exact test were used to compare patient reported outcomes between Chinese and Malays.

Results: The mean age at time of survey was 56.5 (range: 27-79), with 305 (74%) Chinese and 72 (18%) Malays. Median (Interquartile range) ages were 58 (52-64) for Chinese and 52 (46-57) for Malays; the distribution of age was significantly different (p<0.001). Forty five (15%) Chinese and 8 (11%) Malays were originally diagnosed with in situ cancer, 98 (33%) and 18 (25%) with stage 1, 130 (43%) and 33 (46%) with stage 2, and 29 (10%) and 13 (18%) with stage 3 or 4; the distribution of stage was not different for Chinese and Malays (p=0.143). Overall quality of life was not significantly different for ethnicity, median were 67 (58-83) for Chinese and 75 (58-83) for Malays (p=0.773).

Ninety seven (26%) patients reported scores 8 and above for anxiety; with 80 (26%) Chinese and 17(24%) Malays (p=0.765). Sixty two (24%) patients reported scores of 8 and above for depression, with 55 (18%) Chinese and 7 (10%) Malays (p=0.111). Sixty two (24%) patients experienced clinically relevant fatigue, 44(14%) Chinese and 18 (25%) Malays (p=0.034). Malays experienced lower level of physical function than Chinese, 87 (73-93) vs 93 (87-100) respectively (p=0.004), and more financial difficulty, 33 (0-67) vs 0 (0-33) respectively (p<0.001).

Conclusion:
One in 4 patients experience anxiety, depression, and/or clinically relevant fatigue. Malay breast cancer survivors, experience more clinically relevant fatigue and reduced physical functions compared to Chinese breast cancer survivors. In addition, they experienced more financial difficulties.
Title: Meeting the information and psychosocial needs of young Jewish women at increased risk for or diagnosed with breast cancer

Silber E, Fleischmann AK, Shoretz R, Johnson AC, Murphy SE, Mays D, O'Neill SC and Tercyak KP. Sharsheret, Teaneck, NJ and Division of Population Sciences, Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, DC.

Body: Background: Approximately 12% of women living in the United States will be diagnosed with breast cancer during their lifetimes. Although breast cancer survival rates are improving, there remain significant impacts upon women's length and quality of life. This includes women already diagnosed with the disease, as well as those who are at increased risk owing to hereditary breast cancer-causing mutations (e.g., BRCA1/2 genes). While all women face formidable challenges posed by the threat of living with or being at increased risk for breast cancer, those of Ashkenazi and Central or Eastern European Jewish descent face additional challenges owing to higher BRCA1/2 mutation prevalence in this population. Amidst calls for population-based screening for hereditary breast cancer risk, much can be learned from the experiences of young Jewish women at risk for and surviving with breast cancer about their information and psychosocial needs.

Methods: The present study is a secondary analysis of survey data from 2010 to 2014 originally collected by Sharsheret, a non-profit organization dedicated to serving women of all Jewish backgrounds facing or at risk for breast cancer. The evaluation included measures and metrics of community referral practices, social service/program engagement and satisfaction, and resource needs among the target population (N=555). Only survey items administered across all data collection years were analyzed.

Results: Respondents had a mean age of 50 years and ~90% identified as Jewish. Over 1/3 were referred to the organization by family or friends, most often after a breast cancer diagnosis. Within the surveyed population, 25% reported being at risk or confirmed carriers of a BRCA1/2 mutation. Of the education and support programs offered, the greatest level of engagement occurred in the 1-on-1 peer emotional support and health care symposia education programs. Women reported very high levels of satisfaction with the programs and services available, sought additional information and social support services, and noted a strong desire to give back to the community by participating as a peer supporter. Importantly for this high-risk population, women who participated in the organization's breast cancer genetics program were >98% satisfied (on average) with the various evaluated components of the program. Women identified genetic risk information as one of their top needs for future engagement.

Conclusion: These data affirm success of the organization's programs, especially in educating Jewish women about breast cancer genetics. Genetic information is increasingly salient among members of the Jewish community, extending to their cultural needs and need for peer support. Women likely responded well to Sharscheret's peer support program as it connects women to those with similar backgrounds, including culture, lifestyle, and medical similarities. Implications of these findings assert that culturally-relevant information and psychosocial services for young Jewish women living with or at risk for breast cancer can be enhanced for larger dissemination to meet the expected growing demand in this high risk community.
Title: Breast cancer survivorship support services: Evaluation findings of the thriving again survivorship program

Silber E, Stahl S and Fleischmann AK K. Sharsheret, Teaneck, NJ.

Body: Background. While a breast cancer diagnosis can be daunting for women of any age, studies have shown that young breast cancer survivors exhibit more emotional and psychological distress because of their relatively young age and life stage at diagnosis. In September 2011, the Centers for Disease Control and Prevention funded seven organizations, including Sharsheret, a national not-for-profit organization supporting young Jewish women and their families facing breast cancer, to develop support services and educational awareness activities for young breast cancer survivors. With this funding, Sharsheret developed the Thriving Again® (TA) survivorship program, which provides support services and resources, including a tailored survivorship kit with a survivorship care plan template, exercise DVD and healthy living cookbook. Participants were asked to complete an evaluation of services received to further enhance the program.

Methods. Breast cancer survivors who received a TA survivorship kit were asked to complete an online or paper survey evaluating Sharsheret's survivorship support services. Among 972 women who received the TA survivorship kit and were invited to complete an evaluation, 164 women returned the evaluation survey and 85 completed it in its entirety. Descriptive statistics on demographics and factors related to utilizing the survivorship care plan template and Sharsheret's services were calculated and analyzed. The small sample size limited additional analyses.

Results. Of the 85 women who completed the survey, 46% were <45 years of age and 43% were of Jewish descent. 62% of respondents reported that they received the kit and care plan template at the time they needed it most in their survivorship journey. These women more often reported completing their survivorship care plan template either themselves or with a member of their medical team. Care plan completion was also high among women considering themselves as "survivors" (89%). The vast majority of women participating in the Genetics for Life® program (76%) had spoken with a Sharsheret clinical team member at the time they ordered their TA kit. Other factors, such as stage at diagnosis and age, were unrelated to use of the care plan and Sharsheret's programs.

Conclusion. Although breast cancer survivors may identify themselves as "survivors" at any point post-diagnosis, women responding to the survey who were satisfied with the timing of receiving the TA kit during their survivorship journey and who self-identified as a "survivor" were more likely to complete the care plan template. Women who reviewed the kit and learned more about TA with a member of Sharsheret's support team were more likely to engage in other Sharsheret programs, most notably, Genetics for Life®. Although the sample size was small, the findings from this evaluation may be helpful to other survivorship programs. Most notably, other programs may need to be aware of how patients perceive themselves as survivors and offer care plans and resources when patients feel they most need them, even if patients have not yet completed treatment.

The findings in this report are those of the authors and do not necessarily represent the official position of the Centers for Disease Control and Prevention.
Title: Improving provider adherence to breast cancer care quality metrics: Use of a novel care planning tool

Body: Background: With rapid advances in research clinicians often struggle to remain current on evolving care guidelines as well as current National Quality Standards (NQS) relevant to breast cancer management. Adherence to NQS now drives much reimbursement for cancer center services but clinical workflow processes and IT solutions are often not in place to effectively document adherence. The On Q Care Planning System™ (CPS), an evidence-based patient assessment and care planning software, has been designed to close gaps in quality cancer care and facilitate data collection to help centers both better understand and document their adherence rates to quality care standards.

Methods: This multi-site study will enroll approximately 150 non-metastatic breast cancer patients, presenting for no greater than their second medical oncology visit, across five cancer centers. Patients must be planned for but not yet receiving chemotherapy treatment. A between subject design using 150 matched historical controls will be used to assess the impact of the 2-part intervention, at both the patient and provider level, on select quality metrics. At two consecutive clinical visits, patients will engage with the On Q CPS to assess family and medical history and current symptoms and receive two separate care plans. Care plans include (when applicable) recommendations for symptom management and appropriate referrals (i.e. genetic counseling for those at increased hereditary risk, and/or reproductive endocrinology for those interested in preserving fertility). To augment the effectiveness of the On Q CPS, providers will also participate in certified continuing medical education activities designed to educate about evidence-based assessment, decision-making, and management strategies for breast cancer patients. The primary aim is to evaluate provider adherence to select quality metrics among recently diagnosed breast cancer patients following the intervention, and compare to adherence rates for historical controls from the pre-intervention period. Metrics of primary interest include distress screening and management, complete family history assessment, genetic counseling referral, discussion of infertility risk, and discussion of fertility preservation options and/or referral to a specialist. These metrics have been chosen as the primary endpoints given that they have been historically documented as being resistant to change. Outcomes will be assessed by chart abstraction using a score card method of select quality metrics for both enrolled patients and matched historical controls.

Analysis/Results: Patient enrollment begins in June 2015 and thus data will be presented at time of symposium. Patient characteristics and primary outcomes will be analyzed using a multi-step approach to first describe and then compare, at the individual patient level, provider adherence to the select quality metrics evaluated in this study. Descriptive statistics will also be estimated within a mixed model approach for the rate with which each single metric was achieved across patients.

Conclusions: The On Q CPS, a care planning software tool, has the potential to both improve provider adherence to NQS and allow institutions an easy and accessible way to document that adherence.
Mailliez A, Bregegere S and Bonneterre J. Centre Oscar Lambret, Lille, France.

**Body:** 2344 patients (pts) younger than 40 years of age have been diagnosed for breast cancer in France in 2012. Almost all were premenopausal and some of them had not completed their family. We conducted a retrospective study to evaluate the level of information on the impact of breast cancer treatment on fertility. Patients: We selected breast cancer patients without relapse less than 40 treated in our institution between 2003 and 2012 who received (neo)adjuvant chemotherapy (3FEC100-3 Docetaxel). From 2008, only pts with hormone receptor (HR) negative tumours were considered. HR positive pts were receiving hormonotherapy and thus could not be pregnant. A questionnaire was developed and included 18 items on gynaecologic concerns before and after cancer diagnosis and information on the impact of breast cancer treatment on fertility.

Results: 121 met the inclusion criteria. 64 pts returned the questionnaire (52,8%). Median age at diagnosis was 34,3y (25-39). Before the diagnosis of cancer, 90% were married. 76,6% had at least one child, five of them with assisted reproductive technology. 18,8% wanted a pregnancy at the time of cancer diagnosis. 79,7% had regular menstrual cycles. 78,1% had contraception (oral contraceptive 68%, copper intra uterine device (IUD) 8%, Levonorgestrel-impregnated IUD 19%, condoms 6%).

Only 48,4% considered to be informed on the impact of breast cancer treatment on their fertility and 22 % were addressed to a physician of reproductive medicine. Four patients had fertility preservation.

After cancer treatment, only 14,1% had regular menstruations. 75% had a contraception (oral contraceptive 2%, copper intra uterine device (IUD) 63%, Levonorgestrel-impregnated IUD 4%, tubal ligation 2%, condoms 29%). 35,9% decided not to become pregnant. 16 patients (25%) wished to become pregnant. Seven of them had not received any information neither on the impact of treatment on fertility nor on fertility preservation techniques.

18,8% had a pregnancy (unwanted for 3 patients who requested an abortion) without fertility preservation or assisted reproductive technology. Only 9,4% had at least a live birth.

Several patients complained about chemotherapy-induced premature ovarian failure and the ensuing disturbances such as decreased libido, amenorrhea and menopause.

Conclusion: About 50% of the pts considered not to have received adequate information on fertility and other gynaecological consequences of anti cancer treatment.

This study shows how important gynaecologic considerations are for young breast cancer patients. Information about impact of treatment, fertility preservation techniques and symptoms of premature ovarian failure should be part of the treatment of these patients. Specific time should be devoted during the different consultations before, during and after treatments.
Title: Contraception use in young women with breast cancer

Brigham and Women's Hospital, Boston, MA; Harvard Medical School, Boston, MA; Dana-Farber Cancer Institute, Boston, MA; Mayo Clinic, Rochester, MN and Kaiser Foundation Research Institute, Oakland, CA.

Body: Background: Young women with breast cancer need highly effective contraception given the potential implications of unplanned pregnancy for optimal treatment, and the teratogenic risks. We sought to determine the contraceptive methods used by young women after diagnosis (dx) of breast cancer and factors associated with use of less effective methods or no contraceptive method, which confers a 6-90% annual risk of pregnancy in sexually active women in contrast to highly effective methods (risk <1%).

Methods: As part of a randomized trial conducted in 54 sites to test an education and support intervention for young women with breast cancer and their oncologists, we surveyed women about their pre-dx, current, and planned contraceptive use, and about communication with their providers regarding contraception. Women enrolled within 3 months of dx; contraception items were included on 3- and 12-month post-enrollment surveys. Intrauterine device (IUD) use, tubal sterilization, hysterectomy or bilateral salpingo-oophorectomy (hyst/BSO) after dx, or male partner vasectomy were classified as highly effective methods; all other methods and non-use were categorized as less effective. We excluded women not at risk of pregnancy: hyst/BSO prior to dx, or no indication for contraception. We used logistic regression to explore factors associated with use of less effective methods.

Results: Of 424 women who completed the 3-month post-enrollment survey, median age at dx was 39 (range 22-45). 312 women at risk of pregnancy were included in this analysis, including 291 reporting sexual activity with a male partner within the last 6 months, and 21 reporting no recent sexual activity but reporting use of birth control. 123 women (39%) used highly effective contraceptive methods prior to dx; after dx, 161 (52%) reported current use of or a plan to use a highly effective method. 19 women (6%) reported use of a hormonal birth control method since dx; 7 (2%) reported withdrawal as their only contraceptive method; 25 (8%) reported no contraception. 30% of women did not recall a discussion of avoiding pregnancy or need for contraception during treatment with their providers. In multivariable analyses (N=310), desire for additional biologic children (OR 7.54, 95% CI 3.88-14.66) and provider discussion of contraception and pregnancy (OR 2.13 95% CI 1.20-3.78) were associated with use of less effective contraception. Age, race/ethnicity, disease stage, and partner status were not significantly associated with use of less effective methods.

Conclusion: About half of women who are at risk of pregnancy reported use or planned use of less effective contraceptive methods or no method of contraception following dx of breast cancer. Women with breast cancer and their providers may benefit from targeted education on contraceptive options and method effectiveness.
Title: Skin, and nail, infections associated with the addition of pertuzumab to trastuzumab-based chemotherapy

Body: Objectives: We have maintained a local registry of skin and nail infections in patients receiving pertuzumab and trastuzumab as treatment for HER2 positive breast cancer. Over the past 16 months, we have continued to observe an increase in infectious complications in patients receiving the combination of pertuzumab and trastuzumab with or without chemotherapy. We expand a series of prospectively identified patients who developed infections while on these regimens. Methods: We became concerned about an increased incidence of infections shortly after the FDA approval of pertuzumab, and created an IRB approved registry of these patients. Results: Twenty-eight women were identified to have 32 separate infections (often at more than one site); 9 after cycle 1; 6 after cycle 2, 9 after cycle 3 and 8 after 4 or more cycles. The median age was 51 (Range 25-67); 14 received pertuzumab, trastuzumab, carboplatin, and docetaxel (PTCH); 5 pertuzumab, trastuzumab, and docetaxel, 7 pertuzumab, trastuzumab, and nab-paclitaxel, and 2 pertuzumab and trastuzumab. Folliculitis of the scalp, abdomen, and/or buttocks was observed in 19 patients, abscesses in 8 patients (4 of whom required incision and drainage) and cellulitis in 2. Severe paronychial infections involving one to 16 digits were observed in 4; 2 pt required surgical removal of 2 nails. Quantitative immunoglobulins were found to be low in 8 of 17 women tested; 2 patient had low total protein but did not have an assessment of quantitative immunoglobulins. All patients were initially treated with oral antibiotics, and 6 required hospitalization. Cultures were obtained in 10 patients; Staphylococcus aureus was identified in 4, methicillin resistant Staphylococcus aureus (MRSA) in 5, Enterococcus faecalis in 1. A 57 year old pt receiving neoadjuvant PTCH died on cycle 2 day 7. Autopsy was consistent with sepsis and gram positive cocci were identified. A 62 year old became septic and developed renal failure. Skin biopsies were performed in 3 patients and are consistent with changes associated with EGFR inhibition. Conclusions: We believe these infections are a result of combining pertuzumab with trastuzumab as 2 pts received no concurrent chemotherapy. An awareness of this complication is critical as some infections may be life-threatening. We have initiated patient education to ensure awareness of this potential complication.
Importance of the patient voice in drug development: Early-stage breast cancer and measurement gaps concerning the treatment experience

Background: Most early-stage breast cancer (EBC) patients (pts) do not experience signs or symptoms of disease; approximately 90% of women diagnosed in breast screening are asymptomatic in the US (Ryerson et al. 2015). Rather, side effects of cancer therapy have the greatest impact and can be burdensome to pts on and after treatment. Bother and impact have not been thoroughly assessed from the patient perspective in trials. Qualitative research with 56 pts undergoing or completing (after 3 and within 24 mos of) systemic treatment were conducted to assess the need for EBC-focused patient-reported outcome (PRO) measures.

Methods: Semi-structured interviews were conducted to better understand the treatment experience; the interview guide was developed in consultation with breast cancer advocates who were former pts. The interview sample was determined to capture findings across EBC therapies (HER2-targeted [HER2], hormone/endocrine [H/E], and/or chemotherapy [CT]). Treatment experience, including treatment-related symptoms and treatment impact (e.g. on activities of daily living, emotional aspects) were discussed in each 90-minute session. Pts rated level of bother of symptoms and impacts on an 11-point scale. Disease stage, treatment received, surgery, and other health information was collected from medical charts. Qualitative analysis was conducted with ATLAS.ti software. Symptom data was reviewed to appropriately analyze therapy subgroups.

Results: Stage Ia (17.9%), Ib (14.3%), Ila (32.1%), Ilb (25.0%), or IIa (7.1%) pts that received adjuvant (75%) or neoadjuvant (25%) therapy participated; 106 unique treatment-related symptoms were reported. Symptoms most frequently reported included hair loss (86.7%), change in taste (73.3%), and tiredness/fatigue (71.1%) on CT (n=45); tiredness/fatigue (34.8%), runny nose (26.1%), and watery eyes (21.7%) on HER2 (n=23); and hot flashes (50.0%), joint pain (37.5%), and weight gain (20.1%) on H/E (n=24). The most common symptoms reported after therapy completion included memory loss (63.6%), symptoms of neuropathy (numbness, tingling, and pain in fingers, 63.6%), and tiredness/fatigue (45.5%) (n=11). CT symptoms rated by ≥ 25% of pts that were most bothersome included tiredness/fatigue (x̄ =8.2, n=18**), hair loss (x̄ =8.2, n=32**), and memory loss (x̄ =7.7, n=15**). HER2 and H/E ratings of bother were less frequent. EBC treatment was associated with significant impact on pts’ lives; categories described are below:

* Rating on 11-pt scale; 0=none to 10=extremely bothersome ** n=number of patients rating the level of bother
Conclusion: Treatment-related symptoms and associated degree of bother differed by treatment group. Pts' descriptions of treatment impact provided additional insight into the burden of EBC. EBC-specific PROs included in trials that gain pts' perspective on experience with treatment would further inform pts and may also inform therapy choice.
Title: Voice of cancer patients: Analysis of concerns of patients receiving adjuvant chemotherapy for breast cancer

Aggarwal S, Liu M, Sharma R, Gupta A, Singh D, Sharma R, Yang F, Basak A and Aggarwal A. Santa Clara Valley Medical Center, San Jose, CA; Scry Analytics Inc., San Jose, CA and Scry Analytics Inc, Gurgaon, Haryana, India.

Body: Introduction: There is a growing interest in understanding the concerns of patients undergoing cancer therapy. Many patients share their experiences on online support forums, which contain millions of freely shared messages that can be used to analyze patient concerns. Unfortunately, these data are unstructured, which makes them difficult to analyze. In this project we organize the data on these forums using methods from Big Data Science (BDS), and then analyze these data by creating a Decision Support System (DSS): an interactive interface that can be used by both patients and providers to understand patient concerns about their cancer therapies.

Method: We collected approximately 10 million unique messages from 20 unrestricted breast cancer forums that provide information about diagnoses, treatments, side effects, supportive therapies, and specific experiences. After using domain knowledge of breast cancer to build custom ontologies for regimens, side effects, and supportive therapy, we use the following techniques from BDS in order to create our DSS:

• Topic Modeling to find keywords that best represent a given theme
• Information Retrieval to filter for messages that are related to this theme
• Natural Language Processing to extract the relevant data from these messages
• Token Windows and Co-occurrence-based Algorithms to associate regimens with their side effects and supportive therapies.

To use the DSS, a user provides disease-related parameters and the treatment. The DSS then gives the percentage of messages discussing side effects for a similar cohort of patients and the percentage of messages that discuss supportive therapies for each of these side effects.

Results: We retrieved 84938 messages from patients receiving adjuvant chemotherapy with the regimens listed below, and then analyzed the percentage of people mentioning each side effect. The results are summarized in the following table.

</table>

These statistics reflect patient concern about a particular side effect, instead of the true incidence of that side effect. For example, although about 90% of patients receiving the above regimens experience alopecia, only between 2% and 4% of messages on online forums mention alopecia.

Our system can also associate drugs to their side effects and suggest supportive therapies. For instance, 5428 (20.6%) of 26370
messages on Neulasta, mention it as the cause of bone pain. Out of these, 1262 (23.2%) mention Loratidine in context with Neulasta as a suggestion to alleviate bone pain (p < 0.00001).

**Conclusion:** Using methods from BDS, our DSS reliably associates side effects to a particular drug or regimen and suggests a supportive therapy.

Our results reflect the concerns of patients undergoing cancer therapy, which might help the medical community identify areas of resource allocation and unmet needs.
Title: Evaluating the incidence of supportive care referrals generated using patient reported data from the Athena health questionnaire system

Body: Background
Patients at risk for or diagnosed with breast cancer have many symptoms and need for supportive care services. As part of the Athena Breast Health Network (a University of California-wide collaboration), the UCSF Breast Care Center (BCC) has incorporated an electronic health questionnaire system (HQS) prior to new patient and follow-up clinic visits, allowing patients to provide information on their personal health and family history, physical and psychological symptoms, and lifestyle. Based on these patient-reported outcomes (PRO), automated referrals for services including genetic counseling, psycho-oncology, social work, fertility preservation, and smoking cessation are generated. Algorithms defining thresholds to trigger these referrals were developed by clinicians and supportive care providers to proactively meet patients’ needs.

Objectives
To evaluate the incidence and outcomes of supportive care referrals based on existing algorithms, and identify reasons for non-utilization of the services offered. The ultimate goal for this evaluation is to modify the existing algorithms to better meet patients’ needs.

Methods
Patients initiating care at the UCSF BCC are invited by email to complete an HQS that provides information relevant to their clinical care. Patients sign an electronic consent, agreeing to have their PRO stored and accessed for research purposes. Family history, health behaviors, desired services, and responses to National Cancer Institute Patient Reported Outcomes Measurement Information System (PROMIS) items are processed through algorithms, generating referrals based on defined thresholds. A clinician summary report is generated and scanned into the electronic medical record (EMR), identifying services for which the patient has met thresholds. Referrals are sent to the clinician as pended orders through the EMR. Once signed by the care provider (physician or nurse practitioner), the order is routed through the EMR to the appropriate service and the patient is offered a visit or phone consultation when appropriate.

Results
Between 1/1/14 and 12/31/14, 1297 patients initiating care at the UCSF BCC completed an HQS prior to their clinic visit. 1108 patients (85.4%) agreed to have their data used for research. 623 patients (56.2%) were referred to at least one supportive care service. The table below summarizes the percentage of patients who met the defined referral thresholds:

<table>
<thead>
<tr>
<th>Referral Type</th>
<th>Number of Referrals</th>
<th>Percent of Patients Referred (n=1108)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Genetic Counseling Services</td>
<td>443</td>
<td>40.0%</td>
</tr>
<tr>
<td>Psychological Services</td>
<td>257</td>
<td>23.2%</td>
</tr>
<tr>
<td>Social Work</td>
<td>137</td>
<td>12.4%</td>
</tr>
<tr>
<td>Smoking Cessation</td>
<td>34</td>
<td>3.1%</td>
</tr>
<tr>
<td>Fertility Preservation</td>
<td>29</td>
<td>2.6%</td>
</tr>
</tbody>
</table>

Ongoing analyses are underway to determine the percentage of patients who received services, explore barriers to accessing these services, and evaluate patients’ preferences regarding provision of services in alternate formats, including webinars, online content, and group sessions.
Conclusions
Effective use of PRO identifies a high percentage of patients in need of supportive care services. Through analysis of utilization of services based on our existing thresholds, we hope to optimize our algorithms to better serve our patients' needs throughout the continuum of cancer care.
Title: Bladder symptoms in women with newly diagnosed breast cancer

Wong L, Chung C, Flores S and Mortimer J. City of Hope National Medical Center, Duarte, CA and The Angeles Clinic, Los Angeles, CA.

Body: Background: Changes in bladder function are recognized effects of aging and menopause but have not generally been reported in women treated for breast cancer. We initiated a prospective trial to assess the impact of (neo)adjuvant therapy on women with early stage breast cancer.

Methods: Women with newly diagnosed invasive breast cancer who were to initiate (neo)adjuvant chemotherapy or endocrine therapy were approached for study participation. At baseline a urinalysis, urine culture, and self-assessment quality of life questionnaires were completed. The Urogenital Distress Inventory (UDI-6) assesses bladder symptoms and the Incontinence Impact Questionnaire (IIQ-7) assesses the impact of bladder symptoms on quality of life. Three months after initiation of (neo)adjuvant therapy, the quality of life questionnaires were repeated. We report the results of the pretreatment questionnaires.

Results: Between February and June, 2015, forty-nine women with newly diagnosed breast cancer were enrolled on study. The median age was 54 (Range 25-78); 21 were premenopausal and 28 postmenopausal. Twenty nine (59%) were treated in the adjuvant setting; 12 with chemotherapy and 17 with endocrine therapy. Twenty patients, (41%) were treated in the neoadjuvant setting with chemotherapy. Prior to initiation of therapy, "Frequent urination" was reported in 38 (65%), " Leakage related to urgency" in 5 (10%), " Leakage with physical activity" in 32 (55%) and "Small amounts of leakage" in 32 (55%). Bladder symptoms impacted the ability to perform household chores in 8 (16%), Physical recreation in 10 (20%), social activities in 9 (18%), and Emotional health in 5 (10%).

Conclusions: Symptoms of bladder dysfunction are common in women with newly diagnosed breast cancer even before therapy is initiated.
Title: Sarcopenia and toxicities in patients affected by breast cancer in adjuvant treatment

Botticelli A, Mazzuca F, Mazzotti E, Di Girolamo M, Carbonetti F, Casazza I, De Galitiis F, Di Rocco C, Lionetto L, Borro M, Gentile G, Simmaco M, Muscaritoli M and Marchetti P. Faculty of Medicine and Psychology, University of Rome "La Sapienza" Sant'Andrea Hospital, Rome, Italy; University of Rome "La Sapienza", Sant'Andrea Hospital, Rome, Italy; Faculty of Medicine and Psychology, University of Rome "La Sapienza", Sant'Andrea Hospital, Rome, Italy; IDI-IRCSS, Rome, Italy and Sapienza University of Rome, Rome, Italy.

Body: Purpose
Recent evidences suggest that severe depletion of skeletal muscle, known as sarcopenia, is associated with poor prognosis and toxicities of anti-cancer therapy. Sarcopenia, often unrecognized, affects patients with low, normal or high body mass index (BMI). The aim of our study was to evaluate the association between lumbar skeleton muscle status (LSMI) and toxicities in breast cancer patients receiving standard adjuvant chemotherapy.

Patients and Methods
Twenty-two breast cancer patients (mean age = 55.27; standard deviation, SD = 9.83) receiving epirubicin-based chemotherapy were enrolled in a prospective study. Skeletal muscle cross-sectional area at the third lumbar vertebra was measured by computerized tomography (CT) and sarcopenia was defined using the cut off point for LSMI of <38.5 cm2/m2. BMI and BSA were measured at every cycle of chemotherapy. CT scan was performed before cycle 1 and after cycle 4 of chemotherapy. Toxicity was assessed after every cycle of treatment and it was graded according to the National Cancer Institute Common Toxicity Criteria, version 4.0. Serum samples were withdrawn at every cycle to determine drug concentrations.

Results
Before cycle 1 of chemotherapy, 86.36% of patients were classified as sarcopenic. The sarcopenia mean value was 32.22 cm2/m2 (SD, 5.78; range, 20.87-43.87), and no differences by age and BMI were found. The BMI mean value was 23.97 (SD, 4.32; range, 18.00-33.70).

After cycle 4 of chemotherapy the BMI mean value was 24.19 (SD, 4.74; range, 16.80-33.70), and the sarcopenia mean value was 32.18 (SD, 5.68; range, 22.41-45.43). 18.18% of patients reported severe toxicities (grade 3 or 4). Sarcopenia mean values were found significantly different (p-value 0.048) in patients with severe toxicity compared to patients with absent/mild toxicities (mean value, 27.17; SD, 3.27 versus 33.30; SD, 5.55; respectively). Changes in LSMI were associated with significant changes in toxicities (p-value 0.004). In 18% of patients there was an improvement in toxicity grade, and all of them reported an improvement in LSMI. Among the 40% of patients that reported a worsening in toxicity there was also a worsening in LSMI.

Conclusion
Preliminary analysis of available data showed an association between changes in sarcopenia and toxicities, suggesting that sarcopenia could be considered an early condition in breast cancer. We are presently analyzing data on serum drugs concentrations to detect eventual relation between actual drug level, sarcopenia and toxicity. If this findings will be confirmed in larger population, the measure of body composition could be used to personalized dosing of chemotherapy.
Title: Intrathoracic paclitaxel chemotherapy for malignant pleural effusion in breast cancer

Yeu KJ, Park J, Choi JE, Kang SH and Lee SJ. Yeungnam University College of Medicine, Daegu, Republic of Korea.

Body: Background: Malignant pleural effusion in breast cancer has been associated with poor prognosis which median survival rate is 5–16 months. The response rate of local treatment has been very low and in some case, complications have resulted in death.

Patients and methods: We investigated the efficacy and safety of paclitaxel, as an intrapleural chemotherapeutic agent. From January 2006 to June 2015, total 35 times of intrapleural chemotherapy were performed in 26 breast cancer patients who had developed malignant pleural effusion. They were infused 120mg/m2 of paclitaxel through a chest tube, which was clamped for 48 hours. The chest tube was maintained until drainage was reduced to less than 50-100 mL/day.

Results: Mean follow up period after intrapleural chemotherapy was 11 months. The average time of indwelling with a chest tube after intrapleural chemotherapy was 9.7 days.

Mean progression free survival was 7.8 Months. During the follow-up period, 5 patients had no progression of pleural effusion and 2 of them were free from progression for more than 36 months. In 26 attempts, there were effective and could remove chest tube otherwise in 9 attempts, there were no improvement after intrapleural chemotherapy. 1 patients received a second round of ipsilateral intrapleural chemotherapy and had no response unlike earlier attempts. There were 3 severe adverse effect related death caused by respiratory failure with or without G4 neutropenia.

Conclusion: Intrapleural paclitaxel chemotherapy is helpful for some cases of uncontrolled pleural effusion in that reduce the duration of hospital stay and improve quality of life. But it will be determined carefully, considering the side effects and response rate of treatment.
Title: Frozen glove could be a new hope for prevention of chemotherapy induced peripheral neuropathy

Nakayama T, Yasojima H, Morimoto T, Yoshidome K, Mizutani M, Takashima T, Matsunami N, Enami A, Kagawa M, Nomura T, Shiba E, Nishi T, Kamigaki S, Kozuma Y, Yoshinami T and Masuda N. Osaka Medical Center for Cancer and Cardiovascular Disease, Osaka, Japan; NHO Osaka National Hospital, Osaka, Japan; Yao Municipal Hospital, Yao, Osaka, Japan; Osaka Police Hospital, Osaka, Japan; Osaka City University Graduate School of Medicine, Osaka, Japan; Osaka Rosai Hospital, Sakai, Osaka, Japan; Osaka Breast Clinic, Osaka, Japan; Kaizuka City Hospital, Kaizuka, Osaka, Japan; Sakai City Hospital, Sakai, Osaka, Japan and Higashiosaka City General Hospital, Higashiosaka, Osaka, Japan.

Body: Introduction
Chemotherapy induced peripheral neuropathy (CIPN) is a major problem for patients who receive chemotherapy, and it sometimes deteriorate patients' QOL. Many CIPN prevention trials have been conducted, but no one succeeded to date.

Objectives
To investigate if frozen glove (FG) prevents peripheral neuropathy induced by nanoparticle albumin-bound paclitaxel (nab-PTX).

Methods
We conducted CIPN prevention study using FG, as part of multi-institutional phase II study which analyze efficacy and safety of nab-PTX (260mg/m2 q3w) followed by FEC (500/100/500 mg/m2, q3w) in pre-operative setting (KBCSG-TR 1213 trial). Each patient wore an FGs for a total of 60 minutes (15mins before and after nab-PTX treatment) on both hands. CIPN were assessed during treatment period with nab-PTX by the Patient Neurotoxicity Questionnaire (PNQ) and the FACT/GOG (Gynecologic Oncology Group) Neurotoxicity (Ntx) subscale. Patients were asked to access PNQ and FACT/GOG Ntx on a daily basis and recorded in the CIPN diary.

Results
Sixty two patients were registered for KBCSG-TR 1213 trial. And forty two pts (68%) who turned in the diary were analyzed. Median age and median body mass index (BMI) was 48 years old and 21.6 kg/m2, respectively. We analyzed following 6 categories, 1) symptoms of hands and arms, 2) symptoms of foots, 3) symptoms of general, 4) symptoms of ears 5) muscle weakness of hands and arms and 6) muscle weakness of foots. Median time to each event was 1) 25.5 days, 2) 5days, 3) 3days, 4) not available, 5) 46.5days, 6)4 days. By using FG, time to event of hands and arms was much longer compared with that of foots.

Conclusions
CIPN could be prevented or lessened by FG. Randomized phase II CIPN prevention study has been just launched.
Title: Self-reported symptoms and interference issues in breast cancer patients

BACKGROUND: Breast cancer and its treatments produce multiple symptoms that significantly impact patient quality of life (QOL). Distress and impaired function are the most commonly referred symptoms [Cleeland CS, 2007]. Routine cancer care assessment of patient-reported outcomes (PROs), including symptoms, function, and QOL, has been shown to improve symptom management, identification of psychosocial problems, and patient-provider communication. The Symptom Inventory Tool (SIT) is an assessment tool that captures the patients' perceived symptom burden for real-time clinical intervention, taken at the point of no intervention (baseline) and every 21 days or greater. The SIT is comprised of 27 questions utilizing the M.D. Anderson Symptom Inventory tool (MDASI) [Cleeland CS, Cancer 2013], and validated assessment instrument with 8 questions added and a free text box by Cancer Treatment Centers of America (CTCA). CTCA is a national network of five hospitals that specialize in cancer treatment and integrative oncology.

PATIENTS & METHODS: Patients reported symptoms intensity using 19-item MD Anderson Symptom Inventory (MDASI) and 8 additional questions created by CTCA (constipation, swelling, mouth soreness, bleeding, sexual interest, family, hope & QOL). Symptoms were rated "at the worst" on an 11-point numeric scale ranging from 0 ("no present") to 10 ("as bad as you can imagine") in the previous 24 hours. SIT became an integral part of patient care at CTCA beginning in 2012.

RESULTS: From July 2012 to February 2015, a total of 3,740 outpatients with breast cancer were evaluated at CTCA. A total of 13,852 assessments were analyzed. The assessments consisted of 3,513 completed at baseline, 2,237 completed at the 2nd follow up (FU), and 8,014 completed at 3rd FU or greater. Median age was 50 (range, 17-88), 60% of patients were ER+. Race: White (68%), Black (29%), and other (3%). Disease extension: locoregional (86%) and metastatic (13.6%). The average time since cancer was diagnosed were 35 months, and 50.7% of the patients received prior systemic therapy: chemotherapy (55%), hormone-therapy (41%), and immunotherapy (4%). Mean, standard deviation and inter quartile ranges at baseline assessment are depicted in Table 1.

<table>
<thead>
<tr>
<th>Patient Reported Symptom</th>
<th>Baseline assessment statistics</th>

</tbody>
</table>

* IQR is a measure of variability, based on dividing a data set into quartiles. Quartiles divide a rank-ordered data set into four equal parts.

CONCLUSIONS: The SIT was successful in identifying symptoms burden and interference with life issues in breast cancer patients. Distress, sadness, disturbed sleep, mood and pain were the most common reported symptoms. Early identification of patient burden symptoms allowed immediate intervention and improvement in approximately a quarter of patients.
Cultural and religious differences during breast cancer treatment between Dutch and non-Western immigrant women

de Kruif AJ J, Derks MJ J, de Boer MR R, Winkels R, Visser M, Kampman E and Westerman MJ J. VU University, Amsterdam, Netherlands; Wageningen University & Research Centre, Human Nutrition, Wageningen, Netherlands; VU University Health Sciences & VUmc, Amsterdam, Netherlands and Wageningen University Research Centre & VU University Amsterdam, Wageningen, Netherlands.

Body: Background
Twelve percent of the Dutch population consists of non-Western immigrant women with an incidence of breast cancer that has risen from 2.9% in 2005 to 5% in 2015. For the second generation of these women the incidence of breast cancer is expected to meet the native Dutch population rates soon, partly due to adoption of Western style dietary habits and physical activity. Chemotherapeutic treatment (CT) for breast cancer is associated with increased body fatness and interventions to prevent this increase are currently explored. Whether perceptions on cancer and treatment differ between non-Western immigrant women than for Dutch women needs to be evaluated before these interventions can be set up. This study aimed to explore cultural and religious differences on women’s perceptions of the diagnosis of breast cancer and changes in physical activity and eating habits during chemotherapy treatment.

Methods
A longitudinal qualitative multiple case study was conducted. Newly diagnosed women with breast cancer were recruited and purposively selected (n=23, non-immigrant) from six hospitals in the Netherlands. Semi structured interviews were conducted three times (in total 69): before start of CT, halfway and after CT. In addition 38 women (20 non-immigrant and 18 immigrant) were recruited and interviewed after finishing CT. All interviews (n=107, from 61 women) were audiotaped and transcribed verbatim. A thematic content analysis approach was used.

Results
All 43 non-immigrant women, mean age 51.1 yrs. and 18 immigrant women mean age 43.2 yrs., experienced known side effects from CT. Loss of hair and sometimes the breast appeared to be especially for immigrant women a shocking experience and for some even a loss of femininity. Most of the women perceived to have received incomplete and often unclear information from hospitals about weight and CT treatment. Immigrant women participating the Ramadan during treatment encountered resistance from their physicians. Weight gain during period of CT was higher among immigrant women (mean 13.1 kg, 4-28 kg) than among non-immigrant women (mean 2.5 kg, 2-9 kg). Although both groups said to be less physically active and complained about fatigue, non-immigrant women trying to maintain daily structure and were more active with their diet than most immigrants. Immigrant women expressed cancer as a taboo in their culture impeding them to talk openly about their illness, only when side effects of CT such as hair loss were visible they found it inevitable. Cancer was associated with death at time of diagnosis. For most immigrants and a few non-immigrants this was considered a religious ordeal from Allah or God, these women perceived less influence on their behavior during treatment. Most non-religious women perceived breast cancer as bad luck, stress or heredity.

Conclusion
Especially immigrant women experienced little respect for their culture and insufficient information about treatment. Non-immigrants had a need to actively contribute to their treatment while this need was less obvious for immigrants. Probably because they felt not encouraged by their religion and culture.
Title: Randomized trial of aromatherapy vs. conventional care for breast cancer patients during perioperative periods

Tamaki K, Komatsu-Fukuyama A, Terukina S, Kamada Y, Uehara K, Yamashiro K, Arakaki M, Miyashita M, Ishida T, Ohuchi N, Sasano H and Tamaki N.  Nahanishi Clinic Okinawa, Naha, Okinawa, Japan and Tohoku University Graduate School of Medicine, Sendai, Miyagi, Japan.

Body: PURPOSE: The aromatherapy has been performed as palliative care of the breast cancer patients but no studies have been reported regarding whether the therapy improved QOL of the patients during perioperative periods or not. Therefore, in this study, we compared the effects on QOL between aromatherapy and conventional therapy during perioperative periods of the patients.

METHODS: We examined Japanese breast cancer patients operated at Nahanishi Clinic, Okinawa, JAPAN. The patients were randomly assigned to a 2:1 ratio to aromatherapy or usual care following the informed consents were obtained. The aromatherapy group had aroma-oil (lavender, orange or ylang-ylang) placed at the bedside from 9 pm until 6 am. QOL of the patients was the primary endpoints and the changes of vital signs and the rate of hypnotic usage as secondary endpoints. QOL was assessed using the EORTC QLQ-C30, in which the Patients completed a baseline QOL assessment at the time of admission, of surgery day (AM7:00) and at the morning of post-operative day 1. Vital signs and hypnotic usage were also recorded at the same time.

RESULTS: Among 249 women screened, we randomized 153 women, with 102 to aromatherapy and 51 to conventional care. QOL tended to be improved among aromatherapy groups in physical functioning and role functioning at the morning of post-operative day 1, but the differences did not reach statistical significance (P = 0.08 and 0.09, respectively). There were no statistically significant differences between two groups in the other points of QOL assessment. Aromatherapy did by no means improve vital signs and the rate of hypnotic usage of the patients.

### Conclusion

Aromatherapy did not improve the QOL including vital signs and the rate of hypnotic usage during perioperative periods but no adverse effects also detected. Therefore, aromatherapy may not be prohibited during perioperative periods of the patients when they asked to the physicians.

Title: Effect of mind and beauty education on body image among young breast cancer patients: A randomized controlled trial

Lee JK, Cho J, Park SK, Kim I-R, Yoon J-H, Choi E-K, Cho S-Y, Lee S-K, Lee JE, Kim S, Nam S-J, Park YH, Ahn JS and Im YH. Cancer Education Center, Samsung Comprehensive Cancer Center, Samsung Medical Center, Sungkyunkwan University School of Medicine; Health Science and Technology, SAHIST, Sungkyunkwan University; Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine and Hematology/Oncology, Samsung Medical Center, Sungkyunkwan University School of Medicine.

Body: Background
The proportion of young age-onset breast cancer in Korea is relatively higher than Western countries. Young breast cancer patients are more likely to suffer from altered appearance due to cancer treatment such as breast disfiguration, hair loss, skin change and experience poor body image. This randomized controlled trial (RCT) is designed to evaluate the effect of mind and beauty education program on body image among breast cancer patients under 40-years old.

Methods
A total of 109 eligible breast cancer patients aged 18-40 years old, who had surgery and/or chemotherapy within 18 months and who reported poor body image (<66 EORTC QLQ-BR23 body image score) were recruited and randomly assigned to intervention and control group from July 2014 and April 2015 at an university-based hospital in Seoul, Korea. Intervention group received a structured 8 hours education (2 hours for 4 weeks, 1 hour for mind control and 1 hour for altered appearance management) and control group had education after outcome evaluation. Body image as primary outcome was assessed using both EORTC QLQ-BR23 and body image scale (BIS). In addition, socio-demographic characteristic, self-esteem, quality of life, anxiety, and depression were assessed. Outcomes were evaluated before the intervention, right after the intervention (visit 2), and 3 (visit 3) and 6 months (visit 4) after the intervention. T-test and intention-to-treat analysis performed to compare the outcomes of the two groups.

Results
A total of 54 and 55 patients were assigned to intervention and control group respectively with block randomization. Among the intervention group, 43 participants (79.6%) attended for more than 6 hours of education. Total 46 participants (85.2%) in intervention group and 53 participants (96.4%) in control group completed the questionnaire at visit 2.

Mean age of the study population was 35.5 years old and there were 53 (48.6%), 32 (29.3%), 23 (21.1%) stage I, II, and III breast cancer patients respectively. At baseline, none of the socio-demographic, clinical, psycho-social characteristics were different between two groups. While there was no difference with the body image at baseline between intervention (57.69±20.57) and control group (53.09±26.98) (P=0.327), intervention group reported significantly improved body image than control group (EORTC QLQ-BR23 - Intervention; 71.69±20.27 and Control; 55.97±23.07, P<0.001). The results were similar with BIS measured body image (BIS - Intervention; 17.77±6.29 and Control; 21.29±6.94, P=0.012).

Conclusion
This study provided evidence supporting that mind and body education program would be beneficial to young women with breast cancer who would suffer from low body image. Active education program and psychosocial support related to altered appearance would help young breast cancer patients to make a smooth transit when they return to usual life.

Trial registration: This study is registered in Korean Clinical Research Information Service (CRIS) with registration number KCT0001191.

Title: Impact of increased physical activities after diagnosis on fatigue and overall pain during cancer treatment: A prospective cohort study

Lee JK, Kang D, Choi E-K, Kong S, Lee S-K, Lee JE, Han W, Park YH, Ahn JS, Im YH, Noh D-Y, Nam S-J and Cho J. Cancer Education Center, Samsung Comprehensive Cancer Center, Samsung Medical Center; Health, Behavior and Society, SAHIST, Sungkyunkwan University; Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine; Surgery, Seoul National University Hospital and Hematology/Oncology, Samsung Medical Center, Sungkyunkwan University School of Medicine.

Body: Background
Existing evidence strongly suggests that exercise is not only safe but also feasible during cancer treatment. Physical activity is recommended for improving multiple post-treatment adverse effects on bone health, muscle strength, and other quality-of-life measures. Yet, limited evidence exists regarding effect of increased physical activity after diagnosis on symptoms management of breast cancer patients.

Methods
A total of 422 patients were recruited from July 2010 to July 2011 at two cancer hospitals in Seoul, Korea. Physical activity in sports (PAS) was assessed using Minnesota Leisure Time Physical Activity Questionnaire before and 2 weeks, 3-, 6-, 12-, 24- and 36-months after diagnosis. Physical symptoms including fatigue, pain, arm symptom, and insomnia were measured using EORTC-C30 and BR23. Growth mixture models were used to identify trajectory classes of physical activity patterns. Multivariate analysis was used to find impact of PAS on symptom management using SAS.

Results
Three distinct PAS groups were identified according to 3-year change patterns: moderate to moderate (MM): 40.8%, none to moderate (NM): 31.1% and moderate to high (MH): 28.1%. The LM and MH group increased PAS from diagnosis but it began to decrease from 1 year after diagnosis. Compared to the MM, the NM and MH reported significantly lower level of fatigue (MM:40.7, NM:32.2, MH:33.7), pain(MM:28.0, NM:25.6, MH:20.6), systemic therapy side effects (MM:26.9, NM:22.6, MH:21.8), and breast symptoms (MM:25.4, NM:21.7, MH:20.2) during active treatment (6 months after diagnosis)

Change patterns of quality of life according to trajectory groups

Conclusion
The results of the study confirmed that increased physical activity after diagnosis, even with patients who did not exercise at all before diagnosis, helps to control fatigue, pain, systemic side effects, and breast symptoms during treatment. It is necessary to find ways to promote physical activity after diagnosis and help patients to stay active during treatment.
Title: Depression and anxiety after adjuvant ovarian function suppression in premenopausal breast cancer patients

Body: Purpose
The results of the Suppression of Ovarian Function Trial (SOFT) and the Tamoxifen and Exemestane Trial (TEXT) showed that ovarian function suppression (OFS) in premenopausal early breast cancer patients improves disease control. However, mood swings after OFS is one of the chief complaints to make patients stop undergoing endocrine therapy. Studies about complications of OFS in breast cancer patients are not established well. We designed this randomized controlled trial to evaluate psychological functioning of patients after undergoing adjuvant OFS by goserelin.

Patients and Methods
We randomly assigned 64 premenopausal women with hormone receptor positive early breast cancer to the tamoxifen or tamoxifen plus goserelin group for a period of 1 year. Participants were screened for depression and generalized anxiety disorder using Hamilton Rating Scale for Depression (HAMD), Hamilton Rating Scale for Anxiety (HAM-A), Anxiety Sensitivity Index (ASI) and Albany panic and phobia questionnaire (APPQ) at baseline, 6 months and 12 months. Brain-derived Neurotrophic Factor (BDNF) levels were measured, as well. The results were analyzed by using a linear mixed model and a generalized linear mixed model.

Results
Thirty two patients were distributed in each group, equally. Linear mixed-mixed model analyses revealed that, compared with HAM-A scores of each group at baseline, HAM-A scores at 12 months showed increments (p=0.0078). Among HAM-A questions, Questions for intellectual, sensory and autonomic status were scored significantly high at 12 months (p=0.0018, p=0.0132, p=0.0006). Platelet BDNF levels reported a statistically significant rise at 12 months (p=0.0006). There was no significant time-by-study group effect in all scales.

Conclusion
Compared with the patients without OFS, patients with Goserelin showed no difference in anxiety or depression scales. Thought the levels of anxiety of each group at 12 months were increased, they do not indicate medical interventions. Patients with increased levels of BDNF at 12 months are expected to have good recovery from anxious and depressive symptoms.
Title: Psychological morbidity in breast cancer survivors: Prevalence rates and determinants

Sztankay M, Oberguggenberger A, Meraner V, Egle D, Mangweth-Matzek B, Beer B, Huber N, Sperner-Unterweger B and Hubalek M. Innsbruck Medical University, Innsbruck, Austria; Innsbruck Medical University, Innsbruck, Austria and Institute of Legal Medicine and Core Facility Metabolomics, Innsbruck Medical University, Innsbruck, Austria.

Body: Background: The number of breast cancer survivors (BCS) is steadily increasing due to improved treatment options, early detection and younger age at diagnosis. Thus, it is increasingly important to determine and better understand the psychological outcome following a cancer diagnosis and treatment in long-term. This might contribute to meeting the long-term health care demands of cancer survivors. We aimed at investigating levels and determinants of anxiety and depression (AD) in BCS.

Patients and Methods: We included BCS with a non-metastatic disease in the stage of after-care. AD was determined as part of a cross-sectional, comprehensive patient reported outcome (PRO) assessment (incl. Functional Assessment of Cancer Therapy-G/+B/+ES, Eating Disorder Examination-Questionnaire, Sexual Activity Questionnaire and Body Image Scale) using the Hospital Anxiety and Depression Scale (HADS). Prevalence rates of AD and sample characteristics are presented descriptively using percentages, means and standard deviations. Predictors of anxiety and depression are identified by means of regression analysis.

Results: A final sample of 743 breast cancer survivors who were on average 2.9 years post diagnosis (range: 0.1-11.3 years) participated in the study. Mean patient age was 56.4a (SD 11.5a), 2/3 of patients were postmenopausal. 22.5% of patients reported clinically relevant levels of anxiety and 11.2% of depression. Older age (β=0.012, t=2.53, p<0.05), higher endocrine symptoms (β=-0.037, t=-8.89, p<0.01) and reduced functional well-being (β=-0.034, t=-7.73, p<0.01) were predictive for anxiety and depression in the regression model. The model explained 39.3% of the variance of anxiety and depression.

Conclusion: A distinct proportion of BCS report clinically relevant, long-term psychological morbidity. Especially older BCS, experiencing higher levels of endocrine symptoms and reduced functional well-being, seem to be at risk for psychological morbidity. A routine PRO-screening for psychological morbidity including the assessment of associated risk factors in this patient population might contribute to the identification of those women in need for psychological/ psychiatric treatment and in conjunction, improve cancer care.
Patient reporting pain intensity immediately after surgery can be associated with underlying depression in women with breast cancer

Kim YS, Lee JW, Kim J, Lee SB, Yu J, Ko BS, Kim HJ, Son BH and Ahn SH. Chosun University College of Medicine, Gwangju, Korea and University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea.

**Body: Objective**
The aims of this study were to determine the prevalence of severe, definite depression symptoms, as measured using the Center for Epidemiological Studies Depression Scale (CES-D), and the association between high CES-D scores (i.e., ≥25) and sociodemographic and perioperative factors during perioperative period.

**Methods**
Among 1690 consecutive breast cancer patients who were admitted for definitive breast surgery during the study period, 1499 patients were included in this study. Patients with a past medical history of psychiatric medication or support, a plan for elective surgery due to locoregional recurrence or any metastatic disease were excluded. The CES-D score was checked 1 day before definitive surgeries. The sociodemographic data and perioperative data were analyzed.

**Results**
The mean CES-D score was 18.5, with 24.1% (362/1499) and 56.7% (850/1499) having high CES-D scores of ≥25 and ≥16, respectively. Multivariate analysis revealed that the number of family members with any malignancy (≥2 vs 0), sedative medication (yes vs no) and postoperative numeric rating scale (NRS) scores (persistent, severe pain vs stably mild pain) were significant associated factors for severe, definite depression symptoms [CES-D score of ≥25: adjusted odds ratio (OR)=1.56, 95% confidence interval (CI)=1.10–2.21, P=0.013; adjusted OR=1.65, 95% CI=1.00–2.71, P=0.048; and adjusted OR=2.14, 95% CI=1.15–3.95, P=0.016, respectively].

**Conclusion**
Depression may increase the intensity of postoperative acute pain. Self-reporting of persistent postoperative pain intensity is potentially useful in detecting hidden depression symptoms in breast cancer patients during the perioperative period.
**Title:** Long-term patient satisfaction with cosmetic outcome and psychosocial wellbeing after breast conserving therapy is affected only by lumpectomy volume

**Body:** *Introduction:* Breast conserving therapy (BCT) is considered the treatment of choice for early stage breast cancer by National Cancer Institute guidelines. Little data exists on patient-reported satisfaction and quality of life outcomes after lumpectomy with radiation. This study aims to identify factors influencing satisfaction with cosmetic outcome and quality of life in patients receiving BCT using a validated instrument.

**Methods:** All patients treated with lumpectomy and radiation for breast cancer at our institution from 1997-2012 received a mailed questionnaire containing the BREAST-Q breast conservation module (graciously provided by Dr A. Pusic, Memorial Sloan Kettering Cancer Center), a validated quality of life survey instrument. A retrospective chart review was performed for survey responders for demographic, treatment, and staging information. Scores were calculated for satisfaction with appearance of the breast, adverse effects of radiation, sexual wellbeing, psychosocial wellbeing and physical wellbeing: upper body and arm. Pearson correlation coefficients were obtained. Wilcoxon rank-sum and one-way ANOVA were used to identify associations between patient variables and satisfaction scores. Multivariate regression was used to assess confounding variables.

**Results:** A total of 110 questionnaires (response rate of 29.5%) fit criteria for analysis. The mean age of respondents was 65.9±11.2 yrs, and mean time since diagnosis was 91.8±53.1 mos. We observed the strongest correlations between satisfaction with breast appearance and sexual wellbeing (r=0.66, p<0.01), breast appearance and psychosocial wellbeing (r=0.62, p<0.01), and fewer effects of radiation and physical wellbeing (r=0.65, p<0.01). Lumpectomy volume was associated with decreased satisfaction with breast appearance (r=-0.32, p <0.01) and psychosocial wellbeing (r=-0.19, p<0.05). There was no correlation between satisfaction with breast appearance and patient age, time since surgery, history of re-excision, stage or localization technique. Patients with older age at diagnosis reported significantly fewer effects of radiation and better psychosocial, physical, and sexual wellbeing (all p<0.05) (Table1). The incidence of recurrence was 2.7% and did not impact satisfaction scores.

**Conclusions:** In women undergoing BCT, patient satisfaction with appearance of the breast and psychosocial wellbeing at 7.6 years of follow-up correlated with the volume of tissue removed but no other patient or tumor characteristics. Increasing age at diagnosis was associated with greater satisfaction in multiple domains. These results emphasize the importance of precise surgical technique and patient selection in order to achieve long-term patient satisfaction with BCT.

Title: Chemotherapy-induced alopecia prevention and effects on quality of life among women with breast cancer: A study of a scalp-cooling system used in a Mexican public hospital

Nurses' ratings indicated that hair loss frequency was constantly lower, at each cycle of chemotherapy, in study patients with scalp-cooling system (n = 110) than in those without (n = 100). Differences between the two groups were statistically significant at cycles 1 and 4 (P < 0.047). Scalp cooling was generally very well tolerated; only four of 110 patients discontinued use of the cold cap due to discomfort. Alopecia was considered among the most distressing problems and a trend towards higher well-being was found in successfully scalp-cooled patients, as indicated by a general better health-related quality of life, whereas unsuccessfully scalp-cooled patients reported lowest well-being.

Conclusions: This study demonstrates that scalp cooling was an effective and safe method of protection against hair loss caused by chemotherapy and contributes to the well-being of the patients. Its routine use as part of neo or adjuvant chemotherapy should be seriously considered and should be clinically evaluated in a randomized trial and in studies using other chemotherapy regimens to determine optimal temperatures and durations of cooling for maximal efficacy.

**Title:** The experience of caregivers of women with metastatic breast cancer: Insights from the Make Your Dialogue Count survey

Mayer M, Sampayo I, Bell Dickson R, Citron ML L and Brufsky AM M. AdvancedBC.org, NY, NY; SHARE, NY, NY; Harris Poll, NY, NY; ProHEALTH Care Associates, Lake Success, NY and University of Pittsburgh Medical Center, Pittsburgh, PA.

**Body:**

Introduction: Caregivers of patients with breast cancer have demonstrated persistent unmet needs, including reduced physical and psychosocial well-being. This may be particularly acute in caregivers of patients with metastatic breast cancer (MBC), whose ongoing treatments and increasing disability with disease progression offer particular challenges. While prevalence of MBC is currently unknown, caregivers of women with MBC represent a sizable group.

Objective: To explore the emotional, psychological, and social impact on caregivers of patients with MBC and to identify gaps in communications between patients and their caregivers and oncologists.

Methods: The "Make Your Dialogue Count" survey was conducted online, by paper, and by telephone (June-August 2014) among caregivers in the United States (age \(\geq 18\) y) who attended \(\geq 50\%\) of doctor visits of women with MBC (age \(\geq 21\) y). Survey responses were single- or multiple-response, numeric text, or rated on a 4-point Likert scale. Caregiver data were unweighted and representative only of those responding. Statistically significant differences between groups were determined by standard t-test of column proportions and means at the 95% confidence level.

Results: 234 caregivers responded; 73% were men, 44% were the patient's spouse/partner, and 27% were nonwhite. Median age was 44 y. The caregivers' loved ones had a median time from initial breast cancer diagnosis of 44 months prior, and 51% had recurred after early breast cancer. Most caregivers (76%) considered themselves to be extremely or very involved in treatment decisions, but a sizable fraction of caregivers were unaware of the HR (20%) or HER2 (29%) status of the patient's cancer, indicating a lack of basic information needed for informed decision-making. While most (93%) said they felt comfortable speaking with the treatment team about MBC treatment, 41% reported communication barriers. Over half of caregivers (53%) felt that nobody understands what they're going through, and most (86%) reported that their lives had been negatively affected in some way (such as sleep habits, relationships and social life, hobbies and personal time, and financial stability and employment). Most caregivers considered caregiving to be an emotional (77%) and physical (56%) burden and 36% felt unappreciated. At the time of initial MBC diagnosis, 69% of caregivers felt it was important/very important for their loved one's doctor to refer them to support services, but only 25% of caregivers reported receiving such a referral. Subgroup analysis of caregiver's gender revealed some differences in responses relating to communications with oncologists, treatment experience, and emotional impact.

Conclusions: While committed to their roles, these caregivers often found their role to be a physical and emotional burden, and many reported feeling isolated and unappreciated for their caregiving. Our findings indicate a strong need for support services specifically tailored to caregivers, including outreach to address emotional, financial, and practical needs stemming from caring for a loved one with MBC. They also indicate a need for improved disease and treatment information exchange between caregivers, patients, and healthcare providers.
The relationship between breast cancer progression and workplace productivity in the US

Background: A significant proportion of women with breast cancer leave employment due to their disease. Little is known about the effects of breast cancer progression on productivity among those who remain employed. We sought to determine the effect of disease progression on workplace productivity among women with breast cancer.

Methods: By linking health insurance claims data to workplace productivity data, a longitudinal dataset of women with breast cancer was constructed. The study cohort consisted of commercially insured women aged 18 to 64 in the US who were treated for any type of breast cancer between 2005 and 2012. Disease stage was measured through diagnosis codes and treatments observed, to classify women into the following breast cancer groups in each 90-day quarter: local; locally advanced; other non-metastatic; metastatic, 1st line therapy; metastatic, 2nd line therapy; metastatic, ≥ 3rd line therapy; metastatic, end-of-life care. Progression was defined as movement to a more advanced disease stage. Workplace productivity was measured as employment status and total hours away from work per quarter. Covariates included employer industry, comorbidities, age, region of residence, and a time trend. Reduced workplace productivity was valued using average U.S. wages by industry. Kaplan Meier analysis was used to test whether women whose cancer progressed were more likely to drop out of our employment-based sample. Linear and Heckman models were used to measure the effect of disease progression on workplace hours missed. The Heckman model was used to correct for selection bias, given that healthier women may be more likely to remain in our employment-based dataset.

Results: The study cohort included 6,409 women. Mean patient age was 52.0 years (SD: 7.7). The mean number of Charlson comorbidities was 0.52 per patient (SD: 2.9). The majority of our employment-based sample had non-metastatic breast cancer (90.7%). Breast cancer progression was associated with a lower probability of employment (hazard ratio = 0.65, P<0.01). Patients who left our employment-based dataset by the 12th quarter had a greater number of comorbidities (P<0.01) and missed a greater number of hours in the first two quarters (P<0.1), compared with those who remained. This indicated that patients leaving our employment-based sample were less healthy than those who stayed, supporting the use of the Heckman model. According to the Heckman results, progression was associated with increased workplace hours missed per quarter, both when comparing early versus late stage (P<0.001), and first-line versus later-line metastatic therapy (P<0.05). Linear results were similar. Using the Heckman results, the annual valuation of work missed per patient was $29,881 for patients without metastases and $34,141 for patients with, indicating that progression to metastatic cancer adds an additional $6,500 of lost work time, or about 14% of average US wages.

Conclusions: Breast cancer progression leads to increased workplace hours missed, with greater hours missed among those with more advanced disease. Avoiding or delaying disease progression could bring productivity gains to the workplace in addition to the benefits to the patient.

Support: This study was funded by Pfizer Inc.
Title: Abstract Withdrawn
Sequential versus concurrent administration of epirubicin and docetaxel as adjuvant chemotherapy in women with high-risk axillary lymph node negative early breast cancer. An interim analysis of a multicenter randomized study from the Hellenic oncology research group

Purpose: To compare the sequential versus the concurrent administration of epirubicin and docetaxel as adjuvant therapy in high risk axillary node negative women with early breast cancer.

Patients and treatment: Women 18-75 years old with invasive breast adenocarcinoma surgically resected with no infiltrated axillary lymph nodes and absence of metastatic disease were randomized to receive 4 cycles of epirubicin 90mg/m2 followed by 4 cycles of docetaxel 75mg/m2 (sequential regimen) or 6 cycles of epirubicin 75mg/m2 followed by docetaxel 75mg/m2 (concurrent regimen). All chemotherapy cycles were administered every 21 days with prophylactic G-CSF support for days 3-10 only for the concurrent regimen. Stratification was based on menopausal status, tumor size and hormone receptor expression. By protocol amendment in 2008 women with HER2 positive tumors were excluded. The primary endpoint of the study was to compare the disease-free survival (DFS) at 5 years and 329 patients were scheduled to enroll on each arm.

Results: Between 2001-2013, 658 women were randomized and received the sequential (n=329) or the concurrent (n=329) regimen. The median age was 53 and 52 years, premenopausal status 43.8% versus 44.1%, tumor size <2cm in 44.1% versus 44.4%, histological grade 3 tumor in 52% versus 53.5% and hormone receptor negative disease in 33.1% versus 37.4% of patients in the sequential and concurrent regimens, respectively. After a median follow up of 70.5 and 70 months, there were 29 (8.8%) versus 42 (12.8%) disease relapses (p=0.102) and 11 (3.3%) versus 19 (5.8%) deaths (p=0.135), in the sequential and concurrent arms, respectively. The median DFS has not yet been reached in either arm (p=0.053) and the 5-year DFS rates were 92.6% versus 88.2% for sequential and concurrent arms, respectively. Dose reduction was required in 1.2% versus 3% (p=0.001) of the treatment cycles in the sequential and concurrent arms, respectively. Toxicity included grade 2-4 neutropenia in 54% versus 41% (p=0.001), febrile neutropenia 2.7% versus 6.1% (p=0.06), anemia 12% versus 17% (p=0.07), nausea/vomiting 18.5% versus 12.4% (p=0.03) of patients in the sequential and concurrent arms, respectively. There were no toxic deaths.

Conclusion: In this interim analysis both the efficacy and the toxicity profile seem to favor the sequential over the concurrent regimen.
Title: Short term quality of life with epirubicin-fluorouracil-cyclophosphamid (FEC) and sequential epirubicin/cyclophosphamid-docetaxel (EC-DOC) chemotherapy in patients with primary breast cancer – Results from the prospective multi-center randomized Adebar trial

Schwentner L, Harbeck N, Singer S, Eichler M, Rack B, Forstbauer H, Wischnik A, Scholz C, Fink V, Huober J, Friedl T, Weissenbacher T, Härtl K, Kiechle M and Janni W. University Ulm, Germany; Breast Cancer Center, University of Munich, Germany; IMBEI, University of Mainz, Germany; University Munich, Germany; Oncology Rhein-Sieg, Germany; Hospital Augsburg, Germany; Fresenius University of Applied Science, Germany and Technical University Rechts der Isar, Munich, Germany.

Body: Background:
The grade of recommendation for adjuvant dose-dense chemotherapy in patients with high risk primary breast cancer is heterogeneous among international guidelines. Understanding the impact on quality of life (QOL) by adjuvant dose dense chemotherapy in comparison to standard adjuvant chemotherapy is thereby a crucial factor, especially if the benefit is potentially low. This study aims to assess the impact on QOL by adjuvant dose dense chemotherapy in the prospective randomized multi-center ADEBAR trial.

Methods:
QOL was assessed at baseline (t1), before cycle 4 FEC (Epirubicin 60mg/m2 i.v. d 1 + 8, 5-Fluoruracil 500mg/m2 i.v. d 1 + 8, Cyclophosphamide 75mg/m2 p.o. d 1–14, q4w x 6) and cycle 5 EC-DOC (Epirubicin 90mg/m2 plus Cyclophosphamide 600mg/m2 q3w x 4, sequentially followed by Docetaxel 100mg/m2 q3w x 4) (t2), 4 weeks after chemotherapy (t3), 6 weeks after radiation (t4) and 1 year after baseline (t5) using the European Organization for Research and Treatment for Cancer (EORTC) Quality of Life Core Questionnaire (QLQ-C30) and the Breast Cancer-Specific Module (QLQ-BR23). A multivariate mixed model was fitted to test for differences between the two treatment arms. Primary endpoint was global QOL, secondary endpoints physical functioning, nausea&vomiting, fatigue and systemic therapy side effects. A minimum clinically meaningful difference was considered to be 10 points.

Results:
1306 patients were recruited between 3/2002 and 5/2005 675 were assigned to the FEC and 688 to the EC-DOC arm. Compliance to QOL assessment was 74% at baseline and 58% four weeks after therapy, but dropped to 11% after one year follow up. After the beginning of treatment global QOL dropped in both arm by 3 to 4 points. In the EC-DOC arm QOL dropped further at t3 by 7 points and stayed stable in the FEC arm. 6 weeks after radiation QOL exceeded baseline in both arms by 6 to 8 points. The differences between treatment arms were strongest at t3 (54.1 vs. 49.7) but did not reach clinical relevance at any point in time. Physical functioning, nausea vomiting, fatigue and systemic therapy side effects followed with some minor exceptions similar patterns, but showed higher amplitudes.

Conclusion:
In conclusion we could not detect a statistically significant difference between the two treatment arms in QOL parameters, indicating that dose dense adjuvant chemotherapy did not impact QOL at a clinically relevant level compared to standard adjuvant chemotherapy.
**Title:** A phase 2 study of eribulin in breast cancer not achieving a pathologic complete response (pCR) to neoadjuvant chemotherapy (NAC)

Yardley DA A, Peacock N, Shroff S, Molthrop, Jr DC C, Anz B, Daniel BR R, Young RR R, Weaver R, Harwin W, Webb CD D, Ward P, Shastry M, DeBusk LM M, Midha R, Hainsworth JD D and Burris III HA A. Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN; Florida Hospital Cancer Institute, Orlando, FL; Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Chattanooga, TN; The Center for Cancer and Blood Disorders, Fort Worth, TX; Sarah Cannon Research Institute/Florida Cancer Specialists, St Petersburg, FL; Sarah Cannon Research Institute/Florida Cancer Specialists, Fort Myers, FL; Baptist Health Louisville, Louisville, KY; Sarah Cannon Research Institute/Oncology Hematolog Care, Inc, Cincinnati, OH and Sarah Cannon Research Institute, Nashville, TN.

**Body:**

**Background:** Residual breast cancer after NAC is associated with a high risk of recurrence. Little evidence supports the use of further chemotherapy in this setting. Eribulin, an inhibitor of microtubule dynamics, demonstrated a survival advantage in patients with metastatic breast cancer who had progressed after previous anthracycline and taxane therapy. This phase 2 trial assessed the efficacy of eribulin (2-yr disease-free survival) administered postoperatively to breast cancer pts not achieving a pCR following standard NAC.

**Methods:** Women with invasive breast cancer (stage T1-4b, N0-2, M0 at diagnosis) and evidence of residual cancer (>5 mm) in the breast or axillary lymph nodes (LN) following ≥4 cycles of standard anthracycline and/or taxane-containing NAC were eligible. Additional eligibility criteria: age ≥18 yrs, peripheral neuropathy ≤ 1, adequate hematologic, hepatic, and renal function. 3 groups were studied: Cohort A-triple negative (TN), Cohort B-HR+/HER2-, Cohort C-HER2+. After recovery from definitive surgery, all pts received eribulin mesylate 1.4mg/m^2^ IV on days 1 and 8 every 21 days for 6 cycles. Cohort C pts also received trastuzumab 6mg/kg IV day 1 every 21 days for a total of 1 yr from start of NAC. Adjuvant hormonal therapy and loco-regional radiotherapy were administered per institutional guidelines. We hypothesized post-operative eribulin would result in a 40% increase over the reported 40% 2 yr DFS for TN, and a 15% increase over the reported 80% 2 yr DFS for HR+/HER2- pts who did not achieve pCR following standard NAC.

**Results:** 127 pts were enrolled (54, Cohort A; 42, Cohort B; 31, Cohort C). Pts on Cohort C continue with study treatment. Here, we present the results of 95 pts treated on Cohorts A and B. Median age-52 yrs (range, 27-74). 87 pts (92%) had invasive ductal adenocarcinoma, 6 (6%) invasive lobular, 1 (1%) mucinous, and 1 (1%) unknown; 34 pts (36%) had T3 or T4 tumors and 65 (68%) had N1-2 disease at diagnosis. NAC with anthracyclines was administered to 74 pts (78%), taxanes to 88 (93%), and 72 (76%) received both. 71 pts (75%) had mastectomies, 24 (25%) had breast conserving surgery. Median residual tumor was 17.5 mm (range 0.1 to 80); 60 pts (63%) were LN+. 78 pts (81%) completed the planned 6 cycles of eribulin. Adjuvant radiation was administered in 28 pts (30%). 3 pts discontinued treatment due to toxicity (1 each with G3 neutropenia, G3 nausea, and unknown grade neuropathy). The most common treatment-related G3/4 adverse events were neutropenia [29 pts (31%)] and leukopenia [10 pts (11%)]. 3 pts (3%) had G3/4 febrile neutropenia and 2 pts (2%) had G3/4 neuropathy. Growth factors were administered to 22 pts (24%). There were no treatment-related deaths. With a median follow up of 19.2 and 14.9 months for Cohorts A and B respectively, the 2 yr DFS probabilities calculated from date of surgery were 61.1 % (95% CI-41.2-76.0) for Cohort A; 82.2% (95% CI-60.2-92.7) for Cohort B.

**Conclusions:** The addition of eribulin is safe and feasible in pts who do not achieve pCR following anthracycline and/or taxane based NAC. At a median follow up of 19.2 months, a statistically significant improvement in the estimated 2 yr DFS was evident in the TN (Cohort A) pts.
Phase 2 study of dose-dense doxorubicin and cyclophosphamide followed by eribulin mesylate with or without prophylactic growth factor for adjuvant treatment of early-stage breast cancer

Cadoo K, Kaufman PA A, Hudis C, Chang C, Berrak E, Song J, Seidman AD D and Traina TA A. Memorial Sloan-Kettering Cancer Center, NY, NY; Norris Cotton Cancer Center, Dartmouth-Hitchcock Medical Center, Lebanon, NH and Eisai inc, Woodcliff Lake, NJ.

Body: Background: Eribulin has demonstrated antitumor activity and significantly improved overall survival (OS) in patients (pts) with heavily pretreated locally advanced/metastatic breast cancer (BC). This trial assessed the feasibility of eribulin as adjuvant therapy following dose-dense doxorubicin and cyclophosphamide (AC) for pts with human epidermal growth factor receptor 2 (HER2)-negative early-stage BC.

Methods: Pts with HER2(-), stage I–III, invasive BC were enrolled. Pts received dose-dense AC (doxorubicin 60 mg/m² IV and cyclophosphamide 600 mg/m² IV) on D1 of each 14-day cycle for 4 cycles with pegfilgrastim, followed by 4 cycles of eribulin (1.4 mg/m² IV) on D1 and D8 every 21 days. Pts were divided into 2 cohorts: Cohort 1 did not receive any prophylactic growth factor (GF); Cohort 2 received a short course of prophylactic GF (filgrastim) on days 3, 4, 10, and 11 of each eribulin cycle. Primary endpoint of feasibility was determined as %pts who completed eribulin portion of the regimen without a dose delay (>2 days) or reduction due to eribulin-related adverse event (AE). Based on similar previous studies, the target for feasibility was 80%. Relative dose intensity of eribulin and toxicities were also summarized by cohort. Exploratory objectives include efficacy endpoints of 3-yr disease-free survival and OS.

Results: We report data from 81 pts (55 Cohort 1; 26 Cohort 2) enrolled in the study, of whom 88% completed study treatment. Pt characteristics include median age 49 yrs (range 26–69), ECOG status 0 (85%), BC stages 1/2/3 (21%/57%/22%). Of 90% (73/81) pts evaluable for feasibility, 27% and 40% of pts in Cohorts 1 and 2, respectively, had dose delay or reduction during eribulin treatment, indicating the primary endpoint was not met. Overall, results were similar between the 2 cohorts (Table). Median duration of treatment with eribulin was 10.14 weeks in both cohorts (vs 10 weeks planned). Most eribulin-related dose delays were due to grade 3 (n=18) or grade 4 (n=7) neutropenia. Non-fatal serious AEs were observed in 11% of pts in Cohort 1 and 15% in Cohort 2. Discontinuations due to AEs occurred in 6% of pts in Cohort 1 and 0 in Cohort 2. Neutropenia (all grades) was reported in 36% of pts in Cohort 1 and 42% in Cohort 2. Most common AEs (all grades) were fatigue (96%), nausea (75%), alopecia (73%), hot flush (63%), and constipation (57%).

GCSF, granulocyte-colony simulating factor. *With pegfilgrastim 6 mg given subcutaneously on D2 of each AC cycle; † including dose delays (>2 days)/reduction/interruptions, missing, and permanent discontinuation due to AE.

Conclusions: The primary study endpoint of >80% feasibility of planned dose delivery without any dose delays or reduction was not met. However, adjuvant treatment with dose-dense AC-eribulin was given safely, with two-thirds (67%) of pts achieving full dosing with no dose delay or reduction. Investigation into alternative dosing schedules or GF support is recommended.
Title: UCBG intergroup: 3-years efficacy results of the Unicancer-PACS08 trial including poor prognosis patients treated with docetaxel or ixabepilone in adjuvant setting

Campone M, Lacroix-Triki M, Roca L, Spielmann M, Wildiers H, Cottu P, Kerbrat P, Levy C, Mayer F, Bachelot T, Wiston T, Eymard J-C, Uwer L, Machiels J-P, Verhoeven D, Jaubert D, Facchini T, Orfeuvre H, Canon J-L, Asselain B, Lemonnier J and Roché H. ICO Saint Herblain, Saint Herblain, France; IUCT Claudius Régaud, Toulouse, France; ICM, Montpellier, France; Gustave Roussy, Villejuif, France; Catholique Universiteit, Leuven, Belgium; Institut Curie, Paris, France; Centre Eugène Marquis, Rennes, France; Centre François Baclesse, Caen, France; Centre Georges-François Leclerc, Dijon, France; Centre Léon Bérard, Lyon, France; Mayo Clinic Florida, Jacksonville, FL; Institut Jean Godinot, Reims, France; ICL Centre Alexis Vautrin, Nancy, France; Saint Luc University, Bruxelles, Belgium; AZ Klina Oncology, Brasschaat, Belgium; Clinique Tivoli, Bordeaux, France; Polyclinique de Courlan, Reims, France; Centre Hospitalier de Fleyriat, Bourg en Bresse, France; Grand Hopital de Charleroi, Charleroi, Belgium and R&D UNICANCER, Paris, France.

Body: Background: Ixabepilone, an epothilone B analog, has demonstrated single-agent activity in metastatic and neoadjuvant settings. The PACS08 trial aimed to compare adjuvant FEC100-Docetaxel regimen to FEC100-Ixabepilone in poor prognosis early breast cancer (BC) composed of patients presenting with triple-negative (TN) [i.e. estrogen receptor (ER)-/progesterone receptor (PR)-/HER2-] or ER+/PR-/HER2- tumor, which are subgroups significantly associated with worse prognosis.

Patients and methods: Between 2007 and 2010, 762 patients with unilateral TNBC (n=592, 78%) or node-positive ER+/PR-/HER2- BC (n=170, 22%) were enrolled. Recruitment was interrupted due to BMS decision to stop ixabepilone development in adjuvant setting. Main inclusion criteria were: age<70 years, normal cardiac, hepatic, haematological and renal functions. Arm A: pts received 3 cycles of FEC100 (F and C, each at 500 mg/m², E 100 mg/m², every 3 weeks) followed by 3 cycles of Docetaxel (100 mg/m² every 3 weeks); Arm B, Ixabepilone 40 mg/m² replaced Docetaxel. Radiotherapy was mandatory after conservative surgery and endocrine therapy was given to ER+ pts. ER, PR and HER2 status were validated by a central pathology review on 754 cases and Immunohistochemical detection of Ki67, EGFR, cytokeratins (CK) 5/6 and 14, was performed on tissue microarray (TMA).

Results: As of September 2014, the median follow-up was 36 months. The safety profile indicates that Docetaxel is more often associated to significant haemato logical toxicities whereas both neurotoxicities and haematological toxicities are reported in Ixabepilone arm. Log-Rank tests indicate no difference between two arms in terms of both DFS and OS (HR=1.2, 95%CI (0.864-1.728), p=0.256 and HR=1.8, 95%CI (0.751-1.855), p=0.473, respectively). Pathological analysis of the PACS08 collection showed that TNBC displayed significantly higher proliferative activity as shown by mitotic count and Ki67 index (p<0.001). As compared to ER+/PR-/HER2- subgroup, TNBC showed distinct characteristics, and displayed a so-called basal-like phenotype in 80%. Further efficacy analyses are ongoing in order to study whether chemotherapy may have better prognosis according to pathological characteristics including tumor lymphocytic infiltrate. These additional data will be available for the SABCS2015 meeting.

Conclusions: Our results indicate that Ixabepilone doesn't show higher efficiency compared to Docetaxel in adjuvant setting in poor prognosis early breast cancer. We have an unusual biological collection associated to our clinical data which will allow us to correlate efficacy data to breast cancer subgroups. Other several translational researches are still ongoing.
Title: Delayed initiation of adjuvant chemotherapy among breast cancer patients: A population-based study

Chavez-MacGregor M, Clark CA A, Lichetensztajn DY Y and Giordano SH H. The University of Texas MD Anderson Cancer Center and Cancer Prevention Institute of California.

Body: BACKGROUND: Adjuvant chemotherapy improves outcomes of breast cancer patients; however the optimal timing to initiation of chemotherapy remains unknown. No study has evaluated the relationship between time to chemotherapy (TTC) and outcome in a population-based study of patients treated with contemporary regimens according to tumor subtype. In this large study we identified the determinants associated with a delay in the initiation of chemotherapy and determined whether TTC is related to outcome.

METHODS: Breast cancer patients diagnosed with stage I-III breast cancer between 2005-2010 and treated with adjuvant chemotherapy were identified in the California Cancer Registry. TTC was defined as number of days between surgery and the day the first dose of adjuvant chemotherapy was administered. Delayed TTC was defined as >91 days. Logistic regression and Cox-proportional hazard modeling were used.

RESULTS: A total of 24,843 patients were included. Factors associated with delays in TTC included low socioeconomic status, reconstructive surgical procedure, non-private insurance and Hispanic or non-Hispanic black race/ethnicity. Compared to patients receiving chemotherapy within 31 days from surgery, there was no evidence of adverse outcome among those with TTC of 31-60 or 60-90 days. To the contrary, patients treated >91 days from surgery experienced statistically significant worse overall survival (OS) (HR=1.34; 95%CI 1.15-1.57) and worse breast cancer specific survival (BCSS) (HR=1.27; 95%CI 1.05-1.53). In a subgroup analysis according to breast cancer subtype, TTC >91 days had a statistically significant detrimental impact among patients with triple negative breast cancer (TNBC) in terms of both OS (HR=1.53; 95%CI 1.17-2.00) and BCSS (HR=1.53; 95%CI 1.17-2.07).

CONCLUSIONS: In this large cohort of breast cancer patients treated with contemporary regimens, a delaying in the initiation of adjuvant chemotherapy >91 days was associated with adverse outcomes. A delay in TTC is particularly detrimental among patients with TNBC. The majority of the determinants of delays in chemotherapy initiation are socio-demographic in nature. As medical providers we must make every effort to provide timely care to all our patients so they can receive the full benefit of our current treatments.
Title: Factors associated with delays in chemotherapy initiation among patients with breast cancer

Losk K, Vaz Duarte Luis I, Camuso K, Lloyd M, Kadish S, Hirshfield-Bartek J, Cutone L, Golshan M, Lin N and Bunnell C. Dana-Farber Cancer Institute, Boston, MA.

Body: Background: National guidelines endorse time-dependent quality metrics for breast cancer care. We examined factors associated with delays in chemotherapy initiation at an NCI designated comprehensive cancer center.

Methods: We identified 523 patients who received post-operative adjuvant chemotherapy between January 2011 and December 2013 at our center. We defined 28 days from last definitive surgery (LDS) to chemotherapy as the target timeframe, and unacceptable delay in chemotherapy initiation (UCD) as more than 42 days from LDS. Multivariate regression models were used to identify factors associated with UCD and the impact of Oncotype testing in HR+ patients.

Results: Median days between LDS and chemotherapy initiation was 34 (IQR 15), with 30% of patients starting within 28 days of LDS and 23% having UCD (Table 1). Tumor characteristics such as subtype and stage affected UCD; patients with HR+ or HER2+ tumors were more likely to be delayed compared to those with TNBC. Patients with stage I disease were more likely to be delayed as well as patients undergoing mastectomy or mastectomy with reconstruction. Patients whose pathology sign-out was more than 10 days post-operatively were more likely to be delayed. A higher proportion of UCD was found in HR+ patients (31%) who received an Oncotype recurrence score compared to those who did not (20%).

Conclusions: This study provides insight into populations that may be at risk to experience delays in chemotherapy initiation, directing interventions to improve the timeliness of care.
**Title:** The oncologic effect of a gonadotropin releasing hormone (GnRH) agonist for ovarian protection during breast cancer chemotherapy

Kim HJ, Lee MH, Lee JE, Park SH, Lee ES, Kang Y-J, Lee JH, Shin HN, Kim SI, Im SA, Ahn SH, Lee KS, Sohn J, Han W and Nam SJ. Division of Breast and Endocrine, College of Medicine, University of Ulsan, Asan Medical Center; Seoul National University College of Medicine, Seoul; Division of Breast and Endocrine Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine; Yonsei University College of Medicine, Seodaemun-gu, Seoul, Korea; Cancer Biostatistics Branch, Research Institute for National Cancer Control and Evaluation, Research Institute and Hospital, National Cancer Center, Goyang, Korea; Samsung Changwon Hospital, Sungkyunkwan University School of Medicine, Changwon, Korea; Seoul National University College of Medicine; Seoul National University Hospital, Cancer Research Institute, Seoul National University College of Medicine, Seoul, Republic of Korea and Division of Medical Oncology, Yonsei University College of Medicine.

**Body:** Background: Recently, chemotherapy with a GnRH agonist was reported to protect against ovarian failure. This study was aimed at determining the oncologic effect of a GnRH agonist concurrent with chemotherapy for breast cancer patients.

**Patients and Methods:** A total of 1189 patients aged 20 to 40 years with stage I to III breast cancer who received (neo or adjuvant) chemotherapy from five hospitals in Korea from 2002 to 2012 were reviewed. A gonadotropin releasing hormone (GnRH) agonist was given to 410 patients for ovarian protection during chemotherapy (GnRH agonist group), and 779 patients received chemotherapy without ovarian protection (Chemotherapy alone group). A matching strategy was used to create matched sets of two groups by age, stage, hormone receptor status, Her2/neu status, neo or adjuvant chemotherapy, and institute.

**Results:** Survival analysis using Cox regression showed that the GnRH agonist group had better distant metastatic-free survival (HR=0.65, 95%CI 0.44-0.97) outcomes but similar disease free survival (HR=0.78, 95% CI 0.57-1.08) compared with the chemotherapy alone group. The survival benefit was significant for hormone receptor positive, Her2/neu negative breast cancer on distant metastasis (HR=0.44, 95% CI 0.20-0.99) and disease free survival (HR0.47 95% CI 0.23-0.93).

**Conclusion:** Ovarian protection using a GnRH agonist can be safely considered for premenopausal breast cancer patients for whom chemotherapy is planned.
Title: Adjuvant platinum containing regimens significantly improve disease free survival in Chinese triple negative breast cancer patients

Liao N, Zhang G, An S, Lv H, Wen L and Ren C. Cancer Center, Guangdong General Hospital and Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China and School of Public Health and Tropical Medicine, Southern Medical University, Guangzhou, Guangdong, China.

Body: Background: It has been demonstrated that BRCA1/2 mutations predict good response to platinum in triple negative breast cancers (TNBC). However, in Chinese TNBC population whose BRCA1/2 mutation rate is only 3-7% in familial breast cancers compared to that of 20-40% in Caucasians, whether adjuvant platinum containing regimens still benefit these patients is of interest.

Methods: We retrospectively analyzed a consecutive cohort of TNBC patients diagnosed from June 2004 to June 2014 to evaluate the benefit of adjuvant platinum. Included patients were stage 1-3 TNBC patients who had curative surgeries followed by at least 4 cycles of adjuvant chemotherapy with or without radiotherapy. Adjuvant chemotherapy regimens were categorized into either platinum (either cisplatinum or carboplatinum) containing or non-platinum containing. Disease free survival (DFS) and overall survival (OS) were calculated accordingly and Kaplan-Meier survival analysis and multi-variable Cox regression analysis were performed. Clinicopathologic factors such as age, clinical stage, histological grades, and Ki-67 index were used as variables or stratifying factors in the above analyzes.

Results: Totally, 201 Chinese operable TNBC patients who had adjuvant chemotherapy were included. The median age was 48 years (range 22-70 years). Median follow-up was 49 months (range 12 to 120 months). Sixty patients were staged I, 109 staged II, and 32 staged III. Histological stage was I in 7, II in 65, and III in 129. Eighty-seven patients underwent adjuvant platinum containing regimens while 114 underwent adjuvant non-platinum containing regimens. In total, 39 DFS events were recorded with 5 in the platinum group and 34 in the non-platinum group. Kaplan-Meier survival analysis showed that platinum group had significantly better DFS than non-platinum group (Log Rank test, Chi-Square=8.873, P=0.003). Multiple variable Cox regression analysis showed that, platinum containing regimen was the only independent predicting factor for DFS and it decreased the risk of disease relapse by 73.8% (HR=0.262, 95% CI 0.106-0.677, P=0.006). The estimated 5-year survival rate was 94% in the platinum group VS. 69% in the non-platinum group. Only 12 OS events were recorded with 3 in the platinum group and 9 in the non-platinum group. Kaplan-Meier survival analysis showed that OS in the platinum group did not significantly differ from that in the non-platinum group (Log Rank test, Chi-Square=0.839, P=0.360), and Cox regression analysis failed to detect any independent predicting factors for OS.

Conclusions: Adjuvant platinum containing regimens significantly benefit Chinese TNBC patients in DFS but not in OS. Considering the critically low BRCA mutation rate in such patient population, the efficacy of platinum should be attributed to other hidden mechanisms and deserves further investigations. Future prospective randomized control trials are necessary before establishing the role of platinum for TNBC patients in the adjuvant settings.

Title: Early change in topoisomerase 1 (Top1) positive circulating tumor cells (CTCs) is associated with overall survival (OS) in patients with advanced breast cancer after treatment with etirinotecan pegol

Rugo HS S, Cortes J, Awada A, O'Shaughnessy J, Twelves C, Im S-A, Hannah AL L, Lu L, Sy S, Caygill K, Zajchowski D, Davis DW W, Hoch U and Perez EA A. University of California, San Francisco, San Francisco, CA; Vall D’Hebron University Hospital, Barcelona, Spain; Jules Bordet Institute, Université Libre de Bruxelles, Brussels, Belgium; Baylor Sammons Cancer Center, Texas Oncology, Dallas, TX; University of Leeds, Leeds, United Kingdom; Seoul National University College of Medicine, Seoul, Korea; Consultant, Sebastopol, CA; Nektar Therapeutics, San Francisco, CA; Oncology Consulting Services, San Francisco, CA; Apocell, Inc., Houston, TX and Mayo Clinic, Jacksonville, FL.

Body: Background: Etirinotecan pegol (EP) is a long-acting Top1 inhibitor providing sustained levels of active metabolite throughout the entire chemotherapy cycle. The phase 3 BEACON trial compared EP to treatment of physician's choice (TPC) in patients with advanced breast cancer, demonstrating a non-statistically significant 2.1 month difference in survival favoring EP in the intent to treat population. A novel aspect of the BEACON trial is to explore the utility of biomarkers measured in CTCs for predicting efficacy with EP. Pre- and post-treatment CTCs were isolated from blood of 77% of the 852 BEACON patients. Target-specific pharmacodynamic biomarkers for EP measured in CTCs were analyzed to identify patients most responsive to treatment with EP.

Methods: Donation of blood samples for CTC analysis was voluntary. Participating BEACON patients had serial (baseline, Cycle 2 Day 1 [C2D1], Cycle 4 Day 1 [C4D1], End of Treatment) 7.5-mL whole blood samples drawn in EDTA tubes and shipped within 96 hours ambient to ApoCell (Houston, TX) for processing. PBMCs were separated by Ficoll® gradient, and CTCs were isolated using ApoStream® technology. Isolated cells were deposited on three slides and stained for DAPI, CD45, cytokeratin markers, as well as Top1, Top2, Ki67, γH2AX, Rad51, ABCG2, and TUNEL. Biomarkers were quantified by iCys® laser scanning cytometer equipped with image analysis software, and correlated with OS using Cox multiple regression and Kaplan-Meier analyses.

Results: The CTC substudy yielded 611 pre-treatment, 519 C2D1, 268 C4D1, and 431 End of Treatment samples. Among the successfully processed blood samples, 98% had detectable CTCs, with a median of 63, 46, 51, and 57 CTCs/mL at baseline, C2D1, C4D1, and End of Treatment, respectively. Cox regression analyses of CTC number and percentage of Top1, Top2, Ki67, or TUNEL positive CTCs identified a correlation for post-treatment number of Top1-positive CTCs with OS in patients receiving EP. To assess the impact of Top1-positive CTCs, patients were classified as Top1-High (> median) or Top1-Low (≤ median) based on the percent of Top1-positive CTCs at baseline. Among the Top1-High patients at baseline, significantly improved OS (HR 0.54, p=0.007) was observed for those who converted to Top1-Low after their first treatment with EP (C2D1), but not TPC (HR 1.12, p=0.613). These results suggest that decreased number of Top1-positive CTCs may reflect EP target engagement with Top1, as these patients derived the most benefit from treatment.

Conclusions: CTC collection and analysis was successfully incorporated into the phase 3 BEACON study, with 77% patient participation. CTC detection rate using ApoStream® was high, permitting evaluation of biomarkers at baseline and post-treatment. Significantly improved OS was observed in patients who had a decreased number of Top1-positive CTCs following cycle 1 of EP.
Title: Genome wide association study (GWAS) of genetic variants associated with docetaxel toxicity in the ROSE/TRIO-012 trial

Damaraju S, Gorbunova V, Gelmon K, García-Saenz J, Morales-Murillo S, AbiGerges D, Canon J-L, Kiselev I, Cohen GL L, Jerusalem G, Thireau F, Fresco R, Houé V, Press MF F, Kumaran M and Mackey JR R. Cross Cancer Institute; University of Alberta, Edmonton, AB, Canada; N.N. Blokhin Russian Cancer Research Center, Russian Academy of Medical Sciences, Moscow, Russian Federation; British Columbia Cancer Agency, Vancouver, Canada; Hospital Clínico Universitario San Carlos, Madrid, Spain; Hospital Universitario Arnaú de Vilanova, Lleida, Spain; Middle East Institute of Health, Bsaim, Lebanon; Grand Hôpital de Charleroi, Charleroi, Belgium; Kursk Regional Oncology Dispensary, Kursk, Russian Federation; Mary Potter Oncology Center, Pretoria, South Africa; Centre Hospitalier Universitaire du Sart-Tilman, Liege, Belgium; Translational Reserach in Oncology (TRIO), Paris, France; Translational Reserach in Oncology (TRIO), Montevideo, Uruguay and University of Southern California, Los Angeles, CA.

Body: Background: Genetic predisposition to docetaxel (Doc) toxicity contributes to unacceptable toxicity and reduced dose intensity, and may influence disease outcomes. We previously reported variants associated with Doc toxicity in candidate gene single nucleotide polymorphism (SNP) associations in a breast cancer treatment setting (Damaraju et al. Eur J Cancer (suppl); Vol 8 (7), page 175, 2010) and the identified variants were confirmed in an independent validation study (Damaraju et al, J Clin Oncol Vol 33, Issue 15 suppl, 2015: 540). Others have reported candidate SNP (Breast Cancer Res Treat, 2011 SWOG 0221 study) and GWAS (Clin Cancer Res 2012 CALGB 40101 study) identified variants associated with paclitaxel mediated peripheral neuropathy. However, the overlap on the variants identified thus far between Doc and paclitaxel are limited, prompting a genome wide search to find variants contributing to Doc specific toxicity.

Methods: TRIO-012 is a double blinded, multinational trial that randomized 1,144 patients with advanced breast cancer to receive first-line Doc in combination with ramucirumab (RAM) or placebo (Mackey et al. J Clin Oncol Jan 10, 2015:141-148). Study subjects (n=719) in the Doc+RAM or Doc+placebo arm with available germline DNA are being genotyped; all subjects provided ethics-committee approved prospective consent for this genetic study. Genotyping are being performed with Affymetrix SNP 6.0 arrays. Genotype data will be filtered for deviations from Hardy Weinberg Equilibrium and minor allele frequency of >0.05. Doc-induced adverse events (AEs) are based on CTCAE (Common Terminology Criteria for Adverse Events v4.1) toxicity grades. Toxicities >2 scored for fatigue (n=96), myalgia (n=22), peripheral neuropathy (n=17) will be analysed as individual phenotypes in comparison with the no toxicity group (toxicity grades 0-1) and in a combined analysis of all Doc induced toxicities (0-1, n=599 vs. >2, n=120). Dominant genotypic model is assumed; Chi-square test, FDR and/or 10000 permutations were employed using SVS v8.3 and p<0.05 considered statistically significant. We will identify population stratification using EIGENSTRAT method and will correct the association statistics using the Eigenvectors along with age and BMI as covariates. Fine mapping of the identified loci will be attempted using imputation tools. We will interrogate the data for cumulative dose to toxicity and correlate SNPs identified with survival outcomes.

Results and conclusions: We expect to reconfirm the associations of loci reported in candidate SNP and previous GWAS studies; XKR4 (rs4737264) for peripheral neuropathy, CYP3A5*3 (rs776746) with fatigue, and FACND2 (rs7637888) with myalgia in addition to the potential novel variants distinct from paclitaxel AE GWAS studies. Fine mapping around these loci may help identify potential causal variants. Both candidate SNP and GWAS identified variants may aid in developing risk stratification models. The GWAS identified loci and the flanking genes will be interrogated using the ingenuity pathway analysis for insights in to the biological roles in the drug metabolism. We expect to complete the analysis by mid-November 2015.

Title: Higher rate of severe toxicities in obese patients receiving dose-dense chemotherapy according to unadjusted body mass index – Results of the prospectively randomized GAIN study

Furlanetto J, Eiermann W, Marmé F, Reimer T, Reinisch M, Schmatloch S, Stickeler E, Thomssen C, Untch M, Denkert C, von Minckwitz G, Nekljudova V, Loibl S and Möbus V. German Breast Group, Neu-Isenburg, Germany; Inter-disciplinary Oncological Center, Munich, Germany; University Hospital Heidelberg, Heidelberg, Germany; Klinikum Südstadt Rostock, Rostock, Germany; Kliniken Essen-Mitte, Essen, Germany; Elisabeth-Krankenhaus Kassel, Kassel, Germany; University Hospital Freiburg, Freiburg, Germany; Universitity Hospital Halle, Halle an der Saale, Germany; Helios Klinikum Berlin Buch, Berlin, Germany; Charite University Berlin, Berlin, Germany and Klinikum Frankfurt -Hoechst, Frankfurt, Germany.

Body: Background: In routine clinical practice chemotherapy (CT) doses are frequently capped at a body surface area (BSA) of 2.0 m\(^2\) or adjusted to an ideal weight (i.e. [body length in cm - 10%] + 40% [current weight-ideal weight]) for obese patients (BMI>30 according to WHO) due to safety reasons. There are no data on CT dosing within intense dose-dense regimen for obese patients. Therefore, a retrospective analysis of the GAIN study population has been conducted.

Methods: Between August 2004 and July 2008 a total of 3023 patients were enrolled in the GAIN study, a randomized phase III adjuvant trial, comparing two types of dose-dense regimen. Patients were randomized to intense dose-dense ETC (Epirubicin 150 mg/m\(^2\), Paclitaxel 225 mg/m\(^2\), Cyclophosphamide 2500-2000 mg/m\(^2\), i.v. q15 for 3 cycles) or EC followed by T plus capecitabine (X) (EC-TX) (E 112.5 mg/m\(^2\) + C 600 mg/m\(^2\), i.v. q15 for 4 cycles followed by T 67.5 mg/m\(^2\) i.v. q8 for 10 weeks + X: 2000 mg/m\(^2\) p. o. day 1-14, q22 for 4 cycles). An adjustment of CT dose to an ideal weight for obese patients was implemented by a protocol amendment. Yet some patients received a dose adjustment by capping at 2.0 m\(^2\). We retrospectively evaluated a total of 543 patients with a BMI>30. Data on BSA and dose adjustment were collected from case report forms. Toxicities were compared between patients who received CT according to an unadjusted or adjusted BSA using the 2-sided exact test of Fisher. Disease-free survival (DFS) and overall survival (OS) were calculated using the Kaplan-Meier method and the log-rank test.

Results: Overall, 18.0% (n=543) of patients in the GAIN study were obese: 30.9% (n=168) of them received CT according to an unadjusted BSA. For the remainder BSA was adjusted to ideal weight or was capped at 2.0 m\(^2\) (69.1%; n=375). A total of 14.5% (n=24) of obese patients receiving full dose of chemotherapy vs 6.4% (n=24) of obese patients with an adjusted BSA experienced febrile neutropenia (p=0.005) and 9.6% (n=16) vs 2.9% (n=11) high grade thrombopenia (p=0.002). Overall, 16.7% (n=28) vs 10.1% (n=38) had a thromboembolic event (p=0.034), which was high grade in 12.5% (n=21) vs 6.4% (n=24), respectively (p=0.027) and 3.0% (n=5) vs 0.3% (n=1) experienced high grade hot flushes (p=0.012). The only significant differences in favor of the non-adjusted group were for dizziness (4.2% [n=7] vs 10.7% [n=40]; p=0.013), diarrhea (18.5% [n=31] vs 26.9% [n=101]; p=0.039) and an increase in serum creatinine (6.8% [n=11] vs 14.0% [n=52]; p=0.019). No differences in DFS and OS were observed between the two groups (5year DFS 81.9% [CI 74.9%-87.2%] vs 80.8% [76.3%-84.6%]; p=0.850; 5year OS 86.4% [79.9%-90.9%] vs 88.3% [84.4%-91.3%]; p=0.491).

Conclusion: This analysis of patients treated with a dose-dense regimen showed that obese patients who received CT according to their real BSA have a higher risk of severe toxicities, in particular of febrile neutropenia, high grade thrombopenia and high grade thromboembolic events. Therefore, a dose adjustment of intense dose-dense CT should be performed for obese patients to avoid life-threatening complications.
Body: Background: GAIN-2 compares the effectiveness and safety of a predefined intense dose-dense regimen (EnPC) vs. a dose-dense regimen with modification of single doses depending on individual hematological and non-hematological toxicities (dtEC-dtD) (NCT01690702). Moreover, the Trastuzumab substudy compares the subcutaneous administration of the drug to the abdominal wall vs. thigh.

Methods: The primary objective of the GAIN-2 trial is to compare the invasive disease-free survival (iDFS) in patients with high-risk primary breast cancer (luminal A ≥ 4 N+; luminal B N+; HER2+ and TNBC N0/N+). Patients are randomized between EnPC (epirubicin 150 mg/m² q2w x 3, nab-Paclitaxel 330 mg/m² q2w x 3, cyclophosphamide 2000 mg/m² q2w x 3) or dtEC-dtD (dd/tailored epirubicin/cyclophosphamide q2w x 4 followed by dd/tailored docetaxel q2w x 4) Two safety interim analyses after 200 (Noeding et al. Ann Oncol 2014) and 900 patients who have completed chemotherapy were planned. We present the results of the second safety analysis. In addition to the standard analyses for hematological and non-hematological toxicities, any affections of the cranial nerves as well as the rate of macula degenerations and anaphylactic reactions are of special interest.

Results: Between 09/2012 and 05/2015 a total of 1473 patients have been randomized (EnPC n=734; dtEC-dtD n=739). Among those, 84 patients have been included in the trastuzumab substudy. No safety data are currently available for the substudy. Median age was 52 years and median body-mass-index 26. In terms of hematological adverse events, the rate of febrile neutropenia grade 3-4 (12% vs. 8%) and thrombopenia grade 3-4 (12% vs. 5%) was significantly increased in the EnPC arm. As for non-hematological side effects, there were significantly more patients developing an increase in alkaline phosphatase (59% vs. 40%), ALAT (69% vs. 59%), peripheral sensory neuropathy (83% vs. 68%), arthralgia (63% vs. 49%), myalgia (48% vs. 41%) and bone pain (25% vs. 17%) in the EnPC arm, whereas nosebleed (10% vs. 25%), edema (13% vs. 26%) and hand-foot syndrome (12% vs. 28%) were more common in the dtEC-dtD arm. We observed two treatment related deaths, both in the dtEC-dtD arm (cause of death: acute respiratory distress syndrome and pneumonia). There were no differences between the treatment arms for the toxicities of special interest. In the EnPC arm, overall 30% of the patients required dose-reductions due to hematological toxicities compared with only 10% in the dtEC-dtD arm (p<0.001). The dose could be escalated to the maximum (epirubicin/cyclophosphamide 120/1200 mg/m² followed by docetaxel 100 mg/m²) in more than one third of the patients receiving dtEC-dtD. In 9% of women a reduction was required in the 4th cycle of docetaxel.

Conclusion: This interim safety analysis from a prospectively randomized trial investigating iddEnPC with predefined doses and a toxicity adapted idd/tailored strategy (dtEC-dtD) showed no additional or unexpected safety signals in the iddEnPC or dtEC-dtD arm. Therefore, no modifications in the conduction of the study are necessary and the study continues as expected.
Title: Does histological subtype play a role in treatment decision-making for hormone receptor positive metastatic breast cancer? A study of the Southeast Netherlands breast cancer consortium

Lobbezoo DJA JA, Truin W, Voogd AC C, Roumen RMH MH, Vreudingenhil G, Derksen MW, van den Berkmortel F, Smilde TJ J, van de Wouw AJ J, van Kampen RJW JW, van Riel JMGH MGH, Peters NAJB AJB, Peer PGM GM and Tjan-Heijnen VCG CG. Maastricht University Medical Center; Máxima Medical Center; Orbi-Atrium Heerlen; Jeroen Bosch Hospital; VieCuri Medical Center; Orbi-Atrium Sittard; Sint Elisabeth Hospital; St Jans Hospital and Radboud University Medical Center.

Body: Introduction
Breast cancer is a heterogeneous disease with distinct biological subtypes. Invasive ductal carcinoma (IDC) and invasive lobular carcinoma (ILC) are the two most frequent histological breast cancer subtypes. With this study, we aimed to provide insight into the role of histological subtype on the characteristics, choices with respect to systemic therapy in daily practice and outcome of patients with metastatic breast cancer.

Patients and methods
We analyzed 815 patients diagnosed with metastatic breast cancer in eight hospitals between 2007 and 2009. All hormone receptor (HR) positive patients with either IDC or (mixed) ILC were included. Patient and tumor characteristics, outcomes and treatment data were collected. Survival curves and time to first palliative systemic therapy (either chemotherapy or endocrine therapy) were estimated using the Kaplan-Meier method and compared using log-rank tests. To explore the association of palliative systemic therapy with the survival of patients with metastatic breast cancer a Cox proportional hazards model was performed with palliative chemotherapy and endocrine therapy as a time-dependent covariates.

Results
A total of 568 patients with HR-positive tumors were included; 437 with IDC and 131 with (mixed) ILC. Patients with ILC were older at diagnosis of primary breast cancer, had larger primary tumors and more node-positive disease compared with IDC. Median survival was not different between the subtypes (29 months for ILC and 25 months for IDC, \( P=0.53 \)).

One year after diagnosis of metastatic breast cancer, less patients with HR-positive ILC received chemotherapy (33% of patients with ILC and 47% of patients with IDC) and their time to first palliative chemotherapy was significantly longer compared with HR-positive IDC (\( P=0.001 \)). Time to first palliative endocrine therapy was significantly shorter for ILC compared with IDC (\( P=0.0001 \)).

In multivariable analysis for patients with ILC with palliative endocrine therapy and palliative chemotherapy as time-dependent covariates, palliative chemotherapy as first given systemic therapy was associated with an unfavorable outcome (hazard ratio 2.8, 95% CI 1.7-4.6, \( P<.0001 \)) compared to no palliative chemotherapy and treatment with palliative endocrine therapy as first given systemic therapy was associated with a favorable outcome (hazard ratio 0.4, 95% CI 0.2-0.8, \( P=0.005 \)). In multivariable analysis for patients with IDC, treatment with palliative chemotherapy as first given systemic therapy was also associated with unfavorable outcome (hazard ratio 2.1, 95% CI 1.6-2.7, \( P<.0001 \)), whereas treatment with palliative endocrine therapy as first given systemic therapy was not associated with outcome for patients with IDC (hazard ratio 0.9, 95% CI 0.6-1.2, \( P=0.4 \)).

Conclusion
There was no difference in survival of metastatic breast cancer patients with HR-positive ILC compared with those with IDC. This similar outcome was achieved with different treatment strategies, in which patients with ILC were more likely to receive endocrine therapy and less likely to receive chemotherapy.
Superiority of tandem high-dose chemotherapy (HDC) versus conventionally dosed chemotherapy (CDC) in patients with metastatic breast cancer (MBC): Long term follow-up of IBDIS: A prospective random assignment trial (PRT)

Crown J. Svuah, Dublin, Ireland.

Background
The partial chemo-sensitivity of MBC, together with pre-clinical models, provided a rationale for studies of extreme dose-escalation with autologous haematopoietic progenitor support (ASCT). Early studies of HDC as salvage following failure of CDC produced high rates of temporary response. Subsequent single arm studies in pts who were preselected for responsiveness to CDC yielded 10-20% durable remissions suggesting that HDC might cure some MBC pts. The likelihood of selection bias mandated randomised trials of this CDC induction-HDC consolidation approach. We hypothesised that an alternative strategy-accelerated multi-cycle HDC- might provide an optimal HDC strategy (Crown J, Norton L, Ann Oncol 1996).

Methods
In IBDIS, pts received a brief phase of CDC induction (doxorubicin/docetaxel-“AT”), followed by tandem cycles of HDC, or, further CDC (AT followed by CMF), as initial CRx for MBC. Hormone receptor-positive patients received endocrine therapy post-chemotherapy, and pts with localized metastases received consolidative radiotherapy.

Results: Accrual failed in the aftermath of the disclosure of research fraud involving a South African HDC study, and the reporting of negative PRCTs at ASCO 1999. Only 110 of a planned 264 patients were enrolled, but it was decided to maintain follow-up, which is now 15 years. HDC and CDC groups were well-balanced for prior adjuvant (25 v 25), prior anthracycline (8 v 10), positive receptor status (32 v 31). There were 8 treatment-related deaths (6-HDC, 2 CDC). Complete and overall response rates (CR/OR) were significantly superior for HDC v CDC (CR-29% v 6%, OR-71% v 44%). Event-free-survival at median 5 yrs were HDC 6 (11%) versus CDC 0 (p=.027). At fifteen years three HDC pts remain alive and free from relapse. All CDC are deceased. The hazard ratio for PFS is currently 0.59 (0.39-0.88) favouring HDC p=.009. The HR for overall survival is 0.72 (0.48-1.08)p=.11

Discussion:
Despite accrual failure, IBDIS was and remains a positive study for its primary endpoint of PFS. The 100% relapse and death rate for CDC on our study is typical of the published literature. Data from IBDIS are included in the Cochrane meta-analysis of HDC which showed an advantage for PFS. The contention that HDC produced superior activity to CDC appears to have been correct, however the magnitude of the benefit is smaller than was hoped by investigators in the field.

While our data support the hypothesis that there is a dose response relationship in the chemotherapy of MBC, the small benefit and high toxicity of HDC, preclude it being recommended as a standard treatment for any pts with MBC.
Adaptive therapy: Chemotherapy driven by evolutionary principles prolongs tumor control in preclinical breast cancer models

Enriquez-Navas PM M, Luddy K, Garcia L, Gillies RJ J and Gatenby RA A. Moffitt Cancer Center and Research Institute, Tampa, FL.

Background: Disseminated cancers are typically treated with the maximum tolerated dose to achieve the goal of killing as many tumor cells as possible. However, these therapies eventually fail due to emergence of resistant clones. Using mathematical models of Darwinian dynamics in cancer, we have predicted that adapting the chemotherapeutic dosing schedule to the tumor spatial variability and tumor microenvironment can retard the emergence of chemoresistance. Here, we present an evolutionary-guided treatment strategy (Adaptive Therapy, AT) designed to maintain stable chemosensitive populations while limiting the proliferation of chemoresistant clones by exploiting the fitness cost of the resistant phenotype. The efficacy of the AT has been tested in triple-negative and ER+ breast cancer preclinical models.

Methods: Four cohorts (composed by 12, 11, 13, and 10 mice, respectively) of nude mice were injected with MDA-MB-231 cells in the mammary fat pad. An additional cohort of 19 mice were injected in the same place with MCF7 cells. Control animals didn't receive any treatment. Mice under standard therapy received 20mg/kg of Paclitaxel twice per week for a total of 5 times. We defined two different Paclitaxel AT (Table 1).

VT: MRI tumor volume.

When the tumors achieve ∼300 mm³ the therapy started. MRI T2 and DW acquisitions were performed on an Agilent ASR 310 7T scanner to determine volume and cellularity, respectively. Thereafter, dynamic contrast enhanced (DCE) MRI was preformed following bolus of 0.1 mmol/kg Magnevist to assess distribution of blood flow. Images were processed with in-house developed MATLAB scripts to obtain reliable information. At the end of the monitoring time, tumors were collected and processed for H&E, CD31, SMA, MDR-1, and ER expression. The slides were examined using the Aperio ScanScope XT microscope with a pixel-wise resolution.

Results and Discussion: Tumor growth was monitored using the MRI techniques. Among these three protocols (2 AT and one ST), both AT kept the tumor burden under control during more time than ST in the case of the triple-negative model. In the case of the ER+ model, ST kept the tumor control under control for an extended period than AT-2. However, in both models, the continuous and modulated dosage of Paclitaxel, AT-1, resulted in the most significant cancer control: AT-1 protocol was able to maintain tumors at a small size, with a lower percent of necrosis, and a higher tumor vascularity density. Also, in the case of the MDA-MB-231, it showed the lower expression of MDR1 system.

Conclusion: AT schema, especially AT-1, guided by MRI, can maintain a stable small tumor burden with prolonged progression-free survival compared to standard high dose therapy. Also, AT is able to maintain the lower necrotic volume, a
higher vessel density, and a lower expression of resistance mechanisms, which was correlated with tumor stabilization.
Title: Prognostic relevance of prior endocrine treatments in overall survival (OS) at the time of first line chemotherapy in ER[+]/HER2[-] advanced breast cancer (ABC) patients

Llombart A, de la Haba-Rodríguez JR R, Gligorov J, Aguirre E, Sampayo M and Cortes J. Hospital Arnau de Vilanova, Valencia, Spain; Hospital Universitario Reina Sofía, IMIBIC, Córdoba, Spain; APHP, Tenon Hospital, Paris, Spain; Medica Scientia Innovation Research, Barcelona, Spain; Scienco Klinico, Premià de Mar, Barcelona, Spain and Hospital Vall d'Hebron Institut d'Oncologia, Barcelona, Spain.

Body: Background: International consensus stresses the preference for endocrine therapies (ET) for the ER[+]/HER2[-] ABC population. However, in real-world, chemotherapy (CT) is an extended practice long before exhausting endocrine options (Swallow E, Curr Med Res Opin. 2014). There is little knowledge on the prognostic factors that drives OS among the ER[+]/HER2[-] population at the time of first line CT for ABC.

Methods: The Athena trial assessed safety of different first-line CT & bevacizumab regimens in 2,264 patients (pts) treated between 2006 and 2009 over 34 countries. A total of 1,492 ER/PgR[+]/HER2[-] pts were identified, as 585 TNBC pts (control arm). We adapted the ESMO 2012 guidelines of endocrine resistance to the data collected, considering 5 years the median duration of (neo)adjuvant ET. Endocrine resistance status (ERS) at the time of inclusion was measured by: (1) Progression on ET for Early stage (EEP) [on or within the first year of], and (2) Prior ET for ABC (AEP), whatever the duration or number of endocrine lines. Three ES were pre-defined: Low sensitive (LS): patients with both EEP and AEP criteria; moderately sensitive (MS): either EEP or AEP criteria, and Highly sensitive (HS): neither EEP nor AEP criteria. Other prognostic factors (PF) identified in a prior analysis (Llombart-Cussac A, Breast 2014) were incorporated in a multivariate Cox proportional-hazard model.

Results: Median age was 53 years (range 22-93); 5.2% ECOG ≥2 and 28.9% with prior analgesic treatment. ER/PgR positivity were 94.4%/76% respectively. Patients were previously exposed to anthracycline (53.5%) and taxanes (21.4%) for early stage BC. Prior endocrine therapy in (neo)adjuvant and metastatic settings were (65.3%) and (31.8%), respectively. Pts de novo metastatic represented 19.3%, and the median DFI in pts progressing from an early stage was 43.2 mo. Liver involvement was observed in 40.3% of pts and 20.5% presented ≥3 organs involved. The ES for the population was HS: 492 pts (33%), MS: 755 pts (50.6%) and LS: 245 pts (16.4%). After median follow-up of 22.6 months (range: 0.1 to 43.6) and 752 OS events (50.4% of pts), median OS for HS, MS, and LS groups were >40 mo. (median not achieved), 26.3 (95%CI: 24.5–28.4), 20.1 (95%CI: 17.8–23.9) and 18.3 (95%CI: 16.3–19.7) respectively. 3-years OS survival rates for HS, MS, and TNBC were 53.5%, 34.8%, 23.9% and 26.6%, respectively. Multivariate-adjusted hazard ratios of OS for HS vs MS were 2 (IC95%: 1.6–2.5) and 1.5 (IC95%: 1.2–1.8). The other PF related with OS were: ECOG≥2 or analgesics or corticosteroids 1.6 (IC95%: 1.4–1.8); liver mets or≥2 involved organs 1.4 (IC95%: 1.2–1.6) and adjuvant anthracyline and/or taxane 1.2 (IC95%: 1.1–1.4).

Conclusions: Nearly to 40% of ER[+]/HER2[-] ABC pts confronted to first line CT were precluded as highly sensitive to ET, achieving a median OS that doubles the less sensitive groups. Confirmatory studies with post-treatment information may be important to link this benefit to ET. However Endocrine Status may be useful to appropriately characterize or select patients in future first-line CT studies for HER2[-] pts.

Title: Capecitabine in combination with bendamustine in pretreated women with HER2-negative metastatic breast cancer: Stage 1 results of a phase II trial (AGMT MBC-6)

Rinnerthaler G, Gampenrieder SP P, Fridrik M, Petzer A, Hubalek M, Petru E, Jäger T, Andel J, Balic M, Ulmer H, Mlineritsch B and Greil R. Salzburg Cancer Research Institute With Laboratory of Immunological and Molecular Cancer Research and Center for Clinical Cancer and Immunology Trials, Paracelsus Medical University Salzburg, Salzburg, Austria; General Hospital Linz, Linz, Austria; Barmherzige Schwestern Hospital Linz, Linz, Austria; Innbrucker Medical University, Innsbruck, Austria; Medical University Graz, Innsbruck, Austria; General Hospital Feldkirch, Feldkirch, Austria; County Hospital Steyr, Steyr, Austria; Division of Oncology, Medical University Graz, Graz, Austria and Medical University Innsbruck, Innsbruck, Austria.

Body: Background: Although there is no single accepted standard of care after failure of anthracycline and taxane therapy in HER2-negative metastatic breast cancer, capecitabine is a well-established treatment option. Bendamustine is a hybrid cytotoxic drug because of its structural similarity to alkylating agents and purine and it is generally well tolerated. Since bendamustine has already shown anticancer activity in breast cancer we evaluated the efficacy and tolerability of bendamustine in combination with capecitabine in 40 patients with advanced breast cancer after anthracycline and/or taxane pretreatment.

Patients and methods: MBC-6 is a non-randomized, multicenter, open-label, single-arm phase II study in patients with HER2-negative advanced breast cancer (ClinicalTrials.gov identifier: NCT01891227). All patients were pretreated with anthracyclines and/or taxans in the (neo-)adjuvant and/or metastatic setting and measurable disease according to RECIST 1.1. had to be present at baseline. Following a two-stage Green-Dahlberg design, 20 subjects were accrued and treated within stage 1 of the study. The trial was planned to enroll further 20 patients if there were at least four subjects (20%) with a complete (CR) or partial response (PR). Eligible patients received 1000 mg/m² capecitabine twice daily on days 1 to 14 in combination with 80 mg/m² bendamustine on day 1 and 8 of a 3-week cycle. After a maximum of eight cycles capecitabine was continued as single drug therapy until disease progression or unacceptable toxicity. The primary endpoint was overall response rate (ORR). Secondary endpoints were progression free survival (PFS), clinical benefit rate (CBR), safety profile and quality of life. Here we report the efficacy and safety analysis of stage 1 patients.

Results: From September 2013 to May 2015, 40 patients were recruited in eight Austrian centers. Median age of the stage 1 cohort was 59 years (range 29-77), 80% and 20% of patients had an ECOG performance score of 0 and 1, respectively. Thirty-three percent had triple-negative disease, 85% had had (neo-)adjuvant treatment and 65% patients were pretreated with at least one chemotherapy line for metastatic disease (15% one line, 50% two lines, 40% three lines). In stage 1, ORR was 50% with 9 confirmed PR and 1 confirmed CR, and ORR was comparable between hormone receptor-positive and triple-negative disease (54% vs. 43%). CBR was 55%. At data cut-off on 05/28/15 overall 15 of 20 patients had discontinued treatment: 10 patients (50%) due to progressive disease, 3 (15%) because of adverse events (AEs) and 2 patients on their own decision (10%). Five patients (25%) experienced at least one drug related non-hematological AE ≥ grade 3: 2 diarrhea, 2 fatigue, 3 respiratory or viral infections, 1 dyspnea, 1 thromboembolic event (each grade 3). One grade 4 hematological AE (neutropenia) was observed. One patient died as a result of restrictive cardiomyopathy, where a relationship to capecitabine cannot be excluded, but seems unlikely.

Conclusion: The combination of capecitabine and bendamustine has a moderate toxicity profile and the response data of the stage 1 are promising. Final study results are awaited in the first half of 2016.
Title: Phase II, randomized, parallel-cohort study of neoadjuvant buparlisib (BKM120) in combination with trastuzumab and paclitaxel in women with HER2-positive, PIK3CA mutant and PIK3CA wild-type primary breast cancer – NeoPHOEBE

Loibl S, de la Pena L, Nekljudova V, Zardavas D, Michiels S, Denkert C, Rezai M, Bermejo B, Lee S-C, Turri S, Urban P, Kümmel S, Lux M, Piccart M, von Minckwitz G, Baselga J and Loi S. German Breast Group, Neu-Isenburg, Germany; Sana Klinikum Offenbach, Offenbach, Germany; SOLTI Breast Cancer Research Group, Barcelona, Spain; Breast International Group, Brussels, Belgium; Institut Gustave Roussy, Villejuif, France; Pathology Charité, Berlin, Germany; Luisenkrankenhaus, Düsseldorf, Germany; Hospital Clinico Universitario de Valencia, Valencia, Germany; National University Cancer Institute Singapore, Singapore, Singapore; Novartis Pharma AG, Basel, Switzerland; University Hospital Erlangen, Erlangen, Germany; Kliniken Essen-Mitte, Essen, Germany; Institut Jules Bordet, Brussels, Germany; Memorial Sloan-Kettering Cancer Center, NY, USA; and Peter MacCallum Cancer Centre, Melbourne, Australia.

Body: Background: The PI3K/Akt/mTOR pathway is frequently activated in breast cancer (BC) and is important for the oncogenic function of HER2. Buparlisib is an oral pan-PI3K inhibitor that targets all 4 isoforms of class I PI3K (a, b, g, d). Clinical activity was observed with buparlisib in patients (pts) with advanced BC as a single agent, and in combination with endocrine and anti-HER2 treatment.

Methods: NeoPHOEBE (NCT01816594) is a phase II, randomized, double-blind, parallel-cohort study of neoadjuvant buparlisib/placebo plus trastuzumab and weekly paclitaxel in women with, untreated primary HER2-positive BC. Pts were stratified upfront into 2 independent cohorts according to PIK3CA mutation status. Other eligibility criteria: tumor size >2 cm; unilateral disease; available tumor tissue for central review of estrogen receptor (ER), HER2 status, and PIK3CA genotype; known PIK3CA mutation status; and ECOG PS ≤1. Pts in each cohort (PIK3CA mutant or wild-type [wt]) were randomized (1:1) to receive continuous daily buparlisib (100 mg) or placebo and weekly trastuzumab (4 mg/kg loading dose then 2 mg/kg) for 6 weeks, followed by continuous daily buparlisib (80 mg) or placebo with weekly trastuzumab (2 mg/kg) and weekly paclitaxel (80 mg/m²) for 12 weeks. Study treatment was followed by surgery. Stratification at randomization was based on PIK3CA (mutant vs wt) and ER (positive vs negative) status. The primary endpoint was pathologic complete response (pCR; ypT0) rate at time of surgery. The key secondary endpoint was objective response rate (ORR) at the end of week 6. Other secondary endpoints included pCR by other definitions, ORR prior to surgery, pCR and objective response by ER status, percent of pts with node-negative disease at surgery, rate of breast conserving surgery, and safety, as well as pCR by PTEN expression, Ki67 level, apoptosis rates, percentage of tumor infiltrating lymphocytes (TIL), and by phenotype of 50% TIL at baseline. The sample size is based on a minimax 2-stage randomized phase II design with a prospective control. This design allowed for early stopping if the desired efficacy was not observed after stage 1. Both cohorts were powered (80%) to detect a clinically meaningful increase in pCR of 18% at a one-sided significance level (α=0.15).

Results: Between 9/2013 and 10/2014 50 pts were randomized in 38 sites in 4 countries. Recruitment was suspended due to toxicity in 10/2014. Median age was 50 years, 42 pts had a PIK3CA wt and 8 a PIK3CA mutant tumor, 62% of pts presented with HER2+/ER+, 90% with ductal or ductal-lobular invasive, and 62% with G3 tumors; 86% had Ki67 >20%; 9 pts reported a serious adverse event including 3 pts with hepatotoxicity. Overall 14/50 (28 %) pts developed grade 3-4 liver enzyme elevation, of whom 9 (64%) recovered to at least grade1. Final safety and efficacy data on the primary endpoint (pCR) and biomarker data will be presented at the meeting.

Conclusions: The NeoPHOEBE study investigates for the first time the efficacy of adding a pan-PIK3 inhibitor to a taxane/trastuzumab-based neoadjuvant therapy in pts with primary HER2-positive BC with or without a PIK3CA mutation.
**Title:** Disease-free (DFS) and overall survival (OS) data from ACOSOG Z1041 (Alliance) a randomized neoadjuvant trial comparing FEC followed by paclitaxel plus trastuzumab (FEC → P+T) with paclitaxel plus trastuzumab followed by FEC plus trastuzumab (P+T → FEC+T) in HER2-positive operable breast cancer

Buzdar AU U, Suman VJ J, Meric-Bernstam F, Leitch AM M, Ellis MJ J, Boughey JC C, Unzeitig GW W, Royce ME E, Ewer MS S and Hunt KK K. MD Anderson Cancer Center, Houston, TX; Mayo Clinic, 201 W. Center St., Rochester, MN; MD Anderson Cancer Center, Houston, TX; University of Southwestern Medical Center, 2201 Inwood Road, Dallas, TX; Baylor College of Medicine, One Baylor Plaza, Houston, TX; Mayo Clinic, 200 First Street SW, Rochester, MN; Doctors Hospital of Laredo, 6801 Mcpherson Rd, Suite 106, Laredo, TX; University of New Mexico, Albuquerque, NM and MD Anderson Cancer Center, Houston, TX.

**Body:**

**Background**
ACOSOG Z1041 (Alliance) found pathological complete response rates in women with operable HER2-positive breast cancer were similar with FEC → P+T (Arm 1) and P+T → FEC+T (Arm 2) where treatment was administered as 5-FU 500 mg/m2, epirubicin 75 mg/m2 and cyclophosphamide 500 mg/m2 day 1 of a 21-day cycle x 4; paclitaxel 80 mg/m2 weekly x 12 and trastuzumab 4 mg/kg once then 2 mg/kg weekly x 11. We now report DFS and OS results with a median follow up of 4.4 years (range: 26 days to 6.2 years).

**Methods**
All patients who began study treatment were included in the analyses. Stratified log rank tests and stratified proportional hazard models were used to assess differences in DFS and OS from randomization between treatment arms.

**Results**
From September 15, 2007 to December 15, 2011, 282 women with HER2-positive breast cancer were enrolled. Two patients randomized to arm 1 withdrew consent prior to treatment and are excluded from these analyses. Patient and disease characteristics of the remaining 280 women (arm 1, n=138; arm 2, n=142) were similar between treatment arms. Recurrences and deaths are shown in the table. DFS were not found to differ with respect to treatment arm (stratified logrank p=0.6870; HR stratified (Arm2/Arm1)=0.88; 95%CI: 0.48-1.61). Also, OS was not found to differ with respect to treatment arm (stratified logrank p=0.8790; HR stratified (Arm2/Arm1)=1.07; 95%CI: 0.43-2.69).

**Conclusions**
Concurrent administration of trastuzumab with anthracyclines offers no additional benefit in terms of achieving pathologic complete response or improving survival and is not needed.

Title: The evaluation of trebananib plus standard neoadjuvant therapy in high-risk breast cancer: Results from the I-SPY 2 trial

Albain KS S, Leyland-Jones B, Symmans F, Paoloni M, van ’t Veer L, DeMichele A, Buxton M, Hylton N, Yee D, Lyandres Clennell J, Yau C, Sanil A, I-SPY 2 Trial Investigators, Berry D and Esserman L. Loyola University, Chicago Stritch School of Medicine; Avera Medical Group; University of Texas, M.D. Anderson Cancer Center; QuantumLeap Healthcare Collaborative; University of California, San Francisco; University of Pennsylvania, Perelman School of Medicine; University of Minnesota, Masonic Cancer Center and Berry Consultants.

Body: Background: I-SPY 2 is a multicenter, phase 2 trial using adaptive randomization within biomarker subtypes to evaluate a series of novel agents/combinations when added to standard neoadjuvant therapy for women with high-risk stage II/III breast cancer - investigational agent(I) +paclitaxel(T) qwk x 12 +/-trastuzumab(H), doxorubicin & cyclophosphamide(AC) q2-3 wk x 4 vs. T+/-H /AC (control arm). The primary endpoint is pathologic complete response (pCR) at surgery. The goal is to identify/graduate regimens that have ≥85% Bayesian predictive probability of success (statistical significance) in a 300-patient phase 3 neoadjuvant trial defined by hormone-receptor (HR) & HER2 status & MammaPrint (MP). Regimens may also leave the trial for futility (< 10% probability of success) or following accrual of maximum sample size (10%< probability of success <85%). We report the results for experimental arm trebananib, an angiopoietin-1/2-neutralizing peptibody that inhibits interaction with the Tie2 receptor.

Methods: Women with tumors ≥2.5cm were eligible for screening. MP low/HR+/HER2- tumors were ineligible for randomization. MRI scans (baseline, 3 cycles after start of therapy, at completion of weekly T and prior to surgery) were used in a longitudinal statistical model to improve the efficiency of adaptive randomization. Trebananib was initially assigned to HER2- patients only; once additional safety data with H were obtained, it was also assigned to HER2+ patients (trebananib 15 mg/kg IV qwk +T +/-H). Analysis was intention to treat with patients who switched to non-protocol therapy counted as non-pCRs.

Results: Trebananib +/-H did not meet the criteria for graduation in any of the 10 signatures tested. When the maximum sample size was reached, accrual to trebananib +/-H ceased. Trebananib +/-H was assigned to XX patients, and there were XX concurrently randomized controls. We report probabilities of superiority for trebananib +/-H over control and Bayesian predictive probabilities of success in a neoadjuvant phase 3 trial equally randomized between trebananib +/-H and control, for each of the 10 biomarker signatures, using the final pathological response data from all patients (final pCR data available August 2015). There was a suggestion of activity in XX tumors. Safety was assessed in all patients (available August 2015).

Conclusion: I-SPY 2's adaptive randomization was successful in efficiently evaluating trebananib in the setting of neoadjuvant breast cancer. Although no subtype reached the efficacy threshold for graduation, the data suggest potential benefit in XX tumors that may be explored in further studies. Biomarker studies that may be predictive of response are in progress. The I-SPY 2 standing trial mechanism is effective in defining agents/combinations most likely to succeed in phase 3 biomarker-defined patient subsets.
Title: A randomized phase II neoadjuvant (NACT) study of sequential eribulin followed by FAC/FEC-regimen compared to sequential paclitaxel followed by FAC/FEC-regimen in patients (pts) with operable breast cancer not overexpressing HER-2

Body: Background: Neoadjuvant chemotherapy (NACT) is an integral component for locally advanced and large operable breast cancer. The sequence of taxanes followed by anthracyclines has been the standard of care for almost 20 years. Eribulin (E) is a synthetic analogue of halichondrin B with distinct mechanism of action as microtubule dynamics inhibitor. The FDA approved E in 11/2010 for the treatment of patients (pts) with metastatic breast cancer who have previously received at least two chemotherapeutic regimens for the treatment of metastatic disease. Research Hypothesis: Sequential administration of eribulin followed by FAC/FEC-regimen, would have greater pathologic complete response (pCR) rate than sequential administration of paclitaxel followed by FAC/FEC-regimen as primary systemic therapy for woman with operable breast cancer.

Methods: This is a phase II, randomized, single institution, open label study. Pts were randomized 1:1 to receive E (1.4 mg/m2 d1 and d8 q 21 days x 4) or paclitaxel (P) (80 mg/m2 weekly x12). Both arms received FAC/FEC regimen x 4 doses followed by surgery. Eligible pts were women age 18 or older, Karnosky PS 80 – 100, histologically confirmed invasive breast cancer, clinical T2-T3, N0-3, M0, HER2-negative. Baseline LVEF of > 50% and normal hematology, liver and kidney laboratory function tests. Primary endpoint was pathologic complete response (pCR/RCB-0) assessed by residual cancer burden (RCB). [Symmans F, 2007]. This protocol (2012-0167) IRB of The University of Texas, MD Anderson Cancer Center.

Results: A preplanned interim analysis aimed to validate trial assumption was conducted after treatment of 54 randomized pts. Between 8/2012 to 7/2014, 54 pts were randomized and 49 were evaluable for pCR(27 P arm and 22 E arm). Tumor response by RCB is shown in the table. pCR rates were 30% and 4.5% in the P and E arm, respectively

53 pts were evaluable for toxicity. The combination was safe with mostly grade 1 and 2 toxicities in both arms. In the P arm grade 3 peripheral neuropathy and neutropenia was seen in 3% and 7%, respectively. In the E arm one patient died due to multiorgan failure during cycle 1. There was no other grade 3-5 toxicity. Biomarker analysis using CTCs by AdnaTest Breast were evaluated in 39 pts at baseline. 5/39 pts were positive for CTCs. 3 pts had transcripts for EpCAM, 1 for Muc-1 and another had both. 30 pts had an additional sample post therapy. 2 pts were positive for CTC at baseline as well as at follow up (FU) visit at 180 days. None of the samples showed CTC-EMT at baseline or at FU visits.

Conclusions: The interim analysis demonstrated that E arm lead to significantly lower pCR/RCB1 rate compared to P arm. Ongoing biomarker analyses include TIL, hot spot mutation analysis (HSMA) and molecular inversion probes (MIP) will be presented at the time of the meeting. Clinical trial information: NCT01593020.
Three distinct HER2 subtypes identified by BluePrint 80-gene functional subtyping predict treatment-specific response in the prospective neo-adjuvant NBRST registry

Whitworth P, Beitsch P, Baron P, Beatty J, Pellicane JV V, Murray MK K, Dul CL L, Mislowsky AM M, Nash CH H, Richards PD D, Lee LA A, Stork-Sloots L, de Snoo F, Untch S, Gittleman M, Akbari S and Rotkis MC C. Nashville Breast Center, Nashville, TN; Dallas Surgical Group, Dallas, TX; Breast & Melanoma Specialists of Charleston, Charleston, SC; The Breast Place, Charleston, SC; Virginia Breast Center, Bon Secours Cancer Institute, Richmond, VA; Akron General Hospita, Akron, OH; St. John Hospital & Medical Center, Detroit, MI; Coastal Carolina Breast Center, Murrells Inlet, SC; Northeast Georgia Medical Center, Gainesville GA, Gainesville, GA; Blue Ridge Cancer Care, Roanoke, VA; Comprehensive Cancer Center, Palm Springs, CA; Agenda Inc, Irvine, CA; Breast Care Specialists, Allentown, PA; Virginia Hospital Center, Arlington, VA and Northern Indiana Cancer Research Consortium, South Bend, IN.

Background
Ideally classification by subtype predicts treatment response and overall outcome. BluePrint 80-gene functional molecular subtype is based on mRNA expression (as is intrinsic subtype) associated with intact translation to protein (unlike intrinsic subtype). BluePrint (BP) classifies patients into Luminal, Her2 or Basal-type. Presently subtype is approximated using conventional immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH) ("conventional subtype") or assigned by gene expression profiling. The main objective of the prospective neo-adjuvant NBRST study is to compare drug sensitivity as defined by pathological Complete Response (pCR), using 80-gene functional subtype vs. conventional IHC/FISH subtyping.

NBRST enrolled over 1,000 US patients between June 2011 and December 2014. In this analysis we present the results for IHC/FISH Her2-positive patients.

Methods
Here we report findings in the 260 NBRST patients who had IHC/FISH Her2+ breast cancer, according to ASCO CAP guidelines at the time of diagnosis. Treatment, including chemotherapy and HER2-targeted agents, was at the discretion of the physician adhering to NCCN approved or other peer-reviewed, established regimens over the course of the study. pCR was defined as T0/isN0. Fisher's exact test was used to compare pCR rates among IHC/FISH and functional subtypes and treatment groups.

Results
The 260 IHC/FISH Her2+ patients had median age 53 (range 23-81) and included T1-4, N0-3 tumors. Of 169 ER+/Her2+ tumors 49% were re-classified as BP Luminal, 43% as BP HER2, and 8% as BP Basal. The median ER% of ER+/Her2+/BP Luminal tumors was 93% (range 3-100), compared to 79% in ER+/Her2+/BP HER2 (range 1-91) and 8% in ER+/Her2+/BP Basal-type (range 2-99). The overall pCR rate in ER+/Her2+/BP Luminal was 17% (4% with chemo/trastuzumab; 39% chemo/trastuzumab/pertuzumab, p<0.0001) and statistically inferior (p<0.0001) to the 59% pCR rate in ER+/Her2+/BP HER2. Of 91 ER-/Her2+ tumors 74% were classified as BP HER2, 25% were re-classified BP Basal and <1% was BP Luminal. NCT pCR rates for ER-/Her2+/BP HER2 was 67% (64% with chemo/trastuzumab; 77% chemo/trastuzumab/pertuzumab, p=0.40) and significantly superior (p=0.026) to the 39% pCR rate in ER-/Her2+/BP Basal (p=0.026).

Conclusions
In the NBRST study, BP 80-gene functional subtype (based on mRNA expression and translation): 1. Re-classifies over half of all IHC/FISH ER+/Her2+ patients; 2. Predicts treatment response or resistance in Her2+ patients not segregated by conventional IHC/FISH classification and 3. Identifies ER+/Her2+ tumors that are sensitive to chemo/trastuzumab/pertuzumab but resistant to chemo/trastuzumab.

Title: A phase II randomized study with eribulin/cyclophosphamide (ErC) and docetaxel/cyclophosphamide (TC) as neoadjuvant therapy in HER2-negative breast cancer- Final analysis of primary endpoint and correlative analysis results

Yardley DA A, Chandra P, Hart L, Wright GS S, Ward P, Mani A, Shastri M, Finney L, Guo S, DeBusk LM M, Hainsworth JD D and Burris III HA A. Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN; PathGroup, Brentwood, TN; Sarah Cannon Research Institute/Florida Cancer Specialists, Fort Myers, FL; Sarah Cannon Research Institute/Florida Cancer Specialists, New Port Richey, FL; Sarah Cannon Research Institute/Oncology Hematology Care, Inc, Cincinnati, OH; Memorial Cancer Institute, Hollywood, FL and Sarah Cannon Research Institute, Nashville, TN.

Body: Background: Eribulin mesylate (Er) is a non-taxane inhibitor of microtubule growth that results in G2-M cell cycle arrest, disruption of normal mitotic spindles and apoptosis. Er demonstrated an overall survival (OS) but not progression free survival (PFS) advantage in anthracycline and taxane refractory breast cancer pts. This OS rather than PFS benefit has been attributed to Er's potential to suppress new metastases through its effects on the epithelial mesenchymal transition (EMT) pathway, even in the absence of an effect on the primary tumor or established metastases. In this study ErC was compared to TC, a standard regimen for (neo) adjuvant treatment. A companion exploratory analysis examined the EMT markers E-cadherin and vimentin, as well as the endothelial marker CD-31 assessing tumor vasculature. Final assessments of the primary endpoint of pathological complete response (pCR) and results of the correlative studies will be presented.

Methods: Women with histologically confirmed invasive HER2-negative (IHC 0-1+ or FISH/SISH negative), cT1-3, cN0-2, M0 (pN3a disease allowed) adenocarcinoma of the breast were eligible. Following a 10 pt lead-in to confirm the safety/feasibility of ErC, pts were randomized 2:1. Arm 1, Er 1.4 mg/m$^2$ IV (Days 1 & 8) and C 600 mg/m$^2$ IV (Day 1); Arm 2, T 75 mg/m$^2$ IV and C 600 mg/m$^2$ IV on Day 1, both regimens administered q 21 days x 6 cycles followed by surgery. Tumor samples were collected at baseline and from residual breast cancer at the time of surgery. Samples were assayed for E-cadherin, vimentin, and CD-31 expression by immunohistochemistry.

Results: Enrollment was completed 4/2014 (76 pts); 10 pts in lead-in phase, 66 pts were randomized (Arm 1, 44; Arm 2, 22). In the randomized population, 77% had invasive ductal adenocarcinoma; median tumor size 3.1 cm (range, 0.4-10cm; 29.5% were T3); axillary nodes clinically positive in 52%. 34% of pts were triple negative (TN). 59 pts (89%) underwent surgery after receiving neoadjuvant chemotherapy (NAC) on study. pCR rates were 9% and 18% on the TC and ErC arms respectively. 4/7 pts with pCR on the ErC arm were TN. tumor samples were analyzed from 69 pts (including lead-in pts) for expression of the EMT biomarkers. Of these, 40 pts had paired pre- and post-treatment samples, and 29 pts had either a pre- or post-treatment sample (including 8 pre-treatment samples from pts who achieved pCR). In pre-treatment tumor specimens (61 samples), E-cadherin levels were modest-high in 80%, vimentin expression was seen in 39%, and CD-31 expression observed in 21% of the samples. Analysis of pre- and post-treatment paired specimens and differential effects according to treatment regimen will be presented.

Conclusion: The observed pCR rate of 18% with ErC in this HER2- pt population was comparable with other NAC regimens. Correlative evaluation of EMT markers and tumor vascular density with response is ongoing and will be presented.
Title: Association between quantitative values of estrogen receptor expression level and pathological complete response in human epidermal growth factor 2-negative breast cancer: Should the clinical definition of triple-negative breast cancer be redefined?

Fujii T, Kogawa T, Dong W, Moulder S, Litton JK K, Tripathy D, Lim B, Shen Y and Ueno NT T. The University of Texas MD Anderson Cancer Center, Houston, TX; The University of Texas MD Anderson Cancer Center, Houston, TX and National Cancer Center Hospital East, Kashiwa, Japan.

Body: Background: The American Society of Clinical Oncology/College of American Pathologists recommended that the cut-off for negative status of estrogen receptor (ER) should be <1% positively staining cells, although a 10% cut-off has often been used clinically. Prior studies reported that patients with ER ranging from 1% to 9% showed survival outcomes and molecular features similar to those of patients with ER positivity of <1%; however, those studies did not take into account patients' human epidermal growth factor 2 (HER2) status. This means we have yet to clarify the exact clinical definition of triple-negative breast cancer (TNBC) on the basis of response to preoperative chemotherapy. Previous studies reported that hormone receptor–positive tumors were less sensitive to systemic chemotherapies. On the basis of these facts, we hypothesized that in patients with HER2-negative breast cancer ER expression level as a continuous variable has an inverse linear association with pathological complete response (pCR) rate. Our primary objective was to determine whether a quantitative value of ER between 0% and 10% is predictive of pCR rate in HER2-negative patients treated with neoadjuvant chemotherapy. Secondary objective was to find the ideal cut-off value of ER expression.

Methods: We included newly diagnosed stage I-III HER2-negative breast cancer patients with available ER (0%≤ER<10%) who were treated with neoadjuvant systemic chemotherapy. ER status was determined by immunohistochemical (IHC) staining; HER2 status was determined by IHC and/or FISH. We used univariate and multivariate logistic regression models to determine the association between baseline variables and pCR. A backward stepwise method was used to select the covariates for the multivariate analysis. Recursive partitioning and regression tree method were used to identify the potential significant cut-off of ER.

Results: The analysis included 1155 patients with newly diagnosed HER2-negative invasive breast cancer. The univariate logistic regression analysis showed that ER as a continuous variable was not a statistically significant factor for predicting pCR (ER: OR=0.98, 95%CI: 0.9-1.07, P=0.68). In the multivariate analysis, ER status again was not a significant factor for predicting pCR (OR=0.97, 95%CI 0.9-1.06, P=0.55). ER as a categorical variable, there was no significant difference of the pCR rate between 0<ER<1 and 1≤ER<10 groups (OR=1.27, 95%CI: 0.62-2.62, P=0.52). Among ER> 0 (n=229), the recommended cut-off value of ER was 5.5. However, the odds ratio of pCR rate divided by this value of 5.5 was not significant (ER≤5 vs ER>5; OR 1.94 95%CI 0.54-6.95 P=0.31).

Conclusion: Evaluating ER (<10%) as a continuous variable showed no association with pCR rate, and no cut-off of ER was identified with which to stratify patients into groups more or less likely to achieve pCR. A potential meaningful cut-off ER value might exist between 10% and 100% in HER2-negative patients. We will explore whether a meaningful cut-off ER value exists that will change the pCR rate and possibly lead to redefining the clinical definition of TNBC.
Title: Prediction of pathological response (pCR) to neoadjuvant dose dense and intense cyclophosphamide and anthracycline in a prospective series of triple negative locally advanced breast cancers (TNLABC)

Body: Background: Stage II-III TNBC retains a poor outcome despite high chemosensitivity. Patients (pts) with pCR after neoadjuvant chemotherapy have a good prognosis whereas non-responding pts have a 25-40% risk of distant relapse at 5 years. pCR is thus a major goal in TNBC. We previously reported that TNLABC benefit the most of dose dense dose intense cyclophosphamide (C)-epirubicin (E) (S.Giacchetti; BJC, 2014)

Aim: To confirm these results prospectively and analyze the predictive factors of response to high dose chemotherapy in TNBC.

Patients and methods: From january 2009 to april 2015 non inflammatory TNLABC received high dose C (1200 mg/m2 d1 qw 2) with E (75 mg/m2/ d1 qw2) for 6 cycles. The pts had a breast biopsy with frozen tissue. We performed molecular studies: qRT-PCR for AR, FOXA1, PI3K and FASAY technic for p53 mutation. The percentage of stromal Tumor-infiltrating lymphocytes (TILs) was also evaluated by two independent pathologists and assessed as a continuous variable. A18F-FDG PET/CT was performed initially and after 2 courses of chemotherapy and the metabolic answer assessed as a variation of the tumor uptake (ΔSUVmax). We report here the pathological complete response (pCR) (absence of infiltrative carcinomas in the breast and in the lymph nodes) and the factors associated with pCR.

Results: The characteristics of the 74 pts are listed in table1. The median age is 48 years old, 48 pts (65.8%) are premenopausal and 79% did not have any family history of breast cancers. TIL was divided in 3 groups < 10 % (26 pts, 40 %); 10-50 % (30 pts, 46 %) > 50% (9 pts, 14 %). Pathological response was assessed in 66 pts, one pt progressed during chemotherapy and 6 pts did not undergo surgery yet. 28 pts were in pCR (42.4 %). With a median follow up of 25 months, 13 pts (17.8 %) progressed and 8 (11%) died.

</table>
Tumor size, tumor grade, percentage of TILs, the change in 18F-fluorodeoxyglucose tumor uptake ($\Delta$SUVmax) were significantly associated with pCR at univariate analysis. Only one factor remained significant at multivariate analysis, the $\Delta$SUVmax, OR: 0.04 [0.007-0.27], p = 0.0008.

**Conclusion:** In this prospective phase III trial we confirm the efficacy of a dose dense EC in TNBC. The metabolic response evaluated with 18 F-FDG PET/CT is a strong and reliable predictor of pCR and could allow an early change of treatment for the non responders. A clinical trial is planned to test this strategy.
Title: Long term survival of locally advanced breast cancers (LABC) treated with neoadjuvant treatment, results of a multicenter randomised phase II study (Remagus 02 trial)

Body: Background: The primary analysis of the REMAGUS-02 multicenter randomized phase II trial demonstrated that celecoxib did not improve pCR rates in pts with HER2-negative localized invasive breast cancer (BC), whereas trastuzumab increased pCR rates in HER2-positive ones [Pierga BCRT 2010]. We report here the long-term follow-up results of this trial for disease free survival (DFS) and overall survival (OS).

Patients and methods: From May 2004 to October 2007, 340 stage II-III BC patients were randomly assigned to receive 4 cycles (c) of epirubicin–cyclophosphamide q 3 w followed by 4 c of docetaxel q 3 w +/- trastuzumab in HER2 positive pts (120 pts) or +/- celecoxib in HER2 negative pts (n=220). From September 2005, all pts with HER2 positive BC received adjuvant T for a total of 18 c (n=106). Patients with hormone receptors (HR) positive tumor received adjuvant endocrine treatment according to menopausal status

Results: With a median follow up of nearly 8 years (94.4 months, 20-127m), 112 relapses and 75 deaths have been observed (median DFS and OS not reached). Eight years DFS and OS were respectively 63 % [57%-71%] and 75 % [70%-81%] in HER2 negative group; and 75% [67%-83%] and 82 % [74%-90%] in HER2 positive group. DFS was significantly higher in HER+ pts than in HER2-(HR: 0.64 [0.42-0.99], p=0.042), whereas OS did not differ significantly (HR: 0.67, [0.41-1.11], p=0.123).

In the overall population, progesterone receptor (PgR) positivity was associated with a better DFS (p=0.012) and OS (p<0.001) as compared to ER+/PgR- (DFS: HR=2.07 [1.27-3.39]; OS: HR=2.53 [1.3-4.92]) and ER-/PR-; DFS: HR=1.56 [0.98-2.46]; OS: HR: 3.34 [1.87 – 5.97]. In the ER-/PR- group, DFS reached a "plateau" after three years follow-up, while the annual risk of relapse remained constant in the ER+/PR- subgroup .

In the HER2- subgroup, no effect of neoadjuvant celocoxib was observed on survival, neither in intention to treat (ITT) nor in per protocol analyses. In the multivariate analysis clinical stage (T3/T4 versus T2, HR: 1.92 [1.209 - 3.05], p=0.006), PgR status (positive versus negative HR : 0.52, [0.32-0.84], p=0.007) and pCR (yes vs no, HR : 0.213 [0.066-0.687], p=0.01) were significant predictors of DFS.

In the HER2+ subgroup, neoadjuvant versus adjuvant trastuzumab was not significantly associated with DFS, neither in the ITT, nor in the per protocol analysis.

Conclusion: Celecoxib was not associated with pCR or survival benefit when added to conventional neoadjuvant CT in Her2-negative BC pts. Lack of PgR expression is a major prognostic factor for survival. Neoadjuvant versus adjuvant trastuzumab increased pCR rates but did not change significantly DFS and OS of HER2 positive BC pts.
**Title:** Phase II trial of neoadjuvant chemotherapy with carboplatin and nab-paclitaxel in patients with triple negative locally advanced and inflammatory breast cancer

**Body:** Background: Pathologic complete response (pCR) and residual cancer burden (RCB scores of 0 [pCR] or 1[near CR]) after neoadjuvant chemotherapy (NCT) may predict for improved survival (Symmans et al. J Clin Oncol 25:4414-22, 2007). We set out to test the pCR rate with an anthracycline-free regimen of carboplatin (carb) and nab-paclitaxel (nab) in patients (pts) with triple negative breast cancer (TNBC).

**Materials and Methods:** Forty-nine pts with stages II-III BC were to receive carb (AUC 6) on day 1 of a 28 day cycle, and nab 80 mg/m$^2$ weekly, for a total of 4 cycles. Core biopsies were performed prior to NCT. Blood procurement for circulating tumor cell (CTC) analysis using the CellSearch platform was carried out pre-treatment, mid-treatment, and at surgery. We set out to assess the predictive value of Mammaprint (poor vs. good), BluePrint (basal, vs. luminal, vs. HER2) molecular subtype as well as microarray RNA and miRNA profiling, for pCR. Responses were also dichotomized as complete or near complete response (Symmans RCB scores of 0-1) vs. suboptimal response (RCB score > 1).

**Results:** The median age was 53 (28-75). Pts presented with clinical stages II (63%) and III (37%). So far, 38 of the 49 pts accrued between 2/2012 and 6/2015, have undergone surgery, 68% of whom underwent modified radical mastectomy. The pCR rate (breast and lymph nodes in CR) was 53%, and RCB 0 and 1 were seen in 68% of pts. Toxicites included grade ¾ anemia (45%), thrombocytopenia (13%) and neutropenia (53%, 1 pt with neutropenic fever). Dose adjustments were needed in over 80% of pts. Grades 2 or 3 peripheral neuropathy were seen in 8% each, and grades 3-4 fatigue (13%), hypokalemia (3%), and hyponatremia (3%) were observed. The median number of CTCs (pre-NCT) observed in 7 CTC positive pts of the first 27 pts who completed surgery was 1 (0-7), and 2 of the 7 pts continued to have CTCs at the time of surgery (1 CTC each), while 2 pts without CTCs pre-NCT had CTCs (1 each) detected at surgery. The final pt enrolled is expected to complete surgery by 10/2015. Results of sequential CTC assessments, Mammaprint/Blueprint and RNA/miRNA analysis of pre- and post-treatment specimens and their correlation with pCR will be presented.

**Conclusion:** The non-anthracycline-containing regimen of carb and nab-paclitaxel induced a high pCR rate in TNBC, in preliminary analysis. Ongoing profiling may allow for future subset-specific modification of this regimen to increase pCR across all molecular subtypes of TNBC.
Title: nab-paclitaxel at a dose of 125 mg/m$^2$ weekly is more efficacious but less toxic than at 150 mg/m$^2$. Results from the neoadjuvant randomized GeparSepto study (GBG 69)

von Minckwitz G, Untch M, Jakisch C, Schneeweiss A, Conrad B, Aktas B, Denkert C, Eidtmann H, Weibringhaus H, Kümmel S, Hilfrich J, Warm M, Paepke S, Just M, Hanusch C, Hackmann J, Blohmer J-U, Clemens M, Costa SD, Gerber B, Nekljudova V and Loibl S. German Breast Group, Neu-Isenburg, Germany; Helios Klinikum Berlin-Buch, Berlin, Germany; Sana Klinikum Offenbach, Offenbach, Germany; University Hospital Heidelberg, Heidelberg, Germany; Elisabeth Krankenhaus, Kassel, Germany; University Hospital Essen, Essen, Germany; Charité-University of Berlin, Berlin, Germany; Universitätsklinikum Schleswig-Holstein, Kiel, Germany; St. Barbara Kliniken Heessen, Heessen, Germany; Kliniken Essen Mitte, Essen, Germany; Eilenriede Klinik Hannover, Hannover, Germany; Kliniken der Stadt Köln, Köln, Germany; Universitäts-Frauenklinik Rechts der Isar, München, München, Germany; Onkologie Praxis Bielefeld, Bielefeld, Germany; Rotkreuzklinikum München, München, Germany; Marienhospital Witten, Witten, Germany; Mutterhaus Trier, Trier, Germany; University Hospital Magdeburg, Magdeburg, Germany and University Hospital Rostock, Rostock, Germany.

Body: Background: We previously reported that nab-paclitaxel (nP) increases the pathological complete response (pCR, ypT0 ypN0) rate when it replaces solvent-based paclitaxel (P) as part of a sequential taxane followed by epirubicin/cyclophosphamide (EC) neoadjuvant chemotherapy for patients with early breast cancer (Untch et al. SABCS 2014). Here, we report efficacy and safety of patients being treated either with 150 mg/m$^2$ nab-paclitaxel (nP150) before an amendment or with 125 mg/m$^2$ nab-paclitaxel (nP125) thereafter in comparison to solvent-formulated paclitaxel at 80 mg/m$^2$ (P80).

Methods: In the GeparSepto study (NCT01583426), 1207 patients were randomized to either nP150 or P80 q1w for 12 weeks followed by 4 cycles of conventionally dosed EC (E: 90mg/m$^2$; C: 600 mg/m$^2$) q3w. The primary objective of the study was to compare the pCR rate (pCR, ypT0 ypN0). Patients with untreated, histologically confirmed uni- or bilateral, cT2- cT4d carcinoma, and no clinically relevant cardiovascular and other co-morbidities were included. Patients with HER2+ tumors received trastuzumab (loading dose 8mg/kg; 6 mg/kg) plus pertuzumab (loading dose 840 mg; 420 mg) q3w concomitantly to all chemotherapy cycles. After a safety analysis showed a higher rate of dose reductions and treatment discontinuations with nP150 compared to P80, weekly dose of nP was reduced to 125 mg/m$^2$.

Results: nP was given for the majority of cycles at a dose of 150 mg/m$^2$ to 179 patients and at a dose of 125 mg/m$^2$ to 426 patients. Treatment characteristics were fairly balanced between these two sequential cohorts as well as compared to 601 patients receiving P80 except for HER2 status (HER2-positive: nP150 22%, nP125 37% and P80 33%) and Ki67 (<20%: nP150 60%, nP125 73% and P80 69%). Taxane treatment was discontinued in 16% (nP150), 11% (nP125) and 6% (P80) of patients, respectively. Median dose per cycle (based on relative total dose intensity (RTDI)) was 129 mg/m$^2$ with nP150, 119 mg/m$^2$ with nP125 and 78 mg/m$^2$ with P80, respectively. Peripheral sensory neuropathy (PNP) grade 3/4 (NCI-CTCAE v4.0) was observed in 15% with nP150, 8% with nP125 and 3% with P80, respectively. pCR was 32% with nP150, 41% with nP125 and 29% with P80 in all patients and 46% with nP150, 49% with nP125 and 26% with P80 in 277 patients with triple-negative breast cancer, respectively.

Conclusions: Risk-benefit ratio of nP125 was improved over nP150 with better drug adherence and RTDI, lower frequency of PNP but a higher pCR rate. It should therefore be considered as the preferred schedule when nP is used as neoadjuvant treatment for primary breast cancer.

The trial was financially supported by Celgene and Roche.

Body: Pathological evaluation of response after NAC is a controversial issue. M&P has been for years the most widely employed score. Recently RCB index, a new system including axillary evaluation, seems to improve prognostic discrimination.

PURPOSE: The aim of this study was to validate the RCB index as a method to define prognosis in a real-life cohort of EBC patients treated with NAC and compare it to M&P system.

METHODS: We performed a retrospective analysis of our database. Patients with stage I-III considered candidate for NAC between January 2003 and August 2011 were included. RCB and M&P were calculated as previously published. Hormone receptor expression (RH), and Her2 were assessed following international guidelines. The Harell c-index and Roc curves were used to compare the prognostic value of RCB and M&P. Clinical, therapeutic and pathological data were obtained from medical records. A correlation with disease-free survival (DFS) and overall survival (OS) was done using the Kaplan-Meier method and Cox regression model.

RESULTS: 333 patients were included in this study. Distribution of breast cancer subtypes was: luminal 50.9%, Her2+ 31% and triple negative 18.1%. Mean tumour size was 42.3 mm. The majority of the patients had histological grade II-III tumours (87.3%), with N stage 0-1 (97.3%). 87.4% received anthracycline and taxane-based NAC, associated to trastuzumab in her 2+ patients. Pathological complete response was 14% for the global population, being 30% for TN and 21.3% Her2+ subtypes. With a median follow-up of 56.3 months, DFS and OS at 5 years were as follows: RCB-0 93.6% and 97.9%, RCB-I 84.2% and 98.2%, RCB-II 79.1% and 89.5%, RCB-III 38.3% and 63.6%. Harell c-index value of RCB was statistically superior to M&P in both DFS (0.80 vs 0.68, p= 0.001) and OS (0.87 vs 0.69, p<0.001). This superiority value of RCB was consistent among all breast cancer subtypes.

CONCLUSION: RCB index is as more accurate prognostic score to predict DFS and OS compared to M&P.
Title: Residual proliferative cancer burden (RPCB) is superior to RCB index as prognostic tool in early breast cancer patients (EBC) treated with neoadjuvant chemotherapy (NAC)

Body: BACKGROUND: Many different scales have been developed in order to assess response to NAC. Apart from Miller and Payne and RCB systems, recently the addiction of post-NAC pathological Ki 67 (yp Ki67) to RCB, called RPCB system, has been considered as a more accurate prognostic tool. The aim of this study is to assess the prognosis value of RPCB in a routine practice cohort and to compare it to RCB index and ypKi67.

METHODS: We performed a retrospective analysis of our database. Patients with stage I-III considered candidate for NAC from July 2008 and August 2011 were included. RPCB and RCB were calculated as previously published. Hormone receptor expression (HR), ypKi 67 and Her2 were assessed following international guidelines. The Harell c-index were used to compare the prognostic value of RPCB, RCB and ypKi67. Clinical, therapeutic and pathological data were obtained from medical records. A correlation with disease-free survival (DFS) and overall survival (OS) was done using the Kaplan-Meier method and Cox regression model.

RESULTS: From our database including 333 EBC patients treated with NAC 184 had data to calculate RPCB, RCB and ypKi 67, of whom 51.6% were HR+Her2- tumours, 21.7% HR+Her2+, 8.2% HR- Her2+ and 18.5% triple negative. Mean tumour size was 37.5 mm (25-45). The majority of the patients had histological grade II-III tumours (84.2%) and N stage 0-1 (96.7%). 67.4% of the patients received anthracycline and taxane-based NAC, associated to trastuzumab in Her2+ patients (26.1%). Pathological complete response by subtypes were 6.3%, 17.5%, 60% and 26.5%, respectively. With a median follow-up of 49.9 months, DFS and OS at 36 months were 85.2% and 95.1%. In the multivariate analysis all three systems were prognostic for DFS (RPCB p<0.001; RCB p=0.001; ypKi 67 p= 0.002) and OS (RPCB p<0.001; RCB p=0.011; ypKi 67 p= 0.037). Comparison of Harell c-index for DFS between RCPB and RCB showed a trend of RPCB towards a more accurate prognostic power (0.89 vs 0.81, p=0.061) that was significant when comparing RCPB vs ypKi67 and RPCB vs ypKi67 (0.89 vs 0.77, p=0.010). However no statistically differences were found in terms of OS (RPCB vs RCB 0.85 vs 0.82, p=0.357 and RPCB vs ypKi67 0.85 vs 0.72, p= 0.088).

CONCLUSION: RPCB, RCB and ypKi67 are prognostic for both DFS and OS in EBC patients treated with NAC. RPCB is a more accurate prognostic tool than ypKi67 and showed a trend towards superiority compared to RCB.
2015 San Antonio Breast Cancer Symposium

Publication Number: P1-14-14

Title: Impact of body mass index (BMI) and neo-adjuvant chemotherapy (NAC) dosing on pathologic complete response (pCR) in operable breast cancer (bc)

Raman R, Mott SL L, Schroeder MC C and Thomas A. University of Iowa, Iowa City, IA.

Body: Introduction:
pCR following NAC is associated with improved long term outcomes. Though obesity is associated with chemo-resistance, its impact on pCR is less clear, likely because most studies were unable to account for NAC dose adjustments. An association between taxane dose reduction and BMI has previously been shown in European populations. However, most patients (pts) with increased BMI had doses capped at BSA of 2. We studied the impact of BMI on NAC dosing when treatment is based on actual weight and whether dosing adjustments preferentially impact pCR rate.

Methods: Pts prospectively enrolled in the University of Iowa Breast Molecular Epidemiologic Resource from 2010-14 with invasive bc who received at least one cycle of NAC were eligible. Pts were stratified by BMI category: normal (BMI ≤25) or overweight-obese (BMI >25). Planned total dose was calculated based on both dosing and number of cycles. Dose reduction was defined as any decrease in total intended dose. pCR was defined as no residual invasive disease in breast and lymph nodes. To investigate the relationship between BMI, dose reductions, and pCR, chi-square tests and logistic regression models were used.

Results: 87 pts were eligible. 22 (26%), 25 (29%) and 51 (59%) of pts had HER2 positive, triple negative and hormone receptor positive bc (HER- or +), respectively. 62 (71%) pts had Stage I-II bc. All pts received a combination of taxanes with other agents (Cytoxan, 5FU, Carboplatin, Gemcitabine) with or without an anthracycline (Adriamycin or Epirubicin) or anti HER 2 therapy (Pertuzumab, Trastuzumab or Lapatinib) and were initially dosed based upon actual body weight. Taxanes were planned at treatment initiation in all pts. Anthracyclines were given to 71 (82%) pts. pCR was achieved in 28 (32%) pts. Association between BMI and NAC dosing as shown in -

Table 1: Association between NAC dosing and BMI category

Relative to normal weight pts, overweight-obese pts were more likely not to achieve a pCR (OR 2.09, CI 0.84-5.21, p=0.11) and have residual disease in the breast alone (OR 2.92, CI 1.18-7.24, p=0.02). Overweight-obese pts with taxane reductions, relative to overweight-obese pts without taxane reductions, were at elevated odds of not achieving a pCR (OR 2.03, CI 0.53-7.73).

Interaction between BMI and taxane dose reduction on pCR trended towards significance (p=0.10), a trend not seen for non-taxane drugs. The most common adverse event resulting in taxane dose reduction was neuropathy (10/28 pts).
Conclusion: Overweight-obese women experienced significantly higher rates of taxane dose reductions during NAC for bc with initial full-weight dosing. BMI status may modify the effects of taxane dose reduction on the likelihood of not achieving a pCR. Further investigation of this outcome in a larger cohort is warranted.
Title: A randomized phase III trial of neoadjuvant sequential chemotherapy with 4 cycles of Adriamycin plus cyclophosphamide followed by 4 cycles of Docetaxel (AC4-D4) versus shorter 3 cycles of FEC followed by 3 cycles of Docetaxel (FEC3-D3) in node-positive breast cancer (Neo-Shorter): First report of efficacy & toxicity profile

Body: Background: The addition of a taxane to anthracycline-based chemotherapy provided an improved outcome in neoadjuvant setting. Two neoadjuvant chemotherapy with 4 cycles of AC followed by 4 cycles of docetaxel (AC4-D4) and 3 cycles of FEC followed by 3 cycles of docetaxel (FEC3-D3) are widely used. Short duration of chemotherapy, 6 cycles rather than 8 cycles might be an attractive approach.

Methods: This is a randomized, single-center, prospective, parallel group, comparative phase III trial (NCT02001506). Patients (pts) with breast cancer of clinically stage II or III, or sized > 1.5 cm with histologically proven lymph-node involvement were included. Pts were stratified according to hormone receptor and HER2 expression status and randomized to AC4-D4 and 3 cycles of FEC3-D3 treatment. The primary endpoint was pathological complete response, defined as the absence of invasive disease in the breast and axillary lymph nodes, analyzed by intention to treat.

Results: At the time of submission, a total of 207 pts were enrolled; 1 pt failed screening; 25 pts dropped out (5 pts in AC4-D4 arm and 2 pts in FEC3-D3 arm discontinue treatment due to progressive disease); 39 pts are still receiving neoadjuvant chemotherapy; 142 pts, who received surgery, were included for this analysis. In AC4-D4 arm, among 64 pts, 57 pts achieved clinical response (6 complete response [CR] and 51 partial response [PR]) and among them 9 pts achieved pathologic complete response [pCR]. In FEC3-D3 arm, among 78 pts, 66 pts achieved clinical response (7 CR and 59 PR) and among them 11 pts achieved pCR. Addition of docetaxel increased clinical response in both arms. The most common adverse event was febrile neutropenia. Without prophylactic G-CSF, grade ≥3 febrile neutropenia (FN) occurred 23/661 cycles (3.5%) in AC4-D4 arm and 23/552 cycles (4.2%) in FEC3-D3 arm, respectively. Grade 3 and 4 toxicities other than FN were reported at expected levels in both groups. Sixty-one severe adverse events were reported; 33 (including 23 FN) in AC4-D4 arm and 28 (including 23 FN) in FEC3-D3 arm.

Conclusion: Compared to AC4-D4, shorter duration of FEC3-D3 neoadjuvant chemotherapy showed similar efficacy of pCR rate of 14.0% (versus 14.1% in AC4-D4 arm). The most common and important adverse event was febrile neutropenia in both arms. Updated study findings will be provided.
Body: Background A trastuzumab/carboplatin/docetaxel regimen is an established alternative for the more commonly used and toxic anthracycline/cyclophosphamide containing regimen in HER2-positive breast cancer. Weekly paclitaxel, however, may be more effective and better tolerable than three-weekly docetaxel.

Aim To assess the efficacy and safety of an anthracycline/cyclophosphamide-free neoadjuvant treatment regimen with weekly paclitaxel, carboplatin and trastuzumab in HER2-positive breast cancer.

Patients and methods The TRAIN-study is a multicenter phase II trial which was developed during the 9th ECCO/AACR/ASCO Workshop on "Methods in Clinical Cancer Research" in Flims, Switzerland. Patients with stage II or III HER2-positive breast cancer were eligible. Treatment consisted of weekly administrations of paclitaxel ([P], 70mg/m2), trastuzumab ([T], 2mg/kg, loading dose 4mg/kg), and carboplatin ([C], AUC = 3mg/ml/minute) for a total of 24 weeks. In cycles 7, 8, 15, 16, 23 and 24 only trastuzumab was administered. The primary endpoint was pathologic complete response (pCR), defined as no residual invasive tumor cells in the breast and axilla. Event-free survival was evaluated as a secondary endpoint. In addition, we report efficacy results in an additional cohort of patients treated with the same regimen after study closure. Toxicity data were only recorded for the study population.

Results Baseline characteristics of 109 study patients and 72 additional patients were similar. The pCR rate in the study population was 43% (95% confidence interval [CI] 33-53%) and in all evaluable patients combined 47% (95% CI 39-54%). The median follow-up was 41 months (interquartile range [IQR] 20-53). The 3-year event-free survival estimate was 89% (95% CI 84-95%). Patients who achieved a pCR had a better prognosis than patients who did not (hazard ratio [HR] 0.33; 95% CI 0.11-1.00, p<0.05).

In the study population the most common grade 3-4 adverse events were neutropenia (67%) and thrombocytopenia (43%). Febrile neutropenia occurred in less than five percent of patients. During the neoadjuvant treatment period no symptomatic left ventricular systolic dysfunction was observed. Dose reductions were implemented in 56% of study patients and at least one chemotherapy dose was skipped in 67% of patients.

Conclusion Weekly paclitaxel, trastuzumab, and carboplatin is a highly effective neoadjuvant regimen in HER2-positive breast cancer with manageable toxicity. In the currently running randomized TRAIN-2 study this regimen will be directly compared to an anthracycline/cyclophosphamide containing neoadjuvant regimen in the setting of dual HER2-blockade with pertuzumab (clinicaltrials.gov NCT01996267).
Title: Pathologic complete response rate with doxorubicin and cyclophosphamide followed by weekly paclitaxel with trastuzumab and pertuzumab in patients with HER2-positive early stage breast cancer: A single institution experience

Body: Background:
Trastuzumab and pertuzumab (HP) with standard chemotherapy is approved for use in the neoadjuvant setting. We performed a retrospective analysis of patients (pts) treated with dose-dense doxorubicin and cyclophosphamide (AC) → paclitaxel, trastuzumab, pertuzumab (THP) in the neoadjuvant setting. Here we report the pathologic complete response (pCR) rate.

Methods:
We abstracted medical records of patients who were treated with pertuzumab-based therapy in the neoadjuvant setting from September 1, 2013 to March 1, 2015. Charts were analyzed for pt demographics, stage of breast cancer, pathology reports, surgical data, and information on systemic therapy.

Results:
Charts from 66 pts were reviewed; 60 pts were evaluable for pCR defined as absence of invasive disease in the breast, and 6 were not (3-no anthracycline, 1-incomplete chart, 1-no surgery yet, 1-metastatic). Median age was 47 years (range 28-68 years). Of 60 pts, 52 (86%) had operable breast cancer (T1-3, N0-1, M0) of which 7 had clinical stage I disease (T1N0); 7 (12%) had locally advanced disease (T2-3, N2-3, M0 or T4a-c, any N, M0), and 1 (2%) had inflammatory breast cancer (T4d, any N, M0). 49 (82%) and 11 (18%) had hormone receptor (HR)-positive and negative diseases, respectively. All patients had HER2-positive breast cancer defined as immunohistochemistry (IHC) 3+ and/or fluorescent in-situ hybridization (FISH) of > 2.0. 30 pts (50%) underwent mastectomy and lumpectomy, respectively. Out of 60 evaluable pts, 41 (68%) had pCR; 32/49 (65%) with HR-positive and 9/11 (82%) with HR-negative diseases had pCR, respectively. Overall 58/60 (97%) pts completed neoadjuvant therapy; 2 did not (1 developed Steven Johnson Syndrome after one cycle of AC and 1 developed pneumonitis after third weekly dose of T with HP).

Conclusions:
At our single center experience the pCR rate of dose dense AC→THP is high at 68 %. These data are similar to results seen in the TRYPHAENA study, and we await the results from the BERENICE trial evaluating pCR as a secondary endpoint.

Title: Postmastectomy radiotherapy improves the outcomes of stage III breast cancer patients with negative lymph nodes after neoadjuvant chemotherapy

He M, Li J, Ni X-J, Chen S, Jiang Y-Z, Di G-H and Shao Z-M. Fudan University Shanghai Cancer Center, Shanghai, China.

Body: Purpose: The aim of this study is to evaluate the role of postmastectomy radiotherapy (PMRT) in clinical stage II and III breast cancer patients who achieved negative node status (pN0) after neoadjuvant chemotherapy (NAC).

Material and methods: We retrospectively analyzed the outcomes of 143 patients with pN0 after NAC and mastectomy at Fudan University Shanghai Cancer Center. In total, 103 (72%) patients received PMRT, and 40 (28%) patients did not. Univariate and multivariate survival analyses were performed to evaluate the effect of PMRT on locoregional recurrence-free survival (LRRFS) and overall survival (OS) of the two groups.

Results: There were no differences between the two groups with respect to age, nuclear grade, estrogen receptor (ER) status, HER2/neu receptor status, lymphovascular space invasion (LVSI) status or pathological tumor size. However, a significantly higher proportion of patients in the irradiated group (64%) had clinical lymph node involvement than in the nonirradiated group (45%). After a median follow-up time of 49 months, 10 locoregional recurrence events occurred. For the entire cohort of patients, use of radiation therapy improved the 5-year LRRFS rate (94.5% vs. 80.2%; P = 0.032) but not the 5-year OS rate (92.2% vs. 88.7%; P = 0.617). In the subset of patients who presented with clinically stage II disease, the 5-year LRRFS and 5-year OS did not differ significantly between the PMRT and no-PMRT group (96.3% vs. 91.3%; P = 0.190 and 96.2% vs. 91.3%; P = 0.199, respectively). For patients with stage III disease at diagnosis, a trend was seen toward better local regional control with PMRT (the 5-year LRRFS rate was 92.7% vs. 64.2%; P = 0.063), although the benefit from radiation with respect to OS was not significant (5-year OS rate was 88.1% vs. 85.2%; P = 0.657). On multivariate Cox regression analyses, the clinical tumor size (hazard ratio [HR], 3.27; 95% confidence interval [CI], 1.05-10.18; P = 0.041), pathologic breast tumor response (HR, 1.82; 95% CI, 1.11-3.77; P = 0.046) and delivery of radiation therapy (HR, 1.27; 95% CI, 1.08-9.25; P = 0.047) were independent predictors of locoregional recurrence.

Conclusions: For patients who achieved pN0 after NAC, PMRT seemed to provide a clinical benefit for breast cancer patients with stage III disease. Omission of PMRT in patients with stage II disease did not increase the risk of locoregional recurrence and death.
Clinical and morphological results of neoadjuvant treatment with tumor necrosis factor-alpha-thymosin-alpha1 (TNF-T) of triple-negative locally advanced breast cancer patients

Background. There is a few data on tumor necrosis factor drugs used in neoadjuvant treatment in locally advanced breast cancer (LABC) patients but there is a clinical need to increase the efficiency of standard therapy and to gain complete regression which is of great importance for survival. The aim of the study was to evaluate the efficacy of recombinant hybrid protein of tumor necrosis factor-alpha-thymosin-alpha1 (TNF-T) in neoadjuvant treatment of triple-negative LABC (TN LABC).

Methods. Eligibility criteria included TN LABC of IIB-IIIB stages, ECOG ≤ 1, adequate liver, kidney and bone marrow function, no brain metastases. Recombinant hybrid protein of TNF-T 200000 IU was used peritumorally (injected around the tumor) on D1-5 (30 min before cytostatics injection), combined with standard FAC or PA regimens.

Results. 52 women were recruited between April 2012 – October 2013 (mean age 53.3±1.1 years). Group A (20 pts) received recombinant hybrid protein of TNF-T combined to PA (11) and FAC (9) up to 6 courses. Group B (32pts) received standard PA (18) and FAC (14). Tumor response (TR) in Group A was 80% and in Group B 71.9% (p<0.05), including CR 15% and 6.25% correspondingly (p<0.05). After neoadjuvant chemotherapy quantity of CD3+CD8+ cells in group A (PA) was significantly higher than in group B (PA) (31.5±2.8% and 21.7±2.25% correspondingly, p<0.05). Content of B-lymphocytes (CD20) decreased during the treatment in group B (from 15.5±0.53% to 13.7±0.55% (FAC) and from 16.7±0.97% to 12.7±1.0% (PA) correspondingly, p<0.05). CD20 level in group A after the treatment PA+TNF-T was 15.0±1.0%, after FAC+TNF-T was 15.4±1.4% which were different significantly from those in group B (p<0.05). Common toxicities in Group A were: neutropenia Gr1 – 15.9% courses, nausea and vomiting Gr2– 27.2%, polynueropathy Gr1/2 – 9%. TNF-T-specified toxicities were: hyperthermia Gr1 – 45.4%; local reaction (aula, pain) Gr1 lasted for 24-48 hrs – 90.9%. Group B: neutropenia Gr 1/2 – 21.2%, nausea and vomiting Gr2– 32.5%, polynueropathy Gr1/2 – 10.6%, diarrhea Gr1 – 4.5. All patients in Group A were operated successfully, no postoperative complications connected with recombinant hybrid protein of TNF-T use were observed. By the time of abstract submission OS in Group A was 28.4±1.1mos, in Group B was 26.1±1.4mos; EFS in Group A was 26.9±1.3mos, in Group B was 22.9±1.2mos (p<0.05).

Conclusions. TNF-T injected peritumorally is well-tolerated and allows to enhance an antitumor effect of cytostatics (pCR) which is of great importance for survival in TN LABC. The proposed method of the locally application of recombinant hybrid protein of TNF-T has mainly immunostimulant effect on CD3+CD8+ in patients with PA regimen. Recombinant TNF-T with PA and FAC has protected B-cell component of the immune system from immunosuppressive effect as well.
**2015 San Antonio Breast Cancer Symposium**

**Publication Number:** P1-14-20

**Title:** HER2 and estrogen receptor status drive decisions regarding the use of neoadjuvant chemotherapy

**Body: Background:** Neoadjuvant chemotherapy (NC) is widely utilized to facilitate breast-conserving surgery and is considered equivalent to adjuvant chemotherapy with regard to recurrence-free and overall survival. However, controversy exists about specific indications for NC and its effects on other outcomes, particularly related to surgery in the breast and axilla. Limited data are available about specific recommendations of breast cancer-focused clinical investigators (CI).

**Methods:** A 139-item survey was sent in May 2015 to 94 US-based surgical (S) and medical oncology (MO) CI from a proprietary database to assess their usual practice patterns. A modest honorarium was provided.

**Results:** The assessment was completed by 59 CI (28 S and 31 MO; 63% of those sent the survey). Most (86%) recommend NC to patients with estrogen receptor-negative/HER2-negative (ER-/HER2-) and HER2-positive (HER2+) tumors larger than 2 cm or with biopsy-proven axillary node involvement. For such patients with HER2+ tumors, MO routinely (98%) use pertuzumab (P) with trastuzumab (T) combined with NC — either paclitaxel (14%), docetaxel (7%), docetaxel/carboplatin (55%) or a taxane and doxorubicin (24%). For patients with these higher-risk HER2+ tumors not receiving NC, 52% of MO use P in the adjuvant setting, either during chemotherapy or continuing for a year. There was more heterogeneity and less use of NC in patients with ER-positive (ER+)/HER2- tumors, and 48% of MO use genomic profiling (generally the 21-gene Recurrence Score® to facilitate this decision. Globally, for the 36 defined scenarios that were evaluated, S were somewhat more likely to recommend NC (70%) than MO (63%). In terms of axillary management, S typically employ post-NC sentinel node biopsy (SNB; 82%) and only proceed to axillary dissection if the SNB is positive.

**Conclusions:** S and MO CI consider ER and HER2 (with tumor size and axillary node status) essential factors in NC decisions. In 2013, P (in combination with NC/T) became the first agent to receive FDA approval in the neoadjuvant setting in patients with HER2+ tumors, and it is now commonly used in both the adjuvant and neoadjuvant settings. The algorithms generated by this assessment will be helpful in educating community-based physicians, and as a result an online point-of-care tool to facilitate these decisions is being developed and evaluated.

Title: Predictive factors of pathologic complete response of HER2-positive breast cancer after preoperative chemotherapy with trastuzumab: Development of a specific predictor

Jankowski C, Guiu S, Cortet M, Hudry D, Arnould L, Charon-Barra C, Desmoulins I, Rouzier R, Fumoleau P, Coudert B, Reyal F and Coutant C. Georges Francois Leclerc Cancer Center, Dijon, France; Institut Régional du Cancer, Montpellier, France; Georges Francois Leclerc Cancer Center, Dijon, France; Georges Francois Leclerc Cancer Center, Dijon, France; Georges Francois Leclerc Cancer Center, Dijon, France; Georges Francois Leclerc Cancer Center, Dijon, France; Georges Francois Leclerc Cancer Center, Dijon, France; Institut Curie, Paris, France; Georges Francois Leclerc Cancer Center, Dijon, France; Georges Francois Leclerc Cancer Center, Dijon, France; Institut Curie, Paris, France and Georges Francois Leclerc Cancer Center, Dijon, France.

Body: Purpose: The aim of this study was to assess the M.D Anderson Cancer Center / Gustave Roussy Institute (MDACC/IGR) nomogram in predicting pathologic complete response (pCR) to preoperative chemotherapy in a cohort of HER2 tumors treated with preoperative chemotherapy with trastuzumab. Then, we combine clinical and pathological variable associated with pCR into a new nomogram specific of HER2 tumors treated by preoperative chemotherapy with trastuzumab.

Methods: Data from 270 patients treated with preoperative chemotherapy with trastuzumab at Curie Institute and at Georges Francois Leclerc Cancer Center were used to assess MDACC/IGR nomogram and then to develop a nomogram for pCR based on multivariate logistic regression. Model performance was quantified with respect to calibration and discrimination.

Results: The IGR/MDACC was not accurate to predicting pCR in HER2 tumors treated by preoperative chemotherapy with trastuzumab with poor discrimination (AUC=0.54, IC [0.51-0.58]) and poor calibration (p=0.01). After uni and multivariate analysis, the new pCR nomogram was based on T stage (TNM), hormonal receptor status, and ki67(%). The model had a good discrimination 0.74 (IC95% : [0.70-0.79]) and a good calibration (p=0.93).

Conclusion: To our knowledge, this is the first nomogram to predict pCR in HER2 tumors treated by preoperative chemotherapy with trastuzumab. To ensure exportability, the model need to be evaluate with a external validation set.
**Title:** Neo-adjuvant chemotherapy for the treatment of breast cancer exterts a selection pressure toward luminal phenotype

**Body:** The effect of anthracycline and taxane based chemotherapy on biological features of residual disease after neo-adjuvant therapies in breast cancer patients is poorly described.

**PATIENTS AND METHODS:** We collected information through the institutional clinical database on all consecutive breast cancer patients treated with neo-adjuvant chemotherapy at INT, Milan, Italy, between January 2010 and March 2015. We selected patients who did not achieve pathological complete response at final surgery. All patients had a pathological evaluation including the shrinking pattern (scattered or concentric); ER, PgR, HER2 and Ki-67 expression were evaluated both at diagnostic biopsy and at final surgery. McNemar's test was used to compare paired proportions.

**RESULTS:** We identified a total of 325 patients. Median age was 51 yrs (range: 23 - 85 yrs). 304 (93%) pts received anthracycline and taxane containing chemotherapy for a median number of 6 (range 2-18) cycles. Radical modified mastectomy was performed in 68% of cases. Scattered residual disease was diagnosed in 112 (34%) cases. HER2 over-expression in diagnostic biopsy was significantly associated to scattered response (OR 1.94, CI 1.13 – 3.36, p= 0.017). 11/220 pts (5%) with ER-positive diagnostic biopsy had ER-negative residual tumor; 9/54 pts (17%) with initial ER-negative tumors became ER-positive. 34/183 (19%) pts with initial positive PgR at diagnostic biopsy had PgR-negative residual tumor; whereas, 17/86 pts (20%) with negative PgR became positive. The HER2 expression changed from positive to negative in 9/49 (18%) cases and from negative to positive in 7/190 (4%) cases. The Ki-67 expression changed from > or =20% to <20% in 63/175 (36%) cases and vice-versa in 14/54 (26%) cases. Compared to diagnostic biopsy, the rate of PgR-positive tumors decreased from 68 to 62% (p= 0.024) and the rate of Ki67<20% tumors increased from 24 to 45% (p=<0.001) in surgical specimen. Subtype changes at surgery occurred in 37/245 (15%) of cases, i.e. none in triple negative, 8/20 (10%) in HER2 positive, and 29/202 (14%) in luminal tumors. 73% of cases that changed after treatment showed a trend towards luminal differentiation. There was no significant correlation between pre- and post-treatment biological characteristics and the type of tumor shrinkage.

**CONCLUSION:** Anthracycline and taxane-based neo-adjuvant chemotherapy induces loss of PgR and Ki-67 in breast cancer. These changes are independent of the pattern of tumor shrinkage. The subtype switching toward more luminal phenotype suggest an endocrine effect of chemotherapy and paves the way to possible combinatorial approach of chemo- and hormone-therapy.
Title: Adjuvant trastuzumab +/- anthracycline and cardiotoxicity in a community cohort of 962 HER2+ breast cancers from 2005-2011: Comparison of incidence by risk factors and by diagnostic codes vs clinical chart review

Fehrenbacher L, Capra A, Krishnaswami A, Quesenberry C and Habel L. Kaiser Permanente Medical Center Vallejo, Vallejo, CA; Division of Research, Kaiser Permanente, Northern California, Oakland, CA and Kaiser Permanente Medical Center, Santa Theresa, San Jose, CA.

Body: Background: Prospective clinical trials using clinical criteria and observational studies using diagnostic codes from electronic health records have reported seemingly contradictory cardiotoxicity risk for adjuvant trastuzumab (T). Accurate estimates of individualized patient specific cardiotoxicity risk are essential for treatment decisions in early HER2+ breast cancer (BC).

Methods: 1,109 consecutive non-metastatic HER2+ invasive BC's diagnosed 5/1/2005 to 12/31/2011 at Kaiser Permanente Northern California receiving adjuvant T were reviewed for symptomatic congestive heart failure (SxCHF), baseline and post-T cardiac ejection fraction (EF), anthracycline (A) use, and CHF risk factors (RF) including age, race, hypertension (HTN), diabetes (DM), obesity, smoking. Records of patients with CHF ICD9 codes or an EF drop to <50% were reviewed by a RN, a cardiologist, and an oncologist. Primary outcomes were SxCHF (NYHA Class II or higher), EF fall to <50%, and <38 weeks of T (75% of prescribed).

Results: Median age of 962 eligible patients was 54 years (range 24-95). 305 (31.7%) were > 60 years old. During a median follow-up of 4.1 years, 4.6% of patients had CHF ICD9 codes, but only 2.5% had SxCHF or cardiac death confirmed by clinical review. At 1 year, cumulative incidence of an EF fall to <50% was 5.7% with T alone and 17.7% with T+ A. A total of 15.3% finished <38 weeks of T, 9.4% with T alone and 20.6% with T+A. The overall 2- and 5-year cumulative incidence of SxCHF/cardiac death was low: 1.3% and 2.2% with T alone and 2.7% and 3.1% with T + A. These rates were lower than reports based solely on diagnostic or billing codes, and varied substantially by RF (see table). The rates were similar to those predicted by the NSABP B-31 Cardiac Risk Score. Clinical heart failure based on diagnostic codes was not confirmed at chart review 48% of the time. Results from multivariable analyses will be presented.

Conclusions: Risk of clinically confirmed CHF/cardiac death was substantially lower than risk based on ICD codes alone. Risk was consistent with prior clinical trials and differed substantially by age, baseline EF, use of A, and other CHF risk factors. Greatest risk was with age of 70+, borderline baseline EF, and comorbidities known to increase CHF risk. Quite low risk (1.1% at 5 years) was seen in patients under 60 years old.
Title: Gene expression profiling of doxorubicin cardiotoxicity in peripheral blood cells of breast cancer patients

Todorova VK K, Siegel ER R, Makhoul I, Marquette M, Wei JY Y and Klimberg VS. University of Arkansas for Medical Sciences, Little Rock, AR.

Body: **Background:** Doxorubicin (DOX), a widely used anti-cancer drug for treatment of breast cancer is known for its cardiotoxicity. DOX cardiotoxicity is cumulative-dose-dependent and begins with the first dose of chemotherapy. To date, no biomarker for early presymptomatic detection of DOX cardiotoxicity has been validated. Our previous data indicated that peripheral blood mononuclear cells (PBMCs) can be used as a surrogate tissue for identification of biomarkers for DOX cardiotoxicity. The aim of this study was to analyze PBMC gene expression induced by a single dose of DOX-based chemotherapy in breast cancer patients and correlated the data with DOX-induced cardiotoxicity.

**Materials and Methods.** Blood samples of 33 women treated for breast cancer with DOX-based chemotherapy were collected before the start and after the first cycle of chemotherapy. Total RNA was isolated from PBMC and whole-genome gene expression was performed using Illumina HumanHT-12 v4 Expression BeadChip array. Gene expression data were log2 – transformed and gene transcripts with average log2-intensities > 7 were considered to be expressed. The group-specific means were analyzed via repeated-measures with ANOVA for expression changes after DOX. Genes with p-value<0.05 were considered differentially expressed. Cardiac function was assessed before and after the completion of chemotherapy by echocardiogram and/or multigated acquisition scan. An absolute decrease of left ventricle ejection fraction >10% or <55% was considered abnormal. Differentially expressed genes (DEG) of patients who developed abnormal LVEF decrease were compared with DEG of patients who did not.

**Results.** A single dose of DOX-based chemotherapy resulted in 235 DEG in PBMC (P<0.05, FDR<0.05), mapped to cell death, oxygen transport and iron ion binding. Further analysis identified 87 DEG in the PBMC of eight (n=8) women who developed abnormal decline in LVEF from the baseline in comparison with women who did not (n=25). Most of the 87 DEG encode proteins secreted by activated neutrophils, such as alpha-defensins, arginase, cathepsin G, elastase, haptoglobin. The functional analysis of the 87 DEG showed enrichment for inflammatory response, immune response, cell death and peptidase activity.

**Discussion.** The results from this study indicated that elevated neutrophil-associated transcripts in the early stages of DOX-based chemotherapy were independent of the neutrophil count. These data suggest an association between the neutrophils activation after a single dose of DOX-based chemotherapy and later impairment of cardiac function. The early PBMC transcriptome signature can be used in the future development of biomarkers for DOX-associated cardiotoxicity.
**Title:** Prevention of letrozole–induced bone loss using risedronate in postmenopausal women with hormone receptor positive breast cancer: A multicenter randomized clinical trial

Kadoya T, Masumoto N, Shigematsu H, Emi A, Kajitani K, Kobayashi Y, Funakoshi M, Kawabuchi Y, Ohara M, Matsuura K, Noma M, Sasada T and Okada M. Research Institute for Radiation Biology and Medicine, Hiroshima University, Hiroshima, Japan; Hiroshima City Asa Citizens Hospital, Hiroshima, Japan; Hiroshima General Hospital, Hatsukaichi, Japan; Hiroshima Prefectural Hospital, Hiroshima, Japan and Onomichi General Hospital, Onomichi, Japan.

**Body**

**Background**
Prevention of letrozole–induced bone loss using oral risedronate has not been proved in the Japanese women. The aim of this study was to assess the effect of risedronate 17.5mg/week on bone mineral density (BMD) in postmenopausal, early breast cancer patients scheduled to receive adjuvant letrozole.

**Patients and Methods**
Postmenopausal women with hormone receptor–positive early breast cancer were assigned to one of two strata according to their baseline BMD T-score as being at low and high risk of osteoporosis. Patients with low risk (-2.5 ≤ T score) were randomly assigned to letrozole and risedronate (L+R) or to letrozole alone (L). Patients with high risk (-2.5 > T score) received letrozole and risedronate (L+R). Letrozole was given at a dosage of 2.5 mg/day while oral risedronate was given at 17.5mg/week. The primary end point was the change in lumbar spine (LS) BMD at 12 months. The secondary end points included change in total hip (HP) BMD and bone turnover markers.

**Results**
In the low risk group (N=103), treatment with L+R resulted in a significant increase in BMD at LS and at HP compared to treatment with L only at 12 months (1.8% vs -2.2%, P < 0.001, and -0.3% vs -2.9%, P = 0.001, respectively). In the L+R group, significant decreases in bone turnover makers, NTX and PINP, were recognized compared with L only at 12months (-11.1% vs. 27.5%, P<0.001, -42.3% vs. 15.2%, P<0.001, respectively). In the high risk group (N=28), treatment with L+R resulted in a significant increase in BMD at LS and prevention of decrease in BMD at HP (3.6%; 95%CI, 1.8% to 5.3%, p=0.003, 0.3%; 95%CI, -1.3% to 1.8%, p=0.47, respectively).

**Estimated Percentage Change From Baseline to 6 and 12 Months in Lumbar Spine and Total Hip BMD**

BMD: bone mineral density, L: Letrozole, R: risedronate

Four patients (14.3%) improved from osteoporotic region to the osteopenic region with L+R treatment. Letrozole and risedronate were well tolerable and there was no serious adverse event including osteonecrosis of jaw.

**Conclusions**
At 12 months, 17.5mg/week risedronate therapy prevented bone loss in postmenopausal women with breast cancer who were receiving adjuvant letrozole, of which results were compatible with previous findings of western populations.
Title: Irrversible chemotherapy-induced alopecia in breast cancer patient

Kim S, Park HS, Kim JY, Nam S, Kim GM, Sohn JH and Kim SI. Yonsei University College of Medicine, Seoul, Republic of Korea and Yonsei University College of Medicine, Seoul, Republic of Korea.

Body: Introduction
Patients with breast cancer who received chemotherapy have distressing side effects such as mucositis, alopecia, gastritis, and BM suppression. Chemotherapy-induced alopecia (CIA) is one of considerable psychological events in self-esteem in patients with breast cancer, but the possibility of irreversible alopecia is often overlooked by physician.

We investigated clinical characteristics of CIA and prevalence of irreversible severe hair loss in patient with breast cancer who received chemotherapy.

Methods
We conducted a survey to collect demographic information about CIA with 150 breast cancer patients who had passed at least 6 months since their last day of chemotherapy from February 2015 to May 2015 in Yonsei Cancer Center. We obtained clinical information as age, elapsed time from end of chemotherapy, chemotherapy regimen, and other adjuvant therapy using their electrical medical records. We compared irreversible CIA characters between anthracycline and cyclophosphamide (AC) and taxane based regimen groups. The severe alopecia was defined as the hair density loss over 50% compared to the hair density before chemotherapy.

Results
The mean age at chemotherapy was 48 years old (±17.3) and the mean elapsed time after chemotherapy was 37 months (±9.5) in total patients.

Remnant alopecia was reported in 71 patients (47.3%). Wig or hat were used in 39 patients (26.0%).

The mean satisfaction score with a five-point scale was 4 in patients without alopecia or hair character change and 2.2 in patients with irreversible alopecia (p<0.001). The severe irreversible hair loss was complained by the 12 (8.2%) patients.

AC and taxane based chemotherapy were carried out in 65 and 85 patients, respectively. In AC group, remnant alopecia was shown in 18 patients (27.7%), and more than a half of patients in taxane group, 53 patients (62.4%), showed remnant alopecia (p<0.001). While only five patients (7.8%) in AC group suffered for severe hair loss, 26 patients (31.3%) in taxane group were affected by severe hair loss (p=0.001). The mean satisfaction level of hair status in patients in taxane group was 2.5 as compared to 3.6 in those in AC group (p<0.001).

Conclusion
Contrary to general expectation, About a half of breast cancer patients who received chemotherapy complained of irreversible hair loss even though at least 6 months has elapsed since the end of chemotherapy. In particular, patients with taxane based chemotherapy had more irreversible and severe alopecia than those with AC chemotherapy.
Title: Predictors of chemotherapy-induced peripheral neuropathy among breast cancer patients treated with taxanes

Candelario N, Wongrakpanich S and Morginstin M. Internal Medicine, Einstein Medical Center, Philadelphia, PA and Division of Hematology and Oncology, Einstein Medical Center, Philadelphia, PA.

Body: Background
Breast cancer is one of the most common types of cancer. Taxanes are approved in various treatment algorithms for both early and metastatic breast cancer. Chemotherapy-induced peripheral neuropathy (CIPN) is the most common dose-limiting side effect of the taxanes. This side effect is debilitating and could alter the treatment and patients' quality of life. This study aims to assess the predictors in the development and severity of CIPN.

Methods
A retrospective chart review of 229 stage I to IV breast cancer patients was done to identify if age, BMI, race, smoking history, alcohol use, diabetes, chronic kidney disease, estrogen and progesterone receptor and HER2 status, type and dose of taxane (Docetaxel or Paclitaxel) were predictors in the development and severity of CIPN. Severity of peripheral neuropathy was graded from 1 to 4 based on the common terminology of adverse events for peripheral neuropathy. Pearson Chi-square and T-test were done to see if there was a statistical difference in the development and severity of peripheral neuropathy among the above predictors. Odds ratio was computed using a logistic regression analysis for the predictors that showed statistical difference from the initial analysis.

Results: Among the 229 patients in this study, 158 patients (69%) developed neuropathy with 90 patients (57%) having grade 1 neuropathy and 25 (15.8%) suffering from grade 3 neuropathy. Majority of the subjects included in this study were African American (75.1%). Age, BMI, race, smoking, alcohol use, chronic kidney disease and diabetes did not show any statistical significance as predictors of development and severity of CIPN (p > 0.05, 95% CI). There was a significant difference in the development of neuropathy in terms of estrogen and progesterone receptor status (p=0.014). On logistic regression analysis, patients with ER+/PR- and ER+/PR+ had lower odds of developing neuropathy with OR 0.36 (p= 0.006, 95% CI 0.17-0.75) and 0.44 (p=0.026, 95% CI 0.21-0.91) respectively. HER2 positivity was associated with higher chances of neuropathy (OR 2.11, p=0.028, 95% CI 1.09-4.11). Paclitaxel was associated with higher chances of neuropathy compared to docetaxel (OR 2.89, p= 0.02, 95% CI 1.49-5.59). Dose of paclitaxel did not show any difference in the occurrence of CIPN. Those treated with paclitaxel had more severe neuropathy (p= 0.04).

CIPN: Chemotherapy Induced Peripheral Neuropathy; ER: Estrogen Receptor; PR: Progesterone Receptor
Conclusion: Breast cancer patients with ER+ and PR+ have lower chances of developing CIPN. HER2 positivity increases the odds of developing neuropathy. Paclitaxel is more neurotoxic than docetaxel though a dose-dependent risk was not seen in this study. Age, race, body mass index, smoking, alcohol use, diabetes and chronic kidney disease were not predictors in the development and severity of chemotherapy induced peripheral neuropathy.
Title: Evaluation of miracle mouthwash (MMW) plus hydrocortisone versus prednisolone mouth rinses as prophylaxis for everolimus-associated stomatitis: Preliminary results of a randomized phase II study

Jones VL L, Jensen LL L, McIntyre KJ J, Oommen SP P, Patt DA A, Cortas TE E, Harris RP P, Wilks ST T, Fox P and O'Shaughnessy JA A. US Oncology Research, Inc., The Woodlands, TX; Yakima Valley Memorial Hospital/North Star Lodge, Yakima, WA; Rocky Mountain Cancer Centers, LLP, Boulder, CO; Texas Oncology - Dallas Presbyterian Hospital, Dallas, TX; Texas Oncology - Fort Worth 12th Ave., Fort Worth, TX; Texas Oncology - Austin Central, Austin, TX; Arizona Oncology Associates, PC - HAL, Phoenix, AZ; Broome Oncology, LLC, Johnson City, NY; Cancer Care Centers of South Texas, San Antonio, TX; McKesson Specialty Health, Inc., The Woodlands, TX and Texas Oncology - Baylor Charles A. Sammons Cancer Center, Dallas, TX.

Body: Background: Oral stomatitis is a frequent adverse event (AE) associated with mTOR-inhibitor therapy, and can impact treatment adherence. In the BOLERO-2 trial in patients (pts) with hormone receptor-positive (HR+) metastatic breast cancer (MBC) treated with exemestane (EXE) plus everolimus (EVE), the incidence of all-grade stomatitis or related AEs was 67%, with 24% and 8% of pts developing Grade (G) 2 and G3 stomatitis or related AEs, respectively (Perez et al ASCO 2013 Abst 7029). In BOLERO-2, 24% of pts required EVE dose reduction for stomatitis (Rugo et al Ann Oncol 2014;25:808). The current study evaluated 2 different steroid-based mouth rinses for the prevention or amelioration of oral stomatitis in pts with MBC treated with EVE.

Methods: This prospective randomized phase II study enrolled postmenopausal pts (planned accrual=100) with HR+ MBC within the US Oncology Network who were initiating therapy with an aromatase inhibitor plus EVE (10 mg/day). Eligible pts were randomized, blinded, 1:1 to prophylactic treatment with 1 of 2 oral rinses (ARM 1: MMW 480 ml recipe: 320 mL oral Benadryl, 2 g Tetracycline, 80 mg Hydrocortisone, 40 mL Nystatin suspension, water; or ARM 2: Prednisolone 15mg/5mL oral solution). Pts were instructed to swish/expectorate 10 ml of the assigned rinse 4 x daily starting with Day 1 of EVE treatment, for a total of 12 wks. The primary objective was to determine the incidence of G≥2 stomatitis during the first 12 wks of treatment. Secondary objectives included assessment of AEs (all grades), determination of the percentage of pts requiring dose interruption and/or dose reduction of EVE or discontinuation of therapy due to toxicity, and evaluation of the impact of the oral rinses on the duration and severity of stomatitis.

Results: As of April 16, 2015, a total of 48 pts have been randomized and 47 pts have received treatment, with a mean time on mouth rinse of 68 days (range 2-84 days). Median age was 65 yrs (range 31-82 yrs). Twelve patients developed an oral AE and the incidence of all-grade stomatitis was 25% (n=12/48). The incidence of G1 stomatitis was 17% (8/48), G2 stomatitis was 8% (4/48) and there were no G3 events. The 4 G2 stomatitis AEs occurred within the first 30 days of treatment. One pt (1/48; 2%) required EVE dose delay. One pt developed oral candidiasis while on the steroid mouth rinse and no pts have stopped the steroid mouth rinse therapy due to mouth rinse-related toxicity.

Conclusion: These preliminary data are the first from a prospective trial to provide evidence of a reduced incidence of mTOR-associated stomatitis with prophylactic use of a steroid mouth rinse. The 25% incidence of all-grade and 8%/0% incidence of G2/3 stomatitis compare favorably with the 67% and 24%/8% incidence of all-grade and G2/3 stomatitis, respectively, in BOLERO-2. These preliminary data also demonstrated the safety and tolerability of these 2 steroid mouth rinses. The incidence of stomatitis on each study arm will be available when accrual is completed. The prophylactic use of steroid mouth rinses substantially decreases the incidence of G2/3 stomatitis and the need for EVE dose interruption/reduction.
The neuroprotective aminopropyl carbazole, P7C3-A20, prevents paclitaxel-induced pain

LoCoco PM M, Rissing AL L, Mooberry SL L, Berg KA A and Clarke WP P. University of Texas Health Science Center at San Antonio, San Antonio, TX.

Body: Paclitaxel (PTX), a microtubule-targeting anticancer agent, produces a debilitating peripheral neuropathy that is accompanied by neuropathic pain. Currently, there are only marginally effective therapeutic interventions available. Consequently, patients are forced to reduce or discontinue life-saving chemotherapy to cope with the pain. Recently, a newly identified agent, P7C3-A20, was found to be protective in several models of neurodegeneration, including Parkinson's disease and traumatic brain injury. Given that PTX triggers progressive degeneration of peripheral afferent neurons, this study was performed to evaluate the potential neuroprotective efficacy of P7C3-A20 in rodent models of PTX-induced peripheral neuropathy. P7C3-A20 (10 mg/kg) or vehicle (Cremophor EL/DMSO/5% Dextrose; 1:1:3) was administered intraperitoneally (i.p.) to Sprague-Dawley rats (250-300 g) everyday over a 28-day experimental paradigm. Following two days of treatment with P7C3-A20 or vehicle, rats also received 3 injections of PTX (11.7 mg/kg, i.p.) or vehicle (Cremophor EL/DMSO/5% Dextrose; i.p.) administered every other day. Treatment with P7C3-A20 did not alter body weights or leukocyte counts in control or PTX-treated rats. PTX treatment increased sensitivity to mechanical and cold stimulation (allodynia) of the hindpaw, evidence of peripheral neuropathy. Notably, P7C3-A20 treatment prevented the development of allodynia in response to PTX. Immunohistochemical analysis of paw biopsies indicated that P7C3-A20 prevented PTX-mediated degeneration of terminal nerve endings. Collectively, these data suggest that P7C3-A30 prevented the neurotoxic effects of PTX on peripheral sensory neurons. A xenograft tumor model of triple negative breast cancer was then used to determine whether P7C3-A20 diminished the antitumoral efficacy of PTX. MDA-MB-231 tumors were bilaterally implanted into flanks of female athymic nude mice and allowed to grow for 3 weeks prior to treatment. Using the same treatment protocol as the rats, tumor-bearing mice received daily treatment with P7C3-A20 (20 mg/kg, i.p.) or vehicle for 16 days. P7C3-A20 did not alter PTX-mediated inhibition of tumor growth. Furthermore, P7C3-A20 prevented PTX-induced mechanical allodynia in the mice. Taken together, this work indicates that P7C3-A20 prevents PTX-induced neuropathic damage without diminishing its antitumoral efficacy. P7C3-A20 may be an exciting new candidate to prevent peripheral neuropathy in patients undergoing cancer treatment with PTX.
Body: Introduction: About 5-10% of newly diagnosed breast cancers present with de novo metastatic disease. Clinicians are increasingly faced with the dilemma of how to manage a primary tumor that may produce physical and emotional discomfort in the setting of stable distant disease. Lack of outcome data for primary local therapy (PLT) in locally advanced metastatic breast cancer (LAMBC) makes patient counseling difficult. We conducted a population-based analysis of morbidity of PLT among older women with LAMBC. Methods: Patients with de novo LAMBC (T4M1) diagnosed between 2005 and 2009 were identified in the Surveillance, Epidemiology, and End Results (SEER)-Medicare database. Rates of treatment-related complications seen within 1 year of diagnosis and overall 1-year survival were analyzed. Complications were identified using ICD 9 codes (table 1). Results: Among 5,111 patients with LAMBC most did not have PLT (N=3699, 72%). PLT included surgery (N=656, 13%), radiation (N=542, 11%), and both surgery and radiation (N=214, 4%). The most common surgeries were modified radical mastectomy (N=558, 53%) and total mastectomy (N=207, 20%). Complication rates differed significantly by type of PLT, with highest rates seen in patients who had surgery plus radiation.

. Patients who did not have PLT had a complication rate of 9.8%. Cancer-related pain was the most frequent complication, with
patients who had surgery and radiation and radiation alone having higher rates of it (13%) vs. surgery only and no intervention (4% each, p<0.0001). One-year survival was higher in patients who had surgery and radiation (87%), surgery only (74%), and radiation only (69%) vs. no intervention (51%) (p<0.0001). **Conclusions:** Few LAMBC patients who did not undergo PLT had local complications, suggesting a low burden of discomfort from untreated local disease. Women who had both surgery and radiation were found to have the highest complication rates and the highest 1-year overall survival. These results should be interpreted with caution, as patients having PLT are likely to be a highly selected group. Prospective data to inform these patients' management are required.
Title: Efficacy of hyaluronidase for treatment of chronic lymphedema

Kim W and Kim W. Haeundae Paik Hospital, Inje University College of Medicine, Busan, Korea and Haeundae Paik Hospital, Inje University College of Medicine, Busan, Korea.

Body: Current management of lymphedema is based on complex decongestive therapy (CDT), including manual lymph drainage, low-stretch bandaging, exercises and skin care. CDT may be insufficient for achieving efficacious volume reduction in chronic status of secondary lymphedema. Concentration of hyaluronic acid (HA) in the tissue of lymphedematous limb is 8 times higher, and use of hyaluronidase may improve lymphatic flow by reducing HA concentration, thus reducing edema volume. However, its efficacy for treatment of secondary lymphedema has not been studied sufficiently due to impurities such as other animal derived protein ingredients, which may cause allergic reactions, and even anaphylactic shock. The objective is to study the effects of Hirax®, highly purified solutional hyaluronidase, for treatment of chronic secondary lymphedema.

100 secondary lymphedema patients in maintenance phase without change in limb volume after CDT were recruited and randomized into two groups, G1 (CPT+injection, n=50) and G1 (CPT, n=50). Selection of injection sites were based on the findings of lymphscintigraphy and circumferential difference. Injection was performed twice, day 1 and day 4 (72hours from initial injection). Limb volume was measured and compared using the Casley-Smith truncated formula. Intragroup and intergroup difference in volume of affected limb (VLΔ), percent excess volume (PEVΔ) and percent reduction of excess volume (PREVΔ) at pre-, post 1 and post 2 were compared using t-test.

The VLΔ between the two groups revealed significant change at both post 1 and post 2 (p = 0.014, p = 0.004) The PEV difference (PEVΔ) within each group revealed significant change in G2 between post 1 and post 2 (p <0.001). The PEVΔ between the two groups revealed significant difference at both post 1 and post 2 (p <0.001, p <0.001). The PREV difference between the two groups also revealed greater PREV in G1 and significant differences at post 1 and post 2 (p <0.001, p <0.001).

We found highly purified solutional hyaluronidase, Hirax® injection in chronic secondary lymphedema patients in maintenance phase to be a useful adjunct for reducing lymphedema volume. Further studies with larger number patients as well as long term follow up evaluation on effectiveness and safety is needed in the future.
Title: Quantitative versus semi-quantitative assessments of radiation-induced pulmonary fibrosis post adjuvant breast radiotherapy

Pramana A, Browne L, Cox H, Saba A, Pham K, Trakis S, Crawford K, Hall M, Batchelor N, Lim J and Graham P. St George Cancer Care Centre, Sydney, NSW, Australia; St George Hospital, Sydney, NSW, Australia and The University of New South Wales, Sydney, NSW, Australia.

Objective
To evaluate the quantitative versus semi-quantitative assessments of radiation induced pulmonary fibrosis (RIPF) post adjuvant breast radiotherapy (RT).

Methods
High resolution computed tomography (HRCT) assessed lung physical density changes (CTD) and physician identified HRCT visual grading scores (CTS) were analysed at the minimum of 12 months post RT at one institution. The treated side in-portal lung regions for CTD and CTS assessments were: central-axis (CA) + regions 5cm superior & inferior to CA and the corresponding mid anterolateral region respectively. Respiratory motion was accounted for by subtracting the untreated side lung density from the treated side. Mean lung densities correspond to each voxels were automatically calculated by Pinnacle software (Phillips, Eindhoven, The-Netherlands). Grading of CTS was according to the RTOG/EORTC (grade 0, 1, 2, and 3 defined as none, slight, patchy, and dense HRCT appearance respectively) and analysed by a radiologist (JL) and re-checked a radiation oncologist (PG).

Results
Total numbers of 403 patients were analysed. A substantial association was verified between CTD and CTS assessment. An increase of $\sim 0.01$ g/ml (95% CI 0.003-0.02) in CTD with each CTS score increase of 1 was observed (Table-1a). The RIPF can be categorised quantitatively into three groups of CTS 0 vs. 1-2 vs. 3 based on the mean CTD (Table-1b).

A cut off CTD of 0.089 g/ml exemplified the best compromise between sensitivity (100%) and specificity (88.2%) for dense HRCT appearance. However, there was no good compromise of CTD cut off for slight and patchy HRCT score possibly due to intra observer variation and the scale of the CTD measure (small increase in CTD may not be detected visually by the observer). Multivariable analysis revealed increasing age, current smoker, V20 $\geq 10\%$ (the volume of lung that was covered by the 20Gy
isodose line), central lung distance $\geq 2\text{cm}$ (the distance between posterior RT tangents and the chest wall), combined endocrine & chemotherapy, and treated side mean CTD to be significantly associated with development of grade $\geq 1\text{RIPF}$.

Conclusions
There was a good correlation between quantitative (CTD) and semi-quantitative (CTS) assessment of RIPF post adjuvant breast RT. The CTD method could be advantageous for both routine clinical practice and future clinical trials that require more detailed quantification of dense RIPF.
Title: First-line chemotherapy for breast cancer patients by site of care (SOC): Treatment patterns, cost and quality indicators

Body: Background: Previous studies found differences in treatment patterns and costs by SOC for first-line chemotherapy treatment for both early stage and metastatic breast cancer (esBC and mBC) in commercial populations. This study extends the research to a predominantly Medicare population comparing chemotherapy treatment patterns, cost and quality of care in physician office (PO) and hospital outpatient (HO) centers.

Methods: First-line chemotherapy or biologic therapy for esBC and mBC patients was compared by SOC. Patients initiating infusion therapy in 2008–2012 were identified in Humana medical claims data. First-line length of therapy (LOT) in days and number of infusions (NI) were calculated. SOC cohort (HO vs PO) was based on where the patient received ≥90% of their infusions. Total healthcare costs based on medical and pharmacy claims were assessed. Differences in quality indicators, use of infusions or hospitalizations 30 days prior to death were evaluated. SOC differences were assessed using \( \chi^2 \), T-tests and Wilcoxon Rank Sum (Wil) tests. P-values are for \( \chi^2 \) and Wil tests. Cost-related results are from generalized linear models adjusted for age, sex, comorbidity and geographic region. LOT and NI are presented as median (IQR).

Results: A total of 2,784 esBC patients (73% PO and 27% HO) and 1,602 mBC patients (64% PO and 36% HO) were identified. Most patients (67%) were Medicare beneficiaries. Mean comorbidity index was similar by SOC for esBC patients (PO 4.2, HO 4.1, \( p=0.3308 \)) but higher in HO for mBC patients (PO 7.5, HO 7.9, \( p=0.0003 \)). LOT in days for esBC was greater in the PO for anthracycline-based therapy, PO 64(43-72), HO 47(43-64), \( p=0.0420 \) and taxane-based therapy, PO 64(64-106), HO 64(64-76), \( p=0.0005 \). NI for esBC was greater in the PO for patients on biologic and cytotoxic therapy, PO 21(17-29), HO 18(16-25), \( p=0.038 \) and taxane-based therapy PO 4(4-6), HO 4(4-4), \( p=0.0005 \).

No difference in LOT by SOC was seen for mBC patients; however, patients on taxane-based therapy had a greater NI at the PO 6(4-12) vs HO 5.5(4-9), \( p=0.0225 \).

Total healthcare costs were higher in the HO vs PO setting for esBC and mBC patients. Costs were 22% higher in the HO $51,191 vs PO $41,943, \( p<0.0001 \) for esBC patients and 17% higher in the HO $58,105 vs PO $49,591, \( p<0.0001 \) for mBC patients.

Conclusion: Differences by site of care, particularly in healthcare costs, were found in a mostly Medicare population of esBC and mBC patients. Patients in the HO setting had shorter length of therapy and fewer infusions, but had higher total healthcare costs than those in the PO setting. Quality indicators, infusions and hospitalizations prior to death were similar by site of care. Future research will focus on other quality indicators and patient satisfaction.
Body: Background: Fulvestrant (FUL), an estrogen receptor (ER) antagonist, is an effective treatment for patients (pts) with hormone receptor-positive (HR+) breast cancer (BC) whose disease has progressed or recurred during previous anti-estrogen therapy. The androgen receptor (AR), expressed in the majority of HR+ BC, may contribute to resistance to hormonal therapy. Enzalutamide (ENZA) is a potent inhibitor of AR signaling. Preclinical models with ER+/AR+ BC cell lines showed synergistic inhibitory effects for ENZA combined with FUL on tumor cell growth. ENZA is a potent CYP3A4 inducer, and in vitro studies show that CYP3A4 is the only CYP enzyme involved in the oxidative metabolism of FUL. In this phase 1 trial (NCT01597193), we evaluated the potential for ENZA to affect FUL pharmacokinetics (PK), as well as the safety and tolerability of the combination of ENZA with FUL.

Methods: Postmenopausal pts with HR+/AR+ advanced BC were enrolled; any number of prior therapies were permissible. Tumor tissue was analyzed centrally for AR expression; pts who had ≥10% tumor cells with nuclear AR staining were eligible. All pts received at least 3 doses of FUL (500 mg intramuscularly on days 1, 15, and 29 and once monthly thereafter) to ensure steady-state concentrations prior to initiating ENZA 160 mg/day orally. The combination of ENZA with FUL was given until disease progression. PK and hormone sampling occurred on day 1 prior to ENZA initiation and on days 29 and 57. All pts were monitored for safety and response to treatment.

Results: As of 01May2015, 11 pts were enrolled; PK data are available for 8 of 11 pts, and 6 pts remain on study. Median age was 59 years; median ECOG performance status was 1. Two pts previously received FUL as a prior therapy for advanced BC; 4 pts received no prior therapy for advanced BC. The median duration of exposure to the combination was 16.6 weeks (range 4.0-42.3); the median duration of exposure to FUL (including at least 3 preloading doses) was 24.4 weeks (range 11.7-67.3). Common (>2 pts) ENZA-related adverse events (AEs) included fatigue (n=6), nausea (n=5), cognitive disorder (n=4) and diarrhea (n=3). Cognitive changes Grade 1/2 were reported in 4 pts based on the cognitive function assessment questionnaire. Two pts reported unrelated serious AEs (erosive gastritis, urinary tract infection, iron deficiency anemia, and dehydration). Four pts had AEs ≥ Grade 3: hypertension, anemia, hyperglycemia, urinary tract infection, asthenia, erosive gastritis, dehydration, and iron deficiency anemia; only asthenia and hypertension were considered treatment-related. Circulating levels of estradiol and estrone were within the expected range. Trough plasma concentrations of FUL (C_{min}) were similar for FUL alone and FUL combined with ENZA (C_{min}=13.7 ± 2.8 and 12.5 ± 1.8 ng/mL, respectively).

Conclusions: The safety profile for the combination of daily ENZA with FUL appears to be consistent with the published data for ENZA and FUL monotherapies. ENZA with FUL achieves similar plasma exposure to FUL alone, indicating no PK drug interaction.

Title: Luteolin inhibits progestin-dependent VEGF induction, stem-cell like characteristics, and tumor progression of human breast cancer cells

Hyder SM M, Cook MT T, Besch-Williford C and Liang Y. University of Missouri, Columbia, MO and IDEXX BioResearch, Columbia, MO.

Body: Clinical trials and epidemiological evidence show that combined estrogen (E) and progestin (P) hormone replacement therapy (HRT) increases the risk of breast cancer in postmenopausal women, whereas HRT containing E alone does not. Tumor progression is dependent on angiogenesis, which provides nutrients vital to the developing cancer. We previously showed, both in vitro and in vivo, that natural and synthetic P (including the widely used progestin Medroxyprogesterone acetate, MPA), increase production of vascular endothelial growth factor (VEGF), a potent angiogenic factor, in human breast cancer cells (Cancer Res., 1998, 58:392). This effect is blocked by the anti-progestin RU-486, suggesting involvement of progesterone receptors in the process (Int J Cancer, 2001, 92:469). Evidence from our laboratory using in vivo breast cancer models suggests that P accelerates the development of tumors from latent tumorigenic cells. This leads to the formation of palpable tumors and tumor metastasis, processes that may be attributed to increased production of VEGF (Cancer Res., 2007, 67:9929; Menopause, 2010, 17:1040). RU-486 blocks P-dependent VEGF production and thereby reduces tumor growth; however, the anti-progestin has severe side-effects averting its long-term use. Recently, we have studied less toxic naturally-occurring compounds for their ability to antagonize P-dependent VEGF induction and block tumor progression. In this study, we tested the effects of luteolin, a flavonoid commonly found in fruits and vegetables, on proliferation of BT-474 and T47-D breast cancer cells and their P-dependent production of VEGF. Luteolin treatment (25-100 µM) for 24-48 h reduced in vitro tumor cell viability and induced apoptosis. Interestingly, treatment with a lower concentration of luteolin (10 µM) blocked the production of P-dependent VEGF, indicating that VEGF suppression precedes luteolin-mediated loss of cell viability. Furthermore, luteolin (20 mg/kg, i.p.) suppressed the growth of MPA-dependent T47-D human xenograft tumors in nude mice. Immunohistochemical analysis showed that luteolin reduced P-induced VEGF in tumor sections (p<0.05). These findings strongly suggest that the flavonoid disrupts tumor progression by blocking P-dependent angiogenesis and preventing tumor cell proliferation. Furthermore, luteolin blocked the MPA-induced acquisition of stem cell like properties by breast cancer cells; CD44 expression, ALDH activity and mammosphere formation were all reduced by the flavonoid. We contend therefore that luteolin is a compound with valuable therapeutic properties. Its ability to reduce levels of VEGF, coupled with its capacity to interfere with the acquisition of stem-cell like properties by breast cancer cells, make luteolin a compound with significant clinical potential in the battle against P-dependent human breast cancer.

Supported by a COR award from the College of Veterinary Medicine and in part by funds from generous donors to the Ellis Fischel Cancer Center, University of Missouri.
Title: Pharmacogenomics-pharmacokinetics study of selective estrogen-receptor modulators with intra-patient dose-escalation for Japanese breast cancer patients

Ohno S, Ishiguro H, Yamamoto Y, Takao S, Sato N, Fujisawa T, Kadoya T, Kuroi K, Bando H, Teramura Y, Iwata H, Tanaka S and Toi M. The Cancer Institute Hospital Of JFCR, Tokyo, Japan; Graduate School of Medicine Kyoto University, Kyoto, Japan; Graduate School of Medical Sciences, Kumamoto University, Kumamoto, Japan; Hyogo Cancer Center, Akashi, Hyogo, Japan; Niigata Cancer Center Hospital, Niigata, Japan; Gunma Prefectural Cancer Center, Ohta, Gunma, Japan; Hiroshima University Hospital, Hiroshima, Japan; Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo, Japan; University of Tsukuba, Tsukuba, Ibaraki, Japan; Hikone Municipal Hospital, Hikone, Shiga, Japan; Aichi Cancer Center Hospital, Nagoya, Aichi, Japan and Graduate School of Medicine and Public Health, Kyoto University, Kyoto, Japan.

Body: Background
The association between CYP2D6 polymorphisms and efficacy of tamoxifen (TAM) is inconclusive, partly due to inaccurate prediction of active metabolite, endoxifen exposure by solely CYP2D6 genotype. Moreover, TAM dose escalation is not effective for poor metabolizers. Since the contribution of CYP2D6 to toremifene (TOR) activation is small, TOR might be a good alternative to TAM for poor metabolizers.

Methods
Patients who maintained good compliance with TAM or TOR without regular use of strong CYP2D6 inhibitors were enrolled in a screening study. The pharmacokinetics (PK) of TAM or TOR and the pharmacogenomics (PGx) of metabolizing enzymes and transporters were assessed. Associations between TAM and TOR PK and PGx, other CYP inhibitor use, and smoking status were examined by regression analysis. An intra-patient dose escalation study was conducted for patients showing low endoxifen levels during TAM treatment (n = 14). TAM was switched to 40 mg of TOR, and then increased to 120 mg for ≥24 weeks with periodic PK sampling. Total TAM or TOR activity was calculated as the sum of the concentration of each active metabolite adjusted by their respective in vitro activity.

Results
CYP2D6 genotype was the major determinant for TAM activity (p < 0.01) for Japanese breast cancer patients. Current smoking status (p = 0.07) and CYP2C19 (p = 0.07), but not CYP2D6 genotype (p = 0.61), showed marginally significant effects on TOR activity. TOR activity sufficiently increased with dose escalation from 40 mg to 120 mg, even among the poor TAM metabolizers, and was maintained for ≥24 weeks.

Total Activity of TOR (ng/mL)

*(Sample taken at ≥24 weeks)*

Conclusion
Since the contribution of CYP2D6 to TOR metabolism is relatively small, TOR is a valid alternative to TAM, especially in patients predicted to be poor TAM metabolizers. Further clinical trials are warranted to validate this concept.
Title: Inhibition of β-catenin pathway to overcome endocrine resistance in breast cancer

Won HS, Lee KE, Lee KM, Nam EM, Mun Y-C, Seong C-M and Lee SN. Uijeongbu St. Mary’s Hospital, The Catholic University of Korea, Gyeongg-do, Korea and School of Medicine, Ewha Womans University, Seoul, Korea.

Body: Background: It is well known that Wnt/β-catenin signaling pathway is involved in hormone receptor negative breast cancer, especially triple-negative breast cancer. In the case of hormone resistant breast cancer cells, they rarely showed hormone receptor expression. So we aimed to investigate whether the β-catenin pathway becomes activated in endocrine-resistant breast cancer cells and inhibition of β-catenin pathway can overcome endocrine resistance.

Methods: We have established an MCF-7-derived tamoxifen-resistant cell line (TamR) by long-term culture of MCF-7 cells with gradually increasing 4-hydroxytamoxifen concentration till 3µM. The levels of protein expression and mRNA transcripts were determined using western blot analysis and real-time quantitative PCR. The transcriptional activity of β-catenin was measured using luciferase activity assay. We used ICG-001 as inhibitor of β-catenin transcription activity.

Results: The expression of estrogen receptor was significantly decreased in TamR cells. On the other hand, the expressions of HER2 and EGFR were increased in TamR cells than in control cells. The active (uncomplexed form) β-catenin level was increased in TamR cells, and also showed a significantly increased β-catenin transcriptional activity. The ICG-001, small-molecular inhibitor of Wnt/β-catenin pathway, treatment significantly reduced β-catenin transcriptional activity in TamR cells. The ICG-001 reduced cell viability to TamR cells which showed resistance to tamoxifen by 65.3%, and also inhibited target gene cyclin D1 expression. The combination of ICG-001 and mTOR inhibitor, rapamycin reduced cell viability of TamR cells by 81.7% and there was an additive effect of two drugs as a combination index of 1.022.

Conclusions: The β-catenin pathway is activated in endocrine-resistant breast cancer cells and inhibition of that pathway would be a new therapeutic strategy which overcomes endocrine resistance in breast cancer.
Impact of statin use on cancer recurrence and mortality in patients with breast cancer: A systematic review and meta-analysis

Manthravadi S, Shrestha A and Madhusudhana S.  Internal Medicine, University of Missouri-Kansas City, Kansas City, MO and Hematology and Oncology, University of Missouri-Kansas City, Kansas City, MO.

Background:
Statins have been described as having an association with a decreased risk of breast cancer. They have also shown antineoplastic properties in preclinical studies. Statins inhibit the enzyme ‘HMG CoA reductase’ and the expression of this enzyme in cancer cells has been implicated as an adverse prognostic factor in patients with breast cancer.

Methods:
We performed a systemic review of literature through April 2015 and utilized PubMed and Embase to identify studies that described an association between statin use and survival in breast cancer. Studies which did not report a comparison of survival using Kaplan-Meier curves were excluded. Summary hazard ratio (HR) with 95% confidence intervals (CI) was estimated using the random effects model, and heterogeneity was measured using the inconsistency index ($I^2$).

Results:
After reviewing 637 abstracts, 12 studies which included a total of 87951 patients were identified and data was extracted. 8 studies provided a summary statistic for the association of statins with recurrence-free survival (RFS) in patients with breast cancer and were included in a meta-analysis. Statin use was associated with improved RFS (N= 29729 patients, HR 0.66; 95% CI 0.53- 0.84) with moderate heterogeneity ($I^2$ = 48%). Furthermore, this survival benefit appeared to be confined to use of lipophilic statins (3 studies, HR 0.72; 95% CI 0.59- 0.89) as hydrophilic statin use was not associated with improvement in RFS (3 studies, HR 0.80; 95% CI 0.44- 1.46). A meta-analysis of 5 studies showed no significant association between the use of statins on breast cancer-specific survival (CSS) (N= 60686 patients, HR 0.71; 95% CI 0.49- 1.03, $I^2$ = 84%). We also found no association between statin use and overall survival (OS) (5 studies and 22283 patients, HR 0.83; 95% CI 0.58- 1.19, $I^2$ = 62%).

Conclusions:
Statin use, or more specifically, lipophilic statin use is associated with an improved recurrence-free survival for patients with breast cancer. However, there was no effect of statin use on either cancer-specific survival or overall survival. These benefits need to be assessed in a prospective randomized cohort and the choice of statin, dose and biomarkers that may predict the efficacy of these drugs will need to be identified.

Title: Statin use and breast cancer incidence in the Nurses' health study

Ahern TP P, Tamimi RM M, Chen WY Y, Garber JE E, Eliassen AH and Borgquist S. University of Vermont; Brigham and Women's Hospital; Dana-Farber Cancer Institute and Lund University.

Body: Background
Statin drugs lower cholesterol and prevent cardiovascular disease. Laboratory and epidemiologic evidence suggests that statins may also have anti-cancer properties. Published associations between statin use and breast cancer incidence are heterogeneous. Few studies have comprehensively addressed confounding by lifestyle and reproductive factors, or detection bias due to potentially higher screening rates among medication users. The most recent study on this topic reported an increased risk of invasive breast cancer among statin users.

Methods
To improve upon the present evidence base we studied the association between statin use and incident breast cancer among 79,518 postmenopausal women in the Nurses' Health Study cohort. We followed these women from 2000 (the year statin exposure was first ascertained prospectively) until the first of breast cancer diagnosis, death from any cause, or the end of follow-up in 2012. We defined statin exposure as current or former use (both factored with duration) or never use. We fit Cox regression models to estimate associations, encoding statin use and covariates as time-dependent variables updated every two years. We evaluated confounding by adiposity, reproductive history, menopausal hormone therapy, family history of breast cancer, history of benign breast disease and diabetes, alcohol consumption, physical activity, and use of co-medications. We also measured associations among those cohort members who underwent screening mammograms every two years.

Results
Over 823,086 person-years of follow-up, 3,055 cases of invasive breast cancer were diagnosed (1,078 of which were among statin users). Compared with non-users, statin users were somewhat older, had a higher mean BMI, were more likely to be users of aspirin, beta blockers, calcium channel blockers, digoxin, and ACE inhibitors, had a higher prevalence of diabetes, and were more likely to undergo mammographic screening. Current users of any statin had a similar rate of breast cancer incidence as never users (for current users of ≥8 years' duration, HR_{adj}=1.1, 95% CI: 0.91, 1.3). Analyses of specific statin exposures among new initiators of therapy in 2004 returned similarly null associations (for current use of hydrophilic statins, HR_{adj}=1.0, 95% CI: 0.82, 1.3; for current use of lipophilic statins, HR_{adj}=1.1, 95% CI: 0.95, 1.3). Associations did not vary substantially by duration of statin use or according to breast cancer subtypes defined by histology (invasive ductal vs. invasive lobular disease) or estrogen receptor status. Statin use was not associated with incident breast carcinoma in situ. These results were similar in analyses restricted to women who underwent regular screening mammograms.

Conclusions
Our results indicate that cholesterol-lowering statin therapy neither increases nor decreases breast cancer incidence rate in postmenopausal women. Considering the latest report indicated an increased breast cancer risk among statin users, our neutral findings should reassure physicians that statin therapy for the prevention of cardiovascular disease is safe with respect to breast cancer risk.
Title: Cholesterol, cholesterol lowering medication use, and breast cancer outcomes in the BIG 1-98 study

Body: Background:
Cholesterol lowering medications (CLM)—statins in particular—may exert anti-cancer effects. A proposed mechanism involves attenuated signaling through the estrogen receptor by the cholesterol metabolite, 27-hydroxycholesterol, which correlates with systemic total cholesterol. Assessment of cholesterol levels and use of cholesterol-lowering medications among breast cancer patients receiving endocrine treatment may enrich our understanding of factors affecting endocrine therapy effectiveness and the role of statins and cholesterol in cancer survival.

Aim:
To investigate the prognostic effect of baseline cholesterol level and baseline CLM use, and to study the effect on outcome of concurrent use of CLM and endocrine therapy in the BIG 1-98 study.

Design and Methods:
The BIG 1-98 study enrolled 8,010 postmenopausal women with early-stage, estrogen receptor-positive invasive breast cancer from 1998-2003. Participants were randomized to five years of tamoxifen, letrozole, or their sequence. Cholesterol levels and use of CLM were assessed at baseline and every six months up to 5.5 years. Multivariable prognostic models of baseline cholesterol or baseline CLM use were adjusted for patient- and tumor characteristics and treatment regimen. Prognostic analyses of baseline cholesterol were restricted to women not taking CLM at baseline. Marginal structural modeling was used to investigate the relationship between initiation of CLM during endocrine therapy and outcome. Median follow-up was approximately 8 years. Endpoints were: disease-free survival (DFS), breast cancer-free interval (BCFI), and distant recurrence-free interval (DRFI).

Results:
Among 7,963 women who received at least one dose of endocrine therapy, 637 reported use of CLM at baseline, including statins (n=490) and non-statins (n=147). Compared with non-users, women on CLM at baseline were older, more often had a history of diabetes, were more likely to use hormone replacement therapy, and were more often diagnosed with smaller tumors or node-negative disease. During follow-up, 2,005 DFS-events, 1,303 BCFI-events and 1,004 DRFI-events were reported. Among non-users of CLM at baseline, baseline cholesterol levels showed a significant U-shaped association with BCFI and DRFI when grouped according to the quartiles of the distribution; however, these results were not maintained using cardiovascular risk-based cholesterol cut points. Prognostic models also suggested that use of any CLM at baseline was associated with better DFS compared with non-use (HRadj=0.82, 95% CI: 0.68, 0.99); similar, but non-significant associations were seen for BCFI (HRadj=0.83, 95% CI: 0.65, 1.06) and DRFI (HRadj=0.81, 95% CI: 0.61, 1.09). Results from the marginal structural modeling showed no differences in outcomes for women who initiated CLM during endocrine therapy compared with those who did not.

Conclusions:
In the BIG 1-98 study investigating the use of tamoxifen, letrozole or their sequence as endocrine therapy in the adjuvant setting, use of cholesterol-lowering therapy at baseline was associated with beneficial tumor characteristics. The effects on clinical outcome need further investigation.
Title: Association of aspirin and clinical outcomes in patients with invasive breast cancer

Li YR R, Steel L, Carrigan E and Tchou J. Medical Scientist Training Program, Perelman School of Medicine; University of Pennsylvania, Philadelphia, PA; Cell and Molecular Biology Graduate Program; Perelman School of Medicine; University of Pennsylvania, Philadelphia, PA; Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA and Abramson Cancer Center, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

Body: Long-term low-dose aspirin use has been observed to reduce the risk of colorectal, breast and other cancers. The most prominent effect has been in colorectal cancer, in which large-scale meta-analyses have shown that there is an approximately 20% relative risk reduction in participants who took aspirin for four or more years. The role of long-term NSAID use in breast cancer risk is less clear although preliminary observational case-control studies suggest an association between aspirin use and reduced incidence of hormone receptor-positive breast cancers though no clear evidence exists to support a clear mortality benefit among patients with a history of prior NSAID use as opposed to those who do not.

To investigate whether a history of aspirin use is associated with improved clinical outcome in breast cancer, we examined the pattern of aspirin use, cancer pathology and overall survival of over 1000 patients diagnosed with and treated for invasive breast cancer at our institution, for whom long-term follow up was available. A history of aspirin use for at least a period of 30 days prior to breast cancer diagnosis was reported in nearly 14% of individuals. Aspirin use was associated with being older than the age of 50 at diagnosis (79.8% vs 66.5%; Fisher's Exact Test (P < 3.2x10^-3) and being of African American race (49.1% vs 28.7%; P < 3.4x10^-2), when compared to those who have not used aspirin.

Aspirin use correlated with prognostic factors that are known to be associated with poor outcomes. They include axilla node positive disease (44.5% vs 27.0%, p< 0.032), evidence of lymphovascular invasion (24.7% vs 15.4%, p< 0.049), Her2-neu positive disease (<0.0083). In contrast to prior retrospective case-control studies, no significant association between aspirin use and hormone receptor positive disease was noted for either ER (p=0.19) or PR(+) receptor status (p=0.12). Finally, we examined if aspirin use prior to breast cancer diagnosis has any impact on disease outcome. Over a median follow up of 60.0 months, univariate analysis using cox proportional hazard modeling demonstrated that the use of low-dose aspirin prior to the diagnosis of breast cancer was associated with an increased all-cause mortality when compared to patients without aspirin use prior to cancer diagnosis (HR=3.084, 95% CI=1.961 to 4.848). On multivariate analysis, we found that recent history of aspirin use was significantly associated with a worse overall survival (HR 2.65; 95%CI 1.37 - 5.12, P < 3.77 x 10^-3), when controlled for other prognostic factors including receptor status, tumor size, tumor grade, number of positive regional lymph nodes, positive margins, as well as race and age at diagnosis.

This is the first study to report on the association of aspirin use with breast cancer outcomes in a large patient cohort treated at a single institution. Although aspirin in breast and cancers has been associated with reduced cancer incidence, a history of aspirin use prior to breast cancer diagnosis does not appear to be protective or associated with improve clinical outcomes or survival among breast cancer patients. Ongoing efforts are examining the mechanism underlying this association.
Body: **Background:** Current breast cancer prevention agents have substantial side effects and do not prevent estrogen receptor negative (ER-) breast cancer. Aspirin is a promising breast cancer prevention therapy; it is cheap, safe, well tolerated, with strong biologic and epidemiologic evidence for a prevention effect on both ER- and ER+ breast cancers. However, clinical trials to date have failed to corroborate a prevention effect; these results are potentially related to study design (dose, duration of therapy and followup, population treated). We sought to evaluate the effect of aspirin on mammographic density, as breast density is a well-accepted, modifiable risk factor for both estrogen receptor positive (ER+) and ER- breast cancer. **Methods:** Electronic medical records from the University of Pennsylvania were retrospectively evaluated for women from a core set of 36 primary care/ObGyn practices. Individuals were selected if they had both undergone routine screening mammography during 2012-2013 and had an ambulatory visit within the year prior with a confirmed list of medication use. We selected the medication record closest to the screening exam. Logistic regression was performed to test for associations between clinically-recorded BIRADS breast density and aspirin use, after adjusting for the additional risk factors of age, body mass index (BMI) and ethnicity. **Results:** We identified 26000 women who fit the above criteria, of whom 19.7% reported current aspirin use and 41% were African American. Mean age was 57.3 (standard deviation [sd], 10.9) and mean BMI was 28.9 (sd, 7.3) kg/m² for the entire cohort. Aspirin users were significantly older and had higher BMI (see Table). There was an independent, inverse association between aspirin use and mammographic density ($P_{\text{trend}} < 0.001$). Compared to women with extremely dense breasts, women with fatty (OR=1.73, CI: 1.33-2.25) or scattered fibroglandular (OR=1.50; CI: 1.17-1.92) breasts were more likely to be aspirin users. A dose-response pattern was observed, as there was a lower likelihood of having extremely or heterogeneously dense breasts with increasing aspirin dose (OR=0.62, CI: 0.50-0.76 for >300 mg; OR=0.84, CI=0.77-0.91 for <=300 mg; compared to non-users as reference group). The association between aspirin use and density was more pronounced for women <60 and for African American women ($P<0.01$). **Conclusion:** We demonstrate an independent association between aspirin use and lower mammographic density in a large, diverse screening cohort. Our results suggest that this association is stronger for younger and African American women: two groups at greater risk for ER- breast cancer. Future evaluation of this cohort will examine duration of aspirin use, and evaluate an automated measure of breast density. These results and others highlight the potential value and need for a randomized, controlled trial of aspirin as a preventive agent for breast cancer.

Mammographic breast density as a predictor of hormone receptor positive breast cancer recurrence: A single centre longitudinal analysis

Redfern AD D, Martin HL L, Stone J, Davidson JA A, Yap F and Chung K. Fiona Stanley Hospital, Perth, WA, Australia; University of Western Australia, Perth, WA, Australia; Royal Perth Hospital, Perth, WA, Australia and Sir Charles Gairdner Hospital, Perth, WA, Australia.

Body: Mammographic breast density as a predictor of breast cancer recurrence: a single centre longitudinal analysis of women with hormone receptor positive breast cancer Background Mammographic breast density has been associated with risk of development of breast cancer. To date clinical studies examining the use of tamoxifen and fall in mammographic breast density during this treatment have shown reduction in mammographic breast density examining change in mammographic breast density between baseline and a single follow-up mammogram to be predictive for disease recurrence.

Aim
To examine serial change in mammographic breast density over years to describe the changes which occur with use of aromatase inhibitors and tamoxifen, as well as changes following cessation of this treatment and to determine whether changes observed correlate with outcome.

Method
Eligible patients were identified from the Royal Perth Hospital breast unit database between January 1994-December 2011. Patient data was prospectively collected through the breast unit database. Additional data regarding endocrine therapy, adherence, weight, height and concomitant medications were obtained from case note review. Recurrence data was obtained from the hospital medical records system, as well as the breast unit database. Mammograms were obtained and mammographic breast density readings undertaken by a single reader using Cumulus. Percentage breast densities were obtained and statistical analysis undertaken to investigate changes in mammographic density on endocrine therapy, at switch of therapy, and cessation of therapy and correlation with disease free and overall survival.

Results
1942 eligible patients were identified. 417 were premenopausal at time of diagnosis, 148 perimenopausal, 1328 postmenopausal and the remainder unknown status. 12 declined adjuvant endocrine therapy, 520 received both at least 1 aromatase inhibitor and tamoxifen during follow-up, 1189 tamoxifen only, 56 tamoxifen plus goserelin, and the remainder either aromatase inhibitor only or aromatase inhibitor with ovarian suppression. Over 10,000 mammograms were obtained for analysis. Currently results are available from 4301 mammograms from 689 patients. Mean density change between baseline scan and subsequent imaging after between 11-24 months of patient-reported endocrine adherence was -6.0%, with mean reduction of -11% in patients who were premenopausal at baseline and -4.5% in those who were postmenopausal at baseline. Kaplan Meier analysis showed late separation of overall survival curves favouring those with reduction in mammographic breast density however there was no statistically significant difference in the curves Conclusion Reduction in mammographic breast density was greatest in those who were premenopausal at baseline. Further multivariate analysis and assessment of the additional mammograms in this data set is required to assess the association between mammographic breast density and outcome in this cohort.
**Title:** Mammographic density and SNPs add to Tyrer-Cuzick and Gail model breast cancer risk in a UK screening cohort

Evans DG, Astley SM M, Brentnall A, Howell A and Cuzick J. University of Manchester, Manchester, United Kingdom and Queen Mary University London, London, United Kingdom.

**Body:**

**Background:** The predicting risk of cancer at screening study (PROCAS) in Manchester UK is a prospective study of breast cancer risk estimation. This article considers whether mammographic density and SNPs in PROCAS may help refine breast cancer risk estimation using the Gail (BCRAT) and Tyrer-Cuzick (TC, or IBIS) models, based on incident and prevalent breast cancers identified between two three-yearly screening rounds.

**Methods:** Mammographic density was measured at entry as a percentage using the average visual assessment from two trained readers. Tyrer-Cuzick and Gail risks were based on a questionnaire completed at the same time. The contribution of density to risk models was assessed after adjustment for age and body mass index (BMI) using odds ratios (ORs) and profile likelihood confidence intervals (CIs). A secondary analysis compared cancer pathology characteristics using a two-sided Wilcoxon test. Eighteen breast cancer risk variants (SNP18) were assessed with a polygenic risk score (PRS) alongside TC and density in a subset of 8870 women with 341 prospective cancers.

**Results:** Analysis included 50628 women of routine screening age (47-73 yrs), recruited between Aug 2009 and Jul 2014. 697 had a breast cancer diagnosed after enrolment. Median follow-up was 3.2 years. Visually assessed percentage breast density (inter-quartile range odds ratio (IQR OR) 1.48 (95%CI 1.34-1.63)) was a slightly stronger univariate risk factor than TC (IQR OR 1.36 (1.25-1.48)) or Gail (IQR OR 1.22 (1.12-1.33)). It continued to add information after allowing for TC (IQR OR 1.47 (1.33-1.62)) or Gail (IQR OR 1.45 (1.32-1.60)). 36472/50628 (72%) women had less than 3.5% 10-yr risk from the TC model and breast density combined. Women with dense breasts were more likely to have a higher stage breast cancer (P <.001). SNP18 showed a 2 fold relative breast cancer risk between the top and bottom quintile. Using a combined analysis of SNP18, TC and density there was a 5.6 fold risk between those identified at NICE defined high risk compared to low risk.

**Conclusion:** Breast density and SNPs when combined with the TC or Gail risk model identify a larger number of high risk women at screening, and it is associated with higher stage of disease. Approximately 70% of women are identified with a combined TC and density risk assessment of less than 3.5% 10-yr risk (average or less than average risk), for whom three-yearly screening might be effective. SNP18 adds further precision and addition of further newly identified SNPs is likely to add greater discrimination.
Factors affecting uptake and adherence to breast cancer chemoprevention: A systematic review and meta-analysis

Chemoprevention is a risk reduction option for women who have increased risk of breast cancer. Selective Estrogen Receptor Modulators (SERMs) have been extensively tested, and alternative agents are being evaluated. Long-term adherence to chemoprevention is critical to obtaining the drug's full benefit. We systematically reviewed articles reporting uptake rates and adherence among healthy adult women, who were prescribed medication to prevent primary breast cancer. We also extracted data on the clinical, socio-demographic and psychological predictors of uptake and adherence.

Searches were performed in PubMed, CINAHL, EMBASE, and PsychInfo, yielding 3851 unique articles. Title, abstract and full text screening left 53 articles that met inclusion criteria, and a further 4 studies were identified from reference lists, giving a total of 57. The mean quality score using the Mixed Methods Appraisal Tool was 3 out of 4.

Thirty-one articles reported uptake, of which 14 tested predictors, and 23 reported adherence of which 11 tested predictors. Seven studies reported qualitative data. Most studies (50) involved SERMs, but 5 tested Aromatase Inhibitors, 1 tested Aspirin, 1 tested a statin. Twenty studies included data from a clinical setting, 35 reported trial data, and 2 reported both.

Twenty-four studies reporting 26 instances of uptake in 21,423 women were included in a meta-analysis. The pooled uptake estimate was 16.3% (95% CI, 13.6-19.0), with high heterogeneity (I^2=98.9%, p<0.0001). Uptake was unaffected by study location or agent, but was significantly higher in trials (25.2% [95% CI, 18.3-32.2]) than in clinical settings (8.7% [95% CI, 6.8-10.9]). Factors associated with higher uptake in two or more studies included having an abnormal biopsy, a physician recommendation, higher objective risk, fewer side-effect or trial-related concerns, and older age. Heterogeneity in data collection prevented a meta-analysis of adherence. Data suggested adequate day-to-day adherence among women who initiated treatment, with 5/6 studies reporting ≥80% of medications being taken appropriately. Persistence over 3-12 months was also high, with 5/7 studies reporting that ≥80% women were still taking chemoprevention. Long-term persistence was lower, with only 1/10 studies reporting a persistence of ≥80% by 5-years. Factors associated with lower adherence or persistence included allocation to Tamoxifen (vs. placebo or Raloxifene), depression, smoking, and older age. Objective and subjective risk was a theme in all qualitative studies, although other topics involved in decision-making included concerns about medications (6/7), low knowledge (3/7), lack of information (2/7), and trial-related issues (2/7).

Chemoprevention uptake for the prevention of breast cancer is low, and long-term adherence is often insufficient for the full preventive effect. Uptake rates were higher in trials than in clinical settings, suggesting further work should focus on implementing chemoprevention within routine patient care. Further research is warranted to identify factors amenable to modification and to improve informed decision-making surrounding chemoprevention.
Body: Background
The FACE trial was designed to evaluate the efficacy and safety of adjuvant letrozole (LET) versus anastrozole (ANA) in postmenopausal patients with hormone receptor-positive (HR+), node-positive breast cancer.

Materials and methods
In this phase 3b, open-label, multicenter trial, postmenopausal women with HR+ and lymph node positive breast cancer were randomized 1:1 to receive either LET (2.5 mg) or ANA (1 mg) daily for 5 years in the adjuvant setting. Randomization was stratified by the number of lymph nodes (1-3 versus 4+) and HER2 status (positive versus negative). Patients with stage IIA, IIB or IIAI invasive cancer were eligible. Treatment continued for 5 years or until disease recurrence. The primary endpoint was disease-free survival (DFS) at 5 years. Key secondary endpoints were safety and overall survival (OS).

Results
Between Dec 2005 and Mar 2008, 4170 patients were randomized to receive LET (n = 2076) or ANA (n = 2094). Baseline characteristics were generally balanced between the two arms. Median age was 62 years; 71.4% of pts had 1-3+ lymph nodes, and 8.7% of cancers were HER2+. Median duration of exposure was 60 months in both arms. With 709 of the protocol-planned 959 DFS events, 5-yr estimated DFS rate was 84.9% for LET vs. 82.9% for ANA (HR = 0.93 [95% CI: 0.80 – 1.07]; p = 0.3150). 5-yr estimated OS rate was 89.9% for LET vs. 89.2% for ANA (HR = 0.98 [95% CI: 0.82 – 1.17]; p = 0.7916). Primary reasons for treatment discontinuation in the LET versus ANA arms were AEs (15.1% vs. 14.3%) and disease progression (9.5% vs. 10.4%). Safety profiles were similar between treatment arms. The most common adverse events (AEs) in the LET versus ANA arms were arthralgia (48.2% vs. 47.9%), hot flushes (32.5% vs. 32.3%) and fatigue (16.8% vs. 16.6%). Suspected drug-related grade 3/4 AEs were reported in 9.5% of patients in the LET arm versus 8.1% of patients in the ANA arm; suspected drug-related AEs leading to discontinuation were reported in 14.0% vs. 12.9% of patients in LET vs. ANA arms, respectively. Preplanned and exploratory subgroup analyses will be presented.

Conclusions
Treatment with LET did not demonstrate DFS efficacy difference over ANA in postmenopausal patients with HR+, node-positive breast cancer. (Funded by Novartis; ClinicalTrials.gov number NCT00248170).
Title: NEO-EXCEL phase III neoadjuvant trial of pre-operative exemestane or letrozole +/- celecoxib in the treatment of ER positive postmenopausal early breast cancer

Body: COX2 has been implicated in breast tumorigenesis, tumour proliferation & invasion. The role of COX2 in carcinogenesis is thought to be related to its abilities to increase production of prostaglandins, convert pro-carcinogens to carcinogens, inhibit apoptosis, promote angiogenesis, modulate inflammation & immune function & increase tumour cell invasiveness. COX2 inhibition may synergise with aromatase inhibition in controlling endocrine responsive breast cancer. The COX2 product prostaglandin E2 (PGE2) & cytokines such as interleukin-6 (IL6) can up regulate aromatase expression suggesting that aromatase inhibition may be more effective in combination with a COX2 inhibitor. There may be additional COX2 mediated anticancer activity. The hypothesis addressed is that activity of aromatase inhibitors(AI) as neoadjuvant endocrine therapy for early breast cancer may be enhanced by the addition of a COX2 inhibitor.

TRIAL OBJECTIVES
To determine whether the activity of AIs as neo-adjuvant endocrine therapy for ER positive breast cancer in postmenopausal women may be enhanced by the addition of the selective COX2 inhibitor celecoxib.

TRIAL DESIGN
Prospective phase III multicentre randomised trial. Patients were randomised to receive 16 weeks of exemestane 25 mg daily or letrozole 2.5 mg daily (open label) and celecoxib 400 mg twice daily or matched placebo (double blinded). Translational research tumour samples were collected before, during & after therapy.

KEY ELIGIBILITY CRITERIA
Post menopausal, ER positive, invasive cancer, 2cms or greater with calipers & visible on USS.

PRIMARY OUTCOME MEASURE
Objective clinical response to neoadjuvant treatment by RECIST criteria.

RESULTS
Primary Outcome; Response to treatment has been calculated for 266 patients (Table 1). Response rate was 73% in the celecoxib arm & 55% in the placebo arm (p=0.0022). The response rates 4 arm comparison are shown in Table 2. After adjustment for AI effect the significant difference in response rates remained (p=0.0023); the difference in response rates was greater in the exemestane treated group (29%) compared to the letrozole group (7%) although heterogeneity between AI arms was statistically non-significant (p=0.06).

Secondary outcome; There was an USS response rate of 42% v 37% for celecoxib & placebo arms respectively (p=0.2513)

CONCLUSION
The addition of the COX2 inhibitor celecoxib to an AI significantly & substantially increased the clinical response from 55% to 73%. Effect on tumour size assessed with USS is less marked with a non-significant increase in responses from 37% to 42%.

Title: Final results of a first-in-human phase I study of the tamoxifen (TAM) metabolite, Z-Endoxifen hydrochloride (Z-Endx) in women with aromatase inhibitor (AI) refractory metastatic breast cancer (MBC) (NCT01327781)

Body: Background: AI's are more effective than TAM in ER+ breast cancer. In AI refractory MBC, the response rate to TAM is 0% (Osborne 2011). Z-Endx is an active metabolite of TAM and among TAM treated women in the adjuvant and metastatic settings, reduced CYP2D6 metabolism and low Endx concentrations (Css <20 nM) have been associated with increased likelihood of disease recurrence. Preclinical studies have demonstrated greater Z-Endx exposure and anti-tumor activity with oral Z-Endx compared to equivalent doses of oral TAM (Reid 2014)

Methods: We conducted a phase I trial to determine the maximum-tolerated dose (MTD) and evaluate the toxicities, clinical activity, and pharmacokinetics (PK) of Z-Endx in patients (pts) with ER+, AI refractory MBC. Unlimited prior endocrine regimens were allowed. An accelerated titration schedule was applied (2 pts/dose level) until moderate toxicity or DLT, followed by a 3+3 design and then to expansion cohorts (40, 80, and 100 mg/day). Z-Endx was administered orally once daily (28 day cycle). Eye exams were performed at baseline, and end of cycles 2 and 6. PK was performed during cycle 1 and prior to subsequent cycles. For pts in the expansion cohorts, tumor biopsies were obtained at baseline for DNA sequencing (Foundation Medicine). Plasma cholesterol levels were obtained at baseline and after 1 cycle.

Results: From March 2011 to Dec 2014, 41 pts (38 evaluable), median age 60, received Z-Endx once daily encompassing 7 dose levels (20-160 mg/daily). The median number of prior hormonal regimens was 2 and 3 for the dose escalation and expansion cohorts, respectively. Dose escalation was stopped at 160 mg/day given MTD not reached and attainment of mean Endx Css of 3.6 uM. Cycle 1 DLT (PE) was observed in one patient (60 mg). No eye toxicity was observed. PK demonstrated mean Endx Css of > 1 uM at all dose levels ≥ 40 mg/day. Antitumor activity was observed at multiple dose levels including 3 confirmed partial responses and an additional 7 with stable disease for ≥6 cycles. Of these 10 pts, 9 had prior progression on both AI and fulvestrant and 3 additionally on TAM. After 1 cycle, total and LDL cholesterol decreased > 20 points in 54% and 40% of pts, respectively. Tumor sequencing in the expansion cohorts (n=14) did not identify ESR1 mutations; however, ESR1 amplification was identified in 1 pt with prolonged stable disease (>200 days). Of 6 pts with rapid progression (≤2 cycles), 4/6 had either CCND1 amplification (n=1) or at least one of the following activating mutations: ERBB2 L755S (n=1), AKT1 E17K (n=1), MTOR E1799K (n=1).

Conclusions: The direct administration of Z-END provides substantial drug exposure, acceptable toxicity, and “proof of principle” antitumor activity in endocrine resistant MBC. While the MTD was not determined, the goal of achieving Endx Css concentrations of > 1 uM was achieved. Tumor sequencing identified pts with predicted and confirmed endocrine resistance. A randomized phase II comparing endoxifen (80 mg/day) with TAM in AI refractory MBC was recently activated (NCT02311933). Supported in part by CA 133049, CA186686, CA15083, CA116201, and CA15083.
Title: ERα phosphorylation at pS294: A biomarker of ligand or mutational (Y537S, D538G) activation, and a receptor target for CDK2 inhibition

Benz CC C, Scott GK K, Chu D, Kaur R, Muthurajah M, Rothschild D, Frazier K and Park BH H. Buck Institute for Research on Aging, Novato, CA and The Johns Hopkins University School of Medicine, Baltimore, MD.

Body: Background: Certain ERα phosphorylation (p) sites are essential for ERα transcriptional activity; and with development of ERα p-specific antibodies, some of these sites predict endocrine responsiveness. Unlike other ERα p-sites, pS294 has been shown to be induced by ligand activation and not by cross-talking growth factor signals. With development of a new rabbit monoclonal, pS294 induction was found to be dependent on a cyclin-dependent kinase (CDK). This study aimed to identify the specific CDK mediating induction of pS294, determine if ligand-independent ERα activating mutations (Y537S, D538G) also induce pS294, and learn if specific CDK inhibitors might enhance endocrine therapeutic efficacy by suppressing pS294.

Methods: MCF7 cells, untreated (stripped media) or stimulated by estradiol (E2, 10nM) or growth factor (EGF, 5nM), were treated with either CDK-specific knockdown siRNAs or small molecule CDK inhibitors (with indicated specificities): Roscovitine (pan-CDKs); Dinaciclib (CDK1, CDK2, CDK5, CDK9); Palbociclib (CDK4, CDK6); JNJ7706621 (CDK1, CDK2); BMS265246 (CDK1, CDK2); and SNS032 (CDK2, CDK7, CDK9). Whole cell, nuclear or cytosolic lysates were either Western blotted (for ERα or specific CDKs) or first immunoprecipitated (total ERα, pS294-ERα) and then immunoblotted. RT-PCR of cellular RNA quantified pS294-ERα induced transcripts (EGF3, AREG, CXCL12 vs. GAPDH) potentially inhibited by CDK inhibitors. MCF7 overexpressing ERα activating mutations (Y537S, D538G) were produced by either transient transfection or knock-in; knock-in clones were inoculated into immunocompromised mice to assess ligand-independent xenograft tumor growth in vivo, while transfected cells and tumors were assessed for ligand-independent ERα phosphorylation.

Results: CDK2 was determined to be the primary kinase mediating ligand-dependent induction of pS294-ERα, with co-precipitation of cyclins A/E confirming the expected mechanism of CDK2 recruitment to chromatin-bound pS294-ERα. Knock-in MCF7 cells expressing either Y537S or D538G ERα rapidly formed tumors in vivo without E2 supplementation; tumors and transiently transfected cells overexpressing mutated ERα showed pS294 >> pS118 expression, with constitutive pS294 suppressed by Dinaciclib but not by Palbociclib. CDK1/2 inhibitors (Dinaciclib, BMS265246) but not a CDK4/6 inhibitor (Palbociclib) cooperated with tamoxifen (4-HT) to induce apoptosis in wildtype MCF7.

Conclusion: CDK2 is the primary mediator of pS294 induced by either ligand stimulation or ligand-independent mutational activation of ERα. While the CDK4/6 inhibitor Palbociclib is a recently approved adjunct to endocrine therapy, it enhances cytostatic growth arrest without affecting ERα phosphorylation or receptor induced gene expression. In contrast, CDK2 inhibitors like Dinaciclib should be explored for their ability to enhance ER-positive breast cancer cell death in combination with antiestrogens and for their ability to prevent the emergence of constitutively active ERα mutations by suppressing pS294 induction, essential for ERα mediated gene transactivation and breast tumor growth.

Title: Evaluating the role of recurrent ESR1-CCDC170 in breast cancer endocrine resistance

Hu Y, Veeraraghavan J, Wang X, Tan Y, Kim J, Schiff R and Wang X-S. Lester ans Sue Smith Breast Center, Baylor College of Medicine, Houston, TX; Dan L. Duncan Cancer Center, Baylor College of Medicine, Houston, TX; Baylor College of Medicine, Houston, TX and Baylor College of Medicine, Houston, TX.

Body: Background
Recurrent gene fusions resulting from chromosome translocations are critical genetic aberrations causing cancer. In our previous study, we identified recurrent rearrangements between ESR1 and its neighbor, CCDC170, in 6-8% of luminal B tumors. Luminal B subtype is a more aggressive ER+ breast cancer, with a higher risk of early relapse after endocrine therapy. These rearrangements enable the expression of N-terminally truncated CCDC170 (∆CCDC170) under ESR1 promoter. Consistent with the behavior of luminal B tumors, ectopic ∆CCDC170 expression in ER+ breast cancer cells, led to markedly increased cell motility, invasion, anchorage-independent growth, and reduced endocrine sensitivity in vitro, as well as enhanced xenograft growth in vivo. In the present study, we studied the role of ESR1-CCDC170 in breast cancer endocrine resistance in vivo and explored the potential mechanism.

Methods
To study endocrine resistance in vivo, we transplanted T47D cells stably overexpressing (OE) control (empty) construct or 2 ∆CCDC170 fusion variants (E2-E7 and E2-E10) bilaterally to 4-6 week old female athymic nude mice (supplemented with 17β-estradiol pellets). The tumor growth was monitored biweekly and tumor volume was measured by the formula 1/2(length × width²). When the tumors reach 150–200 mm³, mice were randomly allocated to vehicle or tamoxifen (tam) treatment groups. For ERE luciferase assay, cells were co-transfected with ERE luciferase reporter (ERE-TK-Luc) and pCMV β-galactosidase. The luciferase levels were measured and normalized to β-gal activity. For immunoblot analysis, T47D OE cells were estrogen-deprived, serum-starved, and treated with vehicle, estrogen (E2) or tam. Reverse Phase Protein Array (RPPA) analysis was performed using ~200 validated antibodies against an array of key signaling molecules in cancer.

Results
Our in vivo endocrine sensitivity study showed that, while T47D vector control tumors mostly regressed after tam treatment, the regression of E2-E7 tumors was significantly slower. Moreover, E2-E10 tumors continued to grow despite tam treatment. These observations suggest that ∆CCDC170 may render the T47D xenografts less sensitive to tam in vivo. Kaplan–Meier analysis revealed a significantly worse progression-free survival (defined by tumor doubling time) for E2-E7 (p<0.01) and E2-E10 (p<0.001) tumors treated with tam compared to control tumors. ∆CCDC170 expression in T47D cells enhanced the ER transcriptional activity in the presence of E2 but not tam, suggesting that the fusion-mediated endocrine-sensitivity changes is unlikely due to restoration of classic ER activity. Immunoblot analysis of T47D OE cells revealed hyperactive growth factor signaling even after serum withdrawal, which was not significantly affected by tam treatment. Preliminary RPPA analysis revealed upregulation of key signaling molecules in T47D cells expressing ∆CCDC170, such as Her3, AMPK, Akt, Erk, c-Myc, and Src-3.

Conclusion
These data suggest a potential role of ESR1-CCDC170 in mediating breast cancer endocrine resistance, presumably due to hyperactive growth factor signaling endowed by this fusion. Further studies are required to elucidate the role of endogenous ESR1-CCDC170 in breast cancer endocrine resistance, and discover the precise engaged mechanisms.

Title: Inhibition of 3-phosphoinositide dependent protein kinase 1 (PDK1) synergizes with CDK4/6 inhibitors against ER-positive breast cancer

Body: Background: Dysregulation in cell cycle checkpoints is common in cancer. Small molecule inhibitors that target the CDK4/6/cyclinD1 pathway of the cell cycle are in clinical development. Recently the combination of the CDK4/6 inhibitor palbociclib and the aromatase inhibitor letrozole was approved for the treatment of post-menopausal women with ER+/HER2-advanced breast cancer. However, not all patients benefit from CDK4/6 inhibitors and a significant fraction of them eventually progress on these agents, underscoring the need to develop potent therapeutic strategies to circumvent drug resistance.

Methods: We performed a high-throughput RNA interference (RNAi) kinome screen targeting 720 kinases to identify targetable molecules whose inhibition, in combination with the CDK4/6 inhibitor LEE011 (ribociclib), induced synthetic lethality in MCF7 ER+ breast cancer cells. PDK1 RNAi oligonucleotides and the PDK1 inhibitor GSK2334470 in combination with each of the CDK4/6 inhibitors, palbociclib and LEE011, were tested against ER+ breast cancer cells. In vivo anti-tumor efficacy of LEE011 and GSK2334470 was assessed in ovariectomized athymic nude mice bearing MCF7 xenografts.

Results: A siRNA kinome screen identified PDK1 as the top RNA whose downregulation sensitized MCF7 cells to CDK4/6 inhibitors. This was confirmed with independent siRNAs in ER+ MCF7, T47D, HCC1428 and HCC1500 breast cancer cells. Pharmacological inhibition of PDK1 with the ATP-competitive, small molecule inhibitor GSK2334470 in combination with each of the CDK4/6 inhibitors, LEE011 and palbociclib, synergistically inhibited proliferation and increased apoptosis of MCF7 and T47D cells (combination index 0.19-0.89). LEE011-resistant MCF7 and T47D cells were generated by chronic treatment with doses of LEE011 up to 1 µM. Drug-resistant cells displayed increased levels of PDK1, phosphorylated Rb, and phosphorylated S6 ribosomal protein (pS6), an effector of the PDK1 substrate p70S6K, compared to parental drug-sensitive cells. Inhibition of PDK1 with siRNA or GSK2334470 re-sensitized the LEE011-resistant cells to the CDK4/6 inhibitors. Genetic (RNAi) and pharmacological inhibition of PDK1 (with GSK2334470) abrogated pS6 levels whereas inhibition of AKT with the small molecule inhibitor MK2206 did not affect pS6 levels, suggesting PDK1 can induce resistance to CDK4/6 inhibitors via p70S6K/pS6 signaling in an AKT-independent manner. The effects observed in cell lines in culture were recapitulated in vivo using MCF7 xenografts established in ovariectomized nude mice in the absence of estrogen supplementation. Treatment with GSK2334470 and LEE011 induced tumor regressions (8/8 tumors by RECIST criteria) more potently than either drug alone.

Conclusions: These data support a critical role of PDK1 in mediating acquired resistance to CDK4/6 inhibitors in ER+ breast cancer cells. Co-targeting of the PDK1 and CDK4/6 pathways may overcome resistance to CDK4/6 inhibitors and is worthy of further translational and clinical investigation in patients with ER+ breast cancer.
Title: Insulin receptor substrate (IRS) targeting by the tyrophostin NT157 inhibits breast cancer cell growth

Yee D, Temiz NA A, Levitzki A and Yang Y. Pharmacology, University of Minnesota, Minneapolis, MN; Masonic Cancer Center, University of Minnesota, Minneapolis, MN and The Hebrew University of Jerusalem, Jerusalem, Israel.

Body: Insulin and insulin-like growth factor (IGF) signaling systems regulate the malignant phenotype. However, targeting of the type I IGF receptor (IGF-IR) has shown little activity in clinical trials. One potential reason for these disappointing results is that activation of the closely related insulin receptor (InR) could compensate for IGF-IR blockade. Since both receptors phosphorylate the insulin receptor substrates (IRS), perhaps a better strategy would involving targeting of this key post-receptor protein. Two IRS proteins are expressed in breast cancer cells. IRS-1 is regulated by estradiol in breast cancer cell lines, while IRS-2 is the predominant IRS species in hormone receptor negative cells. NT157, a small-molecule tyrphostin, binds IGF-1R but does not affect receptor autophosphorylation. Instead, it downregulates IRS proteins in several model systems. In primary breast cancers, IRS-1 was positively correlated to ERα expression in the TCGA database. In ERα+ and basal-like breast cancer cell lines NT157 treatment suppressed IRS protein expression in a dose dependent manner. Short term exposure to NT157 treatment did not affect IGF-I, IGF-II, and insulin induced activation of phosphatidylinositol-4,5-bisphosphate 3-kinase (PI3K) and mitogen-activated protein kinase (MAPK), but longer exposure resulted in inhibition of these signaling pathways. NT157 resulted in serine phosphorylation of IRS proteins and was dependent on MAPK activation. Serine phosphorylation resulted in disassociation between IRS proteins and their receptors resulting in IRS degradation. NT157 decreased S phase fraction, monolayer, and anchorage independent growth after IGF/insulin treatment in ERα+ breast cancer cells. NT157 downregulation of IRS protein expression also sensitized ERα+ breast cancer cells to rapamycin. Moreover, NT157 inhibited the growth of tamoxifen resistant ERα+ breast cancer cells. In the basal-like breast cancer cells (MDA-MB-231), NT157 repressed the proliferation (G2/M abrogation) and migration through downregulation of IRS1/2 protein. Given that both IGF-IR and InR play a role in cancer biology, targeting of IRS adapter proteins could be a more effective inhibitory strategy compared to receptor-targeting approaches.
Body: Invasive lobular carcinoma (ILC) is the eighth most frequently diagnosed cancer in any organ, and accounts for 8-11% of breast cancer. This histological subtype is characterized by loss of E-cadherin, and favorable prognostic factors, such as low Ki67 and high rates of ER/PR-positive tumors. Only recently is the lobular subtype gaining recognition as a distinct disease, displaying a unique growth pattern, unique molecular changes in addition to loss of E-cadherin, and evidence for late recurrences and reduced response to targeted endocrine therapy. It is widely accepted that a late age at first full term birth (FFTB) increases a woman's risk for breast cancer. Interestingly, several published epidemiological studies have shown that the increased risk after a late age at FFTB is preferential for the lobular subtype of breast cancer compared to the ductal subtype. We therefore hypothesized that pregnancy hormones like prolactin play an integral role in the development and progression of ILC. Interrogation of the Cancer Genome Atlas (TCGA) data revealed a high expression of milk protein genes as well as prolactin signaling molecules, specifically Stat5a and Stat5b in lobular carcinomas compared to ductal carcinomas. We developed a lactation score including 7 milk protein genes and found that in the TCGA data set ILC tumors have a significantly higher lactation score than IDC tumors. Additionally, we found that ILC cell lines express increased prolactin receptor mRNA and protein levels compared to IDC cell lines. Prolactin treatment in ILC and IDC cells reveals divergent signaling pathways - prolactin stimulates ERK activation in IDC but not ILC cells. We are currently further delineating the prolactin signaling pathways, and resulting phenotypes, comparing ILC and IDC cells. We expect these experiments to move the field forward by establishing a relationship between prolactin and lobular carcinoma.
Title: Next generation sequencing of circulating tumor DNA to predict recurrence in triple-negative breast cancer patients with residual disease after neoadjuvant chemotherapy

Chen Y-H, Hancock BA A, Solzak JP P, Miller KD D and Radovich M. Indiana University School of Medicine and Simon Cancer Center, Indianapolis, IN.

Body: Background: Incorporation of next-generation sequencing to detect plasma-derived tumor DNA (ptDNA) is emerging as a popular method for tumor genotyping and for monitoring therapeutic response. The vast majority of studies so far have focused on detecting ptDNA from patients with metastatic disease. Herein, we tested whether ptDNA could be used as a biomarker to predict relapse in triple-negative breast cancer (TNBC) patients with residual disease after neoadjuvant chemotherapy and surgery.

Methods: BRE09-146 was a Phase II clinical trial that randomized TNBC patients with residual disease after neoadjuvant chemotherapy to Cisplatin or Cisplatin+Rucaparib. From the combination arm, 1ml of plasma was collected at four predefined time points post-surgery. In total, 39 patients with matched tumor, blood, and plasma were analyzed. Extracted DNA underwent library preparation and amplification using the Ion Ampliseq Oncomine Research Panel which consists of 134 cancer genes that are well-known to be mutated in cancer. Samples were then sequenced on an Ion Proton next-generation sequencer to at least 2500X coverage followed by bioinformatic analyses using the Torrent Variant Caller.

Results: We first detected high-quality somatic mutations in primary tumors. TP53 mutations were the most prevalent (70%) followed by AKT1 (8%). Somatic mutation frequencies in our trial were congruent with publically-available mutation data of TNBCs from The Cancer Genome Atlas. Using these somatic mutations, we then analyzed the plasma-sequencing data to detect the same mutations in the circulation. Out of 39 patients, 14 patients had a clinical relapse (median follow-up for disease free survival = 24 months). Of the 14 patients, we were able to detect somatic ptDNA in 4 patients (3 TP53 mutations, 1 AKT mutation). Notably, all 4 patients had a rapid recurrence (0.3, 4.0, 5.3, and 8.9 months). ptDNA-sequencing was unable to detect distant recurrence. The combination of a paucity of ptDNA molecules in the circulation of patients who have no evidence of disease along with a limited amount of plasma available per patient are potential factors for the inability to detect distant recurrence.

Conclusions: Next-generation ptDNA-sequencing of triple-negative breast cancer patients after neoadjuvant chemotherapy and surgery can detect rapid-recurrence but sensitivity to detect distant recurrence is limited. Studies to increase sensitivity by incorporating mutation calling from ptRNA along with ptDNA are currently underway.

Title: Capturing intra-tumor genetic heterogeneity in cell-free plasma DNA from patients with oligometastatic breast cancer

Ng CKY K Y, Bidard F-C, Piscuoglio S, Lim RS S, Pierga J-Y, Cottu P, Vincent-Salomon A, Viale A, Norton L, Sigal B, Weigelt B and Reis-Filho JS S. Memorial Sloan Kettering Cancer Center, NY, NY; Institut Curie, Paris, France; Center for Molecular Oncology, Memorial Sloan Kettering Cancer Center, NY, NY and Memorial Sloan Kettering Cancer Center, NY, NY.

Body: Background: The analysis of cell-free tumor DNA (ctDNA) from plasma has been heralded as a non-invasive technique for disease monitoring and as a means to overcome the challenges posed by intra-tumor genetic heterogeneity. ctDNA levels have been shown to correlate with tumor burden in breast cancer patients. Hence, we sought to define whether massively parallel sequencing of cell-free plasma DNA would capture the entire repertoire of somatic mutations present in the primary tumors and/or metastases from patients with oligometastatic breast cancer.

Methods: Frozen diagnostic biopsies from primary tumors and their distant metastases were obtained from five prospectively accrued treatment-naïve patients with stage IV breast cancer at presentation (1 estrogen receptor (ER)+/HER2+, 2 ER+/HER2-, 2 ER-/HER2+). A second, independent formalin-fixed paraffin-embedded (FFPE) diagnostic biopsy was obtained from the primary tumor and metastasis from 4 patients. Plasma samples were obtained from all patients. DNA samples from microdissected frozen tumors and peripheral blood, as well as plasma from one patient, were subjected to high-depth whole exome sequencing. DNA samples from all biopsies (frozen/FFPE), plasma and peripheral blood were subjected to targeted capture massively parallel sequencing, with baits for all somatic mutations detected by whole exome sequencing and all exons of the 100 genes most frequently mutated in breast cancer. Driver mutations were defined by state-of-the-art bioinformatic methods and literature search.

Results: We identified and confirmed a median of 54 (range 25-75) and 53 (range 26-85) non-synonymous mutations in the primary tumors and metastases from the 5 cases analyzed, respectively. By sequencing the plasma DNA to a median depth of 248x (range 92-431x), state-of-the-art mutation callers revealed 0-4 mutations (0%-8% of mutations) per patient, and direct interrogation of the sequencing data, based on prior knowledge of the mutations present in the lesions, resulted in the identification of 2-18 mutations (3%-38% of mutations) per patient. Of the bona fide driver mutations, 2/3 TP53 mutations, 0/1 PIK3CA hotspot mutation, 0/1 BRCA2 frameshift mutation, 0/1 GATA3 frameshift mutation and 0/1 ERBB3 activating mutation were captured in the plasma DNA. A SMAD4 pathogenic mutation and a TCF7L2 truncating mutation were found in two diagnostic biopsies of metastatic lesions but not in two biopsies of the primary tumors in one patient each. Whilst the SMAD4 mutation was detected in the plasma DNA from the respective patient, the TCF7L2 mutation was not. Of the 62 mutations restricted to the primary tumors (0-42 per patient) and 74 restricted to the metastatic tumors (1-41 per patient), 4 and 7, respectively, were captured in the plasma DNA.

Conclusions: Massively parallel sequencing assessment of plasma DNA allows for the identification of mutations found in primary tumors and/or their metastases, however, only a subset of these could be detected at up to 431x depth. These observations suggest that current approaches for whole exome or targeted massively parallel sequencing may not be sufficient to capture the genetic heterogeneity of breast cancers in patients with oligometastatic disease.

Title: A method for comprehensive genomic analysis of cell free DNA

Parpart-Li S, Angiuoli SV V, Chesnick B, Galens K, Jones S, Kadan M, Kann L, Lytle K, Murphy D, Nesselbush M, Phallen J, Riley D, Shukla M, Zhang T, Husain H, Velculescu V, Diaz, Jr LA A and Sausen M. Personal Genome Diagnostics, Baltimore, MD; The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD and Moores Cancer Center, University of California San Diego, San Diego, CA.

Body: Circulating tumor DNA (ctDNA) is released from tumor tissue into the blood, carries tumor specific genetic alterations, and can be analyzed through noninvasive "liquid biopsy" approaches to identify genetic alterations in cancer patients. Liquid biopsies offer a considerable advantage as they may eliminate the need for invasive tissue biopsies and allow for the detection of alterations in multiple metastatic lesions throughout the course of therapy. However, the fraction of ctDNA obtained from a blood sample is often very low (<1.0%) and can be difficult to detect. Additionally, most methods to evaluate circulating tumor DNA (ctDNA) interrogate single hot spot mutations or few genetic alterations. The next generation of ctDNA assays must interrogate multiple gene regions from a single sample with high precision and accuracy and need to evaluate all forms of actionable genomic alterations including point mutations, amplifications, and translocations. To address these issues, we have developed a ctDNA approach called PlasmaSelect to detect somatic sequence mutations, amplifications and translocations at low allele frequencies in the circulation of cancer patients. Utilizing digital genomic approaches, PlasmaSelect achieves high sensitivity and specificity while interrogating >250,000 nucleotides spanning 63 well-established cancer genes. In addition to sequence mutations in the entire coding region of 18 genes and the exons of 40 genes that are frequently mutated in cancer, PlasmaSelect also performs a comprehensive genomic analysis of amplifications in 57 genes and translocations in 10 genes significant in cancer tumorigenesis. To evaluate the PlasmaSelect approach, we performed dilution series using tumor-derived DNA, containing well-characterized somatic mutations, in the presence of wild-type DNA. PlasmaSelect was able to detect genetic alterations with high specificity and a lower level of detection of 0.10% for sequence mutations and translocations, as well as a focal amplification of ERBB2 with a lower level of detection of 0.20%. We evaluated the clinical utility of PlasmaSelect for detection of genetic alterations in the plasma and matched tissue biopsy specimens from late stage cancer patients. These analyses demonstrated high concordance between the somatic sequence mutations, amplifications, and translocations identified in the tumor sample and those identified directly in the plasma, including alterations in both driver genes as well as those related to acquired resistance to targeted therapies. PlasmaSelect provides a non-invasive platform to enable liquid biopsy detection of clinically relevant genetic alterations across a large number of genomic loci.
Title: Sensitive blood-based monitoring of breast cancer

Meehan K, Ruhen O, Myna K, Mirzai B and Erber W. University of Western Australia, Perth, WA, Australia and PathWest, Perth, WA, Australia.

Body: Breast cancer is the leading cause of cancer in women worldwide. Although there have been significant advances in the clinical management of breast cancer over the past few decades, women continue to die from this disease. Current methods for detection and monitoring of breast cancer progression, metastasis, and late recurrences lack sensitivity and have not yet been proven to significantly extend overall survival. Current research is focused on identifying novel monitoring methods, with a particular focus on blood-based tumour markers. Monitoring of circulating tumor cells improves detection, but the methods are complex and not applicable to routine practice. A new more sensitive method based on detection of circulating cell free tumor DNA has shown to be more sensitive for women known to have late stage disease. This is a great advance but has not been shown to be a valuable prospective monitoring tool. Tumor derived exosomes (TEX) represent an alternative blood-based method. These are small membrane vesicles that are secreted into the blood and harbor a molecular signature that are directly representative of their ‘parent cell’. Emerging evidence suggests that TEX are a veritable ‘treasure chest’ from which an abundance of stable biomarkers can be isolated and applied to disease monitoring. We hypothesized that: (1) TEX harbor patient-specific DNA mutations similar to those of the patient’s tumor; and (2) determining the number and genomic profile of TEX has the capacity for earlier identification of recurrent or progressive disease. To investigate this in a pilot study, TEX were isolated from the plasma of breast cancer patients (n=11) by ultracentrifugation. Western blotting and electron microscopy were performed to validate TEX isolation. DNA was extracted from TEX, patient-matched breast tumor tissue and buccal swabs. Next generation sequencing was performed using the Ion Torrent platform and the Cancer Hotspot Panel v2 (Life Technologies). Despite the small cohort size, there was a statistically significant association (p=0.028) between exosome protein yield and clinical disease stage. TEX protein levels were higher among patients with axillary lymph node involvement (mean 4.8µg per µl of plasma) compared to those with localized disease (mean 3.5µg per µl of plasma). In keeping with other studies the TEX contained low levels of double-stranded DNA that spanned the majority of the genome. Validation of the variants detected in the TEX is currently underway to confirm whether exosomal DNA contains the same genetic variants present in the primary neoplastic tissue. The early detection of breast cancer recurrence and progression represents an unmet challenge that needs to be overcome. This study demonstrates that with continued exploration, TEX may represent a novel approach for disease monitoring that has the potential to improve clinical management and survival.
Differential proteomics identifies complement factor H proteolytic species as early breast cancer biomarkers

Kuo W-H, Huang Y-C and Tsay Y-G. National Taiwan University Hospital, Taipei, Taiwan; Institute of Biochemistry and Molecular Biology, National Yang-Ming University, Taipei, Taiwan; Institute of Proteomics Research Center, National Yang-Ming University, Taipei, Taiwan and OncoLock Co., Ltd, Taipei, Taiwan.

Background
Breast cancer is the most common cancer among female population worldwide. We have been particularly interested in whether proteolytic species in human blood plasma can be biomarkers for detection of early breast cancer. Thus, a new differential proteomics approach has been implemented to evaluate this hypothesis.

Methods
We first collected plasma samples from 6 patients before and after neoadjuvant chemotherapy. These pairs of samples were then subjected to a modified two-dimensional differential gel electrophoresis (modified 2-D DIGE), comprising fluorescent dye labeling, macroporous reverse phase (mRP) HPLC and reducing/non-reducing SDS-PAGE. The difference protein species were analyzed with LC-MS/MS. Cleavage site-specific antibodies have been produced to perform a large-scale examination of total 379 plasma samples. These samples include 75, 74, 46, 48, and 48 patients at stage 0, 1, 2, 3 and 4, respectively. Also, there are 29 samples from normal individuals and 59 from other cancers/diseases to serve as control.

Results
A group of proteolytic species in some breast cancer patients were found by modified 2-D DIGE. Notably, these species disappeared from the plasma after the diseased tissue was surgically removed. A pair of complement factor H (CFH) derivatives were identified using LC-MS/MS analyses. Through a series of examination, we concluded that proteolytic removal of Arg-341 is likely the molecular mechanism that leads to these findings. According to these data, we have generated antibodies that can specifically recognize these proteolytic products.

We used antibodies to tested over 350 clinical samples and found these biomarkers can be specifically detected in plasma of breast cancer patients. It is quite encouraging that positive detection is shown in 15% of stage 0 pts (11/75) and 20% of stage 1 pts (15/74). Other 20 patients (21–22%) with stage 2 and 3 are found positive. 13 out of 48 patients (27%) with metastatic tumor have also been detected. Surprisingly, the signal did not observed in normal individuals or patients with other diseases, strongly suggesting that these biomarkers are highly specific to breast cancer.

Conclusion
Our initial results show the utility of this novel strategy in detection of cancer-specific proteolysis. About 20% of early breast cancer patients including stage 0 disease can be detected through these biomarkers. The promise of these proteolytic species as early cancer biomarkers and use of the cleavage site-specific antibodies are particularly remarkable, since early breast cancer detection can be applied to establish higher cure rates and thus lead to better prognosis for patients.

Title: Neutrophil lymphocyte ratio and breast cancer: A future prognostic indicator for outcome after surgery?

Williams GJ J, Huws AM M, Holt SDH DH and Sharaiha YM M. Prince Philip Hospital, Llanelli, Carmethenshire, United Kingdom.

Body: There is a growing body of literature highlighting the prognostic use of pre-operatively comparing certain white blood cell differentials, namely neutrophils and lymphocytes, with outcomes in many different types of solid tumour cancers. It has been postulated that a raised neutrophil to lymphocyte ratio (NLR) may reflect a greater tumour burden on the patient, and therefore lead to poorer outcomes. There is some evidence that a raised pre-operative NLR may help to predict poorer outcomes following surgery for breast cancer.

This observational retrospective proof of concept study aims to assess the association between pre-operative NLR and breast cancer outcomes over a three year period of follow-up from a cohort of 147 patients. The results of this study revealed that the cohort of patients with a raised pre-operative NLR was associated with a clinically significant increased rate of local recurrence of their breast cancer following surgery with curative intent (with or without adjuvant chemotherapy and radiotherapy) compared to those that had a low or normal NLR (20.4% ± 4.9% vs 5.1% ± 4.9% respectively, CI 95%; p=0.004). In relation to intra-operative sentinel lymph node biopsy, the analysis also showed that the incidence of a raised pre-operative NLR was not related to whether there was nodal involvement or not at the time of surgery (33% vs 33%, p=1). This suggests that a raised pre-operative NLR may be an independent prognostic indicator for breast cancer outcomes.

This study provides a template for a prospective observational study which is needed to corroborate this result and to account for confounding factors such as concomitant chronic disease. Additionally, a larger cohort sample size with a follow-up of five years is necessary to assess the relationship between pre-operative NLR and mortality due to the latter's relatively low incidence in breast cancer. However, this study further supports that consideration of the pre-operatively calculated NLR may provide an early prognostic indicator for breast cancer outcomes and warrants further investigation.
Title: Adaptive dynamic artificial poly-ligand targeting: Aptamer-based profiling of liquid biopsies to improve the accuracy of breast cancer diagnoses in women with dense breast tissue

Body: Introduction:
Breast cancer screening relies upon mammography, but for women with dense breast tissue this method is often uninformative. Routine screening identifies suspicious breast lesions in some women, but the pain and risk associated with follow-up biopsies along with the poor accuracy of traditional histopathology urgently call for improved approaches to breast cancer screening. This is especially important for those high-risk patients for whom mammography is of limited value. We describe a non-invasive liquid biopsy method of profiling plasma exosome preps designed to improve the accuracy and safety of breast cancer screening for women with dense breast tissue.

Results:
We incubated plasma samples (300 microliters per sample) from breast cancer patients (n=60) and a control cohort (n=60) with a high-complexity DNA aptamer library using a modified SELEX scheme, termed “adaptive dynamic artificial poly-ligand targeting (ADAPTTM)”. Differentially bound (cancer vs. non-cancer) aptamers were recovered from precipitated exosomes and were identified by deep sequencing. Two thousand aptamer sequences were resynthesized and used to probe a larger set of 500 plasma samples from a patient cohort (n=206) and a control cohort comprised of self-reported healthy volunteers (n=117) and patients whose biopsies led to a diagnosis of non-cancer (n=177). We employed several statistical models to build a cancer/non-cancer predictor, including a Random Generalized Linear Model (RGLM) and a Random Forest Model (RFM). Both models yielded an equivalent classification performance with areas under the receiver-operator characteristic curve (ROC AUC) of 0.7. Testing the prediction performance by 100 Out-of-Bag permutations or by pre-filtered (read cutoff and estimated sample size) cross-validation (CV) resulted in ROC AUC values of 0.66 and 0.62, respectively. When samples were randomly assigned to groups, the aptamers were no longer able to distinguish the groups (ROC AUC = 0.54), indicating that the underlying information driving the model is truly specific to cancer. Importantly, incorporation of BIRAD results as a clinical covariate did not influence model performance, signifying that predictions by ADAPTTM were independent of breast tissue density.

Conclusions:
We have identified a set of 2000 DNA aptamers that distinguish women with breast cancer from women without breast cancer. Our liquid biopsy approach requires only 300 microliters of plasma and is amenable to high-throughput processing. By employing a number of statistical approaches including rigorous cross-validation, we consistently achieve cross validation ROC AUC values approaching 0.7. The performance of the predictor was not affected by BIRAD scores, supporting its potential utility in difficult cases where imaging is insufficient, such as in women with dense breast tissue. Further optimization of the aptamer library and testing on additional samples should improve performance. Upon complete validation, an ADAPTTM – derived breast cancer test may serve as a vital diagnostic adjunct that can be easily incorporated into standard clinical practice.
**Title:** In primary breast cancer patients with HER2-negative tumors, HER2-positive circulating tumor cells with stem cell character predict worse outcome

Kasimir-Bauer S, Bittner A-K, Aktas B, Hauch S, Kimmig R and Hoffmann O. University Hospital Essen, Essen, Germany and QIAGEN Hannover GmbH, Langenhagen, Germany.

**Body:** Introduction: The detection of disseminated (DTCs) and circulating (CTCs) tumor cells in patients with early stage breast cancer is a well described independent prognostic factor associated with increased risk of disease recurrence and disease-related death. We recently demonstrated that CTCs in blood of primary breast cancer patients rather than DTCs were significantly associated with reduced progression free survival (p=0.02). Using comprehensive molecular characterization, we here demonstrate that the negative prognostic impact was predominantly related to HER2-positive CTCs with stem cell character from patients with HER2-negative primary tumors.

Patients and Methods: 2 x 5 ml blood from 482 primary breast cancer patients with first diagnosis between 2006 and 2010 were analyzed for CTCs with the AdnaTest BreastCancer (QIAGEN Hannover GmbH, Germany) for the detection of EpCAM, MUC-1, HER-2, and beta-Actin transcripts. The recovered c-DNA was now additionally tested for the expression of the estrogen (ER) and progesterone receptor (PR) (single-plex RT-PCR) and stem cell like CTCs (slCTCs) applying the AdnaTest TumorStemCell (single-plex RT-PCR for ALDH1) and the AdnaTest EMT (multiplex RT-PCR for TWIST, AKT2, PI3K). The analysis of PCR products was performed by capillary electrophoresis on the Agilent Bioanalyzer 2100.

Results: CTCs were detected in 103/482 (21%) of the patients expressing EpCAM (27%), MUC-1 (26%), HER-2 (75%), ER (14%) and PR (8%), respectively. Notably, in 49/103 (48%) of the CTC-positive patients, HER2 was the only marker expressed. slCTCs could be analyzed in 72/103 CTC-positive patients. At least one of the EMT markers was expressed in 56/72 patients (78%), ALDH1 was present in 32/72 patients (44%) and 31/72 (44%) were positive for both, ALDH1 and EMT markers, respectively. Comparisons of expression profiles on CTCs with those on the primary tumor were only performed in CTC-positive patients. Primary tumors and CTCs displayed a concordant HER2, ER and PR status in 37% (p=0.81), 24% (p=0.257) and 27% (p=0.876) of cases, respectively. Most interestingly, in 60/75 (80%) patients with HER2-positive CTCs, primary tumors were HER2-negative. In contrast, the percentage of patients with ER- and PR-positive CTCs but negative ER/PR primary tumors was 29% and 25%, respectively. When the presence of HER2-positive CTCs was correlated with the presence of slCTCs (ALDH1-and/or EMT-positive), the concordance was 83% (p=0.0019). In detail, the concordances were HER2+ vs ALDH1+ (54%, p=0.037), HER2+ vs EMT+ (85%, p=0.0002) and HER2+ vs ALDH1+/EMT+ (80% p=0.00053), respectively.

Conclusion: Our results provide evidence that a) the negative prognostic impact of CTCs in our patient cohort is related to HER2-positive CTCs with EMT and tumor stem cell characteristics which indicate therapy resistant tumor cell populations and, therefore, an inferior prognosis and b) “secondary” adjuvant treatment with HER2-targeting agents, alone or in combination, may probably be effective to eliminate these cells and thus, lead to an overall decreased relapse rate. This study further confirms that the molecular characterization of CTCs might help to stratify patients for individual treatment options.

Title: Predictors for discordance in HER2 phenotype between primary tumor and circulating tumor cells in women with metastatic breast cancer

Janni W, Schramm A, Friedl TWP WP, Schochter F, Huober J, Rack B, Alunni-Fabbroni M, Fasching PA A, Taran F-A, Hartkopf A, Schneeweiss A, Müller V, Aktas B, Krawczyk N, Pantel K and Fehm T. University Hospital Ulm, Ulm, Germany; Klinikum der Ludwig-Maximilians-Universität, Munich, Germany; University Hospital Erlangen, Erlangen, Germany; University Hospital Tuebingen, Tuebingen, Germany; University Hospital Heidelberg, Heidelberg, Germany; University Hospital Hamburg-Eppendorf, Hamburg, Germany; University Hospital Essen, Essen, Germany; Heinrich-Heine-University, Duesseldorf, Germany and University Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Body: Aim: The DETECT study program evaluates whether treatment efficacy in women with metastatic breast cancer (MBC) is increased by taking into account the molecular characteristics of circulating tumor cells (CTCs). Here, we present data on both prevalence and HER2 phenotype of CTCs in patients with HER2 negative MBC screened within the DETECT program. The aim of this study is to evaluate the rate of discordance in HER2 phenotype between primary tumor and CTCs and to analyze whether primary tumor and/or patient characteristics can predict discordance in HER2-status.

Methods: The number of CTCs in 7.5 ml of peripheral blood (using the FDA-cleared CellSearch® System; Janssen Diagnostics, LLC) and their HER2 status were evaluated. Patients were defined as having a positive HER2-status on CTCs if at least 1 CTC with a strong (+++) immunocytochemical HER2 staining intensity was found. To assess which factors predict discordance of HER2 phenotype between primary tumor and CTCs, we used a multivariate binary logistic regression model with backward selection procedure. Patient and primary tumor characteristics included as independent factors were patient age, time since primary diagnosis, tumor stage, nodal stage, grading, histological type, and hormone receptor status (HRS).

Results: 1123 women with HER2-negative MBC were screened for CTCs. Based on a cutoff of ≥ 1 CTC, 711 (63.3%) of 1123 screened patients were positive for CTCs, while 412 (36.7%) of the 1123 screened patients were categorized as CTC positive if a cutoff of ≥ 5 CTCs was used.

At least one HER2-positive CTC was found in 134 of the 711 HER2-negative MBC patients with one or more CTCs (median 2 HER2-positive CTCs, range 1 – 80), indicating a discordance between primary tumor and CTCs with regard to HER2-status in 18.8% of patients. If the analysis was restricted to the 412 patients with 5 or more CTCs, at least one HER2-positive CTC was found in 121 patients, resulting in 29.4% discordance rate.

A multivariate logistic regression with discordance in HER2 phenotype (yes/no) as binary response variable, including number of CTCs (1 – 4 CTCs vs. 5 or more CTCs) to account for the difference in discordance rate observed at different cutoff values for CTC positivity, showed that histological type (lobular vs. ductal, odds ratio OR 2.66, 95% confidence interval CI 1.62 – 4.37, p < 0.001), HRS (positive vs. negative, OR 2.89, 95% CI 1.16 – 7.19, p = 0.022) and CTC number (5 or more CTCs vs. 1 – 4 CTCs, OR 7.57, 95% CI 3.93 – 14.89, p < 0.001) significantly predicted discordance in HER2 phenotype between primary tumor and CTCs.

Conclusion: Our data revealed discordance in HER2 status between primary tumor and CTCs in 19% to 29% of patients with HER2 negative MBC. Discordance in HER2 status was predicted by histological type and HRS of the primary tumor, as well as by the number of CTCs detected. Individualized breast cancer treatment based on CTC phenotype is currently investigated in Phase III trials and not part of clinical routine yet. However, the knowledge of factors associated with discordance in HER2 status may be incorporated in today's clinical practice by guiding the decision process for performing a biopsy to characterize a metastatic relapse.

**Title:** HER2 expression on circulating tumor cells before adjuvant chemotherapy and during follow-up in patients with HER2-negative early breast cancer

Markomanolaki H, Mavroudis D, Kallergi G, Vetsika E-K, Stratigos M, Makrigiannaki K, Georgoulas V and Agelaki S. Laboratory of Tumor Cell Biology School of Medicine, University of Crete, Heraklion, Greece and University General Hospital of Heraklion, Heraklion, Greece.

**Body:**

**Background:** Detection of circulating tumor cells (CTCs) before adjuvant chemotherapy as well as during follow-up is related to poor prognosis in early breast cancer. The presence of HER2-positive CTCs has been also associated with significantly decreased disease-free and overall survival. We hereby assessed the HER2 status of CTCs in HER2-negative patients with early breast cancer, before the initiation of adjuvant chemotherapy and during follow-up.

**Methods:** Double staining immunofluorescent experiments using pancytokeratin (A45-B/B3) and HER2 antibodies were performed in peripheral blood mononuclear cells (PBMCs) of patients. Patients were evaluated before adjuvant therapy (n=103) and during follow-up (n=290) at intervals ranging from 6 months to 20 years post-chemotherapy.

**Results:** CTCs were detected in 28 (27.2%) out of 103 patients pre-chemotherapy and in 94 (32.4%) out of 290 during follow-up. The mean CTC count detected at \( \leq 2 \) years of follow-up was not significantly different compared to baseline [3.4 CTCs (range 1-13) vs 2.9 (range 1-12), respectively]. However, this value showed a significant decrease from 2-5 to \( \geq 10 \) years of follow-up (4.2, range 1-11 vs. 1.8, range 1-4). Among CTC-positive patients, CTCs expressing HER2 were detected in 21 (75%) and in 73 (77.7%) patients pre-chemotherapy and during follow-up, respectively. The mean proportion of HER2-positive CTCs per patient was 73.5% pre-chemotherapy and 67% at follow-up. This proportion showed a significant increase at follow-up time points \( \leq 2 \), 2-5 and 5-10 years [52% (p=0.0027), 65.6% (p=0.0476) and 69% (p=0.0440), respectively] compared to \( \geq 10 \) years (89.2%).

**Conclusions:** These data demonstrate that CTCs persist during follow-up in a significant percentage of early breast cancer patients. Similarly, HER2 positive CTCs are detected in a significant proportion of patients both at baseline and during follow-up. Mean CTC count appears to decrease after 10 years, whereas the population of HER2 positive CTCs seems to increase during follow-up. These results suggest that targeting HER2-positive CTCs may have implications for the prevention of late relapses.
**Title:** Distinct clinical and biological values of subpopulations of circulating tumor cells (CTCs) in primary breast cancer

Mego M, Jurisova S, Karaba M, Minarik G, Benca J, Sedlackova T, Manasova D, Malejcikova M, Sieberova G, Macuch J, Gronesova P, Sufliarsky J, Pindak D, Cristofanilli M, Reuben JN and Mardiak J.  Faculty of Medicine, Comenius University, Bratislava, Slovakia (Slovak Republic);  National Cancer Institute, Bratislava, Slovakia, Bratislava, Slovakia (Slovak Republic); Cancer Research Institute, Bratislava, Slovakia (Slovak Republic); Thomas Jefferson University-Kimmel Cancer Center, Philadelphia, PA and University of Texas, MD Anderson Cancer Center, Houston, TX.

**Body:** Background: CTCs represent a heterogeneous population of cells with different phenotypes and biological values. Epithelial to mesenchymal transition (EMT) gives rise to cells with stem cell-like properties with increased resistance to chemotherapy that may be under detected by currently approved assays. The aim of this study was to characterize CTCs based on the expression of epithelial and mesenchymal markers in primary breast cancer (BC) and to correlate them with patients/tumor characteristics.

**Methods:** This prospective translational study included 422 patients with primary BC enrolled from March 2012 to February 2015. Blood for CTC detection was drawn before surgery (422 patients), before 1st cycle (95 patients) and before 2nd cycle (53 patients) of adjuvant therapy. Isolated peripheral blood mononuclear cells (PBMC) were depleted of cells of hematopoietic origin (CD45+) using RosetteSep kit (StemCell Technologies) negative selection with anti-CD45 antibody. RNA extracted from CD45-depleted (CD45-) PBMC was interrogated for expression of EMT-inducing transcription factors (TWIST1, SNAIL1, SLUG, ZEB1) and epithelial (CK19) gene transcripts by quantitative reverse transcription-PCR. Expressions of gene transcripts in CD45-PBMC from patients were compared to those of CD45- PBMC of 60 healthy donors.

**Results:** Totally, CTCs were detected in 116/422 (27.5%) patients before surgery, in 21/95 (22.1%) patients after surgery and before 1st cycle and in 19/53 (35.8%) of patients before 2nd cycle of adjuvant therapy. Before surgery, CTCs exhibited only epithelial markers in 38 (9.0%) patients, only EMT markers in 68 (16.1%) of patients, while in 10 (2.4%) patients CTCs with both epithelial and EMT markers were detected. Epithelial CTCs were more often detected before surgery compared to after surgery (11.4% vs. 2.1%; p = 0.003), while mesenchymal CTCs were more often detected after the 1st cycle of chemotherapy as opposed to detection before surgery (30.2% vs. 18.2%; p = 0.05). Patients with N2-3 disease had more often detectable CTCs compared to patients with N0-1 disease (41.4% vs. 24.9%, p = 0.01) and this was mainly driven by mesenchymal CTCs (31.0% for N2-3 vs. 16.0% for N0-1; p = 0.007). Similarly, patients that lacked p53 expression (wild type TP53) in primary tumor had more often CTCs with EMT phenotype opposite to patients with p53 expression (p = 0.02). Presence of epithelial CTCs was significantly associated with lower absolute lymphocyte (p = 0.02) and neutrophil (p = 0.02) counts in peripheral blood.

**Conclusions:** Our results support the concept of CTCs phenotypic heterogeneity in breast cancer patients. These results support the role of EMT in cancer pathogenesis and suggest that CTCs with EMT phenotype are involved in tumor dissemination while their increase after chemotherapy might be a mechanism of treatment resistance. Moreover, these data suggest inverse relationship between immune cells and epithelial CTCs which stress the role of immune cells in tumor dissemination.
Circulating tumor cells in triple-negative and non-triple negative breast cancer patients show different genetic profiles

Bittner A-K, Hoffmann O, Hauch S, Kimmig R and Kasimir-Bauer S. University Hospital Essen, Essen, Germany and QIAGEN Hannover GmbH, Langenhagen, Germany.

Background: Triple negative breast cancer (TNBC) is known for its aggressive behavior, poor prognosis and still remains as a difficult disease since treatment options are limited. Despite some success in PARP inhibition in BRCA gene mutation patients or platinating agents that may offer superior outcomes in a subset of TNBC patients (pts), currently, there are no targeted therapies for TNBC available. Specific biomarkers are urgently needed for developing effective treatments to predict which patients will respond to the given therapy. In this regard, circulating tumor cells (CTCs) are discussed to be an ideal surrogate marker for individualized treatment options. Since TNBC is closely related to epithelial-mesenchymal transition (EMT), a stem cell phenotype and, in addition, androgen receptor (AR) expression has been detected in up to a third of TNBC pts, we here established a multi-marker gene panel for the characterization of CTCs in TNBC pts and compared these findings with CTC characteristics in non-TNBC pts.

Methods: 2x5 ml blood of 30 TNBC pts before and/or after neoadjuvant therapy and 30 non- TNBC pts (E+/PR+: n=23; ER+/PR-: n=4; HER2+; n=1; HER2+/ER+: n=1; HER2+/ER+/PR+: n=1) before therapy were analyzed for CTCs applying positive immunomagnetic selection targeting EpCAM, EGFR and HER2 using the AdnaTest EMT-2/Stem Cell Select (QIAGEN Hannover GmbH, Germany). Subsequently, cDNA was gene specifically pre-amplified using TaqMan PreAmp Master Mix according to in house designed assays. Establishment of a 19 gene qPCR panel was performed for the markers PI3K, AKT2, ERCC1, Aurka, HER2, HER3, EGFR, ALK, AR (androgen receptor), BRCA1, c-KIT, c-MET, KRT5, mTOR, NOTCH1, PARP1, SRC1, CD45 (leucocyte control) and GAPDH (housekeeping gene) as well as an internal reference. The cutoff was calculated, taken the false positive rate in healthy donors into account and defined as Ct(cutoff)-Ct(sample)-[Ct(CD45cutoff)-Ct(CD45sample)].

Results: In general, the distribution of the markers across all patients was highly variable. However, different expression patterns were found when CTCs of TNBC pts were compared with those of non-TNBC pts. In TNBC pts, SRC1 was the gene that was predominantly expressed, followed by c-Kit, HER3, BRCA1 and AURKA expression, before as well as after therapy. Interestingly, AKT2, EGFR, ERCC1 and PARP1 expression could not be detected at any time point studied. In addition, ALK, AR, c-Met, HER2 and KRT5 were only detected before but not after therapy. All other genes were expressed below 15%. In contrast, in non-TNBC pts, AKT2 was the gene that was predominantly expressed, followed by c-MET, HER3 and PI3K whereas c-KIT, ERCC1, mTOR and NOTCH1 were never found. All other genes were expressed below 10%.

Conclusion: We successfully established a gene panel for the detection of the heterogeneous CTC population and demonstrated that CTCs in TNBC pts and non-TNBC pts show different genetic profiles. Although these data have to be confirmed in a bigger patient cohort, the knowledge about the individual target gene expression profile might efficiently help to predict a personalized targeted therapy for these pts in the future.
Impact of apoptotic circulating tumor cells in metastatic breast cancer

Wallwiener M, Deutsch TM M, Riethdorf S, Hartkopf AD D, Taran F-A, Trumpp A, Brucker S, Schütz F, Rom J, Pantel K and Schneeweiss A. University of Heidelberg, Heidelberg, Baden Württemberg, Germany; National Center for Tumor Diseases, Heidelberg, Baden Württemberg, Germany; University ofTuebingen, Tuebingen, Baden Württemberg, Germany; Division of Stem Cells and Cancer, German Cancer Research Center (DKFZ), Heidelberg, Baden Württemberg, Germany and University Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Background
Circulating tumor cells (CTC) are a heterogeneous cell population and an independent negative prognostic factor for progression-free (PFS) and overall survival (OS) in patients with metastatic breast cancer (MBC). The study aimed to prospectively assess CTC status for the subtypes apoptotic CTC (aCTC) and intact CTC (iCTC) at baseline (CTCBL) and after one cycle of a new line of systemic therapy (CTC1C). Changes from CTCBL to CTC1C (CTC kinetics, CTCKIN) were evaluated for their utility in predicting response, progression-free (PFS) and overall survival (OS).

Methods
423 MBC patients were included in a prospective trial prior to a new regimen of treatment. Intact and apoptotic CTC were analyzed at baseline (CTCBL) and after one cycle of systemic therapy (CTC1C) using CellSearch™ (Veridex) and morphologic criteria. Samples with ≥5 CTC/7.5ml blood were regarded as positive. Therapy response was assessed using the RECIST-criteria on three-monthly radiological controls. CTCKIN were characterized by ≥25% change from CTCBL to CTC1C to differentiate stable, increased and decreased CTC kinetic.

Results
35% of patients were iCTCBL-positive and 28% aCTCBL-positive at baseline (CTCBL). PFS and OS differ significantly between the iCTCBL-positive and the iCTCBL-negative group (PFS 4.5 vs. 8.0; OS 12.5 vs. 27.2 (months)). Positive aCTC in conjunction with positive iCTCBL at baseline has worst prognostic impact (PFS 6.3; OS 8.7).

Regarding the CTCKIN (BL to 1C), aCTC-decrease (≥25%) is a positive prognostic factor compared to aCTC-stable and aCTC-increase (PFS 7.6 vs. 3.7; 3.3 and OS 21.0 vs. 4.8; 5.7). Decreasing aCTCKIN shows favorable prognostic impact versus decreasing iCTCKIN (PFS 7.6 vs. 5.9 and OS 21.0 vs 16.4).

Conclusion
Elevated aCTC levels at baseline have an unfavorable prognostic impact on both OS and PFS in conjunction with elevated iCTC. Additionally, the decrease of aCTC is a relevant prognostic value for systemic therapy response. aCTCKIN allows better differentiation for therapy response in patients with positive CTC-status at baseline. Differentiated enumeration of intact and apoptotic CTC should be considered in clinical application.
Title: Collection, high-resolution imaging, and single cell isolation of circulating tumor cells from patient derived xenograft models using the AccuCyte® – CyteFinder® system

Ramirez AB B, Sahay D, Lewis MT T, Schiff R, Stilwell JL L, Trivedi M and Kaldjian EP P. RareCyte, Inc., Seattle, WA; University of Houston College of Pharmacy, Houston, TX and Baylor College of Medicine, Houston, TX.

Body: Background: Patient-derived xenograft (PDX) models of human tumors offer many advantages over traditional cell line xenograft models and other mouse models of cancer. A PDX model may be used to randomize a given patient's tumor to multiple treatment regimens in order to predict treatment responses. When PDX models are grouped, they represent a clinical trial “cohort” for testing new therapies and identifying biomarkers of response. One such biomarker is circulating tumor cells (CTCs), which provide a window of the metastatic process. CTCs have been reported in several PDX models, further supporting their clinical relevance. Thus, PDX models may also be used to study the utility of CTC analysis to inform treatment decisions. However, most current CTC technologies intended for use with human samples cannot be used with the small blood volume from mice. The objective of our study was to adapt the AccuCyte® – CyteFinder® (AC-CF) system to detect CTCs from low volumes of mouse blood, and apply this method for the analysis of CTCs in a PDX model, including individual cell retrieval for molecular analysis. Methods: The AC-CF PDX process was modified to include a red blood cell lysis step instead of the density-based separation for the removal of red blood cells. The isolated cells were spread onto microscope slides using a stabilization solution, stained by multi-color immunofluorescence, and visualized by the CF high-resolution multi-channel fluorescence scanner. Automated image analysis identified CTCs, which was followed by single cell retrieval. For optimization of the assay, BT474 breast cancer cells were spiked into blood from a tumor-free control mouse (approx. 500 cells in 250 µl). Slides with BT474 cells were used to test sensitivity by using antibodies against human cytokeratins (pan-CK), epithelial cell adhesion molecule (EpCAM), and erbB family growth factor receptors (EGFR and HER2) to detect the spiked-in cells. Assay specificity was tested by using antibodies specific for the mouse isofrom of CD45. The antibody panel was tested on blood samples from 6 mice carrying small (300-400 mm3) tumors of the breast cancer PDX model (BCM-4888) previously published to have CTCs. Results: BT474 were identified by their large nuclei, positive staining with human specific antibodies against pan-CK, EpCAM, and EGFR/HER2 markers, and negative staining for mouse CD45. BT474 were detected in approximately the same amount as were spiked in. CTCs were identified in the blood of all 6 PDX mice tested. We found 1-6 CTCs per 330 µl of blood, and clusters of CTCs were also identified in 4 mice. Overall, these findings agree with published data on this PDX model. Single CTCs will be isolated using the CytePicker® retrieval module for single cell sequencing to confirm the human origin of these cells. These results along with ongoing work on additional PDX models will be presented at the meeting. Conclusion: The modified AC-CF process is a simple and sensitive method of analyzing small volumes of blood for CTC detection and isolation, features that are critical for the longitudinal analysis of CTCs in PDX models of cancer.
Title: Initial circulating tumor cell count and venous thrombosis-free interval in the course of metastatic breast cancer

Institut Curie, Paris, France.

Body: Background: Circulating tumor cells (CTC) count is a major prognostic factor in metastatic breast cancer. It has been also reported to be associated with venous thrombosis in short-term studies on advanced metastatic breast cancer patients.

Methods: We assessed whether an early CTC detection (CellSearch®), before the start of the first line chemotherapy, impacts Thrombosis-Free Interval during the whole course of metastatic breast cancer. Electronic medical files of all patients included in the large prospective IC 2006-04 CTC detection study (NCT00898014, Pierga et al, Ann Oncol 2012) and treated at Institut Curie (Paris, France) were manually and automatically searched for thrombosis events in the course of their metastatic breast cancer. Superficial venous thromboses were not taken into account. Thrombosis-Free Interval (TFI) was defined as the first event occurring between venous or arterial thrombosis.

Results: In the 142 patients studied, with a median follow-up of 64 months [25-81 months], venous (deep venous thrombosis, pulmonary embolism, catheter thrombosis and portal vein thrombosis) and arterial thrombosis occurred in 21.8% and 4.2% of patients, respectively. Twenty-four (30%) of the 80 patients with ≥1 CTC/7.5ml of blood before the start of first line chemotherapy experienced at least one thrombotic events in the course of their disease, while only 10 (16%) of the 62 CTC-negative patients experienced a similar event (p=0.06). Baseline positive CTC was associated with a higher risk of experiencing a venous or arterial thrombosis (TFI: HR=2.6 [1.2-5.5], p=0.009). The median TFI was 64 months in CTC-positive patients and not reached in CTC-negative patients. Among the other patients characteristics tested at baseline, Performance Status (PS=1 vs PS=0: HR=0.85 [0.4-1.9], p=NS; PS=2 or 3 vs PS=0: HR=3.7 [1.5-8.7], p=0.003) and LDH levels at baseline (LDH>UNL vs LDH<UNL HR=2.4 [1.2-4.9], p=0.012) were also associated with TFI.

Conclusions: Metastatic breast cancer patients with ≥1 CTC before the start of chemotherapy are at higher risk of venous thrombosis; the clinical relevance of thrombo-prophylaxis should be investigated in this population.
Title: Obesity associated factors are inversely associated with circulating tumor cells in metastatic breast cancer

Dowling RJO JO, Chang MC C, Lohmann AE E, Ennis M, Amir E, Elser C, Brezden-Masley C, Vandenberg T, Lee E, Fazaee K, Stambolic V and Goodwin PJ J.  Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada;  Mt. Sinai Hospital, University of Toronto, Toronto, ON, Canada;  Lunenfeld Tanenbaum Research Institute, Mt. Sinai Hospital, University of Toronto, Toronto, ON, Canada;  Applied Statistician, Markham, ON, Canada;  Mt. Sinai Hospital, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada;  Division of Haematology/Oncology, St. Michael's Hospital, University of Toronto, Toronto, ON, Canada;  London Regional Cancer Program, University of Western Ontario, London, ON, Canada;  Mt. Sinai Hospital, Toronto, ON, Canada and University of Toronto, Toronto, ON, Canada.

Body: Background: Elevated levels of circulating tumor cells (CTCs) are associated with adverse outcomes in metastatic breast cancer (BC). However, relationships between CTCs and various patient-related factors that may impact outcome remain undefined. Consequently, associations of CTC counts with obesity and metabolic factors were evaluated in order to gain insight into potential interactions between patient physiology and disease burden. We hypothesized that obesity and associated metabolic factors would be associated with higher CTC counts.

Methods: Non-diabetic women with metastatic BC beginning a new line of treatment due to progressive disease were recruited from four Ontario cancer hospitals between February 2013 and April 2015. Patients provided blood for CTC analysis, which was completed within 72 hours of collection using the Janssen CellSearch platform. Fasting serum was also collected for assessment of metabolic factors including glucose (mmol/L), insulin (pmol/L), leptin (ng/mL) and adiponectin (ng/mL). Associations of CTC counts with these factors, as well as anthropometric measurements (height (cm), weight (kg), BMI (kg/m2)) were evaluated using Pearson correlation coefficients after transforming the variables involved to normality. For CTC counts, the log transformation with half integer correction was used.

Results: 96 patients with a median age of 60.5 years completed the study. Most were post-menopausal (87, 90.6%) and exhibited grade II/III tumors (75, 78.1%). The majority of patients had hormone receptor positive disease (83, 86.5%), but 16.7% (16) were HER2 positive and 10.4% (10) were triple negative. The number of CTCs observed ranged from 0 to 1238 (median 2, geometric mean 3.63). No CTCs were detected in 29 patients (30.2%), whereas 25 patients (26 %) exhibited counts of 1 to 4 CTCs and 42 (43.8%) had 5 or more CTCs. CTCs were not significantly associated with tumor characteristics including ER/PgR, HER2, grade, stage (T/N) or lymphovascular invasion. The number of CTCs inversely correlated with BMI (r=-0.26, p=0.01), leptin (r=-0.29, p=0.004), and leptin-adiponectin ratio (r=-0.3, p=0.004). A similar trend that approached significance was noted for body weight (r=-0.19, p=0.07), insulin (r=-0.19, p=0.06) and homeostatic model assessment (HOMA, an estimate of insulin resistance, r=-0.2, p=0.055). Conversely, adiponectin (r=0.18, p=0.07) and height (r=0.18, p=0.07) were positively associated with CTC counts in correlations that neared significance. No associations were observed for age (r=0.09, p=0.4) or glucose (r=-0.09, p=0.4).

Conclusions: Obesity associated metabolic factors including weight, BMI, insulin, HOMA and leptin were inversely associated (and adiponectin and height positively associated) with CTC counts. These patterns are consistent with weight loss and/or cachexia in women with elevated CTC counts who have higher disease burden. Additional analyses are underway to further characterize these associations and include assessment of serum albumin, free fatty acids, creatine kinase and hepcidin.

Title: Circulating cells from the tumor microenvironment as liquid biopsy biomarkers alongside circulating tumor cells in metastatic breast cancer

Parajuli R, Ao Z, Shah SH H, Sengul TK Koru, Lippman ME E, Datar R and El-Ashry D. University of Miami Miller School of Medicine, Sylvester Comprehensive Cancer Center, Miami, FL; Sheila and David Fuente Graduate Program in Cancer Biology, University of Miami Miller School of Medicine, Miami, FL; University of Miami Miller School of Medicine, Miami, FL and University of Miami Miller School of Medicine, Miami, FL.

Body: Background: Metastasis is a multistep process that involves the shedding of tumor cells in the peripheral circulation. These Circulating Tumor Cells (CTCs) have prognostic implications in patients with metastatic breast cancer (MBC). Cancer Associated Fibroblasts (CAFs) are a major component of the breast tumor microenvironment. The reciprocal signaling between tumor cells and its microenvironment promotes carcinogenesis, invasion, and metastasis. Studies in mouse models have shown that metastatic cells can bring their own stromal components from the primary site to the site of metastasis, and that these cotraveling stromal cells provide an early growth advantage to the accompanying metastatic cancer cells. CAFs have not been identified in the peripheral circulation. Using a microfilter capture technique, we discovered non-tumor, non-immune cells in the blood of metastatic patients and identified these cells as circulating CAFs (cCAFs). The purpose of this study is to demonstrate the presence of cCAFs as a biomarker of metastasis simultaneously with CTCs in patients with MBC.

Materials and Methods: We identified 20 patients with MBC (Metastatic/MET Group) and 10 patients with cured breast cancer (Ductal carcinoma in situ or Stage I post definitive treatment with >5 years of disease free survival i.e. Localized/LOC Group). A total of 7.5 ml of peripheral blood was obtained from each patient. The enumeration of CTCs and cCAFs was carried out by the microfilter capture technique. Identification of these cells was done by a triple immunofluorescence staining for pan-CK (cytokeratin), FAP (Fibroblast Activated Protein) and CD45. cCAFs were identified as CK-, FAP+, CD45- cells and CTCs as CK+, CD45- cells. Identification and confirmation of cCAF was also carried out in parallel samples by a simultaneous FAP/α-Smooth Muscle Actin staining.

Results: cCAFs were detected in 17/20 (85%) MET patients but in only 2/10 (20%) LOC patients. CTCs were detected in 20/20 (100%) MET patients and in 8/10 (80%) LOC patients. The counts of CTCs and cCAFs in MET group ranged between 1-98 (median 13.5) and 0-117 (median 4), respectively. The counts of CTCs and cCAFs in the LOC group ranged between 1-14 (median 6) and 0-2 (median 0), respectively. For patients with exhibited cCAFs, 2/10 LOC and 5/17 MET patients had cCAFs counts of 2 or less. Although the sample size was small, patients exhibiting cCAFs (odds ratio=22.67, 95% CI: 3.14-163.63, p=0.002) were more likely to be in MET group than LOC group.

Conclusion: This is the first demonstration that CAFs, the predominant mesenchymal cell in the breast tumor microenvironment, are shed into the circulation and can be identified and enumerated as cCAFs in MBC patients along with CTCs. There was a clear difference in the numbers of CTCs and cCAFs levels between the MET and the LOC groups suggesting that CTCs and cCAFs are associated with advanced stage disease. While most patients, both in the LOC and MET group, exhibited CTCs, very few LOC patients exhibited cCAFs. We suggest that cCAFs could independently or along with CTCs serve as liquid biopsy biomarkers of metastasis. Validation of these findings in a larger cohort of patients will be presented during the meeting.
 Publication Number: P2-02-11

Title: Detection of activating estrogen receptor 1 (ESR1) mutation on single circulating tumor cells from metastatic breast cancer patients

Paolillo C, Mu Z, Austin L, Nguyen T, Capoluongo E, Fortina P and Cristofanilli M. Catholic University of the Sacred Heart of Rome, Rome, Italy and Thomas Jefferson University and Kimmel Cancer Center, Philadelphia, PA.

Body: Background: 65% of primary breast cancers express the estrogen receptor α (ERα) and the mainstay of treatment are therapies that result in selective estrogen receptor modulation (SERM) of estrogen deprivation (aromatase inhibitors, AIs). Even thought endocrine therapy resulted in reduced recurrence and mortality, a significant portion of patients relapse with a metastatic disease and subsequently progress while of therapy for advanced disease (endocrine resistance). Recent evidence showed that activating hot spot mutation in the ligand binding domain of the ERα are acquired on treatment (frequency of 20%) and can drive resistance to endocrine therapy. Circulating tumor cells (CTCs) provide a non-invasive accessible source of tumor material and the molecular profiling of these rare cells might lead to insight on disease progression and therapeutic strategies. These features suggest that the detection of ESR1 mutation on single CTC may be a useful biomarker for therapy guidance.

Purpose: Investigate the incidence and heterogeneity of ESR1 mutational status within single CTCs isolated from individual metastatic breast cancer patients (mBCs), combining the FDA approved CellSearch® system for enumeration of CTCs with the DEPArrayTM technologies.

Methods: CTCs were enriched and enumerate by CellSearch® in 7.5 ml blood samples collected from 21 mBCs according to standard protocol. Each CTC-enriched sample with at least 20 CTCs was recovered from Veridex cartridge and loaded into the DEPArrayTM A300K chip, since the DEPArrayTM analyzed only the 66% of the sample volume loaded, according to the manufacturer's instructions. The chip scanning was performed by automated fluorescence microscope. The loaded cells were recovered as single cell and subdivided in three different group: Cytokeratin (CK) positive (Dapi+, CK+, ER-, CD45-); ER positive (Dapi+, ER+, CK+, CD45-); White Blood cells (WBCs) (Dapi+, CD45+, CK-, ER-). Single CTCs and WBCs were then submitted to whole genome amplification (WGA) using the Single Cell WGA kit (Yikon Genomics) according the manufacturer's instructions. Detection of target 14 ESR1 hot spot mutations was performed on ABI PRISM® 3700 genetic analyzer by target Sanger sequencing.

Results: 3 out of 21 mBCs with ≥20 CTCs were sorted and a total of 65 cells were recovered. WGA and ESR1 mutational status were performed on a total of 25 cells (respectively 11 ER+, 6 CK+ and 8 WBCs). In 1 of the 3 patients, that failed 2 lines of chemotherapy and previous single agent endocrine therapy, molecular heterogeneity was detected among its ER+ cells. 4 of 5 ER+ cells were heterozygote for the Y537S while one cell was homozygous, maybe due to a loss of heterozygosity. Y537S is one of the most common mutations that leads to a ligand independent ER transcriptional activity that does not respond to endocrine manipulation. No mutations were reported in all the CK+ and WBC cells analyzed.

Conclusions: This study demonstrates the feasibility of a non-invasive approach based on liquid biopsy in mBCs. Evaluation of ER status and early identification of ESR1 mutation in ER+ CTCs might allow to predict effect of the endocrine therapies and switching to other treatments before the emergence of metastatic disease.
Title: Association of inflammatory and tumor markers with circulating tumor cells in metastatic breast cancer

Lohmann AE, Chang M, Dowling RJO JO, Ennis M, Amir E, Elser C, Brezden-Masley C, Vandenberg T, Lee E, Fazae K, Stambolic V and Goodwin PJ J. Mount Sinai Hospital, Toronto, ON, Canada; Lunenfeld Tanenbaum Research Institute, Toronto, ON, Canada; University of Toronto, Toronto, ON, Canada; Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada; Applied Statistician, Markham, ON, Canada; St. Michael's Hospital, Toronto, ON, Canada and London Regional Cancer Program, London, ON, Canada.

Background: Circulating tumor cells (CTCs) are associated with prognosis in metastatic breast cancer (BC). We evaluated the association of inflammatory/tumor markers and CTCs in women with progressing metastatic breast cancer prior to commencing a new line of systemic therapy.

Methods: From February 2013 to April 2015, 96 patients with metastatic BC about to start a new treatment (due to progression), without current diabetes or use of anti-inflammatory agents, were recruited from four Ontario cancer hospitals. Women provided fasting blood for inflammatory and tumor markers and CTC measurement; CTCs were assayed within 72 hours of collection using CellSearch. Blood was frozen at -80C until assays were performed in a single batch (C-reactive protein (CRP), IL-6, PAI-1, Ca15-3, Ca125, VEGF, TNFa). Associations of CTCs with blood factors were evaluated using Pearson correlation coefficients after transforming the variables to normality. For CTCs the transformation log(x+0.5) was used. Associations with categorical variables were tested using one-way analysis of variance. P values <0.05 were significant.

Results: Median age of patients was 60.5 years, 87 (90.6%) were post-menopausal, 83 (86.5%) had hormone receptor positive BC, 16 (16.7%) HER2 positive BC, 10 (10.4%) triple negative; 75 (78.1%) grade II/III. At the time of CTC measurement, bone, lung, liver and brain metastases were present in 79%, 44%, 40% and 6% of patients respectively, with 54%, 37%, 35% and 3% having progression at these sites respectively. PAI-1 and CA15-3 exceeded the limit of the assay in 11 and 5 cases respectively (the upper limit of the assay was used in the analysis). 33.4% of patients were starting first line therapy, 25% second line and 16.7% third line. CTC counts (per 7.5cc) ranged from 0 to 1238 (median 2, geometric mean 3.63); none were detected in 29 (30.2%) patients, 1 to 4 in 25 (26%) and 5 or more in 42 (43.8%) patients. CTCs were not associated with age, estrogen receptor, progesterone receptor, HER2, line of treatment, lymph-vascular invasion or tumor grade. Compared to metastatic disease at other sites, CTCs were higher in the presence of bone (p=0.027) and liver metastases (p=0.002) and with progressing bone (p=0.018) and liver (p=0.012) metastases. CTCs were significantly associated with CRP (R =0.25, p=0.014), IL-6 (R=0.31, p=0.002), PAI-1 (R=0.31, p=0.002), Ca15-3 (R=0.44, p=<0.0001) and Ca 125 (R=0.21, p=0.04) but not with VEGF and TNFa (R = 0.11, p= 0.29 and R = 0.16, p=0.11, respectively).

Conclusion: CTCs were associated with bone and liver metastases and with higher levels of inflammatory and tumor markers, potentially reflecting tumor burden. Additional inflammatory marker assays are underway. Future studies are warranted to confirm these findings.
Title: EpCAM-independent enrichment approach for isolation of circulating tumor cells (CTCs) in breast cancer - What can be found in the EpCAM-depleted fraction?

Fehm T, Schneck H, Gierke B, Pawlak M, Templin M, Niederacher D and Neubauer H. Heinrich-Heine-University of Duesseldorf, Duesseldorf, Germany and NMI Natural and Medical Sciences Institute at the University of Tuebingen, Reutlingen, Germany.

Body: Circulating tumor cells (CTCs) are the potential precursors of metastatic disease. Many assays have been established for the enumeration of CTCs. However, major limitations include the reliance on the expression of the cell surface marker epithelial cell adhesion molecule (EpCAM). These approaches may not detect CTCs that either express no/low levels of EpCAM or undergo epithelial-to-mesenchymal transition (EMT). We present an enrichment strategy combining different antibodies specific for surface proteins and extracellular matrix (ECM) components to capture EpCAMneg cell lines and EpCAMneg CTCs from EpCAM-depleted breast cancer blood samples. Expression of proteins (Trop2, CD49f, cMet, CK8, CD44, ADAM8, CD146, TEM8, CD47) was verified by immunofluorescence on EpCAM-positive (e.g. MCF7, SKBR3) and -negative (MDA-MB-231) breast cancer cell lines; antibodies and ECM proteins (e.g. hyaluronic acid (HA), collagen I, laminin) were further spotted in a single- and multi-arrayed format onto glass slides (Schott, NEXTERION® AL) and coupled to immunomagnetic beads (Dynabeads/Adembeads). Tumor cell adhesion of EpCAMpos/neg cell lines was visualized by Coomassie/MitoTracker; EpCAMneg CTCs enriched via functionalized Adem-/Dynabeads were identified by immunofluorescence staining for anti-pan-Cytokeratin(CK)-FITC/anti-CD45 AF647/DAPI and quantified manually by microscopy. Regarding cell lines, marginal binding of EpCAMneg MDA-MB-231 cells to EpCAM-antibodies could be observed. Efficient adhesion/capturing of EpCAMneg cells could be achieved via HA and immobilized antibodies against CD49f and Trop2. By analyzing 29 EpCAM-depleted fractions from 25 metastatic breast cancer patients, we were able to identify EpCAMneg CTCs in 69% of the samples [range 1-24] applying Trop2, CD49f, cMet, CK8 and/or HA magnetic enrichment. Accessorily, EpCAMneg dual-positive (CKpos/CD45pos) cells could be traced in 28 out of 29 samples [range 1-480]. Herein, we demonstrate an enhanced enrichment strategy to optimize capturing of EpCAMneg CTCs by targeting various cell surface antigens with antibody mixtures and ECM components. Thereby, potential relevant CTCs can be gathered and subjected to subsequent molecular analysis.

Title: Detection and characterization of CTCs isolated by ScreenCell®-Filtration in metastatic breast cancer

Body: Background: Circulating Tumor cells (CTCs) detection has prognostic and predictive implications in patients with metastatic breast cancer (MBC). Genomic and phenotypic analysis of CTCs hold enormous promise as blood-based molecular characterization and monitoring disease progression and treatment benefit with a strong potential to be translated into more individualized targeted treatments. FDA-approved CellSearch™ detection allows only enumeration of CTCs expressing EpCAM without molecular characterization. CTCs represent very heterogeneous populations of tumorigenic cancer cells and some subpopulations have undergone epithelial-Mesenchymal transition (EMT), which is associated metastasis process and an unfavourable outcome. EpCAM-based enrichment technique has failed to detect EMT subpopulations due to the decreased expression or loss of epithelial markers. Non-EpCAM-based approaches are needed for identifying EMT CTCs. The ScreenCell® devices are single-use and low-cost innovative devices that use a filter for enrichment-free isolation of CTCs by a two-steps combining size-based separation and staining using different markers. The DEPArray™ system is the ideal downstream isolation system to collect single or pooled CTCs for molecular and genetic analysis. In this study, we evaluated the feasibility of achieving CTCs detection/ enumeration using ScreenCell® filtration followed by single cell isolation with the DEPArray™ in MBC patients.

Methods: The first part of the study consisted in evaluating CTCs detection/enumeration in 30 patients with stage III and stage IV breast cancer. 3 mL of whole blood in an EDTA or Transfix tubes was collected and processed on the ScreenCell® Cyto device following the instructions of the supplier. CTCs were stained with cytokeratin (CK-8, 18, and 19), leukocyte antigen (CD45), and a nuclear dye (DAPI) and counted under fluorescence microscope. CTCs were identified as positive staining for CK and DAPI and negative staining for CD45 (CK+/DAPI+CD45-). In the second part, After enrichment, CTCs were stained with CK, CD45, and DAPI and sorted with DEPArray™ Platform (Silicon Biosystems, Inc). Single CTCs were collected and the DNA of each single CTCs was amplified with Ampli1™ WGA kit, and the genome integrity index (GII) was assessed by Ampli1™ QC kit (Silicon Biosystems, Inc). Library was constructed and whole exome sequencing (WES) of DNA mutations was conducted.

Results: Twenty patient samples had CTCs detected (66.7%), the number of CTCs was 1 to 347 per 3.0 ml of whole blood. CTC-clusters were detected in 7 patient samples (23.3%). Single CTCs were collected on DEPArray™ platform after enrichment with ScreenCell filtration. GII was confirmed with the presence of short, medium, and long DNA fragments (3 to 4 PCR bands) in the WGA library by PCR-based assay. All collected CTCs showed high GII as measured by Ampli1™ QC kit (GII ≥ 3) for WES of DNA mutations. The data analysis of WES results is under processing.

Conclusions: ScreenCell® filtration is simple and effective devices to isolate CTCs and identify CTC-clusters. Isolation of single cells for molecular analysis using the combination of ScreenCell® filtration and DEPArray™ Platform is feasible for genetic characterization of CTCs.
Title: Discovery of putative circulating tumor cells through somatic mutation profile of epithelial cell adhesion molecule positive single cells from blood of metastatic breast cancer patients

Lee H-B, Jeon S, Kim BC, Jho S, Kim J, Kang YJ, Yoo T-K, Han JH, Kim Y, Im S-A, Moon H-G, Noh D-Y and Han W. Seoul National University College of Medicine, Seoul, Republic of Korea; The Genomics Institute, UNIST, Ulsan, Republic of Korea; Personal Genomics Institute, Genome Research Foundation, Suwon, Republic of Korea; Borame Medical Center, Seoul, Republic of Korea; Seoul National University College of Medicine, Seoul, Republic of Korea and Cancer Research Institute, Seoul National University College of Medicine, Seoul, Republic of Korea.

Body: Background: Circulating tumor cell (CTC) enumeration provides prognostic information for chemotherapy in metastatic breast cancer. However, due to its rarity and heterogeneity, it is difficult to distinguish true CTCs from normal blood cells and perform genomic analysis on them for use in therapeutic strategies. The main application of most currently available CTC detection systems consists of an enumeration of putative CTCs without further analysis. The aim of this study was to evaluate the feasibility of single cell picking and target sequencing of epithelial cell adhesion molecule (EpCAM)-positive cells for detecting CTCs.

Methods: Whole blood sampled from metastatic breast cancer patients who were newly diagnosed with metastasis or who had disease progression during palliative treatment were used for this study. After applying IsoFlux Circulating Tumor Cell Enrichment Kit (Fluxion, South San Francisco, CA, USA), single CTC candidates were picked from a pool of EpCAM-positive cells. Genomic DNA from the picked cells was whole genome amplified and target sequencing was performed using Ion AmpliSeq™ Cancer Hotspot Panel (Life Technologies, Carlsbad, CA, USA). Target sequencing reads were mapped to human genome reference (hg19) using BWA-MEM (0.7.10). Single nucleotide variants (SNVs) were annotated using dbSNP, Variome Data 0.2, and COSMIC databases.

Results: A total of 172 EpCAM-positive cells were selected according to size and EpCAM status from whole blood of 11 patients. The remaining cells were grouped into a pooled sample for each patient. The mean read depth of the target genes was 13455×. A mean 7.82 mutations as determined by SNVs listed in the COSMIC database but not in dbSNP and Variome Data 0.2 were detected in each patient. Cells with multiple mutated genes, or those with a mutated gene repeatedly observed in another cell from the same patient were judged to be putative CTCs. At least 2 putative CTCs were detected in 7 patients while no CTCs were detected in 2 patients. Mutated genes observed in the putative CTCs were ABL1, AKT1, APC, CDH1, CDKN2A, ERBB2, FGFR3, HRAS, IDH1, JAK2, KDR, NPM1, RB1, RET, SMARCB1, STK11, and TP53.

Conclusions: Potential CTCs were successfully identified by single cell picking and target sequencing of EpCAM-positive cells from whole blood of metastatic breast cancer patients. Unique mutations not detected in other single cells and pooled samples can be used to distinguish putative CTCs from normal cells. Genomic profiling of corresponding primary tumor and metastatic site biopsy is warranted to verify the CTCs and investigate their role in disease progression.
**Title:** The proliferation index of circulating tumor cells (CTCs) is not influenced by the administration of adjuvant chemotherapy in early breast cancer (BC) and seems to reflect Ki67 expression of the primary tumor

Agelaki S, Spiliotaki M, Spanaki A, Kassiou L, Tzardi M, Koinis F, Kafousi M, Georgoulias V and Mavroudis D. Laboratory of Tumor Cell Biology, School of Medicine, University of Crete, Heraklion, Greece; University General Hospital of Heraklion, Heraklion, Greece and University General Hospital of Heraklion, Heraklion, Greece.

**Body:** Background: The assessment of Ki67 in the primary tumor represents a prognostic marker with potential predictive implications in early BC. We evaluated Ki67 expression in CTCs from patients with early BC and assessed the effect of adjuvant chemotherapy as well as Ki67 expression in the primary tumor.

Methods: Ki67 was evaluated in CTCs of 97 patients with early BC pre- and post- adjuvant chemotherapy by the use of immunofluorescence analysis. Cytospins of peripheral blood mononuclear cells were double stained with A45-B/B3 cytokeratin mouse antibody and a Ki67 rabbit antibody. Ki67 staining of the primary tumor was also performed for 13 CTC-positive patients. A proliferation index (PI) in CTCs was considered as the ratio of Ki67-positive CTCs/total CTCs. A PI of up to 14% was defined as 'low' whereas a PI above 14% was defined as 'high'.

Results: CTCs were detected in 26 (26.8%) patients before and/or after chemotherapy. Seven (27%) of 26 CTC-positive and 8 (11%) of 74 CTC-negative patients relapsed (p = 0.047). Ki67-positive CTCs were identified in 20 (76.9%) of 26 patients, whereas in 1 (3.9%) and 5 (19.2%) patients, exclusively Ki67-positive and Ki67-negative CTCs, respectively, were detected. Seven (33%) of 21 Ki67-positive patients relapsed in contrast to none among the exclusively Ki67-negative patients (p = 0.13). A total of 154 and 161 CTCs were detected pre- and post-chemotherapy, respectively; the PI in CTCs was 56% and 55%, respectively. In 8 patients with detectable CTCs at both time points, the PI was 65% and 49% pre- and post-chemotherapy, respectively. In 5 (62.5%) out of 8 patients, the PI remained high, in 2 (25%) increased and in 1 patient no Ki67–positive CTCs were detected post-chemotherapy. Seventeen patients were CTC-positive at baseline [HER2 positive, n=5; triple negative, n=1; hormone receptor positive, n=11]. A concordance in Ki67 staining between the primary tumor and CTCs was recorded in 10 (77%) out of 13 patients. Moreover, in 2 (67%) of 3 patients with exclusively Ki67-negative CTCs, low Ki67 expression was also observed in the primary tumor. Interestingly, 2 out of 5 patients with HER2 positive primary relapsed and both had high PI in their CTCs, whereas 2 out the 3 HER2 positive patients that did not relapse had low CTC proliferation index. Similarly, the triple negative patient had low PI in her CTCs and has not relapsed after 4 years of follow up.

Conclusions: Adjuvant chemotherapy fails to decrease the proliferation index in CTCs. Ki67 expression in CTCs seems to reflect Ki67 expression in the primary tumor and could be predictive of patient outcome.
T-DM1 in HER2-negative metastatic breast cancer patients with HER2-amplified circulating tumor cells: Current status of the CirCe T-DM1 phase II trial

Bidard F-C, Romieu G, Jacot W, Cottu P, Dieras V, Lerebours F, Servent V, Luporsi E, Lortholary A, Tubiana-Mathieu N, Espie M, Bollet M, Bourgeois H, Renaud N, Pelissier S, Armanet S, Baeten K and Pierga J-Y. Body: **Background:** Liquid biopsy can reassess key therapeutic targets in metastatic breast cancer. Several studies showed that a low albeit significant rate of metastatic breast cancer initially considered as HER2-negative can be reclassified as HER2-positive by systematic biopsy procedures. We report here the current status of the CirCe T-DM1 trial [NCT01975142] which aims to demonstrate the clinical utility of HER2 status reassessment on circulating tumor cells (CTCs).

**Methods:** The first step of the trial consists in CTC count and HER2/CEP17 FISH on detected CTCs (CellSearch, Janssen Diagnostics) in patients (pts) with measurable disease progressing after the second line of chemotherapy. Pts with amplified CTCs (HER2/CEP17 ratio equal or higher than 2.2) are eligible to the treatment step of the study in two distinct cohorts: low CTC count (1 or 2 HER2-amplified CTCs) and high CTC count (3 and more HER2-amplified CTCs). In the treatment step has a Simon's two stage design, the anti-HER2 antibody-drug conjugate T-DM1 being administered until tumor progression. The primary objective of the trial is the confirmed response rate (RECIST). This trial is supported by Roche.

**Results:** CirCe T-DM1 has been initiated in 10 centers in France. As of June 2015, 105 metastatic breast cancers pts considered as HER2-negative were screened. 29 pts (27%) had no CTC detected, 68 pts (65%) had at least 1 CTC detected with no HER2 amplification, and 8 pts (8%) exhibited HER2-amplified CTCs. Among the 8 pts, 1 pt had 5 HER2-amplified CTC, 2 pts had 2 HER2-amplified CTC and 5 pts had 1 HER2-amplified CTC. HER2/CEP17 ratios among HER2-amplified CTCs ranged from 2.5 to 7. Five of the 8 pts were treated by T-DM1. One objective confirmed partial tumor response has been observed (20%).

**Conclusion:** The accrual is ongoing; the first efficacy assessment will occur after having treated 14 pts. This innovative trial highlights the promise and the complexity of liquid biopsy-based programs in the era of precision medicine: scarcity of the target, reliability and reproducibility of the target assessment, major efficacy when the target is matched to the appropriate drug.
Targeted next-generation sequencing reveals heterogeneity of single CTCs in metastatic breast cancer

Background: Cell-free DNA (cfDNA) and circulating tumour cells (CTCs) are under investigation as a "liquid biopsy" for real-time monitoring of patients with cancer. We aimed to compare single CTCs with matched cfDNA by targeted NGS in metastatic breast cancer (MBC).

Methods: CTCs were enriched and enumerated by CellSearch® from 7.5 ml of blood in 2 patients with MBC. For the first patient, five single CTCs and 5 lymphocytes were isolated for the CellSearch® cassette by DEParray™ and DNA was extracted and amplified using the Ampli1 WGA kit (Silicon Biosystems). For the second patient DNA was extracted from the total pool of 3808 CTCs. Targeted NGS was performed with 2 amplicon panels (Ampli1 and a custom mutation panel (1)) using the Ion PGM™ platform.

Results: The 5 single CTCs showed mutational heterogeneity. Two CTCs had both a PIK3CA p.H1047R and an ESR1 p.E380Q mutation present and 2 other CTCs had a TP53 p.P72R mutation. A number of novel variants were also identified that were heterogeneous between the 5 CTCs but not seen in the matched lymphocytes. All mutations found across the 5 CTCs were detected in the paired cfDNA sample with no additional mutations unique to cfDNA. In the second patient with an extremely high CTC count, an ESR1 p.D538G mutation was detected in the CTC pool and matched cfDNA, but the cfDNA also had a novel variant in exon 7 of FGFR1.

Conclusion: These data confirm the molecular heterogeneity of single CTCs and suggest cfDNA as a suitable biomarker for the genetic landscape of CTCs in MBC. Analysis of other samples is ongoing.

Title: Somatic genetic profiling of circulating tumor cells (CTC) in metastatic breast cancer (MBC) patients

Body: Introduction: Somatic mutations, including those in TP53, PIK3CA, and estrogen receptor alpha (ESR1), are key to the biology of cancer and response to therapy. Recently, somatic cancer-associated mutations have been identified in circulating cell free plasma tumor DNA (ptDNA). Less is known about the mutation profile of DNA extracted from CTC (CTC-DNA). Since CTC-DNA provides mutational information of single cells, we hypothesize CTC-DNA will complement ptDNA to give greater insight into tumor heterogeneity.

Methods: Patients with ER positive MBC who were enrolled in the Mi CTC-ONCOSEQ, a companion trial to Mi-ONCOSEQ (the Michigan Oncology Sequencing Program), and who had ≥5CTC/7.5 ml whole blood were included. CTC were enriched from white blood cells (WBC) with CellSearch® (CXC kit). CTC and WBC were then purified using DEPArray™. DNA from individual CTC and WBC was isolated and subjected to whole genomic amplification (Ampli1™ WGA). Genetic analysis was performed on individual CTC, pooled CTC and pooled WBC DNA by multiplexed PCR based targeted next generation sequencing (NGS) using the Oncomine Comprehensive Panel (targeting ~130 onco- and tumor suppressor genes) and the Ion Torrent Proton. All patients had exome sequencing performed on research biopsies of metastases using an Illumina HiSeq 2500 platform.

Results: This pilot study was conducted using high quality DNA from two patients assessed to date. Both patients had lobular carcinoma and as expected harbored somatic, deleterious CDH1 (E-cadherin) mutations (frameshift and non-sense) in both research biopsy and CTC-DNA. These data supported our approach. Patient #1 was TP53 wild type in her research biopsy, but multiple CTC harbored somatic TP53 frame-shift mutations (Table). Patient #2 harbored an ESR1 Y537S mutation in her research biopsy. However, only 4 of 7 CTC also harbored this somatic, heterozygous mutation.

**Conclusions:** We demonstrate the ability to purify CTC, isolate, and amplify DNA of suitable quality for genetic analysis using a comprehensive targeted sequencing panel. Both known and novel alterations were identified in comparison to research biopsy specimens. This approach allows single cell analysis demonstrating heterogeneity of mutational status in different single cells. Studies of CTC-ESR1 and other genetic abnormalities in patients with known tissue mutations who participated in Mi CTC-ONCOSEQ are now underway.
Title: Enumeration of heterogeneous circulating tumor cells (CTCs) in metastatic breast cancer patients based on size and deformability

Tozuka K, Nagai SE E, Inoue K, Komatsu K, Matsumoto H, Hayashi Y, Kurozumi S and Suganuma M. Division of Breast Surgery, Saitama Cancer Center, Ina, Kita-adachi-gun, Saitama, Japan; Division of Breast Oncology, Saitama Cancer Center, Ina, Kita-adachi-gun, Saitama, Japan; Division of Breast Surgery, 2 Division of Breast Research Institute for Clinical Oncology, Saitama Cancer Center, Ina, Kita-adachi-gun, Saitama, Japan and Graduate School of Science and Engineering, Saitama University, Shimo-okubo, Sakura-ku, Saitama, Japan.

Body: Background:
The detection of circulating tumor cells (CTCs) in peripheral blood is an independent predictor of the efficacy of systemic therapy and a prognostic marker for patients with metastatic breast cancer. One of the leading techniques to detect CTCs uses immune-magnetic separation followed by immunocytochemistry. A microdevice can capture and enumerate CTCs using distinctive physiological difference (size and deformability) between cancer cells and blood cells. This microdevice thus obtains a larger CTC yield than that of affinity based separation which enriches the samples from a particular subgroup of cells based on biomarker (EpCAM) used. In this study, we investigated CTCs in peripheral blood from metastatic breast cancer patients using this microdevice.

Patients and methods:
We examined blood samples of 9 patients with heavily treated locally recurrent or metastatic breast cancer. Informed consent from these patients was obtained before blood extraction. Blood samples were taken into sodium EDTA tubes after discarding the first 1 ml of blood samples. Two ml whole blood were subjected to the microdevice (Clear cell system), and CTCs were trapped in the microwells: Trapped cells were analyzed by immunocytochemistry with monoclonal antibodies specific for leukocytes (CD45) and epithelial cells (CK8/18), along with 4,2-diamidino-2-phenylindole dihydrochloride (DAPI) for nuclei. CK8/18-positive, DAPI-positive and CD45-negative cells were defined as CTCs. Three patients were examined using both this microdevice and affinity-based separation with EpCAM, to compare the yield of CTCs.

Results:
Of the 9 patients: 7 had ER-positive primary tumors, and 6 had PgR-positive ones, HER2 overexpression was detected in 2 primary tumors. CTCs were detected in 8 patients. The single patient in whom CTCs were not detected suffered from local recurrence (axillary lymph node metastasis) only, with no distant metastases. We were also unable to detect CTCs using EpCAM affinity method for this patient. The number of detected CTCs in the other patients ranged from 19/2ml to 156/2ml (mean 90/2ml), and the sizes of CTCs varied from 5 to 16 µm. CK8/18-negative and DAPI positive were detected in most patients, and these cells tended to be larger than CK8/18-positive cells, suggesting that epithelial-mesenchymal transition (EMT) might occur in CTCs. The total number of CTCs detected by the microdevice from 2 patients was larger than that of CTCs detected by EpCAM affinity method (107/2ml vs 1/7.5ml, and 19/2ml vs 39/7.5ml).

Conclusion:
CTCs detected by this microdevice varied in regard to the size of trapped cells and characteristics examined by immunocytochemistry, suggesting the heterogeneity of CTCs. Further research on this heterogeneity is vital in order to develop personalized treatment for patients with metastatic breast cancer.
Title: Longitudinal analysis of circulating tumor cells and cell free tumor DNA by next generation sequencing in triple negative breast cancer

Body: As the practice of genetically profiling patient tumors is considered for making clinical treatment decisions, recent methodologies for screening of genomic aberrations in circulating tumor cells (CTCs) and cell-free plasma DNA (cfDNA) may provide non-invasive tools for such applications. Genomic analysis of DNA from CTCs and plasma can also provide useful insight into tumor heterogeneity and thus disease progression by revealing sub-populations of tumor cells that evolve during treatment, have novel drug-resistant genotypes, or carry alternate cancer driver mutations not identified by the sequencing of primary tumors.

Comprehensive evaluation of DNA isolated from CTCs and cfDNA from a breast cancer patient by whole exome sequencing was performed to better understand the role of liquid biopsies in investigating the etiology of tumor progression. The patient was diagnosed with metastatic triple negative breast cancer (TNBC) six years after remission from estrogen receptor (ER-3+), progesterone receptor (PR-1+), human epidermal receptor growth factor 2 negative (Her2-), grade 3 intra-ductal carcinoma of the right breast. Metastatic lesions were found in the spine, pelvis and sacrum and bone-marrow. The patient was enrolled in the Intensive Trial of OMics in Cancer clinical Trial (ITOMIC-001; ClinicalTrials.gov ID NCT01957514) and initially received weekly cisplatin infusions followed by additional targeted therapy.

Peripheral blood was obtained during regular clinic visits over the 272 days the patient was enrolled in the clinical trial. CTCs were identified and enumerated from each blood draw using the AccuCyte® -CyteFinder® (AC/CF) system (RareCyte, Seattle WA). Multiple CTCs along with white blood cells (WBCs) were picked from various time points throughout the treatment regimen. The selected CTCs and WBCs were whole genome amplified and whole exome sequencing was performed to identify tumor specific variants. A comparative analysis with variants present in genomic DNA isolated from the bone-marrow metastasis tissue biopsy samples and cfDNA revealed the evolution of tumor-specific variants during therapy. Each CTC had somatic alterations in genes associated with therapies in current use or those in the clinical trials setting. Sequencing analysis of cfDNA provided similar information on potential therapeutic approaches. The monitoring of disease over time through genomic analysis of CTCs and cfDNA can identify novel sub-populations related to disease progression for the tailoring of cancer treatment regimens. Further analysis is being performed to better understand the evolution of the genomic heterogeneity among CTCs at the same time point and across different time points and therefore better understand the etiology of progression of metastatic breast cancer in this patient.
Title: Differentially methylated miRNA methylomes of normal breast tissue from ER negative and ER positive breast cancer mimic their respective tumor phenotypes

Worsham MJ J, Chen KM Mei, Chitale D, Stephen JK K and Divine G. Henry Ford Health System, Detroit, MI.

Body: Background: The unique structure and function of normal tissues is known to be regulated by epigenetic mechanisms. Understanding how normal cells in their respective tumor milieus might affect their susceptibility to become not only malignant but acquire breast cancer (BC) subtype-specific phenotypes, may determine tumor clinical behavior outcomes. The goal was to compare genome wide methylation profiles of non-coding miRNAs of breast cancer tissue and normal breast epithelium, respectively, from ER negative and ER positive tumors, and assess their miRNA methylomes in the context of tumor ER phenotypes as ER negative vs ER positive.

Methods: Breast cancer tissue from 79 patients (40 ER-positive and 39 ER-negative) and normal tissue from 39 of these patients (19 ER-negative and 20-ER-positive) were assayed using the Illumina 450K bead array. A sub analysis focused on 2249 miRNA CpGs assigned to 615 unique miRNAs. M-values were computed as a logit function \([(\log (\beta/ (1-\beta)))]\) of the methylation beta values. T-tests were used to compare the means of the M-values for the ER-positive and ER-negative groups. The t-test p-values were used to generate adaptive FDR (aFDR) levels and aFDRs of 0.05 or lower were considered to be statistically significant (Tier 1). Tier 1 CpGs were subsequently filtered to select only those with a mean beta ratio between ER-positive and ER-negative of under 0.5 or over 2.0 (Tier 2). The Tier 2 CpGs were further filtered to select only those with a mean beta difference of 0.2 or more (Tier 3).

Results: In the tumor cohort, 1224/2249 (54%) CpGs were differentially methylated between ER negative and ER positive BC at Tier 1 (aFDR 0.05 or lower). Of the 1224, 963 (78.7%) were hypermethylated, and 1035 (84.6%) were associated with the promoter region. The 1224, 24 and 2 CpGs were associated with 379, 22 and 2 genes for Tiers 1, 2 and 3, respectively. When the same analysis was performed on normal tissue only (19 ER-negative and 20-ER-positive) 76 of the 2249 CpGs had significant aFDR values and none of those met the Tier 2 or Tier 3 criteria. Seventy-one of the 76 (93.4%) where hypermethylated, and 65 (85.5%) were associated with the promoter region. The 76 significant Tier 1 (aFDR) differentially methylated CpGs were associated with 48 genes of which 43 were common to tumor Tier 1 differentially methylated miRNA genes, 10 were common to tumor Tier 2 genes, and 5 were restricted to normal tissue only.

Conclusions Normal epithelial tissues demonstrated similar differential methylation directionality as their respective tumor counterparts (although to a lesser extent), favoring promoter region localization. Accordingly, the recognition of normal breast tissue-specific epigenetic propensities that align with their tumor phenotypes, suggest the possibility of progression markers specific for estrogen receptor status as well as markers not associated with progression. This provides insights into our view of possible links between epigenetic programming, progression continuums, and how hormonal receptor subtypes may be determined. Title: Modulatory action of melatonin and miR-17 on ROCK-1 in breast cancer metastasis model

Borin TF Ferraz, Pongeluppi RI Inacio, Gelaleti GB Bottaro, Leonel C, Moschetta MG Gobbe, Ferreira LC Carvalho and Zuccari DAPdC Aparecida Pires de Campos. Faculdade de Medicina de Sao Jose do Rio Preto - FAMERP, Sao Jose do Rio Preto, Sao Paulo, Brazil; Universidade Estadual de Sao Paulo - UNESP, Sao Jose do Rio Preto, Sao Paulo, Brazil and Laboratorio de Investigação Molecular do Cancer - LIMC, Sao Jose do Rio Preto, Sao Paulo, Brazil.

Body: Breast cancer is the most common cancer in women is often associated with high morbidity and mortality rates, with great financial impact on health system. Besides, the disease is characterized by the high rates of metastasis, which worsen significantly the prognosis. This process is associated with two regulatory molecules, microRNAs (miR), specially miR-17, and ROCK-1, which overexpression has been associated to tumor growth and metastasis. In contrast, melatonin has shown oncostatic and anti-metastatic properties by reducing the cell ability to migrate and invade the tissue, besides the inhibition of cell proliferation. The aim of this study was to investigate the effect of melatonin to modulate miR-17 and ROCK-1, a possible candidate gene to miR-17 target in metastatic breast cancer cell line, MDA-MB-231. To determine the effect of melatonin to modulate miR-17 and ROCK-1, MDA-MB-231 cells were treated with melatonin and anti-miR-17-5p. ROCK-1 and miR-17 gene expression were accessed by real time PCR and ROCK-1 protein expression verified by immunocytochemistry and western blotting. Migration and invasion assay was performed to verify the action of melatonin and anti-miR-17-5p to inhibit these processes. In the in vivo study, was developed pulmonary metastasis model followed for six weeks, the tumor induction was continued for 4 weeks, and treatment with anti-miR-17-5p inhibitor for two more weeks. At the end of treatment, animals were euthanized, the lungs removed and used for analysis of miR-17-5p and Let-7c (positive control) and ROCK-1 gene expression. ROCK-1 protein was analyzed by immunohistochemistry. MiR17-5p inhibition managed directly modulate gene and protein expression of ROCK-1 in MDA-MB-231 cells, as well, the gene expression of MYC. In additional, the migration and invasion were decreased after melatonin and anti-miR-17-5p treatment. To validate the findings of the study in vitro with miR-17, was used for lung metastasis model in athymic nude mice. According to our findings, normal animals without metastasis (negative control) had lower levels of miR-17 compared to animals with metastasis and without treatment (positive control). In contrast, animals with metastasis who received anti-miR17-5p treatment, interestingly also had low miR-17 levels compared to positive control animals. Furthermore, it was observed fewer metastases and a reduction in ROCK-1 protein expression in these treated animals compared to positive control animals. Our results demonstrated that miR-17-5p inhibition can modulate ROCK-1 gene and protein in MDA-MB-231 cells and decreasing the number of lung metastases in treated animals. Furthermore, melatonin can act as a synergic mechanism to decrease migration and invasion on metastasis processes mediated by ROCK-1.
MicroRNA-497 targets SMAD7 and has a tumour suppressive effect and its prognostic significance in breast cancer

Liu J, Zhang S, Hu Y, Zhang M, Li C, Liu Y, Zhang X and Zhang J. China Tianjin Breast Cancer Prevention, Treatment and Research Center, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China.

Background: Latest studies have shown that SMAD 7 played a major role in breast cancer during tumour development and progression. In the current study, we aimed to examine the relationship between microRNA-497 (miR-497) and SMAD 7 and its function in MDA-MB-231 breast cancer cells and MCF-7 breast cancer cells. And to investigate the clinicopathologic and prognostic significance of miR-497 expression in human breast cancer.

Methods: Quantitative polymerase chain reaction was used to measure the expression levels of miR-497 in 40 breast cancer specimens and adjacent normal breast tissues. MTT assays, colony formation assays and cell cycle assays were used to explore the potential function of miR-497 in MDA-MB-231 breast cancer cells and MCF-7 breast cancer cells. Dual-luciferase reporter assays were performed to analyze the regulation of putative target of miR-497, and western blot assays were used to validate the dual-luciferase results. Also, miR-497 expression was detected in another 240 breast cancer tissues and its correlations with clinicopathologic features of patients were analyzed. Kaplan-Meier analyses were used to assess survival of patients.

Results: The results showed that MiR-497 was downregulated in breast cancer tissues compared with normal tissues (P <0.05). Dual-luciferase reporter assays manifestations that SMAD 7 is the target of miR-497. Quantitative polymerase chain reaction and Western blot assays validated that overexpression of miR-497 can reduce SMAD 7 protein levels, miR-497 can inhibit cellular growth and cause a G1 arrest. Of 240 BC patients, 132 (55%) were placed in the high miR-497 group and 108 (45%) were placed in the low-miR-497 group. By statistical analyses, The miR-497 expression levels were significantly lower in HER2-positive and base-like patients than luminal subtype patients (p=0.036). Moreover, patients with high miR-497 expression had better 5-year disease-free and overall survival compared with the low miR-497 group (P = 0.0027 and 0.0032, respectively). In the TNBC subtype with high miR-497 expression had better 5-year DFS and OS compared with the low miR-497 group (P = 0.0491 and 0.035). In the HER-2 + subtype with high miR-497 expression had better 5-year DFS and OS compared with the low miR-497 group (P = 0.0142 and P=0.024).

Conclusions: In summary, MiR-497 act as a tumor suppressor gene in breast cancer. Overexpression of miR-497 inhibited cell proliferation and G1 cell cycle arrest were observed. Downregulation of miR-497 was correlated with breast cancer progression and has negative correlation with SMAD7, The above results indicated that miR-497 might be a potential molecular biomarker for predicting the prognosis of patients and miR-497 could be considered an ideal therapeutic target for the HER-2 positive and TNBC breast cancer.
Title: Down-regulation of Bcl2-related ovarian killer (BOK) by miR-296-5p protects breast cancer cells from paclitaxel-induced apoptosis

Body: Accumulating evidence shows that miRNAs play a role in drug resistance. Despite these observations, little is known about the identities of the miRNAs involved in drug resistance and their downstream targets. In the present study, we identified miR-296-5p for which a tumor suppressive role has been previously described, as a miRNA that is involved in paclitaxel drug resistance in triple negative breast cancer (TNBC) cells. Enforced expression of miR-296-5p suppressed cell growth, migration, and invasion in MDA-MB-231 breast cancer cells. Using a microarray approach, we identified BCL2-related Ovarian Killer (BOK), a pro-apoptotic gene as a target of miR-296-5p. BOK levels were validated BOK levels in miR-296-5p transfected MDA-MB-231 and MDA-MB-468 cells using real-time PCR and Western blot. Our results demonstrated that over-expression of miR-296-5p down-regulated BOK expression in TNBC cells. Transfection of miR-296-5p significantly suppressed luciferase reporters containing wild-type BOK-3′-UTR constructs. In contrast, mutant BOK-3′-UTR constructs were unaffected by ectopic miR-296-5p. Furthermore, BOK expression was induced in the presence of paclitaxel, but ectopic miR-296-5p significantly suppressed BOK induction by paclitaxel treatment compared to the control cells. These data provide new insights on the role of miRNAs in drug resistance and suggests that therapeutic strategies against miR-296-5p may be warranted.

Title: MiRNA expression in breast cancer varies with lymph node metastasis and other clinicopathologic features

Body: Background: Breast carcinoma is the most common malignant tumor in females, lymph node status is one of the most important prognostic factors in patients with breast cancer. MiRNAs have been shown to have important role in oncogenesis, invasion, and metastasis via epigenetic posttranscriptional gene regulation. However lymphatic metastasis related miRNAs of breast cancer has not been well documented. The aim of this study was to identify and evaluate miRNAs related to breast cancer lymph node metastasis, and explore the clinical significance of the differential expressed miRNAs in breast cancer patients.

Methods: The expression of miRNAs in primary breast cancer patients with lymph node metastasis and that without lymph node metastases was compared by miRNA microarray. We further validated the miRNAs (miR-185-5p, miR-339-5p, miR-542-5p, miR-3923) between lymph node (n=31) and non-lymph node (n=42) group using real-time reverse transcriptase polymerase chain reaction. Furthermore, the relationship between miRNA expression and clinical pathological features was analyzed.

Results: The miRNA microarray initially identified that 8 miRNAs (miR-206, miR-3923, miR-181a, miR-92a, miR-421, miR-339-5p, miR-3196, and miR-29b) were down-regulated in lymph node metastasis group, whereas 5 (miR-542-5p, miR-200a, miR-564, miR-451, miR-30c, miR-200b, miR-191-3p, miR-142-5p, and miR-185-5p) were up-regulated in lymph node group when compared with those in non-lymph node group. In the validation cohort, the expression levels of miR-185-5p and miR-542-5p were significantly higher expressed in lymph node group (P=0.002, and P=0.000, respectively), the expression levels of miR-339-5p and miR-3923 were significantly lower expressed in lymph node group (P=0.000, and P=0.000, respectively).

Conclusions: Our results indicated the potential role of miR-185-5p, miR-542-5p, miR-339-5p and miR-3923 in predicting metastasis to the lymph node and prognosis in breast cancers.

Title: Dysregulation of miR-34a-SIRT1 axis reduced breast cancer stemness

Xiao GG G, Ma W, Mao J and Li L. School of Pharmaceutical Science and Technology, Dalian University of Technology, Dalian, Liaoning, China and Dalian Medical University.

Body: Recent studies show that enforced expression of miR-34a results in elimination of cancer stem cells (CSCs) in many malignant tumors. Sirtuin-1 (SIRT1) being confirmed as a direct target of miR-34a was reported to be involved in regulation of growth and survival of leukemia stem cells (LSCs). In this study, we aim to understand regulatory mechanism of miR-34a-SIRT1 axis in breast cancer stem cells (BCSCs). Lower endogenous level of miR-34a and higher level of Sirtuin1 (SIRT1) gene were identified in CD44+/CD24- BCSCs than breast cancer cells. Either ectopic expression of miR-34a or silenced SIRT1 in MCF-7 cells inhibited cellular proliferation, and led to cell apoptosis. Overexpression of miR-34a also suppressed expression of ALDH1, BMI1 and Nanog, and decreased capacity of mammosphere formation significantly. Studies in vivo showed that stable expression of miR-34a reduced tumor burden significantly in nude mice xenografts. Taken together, our results showed that miR-34a inhibit the proliferative potential of BCSCs in vitro and in vivo, at least partially through downregulating SIRT1. miR-34a-SIRT1 axis may play an important role in self-renewal and stemness maintenance of BCSCs. This study may provide a novel BCSCs specific therapeutic strategy to improve breast cancer treatments.
Title: Rhythmic time oscillations of microRNAs in human breast epithelial normal and cancer cell lines

Chacolla RJ J, Trevino VM M, Scott SP P and Moreno JE E. Instituto Tecnologico y de Estudios Superiores de Monterrey, Monterrey, Nuevo Leon, Mexico.

Body: BACKGROUND: Diverse molecular mechanisms are being reported in human breast cancer (BC), which can affect the biochemical functions throughout malignant cells development. The microRNAs (miRNAs) are an emerging class of modulators of gene expression with relevant roles in several biological processes, as oncogenic, tumor-suppressive, and metastatic-influencing in BC cells. Recently, a few reports have implied the possible pattern of expression (time oscillation) of miRNAs in time that may be related to molecular changes in mammalian cells. These findings suggest a biological connection among normal and cancer cells, and rhythmic regulation of some miRNAs, but such connection has not yet been studied. In this study, we aimed to identify and compare the rhythmic expression of miRNAs in human breast epithelial normal and cancer cell lines.

METHODS: We used cell culture to explore three cell lines, one breast epithelial normal (MCF10A) and two cancer (MCF-7 and MDA-MB-231) cell lines under standard growth conditions in vitro. The cells were synchronized by serum shock (50% horse serum for 2 h), and we collected sample cells (triplicate) for intervals of 4 hours during 48 hours. Collected cells at 12h to 40h (8 time-points) were genome-wide analyzed of miRNA expression using high-throughput Agilent Human miRNA microarray of 2006 human miRNAs. Analysis for identification of rhythmic miRNAs was developed by cosine analysis in R software.

RESULTS: We observed diverse oscillation patterns (minimum 6 patterns, i.e. cosine or sine oscillation) of miRNAs in cell lines. Each cell line shows approximately 85 miRNAs with rhythmic oscillation. These also showed distinct phases between cell lines, which could suggest as part of molecular changes in breast normal and cancer cell lines.

CONCLUSIONS: Our results suggest that miRNAs may present rhythmic oscillation in the regulation of molecular changes of human breast normal and cancer cells.
miR-621 suppresses the metastatic cascade in breast cancer patients

Xue J, Chi Y, Chen J, Yang B and Wu J. Fudan University Shanghai Cancer Center, Shanghai, China and Shanghai Medical College, Fudan University, Shanghai, China.

Body: Purpose: In previous study, we had shown that miR-621 could sensitize breast cancer to chemotherapy by suppressing FBXO11 and enhancing p53 activity. In this study, we aimed to define miR-621 prognosis value in breast cancer patients, and to explore the potential molecular mechanisms.

Experimental Design: 70 patients with stages II and III breast cancer were included as validation set. The correlation between miR-621 expression level and prognosis in breast cancer patients was confirmed. In parallel, in vitro and in vivo analyses were carried out to determine the potential mechanisms of miRNA-dependent prognosis.

Results: We validated that lower than higher miR-621 expression level was markedly associated with poor metastasis-free survival in breast cancer patients (P=0.03). In breast cancer cell lines, ectopic overexpression of miR-621 inhibited proliferation, migration, invasion, and metastasis both in vitro and in vivo. The potential miR-621-target genes were determined by TargetScan and miRNA CLIP-seq database. Among those, PAK7 was verified as one of the direct targets of miR-621 in breast cancer cells, whose expression level positively associated with recurrence and metastasis in breast cancer patients. The molecular mechanisms by which miR-621/PAK7 axis regulates recurrence and metastasis may involve regulation of epithelial-mesenchymal transition (EMT) in breast cancer cells.

Conclusions: Our study revealed a strong correlation between miR-621 expression and metastasis in breast cancers. High level of miR-621 was negatively associated with poor metastasis-free survival. The increased metastasis-free survival may be mediated by down-regulation of PAK7 gene, which leads to reduced EMT in breast cancer cells. Therefore, miR-621 may represent a therapeutic target for early metastasis breast cancer.
The role of Jmjd1a in mammary gland development and breast tumor growth

Qin L, Xu Y, Wu Y, Yu X, Toneff MJ Joseph, Liao L, Li Y and Xu J. Baylor College of Medicine, Houston, TX; Baylor College of Medicine, Houston, TX; Baylor College of Medicine, Houston, TX; Baylor College of Medicine, Houston, TX; Baylor College of Medicine, Houston, TX; Baylor College of Medicine, Houston, TX and Baylor College of Medicine, Houston, TX.

Body: Histone modification alters chromatin architecture and thereby influences gene transcription. Histone methylation status is reversible and counter-regulated by methyltransferases and demethylases. Jmjd1a (also known as KDM3A, TSGA, JMJD1, JHDM2A and JHMD2A) is a histone demethylase. It belongs to JmjC domain-containing protein family and could specifically remove di- and mono-methyl residues from di or mono-methylated histone H3K9 (H3K9me2/me1). Recent studies showed that Jmjd1a plays an important role in embryonic stem cell self-renewal, spermatogenesis, regulation of metabolic gene expression and body weight, sex determination, tumor angiogenesis, and macrophage infiltration. However, its role in mammary gland (MG) development, breast carcinogenesis and breast cancer progression hasn’t been systemically investigated. In this study, we found that Jmjd1a is expressed in mouse luminal epithelial cells. Genetic disruption of the Jmjd1a gene significantly slowed down MG development as indicated by retarded MG elongation and decreased ductal density in virgin mice observed at the ages of 4, 6 and 8 weeks. In agreement with the retarded MG development, the expression of Ki67 and cyclinD1 in epithelial cells of MGs from Jmjd1a knockout (KO) mice dramatically reduced compared with that from wild type (WT) mice. H3K9me1 and H3K9me2 levels in the epithelial cells of KO MGs are much higher than that in WT MGs. To assess the role of Jmjd1a in breast cancer progression, we crossbred Tg(Jmjd1a-/-) mice with MMTV-TVA(RCAS-PyMT) mice and obtained Tg(Jmjd1a-/-)×MMTV-TVA(RCAS-PyMT) mice. Infection of the TVA-expressing MG epithelial cells with the RCAS-PyMT virus induced mammary tumors in these mice and MMTV-TVA(RCAS-PyMT) control mice. We found that KO of Jmjd1a slightly accelerated mammary tumor initiation but significantly decreased tumor growth. Ki67 and cyclinD1 expression statistically reduced in KO tumors versus WT tumors. At the molecular level, Jmjd1a expression positively correlated with cyclin D1 expression in mammary epithelial cells and mammary tumors. Knockdown of Jmjd1a in MCF-7 cells significantly reduced cyclin D1 expression, while ectopic expression of Jmjd1a in MCF-7 cells increased cyclin D1 expression. ChIP assay revealed that Jmjd1a is associated with a promoter region of cyclin D1. Co-expression of c-Myc and Jmjd1a boosted the activity of the cyclin D1 reporter. In conclusion, our study indicated that Jmjd1a plays an important role in promoting mammary gland development and breast tumor growth by up-regulating cyclin D1 expression. Targeting Jmjd1a may inhibit breast cancer progression.
Title: Immunomodulatory effects of entinostat on PD-L1 and MHC class I and II in different subtypes of breast cancer

Body: Background: Targeting immune checkpoint programmed death receptor 1 (PD-1)/PD-L1 pathway has shown promising clinical activity with some preliminary association of clinical benefit with PD-L1 expression on tumors. Recent preclinical and clinical studies highlight the beneficial immunomodulatory potential of epigenetic therapy. Entinostat is a class I specific histone deacetylase inhibitor (HDACi). A promising preclinical study showed that entinostat in combination with immune checkpoint blockade agent can eradicate modestly immunogenic breast tumors in mice via reduction in immunosuppressive myeloid-derived suppressor cells. In this study, we investigated the effects of entinostat on expression of immune-related genes in breast cancer cells to further explore the potential mechanism of its combined activity.

Method: Gene expression was assessed on Nanostring platform using the nCounter GX Human ImmunologyV2 panel comprised of 594 immune-related and 15 reference genes. Gene expression was normalized to the internal positive controls and reference genes using nSolver2.0 software. Hormone receptor-positive (HR+) breast cancer (MCF-7 and T47D) and triple negative breast cancer (TNBC) cell lines (MDA-MB-231 and Hs578T) were used for the analysis. Gene expression analysis was performed on control and after 24-hour treatment of entinostat at clinically relevant 125 and 500 nM concentrations.

Results: Overall, a greater number of immune-related genes were induced > 2 fold with entinostat at 125 and 500 nM in TNBC compared to HR+: 77 and 118 genes in MDA-MB-231, 80 and 147 genes in Hs578T, 20 and 64 genes in MCF-7, and 73 and 72 genes in T47D, respectively. In particular, MHC class I (HLA-A, HLA-B, HLA-C) and II (HLA-DMA, HLA-DMB, HLA-DOA, HLA-DOB, HLA-DPA1, HLA-DPB1, HLA-DQA1, HLA-DQA2, HLA-DQB1, HLA-DQB2, HLA-DRA, and HLA-DRB1) genes were induced by entinostat in a dose dependent manner (range 1.5-22.44 fold). These inductions were observed in both HR+ and TNBC cell lines. Interestingly, we found higher baseline expression and a several fold increase in PD-L1 expression in TNBC. PD-L1 mRNA expression increased by 1.74 and 2.14 fold in MDA-MB-231 and 3 and 9.6 fold in Hs578T with 125 and 500 nM treatment, respectively. Corresponding increase in PD-L1 protein expression after entinostat treatment was also observed. In contrast, there appeared to be no significant changes in PD-L1 expression after entinostat treatment in MCF-7 and T47D.

Furthermore, we also identified 21 genes that were differentially induced by entinostat in TNBC but not in HR+. These genes include PTPN22, ARG2, CISH, IL17A, ICAM2, KIR3DL1, CXCR3, TLR2, CFD, CCR5, IL13, LILRA3, IL8, TNFRSF9, DPP4, MR1, SELPLG, PTGS2, IL1B, CD3D, and MBL2. No significant change in PDL2 expression was observed in any of the cell lines.

Conclusion: Our data suggest that entinostat induces immune-related genes involved in antigen presentation in both ER+ and TNBC cells, potentially increasing the immunogenicity of these tumors. Given the significant induction of PD-L1 expression with entinostat in TNBC, our preclinical data provides support for further investigation of entinostat in combination with anti-PD1 or anti-PD-L1 in this subtype of breast cancer.
Title: SUMO wrestles breast cancer: SUMO posttranslational modification directs breast cancer cell epigenome

Bawa-Khalfe T, Kumar S and Lin F-M. University of Houston, Houston, TX and MD Anderson Cancer Center, Houston, TX.

Body: Epigenetic reprogramming allows breast cancer (BCa) cells to bypass normal growth checkpoints and acquire an aggressive morphology. Function of critical epigenetic proteins is directed by small ubiquitin-like modifiers (SUMO) posttranslational modification (PTM). Components of the SUMO system are dysregulated in BCa. Our objective is to delineate how changes to SUMO-PTM affect epigenetic programs that coordinate BCa pathology. We report that chromatin-bound SUMO protease SENP7L is upregulated in metastatic tamoxifen-resistant (TamR) and triple-negative BCa. SENP7L facilitates chromatin remodeling that potentiates the growth and invasiveness of these BCa subtypes. SENP7L interacts with and deSUMOylates heterochromatin protein 1 alpha (HP1-alpha/CBX5) to mediate these responses. Canonical models suggest that HP1-alpha reads the histone mark to localize predominantly at constitutive heterochromatin. Our studies challenge the old paradigm as we show that SUMOylated HP1-alpha is enriched outside heterochromatin at euchromatin, including E2F-responsive and mesenchymal gene loci. Recruitment of SUMOylated HP1-alpha supports de novo heterochromatin formation at these loci. However, SUMOylated HP1-alpha is lost in aggressive BCa due to SENP7L induction. Consistently, SENP7L upregulation prompts chromatin de-condensation and gene transcription. Nucleic acid and chemical targeting of SENP7L reduces self-renewal/differentiation properties of TamR mammospheres as well as tumor volume and secondary tumor formation of TamR cells. Hence, SENP7L inhibitors can serve as promising tools to modulate epigenetic abnormalities in TamR BCa.
Title: Single cell sequencing analysis of formalin-fixed paraffin-embedded ductal carcinomas in situ and invasive breast cancers reveals clonal selection in the progression from in situ to invasive disease

Body: Background: Ductal carcinoma in situ (DCIS) is considered to be a precursor of invasive breast cancer (IBC), and is found synchronously in over 45% of patients with invasive disease. Whether the progression from DCIS to IBC results in clonal shifts and the genomic imbalances that may drive this process remain to be elucidated. Single-cell sequencing constitutes a powerful approach to address these questions as it enables the phylogenetic reconstruction of subpopulations of cancer cells at single cell resolution. To date, single-cell sequencing approaches remain limited to fresh/frozen samples, precluding the use of archival formalin-fixed and paraffin-embedded (FFPE) samples, the largest source of tumor material in pathology departments. Here, we describe the development of a methodology for single-cell copy number (CN) profiling of single nuclei derived from FFPE tumor samples and subsequently employed this approach to define whether DCIS displays intra-lesion genetic heterogeneity and if clonal shifts are observed in the progression from DCIS to IBC.

Methods: DCIS and IBC areas were independently microdissected from archival FFPE samples. Microdissected tissue fragments were subsequently reverse-crosslinked, and their extracellular matrix was digested. Intact individual diploid nuclei from cells in G1 were FACS-sorted into individual wells of 96-well plates. DNA was extracted from each cell and subsequently repaired and amplified. Sequencing libraries were prepared using standard protocols followed by whole genome sequencing on a HiSeq 2000. Single-cell sequencing data were analyzed to define the CN profiles for each cell, to infer the clonal composition of each DCIS and IBC, and to trace the genomic events that occurred during the progression from in situ to invasive disease.

Results: We performed single-cell sequencing of 192 cells derived from two synchronous FFPE DCIS and IBCs. One pair of DCIS and IBC was diploid and the other was tetraploid. Principal component analysis discriminated neoplastic from normal cells and resulted in the identification of clonal cancer cell populations. Genome-wide CN profiling of single cells from DCIS and IBC components demonstrated the extent of intra-tumor genetic heterogeneity present in these samples. In addition, founder CN events present in these lesions, including TP53 and RB1 losses and FGFR1/BRF2 and CCND1 amplifications, were already detected in the DCIS samples. Phylogenetic analysis based on CN profiles from single cells revealed that the invasive cancer likely stemmed from minor subclones from the DCIS and provided evidence of branched evolution in the progression from DCIS to IBC.

Conclusions: We developed a robust procedure to perform single-cell massively parallel sequencing of individual nuclei isolated from FFPE samples. This approach revealed that the progression from DCIS to IBC results in clonal shifts, suggesting that this biological phenomenon may constitute an evolutionary bottleneck.
Title: Divergent patterns of copy number changes in primary breast carcinomas versus synchronous lymph node metastases

Body: Background: Breast cancer is the most common malignancy among women, and although early detection and new treatment regimens have improved the survival, metastatic spread to lymph nodes is indicative of a more aggressive disease. Molecular analyses of primary tumors versus synchronous lymph nodes have shown variation in gene expression and in phenotype. Further, dissimilarities in genomic changes have been found, but the studied cases are few and often based on selected markers only.

Methods: In this study, we have analyzed paired primary tumors and lymph node metastases from 35 breast cancer patients with high-resolution genomic SNP array analyzes (SNP6 arrays, Affymetrix). The ASCAT algorithm (Allele specific copynumber analysis of tumors) was used to estimate both DNA ploidy level, tumor cell percentage as well as allele specific genome wide copy number alterations.

Results: Of the 35 sample pairs, 20 had high tumor cell percentage and high quality data from both samples. Seven of these showed similar alterations in the primary tumor and in the metastasis. In 13 cases a divergent profile was observed either in the direction of fewer alterations in the lymph node metastasis or fewer alterations in the primary tumor. The estimated ploidy value also varied between the primary and lymph node for several of the patients.

Conclusion: Lymph node metastases can have more, less or equal number of genomic copy number alterations compared to the corresponding primary breast carcinoma. This indicates that the metastatic process can occur at different time points during tumor evolution. A more detailed characterization of genomic alterations in relation to clinical and pathological characteristics will be presented.
Whole genome transcriptome analysis of sequential breast to brain metastasis uncovers new signalling pathways and druggable targets

Varešlija D, Fagan A, Buckley P, Farrell M, Hill A and Young L. Royal College of Surgeons in Ireland, Dublin, Ireland and Beaumont Neuropathology Department, Dublin, Ireland.

Body: The occurrence of brain metastasis (BM) in breast cancer (BC) is currently on the rise across all molecular subtypes with 10-30% reported incidence. The need to uncover the mechanisms underlying this clinically devastating complication is apparent, and in the current study we sought to identify BC cell mediators of BM.

In our cohort of metastatic patients (n=196) we found that BM developed in 13% of the cases. Despite the previous reports of negative ER status being a risk factor for BM, the ER+ve patients accounted for 42% of all diagnosed BM. To elucidate the gene alterations required for successful colonisation of the brain we undertook RNA sequencing (RNA-seq) of sequential breast to brain metastasis of known receptor status (n=7). This study presents the first whole transcriptome next-generation RNA-seq analysis of resected BM and their matching primary breast tumours.

We identified 500 differentially expressed genes (DEGs) (< 0.05, fcThreshold >±1.5), accounting for those that were both upregulated and downregulated in BM compared to the primary. Analysis of protein-coding genes identified collective ER-specific metastatic pathways. Additionally, common functional pathways altered included ECM, cell adhesion and neuronal differentiation. Our analysis of the BM transcriptomic landscape and verification in cell line models that preferentially metastasise to the brain has unravelled a complex network of driver genes, cooperating with stromal derived factors, responsible for the organ-specific behaviour of the metastatic cells. Genes such as ANTRX1, THBS2, FAP, VCAN and TIMP2 were found to be part of the invasion and migration network that drives the extravasation of the BM cells. Furthermore, an EMT stemness signalling network driven by ANTRX1 and WNT pathway driven RUNX was prominent in the cells acquiring the ability to migrate to the brain. Additional work is being carried out on uncovering the adaptations that re-activate the dormant brain metastatic cells and the contribution of the neuronal niche in the facilitating the colonisation by the MBC.

This study highlights the requirement of unique gene sets for the invasion, migration and colonisation to the brain and that functional characterisation of the DEGs will enable the identification of novel molecular targets for prevention and treatment of breast cancer BM.
Title: The development of the metastatic site pattern during time in different subtypes of breast cancer

Lindman H and Haji A. Uppsala University, Uppsala, Sweden and Uppsala University, Uppsala, Sweden.

Body: Introduction:
The most common metastatic sites in breast cancer (BC) are bone, lung and liver, but metastases to CNS, other visceral organs, skin and lymph nodes are often seen. Depending on the BC subtypes there are data on different patterns of the metastatic sites. However, little is known about the risk for development of new metastatic sites during the course of the disease. Possibly, the development of new sites of the disease is signs of novel intrinsic capabilities of the metastases that might be explained by new mutations. Primary aim of this study was to examine the metastatic pattern and development of new metastatic sites in different BC subgroups.

Materials and Methods:
This is a population based cohort study covering patients in the Uppsala County treated for metastatic BC (MBC) from 2009 to 2014. The information was collected from the real-time treatment registry and medical records. The distant sites were classified as bone, lung/pleura, soft tissue, other visceral and CNS and the timing was defined in steps starting with M1 when patient first was defined as having MBC. The BC subtypes were defined as luminal A, luminal B, HER2-positive (HER2) and triple negative (TN) based on immunohistochemical analyses. The metastatic patterns at death were compared with the patterns at M1.

Results:
Totally 391 patients with MBC with a median age of 65 years were included. Median disease-free survival was 51 months. The development of metastases in new sites occurred in up to three distinguished steps, with median lag times of 22, 13 and 14 months, respectively. The median survival from M1 was 69, 37, 64 and 17 months for the luminal A, luminal B, HER2 and TN subtypes.

The frequencies of metastases in in first (M1) and subsequent sites (next) in each subtype

The sums of the figures represent the risk for metastases in a certain site at death.

Conclusion:
The pattern of metastatic sites at M1 in different BC subtypes does not represent the pattern for development of new metastatic sites during the course of the disease. We observed a significantly different risk for developing new metastatic sites depending on subtypes, most obvious regarding liver metastases. TNBC seemed to have less ability to develop new metastatic sites.
Expression profiling of in vivo DCIS progression models identified BCL9 as a molecular driver of invasive progression

Behbod F, Elsarraj H, Hong Y, Valdez K, Chien J, Godwin A and Fields T. University of Kansas Medical Center, Kansas City, KS.

Introduction: There are an estimated 60,000 new cases of ductal carcinoma in situ (DCIS) each year. At present, it is not clear why some DCIS remain non-invasive for decades while others become invasive. A lack of understanding in DCIS pathobiology has led to overtreatment of more than half of DCIS patients. To identify factors that promote DCIS invasion, we have profiled the temporal molecular changes during DCIS transition to invasive ductal carcinoma (IDC) using two in vivo models, MIND (mouse-intraductal) and DCIS/IDC tandem lesions. These studies led to the identification of B cell lymphoma-9 as a potential molecular driver of early invasion. BCL9 is a newly found co-activator of Wnt-stimulated β-catenin-mediated transcription. BCL9 has been shown to promote progression of multiple myeloma and colon carcinoma. However its role in breast cancer progression had not been recognized.

Methods: Microarray and RNA sequencing were utilized to characterize the sequential and temporal changes in mRNA expression during DCIS invasive transition. BCL9 shRNA knockdown was performed to assess the role of BCL9 in in vivo invasion, EMT and canonical Wnt signaling. Immunofluorescence of 28 patient DCIS samples was used to assess a correlation between the expression of BCL9 and biomarkers of high risk DCIS. TCGA data was analyzed to assess the status of BCL9 gene alterations in 959 human breast cancers.

Results: Analysis of BCL9, by RNA and protein showed BCL9 up-regulation to be associated with DCIS transition to IDC. Analysis of patient DCIS revealed a significant correlation between high nuclear BCL9 and pathologic characteristics associated with DCIS recurrence: ER and PR negative, high nuclear grade, and high HER2. In vivo silencing of BCL9 resulted in the inhibition of DCIS invasion and reversal of epithelial-mesenchymal transition (EMT). Analysis of the TCGA data showed BCL9 gene to be altered in 26% of breast cancers. This is a significant alteration when compared to ERBB2 (19%) and ESR1 (8%). A significantly higher proportion of basal like invasive breast cancers showed BCL9 amplification.

Conclusion: BCL9 is a molecular driver of DCIS invasive progression and may predispose to the development of basal like invasive breast cancers. As such, BCL9 has the potential to serve as a biomarker of high risk DCIS and as a therapeutic target for prevention of IDC.
Clinical utility of systematic biopsy of first metastatic event in breast cancer: Results from a prospective multicenter trial

BACKGROUND: Cumulative evidence for phenotypic and molecular heterogeneity between primary breast cancer (BC) site and matched metastasis (mets) has been obtained in retrospective studies. Current expert consensus suggests performing biopsies of mets, but clinical utility and cost are unknown. The primary objective of the ESOPE study (NCT01956552) was to compare the phenotype and genotype of the primary tumor (PT) with those of matched mets at time of first distant relapse, before the start of any treatment, in order to optimize the treatment of mets

PATIENTS and METHODS: Between Nov. 2010 and Sept. 2013, we conducted a prospective multicenter study on BC patients (pts) with diagnosis of first mets. All pts were to have available Formalin-Fixed Paraffin-Embedded (FFPE) PT sample and mets accessible to either percutaneous or surgical sampling. All tissue samples were centrally analyzed with immunohistochemistry (ER, PgR, HER2, and Ki67) and FISH when indicated. Frozen samples were stored for further analyses. We recorded intended therapeutic decision before and after biopsy.

RESULTS: Of 93 pts included, 89 were eligible for biopsy. Median age was 57 years (28-81); median interval between PT and mets was 42 months (0-211), including 14 pts with novo metastatic breast cancer. Mets biopsy was performed in 85 pts (96%, refusal n=2, not feasible n=2). Toxicity was limited to only 1 grade 1 hemorrhage. Sampled sites were liver (44%), lung (16%), bone (13%), lymph node (13%), skin/muscle/chest wall (9%), ovary/peritoneum (4%), and adrenal gland (1%). PT was not available in 4 pts; mets biopsy was non contributive in 6 pts but led to a diagnosis of second primary cancer in 3 pts. In 72 pts with matched PT and mets, PT were luminal A (n=11), luminal B (n=33), triple negative (n=13), HER2 (n=13), non-evaluable (n=2). Mets were luminal A (n=6), luminal B (n=30), triple negative (n=16), HER2 (n=14), non-evaluable (n=6). Discrepancy rates were: ER 18% [kappa for concordance =0.6, CI 95% (0.42-0.77)], PgR: 39% [kappa=0.19, CI 95% (0.01-0.39)], Her2: 4% [kappa=0.86, CI 95% (0.7-1)], Ki67: 25% [kappa=0.19, CI 95% (-0.09; 0.49)]. The most frequent discrepancy rate was observed in pts with lum A PT, as only 3/10 developed Lum A mets. HER2 and triple negative were the most stable subtypes (12/13 and 12/12 respectively). Most importantly, mets biopsy led to a change in therapeutic decision in 25 pts (independent evaluation by 2 oncologists). Additional comparative targeted NGS analyses are ongoing on a first subset of 54 FFPE paired samples, and parallel whole exome sequencing is planned on 38 paired samples with available constitutional DNA.

CONCLUSION: Comparative analysis of breast cancer PT and first mets is routinely feasible, with very low morbidity and a significant impact for patients' management: 29% had a second cancer diagnosis or were proposed a therapeutic change. Furthermore, this study will provide additional data on quality and quantity of tissue available for molecular analysis, and ultimately in terms of cost-efficacy.
Title: RAGE-ligand signaling drives breast cancer metastasis through affecting cells of the tumor and microenvironment

Kwak T, Drews-Elger K, Ergonul A, Zhao D, Besser A, Slingerland JM M, Lippman ME E and Hudson BI I. University of Miami, Miami, FL.

Body: Breast cancer is most common malignant state in women, with 20% of these patients developing metastasis during the course of their disease. Further understanding is needed of the process and mechanisms of metastasis. Our lab and others have been shown that Receptor of Advanced-Glycation End-products (RAGE) plays a role in tumorigenesis and metastasis. RAGE is highly expressed in various cancers including breast cancer and its protein levels correlate with poor patient outcome in breast cancer and other cancers. Activation of RAGE results in increased proliferation, migration and invasion of cancer cells. Further studies in mice have shown it may be a therapeutic target to reduce tumor growth and the resulting metastasis. Further understanding is needed of the role of RAGE in driving metastasis through affecting cells of both the tumor and tumor stroma to design novel therapeutics. Using the breast cancer cell model (MDA-MB-231) and its organotropist sister cells lines selected in vivo for increased metastasis to lung (4175) and bone (1833), we tested the role of RAGE in driving tumor metastasis in vitro and in vivo with xenograft mouse models. To test the role of RAGE in the tumor microenvironment we used the AT-3 syngeneic breast cancer cell model in C57BL6 wild-type and RAGE knockout mice. We demonstrated that the highly metastatic variant of 231 cells (4175 and 1833) have increased expression level of RAGE compared to MDA-MB-231 parental cells. Ectopic over-expression of RAGE in parental 231 cells led to increased migratory and invasive properties compared to vector control cells, without affecting cell proliferation or viability. RAGE knockdown by shRNA in 4175 and 231 parental cells showed decreased cell invasion in transwell assays compared to control scramble shRNA. To validate our data in vivo, we performed mammary fat pad injection of 4175 cells (RAGE and scr shRNA) in NOD SCID gamma mice. Tumor growth and weight was impaired in RAGE gene knockdown 4175 cells compared to scramble (scr) controls. Analysis of lung and liver tissue retrieved from mice revealed RAGE knockdown in 4175 cells prevented metastasis compared to 4175 scr control cells. To test the role of RAGE on non-tumor cells of the breast stroma we next performed syngeneic studies with AT-3 cells (MMTV-PyMT spontaneous BC cell model), by injection into the mammary fat pad of wild-type and RAGE knockout C57BL6 immunocompetent mice. RAGE knockout mice (RAGE -/-) displayed striking impairment of tumor cell growth compared to wild-type (RAGE +/-) mice. We are currently testing whether novel RAGE inhibitors impact breast cancer progression and metastasis.

These data highlight RAGE drives breast cancer progression and metastasis through affecting both tumor cell intrinsic and non-tumor cell microenvironment effects. Future studies will demonstrate the potential of RAGE inhibition as a novel therapeutic approach for preventing and treating metastatic disease in breast and other cancers.
Title: p53 deficiency enhances metastatic potential of triple negative breast cancer by promoting growth in primary and metastatic sites

Powell E, Shao J, Mistry N, Yuan Y, Tieu T, Decker K, Chen H-C, Cai S, Do K-A, Heffernan TP P, Edwards J, Piwnica-Worms D and Piwnica-Worms H. The University of Texas MD Anderson Cancer Center, Houston, TX and Washington University School of Medicine, St. Louis, MO.

Body: TP53 is one of the most commonly mutated genes in human cancer. Mutation or loss of TP53 can occur during the early stages of oncogenesis or as a later event as tumors progress to more aggressive forms. We used a patient-derived xenograft (PDX) model of triple negative breast cancer (TNBC) to investigate how p53 deficiency contributes to metastasis. The PDX line was generated by engrafting the primary breast tumor of a patient with TP53 wild-type metastatic TNBC into the humanized mammary fat pad of NOD/SCID mice. Isogenic lines differing only in TP53 status were generated from this model by silencing p53. Here we demonstrate that the p53-proficient and -deficient tumors metastasized from the mouse mammary gland and colonized the lung, liver, bone, brain, and lymph nodes with similar frequency. p53-deficient tumors grew faster in both the primary and metastatic sites as a result of increased mitosis and decreased apoptosis. Circulating tumor cells (CTCs) are currently being evaluated in p53-proficient and –deficient PDX models. Gene expression profiling identified candidate genes with potential clinical relevance that may be responsible for increased tumor growth upon p53 loss in late stage tumors. This model is also being used to identify genes that promote breast cancer metastasis. To enrich for metastasis, metastatic subpopulations of tumor cells were isolated from lungs and serially passaged in vivo. This serial passaging enriched for metastasis to multiple secondary sites. A transcriptional signature of putative metastasis genes was generated and is being functionalized with high throughput screening in vivo.
Title: Vascular mimicry in metastatic breast cancer patients: Molecular insight to vascular mimicry using in vitro and in vivo models

Body: Background: Vascular Mimicry (VM) is an endothelium-independent matrix-embedded, blood-perfusion phenomenon exhibited by highly plastic and aggressive tumor cells in patients with solid tumors including breast. VM is characterized by PAS⁺ de novo formations of micro-vascular networks which are essentially CD31⁻ and CD34⁻. VM is a micro-circulatory phenomenon which perfuses rapidly growing tumors, transporting fluid from leaky vessels and/or connects with the constituent endothelial-lined vasculature. One of the hallmarks of metastasis in BC is the heterogeneity observed between primary tumors and metastases (& among metastases) (Marino et al., 2013). Recently a model of BC heterogeneity revealed VM as a driver of metastasis which in turn has been associated with disease heterogeneity (Wagenblast et al., 2015). Aim: Since BC is an aggressive and heterogeneous disease and VM is associated with the aggressiveness / poor outcome in BC, we sought to understand the functional relationship of VM with metastasis. Method: Tumors from our BC patients and TMAbs were stained for CD31/PAS and CD34/PAS to identify VM. Genomic and proteomic data from these patients were obtained from re-biopsied (after consultation) samples (IHC for ER, PR, and HER2; FFPE samples for genomic [Foundation Medicine] and proteomic [Theralink] analyses).

Result: VM was identified in metastatic tumors from ER+ and TNBC patients as CD31⁻/PAS⁺ and CD34⁻/PAS⁺ structures in contrast to the CD31⁺/PAS⁺ and CD34⁺/PAS⁺ angiogenic compartment of the individual tumor(s). Metastatic tumors exhibiting VM were characterized by pathological features like metaplastic lesions, positive lympho-vascular invasion and were found to be poorly differentiated. Predominant genetic alterations in these patients included (1) PI3K-mTOR pathway genes, (2) p53 (R273P, D281V), (3) BRCA1 E1683* (for TNBC), (4) MYC amplification, (5) aurora kinase, (6) CCND1 & CDK4 amplifications and (7) loss of CDH1 exons1-3. Amplifications of cell surface TKIs/ligands included EGFR, FGFR and several FGFs. Proteomic data indicated an overexpression/activation of HER family (HER1/HER2/HER3), mTOR activation (p~S2448), MEK1/2 activation (p~S217-221) and JAK2 activation. In order study VM, we standardized VM formation both in 2D and 3D configurations in multiple BC cell lines which exhibited VM at differing times. The earliest response was observed around 2-3 hours in BT20, Hs578t and MDA-MB231. By 24 hours BT474, BT474HerR, SUM149, DKAT, MDA-MB231BR, Hs578t and MDA-MB468 cells demonstrated 2D VM. The BT20 cell line showed the most pronounced 3D-VM at 24 hours while MDA-MB468 was least sensitive to VM. Typical cord formation in HUVEC cells stained with hematoxylin and PAS were used for comparison. Using 2D and 3D models of VM we demonstrated the involvement of PI3K and Wnt-beta-catenin pathways in VM. Considering the involvement of VM in mediating the aggressive/metastatic nature of TNBC, we also tested VM in in vivo xenograft models using brain metastatic specific MDA-MB231BR cells, results of which will be presented in the meeting. Significance: To our knowledge this is the first report to identify genetic alterations and proteomic changes associated with VM in metastatic BC.
Abstract Withdrawn
Title: Sphingosine-1-phosphate signaling promotes metastatic niches and lung metastasis in obesity-related breast cancer

Body: INTRODUCTION: The link between obesity and elevated breast cancer mortality is well known, however, the underlying mechanisms are poorly understood. Sphingosine-1-phosphate (S1P) is a pleiotropic bioactive lipid mediator produced by sphingosine kinases (SphKs) that plays critical roles in inflammation and cancer progression. Previously, we found that obesity increases levels of S1P not only in breast tumors, but also in the lung. "Metastatic niches" are specialized microenvironments in distant organs primed by factors from cancer cells. We hypothesized that S1P secreted from the primary tumor could promote formation of a "metastatic niche" in the lung, which assists circulating cancer cells to form metastatic lesions. Further, HFD-induced obesity increases S1P secretion from the primary tumor, which could promote the formation of "metastatic niches" in the lung and lung metastasis. The aim of this study is to test these hypotheses.

METHODS: A mouse model utilizing tail vein injection of E0771 syngeneic breast cancer cells was used. Prior to tail vein injections of naive E0771 cells, mice were treated with conditioned media from E0771 breast cancer cells overexpressing SphK1 (K1-CM) or that from E0771 cells cultured with the vector control (CT-CM). Histological analysis, RT-qPCR, and western blot were used.

RESULTS: The lungs after K1-CM treatment demonstrated much more infiltration of macrophages with greater IL-6 secretion than lungs from CT-CM mice in areas without metastasis. Furthermore, SphK1, S1P receptor 1 and IL-6 expression were all significantly higher in the lungs of mice treated with K1-CM than with CT-CM, suggesting that S1P secreted from the primary tumor promotes formation of a metastatic niche in the lung. Next, mice were fed with HFD or ND for 12 weeks before treatment with SphK1-CM, and lungs were examined 7 days after intravenous injection of E0771 cells. Histological analysis demonstrated that there were significantly more lung metastases in mice on HFD than in mice on ND. Importantly, treatment with FTY720, a functional antagonist of S1P receptor 1, significantly reduced the lung metastases in HFD fed animals. Immunofluorescent staining revealed higher expression of IL-6 and greater number of F4/80 positive macrophages in mice fed with HFD compared with mice fed with ND, whereas FTY720 dramatically suppressed both IL-6 and macrophage infiltration in the lung of HFD-fed mice. HFD-induced obesity also increased pERK, pAKT, pStat3, and pp65 in the lung, and FTY720 suppressed these signaling pathways.

CONCLUSION: Our results suggest that S1P plays a role in the formation of "metastatic niches" in the lung and lung metastasis of breast cancer, and obesity promotes this process. S1P will be a promising target for treatment of breast cancer metastasis, especially in condition with obesity. Title: Epithelial paradox; clinical significance of co-expression of E-cadherin and vimentin in invasive breast cancer

Yamashita N, Tokunaga E, Inoue Y, Tanaka K, Ueo H, Saeki H, Oki E and Maehara Y. Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; National Hospital Organization Kyushu Cancer Center, Fukuoka, Japan and Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.

Body: Background: E-cadherin and vimentin are now regarded as major and conventional canonical markers of epithelial-mesenchymal transition (EMT). It is commonly assumed E-cadherin is uniformly lost during the process of EMT. We previously reported that the elevated expression of vimentin contributes to the aggressive phenotype in invasive breast cancer. On the other hand, the role of E-cadherin in breast cancer biology might be unclear and more complex. Although, cell cohesion during breast cancer invasion is often overlooked, accumulating evidences indicate breast tumor cells are typically cohesive and often display membrane-localized E-cadherin in both the primary tumor and distant metastases, termed collective invasion. Multiple mechanisms have emerged to address how epithelial breast tumors invade.

Aims: The aim of this study is to reveal the clinical importance of the expression of E-cadherin and vimentin in breast cancer.

Methods: The E-cadherin and vimentin protein expression were evaluated by immunohistochemistry (IHC) in 177 invasive breast cancer samples. Among these, E-cadherin and vimentin expression were evaluated in the set of primary breast cancer and metastatic lymph nodes in 65 cases.

Results: The positive vimentin expression was highly correlated with poor disease-free survival (DFS) and overall survival (OS) (p=0.019 and p=0.0044), however, the E-cadherin expression alone did not correlate with prognosis. Interestingly, Both E-cadherin and vimentin positive tumor had the worst DFS and OS among all breast cancer (p=0.03 and p=0.0089). Vimentin expression was highly correlated between primary tumors and metastatic lymph nodes. However, E-cadherin expression levels were significantly elevated in metastatic lymph nodes (p=0.0017), Co-expression of E-cadherin and vimentin in the metastatic lymph nodes also showed worst DFS and OS (p=0.12 and p=0.027). Conclusions: Co-expression of E-cadherin and vimentin seems to be associated with the most aggressive phenotype and poorest prognosis in breast cancer, and positive E-cadherin expression may not always play roles for tumor suppression.
Title: A novel mutagenesis screen identifies SHARPIN as a breast cancer metastasis gene that predicts survival of breast cancer patients

Bii VM M, Rae DT T and Trobridge GD D. Washington State University College of Pharmacy, Spokane, WA and Washington State University School of Molecular Biosciences, Pullman, WA.

Body: Breast cancer (BC) is a heterogeneous disease and the second leading cause of malignancy among women in the U.S. Metastasis of the primary tumor results in poor prognosis and increased mortality and the molecular mechanisms by which metastatic tumors occur are not well understood. Identifying the genes that drive the metastatic process could provide targets for improved therapy and biomarkers to improve outcomes for BC patients. Here, we utilized a replication-incompetent gammaretroviral vector (γRV) to perform a forward insertional mutagenesis screen to identify genes involved in BC metastasis. In this approach, BC cells mutagenized with a γRV were xenotransplanted into the mammary fat pad of immunodeficient mice, and primary tumors and metastases were allowed to develop. Metastatic lesions were collected and analyzed for proviral integration sites to identify vector integration sites and nearby candidate metastasis genes. The γRV has a bacterial origin of replication and kanamycin resistance gene that allows for rescue in bacteria and rapid identification of vector integration sites. Using this approach, we identified the previously described metastasis gene WWTR1, and several other novel candidate metastasis genes including SHARPIN. SHARPIN was then independently validated as a BC metastasis gene in vivo using RNAi. Analysis of patient data showed that SHARPIN expression predicts metastasis-free survival after adjuvant chemotherapy (p < 0.005, Concordance Index = 55.3, Risk Groups Hazard Ratio = 1.87). Our replication-incompetent γRV approach is efficient and has broad potential to identify genes involved in oncogenic processes for BC and other cancers.

Keywords
Insertional mutagenesis screen, Gammaretroviral vector (γRV), Metastasis, Inducible shRNA, Prognostic biomarker.
Increased emphasis on breast cancer screening has led to a dramatic surge in diagnosis of pre-cancerous ductal carcinoma in situ (DCIS) over the past 30 years. Unfortunately, diagnosis of late stage invasive and metastatic disease has not proportionally declined, suggesting significant over diagnosis and over treatment of innocuous DCIS. Due to a lack of biomarkers, the heterogeneity of DCIS lesions, and an insufficient understanding of mechanisms of invasive progression, there is currently no clinically relevant method of predicting which DCIS lesions will advance to invasive disease. As a result, all DCIS patients undergo an aggressive treatment regimen to prevent disease progression. Therefore, there is a critical need to determine the underlying mechanisms driving breast cancer progression to better inform patient treatment options and nominate novel therapeutic entry points for treatment of invasive disease.

Recently, long noncoding RNAs (lncRNAs) have gained attention as critical regulators of epigenetic states and gene expression. Although the study of lncRNAs is in its infancy, they are being uncovered as pivotal regulators of development and tumorigenesis, thus they are a rich source of potential drivers of breast cancer progression. We propose that lncRNAs functionally drive breast cancer invasion and their expression can discriminate between innocuous and potentially invasive DCIS.

Using biopsies from women that exhibit tandem DCIS and invasive breast cancer lesions, we have identified a cohort of long noncoding RNAs (lncRNAs) that are enriched in the invasive biopsy. From this cohort we have identified the lncRNA BHLHE40-AS1 as increasing in a step-wise manner in a breast cancer progression series that escalates from normal, non-transformed cells to highly invasive disease. Preliminary evidence suggests that BHLHE40-AS1 expression regulates invasive potential in vitro. Using a GeneChip® Human Transcriptome 2.0 Array (HTA) we have identified several targets previously associated with driving breast cancer invasion as being potentially regulated by BHLHE40-AS1. Future directions will focus on determining the effect of BHLHE40-AS1 expression on tumor cell invasion in an orthotopic xenograft model, mechanistically elaborating its function, and determining the utility of BHLHE40-AS1 as a clinically relevant biomarker of invasive breast cancer.

Title: NOS2 & COX2 activation of TLR4 & EGFR signalling causes poor outcome in oestrogen receptor-negative breast cancer via pro-survival signals and immune polarisation

Glynn S, Garrido-Cuesta P, Wink D, Ridnour L, Ambs S, Keane M, Walsh E and Callagy G. National University of Ireland Galway, Galway, Ireland; National Cancer Institute, Bethesda, MD and Galway University Hospital, Galway, Ireland.

Body: Background
We seek to further elucidate mechanisms by which inflammatory mediators promote estrogen receptor (ER)-negative breast cancer progression and poor survival. We previously reported association between inducible nitric oxide synthase (NOS2) and poor outcome in ER-negative tumours. In tumours aberrant NOS2 induction facilitates tissue remodelling and stimulates neovascularisation. Also involved in inflammation and wound healing is cyclooxygenase-2 (COX2). We demonstrated that COX2 is associated with Akt activation and poor outcome in ER-negative tumours. We hypothesise that co-expression COX2 with NOS2 in ER-negative tumours amplifies effects of NOS2 on poor outcome, via EGFR and TLR4 signalling loop activation, and polarization of the tumour immune-compartment to pro-tumorigenic M2 phenotype.

Methodology
We determined the association of NOS2 and COX2 co-expression on breast cancer specific survival in ER-negative and triple negative breast tumours (N=102), via immunohistochemistry and cox regression statistical analysis. To explore the mechanism of NOS2 induction of COX2 through transactivation of EGFR, NO donors in combination with EGFR inhibitors were used to determine if NO exposure results in amplified EGFR and PGE2 pro-survival and pro-metastatic signalling in triple negative breast cancer cell lines. Finally, we explored the ability of NO to modify the ability of triple negative breast cancer secretome to induce polarisation of macrophages to a pro-tumorigenic M2 phenotype.

Results
Co-expression of NOS2 and COX2 in triple negative breast cancer results in poor outcome, via activation of pro-survival signalling and modification of the immune compartment to a pro-tumorigenic M2 associated phenotype. NO induces activation of growth factor signalling pathways and secretion of M2 promoting cytokines that induce THP1 macrophage polarization to an M2 phenotype.
Enhanced invasion and migration into the surrounding tissues are hallmarks of the malignancy of tumor cells. To successfully metastasize, a cancer cell has to detach from the primary tumor, invade into surrounding tissues, and intravasate into blood or lymphatic vessels. These processes are composed of complex mechanisms involving tumor recognition, degradation of extracellular matrix (ECM) proteins and migration into tissue. Triple negative (TN) breast cancers are defined by a lack of expression of estrogen, progesterone, and HER2 receptors. It is widely recognized that TN breast cancers have a poorer prognosis than any other subtype of breast cancer. Given the lack of effective targeted therapies for TN breast cancer patients, understanding of the mechanisms of migration and invasion of these tumors will provide insight into developing novel approaches to lower the mortality from TN breast cancer.

Previous studies demonstrated that NEDD9 plays a key role facilitating progression and metastasis of various tumor cells including breast. We previously demonstrated that NEDD9 plays a critical role in promoting migration and growth of MDA-MB-231. In order to further characterize the mechanisms of NEDD9-mediated cancer migration and growth, we established stable cell lines expressing NEDD9 using HCC38 as a parental cell line which expresses low level of endogenous NEDD9. Microarray studies demonstrated that enzymes (CHST11, CHST15, and CSGALNACT1) involved in biosynthesis of chondroitin sulfate (CS) but not heparan sulfate (HS) were markedly upregulated in HCC38(NEDD9) compared to control HCC38(Vector) cells. These results suggest that NEDD9 regulates specific structures of tumor-associated glycans such as chondroitin sulfate. Core proteins of CD44 and Serglycin were markedly upregulated in HCC38(NEDD9) cells compared to HCC38(Vector) cells, while those of Syndecan-1, Syndecan-2, and Versican were downregulated in HCC38(NEDD9). Immunofluorescence studies using specific antibody, GD3G7, confirmed the enhanced expression of CS-E subunit in HCC38(NEDD9). Immunoprecipitation and western blotting analysis demonstrated that CS-E was attached to Serglycin and CD44 core proteins. We demonstrated that removing CS by chondroitinase ABC significantly inhibited anchorage-independent growth of HCC38(NEDD9) in methylcellulose. Importantly, the fact that GD3G7 significantly inhibited colony formation of HCC38(NEDD9) cells suggest that CS-E subunit plays a key role in this process. Furthermore, treatment of HCC38(NEDD9) cells with chondroitinase ABC or GD3G7 significantly inhibited mammosphere formation. Exogenous addition of CS-E enhanced colony formation and mammosphere formation of HCC38 parental and HCC38(Vector) cells. These results suggest that NEDD9 regulates the synthesis and expression of tumor associated glycocalyx structures including CS-E, which plays a key role in promoting and regulating breast cancer progression metastasis and possibly stem cell phenotypes.

Title: ARGX-111 depletes MET-expressing circulating tumor cells via enhanced ADCC, resulting in inhibition of metastasis

Body: Several lines of experimental evidence suggest that Hepatocyte Growth Factor (HGF) and its receptor MET play an important role in breast cancer progression and drug resistance. To date, targeted MET inhibitors in clinical development have primarily shown cytostatic rather than cytotoxic effects. Development of a cytotoxic MET inhibitor would serve to complement standard breast cancer therapy, especially when administered in the adjuvant/neo-adjuvant setting.

We have developed ARGX-111, a human antibody antagonist of MET function. ARGX-111 blocks both HGF-dependent and -independent signaling, down-regulates tumor cell surface expression of MET and kills MET-overexpressing cells by enhanced antibody-dependent cellular cytotoxicity (ADCC).

ARGX-111 was shown to be more efficacious than an ADCC-inactive control antibody in both HGF-dependent and -independent tumor xenograft models. ADCC reporter assays confirmed the cytotoxic effects of ARGX-111 in patient-derived primary tumor specimens, including MET-expressing breast cancer stem-like cells. In an orthotopic mouse model of metastatic mammary carcinoma (MDA-MB-231), adjuvant or neo-adjuvant treatment with ARGX-111 was significantly more effective in depleting circulating tumor cells (CTCs) and suppressing the development of bone and lung metastases than the ADCC-inactive control. Taken together, these results provide a rationale for clinical investigation of ARGX-111 in the early breast cancer setting. An ongoing Phase 1 study (NCT02055066) is examining the effects of ARGX-111 on CTCs, alongside the assessment of its safety and efficacy.
Title: Mesofluidic platform for high throughput screening of inhibitors of metastasis

Spencer A, Spruell C, Nandi S, Le V, Crexiell M, Dunn AK K and Baker AB B. University of Texas at Austin, Austin, TX.

Body: A fundamental limitation in the development of new therapies to prevent metastatic cancer is a lack of in vitro systems that can accurately recapitulate the steps of cancer cell metastasis. Currently, most assays for examining the steps of metastasis fail to incorporate the biophysical forces experienced by tumor cells due to blood flow, or are low throughput and thereby not amenable to drug screens or high throughput experimentation.

We have developed a novel high throughput mesofluidic platform for assaying cell adhesion under flow in a 96-well format. This device functions like a cone and plate viscometer in each well by inducing shear stress on cells cultured in a standard 96-well plate. We validated the fluid flow and alignment of the device and studied the adhesion of cultured leukocytic monocytes (THP-1 cells) and multiple cancer cell lines (MDA-MB-231 and MCF-7 breast cancer cell lines) to purified extracellular matrix molecules (ECM), endothelial cells and immobilized platelets. Assays were carried out under flow (0.5 dynes/cm² shear stress) and static conditions.

Our studies show that adhesion assays performed under flow yield markedly different results from static adhesion assays. Treatment of breast cancer cells with a small library of integrin inhibitors demonstrated that these compounds had minimal effect on cancer cell adhesion to endothelial cells or immobilized platelets under static conditions, whereas under shear conditions many of these compounds significantly reduced adhesion of cancer cells. As well, this experiment elucidated integrins important for breast cancer adhesion to endothelial cells and platelets.

A static adhesion assay of breast cancer cells to various types of ECM showed greater adhesion of the less aggressive MCF-7 cell line in comparison to the more aggressive MDA-MB-231 cell line. In contrast, flow incorporating assays showed increased adhesion of the more aggressive MDA-MB-231 breast cancer cell line. Specifically, the shear assay saw a significant increase in adhesion for multiple ECM as well as an increase in the strength of adhesion to laminin.

Finally, we performed a high throughput screening experiment using a kinase inhibitor library of 80 compounds and found that the shear based assay yielded notably different results from a similar screen under static conditions for breast cancer cell adhesion to endothelial cells, immune cell adhesion to endothelial cells and breast cancer cell adhesion to platelets. This shear experiment yielded seven "hits", many of which match targets of drugs in clinical trials.

In conclusion, our studies show that adhesion assays performed under flow yield markedly different results from static adhesion assays, and are better at identifying both aggressive cancer cells lines and known pathways for circulating cancer and immune cell adhesion. Thus, this high-throughput screening platform may enable the development of novel compounds to inhibit cancer metastasis and facilitate the study of the systems level behavior of cancer-endothelium adhesion.
Body: Breast cancer (BrCa) mortality continues to result predominately from distant metastases that can emerge years after successful treatment of the primary disease. Metastatic resistance to agents that eradicate the primary mass is likely due to protection from the metastatic microenvironment and the quiescent state of dormant BrCa cells. Advancements for the treatment of metastatic tumors have been made, but significant progress has been hampered by the lack of relevant model systems, particularly for dormancy. We address this gap with an innovative all-human 3D liver microphysiological system (MPS). The liver is both a major site for BrCa metastasis (and other solid tumors) and the primary site of drug metabolism and limiting toxicities, an important consideration in evaluating cancer therapy efficacy and availability.

Primary hepatocytes and non-parenchymal cells (NPC) from human liver resections were seeded into the MPS. Following tissue formation on day 3, tagged BrCa cells were seeded and allowed a minimum of 4 days to integrate into the tissue before interventions were initiated. On day 7, chemotherapy treatment of micrometastases was initiated for 72h. Cultures were allowed 3 days to recover before the MPS was challenged with inflammatory factors (LPS/EGF) for 48h. BrCa cells were then re-treated with chemotherapy (either the same or alternate therapy) on day 21 for 72h. Hepatocyte function and injury were measured by urea, AST, ALT, A1AT, fibrinogen and CYP P450 assays. BC proliferation was monitored by quantification, Ki67 staining, and EdU incorporation. Communication networks within the metastatic microenvironment during different stages of metastatic BrCa progression were identified using Luminex assays (55 analytes).

The metastatically aggressive MDA-MB-231 BrCa cells demonstrated growth attenuation after 12d of culture in a subpopulation of cells (Ki67-/EdU-). Treatment of BrCa cells with doxorubicin for 72h eradicates the cycling cells, leaving behind a dormant cell population (Ki67-/EdU-) that can be subsequently stimulated to cycle by addition of inflammatory stimuli. A second dose of doxorubicin or cisplatin reduced the BrCa load but did not eradicate the BrCa. Luminex analysis of culture supernatants identified signaling molecules potentially involved in metastatic progression. In addition, we present the use of adjuvant therapy in the MPS to prevent this outgrowth of the dormant tumor cells.

In parallel, we have piloted hydrogel scaffolds that better support tissue formation and produce signals consistent with a healthier liver physiology. Hydrogels enhanced MDA-MB-231 cell entry into dormancy, resulting in reduced efficacy of doxorubicin treatment with greater persistence of tumor load.

The MPS provides a mechanism to close the gap in understanding metastatic dormancy. We demonstrate spontaneous dormancy for the first time in an all-human system and mimicked the dormancy and outgrowth observed in patients. Namely, that dormant BrCa are resistant to chemotherapy and can be stimulated to reemerge following an inflammatory insult. The completion of these studies will provide insights into the tumor biology of metastatic seeding, dormancy, and re-emergence and provide an accessible tool for testing therapeutics against metastatic BrCa in a metabolically competent system capable of evaluating dose-limiting toxicity.
Title: SSBP1 suppresses TGF-β-driven epithelial-mesenchymal transition and metastasis by regulating mitochondrial retrograde signaling in triple-negative breast cancer

Jiang H, Sun H, Wu J, Shao Z and Jin W. Key Laboratory of Breast Cancer in Shanghai, Fudan University Shanghai Cancer Center, Shanghai, China.

Body: Background: Triple-negative breast cancer (TNBC) is a highly aggressive tumor subtype associated with poor prognosis. The onset of metastasis in organs such as the lung, bone and brain is a major cause of mortality in TNBC patients. Thus, identification of novel targets for the treatment of triple-negative breast cancer is urgent for improved outcomes in patients with this disease.

Methods and Results: In this study, by performing quantitative proteomic analyses (iTRAQ) using highly metastatic and parental breast cancer cell lines, we found that single-strand DNA-binding protein 1 (SSBP1) was significantly down-regulated in highly metastatic breast cancer cells. Moreover, SSBP1 down-regulation was found to promote TNBC cell metastasis in vitro and in vivo. We confirmed that silencing of SSBP1 expression by RNAi in MDA-MB-231 and MDA-MB-468 breast cancer cells, can potentiate the proclivity to metastasize in Transwell assay and enhance lung colonization by tail vein injection in mice. In a reverse-complimentary approach, we determined that elevated SSBP1 expression in highly metastatic breast cancer cell lines can suppress the ability of invasion and metastasis in vitro and in vivo. Mechanistically, SSBP1 loss resulted in a significant decrease of mitochondrial DNA copy number in breast cancer cells, which initiated calcineurin-mediated mitochondrial retrograde signaling pathway. The activated mitochondrial retrograde signaling induced c-Rel/p50 nuclear localization, activated transforming growth factor-β (TGF-β) promoter activity and promoted TGF-β-induced epithelial-mesenchymal transition (EMT). Furthermore, Oncomine database and cBio database showed that SSBP1 is down-regulated in various human cancers. In addition, through examining tissue microarrays containing 250 breast tumor specimens, we figured out that patients with low SSBP1 expression were significantly associated with histological grade (grades III and IV; $P = 0.001$, Pearson $\chi^2$-test) and lymph node metastasis ($P = 0.009$). Importantly, low SSBP1 expression correlated with worse disease-free survival in breast cancer patients.

Conclusion: Cumulative results provide compelling evidence that SSBP1 is a critical tumor suppressor involved in human triple-negative breast cancer and provide a novel paradigm for regulation of TGF-β-induced EMT through SSBP1’s regulation of mitochondrial retrograde signaling pathway. Low SSBP1 expression has important prognostic power for patients with TNBC.
Title: The AKT-mTOR pathway as a potential organ-specific drug target signature of hepatic metastases from breast cancer

Body: Background: The identification of organ-specific targetable signatures may help design more effective treatment for patients with metastatic breast cancer (MBC). We took a multi-OMIC approach to assess whether the AKT-mTOR pathway is globally activated during metastatic progression or whether it represents an organ-specific target.
Methods: Snap frozen biopsies from 25 MBC patients enrolled in a prospective phase II trial were used. Sites of metastasis were classified as liver (n=8) and others (n=17), the latter including cutaneous, lung, lymph nodes, and intra-abdominal lesions. Signaling analysis of the 25 cases was performed using Reverse Phase Protein Microarray (RPPA) coupled with Laser Capture Microdissection. Activation of the AKT-mTOR pathway was quantified as phosphorylation of AKT (S473) and the mTOR target p70S6 (T389). Matched exome (WES) and RNASeq data were available for 17 of 25 patients, five with liver metastases. Sequencing data was processed using an in-house developed pipeline to identify somatic events including coding mutations, copy number alterations, gene fusions, and differential expression. Activation of the AKT-mTOR pathway and sequencing data were compared between hepatic and non-hepatic lesions using an integrated RPPA and genomic approach.
Results: Among liver metastases, AKT was activated in 4 of the 8 (50.0%) patients, while 6 of the 8 cases (75.0%) showed activation of p70S6. Sequencing data revealed mutation of PIK3CA in 4 of the 5 liver metastases (80.0%). Three of the PIK3CA mutated specimens with catalytic domain mutations (codons 1023 and 147) demonstrated co-activation of AKT and p70S6, while the fourth case, containing a helical domain mutation (E542K), had activation of p70S6 only. The PIK3CA wild-type liver metastasis demonstrated low activation of AKT and p70S6. For non-hepatic metastases AKT was activated in 2 of the 17 cases (11.8%) and p70S6 in 5 of the 17 patients (29.4%).
Discussion: Although these results need further validation, activation of the AKT-mTOR pathway appears to be a hepatic specific signature in MBC and could be used for the selection of targeted agents for hepatic lesions.
Title: Pre-clinical findings on obesity reversal and breast cancer progression: Targeting persistent inflammation

Rossi EL L, Bowers LW W, Khatib SA A, Doerstling SS S and Hursting SD D. The University of North Carolina at Chapel Hill, Chapel Hill, NC.

Body: Background
Obesity is an established risk and progression factor for several intrinsic subtypes of breast cancer, including basal-like breast cancer (BLBC). Increased local and systemic levels of pro-inflammatory mediators, which typically accompany obesity, can independently influence tumor growth. Currently, it is unclear whether weight loss can reverse the enhancing effects of obesity on breast tumorigenesis. We hypothesize that chronic obesity results in epigenetic reprogramming, which may mediate residual inflammation, and lead to persistent mammary tumor growth despite moderate weight loss.

Methods
Female C57BL/6 mice (n=51) were administered a control (10% kcal from fat) or diet-induced obesity (DIO; 60% kcal from fat) regimen. After 17 weeks, DIO mice either continued on DIO diet or were switched to control diet to stimulate gradual weight loss, subsequently designated as Formerly Obese (FOb). Mice were orthotopically injected with Wnt-1 mammary tumor cells (a model of BLBC) at week 25, and monitored for an additional 9 weeks, then killed and their tumors excised, measured and stored for subsequent analysis. In an ongoing tumor study, we will randomize mice to the control or DIO regimen, switching half the DIO mice to the control diet after 15 weeks, resulting in normal weight, obese, and FOb mice. Within each of these groups, the mice will be further randomized to +/- supplementation with Sulindac, a non-steroidal anti-inflammatory drug (NSAID), starting at the time of the diet switch. After 10 weeks of +/- Sulindac supplementation, mice will receive orthotopic injections of a mesenchymal derivative of an MMTV-Wnt-1 transgenic tumor, the M-Wnt cell line, and will continue on diet and treatment until euthanization.

Results
In our initial study, body weight, adiposity, and serum levels of leptin and insulin were similar in FOb and control mice, but serum levels of IL-6 were similar in FOb and DIO mice, and significantly higher than controls. Moreover, tumor burden, the mammary gland expression of key inflammatory genes, and the prevalence of hypermethylated inflammation-related genes in DNA from mammary tissue were comparable in DIO and FOb mice and significantly higher than in control mice, and there was high concordance with DNA methylation profiles in breast DNA from obese versus normoweight women participating in the UNC Normal Breast Study.

Conclusions
Our preclinical findings suggest that modest weight loss may not be sufficient to reverse the effects of chronic obesity on epigenetic reprogramming and inflammatory signals that are associated with obesity-related mammary tumor progression. Moreover, we have identified several genes with concordant obesity-related hypermethylation in humans and mice; which were unchanged in FOb mice. Thus combining weight loss regimens with epigenetic or inflammatory modulators may be an effective strategy for breaking the obesity-breast cancer link. We are currently assessing whether combining moderate weight loss with anti-inflammatory interventions (Sulindac or omega-3 fatty acids), or reprogramming metabolism with a bariatric surgical intervention, is more effective than moderate weight loss alone at offsetting the persistent enhancing effects of chronic obesity on BLBC.
Title: TWIST1 silences FOXA1 transcription to promote breast cancer progression

Xu Y, Feng Z, Xu Y, Mo Q, Qin L, Sun T, Wu H, Li Y, Liao L and Xu J.  Baylor College of Medicine, Houston, TX;  Texas A & M Health Science Center IBT, Houston, TX;  East China Normal University, Shanghai, China;  Third Military Medical University, Chongqing, China and  Sichuan Medical University, Luzhou, China.

Body: TWIST1 promotes epithelial-mesenchymal transition (EMT), invasion and metastasis of breast cancer cells, but the underlying mechanism is still not well understood. We generated mammary gland tumor specific Twist1 knock out mouse model and found that TWIST1 does not affect PyMT-induced mammary tumor initiation and growth but promotes tumor lung metastasis. We identified FOXA1 as a novel direct target of TWIST1 in both mouse and human breast cancer. We further found that TWIST1 inhibits FOXA1 expression through direct binding to its proximal promoter region and recruiting Mi2/nucleosome remodeling and deacetylase (Mi2/NuRD) transcriptional repressor complex. Moreover, TWIST1 also diminished transcriptional activator AP1 binding to FOXA1 promoter. TWIST1 mediated FOXA1 down-regulation is essential for promoting breast cancer migration, invasion and metastasis. FOXA1 significantly inhibits TWIST1 dependent cell migration and invasion capability of MCF7 cells through inhibiting integrin α5, β1 and MMP9 expression. Importantly, TWIST1\textsuperscript{high} FOXA1\textsuperscript{low} correlates with the poorest prognosis in breast cancer patients.
Title: OPG+ bone marrow B cells induced by non-metastatic tumors inhibit the pre-metastatic bone niche induced by T cells

Bonomo A, Monteiro AC, Leal AC, Fontão AP, Spinetti E and Balduino A. Fiocruz, Brazil; UFRJ, Brazil; Universidade Veiga de Almeida, Brazil and Excellion Biomedical Services.

Body: Using the 4T1 model of experimental breast cancer we had recently shown that cancer induced bone disease starts before metastatic colonization and is mediated by RANKL expressed by tumor specific T cells. The role of anti-tumor B cell immune response in the context of cancer induced bone disease has never been investigated. There is evidence in the literature that B cells are good prognostic markers for metastatic breast cancer. B cells have an intimate relationship with bone cells as they differentiate from HSC present on endosteal surfaces; cross-talk with skeletal system through the RANK-RANKL-OPG signaling axis; and produce OPG, a decoy receptor of RANKL.

Here we used the BALB/c derived 4T1 (metastatic) and 67NR (non-metastatic) sibling cell lines of mammary mouse carcinomas. By day 7, 14 and 21 after tumor injection, B220+ BM B cells from 67NR+ animals produce high amounts of OPG in vitro in contrast to B220+ BM B cells of 4T1+ mice. In vitro, BM B cells from 67NR+ mice, but not from 4T1+, could inhibit the RANKL dependent, anti-4T1 T cell mediated-OC differentiation ascertained by TRAP enzymatic activity, morphology and osteolytic disk assay.

Transference of BM B cells from 67NR+ mice together with 4T1 tumor cells to BALB/c mice led to inhibition of osteoclastogenesis, increased numbers of bone lining cells and mesenchyme stem cell. Besides acting directly on the bone remodeling system, these B cells also modulated T cell activity evidenced by diminished RANKL and IL-17F production. All the anti-osteolytic and pro-osteogenic activity of B cells modulate and inhibits the pre-metastatic niche formation. Indeed transference of such cells to 4T1 animals inhibited LN and BM metastatic colonization.

We conclude that 67NR induced OPG+ B cells can inhibit pro-osteoclastic / pre-metastatic activity of tumor induced T cells, favoring a bone metastasis free-phenotype. These findings have implications, not only for the understanding of the direct contribution of B cells in the control of bone metastasis but also it might be a promising prognostic tool for predicting cancer-induced bone metastasis.

Title: TIMP-4 expression correlates with disease progression among HER2-positive breast cancers

Isaac KM M, Zemba-Palko V, Sabol JL L, Blair L, Behbod F and Wallon UM. Lankenau Medical Center, Wynnewood, PA; The University of Kansas Medical Center, Kansas City, KS and Lankenau Institute for Medical Research, Wynnewood, PA.

Body: Breast cancer with HER2 gene amplification accounts for 20-25% of invasive breast cancer. HER2 activates the PI3K/Akt and MAPK pathways promoting survival and cell proliferation resulting in aggressive biological behavior and poorer prognosis for the patient. Although trastuzumab (Herceptin®), a recombinant humanized antibody, offers effective treatment of HER2-positive cancers, a proportion of patients will not respond to trastuzumab-based regimens and those who do respond can lose clinical benefit during the late stages of their treatment.

In this IRB-approved study we have assessed HER2 and LuminalB subtypes of invasive breast cancer from an archival collection together with specimens collected in an on-going prospective study for the expression of tissue inhibitor of metalloproteinase-4 (TIMP-4), an inducer of the PI3K/Akt pathway and its possible correlation to trastuzumab resistance. Circulating TIMP-4 in the stroma binds to CD63 on the tumor epithelial cells and initiates a signaling cascade through interaction with β1-integrin.

We have previously demonstrated that elevated levels of TIMP-4 confers poor survival prognosis for triple-negative breast cancers. Genomics data found at TCGA, cBioPortal for Cancer Genomics¹ have showed that TIMP-4 is amplified in 24% of breast cancer patients. Therefore, we propose that the reported ~20% of HER2-positive patients that will not respond to trastuzumab could in fact be TIMP-4 positive and have active PI3K/Akt signaling. In this on-going study, we have to date examined twenty-nine patients with HER2 gene amplification. Among these, eight had elevated levels of TIMP-4 as determined by immunohistochemistry, and seven had progression of their disease within one year of starting systemic therapy (all with metastasis to brain) while one had local recurrence 5 years after starting therapy. Two of these patients had stage IA disease, one had IIA, three had IIB and two were diagnosed with stage IIIC disease. These results suggest that TIMP-4 amplification could be, at least in part, responsible for the trastuzumab resistance due to TIMP4's ability to promote survival and cell proliferation by a continuous activation of the PI3K/Akt pathway.

In an attempt to test if a monoclonal antibody specific for human TIMP-4 could be used to prevent or alleviate the trastuzumab resistance, we are using human breast cancer cell-lines with amplified HER2, with and without CD63 expression as well as a CD63 knock-out line. From these experiments we hope to learn if treating for TIMP-4 could be an approach for future clinical intervention for the patients that have HER2 gene amplification and elevated levels of TIMP-4.

Title: Focal adhesion kinase is required for efficient tumor-induced osteoclastogenesis via control of macrophage colony stimulating factor expression

Landon K, Howe GA A, Zhao H and Addison CL L. Ottawa Hospital Research Institute, Ottawa, ON, Canada and University of Ottawa, Ottawa, ON, Canada.

Body: Breast cancer most commonly metastasizes to bone where metastases cause the potentiation of the vicious cycle. During this process, breast cancer bone metastases inhibit osteoblasts from forming new bone, while also activating osteoclasts to degrade bone. This in turn causes release of bone-matrix bound growth factors which propagate tumor growth. The overall net bone destruction can lead to significant adverse clinical consequences for patients including fractures or substantial pain. While agents such as bisphosphonates or the monoclonal antibody to RANKL denosumab, both of which inhibit the osteolytic activity of osteoclasts, are currently used in breast cancer bone metastatic patients to alleviate these adverse clinical outcomes, they have not been associated with increased patient survival. Given the lack of successful treatments for bone metastases providing survival advantages, we sought to evaluate the role of focal adhesion kinase (FAK), a novel therapeutic target, in breast cancer mediated osteolysis. FAK is a non-receptor tyrosine kinase that regulates many pathways that contribute to enhanced tumor progression and metastasis. FAK is also expressed in all the cell types involved in the vicious cycle. We thus hypothesized that FAK plays an important role in breast tumor-induced osteolysis and that its inhibition would lead to restoration of bone homeostasis, in addition to inhibition of tumor progression. Using in vitro siRNA-targeted depletion of FAK in breast cancer tumor cell lines, we found that production of numerous soluble growth factors, many of which are known contributors to osteoclastogenesis, was inhibited. We confirmed that FAK regulates the expression of the osteoclastogenic factor macrophage colony stimulating factor in breast cancer cell lines. Further, using conditioned media from FAK expressing versus depleted breast cancer tumor cells in osteoclastogenesis assays, we show that FAK-depletion results in impaired osteoclastogenesis. These data suggest that in addition to its proven direct anti-tumor effects, inhibition of FAK may also result in therapeutic blockade of bone degradation.
The ratio of progesterone receptor isoform A to B determines the effect of antiprogestins on preclinical models of breast cancer metastasis

Body: In previous studies using several experimental models expressing different progesterone receptor (PR) isoform ratios, we have shown that only those with high levels of isoform A (PRA) are inhibited by antiprogestins whereas those with high levels of isoform B (PRB) are resistant to antiprogestin therapy. Moreover, results obtained using tissue cultures of breast cancer patients confirmed the data observed in these experimental models (May and Rojas et al., ASCO meeting 2015).

The aim of this study was to evaluate the role of progestins and antiprogestins on the outgrowth of spontaneous metastatic foci of mammary carcinomas with different PR isoform ratios.

We used metastatic tumors from the murine medroxyprogesterone acetate (MPA)-induced breast cancer model: C7-2-HI (PRA>PRB) and C7-HI (PRA<PRB), and human MDA-MB-231 cells genetically modified to overexpress PRB. Tumors were orthotopically inoculated in the fourth mammary gland and Mifepristone (MFP; 6 mg), Telapristone (TLP; 6 mg), MPA (20 mg) or vehicle silastic pellets were sc implanted when the tumors reached a size of 25 mm2. Tumors were measured twice a week and animals were followed to detect the presence of axillary lymph node metastasis. Animals were euthanized before tumor size exceeded 2 cm at the largest diameter or showed a deterioration of the physical conditions.

Both antiprogestins had similar effects, MFP induced almost complete regression of the C7-2-HI tumor as already described, and TLP inhibited significantly its growth as compared with control tumors, while no changes in tumor size were observed in MPA-treated mice. Lung or lymph node studies confirmed the lack of metastatic foci in MFP-treated mice while no changes in tumor size were observed in MPA-treated mice. In C7-HI tumors, with higher levels of PRB than PRA, MFP clearly stimulated the number of lung foci as compared with control animals (p<0.05). The effects of TLP and MPA on tumor metastasis, although not inhibitory, need to be confirmed. Studies performed using MDA-MB-231-PRB xenografts growing in NSG mice showed that MFP stimulated the growth of lung foci, while MPA was inhibitory. No significant changes were observed in mice inoculated with empty vector transfected cells. To investigate the mechanisms underlying the metastatic process, we evaluated the expression of a metastatic suppressor gene (Nm23-H1) and a prometastatic enzyme (MMP-2). We found a lower expression by immunohistochemistry of the former and an increase in the latter by qPCR in MFP-treated MDA-MB-231-PRB xenografts compared with untreated tumors.

In conclusion, we have demonstrated that MFP impedes the metastatic process in tumors with higher levels of PRA than PRB while it might promote metastasis in those with the opposite ratio. We suggest that MFP, through PRB receptors, downregulate the expression of Nm23-H1 and increase the expression of MMP-2. The conclusive effects of TLP and MPA need further investigation. These data underscore the importance of isoform ratio determination before treatment of breast cancer patients with endocrine therapies that target PR.
Title: The impact of the plant lignin secoisolariciresinol diglycoside on preclinical models of estrogen receptor positive breast cancer

Bowers LW W, Ford NA A, Rossi EL L, Shamsunder MG G, Kimler BF F, Fabian CJ J and Hursting SD D. University of North Carolina at Chapel Hill; University of Texas at Austin and University of Kansas Medical Center.

Body: Background: Several preclinical studies indicate that secoisolariciresinol diglycoside (SDG), a polyphenolic plant lignin found most abundantly in flaxseeds, inhibits the progression of both estrogen receptor (ER) positive and negative mammary tumors. SDG is metabolized by gut bacteria into the biologically active metabolites enterolactone (ENL) and enterodiol (END), which are known to have anti-estrogenic activity. However, the mechanisms mediating SDG's anti-tumor effects remain poorly understood.

Methods: In a dose-determination pilot study linked to an ongoing clinical trial of SDG in women at high risk for breast cancer, 18 week old C57BL/6 mice were randomized to a control diet or SDG-supplemented diets (25 or 74 mg/kg of food) for 8 weeks prior to euthanization, and the levels of serum and tissue SDG metabolites (particularly ENL and END), metabolic hormones and inflammatory markers were measured. In an ongoing tumor study, 12-week old C57BL/6 and foxn1 nu/nu mice were randomized to the control or control plus SDG (100 mg/kg of food, a dose projected to match ENL and END metabolite levels achieved in the clinical trial) diet regimen. After 8 weeks on diet, they will receive orthotopic injections of E0771 mouse mammary tumor cells or BT-483 human breast cancer cells (both ER positive), continuing on the same diets until euthanization. Cell culture studies examining the impact of biologically relevant concentrations of ENL and END on E0771 and BT-483 cells are also in progress.

Results: In comparison to those maintained on the control diet, the higher dose SDG diet reduced estrogen and pro-inflammatory signaling in the pilot study mice, as evidenced by higher interleukin 10 and lower C-reactive protein mammary fat pad expression as well as lower circulating levels of the adipokines leptin and resistin, which have been linked to chronic inflammation. High dose SDG also decreased serum insulin and glucose levels, indicating improved metabolic function. Because serum ENL and END levels in the pilot study did not reach those achieved in the SDG clinical trial, a 100 mg/kg SDG dose was chosen for the tumor study. Cell culture studies indicate that ENL (150 nM) inhibits E0771 and BT-483 cell proliferation and ER alpha:beta expression ratio.

Conclusions: Preliminary data suggests that the anti-tumor effects of SDG's metabolites may be mediated through multiple mechanisms, including improvements in metabolic function and inflammatory signaling as well as modulation of breast cancer cell gene expression. The results of the ongoing tumor study will inform the design of additional cell culture studies aimed at further defining these mechanisms.
Title: Characterisation of C11orf67, an oncogenic driver in a new subtype of aggressive endocrine receptor positive breast cancer

Redfern A, Rashwan R, Sorolla A, Ratajska M, Kardas I, Kuzniacka A, Parry J, Curtis C, Woo A, Sgro A and Biernat W. School of Medicine and Pharmacology, University of Western Australia, Perth, Western Australia, Australia; Cancer Epigenetics Division, Harry Perkins Institute of Medical Research, Perth, Western Australia, Australia; Medical University of Gdansk, Gdansk, Poland; School of Pathology and Laboratory Medicine, University of Western Australia, Perth, Western Australia, Australia; School of Medicine and Stanford Cancer Institute, Stanford, CA and Medical University of Gdansk, Gdansk, Poland.

Body: The recent integration of both genomic and transcriptomic datasets have added a further dimension to the landscape of breast cancer (BrCa) subtyping, defining novel functional subgroups with distinctive oncogenic drivers that carry important implications for therapy. This integrative clustering has unveiled a novel subtype of hormone receptor positive (HR+) BrCa associated with high proliferation and very poor survival characterised by copy number amplification and overexpression of a cluster of candidate oncogenic drivers at the 11q13.5-14 locus (1). At the heart of this amplicon we have demonstrated the selective overexpression of C11orf67/AAMDC (Adipogenesis associated Mth938 domain containing) which encodes a hypothetical protein of 122 aa with unknown function. In a pilot tissue microarray of 75 BrCa cases C11orf67 amplification and expression were significantly correlated with hormone receptor positivity. These positive cases also demonstrated high risk features with 75% demonstrating lymph node involvement.

In functional elucidation studies knockdown of C11orf67 in the highly expressing T47D cell line lead to decreased cell proliferation, cell migration, anchorage independent cell growth and induction of senescence. T47D xenografts with stable shRNA-induced C11orf67 knockdowns introduced into BALB/c mice showed significantly lower tumour volumes relative to T47D with empty vector. A genome wide analysis of these T47D-C11orf67 shRNA cells compared to T47D-empty vector cells using the Illumina HumanHT-12 platform demonstrated 40 differentially expressed genes. Network analysis revealed a proliferation node, enriched in cell cycle proteins, and a metabolic node comprising several biosynthetic enzymes such as MTHFD1L involved in one-carbon folate metabolism. Supporting this link and pointing to potential utility in chemotherapy selection, induction of ectopic C11orf67 expression in MCF7 cells increased sensitivity to fluorouracil and methotrexate but not to paclitaxel.

Investigating potential novel binding partners and effectors, in yeast two hybrid screening C11orf67 was found to associate strongly with RABGAP1L, a protein involved in controlling GTPase signalling, protein trafficking, and autophagy. Exploring the molecular cues that control C11orf67 expression, our data suggest the locus is regulated by transcription factors associated with high proliferation and metabolic control, notably Myc and NFkB, as well as HRs. E2 lead to a significant down-regulation of C11orf67 in T47D cells, which was reversed by the antiestrogen drug tamoxifen, whereas PG significantly increased C11orf67 levels. In keeping with this MCF7 cells ectopically expressing C11orf67 were resistant to the anti-proliferative effects of tamoxifen compared to the parent cell line.

These observations endorse C11orf67 as a novel oncogenic driver with exciting therapeutic potential, which could serve to distinguish the HR+ tumours at high risk of relapse and guide both the selection of current chemotherapeutical and endocrine treatments as well as the design of future precision therapeutics, notably anti-folate/one carbon drugs and novel endocrine agents.

Title: BIN3 is an 8p21 tumor suppressor regulating the epithelial attachment checkpoint

Silva J, Marshall N, Sanchez-Garcia F, Parsons R and Pe'er D. Mount Sinai School of Medicine, NY, NY and Columbia University, NYC, NY.

Body: An important characteristic of multicellular organisms is the control that tissue architecture exerts on the growth and differentiation of individual cells. Epithelial cells sense their location through interactions with the extracellular matrix (ECM) as well as neighboring cells. These interactions generate input signals, including survival, that are critical to maintain tissue and cellular homeostasis. When attachment is compromised, epithelial cells undergo an intrinsically programmed cell death (apoptosis) that is termed anoikis (from the Greek "loss of home"). Importantly, failure to execute the anoikis program could result in adherent epithelial cells surviving in suspension or being able to proliferate at sites different from their original environment. Thus, anoikis is a line of defense that must be circumvented by cancerous epithelial cells for them to leave their home niche, thrive in inappropriate ECM environments, and establish long distance metastases. Thus, elucidating how epithelial cancer cells escape anoikis is critical to understanding cancer progression.

In order to uncover genes that modulate the anoikis response and are altered in human cancers, we performed a functional genomics study. We couple genome wide RNAi to identify gene functions that, when silenced, induce resistance to anoikis with a novel computational method, ISAR-DEL, specifically aimed at pinpointing candidate tumor suppressor genes based on recurrent loss of copy number. Our studies identified Bridging Integrator 3 (BIN3) as a novel tumor suppressor located on the chromosomal region 8p21.3, one of the most frequently lost regions in epithelial cancers.

Mechanistically, we link BIN3 tumor suppression function to its ability to sense changes in the curvature of the cell membrane and relocate to the cell membrane after cell detachment to induce a proapoptotic cascade. Once BIN3 has translocated to the cell membrane it modulates the relocation and function of CDC42. In these conditions, CDC42 transmits the signal that leads to the activation of the stress protein P38-α and programmed cell death mediated by accumulation of the apoptotic facilitator BimEL. Overall, our results explain how changes in cell geometry are integrated in the cellular signaling network and present, for the first time, BIN3 as a novel breast cancer tumors suppressor.
Leukemia inhibitory factor receptor as a tumor suppressor: A study on migration and invasion of breast cancer cells upon LIFR stimulation

Dempsey NG G, Miller P and Lippman M. University of Miami Miller School of Medicine, Miami, FL.

BACKGROUND: Tumorigenesis is the result of a step-wise process during which a mutation activates an oncogene or inactivates a tumor suppressor gene. Identification of these genes is critical in order to develop effective therapies for breast cancer patients. Our group previously discovered the Leukemia Inhibitory Factor Receptor (LIFR) as a novel tumor suppressor gene via an in vivo RNAi screen in HMLE cells. HMLE is a partially transformed non-tumorigenic cell line; these cells can become tumorigenic with a single mutation, such as the Ras mutation that creates the HMLER line. HMLEs were transduced using an shRNA library targeting the entire human genome, and stably transfected cells were xenografted into NOD/SCID mice. Genomic DNA from resultant primary tumors were analyzed for the shRNA sequences that, when integrated, made HMLEs tumorigenic. LIFR emerged from this screen as a novel candidate tumor suppressor gene in breast cancer. Here we report on the decreased migration and invasion of breast cancer cells activated by LIFR stimulation.

METHODS: HMLER cells were plated at 500,000 cells per well of a six-well plate. Twenty-four hours later, HMLERs were treated with 100, 25, 12.5, 5, 2.5, or 0 ng/ml recombinant hLIF. Protein lysates were analyzed for phospho-STAT3 induction upon LIF stimulation. Based on the results, we selected 25 ng/ml as the appropriate hLIF concentration to maximally stimulate LIFR in the migration assay described here. HMLERs were serum starved for 8 hours. DMEM with 10% fetal bovine serum was added to the bottom of the migration assay plate as a chemoattractant. The cells were suspended in DMEM with 0.1% bovine serum albumin and either treated with 25 ng/ml LIF or no LIF. Thereafter, 25,000 cells were added to either a Corning Biocoat Matrigel Invasion Chamber or a control insert lacking a migration matrix. The migration assay plate was incubated at 37°C and the cells were allowed to migrate for 20 hours. Migrated cells were enumerated under the light microscope and a migration percentage was calculated.

RESULTS: In the first portion of the study, we found that low concentrations of LIF (2.5 ng/ml) resulted in p-STAT3 induction in HMLERs, but that p-STAT3 was maximally induced with 25 ng/ml of LIF. In the invasion and migration assay, HMLER cells that had not been treated with LIF displayed an aggressively invasive and migratory phenotype with 61.1% migration in matrigel compared to control inserts without the migration matrix. When HMLERs were treated with 25 ng/ml LIF, the cells displayed decreased invasion and migration with only 50.0% of cells migrating. Based on these results, LIFR stimulation inhibits the invasion and migration of breast cancer cells.

CONCLUSIONS: As a tumor suppressor gene, LIFR is vital to the normal functioning of a non-cancerous cell, and its loss can produce a tumorigenic and metastatic phenotype. Treatment with LIF converts aggressively metastatic breast cancer cells to a less invasive phenotype. Through a deeper understanding of LIFR's tumor suppressor effects, we can harness the anti-tumorigenic and anti-metastatic properties of LIFR stimulation and develop targeted therapies to prevent growth and metastasis of breast cancer.

**Publication Number:** P2-06-04

**Title:** The power of next generation sequencing in the detection of breast and ovarian cancer susceptibility genes other than BRCA

**Body:** Background: Most cases of breast and ovarian cancer susceptibility remains unexplained. Testing multiple genes in one go with next generation sequencing is then an asset with the recent discovery of new genes involved in breast and ovarian cancer susceptibility.

Methods: We studied 457 patients originated from Burgundy (France) fulfilling the criteria for BRCA1/2 testing using a next generation sequencing 25-gene panel including 17 genes of predisposition for breast and/or ovarian cancer (ATM, BARD1, BRCA1/2, BRIP1, CHEK2, PALB2, RAD51C, TP53, PTEN, RAD50, MRE11, MLH1, MSH2, MSH6, PMS2, STK11).

Results: A pathogenic BRCA1/2 mutation was found in 8% (n=37) of patients. Besides, we found 39 deleterious or probably deleterious mutations in 13 different genes. The most frequently mutated genes were CHEK2 (n=10 ; 2.1 %), ATM (n=9 ; 2 %), and PALB2 (n=4 ; 0.9%). One patient had deleterious mutations in both TP53 and PALB2, and another one had deleterious mutations in both BRCA2 and CHEK2. The mutation could explain the phenotype in the majority of cases, but a pathogenic mutation was found in a different predisposing gene in 7 patients, and could be considered as incidental findings with the currently published spectrum of cancer locations.

Conclusion: Besides BRCA1/2 mutations, that remain the most frequent susceptibility genes for breast and ovarian cancer, gene panels remain a powerful tool for identifying the other less frequent susceptibility genes. The penetrance and spectrum of cancer associated to these other genes remain sometimes undefined, and further collaborative work is crucially needed to address this question. The possibility of double hits should led to careful genetic counseling.
LncRNAs may play a role in cancer and serve as new potential targets for improving cancer diagnosis, prognosis or treatment. Long intergenic non-protein coding RNA 478 (LINC00478), the miR99a-let-7c cluster host gene, has been shown to be downregulated in estrogen-independent ER-positive (ER+) breast cancer cells. However, its expression in breast tumors and its significance in recurrence has not been well characterized.

Methods:
The clinical relevance of LINC00478 in ER+ breast tumors was first determined by analysis of the expression levels in MiTranscriptome database (RNAseq-based), which contains ∼8000 most differentially expressed lncRNAs for each cancer and/or tissue type. Additionally, the expression of LINC00478 mRNA was determined in a) a cohort of matched pairs of primary and (nodal) metastatic tumors (n=18) (RNA-seq) and b) a cohort of 60 paraffin-embedded ER-positive, node-negative breast carcinomas with Oncotype DX recurrence scores (QRT-PCR).

Results:
LINC00478 was significantly downregulated in patients with ER-positive tumors compared to uninvolved normal breast tissue. In RNA-seq analysis, metastatic tumors had significant low expression as compared to matched primary tumors (FC: -2.2 fold-down; P=0.0027). Quantitative RT-PCR analysis showed that LINC00478 expression was significantly lower in ER+ node-negative patients with Oncotype DX high recurrence score when compared with low recurrence score patients (FC: -4.14-fold down; P=0.02).

Conclusion:
We document for the first time that LINC00478 functions as a tumor suppressor in ER-positive breast cancer. Its loss is associated with tumor progression and recurrence/metastasis. Novel strategies that focus on re-expression of LINC00478 might be useful for targeting breast cancer and preventing the metastases.
Body: Breast cancer is the most commonly diagnosed cancer and 2nd leading cause of cancer death in women in the United States. Despite high rates of diagnosis and numerous drug treatments, the response to treatment is difficult to predict due to different breast cancer subtypes with varying molecular signatures. Recurrence of breast cancer is now more prevalent and is often associated with drug resistance, which accounts for nearly 90% of all metastatic breast cancer deaths. Expression of the tumor suppressor protein Adenomatous Polyposis Coli (APC) could be one important molecular marker in breast cancer treatment. APC is lost by mutation or hypermethylation in up to 70% of sporadic breast cancers, and predicts resistance to cisplatin in other tumor types. Using the \textit{Apc}^{min/+} mouse crossed to the mouse mammary tumor virus Polyoma middle T antigen (MMTV-PyMT) transgenic model, we showed that APC loss enhanced PyMT-mediated breast tumorigenesis. \textit{In vitro} studies recently demonstrated that cells isolated from MMTV-PyMT;\textit{Apc}^{min/+} tumors are more resistant to doxorubicin- or cisplatin-induced apoptosis, have increased multidrug resistance protein 1 (MDR1), and have an enhanced tumor initiating cell (TIC) population. Reintroduction of full-length APC into the MMTV-PyMT;\textit{Apc}^{min/+} cells restores sensitivity to both cisplatin and doxorubicin. Therefore the current study focuses on determining the mechanism(s) responsible for APC-mediated chemotherapeutic resistance. We have found that cells from MMTV-PyMT;\textit{Apc}^{min/+} tumors have greater expression of phosphorylated signal transducer and activator of transcription 3 (STAT3) and production of interleukin 6 (IL-6) compared to cells from MMTV-PyMT;\textit{Apc}^{+/+} tumors. Given that IL-6 can activate STAT3, and both of these factors can contribute to increased MDR1 and TICs, our future studies will investigate whether STAT3 and IL-6 contribute to the development of APC-mediated chemotherapeutic resistance.
Title: PRKCQ regulates taxol sensitivity of triple negative breast cancer cells via IL-6/Stat3 signaling

Irie HY Y and Byerly J. Icahn School of Medicine at Mount Sinai, NY, NY.

Body: Background/Rationale. While some patients with triple negative breast cancer achieve long-term remission with chemotherapy, many have cancers that are chemotherapy resistant. The lack of targeted therapies for this subtype also makes some triple negative cancers difficult to treat and control. PRKCQ, a member of the novel protein kinase C family, is preferentially expressed in triple negative breast cancers compared to ER+/Luminal cancers. We previously reported that PRKCQ expression drives growth-factor independent growth, anoikis resistance and migration of breast epithelial cells. In addition, PRKCQ is required for in vivo growth of triple negative breast cancers tumor xenografts. We sought to determine if PRKCQ expression modulates sensitivity of triple negative breast cancer cells to standard of care chemotherapy and whether PRKCQ inhibition could be a strategy to induce death of chemotherapy-resistant triple negative breast cancer cells. Methods. We determined the effects of modulating PRKCQ expression, using PRKCQ cDNA or shRNA vectors, on Doxorubicin or Taxol treatment-induced effects on triple negative breast cancer cells, including those that are relatively chemotherapy resistant at baseline. We determined the mechanisms by which PRKCQ expression regulates sensitivity to Taxol. Results. Increased PRKCQ expression in MCF-10A breast epithelial cells suppresses the apoptosis-inducing effects of Doxorubicin or Taxol treatment. PRKCQ-induced Taxol resistance is dependent on PRKCQ kinase activity. PRKCQ-expressing MCF-10A cells secrete enhanced levels of IL-6, leading to the autocrine activation of Stat3; IL-6/Stat3 activation is necessary for PRKCQ-induced resistance to Taxol. Finally, downregulation of PRKCQ sensitized MDA-231-Luc cells to Taxol treatment and induced apoptosis of these cells which are relatively resistant to Taxol at baseline. Conclusions. PRKCQ regulates sensitivity to standard of care chemotherapies used in the treatment of triple negative breast cancer. IL-6/Stat3 signaling induced by PRKCQ kinase activity is responsible for resistance to the effects of Taxol treatment. Targeting PRKCQ therefore could be an attractive strategy to overcome chemotherapy resistance of a subset of triple negative breast cancers.
Title: Interplay of Smad2 and Smad3 during TGF-β induced TMEPAI/ PMEPA1 mediated triple negative breast cancer cell growth

Singha PK K, Pandeswara S, Venkatachalam MA A and Saikumar P. University of Texas Health Science Center at San Antonio, San Antonio, TX.

Body: Background: Despite the known effects of TGF-β mediated canonical and non-canonical Smad signaling in cancer cell growth and metastasis, the role played by individual R-Smads in mediating TGF-β dependent late growth and metastasis remained enigmatic. Previously we have reported that transmembrane prostate androgen induced (TMEPAI/PMEPA1), a TGF-β target gene has unique role in subverting TGF-β mediated growth suppression into growth promotion of triple negative breast cancer (TNBC) cells. But the relationship between Smads and TGF-β mediated TMEPAI induction and TNBC proliferation is not known. Therefore, we undertook the present study to know the differential role played by Smads in TGF-β mediated induction of TMEPAI and TNBC growth.

Materials and Methods: Cells were cultured as recommended by ATCC. Knockdown of TMEPAI and Smad2, Smad3 proteins was achieved by lentiviral or retroviral shRNA vectors. Transfections, luciferase assays, RT-qPCR and immunoblotting were performed according to standard methods. Cell proliferation was measured by quantitation of total cellular DNA.

Results: Although no significant differences were found in mRNA levels of Smad2 and Smad3 in normal human mammary epithelial cells (HMEC) and different TNBC cell lines, at the protein level aggressive TNBC cells expressed more Smad3 protein than Smad2 compared to normal cells. TMEPAI knockdown did not modify this profile in TNBC cells. However, HMEC that expressed more Smad2 protein than Smad3, produced little TMEPAI and growth arrested in response to TGF-β. In contrast, MDA-MB-231 (231) cells, which contained more Smad3 over Smad2 produced high levels of TMEPAI and grew robustly in response to TGF-β. To delineate the role of individual R-Smads in TGF-β mediated growth regulation and TMEPAI expression, Smad2 or Smad3 were selectively knocked down using shRNAs. Knockdown of either Smad2 or Smad3 rescued HMEC from TGF-β mediated growth arrest, suggesting that Smad signaling is growth suppressive in HMEC. In contrast, selective Smad2 or Smad3 knockdown had distinctive effects on 231 cell proliferation and TMEPAI expression. Interestingly Smad3 knockdown, which showed diminished TMEPAI expression in 231 cells, greatly inhibited their growth both in the absence or presence of TGF-β. In contrast, Smad2 knockdown in 231 cells caused augmented TMEPAI expression in response to TGF-β and increased cell proliferation at the rates similar to control cells either in the absence or presence of TGF-β. Notably, individual R-Smad deficiency caused a compensatory increase in the complementary R-Smad and its associated signaling in 231 cells. Therefore, the effect of Smad3 shRNA on TNBC proliferation was similar to that of TMEPAI shRNA reported by us earlier. Like TMEPAI knockdown, Smad3 knockdown also elevated PTEN protein levels with reduced Akt phosphorylation that reduced growth both in the absence or presence of TGF-β.

Conclusion: Our results suggest that growth of TNBC in the presence of TGF-β is unique to cancer cells and is pathological in a TGF-β-Smad3-TMEPAI axis dependent manner. Smad3 plays an important role in growth promoting TGF-β dependent non-canonical signaling not only with respect to the induction of TMEPAI but also by decreasing the PTEN.
Title: Co-expression plasmid carrying GRIM-19 and LKB1 genes acted synergistically on breast cancer in vitro and in vivo

Du Y, Hou W, Han B, Guan X, Zhu Z, Zheng C and Fan Z. The First Hospital of Jilin University, Changchun, Jilin, China and The First Hospital of Jilin University, Changchun, Jilin, China.

Body: Background:
The onset and progression of cancer is a multistage, multi-gene and multi-factor process. It is very difficult to cure the tumor by using a single therapeutic gene. Combination of many genes is more effective to inhibit the cancer growth than that observed with individual genes. Both GRIM-19 and LKB1 act as tumor suppressor genes, are ideal targets for cancer gene therapy. Increasing evidence demonstrated that GRIM-19 and LKB1, two kinds of tumor suppressor genes, combination other gene could inhibit several tumor growth.

Methods:
In the present study, a recombinant eukaryotic expression plasmid carrying GRIM-19 was constructed and then transfected into the MCF-7 to examine its effects on breast cancer cell growth, migration and invasion using several in vitro approaches, including qRT-PCR, western blot analysis, cell proliferation and colony formation, cell apoptosis, cell cycle distribution, cell migration and invasion assay, etc. In addition, tumor growth ability in nude mice was detected to define the Synergistic inhibition of tumor growth in vivo by co-expression plasmid pGRIM-19-LKB1.

Results:
In this study, we developed a dual expression plasmid that coexpressed GRIM-19 and LKB1, and then, we evaluated the synergistic effects of the two genes on anticancer activity in breast cancer in vitro and in vivo. We found that simultaneous expression of GRIM19 and LKB1 (pGRIM19-LKB1) in MCF-7 cancer cells significantly inhibited the proliferation, colony formation, migration and invasion compared with treatments of either pGRIM-19 or pLKB1 alone. We also found that treatment with a combination of GRIM19 and LKB1 (pGRIM19-LKB1) in MCF-7 cancer cells synergistically induced cell apoptosis and cell arrest at G0/G1 stage relative to pGRIM-19 or pLKB1 alone. In vivo study in MCF-7 xenograft tumor model demonstrated that intravenous injection of eukaryotic coexpression plasmid (pGRIM19-LKB1) caused an additive effect on tumor growth inhibition, compared to pGRIM-19 or pLKB1 alone.

Conclusion:
In summary, these findings suggest that combined therapy with eukaryotic coexpression plasmid carrying GRIM19 and LKB1 synergistically and more effectively suppressed tumor growth of breast growth in vitro and in vivo, and have therapeutic potential for treatment of human breast cancer.

Title: Loss of COX5B inhibits proliferation and promotes senescence via mitochondrial dysfunction in breast cancer

Gao S-P, Sun H-F, Jiang H-L, Li L-D and Jin W. Key Laboratory of Breast Cancer in Shanghai, Fudan University Shanghai Cancer Center, Shanghai, China.

Body: Background: COX5B, a peripheral subunit of the cytochrome c oxidase complex, is reported to maintain the stability of this complex and impact on cell viability. Recently, several studies demonstrated that cox5b may involve in cancer progression. In our study, we also found that COX5B was upregulated both in breast cancer tissues and cells. However, the role and mechanism of COX5B in breast cancer remain unclear. Therefore, the aim of this study is to validate COX5B functions and its underlying mechanisms in breast cancer cells.

Methods: SILAC (stable isotope labeling with amino acids in cell culture) assay was conducted in mammary epithelial cells and its paired breast tumor cells, and the results was validated by other two paired tissues. Forty tumors and twenty normal or benign samples were implied for COX5B expression by IHC. Online Kaplan Meier plotting tool was used to confirm the association between COX5B expression and clinical outcome. Three Cell lines (MDA-MB-231, MDA-MB-468 and MCF-7) were constructed by sh-RNA and the efficiency was confirmed by qPCR and western blot and then migration, proliferation and senescence characteristics were evaluated. Furthermore, microarray was implemented to detect potential mechanisms and the associated genes were assessed by qPCR. ELISA was carried out for IL8 secretion. Condition medium was collected from stable knock down cells and used as attractant in lower chamber of tranwell assay to examine microenvironment influence. Finally, the intracellular ATP glucose uptake and lactate secretion were evaluated, as well as mitochondrial membrane potential and ROS production.

Results: We found that the level of COX5B was elevated in breast cancer and cell lines. Patients with high levels of COX5B were likely to have a longer disease-free survival than patients with low levels. Furthermore, loss of COX5B inhibited proliferation and induced the senescence of breast cancer cells, which was accompanied by increases in the secretion of IL-8 and other cytokines. Additionally, conditioned medium from COX5B knockdown cells increased the migration of breast cancer cells compared with conditioned medium from control cells. The mechanisms underlying these processes were associated with mitochondrial dysfunction due to increased ROS production and decreased MMP and metabolism disorder.

Conclusion: Our results show that loss of COX5B inhibits proliferation and promotes senescence in breast cancer cells, which is associated with mitochondrial dysfunction. Indeed, loss of COX5B has different functions in target cells and the surrounding environments. These findings may provide a new perspective for the design of anti-cancer therapy combining with anti-IL8 treatment.
Wild type N-Ras, overexpressed in basal-like breast cancer, promotes tumor formation by inducing IL8 secretion via JAK2 activation

"Basal-like" breast cancer (BLBC) is a very aggressive subtype of breast cancer. BLBC has very poor prognosis — median time to distant recurrence is just 2.6 years vs. 5 years overall, and survival time from diagnosis of distant metastatic disease is 9 months vs. 22 months. BLBC tumors usually do not express ER, Her2, or progesterone receptor. As such, they cannot be treated by the current targeted therapies, which tar¬get these molecules. What drive the formation and progression of BLBCs is largely unclear.

Ras GTPases are best known for mediating growth factor signaling. Oncogenic mutations in the RAS genes, K-RAS in particular, are found in more than 30% of human tumors. Surprisingly, oncogenic RAS mutations are rare in breast cancer. However, we found that wild-type N-RAS is overexpressed in BLBCs, possibly partly via promoter demethylation, but not in other breast cancer subtypes. Repressing N-RAS inhibits transformation and tumor growth, while overexpressing it enhances these processes even in preinvasive BLBC cells. In contrast, in breast cancer cells of other subtypes, repressing N-RAS expression does not affect growth and transforming activities. We identified N-Ras-responsive genes, most of which encode chemokines and cytokines, e.g., IL8. High expression levels of these N-Ras-responsive genes as well as of N-RAS itself in tumors correlate with poor patient outcome. N-Ras, but not K-Ras, induces IL8 by binding and activating the cytoplasmic pool of JAK2; IL8 then acts on both the cancer cells and stromal fibroblasts.

In conclusion, N-Ras drives BLBC by promoting transformation in epithelial cells, which may in turn remodel the tumor microenvironment to create a proinvasive state. Although oncogenic mutations affecting RAS are common in many other human cancers, tumorigenesis in an important subset of breast cancers is driven instead by increasing activity of wild-type N-Ras. Thus, to fully assess the impact of Ras on tumorigenesis, the role of wild-type as well as mutant Ras proteins must be carefully examined.
**Title:** Association of TILs with clinical parameters, recurrence score, and prognosis in patients with early HER2-negative breast cancer (BC) – A translational analysis of the prospective WSG planB trial

Liedtke C, Gluz O, Heinisch F, Feuerhake F, Kreipe HH H, Clemens M, Nuding B, Kraemer S, Reimer T, Svedman C, Shak S, Nitz U, Kates RE E, Harbeck N and Christgen M. Westdeutsche Studiengruppe GmbH, Moenchengladbach, Germany; University Clinics Schleswig-Holstein/Campus Luebeck, Women's Clinic; Ev. Hospital Bethesda, Breast Center Niederrhein; Medical School Hannover, Institute of Pathology; Mutterhaus der Borromäerinnen Trier; Ev. Hospital Bergisch Gladbach; University Clinics Cologne, Breast Center; Clinics Suedstadt Rostock; Genomic Health, Inc.; Palleos Healthcare Services, Statistics and Breast Center, University of Munich and CCCLMU.

**Body:**

Introduction:
Tumor-infiltrating lymphocytes (TILs) have been associated with prognosis and with chemotherapy response among patients with BC, particularly in presence of high-risk features. The WSG planB trial randomized 2448 patients with HER2- N0/1 BC for comparison of anthracycline-free (6xTC) vs. standard anthracycline-taxane chemotherapy (4xEC-4xDoc). Recurrence Score® (RS) was incorporated for risk stratification in hormone receptor positive (HR+) BC. The present analysis focuses on the correlation of TILs with clinical/pathological parameters and their prognostic impact among planB patients.

Methods:
Stromal TILs were evaluated using a pathologist and two-observer approach. Three independent observers evaluated digital sections on H&E staining as previously suggested (Salgado et al., Ann Oncol. 2014); the median of the three values (TILmed) was used for statistical analysis. Spearman correlations of TILmed with clinical/pathological parameters (including central Ki67 expression, quantitative ER measurements, nodal involvement, and RS) and univariate impact on event-free survival (EFS) were analyzed.

Results:
Our analysis included 300 patients with HR- and 1124 patients with HR+ HER2- BC. Both in HR- and HR+ BC, a significant association between TILmed and (i) central grading (correlation coefficient r=0.147, p=0.012 and r=0.195, p<0.001, respectively) and (ii) central Ki67 expression (r=0.202, p=0.001 and r=0.152 and p<0.001) was observed. Among HR+ cases, a significant association between TILmed and quantitative ER measurements (r=−0.412, p=0.041) and RS (r=−0.190, p<0.001) was found. Furthermore, univariate Cox analysis revealed a significant association between TILmed (coded as fractional rank) and event-free survival (EFS). The hazard ratio of 75th to 25th percentile was 1.58 (95%CI: 1.06-2.36, p=0.025). This impact was not separately significant in HR subgroups due to lack of events.

Conclusion:
In this dataset, presence of stromal TILs was moderately associated with clinical features of high-risk breast cancer (including RS) and decreased EFS. TILs will be evaluated as a prognostic or predictive factor (in multivariate and subgroup analyses) when the outcome results are evaluated after prolonged follow up. Furthermore, an updated analysis including the complete planB dataset will be presented.
Tumor infiltrating lymphocytes density and coding mutations effects on the outcome of operable triple negative breast cancer patients

Background-Aim: Neoantigens are considered to trigger host immune responses against tumors, which may be reflected by tumor infiltrating lymphocytes (TILs) density within the tumor stroma. High TILs levels have been associated with favorable triple-negative breast cancer (TNBC) patient outcome. Herein we evaluated the presence of coding mutations and TILs density with regard to outcome in a cohort of TNBC patients treated with anthracycline-based adjuvant chemotherapy.

Patients and Methods: Paraffin TNBC tissues from 242 patients treated in the context of four prospective clinical trials were histologically reviewed and submitted to massively parallel semiconductor sequencing with a custom panel targeting 57 breast cancer (BC)-related genes. Mutations (mut) were evaluated in 210 informative samples as missense/nonsense amino acid changing variants, with minor allele frequency <1% in the case of single nucleotide polymorphisms. TILs density was morphologically evaluated as percent of the stromal area in 197 tumors; lymphocyte predominant (LP) BC tumors were called for TILs >50%. Disease-free survival (DFS) was used as the endpoint for the present analysis.

Results: 426 Mut were observed for 40 genes in 147 TNBC patients (70%). Among mutated genes, ranging from 1 in 97 tumors up to >10 in 8 tumors, the most frequently affected were TP53 (102 tumors, 69%) and PIK3CA (40 tumors, 27%). Intriguingly, mut rate (p=0.042) and number of mut genes (p=0.018) per tumor were inversely associated with TILs density. Nineteen tumors (10%) were LP-TNBC, carrying TP53 and PIK3CA mut as the only coding alterations in 10 and 3 cases, respectively. LP-TNBC patients did not experience any relapses during a follow-up period of 46-152 months (mean 66 months). For the 90% of non-LP-TNBC, the previously reported outcome benefit for 10% increments of TILs density was only demonstrated for tumors with 31-50% TILs. In non-LP-TNBC, upon adjustment for standard clinicopathological parameters, PIK3CA mut, TP53 mut and TILs density as a continuous variable, TP53 mut and nodal status independently conferred unfavorable DFS (HR=1.89, 95% CI 1.03-3.47, p=0.040 and HR=2.89, 95% CI 1.59-5.24, p=0.001, respectively). When continuous TILs density was added in the multivariate models in the entire cohort, 10% increments significantly predicted favorable DFS (HR=0.73, 95% CI 0.59-0.91, p=0.006), while high nodal status predicted unfavorable DFS (HR=2.75, 95% CI 1.51-4.99, p<0.0001).

Conclusions: In the present study, tumors with higher TILs density, including LP-TNBC, were not characterized by multiple mutations or mutated genes with the panel tested. In TNBC, increasing TILs density is a strong favorable and high nodal status a strong unfavorable prognosticator. Importantly, LP-TNBC may be regarded as a distinct subgroup with excellent prognosis concerning 10% of TNBC. In non-LP-TNBC, TP53 mut and nodal status were significant unfavorable prognosticators. These data may suggest that the level of morphologically assessed TILs density does not necessarily correspond to the tumoral mutational load and merit validation in larger cohorts.
Title: Nomograms to estimate long-term overall survival and breast cancer-specific survival of patients with luminal breast cancer

Sun W, Jiang Y-Z, Liu Y-R, Ma D and Shao Z-M. Fudan University Shanghai Cancer Center, Shanghai, China.

Body: Purpose
Luminal breast cancer (estrogen receptor [ER] and/or progesterone receptor [PR] positive) represents approximately two-thirds of all breast cancer. This type of cancer constitutes a group of highly heterogeneous diseases with a sustained high risk of late recurrence. In this study, we aimed to develop comprehensive and practical nomograms for the first time to better estimate the long-term survival of luminal breast cancer. Thus, those patients with high risk of late recurrence and poor prognosis could be screened out and individualized treatments can be applied.

Methods
Patients with luminal breast cancer diagnosed between 1990 and 2006 were retrieved from the Surveillance, Epidemiology, and End Results (SEER) database, and randomly divided into the training (n=87,867) and validation (n=88,215) cohorts. The inclusion criteria we used to identify eligible patients were as follows: female; aged 18 to 79 years old at diagnosis; known time of diagnosis from January 1, 1990, to December 31, 2006; unilateral breast cancer; breast cancer as the first and only cancer diagnosis; diagnosis not obtained from a death certificate or autopsy; surgical treatment with either mastectomy or breast-conserving surgery; pathologic confirmation of invasive carcinoma; AJCC stages I-III; histological grade I-III and known ER and PR statuses. Patients with inflammatory breast cancer or Paget's disease and lack of data on the above inclusion criteria were also excluded. Univariate and multivariate survival analyses were applied to identify prognostic factors for overall survival (OS). The cumulative incidence function (CIF) and a competing-risks model were used to estimate the probability of breast cancer-specific survival (BCSS) and death from other causes. We integrated significant prognostic factors to build nomograms, and subjected the nomograms to bootstrap internal validation and external validation.

Results
We screened 176,082 luminal breast cancer cases. The mean age at diagnosis was 57.5 years, and mean survival time was 107.4 months. By the end of the last follow-up, 36,911 (21.0%) patients had died, including 17,855 (10.1%) died from breast cancer and 19,056 (10.8%) from other causes. The 5- and 10-year probabilities of overall death were 0.089 and 0.202, respectively. The 5- and 10-year probabilities of breast cancer specific-mortality (BCSM) were 0.053 and 0.112, respectively. Independent prognostic factors for both OS and BCSS were integrated to construct the nomograms, including age at diagnosis, race, tumor size, histology, grade, positive lymph nodes, ER/PR status and radiation. The calibration curves for the probabilities of 5- and 10-year OS and BCSS showed excellent agreement between the nomogram prediction and actual observation. The C-indexes of the nomograms were high in both internal validation (0.732 for OS and 0.800 for BCSS) and external validation (0.731 for OS and 0.794 for BCSS).

Conclusion
We established and validated nomograms that accurately predict OS and BCSS of luminal breast cancer based on a large, population-based cohort with long-term follow-up. The nomograms can identify patients with higher risk of late overall mortality and BCSM, helping physicians in facilitating individualized treatment.
A novel diagnostic androgen receptor gene signature links clinical outcomes and preclinical response to enzalutamide, paclitaxel or the combination in triple-negative breast cancer

Body: Background: The androgen receptor (AR) is expressed in ≈70% of all breast cancers (BCs) and may be necessary for proliferation and survival advantage in AR+ tumors. A novel gene signature associated with AR-signaling biology (PREDICT AR) was developed by sequencing triple-negative BC (TNBC) tumors collected in a phase 2 study evaluating enzalutamide (ENZA) monotherapy\(^1\); clinical outcomes were superior in patients (pts) with PREDICT AR+ vs PREDICT AR- tumors.\(^1,2\) ENZA blocks nuclear localization and suppresses its activity.\(^3\) Paclitaxel (PTX) stabilizes microtubules and may also block AR nuclear localization. Thus we hypothesize that response to PTX-based therapy may be additive in PREDICT AR+ vs PREDICT AR- disease. This study sought to identify independent clinical datasets with PREDICT AR+ gene signature to assess outcomes following PTX-based therapy. Preclinically, we investigated the antitumor activity of ENZA, PTX, or ENZA+PTX in AR-driven TNBC models.

Methods: We probed publicly available TNBC clinical databases from Gene Expression Omnibus datasets to assess PREDICT AR status and clinical outcomes. Similarly, we assessed 21 TNBC lines for PREDICT AR status. BT549, MDA-MB-436, and MDA-MB-453 were treated with ENZA, PTX, or ENZA+PTX to determine activity. Cell signaling and pathway activation were assessed by western blot. ENZA and PTX activity was assessed in PREDICT AR+ xenograft models. Tumor RNA sequencing and immunohistochemistry were used to identify gene signatures, potentially predictive biomarkers, and potential synergistic effects of ENZA+PTX.

Results: The prevalence of PREDICT AR+ tumors in one cohort of 182 pts with primary TNBC\(^4\) was 51%. Distant relapse-free survival following PTX-based adjuvant/neoadjuvant therapy was not statistically different between pts with PREDICT AR+ vs PREDICT AR- TNBC (p=0.605). Pathologic complete response rates were 12.5% for PREDICT AR+ vs 21.0% for PREDICT AR- TNBC. Additional sets of pts with primary TNBC are being evaluated. Preclinically, we observed a dose-dependent inhibition of cell viability with either ENZA or PTX in AR+ TNBC cell lines and additive effects from ENZA+PTX. In PREDICT AR+ xenograft models, ENZA or PTX treatment resulted in a dose-dependent antitumor response. Combination studies are underway. Tumor RNA sequencing are being evaluated for gene signature of synergistic antitumor response to ENZA+PTX.

Conclusion: Analyzing publicly available clinical datasets, we found that PREDICT AR+ status was not associated with differential outcomes following PTX-based therapy in primary TNBC, suggesting there is potential to provide additive benefits in PTX-based therapy with ENZA. In preclinical studies, we observed additive effects when combining ENZA+PTX in PREDICT AR+ TNBC lines compared with single agent treatments. Taken together, these data suggest ENZA combined with PTX might provide additive benefits in a clinical setting for pts with PREDICT AR+ TNBC.

Title: Class IIa histone deacetylase HDAC5 expression in human breast cancer and its role in tumor cell lines

Li M, Li A, Liu Z, Zhou S, Xu Y and Yang W. Fudan University Shanghai Cancer Centre, Shanghai, China and Fudan University Shanghai Medical College, Shanghai, China.

Body: Background: Previous studies have underlined the expression of class I histone deacetylases (HDACs) in breast cancer (BC). However, little is known about the specific contribution of class II HDACs in BC, due to their particular structure and relatively weak enzymatic activity. HDAC5 has recently been reported to play an important role in medulloblastoma and in BC cells growth, and may potentially be a novel drug target. Thus, we attempt to investigate HDAC5 expression in tumor samples of BC patients.

Methods: Quantitative real-time PCR was performed to examine HDAC5 mRNA that extracted from 149 fresh frozen tumor samples of BC. By western blot, HDAC5 protein expression was measured in another 8 paired breast tumor and non-tumor samples. Immunohistochemical staining for HDAC5 expression was performed on TMA with 350 breast tumor samples. All of the specimens in this study were retrieved from BC patients that underwent surgery and were diagnosed with primary invasive ductal carcinoma at Fudan University Shanghai Cancer Center between January 1st, 2001 and December 31th, 2009. Patient data, clinicopathologic features and prognostic factors were obtained from patients charts. In addition, siRNA-mediated knockdown of HDAC5 was conducted in BC cells.

Results: Using the median value as a cut-off point, a total of 75 (50.3%) patients had high mRNA expression of HDAC5. Patients with high HDAC5 mRNA expression was significantly associated with distant metastasis (P<0.028), lymph node status (P=0.017), and molecular subtypes (P=0.009). During a median follow up of 51.2 months (4.6 - 82.7 months), there were 23 (15.4%) metastatic relapses and 10 (6.7%) deaths. Multivariate cox regression analysis showed that HDAC5 mRNA expression was an independent factor that was associated with disease free survival (DFS) (HR=2.33; 95% CI, 1.00-5.30; p=0.04), as well as lymph node status (HR=1.37; 95% CI, 1.00-1.87; p=0.047). The Kaplan-Meier survival curve demonstrated that overexpression of HDAC5 correlated with decrease in DFS (HR=2.148; 95%CI, 1.037-4.449; p=0.0396), whereas its overexpression was not significantly correlated with OS (HR=0.9480; 95% CI, 0.287-3.129; p=0.9295). Western blot analyses showed that HDAC5 protein expression was substantially stronger in tumor tissues than in non-tumor tissues. Moreover, HDAC5 expression in luminal subtypes was relatively higher than that in HER2 and basal-like breast tumors. Immunostaining showed that HDAC5 was predominantly expressed in the cytoplasm of malignant epithelial cells. HDAC5 expression was divided into two groups according to cut-off value set by ROC analysis. HDAC5 overexpression was significantly associated with metastasis (p=0.001), which is consistent with mRNA results. The prognostic value of HDAC5 protein expression in terms of DFS and OS was similar with mRNA expression in 350 patients. siRNA-mediated knock down of HDAC5 inhibited cell proliferation, migration and invasion.

Conclusions: Class IIaHDAC5 was expressed extensively in human BC, and its expression was significantly associated with distant metastasis, lymph node status and patients' DFS, which indicat...
Title: Periostin is associated with breast tumor progression and epithelial periostin expression is correlated with poor survival in patients with invasive breast carcinoma

Lee JS, Kim G-E, Park MH and Yoon JH. Chonnam National University Medical School, Gwangju, Republic of Korea and Chonnam National University Medical School, Gwangju, Republic of Korea.

Background: Invasion and metastasis are the direct causes of mortality in patients with breast cancer and require reciprocal interactions between cancer cells and the extracellular matrix (ECM). Periostin, a fasciclin-containing adhesive ECM glycoprotein, is frequently overexpressed in various types of human cancer, and its overexpression in cancer-associated stroma and/or cancer cells is usually associated with poor clinical outcomes. However, the expression of periostin in the successive steps of breast tumorigenesis and its association with outcome variables have not been well established in breast carcinoma. The purposes of the present study were to assess the role of periostin alteration in breast tumorigenesis and evaluate the putative prognostic value of periostin as a function of its compartmentalization.

Materials and Methods: Immunohistochemical staining with anti-periostin antibody was performed in a total of 300 patients (26 patients with normal breasts, 76 patients with ductal carcinoma in situ [DCIS], and 198 patients with invasive breast carcinoma [IBC]) using tissue microarray. Periostin immunoreactivity was assessed in both epithelial tissue and the surrounding stromal compartment. In addition, the mRNA and protein expression of periostin was analyzed in 10 paired normal/invasive cancer frozen specimens by quantitative real time-polymerase chain reaction and western blot analysis, respectively.

Results: Periostin mRNA and protein expression in cancer tissues was increased compared with that in adjacent normal tissues. Both epithelial and stromal periostin staining scores were significantly increased with disease progression in a stepwise manner to DCIS and IBC compared with those in normal breast tissues (P = 0.000 and 0.000, respectively). High epithelial and stromal periostin expression was observed in 109 of 189 (57.7%) and 158 of 189 (83.6%) cases of IBC, respectively. High epithelial periostin expression was more frequently observed in the distant metastatic relapse-positive group than in the distant metastatic relapse-negative group (41 [80.4%] of 51 cases versus 68 [49.3%] of 138 cases [P = 0.000]). Furthermore, high epithelial periostin expression was associated with reduced disease-free and overall survival on univariate and multivariate analyses.

Conclusion: Periostin might play an important role in the progression of breast tumor, and epithelial periostin expression may serve as a new parameter for prognostic prediction in patients with IBC. Further study of periostin expression and its potential as a target of therapy for IBC appears warranted.
Title: Prospective trial of endocrine therapy alone in patients with estrogen receptor positive, HER2-negative, node-negative breast cancer: Results of the TAILORx low risk registry

Sparano JA A, Gray RJ J, Makower DF F, Pritchard KI I, Albain KS S, Hayes DF F, Geyer Jr CE E, Dees EC C, Perez EA A, Olson Jr JA A, Zujweski J, Keane MM M, Gomez Moreno HL L, Reddi RP P, Goggins TF F, Mayer IA A, Brufsky AM M, Toppmeyer DL L, Kaklamani VG G, Atkins JN N, Berenberg JL L and Sledge Jr GW W. Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY; Dana Farber Cancer Institute, Boston, MA; Sunnybrook Research Institute, Toronto, ON, Canada; Loyola University Medical Center, Maywood, IL; University of Michigan, Ann Arbor, MI; Virginia Commonwealth University School of Medicine and the Massey Cancer Center, Richmond, VA; University of North Carolina, Chapel Hill, NC; Mayo Clinic, Jacksonville, FL; Duke University Medical Center, Durham, NC; National Cancer Institute, Bethesda, MD; University College Hospital, Galway, Ireland; Oncosalud SAC, Lima, Peru; Via Christi Regional Medical Center, Wichita, KS; Fox Valley Hematology and Oncology, Appleton, WI; Vanderbilt University, Nashville, TN; University of Pittsburgh, Pittsburgh, PA; Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; Northwestern University, Chicago, IL; Southeast Clinical Oncology Research Consortium, Goldsboro, NC; University of Hawaii Cancer Center, Honolulu, HI and Stanford University, Stanford, CA.

Body: Background: The Trial Assigning Individualized Options for Treatment (TAILORx) is a prospective trial evaluating the role of endocrine therapy or chemoendocrine therapy in patients 18-75 years of age with estrogen receptor (ER)-positive, HER2-negative breast cancer, a primary tumor between 0.6-5.0 cm, and negative axillary nodes, a population for whom chemotherapy is typically recommended or least considered based on National Comprehensive Cancer Center Network (NCCN) guidelines.

Methods: The trial was designed to demonstrate non-inferiority of endocrine therapy compared with chemoendocrine therapy in the randomized group with an Oncotype DX Recurrence Score (RS) of 11-25. Patients with a low RS < 11 were assigned to endocrine therapy alone and with a high RS > 25 assigned to chemoendocrine therapy, and both groups were followed in a prospective registry. The definition of an intermediate RS differed in this trial (RS 11-25) from the original reports (RS 18-30) in order to reduce the risk of chemotherapy undertreatment in patients with a mid-range or low RS (Sparano & Paik. J Clin Oncol 2008; 26:721-728).

Results: The trial enrolled 10,273 patients between April 2006 and October 2010, of whom 6907 patients (67.2%) had a mid-range RS of 11-25, 1737 (16.9%) had a high RS > 25, and 1639 (15.9%) had a low RS of < 11. At the fourth planned interim analysis, the ECOG-ACRIN data monitoring committee recommended that the study continue as planned for the randomized group with a RS 11-25, and that the results be released to the investigators for the low risk group with a RS <11. The characteristics of the low risk registry population are as follows: age 50 or less (27%), 51-60 (35%), > 60 (39%); tumor size < 1 cm (8%), 1-2 cm (61%), > 2 cm (31%); histologic grade low (34%), intermediate (59%), high (7%); breast conservation (68%) or mastectomy (32%). Initial endocrine therapy included tamoxifen in 35%, aromatase inhibitors in 59%, ovarian function suppression in 3%, and unspecified therapy in 3%; 5 patients received adjuvant chemotherapy (1 of whom relapsed). Five-year rates (and 95% confidence intervals [CI]) for low RS group were 99.2% (98.5, 99.6%) for distant relapse free interval, 98.5% (97.7, 99.1%) for relapse-free interval, 93.7% (92.2, 94.9%) for invasive disease free survival, and 98.2% (97.3, 98.7%) for overall survival. Information regarding ER, PR, and HER2 RNA expression will be presented.

Conclusions: Despite meeting guidelines for recommending or at least considering adjuvant chemotherapy based on classical clinicopathologic features, the risk of recurrence was very low at 5 years in patients with ER-positive, HER2-negative, axillary node-negative breast cancer and a low RS of < 11 treated with endocrine therapy alone without chemotherapy.
Tumor-infiltrating lymphocytes (TILs) are a powerful prognostic marker in patients with triple negative breast cancer treated by induction chemotherapy with or without oral low dose cyclophosphamide-methotrexate maintenance chemotherapy (CMM).

Background: TILs have been reported to have a prognostic role in patients with triple negative breast cancer (TNBC) receiving AC-containing regimens, but their predictive role has not been demonstrated. IBCSG Trial 22-00 is a randomized, phase III clinical trial, assessing the efficacy of low dose CMM, following standard adjuvant chemotherapy, in hormone receptor negative breast cancer. Patients were randomly assigned to treatment with adjuvant induction chemotherapy plus oral CMM for 1 year, or induction with no further treatment.

Patients and Methods: Of 724 patients enrolled in Trial 22-00 with TNBC confirmed centrally per 2013 St Gallen criteria (<1% ER/PgR, Her2 negative by IHC or FISH), 672 (93%) had blocks/slides available and gave consent. TILs analysis was retrospectively performed on prospectively collected full face H&E slides, following recent TILs Working Group guidelines. The analytic cohort included 647 (96%) of the 672 samples with TILs results available. Endpoints were breast cancer free interval (BCFI) and overall survival (OS). Cox proportional hazards regression models tested for prognostic association of stromal TILs as a continuous (10% increase) or binary (<50% or ≥50 TILs, lymphocyte-predominant breast cancer, LPBC) variable in univariable (UVA) and multivariable analyses (MVA) adjusted for pathological and demographic factors (age, nodal status and tumor size), and for TILs-by-treatment interaction to assess predictive associations in subgroups.

Results: The median follow-up for the cohort was 6.9 (95% CI: 6.6-7.2) years. Median TILs score was 18%, and 119 (18%) patients had ≥50% TILs. Continuous TILs score was significantly associated with improved BCFI and OS in UVA, with an estimated HR for each 10% increase in TILs score accounting for 0.87 (95% CI: 0.79-0.95, p=.003) and 0.83 (95% CI: 0.74-0.92, p<.001), respectively. The MVA showed consistent results, indicating that TILs as a continuous variable was a powerful prognostic factor for BCFI (HR 0.88, 95% CI: 0.8-0.96, p=0.007) and OS (HR 0.84, 95% CI:0.75-0.93, p=.001) for every 10% TILs increase, independent of age, lymph node status and tumor size. When assessed as a binary variable (LPBC vs. non LPBC), the estimated HR for BCFI was 0.56 (95% CI: 0.33-0.94, p=.03) in UVA, and 0.6 (95% CI: 0.36-1.03,p=0.06) in MVA. Patients with higher TILs (LPBC) receiving CMM had breast cancer risk reduction (HR=0.65, 95% CI: 0.22-1.91) when compared with observation, less apparent in patients with <50% TILs (HR=0.94, 95% CI:0.65-1.37), although the TIL-by-treatment interaction was not statistically significant.

Conclusions: TILs are highly prognostic in patients with TNBC treated with different chemotherapy regimens. Interestingly, the risk reduction observed in CMM for patients with higher TILs suggests that TILs may predict clinical benefit from metronomic chemotherapy, a hypothesis deserving further investigation in the lymphocyte subpopulations involved in tumor immunity. The study further demonstrates the need for mandatory collection of tissue blocks from clinical trials.

Title: Survival analysis of the prospective randomized Cher-Lob study: Correlation with tumor infiltrating lymphocytes

Dieci MV, Bisagni G, Cagossi K, Generali DG G, Sarti S, Piacentini F, Conte P and Guarneri V. University of Padova, Padova, Italy; Azienda Ospedaliera ASMN, IRCCS, Reggio Emilia, Italy; Division of Medical Oncology, Ramazzini Hospital, Carpi, Italy; U.O. Multidisciplinare di Patologia Mammaria, AO. Istituti Ospitalieri di Cremona, Cremona, Italy; Division of Medical Oncology, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori IRCCS, Meldola, Italy; University Hospital, Modena, Italy and Medical Oncology 2, Istituto Oncologico Veneto IRCCS, Padova, Italy.

Body: Background: We previously reported the correlation between tumor infiltrating lymphocytes (TIL) at baseline and pathological complete response (pCR) after neoadjuvant chemotherapy plus anti-HER2 agents for HER2-positive patients included in the prospective randomized CherLOB study (Dieci, SABCS 2014). Here we report the survival analysis results.

Methods: The phase II neoadjuvant CherLOB study (Guarneri, J Clin Oncol 2012) randomized 121 HER2-positive, stage II-IIIA breast cancer patients to anthracyclines/taxane-based chemotherapy plus trastuzumab, lapatinib, or both. A part from endocrine therapy for hormone receptor-positive patients, adjuvant treatment was left to physicians’ decision. This included trastuzumab for up to 1 year. Intratumoral (It) and stromal (Str) TIL were centrally evaluated on Hematoxylin and eosin-stained slides from pre-treatment biopsies and post-treatment surgical samples. For the present analysis, follow up was updated as of May 2015 (median follow up 68.3 months). Event-free survival (EFS) was calculated as the time interval from randomization to: recurrence, second primary cancer, death from any cause.

Results: Among the 118 patients evaluable for pathological response, pCR (ypT0/is ypN0) was confirmed as a strong prognostic factor for EFS (HR 0.15, 95% CI 0.04-0.64, p=0.01). Both pre-treatment ItTIL and StrTIL evaluations were available for 105 patients, median values were 5% and 17% (interquartile range 0%-15% and 9%-40%, respectively). Table 1 summarizes the results of the survival analysis for the association of TIL with EFS.

A non-significant trend for better EFS with increasing It-TIL (per 10%) was observed. Patients with ItTIL above the median value had a more prolonged EFS compared to patients with ItTIL below median (5-yrs EFS rate 89% vs 76%), with borderline statistical significance for the comparison between the two groups. No difference according to StrTIL above vs below median value was observed (5-yrs EFS rate 83% vs 82%, respectively). A comparison between lymphocyte predominant (LP) tumors, as defined by the generally accepted cut-off of ItTIL and/or StrTIL >=60%, vs non-LP cases was not performed due to low number of patients (n=17) and events (n=1) in the LP group. Among the 63 patients with residual disease, ItTIL and StrTIL evaluated on the surgical sample were not associated to EFS.

Conclusions: In this low-powered analysis, TIL did not provide significant prognostic information for HER2-positive breast cancer patients treated in the CherLOB study. However, a non-significant trend suggests a positive correlation between increased levels of It-TIL and better EFS. The evaluation of immune gene expression signatures and their correlation with survival is ongoing, results will be available for the meeting.
Title: Prognostic impact of tumor-infiltrating lymphocytes (TIL’s) and stromal-infiltrating lymphocytes (SIL’s) in triple negative breast cancer

Sherwell-Cabello S, Maffuz-Aziz A, Bautista-Piña V, Labastida-Almendaro S, Camacho-Ramírez DA A, Ríos-Luna NP P and Rodríguez-Cuevas S. Breast Disease Institute, FUCAM, Mexico City, Coyoacan, Mexico.

Body: Background. Immune response seems to improve outcome in women with Triple-Negative Breast Cancer (TNBC). Recent data suggests that the presence of Tumor-Infiltrating Lymphocytes (TIL’s) is an independent factor associated with favorable prognosis. In this study, we evaluate the prognostic impact of both the TIL’s and SIL’s in patients with TNBC.

Methods. Data on women diagnosed with triple negative breast cancer between 2005 and 2013, was collected by retrospectively reviewing at Breast Disease Institute, FUCAM. The rate of intratumoral and/or stromal lymphocytes was evaluated in all histopathologic biopsies according to Denkert et al. Lymphocyte infiltrate was assessed in hematoxylin and eosin-stained sections. TIL’s were reported as the percentage of tumor epithelial nests containing infiltrating lymphocytes, while SIL’s as the percentage of stroma area with lymphocytic infiltrate without contact with tumor cells. The five-year disease-free survival (DFS) and overall survival (OS) were compared between groups with the presence or absence of Tumor-Infiltrating Lymphocytes or Stromal-Infiltrating Lymphocytes. Demographic and clinical characteristics were assessed, and the variables with a statistically significant difference between groups were analyzed in a multivariate analysis.

Results. A total of 172 patients with Triple-Negative breast cancer treated this institution were included with a mean age of 49.8 years. A complete absence of tumor lymphocytes was found in 88 patients while the presence of intratumoral, stromal or both was found in 84 (48.8%). A mean follow-up of 46.12 months showed significantly higher rates of both disease-free survival and overall survival in women with SIL’s and TIL’s (p = 0.014 and 0.042 respectively) in locally advanced stages (LAS), regardless the rate of infiltrating lymphocytes found.

Non-significant differences were found in early stages (p = 0.255).

Conclusion. Immunity seems to play a key role regarding the outcome in women with Triple-Negative Breast Cancer. We show
that the presence of SIL's or TIL's are strongly associated with higher rates of disease-free and overall survival in LAS, especially when stromal lymphocytes are found. Independent to the rate of lymphocytic infiltrate, its presence has a statistical significance. Because it is a feasible, reproducible and inexpensive test that can be used as a prognostic predictor, we recommend assessing both SIL’s and TIL’s histopathologic biopsies of patients with TNBC.
Introduction: A high neutrophil-to-lymphocyte ratio (NLR) has been reported to be a poor prognostic indicator in several malignancies including breast cancer. It is unknown whether the prognosis associated with high NLR can be explained by other prognostic factors such as proliferation or estrogen receptor signalling. Here we explore the association between NLR and the 21-gene recurrence score (RS).

Methods: The associations between RS, NLR, tumor size, histologic grade, and estrogen receptor (ER) and progesterone receptor (PgR) expression (assessed by immunohistochemistry) were explored in sequential women with early-stage, lymph node-negative (or with lymph node micrometastases), ER-positive and HER2-negative breast cancer treated at Princess Margaret Cancer Centre in Toronto, Canada and in whom results of the RS were available. NLR was measured prior to surgery. Patients with a documented history of pre-existing infectious/inflammatory condition were excluded. Associations were explored using simple linear regression and statistical significance was defined as p<0.05.

Results: A total of 130 women diagnosed between January 2006 and April 2015 were included in the analysis. Median age was 55 (range 32-79), 87% were lymph node negative and 13% had nodal micrometastases. The median NLR was 2.2 (range 0.9-9.1) and was collected at a median of 12 days prior to surgery (range 0-60). The median RS was 18 (range 0-41). There was no association between RS and NLR (R=-0.10, p=0.31), grade (R=0.13, p=0.15), age (R=-0.05, p=0.58) or tumor size (R=0.06, p=0.48). RS was negatively associated with the magnitude of expression of both ER (R=-0.22, p=0.01) and PgR (R=-0.44, p<0.001). There was no association between NLR and grade (R=0.20, p=0.15), age (R=-0.13, p=0.17), tumor size (R=0.14, p=0.93), ER (R=0.01, p=0.94) or PgR (R=0.13, p=0.23)

Conclusion: The poor outcomes associated with high NLR are unlikely explained by proliferation of estrogen receptor signalling.
Title: Usefulness of the pre-treatment neutrophil-to-lymphocyte ratio in predicting first-line progression free-survival in triple-negative breast cancer patients

Body: Background: The neutrophil-to-lymphocyte ratio (NLR) is an independent predictor of poor prognosis in unselected breast cancer patients with NLR >3.3. Moreover, pre-treatment NLR has been associated with disease-free and overall survival (OS) in patients with early triple-negative breast cancer (TNBC). We aimed to determine whether the NLR is predictive of progression-free survival (PFS) in metastatic TNBC.

Methods: We reviewed the records of 48 TNBC patients who received at least one administration of first-line (1stL) chemotherapy for advanced disease from October 2004 to April 2014. The NLR (absolute neutrophil count/absolute lymphocyte count) was calculated from the full blood count routinely performed immediately before the initiation of first-line treatment. The association between categorical variables was calculated by X2 test. PFS (from start of 1stL treatment to disease progression or death) and OS (from start of 1stL treatment to death) were estimated using Kaplan Meier method. Multivariable Cox regression was used to determine the independent prognostic significances of the NLR (co-variables stage at diagnosis, histology, and tumor grade).

Results: NLR was not associated with stage at diagnosis (p=0.214), histology (p=0.597), or tumor grade (p=0.775). After a median follow-up of 10.9 months (range 1.3-54.9), 88.6% of TNBC patients with NLR≤3.3 versus 0.0% of patients with NLR>3.3 had a 1stL PFS>3 months (p<0.001). Similarly, 62.9% of TNBC patients with NLR≤3.3 versus 30.8% of patients with NLR>3.3 had an OS>10 months (p=0.047). Metastatic TNBC patients with NLR≤3.3 had a longer median 1stL PFS (5.2 months) and median OS (13.5 months) compared with patients with NLR>3.3 (1stL PFS 2.1 months, p<0.001; OS 7.7 months, p=0.018). In multivariable analysis, NLR>3.3 is associated with a shorter PFS (hazard ratio [HR] 22.4; 95% confidence interval [CI] 6.7-75.1, p<0.001) and higher risk of death (HR 3.2, 95%CI 1.4-7.4, p=0.005).

Conclusion: Our study showed that pre-treatment NLR is associated with 1stL PFS and OS in patients with metastatic TNBC. However, further investigation in larger series of metastatic TNBC is warranted.
Title: Prognostic significance of immune checkpoint receptors in node-negative breast cancer

University Hospital, Mainz, Germany; Technical University, Dortmund, Germany and Leibniz Research Centre for Working Environment and Human Factors (IfADo) at Technical University, Dortmund, Germany.

Body: Background: Immune checkpoint blockade is increasingly discussed in breast cancer. We examined the prognostic significance of the immune checkpoint receptors cytotoxic T lymphocyte-associated antigen 4 (CTLA-4) and programmed cell death protein 1 (PD-1) in node-negative breast cancer.

Methods: Microarray based gene-expression data for CTLA-4 (221331_x_at) and PD-1 (207634_at) were analysed in four previously published cohorts (Mainz, Rotterdam, Transbig, Yu) of node-negative breast cancer patients not treated with adjuvant therapy (n=824). A meta-analysis of previously published cohorts was performed using a random effects model. Prognostic significance of CTLA-4 as well as PD-1 for metastasis-free survival (MFS) was examined in the whole cohort and in different molecular subtypes: luminal (ER+/HER2-), basal-like (ER-/HER2-) and HER2+. Independent prognostic relevance was analysed using multivariate Cox regression.

Results: Higher RNA expression of CTLA-4 was related to better MFS in a meta-analysis of the whole cohort (HR 0.58, 95% CI 0.38-0.88, P=0.0102). Prognostic significance was most pronounced in the HER2+ positive molecular subtype (HR 0.23, 95% CI 0.08-0.65, P=0.0062) as compared to luminal (HR 0.68, 95% CI 0.39-1.18, P=0.1744) and basal-like (HR 0.53, 95% CI 0.25-1.15, P=0.1087) carcinomas of the breast. PD-1 RNA expression, however, was not associated with outcome in the whole cohort of patients (HR 0.88, 95% CI 0.32-2.43, P=0.1853). A trend for improved survival was noticed in basal-like breast cancer (HR 0.40, 95% CI 0.15-1.08, P=0.0701). Neither luminal (HR 0.81, 95% CI 0.28-2.36, P=0.2122) nor HER2+ (HR 0.85, 95% CI 0.27-2.68, P=0.7759) patients showed an association of PD-1 with MFS. CTLA-4 showed independent prognostic significance (HR 0.393, 95% CI 0.224-0.688, P=0.001) in multivariate analysis. In addition to CTLA-4, only histological grade of differentiation (HR 2.335, 95% CI 1.490-3.660, P<0.0001) and tumor size (HR 1.924, 95% CI 1.260-2.937, P=0.002), but neither PD-1 nor age nor HER2 status nor hormone receptor status retained an independent prognostic association with MFS.

Conclusions: The immune checkpoint receptor CTLA-4 has independent prognostic significance in node-negative breast cancer. Higher expression of CTLA-4 is associated with improved outcome. The prognostic impact of CTLA-4 differs between molecular subtypes and is most pronounced in HER2+ breast cancer.
Body: Background: The European Pooled Analysis of CTC (EPAC) in metastatic breast cancer, based on 1,944 individual data from patients with various tumor types and clinical settings (Bidard et al, Lancet Oncol 2014), has established CTC count (CellSearch) at baseline and during therapy as a level of evidence 1 independent prognostic biomarker and demonstrated its superiority over serum blood markers. As part of the study pre-planned objectives, we sought to establish nomograms allowing accurate individual survival predictions.

Methods: Using individual data from 17 centers, we built simplified multivariate prognostic models taking into account the independent prognostic clinico-pathological (CP) characteristics including CTC count, dichotomized using the 5CTC/7.5ml threshold, at baseline and at 3-5 weeks after the start of a new treatment regimen, and derived nomograms for progression-free survival (PFS) and overall survival (OS) prediction at baseline and after 3-5 weeks of treatment. We report here the internal validation of these nomograms. Discrimination of the models was assessed using the c-index estimated by a jackknife procedure and the calibration was visually assessed through 10-fold crossvalidated calibration plots at 1,2,3 years for OS and 1,2 years for PFS.

Results: Multivariate models at baseline for PFS and OS were fitted on 1501 and 568 individual patient data with CTC count at baseline and CTC count at baseline and after 3-5 weeks, respectively. Models include tumor subtype, the number of previous chemotherapy lines (0/1/>2), PS, age (<=50/>50-65/>65 years), metastasis-free intervals (0/>0-3/>3 years), metastatic sites (liver and CNS) and CTC count at baseline and eventually at 3-5 weeks of treatment. The C-index increased from 0.722 to 0.755 (increase in C-index:0.033, 95% CI [0.019;0.045]) when adding baseline CTC to the CP only model for OS (n=1501). For those patients with CTC values at 3-5 weeks (n=568), there was an additional increase in the C-index when adding CTC at 3-5 weeks to a model with already CP and baseline CTC from 0.731 to 0.743 (increase in C-index 0.013, 95% CI [-0.004;0.025]). The model with CP and baseline CTC counts showed a good calibration for OS at 1,2,3 years and the model with CP, baseline CTC and CTC count at 3-5 years a moderately good calibration. Similar results were obtained for PFS.

Conclusion: From the largest database with individual CTC data, we were able to build PFS and OS survival nomograms, with satisfactory discrimination and calibration. Our planned next step is to validate the nomogram in an additional cohort.
Title: Prognostic values of circulating tumor cell (CTC) enumeration and their clusters in advanced breast cancer

Ye Z, Mu Z, Wang C, Palazzo JP P, Biederman L, Li B, Jaslow R, Avery T, Austin L, Yang H and Cristofanilli M. Division of Population Science, Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA; Division of Solid Tumor Oncology, Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA; Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA and Vanderbilt University, Nashville, TN.

Body: Background The enumeration of circulating tumor cells (CTCs) has been proven to have prognostic values in several solid tumors including breast cancer. It has been established that a cut-off of 5 CTCs in 7.5 ml of blood may significantly differentiate breast cancer patients with favorable and unfavorable survival. However, CTC enumeration has not been shown to further predict the prognosis in those patients with more than 5 CTCs in 7.5 ml of blood. There are several recent in vitro and in vivo studies suggesting that clusters of CTC can be identified in blood and those clusters may play an important role in tumor progression and metastasis. Few clinical studies have been reported to enumerate CTC clusters and evaluate their prognostic values. In the current study, we hypothesize that the enumeration of CTC clusters play an important role in the prognostication of advanced breast cancer patients by providing additional predictive performance independent of CTC enumeration.

Methods In an ongoing study of blood-based breast cancer biomarkers, we enrolled 114 patients with stages III and IV breast cancer. Among them, 68 patients had inflammatory breast cancer (IBC), an extremely aggressive form of breast cancer with a much lower survival rate than non-IBC breast cancer patients. The number of single CTCs and CTC clusters (two or more CTCs bound together) in 7.5 ml blood sample were counted using the CellSearch™ system (Janssen Diagnostic) at baseline study entry, and their associations with the progression-free survival (PFS) of patients were evaluated using Kaplan Meier curves and Cox proportional hazards modeling.

Results Baseline CTCs were detected in 67 (58.77%) patients. Thirty-five (30.70%) and 19 patients (16.67%) had elevated CTCs (≥5 CTCs/7.5 mL) and clusters, respectively. IBC patients had a slightly higher percentage of cluster (17.65%) compared to non-IBC patients (15.22%). Compared to patients with < 5 CTC and without cluster, those patients with elevated CTC without cluster, and those with elevated CTC with cluster had an increasingly higher risk of disease progression with an hazard ratio [HR] of 1.93 (95% confidence interval [CI] 1.01-3.67) and 2.91 (1.54-5.50), respectively (P for trend = 0.001). Moreover, the combined analysis of baseline CTC and cluster enumerations showed similar effect when the analysis was restricted to IBC patients (HR 3.03, 95% CI 1.34-6.86).

Conclusion Baseline enumerations of both individual CTCs and CTC clusters predict PFS in advanced stage breast cancer patients. CTC clusters provide further prognostic value in patients with elevated CTC and their molecular characterizations may provide novel insights into the metastasis process.
**Title:** Validation of prediction of local recurrence (LR) by Prosigna® (PAM50) in a Danish breast cancer cooperative group (DBCG) cohort of hormone receptor positive (HR+), postmenopausal early breast cancer (EBC) patients allocated to 5yr of endocrine therapy (ET)

Ole Eriksen J, Jensen M-B, Laenkholm A-V, Kibøll T, Bruun Rasmussen B, Knoop AS S, Ferree S, Haffner T, Buckingham W, Schaper C and Ejlertsen B. Region Zealand, Denmark; The Danish Breast Cancer Cooperative Group, DBCG Secretariat, Rigshospitalet, Copenhagen, Denmark; Herlev Hospital, Herlev, Denmark; Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark and NanoString Technologies, Inc., Seattle, WA.

**Body: Background:** HR+EBC patients are routinely treated with both adjuvant radiation therapy (RT) and ET. RT is considered an important tool for achieving local control of disease. A limited number of biomarkers have been demonstrated to predict LR. In a previously performed retrospective analysis of a randomized trial, Prosigna (PAM50) risk of recurrence (ROR) score identified low risk patients with a local recurrence rate of 1.6% at 9.5yr median follow-up. In this study, we seek to validate the ability of ROR to predict LR in a comprehensive nationwide cohort from Denmark. **Methods:** Using the population based DBCG database primary FFPE tumor blocks and follow-up data were collected from all postmenopausal Danish women diagnosed from 2000-2003 with HR+EBC (N=2,722). Prosigna (PAM50) on the NanoString nCounter® Dx Analysis System assigned each patient an ROR score and associated risk group based on pre-specified cutoffs. Patients are also assigned an intrinsic subtype (Luminal A, Luminal B, Her2-Enriched, Basal-Like) based on gene expression. Univariate and multivariate analyses were performed to assess the ability of Prosigna (PAM50) to predict LR. **Results:** 48 local recurrences were observed with median follow-up of 9.25 yr. Continuous ROR was significantly associated with LR in univariate and multivariate models including node status (0, 1, 2, or 3 positive nodes), tumor size (≤2 vs.>2cm), grade (I, II, III, or unknown), age (≤65 vs.>65yr), and local treatment (mastectomy (MX), lumpectomy+RT, or MX+RT) (p=0.036 and p=0.049, respectively). Clinicopathologic variables were not significant in the multivariate model alone or in combination (p=0.85 for full model excluding ROR). Utilization of a pre-specified LR cutoff, hazard ratio (HR) and [95%CI, p-value] for high risk vs. low risk patients in a univariate analysis was 1.96 [1.11-3.46, p=0.0205] and 2.04 [1.08-3.83, p=0.0275] in the multivariate analysis. 10-year cumulative incidence of LR for low risk patients was 1.7% [1.1%-2.6%]. Similarly, 10-year cumulative incidence of LR for Luminal A patients was 1.7% [1.1%-2.6%]. 10-year cumulative incidence for high risk patients was 2.3% [1.3%-3.2%]. **Conclusions:** In a large population-based study of n=2,722 patients, Prosigna (PAM50) predicted LR over standard variables. These data validate a pre-specified cutoff separating patients at high and low risk of LR. Additional studies of Prosigna (PAM50) in RT-untreated populations are ongoing.
Title: Abstract Withdrawn
Title: Integration of tumor size and grade with the breast cancer index (BCI) for prediction of distant recurrence in hormone receptor-positive breast cancer with 1-3 positive lymph nodes

Sestak I, Zhang Y, Schroeder B, Dowsett M, Sgroi D, Cuzick J and Schnabel CA A. Centre for Cancer Prevention, Queen Mary University, London, United Kingdom; BioTheranostics, Inc., San Diego, CA; Royal Marsden Hospital, London, United Kingdom and Massachusetts General Hospital, Boston.

Body: Background: BCI is a genomic signature (Molecular Grade Index (MGI) and HOXB13/IL17BR (H/I)) that significantly predicts risk of distant recurrence (DR) in hormonal receptor-positive, lymph node negative (LN-) breast cancer. As previously shown in the TransATAC and MA.14 studies, BCI was also prognostic for DR in lymph node-positive (LN+) patients. Here, a distinct BCI model that integrates tumor size and grade was evaluated for prediction of DR in women with 1-3 lymph node positive disease.

Methods: 219 primary tumor samples from hormonal receptor-positive patients with 1-3 positive lymph nodes treated with 5 years of tamoxifen or anastrozole were examined. Women with four or more positive lymph nodes were excluded. BCI was combined with tumour size and grade into a comprehensive risk score, BCIN+. Kaplan-Meier (KM) estimates of 10 year DR and hazard ratios (HR) and 95% confidence intervals (CI) were estimated. Change in likelihood ratio 2 (LR-2) values were used to measure prognostic information of each variable alone or combined in new score. New cutpoints for low versus high risk groups for the new model were determined to ensure the low risk patients had minimal 10-year residual disease.

Results: In 219 LN+ patients, BCI alone provided substantial additional prognostic information to tumor size (LR-2=11.83, P=0.0006) and grade (LR-2=8.33, P=0.004). Both clinical variables provided additional significant prognostic information to BCI alone (BCI alone: LR-2=9.59, P=0.0004; T: LR-2=7.09, P=0.008; G: LR-2=27.59, P<0.0001). Integration of tumor size and grade with BCI (BCIN+) provided additional highly significant prognostic information compared to BCI alone (Interquartile HR=3.15 [95% CI: 1.54-6.04]; LR-2=33.89, P<0.0001). A cut-point for a very low risk group in this LN+ population was determined, and included 55 (25%) women with no DR within 10 years. In contrast, 51 (31.1%) women developed a DR in the high risk group (N=164). 10-year DR risk for those in the high risk group was 35.4% (95% CI 28.0-44.1%).

Discussion: Integration of tumor size and grade significantly enhanced the prognostic ability of BCI to predict 10 year DR risk in hormonal receptor-positive patients with 1-3 positive nodes. A significant number of patients have been identified to have a very low 10-year risk for DR, who may choose to safely forego unnecessary adjuvant chemotherapy or extended adjuvant endocrine therapy. Validation of BCIN+ in other datasets is ongoing.
Title: Integrating multiplex and next generation sequencing (NGS) platforms in routine molecular profiling of metastatic breast cancer (MBC) patients (pts): Trends for enrollment in genotype-directed clinical trials (GDTs)

Body: Background/aims: Multiplex or NGS platforms increase the number of mutations (mut) detected in tumor samples respect to single-gene sequencing techniques. We aimed to assess the actionable molecular alteration (ActMA) detection rate and the enrollment in GDTs derived from the integration of these platforms in routine molecular profiling of MBC pts, in addition to FISH and IHC techniques already in use. Methods: Consecutive MBC pts screened for gene mut by Sequenom (Seq) or AmpliconSeq (ASeq) were identified. Data on FGFR1 amplification (amp), PTEN IHC, and enrollment in GDTs were collected. ActMA: any mut, PTENnull (IHC score=0), or FGFR1/HER2amp for which a matched targeted drug might be available. Targeted therapy: treatment with PI3K/mTOR, novel anti-HER2, FGFR, or AKT inhibitors (inh) irrespective of having ActMA. GDT: treatment matched to ActMA. Results: From Oct2010-Apr2015, 260 pts screened (Seq 207, ASeq 53). IHC subtype: HR+/HER2- (LUM) 65%, HER2+ 13.5%, TN 19.6%, unk 1.9%. 84 samples from a metastatic site (32.3%).

*5 pts with unk subtype not shown
Pts with ≥2 ActMA (excluding HER2amp): 11 LUM (interestingly, 3 pts with PIK3CAmut+FGFR1amp), 1 HER2+, and 4 TN. Overall, 56% of pts received ≥1 targeted therapy (range 0-4). From the 139 pts with ≥1 potential ActMA (including HER2amp if treated with a novel anti-HER2), 61.8% received a targeted therapy and 42.4% were enrolled in a GDT: PI3K/mTOR inhibitor (inh) 54 (64.3%), novel anti-HER2 16 (19.1%), FGFR inh 8 (9.5%), AKT inh 6 (7.1%). Of the 121 pts that did not have potentially ActMA, 50% received a targeted therapy. The OR for receiving targeted therapy if ActMA was present was 1.59 (95% CI 0.94-2.70, P=0.08). **Conclusion:** Integration of multiplex and NGS platforms in routine molecular profiling of MBC pts yields a detection rate of ActMA >50%, which translates into higher probability of receiving a targeted agent and enrollment in a GDT. This suggests that physicians are pushing towards matched targeted therapies for pts that participate in molecular screening programs and have ActMA. Results on the outcome of these pts will be presented.
Purpose
We have identified 34 genes of interest that can distinguish post-mastectomy cancer patients into high- and low-risk of locoregional recurrence (LRR) in 2006. In this study, we validate the performance of 18 of 34 genes in prediction of LRR after mastectomy and breast conserving surgery (BCS).

Materials and methods
A total of 124 breast cancer patients who underwent mastectomy from 2005 to 2012 and had DNA microarray study on the primary tumor tissues were chosen for this study. Eligible patients should have no post-mastectomy radiotherapy (PMRT) with a minimum of 2-year follow-up. Among the 34 genes in previous report, only 30 genes could be found in Affymetrix U95 to U133 Plus2.0 array. Eighteen of 30 genes (18-Gene classifier) were used to distinguish low-risk and high-risk patients. Patients with 18-Gene score 31 or more were defined as high-risk and score less than 31 defined as low-risk group. We then examined the performance of the 18-Gene classifier in breast conserving patients (n=87) who usually had adjuvant radiotherapy (94%) and were treated in the same study periods.

Results
The overall accuracy of the prediction of LRR is 87% (sensitivity 91% and specificity 87%). By the 18-Gene classifier, the 5-year LRR rate in high-risk group was 42%, and in low-risk group <1% (p < 0.0001).

LRR: Locoregional recurrence

Multivariate analysis of mastectomy patients revealed that 18-Gene score is the independent prognostic factor that predicts the likelihood of LRR regardless of nodal status and breast cancer subtype. The predictive ability of LRR by the 18-Gene classifier in BCS patients is independent from adjuvant radiotherapy, and is consistent with the performance in mastectomy patients.

Discussion
This 18-Gene classifier is capable of identifying high-risk patients of LRR after mastectomy and breast conserving surgery.
Title: Impact of OncotypeDX on treatment decision for early stage, hormone-receptor-positive breast cancer

Anastasiadou L, Schneider M, Barinoff J, Khandan F, Falk S and Thill M. Agaplesion Markus Krankenhaus, Frankfurt am Main, Germany and OptiPath Gemeinschaftspraxis für Pathologie, Frankfurt am Main, Germany.

Body: BACKGROUND and OBJECTIVE
The OncotypeDX multigene assay analyzes the individual biology of an invasive breast cancer by examining the activity of 16 breast cancer related genes and 5 reference genes in the tumor tissue. It is used in patients with early hormone-receptor-positive breast cancer with up to 3 positive lymphnodes. The results of the analysis are fed into a formula that calculates a Recurrence Score® (RS) result. The RS result is a number between 0 and 100, and can provide information about how likely your breast cancer is to recur within 10 years of diagnosis. Since becoming available, the test is successfully validated in 18 studies for both N0 and N1.

The primary study objective was to evaluate the impact of the RS on physicians’ adjuvant therapy decision-making in a cohort of consecutive patients with early ER+, HER2-negative, N0/N1 (until two positive lymph-nodes) breast cancer in our multidisciplinary team (MDT). Secondary study objectives were to assess the impact of the RS on patients’ decisional conflict.

PATIENTS and METHODS
This prospective clinical study was carried out in the Breast Cancer Center at the AGAPLESION Markus Hospital. 140/890 (15.7%) patients were enrolled between 02/2013 and 04/2015 with early ER+, HER2-negative (IHC or FISH), N0/N1, T1-3, histological grade 1-3. We kept records from the treatment decision before and after having the result of OncotypeDX. Further inclusion criteria were age >18 years and no contraindication for receiving systemic chemoendocrine therapy. Also, the treating physician and the enrolled patient had to confirm that she was principally willing to consider her initial recommendation and decision.

Each patient's case was discussed twice within the respective institution's MDT. In the first meeting, adjuvant treatment was recommended based on available clinical and histopathological data according to the guidelines. In a second meeting, the case was rediscussed and treatment was recommended with the RS result as an additional piece of information.

RESULTS
100/140 (71.4%) patients were node negative (N0), whereas 40/140 (28.6%) were node positive (N+). Treatment recommendation changed in overall 34.3% of the cases (N0 33%, N+ 35%). In 48% of all patients (N0 43.5%, N+ 52%) with an initial recommendation for chemoendocrine therapy, the post-RS recommendation changed into endocrine therapy, in 25% (N0 30%, N+ 6.7%) of the cases with an initial recommendation for endocrine therapy only to combined chemoendocrine therapy, respectively. Only 48% of the patients with an initial endocrine therapy recommendation followed post-RS recommendation change to chemoendocrine therapy. On the other hand, 100% of the patients with an initial chemoendocrine therapy recommendation followed the post-RS recommendation change to endocrine therapy.

CONCLUSION
Our results show that OncotypeDX has an impact on the initial treatment decision on node positive as well as node negative patients. A substantial therapy change was evident in 34.3% of the cases. The data confirm, that OncotypeDX can help the doctor to formulate an individually treatment plan for patients with conflicting combination of clinical and pathological parameters.
Title: Prognostic and predictive abilities of intrinsic subtype in hormone receptor-positive metastatic breast cancer from the EGF30008 phase III clinical trial

Body: Background
Combination of letrozole and lapatinib improved progression-free survival (PFS) compared with letrozole and placebo in patients with hormone receptor-positive (HR+)/HER2+ metastatic breast cancer (MBC), but not HR+/HER2-negative (HER2-) disease (JCO 2009). However, HR+ disease is clinically and biologically heterogeneous with all intrinsic molecular subtypes (Luminal A, Luminal B, HER2-enriched [HER2E] and Basal-like) identified. Here, we tested retrospectively the prognostic and predictive ability of intrinsic subtype in tumor samples of the EGF30008 trial.

Methods
Expression profiling from FFPE tumor tissues was performed on the nCounter platform. Tumors were classified into each intrinsic subtype using the research-based PAM50 classifier (JCO 2009). Cox proportional hazard models for PFS and overall survival (OS) were used to generate point estimates of hazard ratios (HR) and corresponding 95% confidence intervals (CIs). Changes in likelihood ratio $\chi^2$ values were used to measure and compare the relative amount of information of each variable. Variables evaluated were: age, prior endocrine therapy, presence of visceral disease, number of metastatic sites, performance status, clinical HER2 status, and treatment. To determine whether the intrinsic subtypes were predictive of lapatinib benefit, we tested the interaction term of subtype by treatment arm in a Cox model that also included the main effects. Kaplan-Meier plots were used to depict the proportion of patients free from progression as a function of time.

Results
Tumor samples from 821 patients (63.8%) were profiled (85.7% primary and 14.3% metastatic tumor samples). Clinical-pathological features of this patient subset were well balanced compared with the original set. Within the entire cohort, all subtypes were identified: Luminal A (46.5%); Luminal B (29.7%); HER2E (7.4%); Basal-like (3.4%) and normal-like (12.9%). Within HER2+ disease, 28.6% of samples were HER2E. Intrinsic subtype was found the strongest prognostic factor independently associated with PFS and OS in all patients, and in patients with HER2-negative or HER2+ disease ($P<0.0001$). Median PFS and OS for each subtype within clinically HER2-negative disease were: Luminal A (16.85 and 45.0 months), Luminal B (10.97 and 37.0 months), HER2E (4.67 and 16.0 months) and Basal-like (4.14 and 23.0 months). Within clinically HER2-negative disease ($n=644$), 16 patients (2.5%) had HER2E disease. Patients with HER2-/HER2E disease benefited from lapatinib (6.5 vs 2.6 months; PFS HR =0.24, 95% CI: 0.07-0.86; $P=0.019$; HER2E vs not treatment interaction $P=0.016$). Finally, intrinsic subtype was not predictive of benefit from lapatinib within HER2+ disease.

Conclusions
HR-positive disease is biologically heterogeneous and intrinsic subtypes are strongly prognostic in a first-line MBC setting. HR+/HER2- disease with a HER2E profile may benefit from lapatinib. The clinical value of intrinsic subtyping in HR+ MBC warrants further investigation, but patients with Luminal A/HER2-negative MBC disease might be good candidates for letrozole monotherapy in the first-line setting regardless of visceral disease and number of metastases.
Title: Prognostic impact of breast cancer subtypes in elderly patients

Bergen ES S, Tichy C, Berghoff AS S, Rudas M, Dubsky P, Bago-Horvath Z, Mader RM M, Gnant M, Dieckmann K, Zielinski CC C, Steger GG G, Preusser M and Bartsch R. Comprehensive Cancer Center Vienna, Austria; Medical University of Vienna, Austria; Medical University of Vienna, Austria and Medical University of Vienna, Austria.

Body: Background
We aimed to analyze the impact of BC subtypes on the clinical course with special emphasis on the occurrence of brain metastases (BM) and outcome in an elderly breast cancer population.

Patients and Methods
571 patients ≥65 years receiving treatment for BC from 2007-2011 were identified from a BC database. BC subtypes and clinical characteristics including overall survival (OS) were obtained by chart review. Statistical analysis was performed using the Chi Square test, the log rank test and time depended covariate cox regression model as appropriate.

Results
Three-hundred-eighty/571 (63%) were grouped among the young-old (65-74 years), 182/571 (31.9%) among the old-old (75-84 years), and 29/571 (5.1%) among the oldest-old (≥85 years). 392/571 (68.8%) patients presented with luminal BC, 119/571 (20.8%) with HER2 positive and 59/571 (10.3%) with triple negative BC. After a median follow up of 38 months (range 0-204), 115/571 (20.1%) patients presented with metastatic recurrence. Highest recurrence rate was observed in HER2 positive BC patients (43/119 (36.1%)), followed by triple negative (15/59 (25.4%) and luminal BC (57/392 (14.5%); p<0.001; Chi Square test). BM occurred significantly more frequently in HER2 positive BC patients (9/119 (7.6%) compared to triple negative (2/59 (3.4%)) and luminal BC patients (6/392 (1.5%); p=0.003; Chi Square test). Occurrence of metastases (HR 7.7; 95% CI 5.2-11.4; p<0.001) as well as development of BM (HR 3.5; 95% CI 1.9-6.4; p<0.001) had a significant impact on OS prognosis as entered in a time depended covariate cox regression model.

Conclusions
In contrast to younger BC patients, HER2 positive BC subtype and not triple negative BC subtype was linked to the most aggressive clinical course including the development of metastatic disease and BM in our elderly cohort.
Body: Background: The genotype and phenotype of breast cancer may change during disease progression. But technical issues may affect biomarker assessment when comparing primary tumor tissues with biopsies of metastasis at distant sites. As the exact determination of molecular subtype in primary tumors for prevention of distant metastasis is of the utmost importance in clinical decision making, we compared RNA expression levels of ESR1, PGR, ERBB2 and MKI67 in pairs of PBC and MBC tissue using RT-qPCR and evaluated our results against conventional immunohistochemistry (IHC).

Methods: The tumor bank of a single institution was screened for paraffin-embedded pairs of PBC and MBC tissue samples and a total of 34 matched PBC and MBC pairs.

RNA was extracted using a bead-based extraction method (RNXtract® IVD kits, BioNTech Diagnostics GmbH). Multiplex RT-qPCR was performed using TaqMan® based primer probe sets for ESR1, PGR, ERBB2 and MKI67 (MammaTyper® IVD kits, BioNTech Diagnostics GmbH). Results were compared with IHC analysis of ER (clone 1D5), PR (clone PgR636) and HER2 (A0485) in both primary and metastatic tissue. Associated survival data will be presented at the meeting.

Results: Samples from 34 patients with MBC and PBC were available. Positivity of PBC for ER, PR & HER2 IHC was 71%, 76% and 7%, while positivity for RT-qPCR for ESR1, PGR and ERBB2 was 78%, 70% and 3%. The overall agreement between matched primary and metastatic lesions by IHC was 80%, 60% and 100% by IHC and 90%, 70% and 100% for RT-qPCR of ESR1, PGR and ERBB2. When comparing PBC with MBC the NPA was substantially lower for IHC (ER 56%, PR 50% and HER2 100%) than for RT-qPCR (ESR1 100%, PGR 100% and ERBB2 100%). Strikingly, there were some shifts from negative to positive for IHC based ER/PR determination, and from positive to negative for RT-qPCR, when comparing differences between PBC and matched MBC. By IHC several primary "non-luminal tumors" turned into metastatic "luminal" tumors exhibiting hormone receptor expression, while no such case was observed for RT-qPCR determination.

Conclusion: Overall concordance between PBC and MBC is high, particularly when tested by RT-qPCR. As shifts from non-luminal to luminal and aggressive to less aggressive subtypes does not seem to reflect the more aggressive nature of metastatic lesions, the RT-qPCR based methods seem to be more reliable. Metastatic tissue should therefore be reevaluated with regard to markers relevant to treatment such as ESR1 and ERBB2; preferably by standardized RT-qPCR methods. Validation of these findings in an independent cohort of similar size is ongoing and will be presented at the meeting.
Title: Prognostication of HER family gene expression collaborate with ESR1 expression in patients with triple negative breast cancer

Body: Background: Triple-negative breast cancer (TNBC) consists of heterogeneous sub-population. Although many investigators made an effort to categorize and classify TNBCs using genetic expressions, it is still needed to be defined for prognostication. Traditionally, HER family genes have been known to contribute mammalian glands formation and breast cancer generation as well as ESR gene. Moreover, target agents for HER family genes have been already developed. Accordingly, we investigated the expression profiles of HER family genes with ESR in patients with TNBC to categorize into sub-types and determine the prognostic value of HER family genes in search of clinical implications.

Methods: We investigated the results of the nCounter expression assay (NanoString®) for ERBB1, ERBB2, ERBB3, ERBB4 and ESR1 using mRNA extract from paraffin-embedded tumor tissues in 203 patients diagnosed as TNBC. We used the results of nCounter expression assay using 84 TNBC tissues for validation and 52 breast cancer tissues diagnosed as other subtypes to control the expression assay results of these five genes.

Results: Two-hundred and three patients were diagnosed as TNBC from 2000 to 2004 and received adjuvant chemotherapy after curative surgery. Eighty-four TNBC patients for validation set and 52 patients diagnosed as other subtypes for control set were selected from the patients diagnosed as breast cancer from 2005 to 2010 and received curative surgery. Through analyzing 5 genes using the nCounter expression profiles from 203 TNBC tissues, we found that increased expression of ERBB4 was associated with poor prognosis by survival analysis (5 year disease recurrence free survival (DRFS), low vs. high expression [cut-off: median]: 90.1% vs. 80.2%; p = .002). This trend was still remained in validation set composed of TNBC (5 year DRFS, low vs. high expression [cut-off : median]: 61.1% vs. 44.0%), whereas was not observed in other subtypes of breast cancer (44.4% vs. 80.8%). The Kaplan-Meier estimates of the rates of 5 year DRFS in the subgroups classified according to the level of 5 genes expression showed that the group of higher expression of all HER family genes and lower expression of ESR1 gene had dismal prognosis rather than other groups in patients with TNBC (5 year DRFS, this group vs. others: 50.0% vs. 88.2%; p < .001). In a multivariate Cox regression model, ERBB4 expression identified as a useful marker for predicting long-term prognosis in patients with TNBC although other HER family genes and ESR1 expressions did not predict prognosis of TNBC with statistical significance (Table 1).

Conclusions: The expression profile of HER family genes could be used as a prognostic marker in patients with TNBC. Further study is needed to identify the expression profiles of HER family gene as predictive marker of HER targeting treatment in patients with TNBC.

Impact of the mRNA expression levels of ERBB family and ESR1 on DRFS

Title: Clinical outcomes among HR+/HER2- metastatic breast cancer patients with multiple metastatic sites

Xie J, Hao Y, Li N, Lin PL L, Ohashi E, Koo V and Wu EQ Q.  Analysis Group, NY, NY; Novartis Pharmaceuticals Corporation, East Hanover, NJ and Analysis Group, Boston, MA.

Body: Background:
Hormone receptor-positive, human epidermal growth factor receptor-2-negative (HR+/HER2-) is the most common type of metastatic breast cancer (mBC). While overall the prognosis among these patients is poor with short progression-free survival (PFS) and overall survival (OS), those with multiple metastatic sites (multiple mets) may have even worse clinical outcomes due to multiple organ involvement. This real-world study examined clinical outcomes among HR+/HER2- mBC patients with multiple mets.

Methods:
In this retrospective chart review, a sample of postmenopausal women with HR+/HER2- mBC was collected from community-based oncology practices in the US. Patients were required to have failed a non-steroidal aromatase inhibitor and later initiated a new treatment (defined as the index therapy) for mBC between July 1, 2012 and April 15, 2013. Patients were classified into two mutually exclusive groups: multiple mets or single metastatic site (single met), based on the number of non-lymph-node metastatic sites at index therapy initiation. PFS, time on treatment (TOT), and OS were compared between the two study groups using Kaplan-Meier analyses with log-rank tests and multivariable Cox proportional hazards models adjusting for baseline characteristics, including age, race, insurance, mBC type, and months from initiation of last adjuvant endocrine therapy to mBC diagnosis, index therapy type, index therapy line, adjusted Charlson comorbidity index (CCI), Eastern Cooperative Oncology Group (ECOG) performance status, and prior chemotherapy for mBC. Patients without an event were censored at the last follow-up. In addition, separate Cox proportional hazard models were conducted including an interaction term between line of therapy and study group to assess the impact of multiple mets on clinical outcomes across different lines of therapy.

Results:
A total of 408 patients in the single met group and 291 patients in the multiple mets group were included. Patients with multiple mets had worse ECOG performance status and a higher rate of prior chemotherapy use for mBC compared with patients in the single met group. Relative to patients with single met, patients with multiple mets were associated with significantly shorter PFS (log-rank test p<0.001, hazard ratio (HR)=1.68, 95% confidence interval (CI): 1.32-2.14), TOT (log-rank test p<0.001, HR=1.37, 95% CI: 1.09-1.72) and OS (log-rank test p<0.001, HR=1.71, 95% CI: 1.12-2.63). Similar outcomes were observed in each line of therapy.

Conclusion:
Among HR+/HER2- mBC patients, those with multiple mets had significantly worse clinical outcomes, highlighting substantial disease burden and unmet need for more efficacious treatment for these patients.
Stromal co-expression of urokinase-type plasminogen activator (uPA) and plasminogen activator Inhibitor (PAI-1) protein by IHC predicts poor disease outcome in endocrine-treated postmenopausal patients with receptor-positive early breast cancer

Singer CF F, Filipits M, Jahn S, Abete L, Jakesz R, Greil R, Bauernhofer T, Kwasny W, Seifert M, Fitzal F, Schmitt M, Moinfar F and Gnant M. Medical University of Vienna; Medical University of Vienna, Cancer Institute; Medical University of Graz; Medical University of Vienna; Paracelsus Medical University Salzburg; Med University of Graz; Landeskrankenhaus Wiener Neustadt; Krankenhaus Barmherzige Schwestern Linz, Center for Breast Health; Technical University Munich and Krankenhaus Barmherzige Schwestern Linz.

Background Elevated levels of intratumoral uPA and PAI-1 in ELISA-based measurements are associated with a high recurrence risk and allow to identify patients who might particularly benefit from adjuvant chemotherapy. The clinical utility of ELISA-based protein analysis is, however, greatly limited by the requirement of fresh tumor tissue. We have therefore evaluated in a large clinical trial patient cohort with long-follow-up whether immunohistochemical detection of uPA and PAI-1 in FFPE archived tumor samples is also able to identify women with poor prognosis.

Patients and Methods 547 postmenopausal women with hormone receptor–positive, early breast cancer who had received at least 5 years of endocrine therapy in the prospectively designed ABCSG-06 trial, and in whom FFPE tumor tissue was available, were included in this analysis. uPA and PAI-1 protein expression was evaluated by immunohistochemistry, and correlated with distant-disease free (DDFS) and overall survival (OS).

Results Stromal co-expression of uPA and PAI-1 was detected in 166 of 276 (60%) evaluable tumor samples and was weakly associated with tumor size (p=0.012, Chi Square test) but not with age, nodal status, grading, or receptor status. Women with intratumoral uPA/PAI-1 expression were more likely to have a shorter DDFS in multivariate analysis (HR for relapse p=1.870; 95% CI 1.184-2.955; p=0.007 Cox regression analysis) and and OS (adjusted HR for death p=1.291; 95% CI 0.928-1.795; p=0.129) than women without. After a median follow-up of 10 years, women with uPA/PAI-1-positive tumors experienced a significantly shorter DDFS (p<0.0001 log rank test) and OS (p=0.020).

Conclusions Stromal co-expression of uPA and PAI-1 in breast cancer samples predicts poor DDFS and OS in postmenopausal women with hormone-receptor positive early-stage breast cancer who receive endocrine therapy.
**Title:** The ASCO-recommended biomarkers urokinase-type plasminogen activator (uPA) and its inhibitor PAI-1 define a subgroup of patients with very low risk of recurrence under routine conditions

Kantelhardt E-J, Thomssen C, Grosse R, Papendick N, Steer S, Buchmann J, Wickenhauser C and Vetter M. Martin-Luther-University, Halle (Saale), Germany; Institute of Pathology, Martha-Maria, Halle (Saale), Halle (Saale), Germany and Institute of Pathology, Martin-Luther-University, Halle (Saale), Germany.

**Body:**

**Background:**
ASCO Tumor Marker Guidelines 2007 recommended clinical routine use of the invasion markers uPA and PAI-1 for risk assessment in node-negative breast cancer patients (Harris et al. JCO 2007; 25:5287), and in some countries, e.g. Germany and France, risk assessment using these markers is broadly used. We wanted to evaluate the impact of uPA/PAI-1 on identifying patients with low risk of recurrence also in the daily routine in order to demonstrate that >25 years since their first description, these markers are still valuable.

**Material and Methods:**
We identified a cohort of 227 patients who were tested for uPA and PAI-1 in the clinical routine before 2012. Fresh frozen tissue of the primary tumor was obtained at biopsy or operation and processed for testing by a commercially available ELISA (FEMTELLE®, Sekisui Diagnostics GmbH) as previously described (Thomssen et al. JNCI 2009;101:1028). Tumor and patient characteristics were documented and all patients were regularly followed. Tumor concentrations below 3 ng/mg protein for uPA and below 14 ng/mg protein for PAI-1 were considered indicating low risk of recurrence (Harbeck et al. EJC 2013; 49:1825). Disease-free survival was defined as survival free from metastasis and loco-regional recurrence.

**Results:**
In our cohort, 86 patients had low tumor levels of uPA/PAI-1 (37.9 %). The median follow-up was 38.9 months (0.4 – 113.5 months). Adjuvant chemotherapy was delivered to 25 of 86 patients (29.1%) in the low risk group and to 85 of 141 patients (60.3%) in the high risk group; if steroid hormone receptor status was positive, generally adjuvant endocrine therapy for five years was advised. Using immunohistochemical subtyping, 73 of 86 patients with low uPA/PAI-1 values were luminal-like, 9 patients had a HER2-positive tumor and 3 patients had a triple negative breast cancer (TNBC). In patients with uPA or PAI-1 or both elevated, 105 of 141 patients had a luminal-like cancer, 12 patients were HER2 positive and 22 had TNBC; 1 case unknown. At 60 months of follow-up, patients with low uPA and/or PAI-1 tumor values had not experienced any recurrence, while in the high risk group 7 recurrences were observed although adequate adjuvant therapy was delivered (log-rank p=0.07). In node-negative pts with low uPA/PAI-1 values (n=72; pN0 70, cN0 2), no recurrences were observed, in 104 high risk patients 5 recurrences were observed (p=0.057).

**Conclusions:**
This observation confirms that also in daily routine, patients with a very low risk of recurrence can be identified by testing for uPA/PAI1. This group of pts comprises nearly 40% of pts and in these patients further evaluation with expensive predictive tests can be avoided and - above all - potentially toxic adjuvant chemotherapy can be spared.
Title: TP53 mutation is a biomarker for prognosis in triple-negative breast cancer patients treated with post-neoadjuvant cisplatin

Hancock BA A, Chen Y-H, Solzak JP P, Miller KD D and Radovich M. Indiana University School of Medicine, Indianapolis, IN.

Body: Introduction: Patients with Triple-Negative Breast Cancer (TNBC) who have residual disease (RD) after neoadjuvant chemotherapy are at an increased risk of relapse and have a poor prognosis. No adjuvant therapies are currently indicated for this group. BRE09-146 was a Phase II post-neoadjuvant clinical trial testing Cisplatin or Cisplatin + Rucaparib in TNBC patients with RD after neoadjuvant chemotherapy. As TP53 is mutated in 70-80% of TNBCs, and is well known to play a role in the DNA damage response, we sought to determine the prognostic capability of mutated TP53 in BRE09-146.

Methods: We performed full sequence and copy number analysis of 134 genes in 76 tumors from BRE09-146 using the Oncomine Research Panel along with Ion Proton Next Generation Sequencing. All patients included had RD. Somatic mutations were called by identifying mutations that were present in the tumor that were not present in the germ line DNA from a normal blood sample. Mutations were annotated using the IARC TP53 somatic mutation database. Gene copy numbers in tumors were identified using the Ion Reporter system from Thermo-Fisher Scientific and called as copy number loss, normal, or gain based upon a comparison to a reference range established from the normal blood samples. Survival analyses were generated using the Log-Rank and Kaplan-Meier methods.

Results: 84% (64/76) of our TNBC tumors harbored a somatic mutation in the TP53 gene. The majority were missense mutations (particularly in the DNA binding and tetramerization domains) followed by frameshift insertions/deletions, and copy number loss. Patients whose tumors harbored somatic TP53 mutations were observed to have a significantly inferior disease free survival (DFS) compared to non-mutated tumors (events = 29/64 vs. 1/12; median = 25.9 mos vs. NR (Not Reached); p=0.021, HR=7.28 (95% C.I.: 2.98-17.79). The same was observed for overall survival (OS) (events = 23/64 vs. 0/12, median = 33.78 vs. NR; p=0.017, HR = Not evaluable). There was no difference in DFS or OS when comparing the nature of the mutation (point mutation vs. indel vs. copy loss) at a p=0.88 and p=0.91, respectively. We then sought to determine if clonal status of TP53 mutations was also associated with survival. Cases were divided into non-mutated, subclonal (mutations present in a fraction of cells), or truncal (mutation present in most or all cells). Interestingly, tumors that harbored subclonal TP53 mutations had a superior OS compared to truncal mutations (events = 1/9 vs. 22/55; median = NR vs. 29.1, p=0.036, HR =0.16 (95% C.I.:0.06-0.42). OS for subclonal mutations was highly similar to non-mutated tumors (p=0.25).

Conclusions: While RD after neoadjuvant chemotherapy in TNBC is a well-known risk factor for poor prognosis, in our study, we observed a subset of RD patients defined by a lack of TP53 mutation or presence of a subclonal mutation that portended a superior survival outcome after post-neoadjuvant Cisplatin. If validated, these results reveal that the presence and clonal status of TP53 mutations is important to accurate prognostication and should be considered in decision-making algorithms for this patient population.
Title: High levels of serum C-terminal crosslinking telopeptide of type 1 collagen at baseline are associated with poor prognosis for breast cancer patients

Imamura M, Nishimikai A, Yanai A, Miyagawa Y, Higuchi T, Ozawa H, Murase K, Takatsuka Y and Miyoshi Y. Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.

Body: Background: It has been demonstrated that adjuvant treatment using bisphosphonate may reduce recurrence among breast cancer patients. However, these improved prognoses of patients are reportedly limited to breast cancers of estrogen receptor (ER)-positive and postmenopausal women. Although the mechanisms of the effects of bisphosphonate remain unknown, this finding seems to represent support for the hypothesis that suppression of bone resorption by bisphosphonate results in favorable prognoses at least for patients in this subset. In order to determine the prognostic significance of bone resorption in breast cancer patients, we investigated these markers c-terminal crosslinking telopeptide of type I collagen (1CTP) and N-telopeptide of type I collagen (NTX).

Patients and Methods: 469 breast cancer patients were recruited who were operated on Hyogo College of Medicine and histologically confirmed to have invasive carcinoma. Serum 1CTP and NTX were measured preoperatively with the two-antibody radioimmunoassay and enzyme-linked immunosorbent assay methods, respectively, and blood samples were obtained before treatment from patients who were treated with neoadjuvant chemotherapy or endocrine therapy. The area under receiver operating characteristic curves were applied and optimal cutoff values were set at 3.6 ng/ml for 1CTP, and 10.55 nmol BCE/L premenopausal and 14.05 nmol BCE/L postmenopausal for NTX. The relationships between these bone turnover markers and various clinicopathological characteristics were evaluated with the chi square or Fisher's exact test. The log-rank test was used to compare relapse-free survival (RFS) in Kaplan-Meier plots. Associations of RFS were assessed with a Cox proportional-hazards model based on the results of univariate and multivariate analyses. Differences were considered statistically significant if p<0.05.

Results: There were significantly more 1CTP-high patients among postmenopausal women and RFS of 1CTP-high patients was significantly worse than that of 1CTP-low patients (5-year RFS: 0.65 vs 0.86; p=0.0002). Similarly, NTX-high patients were significantly associated with postmenopausal status, but there was no significant association between NTX-high worse RFS (p=0.0976). Multivariate analysis of tumor size, lymph node metastasis and nuclear grade identified 1CTP (hazard ratio: 2.04, 95% confidence interval: 1.13-3.68; p=0.018) as a significant independent prognostic factor. Subset analyses of 1CTP showed that prognosis was consistently worse recognized for postmenopausal (p=0.0002), but not premenopausal (p=0.37) patients. Furthermore, prognosis for 1CTP-high patients was worse for the estrogen receptor (ER)-positive subset (p=0.0005) but not for the ER-negative subset (p=0.22).

Conclusion and discussion: High levels of serum bone resorption markers at baseline were identified as significant unfavorable prognostic factors for breast cancer patients. The prognostic significance of 1CTP seems to be prominent for postmenopausal patients with ER-positive breast cancers. These findings suggest the use of bone-modifying agents as an adjuvant therapy may be beneficial for breast cancer patients, especially for patients with high serum levels of 1CTP.
**Title:** Impact of kynurenine 3-monooxygenase expression on outcome in patients with triple-negative breast cancer undergone primary treatments

Wu C-Y, Chu P-Y, Wang W-L, Liu C-Y and Tseng L-M. Division of Hematology and Oncology, Taipei Veterans General Hospital, Taipei, Taiwan; School of Medicine, National Yang-Ming University, Taipei, Taiwan; Taipei Veterans General Hospital, Taipei, Taiwan; Show Chwan Memorial Hospital, Changhua City, Taiwan and School of Medicine, College of Medicine, Fu-Jen Catholic University, New Taipei City, Taiwan.

**Body:**

**Background**

Triple-negative breast cancer (TNBC), characterized by aggressive behavior and poor prognosis, represents an important clinical challenge because there is no well-established target therapy. Tryptophan-kynurenine metabolism in cancer is increasingly being recognized as a key factor that suppresses antitumor immune responses. Previous studies have focused on the expression and function of the rate-limiting enzyme indoleamine-2,3-dioxygenase in tumor cells, whereas the second step catabolic enzyme Kynurenine 3-monooxygenase (KMO) was rarely addressed in cancer. This study aimed to explore the clinical impact of KMO expression in patients with TNBC undergone primary treatments.

**Methods**

Primary tumors from 103 patients with TNBC who received surgical resection were enrolled for analysis. The expression of KMO and other clinicopathologic parameters, including tumor-infiltrating lymphocytes (TILs) and tumor expression of vascular endothelial growth factor (VEGF), was assessed semiquantitatively using immunohistochemistry-based scoring. Spearman rank correlation was used to examine the association between the expressions of KMO, TILs and VEGF. The clinical impact of KMO expression on survival was analyzed using Kaplan-Meier curve and Cox regression.

**Results**

The expression of KMO is significantly higher in breast tumor tissue, as compared with non-tumor tissue. In addition, a median of threefold higher KMO expression was observed in cancerous part comparing to non-cancerous part in resected specimens of TNBC, either in tumor/non-tumor paired or non-paired samples. The expression of KMO was negatively correlated with TILs ($r = -0.389, p < 0.001$) and positively correlated with VEGF expression ($r = 0.344, p < 0.001$). Patients with higher KMO expression had a more advanced disease and demonstrated a trend toward poorer disease-free survival (DFS) ($p = 0.065$)(Table 1). Interestingly, an inverse distribution of TILs that contacted with tumor cells showing high KMO expression was observed in higher power field of microscopic examination. Moreover, patients with both higher expressions of KMO and VEGF had a poorer DFS, as compared with those without both higher KMO and VEGF expressions (hazard ratio, 1.52; 95% confidence interval, 1.17-1.97), after adjusted for tumor stage.

**Conclusion**

Our data suggested KMO expression correlates with tumor infiltrating lymphocytes as well as VEGF expression, and may have a negative impact on outcome of patients with TNBC. The role of KMO in TNBC warrants further investigation.

Presented as number (percentage)
**Body:** Introduction: Tumor related inflammation plays an important role in breast cancer progression, tumor-associated macrophages (TAMs) being a crucial part of this microenvironment. Platelet-derived growth factor-C (PDGF-C) is abundant in the breast cancer microenvironment having an anti-apoptotic effect on macrophages. Previous reports suggest that tumor cell derived PDGF-C promotes TAM survival, enhancing tumor progression. In this study we analyzed the prognostic value of PDGF-C density associated with TAM infiltration in human breast cancer.

Materials and Methods: TAM and PDGF-C density was evaluated by immunohistochemistry of CD163+, CD68+ and PDGF-C myeloid cells in tumor stroma. Tissue microarrays from 140 invasive breast cancer cases were used. Survival analysis to evaluate the impact of TAM and PDGF-C density on disease free survival (DFS) was done using Kaplan-Meier and Cox regression analysis.

Results: Infiltration of CD163+ and CD68+ macrophages into tumor stroma had a tendency, but not significant, for reduced DFS (p=0.204, p=0.314 respectively). Whereas PDGF-C strong density was significantly associated with worse DFS (p=0.024). This inverse correlation with DFS was demonstrated stronger when PDGF-C density was combined with CD163+ and CD68+ macrophage infiltration (p=0.008, p=0.018, respectively). But, CD163+ or CD68+ infiltration with strong PDGF-C density did not demonstrate as an independent prognostic factor when adjusting for tumor size, lymph node metastasis, hormone receptor and histologic grade. This result is probably due to small number of patients having both TAM infiltration and strong PDGF-C density.

Conclusion: Our results show that PDGF-C infiltration adversely affects DFS and also enhances the inverse correlation between tumor-associated macrophages and DFS. To support these results, a study with larger numbers is on progress.
Title: Prediction of bone metastases of breast cancer using combined markers of bone metabolism and inflammation

Shimoda M, Nishimukai A, Shibata N, Kikuchi W, Hutawatari H, Ishihara H, Miyoshi Y and Noguchi S. Osaka University Graduate School of Medicine, Suita, Osaka, Japan; Hyogo College of Medicine, Nishinomiya, Hyogo, Japan and Nittobo Medical Co., Ltd, Koriyama, Fukushima, Japan.

Body: Introduction
Luminal breast cancer patients show a relatively favorable prognosis when treated with adjuvant hormonal therapy alone. However, some of these patients develop recurrence and they might derive benefit from adjuvant chemotherapy. Although several genomic profilings successfully developed to decide whether to administer adjuvant chemotherapy, clinically practical prediction methods of recurrence sites do not exist. Our previous study showed a possible prediction of bone metastases by using two serum markers; TRACP-5b as a marker of bone metabolism; likelihood of bone metastases, and CRP as a marker of inflammation; likelihood of distant recurrence. The incidence of bone metastases was significantly higher in high risk patients(+/+) than in the others(odds ratio: 10.9, P=0.040). In this study, we examined the potential of the two-marker prediction in the newly enrolled luminal patients.

Patients and methods
One hundred sixty luminal patients who underwent surgery were enrolled in this study. Their serum levels of TRACP-5b and CRP were measured in a blinded manner at the R & D laboratory of Nittobo Medical Co., Ltd. In the preliminary study, we identified that the median value of TRACP-5b in the premenopausal patients was lower than in the postmenopausal patients. We adjusted the value of TRACP-5b in the premenopausal patients and the cutoff value of TRACP-5b from 334 to 396mU/dL. The cutoff value of CRP was same as previous study(0.016 mg/dL). The odds ratio between +/+ and the others were calculated using MedCalc statistical software.

Results
One hundred sixty patients stratified into four classes according to the value of TRACP-5b and CRP: +/+ (n=43), +/- (n=38), -/+ (n=42) and -/- (n=37). Six of the 160 patients developed bone metastases as the initial site of relapse within five years from surgery. The incidence of bone metastases was 9.3%(4/43) in the +/+ patients and 1.7%(2/117) in the others. The incidence was significantly higher in the +/+ patients than in the others(odds ratio: 5.9, 95% CI 1.31 to 33.46, p= 0.045). When the other relapses than bone metastases were included in the analysis, no significant difference was observed between the two groups (odds ratio: 0.4, 95% CI 0.02 to 7.43, P=0.521). TRACP-5b concentration alone could not classify the patients into two groups according to significantly different incidences of bone metastases(odds ratio: 13.7, 95% CI 0.76 to 247.22, P=0.076).

Conclusion
The results in here show that the prediction of bone metastases by the combination of TRACP-5b and CRP concentrations is clinically relevant in the luminal patients. Reliable prediction of bone metastases would be realized by combination of our prediction method and one of genomic profilings. We plan to increase the number of patients to provide sufficient statistical power to confirm this diagnostic potential.
Title: Association between rim enhancement on magnetic resonance imaging and response of chemotherapy

Body: Background: Triple-negative breast cancers (TNBC) are defined as tumors that lack expression of estrogen receptor (ER), progesterone receptor (PR), and HER2. TNBC is characterized as a cancer with a high malignancy potential and a poor prognosis. Systemic therapy that is effective in TNBC is only chemotherapy. On magnetic resonance imaging (MRI), rim enhancement was frequently seen in TNBC. It is reported that rim enhancement on MRI may associated with long-term outcome of patients with triple-negative breast cancer and may potentially serve as a prognostic biomarker in these patients. It is not well known about the relationship of rim enhancement on the MRI and treatment effectiveness of TNBC.

Purpose: We investigated the relationship between rim enhancement on MRI and response of chemotherapy and outcome in patients with TNBC.

Methods: MRI findings of 144 consecutive female TNBC patients, who underwent surgery from 2007 to 2012 in our hospital, were retrospectively reviewed. All patients have taken the MRI in our hospital before treatment, and had undergone chemotherapy before or after surgery. Presence of rim enhancement on MRI was assessed. Rim enhancement was defined more pronounced at the periphery of the mass at early phase.

Association of the presence of rim enhancement on MRI and the pathological complete response (pCR) rate in patients who underwent neo adjuvant chemotherapy (NAC) was assessed using two-sided Pearson's Chi squared tests. Disease free survival (DFS) rates were calculated by the Kaplan-Meier method. Univariate analysis was performed using the log rank test. pCR was defined as the disappearance of invasive cancer.

Results: The median age was 51yo (26-82), and the median observation period was 49 months (5-92). Eighty-one patients (56.2%) underwent NAC and 63 patients (43.7%) underwent adjuvant chemotherapy. Twenty-six cases (18.0%) occurred recurrence or distance metastasis. The presence of rim enhancement were observed 68 cases (42.3%), and non-rim enhancement were 66 cases (57.6%). DFS were not significantly different according to the presence of rim enhancement on MRI(P=0.31).

In NAC patients, 28 patients (34.5%) were led to pCR and 53 (63.4%) were non-pCR. The presence of rim enhancement were observed 44 cases (54.3%), and non-rim enhancement were 37 cases (45.6%). In pCR rate, rim enhancement is higher than non-rim enhancement (40.9%, 27.0%, respectively). However, the presence of rim enhancement on MRI was not significantly associated with pCR in TNBC patients (p= 0.190).

Table1. Association between rim enhancement and pCR

Conclusion: The presence of rim enhancement on MRI showed high pCR rate. While, it is not a significant predictor of pCR in TNBC patients.
Title: Defining a signature of residual risk following endocrine treatment in the tamoxifen and exemestane adjuvant multinational (TEAM) trial

Bayani J, Yao CQ Q, Quintayo MA, Haider S, Brookes CL L, Yan F, van de Velde CJH JH, Hasenburg A, Kieback DG G, Markopoulos C, Dirix L, Seynaeve C, Boutros PC C, Rea DW W and Bartlett JMS MS. Ontario Institute for Cancer Research (OICR), Toronto, ON, Canada; University of Birmingham, Cancer Research UK Clinical Trials Unit, Birmingham, United Kingdom; Leiden University Medical Center, Leiden, Netherlands; University Hospital, Freiburg, Germany; Helios Medical Center, Aue, Germany; Athens University Medical School, Athens, Greece; St. Augustinus Hospital, Antwerp, Belgium; Erasmus Medical Center-Daniel den Hoed, Rotterdam, Netherlands and University of Toronto, Toronto, Canada.

Body: Introduction: There are a number of commercially-available tests to stratify risk for women diagnosed with early breast cancer. While such “Generation I” tests are increasingly being used, a consensus is growing that these tests are moderately accurate in assessing risk. Moreover, Generation I tests fail to direct more personalized treatment. Therefore, there is a clear need for more informative "Generation II" tests that better assess risk, also on the long term, and provide theranostic targets. To this end, we have performed an mRNA abundance-based analysis trained in the 790 patients of the UK TEAM cohort to identify a signature of residual risk, to be validated in the remaining 3000 patients from the TEAM pathology study.

Methods: RNA extracted from the tumors of respective TEAM pathology study patients were profiled using a 165-gene NanoString code set. The gene list was compiled from targets that comprise many of the existing risk assessment tests, in addition to genes known to be of importance for breast cancer pathogenesis. Signal intensities were normalized using the R statistical environment; 336 different combinations of preprocessing methods were assessed and the most optimal method selected using unbiased criteria. A10-fold cross-validation approach, in combination with a network-based patient risk score calculation formula, was used to derive a 95-gene signature. Briefly, genes were first filtered based on a Cox regression p-value threshold of 0.25; the sum of the weighted mRNA abundance levels of the result genes was calculated for each patient as the risk score. Patient-wise risk scores were then used in a multivariate Cox proportional hazards model along with clinical covariates such as age, grade, HER2 status and nodal status, using DRFS truncated to 10 years as an end-point.

Results: Univariate survival analysis revealed a number of significantly prognostic candidates. The resulting 95-gene signature identified in the training set, stratified patients into high and low risk with an HRhigh of 2.74 (p<2.06 x10-4) when adjusted for age, grade, HER2 status and nodal status; resulting in an AUC of 0.73. Modular analyses of the genes comprising the 95-gene signature identified pathways associated with receptor tyrosine kinase signalling, regulation of cell cycle, and the spindle assembly checkpoint. Additionally, the composition of the gene-list made it possible to characterize the patients into their intrinsic subtypes and to determine their relative risk for recurrence relative to assessment tools available today. The validation of the 95-gene signature will be conducted in the remaining samples in the TEAM pathology study using the bioinformatics strategy described above.

Conclusions: The impact of test-guided therapy using multi-parametric tests is increasingly being felt in the clinic, and is reshaping modern health-care economics. A successful Generation II multi-parametric test will better discriminate those that are truly at high risk for recurrence following endocrine therapy and indicate potential therapeutic options for intervention for those who would not benefit from current modalities.
Title: The role of skeletal muscle volume on prognosis of breast cancer survivors using with cross-sectional image analysis

Body: Background: Obesity is one of the well-known cause and prognostic factor of breast cancer. Body mass index (BMI) is often used to estimate the magnitude of obesity. Currently, muscle weight itself, instead of higher BMI, is more closely related to poor outcomes in chronic metabolic disease. However, this question was not thoroughly questioned in breast cancer survivors. We aim to find out whether the prognosis of breast cancer survivors is affected by muscle mass and fat volume. We also present that the higher muscle mass and muscle fat ratio do have a good influence on the prognosis.

Methods and Materials: Between January, 2001, and December, 2009, all consecutive patients diagnosed the breast cancer in National cancer center, Republic of Korea were 3909. Of all populations, the patients who had available chest Computed Tomography (CT) images within two years after the time of diagnosis were extracted. CT images were analyzed for total skeletal muscle and adipose tissue in cross-sectional area of 10mm thickness at level 3 of the lumbar vertebrae.

Results: Of all consecutive 3909 patients, final eligible cases were 1493. The median age was 46.0 (range 25–77). Median follow up period was 96.8 months and the 5 year survival rate was 96.5%. Recurrence free survival rate was 92.1%, and local recurrence free survival was 98.6% in 5 years. Median skeletal muscle volume of all patients was 93.3cc (range 39.6–236.9). Median fat volume of the same sections was 419.7cc (range 19.5–1392.3) and the median muscle-fat ratio was 0.22 (0.08–3.18). There is no known standard value of muscle mass in Korean women, the median volume was used as an indicator for comparison of two groups in terms of overall survival and recurrence free survival. The group with muscle volume greater than median value appeared better outcomes in overall survival and recurrence free survival than those of the other group (p=0.007, p=0.019). There were several factors related to overall survival and recurrence free survival such as age, operation types, clinical stage, pathologic stage, and tumor size in univariate cox regression analysis. In multivariate analysis by adjusting those factors, the muscle volume showed a remarkable correlation with survival, especially in recurrence free survival (Hazard ratio 0.61, p=0.029). As the indicator using with median muscle-fat ratio, the analysis revealed that overall survival had no significant difference (p=0.177) between two groups. However, the group with higher muscle-fat ratio showed better recurrence free survival and local recurrence free survival (p-value <0.0001, 0.038 respectively).

Conclusions: Our study showed that the actual amount of skeletal muscle rather than fat volume has higher effect on the prognosis of breast cancer survivors. In our knowledge, this is the largest study to analyze the prognosis of breast cancer with skeletal muscle volume. In view of the different magnitude of obesity among multiple ethnics, the actual muscle mass could be the most important parameter to assess the amount of exercise and patient's health status.
Introduction: Evaluation of the benefit of primary chemotherapy (PC) is not easy to establish. Pathologic complete response (pCR) has been considered the main surrogate prognostic factor of patient's survival. However, patients achieving a pCR are not the only ones who benefit from PC. The purpose of our study is to find a measure of response that includes the maximum of patients that benefit from PC in terms of survival.

Patients and methods: 224 breast cancer patients were treated in Breast Cancer Unit from Institut Català d'Oncologia (ICO) L'Hospitalet with taxans and antracyclines-based PC +/- trastuzumab between 2009 and 2011. pCR was defined as no invasive carcinoma found in the tumor and in the axillary lymph nodes (ypT0/ypTis ypN0). Tumor and nodal downstaging (TNDS) was calculated according to the "neoadjuvant response index" (NRI) from Rodenhuis and also as a dichotomic variable: Positive includes those patients achieving downstaging of both T and N plus T downstaging N0 and negatives those patients without downstaging in any of both variables. Those parameters were related to patient's overall survival (OS). Statistical analysis was performed with SPSS version 15.

Results: Median age 45.5 years (24-83). Main tumor characteristics: T2 (62.6%); N1 (50%); ductal infiltrating carcinoma (95.5%) and grade III (57.1%). Biological sub-type according to the last St Gallen classification: luminal A: 28 patients (pts); luminal B/Her2-: 61 pts; luminal B/HER2+: 34 pts; HER2+: 33 pts and triple negative: 69 pts. Pathologic complete response was achieved in 49 pts (22.5%). TNDS was evaluated in 181 patients and of those 90 was positive. According to NRI 74 patients presented cut-off> 0.5 and 52 pts > 0.7. Parameters related to OS were: biological subtype (P: 0.007); achieving a pCR (p: 0.007); NRI cut-off 0.5 (P: 0.001) and TNDS (p:0.000). In the multivariate analysis only TNDS and biological subtype remained statistically significant. When comparing those patients with positive vs. negative TNDS, the HR for recurrence was of 10.05 (IC 2.33 -43.57). The median OS of the series has not been reached. OS at 5y was 82.7% (IC: 77.1%-88%) and specific breast cancer OS at 5 y was 85% (IC:79.5%-90%). The number of events (breast cancer deaths) for each biological subtype according to positive vs. negative TNDS was: luminal A: 0/5 vs. 0/18; luminal B Her2-: 0/10 vs. 8/43; luminal B HER2+:0/23 vs. 2/9; HER2+: 0/22 vs. 0/2 and TN: 2/30 vs. 8/18. Survival data per subtypes and TNDS is immature due to the scarce number of events. Estimated 5y OS for TNDS positive vs. negative in luminal A: 100% vs. 100%; luminal B Her2-: 100% vs. 82%; luminal B HER2+:100 vs.77.7%; HER2+: 100% vs. 100% and TN: 93% vs. 55%, respectively.

Conclusion: In our series, TNDS measured either with the NRI from Rodenhuis or as a dichotomic variable was the best parameter to evaluate response to PC in terms of OS. OS of luminal A and luminal B/Her2 negative is less influenced by PC than the rest of subgroups. In fact both subgroups have good prognosis despite their poor sensitivity to chemotherapy. Those tumors that benefit most from PC were luminal B/ Her2+; Her2+ and triple negative patients who achieved a positive TNDS.
**Title:** Patient reported outcomes of multiplex breast cancer susceptibility testing utilizing a tiered-binned counseling and informed consent model in BRCA1/2 negative patients

**Body:** Background: The risks, benefits and utilities of multiplex panels for breast cancer susceptibility are unknown and new counseling and informed consent models are needed. We sought to obtain patient reported outcomes of multiplex testing in BRCA1/2 negative patients utilizing a novel, previously piloted tiered-binned counseling model for multiplex testing.

**Methods:** BRCA1/2 negative participants completed pre(V1) and post-test counseling(V2) and surveys evaluating cognitive, affective and behavioral responses to a 25-gene multiplex testing panel. We used linear regressions with estimation by GEE where appropriate.

**Results:** 376 patients have been approached. To date, 124 participants(33%) have consented to the study, 21(6%) declined and 231(61%) are considering. Of 95 who have completed pre-test counseling(V1), 88(93%) elected to proceed with 25-gene panel testing and (81%) were classified as making an informed choice after tiered-binned counseling. 6/53(11%) participants received a positive result, including 1 mutation in MSH2 and 5 in moderate penetrance genes (2 ATM, 1 BARD1, 1 CHEK2, 1 PALB2). 22/53(42%) participants received a variant of unknown significance(VUS). General anxiety and perceived utility decreased significantly with pre-test counseling and after results (Table 1). Knowledge increased with pre-test counseling; cancer worry increased after receipt of multiplex results. Higher cancer worry was associated only with lower income (2.6 points/income category, p<0.01). Those with a VUS had greater decreases in perceived utility compared to negative (p=0.01) or positive (p=0.003) results. To date, there are no other significant differences in knowledge, distress or uncertainty by test result. Medical management recommendations for the proband changed in 3/6 with a positive result. Cascade testing in the family was discussed as an option in 3/6 with a positive result. Conclusions: Many BRCA1/2-negative patients proceed with 25-gene cancer susceptibility testing if offered and most make informed choices utilizing a tiered-binned genetic counseling model. The tiered-binned counseling model is associated with increased knowledge, decreases in general anxiety and uncertainty after pre-test counseling and disclosure of results, but an increase in cancer worry after result disclosure. The clinical utility, long-term outcomes and differences in patient reported outcomes by test result remain unknown.

Gene panel sequencing is revolutionizing germline risk assessment for hereditary breast cancer. Despite scant evidence supporting the role of many of these genes in breast cancer predisposition, results are often reported to families as the definitive explanation for their family history. We assessed the frequency of mutations in 18 genes commonly included in hereditary breast cancer panels among 2,000 index cases from breast cancer families and 1,997 population controls. Cases were predominantly breast cancer-affected women referred to specialized familial cancer centers (BRCA1 and BRCA2 wild-type). Controls were cancer-free women from the LifePool study (www.lifepool.org). Sequencing data were filtered for known pathogenic or novel loss of function mutations.

The frequency of pathogenic mutations in BRCA1 and BRCA2 in the control group was 0.2% (4 mutations) and 0.4% (8 mutations), respectively, which is consistent with previous indirect estimates for Caucasian populations but to our knowledge this the largest direct assessment of their prevalence.

Excluding 18 mutations identified in BRCA1 and BRCA2 among the cases and controls, a total of 69 cases (3.5%) and 26 controls (1.3%) were found to carry an "actionable mutation". PALB2 was most frequently mutated (22 cases, 3 controls), while no mutations were identified in PTEN or STK11. Among the remaining genes, loss of function mutations were rare with similar frequency between cases and controls.

The frequency of mutations in most breast cancer panel genes among individuals selected for possible hereditary breast cancer is low and in many cases similar or even lower than that observed among cancer-free population controls. While multi-gene panels can significantly aid in cancer risk management, they equally have the potential to provide clinical misinformation and harm at the individual level if the data is not interpreted cautiously.
Title: Breast cancer prevention: Is it time for population-based mutation screening of high risk genes?

Body: The traditional model of familial breast cancer practice involves ascertaining high-risk individuals based on family history. However, most individuals who carry a BRCA1 or BRCA2 mutation will not have a family history of breast or other cancer in a close relative. Moving germline testing from the familial cancer center to the population will result in many essentially unanticipated findings of great significance in regards to the risk of breast cancer in healthy relatives. To date there have been no large studies that have directly measured the frequency of BRCA1 and BRCA2 mutations in a cancer-free general population. As a first step toward population based BRCA1 or BRCA2 screening, we sequenced the entire coding region of these genes in 1,997 cancer-free Australian women recruited from the lifepool study (www.lifepool.org) which is a cohort of women attending the Australian population based mammographic screening program. Sequencing data were filtered for known pathogenic or novel loss of function mutations. Twelve individuals were identified with pathogenic mutations in either BRCA1 (4 mutations) or BRCA2 (8 mutations), which is consistent with previous indirect estimates for Caucasian populations but to our knowledge this is the largest direct assessment of their prevalence. Interestingly, the self-reported cancer family history of the majority of the 12 mutation positive women was unremarkable. All 12 women subsequently accepted an invitation to attend a Familial Cancer Centre for advice on whether to proceed with formal clinical genetic testing.

A population carrier frequency of 0.6% for mutations in BRCA1 and BRCA2, coupled with the rapidly declining costs of gene panel sequencing, suggests that population-based screening for these genes will be a highly cost effective way of reducing the incidence of breast and ovarian cancer through preventative strategies.
Title: Implementation of next generation cancer gene panel testing in a large HMO

Body: Background: Next generation cancer gene panel testing is fairly new in clinical practice. Little is known about the diagnostic yield of multigene cancer panel testing in community based hospitals.

Objective: To describe characteristics of a diverse cohort who underwent high/moderate risk multigene panel testing for either a personal or a family history of cancer in a large health plan, and report the proportion of pathogenic/likely pathogenic variants (PV/LPV) and variants of unknown clinical significance (VUS) by race/ethnicity.

Methods: Subjects included all 586 female patients who were referred for genetic counseling and underwent multigene panel testing between July 2014 and January 2015. Based on a literature review, the custom-designed high/moderate risk gene panel included 20 cancer susceptibility genes (described below). All tests were performed by the same commercial laboratory (GeneDx).

Results: Of the 586 women, 78 (13.3%) tested positive PV/LPV; 316 (53.9%) tested negative; and 192 (32.8%) carried one or more VUS. Age at testing ranged from 22-81 years (median 50 years). More women with PV/LPV results tended to be obese than those who tested negative (39.7% vs. 31.2%), and had greater comorbidity (Charlson Index of ≥3, 35.9% vs. 33.2%). Of 586 women, 305 (52.0%) had a cancer diagnosis, mainly first primary breast cancer (n=290, 95.1%), while some also had a second primary breast cancer (n=67, 11.4%). Of the 305 women with cancer, 131 (42.9%) were diagnosed prior to the multigene testing implementation (1987-2013), while 174 (57.1%) were diagnosed after implementation.

The cohort was diverse in terms of race/ethnicity: Western/Northern European (31.2%), Latina/Caribbean (30.0%), Asian (14.8%), African-American (7.2%), Ashkenazi Jewish (6.3%), Native American (5.9%), and other (14.9%) (percent exceeds 100% due to mixed race/ethnicity). Of the 192 women who carried a VUS, 60.4% were Western/Northern European, and 46.4% were Latina/Caribbean. Pathogenic or likely pathogenic mutations were higher in Latina/Caribbean women (37.2%), followed by Western/Northern European (26.7%), and African (10.3%). We identified a total of 84 pathogenic mutations among the 78 women with PV/LPV in the following genes: BRCA1 (n=22), BRCA2 (n=17), MUTYH (n=16; all heterozygous), CHEK2 (n=9), ATM (n=4), PALB2 (n=4), PMS2 (n=3), MLH1 (n=2), VHL (n=2), and one mutation in each of the following genes: APC, CDH1, PTEN, TP53, and STK11. VUS were detected in 192 patients (32.7%) of the 586 tested. VUS in ATM (n=57), APC (n=32) and CHEK2 (n=25) comprised 59.4% of all VUS detected.

Discussion: The large percent of VUS was surprising, given that our panel included only high/moderate risk cancer genes. The over-representation of BRCA1/2 among all mutations (45.1%) likely reflected a greater proportion of patients referred for genetic counseling with a personal and/or family breast cancer history. Given that 35% of our positive results were dominant-acting pathogenic or suspected pathogenic mutations, our results suggest that multigene cancer panel testing is an appropriate method for detecting germline mutations in a high-risk cohort in a managed care setting.
Title: Multiple-gene panel sequencing prompts no change in care compared to BRCA1 and BRCA2 testing in male breast cancer patients and their families

Fostira F, Saloustros E, Konstantopoulou I, Tryfonopoulos D, Barbounis V, Mauroudis D, Georgoulias V, Fountzilas G and Yannoukakos D. NCSR Demokritos, Molecular Diagnostics Laboratory, Athens, Greece; University Hospital of Heraklion, Heraklion, Greece; Saint Savvas Anticancer Hospital, Athens, Greece; Metropolitan Hospital, Athens, Greece and Aristotle University of Thessaloniki School of Medicine, Thessaloniki, Greece.

Body: Male breast cancer is a rare cancer entity, representing just 1% of all cancers diagnosed in men. It shares clinical and biological characteristics with post-menopausal female breast cancer, although recent reports showed that they are not identical. Approximately 10% of unselected male breast cancer cases carry BRCA1 & BRCA2 mutations, with the most frequently mutated gene being BRCA2. Multiple-gene sequencing has already entered clinical practice and leads in detection of potential pathogenic variants in other cancer predisposition genes, in as many as 15% female breast cancer patients without BRCA1 & BRCA2 mutations. We evaluated the performance of a customized panel for cancer risk assessment in a representative sample of male breast cancer patients.

Ninety eight male individuals diagnosed with breast cancer (mean age 59y, range 38y-81y) and referred for genetic counseling between 2010 and 2015 were invited to donate a research blood sample. Patients were eligible irrespectively of family history and age at diagnosis. Genomic DNAs were used to prepare libraries for the capture of the entire coding regions of twenty six known -or suspected- breast cancer genes. These were: BRCA1, BRCA2, TP53, STK11, CDH1, PTEN, PALB2, ATM, CHEK2, NBN, BRIP1, BARD1, RAD51C, RAD51D, RAD50, BLM, SLX4, MRE11A, FAM175A, MLH1, MSH2, EPCAM, MHS6, PMS2, MUTYH, NF1.

Loss-of-function mutations have been found in three genes; BRCA2, BRCA1 and PMS2. Not surprisingly, the most frequently mutated gene was BRCA2 accounting for 5% of the cases, while BRCA1 and PMS2 mutations have been detected in single cases, accounting each for 1%. Interestingly, no mutations were identified in any of other genes that have been reported in female breast-ovarian cancer families (PALB2, TP53, ATM, CDH1, RAD51C, RAD51D, etc). Compared to BRCA1 & BRCA2 testing, gene panel prompted consideration of change in care (early colon cancer screening) in a single family (1%).

This is the first evaluation of the performance a multiple-gene panel in male patients with breast cancer. Our findings confirm that genetic counseling and BRCA1 & BRCA2 should be the primary concern for these patients and their families. Mutations in other genes been reported in female breast-ovarian cancer families were not identified in this cohort. If larger studies confirm our results, then multiple-gene sequencing panels may be of limited benefit for male breast cancer patients and their families.
Title: Multi-gene panel testing for hereditary cancer risk

Yadav S, Ladkany R, Fulbright J, Dreyfuss H, Reeves A, Campian S, Thomas V and Zakalik D. Beaumont Health System, Royal Oak, MI and Nancy and James Grosfeld Cancer Genetics Center, Beaumont Health System, Royal Oak, MI.

Body: Background: Multi-gene panels are widely available for assessing hereditary cancer risk in high risk individuals. Due to the use of these panels, many genetic mutations other than BRCA 1 or 2 can be detected which can potentially affect management. This study presents the results of multi-gene panel testing performed at Beaumont Health System.

Methods: All patients who underwent multi-gene panel testing at Beaumont Health System between November 1, 2012 and January 15, 2015 were included in this study. This cohort consisted of patients who met criteria for genetic testing due to personal or family history. All patients received comprehensive pre and post-test genetic counseling. The panels ranged from 5 to 43 genes associated with risk for breast and other cancers.

Results: 653 multi-gene panel tests were performed. The majority of these consisted of either a 5 gene high risk breast panel (25%), an 18 gene moderate to high risk breast panel (21%), or a 9 gene high risk breast and gynecologic panel (17%). 184 variants of undetermined significance (VUS) were identified with a pooled VUS rate of 28%. Among the commonly used panels, there was a positive correlation between VUS rate and the number of genes included in the panel (r = 0.86, p = 0.01, Range 6% to 70%). A pathogenic mutation was identified in one or more genes in 65 (10%) panels for a total of 67 mutations. Of these, 17 mutations were in BRCA1 or BRCA2 gene. Fifty non-BRCA deleterious mutations were identified with the following frequencies: CHEK2(12), MUTYH(7 monoallelic, 1 biallelic), TP53(4), PTEN(4), ATM(4), MSH6(3), PALB2(3), MSH2(2), CDH1(2), APC(2), NF1(2), BARD1(2), MLH1(1) and PMS2(1). Of these non-BRCA mutations, 41(82%) had a significant impact on management.

Conclusions: Our study demonstrates that multi-gene panel testing identifies several genes that can impact management and would likely not have been discovered by pedigree analysis alone. However, this added detection is associated with a higher VUS rate, especially using larger panels. Further research is needed to better define the role of multi-gene panel testing in high risk patients, with a focus on choosing appropriate genes, understanding the magnitude of cancer risk and delineating impact on management.
Title: The patient experience in a prospective trial of multiplex gene panel testing for cancer risk

Kurian AW, Idos G, McDonnell K, Ricker C, Sturgeon D, Culver J, Lowstuter K, Hartman A, Allen B, Rowe-Teeter C, Kingham KE, Koff RB, Lebensohn A, Chun NM, Petrovchich IM, Mills MA, Hong C, Ladabaum U, Ford JM and Gruber SB. Stanford University School of Medicine, Stanford, CA; University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA; Keck School of Medicine, University of Southern California, Los Angeles, CA and Myriad Genetics, Salt Lake City, UT.

Body: Background: Multiplex gene sequencing panels (MGP) are increasingly used for assessment of hereditary breast cancer risk. Compared to testing for BRCA1 and BRCA2 (BRCA1/2) only, testing more genes increases the likelihood of identifying a deleterious mutation (DM) and/or a variant of uncertain significance (VUS), which might cause distress, uncertainty or regret about testing. Little is known about the patient experience of MGP testing.

Methods: We conducted a prospective study of MGP testing, using a panel of 25 genes: APC, ATM, BARD1, BMPR1A, BRCA1, BRCA2, BRIP1, CDH1, CDK4, CDKN2A, CHEK2, EPCAM, MLH1, MSH2, MSH6, MUTYH, NBN, PALB2, PMS2, PTEN, RAD51C, RAD51D, SMAD4, STK11, and TP53. Participants were enrolled at three medical centers and were eligible if they met standard genetic testing guidelines or if they had ≥2.5% probability of a DM in any gene on the panel, as calculated by predictive models (e.g. IBIS, Penn II, MMRPro). Participants were surveyed about their experiences with MGP testing including distress and uncertainty at baseline (before test results disclosure) and three months later. The 25-item Multidimensional Impact of Cancer Risk Assessment (MICRA) scale measured distress, uncertainty and positive testing experiences at three months after testing. We present a planned interim analysis after enrolling 500 of 2000 total participants.

Results: Of 500 participants, 332 (66%) were referred for suspicion of hereditary breast/ovarian cancer syndrome. Of these 332, 97% were female, 79% were white, 43% were Hispanic and 33% were Spanish-speaking only; for 25%, high school was their highest level of education. A total of 48% had breast cancer, 5% had ovarian cancer, and 7% had another cancer; 11% had a DM and 35% had VUS in one or more genes. At study entry most participants thought about cancer rarely or not at all (69%, 95% confidence interval (CI) 58%-77%), and few (7%, CI 3%-14%) had thoughts of cancer that affected their daily lives; results were unchanged three months later, after genetic results disclosure (Chi-squared test, p-value >0.1). MICRA scores at three months were low for distress (mean score 2 out of a possible 30) and uncertainty (mean score 7 out of 45), and high for positive testing experiences (mean score 9 out of 15). Most (82%, CI 72%-88%) participants wanted to know all of their MGP results even if the clinical relevance was not fully understood, and most (87%, CI 79%-93%) never regretted learning their MGP results.

Conclusions: Among diverse participants of a prospective, multi-center MGP testing trial, cancer- and genetic testing-related distress were low at entry and remained low three months later. These results provide no evidence for an increase in distress or uncertainty after MGP. Longer-term follow-up in a larger cohort is underway.
Title: Universal BRCA testing and family outreach for women with triple negative breast cancer

Emborgo T, Muse KI I, Bednar E, Oakley HD D, Litton J, Lu KH H and Arun BK K.  The University of Texas MD Anderson Cancer Center, Houston, TX.

Body: Background Germline mutations in BRCA1 or BRCA2 significantly increase the lifetime risk for a woman to develop breast and ovarian cancers. Triple negative breast cancer (TNBC) is enriched for BRCA mutations, with approximately 20% of unselected TNBC patients having a BRCA1 or BRCA2 mutation. Current guidelines recommend individuals with TNBC age 60 or younger undergo BRCA genetic testing. Studies suggest that expanding testing beyond age 60 may capture additional BRCA positive women. Identification of a BRCA mutation has significant implications for early cancer detection and prevention, treatment options, and at-risk blood relatives. Many at-risk relatives are not aware of, or pursue genetic testing for mutations identified in their family. Our previous prediction models have shown that testing all at-risk first degree relatives of TNBC patients may reduce the risk of breast and ovarian cancers by 23%, and 41%. Few studies exist regarding the occurrence or success of intra-family cascade genetic testing. Study Design This study is conducted through the University of Texas MD Anderson Cancer Center’s Women’s Cancer Moonshot program. This is a five year prospective cohort study of unselected women with confirmed TNBC. It provides universal BRCA genetic testing for TNBC patients. TNBC patients are enrolled in a research registry which provides clinical BRCA genetic testing regardless of age of diagnosis. BRCA positive TNBC patients are consented for a separate prospective family outreach protocol (REACH registry). The REACH registry includes questionnaires and active outreach to at-risk family members using an innovative information-technology platform and a variety of web-based patient education tools. Results In year one of our study, a total of 439 patients with TNBC have been seen for genetic counseling and 377 (86%) have undergone BRCA genetic testing. Fifty-one (14%) patients were identified as having a BRCA mutation. Of those with a BRCA mutation, 48 (94%) have a BRCA1 mutation, 3 (6%) have a BRCA2 mutation and 1 (2%) would not have been identified by current testing guidelines. Further, 74 patients with identified BRCA mutations and 50 at-risk family members have enrolled in the REACH registry. Recruitment and data collection of patients and family members, and their communication, genetic testing, cancer risk reduction, and surgical choices are on-going. Using our innovative IT platform to collect information and to communicate with patients and families, we anticipate an increased study recruitment, patient and family participation, and ultimately improved awareness, education, and cancer-prevention and screening among our patients and their family members. Conclusion Through this study we have maximized awareness and identification of high-risk hereditary cancer patients through implementation of universal BRCA1 and BRCA2 genetic testing of all TNBC patients. We have shown initial feasibility to successfully recruit family members to our REACH registry. REACH registry is an innovative research platform providing education and awareness to patients and at-risk family members to aid communication and dissemination of BRCA test results and to assess the psychosocial and behavioral impacts of a mutation in a family.
**Title:** Risk-reducing surgery and cancer-related distress among female *BRCA1* and *BRCA2* mutation carriers

Liede A, Fairchild A, Friedman S, Amelio J, Hallett DC C, Mansfield CA A and Metcalfe KA A. Amgen Inc., CA; Facing Our Risk of Cancer Empowered (FORCE), Tampa, FL; University of Toronto, Toronto, ON, Canada and RTI Health Solutions, Research Triangle Park, NC.

**Body:**

**Background:** Distress levels among female *BRCA1* and *BRCA2* mutation carriers can be similar to levels reported among breast cancer patients. However, there is a lack of data on long-term psychosocial functioning, and it is not known if uptake of risk-reducing surgery influences long-term cancer related distress in women with a *BRCA* mutation who are unaffected with cancer. The objective of this study was to evaluate long-term cancer-related distress in women with a *BRCA* mutation, and to evaluate predictors of distress, including uptake of cancer risk reducing surgery.

**Methods:** Female *BRCA1* or *BRCA2* mutation carriers, ages 25-55, and without cancer were eligible to complete the survey online. A validated instrument, Impact of Events Scale (IES)-Revised (Horowitz 1979, Weis & Marmar 1995; 0-80 overall scale), was used to assess current levels of cancer risk-related psychological distress. Respondents were recruited through the Facing Our Risk of Cancer Empowered (FORCE) advocacy organization, which includes women at high risk of breast cancer. This interim analysis is part of a larger multi-center patient preference study of *BRCA* mutation carriers designed to assess women's willingness to adopt hypothetical treatments to prevent breast cancer. Linear regression was used to evaluate predictors of IES distress levels.

**Results:** Between January and April 2015, 259 women completed the survey. The mean age of the participants was 41 years, and the mean time since receipt of genetic test results was 3.5 years (range 0-16; median 2 years). One hundred thirty-six (52%) women elected for prophylactic bilateral mastectomy (PBM), 139 (54%) elected for bilateral salpingo oophorectomy (BSO) (93 [36%] women had both surgeries), and 77 (30%) had not undergone risk-reducing surgery. The mean total IES score was 15.1 (range 0-72; median 11). Overall, 54 (21%) women reported moderate or severe cancer-related distress, and those who had undergone risk-reducing surgery reported lower perceived risk of developing breast cancer. Results to date indicate that shorter time since notification of mutation status, not having PBM (with or without BSO) (table), and not completing post-secondary education were independent predictors of higher IES distress scores.

**Conclusions:** This study measured cancer-related distress in a large population of women with *BRCA* mutations who participate in the FORCE online support community. Higher levels of distress were associated with not having PBM and more recent genetic test disclosure. These findings are specific to a more informed community of women with high levels of understanding of cancer risk than may be seen in the clinical setting.
Double heterozygosity for BRCA1 and BRCA2 pathogenic variants in a French metastatic breast cancer patient

Double heterozygosity is an extremely rare occurrence in hereditary breast and ovarian cancer syndrome (HBOC [MIM 604370; MIM 612555]) where two pathogenic variants, one in BRCA1 and one in BRCA2, are found in an individual. To date, only a few case reports and case series have been reported in the literature (1-3). Furthermore, little is known about the clinical characteristics, family history, and tumor histology in these patients. In this study, we utilized targeted gene testing with next-generation sequencing (NGS) technology in an early-onset metastatic breast cancer patient from France. We evaluated germline variants using Pathway Genomics' BRCATrueTM NGS test, which analyzes variants covering all exons and exon flanking regions in both the BRCA1 and BRCA2 genes. All variant calls were determined after alignment and mapping to the GRCh37/hg19 reference genome. Variant calls were confirmed by Sanger sequencing. In this patient, a c.1016dupA (p.V340GfsX6) frameshift variant was found in BRCA1 along with a c.6814delA (p.R2272EfsX8) frameshift variant in BRCA2. Both frameshift variants are predicted to truncate the BRCA proteins. The BRCA1 c.1016dupA variant is considered a Norwegian founder mutation but has also been observed in individuals who are of French-Canadian, French, Italian or Dutch ancestry (4-7). The BRCA2 c.6814delA (p.R2272Efs*8) pathogenic variant, also known as 7042delA, is predicted to truncate the BRCA2 protein and has been identified in individuals with a personal or family history of breast and/or ovarian cancer (8,9). To the best of our knowledge, the combination of these two pathogenic variants in an individual has not been previously reported. In a clinical diagnostic setting, the possibility of double heterozygosity of pathogenic variants in more than one susceptibility gene should be considered, especially in patients with early-onset metastatic cancers. Furthermore, genetic testing and genetic counseling should also be indicated for high-risk family members.

Title: Consistency of pathogenicity determinations for hereditary cancer gene mutations

Background: As the number of laboratories offering genetic tests grows, the potential for inconsistent variant classifications increases. New resources can help address this: (a) ClinVar, a rapidly growing public database of clinical variants to which many (but not all) laboratories contribute; (b) the public release of thousands of BRCA1/2 reports from Myriad Genetics through the Sharing Clinical Reports Project (SCRP), the Free the Data (FTD) initiative, and recent publications; and (c) ExAC, a greatly improved database of population allele frequencies. These complement longstanding efforts, e.g. the ENIGMA consortium. In addition, the American College of Medical Genetics (ACMG) recently updated guidelines for the interpretation of sequence variants. Using these resources, we sought to investigate the consistency of variant classifications to help inform ongoing practice.

Methods: Pathogenicity assessments for variants in hereditary cancer genes were collected from multiple sources. Among these were 15,364 BRCA1/2 submissions to ClinVar, including 5416 submissions from SCRP and 1062 from our prior work [1]. When 3 or more submissions for a variant were available, we determined a consensus interpretation requiring 2 of 3 submitters to agree (or 3 of 4, etc.) to identify outliers. For our own classifications, we established a point-based system based on the 2015 ACMG guidelines, and independently applied it to publicly available evidence of pathogenicity without regard to other labs’ classifications.

Results: Initially, discordance among ClinVar submissions appears high (20-30%). However, upon investigation much of this discordance is a result of (i) research submissions to ClinVar, (ii) differences in confidence (e.g. benign vs. likely benign), (iii) older data in ClinVar, (iv) single lab outliers, and (v) nuances in the detailed structure of the ClinVar database. A careful comparison using the consensus methodology of objectively filtered ClinVar data shows high concordance between our interpretations and consensus: 95% were identical and 99% were similar (e.g. benign and likely benign were considered similar). Where consensus was not achieved (8% of variants with 3 or more independent sources) or not possible (any variant with only 2 sources), pairwise comparisons showed that few of these remaining differences (5%) were clinically significant. Also, many variants with significant discordances appeared to be particularly rare in the human population, and thus would be present in few patients. The rate of discordances with SCRP/FTD data was similar with that of other ClinVar submitters.

Conclusions: Evaluations of inter-laboratory concordance need to be done carefully to avoid over-counting differences. Laboratories generally agree on the clinical significance of the vast majority of variants. Furthermore, the inter-laboratory consensus classification is often reached using a careful implementation of the ACMG guidelines and publicly available data. Thoroughly understanding the remaining differences is challenging when the evidence used by any laboratory is not available for peer review. Detailed data and methods from this study are available for review and alternate analyses.

Title: Prevalence of Hispanic BRCA1 and BRCA2 mutations among HBOC patients from Southern Brazil reveal differences among Latin American populations

Aleman B, Herzog J, Ashton-Prolla P and Weitzel J. Programa de Pós-graduação em Genética e Biologia Molecular, Universidade Federal do Rio Grande do Sul; Laboratório de Medicina Genômica, Hospital de Clínicas de Porto Alegre, Porto Alegre, Rio Grande do Sul, Brazil and Division of Clinical Cancer Genetics, City of Hope, Duarte, CA.

Body: Background. Breast cancer (BC) is the most common malignancy in women around the world, and 5% of BC cases and 15% of ovarian cancer (OC) cases can be attributed to BRCA1 and BRCA2 germline mutations, configuring Hereditary Breast and Ovarian Cancer Syndrome (HBOC). Considering that the genetic similarities between Latin American populations are largely unknown, we aimed to address if a panel of Hispanic BRCA mutations could be useful for a Brazilian population.

Methods. Unrelated patients fulfilling NCCN criteria for HBOC syndrome were recruited. ASCO, Myriad and Penn II clinical testing criteria were analyzed for all patients. Blood-derived DNA samples were screened for 114 BRCA mutations, in a panel estimated to account for up to 90% of all BRCA Hispanic mutations (HISPANEL), using the Sequenom MassArray platform. Results. Among a total of 233 unrelated patients included (225 women and 8 men), 85% were BC patients and 14 patients were cancer unaffected. The mean age at diagnosis was 43 years for BC affected individuals and 45 years for patients with OC. Fifty-three patients fulfilled ASCO criteria, and 182 had Penn II ≥ 10%, while only 64 had a Myriad score ≥10%. BRCA mutations were detected in 9 of 233 patients (prevalence of 3.86%). Among BC and/or OC affected individuals, this prevalence was 4.22%. Features of mutation carriers are depicted in table 1.

BrCa=breast cancer; OvCa=ovarian cancer.

Conclusions. The HISPANEL detects 59 BRCA1 and 55 BRCA2 mutations, including some mutations previously reported in Brazilian individuals. Most mutation carriers had the BRCA1 c.5266dupC (5382insC) mutation, a common founder mutation in several populations. Our results are largely different from other Latin American published data. Although low BRCA prevalence mutational rates were also seen in Peru and Mendellín (Colombia), in Mexico and Bogota (Colombia) a prevalence of 27% and 15%, respectively, was found in studies using HISPANEL and all studies included patients unselected for family history. Our
findings reinforce that different Latin-American populations have different \textit{BRCA} mutational profiles.
Title: BRCA mutations in South Texas and the Rio Grande Valley among Hispanics with a personal or family history of breast cancer

Mette LA A, Poullard NE E, Pulido Saldivar AM, Torres IC C, Seth SG G, Seigler D, Jatoi I and Tomlinson GE E. University of Texas Health Science Center at San Antonio, San Antonio, TX; Greehey Children’s Cancer Research Institute, University of Texas Health Science Center at San Antonio, San Antonio, TX; Laredo Regional Campus, University of Texas Health Science Center at San Antonio, Laredo, TX; Regional Academic Health Center, University of Texas Health Science Center at San Antonio, Harlingen, TX; University of Texas Health Science Center at San Antonio, San Antonio, TX and Cancer Therapy & Research Center, University of Texas Health Science Center at San Antonio, San Antonio, TX.

Body: South Texas, including regions along the US-Mexico border, is characterized by a predominantly Hispanic population, most of who are of Mexican decent. In the past decade, the discovery of Mexican-American founder mutations in BRCA1/2 has established the importance of large rearrangement testing in this population. Recent studies estimate that 15-25% of Mexican women with early-onset breast cancer carry a BRCA mutation, with the BRCA1 EX9-12 deletion accounting for 10% of all mutations. Here we review the BRCA1/2 pathogenic and unclassified variants in our South Texas Hispanic population who underwent cancer genetic risk assessment and testing between June 2013 and May 2015. All mutation carriers had either a personal history of early-onset breast cancer (before age 50), or early-onset breast cancer in a first-degree relative. A total of 23 unique mutations were identified in 28 kindreds. Three affected individuals harbored mutations that had not previously been reported in the literature at the time of testing (BRCA1 134+3A>T; BRCA2 428C>G; BRCA2 8265A>T). Pathogenic mutations in BRCA1 were the most common finding, accounting for 64.3% of identified variants. The BRCA1 EX9-12 deletion was only found in only family. We also identified a co-segregating pathogenic mutation (1793delA) and variant of uncertain significance (1149G>A) in BRCA1 in two unrelated kindreds, suggesting a possible founder mutation. Although previous studies have identified recurrent BRCA mutations in Hispanic families with breast cancer in the Southwestern United States, this was not seen in our sample of South Texas Hispanics. While only one (3.5%) of our families had the BRCA1 EX9-12 deletion, other large rearrangements, such as BRCA1 EX1-2 deletion, BRCA1 EX21-22 duplication and whole gene deletions demonstrate the continued importance of comprehensive BRCA1/2 analysis in Hispanics. This work was supported by CPRIT Grant PP120089 and NIH 2P30CA054174.

Title: Surveillance program for women carrying BRCA1/BRCA2 genetic predisposition

Sidoni T, Coccioitone V, Cannita K, Di Giacomo D, Ciccozzi A, Bafille A, Pizzorno L, Resta V, Marsecano C, Ferrari F, Di Cesare E, Ficorella C and Ricevuto E. Medical Oncology, San Salvatore Hospital, University of L'Aquila, L'Aquila, Italy; University of L'Aquila, L'Aquila, Italy; Breast Imaging Unit, San Salvatore Hospital, L'Aquila, Italy; Breast Unit, San Salvatore Hospital, L'Aquila, Italy; Radiology, San Salvatore Hospital, University of L'Aquila, L'Aquila, Italy; Radiotherapy, San Salvatore Hospital, University of L'Aquila, L'Aquila, Italy and Oncology Territorial Care, Network ASL1 Abruzzo, San Salvatore Hospital, L'Aquila, Italy.

Body: Between January 2003 and January 2015, women at genetic risk of developing breast and/or ovarian cancer were selected for a surveillance program. The monitoring strategy consisted of the association of breast ultrasound (US), every six months, and Rx-mammography (XM) and breast MRI (MRI) to be performed annually. To date, 29 women have been included in the surveillance program: BRCA1 mutation carriers, 18; BRCA2 mutation carriers, 11.

Eight women (28%) had already developed breast and/or ovarian cancer, while 21 (72%) were unaffected carriers. At a median surveillance time of 33 months (range 0-144), 4 incidental breast cancers were diagnosed in 4 BRCA1/2 mutation carriers (4/29, 14%), 2 BRCA1+ and 2 BRCA2+; 3/21 (14%) unaffected carriers and 1/8 (13%) previously affected carriers. Two cancers (50%) were detected by all three diagnostic tools; 2 (50%) were identified only by US and MRI in patients aging 33 and 43, respectively.

One of these four patients, affected by breast cancer, died at 31 months of overall survival; three underwent surgery, chemotherapy and radiotherapy and are still disease free, in follow-up at 59, 28 and 26 months, respectively.

In conclusion, 29 BRCA1/2 carriers have been included in the surveillance program, the median age was 42.5 months (range 27-68) and the median surveillance time was 33 months (range 0-144). Our preliminary data confirm the 3% expected rate of diagnosed cancers and the effectiveness of performing the triple diagnostic surveillance with US, XM and MRI.
Title: Rapid BRCA analysis: Experience of a single institution

Body: The interest of rapid BRCA analysis, even before the initial treatment could modify the surgical indications (ie total mastectomy and immediate reconstruction even in case where tumorectomy would be suitable). The aim of this study was to evaluate the indications and consequences of this rapid determination of BRCA status in our institution.

Patients
Rapid BRCA analysis was conducted in 129 patients (pts) treated for breast cancer and addressed to the genetician at Oscar Lambret Center between 2009 and 2014: in 98 pts to discuss breast and axilla surgical modalities, in 4 cases to discuss oophorectomy, in 3 cases to have access to PARP inhibitors. In the other 24 pts, the reasons were debatable: patient leaving abroad, patient requiring reproductive assisted technology.....

Results
38 deleterious mutations (29.4%) were identified (31 BRCA1, 7 BRCA2) in 38 pts.
Cancer treatment was on going for 107 pts, programmed for 12 pts and finished for 10.
The median time between cancer diagnosis and genetic counseling was 81 days (5-5160), between blood sample collection and BRCA analysis 37 days (13-132), between availability of the laboratory results and the information to the patient: 39 days (1-234); 7 pts (5.4%) never came to obtain the laboratory results.
Treatment was modified after genetic counselling for 8 pts out of 119 (7%). Six of them had BRCA1 deleterious mutations. Three decided subsequent radical mastectomy and adjuvant radiation was cancelled, another had a radical mastectomy before radiation, another treated for bilateral breast cancer had a bilateral radical mastectomy before radiation and the last treated for unilateral breast cancer had a bilateral radical mastectomy before radiation.
Out of these 8 pts, two did not have a deleterious mutation. One had a bilateral radical mastectomy before laboratory result and one with BRCA variant of unknown significance had a homolateral radical mastectomy.

Conclusion discussion
Our experience shows that rapid BRCA analysis is feasible. In this selected population the mutation rate is very high. However, first, it appears that indications for rapid BRCA analysis were variable and not always relevant. Second, genetic result impacts on treatment only in 7% of pts. Indications could be justified by the use of PARP inhibitors. Up to now, the indications of rapid genetic analysis are rare.
2015 San Antonio Breast Cancer Symposium

Publication Number: P2-09-16

Title: Comparison of prediction models of breast cancer in high risk populations?

Body: Breast cancer is the most frequent female cancer with 48 800 new cases each year in France. A French national screening program in women without genetic risk factors has been initiated in 2004. Women with BRCA 1 or 2 mutations are included in surveillance programs. Women without such mutations can be assessed for breast cancer risk using risk prediction models. The aim of this study is to compare the performance of three breast cancer risk prediction models: GAIL2, BODICEA and IBIS in a population of patients (pts) who developed breast cancer.

Patients and Methods: The GAIL1 model was performed to 188 pts at high risk of breast cancer according to their family history and who developed breast cancer. Personal and familial data was regenerated at the day before the diagnosis of breast cancer and the three models were applied. From this population, 60 pts were selected: for whom all information necessary to use the 3 models was available and for whom the GAIL1 model provided sufficient variability in the relative risk of breast cancer.

The GAIL2 model takes into account individual risk factors: age, menarches, parity, age at first birth, history of breast biopsy, atypical hyperplasia or in situ lobular carcinoma. The BODICEA model considers age and familial risk factors: number of related affected by breast ovarian, prostate and pancreas cancer and age at diagnosis. Both personal and familial risk factors are used for the IBIS model.

We estimated lifetime breast cancer risk for each patient with the three models from the available software packages. We assessed Pearson's correlation coefficient between the three models.

Results

Median (range) age was 45 years (25-74). Risk prediction could not be evaluated by the GAIL2 model for 14 pts since they were less than 35 years of age.

Lifetime breast cancer risk was 16.1% (4.4-38.7) for GAIL2, 11.6% (2.2-39.5) for BODICEA and 16.5% (3.5-36.3) for IBIS. Pearson's correlation coefficient between BODICEA and GAIL2, IBIS and GAIL2 and between BODICEA and IBIS were 0.36, 0.38 and 0.69 respectively.

In most cases, IBIS risk predictions were higher than GAIL2's which were higher than BODICEA's as soon as lifetime risk was at least 20%. When the three models were applicable (46pts), IBIS estimated a higher risk in 31 cases (67%) versus 10 for GAIL2 (21.74%) and 5 for BODICEA (10.86%).

The median (range) time for use of the tools per patient was 30 seconds (16-80) for GAIL2, 588 (198-1804) for BODICEA and 86 (46-135) for IBIS.

Discussion

Results in this selected population of pts who developed breast cancer show that IBIS seems to be the better performer to predict breast cancer risk: Results are obtained faster and the risk predictions provide higher estimates. The GAIL2 model is quick and easy to use but with a limited number of items. Conversely, BODICEA requires a very large number of items, not always available, and does not consider incomplete data.

In conclusion, IBIS model seems to be the most suitable for practical use in the evaluation of breast cancer risk.
Title: Frequency of large rearrangements in BRCA1, BRCA2, ATM, CHEK2, and PALB2 in hereditary cancer testing

Bissonnette J, Doonanco K, Xu Z, Klein RT T and Hruska KS S. GeneDx, Gaithersburg, MD.

Body: Objectives
Large deletions and duplications are recognized as a cause of many inherited cancer syndromes; however, few studies have examined the frequency. In one study, large rearrangements accounted for 11-14% of pathogenic variants in BRCA1 and 1-3% of pathogenic variants in BRCA2 (Judkins 2012). Additionally, in a study of invasive ovarian cancer patients, large deletions and duplications accounted for 6% of BRCA1 and 3% of BRCA2 pathogenic variants (Zhang 2011). The frequency of large deletions and duplications in moderate penetrance genes, such as ATM, CHEK2, and PALB2, has not been carefully studied. We therefore sought to determine the frequency of pathogenic and likely pathogenic (P/LP) large deletions and duplications in BRCA1, BRCA2, ATM, CHEK2, and PALB2.

Methods
We analyzed a consecutive case series of patients who had BRCA1/2 and cancer panel testing. The data were analyzed to determine the percentage of deletions or duplications of greater than 250 bp identified on array comparative genome hybridization as a percentage of all pathogenic variants (PVs)/likely pathogenic variants (LPVs) in each of BRCA1, BRCA2, ATM, CHEK2, and PALB2.

Results
Large deletions/duplications accounted for 10.1% (55/545) of cases with a BRCA1 PV/LPV and 1.8% (10/556) of cases with a BRCA2 PV/LPV. By ethnicity, BRCA1/2 large deletions/duplications accounted for a higher fraction of PV/LPVs in Asians (11.3%) and Hispanics (8.1%). In Hispanic individuals, all of the large deletions/duplications were identified in BRCA1, accounting for 14.6% of all BRCA1 PV/LPV in this group. In the moderate penetrance genes, large deletions/duplications accounted for 4.6% (9/195), 5.1% (22/436), and 9.9% (13/132) of cases with a PV/LPV in ATM, CHEK2, and PALB2, respectively. There were two recurrent deletions in our cohort: the CHEK2 founder Slavic deletion of exons 9-10 observed in 16 of our cases, and a deletion of exon 11 in PALB2 observed in 6 cases.

Conclusions
Large deletions/duplications account for a substantial proportion of clinically significant variants in hereditary cancer genes. The proportion of large deletions/duplications in BRCA1 and BRCA2 reported here is similar to previous data. However, our cohort suggests that Asian individuals may have a higher proportion of mutations due to large deletions/duplications than previously reported. Among moderate risk cancer genes, PALB2 has the highest proportion of large deletions/duplications.
**Title:** Exploration of the diagnostic utility of next generation sequencing with TruSight cancer panel for BRCA negative hereditary breast and ovarian cancer patients

Dacheva D, Dodova R, Mitkova A, Kamenarova K, Tzveova R, Popov I, Vlahova A, Taushanova – Hadjieva M, Valev S, Dikov T, Timcheva K, Christova S, Mitev V and Kaneva R.  Molecular Medicine Center, Medical Faculty, Medical University of Sofia, Sofia, Bulgaria;  General and Clinical Pathology Clinic, University Hospital "Alexandrovska"/Medical University of Sofia, Sofia, Bulgaria and  Clinic of Medical Oncology (Chemotherapy), Nadezhda Women's Health Hospital, Sofia, Bulgaria.

**Body:** Background. Breast cancer is the most commonly diagnosed malignancy and the most frequent cause of death in women due to cancer. About 5% to 10% of breast cancers are thought to be hereditary. Pathogenic mutations in BRCA1/2 genes across Hereditary Breast and Ovarian Cancer (HBOC) patients estimates are at around 15-20%. Other less common genes have also been associated with an increased risk of developing breast cancer, such as mutations in the TP53, PTEN, RAD51C, CDH1, ATM, CHEK2 or PALB2 tumor suppression genes. NGS based sequencing panels allow fast and simultaneous screening of large number of high- and low-penetrance susceptibility genes in these patients.

Methods. In the current study we included a group of 31 Bulgarian female breast cancer patients, selected following the strict BCLC and NCCN criteria for hereditary cancer. All of them were prescreened by direct sequencing and MLPA analysis, and tested negative for pathogenic mutations in BRCA1 and BRCA2 genes. Next generation target resequencing using a panel of 94 cancer related genes (Illumina TruSight cancer panel) was performed to explore the hereditary component beyond BRCA1/2 genes in these patients. All detected mutations and variants of unknown clinical significance (VUSs) were confirmed by Sanger sequencing method.

Results. Pathogenic and likely pathogenic mutations were found in 14 out of 31 BRCA1/2 negative patients: 1 new frameshift mutation in ATM gene; 6 new likely pathogenic missense mutations in PTCH1, RAD51C, MET, MUTYH, ATM and CHEK2; 7 previously reported pathogenic missense variants in WRN, ERCC4, PALB2, PRF1, RET, SDHB and AIP genes. In addition 27 VUSs (one new splice donor variant in ALK gene and 26 missense variants) were found.

Conclusions. The use of next generation target resequencing with TruSight Cancer panel lead to identification of clinically relevant pathogenic variants in 45% of the investigated patients. This could be the preferred diagnostic method in HBOC patients, carefully selected according the strict BCLC and NCCN criteria.

Title: The performance of next generation panel testing in individuals assessed by a community-based genetics program

Daib S, Sedlacek S, Hamlington B, Brzeskiewicz L, Goetsch B, Tedesco K, Patel G, Sudhoff K, Mullineaux L and Langer L. Rocky Mountain Cancer Centers, Denver, CO; 207 Perry Parkway, Gaithersburg, MD; Texas Oncology; Compass Oncology and New York Oncology/Hematology.

Body: INTRODUCTION: Genetic testing identifies patients with an increased risk for hereditary cancer and assists in development of clinical management or cancer prevention strategies. Utilization of multigene panels for patients with a personal or family history of cancer has the ability to identify a significant number of pathogenic variants in high risk and moderate risk genes. Importantly, at-risk patients with previously negative single gene testing can be retested with multigene panels. We characterized the mutations found in patients who had inherited cancer multi-gene panel testing, including patients with negative BRCA testing, and explored the phenotypes associated with the most prevalently mutated gene.

METHODS: Patients were identified by a Community-Based Genetics Program and sent to a commercial laboratory for multi-gene panel testing. A retrospective query of multi-gene oncology tests was performed: patient history, family history and previous genetic test results were reported on the requisition. The following Genes were Utilized in the Inherited Cancer Panels: High risk genes (APC, BMPR1, BRCA1, BRCA2, CDH1, CDKN2A, EPCAM, MLH1, MSH2, MSH6, MUTYH, PMS2, PTEN, SMAD4, STK11, TP53, VHL), moderate risk genes (ATM, CHEK2, PALB2), and genes with increase risk of unknown magnitude (AXIN2, BARD1, BRIP1, CDK4, FANCC, NBN, RAD51C, RAD51D, XRCC2). The combination of genes analyzed was depends on the panel ordered.

RESULTS: 529 individuals were tested with 38 individuals with pathogenic variant (PV) or variant expected to be pathogenic (VEP). Of the 529 individuals, 154 (29%) had previous testing and 12 (7.8%) had PV/VEP. Interestingly, 48% of PV/VEP were in the moderate risk genes ATM, PALB2, CHEK2, and CHEK2 being the most commonly mutated gene. The following table details the genes with Positive and VEP Results:

**CONCLUSION:** Inherited cancer panels provide patients with genetic information that would otherwise be missed by single gene testing and provides access to risk assessment and medical management. Using multigene panels, PV/VEP were discovered in 7.8% of patients with previous negative BRCA testing. CHEK2, a moderate risk gene, was identified in 33% of patients with a PV/VEP. The phenotypic expression for CHEK2 is primarily breast cancer with a wide spectrum of solid and hematological tumors.
Title: Evaluation on the mutation screening by next-generation sequencing in hereditary breast and ovarian cancer: Implementation of recurrent mutation panel

Body: Background: Hereditary disposition accounts for 10-15% in breast cancers and 20-25% in ovarian cancers, in which 5-10% of women have genomic alteration in breast cancer predisposition genes, BRCA1 and BRCA2, while the rest are likely due to less penetrant genes. In specific ethnicities such as Ashkenazi Jewish, three founder mutations have been identified which covers 95% of all the BRCA mutations identified in this race. These genes are screened prior to the gold standard Sanger Sequencing in order to reduce cost. Sanger Sequencing, however, still has the limitation on the necessity of laborious processing and results interpretation. Moreover, it limits the number of genes that can be analyzed in one setting. With the use of next-generation sequencing (NGS), identification of hereditary breast and ovarian cancer (HBOC) syndrome associated genes, other than BRCA, can be sequenced at the same time but yet a faster turnover time. This allows more timely targeted risk-reducing strategies and interventions to be implemented for mutation positive carriers and their family members.

Methods: In this study cohort, 948 high-risk breast/ovarian patients who met the HBOC selection criteria were recruited for mutation screening by our NGS pipeline. With the inclusion of 90 Sanger-validated known mutation cases, the performance of the NGS pipeline were proven to be comparable to Sanger sequencing. PTEN and TP53, other than BRCA1 and BRCA2, a 4 gene sequencing panel were included in the mutation screening for high-risk patients.

Results: The prevalence of BRCA1/BRCA2 germline mutations was 7.28% in our Chinese cohort and 47.8% of the mutation were recurrent mutations. Based on this finding, we further adopted a new workflow by screening the recurrent mutations including founder mutations from Chinese cohort prior to NGS for those who tested negative. In a testing cohort of 343 cases, the recurrent mutation pick-up rate was 3.5%, this implicated a more cost-effective method for mutation screening in the clinical setting. Moreover, the frequencies of PTEN and TP53 were 0.21% and 0.53% respectively in our population with breast and ovarian cases.

Conclusion: Taken together, our data demonstrated a strategic upfront screening for recurrent mutations in Chinese population which is highly applicable in most of the diagnostic laboratories. Multi-gene sequencing using the NGS technology will be the upcoming strategies for mutation screening for HBOC patients.
Background: In 2003, the American Society of Clinical Oncology (ASCO) issued a policy statement that addressed the oncologist’s role in integrating cancer genetic risk assessment and management into clinical practice. ASCO supports access to genetic counseling for patients offered genetic testing and after results disclosure. In 2014, Integrated Genetics (IG) began offering genetic counseling in partnership with OBGYNs and oncologists whose patients have a personal or family history of breast or ovarian cancer. The goal of the program was to provide an easily accessible and comprehensive genetic counseling service for Hereditary Breast and Ovarian Cancer (HBOC) to meet the needs of patients and to support clinicians who currently provide pre- and post-test counseling.

Methods: In this study we describe IG’s HBOC genetic counseling service and in a retrospective analysis, describe the characteristics of patients referred to the program in 2014. Clinicians were provided a toll free number for patients to call to schedule a genetic counseling session. The scheduling staff facilitated medical record requests and emailed a family history questionnaire. In person or telegenetic counseling (via WebEx) was offered. Telegenetic counseling allowed the patient and genetic counselor to see one another via webcam and view counseling visual aids and relevant medical records. Pedigree analysis and cancer genetic risk assessment were performed and genetic testing options discussed based on National Comprehensive Cancer Network (NCCN) testing criteria. Information discussed at the session, including patient decisions about testing, was documented for the referring physician and patient in the Genetic Counseling Consultation Report. The physician ordered testing and managed patient screening and surveillance.

Results: During 2014, 247 counseling sessions were provided to patients from 23 states. All patients had a personal or family history of breast or ovarian cancer and the average age of patients was 44 years (range: 16-85). Sixty four percent (64%) of sessions were done via WebEx and 36% in person. Of the 247 sessions, 198 (80.2%) were for pre-test genetic counseling; of those, 173 (87.4%) met NCCN HBOC genetic testing criteria and genetic testing for BRCA1/2 was offered. Of this group, 70.52% desired testing, 27.75% declined and 1.73% were undecided. The remaining sessions (n=49) included post-test counseling for pathogenic mutations or variants of unknown significance (n=39), and patients who had accepted testing but whose results were pending (n=10).

Conclusions: The IG HBOC genetic counseling program extended comprehensive genetic counseling to patients at increased risk for BRCA1/2 mutations who might not otherwise have access to this service. Physicians appropriately selected patients for referral (87% met NCCN testing criteria). The genetic counselors provided cancer genetic risk assessment, time-intensive patient education to facilitate informed decision making, and counseling about the implications of results, including the complexities of variants of unknown significance. This partnership model allowed physicians to retain patient care oversight, including management of screening and surveillance, while leveraging genetic counselor expertise.
Title: Long-term psychosocial consequences and counsellees' satisfaction after genetic counselling for hereditary breast- and ovarian cancer - A patient reported outcome study

Sztankay M, Meraner V, Martini C, Sperner-Unterweger B, Hubalek M, Weber I, Morscher R, Zschocke J, Egle D, Dünser M and Oberguggenberger A. Innsbruck Medical University, Innsbruck, Austria; Innsbruck Medical University, Innsbruck, Austria; Division of Human Genetics, Innsbruck Medical University, Innsbruck, Austria and Innsbruck Medical University, Innsbruck, Austria.

Body: Background: Genetic counselling and testing (GCT) for hereditary breast and ovarian cancer (BOC) has become a standard option in BOC care in Europe allowing for prognostic information on the individual risk for disease onset/ relapse as well as on treatment options comprising prophylactic surgery or surveillance programs. However, data on the psychosocial long-term consequences is limited, especially in high-risk counsellees opting against genetic testing. We aimed at investigating the long-term psychosocial consequences of GCT for hereditary BOC in all counsellees irrespective of their decision after counselling.

Patients and Methods: Counsellees for BOC with and without a previous disease who had undergone genetic counselling at Innsbruck Medical University between 2011 and 2014 were asked to participate in a cross-sectional Patient Reported Outcome (PRO) assessment (incl. Multidimensional Impact of Cancer Risk Assessment, Genetic counseling satisfaction scale, Satisfaction with Decision Scale, Breast Cancer Heredity Knowledge Scale, Hospital Anxiety and Depression Scale/ HADS, Short Form 12 Health Survey, Cancer Worry Scale/ CWS) targeting on psychological distress, cancer worry, patient knowledge and patient satisfaction with genetic counselling and decisions by means of an anonymous mail survey. Subsequent decisions for vs. against genetic testing and if eligible, for surveillance vs. prophylactic surgery were also assessed. A reference sample of BC survivors was recruited at the outpatient unit.

Results: An overall sample of 137 counselees was included in the analysis (67.9% decided to undergo genetic testing for a HCPS, 22.6% decided not to be tested, 9.5% were still uncertain about their decision). 22.6% of counsellees experienced clinically relevant levels of anxiety and 9.8% scored above the cut-off for clinically relevant depression according to the HADS. Mean CWS score was 11 (SD 3.6, 3-24). Counsellees did not differ from breast cancer survivors regarding anxiety and depression according to the HADS (depression: p<0.5). Mean patient satisfaction with decisions amounted to 25.4 (SD 5.78, min. 4 to max. 30); a mean satisfaction with counselling of 25 (5.4) was observed. Less overall satisfaction with genetic counselling (β=0.445, t=5.552, p=0.000) and lower certainty about decision for/ against genetic testing after counselling (β=-0.169, t=-2.105, p=0.037) were highly predictive for lower long-term patient satisfaction with decisions.

Conclusion: Our results indicate that genetic counselling for BOC has no overall deleterious psychosocial consequences in long-term. Levels of depression and anxiety were comparable to those of the general population, while distress levels did not differ from those of breast cancer survivors without a hereditary BOC predisposition. The overall satisfaction with counselling as well as the certainty with decisions on testing and related medical interventions are highly predictive for the long-term satisfaction with decisions. Hence, genetic counselling should focus on supporting counsellees in forming clear decisions and include identifying counsellees with increased cared needs in this regard by means of PRO assessment in follow-up.
Factors associated with BRCA genetic testing intention and uptake among Orthodox Jewish women

Background: Ashkenazi Jews have a 1 in 40 prevalence of carrying a BRCA1/2 mutation, mainly due to 3 founder mutations. Prior literature suggests that population-based genetic testing among Ashkenazi Jews is cost-effective and may detect over 50% more mutation carriers than family history-based screening. Orthodox Jewish women are an understudied population with unique social, cultural, and religious factors that may influence BRCA genetic testing. The aim of our study was to examine factors associated with BRCA genetic testing intention/uptake among the Orthodox Jewish community.

Methods: A one-time online survey was distributed to Orthodox Jewish women by 3 shuls from Washington Heights, NY (53% response rate) and through additional referrals. The questionnaire obtained information regarding demographics, breast cancer risk factors, genetic testing knowledge, decision self-efficacy, perceived breast cancer risk, breast cancer worry, and religious and cultural factors affecting medical decision-making. The Tyrer-Cuzick model was used to calculate lifetime breast cancer risk and accurate risk perception was defined as within +/-10% of actual lifetime risk. Descriptive statistics and multivariable logistic regression models were used to identify independent predictors of genetic testing intention/uptake.

Results: Among 342 evaluable participants, median age was 26 years (range, 19-77); 92% were Ashkenazi and 8% Ashkenazi/Sephardi; 98% had a college education, including 47% with post-graduate degrees. Despite being highly educated, only 54% of women had adequate genetic testing knowledge. Median lifetime breast cancer risk was 16% (range, 2.3-60.9) and only 44% had accurate breast cancer risk perceptions. Although 48% had a family history of breast cancer and 16% had a relative that tested positive for BRCA1/2 mutation, only 5% had undergone BRCA testing while 48% had the intention of undergoing genetic testing. Higher lifetime breast cancer risk, high decision self-efficacy regarding genetic testing, overestimation of breast cancer risk, and increased breast cancer worry were associated with genetic testing intention/uptake. The most important factors in the decision to have BRCA testing were to help prevent dying of cancer (55%), to help prevent getting cancer (54%), and effect on children (40%).

Conclusions: By understanding the religious and cultural issues regarding genetic testing in the Orthodox Jewish community, we can develop targeted interventions designed to enhance decision self-efficacy and improve accuracy of breast cancer risk perceptions to decrease unnecessary worry. This may in turn increase informed decision-making about BRCA genetic testing and...
implementation of cancer prevention strategies among Ashkenazi Jews.
Title: Information preferences and short-term psychological responses to multiplex genetic testing among individuals at risk for hereditary breast cancer

Body: Background: Multiplex genetic testing involves the simultaneous analysis of a panel of known cancer susceptibility genes. Although efficient and cost-effective, multiplex testing presents several challenges for patients and clinicians: these tests provide information about high and moderate penetrance genes of varying clinical utility, patients cannot choose which specific genes are tested, and multiple variants of uncertain significance can be identified at once. Multiplex testing is being increasingly integrated into clinical care, yet little is known about patients' preferences, uptake, or psychological responses to these tests.

Methods: To address this gap, we examined two data sources: Sample A) a cross-sectional clinical ascertainment of 189 patients evaluated for hereditary breast and other cancer syndromes (89% female), and Sample B) an ongoing prospective research study of multiplex testing among 194 breast cancer patients and survivors who previously received uninformative BRCA1/2 results (99% female, 84% white, ages 27-76, 60% had BRCA1/2 testing in the past year).

Results: In Sample A, 32% declined clinical multiplex testing in favor of more targeted testing. Female patients were more likely than males to decline ($p=0.004$). Self-reported reasons for declining included: concerns about uncertain clinical utility of moderate penetrance genes (51% of patients) and variants of uncertain significance (38%), feeling emotionally overwhelmed (23%), and not seeing the value of multiplex testing (20%). In Sample B, participants were allowed to select which information to receive from a multiplex test; 16% chose to learn less than all of the information available (e.g., not genes unrelated to breast/ovarian cancer, not genes without established clinical utility, not CDH1 or TP53). Information preferences were unrelated to demographic (age, race, time since cancer diagnosis and BRCA1/2 testing) and self-reported psychological factors (baseline genetic testing-related distress, uncertainty, and positive experiences; anxiety; depression). Participants who chose to learn all possible information reported greater concerns about their children's cancer risk than did those who chose to learn less information ($p=0.01$). Participants reported a small increase in both genetic testing-related distress and positive experiences from before testing to 1 week after receiving results ($p<0.001$). In multivariable analyses controlling for baseline psychological functioning, only non-white race was consistently associated with significantly increased post-result anxiety, depression, and genetic testing-related distress and uncertainty. Participants who had BRCA1/2 testing one or more years ago also reported fewer positive experiences 1 week after receiving results.

Conclusions: Together, these findings demonstrate that a sizable minority of patients have important concerns regarding multiplex tests that may limit their uptake of this novel testing, and suggest that some patients may prefer to customize the specific risk information provided. Results also highlight characteristics of those at risk for poorer emotional outcomes following testing; these individuals may benefit from additional support in this context.
Title: Constitutional mosaicism in hereditary cancer genes

Background: Mutations conferring cancer risk are typically inherited from one biological parent. Alternatively, a mutation may be constitutional mosaic, meaning that a fraction of cells in the body carry the mutation. This can result e.g. from a de novo mutation early in embryogenesis. Constitutional mosaicism may be an underreported cause of genetic disease [1,2] for 2 reasons: Family histories can be uninformative (mosaic mutations are typically not inherited, but can be passed on to children). Also, germline laboratory tests (if performed) are traditionally not optimized to detect low allele frequency events (in contrast to tumor tests for somatic mutations). Following our recent identification of a mosaic BRCA1 cancer patient [3], we sought to characterize additional such cases in our laboratory population.

Methods: We examined high-depth next-generation sequencing (NGS) data for pathogenic or suspected pathogenic mutations with unequal allele balance (i.e., not the expected 50-50 ratio) in blood-derived DNA. Because many factors can cause unequal allele balance in NGS, we reviewed the lab and clinical data in detail to remove cases likely due to (a) technical artifacts in NGS, (b) other somatic events, as may happen in response to chemotherapy, or (c) undiagnosed, residual or progressing blood cancers. An orthogonal assay was used for confirmation.

Results: To date, 14 cases with mosaic mutations (7-29% allele frequency) have been confirmed: 8 of these patients have breast/ovarian cancer and 6 have other cancers. These allele frequencies are unlikely to be caused by circulating tumor DNA or cells. These findings include our published BRCA1 case, 7 TP53 cases, 1 NF1 case, 2 CHEK2, 2 MLH1, and 1 PTCH1. 3 additional mutations were determined to be part of a haematopoietic neoplasm (1 previously undiagnosed). Cases of note include (i) a young breast cancer patient, with no cutaneous findings, positive for NF1 at 9%, and (ii) a patient presenting with the Muir-Torre variant of Lynch syndrome who had negative MLH1/MSH2 Sanger sequencing 14 years ago, identified to be positive for MLH1 at 25% by NGS.

Conclusion: Constitutional mosaic mutations may be an under-recognized cause of cancer and unique clinical considerations apply to such cases. First, a mosaic patient may not show the same gene-associated phenotypes as patients with inherited heterozygous mutations in the same gene. Second, patients with syndromic presentations who tested negative for the indicated gene(s) by traditional methodologies may warrant reexamination by NGS. Similarly, patients with heterozygous mutations (50-50) may have a mosaic parent, for whom the mutation could be missed by traditional testing. Testing of family members beyond first degree relatives of a mosaic patient is unlikely to modify risk assessments, unlike the situation for patients with inherited heterozygous mutations. Finally, apparent mosaicism may warrant an evaluation for a underlying haematologic malignancy. We note that the prevalence of mosaic findings in hereditary cancer genes is currently unclear but may higher than once thought.

Further clinical research on this topic is clearly warranted.

Title: Women without significant claus model breast cancer risks may warrant breast MRI when a pathogenic/likely-pathogenic variant (PV/LPV) is detected in a hereditary cancer moderate risk gene

Alvarado M, Tiller GE E, Kershberg H, Solomon SR R, Mullineaux L and Haque R. Kaiser Permanente Southern California, Pasadena, CA and GeneDx, Gaithersburg, MD.

Body: Background: Hereditary cancer gene panel testing can assess breast cancer risk for women with significant family histories. The Claus risk model is another method to determine which women qualify for annual breast MRIs based on family history, and can be used for those with BRCA negative status or for those who do not qualify for BRCA testing. In July 2014, Kaiser Permanente Southern California, a large integrated health plan, began using hereditary cancer panels comprised of moderate and high-risk breast cancer genes (GeneDx). At the time of implementation, no clinical management guidelines existed for patients with PV/LPV in moderate risk genes. In March 2015, the National Comprehensive Cancer Network (NCCN) amended the Genetic/Familial High Risk Assessment Breast and Ovarian guidelines to include breast cancer surveillance for patients with PV/LPV in moderate risk genes including ATM, CHEK2 and PALB2.

Objective: To determine if the identification of PV/LPV in moderate risk genes versus Claus model calculation increases the number of women warranting breast MRI in a managed care setting.

Methods: We performed a retrospective query of our gene panel results from 6/2014 to 5/2015 to identify patients with ATM, CHEK2 and PALB2 PV/LPV. Personal and family histories were obtained from the test requisitions. Patients with personal histories of breast cancer were excluded from analysis. We calculated the lifetime breast cancer risk using the Claus model for all eligible female patients with a moderate risk gene PV/LPV. To calculate the risk, the Claus model included family history of breast cancer in first and second-degree relatives. A lifetime breast cancer risk of >20% indicates "high" risk.

Results: A total of 19 female patients without breast cancer had a PV/LPV detected in a moderate risk gene (ATM, CHEK2, and PALB2. Claus model calculation was feasible in 12 patients. Of these 12, 4 had a PV/LPV in ATM, 6 in CHEK2 and 2 in PALB2. Only one out of these 12 women was identified with >20% risk of breast cancer based on the Claus model, and was recommended a breast MRI.

A review of electronic medical records (EMR) notes to date (June 1, 2015) revealed that breast MRI was recommended for 10 of the 12 patients above, and completed in 6. MRI identified a suspicious breast lesion in one patient. Follow-up tests and lumpectomy revealed atypical ductal hyperplasia and she will be followed with annual MRI and mammogram. The remaining 2 of12 women had no mention of MRI in their EMR, and will be flagged for follow-up to determine MRI status.

Conclusions: Eleven out of 12 women with a PV/LVP in a moderate risk gene would not have been identified as having an increased breast cancer risk by the Claus model. In our small sample, utilization of a High/Moderate Risk Gene Panel identified more patients potentially warranting enhanced breast cancer surveillance with annual breast MRI than the Claus model. This finding suggests that the use of hereditary cancer gene panel testing may impact the medical management of women with a familial risk for breast cancer. Larger studies with outcome data are needed to determine optimal surveillance guidelines.
**Title:** The BRCA-1 polymorphism (major homozygous rs5820483) is associated with higher expression of phosphorylated -IGF-1 receptor

Singh B, Bochaca II I, Ruiz de Garibay G, Damiola F, Mazoyer S, Antoniou A, Chenevix-Trench G, Pujana MA A, Barcellos-Hoff MH H and Kleinberg D. New York University Langone Medical Center, NY, NY; Catalan Institute of Oncology (ICO), Bellvitge Institute for Biomedical Research (IDIBELL), L'Hospitalet del Llobregat, Barcelona, Catalonia, Spain; Unité Mixte de Génétique Constitutionnelle des Cancers Fréquents, Hospices Civils de Lyon–Centre Léon Bérard, Lyon, France and CIMBA and University of Cambridge, Cambridge, United Kingdom.

**Body:**

**Background:** Data from the Consortium of Investigators of Modifiers of BRCA1/2 (CIMBA) indicates that common variation in the BRCA1 locus modifies the penetrance of mutations. The rs5820483 variation is one such polymorphism in which patients homozygous for the major allele have a greater risk of breast cancer. The BRCA1 gene contains 24 exons that generate a full-length (FL) protein. Major alternatively spliced isoforms include skipping of exon 11 (Δ11) and a truncated form (IRIS), each of which appear to have distinct roles in cellular processes. rs5820483 is the only variant that maps to intron 10, flanking exon 11. Experimental models suggest that deregulation of the FL/D11 isoform ratio can have profound functional consequences. We have shown that cells from patients with the major rs5820483 allele express more FL relative to Δ11 compared to cells from patients with the minor allele. Breast cancer exhibit increased IGF-1 and IGF-1 activity in patients with BRCA1 mutations relative to breast cancer in women without BRCA1 mutations. IGF-1 produced in the mammary stroma mediates estrogen dependent proliferation. Here we test whether the rs5820483 allele affects IGF-1 activity in breast tissue of BRCA1 mutation carriers.

**Design:** We assessed the zyosity of the rs5820483 alleles in 28 BRCA1 mutation carriers. Phosphorylated IGF-1 receptor (p-IGF-1R rabbit polyclonal Ab39398, Abcam, MA) was measured by immunofluorescence and Ki-67 was measured by immunohistochemistry in sections from histologically normal breast tissue from these cases were compared to heterozygous controls. Image analysis was used to assess the intensity of the p-IGF-1R immunofluorescence at the epithelial cell membrane with appropriate controls. Ki67 immunohistochemistry was also performed on these specimens.

**Results:** The rs5820483 allele was heterozygous in 10 specimens, homozygous for the major allele in 11 and homozygous for the minor allele in 7. The intensity of p-IGF-1R was higher in major homozygous cases (140±54 SD) than in either the minor homozygous (99±24) or heterozygous cases (95±44). The frequency of Ki-67+ cells was higher in the major homozygous case (3.1±2.9 SD) than in either the minor homozygous (1.5±1.9 SD) or heterozygous cases (2.2±2.5 SD). However, neither p-IGF-1R immunoreactivity nor frequency of Ki-67+ cells was statistically different between groups.

**Conclusion:** Breast cancer risk in BRCA1 mutation carriers is modified by common genetic variation at the corresponding locus. We have identified a variation at rs5820483 that affects the isoform ratio. Our preliminary analysis suggests that IGF-1 activity increases in those women homozygous for the major allele, concomitant with increased Ki-67. Corroboration of this analysis in a larger series is ongoing. A statistically significant difference might have fundamental implications for cancer prevention in those carriers.
Introduction: We are conducting a phase II clinical trial of the GP2+GM-CSF vaccine for the prevention of breast cancer recurrence in disease-free, node-positive or high-risk node negative patients (pts). GP2 is an HLA-A2+-restricted immunogenic peptide from the HER2 protein (aa: 654-662) capable of stimulating CD8+ cytotoxic T-lymphocytes (CTLs) to recognize and destroy HER2-expressing tumor cells. Here, we present the final pre-specified analysis of our study, disease free survival (DFS) at one year from last enrolled pt.

Methods: The trial is a prospective, randomized, multi-center, placebo-controlled, single-blinded, phase I/II trial designed to evaluate the safety and clinical efficacy of GP2 in breast cancer patients. Pts with any level of HER2 (immunohistochemistry [IHC] 1-3+) expression were enrolled after standard of care therapy. Blinded HLA-A2+ pts were randomized 1:1 to receive GP2 + GM-CSF or GM-CSF alone. Pts in both treatment arms received 6 monthly intradermal inoculations during the primary vaccine series (PVS) followed by 4 booster inoculations administered every 6 months. Data was collected for demographic, safety, immunologic, and clinical recurrence. Per the statistical plan, DFS was analyzed for both intention-to-treat population (ITT; all randomized pts) and per-treatment population (PT; excluding recurrences during the PVS and second malignancies) using Kaplan-Meir methods. Continuous variables are compared using analysis of variance techniques and proportions compared with Fisher's exact test.

Results: This trial enrolled 180 pts (vaccine group n=89 and control group n=91). There were no differences in age, grade, hormone receptor status, tumor size or nodal status between groups (all p>0.2). With median follow up of 36.2 months, the five-year DFS estimates did not demonstrate a difference between vaccinated (VG) and control groups (CG) with ITT (82.6% v 80.4%, p=0.96, respectively) or PT (88.9% v 84.3%, p=0.52, respectively). On further subset analysis, in HER2 3+ by IHC (or positive via FISH) pts, ITT analysis showed a DFS of 93.8% v 87.2% (VG, n=50 v CG, n=51; p=0.67, respectively) while the PT analysis revealed a DFS of 100% v 87.2% (VG, n=48 v CG, n=50; p=0.052, respectively). In ER/PR+ pts, ITT analysis showed a DFS of 88.1% v 80.6% (VG, n=54 v CG, n=60; p=0.41, respectively) while PT analysis demonstrated a DFS of 91.5% v 85.2% (VG, n=52 v CG, n=57; p=0.42, respectively).

Conclusions: The final pre-specified analysis of this randomized phase II trial of the GP2+GM-CSF adjuvant breast cancer vaccine shows no statistical differences between treatment arms. However, it does identify a particular patient population where the vaccine may have efficacy; HER2 3+ patients appear to derive the greatest clinical benefit from GP2 vaccination after trastuzumab treatment with the PT analysis nearing statistical significance. Further studies are required to confirm these findings and investigate the potential link between hormone receptor status and the induction of clinically beneficial anti-tumor immunity with this vaccine.
Robust generation of T cell immunity to HER2 in HER2+ breast cancer patients with a degenerate subdominant HLA-DR epitope vaccine

Background: Recent studies have indicated that vaccination can protect against cancer development. One key aspect of developing vaccines is circumventing peripheral tolerance by identifying subdominant epitopes that are unique to the deregulated tumor microenvironment. While existing subdominant epitope vaccines are showing efficacy in preventing cancer, these vaccines are applicable only for subsets of patients with specific HLA subtypes. Therefore, we recently developed a degenerate HER2 subdominant epitope-based vaccine that should be useful in approximately 85% of all patients. The vaccine consists of a pool of four HLA-DR-restricted 15-amino acid epitopes (p59, p88, p422, and p885) that are naturally processed and are designed to elicit helper T cell immunity, the cornerstone of immune surveillance. Here we present Phase I trial results of this multi-peptide HER2 vaccine.

Methods: Eligible women had HER2+ breast cancer (Stages II-III) and had completed standard treatment (i.e. surgery, chemotherapy, and trastuzumab) at least 90 days prior to enrollment and were rendered disease free. Vaccine included the above epitope pool along with adjuvant GM-CSF. Patients were vaccinated six times over six months and were monitored for toxicity at each visit. Peripheral blood samples were collected for immune responses evaluating for T cell and antibody immunity. Endpoints were safety and immunogenicity leading to the development CD4 helper T cells that recognized naturally-processed HER2.

Results: Twenty-two subjects (age 33 to 69 years) were enrolled. At the present analysis, 21 have completed all 6 vaccination cycles; one patient withdrew after developing a grade 1 injection site reaction during the first vaccination cycle. Twenty patients have had LVEF measured after vaccination; only 2 patients had an LVEF drop of 10% or more but remained in the normal LVEF range. One severe toxicity was reported: a grade 3 INR increase considered unrelated to treatment. Mild to moderate (grade 1-2) toxicities included injection site reactions, fatigue, and white blood cell count decreases. All patients were alive at analysis and only one experienced a recurrence (median follow-up 507 days, range 22 – 844). Twenty patients have had immune response assessments. Vaccine induced T cell immunity was observed in 94% of patients to p59, in 94% of patients to p88, in 82% of patients to p422, and in 74% of patients to p885. Importantly, T cell immunity to naturally processed HER2 proteins occurred in 94% of patients. The mean number of T cells specific for each peptide, post vaccination, ranged from 349–528 T cells per million peripheral blood mononuclear cells (PBMCs). The mean number of T cells specific for whole HER2 protein was 783 T cells per million PBMCs compared to a mean of 898 T cells/million PBMCs specific for the foreign tetanus toxin. In contrast to T cell responses, modestly increased antibody immunity to HER2 occurred in 35% of patients, consistent with the T cell-inducing design of the vaccine.

Conclusion: Our results show that it is possible to develop vaccines with broad HLA coverage that circumvent natural tolerance and induce tumor antigen-specific immunity in the vast majority of patients.
Title: Phase I/II randomized study of combination immunotherapy with or without polysaccharide krestin (PSK) concurrently with a HER2 ICD peptide-based vaccine in patients with stage IV breast cancer receiving HER2-targeted monoclonal antibody therapy

Body: Natural killer (NK) cell defects, commonly seen in metastatic breast cancer (MBC) lead to decrease in dendritic cell (DC) maturation, proinflammatory cytokine production, and tumor infiltrating T-cells (TILs). This results in a protumorigenic Th2 immune microenvironment with low response rates to immunotherapy (i.e., immune checkpoint blockade) and standard chemotherapy. PSK, a potent TLR-2 agonist, activates NK cells to produce IFN-γ and IL-12 and promote DC maturation/differentiation toward a Th1 profile in the tumor microenvironment which results in antigen specific TIL that can eradicate tumor. The combination immunotherapy of PSK and HER2 directed therapy described here, aims at inducing Th1 immunity and tumor specific T-cells. This proposed regimen could eradicate microscopic residual disease and prevent recurrence in optimally treated HER2+ MBC patients. Moreover, the regimen could result in enhanced trafficking of TILs to the site of tumor and improve the efficacy of checkpoint inhibitors and other therapies. A phase I/II randomized 2 arm study of combination immunotherapy with oral PSK (or placebo) given with a HER2 peptide vaccine and HER2 mAb therapy (trastuzumab (TZ) +/- pertuzumab (PZ)) was initiated to assess the safety of the approach and evaluate the effect of PSK on NK cell activity, pro-inflammatory cytokine/chemokine profile; and HER2 vaccine-induced T cell immunity.

Methods: Up to 30 patients with HER2+ MBC who are without evidence of disease after definitive therapy and currently on maintenance TZ +/- PZ are enrolled and randomly assigned in equal numbers to 1 of 2 arms (15 patients/arm): Arm 1: HER2 ICD vaccine + placebo or Arm 2: HER2 ICD vaccine + PSK. All patients receive concomitant treatment with 4 months of daily oral PSK or placebo, 3 monthly intradermal HER2 ICD vaccinations and continued TZ +/- PZ. Toxicity is evaluated per CTEP CTCAE 4.0, during and post vaccination. Serial blood draws for immunologic evaluation of NK cell activity and antigen-specific T cell immunity via flow cytometry and IFN-γ ELISPOT, respectively; and pro-inflammatory cytokines/chemokines.

Results: 24 subjects have been enrolled and 60 vaccines have been given. 16 subjects have completed all 3 vaccines and PSK/placebo; and 6 subjects are currently in progress. 2 subjects received < 3 vaccines and were taken off study. Of 144 reported adverse events (AEs), 97% were Grade 1-2; 66 (46%) were possibly, probably, or definitely related to study treatment. Most common AEs are injection site reaction and flu-like symptoms. There have been a total of four Grade 3 AEs, 1 episode of self-limited nausea/vomiting attributed to study treatment; and cognitive disturbance, fatigue, and lymphopenia all in 1 subject and attributed to disease progression. There have been no Grade 4 AEs. Immunologic analyses are ongoing and will be presented along with completed clinical data on all patients.

Conclusion: Combination immunotherapy with PSK/placebo and concurrent HER2 directed therapy is safe and well-tolerated. Further ongoing immunologic studies will help define the immunogenicity of the approach.
Title: Serum IgG response against prostate-related antigen revealed by personalized peptide vaccination in patients with metastatic recurrent breast cancer

Toh U, Okabe M, Iwakuma N, Mishima M, Shichijo S, Yamada A, Noguchi M, Itoh K and Akagi Y. Kurume University School of Medicine, Kurume, Fukuoka, Japan and Kurume University Cancer Vaccine Center, Kurume, Fukuoka, Japan.

Body: Purpose: We have indicated that IgG and CTL boosting response could be a potential prognostic factor for overall survival (OS) and progression free survival (PFS) in metastatic recurrent breast cancer (mrBC) patients, who had received personalized selected peptide vaccine (PPV) therapy in our previously reported clinical phase II study. The aim of this study is to identify the prognostic role of serum value of IgG antibody against prostate related-antigen (PRA), including prostate-specific antigen (PSA), prostate specific membrane antigen (PSMA) and prostate acid phosphatase (PAP) in mrBC patients.

Methods: Peripheral blood samples of 77 patients with mrBC were analyzed for serum anti-PRA IgG levels before and after 6th and 12th PPV therapy prospectively. Most of the peptides using for PPV are derived from cancer associated antigens expressing in various types of advanced cancers, but the peptides derived from PRAs were not used in this study.

Results: After PPV therapy, total serum levels of anti-PRA IgG were significantly increased in 31 mrBC patients (Group 1) whereas in remaining 46 rmBC patients (Group 2). Either serum anti-PSA, anti-PAP and/or anti-PMSA IgGs showed a significant increase in patients of Group 1 after 6th (p=0.045) and 12th PPV treatment (p < 0.001), irrespective of their intrinsic subtypes. The median PFS and median OS of Group 1 patients were 8.1 and 14.3 months, while those of Group 2 patients were 5.1 and 10.8 months, respectively. Anti-PRA IgG levels were significantly associated with PFS (p=0.0073; HR: 0.37) and OS (p=0.025; HR: 0.43) between these two groups, whereas no significant relation was found with age, clinical response rate and recurrent metastatic status.

Conclusions: The Group 1 patients with elevated anti-PRA IgG may have better prognosis compared to Group 2 patients who showed no IgG elevation after PPV treatment for rmBC. These results indicated a clinical significance between pre-and post-treatment measurement of serum anti-PRA IgGs in mrBC patients receiving PPV therapy, and may be a useful prognostic marker for monitoring the outcome to PPV treatment of breast cancer.
**Title:** Overall survival in inflammatory breast cancer patients receiving Her-2 Neu directed tumor vaccine therapy: Matched comparison with SEER registry patients

**Body:**

**Background**
 Patients with inflammatory breast cancer (IBC) have a poor prognosis, primarily due to distant dissemination. Additionally, IBC patients have an increased rate of HER2 overexpression when compared to patients with non-inflammatory breast cancer. The forms the rationale for HER2 directed tumor vaccine therapy in these patients. The purpose of this study was to examine overall survival in IBC patients receiving HER2 directed tumor vaccine therapy when compared with matched control patients from the SEER Registry.

**Methods**
 Patients with diagnosis of Stage III or IV HER2 positive IBC having completed standard initial therapy and without evidence of disease received HER2 vaccinations after being enrolled on 5 prospective clinical trials. Overall survival data were pooled and analyzed. A control group of matched IBC patients were identified by querying the SEER database from 1997-2011. The control group was identified as any individual in the database with a code for IBC. A secondary analysis comparing survival in HER2 positive IBC vs HER2 negative IBC patients was performed by querying the SEER database from 2010 onwards, the time point when the HER2 status was coded in the database. Propensity score adjustment were made to the control group to account for any imbalances between groups in measured covariates such as stage, race, age, sex, and era of enrollment and the time interval from diagnosis to enrollment on vaccine trial (median ~2 years).

**Results**
 A total of 37 IBC patients received HER2 directed vaccine therapy and 676 patients were identified for the SEER control group; Stage at enrollment: stage IIIB: 30 patients in the vaccine group and 639 patients in the control group; stage IIIC: 1 patient in the vaccine group and 15 patients in the control group; stage IV 6 patients in the vaccine group and 22 in the control group. The median survival of the overall population was 112 months for the vaccine group and 47 months for the control group (p=0.04). After using propensity scores to adjust the control for imbalances in measured covariates, the median survival for the overall population was 112 months for the vaccine group and 37 months for the control group (p=0.03). There was no difference in survival between HER2 positive and HER2 negative IBC patients in the control group (p=0.6).

**Conclusion**
 These results demonstrate promising overall survival in HER2 positive IBC patients receiving HER2 directed vaccine therapy after initial therapy. Propensity matching was performed to adjust for imbalances in measured covariates and resulted in a modest decrease in survival of the control group after adjustment, suggesting that the vaccine trial group had relatively unfavorable pre-treatment characteristics. Despite these unfavorable characteristics, patients receiving vaccine had a median survival of 112 months. These results must be further confirmed in a prospective randomized trial.

Title: Safety and clinical activity of atezolizumab (anti-PDL1) in combination with nab-paclitaxel in patients with metastatic triple-negative breast cancer

Adams S, Diamond J, Hamilton E, Pohlmann P, Tolaney S, Molinero L, Zou W, Liu B, Waterkamp D, Funke R and Powderly J. New York University Langone Medical Center, NY, NY; University of Colorado Anschutz Medical Campus, Aurora, CO; Sarah Cannon Research Institute, Nashville, TN; Georgetown Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC; Dana-Farber Cancer Institute, Boston, MA; Genentech, Inc, South San Francisco, CA and Carolina BioOncology Institute, Huntersville, NC.

Body: Background: Metastatic triple-negative breast cancer (mTNBC) is associated with poor prognosis, and chemotherapy remains the mainstay of treatment. Cancer immunotherapy represents a promising treatment approach for mTNBC, which is characterized by a high mutation rate, increased levels of tumor-infiltrating lymphocytes and high programmed death ligand-1 (PD-L1) expression levels. Atezolizumab (atezo; MPDL3280A) is a humanized monoclonal antibody that can restore tumor-specific T-cell immunity by inhibiting the binding of PD-L1 to PD-1. Atezo has demonstrated durable responses as monotherapy in mTNBC (Emens et al, AACR 2015). In addition, high objective response rates (ORRs) and durable responses have been observed with atezo plus chemotherapy in patients with non-small cell lung cancer (Liu et al, ASCO 2015). This study is the first combination trial of a checkpoint inhibitor with chemotherapy in patients with mTNBC.

Methods: This arm of a multicenter, multi-arm Phase Ib study (NCT01633970) evaluated atezo in combination with weekly nab-paclitaxel in patients with mTNBC. Primary endpoints were safety and tolerability, with secondary endpoints of PK and clinical activity. Key eligibility criteria included measurable disease, ECOG PS 0/1 and ≤ 2 prior cytotoxic regimens. Patients received atezo 800 mg q2w (days 1 and 15) with nab-paclitaxel 125 mg/m² q1w (days 1, 8 and 15) for 3 weeks in 4-week cycles, continued until loss of clinical benefit. If nab-paclitaxel was discontinued due to toxicity, atezo could be continued as monotherapy. ORR was assessed by RECIST v1.1. PD-L1 expression was scored at 4 diagnostic levels based on PD-L1 staining on tumor cells and tumor-infiltrating immune cells with the SP142 immunohistochemistry assay.

Results: As of February 10, 2015, 11 patients were evaluable for safety. All patients were women with a median age of 58 y (range, 32-75 y). No unexpected or dose-limiting toxicities were observed. The median duration of safety follow-up was 79 days (range, 27-182 days). The efficacy-evaluable population consisted of 5 patients who had ≥ 1 scan and ≥ 3 months follow-up. Four PRs and 1 SD were observed. By the next data cutoff of June 15, 2015, 21 patients will have been enrolled (7 in the safety cohort and 14 in the expansion cohort). All patients in the expansion cohort were required to undergo serial biopsies for correlative analyses. Approximately 21 and 19 patients will be evaluable for safety and efficacy, respectively. Updated safety, efficacy and biomarker data will be presented.

Conclusions: Preliminary results indicate that the combination of atezo plus nab-paclitaxel is tolerable with promising activity in patients with mTNBC. Based on these results and the observed activity of single-agent atezo in these patients, the combination of atezo and nab-paclitaxel is being evaluated in a Phase III study (NCT02425891) of patients with previously untreated mTNBC. Sponsor: Genentech, Inc. ClinicalTrials.gov: NCT01633970.

Title: Mutually exclusive expression pattern of the immune co-inhibitory molecules B7-H4 and PD-L1 in triple negative breast cancer

Body: B7-H4 (VTCN1, B7x, B7S1) is a transmembrane protein belonging to the B7 family of costimulatory proteins and has been shown to inhibit T cell proliferation, cytokine secretion, and cytotoxic lymphocyte (CTL) induction. B7-H4 expressed on tumor cells or macrophages has been associated with poor prognosis and impaired T cell function in renal cell and ovarian cancers. Here we show B7-H4 is abundantly expressed in human breast cancer with triple negative breast cancer (TNBC) having the highest overall B7-H4 mRNA expression. We developed a specific and sensitive immunohistochemistry (IHC) assay for evaluation of B7-H4 protein and quantified B7-H4 expression in 156 breast tumor samples. Approximately 70% of the breast tumor samples had detectable B7-H4 expression whereas none of the normal or benign breast tissues stained positive for B7-H4. Multiplex IHC and flow cytometry studies showed that the majority of B7-H4 expression was restricted to the tumor epithelial cells, the CD45+ immune cells were negative for B7-H4 expression. Interestingly none of the TNBC samples that were positive for B7-H4 showed detectable expression of PD-L1 suggesting that B7-H4 and PD-L1 checkpoint proteins may act in a mutually exclusive manner. To evaluate the role of B7-H4 on tumor immune evasion, we overexpressed murine or human B7-H4 on the mouse colon-26 (CT26) tumor cell line and injected these cells intravenously into Balb/c mice. By day 14 we observed significantly more tumors as well as larger percent tumor area in the lungs of mice given CT26 cells transduced with human or mouse B7-H4 as compared to vector control transduced cells. These data suggest B7-H4 expression in tumors can accelerate tumor growth in immune competent mice and that targeting B7-H4 may provide therapeutic benefit. Given the mutually exclusive expression patterns of B7-H4 and PD-L1 a B7-H4 targeting agent may provide particular benefit in those patients where current anti-PD-1/PD-L1 therapies are not effective.
Title: Abstract Withdrawn
Title: A phase 2 randomized trial of the IDO pathway inhibitor indoximod in combination with taxane based chemotherapy for metastatic breast cancer: Preliminary data

Tang S-C, Montero A, Munn D, Link C, Vahanian N, Kennedy E and Soliman H. Georgia Regents University, Athens, GA; Cleveland Clinic, Cleveland, OH; NewLink Genetics, Ames, IA and Moffitt Cancer Center, Tampa, FL.

Body: Background: Indoleamine 2,3 dioxygenase (IDO) is a tryptophan-catabolizing enzyme that plays a key role in the normal regulation of peripheral immune tolerance. Tumors also employ this mechanism to induce a state of immunosuppression, evading immune mediated destruction. Indoximod (D-1-methyltryptophan) is a broad IDO pathway inhibitor as it has been shown to potentially interfere with multiple targets within the IDO pathway. Preclinical studies in MMTV-neu mouse models have demonstrated that combining indoximod with cytotoxic chemotherapy had a greater in-vivo anti-tumor effect than either agent alone. A phase 1 trial combining docetaxel and indoximod demonstrated safety and responses in metastatic breast cancer (mBC) patients. Based on these data a phase 2 trial evaluating indoximod in combination with taxane chemotherapy as first line therapy in patients with metastatic breast cancer was initiated.

Methods: The study is a 1:1 randomized, placebo controlled, four arm phase 2 trial. The study treatment is docetaxel 75mg/m2 IV D8 plus indoximod 1200mg PO BID D1-14 every 21 days or matching placebo in study arms 1A and 2A or paclitaxel 80 mg/m2 IV weekly 3 out of 4 weeks with indoximod or matching placebo given BID Days 1-14 in arms 1B and 2B. The primary endpoint is progression free survival. Secondary endpoints include overall survival, response rate, safety, and immune response correlative assays. Patients with measurable, histologically confirmed mBC, no prior chemotherapies (hormonal therapies allowed) in the metastatic setting, ER+ or ER –, HER2 -, ECOG PS 0-1, no active CNS disease, no active autoimmune disease are eligible. Target enrollment is 154 patients.

Results: At submission, 65 patients have evaluable safety data on trial. The pooled, blinded data was evaluated for any safety signals. Patient demographics include median age 58 years, 95% female, 17% African American, 25% triple-negative disease, and 82% with multiple sites of metastatic disease. 28% of patients had at least one Grade 3 or 4 adverse event. Those occurring in multiple patients include dyspnea 5%, pleural effusion 3%, non-cardiac chest pain 3%, and febrile neutropenia 3%. Most patients had at least one adverse event (86%). The most common were anemia 14%, tearing 11%, constipation 19%, diarrhea34%, nausea 44%, vomiting 22%, fatigue 48%, peripheral edema 17%, increased liver function tests 10%, lymphopenia 17%, hyperglycemia 15%, myalgia 14%, dizziness 14%, dysguesia 16%, headache 20%, peripheral neuropathy 12%, dyspnea 19%, alopecia 34%, and rash 14%, all compatible with the side effect profile of single agent taxanes. No immune specific serious advents were reported. No treatment related deaths have been reported.

Conclusion: The aggregate safety data for these 65 patient are similar to what is typically observed with docetaxel and paclitaxel. No unexpected serious immune linked adverse events were reported. The trial is currently open at multiple clinical sites in the US and Europe and actively enrolling patients. Updated data will be presented. NCT01191216.
Title: Epigenetic immune modulation by entinostat in breast cancer: Correlative analysis of ENCORE 301 trial

Body: Background: Entinostat, a class I HDAC inhibitor (HDACi), has shown promising activity in ENCORE 301, a randomized, placebo-controlled, phase II trial of entinostat + exemestane (EE) vs. exemestane + placebo (EP) in advanced hormone receptor-positive breast cancer progressed on nonsteroidal aromatase inhibitors. ENCORE 301 met the primary progression free survival endpoint and showed a median 8.3-month improvement in the overall survival (OS) exploratory endpoint for the EE arm. Emerging preclinical work suggests that entinostat has immunomodulatory effects and can eradicate modestly immunogenic mouse tumors in combination with immune checkpoint blockade agents via reduction of circulating myeloid-derived suppressor cells (MDSC). Based on these data, we conducted an analysis of immune subsets in blood samples from ENCORE 301 breast cancer patients.

Method: Blood was collected from a subset of 49 patients (27 EE and 22 EP) representative of the 130 patients enrolled in ENCORE 301 on cycle 1 day 1 (C1D1; pre-treatment), C1D2, C1D8, and C1D15 for biomarker analysis. Of these, 34 patient samples (20 EE and 14 EP) were analyzed for circulating immune subsets. The percent change in subsets at C1D15 vs. baseline was assessed based on the following surface markers: Lin-MDSC (lin; CD3, CD19, CD56)-HLA-DR-CD11b+CD33+), granulocytic MDSC (CD14-CD11b+CD33+), monocyctic MDSC (Lin-HLA-DR-CD11b+CD33+CD14+), immature MDSC (Lin-HLA-DR-CD11b+CD33+CD14-), CD8+ T-cells (CD4-CD8+), Foxp3-CD4+ T-cells (CD8-CD4+Foxp3-), and Tregs (CD4+CD8-CD25hiFoxp3+). Monocytes were analyzed for three populations: CD14+, CD14+HLA-DRhi, and CD14+HLA-DRlow/negative. In addition, PD-1, CTLA-4, and TIM-3 were measured on T-cell subsets, and CD40 was measured on MDSCs.

Results: In line with preclinical data, we observed a significant reduction in granulocytic MDSC (-14.67% vs. +20.56%, p 0.029) and monocyctic MDSC (-62.3% vs. +1.97%, p 0.002) in EE. Entinostat did not alter immature MDSC levels (-20.9% vs. -15.0%, p 0.93) suggesting a downstream effect of entinostat on MDSC subsets. Interestingly, CD40, a costimulatory receptor required for MDSC-mediated immune suppression was significantly down-regulated in all MDSC subsets except granulocytic MDSC where a downward trend was observed. Entinostat did not significantly impact the ratio of CD8+ T-cells per CD4+ T-cells or per Tregs or alter expression of CTLA4, PD-1, or TIM3 on T-cell subsets. Reduced expression of HLA-DR on monocytes has been associated with poor prognosis in cancer. Consistent with entinostat-mediated immunomodulatory effects, a significant increase in the number of HLA-DR+ monocytes (34.1% vs. -11.38%, p 0.0004) and level of HLA-DR expression on monocytes (16.3% vs. -4.7%; p 0.015) was observed.

Conclusion: Data with entinostat combined with exemestane in ENCORE 301 provide the first evidence of HDACi-mediated reduction of immunosuppressive MDSCs and increased immunocompetent CD14+HLA-DRhi monocytes in patients. These findings may explain the improved OS seen with EE in ENCORE 301 and provide strong rationale for planned combination studies of entinostat with immune checkpoint blockade agents.

Title: Phase II trial of exemestane with immunomodulatory oral cyclophosphamide in metastatic hormone receptor (HR)-positive breast cancer: Prolonged progression-free survival (PFS) in patients with distinct T regulatory cell (Treg) profile

Body: Background: Resistance to endocrine therapies in HR-positive breast cancer is a significant challenge. The steroidal aromatase inhibitor (AI) exemestane (EXE) has demonstrated short-term efficacy in metastatic HR-positive HER2-negative breast cancer (mHR⁺BC) that has progressed during treatment with a non-steroidal AI. Combination strategies have not shown a survival benefit. Immunotherapy represents a promising approach as it may increase durability of responses. Low dose cyclophosphamide (CTX) has demonstrated efficacy in combination with neoadjuvant letrozole in HR⁺BC, conceivably by enhancing anti-tumor immune responses. Here we investigated whether EXE combined with immunomodulatory CTX could provide durable responses in heavily pretreated patients and assessed immunological profiles (NCT01963481).

Methods: Phase II trial of EXE (25mg PO daily) with CTX (50 mg PO daily) enrolled postmenopausal women (n=23) with mHR⁺BC who had progressed on prior endocrine therapy (including nonsteroidal AI, tamoxifen, and/or fulvestrant); prior chemotherapy was allowed. The primary endpoint was PFS (per RECIST 1.1) at 3 months; secondary endpoints were response rate, tolerability, and immune correlates. Detailed functional immune profiling of peripheral T cell subsets were performed by flow cytometry at baseline, 1, 3, 6, 9 & 12 months, with healthy donors available as controls.

Results: All 23 patients have been enrolled, and 21 are evaluable for response. Median age was 54 (range 31-77), median prior lines of endocrine therapy was 2 (1-3) and chemotherapy was 1 (0-5). The majority (15/23) had visceral organ involvement. Combination treatment was well tolerated with one grade 3 urinary tract infection but no grade 4 or 5 toxicity. An objective response was observed in 19% of patients (4/21, 1 CR and 3 PR) and an additional 33% (7/21) had SD, resulting in a 3-month-PFS of 48.5% (95% CI, 30.5-77.1). Responses were durable in all patients, lasting ≥/> 9 months and included patients with liver metastases. Comparison of peripheral immune cell subsets of patients (n=16) at baseline to age/sex-matched healthy controls demonstrated an increased proportion of CD4⁺ memory T cells with central memory phenotype (CD45RO⁺CD27⁺, p<0.0001). When patients were stratified based on PFS at 3 months, the proportion of naïve Tregs (CD4⁺CD45RO⁻FOXP3⁺Helios⁺) at baseline was significantly lower (p=0.003) in the non-progressor group compared to patients with progression. Remarkably, when these patient groups were compared for changes in T cell subsets during treatment, the proportion of both naïve and memory Treg subsets increased from baseline to 3 months (p<0.01), but only in the non-progressor patient group. While preliminary, these findings are possibly indicative of novel predictive biomarkers.

Conclusion: EXE and CTX had a favorable safety profile with evidence of clinical activity in patients with heavily pretreated mHR⁺BC, including durable responses in liver and bone. Correlative studies are ongoing to identify potential biomarkers of response or resistance to therapy.
**Title:** Novel protocol combining metronomic nant-paclitaxel with HER2-targeted natural killer cells (innate immunotherapy) for HER2-positive metastatic breast cancer

Rabizadeh S, Simon B, Klingemann H, Sims D, Weiss R and Soon-Shiong P. NantCell, Inc, Culver City, CA; NantKwest, Inc, Culver City, CA and Windber Medical Center, Windber, PA.

**Body:**

**Background.** Natural killer (NK) cells are an important effector cell type for adoptive cancer immunotherapy. Phase 1 clinical trials in patients with advanced cancers demonstrated the safety of unmodified, activated NK-92 cells (aNK), with no evidence of cytokine storm from 18 infusions delivered over 6 months; clinical responses were observed in a subset of patients. Like T cells, NK cells can be engineered to express chimeric antigen receptors (CARs) to enhance their antitumor activity. A stable clonal HER2-specific NK-92 cell line (HER2.taNK) mediated selective and sequential killing of HER2-expressing MDA-MB-453 cells in vitro (Schönfeld. *MolTher.* 2015;23:330-338). In addition, HER2.taNK cells were enriched in MDA-MB-453/EGFP xenografts and reduced the number of pulmonary metastasis in a renal cell carcinoma model, suggesting that HER2.taNK cells are a promising clinical candidate for use in adoptive cancer immunotherapy. Metronomic (low-dose, continuous) chemotherapy can be more effective than high-dose therapy in patients with advanced breast cancer (Montagna. *Canc. Treat. Rev.* 2014;40:922-950). Here we evaluate HER2.taNK cells in combination with metronomic nant-paclitaxel (lyophilized polymeric micellar formulation of paclitaxel) in a mouse model of HER2-positive breast cancer to determine the feasibility of a human clinical trial of HER2.taNK in combination with metronomic nant-paclitaxel.

**Methods.** HER2.taNK cells were generated as described previously (Schönfeld. *MolTher.* 2015;23:330-338). MDA-MB-453 cells were implanted into the mammary fat pads of female nude mice. When tumors reached 100 mm$^3$, mice were divided into 6 groups of 5 mice and dosed (IV) with saline (10 mL/kg, qd x 15), nant-paclitaxel (2.5-4 mg/kg q2d x 15), γ-irradiated (5 Gy) HER2.taNK cells (1 x 10$^7$ cells, days 1, 3, 5, and 8), or nant-paclitaxel + γ-irradiated (5 Gy) HER2.taNK cells—γ-irradiation is a potential safety measure for clinical application and prevents HER2.taNK cell replication while preserving antitumor activity. Tumor size and animal weights were measured every other day post-implantation.

**Results:** Results obtained 20 days post-treatment are shown in the table. Nant-paclitaxel alone and HER2.taNK alone significantly inhibited tumor growth. The combination of nant-paclitaxel + HER2.taNK led to significant tumor regressions (p<0.05).

**Conclusions:** Single agent nant-paclitaxel and HER2.taNK were similarly effective at inhibiting tumor growth in this mouse model of HER2+ breast cancer. The combination of nant-paclitaxel + HER2.taNK appeared to be synergistic resulting in tumor regressions and significantly better efficacy vs each agent alone. This study illustrates the potential for combining metronomic low-dose chemotherapy with NK-based immunotherapy in a clinical trial of patients with metastatic breast cancer.
Title: 3 years follow-up results of arm node preserving surgery

Park J, Yeu KJ, Choi JE, Kang SH, Bae YK and Lee SJ. Yeungnam University College of Medicine, Daegu, Republic of Korea and Yeungnam University College of Medicine, Daegu, Republic of Korea.

Body: Background: Arm nodes can be identified by using axillary reverse mapping technique during axillary lymph node dissection. Many articles reported about feasibility of arm node preserving surgery for preventing lymphedema in breast cancer patients. But there are only a few studies about long-term follow-up results. The purpose of this study is to evaluate the incidence of lymphedema and the rate of regional recurrence and distant metastasis after arm node preserving surgery for 3 years follow-up period.

Methods: From January 2009 to October 2014, 167 breast cancer patients who underwent axillary reverse mapping were included. Before axillary lymph node dissection, 2.5mL of blue dye was injected in the medial intermuscular groove of the ipsilateral upper arm, subcutaneously. After elevation of the arm for at least 15 minutes, axillary lymph node dissection was performed. Blue-dyed lymph nodes and lymphatics were identified and preserved unless they showed radioactivity or suspiciousness for metastasis. Bilateral upper arm circumferences were measured preoperatively and postoperatively in all patients. Over 2cm circumference difference between ipsilateral and contralateral upper arm was defined as lymphedema. Follow-up studies such as ultrasound, mammography and/or PET were checked every 6 months for 5 years and then annually.

Results: 125 patients had their arm node preserved and 42 patients had their arm node removed. The mean number of harvested nodes was 17.85±6.74 in arm node preserved group and 20.17±6.08 in arm node removed group (p=0.050). The mean number of identified arm nodes was 1.35±0.84. The mean follow-up period was 40.25±20.57 months. 15 patients complained subjective symptoms of lymphedema, 3 patients in arm node preserved group and 12 patients in arm node removed group (2.4% vs 28.6, p<0.001). Among them, only 6 patients in arm node removed group were diagnosed with lymphedema by objective criteria whereas in arm node preserved group, there was no actual lymphedema (14.3% vs 0%, p<0.001). The mean measured circumference difference between ipsilateral and contralateral upper arm was 0.19±0.66 in arm node preserved group and 0.67±0.92 in arm node removed group (p=0.003). There were 11 cases of distant metastasis with a median time to metastasis of 30 months, 9 cases in arm node preserved group, 2 cases in arm node removed group (7.2% vs 4.8%, p=0.732). Among them, two patients whose arm nodes were preserved had ipsilateral axillary recurrence simultaneously (p=1.000). 5-year disease-free survival was 92.7% in arm node preserved group and 85% in arm node removed group (p=0.963)

Conclusion: Arm node preserving surgery during axillary lymph node dissection in breast cancer patients can reduce the incidence of lymphedema and it can be performed safely without increase of the rate of regional recurrence and distant metastasis.

Publication Number: P2-12-02

Title: Axillary reverse mapping: A feasibility study

Khare S, Singh G, Das A and Bal A. PGIMER, Chandigarh, Chandigarh, India.

Body: Background

The mainstay of the therapy in breast cancer has been mastectomy or wide local excision along with axillary lymph node dissection (ALND). There are a lot of adverse effects associated with ALND, lymphedema being the most devastating. Sentinel lymph node biopsy (SLNB) can identify women who may or may not need axillary dissection and translate into a smaller number of patients undergoing axillary dissection. However, patients having positive lymph node on SLNB will still have to undergo ALND. To reduce the occurrence of lymphedema and its associated complications the technique of Axillary Reverse Mapping (ARM) has been developed. It is based on the hypothesis that the lymphatic pathway of the arm is not involved by the metastasis of the breast primary and after accurately identifying and preserving the arm lymphatics, there would be risk of neither lymphedema, nor leaving behind metastatic cells in the lymph nodes. This prospective study was carried out to evaluate the feasibility of ARM in patients undergoing ALND.

Methods

This prospective study was carried out in the Department of General Surgery, PGIMER, from July 2010 to Dec 2011. There were seventy five Biopsy/FNAC confirmed breast cancer female patients between 18 to 75 years. All patients were undergoing ALND as part of their treatment. Patients with any prior surgical treatment for primary invasive breast cancer, bilateral breast cancer and metastatic breast disease were excluded. Patients with heart diseases, active or uncontrolled infection, dementia, altered mental status or any psychiatric condition, pregnant or lactating women and with known allergies to blue dye were also excluded. All patients were treated as per the standard treatment for stage. All ALNDs were performed by a single surgeon. ARM was performed in all the patients by giving 5 ml of Isosulfan Blue Dye (Sterlized 1% solution) in the upper inner arm of the involved site approximately 60 minutes before exposure.

Results

The results were analyzed clinically during surgery and post-operatively by histo-pathological examination of lymphnodes. Intra-operatively, the identification of lymphnodes and lymphathics were noted in 17(22.7%) and 33 patients(44%) respectively. In none of the patient any attempt was made to preserve the blue nodes and all the lymph nodes were resected and sent for histopathological examination. In only 2 of 17 patients (11.76%) the lymph node was positive for malignant tumour cells. The tumour burden in both these patients was very high (more than 10 nodes involved). No association was found in the identification rates of ARM nodes and lymphatics to age, BMI, size of tumour, site of tumour, pathological status of axilla and timing of dye.

Conclusion

The identification rate of ARM lymphatics and nodes is low when only blue dye is used. The method appears it to be oncologically safe in patients with low tumour burden. However there is need for further studies will before this procedure can be universally applied without compromising the oncologic safety.

Once the technique is proven to be oncologically safe even in a selected group of patients, a large randomized trial will be needed to give a satisfactory answer whether the problem of lymphedema be eliminated or minimized in the patients in whom arm lymphatics are successfully preserved.
Title: Endofascial axillary lymphadenectomy – Towards a drainless protocol

Meredith IC C, Popadich A, Mouat CH H, Barrett K and King B. North Shore Hospital, Auckland, New Zealand; Wellington Hospital, Wellington, New Zealand and The Breast Centre, Wellington, New Zealand.

Body: Background:
The pathogenesis of seroma formation following axillary dissection continues to be poorly understood, although it seems that the greater the surgical disruption of the axilla, the higher the incidence of seroma and lymphoedema. We have previously described the laminated, three-dimensional structure of the clavipectoral fascia (CPF) that is evident during axillary ultrasonography and dissection. We propose that reconstituting the CPF reduces dead space, partially restores pressure gradients and facilitates collateralization to improve lymphatic flow, thereby reducing the incidence of seromas. Herewith, is a description of our technique for reconstitution of the CPF and our experience thus far.

Method:
Technique:
Following mastectomy or breast conservation surgery, the lateral border of pectoralis major is defined. Here, the medial, anterior laminae of the CPF are identified but not incised. Once the anterior extent of the CPF is displayed, a longitudinal incision is made through the midpoint of the CPF to access the axillary contents. If there is a substantial axillary tail, then the CPF is incised along the perimeter of the tail to include intra-mammary lymph nodes. A loose areolar tissue plane is encountered; the edges of the CPF are grasped and elevated and this areolar tissue plane developed by blunt and sharp dissection. Medially, this loose areolar tissue plane leads directly to a posterior gutter, and the long thoracic nerve on serratus anterior is identified and preserved. Superiorly, a deeper lamina of the CPF along the inferior border of the axillary vein has to be incised to find the thoracodorsal nerve. Identification of the intercostobrachial nerves is standard, as is the lateral dissection. Identification of the long thoracic nerve and thoracodorsal bundle results in definition of a vertical sheet, ‘the interneural tissue’. This can be grasped between the thumb and index finger and is excised en bloc. This tissue contains fat, lymph nodes and lymphatic vessels and is lined by thin fascial layers that we consider related to the CPF3.
At this stage, the anterior laminae of the CPF and axilla are carefully palpated for any residual nodes. After haemostasis, the CPF is reconstituted with a running, absorbable ‘lymphostatic' suture. No drain is placed in the axilla.

Results:
Between 2012 – 2015, 64 patients have undergone axillary dissection with reconstitution of the CPF in our unit. The average age was 54 years (range 29-87 years). An average of 12 nodes were procured (range 2-26 nodes). Only 5 women (8%) required seroma aspiration.

Conclusion:
We have dispensed with axillary drains in those who have had reconstitution of the CPF and only a minority of our patients required axillary seroma aspiration. We believe this technique should be given consideration to decrease the use of drains following axillary dissection.
Title: Is there any benefit to perform extensive nodal dissection in primary or recurrent aggressive form of breast cancer?

Berliere M, Duhoux F, Nardai P, Schmitz S, Taburiaux L, Galant C, Leconte I, Piette P and Lengele B. Cliniques Universitaires St Luc, King Albert II Cancer Institute, Brussels, Belgium and Grand Hopital de Charleroi, Charleroi, Belgium.

Body: Background: Breast oncologic surgery and especially nodal surgery has become ever more minimally invasive. However, some aggressive breast cancers exhibit at their primary or recurrent presentation extensive nodal invasion at the axillary, retropectoralis and sometimes supraclavicular and cervical levels. Surgical treatment of these tumors is not standardized.

Material and methods: Between January 2012 and April 2015, 7 primary breast cancer patients (group I) and 7 recurrent breast cancer patients (group II) were included in a prospective, non randomized study approved by our local ethics committee. All the patients had cytologically proven retropectoralis and infraclavicular lymph node invasion and 7 of them had cytologically proven cervical lymph node invasion (5 in the group of primary tumors and 2 in the group of recurrences). Four of the 7 primary tumors were triple negative and 3 were HER2 positive tumors, while 4 out of the 7 recurrent tumors were triple negative and 3 were HER2 positive. All the patients underwent PET/CT and breast MRI at baseline. Visceral metastases were absent in all cases. In the group of primary tumors, all the patients were treated with neoadjuvant chemotherapy (plus trastuzumab for the 3 HER2 positive tumors); in the group of recurrent tumors, neoadjuvant chemotherapy associated with trastuzumab was administered in 3 patients, while the 4 other patients underwent complementary mastectomy plus extensive nodal surgery followed by chemotherapy. Radiotherapy was administered in all primary breast cancer patients and cervical radiotherapy was administered in 3 of the 7 recurrent diseases. The following parameters were assessed: disease-free survival, overall survival and adverse events of surgical treatment.

Results: All the patients are still alive after a relatively short mean duration of follow-up [24 months in group I (6 to 40 months) and 29 months in group II (3 to 39 months)]. Six of the 7 patients in group I have no signs of recurrence, one has metastatic evolution (bilateral cervical and mediastinal node evolution) and is currently receiving chemotherapy in combination with a PARP inhibitor. In group II, 6 of the 7 patients have no signs of recurrence and one has metastatic evolution (inguinal nodes and bone metastases), treated with chemotherapy and HER2-targeted therapy. The major adverse event is arm lymphedema, affecting 4 out of 14 patients (28%). No persistent pain nor motor troubles are noted.

Discussion: Patients with nodal metastases outside the axilla seem to benefit from extensive surgery integrated in a multidisciplinary therapeutic approach. Some studies have demonstrated survival benefits for patients undergoing surgical resection of these nodes.

Conclusion: In aggressive breast tumors (HER2 positive or triple negative tumors) presenting with extensive nodal invasion, surgical excision of these nodal metastases must be integrated in the multidisciplinary treatment and patients need to be followed prospectively for a long time to confirm survival benefits.
Trans-peri-areolar breast conservative surgery followed by endoscopic axillary lymph node dissection: A novel surgical option

Objective
Endoscopic surgery currently is a standard method in most surgical fields. Although endoscopic breast surgery has been introduced since 1993, it is not widely applied due to limited benefits. Changing the conventional local treatment may require new attempts that enhance cosmetic outcomes and diminish complication rates. We report the cosmetic outcomes and postoperative complications of a breast conservative surgery (EBCS) procedure, which consists in using a 3cm peri-areolar incision to perform lumpectomy, and followed by endoscopic axillary lymph node dissection without liposuction.

Patients and methods
From Nov 2013 till May 2015, 53 patients diagnosed with early stage breast cancer were categorized into the conventional breast conservative surgical group (CBCS) and EBCS group.

Indications for EBCS were
1. tumor/breast ratio below 20%
2. no distant metastasis
3. Tumor mass not located in the lower-inferior quadrant.

Inform consents were obtained from all patients. 25 patients were enrolled in the EBCS and 28 patients in the CBCS group.

Number of lymph nodes harvested, tumor size, intra-operative bleeding, drainage volume, pain score (10scale survey) were collected.

The breast symmetrical score (BSS, direct distance from nipple to fovea jugularis, midclavicular, midsternal, inframammary fold and anterior axillary line of both breast was measured 3days after surgery and distance difference ratio of operated to contralateral site was calculated. BSS is the sum of each absolute value of distance difference ratio) and patient satisfaction (4scale survey) were used to evaluate cosmetic outcomes.

Results
There was no statistical difference in intra-operative bleeding (EBCS:36.00±17.08ml, CBCS:29.29±19.99ml, P=0.20) and drainage volume (EBCS:124.60±50.22, CBCS:120.82±74.58, P=0.832). An increased number of harvested lymph nodes was observed in the EBCS group (EBCS:17.88±6.21, CBCS:14.25±5.82, P=0.03). No statistical difference reported for lymph metastasis among two groups (EBCS:1.68±3.59, CBCS:0.96±1.45, P=0.34). The average tumor size showed no difference (EBCS: 2.41±0.87, CBCS:1.96±0.95, P=0.07). The pain score (EBCS:3.88±1.53, CBCS:4.39±0.74, P=0.04) meanwhile BSS was significantly superior in the EBCS group (EBCS:0.097±0.084, CBCS:0.20±0.13, P=0.002). Patient satisfaction survey reported a positive feedback (EBCS:4.00±0.00, CBCS:3.68±0.48, P=0.001).

Conclusions.
We evaluated cosmetic outcome using a thorough BSS as an index plus adding the lack of scar in the axilla. EBCS patients
displayed a significantly superior outcome in comparison with CBCS, which was further appraised by a considerable satisfied patient's feedback.

Evaluation of long-term survival, complication rates and cosmetic results are mandatory in order to further estimate the applicability of this surgical management in treatment of breast cancer. EBCS may be a feasible surgical alternative with minimal invasiveness, suitable to patients demanding excellent cosmetic outcome.

Title: Prevention of seroma formation after mastectomy by local methylprednisolone injection - A randomized controlled clinical trial

Qvamme G, Axelsson CK, Lanng C, Wegeberg B, Mortensen MB, Okholm M, Arpi MR and Szecsi PB. Copenhagen University Hospital Herlev, Herlev, Denmark; Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark; Copenhagen University Hospital Herlev, Herlev, Denmark and Copenhagen University Hospital Gentofte, Hellerup, Denmark.

Body: Objective: To investigate the effect of local steroid administration on seroma formation until 14 days of dryness.

Background: Seroma formation, the most prevalent postoperative complication after mastectomy, is an inflammatory process that is potentially preventable via local steroid administration.

Methods: This double-blind, randomized, placebo-controlled intervention study included 212 women who were scheduled for mastectomy for primary breast cancer. The patients were classified according to the surgical axillary procedure: mastectomy with sentinel lymph node biopsy (M+SLNB) or mastectomy with level I-II axillary lymph node dissection (M+ALND). The participants received either 80 mg of methylprednisolone or saline intracavitary via the drain orifice upon drain removal.

Results: After M+SLNB, 46% (32 of 69) of the patients developed seromas in the steroid group vs. 78% (52 of 67) in the saline group (p<0.0001). The mean cumulative seroma volume in the intention-to-treat material for the first 10 and 30 days was significantly lower in the steroid group than in the saline group (24 vs.127 mL and 177 vs. 328 mL, respectively) (p<0.0001). After M+ALND, 94% of the patients developed seromas in both the steroid (35 of 37) and saline (34 of 36) groups, and steroid administration displayed no significant effect on seroma formation. Additionally, no difference in the infection rate was observed.

Conclusion: Methylprednisolone administered intracavitary on the first postoperative day after M+SLNB exerted a highly significant preventive effect against seroma formation during the first 30 days. Future studies may clarify whether higher or repeated steroid doses enhance these effects.
Title: Treatment of the breast in occult breast cancer: Results of a prospective Dutch national cohort study with 5 years follow up

de Maat M, Bretveld R, Steevens J, Vissers Y and Hulsewé K. Maastricht University Medical Center, Maastricht, Netherlands; Dutch National Cancer Registry, Utrecht, Netherlands; Maastricht University, Maastricht, Netherlands and Atrium-Orbis Medical Center, Heerlen - Geleen, Netherlands.

Body: Introduction
Occult breast cancer (cT0N+M0) is a rare diagnosis and there is insufficient evidence on which to base treatment of the ipsilateral breast.

Methods
From 2006 till 2008 the Dutch National Cancer Registry identified patients nationwide with possible occult breast cancer. These patients were diagnosed with axillary nodal metastases with no evidence of the primary tumor on physical examination, mammography and ultrasound. Data on histopathology, imaging diagnostics and treatment were collected. After a minimum of 5 years follow up, data on recurrence and survival were gathered and analyzed.

Results
A group of 71 patients with occult breast cancer was identified. Of these, 7 patients received no local therapy. The remaining 64 patients all underwent surgery with axillary lymph node dissection. Ninety-two percent had MRI of the breast. Three groups were formed: Group A (n=25) had surgery of the breast, group B (n=28) received breast irradiation and group C (n=11) consisted of patients who had no treatment of the breast. Recurrence in the ipsilateral breast was seen in 4 patients (14%) in group B and in 3 patients (30%) in group C. There was 1 local recurrence in group A after breast conserving treatment and no significant differences between groups. After a median of 85 months of follow-up, overall survival (72%, 82% and 82% for group A, B and C, respectively) and distant recurrence rates (12%, 11% and 10% for group A, B and C, respectively) were not significantly different between groups assessed by log-rank test.

Conclusion
In occult cT0N+M0 breast cancer, conservative treatment of the breast is an acceptable modality which results in similar distant recurrence and overall survival rates. Surgery and breast irradiation appear to reduce the risk of ipsilateral breast recurrence. This is the first prospective study that provides evidence in the current clinical setting to guide treatment for patients with occult breast cancer.
Oncologic outcomes after nipple-sparing mastectomy: A single-institution experience

**Body: Introduction:** Nipple-sparing mastectomy (NSM) is the latest advancement in the treatment of breast cancer. Long-term oncologic outcomes in nipple-sparing mastectomy (NSM) continue to be defined. Rates of locoregional recurrence for skin-sparing mastectomy (SSM) and NSM in the literature range from 0 to 14.3%. We investigated the outcomes of NSM at our institution.

**Methods:** Patients undergoing NSM at our institution from 2006 to 2014 were identified. Patient demographics, tumor characteristics, and outcomes were collected. Locoregional recurrence was compared to previously published NSM and SSM results compiled from 14 and 11 studies in the literature. Institutional review board approval was obtained prior to the initiation of this study.

**Results:** From 2006 to 2014, 319 patients (555 breasts) underwent NSM. 149 patients (248 breasts) had long-term follow-up available. Average patient age and BMI were 47.4 and 24.28. Eighty-five percent of patients underwent mastectomy primarily for a therapeutic indication. Average tumor size was 1.41 centimeters with the most common histologic type being invasive ductal carcinoma (66.7%) followed by DCIS (23.8%). Nodal disease was present in 14.8% of patients. Average patient follow-up was 30.72 months. There was one (0.7%) incidence of ipsilateral chest-wall recurrence in a 44 year-old (p<0.0001, compared to aggregate NSM and SSM data). There were 0.36 complications per patient. There were 3 incidences of nipple-areola complex (NAC) necrosis: 2 partial thickness necrosis and 1 full thickness necrosis.

**Conclusions:** We examined our institutional outcomes with NSM and found a locoregional recurrence rate of 0.7% with no nipple-areolar complex recurrence. This rate is significantly lower than aggregate published rates for both NSM and SSM.
Title: Long-term follow-up of nipple-sparing mastectomy for early-stage breast cancer without radiotherapy: A single-center study at a Japanese institution

Sakurai T, Suzuma T, Yoshimura G, Jinta E, Umemura T and Sakurai T.  Wakayama Medical University Kihoku Hospital, Ito, Wakayama, Japan; Kushimoto Arida Hospital, Kushimoto, Wakayama, Japan; Kishiwada City Hospital, Kishiwada, Osaka, Japan; Kiwa Clinic, Hashimoto, Wakayama, Japan and Sakurai Breast Clinic, Wakayama, Japan.

Body: Introduction: Achievement of a good cosmetic outcome is one of the most important goals of surgical treatment of breast cancer. However, most patients must undergo a mastectomy if the outcome of breast-conserving surgery is discordant. All potential techniques that maintain oncological safety should be considered to maximize the cosmetic outcome for patients who require a mastectomy. We began performing nipple-sparing mastectomy (NSM) in 1978. Recent reports have suggested that NSM is oncologically as safe as mastectomy and affords a better cosmetic outcome. Conversely, the surgical complications and recurrence associated with NSM remain controversial.

Objective: In the present study, we review the safety of the NSM surgical technique, discuss nipple–areola recurrence and skin flap recurrence after NSM, and compare recurrence and prognosis between NSM and mastectomy based on our long-term follow-up data.

Patients and Methods: We retrospectively analyzed 723 patients with early-stage breast cancer who underwent NSM from 1985 to 2007. The patients' median age, tumor size, and tumor–areola distance were 50 y, 2.1 cm, and 1.5 cm, respectively. We used a thick skin flap method to avoid surgical complications including nipple and skin flap necrosis. We analyzed nipple–areola recurrence and skin flap recurrence after NSM. We also analyzed 100 patients who underwent mastectomy for early-stage breast cancer during the same period as those who underwent NSM. We compared the local recurrence rate (LRR), disease-free survival (DFS) rate, and overall survival (OS) rate among all 723 patients who underwent NSM and 100 patients who underwent mastectomy. No patients in either group received radiotherapy.

Results: Among all patients who underwent NSM, stage 0, 1, 2A, and 2B disease was present in 21, 320, 253, and 129 patients, respectively. Notably, no nipple necrosis occurred during the average 114-month follow-up period. Local recurrence developed in 49 patients (6.7%), including recurrence at the nipple–areola complex in 24 (3.3%) and recurrence at the skin flap in 25 (3.4%). The average disease-free interval in patients with nipple–areola recurrence was 50 months, and that in patients with skin flap recurrence was 68 months. The clinical features of nipple–areola recurrence were a low rate of ER positivity (27%), high rate of Her2/neu positivity (60%), Paget type recurrence rate of 52%, and small tumor–areola distance (0.5 cm). The clinical features of skin flap recurrence were a relatively high rate of ER positivity (55%), solitary type recurrence rate of 88%, and diffuse type recurrence rate of 12%. The prognosis of diffuse type skin flap recurrence was significantly worse than that of solitary type recurrence (p = 0.01). There were no significant differences between the NSM and mastectomy groups in the LLR (6.7% vs. 4.0%, respectively), 10-y DFS rate (88% vs. 90%, respectively), or 10-y OS rate (92% vs. 91%, respectively).

Conclusion: Our long-term follow-up data show that NSM should be considered as an alternative option for mastectomy when the outcome of breast-conserving surgery is discordant in patients with early-stage breast cancer.
Title: The oncological safety of nipple sparing mastectomy: A pooled analysis of 12358 procedures

Body: The nipple sparing mastectomy is an increasingly popular procedure for the treatment of breast cancer and as a prophylactic procedure for those at high risk of developing the disease. However, it remains a controversial option due to questions regarding its oncological safety and concerns over locoregional recurrence. In order to assess its safety, a literature review and pooled analysis was performed using the current literature regarding nipple sparing mastectomy. This resulted in seventy-three studies which met inclusion criteria, yielding a total of 12358 procedures. The overall pooled locoregional recurrence rate was found to be 2.38%, the overall complication rate was 12.3% and the incidence of nipple necrosis, either partial or total, was 4.6%. Through analysis of this data, we concluded that nipple sparing mastectomy appears to be an oncologically safe option in appropriately selected patients, where tumours are less than 5cm in diameter, more than 2cm away from the nipple margin an are Her-2 negative, although separate histopathological examination of subareolar tissue remains essential to rule out malignancy at this site and provide safe oncological practice.
Title: Does postmastectomy radiotherapy improve survival in patients with 1-3 positive axillary lymph nodes? A systematic review and meta-analysis of the current literature

Body: In breast cancer with more than four positive axillary lymph nodes, it is common practice to deliver radiotherapy to the affected site following a mastectomy. However, less is known about the benefits this might offer in women with 1-3 positive lymph nodes. In order to assess whether postmastectomy radiotherapy has any benefit in these women, a meta-analysis was performed to assess whether postmastectomy radiotherapy improved overall survival or reduced locoregional recurrence in this group of women. It was found that postmastectomy radiotherapy significantly reduced the risk of locoregional recurrence, with a relative risk ratio of 0.3 (95% confidence interval 0.23-0.38), and resulted in a small benefit in overall survival, with a relative risk ratio of 1.03 (95% confidence interval 1.00-1.07). Therefore, in women with 1-3 positive lymph nodes, postmastectomy radiotherapy reduces the risk of locoregional recurrence and is associated with a small benefit in overall survival, so should be recommended within this group after careful multidisciplinary discussion.
Title: MarginProbe device use and re-excision rates for breast conservation surgeries

Body: Background: Current methods of intraoperative assessment of lumpectomy margins are limited. Previous studies have found a lower rate of re-excisions with the adjunctive use of the MarginProbe device (Dune Medical Devices Ltd, Israel). The purpose of this study was to compare the tumor characteristics and re-excision rates before and after the use of MarginProbe for patients who had breast conservation surgery (BCS) at our institution.

Methods: The Breast Cancer Database of our medical center was queried for patients who underwent BCS from 1/2010-3/2015 by three breast surgeons. 2 surgeons used the MarginProbe to direct excision of additional margins at the time of primary lumpectomy surgery and 1 surgeon performed routine 6-surface cavity shavings. We compared our historical data (1/2010-12/2014) to MarginProbe data (1/2015-4/2015). The following variables were included: age, mammographic breast density, tumor characteristics, and re-excision rates. Statistical analyses were performed using Pearson's Chi-Square and Fisher's Exact Tests.

Results: We had a total of 1201 women who had BCS among the 3 breast surgeons. The median age was 61 years. The median invasive size was 1.2 cm. Majority of cancers were early stage (stage 0, I), invasive ductal carcinoma (61%), ER-positive (86%), PR-positive (74%), and Her2Neu-negative (88%). These tumor characteristics were not statistically different in the pre- and post-MarginProbe groups. The majority of patients had dense breasts (51%) and density did not differ among the pre- and post-MarginProbe groups (p=0.86). For the surgeons who used the MarginProbe for margin assessment at the time of surgery, the re-excision rate fell from 17% to 0% and 35% to 20% during the 4-month period. In contrast, the surgeon who routinely performed 6-surface shavings had a re-excision rate that fell from 13% to 12% in the same time period. 88% of MarginProbe readings were false positive. There was one false negative reading.

**Conclusions:** Routine use of the MarginProbe device was associated with lower re-excision rates compared to historical data and concurrent 6-cavity shaving approach. Better intraoperative margin assessment and lower re-excision rates will decrease the burden of breast cancer on patients and the health care system and support the practice of breast conserving surgery.
**Title:** Modified pectoral nerves block for postoperative analgesia after modified radical mastectomy: A comparative study

Kanitkar R, Mane A, Agashe A, Kulkarni M and Deshmukh S. Ruby Hall Clinic, Pune, Maharashtra, India and Sunnybrook Health Sciences Centre, Toronto, ON, Canada.

**Body:**

**Background:** The modified pectoral nerves block (Pecs II) as a method of analgesia for breast cancer surgery has shown excellent results in recent publications. This technique blocks the long thoracic nerve, thoracic intercostal nerves from T2-T6 & thoracodorsal nerve.

**Aims:** To evaluate the effectiveness of the Pecs II block for pain relief in the postoperative period of patients undergoing modified radical mastectomy (MRM).

**Methods:** A prospective comparative study was conducted at our institution between November 2014 and March 2015. Patients scheduled to undergo MRM were randomly assigned to the test group (endotracheal anaesthesia along with Pecs II) and the control group (endotracheal anaesthesia only). In the postoperative period the patients were evaluated using a visual analogue scale to determine pain scores at 6, 12 & 24 hours.

**Results:** Fifty patients (25 in each group), between the ages of 24 to 76 years (54.76 ± 10) were included in the study. There was no significant difference in ages between test & control groups. In the postoperative period, the test group had significantly lower median pain scores at 6, 12 & 24 hours as compared to the control group.

**Conclusion:** The modified pectoral nerves block (Pecs II) is a novel & effective technique for postoperative analgesia in patients undergoing modified radical mastectomy.
Therapeutic mammoplasty reduces high incomplete excision rate in lobular cancer

Romics L, Kabir SA A, Mansell J, Mallon EA A, Stallard S and Doughty JC C. Victoria Infirmary Glasgow, Glasgow, United Kingdom; Royal Infirmary Glasgow, Glasgow, United Kingdom; New Southern University Hospital Glasgow, Glasgow, United Kingdom and Western Infirmary Glasgow, Glasgow, United Kingdom.

Body: Introduction: Incomplete excision rate for lobular cancer is much higher compared to other types of breast cancer, since lobular cancer is frequently occult on imaging. This, and the inability to downstage lobular cancer with neoadjuvant therapy lead to the highest mastectomy rate of all subtypes. Here, we investigated the association between histopathological characteristics and incomplete excision as well as mastectomy rates.

Further, we investigated whether the application of level 2 therapeutic mammoplasty (TM) would extend the indication for conservation with lobular cancers.

Methods: Data of 1389 consecutive patients underwent surgery for (non)invasive breast cancer between January 2008 and June 2012 was analysed. Pathological and preoperative radiological results were analysed in the context of final surgery and tumour excision margins. Statistical significance was calculated using Chi-square, Mann-Whitney and Z-tests with a significance<0.05.

Results: Overall incomplete excision rate was 13.74% (131/953), and mastectomy rate was 35.35% (491/1389). Higher incomplete excision and mastectomy rates were strongly associated with lobular subtype (IE: 26.03% (19/73)); M: 51.22% (63/123); p<0.01 vs. other subtypes), node positivity (IE: 25% (36/144) vs. 10.43% (68/652); p=0 and M: 60.69% (193/318) vs. 25.65% (216/842); p=0) and tumour size (IE: T3 80% (4/5) vs. T2 22.51% (43/191) vs. T1 9.23% (55/596); all p<0.01; and M: T3 95.35% (41/43) vs. 59.46% (242/407) vs. 16.16% (112/693); all p=0). Incomplete excision rates were independent of hormonal and HER-2 expressions (ER+: 12.55% (89/709) vs. ER-: 16.67% (15/90); p=0.27 and HER2 neg.: 12.67% (91/718) vs. HER2 pos.: 16.67% (13/78); p=0.32) and it was just higher in grade 2 and 3 cancers (14.6% (60/411); p=0.037 and 16.22% (36/222); p=0.021 vs. G1:6.86% (7/102). However, hormonal and HER-2 expressions as well as tumour grade were in strong association with mastectomy rate (ER pos.: 33.28% (335/1007) vs. ER neg.: 48.75% (78/160); p<0.01; HER2 neg.: 33.43% (341/1020) vs. HER2 pos.: 49.65% (71/143); p<0.01; G3: 50.49% (205/406) vs. G2: 30.77%(172/559) vs. G1: 14.28% (17/119); all p=0).

135 patients underwent surgery for lobular cancer (simple wide excision: 66; TM:19; mastectomy: 50). TM was offered for significantly larger tumours than lumpectomy (28.29mm (10-62) vs. 19.96mm(5-57);p<0.01; vs. mastectomy: 37.56 mm(5-110);p=0.096). Incomplete margins were found with significantly smaller tumours when lumpectomy was applied compared to TM(25.94 mm(6-56) vs. 38.6 mm(30-45);p=0.031). Conservation was achieved with significantly bigger tumours when TM was used (25.46mm (10-62) vs. 17.66mm (5-57); p=0.032). Multifocality, however, significantly increased the chance for incomplete excision even after TM (4/7; p=0.019).

Conclusion: Higher incomplete excision rate is strongly associated with lobular subtype, node positivity and tumour size, but independent of hormonal and HER-2 expression, while tumour grade is not a strong predictor. All histopathological characteristics are strong predictors of final mastectomy rate. Using TM, breast conservation can be achieved for significantly larger lobular cancers, and incomplete excision rate decreased in smaller cancers, which are routinely treated with wide excision.
Title: The role of neck dissection in breast cancer patients with synchronous and metachronous ipsilateral supraclavicular lymph node metastasis

Xiao C, Qi X, Chen A, Zhang W, Zhang P and Cao X. Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer, Tianjin, China; Key Laboratory of Cancer Prevention and Therapy, Tianjin, China and Key Laboratory of Breast Cancer Prevention and Therapy, Ministry of Education, Tianjin, China.

Body: Purpose: To evaluate the effect of neck dissection in breast cancer patients who present with ipsilateral supraclavicular lymphnode metastasis (ISLM) without distant metastasis and to reveal the outcomes of neck dissection in different molecular subtypes.

Methods: A total of 90 patients with synchronous ISLM and 36 patients with metachronous ISLM without distant metastasis between 2000 and 2009 were retrospectively analyzed. Combined-modality treatments were performed, and patients were respectively divided into two parts according to whether they received neck dissection or not.

Results: In the synchronous ISLM group, there was no significant difference between the neck dissection and non-dissection group with respect to age, menstrual status, tumour size, and histological type, PR and HER2 status. Patients with negative ER status and a higher number of positive axillary nodes were more common in the neck dissection group. The five-year locoregional relapse free survival (LRFS) was 63.6% in the neck dissection group VS. 48.9% in the non-dissection group, respectively (P=0.359). The 5-year distant metastasis free survival (DMFS) was 37.3% in the neck dissection group VS. 38.5% in the non-dissection group, respectively (P=0.882). Further analyses were performed by the site of metastases. Results showed that the incidence of bone metastasis was lower in neck dissection patients (14.7% vs. 28.6%, P=0.132). Due to the limited amount of patients, subgroup analysis was just performed in the subtypes with negative ER status, negative PR status and negative HER2 status, respectively. The five-year LRFS of patients receiving neck dissection in the subtypes with negative ER status, negative PR status and negative HER2 status was 63.7%, 59.8% and 61.2%, which was much better than their matched non-dissection group, respectively. However, the difference was not statistically significant. The 5-year overall survival (OS) was similar between the neck dissection and non-dissection group in the subtypes of negative ER status and negative PR status, respectively. However, the 5-year OS of HER2 negative subtype significantly decreased in the neck dissection group (37.2% vs. 65.4%, P=0.032). Besides, it's worth mentioning that in the HER2 positive subtype, the mean time to relapse, metastasis and death was shorter in the neck dissection subgroup compared with the non-dissection subgroup. In the metachronous ISLM group, a trend of better regional control, with similar PFS and OS, was achieved in the neck dissection group.

Discussion: Neck dissection is an effective approach to improve the regional control for the patients with ISLM, especially for the subtypes with negative ER status, negative PR status and probably positive HER2 status in the synchronous ISLM. But, it might not be comfortable for the patients with negative HER2 status, because of the unfavorable effect on its overall survival. In addition, neck dissection, with better regional control, might be helpful for the control of bone metastasis, which is beneficial for long term survival.
2015 San Antonio Breast Cancer Symposium

Title: Current trend and indications of endoscopy-assisted breast surgery for breast cancer: Experience from Taiwan endoscopic breast surgery cooperative group

Lai H-W, Kuo Y-L, Hung C-S, Chen S-T and Chen D-R. Changhua Christian Hospital, Changhua, Taiwan; National Cheng Kung University Hospital, Tainan, Taiwan and Taipei Medical University Hospital, Taipei, Taiwan.

Body: Background: Endoscopy-assisted breast surgery (EABS) performed through minimal axillary and/or periareolar incisions is a possible alternative to conventional surgery for certain patients with breast cancer. In this study, we report the early results of an EABS program in Taiwan.

Methods: The medical records of patients who underwent EABS for breast cancer during the period May 2009 to December 2014 were collected from the Taiwan Endoscopic Breast Surgery Cooperative Group database. The Taiwan Endoscopic Breast Surgery Cooperative Group (T-EBSCG) was established to monitor the effectiveness of and clinical outcome associated with EABS in Taiwan. The T-EBSCG comprises members from three major endoscopic breast surgery centers, namely Changhua Christian Hospital, National Cheng-Kung University Hospital, and Taipei Medical University Hospital in Taiwan. Data on clinicopathologic characteristics, type of surgery, method of breast reconstruction, complications and recurrence were analyzed to determine the effectiveness and oncologic safety of EABS in Taiwan.

Results: A total of 315 EABS procedures were performed in 292 patients with breast cancer, including 23 (7.8%) patients with bilateral disease. The mean tumor size of these 315 EABS was 2.2 ± 1.8 cm, and 44 (13.9%) of them were multifocal/multicentric breast cancer. Lymph node metastasis was found during 23.3% of the procedures. The stage distribution of them were stage II cancer (n=103, 34.4%), followed by stage I cancer (n=92, 30.7%), ductal carcinoma in situ (stage 0) (n=86, 28.7%), and stage III breast cancer (n=19, 6.3%). The number of breast cancer patients who underwent EABS increased initially from 2009 to 2012 and then stabilized during the period 2012-2014. The most commonly performed EABS was endoscopy-assisted total mastectomy (EATM) (85.4%) followed by endoscopy-assisted partial mastectomy (EAPM) (14.6%). Of the 269 patients who underwent EATM, 198 (73.6%) received immediate breast reconstruction. The majority (72.2%) of them received implant-based (cohesive Gel implant or tissue expander) reconstruction and the remaining 27.8% received autologous pedicled TRAM flap for breast reconstruction. Endoscopic assisted nipple sparing mastectomy with Gel implant reconstruction was the most frequently performed EABS now. During the six-year study period, there was an increasing trend toward more frequently use of EABS in the management of breast cancer when total mastectomy was indicated (EATM) than breast conserving surgery (EPM). Overall, the rate of complications associated with EABS was 15.2% and all were minor and wound-related. There were no major or life threatening complications. The positive surgical margin rate was 1.9%. During a median follow-up of 26.8 months (range, 3.3-68.6 months), there were 3 (1%) cases of local recurrence (1 ipsilateral breast recurrence, 1 axillary local recurrence, and 1 core needle biopsy tract recurrences), 1 (0.3%) case of distant metastasis, and 1 death.

Conclusion: The EABS program in Taiwan showed that EABS is a safe procedure and results in acceptable cosmetic outcome, these findings could help to promote this under-used surgical technique in the field of breast cancer.
Title: Mini latissimus dorsi flap increases breast conserving surgery rate in early stage breast cancer patients

Ozmen V, Sarsenov D, Ozmen T, Ilgun S, Alco G, Ordu C, Agacayak F, Elbuken F, Erdogan Z and Pilanci KN Nur. Istanbul Florence Nightingale Hospital, Istanbul, Turkey; Gayrettepe Florence Nightingale Hospital, Istanbul, Turkey; Marmara University Medical Faculty, Istanbul, Turkey and Haseki Training and Research Hospital, Istanbul, Turkey.

Background
Oncoplastic techniques enabled performing breast conserving surgery (BCS) to larger tumors. Mini latissimus dorsi flap (MLDF) is a novel approach promising successful cosmetic outcome after wide excisions for breast cancer surgery. The aims of this study are to evaluate the effect of MLDF on BCS rate in early stage breast cancer patients, and to compare patient and tumor characteristics between BCS patients with and without MLDF.

Patients and Methods
Data of early stage breast cancer patients (cT1-3N0-1M0) operated between years 2005 and 2015 were prospectively collected. We started to perform MLDF after 2010, and 157 consecutive patients who underwent BCS + MLDF reconstruction composed the study group. To prevent any selection bias, we comprised the control group from patients, who underwent BCS before our clinic started performing MLDF. 152 tumor stage-matched patient underwent BCS before 2010 composed the control group. The MLDF reconstruction was performed after lumpectomy and sentinel lymph node biopsy and/or axillary dissection via axillary incision. The volume of prepared latissimus dorsi muscle flap was depended on volume of the tumor cavity. Ink on the tumor in the specimen was accepted as negative positive surgical margin. All patients took whole breast and boost radiation. Systemic treatment decision was given after assessment of patients on the tumor conference.

Results
Between 2005 and 2015 data on 994 patients who underwent BCS were prospectively gathered with 371 patients registered in between 2005-2009 and 631 patients in between 2010-2015. The BCS rate increased from 66.5% to 78% after our clinic started performing MLDF in 2010 with MLDF rate being nearly 12%. The mean age and the mean body mass index were higher in the control group (54.2 vs. 46.7, p<0.001 and 27.85 kg/m² vs. 25.01 kg/m², p<0.001, respectively). Mean tumor size was larger in the study group (27.8 mm vs. 21.0 mm, p<0.001). Multifocality rate was higher in the study group (26.75% vs. 9.79%, p=0.001). Early complications (seroma, prolonged wound drainage, wound infection, hematoma, wound dehiscence) rates were similar in both groups (Table 1).

Conclusion
The MLDF significantly increased breast conserving surgery rate in patients with early stage breast cancer. It should be considered in patients with young age (<40 years), having large and multifocal tumors.

**Title:** Outpatient mastectomy with reconstruction in a freestanding surgery center using multimodality opioid-sparing perioperative analgesia including liposomal bupivacaine

Rock DT T, Jandik AL L, Wittenborn WS S, Fairfax K and Sandadi S. Regional Breast Care, Fort Myers, FL; Medical Anesthesia and Pain Management Consultants, Fort Myers, FL; Wittenborn Plastic Surgery, Fort Myers, FL and Lee Memorial Health System, Fort Myers, FL.

**Body:**

**HYPOTHESIS:**
The introduction of effective non-narcotic analgesics and the long-acting local anesthetic bupivacaine liposome (Exparel) has resulted in improved postoperative pain control and decreased reliance on opioid analgesics that often have the undesirable adverse effects of sedation, nausea, respiratory depression, and dysphoria or confusion. This has resulted in shorter postoperative care unit stays, earlier return to normal activity, and improved patient satisfaction without sacrificing appropriate pain control. Based on a positive experience with these agents in the inpatient setting, we hypothesized that mastectomy with immediate implant-based reconstruction could be performed safely in a freestanding outpatient surgery center using a multimodality opioid-sparing analgesic regimen.

**METHOD:**
Over a 6 month period we performed unilateral or bilateral mastectomy with concurrent implant-based reconstruction on 20 patients. One patient had a unilateral mastectomy and 19 patients had bilateral mastectomy performed. Sixteen of the patients had nipple sparing mastectomy procedures. Reconstruction was performed with tissue expanders in 6 patients and as a single stage procedure with silicone gel implants in 14 patients. Acellular dermal matrix was used to support the implant in all but 1 patient. All patients were given gabapentin 600mg on the evening prior to and morning of surgery. Acetaminophen 1gm IV was given prior to induction of anesthesia in the preoperative area and again 6 hours later in the post anesthesia care unit. Ketorolac 30mg IV was given during the last half of the surgical procedure. All patients had general anesthesia with standard inhalational agents and IV fentanyl as needed. The retropectoral and serratus fascia were infiltrated with liposomal bupivacaine after surgical removal of the breast tissue, before reconstruction was started. The drain sites were also infiltrated with liposomal bupivacaine. Patients were discharged with prescriptions for gabapentin 300mg twice daily for 7 days followed by 300mg nightly for 7 days, carisoprodol 350mg every 6 hours as needed for muscle spasms, ibuprofen 800 mg every 8 hours for 5 days, hydrocodone/acetaminophen every 4 hours as needed for pain, and oral antibiotics of the surgeon's choice.

**RESULTS:**
All 20 patients completed their surgery and were discharged home after a brief stay in the postoperative care unit. No patient required readmission for pain control or any other complication in the perioperative period. No patient reported inadequate pain control. All patients were highly satisfied with their perioperative care as reported during postoperative follow-up phone calls the day after surgery and during their post-operative follow up visit.

**CONCLUSION:**
In our experience, outpatient mastectomy with reconstruction in a freestanding surgery center is safe and has a high degree of patient satisfaction when using a multimodality opioid-sparing analgesia regimen including liposomal bupivacaine. By avoiding opioid-related adverse effects, patients have a more rapid recovery, earlier return to activities of daily living, and therefore improved quality of life. Proper patient selection requires a multidisciplinary team approach for success.
Title: Comparison between ultrasound-guided-vacuum-assisted excision and surgical excision of benign phyllodes tumor of the breast: A single center retrospective study

Ouyang Q, Chen K, Zhu L, Song E and Su F.  Sun Yat-Sen Memorial Hospital, Sun Yat-sen University, Guangzhou, Guangdong, China.

Body: Background: Wide local excision (WLE) is the recommended treatment for patients with phyllodes tumor of the breast, regardless of the tumor subtype (benign, borderline and malignant). However, the association between margin status and local recurrence is still controversial. In our institution, surgical excision (SE) alone (margin width<1cm) is the standard treatment for patients with benign phyllodes tumor. In addition, ultrasound-guided-vacuum-assisted excision (UGVAE) is also employed as an alternative, minimally invasive way to remove benign phyllodes tumor. We hypothesized that UGVAE alone is adequate and as safe as SE alone for benign phyllodes tumor.

Method:
We searched our database for patients with benign phyllodes tumor diagnosed in Sun Yat-sen Memorial Hospital between 2000 and 2014, and identified 136 patients with valid follow-up information. Formalin fixed slices of each patient were reviewed for pathology diagnosis. In UGVAE group, we used 8G Mammutome to remove all lesions detected by ultrasound and surgical re-excision after pathology diagnosis was not performed. In SE group, patients received SE with no intention to achieve a surgical margin >=1cm. Macroscopically negative margins is guaranteed by gross examination. Comparison of patients' features were performed using student t-test, Mann–Whitney u-test or Chi-square test, when appropriate. Association between surgery (UGVAE & SE) and local recurrence was analyzed using univariate (Kaplan-Meier analysis) and multivariate approaches (Cox-regression analysis). Age, tumor size and the presence of accompanied fibroadenoma were included in the multivariate analysis.

Results:
Patients had significantly smaller tumor in the UGVAE group and those in the SE group (Median size: 2.1 vs. 3.0cm, P<0.01). There were more patients in the UGVAE group that had accompanied fibroadenoma, when compared with those in the SE group (67.2% vs. 29.1%, P<0.01). The median age was 38 and 37 in the UGVAE and SE group, respectively (P=0.66). With a median follow-up of 43 months, the 3-year and 5-year recurrence-free survival was 89.6% and 86.5% in UGVAE group, 97.3% and 90.0% in SE group, respectively (Log-rank test: P=0.26). In multivariate analysis, Surgery type (UGVAE or SE) (HR=0.37, P=0.19), age(HR=0.97, P=0.45), tumor size (HR=0.88, P=0.58) and the presence of accompanied fibroadenoma (HR=0.38, P=0.16) were not associated with recurrence-free survival.

Conclusion: UGVAE alone did not significantly increase the local recurrence rate of benign phyllodes tumor, when compared with SE, in this study. A prospective study with more patients and longer follow-up is needed in future.
Title: Rapid evaporative ionisation mass spectrometry towards real time intraoperative oncological margin status determination in breast conserving surgery

Body: Introduction: Positive tumour margins following attempted breast conserving surgery (BCS) is an important risk factor for local recurrence. Nationally in the United Kingdom on average approximately 25% of patients undergoing BCS require additional surgery for positive margins. Traditional techniques such as specimen xray, frozen section & imprint cytology to optimise margin clearance have significant limitations. Various research methods under investigation include optical spectroscopy, high resolution imaging and radiofrequency spectroscopy. Rapid Evaporative Ionisation Mass Spectrometry (REIMS) is a new method that uses mass spectrometric analysis of the tissue specific ionic content of the surgical diathermy smoke plume for the rapid identification of dissected breast tissues as an intelligent knife (iKnife). We investigate the ability of the “iKnife” to analyze heterogeneous breast tissue intraoperatively using mass spectrometric techniques.

Method: The study involved three stages that comprised: method development, tissue specific ex-vivo database construction and intraoperative analysis. Smoke aerosol produced as a result of electrosurgical diathermy from a variety of frozen, fresh and in-vivo breast samples were aspirated into a mass spectrometer via a modified surgical handpiece. Tissue diagnosis was confirmed by subsequent histopathological validation. The data underwent computational analysis using multivariate statistics –predominantly Principal Component Analysis (PCA) and Linear Discriminant Analysis (LDA), along with leave one patient out cross-validation. A total of 128 patients (n=40 method development, n=66 ex-vivo database, n=22 intraoperative analysis) undergoing breast surgery were enrolled in this study. Ethical approval was obtained from the Research Ethics Committee.

Results: 40 patients contributed breast samples (normal and cancerous) for method optimisation to enable analysis of high intensity spectra from heterogeneous breast tissue. Following optimisation an ex-vivo database was constructed from 89 excised fresh breast tissue samples from 66 patients using 330 spectra (246 Normal, 60 Tumour – IDC, ILC, IMC and 24 Benign - fibroadenoma). Multivariate statistical analysis of data revealed classification of tumour compared to normal tissue with sensitivities of 93.0% and specificity of 91.9%. The iKnife was used intraoperatively during the entire operation of 25 surgeries. Spectral data was obtained within 1-2 seconds. Specific margin analysis correctly identified negative margins in 10 cases.

Conclusions: The iKnife has been successfully developed for analysis of intraoperative heterogeneous breast tissue. Preliminary data suggests that this technique is suitable with high accuracy for the separation of normal, benign (fibroadenoma) and cancerous (invasive ductal and invasive lobular carcinoma) breast tissues. In comparison to the normal breast, cancerous tissues exhibit statistically different spectral profiles. Further work is aimed at the development of a real time algorithm able to match intraoperative data with the pre-existing database for the rapid interpretation and real time feedback of intraoperative data towards detecting positive margins intraoperatively.
Title: The “penny farthing” incision for mastectomy: A novel technique to reduce “dog ear” deformity and improve access to the axilla

Poole G and Sheikh L. Middlemore Hospital, Auckland, New Zealand.

Body: Introduction:
Medial and lateral “dog ear” deformities are a common problem with mastectomy incisions. The challenges include different skin tensions superiorly and inferiorly and variable BMI. Also, the standard mastectomy incision is also not in the optimal place for sentinel node biopsy access.

No published technique is universally applicable and some advanced techniques require excess dissection and operative time.

Aims:
1) To perform a literature search for all published techniques
2) To pilot test a new, simple incision

Methods:
A literature search using PubMed was performed that revealed eight previous techniques (1).

A new, simple technique was developed to incorporate most of the historical principles. Circles of different sizes are marked out medially (small) and laterally (large). The lateral circle incorporates the optimal position for access to the axilla for sentinel node biopsy or axillary clearance. These circles are joined by asymmetrical superior and inferior lines to encourage rotation during closure. Tumour size and position are taken into consideration. Wound closure begins from the centre which allows the wound to “choose” its own corners and tuck them inwards therefore minimising “dog ear” formation.

Results:
Seventy-five consecutive patients had the procedure by a single surgeon over an 18 month period.
At the conclusion of each procedure there was no residual "dog ear" deformity at either wound end.
Of the 36 patients seen for 12 month follow up only one (BMI 42) has required revision of the wound.

Conclusion:
The "Penny Farthing" incision is a novel, simple and promising technique to deal with "dog ear" deformity in mastectomy.

Introduction
Atypical ductal hyperplasia (ADH) is known to be associated with underlying pre-malignant or malignant breast conditions. Here we report our 10-year data on ADH found in core biopsy, lumpectomy and mastectomy specimens.

Methods
From 1st January 2005 to 31st December 2014, a total of 104 core needle biopsy specimens and 218 lumpectomy / mastectomy specimens were found to contain ADH. Clinical, radiological and pathology data were retrieved and analysed from a prospectively-maintained database.

Results
Out of the 104 patients with core biopsy showing ADH, 101 patients received excision and 3 refused operation. 34 patients turned out to have ductal carcinoma in-situ (DCIS) on excision, while 6 had invasive ductal carcinoma (IDC), 1 had lobular carcinoma in-situ (LCIS) and 1 had angiosarcoma resulting in an upstaging rate of 40.4% (42/104). The remaining patients had benign lesions including papillary lesions, fibrocystic disease, or ADH alone. Multivariate analysis found that the only correlating factor for the presence of DCIS or IDC was suspicious mammographic features (BIRADS 4 or above) (P = 0.008 and 0.02 respectively) but not other parameters such as extent of micro-calcifications (P = 0.12) or age (P = 0.11).

Histopathological diagnosis after excision of lesions containing ADH on core biopsy

</tbody>
</table>

218 lumpectomy or mastectomy specimens were found to harbor ADH. 62 (28.4%) had co-existing pre-malignant or malignant breast diseases. The only determining factor for the presence of malignant or pre-malignant condition was suspicious breast imaging features (BIRADS 4 or above) after multivariate analysis (P = 0.0003).

Invasive ductal carcinoma 23 (10.6%)
Lobular carcinoma in-situ 1 (0.5%)
Invasive lobular carcinoma 1 (0.5%)
Malignant phyllodes tumor 1 (0.5%)

Conclusion
ADH is closely related to the presence of invasive cancer or DCIS especially when suspicious breast imaging features are present. The upstaging rate is still high in patients where initial biopsy was ADH.
Social networks and the decision to undergo contralateral prophylactic mastectomy

Baptiste D, Venetis MK K, MacGeorge EL L, Lagoon J, Mouton A, Pastor R, Friley LB Brooke, Clare SE E and Bowling MW W. Indiana University School of Medicine, Indianapolis, IN; Purdue University Brian Lamb School of Communication, West Lafayette, IN; Pennsylvania State University, University Park, PA and Northwestern University Feinberg School of Medicine, Chicago, IL.

Body: Background: Multiple studies indicate that the choice of contralateral prophylactic mastectomy (CPM) is increasing, predominantly in women younger than 50. This is despite the lack of demonstrated survival advantage for removing the non-cancerous breast, and contradicts expert medical recommendations, such as those of The National Comprehensive Cancer Network, that discourage CPM unless the patient is at elevated risk for breast cancer (e.g., BRCA1/2 mutation). An underexplored area with regard to selection of CPM is the influence of patients’ social and support networks. Breast cancer patients typically involve one or more intimates in their treatment decisions. Further, breast cancer is rarely stigmatized, making it acceptable to disclose the condition, even to non-intimates. Thus, others, in person or using social media, are likely to know when patients are making treatment choices, and may provide information, opinions, or advice that affects these choices. The scope and strength of social network influence on CPM decision-making remains unexplored to date.

Methods: Potential participants for this study were identified from Indiana University and Wishard Health Services billing records using the procedure code for bilateral mastectomy during the years 2007-2012. The lists were then curated to identify patients who had undergone CPM. These patients were mailed an introductory letter and study information sheet, after which they were contacted by telephone and the questionnaire administered to those who agreed. Questions focused on the people with whom participants discussed the CPM decision.

Results: 117 women of 326 invited agreed to participate. 88% of participants were Caucasian and 11% African-American. The mean age at diagnosis was 50. Most respondents (97%) discussed their surgical options with at least one person other than their surgeons (median = 3, mean = 6.7). The individuals most frequently consulted were spouses/partners, and friends or relatives who had experienced breast cancer. Children, relatives and friends who had not experienced breast cancer, and health care providers or counseling professionals were also engaged in discussion. Most respondents (92%) reported that at least one of the people they talked with (median = 2, mean = 2.6) had some degree of influence on the CPM decision. The average influence of these individuals was 3.2 on a 5-point scale (5 = played a strong role in the decision). Children had the strongest average influence (3.7/5), followed by spouses, and friends or relatives who had experienced breast cancer. Consistent with the sample (all respondents had elected CPM), most people who influenced the respondents were reported to be positive or neutral toward CPM. In the few instances in which the advisor was negative with regard to CPM, respondents reported that this person did not influence their decision.

Conclusion: The current study corroborates prior research indicating that breast cancer patients discuss their treatment options with others, and underscores the potential for social and support networks to influence CPM decisions. To reduce the incidence of CPM, it may be necessary for health care professionals to educate and inform large segments of the lay public about the actual benefits and risks of CPM.
Title: An innovative risk-reducing approach to post-mastectomy radiation delivery following autologous breast reconstruction

Body: Introduction:
There is no consensus among radiation oncologists regarding delivery of post-mastectomy radiation therapy (PMRT) after immediate autologous breast reconstruction, and plastic surgeons rarely participate in this decision-making process. However, radiation-induced changes markedly influence flap outcomes and affect the flap permanently. We present an innovative approach for PMRT delivery, through the use of custom bolus. This technique provides individualized, targeted PMRT to the reconstructed breast to minimize flap-related complications.

Methods:
All patients who underwent mastectomy with immediate autologous reconstruction between 2005 and 2014 at our institution were identified. Radiation was delivered to the reconstructed autologous breast in 29 patients. Post-irradiation complications and reconstruction outcomes were compared for patients treated with custom bolus, standard PMRT, and historical controls.

Results:
Over the past 10 years, 157 patients (226 breasts) underwent immediate autologous tissue breast reconstruction following mastectomy. Of the 29 patients who received PMRT, 10 were treated with custom bolus. The custom bolus uses perforated Aquaplast and a nearly tissue-equivalent wax to form a cast which conforms to the irregular contours of the chest wall, allowing for easy application through the duration of treatment. Pre-irradiation computed tomography was used to optimize dose distribution, evaluate the internal mammary vessels, and target the deeper tissues adjacent to the chest wall (minimizing dose inhomogeneity to the skin). Custom bolus resulted in fewer radiation-induced skin changes and less skin tethering/fibrosis than standard bolus (0% vs 10% and 20% vs 35%, respectively), and less volume loss and contour deformities compared with historical controls (10% vs 22.8% and 10% vs 30.7%, respectively).

Conclusion:
The use of custom bolus tailors radiation delivery to the internal mammary vessels, anastomoses, and skin; uniformly doses the surgical incision; and provides the necessary radiation dose to prevent recurrence, thus not compromising oncologic safety. It is easily fabricated, cost-effective and placement is straightforward and reproducible. Because radiation has negative effects on autologous breast reconstruction and often results in vascular intimal fibrosis and fat necrosis, plastic surgeons should participate in radiation planning. Our custom bolus PMRT technique reduces the incidence of these radiation effects.
Body: Background: Rates of implant failure, wound healing delay, and infection are higher in patients having RT after tissue expander (TE) and permanent implant reconstruction. Some have suggested greater complications with increased body mass index (BMI) and with diabetes.

Patients and Methods: 127 patients had bilateral TE reconstruction and radiation from 2003 to 2013 at two centers. In 95% (121/127) of cases RT was performed while the TE was in place with the permanent implant inserted after RT. 3D-CRT technique included 50 Gy with daily or every other day bolus and forward planned segments. The supraclavicular and/or internal mammary lymph node bearing regions were treated in 82.7% (105/127) cases. The non-irradiated breast provided an internal control. Chi-squared testing of pretreatment factors included radiation, chemotherapy, and medical history of hypertension, diabetes, cardiovascular, and pulmonary disease. BMI, tobacco and alcohol use, use of antiestrogen, statin, antidepressant, antihypertensive, anxiolytics, and antidiabetic medications were also studied. Comparison of differences in means for continuous variables used analysis of variance, then multiple pairwise comparisons with Bonferroni correction of p-value.

Results: Mean age was 53 ± 10.1 years with just 14.6% African-American. Twelve (9.4%) were BRCA positive (9 BRCA1, 4 BRCA2, 1 Both). Nearly all complications were in the radiated breast. Complications were: Grade 0 (no complication; 43.9%), Grade 1 (tightness and/or drifting of implant or Baker grade II capsular contracture; 30.9%), Grade 2 (infection, hypertrophic scarring, or incisional necrosis; 9.8%), Grade 3 (Baker grade III capsular contracture, wound dehiscence, or impending exposure of implant; 5.7%), Grade 4 (implant failure, exchange of implant, or Baker grade IV capsular contracture; 9.8%). 15.3 percent (19 cases) experienced grade 3 or 4 complication and 9.8% (12 cases) had grade 4 complication. Considering non-irradiated breasts, there were two (1.6%) Grade 3-4 complications. For BMI, there was no significant difference by category as defined by the CDC (p=0.91). Patients history of HRT tended to be more likely to have Grade 3 or 4 complications (31.8% vs 12.4% respectively; p=0.08). Patients with depression were more likely to experience a Grade 3 or 4 complication (29.4% vs 13.2%; p=0.01). Multiple logistic regression was used to predict the probability of a Grade 3 or 4 complication with HR use and depression as independent variables. Patients with depression were 4.2 times more likely to have a Grade 3 or 4 complication (OR=4.2, p=0.03) and patients with a history of HRT use were 3.4 times more likely to experience a Grade 3 or 4 complication (OR = 3.4, p=0.04). Only clinical diagnosis of depression was considered as 12/31 (38.7%) with antidepressants used only venlafaxine. Neither BRCA status (p=0.72) nor chemotherapy factors (p=0.42) were associated with complication rates.

Conclusions: Higher rates of TE reconstruction complications may be expected in patients receiving radiotherapy. Patients reporting medical history of depression or HRT use showed statistically significant increase in complication rates. This effect might be attributed to a drug effect or to patient factors such as body image.
2015 San Antonio Breast Cancer Symposium

Title: Complications following total skin-sparing mastectomy and expander-implant reconstruction: Effects of radiation therapy on the stages of reconstruction

Body: BACKGROUND
With increasing numbers of patients requiring post-mastectomy radiation therapy (PMRT), many patients undergoing total-skin sparing mastectomy (TSSM) and immediate two-staged expander-implant (TE-I) reconstruction will receive radiation therapy (XRT) during the course of their reconstruction. Additionally, many patients undergoing TSSM for recurrent cancer have a history of prior lumpectomy and XRT. While the increased risk of reconstructive complications in the setting of XRT has been well-documented, few studies have looked at the impact of XRT on the stages of TE-I reconstruction.

METHODS
All patients undergoing TSSM and immediate two-staged TE-I reconstruction between 2006 and 2013 were identified from a prospectively maintained database. The incidences of TE-I loss and severe infection requiring admission for IV antibiotics were assessed in the subsets of patients with a prior history of XRT and those who received PMRT. Complications were divided into those following the first stage of reconstruction (TSSM and TE placement) and those following the second stage (TE-I exchange).

RESULTS
A total of 218 TSSM and TE-I reconstruction cases were included in the analysis, 85 (39%) with prior XRT and 133 (61%) with PMRT, all of whom received PMRT prior to TE-I exchange. Mean follow-up time was 2.5 years. Nearly all cases of prior XRT occurred in patients who developed a local recurrence and then underwent TSSM; mean time from prior XRT to TSSM was 7 years (range: 2 months to 22 years). Patients with prior XRT were much more likely to develop complications following the first stage of reconstruction than after the second stage (TE-I loss: 15% vs. 4%, p = 0.02; infection: 20% vs. 8%, p = 0.02). Patients who received PMRT had low rates of complications following the first stage of reconstruction, when they had not yet received any radiation exposure (TE-I loss: 3%; infection: 8%). However, rates increased significantly following TE-I exchange, with an 18% TE-I loss and 30% rate of infection, which was nearly 4-fold higher than patients with a prior history of XRT.

CONCLUSIONS
Patients with prior XRT are at significantly increased risk of reconstructive complications following the first stage of TE-I reconstruction after TSSM, even with a remote history of XRT. However, if these patients are able to successfully maintain their reconstruction through tissue expansion, their risk of complications at the second stage is comparable to patients without radiation exposure and significantly lower than patients receiving PMRT. Careful patient selection and appropriate pre-operative counseling for TSSM and TE-I reconstruction is critical to optimize outcomes and set appropriate expectations.
Title: Clinical outcome and patient satisfaction with the use of bovine-derived acellular dermal matrix (SurgiMendTM) in implant-based immediate reconstruction following skin sparing mastectomy: A prospective observational study

Body: The advent of acellular dermal matrix devices (ADMs) has facilitated immediate breast reconstruction (IBR) with mammary implants following skin sparing mastectomy (SSM) for breast cancer treatment or risk reduction. This is a prospective observational single institution study of 118 consecutive patients undergoing a total of 164 SSM and IBR procedures using an implant and bovine-derived ADM (SurgiMend) for breast cancer or risk reduction purposes during 2012-2014. The primary endpoint was the explantation rate and secondary endpoints included patient quality of life, patient satisfaction, objective assessment of aesthetic outcome, surgical complications, recurrence and mortality.

The mean age of the patients was 50.1 years (median age of 48, range of 27-78). Median follow up time was 21 months (mean of 21.4 months, range of 2-40 months). 46 patients had a bilateral SSM and IBR, 5 of whom had bilateral breast cancer and 3 for risk reduction due to a significant genetic mutation. The remaining 37 patients had unilateral breast cancer and a contralateral risk reducing mastectomy. 27 (37.5%) of the 72 patients who had unilateral SSM underwent contralateral adjustment procedures to optimise symmetry, including 9 augmentation mammoplasty, 12 mastopexy and 4 reduction mammoplasty procedures and 2 combined augmentation-mastopexies. 61 patients (51.7%) received chemotherapy, 5 of whom had primary systemic therapy prior to surgery. 32 (27.1%) patients received radiotherapy (10 patients had prior radiotherapy and 22 patients had post mastectomy radiation: PMR). Those with ER positive disease received hormonal therapy. Those with Her2 positivity received Herceptin +/- Pertuzumab.

Over the study period, 2 implants had to be removed resulting in an explantation rate of 1.2%. Overall, wound complications were observed in 6 (3.7%) cases. There were 2 cases of local recurrence (1.7%), one distant recurrence (0.8%) and one patient died of metastatic breast cancer (0.8%). Overall survival was 99.2% and locoregional disease free survival (LRFS) was 98.3%. One patient (0.8%) developed a mild inflammatory reaction secondary to the underlying mesh. Wound complications were observed in 3 other patients (2 haematomas and wound dehiscence/persistent seroma requiring implant replacement).

Patient satisfaction with the procedure was very high. The mean Breast Q Score was 85 and mean overall patient satisfaction was 9 out of a possible 10. The mean objective assessment score was 8.9 out of a possible 10 and the mean subjective capsular contracture severity score was 2.9 out of 10.

In patients undergoing reoperations, the incorporation rate of the mesh was found to be very high almost approaching 95%. SurgiMendTM is an effective adjunct to IBR using implants following SSM for breast cancer or risk reduction, with a very low rate of implant loss and a high level of patient satisfaction. Furthermore, this ADM seems to incorporate readily and is associated with a very low incidence of inflammatory reactions. Neither prior radiotherapy nor PMR radiation represents a contraindication to its use.
Title: A head to head comparison between SurgiMend® - Fetal bovine acellular dermal matrix and Epiflex® - Decellularized human skin tissue in breast reconstruction in 127 cases

Eichler C, Vogt N, Brunnert K, Sauerwald A, Puppe J and Warm M. Breast Center, Municipal Hospital Holweide, Cologne, NRW, Germany; Municipal Hospital Holweide, Cologne, NRW, Germany; Clinic for Senology, Osnarbrueck, Germany; Hospital Düren GmbH, Dueren, NRW, Germany and University of Cologne, Cologne, NRW, Germany.

Body: Introduction: The use of acellular dermal matrices (ADM) has become a widely used option in breast reconstruction. A great deal of literature is available, totaling over 2400 ADM reconstructions. Nonetheless, head to head comparisons between SurgiMend® and Epiflex® are not yet reported. In fact, this is the first clinical data report on the use of Epiflex®. This work will therefore compare postoperative complication rates and costs for these ADMs.

Methods: This analysis is a retrospective review of a single surgeon's 6-year experience with both SurgiMend® – an acellular bovine dermal collagen matrix for soft-tissue reconstruction and Epiflex® – a decellularized human skin tissue from 2008 to 2013.

Results: One hundred patients had a total of 127 implant based reconstructions using SurgiMend® (64 cases; 50.4 %) or Epiflex® (63 cases; 49.6 %). Gross complication rates were 11.1 % for SurgiMend® and 40.6 % for Epiflex® including hematoma, postoperative skin irritation, infection, necrosis and revision surgery. The most common complication was postoperative red breast syndrome. Severe complications requiring revision surgery were significantly increased in patients treated with Epiflex® (12.5 %) compared to SurgiMend® (4.8 %). Conclusions: This retrospective analysis favors the use of SurgiMend® over Epiflex® due to significantly lower gross complication rates. Severe complication rates are comparable to those reported in literature for both products. Although results promote the use of SurgiMend®, the single surgeon, retrospective nature of this work limits its clinical impact.
**Title:** Acellular dermal allograft fenestrations decrease outpatient expander fills and increase direct to implant incidence in implant-based immediate breast reconstruction

**Body:** Introduction: The innovation of fenestrated allograft (acellular dermal matrix, ADM) has improved patient outcomes in two-stage tissue expander/implant breast reconstruction. This technical alteration utilizes optimal fenestration overlap and has enhanced the efficiency of the reconstructive experience. We present a follow-up study of one- and two-stage breast reconstruction with a more refined, standardized method of surgeon-designed fenestration of ADM. Methods: We conducted a retrospective review of 52 patients (91 breasts) having undergone one- and two-stage breast reconstruction using fenestrated ADM at our institution from 2013 to 2014. Results: Mean intra-operative fill volume (IOFV) measured 402cc (SD=118cc), and IOFV as a percent of tissue expander size averaged 79.1% (SD=16.7%). Ten breasts were expanded to 100% and completed reconstruction in one stage with implant placement. IOFV as a percentage of total fill volume at completion of expansion averaged 73.6% (SD=16.6%). Two-stage reconstruction patients underwent 1.8 post-operative expansions on average (range 0-4) and averaged 81.2cc (SD=29.3cc) per in-office expansion. Days to full expansion averaged 45.1 days, while days to exchange averaged 137.8 days (Table 1). Mean days to exchange between our first 24 breasts to complete reconstruction vs. our last 23 breasts to complete reconstruction differed significantly, with 205 ± 43.8 days vs. 137.7 ± 138.1 days, respectively (p=0.03). The major complication rate requiring re-operation within 30 days post-operatively was 11.0%. Four breasts experienced partial mastectomy flap necrosis requiring re-operation with implant salvage (4.4%). Six breasts (6.6%) underwent explantation due to: infection (three), flap necrosis (two), and patient preference (one) (Table 2). Conclusion: Our fenestrated technique is demonstrated to increase intra-operative fill volume, decrease number of post-operative expansions and time to full expansion, and improve expansion rate with subjectively less pain. We believe our patients benefited from improved cosmetic outcomes with better shape, maintenance of breast footprint, and enhanced comfort due to the decreased number of intra-office fills and increased intra-operative expansion.

Title: Clinical application of adipose derived stem cells in reconstructive breast surgery: A decade and a half later… are we there yet?

Westbroek D, Dontu G and Roberts JW W. KHP, London, United Kingdom.

Body: Background:
The unbroken narrative of the past three decades of modern ablative and reconstructive breast surgery has been (i) the minimising of surgical insult (integument preserving resection and staging) and; (ii) decreasing donor site morbidity (perforator flap surgery) respectively with equivocal oncological outcomes. Reconstructive surgical oncology aims to advance loco-regional disease control whilst approximating pre-morbid status ("like for like tissue replacement") with the least possible morbidity. Adipose derived mesenchymal stem cells (ASC’s) first reported in 2001, hold great promise to drive this singular trend forward. ASC’s are pluripotent cells, abundantly present in the vascular stromal fraction of the body’s fat tissue. They hold the key to unlocking the body’s regenerative potential by replacing & repairing the sequelae of surgery and adjuvant radiation therapy. ASC harvest is a relatively straightforward procedure with minimal donor site morbidity (Coleman's lipofilling). Evidence of a further ASC- driven turn of the evolutional wheel is currently lacking. We aim to review the evidence to date of the clinical utility of ASC’s in breast surgery and evaluate options available to enhance their further clinical application.

Method:
We searched the Cochrane Central Register of controlled trials, Medline® (2000 – June 2015), Embase® (2000 – June 2015) and Evidence Search Results (last search June 2015). Search terms used: "adult and/or pluripotent stem cells"; and "adipose tissue". Results were limited to "English language, Humans and Clinical and/or Randomised Controlled Trial" yielding 60 items. We also hand searched conference proceedings, reference lists and review bibliography. Two review authors independently screened articles for primary outcome - clinical efficacy in breast surgery (assessed as "volume retention") at follow-up (minimum of six months). Secondary outcomes included: donor site morbidity and neoplastic transformation (recurrent disease at final follow-up).

Results:
There are to our knowledge, no reported RCT’s or matched controlled studies in humans of ASC assisted lipofilling. There is one single-arm study with no controls (RESTORE-2, Cytori Therapeutics. 2011) and several case series reports with variable clinical endpoints. No adverse oncological events were reported. No donor site complications beyond Clavien-Dindo Grade I were recorded.

Conclusions:
ASC assisted lipofilling theoretically has game-changing potential to improve outcomes following ablative breast surgery. Clinical efficacy and oncological safety are unresolved. A controlled study in humans with long-term outcomes remains the way forward.

**Title:** Breast lipofilling: A systematic review of current practice and oncological safety

**Body:**

**Background:** Lipofilling is a reconstructive and aesthetic technique that has recently grown in popularity and is increasingly being used in breast surgery. Concerns had been raised regarding its safety when used for remodelling and reconstruction of the breast.

**Methods:** We reviewed the current literature by systematically searching PubMed and Google Scholar databases regarding the current evidence regarding the oncological safety of the procedure in patients seeking aesthetic breast enhancement and in patients requiring oncoplastic reconstruction.

**Results:** Among the 864 patients included in the currently available studies on breast cancer patients who underwent lipofilling, only 14 (1.6%) recurrences were identified. However, evidence has emerged suggestive that the use of lipofilling in the background of ductal carcinoma in situ (DCIS) may be associated with an increased risk of neoplasia.

**Conclusions:** Over the subsequent two decades, little evidence has been found to support these early theoretical concerns, and growing numbers of proponents of the procedure are confident in its safety. Further study is required to better delineate the effect of lipofilling on DCIS.
Title: Is nipple-sparing mastectomy with implant reconstruction for breast cancer safe and worthwhile?

Regis C, Mesdag V, Tresch E, Chauvet MP P, Boulanger L, Collinet P and Giard S. Centre Oscar Lambret, Lille, France; Biostatistics Unit, Centre Oscar Lambret, Lille, France and Hospital Jeanne de Flandre, University Hospital, Lille, France.

Body: Background: Nipple-sparing mastectomy (NSM) is a standard for bilateral prophylactic surgeries. However for cancer treatment, the preservation of the nipple areolar complex (NAC) is still discussed because of suspected increase of local recurrence and surgical specific complications as nipple or mastectomy flap necrosis. The aim of the study was to investigate both the relapse risk associated with NSM for breast cancer and women's satisfaction with preservation of the NAC.

Methods: We included retrospectively all patients who had skin-sparing mastectomy (SSM) or NSM from 2007 to 2012 for breast cancer or ductal carcinoma in situ (DCIS). We compared NSM and SSM group for oncological (overall survival (OS) and disease-free survival (DFS)) and surgical outcomes. Patients' satisfaction and quality of life has been evaluated by a specifically designed questionnaire, addressed by mail and inspired by the Breast-Q questionnaire with specific assessment of global esthetic result, harmony with the native breast and need for psychological support.

Results: During the study, we operated 5600 patients for a breast cancer, among them, 152 had NSM (n=63 / 41.5%) or SSM (n=89 / 58.5%) with immediate implant breast reconstruction. Eighty-nine (58.6%) patients had DCIS, and the other had invasive disease (86.9% of T1). The mastectomy has been indicated for primary cancer (81%) or recurrence (19%). The two groups did not differ significantly according to histological type (p=0.10), grade (p=0.84), hormonal receptor (p=0.7), HER2 (p=1.00), Ki67 (p=0.75) or node metastases (p=0.64). Median follow-up was 42 (IQR: 18-58 ) months. No cancer-related death occurred during the study. Local recurrence rate was 1.7% (n=1) in NSM group and 0% in SSM group (p=0.35). The recurrence did not appear on the preserved nipple. Severe complication requiring surgery (Grade 3 of Clavien-Dindo classification) occurred in 9.9% of the cases. In the NSM group, one patient had complete NAC necrosis and three patients suffered partial necrosis. Severe skin-flap necrosis leading to implant removal was more frequent in the SSM group (SSM: 6.7% (n=6) ; NSM: 0% (n=0); p=0.042). One hundred and four (80%) patients answered the questionnaire. Satisfaction about the aspect of the NAC was higher in the NSM group compared to SSM with delayed reconstruction of the nipple (75% vs 59%, p=0.14). Patients with NSM needed less psychological support before (p=0.028) and immediately after surgery (p=0.14) than patients in the SSM group, which may suggest a better acceptation of the surgery in this group.

Conclusion: NSM for breast cancer surgery was not associated with significant increase of local recurrence rate or surgical complications. Patient's satisfaction was high. Therefore, nipple-sparing mastectomy with immediate implant reconstruction can successfully and safely be performed for pre-invasive and small invasive breast cancer. Besides esthetic aspects, preserving the nipple may ease the acceptation of these radical surgeries.
**Title:** Expanding the scope of implant based reconstruction; Good results can be achieved in challenging and high-risk patients

**Body:** Aims: Implant based reconstruction can be challenging, especially in higher risk patients, resulting in implant loss, poor cosmesis and delayed wound healing. We assessed outcomes of higher risk patients with a multi-centre study, including 5 hospitals in the North West of England. Our trainee-led, regional data collection removes any single surgeon or institution bias. Methods: A multi-centre, retrospective review of implant-based reconstructions between 01/01/12 & 31/12/12 was performed. Rates of implant loss from complications, unplanned explantation for cosmesis and delayed wound healing were assessed for those deemed at high risk (obese BMI>30, Smokers, previous chest wall radiotherapy (RT), elderly >65years, underweight BMI<20 & neo-adjuvant chemotherapy(NAC)).

Results: 216 reconstructions were assessed, with follow-up for minimum of 24 months. 117/216 patients had at least one of the high-risk features of which; 59 were obese, 50 smokers, 28 previous RT, 18 elderly, 10 underweight & 7 had NAC. Reconstructive strategy in the High Risk group was implant/expander only 42 (36%), implant & flap 35(30%), implant- ADM 27(23%), implant & dermal-Sling 11(9%), & other 2(2%), vs. the Low Risk group (n=99); implant/expander only 29(29%), implant & flap 22(22%), implant-ADM 35(35%), implant & dermal-sling 9(9%), & other 4(4%).

Of the 59 obese patients 10(17%) implants were explanted (6 for complications and 4 for unplanned cosmetic revision) and 14(24%) had delayed wound healing, compared to 18(11%) explant and 22(14%) delayed wound healing in non-obese; suggesting obesity increases risk in implant reconstruction (p=0.36 & p=0.1 respectively).

Smoking is associated with increased risk, with 13(26%) implants lost (9 from infection & 4 for unplanned cosmetic revision) compared to 15(9%) in non-smokers (p=0.01) and 12(24%) having delayed wound healing compared to 24(14%) (p=0.1).

Of the 28 patients who had previous RT the predominant reconstructive strategy was implant with LD-flap (17/28, 61%). Of all RT patients, 5(18%) implants were lost (3 for complications, 2 unplanned revision) compared to 12% in non-RT patients. Delayed wound healing was common; 10(36%) compared to 26(13%) (p=0.01).

Implant based reconstruction in the elderly, underweight and NAC groups have similar implant loss and delayed wound heal rates as the non-RT comparison groups, see table 1.

Only 6/216(3%) patients were diabetic, suggesting surgeons may negatively select this patient group for implant reconstruction.

Conclusions; Implant based reconstruction is feasible in many of the higher risk, challenging patients that are encountered in a UK NHS practice. However even with the limited numbers of high-risk patients in this study smoking and RT, are associated with increased risk.

Title: Assessing the impact of post-surgery areola repigmentation and 3-dimensional nipple tattoo procedures on body image and quality of life among medically underserved breast cancer survivors

Burke NJ J, Orenstein F, Napoles T, Chaumette S and Luce J. University of California, San Francisco, San Francisco, CA and San Francisco General Hospital, San Francisco, CA.

Body: Background: The benefits of 3D nipple tattooing include restoration of a natural looking breast as well as the avoidance of additional surgeries to create a breast that more closely resembles its pre-surgical appearance. 3D nipple tattooing forms part of completion of the physical reconstruction process, offers women opportunity for a greater sense of closure around the loss of their breast, and plays an important role in helping a woman feel "whole again" physically, sexually and emotionally. The project's aim was to evaluate the experience of 3D-nipple/areola tattooing for medically underserved women who have undergone breast reconstruction and remain without a nipple or areola.

Methods: In-depth interviews were conducted with 20 women who had undergone 3D-nipple/areola tattooing. Interviews were conducted in English and Spanish, recorded, translated and transcribed into English for analysis. Two research team members coded all interview transcripts and the research team met monthly to discuss emergent themes.

Results: Interview narratives addressed the often unexpected impact 3D nipple-tattooing had on body image, self-esteem, emotional well-being, intimacy, and inter-personal relationships. Women described their decision-making processes as weighing concern about the needle, the pain, and the uncertainty of the outcome with the opportunity for returning to a more 'normal' appearance. Women also discussed the impact of the experience on their survivorship and sexuality in positive ways.

Conclusions: 3-D nipple and/or areola tattooing is an acceptable and meaningful reconstruction process for medically underserved public hospital patients. The decision to undergo 3-D nipple and/or areola tattooing can be complex and is impacted by a woman's surgical history and outcomes. The emotional response and positive impacts of the tattooing on body image and self-esteem illustrate the value of the procedure in the context of women's lives.
Body: Background
The scheduling of mastectomy with immediate reconstruction (M-IR) procedures requires coordination between breast and plastic surgical teams that can contribute to delays in breast cancer treatment and subsequently impact patient outcomes and satisfaction. The breast center leadership at our comprehensive cancer center established a time-to-treatment target of 28 days from initial consultation with a breast surgical oncologist to M-IR. We sought to determine if a centralized breast surgical coordinator (BC) could reduce preoperative delays.

Methods
We initiated a 60-day pilot program to evaluate the impact of a BC on the workflow, efficiency, and timeliness for patients seen at our breast center. All reconstructive surgery candidates were referred to the BC, who had access to the clinic and operating room schedules of the breast and plastic surgeons. The BC worked with patients and both surgical services to identify the earliest consult and surgery dates and facilitated case booking. Interval days between initial surgical consult and M-IR were calculated. The median time to M-IR and the proportion of M-IR cases that met the time-to-treatment goal was determined. These results were compared to a reference cohort of breast cancer patients undergoing M-IR during the same time period (January-March) in 2013 and 2014, who had their consults and surgeries scheduled independently by breast surgery administrative staff. Patients who received neoadjuvant therapy or did not have a definitive cancer diagnosis at initial consultation were excluded from the time-to-treatment calculation.

Results
A total of 99 patients were referred to the BC (62% cancer, 21% neoadjuvant, and 17% prophylactic) during the pilot period. Focusing exclusively on patients with a definitive breast cancer diagnosis at initial consultation, an 18.5% increase in the percentage of cases that met the target (p=0.04), and a 7 day decrease in the median number of days to M-IR (p=0.02) was observed with the implementation of the BC (Table 1).

Conclusion
The coordination of care between breast surgical and reconstructive services presents timeliness challenges which may be partially alleviated through the implementation of a BC role. Establishing a centralized position to coordinate co-surgeon cases has improved time-to-treatment for M-IR at our cancer center. Further research is warranted to validate these preliminary findings, and determine the impact the BC has on operational efficiency and workflows.
Title: CDK7: A marker of poor prognosis and tractable therapeutic target in triple-negative breast cancer

Body: Triple-negative breast cancer (TNBC) is defined by absent expression of estrogen receptor (ER), progesterone receptor (PR) and non-overexpression of human epidermal growth factor receptor 2 (HER2), representing a heterogeneous subgroup of breast cancer with substantial genotypic and phenotypic diversity. TNBC patients commonly exhibit poor prognosis and high relapse rates at early stages after conventional treatments. Currently, there is a lack of biomarkers and targeted therapies for the management of TNBC. During tumour development and progression, alterations in cellular behaviour are frequently linked with kinase expression and activity. Here, we aimed to identify novel kinase targets that may play a pivotal role in the progression of TNBC and, thus, offer new therapeutic vantage points.

We initially focused on identifying kinases correlated with differential outcome. Using publicly available transcriptomic data from a collated set of TNBC patients (n = 483), we identified 9 kinases that were significantly associated with survival at the mRNA level. From this in silico screen, CDK7 (cyclin-dependent kinase 7) was found to be correlated with poor recurrence-free survival. CDK7's trait as a marker of poor prognosis was further validated within another TNBC cohort (n=109) via assessment of a tissue microarray generated as part of the RATHER Consortium (www.ratherproject.com). At the protein level, high CDK7 expression was associated with poor breast cancer-specific, recurrence-free and distant recurrence-free survival.

To evaluate CDK7 as a therapeutic target in TNBC, two TNBC cell lines (BT-549 and MDA-MB-231) were selected to evaluate phenotypic alterations post shRNA-mediated CDK7 knockdown. CDK7 silencing led to decreased cell proliferation, colony formation and migration in vitro. CDK7 down-regulation also increased TNBC cell sensitivity to doxorubicin. BS-181 and THZ1, two highly specific CDK7 inhibitors, attenuated TNBC tumour growth by inducing G2/M phase cell cycle arrest and apoptosis, as well as down-regulation of RNAPII phosphorylation, an indication of global RNA transcription inhibition. Moreover, the covalent CDK7 inhibitor THZ1 demonstrated 1000-fold higher potency than BS-181. Inhibition of global RNA transcription preferentially affects proteins with short half-lives. Accordingly, we detected a reduction in the expression of the anti-apoptotic protein MCL-1 in both cell lines.

Next, we assessed anti-apoptotic dependence in MDA-MB-231 cells following treatment with THZ1 via BH3 profiling technology, and observed an increased response to the BAD and HRK peptides, inferring an elevated survival dependence on BCL-2/BCL-XL. We subsequently evaluated the combination of the BCL-2/BCL-XL inhibitor ABT-263 with THZ1 and discovered a synergistic inhibition of cell growth and apoptosis. Resulting combination index (CI) values demonstrated that synergistic cell death occurred following combined treatment with THZ1 and ABT-263/ABT-199 at various doses in both TNBC cell lines tested. Our data implicate high CDK7 expression as a promising biomarker of poor prognosis in TNBC. Moreover, these findings suggest that targeting CDK7, combined with the BCL-2/BCL-XL inhibitor ABT-263, may be a useful therapeutic strategy for TNBC.
Second-generation selective glucocorticoid receptor modulators in triple-negative breast cancer

Body: Triple-negative breast cancer (TNBC) lacks expression of the estrogen receptor (ER), progesterone receptor (PR), and HER2. A subset of primary TNBCs (at least 30%) expresses moderate to strong glucocorticoid receptor (GR) in greater than 10% of invasive tumor cells; in addition, we have reported that increased GR signaling promotes TNBC cell survival. Furthermore, our laboratory recently observed that patients with early stage/high-GR-expressing TNBCs have a relatively poor prognosis. Therefore, GR is being explored as a target for improving outcome in TNBC. Indeed, mifepristone, a well-characterized non-selective steroidal GR/PR antagonist, has shown promise in reversing GR-mediated tumor cell-survival signaling in TNBC. In vivo, increased TNBC xenograft chemosensitivity was observed when mifepristone was added to chemotherapy treatment. Most recently, a Phase I clinical trial demonstrated the safety and potential efficacy of mifepristone added to nab-paclitaxel chemotherapy in Stage IV TNBC patients.

Three highly selective non-steroidal GR antagonists (GRAs) have been investigated, CORT108297, CORT125134 (two aryl pyrazole-fused azadecalins) and CORT118335 (a pyrimidine dione). These new GRAs have 1) far less cross-reactivity than mifepristone with other nuclear receptor family members and 2) lower interaction profiles for drug metabolizing CYP enzymes. We hypothesized that selective GRAs would not only inhibit GR-induced pro-survival gene expression, but also increase TNBC chemosensitivity, and may eventually be a valuable adjunct therapy for treating chemotherapy-resistant TNBC.

To understand how GR modulators interact with the GR ligand-binding domain (LBD), we are employing two approaches: 1) computational modeling of the GRA-GR LBD based on published crystal structures of the GR LBD with mifepristone (in collaboration with UIUC), and 2) crystal structure analysis of the GR LBD with GR modulators. Preliminary computational results indicate that CORT108297 docks into the LBD and antagonizes GR activity by indirectly disordering Helix 12. Experiments are ongoing using various buffer conditions to produce crystals of the GR LBD with CORT108297 and CORT118335 for x-ray crystallography.

Secondly, we are functionally characterizing CORT108297, CORT125134, and CORT118335 for their ability to inhibit glucocorticoid induction of key GR-mediated target genes. Over the course of eight hours, we observed that the compounds exhibited temporal antagonism of the expression of GR target genes encoding anti-apoptotic proteins such as SGK-1, MCL-1, and MKP-1/DUSP1. Lastly, we are examining the selective GRAs’ ability to enhance tumor cell cytotoxicity from paclitaxel in cell culture and in TNBC xenograft models. Preliminary results indicate that CORT125134 and CORT108297 significantly increase GR+ TNBC sensitivity to paclitaxel, and are well-tolerated in our in vivo models.
Title: Inhibition of the autocrine IL6-JAK2-STAT3-calprotectin axis as targeted therapy for HR-/HER2+ breast cancers

Body: Although HER2+ tumors are commonly considered as a single entity there is increasing evidence indicating that important intrinsic differences associated to hormone receptor status (HR) exist. Indeed, while HR+/HER2+ patients benefit from anti-hormonal and HER2 targeted therapies, the outcome of HR-/HER2+ patients strongly depends on their response to chemotherapy as well as anti-HER2 therapy. To identify genes that represent novel mechanistic dependencies in HR-/HER2+ breast cancer cells, we designed an integrative approach that combines functional genomic (RNAi screens) and computational algorithms to interrogate regulatory networks reverse engineered.

Our analysis identified STAT3 as a de novo master regulator (MR) gene associated to HER2 mediated transformation in HR-breast cancer cells. Importantly, we demonstrate that aberrant STAT3 activity is necessary to maintain HR-/HER2+ tumor state, thus representing a non-oncogene dependency. Mechanistically we found that HR-/HER2+ breast tumors secrete high levels of IL-6. This acts in an autocrine way to induce the activation of STAT3 via the canonical JAK2/STAT3 pathway. Aberrant STAT3 activity induces upregulation and secretion of the S100A8/9 complex (Calprotectin) triggering a second autocrine stimulus that enhances proliferation and survival via ERK1/2 and AKT. As a result, disruption of the "IL6-JAK2-STAT3-S100A8/9 cascade" compromises HR-/HER2+ cell viability suggesting that the components of this pathway represent putative therapeutic targets in HR-/HER2 tumors.

Importantly, small molecule inhibitors and blocking antibodies for components of this double autocrine loop are already FDA approved or in clinical trials. Here, we demonstrate in vivo that blocking the IL-6 receptor (IL-6R) with the humanized monoclonal antibody Tocilizumab, STAT3 inactivation with the dual JAK1/2 inhibitor Ruxolitinib or Calprotectin inhibition with the small molecule inhibitor Tasquinimod), alone or in combination with anti HER2 therapies, compromises the viability of HR-/HER2+breast cancer cells. Availability of FDA-approved inhibitors to target this novel mechanism represents an exciting opportunity for rapid translation of these findings to the clinics.
Title: PAK-1 amplified breast cancer cell lines are preferentially sensitive to PAK inhibition with G-5555

Body: The small GTP-binding proteins Rac1 and Cdc42 stimulate activity of the serine/threonine kinase p21-activated kinase-1 (PAK-1) to drive growth factor signaling networks and Ras-driven tumorigenesis. Genomic amplification and over-expression of PAK1 are prevalent in luminal breast cancer and correlate with poor clinical outcome. Here we use a novel and selective small molecule inhibitor, G-5555, of the group I PAKs (PAK1, 2, and 3) to evaluate the importance of PAK1 in promoting growth of PAK1 amplified breast cancer cells. Cell lines with amplification of PAK1 were found to be more sensitive to PAK1 inhibition than non-amplified cell lines. Additionally, reverse phase protein array (RPPA) was used to assess the effects of PAK1 inhibition on a wide range of signaling pathways in both amplified and non-amplified cell lines. Reduced levels of phosphorylation of MEK S298 was observed in all cell lines exposed to G-5555 irrespective of amplification status, consistent with PAK1 inhibition in these cell lines. However, modulation of this downstream PAK1 substrate did not correlate with inhibition of cell proliferation or induction of cell death. Cell lines that showed inhibition of proliferation in response to G-5555 also showed enhanced levels of cell death along with apoptosis. Moreover, G-5555 reduced tumor growth in the PAK1 amplified MDA-MB-175 xenograft tumor model. Finally, we compared the in vitro activity of G-5555 with palbociclib, a recently approved inhibitor of the cyclin-dependent kinases CDK4 and CDK6, in PAK1 amplified luminal breast cancer cell lines. Our data supports PAK1 as an attractive target in PAK1 amplified cells and tumors and suggests that inhibiting PAK1 rather than CDK4/6 in this context may be a more attractive therapeutic strategy.
Title: Inhibition of fatty-acid oxidation as a therapy for triple-negative breast cancer

Body: Expression of the oncogenic transcription factor MYC is disproportionately elevated in triple-negative breast cancer (TNBC) compared to estrogen, progesterone and/or human epidermal growth factor 2 receptor-positive (RP) breast tumors. We and others have shown that MYC alters metabolism during tumorigenesis. However, the role of MYC in TNBC metabolism remains largely unexplored. We hypothesized that pharmacologic inhibition of MYC-driven metabolic pathways may serve as a therapeutic strategy for this clinically challenging subtype of breast cancer. Using an unbiased metabolomics approach, we identified fatty acid oxidation intermediates as dramatically up-regulated in MYC-driven models of TNBC. A lipid metabolism gene signature was identified in patients with TNBC in the TCGA and multiple other clinical datasets, implicating fatty acid oxidation as a deregulated pathway critical for TNBC metabolism. We find that MYC-overexpressing TNBC, including transgenic models and patient-derived xenografts (PDX), display increased bioenergetic reliance upon fatty-acid oxidation (FAO). Pharmacologic inhibition of FAO catastrophically decreases energy metabolism of MYC over-expressing breast cancer, blocks growth of a MYC-driven transgenic TNBC model and MYC-overexpressing patient-derived xenografts. In vivo inhibition of FAO induced proliferation arrest and increased cell death in PDX models of TNBC. Our results demonstrate that inhibition of FAO is a novel therapeutic strategy against TNBCs that over-express MYC.
Title: Safety and efficacy of anti-Trop-2 antibody drug conjugate, sacituzumab govitecan (IMMU-132), in heavily pretreated patients with TNBC

Bardia A, Diamond JR R, Mayer IA A, Starodub AN N, Moroose RL L, Isakoff SJ J, Ocean AJ J, Guarino MJ J, Berlin JD D, Messersmith WA A, Thomas SS S, O'Shaughnessy JA A, Kalinsky K, Maurer M, Chang JC C, Forero A, Traina T, Gucalp A, Wilhelm F, Wegener WA A, Maliakal P, Sharkey RM M, Goldenberg DM M and Vahdat LT T. Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA; University of Colorado Cancer Center, Aurora, CO; Vanderbilt-Ingram Cancer Center, Nashville, TN; Indiana University Health Center for Cancer Care, Goshen, IN; University of Florida Health Cancer Center, Orlando, FL; Weill Cornell Medical College, NY, NY; Helen F. Graham Cancer Center & Research Institute, Newark, DE; Baylor Sammons Cancer Center, Texas Oncology, Dallas, TX; Columbia University Medical Center, NY, NY; Houston Methodist Cancer Center, Houston, TX; University of Alabama Medical Center at Birmingham, Birmingham, AL; Memorial Sloan Kettering Cancer Center, NY, NY and Immunomedics, Inc., Morris Plains, NJ.

Body: Background: Triple-negative breast cancer (TNBC) comprises about 15% of all breast cancer types, and has a particularly aggressive course. Following first-line therapy, the median PFS is <3 months, and OS is <10 months. Therefore, new treatment strategies are needed. Since Trop-2 is expressed in >90% of TNBC, as measured by IHC, we conducted a trial to evaluate the safety and efficacy of a humanized anti-Trop-2 monoclonal antibody conjugated to a high concentration of SN-38, a camptothecin that is a topoisomerase I inhibitor and the active metabolite of the prodrug irinotecan, with 2-3 logs higher potency than the prodrug.

Methods: After establishing the optimal repeated dose in a Phase I trial (ClinicalTrials.gov, NCT01631552) involving many different solid cancer types, an expanded Phase II was undertaken in a number of cancers, including TNBC. Patients received 8 or 10 mg/kg IMMU-132 i.v. on days 1 and 8 of 21-day repeated cycles. Assessments of safety and response by RECIST1.1 were made weekly and bimonthly, respectively. Tumor biopsies (archival, at baseline prior to treatment, and at disease progression) were obtained when safe and feasible.

Results: As of May 10, 2015, 58 patients with TNBC, with a median of 4 prior therapies (range, 1-11), were treated with IMMU-132. Grade 3-4 toxicities included neutropenia (26%), febrile neutropenia (2%), diarrhea (2%), anemia (4%), and fatigue (4%). No patient developed antibodies to SN-38 or the antibody, and no patient discontinued therapy due to toxicity. Tumor responses were defined as ORR (CR+PR) in 31% of 49 evaluated patients, including 2 with CR, and a clinical benefit ratio (CR+PR+SD>6 mo) of 49% (63% with SD>4 mo; 23 patients continuing treatment after 1st assessment). The current median progression-free survival is 7.3 months with 44% maturity in 50 patients treated at the 8 or 10 mg/kg dose level. Overall survival data are still not mature 20 months after enrollment of first patient. Clinical efficacy correlated to biomarker studies, including Trop-2 expression (target of antibody), topoisomerase-1 expression (target of SN-38), and homologous recombinant deficiency (HRD) assay (marker of DNA repair), is being studied. Immunohistochemistry results in archival specimens currently show 97% positivity of Trop-2 among 34 specimens evaluated, with 79% having high intensity (2+/3+) staining.

Conclusions: The Trop-2-targeting IMMU-132, delivering cytotoxic doses of the topoisomerase I inhibitor, SN-38, shows manageable toxicity, and encouraging anti-tumor activity in relapsed/refractory patients with TNBC. This ADC appears to have a high therapeutic index in heavily pretreated patients.
Title: TEM8 specific CAR T cells serve as a novel targeted therapy for triple negative breast cancer and its supporting endothelium

Byrd T, Fousek K, Pignata A, Szot C, Bielamowicz K, Wakefield A, Koch J, Landi D, Seaman S, Wels W, Fletcher B, Hegde M, St Croix B and Ahmed N. Baylor College of Medicine, Houston, TX; National Cancer Institute, Frederick, MD; Georg Speyer Haus, Frankfurt am Main, Germany and University of Florida, Gainesville, FL.

Body: Background: Triple Negative Breast Cancer (TNBC) refers to an aggressive subtype of breast cancer negative for HER2, estrogen and progesterone receptors. Lacking these receptors, individuals with TNBC do not benefit from many of the targeted therapies for breast cancer. Tumor endothelial marker 8 (TEM8), originally identified as a tumor endothelium associated antigen, has more recently been implicated in TNBC pathogenesis and as a marker of breast cancer stem like cells. Here we report that T cells expressing a TEM8-specific chimeric antigen receptor (CAR) serve as a novel approach to target both TNBC cells and its supporting endothelium. CARs combine the specificity of a monoclonal antibody with the signaling properties of a T cell. Methods: We designed two novel TEM8-specific CAR molecules. A CAR molecule containing an exodomain derived from the anti-TEM8 L2 antibody, followed by CD28 and CD3-zeta signaling domains (second generation CAR) and CD28, 41BB and CD3-zeta signaling domains (third generation CAR), respectively. Retroviral transduction was used to express the TEM8 CAR transgene constructs on HEK 293T cells, then on primary T cells. Results: Immunofluorescence staining revealed that in a panel of primary TNBC breast cancer samples, TEM8 was overexpressed in comparison to normal adjacent breast tissue (6/6). Costaining with the pan-endothelial cell marker CD31 revealed that this overexpression was not confined to the endothelial compartment, but also present on tumor parenchymal cells. The immortalized TNBC cell lines (MDA-MB-231, MDA-MB-436, MDA-MB-468 and Hs578T) expressed endogenous levels of TEM8 protein as revealed by western blot. Greater than 90% transduction of primary human T cells was achieved using both of our CAR constructs, as detected by flow cytometry. TEM8 specific T cells displayed significantly higher killing of TEM8 positive TNBC and tumor endothelial cells (2H11 and bEND.3) in standard four hour chromium release assays when compared to both non-transduced or irrelevant (CD19) CAR T cells and secreted immunomostimulatory cytokines upon encounter of TEM8 positive cells in coculture assays. In a vascularized xenograft model, MDA MB468 cells were injected subcutaneously with matrigel into athymic nude mice and followed via bioluminescence imaging over the course of two months. Established tumors were treated with either, second or third generation TEM8 specific T cells, HER2 specific T cells, non-transduced T cells or left untreated. Relative to non-transduced T cells, TEM8 specific second and third generation CAR T cells significantly delayed tumor growth by 36 days and 50 days, respectively. Conclusion: TEM8 specific CAR T cells could serve as a novel targeted therapy for TNBC and supporting endothelium.

Title: Modulation of immunity with 2-fluorofucose (2FF) for breast cancer treatment and prevention

Disis ML L, Rastetter L, Gad E, Koehnlein M, Senter PD D, Gardai S and Okeley NM M. Tumor Vaccine Group, University of Washington, Seattle, WA and Seattle Genetics, Inc., Bothell, WA.

Body: The majority of patients with breast cancer have robust Type II immune responses directed against their tumors with little to no Type I immunity. The dominance of a Type II microenvironment is established early in breast tumorigenesis with a Type II immune signature prevalent even in pre-invasive lesions such as ductal carcinoma in situ. As a result, breast cancer is associated with abundant autoantibodies directed against tumor associated antigens and few infiltrating T-cells in the majority of patients. A recently reported inhibitor of protein and cellular fucosylation, 2-fluorofucose (2FF) has been shown to enhance immune cell function, in part through the generation of fucose-deficient antibodies which result in enhanced antibody dependent cell mediated cytotoxicity, as well as apparent modulation of T-cell dependent activity [Ca Res, Oct 1, 2014 74;2890].

For treatment studies, TgMMTV-neu (MMTVneu; luminal) and C31-Tag (C3T; triple negative) mice were treated orally with vehicle alone and 20mM 2FF when spontaneous tumor volume reached 75-100mm3 until sacrifice (n=20/grp). To assess the ability to prevent breast cancer development, mice were treated orally with vehicle alone, 20 or 50mM 2FF for up to 200 days starting at 6-8 weeks of age (n=20/grp). Tumor kinetics, disease free survival, and overall survival were calculated. Immune responses were evaluated by both DTH and IFN-gamma ELISPOT. To determine immune mechanism of action, NK, B, CD4, or CD8 cells were depleted concurrently with tumor implant.

When tumor bearing mice were treated with 2FF, tumor growth was significantly inhibited in both groups over the course of therapy (MMTVneu p<0.0001 and C3T p<0.0001 compared to controls). In addition, survival was significantly prolonged in both models (MMTVneu p<0.0001 and C3T p=0.0014). In the prevention setting, 2FF significantly delayed the average age of tumor onset in both models at both doses with the higher doses showing greater efficacy; MMTVneu 20mM, p=0.001, 50mM, p=0.0002. At the time of study termination (300d), 45% of 2FF-treated MMTVneu mice had no evidence of mammary tumors. 2FF also significantly improved the average age of tumor onset in C3T mice when comparing untreated to 20mM (p=0.007), and 50mM (p=0.0007) treated mice. At study termination, 33% of all 2FF-treated C3T animals were disease free. 2FF anti-tumor activity was associated with the induction of tumor antigen specific immunity. After treatment both the MMTVneu (p<0.0001) and C3T (p<0.0001) developed a DTH response to syngeneic tumor lysates. Of note, the DTH response was inversely associated with the rate of tumor growth (p<0.0001). 2FF anti-tumor activity was associated with the induction of tumor antigen specific immunity. Depletion of immune cell subsets using targeting antibodies demonstrated that the anti-tumor response was mediated in large part by CD4 T-cells which are involved in stimulating both humoral and CD8 T-cell responses.

2FF, a novel inhibitor of fucosylation has potent anti-tumor effects in 2 transgenic models of breast cancer; luminal and triple negative mammary tumors. The agent is active in these mouse models in both the treatment and prevention setting and thus may represent a rational therapeutic approach to evaluate in breast cancer patients.
Title: EndoPredict (EPclin) score for estimating residual distant recurrence (DR) risk in ER+/HER2- breast cancer (br ca) patients treated with 5 years adjuvant endocrine therapy alone: Validation and comparison with the oncoyte DX recurrence score (RS)

Dowsett M, Sestak I, Buus R, Kronenwett R, Denkert C, Krappmann K, Scheer M, Petry C, Dubsky P and Cuzick J. Institute of Cancer Research, London, United Kingdom; Royal Marsden Hospital, London, United Kingdom; Queen Mary University of London, London, United Kingdom; Sividon Diagnostics, Cologne, Germany; Charité Universitätsmedizin Berlin, Berlin, Germany and Medical University Vienna, Vienna, Austria.

Body: Background: RS is widely used for estimating 10-yr risk of DR for br ca patients receiving 5yrs adjuvant endocrine treatment alone. EndoPredict is a prognostic test which unlike RS combines its eight-gene expression signature (EP score) with tumor size and nodal status to provide the EPclin score with a single low/high risk cut-off at 10% risk of DR at 10yrs similar to the low/intermediate risk cut-off with RS.

Aims: To determine the prognostic value of EP/EPclin over 10yrs, 0-5yrs and 5-10yrs in ER+/HER2- br ca patients and to compare this with the RS (i) alone (primary objective) and (ii) in addition to the clinical treatment score (CTS [developed in TransATAC]: nodes (N); tumour size; grade; age; tam or AI).

Methods: mRNA from 928 ER+/HER2- primary br ca from patients treated with anastrozole or tamoxifen in the ATAC trial on which RS was already available were assessed for the EP/EPclin. Primary end point was DR. Kaplan–Meier and Cox regression analyses were used to determine DR risk for 0-10, 0-5 and 5-10yrs follow-up. Likelihood ratio tests (LR-chi sq) were used to assess the prognostic information provided by EP, EPclin, and RS alone and in combination with CTS.

Results: Median follow-up was 9.95 yrs. The table shows the LR-chi sq for the prognostic information provided by each marker alone (univariate) and the information on top of CTS for all patients, and N- and N+ subgroups in 0-10, 0-5 and 5-10yrs. EP and EPclin provided substantially more prognostic information than RS across all three time periods and subgroups, except for N-patients in 0-5yrs. EP and EPclin also provided more information in addition to CTS than RS in 0-10yrs due to better performance of EP and EPclin in 5-10yrs where RS added no significant information to CTS. Using predefined cut-offs, EPclin and RS identified 546 (58.8%) and 573 (61.7%) patients as low risk respectively (HR (95%CI) low vs. non-low risk: 5.9 (3.9-9.1) and 2.7 (1.9-3.8), respectively). The EP score significantly added prognostic information to the RS over 0-10yrs and 5-10yrs in the overall, N- and N+ populations. Cases classified discordantly by EPclin and RS followed the EPclin classification more closely than RS classification.

Table: Prognostic information from EP, EPclin, RS

Conclusions: EPclin was highly prognostic for DR in all patients, N-, N+, early and late metastasis. EPclin provided more...
prognostic information than RS in part but not solely because of the integration of the EP score with N and tumour size parameters. The data stress the importance of including clinicopathological factors in deriving an overall estimate of risk.
**Title:** Molecular predictors of outcome on adjuvant CAF plus tamoxifen (T) vs T in postmenopausal patients (pts) with ER+, node+ breast cancer – Transcriptome expression analysis of the phase III trial SWOG-8814

Albain KS S, Crager MR R, Barlow WE E, Baehner FL L, Bergamaschi A, Rae JM M, Ravdin PM M, Tripathy D, Gralow JR R, Livingston RB B, Osborne CK, Ingle JN N, Pritchard KL I, Davidson NE E, Carey LA A, Cherubavaz DB B, Sing AP P, Shak S, Hortobagyi GN N and Hayes DF F. Loyola Univ Chicago Stritch School of Medicine, Maywood, IL; Genomic Health, Inc., Redwood City, CA; Cancer Research and Biostatistics, Seattle, WA; Genomic Health, Inc. and Univ of California, San Francisco, Redwood City and San Francisco, CA; University of Michigan, Ann Arbor, MI; University of Texas Health Science Center Cancer Therapy and Research Center, San Antonio, TX; The University of Texas MD Anderson Cancer Center, Houston, TX; University of Washington, Seattle Cancer Care Alliance, Seattle, WA; University of Arizona Cancer Center, Tuscon, AR; Baylor College of Medicine, Houston, TX; Mayo Clinic, Rochester, MN; Sunnybrook Odette Cancer Centre and the University of Toronto, Toronto, ON, Canada; University of Pittsburgh Medical Center, Pittsburgh, PA and University of North Carolina at Chapel Hill, Chapel Hill, NC.

**Body:** BACKGROUND: In SWOG-8814A, pts with ER+ node+ breast cancer and low 21 gene recurrence scores (RS) had good prognosis and no CAF benefit, but high RS predicted longer survival from CAF followed by T (CAF-T) vs T (Albain, Lancet Oncol 2010). The aims of SWOG-8814B were to identify novel genes and networks for 1) prognosis of early and late relapse and 2) prediction of CAF benefit, using whole transcriptome expression analysis with next generation RNA sequencing (NGS).

METHODS: Stored RNA previously extracted for SWOG-8814A (T, CAF-T arms; T, 5 yrs) was analyzed for RNA/library yield (see companion abstract Cherubavaz et al. for methods). Genes were sequenced and expression of mRNA species was related to disease-free survival (DFS) using Cox proportional hazards. Discovery analyses controlled false discovery rate (FDR) at 10%. Genes were identified for prognosis on T and prediction on CAF-T vs T. Networks of genes/pathways were explored. Early (0-5 yrs) and late (5-13+ yrs) time periods were studied. Gene Ontology, Cytoscape, pathway and hierarchical clustering were used for functional gene and metagene analyses.

RESULTS: Of 367 samples, 354 (96%; 142 T, 212 CAF-T; 141 DFS events) had sufficient RNA/library yield, with 20,101 genes sequenced. For prognosis on T, there were 2327 and 568 genes discovered in early and all-yrs follow-up, with only 9 genes prognostic after 5 yrs. Prognosis analyses for residual risk after CAF-T were uninformative. Functional mapping found that genes prognostic for worse DFS were enriched for proliferation (G2M, M-phase), cellular metabolism, DNA repair, stress response and EMT; whereas, those with better DFS involved transcription regulation/repression via zinc finger proteins. Hierarchical clustering (T arm) found significant DFS prognostic metastatic signatures for ER-related genes, immune response, ECM/stroma, chromatin remodeling-transcription factor activity and TGFβ pathway. All varied for early vs late DFS events. For example, low ER/high stroma expression signatures correlated with high proliferation gene expression and were strongly associated with early events (standardized [st] HR 2.94, p<0.001). Late recurrence was associated with high proliferation, both individually (stHR 1.51, p=.035) and in combination with higher ER expression (stHR 1.51, p=0.09). Fifteen genes predicted CAF benefit (9 better DFS, 6 worse), or 129 genes if FDR relaxed to 20%. Cluster analysis for CAF prediction is ongoing.

CONCLUSIONS: Unique genes, clusters and pathways were identified by NGS of archival material in ER+ N+ breast cancer, including previously unreported signatures. While ER, stroma and proliferation-related signatures were associated with early prognosis, proliferation best predicted worse DFS after 5 yrs. NGS of the primary tumor is most informative for early events in pts with only 5 years of T, with few genes selecting only for late relapse. If validated, these signatures may identify pts with excellent DFS despite positive nodes for endocrine therapy alone as well as others for whom chemotherapy and/or biologics are also required.

Title: Nuclear FGFR1 interaction with estrogen receptor (ER) α is associated with resistance to endocrine therapy in ER+/FGFR1-amplified breast cancer

Body: Background: Estrogen receptor (ER)-positive breast cancers (BC) initially respond to antiestrogens but eventually become hormone-independent and recur. FGFR1 is amplified in ~10% of ER+ BC and is associated with early recurrence on antiestrogen therapy. Notably, one third of FGFR1-amplified tumors have simultaneous amplification of CCND1, FGF3, FGF4 and FGF19 on chromosome 11q12-14. Herein, we investigated the mechanisms by which FGFR1 amplification confers resistance to antiestrogen therapy in ER+ BC cells.

Results: We performed whole exome sequencing in tumor biopsies from 130 patients with an operable ER+/HER2- BC who had received letrozole for 10-21 days prior to surgery. Tumors were categorized by the natural log (ln) of post-letrozole Ki67 as sensitive (ln ≤ 1 or ≤ 2.7% Ki67+ cells; n=68) or resistant (ln ≥ 2 or ≥ 7.4%; n=18). We found amplifications in FGFR1 and/or 11q12-14 in 6/11 (55%) resistant tumors compared with 5/34 (15%) in sensitive tumors (p=0.006); all cases were confirmed by FGFR1-fluorescence in situ hybridization (FISH). Resistant tumors with FGFR1 and/or 11q12-14-amplification showed a marked increase in nuclear FGFR1 with letrozole. ER+/FGFR1-amplified CAMA1 and MDA134 cell lines also exhibited co-localization of ER and FGFR1 in the nucleus. Cell proliferation was partially reduced by estrogen deprivation, and FGFR1 siRNA further reduced cell growth in hormone-depleted medium. We generated CAMA1 and MDA134 cells resistant to long-term estrogen deprivation (LTED). These cells exhibited overexpression of FGF3/4/19 and ERα with a concomitant increase in ligand-independent ER transcriptional activity and growth. An ER-FGFR1 interaction was observed in the nucleus and cytosol of CAMA1 parental cells with enhanced interaction in CAMA1 LTED cells. Genetic (with siRNA) and pharmacologic (with lucitinib) inhibition of FGFR1 reduced a) nuclear localization of FGFR1; b) ER transcriptional activity; and c) cell proliferation. Nuclear localization and ER-FGFR1 interaction were disrupted by a kinase-deficient FGFR1. Conversely, addition of FGF3 ligand stimulated ER-FGFR1 interaction and ER transcriptional activity, suggesting FGFR activation can regulate ER function. Inhibition of FGF receptor-specific substrate (FRS2), a principal mediator of FGFR1 signal transduction to the MAPK and PI3K pathways, with siRNA or pharmacologic inhibition of PI3K with buparlisib or MEK with GSK1120212 did not reduce ER transcriptional activity suggesting that, in ER+/FGFR1-amplified cancer cells, ER function is not modulated by FGFR signal transducers. Finally, using chromatin immunoprecipitation (ChIP) we showed that FGFR1 binds directly to estrogen response elements (ERE). This association was reduced with lucitinib. We are currently investigating genes modulated by ER/FGFR1 in ER+ BC and the in vivo anti-tumor efficacy of dual inhibition of FGFR1 and ER in ER+/FGFR1-amplified patient-derived breast cancer xenografts.

Conclusions: These data support a critical role of ER and FGFR1 interaction in endocrine resistance in ER+/FGFR1-amplified breast cancer. Targeting of FGFR1 in combination with antiestrogens may abrogate resistance to endocrine therapy in these tumors and is worthy of clinical investigation.

Title: ESR1 coregulator binding inhibitor (ECBI) as a novel therapeutic to target hormone therapy resistant metastatic breast cancer

Body: BACKGROUND: Estrogen contribute to the progression of breast cancer via estrogen receptor 1 (ESR1) and current therapies involve either antiestrogens or aromatase inhibitors. However, most patients develop resistance to these drugs. Critically, therapy-resistant tumors retain ESR1-signaling. Mechanisms of therapy resistance involve the activation of ESR1 in the absence of ligand or mutations in ESR1 that allow interaction between the ESR1 and coregulators leading to sustained ESR1 signaling and proliferation. For patients with therapy-resistant breast cancers, there is a critical unmet need for novel agents to disrupt ESR1 signaling by blocking ESR1 interactions with its coregulators.

METHODS: Using rational design, we synthesized and evaluated a small organic molecule (ESR1 coregulator binding inhibitor, ECBI) that mimics the ESR1 coregulator nuclear receptor box motif. Using in vitro cell proliferation and apoptosis assays, we tested the effect of ECBI on several breast cancer and therapy-resistant model cells. Mechanistic studies were conducted using established biochemical assays, reporter gene assays, RT-qPCR and RNA-Seq analysis. Differentially expressed genes were analyzed using Ingenuity Pathway Analysis (IPA). ESR1 positive (MCF7 and ZR75) xenografts were used for preclinical evaluation and toxicity. The efficacy of ECBI was tested using ex vivo cultures of freshly extirpated primary human breast tissues.

RESULTS: In estrogen induced proliferation assays using several ESR1 positive model cells, ECBI significantly inhibited growth and promoted apoptosis. Importantly, ECBI showed little or no activity on ESR1 negative cells. Further, ECBI also reduced the proliferation of several ESR1 positive hormonal therapy resistant cells. Mechanistic studies showed that ECBI interacts with ESR1, efficiently blocks ESR1 interactions with coregulators and reduces the ESR1 driven ERE reporter gene activity. Further, ECBI directly interacted with mutant-ESR1 with high affinity and significantly inhibited mutant-ESR1 driven oncogenic activity. RNA sequencing analysis revealed that ECBI blocks multiple ESR1 driven pathways, likely representing the ability of a single ECBI compound to block multiple ESR1-coregulator interactions. Treatment of ESR1-positive xenograft tumors with ECBI (10 mg/kg/day/oral) significantly reduced the tumor volume compared to control. Further, ECBI also significantly reduced the tumor growth of coregulator-overexpressed breast cancer cells in xenograft model. Using human primary breast tissue ex vivo cultures, we have provided evidence that ECBI has potential to dramatically reduce proliferation of human breast tumors.

CONCLUSIONS: The ECBI is a novel agent that targets ESR1 with a unique mechanism of action. ECBI has distinct pharmacologic advantages of oral bioavailability, in vivo stability, and is associated with minimal systemic side effects. Remarkably, ECBI block both native and mutant forms of ESR1 and have activity against therapy resistant breast cancer cell proliferation both in vitro and in vivo and against primary human tumor tissues ex vivo. Thus development of ECBI represents a quantum leap in therapies to target ESR1.
Title: Higher 10-year overall survival after breast conserving therapy compared to mastectomy in early stage breast cancer: A population-based study with 37,207 patients

Title: Treatment outcomes in patients with invasive breast cancer treated with neoadjuvant systemic therapy and breast MR imaging: Results of a secondary analysis of TBCRC 017

De Los Santos J, Hyslop T, Alvarado M, Forero A, Golshan M, Hieken T, Horton J, Hudis C, McGuire K, Meric-Bernstam F, Nanda R, Zagar T and Hwang S. University of Alabama at Birmingham, Birmingham, AL; Duke Cancer Institute, Durham, NC; University of California San Francisco, San Francisco, CA; Dana-Farber Cancer Institute, Boston, MA; Mayo Clinic, Rochester, MN; Duke University School of Medicine, Durham, NC; Memorial Sloan Kettering Cancer Center, NY, NY; University of Pittsburgh Medical Center, Pittsburgh, PA; The University of Texas MD Anderson Cancer Center, Houston, TX; The University of Chicago Medicine, Chicago, IL and University of North Carolina at Chapel Hill, Chapel Hill, NC.

Body: Background: Neoadjuvant chemotherapy (NCT) is used frequently to downstage locally advanced tumors and facilitate breast conservation. However, we have previously reported that achievement of radiographic complete response (rCR) or pathologic complete response (pCR) does not impact choice of surgery for many patients. This secondary analysis reports treatment outcomes across 9 NCI comprehensive cancer centers in women receiving both NCT and breast MR imaging to assess whether treatment outcomes among women receiving NCT differs according to choice of locoregional treatment.

Methods: 1077 women from 9 institutions were retrospectively identified as having undergone NCT with MR imaging obtained both before and after systemic treatment. Systemic treatment regimen was not prespecified, but receipt of at least 80% of all planned cycles was required prior to final MR imaging. We performed a univariate analysis as well as a multivariable Cox proportional hazard regression to identify covariates associated with overall survival (OS), disease-free survival (DFS) and time to recurrence (TTR). rCR was defined as no residual enhancement on post-treatment breast MRI.

Results: 1077 patients diagnosed and treated with NCT for stage I-III invasive breast cancer from January 1, 2002 to June 16, 2014 were analyzed for all endpoints. Median follow-up was 4.2 years, (range 0.1 to 13 years). Median age of the cohort was 50 years, (range 19-87 years). 473 (43.9%) had ER(+) and/or PR(+)/HER2(-) disease, 348 (32.3%) had HER2(+) disease, and 256 (23.8%) had ER(-)/PR(-)/HER2(-) (triple negative) disease. Mastectomy or breast conserving therapy (BCT) was recorded as the definitive surgery in 675 (62.7%) and 402 (37.3%) of patients, respectively. Radiation receipt was confirmed in 84.1% of BCT and 68.3% of mastectomy patients. Overall there were 134 recurrences, 168 disease events and 89 deaths. Among patients with pCR, there were 7/161 (7.2%) recurrences in those undergoing mastectomy and 6/143 (5.1%) in those undergoing lumpectomy (p=0.81). Among patients who achieved an rCR, there were recurrences in 5% of those undergoing mastectomy and 2.9% in those undergoing lumpectomy (p=0.53). In multivariable analysis of the entire cohort, only clinical stage, ER status and pCR remained independently associated with DFS. Notably, subset analysis showed that lumpectomy was independently associated with improved TTR (HR 0.40; 95% CI 0.17-0.97) in the triple negative group only, but this did not translate into improved DFS with lumpectomy in this group. Radiographic CR as determined by breast MRI accurately predicted presence or absence of pCR in 74% of cases, but was not independently associated with DFS, OS or TTP.

Conclusions: Among a contemporary cohort of women receiving neoadjuvant systemic therapy and breast MR imaging at 9 NCI designated cancer centers, type of surgery did not impact DFS, OS or TTP. The only exception was found in the triple negative group in which the lumpectomy group had a more favorable TTP compared to the mastectomy group. These findings provide additional evidence that in women who are appropriate candidates for lumpectomy after NCT, BCT does not compromise long-term cancer outcomes.
Title: Complication and economic burden of local therapy options for early breast cancer

WITHHELD PENDING PRESS CONFERENCE
Identification of early versus late drivers of breast tumors and metastasis

Body: Background: The molecular characterization of primary breast cancers has led to signatures identifying risk of future metastasis and survival; however the underlying biology driving metastasis development is largely unknown.

Methods: Utilizing a Rapid Autopsy Program, we have collected 61 metastatic breast cancer tumors from 7 individuals (4 triple negative, 2 HER2+, 1 ER+/HER2-) including primary tumors and 3-6 metastases/patient. We performed mRNA and DNA exome sequencing. We next used DawnRank, a novel network-based method that integrates DNA and RNA data to identify computationally determined "driver" genes (i.e. a DNA variant that significantly alters its gene expression-network) in each individual sample. Phylogenetic tree and clonal analysis were also performed, with the computationally determined drivers mapped onto these trees.

Results: The breast cancer primaries were molecularly subtyped as 5 Basal-like, 1 HER2-Enriched, and 1 Luminal A; in all cases, the metastases clustered immediately adjacent to their primary tumor by hierarchical clustering analysis. Widespread DNA copy number alterations identified in the primary tumors were typically maintained throughout metastasis. On average, 1.9 ± 1.3% of DNA copy number altered genes, and 2.4 ± 0.95% of the somatic mutations per tumor were identified as "drivers" by DawnRank. There were an average of 199 ± 72 total drivers per tumor due to copy number alterations (amplifications or deletions) and 12 ± 23 drivers per tumor from somatic mutations.

Phylogenetic tree analysis demonstrated that the majority of DNA copy number events occurred early in tumor development. Founding clones were defined as genetic events present in the primary and all matched metastases. Chr5q13 loss and TP53 mutation were the only consistent alterations in the founding clones of all 7 patients. Drivers on chr5q13 identified in this cohort include CCNB1, CDK7, and TAF9. Among the basal-like patients, all 5 patients' TP53 mutations were identified as a driver by DawnRank.

39% and 20% of drivers from copy number gains and losses, respectively, were identified in the primary tumor, while another 34% and 30% were not seen in the primary but were present in more than 1 metastasis within each patient. Metastasis-enriched copy number drivers not seen in any primary included FLT1, MAP2KR, and ARNT.

38% of the drivers resulting from somatic mutations were established in the primary and maintained in metastases. Of the remaining drivers from somatic mutation, only 18% were shared among metastases but not seen in the primary while 47% were not seen in any other tumor within a given patient (i.e. private to a single sample). TP53, PSEN1, CDC27, HDAC1, and BRCA1 were somatic mutation drivers established early in metastatic development, while CCNH was a consistent late driver.

Conclusions: We present a novel computationally determined genetic "driver" analysis of matched breast cancer primaries and multi-organ metastases. In this cohort, our results suggest that most genetic drivers in a single tumor are based on copy number aberrations, are established early, and are maintained in metastases. In contrast to copy number, drivers from somatic mutations are acquired later, and most of the metastases continued to acquire new genetic driving features.
Title: A comprehensive analysis of fusion transcripts in breast cancer reveals associations between number of fusion transcripts, copy number events, gene expression profiles, and potentially clinical outcome

Thompson EA, Asmann YW W, Su X, Ellis MJ J, Shao J, Hu Y, White KP P, Cherniack AD D, Hoadley KA A, Serie DJ J, Perez EA A and Perou CM M. Mayo Clinic Comprehensive Cancer Center, Jacksonville, FL; MD Anderson Comprehensive Cancer Center, Houston, TX; Baylor College of Medicine, Houston, TX; Washington University, St. Louis, MO; Sage Bionetworks, Seattle, WA; University of Chicago, Chicago, IL; Broad Institute, Cambridge, MA and Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC.

Body: Fusion transcript analysis by five groups, each using "in house" analytical workflow to analyze RNA-seq data from 813 breast tumors from The Cancer Genome Atlas project detected 2514 high confidence RNA fusions (2 or more junction spanning reads detected by 2 or more groups). A subset of tumors with fusions were evaluated for chromosomal rearrangement using whole genome sequence data (WGS), and about half of the high confidence fusions could be validated, with the remainder likely subclonal and therefore below the limits of detection by WGS at the relatively low depth of coverage (30X) available. The majority of tumors contained one or more fusion transcript (range 0-24 fusions/tumor), but recurrence of specific chimaeric transcripts was low. Only ESR1->CCDC170, C20orf3->ACSS1, and USP22->MYH10 fusions were detected in 10 or more tumors. Additional ESR1 fusions were detected with AKAP12, BNC2, C6orf211, GNAS, POLH, USP25, and UTRN, within 19 tumors, primarily of the Luminal B subtype. RARA was the second most common 5' fusion partner with 17 tumors, predominately of the HER2-enriched subtype, expressing out of frame RARA fusions to 19 different 3' fusion partners. Other common 5' fusion partners included FBXL20, USP22, USP32, BCAS3, MED1, BPTF, ERBB2, MED24, and PPF1A1 (expressed in 10 or more tumors each). The most common 3' fusion partners were ERBB2, CCDC170, PITPNC1, ACSS1, MYH10, IKZF3, and RAB6A (10 or more tumors each). HER2-enriched tumors expressed significantly more fusions than other subtypes (4.9 fusions/tumor vs 3.3 for Basal-like, 1.3 for LumA, and 3.2 for LumB). Almost all HER2-enriched tumors expressed fusions (97%), whereas 85% of Basal-like tumors and 79% of Luminal B tumors expressed one or more fusions. Among Luminal A tumors, only 48% expressed one or more fusion transcript. Those Luminal A tumors with multiple fusion transcripts contained significantly more copy number aberrations and were enriched for expression of mitotic cell cycle genes (p=3.07E-18), characteristic of the recently described high risk CNH subclass of Luminal A tumors. We conclude that, consistent with other observations, breast tumors generally exhibit a high level of genomic instability, associated with multiple copy number alterations and multiple fusion transcripts. However, recurrence of specific fusion transcripts is low. About half of Luminal A tumors express fusion transcripts; and these tumors exhibit multiple copy number events, consistent with high level genomic instability, as well as enriched expression of mitotic cell cycle genes. These tumors appear to be related to the relatively high risk Luminal A CNH subclass, and express high levels of aurora kinases and polo-like kinases, which might be considered as therapeutic targets. Given the increasing emphasis on transcript profiling of clinical samples and the clinical significance of high risk Luminal A tumors, it may be timely to consider inclusion of fusion transcripts in such analyses as surrogate markers of genomic instability and potential therapeutic and/or prognostic indicators.
Title: A functional assay for homologous recombination (HR) DNA repair and whole exome sequencing reveal that HR-defective sporadic breast cancers are enriched for genetic alterations in DNA repair genes

Body: Background: Germline mutations in the BRCA1 and BRCA2 genes lead to hereditary breast cancers that are defective in homologous recombination (HR) repair and sensitive to DNA damaging agents. HR deficiency (HRD) also occurs in sporadic breast cancers, but its incidence and etiology are unclear. Genomic signatures of HRD recently were employed as biomarkers in clinical trials with modest success. We posited that sporadic breast cancers displaying functional HR deficiency would harbor genetic alterations affecting HR DNA repair genes. To test this hypothesis, we applied a functional assay to define lack of competent HR DNA repair and sequenced the exomes of consecutive sporadic breast cancers.

Methods: We developed an assay to assess the ability of cancer cells to localize RAD51 into sub nuclear foci in response to ex-vivo irradiation (IR) in fresh sporadic breast cancer tissue specimens from 60 patients. RAD51 focus formation was compared between mock and IR conditions to determine relative fold induction. Twenty-nine tumors with sufficient DNA underwent whole-exome sequencing. Structural genomic signatures of HRD (i.e. large state transitions (LST), telomeric imbalance (NtAI), loss-of-heterozygosity (LOH)) and a previously reported mutational signature related to BRCA1/2 hereditary breast cancers were assessed. HR deficient tumors were defined as those with both RAD51 foci defects and a genomic signature of HR deficiency (LST>15 or presence of a BRCA mutational signature). Somatic, germ-line, and copy number changes in HR genes were investigated. BRCA1 methylation status was determined.

Results: Seventeen of 60 (28%) tumors displayed defective RAD51 recruitment following ex-vivo IR (RAD51-DEF). RAD51-DEF was seen in all breast cancer subtypes , including 7 of 33 (21%) ER+/HER2-, 4 of 14 (29%) HER2+, and 6 of 13 (48%) triple-negative cases. Of the 29 sequenced tumors, 13 (45%) were RAD51-DEF and 16 (55%) were competent for inducing RAD51 foci. LST was elevated in 10 tumors (LST >15) and associated with RAD51-DEF (p=0.02), whereas NtAI (p=0.10) and LOH (p=0.052) did not show a significant association with RAD51-DEF. The BRCA1/2 mutational signature was evident in 4 tumors, all were RAD51-DEF (p=0.03) and 2 were BRCA2 mutated. Nine of 29 (31%) sequenced tumors were determined to have HRD by the RAD51 assay and presence of a genomic scar. Eight of these 9 (88%) cases with HRD had a genetic alteration of both alleles of a bona fide HR gene due to a pathogenic mutation (somatic or germline) coupled with loss of heterozygosity or a homozygous deletion compared to 1 (5%) tumor without HRD (p<0.001). Both alleles of a gene were affected for BRCA2 (n=4), FAAP100 (n=2), CHEK2 (n=1), [italic]TP53BP1 (n=2) and BRCA1 (n=3). BRCA1 gene promoter methylation was found not to be significantly associated with HRD.

Conclusion: Combined functional and genomic analyses of breast tumors demonstrated that genetic loss of an HR gene may underpin HRD in sporadic breast cancers. Our findings warrant further comprehensive genetic assessment (somatic, germline, and copy number) of HR genes as potential biomarker for HR-directed therapies.
Title: Lobular carcinoma in situ displays intra-lesion genetic heterogeneity and its progression to invasive disease involves clonal selection and variations in mutational processes

Reis-Filho JS S, Schizas M, Piscuoglio S, Sakr RA A, Ng CKY K Y, Lim RS S, Carniello JVS S, Towers R, Martelotto L, Giri DD D, de Andrade VP P, Viale A, Solit DB B, Weigelt B and King TA A. Memorial Sloan Kettering Cancer Center, NY, NY; Memorial Sloan Kettering Cancer Center, NY, NY and Center for Molecular Oncology, Memorial Sloan Kettering Cancer Center, NY, NY.

Body: Introduction: Lobular carcinoma in situ (LCIS) is considered both a risk factor and non-obligate precursor of invasive breast cancer. We sought to determine the genomic landscape of LCIS and the mutational processes involved in the clonal evolution and progression from LCIS to ductal carcinoma in situ (DCIS) and invasive lobular carcinoma (ILC).

Methods: Patients with a history of LCIS undergoing therapeutic or prophylactic mastectomy were prospectively enrolled in an IRB approved protocol. Frozen tissue blocks were collected, screened for lesions of interest (LCIS, DCIS, ILC, invasive ductal carcinomas (IDC)) and subjected to microdissection and DNA/RNA extraction. Matched germline DNA was available for all cases. Whole exome sequencing was performed on a HiSeq2000 and data were aligned to the reference human genome and processed using GATK. Single nucleotide variants (SNVs) and small insertions/deletions were identified using MuTect and Varscan, respectively. Purity and ploidy estimates were calculated using ABSOLUTE. Clonal frequencies were estimated using Pyclone and the clonal structure of each sample was reconstructed using SubcloneSeeker. Shannon index and Simpson index metrics were used to calculate heterogeneity levels. Mutational signatures were defined according to their mutational trinucleotide context, and the expression levels of APOBEC gene family members were assessed by quantitative reverse transcription (qRT)-PCR.

Results: 30 LCIS, 10 ILCs, 7 DCIS and 5 IDCs from 15 patients qualified for data analysis. CDH1 was the most frequently mutated gene and found to be targeted by mutations in 26 LCIS samples (23 somatic, 3 germline). The repertoire of somatic mutations in LCIS was similar to that of luminal A breast cancers, with the exception of the significantly higher frequency of CDH1 mutations and the lower prevalence of TP53 mutations. ILCs were clonally related to at least one LCIS in 10 patients, and in 3/7 patients, DCIS was clonally related to at least one LCIS. Clonal composition analysis revealed that the presence of a minor clone(s) in LCIS, and the levels of intra-tumor genetic heterogeneity were significantly higher in LCIS clonally related with DCIS/ILC than in LCIS unrelated to DCIS/ILC. In two cases, a minor LCIS subclone constituted the major clone in the associated DCIS/ILC. A comparative analysis of the mutational signatures in the truncal and branch mutations of these cases revealed that whilst the truncal mutations displayed an aging signature, branch mutations were enriched for the APOBEC signature. qRT-PCR analysis demonstrated that cases displaying the APOBEC signature also harbored significantly higher levels of APOBEC3B expression than samples with the aging signature.

Conclusions: LCIS displays intra-lesion genetic heterogeneity, and the progression from LCIS to DCIS or ILC may involve the selection of clones resulting from distinct mutational processes during clonal evolution. Our findings also suggest that cytidine deamination driven by the overexpression of APOBEC3B may drive the progression of LCIS to DCIS/ILC in a subset of cases.
**Title:** Interrogating the landscape of long noncoding RNAs in breast cancer to identify predictors of tamoxifen resistance

**Body:**

*Background:* We previously performed an informatics-based analysis on RNA sequencing libraries from 7,256 tumor and normal tissue specimens to delineate the landscape of long noncoding RNAs (lncRNAs) in the human transcriptome. This analysis identified 58,648 lncRNAs, including over 45,000 novel transcripts (Iyer MK et al, *Nature Genetics*, 2015). We now interrogate this lncRNA compendium to identify top candidate estrogen receptor (ER)-associated lncRNAs in breast cancer and characterize their association with disease progression.

*Methods:* To prioritize differentially expressed lncRNAs in cancer vs normal tissue, and in ER+ vs ER- disease, we performed Sample Set Enrichment Analysis (SSEA) on >1000 RNA Seq libraries, from breast cancer and normal tissue samples from The Cancer Genome Atlas project. The effect of the top prioritized lncRNA on cancer phenotypes was studied via in vitro proliferation, colony formation, invasion and tamoxifen resistance assays in MCF7 and T47D cells, and via in vivo mouse xenograft studies and chick chorioallantoic membrane (CAM) assays. To study the mechanism by which this lncRNA promotes tumor progression, we identified its top protein interactors and subdomains responsible for function, and then studied the effects of disrupting function of this lncRNA on cancer phenotypes. Finally, in a "guilt-by-association" study, we developed a signature of 150 protein coding genes most strongly associated with our lncRNA of interest, and investigated the association of this signature with clinical outcomes using Oncomine analyses.

*Results:* SSEA analysis on over 1000 TCGA samples nominated Breast Cancer Associated Transcript (BRCAT 431) as the top overexpressed ER-regulated lncRNA in breast cancer. *In vitro* experiments demonstrate that siRNA-mediated knockdown of BRCAT431 resulted in significantly decreased proliferation, colony formation, and invasion (by >50% in most assays). Tamoxifen resistance was associated with significantly increased BRCAT431 levels in both MCF7 and T47D cells, and knockdown of BRCAT431 reversed tamoxifen resistance. *In vivo* xenograft and CAM studies demonstrate that knockdown of BRCAT431 also significantly decreased xenograft growth and tumor invasion by >50%. RNA pulldown followed by mass spectrometry identified the RNA binding protein hnRNPL as a key protein interacting with BRCAT431. Deletion studies identified a 27 base region of BRCAT431 necessary for its interaction with hnRNPL, and loss of this region abrogated BRCAT431- induced invasion. Finally, guilt-by-association studies demonstrate a strong association between BRCAT431 overexpression and tumor grade, recurrence, and metastases.

*Conclusion:* In this study, we develop the largest reported compendia of breast cancer lncRNAs. We prioritize BRCAT431 as the top lncRNA upregulated in ER-positive breast cancers, and demonstrate that it confers aggressive oncogenic phenotypes *in vitro* and *in vivo*. We identify a novel mechanism by which this lncRNA functions. Our results suggest that by promoting tamoxifen resistance, BRCAT431 increases the clinical risk of recurrence and metastases in breast cancer. Overall, this study supports the rationale for investigating lncRNAs as novel biomarkers and therapeutic targets in breast cancer.
**Title:** HER2 status as predictive marker for AI vs Tam benefit: A TRANS-AIOG meta-analysis of 12129 patients from ATAC, BIG 1-98 and TEAM with centrally determined HER2

Bartlett JMS MS, Ahmed I, Regan MM M, Sestak I, Mallon EA A, Dell’Orto P, Thürlimann BJK J.K., Seynaeve C, Putter H, Brookes CL L, Forbes JF F, Colleoni MA A, Bayani J, van de Velde CJH J.H., Viale G, Cuzick J, Dowsett M, Rea DW W and On Behalf of the Translational Aromatase Inhibitor Overview Group (Trans-AIOG). Ontario Institute for Cancer Research, Toronto, ON, Canada; University of Birmingham, Birmingham, United Kingdom; Dana-Farber Cancer Institute, Boston, MA; Queen Mary, University of London, London, United Kingdom; Western Infirmary, Glasgow, United Kingdom; Breast Center, Kantonsspital St. Gallen, St. Gallen, Switzerland; Erasmus Medical Center Cancer Institute, Rotterdam, Netherlands; Leiden University Medical Center, Leiden, Netherlands; The University of Newcastle, Newcastle, New South Wales, Australia; University of Milan, Milan, Italy; Royal Marsden Hospital, London, United Kingdom and European Institute of Oncology, Milan, Italy.

**Body:** There is now significant evidence emerging from the pivotal trials of AIs versus Tamoxifen (AIOG) demonstrating the value of meta-analysis of key clinical questions. The "Trans-AIOG" group has been tasked with the exploration of key molecular/biomarker questions that are pertinent to meta-analyses of biomarkers (past/present/future) in AIOG trials. HER2 has been long proposed as a marker of endocrine "resistance". Data from three trials, before the era of HER2-directed therapy, suggest a potential role for HER2 to select patients for treatment with upfront AIs. However the individual trials lack power to test treatment-by-HER2 interaction due to sample size and low HER2+ve rates. A meta-analysis of the predictive value of HER2 status, specifically within the first 3 years of endocrine therapy, has the potential to inform patient selection for upfront or sequential strategies with AIs. The pre-existing standardization of methodology for HER2 (IHC/FISH) facilitates analysis of existing data from BIG-1-98, TEAM and ATAC for this key marker.

**Analysis plan:** Following a prospectively-designed analysis plan, patient-level data from 3 randomized phase III trials (ATAC, BIG 1-98, TEAM) comparing AIs to tamoxifen during the first 2-3 years of adjuvant treatment were collected at the CRCTU (Birmingham UK), accounting for both the established time-dependency of relapse in HER2+ve, anti-endocrine treated patients and to address the clinical question of "upfront" vs "sequential" strategies for AIs. For each trial, covariate-adjusted Cox models estimated HER2-by-treatment (Al vs Tam) interaction on distant recurrence-free interval-censored at 2-2.75 years follow-up. A meta-analysis of the HER2-by-treatment interaction terms and of treatment effects according to HER2 status was performed. Results: 12129 patients with centrally-confirmed ER and HER2 status, 1092 (9%) HER2+ve, with 473 (4%; 111 among HER2+ve) distant recurrences were analyzed. The meta-analysis estimated a pooled HER2-by-treatment interaction of 1.61 (95% CI 1.01,2.57), reflecting treatment effect hazard ratio(Al/Tam) of HR=1.13 (0.75,1.71) among HER2+ve and HR=0.70 (0.56,0.87) among HER2-ve. There was heterogeneity among interaction terms (I-squared=59%, p=.09) that resulted from treatment effect heterogeneity among HER2+ve subgroup (I2=71%, p=.03), not the HER2-ve subgroup (I2=0%). The results for disease-free survival were similar.

**Conclusion:** An individual patient data meta-analysis across 3 trials (ATAC, BIG 1-98, TEAM) conducted prior to standard use of HER2-directed adjuvant therapy demonstrated a marginally-significant interaction between HER2 status and treatment with AIs vs Tamoxifen in the 2-2.75 years prior to potential "switching" between Tamoxifen and AIs. Patients with HER2-ve cancers experienced improved outcomes when treated with AIs vs Tamoxifen whilst patients with HER+ve cancers fared no better, or slightly worse, during AI treatment. However, the small number of HER2+ve cancers and events even in this meta-analysis may explain a large degree of heterogeneity in the treatment effects within the HER2+ve subgroups across the 3 trials. Other causes, perhaps related to subtle differences between AIs, cannot be excluded.
Title: Tamoxifen resistance driven by the DNA cytosine deaminase APOBEC3B in recurrent estrogen receptor positive breast cancer

WITHheld pending press conference
2015 San Antonio Breast Cancer Symposium

Publication Number: OT2-01-01

Title: Endocrine therapy alone as primary treatment for elderly patients with clinical stage I to III estrogen receptor positive breast cancer with low recurrence score

Aft R, Trinkaus K and Ma C. Washington University, St. Louis, MO.

**Body: Background:** Approximately 20% of breast cancers are diagnosed in women 75 years of age or older. Elderly patients with breast cancer are at a higher risk for over- or under-treatment. In general, older patients are more likely to die from comorbidities than from their breast cancer. The 21-gene Recurrence Score (RS) predicts 10-year distant recurrence rate in the adjuvant setting in women with early stage ER+ breast cancer. In elderly patients, a large percentage of the cancers diagnosed are ER+. It is likely that a subpopulation of elderly women with good prognosis ER+ tumors can be identified who may benefit from endocrine therapy alone, without surgery, to treat their cancer without compromising clinical outcome. We hypothesize that endocrine therapy alone will provide adequate local and systemic control of breast cancer in the subpopulation of women 75 or older with ER+ breast cancer and low RS.

**Trial Design:** This is a single arm phase II trial in pts with newly diagnosed early stage ER+ breast cancer, age 75 or greater. RS will be obtained on core biopsies collected at the time of diagnosis. Patients whose scores are < 18 will be enrolled into the trial and receive endocrine therapy only. Patients whose scores are ≥ 18 will receive standard of care (SOC) treatment. Tumor assessment will occur every 6 months. Patient can continue on endocrine therapy for up to 10 years. If there is progression of disease, then an alternative endocrine agent may be prescribed or the patient can opt for SOC treatment.

**Objectives:** Primary: To determine the rate of loco-regional progression in women with early-stage ER+ breast cancer, 75 years or older with low RS who are treated with endocrine therapy alone. Secondary: To determine the breast cancer-specific survival and overall survival of women with early-stage ER+ breast cancer who are 75 years or older treated with endocrine therapy alone. To correlate response to treatment with RS.

**Eligibility:** Newly diagnosed invasive breast cancer defined as cT1 or T2, N0-1, M0, age 75 years of age or older and ECOG performance status ≤ 2. Disease must be ER+ (Allred score ≥ 5) and HER2- and measurable defined as lesions that can be accurately measured in at least one dimension by ultrasound or mammogram.

**Statistical Methods:** A Kaplan-Meier model will be used to estimate the 5-year local or systemic progression rate with a Brookmeyer-Crowley confidence interval. If the true 5-year progression rate is 10%, a sample size of 50 will provide power = .90 at a one-sided .05 significance level to demonstrate that the rate is less than 25.5%. A point estimate of the cumulative incidence of local progression at 5 years will be calculated using a Kaplan-Meier model or, if covariate adjustment is desired, a Cox proportional hazards model. The upper bound of a 95% confidence interval will be used to determine whether the rate may plausibly fall above 25.5%.

**Accrual:** Target 50 patients with an RS score < 18 will be enrolled. Anticipated opening is July 2015.
Title: Phase III study of ribociclib (LEE011) in combination with fulvestrant for the treatment of postmenopausal patients (pts) with hormone receptor-positive (HR+), HER2-negative (HER2–) advanced breast cancer (aBC) who have received no or only one line of prior endocrine treatment: MONALEESA-3

Fasching PA A, Jerusalem G, Pivot X, Martin M, De Laurentiis M, Blackwell K, Esteva FJ J, Paquet-Luzy T, Tang Z, Lorenc KR R and Slamon DJ J.  Universitätsklinikum Erlangen, Erlangen, Germany;  Centre Hospitalier Universitaire du Sart Tilman Liège and Liège University, Liège, Belgium;  CHRU Besançon – IRFC, Besançon, France;  Hospital General Universitario Gregorio Marañón, Madrid, Spain;  National Cancer Institute Fondazione Pascale, Naples, Italy;  Duke University Medical Center, Durham, NC;  Laura and Isaac Perlmutter Cancer Center, NYU Langone Medical Center, NY, NY;  Novartis Pharma AG, Basel, Switzerland;  Novartis Pharmaceuticals Corporation, East Hanover, NJ and  UCLA Medical Center, Santa Monica, CA.

Body: Background: Endocrine therapy (ET) is the predominant first-line treatment for HR+, HER2– aBC; however, resistance eventually occurs in a large number of cases. Dysregulation of the cyclin D–cyclin dependent kinase (CDK)4/6–inhibitor of CDK4 (INK4)–retinoblastoma (Rb) pathway has been associated with endocrine resistance. Inhibition of CDK4/6 may overcome such resistance and enhance the efficacy of existing endocrine regimens. Combination of ribociclib (a type of CDK4/6 inhibitor) with fulvestrant (a selective estrogen receptor downregulator) has demonstrated potent tumor regressions in preclinical HR+ breast cancer (BC) models.

Design & Objectives: MONALEESA-3 (NCT02422615) is a randomized, double-blind, placebo-controlled study of oral ribociclib (600 mg QD on Days 1–21 of each 28-day cycle) in combination with fulvestrant (500 mg intramuscularly on Days 1 and 15 of Cycle 1 and Day 1 of each cycle thereafter) in postmenopausal pts with HR+, HER2– aBC. Pts may have newly diagnosed aBC that is treatment-naive, relapsed BC that has progressed at any time during or after (neo)adjuvant ET with no treatment for metastatic disease, relapsed BC that has progressed >12 months after adjuvant ET and then subsequently progressed after one line of ET for metastatic disease (with either an antiestrogen or an aromatase inhibitor), or newly diagnosed aBC that has progressed after one line of ET (with either an antiestrogen or an aromatase inhibitor). Pts must have measurable disease or at least one predominantly lytic bone lesion, and an Eastern Cooperative Oncology Group performance status (ECOG PS) of ≤1. Prior treatment with chemotherapy (except for [neo]adjuvant chemotherapy), fulvestrant, or any CDK4/6 inhibitor is prohibited. Randomization (2:1) to receive ribociclib plus fulvestrant (Arm A) or placebo plus fulvestrant (Arm B) is stratified by visceral disease status and previous ET. Tumor assessments will be performed every 8 weeks for the first 18 months and every 12 weeks thereafter until disease progression, death, withdrawal of consent, loss to follow-up, or patient/guardian decision. The primary endpoint is progression-free survival (PFS; local, RECIST 1.1); secondary endpoints include overall survival, PFS (central, RECIST 1.1), overall response rate, clinical benefit rate, time to response, duration of response, safety and tolerability, ECOG PS, pt-reported outcomes, and pharmacokinetics. Molecular alterations of genes associated with HR+ BC and the cyclin D–CDK4/6–INK4–Rb pathway will also be explored in tumor and blood samples.

Statistical Methods: PFS between Arms A and B will be compared using a stratified log-rank test; 364 PFS events will be required to detect a hazard ratio of 0.67 with 90% power using the log-rank test and a 3-look (interim look futility only, interim look efficacy only, then final analysis) group sequential design at one-sided cumulative 2.5% level of significance.

Target Accrual: Approximately 660 pts at 300 sites worldwide.
Title: A phase 1/2 study of once-daily oral VT-464 in patients with advanced androgen receptor (AR) positive triple negative (TNBC) or estrogen receptor (ER) positive breast cancer (BC)

Body: VT-464, an oral dual lyase-selective CYP17 inhibitor and AR antagonist (wild-type and mutated forms [e.g., F876L and T877A]), is in multiple Phase (Ph) 2 studies as treatment for men with castration-resistant prostate cancer (CRPC). VT-464 inhibits the growth of multiple BC cell lines in vitro including MCF7 (ER+/AR low), tamoxifen-resistant MCF7, and MDA-MB-453 (ER-/AR+) in a dose-dependent manner and with greater potency/efficacy than enzalutamide (submitted, Ellison et al., 2015). A subset of TNBC and most ER+ BC express AR, making them potential targets for VT-464 since it directly inhibits both androgen/estrogen synthesis and AR transcriptional activity.

Objectives: The primary objective of Ph 1, now enrolling, is to establish the once-daily dose of VT-464 in women. Secondary objectives include safety, PK and efficacy endpoints, including determination of clinical benefit rate (CBR) which is the primary objective of Ph 2. Exploratory objectives include the determination of the extent of AR expression and signaling in breast tissue and to evaluate the relationship of expression with VT-464 effects on circulating tumor biomarkers, circulating hormones and clinical outcomes.

Study Design: This study is an open-label, single arm, Ph 1/2 study of VT-464 in women with AR+ TNBC or ER+/HER2 normal unresectable locally advanced or metastatic BC. Ph 1 will follow a modified 3+3 Fibonacci design with cohort expansion to 6 patients following a single DLT in the first 28-days of treatment. Approximately 2-3 dose-levels will be explored in Ph 1. Ph 1 start dose will be the MTD for men with CRPC. AR+ TNBC and ER+/HER2 BC cohorts will be expanded in Ph 2 using the MTD from Ph 1. Ph 2 will follow a Simon’s two-stage design with pre-determined futility parameters. Eligible patients will have ER≥1% BC or AR≥1% (as determined by central IHC testing using the Dako antibody) TNBC. ER+ patients must be postmenopausal and must have received at least 1 prior line of endocrine therapy. Additional eligibility criteria include: ≥ 18 years of age, ECOG PS ≤ 1, unresectable locally advanced or metastatic BC, available representative tumor specimen to enable correlative science.

Treatment Plan: Eligible patients will receive VT-464 once-nightly with dinner in a continuous dosing schedule. Adverse events and concomitant medications will be collected from the time of signing of informed consent until 30 days after end of study visit (EOS). Safety labs will be monitored monthly through EOS. Dense PK will be collected after the first dose of study drug in Ph 1 and single morning samples collected approximately every two cycles thereafter in Ph 1 and Ph 2 until EOS. Blood samples for steroid, circulating tumor DNA and circulating tumor cells will be collected through Cycle 2 and then at EOS. Tumor biopsy will be collected at baseline and at disease progression. Radiographic response will be assessed every 8 weeks and EOS.

Patient Accrual: Accrual is ongoing with 12-18 patients expected to be enrolled in Ph 1.
E2112: Randomized phase III trial of endocrine therapy plus entinostat/placebo in patients with hormone receptor-positive advanced breast cancer. A trial of the ECOG-ACRIN cancer research group

Connolly R, Zhao F, Miller K, Tevaarwerk A, Wagner L, Lee M, Murray J, Gray R, Piekarz R, Zujewski JA and Sparano J. Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD; Dana-Farber Cancer Institute, Boston, MA; Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN; University of Wisconsin Carbone Cancer Center, Madison, WI; Wake Forest University Health Services, Winston-Salem, NC; National Cancer Institute, Bethesda, MD; Cancer Therapy Evaluation Program (CTEP) National Cancer Institute, Bethesda, MD and Albert Einstein College of Medicine, Montefiore Medical Center, NY, NY.

Background: A potential mechanism of resistance to endocrine therapy in breast cancer involves changes in gene expression secondary to epigenetic modifications, which might be modulated with the use of histone deacetylase (HDAC) inhibitors such as entinostat. ENCORE 301, a phase II study evaluating the addition of entinostat to the steroidal aromatase inhibitor (AI) exemestane in patients with hormone receptor (HR)-positive advanced breast cancer who had experienced disease progression after a non-steroidal AI (NSAI), showed a significant improvement in progression-free survival (PFS), and overall survival (OS). Entinostat has been designated a Breakthrough Therapy by the FDA.

Methods: E2112 is a multicenter randomized double-blind placebo-controlled phase III study (NCT02115282) enrolling patients with advanced HR-positive, HER2-negative breast cancer with prior disease progression on a NSAI (n=600). Patients receive exemestane 25mg po daily and entinostat/placebo 5mg po every week. Eligibility: Postmenopausal women and men, ECOG 0-1, locally advanced/metastatic invasive adenocarcinoma of the breast: ER/PR-positive, HER2-negative, measurable or non-measurable (20% cap) disease. Disease progression after NSAI use in the metastatic setting OR relapse while on or within ≤ 12 months of end of adjuvant NSAI therapy.

Statistics: Both PFS (central review) and OS are primary endpoints, and the study is designed to show an improvement in either PFS or OS. Secondary endpoints include: Safety and tolerability, objective response rate, changes in lysine acetylation status in peripheral blood mononuclear cells, patient-reported symptom burden and treatment toxicities, adherence. One-sided type 1 error 0.025 split between two hypotheses tests: 0.001 for PFS test and 0.024 for OS. PFS is tested in the first 360 pts, 88.5% power to detect 42% reduction in the hazard of PFS failure (median PFS 4.1 to 7.1 months); OS is tested in all 600 pts, 80% power to detect 25% reduction in the hazard of death (median OS 22 to 29.3 months).

E2112 was activated in March 2014 and accrual is anticipated to complete in 40 months.
**Title:** A phase 2 randomized, double-blind, placebo-controlled trial of hormone therapy ± radium-223 dichloride in human epidermal growth factor receptor 2–negative, hormone receptor–positive breast cancer patients with bone metastases

Coleman RE E, Huang L, Petrenciuc O, Zaccarini P and Rugo HS S. University of Sheffield, Weston Park Hospital, Sheffield, United Kingdom; Bayer HealthCare, Whippany, NJ; Bayer S.p.A., Milan, Italy and UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA.

**Body:**
**Background:** Treatment options for bone-metastatic breast cancer (MBC) are limited. Multimodality therapy may improve symptom control and survival. In a phase 2a study of advanced breast cancer patients with bone-dominant and no visceral disease, radium-223 dichloride (radium-223), a first-in-class α-emitter selectively targeting bone metastases, reduced baseline bone biomarker levels with favorable safety (Coleman et al. *Breast Cancer Res Treat* 2014). This study (NCT02258464) evaluates efficacy and safety of radium-223 versus placebo in human epidermal growth factor receptor 2–negative (HER2–), hormone receptor–positive (HR+) bone-MBC patients receiving single-agent hormone therapy.

**Trial design:** Patients receive (1:1) radium-223 50 kBq/kg IV or placebo q 4 wk (6 cycles) + concurrent single-agent hormone therapy + best supportive care. Stratification is by geographic region, prior lines of hormone therapy for MBC, and number of prior skeletal events.

**Main eligibility criteria:** Eligible patients are pre- or postmenopausal with estrogen receptor–positive, HER2–, bone-dominant MBC with ≥ 2 bone metastases and ≥ 1 or 2 prior symptomatic skeletal events (external beam radiotherapy for bone pain, pathologic bone fracture, spinal cord compression, orthopedic surgery). Patients had ≥ 1 line of hormone therapy for MBC; are taking bisphosphonates or denosumab for ≥ 1 month before study; are eligible for endocrine treatment; and have evaluable disease (RECIST v1.1), asymptomatic or mildly symptomatic bone disease (Brief Pain Inventory), ECOG performance status 0-1, and adequate hematologic, renal, and liver function. Patients may not have had visceral or brain metastases or leptomeningeal disease, need for chemotherapy for metastases, and untreated spinal cord compression.

**Specific aims:** Patients are assessed for efficacy and safety, and followed to symptomatic skeletal events, radiologic progression, death, or withdrawal. Primary endpoint is symptomatic skeletal event–free survival.

**Statistical methods:** Assuming a 1-sided α of 0.1, power of 90%, ~ 119 symptomatic skeletal events are required for the analysis. Time-to-event variables will be analyzed using a log-rank test, accounting for stratification. Kaplan-Meier estimates and survival curves will be given for each treatment group. Safety analyses will be descriptive.

**Present and target accruals:** As of May 2015, 5 patients have been screened and 3 enrolled. Target enrollment is 227 patients.

Title: Phase 2 open label, multinational, randomized, parallel design study investigating the efficacy and safety of GTx-024 on metastatic (MET) or locally advanced (LA) ER+/AR+ breast cancer (BC) in postmenopausal (PM) women

Overmoyer B, Rugo H, Schwartzberg L, Palmieri C, Taylor R, Hancock M, Small S and Johnston MA. Dana Farber Cancer Institute, Inflammatory Breast Cancer Program, Boston, MA; University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA; The West Clinic, Memphis, TN; University of Liverpool, Liverpool, Merseyside, United Kingdom and GTx Inc., Memphis, TN.

Body: Background: Historically, androgens have been utilized for the treatment of BC as the androgen receptor (AR) is the most highly expressed steroid receptor (~95% in estrogen receptor positive (ER+), ~50% in ER negative). However, steroidal androgens often exhibit virilizing side effects, thus limiting clinical use. A non-steroidal, tissue-selective, AR modulator (SARM), GTx-024, offers a targeted approach of AR activation in ER+/AR+ BC without virilization or estrogenic effects. A previous Phase 2 study of 9 mg GTx-024 in MET ER+ BC demonstrated proof-of-concept, with 6/17 ER+/AR+ patients (pts) exhibiting clinical benefit (CB) following 6 months (m) of treatment. Increasing the dose to 18 mg has the potential for greater efficacy without compromising safety.

Trial Design: Open label, multinational, randomized, parallel design Phase 2 study to assess the efficacy and safety of GTx-024 in PM ER+/AR+ BC. Pts will be randomized to receive GTx-024, 9 mg or 18 mg orally (PO) daily. Therapy continues until disease progression. Pts achieving a CB can be treated for 12 m following the initiation of study treatment; those demonstrating continued CB are offered continuation in a safety extension study under a separate protocol.

Eligibility Criteria:
Inclusion: Informed consent, female, ≥18 years (yr), PM, MET or LA ER+ (≥1% staining) BC, HER2 negative, ≥1 prior hormonal treatment for BC (≥6 m response for MET; ≥3 yr response for adjuvant), provide archived tumor tissue for AR determination, measurable or bone-only disease, evidence of PD within 30 days (d), ECOG 0 or 1.
Exclusion: >1 prior chemotherapy regimen for MET, uncontrolled CNS metastases, radiotherapy ≤14d prior to enrollment, major surgery ≤28d prior to enrollment, currently receiving hormone replacement, hepatitis B/C positive, HIV positive, another active cancer.

Specific Aims: Primary endpoint: proportion of AR+ pts in each arm achieving a CB response (CBR) at 24 weeks (wks). CBR defined as pts with a complete response (CR), partial response (PR), or stable disease (SD); per modified RECIST 1.1. Secondary endpoints: objective response rate, progression free survival, time to progression, and duration of response. Statistical Methods: Simon's two-stage (optimal) design will be used to assess primary efficacy, requiring up to 88 evaluable pts; i.e., pts with centrally confirmed AR+ who receive at least one dose of study drug. The trial will test for an unacceptably low CBR of ≤10% versus a CBR ≥30%. There is no intent to statistically compare the two dose arms, but to determine whether either or both doses result in an acceptable CBR.

Target Accrual: Up to 118 pts will be enrolled. The first stage will be assessed in each arm among the first 18 evaluable pts. If at least 3/18 exhibit CB at 24 wks, then the arm will proceed to the second stage of recruitment up to a total of 44 pts. Otherwise, the arm will be discontinued for lack of efficacy.

2015 San Antonio Breast Cancer Symposium

Publication Number: OT2-01-07

Title: A phase 2 open label, multi-center, multinational study investigating the efficacy and safety of GTx-024 on advanced, androgen receptor-positive triple negative breast cancer (AR+ TNBC)

Rugo H, Overmoyer B, Schwartzberg L, Palmieri C, Taylor R, Hancock M, Small S and Johnston MA. University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA; Dana Farber Cancer Institute, Inflammatory Breast Cancer Program, Boston, MA; The West Clinic, Memphis, TN; University of Liverpool, Liverpool, Merceyside, United Kingdom and GTx, Memphis, TN.

Body: Background: The androgen receptor (AR) is the most highly expressed steroid receptor in breast cancer (BC) with expression seen in up to 95% of estrogen receptor positive (ER+) and up to 50% of ER negative disease. Historically, steroidal androgens exhibited virilizing side effects, thus limiting clinical use. In TNBC, the expression of AR and androgen synthesizing enzymes is associated with lower proliferation, lower tumor grade, better overall survival, and more favorable clinical outcomes as compared to those patients with TNBC not expressing AR. Data from two trials targeting AR in TNBC indicates low level but encouraging clinical activity. A non-steroidal, tissue-selective, AR modulator (SARM), such as GTx-024, offers a targeted approach of AR activation in AR+ TNBC without virilization or estrogenic effects.

Trial Design: Open label, multicenter, multinational, Phase 2 study for the treatment of advanced or metastatic TNBC. Subjects will receive GTx-024, 18 mg orally (PO) daily, continued until evidence of disease progression or toxicity. Subjects whose tumors demonstrate Clinical Benefit (CB) will be treated on study drug until progression.

Eligibility Criteria:
Inclusion: Female, ≥18 years old, confirmed AR+ (≥10% staining) TNBC (confirmed by medical history), up to 1-2 prior chemotherapy regimens, available archived tumor tissue, measurable or bone-only disease, ECOG 0 or 1, with prior toxicities from chemotherapy resolved.

Exclusion: Life expectancy <4 months, uncontrolled CNS metastases, radiotherapy ≤14 days prior to enrollment, active hepatitis, HIV positive, prior treatment with anti-androgens, testosterone or testosterone-like agents, or estrogens or megesterol acetate, or prior treatment for a different cancer (other than BC or non-melanoma carcinoma of the skin) within the past 2 year

Specific Aims: The primary aim is to measure the proportion of AR+ subjects with CB at 16 weeks; defined as subjects with a complete response (CR), partial response (PR), or stable disease (SD); per modified RECIST 1.1. Secondary endpoints include: objective response rate, progression free survival, and time to progression.

Statistical Methods: Simon's two-stage (optimal) design will be used to assess primary efficacy, requiring up to 41 evaluable subjects; i.e., subjects with centrally confirmed AR+ who receive at least one dose of study drug. The first stage will be assessed among the first 21 evaluable subjects. If at least 2/21 achieve CB per modified RECIST 1.1 at 16 weeks, then the trial will proceed to the second stage of recruitment of up to a total of 41 subjects in the evaluable subset of the Full Analysis Set. Otherwise, the trial will be discontinued for lack of efficacy. The trial will test for an unacceptably low CBR of ≤5% versus a CBR more consistent with ≥20%.

Target Accrual: Up to 55 subjects will be enrolled.

Trial Information: www.gtxinc.com
POSITIVE: A study evaluating pregnancy and disease outcome and safety of interrupting endocrine therapy for young women with endocrine responsive breast cancer who desire pregnancy (IBCSG 48-14/BIG 8-13)

Pagani O, Partridge A, Azim Jr HA A, Peccatori FA A, Ruggeri M and Sun Z. International Breast Cancer Study Group, Bern, Switzerland and Dana-Farber Cancer Institute and Alliance for Clinical Trials in Oncology, Boston, MA.

Body: Background
Young breast cancer (BC) patients often face the disease before completing their family planning. The best available retrospective evidence suggests that pregnancy after BC does not negatively impact disease outcome in patients with endocrine sensitive BC and is safe for the offspring. However, given the need for prolonged adjuvant endocrine therapy for 5-10 years, it is not feasible to wait until completion of therapy in most of these women and thus there is a need to explore the safety of temporary interruption of endocrine therapy to allow pregnancy. To date, no definitive prospective study has been conducted in young women desiring future pregnancy.

Trial Design
Young patients with endocrine responsive early BC and pregnancy desire will interrupt endocrine treatment for up to 2 yrs to attempt pregnancy. As resumption of menses and conception depends on many factors, e.g. patient's age and adjuvant treatment received, the 2-yr interruption period is approximate, intended to include treatment wash-out (3 mos) conception (∼3-6 mos), delivery (∼9 mos), breast feeding (∼6 mos). Patients will be strongly advised to resume ET as soon as pregnancy attempts are concluded, and to complete 5-10 yrs ET at the local investigator discretion.

Major Eligibility Criteria
- Histologically-proven stage I-III endocrine-responsive BC.
- Age ≥ 18 and ≤ 42 years at enrollment.
- Adjuvant endocrine therapy (SERM alone, GnRH analogue plus SERM or AI) for ≥18 months but ≤30 months, stopped within 1 month prior to enrollment.
- Patient wishes to become pregnant.
- Premenopausal status at BC diagnosis.

Specific Aim
To assess the risk of BC relapse associated with temporary interruption of ET to permit pregnancy and to evaluate pregnancy success.

Statistical Methods
A true risk of BC recurrence of 2% per year is assumed for patients who do not interrupt endocrine treatment. With 500 patients enrolled in 4.0 yrs and an additional 1.6 yrs of follow up, there will be approximately 1600 patient-yrs of follow up and a median follow up of approximately 3 yrs at the time of the primary analysis, anticipated to occur 5.6 yrs after enrollment of the first patient. If the true risk of BC recurrence is 2% per yr, we anticipate 31 BC recurrences and an estimated 3-yr breast cancer free interval (BCFI) failure of 5.6% (95% CI 4.0% to 7.9%).

Translational Research will investigate different ovarian function parameters; uterine evaluation; and circulating tumor DNA. FFPE tissue of the primary tumor will be collected to integrate different parameters related to biology of BC arising in young women. All material will be banked centrally.

Psycho-oncological Companion Study on fertility concerns, psychological well-being and decisional conflicts is mandatory in the United States and open to interested centers elsewhere.

Accrual: Target: 500; Actual: 4 (31 May 2015)

Title: Randomized phase II trial of CC-486, a DNA methyltransferase inhibitor, in combination with fulvestrant in postmenopausal women with hormone receptor–positive, human epidermal growth factor receptor 2–negative metastatic breast cancer who have progressed on an aromatase inhibitor

Gianni L, Rugo H, Campone M, Hudson M, Chen P, Fandi A and Sachdev JC C. San Raffaele Hospital, Scientific Institute, Milan, Italy; UCSF Comprehensive Cancer Center, San Francisco, CA; Centre Rene Gauducheau, CLCC Nantes Atlantique, Nantes-Saint Herblain, France; Celgene Corporation, Summit, NJ; Celgene Corporation, Summit, NJ; Celgene Corporation, Summit, NJ and Virginia G. Piper Cancer Center, Scottsdale Healthcare, Scottsdale, AR.

Body: Background: Breast cancer is the most common cancer among women in developed countries. The hormone receptor–positive (HR+)/human epidermal growth factor receptor 2–negative (HER2−) subtype comprises approximately 70% of all breast cancers. For patients with HR+ metastatic breast cancer (MBC), sequential endocrine therapies are recommended. Fulvestrant is a selective ER modulator. It is approved in the treatment of HR+ MBC in postmenopausal women with disease progression following antiestrogen therapy. Development of resistance to endocrine therapy poses a major problem in the use of these agents. CC-486 is an orally bioavailable formulation of 5-azacitidine, a cytidine nucleoside analogue that incorporates into DNA and RNA. CC-486 allows for extended dosing and prolonged drug exposure, which may provide the opportunity for incorporation into cycling malignant cells. Epigenetic modifying agents like CC-486 are hypothesized to potentially reverse resistance to hormonal therapy.

Trial Design: This is a phase II, randomized, open-label, 2-arm study. Approximately 92 patients will be enrolled in North America and Europe. Key eligibility criteria include age ≥ 18 years, postmenopausal, metastatic disease, histologically and/or cytologically confirmed estrogen receptor positive (ER+), HER2− (immunohistochemistry [IHC] 0 or 1+ or fluorescence in situ hybridization [FISH], or IHC 2+ and FISH−), refractory to treatment with an aromatase inhibitor (AI) defined as recurrence on or ≤ 12 months after prior AI treatment in the adjuvant setting or disease progression on or ≤ 1 months of prior treatment with an AI in the metastatic setting, and Eastern Cooperative Oncology Group performance status 0 - 1. Measurable disease by Response Evaluation Criteria in Solid Tumors v1.1 is required. Key exclusion criteria include history of or current symptomatic brain metastases, > 1 line of chemotherapy for MBC, prior fulvestrant, or any prior hypomethylating agent. Patients with visceral crisis requiring chemotherapy are also excluded. Patients will be randomized 1:1 to receive CC-486 300 mg on days 1 - 21 of each 28-day cycle plus fulvestrant 500 mg on days 1 and 15 in the first cycle and day 1 in cycles ≥ 2 or fulvestrant 500 mg on days 1 and 15 in the first cycle and day 1 in cycles ≥ 2. The primary endpoint is progression-free survival (PFS). Secondary endpoints include overall response rate, clinical benefit rate, overall survival, duration of response, and safety. Exploratory endpoints include molecular profiling of the tumor for evaluation of predictors of clinical outcome in archival tumor samples, whole blood, and plasma samples. Efficacy will be evaluated every 8 weeks during the first 24 weeks and then every 12 weeks until disease progression, unacceptable toxicity, death, or new therapy. The primary efficacy analysis will be performed after 70 PFS events are documented. The first safety analysis will be conducted after 32 patients have completed ≥ 1 cycle of treatment. The trial is open for enrollment. ClinicalTrials.gov: NCT02374099.
Title: A phase 1 study of RAD1901, a novel, orally available, selective estrogen receptor degrader, for the treatment of ER positive advanced breast cancer

Body: The current NCCN treatment guidelines for ER+ breast cancer involves the use of approved agents such as fulvestrant, tamoxifen and aromatase inhibitors that either inhibit estrogen production or block estrogen receptor binding. While the initial treatment regimens with these selective estrogen receptor modulators (SERMs) and selective estrogen receptor degraders (SERDs) is often successful, many women eventually relapse with more aggressive forms of endocrine-resistant disease. To begin to overcome some of the challenges associated with current therapies including exposure limitations and intramuscular administration, we have developed RAD1901, a novel, non-steroidal, orally available SERD. Preclinical studies with RAD1901 have demonstrated potent dose dependent ER degradation consistent with a SERD mechanism of action, as well as potent inhibition of proliferation in vitro in breast cancer cell lines. RAD1901 also demonstrated significant anti-tumor efficacy in vivo, and notably single agent regressions in both MCF7 and a primary patient derived xenograft models harboring an ESR1 mutations.

A phase 1 monotherapy study conducted in healthy postmenopausal female volunteers evaluated forty four subjects treated once daily with RAD1901 with doses ranging from 200 mg/day up to 1000 mg/day for 7 days. All dose levels were generally well tolerated and pharmacokinetic analysis demonstrated plasma exposures consistent with preclinical efficacy in ER+ breast cancer models. Furthermore, 18F-estradiol positron emission tomography (FES-PET) was also performed at baseline and after 7 days of RAD1901 treatment, to evaluate estrogen receptor engagement. Standardized uptake values (SUV) pre- and post-treatment with RAD1901 demonstrated complete attenuation of FES-PET signal in ER+ tissues such as the uterus from the 200 mg/day dose level. Taken together, these results provide strong preclinical and clinical rationale for the development of RAD1901 as a potent and selective oral SERD for the treatment of hormone driven and hormone resistant ER + metastatic breast cancers.

RAD1901-005 is a Phase 1 study currently enrolling ER+ advanced metastatic breast cancer patients. The study consists of two parts: a monotherapy dose escalation followed by a safety expansion at the maximum tolerated dose (MTD). The dose escalation will follow a standard 3+3 design with once daily dosing to establish, safety, tolerability, and PK. Once the MTD for RAD1901 has been established, the safety expansion will further evaluate the safety, tolerability, biomarkers and preliminary efficacy at the recommended phase 2 dose (RP2D) following a continuous once daily schedule. Key inclusion criteria include post-menopausal women aged 18 years or older, with advanced ER positive, HER2 negative breast cancer, who have received ≤ 2 prior chemotherapy regimens in the metastatic setting and > 6 months of prior endocrine therapy. Patient enrollment started in early 2015, and is currently ongoing.

Title: A phase 2 randomized, double-blind, placebo-controlled trial of radium-223 dichloride with exemestane and everolimus in human epidermal growth factor receptor 2–negative, hormone receptor–positive breast cancer patients with bone metastases

Rugo HS S, Huang L, Petrenciuc O, Zaccarini P and Coleman RE E. UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA; Bayer HealthCare, Whippany, NJ; Bayer S.p.A., Milan, Italy and University of Sheffield, Weston Park Hospital, Sheffield, United Kingdom.

Body: Background: Radium-223 dichloride (Ra-223), a first-in-class α-emitter with a potent, targeted antitumor effect on bone metastases (mets), was well tolerated and reduced baseline bone biomarker levels in a phase 2 study in metastatic breast cancer (MBC) patients (pts) with bone-dominant disease (Coleman et al. Breast Cancer Res Treat 2014). Adding everolimus (EVE) to exemestane (EXE) significantly improved progression-free survival (PFS) versus EXE alone in human epidermal growth factor receptor 2–negative (HER2-), hormone receptor–positive (HR+) MBC pts with advanced disease. This trial will evaluate efficacy and safety of Ra-223 with EXE and EVE in pts with HER2-, HR+ breast cancer and bone mets (NCT02258451).

Trial design: Pts scheduled to receive EXE (25 mg PO once daily) and EVE (10 mg PO once daily) will be randomized 1:1 to Ra-223 (50 kBq/kg IV) or placebo × 6 cycles q4wk. EXE and EVE treatment (tx) will continue until disease progression, unacceptable toxicity, or the pt can no longer travel to the clinic to receive study medication. Stratification will be by geographic region, previous lines of hormone therapy, and presence of visceral disease. Safety and efficacy will be assessed at each 4-week clinic visit during tx. Long-term safety will be assessed until study termination (ie, pt death, pt loss to follow-up, or pt reaching required number of events).

Main eligibility criteria: Eligible pts are pre- or postmenopausal with estrogen receptor–positive and HER2- bone lesion–related asymptomatic or mildly symptomatic MBC not amenable to cure by surgery or radiotherapy, and with ≥2 bone mets visible on bone scan. Pts must have measurable disease per RECIST v1.1, ≥1 prior line of hormonal therapy in the metastatic setting, and 1-2 skeletal related events before study entry; be on bisphosphonates or denosumab for ≥1 mo before study entry; and have ECOG performance status of 0-1, adequate hematologic, renal, and liver function, and life expectancy ≥6 mo. Pts may not have prior or current need for chemotherapy in the metastatic setting, unresolved spinal cord compression, and prior or current EVE tx.

Specific aims: The primary endpoint is symptomatic skeletal event (SSE)–free survival. Secondary endpoints are overall survival, time to opiate use for cancer pain, time to pain progression, time to cytotoxic chemotherapy, radiologic PFS (rPFS), and acute and long-term safety. Exploratory endpoints include time to first on-study SSE, time to bone alkaline phosphatase (bALP) progression, bALP response at wk 12 and end of tx, bone-specific rPFS, resource utilization, biomarker assessments, and time to visceral mets onset.

Statistical methods: Assuming a one-sided α of 0.1, power of 90%, ∼160 SSEs will be required at the time of analysis. A stratified log-rank test will be used to analyze efficacy (intent-to-treat population). Safety analysis will be descriptive.

Present and target accrual: This trial is now enrolling pts. Target accrual is 311.

Title: Comparison of axillary sentinel lymph node biopsy versus no axillary surgery in patients with early-stage invasive breast cancer and breast-conserving surgery: A randomized prospective surgical trial. The intergroup-sentinel-mamma (INSEMA)-trial

Reimer T, von Minckwitz G, Loibl S, Hildebrandt G, Denkert C, Nekljudova V, Kundt G, Becker D and Gerber B. Breast Center University of Rostock, Rostock, Germany; German Breast Group, Neu-Isenburg, Germany; Radiotherapy University of Rostock, Rostock, Germany; Institute of Pathology Charité, Berlin, Germany and Institute of Biostatistics University of Rostock, Rostock, Germany.

Body: Background:
Currently, axillary surgery for breast cancer is considered as staging procedure that does not seem to influence breast cancer mortality, since the risk of developing metastasis depends mainly on the biological behaviour of the primary. Based on this, the postsurgical therapy should be considered on the basis of biologic tumor characteristics rather than nodal involvement.

Trial design:
The goal of INSEMA is to show that early-stage breast cancer patients with reduced extent of axillary surgery are not inferior regarding invasive disease-free survival (IDFS) outcome. Patients with planned breast-conserving surgery (BCS) will be first randomized (1:4 ratio) to either no axillary surgery or axillary sentinel lymph node biopsy (SLNB). Patients with SLNB and pN+(sn) status will be secondly randomized (1:1 ratio) to either SLNB alone or completion axillary lymph node dissection (ALND) in cases with less than three involved nodes (one or two macrometastases).

Primary objective:
-IDFS after BCS (non-inferiority question)

Inclusion criteria:
-Written informed consent
-Histologically confirmed unilateral primary invasive carcinoma of the breast (core biopsy)
-Age at least 35 years
-Preoperative imaging techniques with estimated tumor size of maximal 5 cm (iT1/iT2 irrespective of hormone sensitivity or HER2 status)
-Clinically and sonographically tumor-free axilla prior to core biopsy
-In cases with cN0 and iN+, a negative core biopsy or fine needle aspiration biopsy of the suspected lymph node is required
-No clinical evidence for distant metastasis (M0)
-Planned breast-conserving surgery (R0 resection) with postoperative external whole-breast irradiation (conventional fractionation or hypofractionation)

Statistics:
Assumptions for first randomization:
-The 5-year IDFS for women with cN0/iN0 axillary lymph nodes and T1/T2 disease is considered to be 88%
-Clinical non-inferiority is defined as the non-SLNB group having a 5-year IDFS of not less than 85% and if the hazard ratio (HR) is less than 1.271 when compared with the SLNB group

The total number of patients in the per-protocol set of the first randomization must be increased from 3,796 to 5,940 (936 events) due to unequal-sample-size design.

Assumptions for second randomization:
-The 5-year IDFS for women with pN+(sn) axillary lymph nodes (1-2 macrometastases) and T1/T2 disease is considered to be 81%
-Clinical non-inferiority is defined as the SLNB alone group having a 5-year IDFS of not less than 76.5% and if the hazard ratio (HR) is less than 1.271 when compared with the completion ALND group

The total number of patients to be included into the per-protocol set for the second randomization will be approximately 1,968.

Finally, the calculated total case number for per-protocol analyses is 6,740 (5,940 German and 800 Austrian patients), the expected total number of randomized patients is 7,095.

Time lines:
-First patient in: September 2015
- Last patient in: August 2019
- Final analysis: End of 2024
Funding by Deutsche Krebshilfe (grant no. 110580).
NRG Oncology/NSABP B-51/RTOG 1304: A phase III clinical trial to determine if chest wall and regional nodal radiotherapy (CWRNRT) post mastectomy (Mx) or the addition of RNRT to breast RT post breast-conserving surgery (BCS) will reduce invasive cancer events in patients (pts) with positive axillary (Ax) nodes who are ypN0 after neoadjuvant chemotherapy (NC)

Mamounas EP P, Bandos H, White JR R, Julian TB B, Khan AJ J, Shaitelman SF F, Torres MA A, Vicini FA A, Ganz PA A, McCloskey SA A, Paik S, Gupta N, Li XA, DiCostanzo DJ J, Costantino JP P, Curran Jr WJ J and Wolmark N. NRG Oncology/NSABP, Pittsburgh, PA; UF Health Cancer Center at Orlando Health, Orlando, FL; NRG Oncology and the University of Pittsburgh, Pittsburgh, PA; NRG Oncology/RTOG, Philadelphia, PA; Ohio State University, Columbus, OH; Allegheny Cancer Center at Allegheny General Hospital, Pittsburgh, PA; Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; University of Texas MD Anderson Cancer Center, Houston, TX; Emory Healthcare, Emory Winship Cancer Institute, Atlanta, GA; 21st Century Oncology, Pontiac, MI; University of California at Los Angeles, Los Angeles, CA; Severance Biomedical Science Institute, Yonsei University College of Medicine, Seoul, Korea; Medical College of Wisconsin, Milwaukee, WI and Ohio State University, Wexner Medical Center, Columbus, OH.

**Body: Background:**
This phase III post-NC trial will evaluate if CWRNRT post Mx or whole breast irradiation (WBI) with RNRT after BCS significantly reduces the invasive breast cancer recurrence-free interval (IBC-RFI) rate in pts presenting with positive Ax nodes that are negative after NC. Secondary aims are OS, LRRFI, DRFI, DFS-DCIS, and second primary cancer as well as comparing RT effect on cosmesis in reconstructed Mx pts.

Correlative science examines RT effect by tumor subtype, molecular outcome predictors for residual disease pts, and predictors for the degree of reduction in loco-regional recurrence.

**Methods:**
Clinical T1-3, N1 IBC pts with positive Ax nodes (FNA or core needle biopsy) complete ≥12 wks of NC (anthracycline and/or taxane). HER2-positive pts receive anti-HER2 therapy (tx). After NC BCS or Mx is performed with a sentinel node biopsy (≥3 nodes) and/or Ax dissection with histologically negative nodes. ER/PR and HER-2 neu status before NC is required. Pts receive required systemic tx. Radiation credentialing with a facility questionnaire and a case benchmark is required. Randomization for Mx pts is to no CWRNRT or CWRNRT and for BCS pts to WBI or WBI RNRT.

**Statistics:**
1,636 pts to be enrolled over 5 yrs with definitive analysis at 7.5 yrs. Study is powered at 80% to test that RT reduces the annual hazard rate of events for IBCR-FI by 35% for an absolute risk reduction in the 5-yr cumulative rate of 4.6%. Intent-to-treat analysis with 3 interim analyses at 43, 86, and 129 events, with a 4th/final analysis at 172 events will occur. Accrual as of 6/4/15 is 143. Pt-reported outcomes focusing on RT effect will be provided by 736 pts before randomization and at 3, 6, 12, and 24 months.

Title: Magnetic nano-device for identification of the breast sentinel nodes – A novel method

Beitsch PD, Hunt KK, Bold RJ, Gittleman MA, Blair SL, Alvarado MD, and Harmer QJ. Dallas Surgical Group, Dallas, TX; MD Anderson Cancer Center, Houston, TX; University of California at Davis Medical Center, Sacramento, CA; Coordinated Health Breast Care Specialists, Allentown, PA; University of California San Diego Moores Cancer Center, La Jolla, CA; University of California San Francisco, San Francisco, CA and Endomagnetics Inc, Austin, TX.

Body: Breast sentinel node biopsy (SNB) is a well-established procedure that has supplanted traditional axillary dissection for most clinically node-negative breast cancer patients. Techniques to identify the draining lymph nodes include colored dyes and radioactive compounds. The Sentimag system uses a non-radioactive magnetic tracer and a handheld magnetic probe to identify sentinel nodes (SNs). The Sentimag Intraoperative Comparison (SentimagIC) study compares the magnetic technique with the standard combination of radioisotope and isosulfan blue dye.

Methods: SiennaXP is a nano device composed of coated iron oxide nanoparticles designed to optimize lymphatic uptake and SN retention. The Sentimag breast SNB technique involves injection of 2cc of SiennaXP fluid into Sappey's subareolar plexus followed by 5 minutes of breast massage and an additional 15 minutes of time to optimize drainage prior to beginning the procedure. The Sentimag hand held probe is then used to identify a magnetic 'hotspot' through the skin of the axilla. The usual transverse axillary incision is made and the magnetometer is used to identify the SNs. The SentimagIC study involves utilizing the Sentimag technique in combination with the 'standard' techniques of isosulfan blue dye and 99technetium sulfur colloid. All blue, radioactive and magnetic SNs are removed and identified as stained blue (from isosulfan blue dye) or black/brown (from SiennaXP) or not, and both radioactive and magnetic counts are taken ex vivo on each node. Currently there are 6 active sites with a total of 60 patients enrolled.

Trial design: This is a pivotal, prospective, open label, multicenter, paired comparison of the magnetic technique with the standard of care for lymph node localization in patients with breast cancer.

Primary endpoints: The lymph node detection rate with SentiMag / SiennaXP and the detection rate with the standard of care; and the safety of Sentimag / SiennaXP as indicated by adverse events.

Eligibility: Diagnosis of primary breast cancer or pure ductal carcinoma in situ (DCIS); Scheduled for sentinel lymph node biopsy; Clinical negative node status (i.e. T0-3, N0, M0).

Statistical methods: The primary hypothesis is that the magnetic technique is non-inferior to the standard technique. Based on an expected detection rate of 95% for both techniques and a non-inferiority margin of 5%, 140 subjects will be required to show non-inferiority with 85% power.

Discussion: SNB for breast cancer is a robust procedure, able to identify the draining lymph nodes of the breast in essentially all patients. Many techniques have been used including radioactive tracers (utilized on most cases) and colored dyes. SentiMag utilizes a unique nano device that can identify the same draining nodes but without the radioactivity used in most procedures. Radioactive dyes must be handled carefully to minimize radiation exposure to healthcare providers and the patient from the manufacturing process, delivery to facility, injection under a nuclear physician license, and the surgical procedure. This novel technique may supplant radioactive tracers allowing SNs to be removed without the patient/healthcare providers being exposed to radiation or the scheduling inconvenience of pre-procedure injection.
Title: The LORIS trial: A multicentre, randomised phase III trial of standard surgery versus active monitoring in women with newly diagnosed low risk ductal carcinoma in situ

Francis A, Fallowfield L, Bartlett J, Thomas J, Wallis M, Hanby A, Pinder S, Evans A, Billingham L, Brookes C, Dodwell D, Fairbrother P, Gaunt C, Jenkins V, Matthews L, Pirrie S, Reed M, Roberts T, Wilcox M, Young J and Rea D. University Hospital Birmingham NHS Trust, Birmingham, West Midlands, United Kingdom; Sussex Health Outcomes Research & Education in Cancer (SHORE-C) Brighton & Sussex Medical School, Brighton, Sussex, United Kingdom; Ontario Institute for Cancer Research, Toronto, ON, Canada; Western General Hospital, Edinburgh, Scotland, United Kingdom; Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; University of Leeds, Leeds, Yorkshire, United Kingdom; King's College London, London, United Kingdom; Ninewells Hospital and Medical School, Dundee, Scotland, United Kingdom; University of Birmingham, Birmingham, West Midlands, United Kingdom; ICPV, London, United Kingdom and Brighton & Sussex Medical School, Brighton, Sussex, United Kingdom.

Body: Background: The independent review of the UK National Health Service Breast Screening Programme reported (The Lancet, Volume 380, Issue 9855, Pages 1778 - 1786, 17 November 2012) on the benefits & harms of breast screening. It concluded that breast screening saves lives & acknowledged overtreatment. It encouraged randomized trials to elucidate the appropriate treatment of screen-detected ductal carcinoma in situ (DCIS) to gain a better understanding of its natural history. The LORIS trial addresses overtreatment of low & low/Intermediate grade screen detected (low risk) DCIS by randomizing patients to standard surgical treatment or active monitoring.

Trial Design: LORIS is a phase III, multicentre, 2 arm study, with a 2 year feasibility phase, in patients confirmed to have low risk DCIS by central pathology review. Patients are randomised to standard surgery or active monitoring with annual mammography. Patients will be followed up for a minimum of 10 years.

Key Eligibility Criteria:
1) Female 46 years or over.
2) Screen-detected or incidental microcalcification (with no mass lesion clinically or on imaging)
3) Low risk DCIS on large volume vacuum-assisted biopsy, confirmed by central pathology review
4) Patient fit to undergo surgery

Specific Aims: The LORIS Trial aims to establish whether patients with newly diagnosed low risk DCIS can safely avoid surgery without detriment to their wellbeing (psychological and physical) & whether those patients that do require surgery can be identified by pathological and radiological means.

Primary endpoint: Ipsilateral invasive breast cancer free survival rate at 5 years
Secondary endpoints: Overall survival; mastectomy rate; time to mastectomy; time to surgery; patient reported outcomes & health resource utilisation.

A digital image data repository and tissue bank provide a prospective resource for both translational & imaging studies.

Statistical Methods: A total of 932 patients will be randomized to a non-inferiority design to test the null hypothesis that active monitoring of women diagnosed with low risk DCIS is not non-inferior in terms of 5 year ipsilateral invasive breast cancer free survival (iiBCFS) rate compared to treatment with surgery. The iiBCFS rate will be compared across the two arms on a per protocol and intent-to-treat basis, using a 1-sided ($\alpha=0.05$) log-rank test for non-inferiority. The iiBCFS rate is assumed to be 97.5% in the surgery arm giving 80% power to exclude a difference of more than 2.5% in the active monitoring arm at 5 years.

Present Accrual and Target Accrual: 21 UK centres are open & the feasibility phase of the trial is recruiting to target. The web based central pathology review process is functioning well with a one week maximum turn around. A further 40 centres will be opened on completion of the feasibility phase.

POSNOC: Positive sentinel node—Adjuvant therapy alone versus adjuvant therapy plus clearance or axillary radiotherapy: A randomised trial looking at axillary treatment in early breast cancer

Goyal A. Royal Derby Hospital, Derby, United Kingdom.

Body: Background
Women with early breast cancer that has spread to 1 or 2 sentinel nodes (SNs) undergo axillary node clearance (ANC) or axillary radiotherapy (ART). The publication of the Z11 trial challenged this practice. There are however concerns about this trial which may limit the interpretation and generalisability of its results. These issues include the proportion of patients with micrometastases, variability in radiotherapy and applicability in patients undergoing mastectomy. Therefore further randomized trials are needed to define the role of axillary treatment in patients with 1 or 2 SNs with macrometastases. The UK-ANZ POSNOC trial is asking this question and will provide a more solid evidence base to inform clinical practice.

Methods
Trial design: A pragmatic, randomized, multicenter, non-inferiority trial.
Interventions: All participants will receive systemic adjuvant therapy according to local guidelines and radiotherapy to breast or chest wall if indicated. Women in the intervention group will receive systemic adjuvant therapy alone, whereas those receiving standard care will receive adjuvant therapy plus ANC or ART.
Study population: Women with unifocal or multifocal invasive breast cancer (≤ 5 cm) undergoing breast conserving surgery or mastectomy, who have 1 or 2 nodes with macrometastases at SN biopsy. The sample size is 1900 women. All participants will be followed up for 5 years.
Primary outcome: axillary recurrence at 5 years.
Secondary outcomes: arm morbidity, quality of life, anxiety, loco-regional recurrence, distant metastasis; time to axillary recurrence, axillary recurrence-free survival, disease-free and overall survival, contralateral breast cancer, non-breast malignancy and economic evaluation.
Key differences from Z11
a) stringent radiotherapy quality assurance program, b) prospective pathology reporting, c) axillary ultrasound is mandatory, d) mastectomy patients are eligible, e) axillary treatment in the standard group may be ANC or ART.

Current enrollment
126 patients.

Title: Measuring the Impact of MammaPrint on treatment in breast cancer patients: A prospective registry (IMPaCt)

Hart LL L, Untch S and Stork-Sloots L. Florida Cancer Specialists, Fort Myers, FL and Agendia Inc, Irvine, CA.

Body: Background:
Gene expression profiling in breast cancer offers the potential to improve prognostic accuracy, treatment choice, and health outcomes in women diagnosed with early-stage breast cancer. Numerous gene-profiling assays are now available, which can be applied to a single tumor specimen to provide physicians with a more complete basis for treatment decisions.
• MammaPrint is 70-gene profile to estimate whether patients are at high or low risk of developing metastases within the first 10 years after curative surgery.
• BluePrint is an 80-gene molecular subtyping profile that discriminates between three breast cancer subtypes: Luminal, HER2, and Basal.
• TargetPrint provides a quantitative measurement of estrogen receptor (ER), progesterone receptor (PR), and HER2.

Trial design:
IMPACT is a prospective, case-only, study to measure the impact of MammaPrint on treatment decisions in breast cancer patients. The primary objective will be to measure the impact of MammaPrint on treatment decisions in stage I and II Hormone Receptor (HR)-positive, HER2-negative breast cancer patients. As a secondary objective, the impact of MammaPrint on treatment will be assessed in patients with T1a/bN0/1 (up 1 LN) Triple Negative or HER2-positive breast cancer. Baseline clinical data and physician chemotherapy intention before knowing the MammaPrint result will be entered in CRF 1. After completion of CRF1, the MammaPrint result will be released. CRF2 will be completed after the final treatment decision has been made. This CRF will capture physician chemotherapy intention after the MammaPrint result and the impact of these results.

Eligibility:
The study will include women aged ≥18 years with histologically proven invasive stage I-II, HR-positive, and HER2-negative breast cancer, OR, T1a/bN0/1 (up to 1 node) triple negative or Her2-positive breast cancer who signed informed consent.

Objectives:
Primary objective:
Assess the impact of MammaPrint on chemotherapy + endocrine versus endocrine alone treatment decisions in HR-positive, HER2-negative breast cancer patients. Secondary objectives:
• Assess the impact of MammaPrint on treatment decisions in T1a/b, N0/1 (up to 1 node) triple negative or Her2-positive breast cancer patients
• Assess concordance of TargetPrint ER, PR and HER2 results with locally assessed IHC/FISH ER, PR and HER2
• Compare clinical subtype based on IHC/FISH ER, PR, HER2 and Ki-67 (if available) with BluePrint molecular subtype

Statistical methods:
A sample size of 331 patients is required to detect a 25% overall treatment change (5% significance and 95% power) in stage I and II HR-positive, HER2-negative patients. In addition at least 50 T1a/bN0/1 (up to 1 LN) Triple Negative, and at least 50 T1a/bN0/1 (up to 1 LN) HER2-positive breast cancer patients will be enrolled. A McNemars test will be performed for the comparison of the two proportions of treatment intentions (before and after), both expressed as a percentage.

Accrual: The study did not yet start accrual. First patient visit is expected in August 2015. Approximately 15-20 institutions in the United States will participate.
2015 San Antonio Breast Cancer Symposium

Publication Number: OT2-03-02

Title: DI study: Decision impact of the NanoString® Technologies Prosigna™ in early breast cancers

Hequet D, Guinebretière J-M, Lerebours F, Roulot A, Callens C, Gentien D, Penault-Llorca F, Zilberman S, Salmon R, Foa C, Berseneff H, Huchon C, Katz G, MacDonald M, Morel P, Bieche I, Dubot C and Rouzier R. Institut Curie-Centre René Huguenin, St Cloud, France; Institut Curie, Paris, France; Centre Jean Perrin, Clermont-Ferrand, France; Tenon Hospital, Paris, France; Private Hospital Les Peupliers, Paris, France; Private Hospital Clairval, Marseille, France; René Dubos Hospital, Pontoise, France; Poissy-St Germain Hospital, Poissy, France; Groupe Général de Santé, Paris, France; NanoString Technologies, Seattle, WA and Equipe d'Accueil 7285, Risk and Safety in Clinical Medicine for Women and Perinatal Health, University Versailles-Saint-Quentin, Montigny-le-Bretonneux, France.

Body: Backgrounds: More than a decade of research, clinical studies, and peer reviewed publications support the value of molecular subtyping based on gene expression analyses to assess prognosis and treatment options for patients with early-stage breast cancer. Therefore, genomic assays are now being introduced to supplement the conventional diagnostic tools. Prosigna is a standardized test that measures the expression levels of 50 classifier genes in formalin-fixed, paraffin-embedded (FFPE) breast tumor tissue samples and provide a subtype classification based on the fundamental biology of individual patient's tumor (referred to as molecular subtyping), as well as a prognostic score (referred to as risk of recurrence (ROR) score) that predicts the probability of cancer recurrence over 10 years.

The primary objective of this study is to assess the extent to which Prosigna affects the medical oncologist's treatment recommendations regarding adjuvant chemotherapy and actual treatments received for patients with early-stage breast cancer. Changes will include hormonal therapy alone, hormonal therapy plus chemotherapy, and changes in types of chemotherapy if chemotherapy was recommended before and after the test. Secondary objectives will be to elicit information on investigators' confidence in the recommendations before and after the test, and by cancer recurrence risk groups, rate of chemotherapy related adverse events stratified by administration of chemotherapy, and patients' decisional conflict status, anxiety levels, and functional status before and after Prosigna results.

Multicentric prospective study. Prosigna will be performed on operative piece for all consecutively postmenopausal women matching the inclusion criteria and having signed an informed consent. Data on patient demographics, disease status, intended cancer-specific postoperative management before and after the test, tests results, investigators and patients' confidence in the treatment and in the test, will be recorded in the inclusion visit, after the tests results and 6 month post-assay.

Inclusion criteria: Postmenopausal patients with resected node-negative, estrogen-receptor-positive, HER2-negative (by the local laboratory) early-stage invasive breast cancer (T1-T2, N0, pN0 (i+), pN1 (micrometastatic), M0), able to give consent, eligible for treatment of breast cancer with adjuvant chemotherapy and with ECOG performance status of 0 or 1.

Statistical methods: The clinical and demographic characteristics of the study sample will be described using mean, median, standard deviation, and range for continuous/ordinal variables and frequency and proportion for categorical variables. Bivariate plots and crosstabs will be performed to inspect bivariate associations between variables. The proportion of patients for whom the physicians' choice of treatment changed from baseline to follow-up will be calculated along with the 95% confidence interval. The change in investigator confidence in treatment recommendations before and after Prosigna results were known will be analyzed by calculating the mean and 95% CI for the question regarding whether a physician is more confidence in treatment recommendation after ordering Prosigna.

47 patients have been included on 200 scheduled.
Women's triple-negative, first-line treatment: Improving outcomes in triple-negative breast cancer using molecular triaging and diagnostic imaging to guide neoadjuvant therapy

BACKGROUND:
In triple negative breast cancer (TNBC), pathologic complete response/residual cancer burden-0 (pCR/RCB-0) or minimal residual disease (RCB-I) following neoadjuvant chemotherapy (NACT) is associated with a good prognosis. This is in contrast to extensive residual disease (RCB-II-III) which carries approximately a 50% chance of recurrence. These patients have a particularly poor prognosis as there are currently no targeted agents to salvage chemoresistant disease. It is important to predict pCR in order to direct responsive disease toward standard NACT and non-responsive disease (NRD) to therapy on clinical trials.

TRIAL DESIGN:
The use of genomic signatures (JAMA, 2011; 305:1873-81) and imaging to predict response to NACT will be validated, and the clinical impact of selecting patients with predicted NRD for targeted therapy on clinical trial will be determined. Patients will undergo primary tumor biopsy for molecular profiling and will be randomized 2:1 to know the results versus not (control). Following that, all patients will receive 4 cycles of anthracycline-based NACT, with imaging used for response assessment. Patients with molecular/imaging criteria for NRD will be offered enrollment on a clinical trial based upon molecular profiling or based upon physician/patient choice (control).

INCLUSION CRITERIA:
Tumor size ≥1.5 cm diameter; TNBC by standard assays; ≥18 years of age; LVEF ≥50%; adequate organ and bone marrow function

EXCLUSION CRITERIA:
Stage IV disease; invasive cancer within 5 years; excisional biopsy of the primary tumor; features that limit response assessment by imaging; unfit for taxane and/or antracycline regimens; prior anthracycline therapy; ≥grade II neuropathy; Zubrod performance status of ≥2; history of serious cardiac events

PRIMARY AIM:
- Prospectively determine the impact of a molecular diagnostic/imaging platform in patients with localized invasive TNBC

SECONDARY AIMS:
- Compare rates of clinical trial enrollment
- Evaluate disease free survival in the experimental arms compared to control standard NACT
- Perform integrated biomarker analyses and identify therapeutic targets for resistant disease

STATISTICAL METHODS:
A maximum of 360 patients will be randomized (2:1) using a group sequential design with one-sided O'Brien-Fleming boundaries, with two equally spaced binding interim tests for futility and superiority and one final test, having an overall Type I error .05 and power .80 to detect an improvement in pCR/RCB-I from 50% to 64%.
Title: Optisoins01: Optimizing the patient-breast cancer care pathway; An observational multicentric prospective study

Héquet D, Baffert S, Hoang HL, Brédart A, Asselain B, Alran S, Berseneff H, Huchon C, Trichot C, Combes A, Alves K, Koskas M, Nguyen T, Roulot A and Rouzier R. Institut Curie-Centre René Huguenin, St Cloud, France; Equipe d’Accueil 7285, Risk and Safety in Clinical Medicine for Women and Perinatal Health, University Versailles-Saint-Quentin, Montigny-le-Bretonneux, France; Institut Curie, Paris, France; René Dubos Hospital, Pontoise, France; Poissy-St Germain Hospital, Poissy, France; Antoine Béclère Hospital, Clamart, France; André Mignot Hospital, Versailles, France; Argenteuil Hospital, Argenteuil, France; Bichat Hospital, Paris, France and Louis Mourier Hospital, Colombes, France.

Body: Background: A care pathway is defined as patient-focused global care that addresses temporal (effective and coordinated management throughout the illness) and spatial issues (treatment is provided near the health territory in or around the patient’s home). Heterogeneity of the care pathways in breast cancer (BC) is presumed but not well evaluated. The OPTISOINS01 study aims to assess every aspect of the care pathway for early BC patients using a temporal and spatial scope.

Trial design: An observational, prospective, multicenter study in a regional health territory (Ile-de-France, France) in different types of structures: university or local hospitals and comprehensive cancer centers. The study consists of three work-packages:
- Cost of pathway
  The aim of this WP is to calculate the overall costs of the early BC pathway at one year from different perspectives (society, health insurance and patient) using a cost-of-illness analysis. Using a bottom-up method, we will assess direct costs, including medical direct costs and nonmedical direct costs (transportation, home modifications, home care services, and social services), and indirect costs (loss of production).
- Patient satisfaction and work reintegration
  Three questionnaires will assess the patients’ satisfaction and possible return to work: the occupational questionnaire for employed women; the questionnaire on the need for supportive care, SCNS-SF34 (‘breast cancer’ module, SCNS-BR8); and the OUTPASSAT-35 questionnaire.
- Quality, coordination and access to innovation
  Quality will be evaluated based on visits and treatment within a set period, whether the setting offers a multidisciplinary consultative framework, the management by nurse coordinators, the use of a personalized care plan, the provision of information via documents about treatments and the provision of supportive care.
  The coordination between structures and caregivers will be evaluated at several levels. Day surgery, home hospitalization and one-stop breast clinic visits will be recorded to assess the patient’s access to innovation.

Inclusion criteria: Histologically confirmed, previously untreated, operable breast cancer women; residence in the Yvelines, Hauts-de-Seine or Val d’Oise departments, Ile-de-France, France.

Exclusion criteria: previous history of breast cancer; metastatic, locally advanced, or inflammatory breast cancer, as defined by the AJCC (7th Edition); unstable over the following 12 months.

Statistical methods: Homogeneous groups of patients will be established based on the patients’ individual medical information, and care pathways will be compared. The endpoints are the costs of care pathways, patients’ satisfaction, work reintegration, readmissions and time lapses between care stages. A multiple correspondence analysis will be conducted with care resource use and socio-demographic and medical characteristics as active variables. The variables that constitute the endpoints will be projected onto a space defined by appropriate axes.

Present accrual and target accrual: 307 patients have been included on 800 scheduled.
2015 San Antonio Breast Cancer Symposium

Publication Number: OT2-04-02

Title: A non-interventional study to characterize the real world treatment patterns and outcomes of women with ER+, HER2-advanced or metastatic breast cancer in Italy

De Laurentiis M, Mitra D, Bell T, Nuzzo CMA and De Placido S. National Cancer Institute “Fondazione Pascale”, Naples, Italy; Pfizer, Inc; Pfizer, srl, Italy and University of Naples Federico II, Naples, Italy.

Body: Background: Breast cancer is the most common type of cancer in women. There were an estimated 1.67 million new cases of breast cancer worldwide in 2012. Approximately 75% of women have hormone receptor positive (ER positive or PR positive) disease (Buzdar et al., 2009) and most of these patients have HER2-negative disease (Partridge et al., 2014). Although there is evidence via clinical trials on the efficacy of a number of ER+, HER2- breast cancer treatments, real world treatment patterns and related outcomes among this population are poorly characterized. This study aims at examining real world practice patterns and its impact on outcomes to gain a better understanding of the limitations of current treatments, identify specific areas and subpopulations with the greatest unmet need, and demonstrate the economic impact of current treatments. Additionally, this study will provide a longitudinal assessment of the impact of breast cancer on quality of life and work productivity in this subpopulation.

Study design: This study uses a prospective, observational cohort design. Approximately 500 women with ER+, HER2- ABC or mBC within Italy will be enrolled across 50 to 80 sites that represent diverse geographical and treatment settings. All patients will be followed for a minimum of two years (or until patient withdrawal from the study, death, or study discontinuation).

Eligibility criteria: Women who have been diagnosed with ER+, HER2- mBC or locoregionally recurrent ABC not amenable to resection or radiation therapy with curative intent and are initiating their first or second therapy in the ABC/mBC setting will be eligible to participate. Patients could have a de novo diagnosis of ABC or mBC or recur from an earlier stage. Patients participating in any interventional clinical trial that includes investigational products at the time of enrollment will be excluded from the study.

Specific aims: The key measures of interest are demographic and clinical characteristics, treatment patterns, clinical outcomes (e.g. objective response, progression-free survival, and overall survival, disease specific health care resource use, patient reported quality of life (EQ-5D), work productivity (WPAI-SHP), and disease specific symptoms and functioning (FACT-B and FACT-ES).

Statistical methods: The study is descriptive and not designed for formal hypothesis testing. A sample size of 500 patients ensures that the half-width of the 95% CIs on the proportion of patients with objective response at one year is less than 0.06.

Accrual: Patient enrollment is expected to begin in September 2015.

Disclosure: This study is sponsored by Pfizer Inc.

**Title:** An intrinsic subtype-based platform of translational randomized phase II trials of response-guided neoadjuvant therapy in breast cancer (PREDIX)

Foukakis T, Hellström M, Johansson H, Bergh J and Hatschek T. Karolinska Institutet and University Hospital, Stockholm, Sweden.

**Body:**

**Background:** Pathologic complete response (pCR) after neoadjuvant therapy of breast cancer is associated with a better prognosis. The impact of pCR on outcome differs between intrinsic subtypes.

**Trial design:** With the aim to improve treatment on an individual level, the PREDIX platform is designed as a compilation of randomized phase II studies based on functional "intrinsic subgroups" with the intention to direct treatment in relation to response. Four trials will be pursued:

1. Luminal A,N- (ER+ and/or PR+ without node metastases and age >40);
2. Luminal A,N+ (ER+ and/or PR+ with node metastases or age ≤40)/Luminal B (ER+ and high proliferation);
3. HER2 amplified (including HER2 positive luminal B tumors);
4. Triple-negative (this trial is currently in planning phase)

The clinical management is accompanied by repeated core biopsies and blood sampling. Besides mammography and ultrasound, functional imaging with PET-CT, confined to the breast and regional lymph nodes is applied.

**Treatment plan:**

**Trial 1.** Eligible patients are treated with endocrine therapy (ET) for 4 weeks. A biopsy for Ki67 is obtained before start and after 2 weeks. If no decrease of Ki67 is observed, or no objective response (OR) is seen after 4 weeks of treatment, palbociclib is added to ET. Patients with decrease of Ki67/OR are randomized to continuous therapy with or without the addition of palbociclib for 12 weeks, followed by surgery.

**Trial 2.** Patients are randomized to 12 weeks of palbociclib + ET or weekly paclitaxel, followed by switch to the other arm for additional 12 weeks before surgery.

**Trial 3.** Patients are randomized to the combination of pertuzumab + trastuzumab + docetaxel or trastuzumab emtasine for 2 three-weekly cycles. If OR is documented, 4 additional cycles will be administered followed by surgery. Non-responding patients will switch to the opposite arm.

In trials 2 and 3, additional anthracycline-based chemotherapy will be administered postoperatively. Adjuvant ET and radiotherapy will be used according to standard practice.

**Eligibility criteria:** Patients >18y with primary breast cancer >2 cm or node metastases, with adequate performance status and organ function are eligible. Intrinsic subtype defined by immunohistochemistry or, preferably, by genomic profiling using RNA Seq.

**Specific aims:** To evaluate the impact of response-guided treatment on objective response and long-term outcome and to identify tumor characteristics and treatment-related changes of tumor biology predictive of long-term prognosis.

**Statistical methods:** The PREDIX trials are based on current knowledge of molecular characteristics of breast cancer and designed to find the distribution of objective response to primary medical treatment (primary endpoint) and to find predictors of response, disease-free and overall survival, and to evaluate toxicity and quality of life in the two treatment groups (secondary endpoints).

**Present accrual and target accrual:** Present accrual (May 2015) in the HER2 positive trial is 14 patients. Trials 1 and 2 will open in July and September 2015. Target accrual is based on an explorative design and is between 180 to 200 patients in each trial.
**Title:** PRAEGNANT - A prospective academic translational research network for the optimization of the oncological health care quality in the adjuvant and advanced/metastatic setting: Health care research, pharmacogenomics, biomarkers, health economics (NCT02338167)

**Body:**

**BACKGROUND**

During the last decades the treatment of advanced breast cancer (ABC) patients has improved significantly due to a variety of empirical studies and the implementation and continuous improvement of molecular characterization of patients and tumor characteristics. Nevertheless, many ABC patients are faced with limited prognosis, and their treatment remains a challenge. New targeted therapies complement the well-established treatment options for ABC (anti-endocrine, chemo-, antibody based and bone related therapies), leading to individualized treatment regimes tailored to the needs of special patient sub-populations.

**SPECIFIC AIMS/TRIAL DESIGN**

The PRAEGNANT network study is conducted as an academic, prospective registry and diagnostic translational study, accompanied by biomaterial collection. In the pilot phase, 40 study centers, will document 3500 ABC patients. The primary objective is to discover biomarkers, which predict progression free survival (PFS). Secondary objectives include overall survival (OS), breast cancer specific survival, objective response rate, patient reported outcomes (PRO), description of therapies used in the metastatic setting, therapy adherence, health economics for patients with ABC, incidence of (serious) adverse events. The exploratory objectives comprise correlations of gene alterations and their influence on OS, PFS, side effects and PRO. Exploratory biomarkers are assessed at baseline and at every change of therapy. These include gene expression profiling of the primary tumor and corresponding metastasis, somatic mutations (measured in the tumor and in circulating tumor DNA), germline genetic variations, epigenetic changes and miRNA variations. Furthermore plasma and serum markers will be assessed. If actionable molecular alterations are detected patients are recruited into respective studies if available or treated accordingly.

**ELIGIBILITY CRITERIA:**

Any adult patient (>18 years) with the diagnosis of ABC and who is willing and able to sign the informed consent can be enrolled.

**STATISTICAL METHODS/TARGET ACCRUAL:**

The PRAEGNANT study as a prospective registry and diagnostic translational study aims to identify biomarkers in ABC patients, which may predict PFS. Target accrual for the pilot phase is 3500 patients. Each patient will be documented for up to 36 months with an estimated median PFS for all patients of 10 months.
Title: BRCAsearch: A population based prospective study on screening for BRCA1 and BRCA2 germline mutations in patients with newly diagnosed breast cancer treated in southern Sweden

Nilsson MP P, Borg Å, Henriksson K, Kristoffersson U, Kvist A, Silfverberg B, Törngren T and Loman N. Lund University, Lund, Sweden; Skåne University Hospital, Lund, Sweden; Regional Cancer Centre South, Lund, Sweden and Laboratory Medicine Region Skåne, Lund, Sweden.

Body: The overall purpose of the study BRCAsearch is to evaluate a new method for offering mutation analysis of BRCA1 and BRCA2 to all patients with newly diagnosed breast cancer.

Patients with breast cancer in southern Sweden are offered inclusion in the SCAN-B study at the time of diagnosis pre-surgery. If they consent, a part of the tumor is sent to a lab in Lund, Sweden, for research purposes (RNA sequencing etc.). Patients that are included in the SCAN-B study are eligible for inclusion in BRCAsearch.

Summary of study procedure for BRCAsearch:
1. An envelope with written information is given to the patient at the visit to the surgeon the week after surgery. This envelope contains a written genetic counseling, information about the study, an informed consent form, psychosocial questionnaires and contact information to a genetic counselor and physicians responsible for the study (telephone, e-mail). The patient can contact a genetic counselor for pre-test telephone genetic counseling if she wishes to.
2. BRCA1 and BRCA2 are analyzed.
3. Non-carriers are informed about the test result with a letter. Mutation carriers and VUS (variants of uncertain significance) are telephoned and given a time for an appointment at the Department of Clinical Genetics.
4. Psychosocial self-reported questionnaires are delivered at 3 times over a year.

Inclusion criteria (all):
1. The patient is included in the SCAN-B study.
2. The patient is recently diagnosed with an invasive breast cancer or a ductal cancer in situ.
3. The patient has signed an informed consent form for BRCAsearch.

Exclusion criteria (any of):
1. The patient is unable to understand the written information in Swedish.
2. The patient is a psychological state, due to chronic or temporary reasons, where one could suspect that information about the study substantially could be detrimental to the psychological well-being.

Primary outcome measures:
- Prevalence of BRCA1/2 mutations in an unselected breast cancer cohort in southern Sweden
- Uptake of genetic testing
- Proportion of the mutation carriers that do not fulfill current criteria for genetic testing

Secondary outcome measures:
- How many of the patients that contact us for questions and what type of questions they have
- How uptake of genetic testing varies with patient, treatment, and tumor characteristics
- The patients' attitudes towards the method used for identifying mutation carriers
- The economic cost per QALY (quality-adjusted life year)
- Psychosocial comparisons between mutation carriers and non-carriers

Targeted accrual is 500 patients included in the study, which is expected to be reached by the end of 2016.

The study enrolls patients from two hospitals in southern Sweden:
1. Helsingborg Hospital (study start: February 2, 2015)
2. Kristianstad Hospital (study start: March 2, 2015).
Characterization of the oral, gut, and breast tissue microbiomes in women with invasive breast cancer, ductal carcinoma in situ (DCIS), or no history of breast cancer

Campbell M, O'Meara T and Esserman LJ J. University of California, San Francisco, San Francisco, CA.

Background: We now know that there is an interplay between our bodies and the bacteria that we carry, both in health and in disease. Inflammatory diseases associated with disruptions in microbial equilibria, such as periodontal disease and ulcerative colitis, as well as chronic antibiotic use, have been associated with increased risk for cancer development. In a previous small pilot study, we observed differences in the oral microbiomes of women with breast cancer and healthy women. This presentation describes an ongoing study in which we aim to validate our previous findings in a larger cohort of women, as well as extend the microbiomes studied to include the gut and local breast tissue microbiota.

Trial design and eligibility criteria: Women with invasive breast cancer or with ductal carcinoma in situ (DCIS) who have not received prior therapy for their disease are eligible for enrollment. A cohort of healthy women will also be enrolled. Sample collection kits containing cheek and stool swab materials are distributed to patients in the clinic, and breast tumor tissue is collected at the time of surgery.

Specific aims: 1. To characterize and compare oral and gut microbial diversity from women with early stage invasive breast cancer, women with DCIS, and healthy women; and 2. To characterize the microbiota associated with breast tumor tissue and compare this to healthy breast tissue.

Methods: DNA from the three sites is isolated, the bacterial 16S rRNA gene is PCR amplified and sequenced, and the bacterial species present are enumerated. Oral, gut, and breast tissue microbial diversity at the genus and species levels will be assessed using the Shannon diversity index. Student’s t-test will be used to compare the mean diversity index values. Evaluation of microbial diversity and clinical variables will be determined using Spearman or Pearson correlations depending on the distribution of the data. We will also compare oral microbial diversity and clinical variables across racial and ethnic groups to determine if differences in the microbiomes may explain disparities in incidence across these groups. Classification and regression trees (CART) will be employed to develop rule sets based on the abundance of oral bacteria that discriminate breast cancer vs. DCIS vs. healthy controls.

Present accrual: As of June, 2015, 32 women with early-stage invasive cancer, 8 women with DCIS, and 9 healthy women received sample collection kits. Breast tumor tissue has been collected from 11 invasive breast cancer cases and 2 DCIS cases.

Target accrual: For the oral and gut microbiome analyses: 100 women with early-stage invasive breast cancer, 100 women with ductal carcinoma in situ (DCIS), and 100 healthy women with no history of breast cancer. For the breast tissue microbiome analyses: 20 women with invasive breast cancer, 10 patients with DCIS, and 10 reduction mammoplasty cases from healthy women.
Body: Over the past decade, genomic characterization of tumors has shed enormous light on the molecular underpinnings of cancer. These discoveries have led to the development of novel therapies and preventive measures that have already revolutionized cancer care. Despite this progress, the genomics of metastatic breast cancer (MBC), one of the leading causes of cancer death in the U.S., remains poorly understood.

The challenge in studying tumor samples from patients with MBC has been that the tumors from most patients are not available for research, largely because the vast majority of patients are cared for in community settings where genomics studies are not typically conducted. To address this, we have launched a nationwide study, The Metastatic Breast Cancer Project, which seeks to empower patients to accelerate cancer research through sharing their samples and clinical information. We have developed an outreach program in collaboration with MBC advocacy organizations to connect MBC patients around the country with genomics research performed at the Broad Institute, allowing them to participate regardless of where they live.

Working with MBC patients and advocates, we designed a website (www.mbcproject.org) with an online questionnaire that allows patients with MBC to provide information about themselves and their cancer. Based on their answers, patients are offered an electronic consent form that explains the risks and benefits of the study and asks for permission to obtain a portion of their stored tumor tissue, a saliva sample, and copies of their medical records. For patients who consent, our clinical research team contacts their physicians and obtains copies of their medical records, which are reviewed to confirm eligibility. Enrolled patients are sent a saliva kit and asked to mail back a saliva sample, which is used to extract germline DNA. The clinical research team also contacts the patient's pathology department and requests a portion of the tumor to be sent to the Broad Institute for genomic analysis. Whole exome and transcriptome sequencing is performed on tumor and germline DNA. Sequencing data are linked to de-identified clinical information, and the resulting data are used to identify drivers of tumorigenesis, mechanisms of response and resistance to therapies, and diagnostic, prognostic, and therapeutic biomarkers. The database of clinically annotated genomic information will be shared with the NIH and the cancer research community. Study updates and discoveries are shared at regular intervals with all patients who complete the initial questionnaire.

This direct-to-patient approach should be particularly enabling for the identification of patients with rare phenotypes or clinical behavior. For this reason, the first cohorts being studied are patients with extraordinary responses to therapies and patients who present with de novo MBC. Additional cohorts will be added in the future, including young women with MBC and patients with drug-resistant MBC. This project seeks to establish a patient-researcher partnership to accelerate genomic discoveries and improve outcomes in MBC, and may ultimately serve as a means to build a new clinical and translational research model for all patients with cancer.

Title: The Talazoparib Beyond BRCA (TBB) trial: A phase II clinical trial of talazoparib (BMN 673) in BRCA1 and BRCA2 wild-type patients with (i) advanced triple-negative breast cancer (TNBC) and homologous recombination deficiency (HRD) as assessed by myriad genetics HRD assay, and (ii) advanced HER2-negative breast cancer (BC) with either a germline or somatic mutation in homologous recombination (HR) pathway genes

Afghahi A, Chang P-J, Ford JM M and Telli ML L.  Stanford University Medical Center, Palo Alto, CA.

Body: Background: Poly-ADP-ribose polymerase (PARP) inhibition induces synthetic lethality in tumor cells bearing deleterious mutations in the genes BRCA1/2. Talazoparib (BMN 673) is a novel, dual-mechanism PARP inhibitor that potently inhibits the PARP enzyme and effectively traps PARP on DNA. Talazoparib has shown promising single-agent anti-tumor efficacy in several BRCA1/2 mutation-associated advanced cancers. The efficacy of PARP inhibition in BRCA1/2 wild-type TNBC with HR defects and in breast tumors with mutations in other non-BRCA1/2 HR pathway genes is currently unknown.

Trial Design & Eligibility: This Phase 2 trial (TBB) explores the activity of single agent talazoparib in BRCA1/2 wild-type BC patients using an optimal Simon two-stage design. Eligible subjects will be assigned to one of two parallel cohorts: 1) Cohort A: Subjects (n=29) with advanced TNBC with underlying HR defects as assessed by the HRD assay and, 2) Cohort B: Subjects (n=29) with advanced HER2-negative BC with a somatic or germline deleterious mutation in a non-BRCA1/2 HR pathway gene. Gene mutations of interest are: PTEN, PALB2, CHEK2, ATM, NBN, BARD1, BRIP1, RAD50, RAD51C, RAD51D, MRE11, ATR, Fanconi anemia complementation group of genes (FANCA, FANCC, FANCD2, FANCE, FANCF, FANCG, FANCL). Other key eligibility criteria include metastatic disease treated with at least one prior line of chemotherapy, no deleterious BRCA1/2 mutation, and no prior platinum exposure. In cohort A, TNBC patients must have a HRD score of ≥ 42. Eligible patients will receive oral talazoparib (1.0 mg/day, 28-day cycles) until disease progression or unacceptable toxicity.

Endpoints & Statistical Plan: The primary endpoint is objective response rate (ORR). Secondary endpoints include clinical benefit rate (CBR), progression free survival (PFS), and safety. In this study, we have set a null hypothesis of ≤ 5% objective response rate and alternative response rate of ≥ 20% based on RECIST 1.1. Interim analysis will be performed after accrual of 10 patients in each cohort. If at least one out of the 10 patients responds, then we will accrue 19 additional patients for a total of 29 patients in each cohort. At least four patients have to respond out of the 29 patients in each cohort to declare statistical significance at a one-sided 5% level with 80% power or better. This trial is enrolling patients at Stanford University in California (NCT 02401347).
Title: Fluorescence navigation system using indocyanine green (ICG) instead of radioisotope for sentinel lymph node (SLN) biopsy in early breast cancer

Benson JR R, Pitsinis V, Provenzano E and Wishart GC C. Cambridge Breast Unit, Addenbrooke's Hospital, Cambridge, United Kingdom and Cambridge Breast Clinic, Mediterraneo Hospital, Athens, Attica, Greece.

Body: Background: Dual localisation methods with blue dye and radioisotope are commonly employed for SLN identification but potential drawbacks include allergic reactions, staining of cutaneous/surgical breast tissue, radiation exposure and mandatory licencing. A majority of studies have reported near 100% identification rates using the fluorescent tracer ICG in combination with standard tracer agents. A feasibility study (ICG-10) has confirmed high sensitivity of ICG fluorescence mapping for SLN detection in early breast cancer with 95% of nodes both blue and fluorescent. This follow-on study has specifically evaluated a combination of ICG with blue dye for SLN localization.

Methods: As an observational cohort study, 50 consecutive patients (49 female; 1 male) with core biopsy proven unilateral invasive (37 cases) or non-invasive (13 cases) breast cancer underwent SLN biopsy with blue dye and ICG. All patients were clinically and sonographically node negative. Axillary surgery (SLN biopsy) followed neoadjuvant chemotherapy in 5 patients (10%). The median patient age was 48 years and for primary surgical patients median tumor size was 19mm. Patients received a dual peri-areolar/intradermal injection of blue dye [2ml 2.5% Patent Blue] and ICG [2mls 0.5%] after induction of anaesthesia. The number of sentinel nodes for each patient was recorded numerically and whether blue, fluorescent or both. Subcutaneous lymphatics were visualised with a photodynamic eye camera and nodal and procedural detection rates calculated for ICG alone and in combination with blue dye.

Results: Final analysis was performed on a total of 87 nodes retrieved from 50 patients with an average nodal count of 1.8 per patient (range 1 – 4). Eighty-four nodes were blue and fluorescent and 3 nodes fluorescent only with no harvesting of non-blue, non-fluorescent nodes. At least one transcutaneous lymphatic channel was visible in all cases. Nodal detection rates for ICG alone and combined with blue dye were 100% (87/87) and 96% (84/87) respectively. Metastases (>0.2mm) were present in 18 nodes which were all blue and fluorescent and a total of 10 patients had at least one positive node (node positivity rate = 20%). The procedural detection rate was 96% (48/50) for blue dye and 100% (50/50) for ICG with 2 patients having fluorescent only nodes which were deemed sentinel (4%). No serious adverse reactions were noted.

Conclusion: ICG fluorescence navigation system permits real-time visualization of lymphatic tissues and provides an additional dimension to SLN biopsy using methodology which is sensitive, valuable and safe. These results confirm accuracy of ICG fluorescence for SLN identification with nodal sensitivity of 96% for a combination of blue dye and ICG. With further refinements of the technique, use of ICG as a sole tracer may be possible agent without concerns about excessive nodal yield but improved patient convenience and costs.
Title: A comparison of significance with indocyanine green fluorescence imaging method and computed
tomography-lymphography in sentinel lymph node identification for early breast cancer patients

Abe H, Yamasaki K, Teramoto A, Yoneda K, Ogawa M, Kawasaki M and Kameyama M.  Breast Center, Bell Land General
Hospital, Sakai, Osaka, Japan and  Bell Land General Hospital, Sakai, Osaka, Japan.

Body: Background: Sentinel lymph nodes (SLN) biopsy has been established as a standard of care in the treatment of early
breast cancer. This technique represents a minimally invasive, highly accurate method of axillary staging and is an alternative to
conventional axillary lymph node dissection. The combination of the radioisotope and dye-staining methods is the most accurate
way to identify sentinel lymph nodes. We had reported feasibility and safety of a new technique of SLN identification using
fluorescence imaging of indocyanine green (ICG) injection without any need for training. Recently, SLN identification using
computed tomography-lymphography (CTLG) has been reported in Japan. This study investigated the comparison of significance
with fluorescence imaging method and CTLG.

Patients and method: Between January 2013 and May 2015, 213 breast cancer patients without clinical evidence of lymph node
metastasis were treated. On the day before the operation, CTLG was performed using 64-row multidetector CT. We performed an
intradermal injection in the periareolar area, using 4 ml of contrast agent with 1 ml of local anesthetic. The contrasted lymph flow
and SLN were identified in reconstructed three-dimensional imaging. The SLN spot was indicated by CT laser light navigator
system. During the operation, fluorescence images were obtained using the fluorescence imaging system, Photodynamic Eye
(pde-neo, Hamamatsu Photonics Co., Japan). After 5 mg / 0.3ml ICG was injected intradermally in to the periareolar skin,
lymphatic drainage was observed with fluorescence images. SLN biopsy was performed referring to the point by axillary
compression technique by plastic device.

Results: The median age of the 213 patients was 59 (range 28 – 87) years old. CTLG and fluorescence imaging was safely
performed in all patients. CTLG could visualize lymphatic flow and accurately identify SLN in 189 (89 %) and 196 (92 %) cases,
respectively, whereas fluorescence imaging identified successfully lymphatic flow and SLN in all patients. Fluorescence imaging
with axillary compression technique was visually easy to identify the location of SLN on the axillary skin even in obese patients.
Lymphatic flows of CTLG were completely consistent with those of fluorescence imaging. The number of SLN identified by CTLG
was significantly lower than that by fluorescence imaging (1.1 vs. 1.6, p<0.01). Twenty seven patients (13%) were found to have
lymph node metastases pathologically, and 7 of them had micrometastases of lymph node. In case of partial enhancement of
SLN with CTLG, the rate of positive metastasis was significant higher compared to the cases of whole enhancement (p<0.01),
however, even if enhancement is poor, about 70 % cases without metastasis are present.

Conclusion: Both of fluorescence imaging and CTLG revealed easy and effective to detect SLN. The fluorescence imaging with
fluorescence mapping showed strong fluorescence from all parts of the surgical field, which hindered identification of SLNs, and
fluorescence imaging was more high detection rate of SLN.

**Title:** Optimal concentration of indocyanine green in near-infrared fluorescence guided sentinel lymph node biopsy in breast cancer

Paik H-J, Yi HW, Park S, Ryu JM, Nam SJ, Lee JE, Kil WH, Lee SK, Bae SY and Kim SW. Division of Breast and Endocrine Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.

**Body:**

**Background:** Near-infrared (NIR) fluorescence-guided sentinel lymph node biopsy (SLNB) using indocyanine green (ICG) has been successfully applied in various kinds of cancers, especially in breast cancer. Optimizing the concentration of ICG without using human serum albumin in natural lymphatic system is still required.

**Methods:** 25mg of ICG was diluted with distilled water (DW) or normal saline (NS). Dilution concentrations used for measurement were 0.25µg/mL, 0.5µg/mL, 2.5µg/mL, 5.0µg/mL, 25µg/mL, and 250µg/mL. The brightness of fluorescence was measured by an image system called Visual Navigator (SH System, Korea). We used graphic software (GIMP, version 2.8.14, The GIMP Team) to measure the brightness. We assumed that drained serous lymphatics from a breast cancer patient can reflect a natural lymphatic condition injected with ICG in the operation field. Drained lymphatics were mixed to reduce the concentration of ICG by half that was diluted with DW or NS. We also measured the brightness of fluorescence diluted with DW or NS that was mixed with drained lymphatics. After this screening test, we subdivided the range which brightness was measured as 100 and adjusted the intensity of illumination for more specific results.

**Results:** Highest brightness values were measured as 100 between 2.5µg/mL and 25µg/mL concentration of ICG with DW dilution in screening settings, and the values of brightness were measured as 100 between 2.5µg/mL and 5.0µg/mL concentration of ICG with NS dilution. When drained lymphatics were mixed together, the values of brightness were measured as 100 between 2.5µg/mL and 25µg/mL concentration of ICG with DW or NS dilution. After subdividing the ICG concentration to 2.5µg/mL, 3.13µg/mL, 5.0µg/mL, 6.25µg/mL, 12.5µg/mL and 25µg/mL with adjusting the intensity of illumination, the highest brightness value was measured as 76 in 5.0µg/mL concentration of ICG with DW dilution. When diluting with NS, the highest brightness value was measured as 61 in 5.0µg/mL ICG concentration. After mixing with drained lymphatics, the highest brightness value was both 79 in 5.0µg/mL concentration of ICG with DW and NS dilution.

**Conclusions:** This study showed a practically optimal ICG concentration range in fluorescence guided SLNB. The optimal range of ICG concentration is from 3.13µg/mL to 6.25µg/mL with DW or NS dilution. Although 5.0µg/mL met the best result, adjustment for individual settings may be considered.
Title: Improved sentinel lymph node detection with the use of superparamagnetic iron oxide tracer after neoadjuvant treatment in breast cancer patients

Rubio IT Teresa, Esgueva-Colmenarejo A, Diaz-Botero S, Peg V and Espinosa-Bravo M. Breast Surgical Oncology. Hospital Universitario Vall de Hebron, Barcelona, Spain and Hospital Universitario Vall de Hebron, Barcelona, Spain.

Body: Background. The use of superparamagnetic iron oxide (SPIO) tracer for sentinel node biopsy (SLN) has shown non inferiority compared with the radioisotope technique in early breast cancer. In the neoadjuvant setting (NAC) identification rates with dual technique (blue dye and Tc 99) have been reported to be from 80% to 95%. SLN biopsy false negative (FN) rates after NAC have decreased with the use of dual tracer (radioisotope/ blue dye) and the excision of > 2 SLNs. This study was designed to evaluate the outcome of SLN after NAC using a dual tracer (SPIO and Tc99) versus SLN after NAC with radioisotope (Tc 99) alone.

Material and Methods. After NAC, 188 patients underwent SLN with Tc99 (group Tc99) and 92 patients underwent a SLN with dual technique (group SPIO/Tc99). Inclusion criteria were patients T1-3 N0-1 before NAC and all patients had clinically and /or ultrasound negative axilla before the SLN procedure. Patients were injected subareolar with Tc99 the day before surgery and with the SPIO intraoperatively. SLN was excised if it was radioactive, magnetic or palpable. Patients signed an inform consent. Patients who were N0 pre and postNAC did not undergo an axillary lymph node dissection (ALND) (except for the initial validation patients) , while patients who were N1 pre NAC and N0 post NAC underwent SLN and ALND as part of the protocol.

Results. Mean age of patients between groups were similar, 53.18 (range, 24-90 years old) in the Tc99 group and 52.53 (range, 23-82 years old) in the SPIO/Tc99. Identification rates were 95.72% and 97.8 % in the Tc99 and the SPIO/Tc99 group respectively (p = 0.21). In the Tc99 group, 58 (30.8%) patients were cN1 pre NAC while 13 (14%) in the SPIO/Tc99 (p =0.01). Rates of positive SLN after NAC were 32% in the Tc99 group while 20% in the SPIO/Tc99 group. False negative rates were 4.19% in the Tc99 group (1/50) and 8.3% in the SPIO/Tc99 group (1/13) (p=0.62). There was a statistically significant difference in the median number of SLNs between techniques, being 2.04 in the Tc99 and 2.60 in the SPIO/Tc99 group (p = 0.001). When the mean number of SLNs and the identification rates were differentiated between cN1 and cN0, the statistically significant differences remained unchanged.

Conclusions. The use of dual technique (SPIO and Tc99) for the detection of SLN after NAC increases the identification rates over 97%, better than the reported studies in the NAC setting with Tc99 and blue dye. Although in our study increasing the number of SLNs excised has not decreased the false negative rates, rates of FN are below 10% in both groups. Larger number of cN1 patients is needed in the SPIO/Tc99 technique to validate these initial results. The dual technique with SPIO and Tc99 may optimize the success of SLN after NAC in breast cancer patients.
Title: The use of Tc-99 tilmanocept in sentinel lymph node biopsy after neoadjuvant chemotherapy in clinically node-negative patients with breast cancer

Unkart JT T and Wallace AM M. University of California, San Diego.

Body: Background: Neoadjuvant chemotherapy (NAT) has been shown to induce fibrosis and inflammation that alters lymphatic drainage of axillary lymph nodes in breast cancer. Technetium-99 Tilmanocept (TcTM), a CD206-macrophage receptor targeted radiopharmaceutical, is a small agent with recent FDA-approval for lymphatic mapping. No prior studies have investigated the use of TcTM in the neoadjuvant setting. The aim of this study was to compare the identification rate, node-positivity rate, and number of total nodes evaluated in sentinel lymph node (SLN) biopsy with TcTM and vital blue dye (VBD) in clinically node-negative patients receiving NAT vs. initial surgery.

Methods: A retrospective review was conducted on patients undergoing SLN biopsy with TcTM and VBD from May 2013- May 2015 at UCSD. Patients with a history of prior SLN biopsy or axillary lymph node dissection were excluded. Patients undergoing neoadjuvant chemotherapy or receiving > 3 months of neoadjuvant endocrine therapy were grouped and compared to patients undergoing initial surgical treatment. The SLN identification and node-positivity rates were compared with the X2 test. To compare the number of SLNs evaluated between groups, a zero-truncated negative binomial (ZTNB) count model was constructed to assess the effect of NAT and other covariates on the SLN count. Covariates included age, body mass index (BMI), gender, surgeon, mastectomy vs. lumpectomy, node positivity, pathologist, T-stage, and receptor status. A p-value < 0.05 was used for statistical significance.

Results: Of the 417 total SLN cases identified, 72 (17.2%) cases were in patients who had received NAT (61- chemo, 11- endocrine). The SLN identification rate was 100% in both groups (p= 1.0). Overall, there were 68 (16.3%) cases of SLN-positivity, 14 (19.4%) in the NAT group versus 54 (15.7%) in the non-NAT group (p= 0.54). The median number of identified nodes was 3 in both groups. In the ZTNB count model, age, surgeon and evaluating pathologist were significant predictors of the total number of SLN evaluated. The use of NAT did not significantly affect the number SLNs evaluated. Incident rate ratios, confidence intervals and p-values are reported in the attached table.

Discussion: Prior studies have indicated that NAT may induce fibrosis and inflammation that may obscure lymphatic mapping procedures. For SLN biopsy with TcTM in VBD in our study, the use of NAT did not change the identification rate or node-positivity rate. Additionally, when controlling for covariates, the use of NAT did not change the total number of SLNs evaluated. While NAT might induce fibrosis and inflammation, SLN biopsy with TcTM and VBD is technically successful in clinically node-negative patients undergoing neoadjuvant chemotherapy.
Sentinel lymph node biopsy after NACT: Results of a validation study in large/locally advanced breast cancer patients

Background: Sentinel lymph node biopsy (SLNB) is the current standard of care for surgical staging of clinically node negative axilla (N0) early breast cancer patients undergoing primary surgery. SLN- identification rate (IR) of 90% and SLN- false negative rate (FNR) of 10% are considered minimum acceptable indices for SLNB. Its role in staging axillae in patients undergoing post-NACT surgery is somewhat unclear. In India, and most low-and-middle income countries, large operable breast cancers (LOBC) and locally advanced breast cancers (LABC) constitute a large proportion of breast cancer patients treated. These patients are usually are treated with NACT, followed by surgery and radiation therapy. In a prospective validation SLNB study, we investigated the accuracy of SLNB in staging post-NACT N0 axilla in a patient cohort that were LOBC or LABC at the time of initial presentation.

Methods: Hundred consenting non-inflammatory LOBC/LABC patients (mean age 49.3+8.6; index stage T3,N0-1=21; T4b,N0-1=33; T1-3,N2a=24; T4b,N2a=22) who were N0 after NACT at time of surgery (Breast conservation surgery in 19, Mastectomy in 81) were included. Majority had Infiltrating ductal carcinoma (n=87), and grade II/III tumors (n=93); 45 were hormone receptor positive (+), 29 had HR negative (-) HER2(+); and 26 had triple negative breast cancer on IHC sub-typing. Commonest NACT regimen used was Anthracycline followed by taxanes in 83. SLNB was performed using low-cost methylene-blue and 99mTc-Antimony-colloid, which were produced in-house using well standardized protocols, with clearance of the institutional ethics committee. Irrespective of the SLN histology, a complete axillary dissection (ALND) was carried out in all. SLN-IR and SLN-FNR were calculated, comparing the histological status of the SLN and the ALND specimen. Factors predicting non-identified SLN and false negative SLN were evaluated in uni-variate and multi-variate analysis.

Results: With a combination of methylene blue dye and radiopharmaceutical, the SLN-IR was 81%. Mean number of SLN removed was 2.4+/-1.02. Mean number of nodes removed at ALND was 13.3+/-2.2. SLN-IR varied significantly (p<0.05) per index stage, and were- 90.4% in T3,N0-1; 84.4% in T4b,N0-1; 83.3% in T1-3,N2a; and 63.6% in T4bN2a. The FNR was 17.3% for the whole cohort. FNR varied significantly (p<0.05) per index stage, and were- 8.3% in T3,N0-1; 14.9% in T4b,N0-1; 22.2% in T1-3,N2a; and 30% in T4bN2a. Factors found predictive of non-identified SLN were tumor stage T4b, nodal stage N2a, extra-nodal spread, and LVI. Factors found predictive of FNR SLN were tumor stage T4b, nodal stage N2a, and extra-nodal spread.

Conclusions: Considering SLN-IR of 90% and SLN-FNR of 10% as acceptable standards, SLNB in post-NACT N0 patients undergoing surgery was not found robust in staging the axilla, with the exception of patients with index stage T3,N0-1 who had SLN-IR of 90.4% and SLN-FNR of 8.3%. Patients with (pre-NACT) skin involvement(T4b), matted axillary nodes(N2a) and LVI are fraught with high-risk of non-identification and false-negative SLNB.
Title: Second axillary sentinel lymph node biopsy for breast tumor recurrence: Instituto Alexander Fleming experience in Buenos Aires, Argentina

Body: Sentinel Lymph Node Biopsy (SLNB) is the standard technique for axillary staging of patients with operable breast cancer and a clinically negative axilla because it avoids unwarranted axillary dissection and consequently reduces postoperative morbidity.

Purpose: The aim of this study is to determinate the feasibility and accuracy of the second SLNB for patients with ipsilateral breast cancer recurrences with clinically negative axilla, who were treated previously with breast surgery and study of the axilla.

Methods: Retrospective review of the database of the Instituto Alexander Fleming. Between October 2009 and October 2014, 1029 patients with diagnosis of breast cancer required surgery. The study included 26 patients with the diagnosis of operable local breast cancer recurrence, who had previously undergone axillary surgery either as SLNB, sampling or axillary lymph node dissection (ALND). They subsequently underwent additional breast surgery and a second SLNB.

Results: The mean age of the ipsilateral breast cancer recurrences was 59.23 years (range: 32-87) and the most common histologic subtype was invasive ductal carcinoma in 22 patients (84.6%) and 4 patients (15.4%) with invasive lobular carcinoma. 4 patients (15.4%) had previously ALND or sampling and 22 patients (84.6%) SLNB. The identification rate of the second SLNB was 92.31%. Only 2 patients were not identify, one patient with a previous axillary sampling and another one with previous SLNB. In those patients the ALND was performed and the axilla was negative. Lymphoscintigraphy failed to identify any SLN in 6 patients (23%), 2 patients which were not identify and 4 patients only detected with patent blue. The average number of nodes removed at second SLNB was 1.8 (range: 1-5). Second SLNBs were negative in 21 patients (80.8%), and macrometastasis disease was identified in 2 patients and complete ALND was performed.

In 1 patients additional extra-axillary aberrant drainages was observed in the contralateral axilla and interpectoral, and other 3 patients had aberrant drainage in the contralateral axilla (1 patient), internal mammary regions (1 patient), and interpectoral (1 patient). Aberrant drainage pathways were not routinely dissected. Only those accessible during surgery were removed.

The median time between first surgery and ipsilateral breast tumor recurrence was 7.19 years (range: 1-22). The disease free survival (DFS) was 9.16 years (range: 2.25-24).

Conclusion: In the present serie we show a high identification rate of 92.31% in the second SLNB, comparable with other international series published in the literature (range: 51-97%). A second SLNB should be considered for patients with ipsilateral breast tumor recurrence who underwent conservative surgery and have clinically negative axilla. The procedure is technically feasible and accurate for selected patients, and avoids unnecessary ALND. Extra-axillary sentinel lymph node localization rates are higher than for primary SLNB but the clinical significance and management of extra-axillary nodes needs to be clarified.
Title: Sentinel lymph node biopsy alone after neoadjuvant chemotherapy in patients with cytologically proven node-positive breast cancer

Park S, Ryu JM, Paik H-J, Yi HW, Bae SY, Lee SK, Kil WH, Kim SW, Lee JE and Nam SJ. Division of Breast and Endocrine Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.

Body:

Background
The purpose of this study was to identify the feasibility and accuracy of sentinel lymph node biopsy (SLNB) after neoadjuvant chemotherapy (NAC) in patients with axillary lymph node (ALN) metastasis at diagnosis.

Methods
This is a retrospective study of 332 patients who were diagnosed with invasive breast cancer and ALN metastasis and treated with NAC followed by curative surgery at Samsung Medical Center between January 2007 and December 2013. Patients were classified into five groups according to surgical procedure for the ALNs and pathologic results; group 1, patients with negative SLN status and no further dissection was performed; group 2, patients with negative SLN status undergoing further axillary lymph node dissection (ALND); group 3, patients with positive or undetected SLNs undergoing further ALND; group 4, patients without residual axillary metastasis undergoing complete ALND; and group 5, patients with pathologic nodal positive disease undergoing ALND.

Results
Sentinel lymph nodes identification rate after NAC was 99.1% and false negative rate was 24.1%. The median number of retrieved SLNs was 4 (range, 1–10). There was no difference in the overall survival among the groups (p=0.06). There was no significant difference in the disease-free survival rate between the SLNB only and complete ALN dissection groups who revealed a pathologic complete node response (79.6% versus 80.5%) and the rate of axillary recurrence demonstrated no significant differences among the groups. (p=0.225) There was a statistical difference of recurrence between group 1 versus 2, and group 1 versus 4 in hormone receptor-negative patients. (p=0.027)

Conclusion
SLNB after NAC in breast cancer patients with initial ALN metastasis may help identify downstaging to negative nodal status and thereby reduce the surgical morbidity by avoiding standard ALN dissection.
A phase I clinical trial of VST-1001 (dilute fluorescein) in lymphatic mapping and sentinel lymph node localization in clinically node negative breast cancer

Ross MI I, Bedrosian I, Black DM M, Mittendorf EA A, Caudle AS S, Babiera GV V, Hwang RF F, Meric-Bernstam F, Grissom CB B, Brulotte M and Andtbacka RHI HI. University of Texas MD Anderson Cancer Center, Houston, TX and Vestan Inc., Salt Lake City, UT.

Background: Combined use of a radiocolloid and a vital blue dye is recommended for accurate lymphatic mapping and sentinel lymph node (SLN) identification. However, vital blue dyes can cause tattooing, skin necrosis and allergic reactions. Hence, there is a great need for new lymphatic mapping agents. Here we describe the novel use of VST-1001 (dilute fluorescein) and direct visualization devices in lymphatic mapping and SLN identification.

Methods: A prospective, non randomized, single arm, open label, single dose, dose-finding Phase I clinical trial in patients (pts) with high-grade DCIS and clinical stage I/II breast cancer eligible for SLN biopsy was performed. All pts had SLN localization with technetium-99m-sulfur colloid (Tc99mSC) and intraoperative lymphatic mapping with VST-1001 injected peritumorally, periareolarly, and/or intradermally. SLN radioactivity was identified with a gamma probe, and VST-1001 fluorescence was induced by light emitting diodes and detected as a yellowish-green fluorescence in the visible light range with notch filter spectacles. The primary endpoints were safety, ability of VST 1001 to localize lymph nodes, and the optimal dose of VST\textregistered-1001. SLN concordance of Tc99mSC radioactivity and VST-1001 fluorescence was also assessed.

Results: Fifteen women with a median age of 60 yrs (range, 43-80) were enrolled. In cohort 1, 5 pts received 0.01% VST-1001. All patients had at least 1 SLN that was fluorescent and radioactive. A total of 22 SLNs were identified, many with faint fluorescence. Per protocol, the dose of VST-1001 was increased, and in cohort 2, 10 patients received 0.1% VST-1001. All 10 (100%) pts in cohort 2 had at least 1 SLN that was fluorescent and radioactive. Of a total of 24 SLNs identified, 20 (83%) were fluorescent and radioactive, 2 (8%) were radioactive only, and 2 (8%) were fluorescent only. Four SLNs in 3 patients contained micrometastatic breast cancer; all 4 SLNs were radioactive and fluorescent. There were no adverse events related to VST-1001. A Phase II clinical trial is currently accruing.

Conclusions: VST-1001 safely localized lymph nodes in breast cancer. VST-1001 was able to localize lymph nodes that were not radioactive and had a high concordance with Tc99mSC. VST-1001 may be a novel alternative to vital blue dyes in lymphatic mapping and lymph node localization.
Title: Sentinel lymph node biopsy after neoadjuvant chemotherapy for patients with clinically node-positive breast cancer: A single institution retrospective evaluation

Body: Background: In patients with clinically node-negative breast cancer sentinel lymph node biopsy (SLNB) offers accurate staging information with considerably less morbidity than a full axillary lymph node dissection (ALND). However, for clinically node-positive (cN1) patients who undergo neoadjuvant chemotherapy SLNB is thought to have a high false-negative rate and not suitable for this population. We sought to evaluate the false-negative rate (FNR) of SLNB following chemotherapy in patients initially presenting with cN1 breast cancer at a single institution.

Methods: Patients undergoing neoadjuvant chemotherapy diagnosed with cN1 breast cancer between October 2004 and February 2014 were identified from the University of California, San Francisco cancer registry. All patients underwent single agent mapping with Tc99 and SLNB followed by completion axillary lymph node dissection (ALND). Pathologic complete response, number of sentinel nodes removed and FNR were calculated.

Results: Of the 80 patients who underwent SLNB and ALND, 43 had residual metastatic disease in the nodes producing a nodal pCR of 46.25% (95%CI. 35.0%-57.8%). In 14 patients, cancer was not identified in the SLNs but was discovered in the lymph nodes retrieved by ALND, resulting in an overall FNR of 32.6% (95% CI, 19.1%-48.5%). 49 patients had only 1 SLN removed. Of the patients with only 1 SLN removed, a false-negative SLN was identified in 9 of the 21 patients with a positive node for a FNR of 42.9% (95% CI, 21.8%-66.0%). Of the patient with more than 1 SLN removed, 5 of 18 patients with a positive node had a false-negative SLN yielding a FNR of 27.8% (95% CI, 9.7%-53.5%). Only 14 patients had more than two SLNs excised.

Conclusion: Recent studies including the French GANEA 2 and ACOSOG Z1071 trials demonstrated a significant decrease in FNR when more than 1 SLN was excised. In this retrospective study however a single SLN was sampled from most patients. The FNR from this study was more than three times the generally accepted threshold of 10%. This substantial FNR further supports the need to remove more than 1 SLN during surgery in order to accurately assess nodal disease. Furthermore the implementation of a dual mapping technique would likely facilitate this process.
Title: Sentinel lymph node (SLN) localization is highly successful after neoadjuvant chemotherapy (NCT) for breast cancer

Body: Background: Recent multi-center trial results are concerning for the ability to identify SLNs after NCT. SLN localization was shown to be less successful (80%) after NCT when compared with no NCT (99%) (SENTINA), and the SLN identification rate in Z1071 in which all patients received NCT was 93%.

Purpose: To examine the effect of NCT, patient and disease characteristics, imaging and surgical technique on SLN localization rates in breast cancer patients undergoing chemotherapy.

Methods: Retrospective, single institution study was performed on patients who underwent surgery for breast cancer from January 2008 to December 2013. All patients who underwent SLN biopsy and either adjuvant chemotherapy (ACT) or NCT, were included. All patients underwent lymphoscintigraphy, and SLN biopsy was performed with the definitive breast surgery.

Results: 68 patients underwent NCT, and 133 underwent ACT. Our SLN localization rate was 198/201 (98.5%) overall; 98.6% (67 of 68) with NCT and 97.7% (130/133) with ACT (p=1.0). Compared with the NCT group, the ACT patients were significantly older, white, with more ER/PR positive tumors. The NCT group had more positive nodes on preop imaging (64% v. 20%, p<0.001), FNA (82% v. 22%, p<0.001), and a lower use of blue dye (37% v. 61%, p=0.05) but there were no differences in the number of SLN removed (1.43 v. 1.33 p=0.32), or nodes that were positive on intraoperative evaluation (30 v. 33%, p=0.75). Comparing the patients who had successful and failed SLN localization, there were no differences in demographics, tumor type, Stage, prior breast surgery, preoperative node positivity on imaging or FNA or timing of chemotherapy.

Conclusion: In this single institution series, SLN non-localization was a rare event and not associated with NCT. We were unable to identify any patient or disease characteristics, imaging or surgical techniques associated with SLN non-localization. The etiology of the lower SLN identification rates with NCT in multi-institutional trials remains to be elucidated.
Title: PET/CT might not improve the accuracy of sentinel lymph nodes biopsy and clip-containing nodes dissection to identify candidates for preserving axilla after neoadjuvant chemotherapy in HER2 positive breast cancer

Body: Background: The increasing proportion of axillary lymph nodes pathologic complete response (pCR) after neoadjuvant chemotherapy (NAC) is particularly marked among HER2 overexpression patients which indicates the necessity to tailor the conventional axillary lymphnodes dissection (ALND) to a less invasive process. We designed this study to investigate the optimal process to avoid ALND in HER2 positive patients obtaining axillary pCR after neoadjuvant systemic treatment.

Material and methods: This prospective study enrolled locally advanced breast cancer patients with positive axillary lymph nodes validated by fine needle biopsy. All the patients launched PET/CT scanings before NAC and after 2/3 cycles treatment respectively and the SUVmax of involved LNs was recorded. Patients enrolled place a metal clip to mark the involved nodes since last December. After NAC, patients accepted sentinel lymph node biopsy (SLNB) as well as dissection of clip-containing LNs and ALND was performed eventually to all study population. Receiver operating characteristic (ROC) curve was performed to analyze results and selecting cut off values.

Results: There were 100 patients enrolled including 37 HER2 positive patients receiving final surgery. Here we analyzed the HER2-pos patients only. The overall axillary LNs pCR rate has obtained 86.5% (32/37) among HER2 positive patients after NAC. Of 37 patients, 31 accepted NAC plus trastuzumab, leaving the axillary LNs pCR rate as 87.1% (27/31). We analyzed the decreasing rate between the second SUVmax and the baseline (the formula is $\Delta$ SUVmax = (SUVmax-2-SUVmax-baseline/SUVmax-baseline). The area under the curve (AUC) was only 0.419, which revealed that $\Delta$ SUVmax might provide little guidance to assist us in finding the potential patients who could avoid ALND through NAC. 13 patients in our study accepted SLNB and 9 of them underwent SLNB plus clip-containing LN dissection. The SLNs detection rate was 84.6% (11/13) and the average number of detected SLNs was 2.1. All the marked LNs were removed during the operation through X-ray or ultrasound location just before surgery, making the detection rate of clip-containing LNs 100%. One exception was observed when the pathological outcome showed both negative SLN and marked nodes but another positive lymph nodes. Overall, the accuracy of SLNB and clip-containing LNs dissection was 81.8% (9/11) and 90.9% (10/11) respectively.

Conclusion: HER2 positive patients were the latent candidates to avoid ALND after NAC. PET/CT might have little value in screening the candidates, whereas SLNB plus clip-containing LNs dissection would be the optimal process in screening candidates to preserve their axilla. This study is still ongoing and it will provide more information about the other molecular subtypes in the near future.
Risk factors of non-sentinel lymph node metastasis in breast cancer patients with metastatic sentinel lymph node

Huang J, Chen X, Shen K, Li Y, Chen W, He J, Zhu L, Huang O, Zong Y, Fei X and Jin X. Comprehensive Breast Health Center, Shanghai Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China and Shanghai Ruijin Hospital, Shanghai Jiao Tong University School of Medicine.

Objective To study the factors influencing the non-sentinel lymph node (NSLN) status and to assess Memorial Sloan-Kettering Cancer Center (MSKCC) nomogram performance in predicting SLN metastases in a sentinel lymph node (SLN) positive Chinese breast cancer population. Methods Data were collected from breast cancer patients who were diagnosed with pathological positive sentinel lymph node and received further axillary lymph node dissection (ALND) in Shanghai Ruijin Hospital from January 2011 to August 2014. Use MSKCC nomogram to calculate each patient's NSLN metastasis risk score. The receiver operator characteristic curve (ROC curve) and the area under the ROC curve (AUC) was used to assess the predictive accuracy of the model. Results Among the 1147 patients who received sentinel biopsy in our center, 150 SLN positive patients who received ALND were enrolled in this study. By univariate analysis, multifocal breast cancer (P = 0.017), SLN+/SLN ratio (P = 0.010) and axillary lymphadenopathy displayed by ultrasound (P = 0.005) are the influencing factors of NSLN metastases. By multivariate analysis, multifocal breast cancer (OR 7.25, 95% CI 1.73–30.43, P = 0.007), SLN+/SLN ratio ≥0.5 (OR 2.564, 95% CI 1.22–5.39, P = 0.013) and axillary lymphadenopathy displayed by ultrasound (OR 2.471, 95% CI 1.18–5.19, P = 0.017) are the independent influencing factors of NSLN metastases. The AUC of MSKCC nomogram in this population is 0.677. Conclusion For breast cancer patients with positive sentinel lymph node, multifocality, SLN+/SLN ratio and axillary lymphadenopathy displayed by ultrasound is related to NSLN metastasis. MSKCC has low accuracy in predicting NSLN status of this population.
Title: A nomogram to predict the likelihood of axillary non-sentinel lymph node metastases in sentinel lymph node positive primary breast cancer patients

Hartkopf AD D, Brucker SY Y, Helms G, Henzel M, Hahn M, Wallwiener M, Schoenfisch B, Taran F-A and Fehm TN N. University of Tuebingen, Tuebingen, Germany; University of Heidelberg, Heidelberg, Germany and University of Duesseldorf, Duesseldorf, Germany.

Body: Background:
Completion of axillary lymph node dissection (ALND) was long lasting standard in patients with non-metastatic primary breast cancer (PBC) and axillary sentinel lymph node (SLN) involvement. However, this approach is currently questioned since recent prospective trials have found that some SLN-positive women with PBC might not benefit from subsequent ALND. Nomograms that estimate the probability of further non-sentinel lymph node (NSLN) metastases could guide clinical decisions.

Methods:
We compared the predictability of three different nomograms (MSKCC, Stanford University, Cambridge) on the NSLN status with an own logistic regression model in a training and validation set. SLN-positive women who underwent primary surgery including ALND at Tuebingen University, Germany, between 06/2005 - 12/2009 (training set) and 01/2010 - 02/2012 (validation set) were available for this analysis. The area under the receiver operating characteristics (ROC) curve was calculated for each nomogram.

Results:
295 and 175 patients were included into the training and validation set, respectively. Of these 118 (40%) and 57 (33%) patients were NSLN-positive. Variables within our model were tumor size, proportion of positive SLNs, size of SLN metastases, lymphangiosis carcinomatosa, multicentricity and extracapsular invasion. The respective area under the ROC curve values for the MSKCC / Stanford University / Cambridge / own regression model were 0.73 / 0.70 / 0.63 / 0.75 in the training set and 0.73 / 0.66 / 0.52 / 0.73 in the validation set.

Conclusion:
The predictability of our logistic regression model was comparable to the MSKCC nomogram and superior to the Stanford University and Cambridge nomogram. Although a training and a validation set was used, further testing on an independent patient population is warranted.
Body: Objective
To assess differences in axillary infiltration (global, sentinel, and non-sentinel lymph nodes) according to breast cancer molecular subtype.

Material and methods
Patients with infiltrating breast carcinoma diagnosed in the years 2011 to 2014 in our institution were included. Sentinel lymph node biopsy (SLNB) was performed in all patients staged N0 by clinical examination and axillary ultrasound. One-step nucleic acid amplification (OSNA) was performed in cases positive for cytokeratin-19. Complete lymphadenectomy was done in patients with axillary macrometastasis and, until February 2012, also in those with micrometastasis in the SLNB. Immunohistochemistry-based St. Gallen 2013 criteria were used to assign the molecular subtype (hormonal receptors, ki67 and HER2).

Results
Overall 720 patients were included, 53.9% of whom had axillary infiltration (75.8% macrometastases). Axillary infiltration was most common in the HER2 subtype -82.1% (91.3% macrometastases) and least common in the basal subtype -42.7%.

On the contrary, the HER2 subtype had the lowest risk of axillary infiltration in patients subjected to SLNB (14.3%). No differences were seen in the other subtypes subjected to SLNB.

90 patients underwent complete lymphadenectomy. Positive non-sentinel lymph nodes were most commonly seen in luminal A tumors (30%).

Conclusions

1. Significant differences in axillary infiltration were seen according to molecular subtypes.
2. Most HER2+ tumors had N+ disease detected by ultrasound. However, in those HER2+ with negative ultrasound, the SLNB was usually negative. If positive, non-sentinel lymph nodes were most commonly negative.
3. Half of luminal A tumors had N+ disease detected by ultrasound. In the other half, there was an increased risk of positive SLNB and non-sentinel lymph nodes with regard to other subtypes.
AIM
Evaluate within a pilot setup feasibility and safety of minimally invasive needle-biopsy of sentinel nodes guided by SPECT/US as compared to surgical removal while defining optimal needle for follow-up trial.

METHOD AND MATERIALS
As pretrial test phase of the MinimalSNB study, 38 breast cancer patients (6 centers) were taken a needle-biopsy of their sentinel lymph nodes (SLNs) under guidance of SPECT/US (SentiGuide by SurgicEye, Munich, DE). All patients were indicated for a surgical SLN biopsy which was performed immediately after the needle-biopsy. For the test phase, 4 different biopsy systems were tested: HistoCore 14G (BIP, Tuerkenfeld, DE), elite 10G and 13G (Mammotome, Cincinnati, OH, US) and CASSI II 10G (Scion Medical Technologies, Boston, MA, US). Histopathological examination (H&E, step-sectioning) of needle-biopsies and surgically removed SLNs were compared.

RESULTS
No single complication was reported. Occasionally, small hematomas could be found close to the SLN during surgery. Duration of complete procedure (imaging, needle placement, biopsy) took in average 17min. A learning curve was observed in duration (average after 5 biopsies 12min). 1-14 samples were taken of each SLN (average 5 samples). Final pathological examination of material harvested with both methods matched in 34 cases (33 negatives, 1 positive). The needle biopsy failed to detect metastases in 2 pN1 SLNs. In 1 case, the surgically resected tissue did not contain lymph nodes and the needle biopsy remained the only information on nodal status. In 1 case a metastasis found in needle-biopsy motivated a second reading of an originally negative SLN which resulted in the upstaging of the patient. In both cases a metastases was missed by needle-biopsy, the retrieved lymph tissue was minimal (1x 14G sample, 1x 10G sample tangential to node).

CONCLUSION
SPECT/US showed to be a valid method for percutaneous detection of SLNs and needle-guidance. Sampling SLNs with a needle seems safe and feasible. However it requires proper training and user experienced with axillary needle-biopsies. Retrieving more tissue (more cores and larger lumen needles) improves diagnostic power of needle-biopsy. These considerations will be taken within the upcoming MinimalSNB trial.

CLINICAL RELEVANCE
Sentinel lymph biopsy today is a surgical diagnostic procedure with a nonzero morbidity. Moving it out of the operating theatre to a needle-based intervention has a huge impact on the burden of this procedure for the patient as well as relevant improvements in logistics, workflow and radiation burden.
Purpose: To describe the ultrasound technique for tattooing axillary lymph nodes (ALNs) after lymph node (LN) biopsy in patients with breast cancer.

Background: Preoperative evaluation of metastatic disease within ALNs in patients with newly diagnosed breast cancer has significant prognostic value and is quickly becoming routine, particularly in the neoadjuvant setting. A recent study showed tattooed LNs are visible intraoperatively and on histological evaluation months following the tattooing procedure. These results suggest that LN tattooing can obviate the need for additional localization procedures during axillary staging, such as wire localization. Given the increasing use of preoperative ALN biopsy, a robust technique to insure proper LN tattoo marking is proposed.

Methods and Technique: Tattooing was performed under real-time US guidance using a 5-cm long 21-gauge hypodermic needle attached to a 1 mL tuberculin syringe containing 1 mL carbon suspension tattoo ink (SPOT™, GI-supply Inc).

Imaging was performed with the patient in a supine oblique position with the patient's arm over their head. The anatomically anterior and lateral aspects of the node and perinodal fat were marked with ink. The only regions of the LN not targeted for ink tattooing were the hilum and the posterior cortex and perinodal fat. At least 0.5 mL of ink was used.

Results: Optimal technique for intraoperative visualization was determined to be tattooing the anatomically anterior and lateral aspects of the LN cortex and the adjacent perinodal fat using at least 0.5 mL of ink.

Tattooed LNs which had undergone biopsy and tattooing months prior to surgery were visible intraoperatively and on histological evaluation. Factors contributing to less optimal visualization of the tattooed lymph node included: using less than 0.5 mL of ink, tattooing only the superficial cortex and not the perinodal fat, and tattooing a portion of the LN that was not visible with the patient in the operative position.

Discussion: The most easily accessed portion of the LN during the US procedure may not be the portion of the LN most easily seen intraoperatively. Locating and tattooing the anatomically anterior and lateral aspects of the LN, regardless of the patient position and orientation of the ultrasound probe, is the primary challenge. Doing so will maximize the likelihood that the tattoo ink will be visible by the surgeon when the patient is in a supine position with the arm abducted 90 degrees using an axillary incision. Tattooing using less than 0.5 mL resulted in suboptimal visualization. Using a larger volume of ink may be judged necessary for larger LNs, very fatty axillae, and for deeply seated nodes.

Other reports in the medical literature suggest cutaneous tattooing can result in ink within ALNs. In patients with ipsilateral cutaneous tattoos, an alternative method of marking any biopsied LNs should be considered to avoid false positives associated with prior migration of the cutaneous tattoo ink to the LN.

Tattooing of ALNs under ultrasound guidance is a straightforward technique which can be performed at the time of initial biopsy and obviates the need for future preoperative wire localization of the LN.
Title: Validation of a novel diagnostic kit using the semi-dry dot-blot method for detecting metastatic lymph nodes in breast cancer

Otsubo R, Hirakawa H, Oikawa M, Shibata K, Tanaka A, Matsumoto M, Yano H and Nagayasu T. Nagasaki University Hospital, Nagasaki, Japan; Chiba Aiyuukai Memorial Hospital, Chiba, Japan; Oikawa Hospital, Fukuoka, Japan and Japanese Red Cross Nagasaki Genbaku Hospital, Nagasaki, Japan.

Body: Background: The semi-dry dot-blot (SDB) method is a diagnostic procedure for detecting lymph node (LN) metastases. The metastases are visualized by the presence of cytokeratin (CK) with lavage fluid of sectioned LNs by anti-pancytokeratin antibody, based on the theory that epithelial components such as CK are not found in normal LNs. We previously reported 93.3% sensitivity, 96.9% specificity, and 96.6% accuracy for this method in detecting metastasis in sentinel LNs, compared with permanent pathological diagnosis in breast cancer. In this study, we evaluated a novel kit that applies the SDB method using the newly developed anti-CK19 antibody for diagnosing LN metastases in breast cancer.

Methods: We obtained 141 LNs dissected from 81 breast cancer patients from July 2013 to April 2015 at Nagasaki University Hospital and the Japanese Red Cross Nagasaki Genbaku Hospital, including 33 dissected axillary LNs and 108 sentinel LNs, which were sliced at 2-mm intervals and washed with phosphate-buffered saline. The suspended cells in the lavage fluid of sliced LNs were centrifuged to collect the cell pellet and lysed with lysis buffer to extract protein. This extracted protein was used with the kit to diagnose LN metastasis. The washed LNs were blindly diagnosed by pathologists using hematoxylin and eosin (H&E) stain. Diagnoses based on the kit were compared with their H&E counterparts.

Results: Of the 141 LNs, 57 were assessed as positive and 84 as negative by permanent pathological examination with H&E. Use of the kit resulted in correct diagnoses in 46 of the 57 pathologically positive cases and all of pathologically negative cases. Sensitivity, specificity and accuracy of the kit in detecting LN metastases were 80.7% (95% confidence interval [95% CI]: 75.6–80.7%), 100% (95% CI: 96.5–100%), and 92.2% (95% CI: 88.1–92.2%), respectively. In 11 false-negative cases, there were 9 micrometastases; therefore, sensitivity was 95.5% (95% CI: 90.1–95.5%) in cases of macrometastases. Diagnosis was achieved in approximately 20 min using the kit, reducing the diagnostic time by half compared with the original SDB method. The cost of this kit was within 8 USD, and we are currently developing an improved kit for the detection of smaller metastases.

Conclusions: The kit in our study is accurate, quick, and cost-effective in diagnosing LN metastases without the loss of LN tissue. Its sensitivity in detecting macrometastases is excellent, which is important in clinical practice.
Title: Upper lateral boundaries of the axillary dissection. Result of the SENTIBRAS protocol: Multicentric protocol using axillary reverse mapping in breast cancer patients requiring axillary dissection

Nos C, Bonnier P, Clough K, Lasry S, Le Bouedec G, Flipo B, Classe J-M, Missiana M-C, Doridot V, Giard S, Martel P, Charles-Nelson A and Ngô C. Hôpital Européen Georges Pompidou APHP, Paris, France; Hôpital Privé Beauregard, Marseille, France; Institut du Sein, Paris, France; Institut Curie, Saint Cloud, France; Centre Jean Perrin, Clermont-Ferrand, France; Centre Antoine Lacassagne, Nice, France; Institut de Cancérologie de l'Ouest René Gauducheau, Saint-Herblain, France; Centre Hospitalier Princesse Grace, Monaco, Monaco; Centre République, Clermont-Ferrand, France; Department of Breast Surgery, Centre Oscar Lambret, Lille, France; Institut Claudius Regaud, Toulouse, France and Clinical Research and Epidemiology Unit, Hôpital Européen Geroges Pompidou APHP, Paris, France.

Body: Background: Two thirds of node-positive breast cancer patients have limited pN1 disease and could benefit from a less extensive axillary lymph node dissection (ALND). Recent controversies about management of the axilla lead to a binary decision between sentinel node biopsy (SNB) or ALND. It might be useful, for selected patients, to have a third intermediate option. Patients and methods: From 2009 to 2012, a selection of 172 breast cancers patients requiring an ALND were prospectively enrolled in the French Sentibras Protocol of Axillary Reverse Mapping (ARM) in 11 centers. All patients had breast carcinoma with features that excluded a sentinel node biopsy (SNB) according to French guidelines. We used clinical examination and imaging to select patients with limited axillary disease, N1 or small N2. Clinical N3 patients or patients N2 with 4 or more suspicious LNs on MRI, PET-CT or CT were excluded. Among the 172 patients, 33 (19.2%) patients required an ALND after a positive SNB, 68 (39.5%) patients received neo-adjuvant chemotherapy (NAC) and 71 (42.3%) patients were clinically N+ or had multicentric tumors or tumor greater than 5 cm. Radioisotope was injected in the ipsilateral hand the day prior to surgery. The usual technique for ALND was not modified. Removed lymph nodes were classified into three groups: non radioactive nodes, radioactive nodes draining the upper limb located in the upper outer part of the axilla, above the second intercostal brachial nerve and lateral to the lateral thoracic vein (we called them the SENTIBRAS nodes) and radioactive nodes located in other parts of the axilla. The main objective was: feasibility of identification of the "Sentibras" nodes. Secondary objectives were: metastatic involvement of the "Sentibras" nodes and the lymphedema rate.

Results: The "Sentibras nodes" were identified in 92 % of cases (158/172). Mean number of removed nodes was 14.6 [4-32]. Mean number of radioactive nodes was 4.8 [1-14]. Mean number of SENTIBRAS nodes was 1.8 [1-8]. The global rate of metastatic nodes was 72%. 9.4% of the SENTIBRAS nodes were metastatic. In the SENTIBRAS group, metastatic rate was 4.8% in pN1 patients versus 33% in the pN2/N3 patients (p<0.05). The rate of positive nodes in the SENTIBRAS group was 7.4% in patients undergoing ALND for a positive SNB, 8.8% in case of primary ALND and 21.4% after NAC. After 24 months of median follow up, progression-free survival was 85%. 28 % of patients have a lymphedema and up to 50% of patients complain about their arm.

Conclusion: The ARM technique reliably identifies the "Sentibras nodes". These nodes can also easily be identified using knowledge of axillary anatomy. In selected patients, N1 or N2 < 4 identified by pre-operative imaging and without neo-adjuvant chemotherapy, a less morbid selective ALND sparing the SENTIBRAS nodes could be performed.
Title: The management of axillary lymph nodes guided by ultrasound in patients with early breast cancer: A systematic review, a retrospective analysis of 1200 patients and a classification proposal

Body: Background: Axillary ultrasound is a widely accepted preoperative lymph node staging method with relatively high accuracy and cost-effectiveness. Nevertheless, there is no classification system to guide the management of lymph nodes like the Breast Imaging Reporting and Data System (BI-RADS), which provides a standardized classification for breast imaging findings.

Method: An ultrasound classification system was developed by a committee including breast surgeons, physicians and ultrasound specialists. We performed a systematic literature search regarding the diagnostic accuracy of various ultrasonographic appearance including size and morphology changes in lymph nodes. Based on their positive predictive value (PPV), a preliminary recommendation for the categorization of each finding was provided. Cases with detailed ultrasonographic description of lymph nodes during 2012 to 2014 at our institution were reviewed to assess the malignancy predictive value of this novel classification system.

Results: A final assessment system including 5 categories (category 0, 3, 4, 5, 6) was created on consensus. The linking of assessment categories with concordant management recommendations was recommend to further enhance sound medical practice.

SLNB, Sentinel lymph node biopsy; *, Subsequent definitive surgery choice depends on biopsy results.

Meta-analyses revealed that the PPV of a rounded shape, cortical thickening and hypoechoogenicity were 46%, 58% and 93% relatively. We concluded that nodes with a rounded shape or cortical thickening were assessed as category 4, and nodes with hypoechoogenicity were assessed as category 5. Nodes with thin cortex or no visible nodes were categorized as category 3. The axillary ultrasound records of 1200 patients were reviewed and retrospective assessments on the diagnosis were performed, linking to definitive histological results of axillary lymph nodes. The PPV of category 3, 4, 5 were 8.9%, 53% and 93.5% relatively.

Conclusion: Categorized axillary lymph node assessment linking to concordant management recommendations is feasible in current practice. Prospective validation should be carried out in future.
Title: Is lymph node ratio (LNR) having additional contribution for predict prognosis on pathologic lymph node staging in node-positive breast cancer patients?

Kaplan MA, Odabasi H, Ozdemir N, Harputluoglu H, Aliustaoglu M, Berk V, Gunaydin Y, Uncu D, Elkiran T, Aydin D and Isikdogan A. Dicle University, Diyarbakir, Turkey; Kartal Research and Education Hospital, Istanbul, Turkey; Numune Research and Education Hospital, Ankara, Turkey; Inonu University, Malatya, Turkey; Erciyes University, Kayseri, Turkey and Gazi University, Ankara, Turkey.

Body: PURPOSE:
The aim of the study was to determine whether LNR have additional contribution on pathologic lymph node staging.

METHODS:
To examine the prognostic value of LNR examined the original histopathological reports of 2049 node-positive breast cancer patients treated in the references centers of the Turkey. The LNR was defined as the number of positive lymph nodes (LN) over the total number of LNs removed. The LNR cutoffs were defined as low-risk, 0.01-0.20; intermediate-risk, 0.21-0.65; and high-risk, LNR >0.65.

RESULTS:
The median follow-up was 11.8 years. Median Disease free survival (DFS) was 191.8, 110.6 and 78.2 months in patients with pN1, pN2 and pN3 tumor, respectively (p<0.001). Median DFS was 191.9, 106.4 and 78.1 months in patients with LNR low, intermediate and high risk tumor, respectively (p<0.001). Median DFS was not reached and 200.1 months in patients with pN2 and LNR low risk patients, pN1 and LNR high risk patients, respectively (p=0.254).

CONCLUSIONS:
LNR is an important prognostic parameter for DFS and might provide potentially more information than pN-stage in patients with pN1/LNR high risk and pN2/LNR low risk.
Title: Sentinel lymph node metastases in breast cancer: A contributor to distant metastases?

Pereira ER R, Kedrin D, Jones D, Beech E, Taghian A G and Padera TP. Massachusetts General Hospital, Boston, MA and Harvard Medical School, Boston, MA.

Body: Breast cancer metastasis remains a major cause of mortality in patients. Although significant progress has been made in understanding the mechanisms of this complex process, the findings have yet to be translated into improved survival rates in patients with metastatic disease. The presence of lymph node metastasis in most breast cancer patients is associated with tumor aggressiveness, poorer prognosis and often results in the need for systemic therapy. However, whether tumor cells in the lymph node exit and contribute to distant metastases remains controversial. To track the fate of tumor cells that metastasized to the lymph node, we engineered breast tumor cell lines to express Dendra2, a photo-convertible protein that fluoresces green in the native state and on light activation converts to red fluorescence. Using a novel chronic lymph node window that allows time-lapse imaging over a period of 10 days, we were able to track the movement of cancer cells in the dynamic microenvironment using high-resolution multi-photon microscopy. Our studies show that tumor cells entering the lymph node through the afferent lymphatic vessel proliferate in the sub-capsular sinus and later begin to invade the lymph node parenchyma. Importantly, by photo-conversion of tumor cells in the lymph node, we are able to track the tumor cells that escaped the lymph node and entered the blood circulation. The circulating tumor cells that transited through the lymph node were viable and proliferated in vitro. Our data indicate that metastatic breast cancer cells can exit the node and potentially colonize distant organs.
Title: uPA and PAI-1 expression in breast cancer

Park YL, Kim EY, Hyun K, Byun W and Park CH. Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.

Body: To evaluate expression of uPA and PAI-1 as reliable prognostic markers in breast cancer, we analyzed the demographic and clinicopathological parameters of 214 patients with breast cancer, diagnosed and treated from 2006 to 2010 at Kangbuk Sam Sung Hospital. We used immunohistochemistry as a detection method. In univariate analyses, age at diagnosis, history of hormone replacement therapy, radiation therapy, skin/chest wall invasion, Paget disease, lymphovascular invasion, ER positivity and triple negative subtype had statistically significant influences on patient prognoses (P<0.05). The DCIS group had higher PAI-1 expression levels than did the IDC group (94% and 63%, respectively) (P=0.012). A positive correlation was established between uPA and PAI-1 (HR= 2.608, P=0.002). Lymph node metastasis was more frequent in the group with high uPA levels, compared to the group with low uPA levels. This finding was statistically significant (P=0.001). In conclusion, it is possible that PAI-1 could play some role in tumor progression in the early stages of breast cancer, such as DCIS. The demonstration of a statistical correlation between lymph node metastasis and uPA/PAI-1 levels determined by immunohistochemical evaluation, suggests that this method could be used as a prognostic factor in patients with breast cancer.
Targeting the tumor microenvironment: A phase II study of copper-depletion using tetrathiomolybdate (TM) in patients (pts) with breast cancer (BC) at high risk for recurrence

Background: Bone marrow derived VEGFR2+ endothelial progenitor cells (EPCs) and copper-dependent pathways, including lysyl oxidase (LOX), are critical components to remodeling the tumor microenvironment and establishing the pre-metastatic niche. In preclinical models, it has been well established that copper depletion (CD) inhibits tumor progression. We hypothesized that TM-associated CD would reduce EPCs and other copper dependent processes in the pre-metastatic niche in BC pts at high risk for relapse. We investigated the relationship between CD and its effect on EPCs and other components of the tumor microenvironment including LOX, an enzyme critical for cross-linkage of collagen and priming the pre-metastatic niche.

Methods: In this single arm, phase II study, BC pts at high risk for recurrence, defined as node+ triple negative (TN), stage 3 and 4 with no evidence of disease (NED) were enrolled on a trial of CD with TM. Pts received oral TM to maintain ceruloplasmin (Cp) between 5-17 mg/dl for 2 years on the primary study. The primary endpoint was change in EPCs measured by flow cytometry before and during treatment with TM. Secondary endpoints included tolerability, safety and effect of copper depletion on other markers including LOX, quantified by ELISA.

Results: We enrolled 75 pts. The study treatment duration was 24 cycles (each cycle is 28 days). Over 2200 cycles have been administered. The median age is 51 (range 29-66). 45 pts have Stage 2/3 BC and 30 are Stage 4 NED. TNBC pts represent 48%, and 40% of pts are Stage 4 NED. Median Cp level decreased from 28 at baseline to 15.5 (p<0.0001) after one cycle. Copper depletion was most efficient in TNBC, with 91% achieving a target CP within 4 weeks. TM was well tolerated and the only grade 3/4 toxicities were reversible neutropenia (3.2%) and anemia (0.0005%). CD was associated with a significant decrease in EPCs (p=0.0014) and LOX (p<0.001). At a median follow-up of 5.4 years, the PFS for all 75 pts from the start of TM treatment was 71%, including a PFS of 90% for all stage 2/3 pts with TNBC. The overall survival of all patients enrolled in the trial is 86%. Relapse after two years is a rare event. Conclusions: TM is safe, well tolerated and appears to affect multiple copper dependent biologic processes in the tumor microenvironment known to be important for tumor progression. This seems to be most striking in TNBC. We believe, further phase III trials in a high risk for relapse population are warranted.
Title: Intracranial PDX models of breast cancer metastasis

Nedergaard MK, Wick MJ J, Papadopoulos K, Tolcher AW W, Kjaer A and Nielsen CH H. Minerva Imaging, Copenhagen, Denmark; Rigshospitalet, University of Copenhagen, Copenhagen, Denmark and South Texas Accelerated Research Therapeutics (START), San Antonio, TX.

Body: Background: Overexpression of the human epidermal growth factor receptor 2 (HER2) in breast cancer is an independent factor for development of brain metastases. Up to 37% of patients with HER2 positive disease relapse intracranially despite control of extra-cranial metastatic disease. Inability of anti-cancer agents to cross an intact blood-brain barrier (BBB) is a possible explanation for the increased incidence of brain metastases. Subcutaneous (SQ) patient-derived xenograft (PDX) models are increasingly used for efficacy studies in drug development. However, orthotopic PDX models may confer a translational advantage as the patient tumor microenvironment is more closely mimicked. Especially when targeting brain tumors, the major impact of the BBB on drug bioavailability must be taken into consideration. The aim of this study was therefore to develop a panel of intracranial PDX models of breast cancer brain metastases for pre-clinical efficacy studies of new anticancer drugs.

Methods: SQ tumors from three different HER2 positive PDX breast cancer models designated ST340, ST1339 and ST1616B were enzymatically digested and used for intracranial stereotactic injection in nude mice. Contrast-enhanced T1- and T2-weighted Magnetic Resonance Imaging (MRI) were used to determine tumor take. Intracranial tumor growth was monitored using MRI and positron emission tomography (PET) in conjunction with the amino acid radio tracer ^18^F-FET.

Results: MRI confirmed tumor take in one model as early as 2 weeks after intracranial implantation. Increased ^18^F-FET uptake was detected in all models. MRI could be effectively used to monitor tumor growth and the corresponding ^18^F-FET PET images demonstrated increased ^18^F-FET uptake over time.

Conclusion: Three different HER2 positive intracranial PDX breast metastases models were established from low passage SQ PDX models. We suggest, that using these intracranial PDX models of brain metastases, new drugs for advanced breast cancer can be evaluated in preclinical models that more closely mimic the microenvironment and the BBB in patients. In addition, translational imaging techniques can be evaluated during preclinical testing and the potential of tracers like ^18^F-FET as imaging biomarkers of therapeutic response can be assessed. Together, the established SQ and orthotopic PDX models of breast cancer and brain metastases can be used as a relevant translational platform for testing of new drugs.
Title: Identification of molecular pathways to define the intake rate of patient-derived hormone receptor positive (HR+) breast cancer xenografts (PDXs) in NOD/SCID/interleukin-2 receptor gamma chain null (NSG) mice

Body: Background and Purpose: Despite recent progress in our endocrine therapy of hormone receptor positive (HR+) breast cancers, a significant number of patients with primary breast cancer continue to relapse, and those with stage IV disease face a median overall survival of ~ 3.5 years. Primary or acquired resistance to anti-estrogen-based therapies is an overarching challenge. To guide our treatment selection, there is an essential need to improve our understanding of the biology of HR+ breast tumors responsive to and those resist to anti-estrogens or aromatase inhibitors (AIs). The application of patient-derived xenografts (PDXs) in preclinical studies has begun to open the door to mimicking human disease on the research bench. However, HR+ breast cancer PDXs are difficult to establish. Although preclinical data from DeRose et al [Nat. Med. 2011: 17:1514-1520] indicate that the rate of engraftment serves as an independent predictor for poor outcome, the question which has not yet been adequately addressed is: "why some tumors can grow in mice, and some don't, even when their clinical, pathological stage and subtype (i.e. ER positivity) are same?" Here, we hypothesize that the molecular characteristics of patient HR+ tumors are key determinants to the tumor intake rate in NOD/SCID/interleukin-2 receptor gamma chain null (NSG) mice. Hence, reverse phase protein array (RPPA) analysis has been performed using human patient tumors to identify driver-pathways that impact tumor intake in NSG mice.

Results and Discussion: We compared the protein expression profile of six HR+ patient tumors (four HR+ and two HR+ HER2+), which were successfully engrafted into NSG mice and established as PDX models, with the patient tumors which we were unable to establish as PDX. Of 90 patient HR+ tumors which failed to transplant, 21 tumors were picked to match the tumor type (all of them were invasive ductal carcinoma or its metastases), clinical stage and pathological grade of engrafted tumors [Table 1]. In addition to patient tumors, six established HR+ PDXs were also submitted for analysis. Quantified expressions of 272 cancer-related proteins and phospho-proteins by RPPA have been performed on these specimens. Pathways identified as predictors of intake rate of PDXs in NSG mice, and tissues from paired PDX from mice with different passages, will be evaluated for the protein expression changes to elucidate the passage effects and generate therapeutic models based on protein expression and tumor growth.

Title: A mouse model of sporadic breast tumor with a conditional P53 mutation

Zhang Y, Xiong S, Pant V, El-Naggar A and Lozano G. UT MD Anderson Cancer Center, Houston, TX.

Body: Missense mutations in the tumor suppressor gene p53 are present in more than 50% of human tumors. In particular, the arginine-to-histidine mutation at codon 175 (p53R175H) has been found in more than 4% of human breast cancers. p53 mutations fall into two general categories: germline mutations that are associated with hereditary tumors, and somatic mutations that cause sporadic tumors. Mouse models for cancers induced by p53 germline mutations have been established and characterized. However, hitherto there are no accurate animal models for sporadic tumors induced by p53 somatic missense mutations, although this mechanism of inactivating p53 occurs in a large fraction of human cancers.

We have generated a mouse allele, p53WM, that carries coding sequences for both wild type (WT) and R172H mutant p53 (corresponding to R175H in humans) at the p53 endogenous locus. The coding sequence for WT p53 is flanked by loxP sites and therefore can be deleted by Cre recombinase. In the absence of Cre, following radiation, the p53WM/+ mice have the similar ability as the p53 WT mice to activate p53, as demonstrated by transcriptional activation of p53 targets and induction of apoptosis. In addition, like WT mouse embryonic fibroblasts (MEFs), the p53WM/+ MEFs also underwent cell cycle arrest following radiation.

After crossing p53WM/+ mice with Zp3-Cre mice which express the Cre recombinase in oocytes, the coding sequence for WT p53 was removed, and the mutant p53R172H allele was regenerated as determined by sequencing, western blot analysis and real time reverse transcription PCR.

To investigate whether a somatic p53R172H mutation in mammary epithelium can induce breast tumors, adenoviruses expressing Cre (Ad-Cre) were injected into the mammary duct of p53WM/+ mice. Limiting the adenovirus dose allowed us to induce the p53R172H mutation in 1 of 20, 100 or 1000 cells, generating a mutant p53 surrounded by normal cells which more accurately mimics the clinical situation of sporadic tumors. Meanwhile, p53WM/+; K14-Cre and p53WM/+; WAP-Cre mice have been generated, in which p53R172H mutation are induced through Cre transgene specifically in the mammary epithelial cells. Lastly, to examine how somatic p53 mutation cooperates with an oncogene in mammary tumor induction, MMTV-neu; p53WM/+ mice were also subjected to the mammary intraductal Ad-Cre injection. We are currently monitoring mice and will further investigate the molecular mechanisms of tumorigenesis by studying the loss of heterozygosity, and the co-evolution of tumor epithelial cells and their microenvironment. This mouse model is more likely to share the underlying molecular pathology with human sporadic tumors. Therefore, it will be more predictive of human responses to drugs, and thus a more valuable tool in preclinical testing.
The estrogen receptor (ER or ESR1) drives proliferation and growth of luminal type breast cancers. Endocrine therapies are highly effective in a majority of these cancers types; however, disease progression eventually occurs due to acquired resistance resulting in hormone-independent breast cancer. One mechanism of resistance is acquired mutations at codons 537 and 538 in the ligand binding domain of the receptor which are found in ∼12% of pretreated, ER+ patients. These mutations result in constitutive ER activation and hormone-independent progressive disease. Although ESR1 mutated breast cancers are insensitive to endocrine therapy, novel agents targeting these mutations may be effective; however few preclinical models of ESR1-mutant breast cancer are available for preclinical analysis. To this end we have established two patient derived xenograft (PDX) models harboring mutations at codon 537; ST941 with ESR1Y537S and ST1799 with ESR1Y537C. We have characterized these models using genomic analysis and compared with analysis from paired or serially collected clinical tissue and blood. Dependence on estradiol for model growth and sensitivity to endocrine therapies were also evaluated and compared with a hormone-dependent breast cancer models. The ESR1 mutations were not present in primary clinical tissue while several additional mutations were identified including in TP53 and PIK3CA genes. In vivo the ESR1 mutant models grew in the presence or absence of exogenous estradiol and demonstrated reduced sensitivity to endocrine therapies compared with hormone-dependent breast cancer models. ST941 treated with tamoxifen, letrozole or fulvestrant reported moderate tumor growth inhibition versus control while tumor stasis or regressions were reported in MCF-7 and hormone-dependent PDX breast models. Overall we have established and characterized two models of ESR1 mutant breast cancer which can be utilized for development of targeted therapies.
Establishment and evaluation of ER+ breast cancer models using an optimized methodology for exogenous hormone delivery

Body: Preclinical in vivo models of estrogen receptor positive (ER+) breast cancer rely on exogenous supplementation of hormones for growth. This requirement leads to animal toxicity and mortality over time, limiting development and drug testing in these types of models. Efficacy of test agents, particularly endocrine therapies, may also be altered in these models due to excessive hormone exposure, highlighting the need to improve methods for the establishment and testing of ER+ breast models. We have developed an alternative method of hormone supplementation in ER+ breast cancer models and optimized this method for testing of endocrine therapies. Using two cell-based breast models, we demonstrated improved breast tumor take and time to tumor volume endpoint while reducing animal toxicity and mortality associated with standard hormone supplementation. Subsequent studies identified the lowest effective dose (LED) of supplement for hormone dependent model growth with a preclinically relevant time to tumor volume endpoint. Activity of endocrine therapies including tamoxifen, letrozole, fulvestrant and exemestane were compared at the standard and LED hormone concentrations. In these studies tamoxifen treatment resulted in tumor regressions which was not appreciably improved using the LED dose of supplement. However letrozole activity was improved in the LED study suggesting hormone supplementation can impact activity of some agents. Using this process we also generated a panel of ER+ patient-derived xenograft (PDX) models, including two novel hormone therapy responsive models from chemo-naïve or hormone therapy pretreated patients, designated ST986 and ST2177, respectively. This improved method of hormone supplementation diminishes the adverse effects of standard hormone supplementation and provides utility for development of anticancer therapies in ER+ breast models.
Title: Manual and digital detection of HER2 status of 2721 circulating tumour cells in patients with metastatic breast cancer

Brouwer A, van de Wiel M, Peeters B, van Dam P-J, Vermeulen P, Peeters M, Van Laere S, Peeters D and Dirix L. Center for Oncological Research (CORE), University of Antwerp, Antwerp, Belgium; GZA Hospitals Sint-Augustinus, Antwerp, Belgium; Antwerp University Hospital, Antwerp, Belgium; GZA Hospitals Sint-Augustinus, Antwerp, Belgium and Antwerp University Hospital, Antwerp, Belgium.

Body: Introduction:
In metastatic breast cancer (MBC), discordant expression levels of the human epidermal growth factor receptor 2 (HER2) have been noted between primary tumours (PT) and matched metastatic lesions (Meta). Therefore reassessment of this predictive marker at time of metastatic disease might help to optimize treatment. Circulating tumour cells (CTCs) offer the potential to provide a repeatedly accessible source of tumour cells for the real-time assessment of actual tumour characteristics.

Here we report on a retrospective study analysing over two and a half thousand CTCs in order to evaluate the inter-observer variability when using the semi-quantitative scale (0-3+) described by Riethdorf in 2010. Furthermore we designed a digital scoring system using 13 parameters selected by ImageJ. HER2 status in CTCs was compared to PT and/or Meta of patients with MBC.

Materials and methods:
65 patients starting first or second line systemic therapy for MBC and harbouring more than 5 CTC/7.5 mL blood were selected. HER2 status of 2721 CTCs was determined by immunofluorescence using the CellSearch system. HER2 status of the solid lesions was determined by IHC or FISH. Inter-observer variability was calculated using the Kendalls tau tests. 284 CTCs were analysed with the digital scoring system using ImageJ 'plot profile' and 'analyse particles'. Selected parameters comprise cell size, mean and maximum intensity of the cell and its surrounding, and both ratio's and differences of the aforementioned. Dissimilarity matrix was calculated using Pearson Correlation-Distance.

Results:
Of 2721 CTCs, 1485 cells (55%) were scored 0+ and 2263 cells (83%) were found to be HER2- (0+ or 1+) by both observers. 458 cells (17%) were scored HER2+ (2+ or 3+) by at least one of the observers, however only 175 (6%) by both observers.

Inter-observer variability was 0.703, but when omitting the usually undebatable 0+ cells, this variability showed to be 0.278.

<table>
<thead>
<tr>
<th>HER2- (0+/1+)</th>
<th>HER2+ (2+/3+)</th>

<tbody>
<tr>
<td>2263 (83%)</td>
<td>131 (4.8%)</td>
</tr>
<tr>
<td>152 (5.6%)</td>
<td>175 (6.4%)</td>
</tr>
</tbody>
</table>

24 of 65 patients had at least 80% 0+ CTCs (≥96% HER2- cells). Of these patients, 5 were HER2+ based on their PT. Oppositely, 10 and 20 patients harboured at least 40% and 10% HER2+ CTCs respectively. From these 20 patients only 10 were diagnosed with HER2+ disease on PT or Meta and 1 was shifted form HER2- PT to HER2+ Meta.

The digital scoring system was able to identify four groups with different HER2 expression levels. When comparing the identified clusters with the manually scored cells the two moderately related clusters showed to contain almost only 2+ and 3+ CTCs. A very isolated cluster contained almost solely 0+ CTCs.

Discussion:
The manual scoring system showed to be feasible, however we noticed that there are some discrepancies regarding the scoring of 1+ to 3+ cells. The digital scoring is able to predict the outcome and can by itself cluster CTCs into 4 groups. It strongly distinguishes between the HER2+ and HER2- cells. HER2+ status can change during disease progression, both with gain and
loss of HER2 positivity. This can be monitored using CTCs.
Title: Invasive lobular carcinoma cell lines utilize WNT4 signaling to mediate estrogen-induced growth

Sikora MJ J and Oesterreich S. University of Pittsburgh Cancer Institute, Pittsburgh, PA.

Body: Invasive lobular carcinoma (ILC) is a histological subtype of breast cancer representing 10-15% of newly diagnosed breast tumors. Over 90% of ILC are estrogen receptor (ER)-positive, however, endocrine response and estrogen signaling are not well understood in ILC. Retrospective analyses suggest that ILC patients treated with endocrine therapy have poorer outcomes than invasive ductal carcinoma (IDC) patients, and that ILC patients may not benefit from adjuvant tamoxifen. Based on these observations, we hypothesize that ER regulates unique signaling pathways in ILC cells that control growth and endocrine response.

To identify putative targets that regulate endocrine response in ILC, we assessed genome-wide ER-mediated gene expression and ER genomic binding in the ILC cell lines MDA MB 134VI (MM134) and SUM44PE (SUM44). Among ILC-specific estrogen-regulated genes, the most strongly induced was the secreted ligand WNT4. Additionally, we identified an ILC-specific ER binding site (ERBS) at WNT4, suggesting that WNT4 is directly controlled by ER in ILC cells. Direct ER-regulation of WNT4 is in contrast to control of WNT4 by progesterone receptor (PR) during mammary gland development; however, further ER ChIP experiments suggest that ILC cells place WNT4 under ER control via unique use of the WNT4 ERBS. Thus, ILC cells may hijack a tightly regulated developmental program to drive estrogen-regulated cell phenotypes.

Based on the role of WNT4 in mammary gland growth and expansion, we hypothesized that WNT4 is required for estrogen-induced growth in ILC cells. To test this, we used siRNA to knock down WNT4 in ILC and IDC cell lines. Using either of two siRNAs, WNT4 knockdown completely blocked estrogen-induced growth in ILC cells, but not IDC cells. Consistent with this, WNT4 knockdown abrogated estrogen-regulation of a subset of ER-target genes in MM134 cells, suggesting that these genes are downstream of WNT4 signaling. Wnt signaling typically acts via the canonical, β-catenin-dependent pathway; however, we observed that β-catenin is dysfunctional in ILC cells, and WNT4 cannot activate β-catenin signaling in cancer cell lines. This suggests that WNT4 regulates estrogen-induced growth in ILC cells via a novel non-canonical signaling pathway.

Clinical observations suggest that ER regulates unique downstream pathways in ILC. We identified WNT4 as a putative downstream effector of ER signaling in ILC, as WNT4 is strongly-induced and directly regulated by ER specifically in ILC cells. Further, WNT4 is necessary for estrogen-induced growth in ILC cells, and likely signals via a non-canonical signaling pathway. Targeting WNT4 signaling represents a novel approach to modulate endocrine response specifically for ILC patients. Future studies will focus on characterizing the signaling pathway controlled by WNT4 in order to identify putative therapeutic targets.
Title: Investigating the therapeutic use of estrogen receptor β agonists in breast cancer

Samayoa C, Krishnegowda NK K, Vadlamudi R and Tekmal RR R. University of Texas Health Science Center at San Antonio, San Antonio, TX.

Body: In breast cancer, estrogen receptor status reflects the biology of the tumor and is used to determine the likelihood of responding to endocrine therapy. 70% of all breast cancers express Estrogen Receptor α, which is indicative of estrogen dependence for growth. Current therapies aim to lower estrogen levels, or inhibit estrogen receptor signaling to ultimately prevent recurrence. However, only two-thirds of ERα-positive respond to endocrine therapy. The Estrogen Receptors are ligand-activated transcription factors with similar structures that slightly differ in their DNA binding sites and ligand binding domains. Estrogen Receptor α has been shown to induce the proliferation of mammary gland cells, whereas Estrogen Receptor β exhibits tumor suppressive properties. The objective of this study was to investigate the utility of selective ERβ agonists as a treatment for breast cancer. Using different breast cancer models, we investigated the effects of ERβ agonist treatment on growth, migration, apoptosis, cell cycle distribution and gene expression. In this study, we demonstrate that treatment with ERβ agonist results in inhibition of cell growth and migration. Additionally, treatment also impacts cell cycle distribution and affects key proteins involved in cell cycle regulation. We also demonstrate an increase in ERβ mRNA and protein levels upon treatment. This shift in the ERβ to ERα ratio, represents a viable targeting strategy in the treatment of breast cancer. To determine if our finding translate in-vivo, we employed xenograft and syngeneic mouse models. Our in-vivo studies demonstrated reduced tumor volumes in mice treated with ERβ agonists in combination with conventional therapy, confirming the growth inhibitory activity of ERβ agonists. Selective activation of ERβ, through the use of ERβ agonists has enabled us to exploit its tumor suppressive function and investigate the utility as a treatment for breast cancer. This study suggest that activation of ERβ signaling is a valuable strategy to inhibit breast cancer growth and progression.
Title: Estrogen receptor β5 increases aggressiveness of the triple negative breast cancer cell line SUM159

Faria M, Tin-U C, Dey P, Gustafsson J-A and Strom AM M. University of Houston, Houston, TX; Karolinska Institutet, Huddinge, Sweden and MD Anderson, Houston, TX.

Body: Recent clinical studies are indicating that the estrogen receptor β variant β5 (ERβ5) expression correlates to worse prognosis. We wanted to know if expression of ERβ5 is changing the growth behavior of the triple negative cell line SUM159. Estrogen receptor β5 is highly similar to estrogen receptor β1 except for a truncated C-terminus making the remaining ligand binding domain incapable of binding to estrogen. In addition a 4 amino acid unique peptide is added to the C-terminal end. Stably expressing ERβ5 using a transposon integrated tetracycline regulated expression system we find that expression of ERβ5 increases proliferation of the triple negative SUM159 cells especially in reduced serum condition compared to control cells. Since SUM159 have been shown to depend on autocrine stimulation for growth we are suggesting that expression of ERβ5 is affecting the production of autocrine growth factors.
Title: Prognostic effect of semiquantitative measurement of PgR in luminal type breast cancer

Kim MK and Han W. Kangwon National University Hospital, Chuncheon, Republic of Korea and Seoul National University Hospital, Seoul, Republic of Korea.

Body: Background: The identification of prognostic factors for hormone receptor(HR)-positive and human epidermal growth factor receptor 2(HER2)-negative breast cancer is an important issue for the accurate determination of the indications for chemotherapy. The progesterone receptor(PgR) is a downstream molecule induced by transcriptional activation of estrogen signaling. In recent report, quantitatively low PgR expression was significantly associated with a poorer prognosis for patients treated with anastrozole and/or tamoxifen. These findings seem to suggest that the clinically used Ki-67-based IHC classification of luminal subtypes is inaccurate and that semiquantitative measurement of PgR expression can improve the IHC-based classification.

Method: 1327 consecutive patients with ER and/or PgR-positive HER2-negative invasive breast cancer treated with surgery and adjuvant treatment at the Seoul National University Hospital from January 2009 to December 2011 were reviewed. All patients had been pathologically diagnosed with breast cancer, and patients who had received chemotherapy or endocrine therapy before surgery were included. ER, PgR, HER2, and Ki-67 were determined from surgically resected, formalin-fixed, paraffin-embedded tumor tissue. The RFS and OS in Kaplan-Meier plots for the PgR high and low expression groups was compared using the log-rank test. Univariate and multivariate analyses of DFS and OS in relation to various factors were performed with a Cox proportional hazards model, which yielded the HR and 95% of CI for each variable.

Results: Based on pathology data of semiquantitative measurement of the percentage of PgR-positive cells, patients were separated into two groups with PgR percentage cutoff 20%. Among 1372 patients, 665(48.5%) showed high PgR expression, 707(51.5%) showed low PgR expression. PgR expression was relatively high in younger age(<50 years, p<0.001). Higher PgR expression was related to low Ki-67 expression(<10%, p=0.003), and low cancer stage(p<0.001). The DFS and OS of patients in the high PgR subset were significantly better than the low PgR subset only in patients under 50 years old.(p=0.005 and 0.037) Cox analysis showed that low PgR expression(HR, 3.06; 95% CI, 1.44-6.47) and negative ER expression(HR, 19.68; 95% CI, 5.89-65.80) were significant independent risk factors for DFS. Low PgR expression(HR, 5.66; 95% CI 1.62-19.74) and high Ki-67 expression(HR 1.06; 95% CI 1.01-1.17) were significant independent risk factors for OS.

Conclusion: We were able to demonstrate that high PgR expression is associated with a better prognosis for luminal type breast cancer. The semiquantitative determination of PgR expression might thus improve the accuracy of the IHC-based classification of luminal A and luminal B breast cancer, especially for premenopausal patients.
Title: Expression of genes for peptide/protein hormones and their receptors in breast carcinomas as biomarkers predicting risk of recurrence

Wittliff JL L, Daniels MW W and Brock GN N. University of Louisville, Louisville, KY.

Body: Background: Several reports have suggested expression of certain peptide/protein hormones in breast cancer cells appear to be related to clinical behavior. We have taken a global approach by evaluating relationships between genes for these hormones and their cognate receptor proteins as independent predictors of risk of recurrence.

Methods: Expression of genes for 55 peptide/protein hormones (the ligands) and 73 of their cognate receptor proteins were measured by microarray analyses of LCM-procured carcinoma cells from 247 breast carcinoma biopsies. Using an IRB-approved biorepository and comprehensive database, total RNA was extracted from carcinoma cells to determine expression levels of 22,000 genes. Univariate and multivariate Cox regressions with interaction were determined using expression values of each ligand and its cognate receptor with an interaction term.

Results: When pairs of hormone ligand and cognate receptor genes were evaluated by multivariate Cox regression with interaction, the following sets of genes were identified that predicted risk of breast cancer recurrence (INS/IGF2R, HAMP/SLC40A1, POMC/MC4R, GH1/GHR and VIP/VIPR2) and OS (CORT/SSTR5, VIP/VIPR2 and GHRH/GHRHR, based on unadjusted p-value for interaction term < 0.05). Since expression in situ of both hormone and receptor are necessary to elicit endocrine action, a unique alternative approach using the minimum expression value between ligand and receptor for each patient was applied. These results revealed that the complex of HAMP/SLC40A1 showed significance in both the interaction and minimum models, and was further investigated by splitting the ligand and receptor into low (below 1st quartile) and high (above 1st quartile) expression groups. The group consisting of high expression for both ligand and receptor was contrasted with the other three groups (low expression for ligand, receptor, or both). The higher expression group exhibited a better DFS (hazard ratio (HR) = 0.56 95% CI 0.37-0.84, p=0.004) and OS (HR = 0.59 95% CI 0.37-0.93, p=0.022).

Conclusion: As a result of determining gene expression directly on pure populations of breast carcinoma cells procured by LCM, we have demonstrated the many lesions synthesize mRNA species for a wide variety of peptide and protein hormones as well as for their cognate receptor proteins. Using clinical follow-up that extended as much as 12 years, univariate and multivariate Cox regression analyses with and without interaction models revealed a number of noteworthy candidates of hormone-receptor complexes that predicted risk of breast cancer recurrence as well as overall survival. Collectively, our results suggests that many breast carcinomas exhibit considerable endocrine autonomy for controlling progression, which warrants investigation of the protein products of the gene candidates in isolated populations of breast carcinoma cells.
Title: Molecular analysis of cancer tissue, circulating tumor cells (CTC) and cell-free plasma tumor DNA (ptDNA) suggests variable mechanisms of resistance to endocrine therapy (ET) in estrogen receptor (ER) positive metastatic breast cancer (MBC)

Body: Introduction: Fifty percent of ER positive MBC patients do not benefit from ET. Potential mechanisms of resistance to ET in this patient population include absence of ER expression by deletion or suppression, alteration in ER signaling pathway genes, or upregulation of multiple growth factor receptor pathways. We hypothesized that genotyping and phenotyping of CTC combined with genomic analysis of ptDNA will provide important insights into the multiple mechanisms of ET resistance and that a set of blood tests might serve as a "liquid biopsy" abrogating the need for tissue specimens.

Methods: Twenty-four patients providing informed consent were enrolled into the Mi CTC-ONCOSEQ study, a companion trial to Mi-ONCOSEQ (the Michigan Oncology Sequencing Program). Seven of these patients (5 with ER immunohistochemistry (IHC) positive and 2 with ER negative cancers) who had available archived primary and metastatic cancer tissue, a research metastatic biopsy for genomic analysis, and who had ≥5 CTC/7.5 ml whole blood (WB) characterized for ER protein (CTC-ER) are the focus of this report. All the patients were ET refractory. None of them was progressing on fulvestrant at the time of study entry. CTC enumeration and phenotyping was performed with CellSearch®. Circulating ptDNA was analyzed by droplet digital polymerase chain reaction (ddPCR). ER status from archived tissue was obtained from chart review. ER mRNA expression was determined in the research biopsy of metastatic tissue by using quantitative RNA sequencing. Mutational status of ER gene, ESR1, was determined by Next-gen Sequencing using the Illumina HiSeq 2500 platform.

Results: The 2 control patients with triple negative breast cancer had negative CTC-ER. Discordance between CTC-ER and tissue ER by IHC was observed (Table). Two of the 5 ER positive patients retained CTC-ER positivity (39% and 19% of the CTC). One of them (#7) harbored an ESR1 mutation in the research biopsy tissue and in ptDNA, whereas the other (#14) had wild type (WT) ESR1. CTC-ER protein levels in patients #12, 17 and 24 were negative. All had WT ESR1 in the research biopsy tissue. Of note, patient #12 had WT ESR1 in the research biopsy, but an ESR1 mutation was detected in her ptDNA.

Conclusions: These exploratory data suggest heterogeneous mechanisms of resistance to ET in patients with previously determined ER-positive MBC, including ESR1 mutations in ER positive cases (seen in 2 patients) and loss of ER expression (seen in CTC of 3 patients). In contrast, other cancers continue to express WT ESR1, and therefore must have developed
alternative mechanisms of resistance. At least 2 of these mechanisms can be detected and monitored with complementary circulating assays: CTC and ptDNA. Further investigations are needed to understand the heterogeneous mechanisms of resistance to ET.
Body: Background
About 65% of breast cancers express the estrogen receptor α and the mainstay of treatment are therapies that result in estrogen receptor modulation (selective estrogen receptor modulators, SERMs) or estrogen deprivation (aromatase inhibitors, AIs). Even though endocrine therapy has resulted in reduced recurrence and mortality, a significant portion of patients relapse with metastatic disease and subsequently progress while on therapy for advanced disease (endocrine resistance). Recent evidence showed that activating hot spot mutations in the ligand binding domain of the ERα (ESR1) are acquired on treatment (frequency of 20%) and can drive resistance to endocrine therapy, especially AIs. ESR1 mutations can be detected by evaluation of circulating tumor DNA (ctDNA), a method where circulating DNA fragments with tumor-specific sequence alterations are identified in the blood of patients.

Methods
This is a retrospective evaluation of 9 patients with hormone receptor positive (HR+) metastatic breast cancer (MBC) who had progressed on multiple lines of endocrine therapy (ET) and were found to have ESR1 mutations in ctDNA. Patients had blood drawn for ctDNA analysis either at progression to serve as a baseline before starting a new regimen or to monitor response to ongoing treatment. Guardant360™ (Guardant Health) involves ctDNA isolation from plasma using a Qiagen circulating nucleic acid kit, then a panel of 68 gene mutations associated with solid tumors as reported in the COSMIC database sequenced using single-molecule digital sequencing technology.

Results
All of the patients had MBC and were luminal subtype except for one HER2+, and most had invasive ductal carcinoma although 2 patients were invasive lobular carcinoma (22%). Most patients had both bone and visceral involvement (78%), only two patients had bone only metastasis. The patients were generally heavily pretreated with an average of 3 lines of ETs and 6 lines of therapy altogether (chemotherapy + ET). Duration on endocrine therapy ranged from 23 months to 7 years (mean 4.3 years). All patients were found to have ESR1 mutations on ctDNA, the range of percentage of mutant allele was 0.28-23.76%. Three patients had tissue sent for NGS and none of the tissue samples had an ESR1 mutation detected although they were biopsied at various time points in treatment. One of those patients had two ESR1 mutations in ctDNA, which were not detected on tissue sent for NGS one year prior, and had not been on ET for several years. One patient with abdominal carcinomatosis from lobular carcinoma who had been on ET therapies for 6 years was found to have 4 distinct ESR1 mutations in a single blood draw, suggesting sub-clonal evolution of resistance. One patient also had 5 circulating tumor cells, all of which had ESR1 mutations detected when circulating tumor cells were individually sequenced.

Conclusions
ctDNA is a sensitive test for detection of ESR1 in HR+ MBC patients, with the advantage of being a blood based assay which lends itself to serial analysis. In this patient population ctDNA can be a helpful tool to predict response to ET and predict treatment failure.
Title: Estrogen receptor alpha reactivation for the treatment of anti-estrogen-resistant breast cancer

Hosford SR R, Kaufman PA A and Miller TW W. Dartmouth College, Lebanon, NH and Dartmouth Hitchcock Medical Center, Lebanon, NH.

Body: Adjuvant anti-estrogen therapies that antagonize ER transcriptional activity have improved outcome in many patients, yet resistance to anti-estrogen therapies is common, resulting in disease recurrence in 1/3 of patients within 15 years of follow-up. However, prior to the introduction of tamoxifen, estrogens were used for treatment of breast cancer with response rates similar to those obtained by anti-estrogens in the advanced setting. Similarly, withdrawal of anti-estrogen therapy has shown anti-tumor effects, indicating that reactivation of ER may elicit therapeutic benefit.

MCF-7 cells with long-term (>1 yr) acquired resistance to the selective ER downregulator fulvestrant (fulv; MCF-7/FR) retain ER expression and harbor ESR1 (ER) gene amplification. Upon withdrawal of fulv, these cells re-engage ER as demonstrated by increased luciferase transcriptional reporter activity and re-expression of proteins encoded by ER-inducible genes. Following fulv withdrawal, MCF-7/FR cells show drastically decreased proliferation and increased apoptosis that are temporally correlated with ER reactivation. Protein levels of the anti-senescence protein FoxM1 decline following ∼12 d of fulv withdrawal, paralleled by increased staining for senescence-associated β-galactosidase. Transcriptomic analyses confirmed that fulv withdrawal progressively induces gene expression patterns indicative of stress and senescence. Similar effects were observed in long-term estrogen-deprived (LTED) MCF-7 cells treated with 17b-estradiol. Prospective studies characterizing the development of acquired anti-estrogen resistance have demonstrated the MCF-7 cells at 9 months of fulv resistance do not respond to fulv withdrawal, contrasting the long-term (>1 yr) MCF-7/FR cells. Additionally, withdrawal of fulv from T47D/FR, ZR75-1/FR, or HCC-1428/FR cells did not induce cell death or re-engage ER activity, confirming that ER reactivation is required for anti-cancer effects.

Ongoing studies are characterizing the temporal changes in ER transcriptional activity during 1) development of acquired anti-estrogen resistance, and 2) 17b-estradiol treatment of mice bearing WHIM16 patient-derived xenografts (regress in response to 17b-estradiol) to elucidate the mechanism underlying sensitivity of anti-estrogen resistant cells to ER reactivation. While estrogen therapies have shown clinical efficacy for decades, biomarkers to identify patients with tumors likely to respond to estrogen remain undefined. We are conducting a Phase II clinical trial [Pre-emptive OscilLation of ER activitY levels through alternation of estradiol/anti-estrogen therapies prior to disease progression in ER+/HER2- metastatic breast cancer (POLLY); NCT02188745] that will use tumor biopsy tissues to identify baseline and pharmacodynamic biomarkers that predict response to 17b-estradiol therapy.
Title: Estrogen receptor α-regulation of nucleocytoplasmic transport pathways as modulators of breast cancer therapy effectiveness

Madak-Erdogan Z, Chen-Zhao Y and Wrobel K. University of Illinois, Urbana-Champaign, Urbana, IL.

Body: Estrogen Receptor α (ERα), a member of the large superfamily of nuclear receptors, exerts profound effects on gene expression, cellular response programs, and phenotypic properties of estrogen target cells. Because of these broad and important actions, ERα is considered the single most important predictor of breast cancer prognosis and is the target of endocrine therapies. The importance of kinases in cancer biology is well known, as increased kinase activity through phosphorylation, mutations or increased expression is often observed in clinical samples and is associated with a poorer prognosis. It is believed that, in therapy-resistant breast cancers, control of cellular physiology switches from ERα nuclear-initiated pathways to extranuclear-activated protein kinase pathways, which enable these cells to adopt a more aggressive phenotype. However, the mechanisms underlying the interplay between ERα and protein kinase pathways in cancer, and the processes by which ERα influences these pathways are poorly understood.

Our aim in this study was to elucidate how ERα modulated extranuclear-initiated kinase signaling through alteration of the subcellular localization of ERK5. We have previously shown that upon estradiol treatment ERα elicits nuclear localization of ERK5 and Cofilin in ERα-positive breast cancer cells. This event diminishes ERK5 and Cofilin localization to regions of high actin remodeling in the cytoplasm, thereby possibly accounting for the reduced invasiveness and metastatic potential that is characteristic of many ERα-positive vs. ERα-negative breast cancer cells (PMID: 24505128). In our studies involving an endocrine-resistance cell model, we have found that ERK5 and Cofilin become localized to the cytoplasm as resistance progresses. Using several publicly available tumor gene expression databases, we have identified a signature of genes regulating nucleocytoplasmic transport that are differentially upregulated in more aggressive tumors. Additionally, using RPPA data from TCGA, we find that high expression of the signature genes correlates with higher phosphorylation of key signaling molecules like TAZ, indicative of their mislocalization in invasive breast carcinomas. Low expression of signature genes would successfully predict those patients that would respond to endocrine therapy with Luminal B type tumors that are generally more aggressive and harder to manage clinically. We verified our findings in cell line models by modulating levels and activities of these proteins by overexpression, knock-down and use of small molecule inhibitors. These findings provide insight into how ERα regulates extranuclear initiated kinase signaling by modulating nuclear transport of key kinases in breast cancer. They also suggest that therapeutic targeting of nucleocytoplasmic transport machinery in breast cancer might decrease aggressiveness of breast cancers and increase the efficiency of endocrine therapies by sequestering factors in their proper subcellular localizations where they would contribute to effective anti-estrogenic actions of endocrine targeting agents.
Targeting tumor re-wiring by triple blockade of mTORC1, ERBB and ER signaling pathways in endocrine resistant breast cancer

AIM To target tumor re-wiring by combined mTORC1 inhibition plus hormonal treatment with or without co-blockade of ERBB signaling in endocrine resistant models of human breast cancer (BC).

BACKGROUND Around 80% of BCs are estrogen receptor positive (ER+). Endocrine therapies target estrogenic stimulation of tumor growth but resistance remains problematic. Several strategies have shown that resistance often depends on the acquisition of enhanced cross-talk between ER and growth-factor pathways, allowing the disease to circumvent the need for steroid hormones. We have previously reported the antiproliferative effects of the combination of everolimus (RAD001-mTORC1 inhibitor) with endocrine therapy in resistance models, but potential routes of escape from treatment via ERBB2/3 signaling were observed. We hypothesised that combined targeting of three signaling pathways, namely ER, ERBB and mTORC1 may provide enhanced anti-tumor activity.

METHODS ER+ BC cell lines (MCF7, SUM44 and HCC1428) adapted to long term estrogen-deprivation (LTED) which model relapse on an aromatase inhibitor, along with their wild-type (wt) cell lines were treated with neratinib, a pan-ERBB tyrosine kinase inhibitor, in combination with RAD001 ± estradiol (E2), tamoxifen or fulvestrant. End points included proliferation, cell signaling, cell cycle and effect on ER-mediated transactivation and recruitment by ChIP.

RESULTS All cell lines showed a concentration-dependent decrease in proliferation in response to RAD001 (IC50 0.6-50nM in absence of E2 and 1-10nM in presence of E2). A wide range of IC50 values (300-1000nM) was observed with neratinib treatment in the presence of E2. However, in the absence of E2, wt cell lines showed IC50 values in excess of 1800nM with hormetic dose response curves, in which lower concentrations induced cell proliferation. In contrast, LTED IC50 values ranged between 400-900nM. Combination of either agent with endocrine therapy caused a concentration dependent decrease in proliferation in all wt cell lines and their LTED derivatives, but the maximum effect was observed when a triple combination of RAD001, neratinib and ER-blockade was used. Expression of pS6 was dramatically suppressed by RAD001 ± neratinib in all cell lines tested, whilst neratinib caused a cell line specific reduction in expression of ERBB family proteins. Upregulation of pAKT was observed in all cell lines following treatment with RAD001, indicating both inhibitors were effectively suppressing their respective targets. Combination of RAD001 with neratinib suppressed the upregulation of pAKT and significantly reduced cell cycle progression. In the absence of E2, RAD001 caused a reduction in ER-mediated transcription and decrease in recruitment of ER and the CREB-binding protein (CBP) to the TFF1 promoter. In contrast, neratinib induced a marked increase in ER-recruitment and concomitant rise in ER-mediated transactivation, which was reduced by the addition of RAD001.

CONCLUSION Targeting tumor re-wiring by triple blockade of ERBB, ER and mTORC1 signaling pathways significantly reduces cell proliferation supporting the potential combination in patients who have relapsed on endocrine therapy and retain a functional ER.
Evolution of genomic alterations on endocrine therapy and mTOR inhibition in estrogen receptor (ER)-positive breast cancer

Massarweh S, Romond E, Stewart R, Sun J, Chmielecki J, Mehdi M and Black EP P. Stanford University Medical School and Stanford Cancer Institute, Stanford, CA; University of Kentucky and Markey Cancer Center, Lexington, KY and Foundation Medicine, Cambridge, MA.

Background: Endocrine therapy (ET) and mTOR inhibition are important treatment strategies in ER-positive breast cancer, but no specific genomic alterations reliably predict benefit. Because tumors are tested pretreatment, we hypothesized that this may not capture tumor interaction with therapy.

Methods: We studied tumors from protocol NCT00570921 using fulvestrant and everolimus for metastatic ER-positive breast cancer after aromatase inhibitor (AI) failure. DNA from FFPE tumor tissue was subjected to next-generation genomic profiling using the FoundationOne® assay and alterations were then compared between available paired samples: primary/metastatic, before/after everolimus, and upon progression on everolimus.

Results: The most common alterations encountered were in the PI3K/AKT/mTOR pathway with increased frequency of PIK3CA in endocrine-sensitive disease but no specific association with everolimus benefit (Massarweh et al, ASCO 2015). One patient with lobular carcinoma relapse on ET and a new contralateral primary, had PIK3CA, CDH1, and MAP3K1 in both tumors with no new alterations detected. Her disease was everolimus sensitive. Another patient with PIK3CA at baseline acquired a CTNNA1 mutation upon relapse with no everolimus benefit. Interestingly, one patient with liver metastasis and complete response to everolimus lasting 3 years had no known alterations reported in the primary tumor but had a PIK3CA mutation in one of two simultaneous biopsies of separate liver lesions. Another patient with liver metastasis and a GATA3 mutation at baseline had response to everolimus lasting 18 months, then developed a PIK3R2_c.1936A>T mutation on progression reported as a variant of unknown significance (VUS). Another patient with metastatic lobular carcinoma to skin and bone had PIK3CA, CDH1, and ERBB2 mutations at baseline, and acquired KRAS and MCL1 amplification on two sequential skin biopsies in the first month on everolimus. She remained on therapy for 1 year. One patient with locally advanced disease and de novo bone metastasis had TP53 and GATA3 mutations at baseline with resistance to multiple chemotherapy and endocrine treatments. Upon progression on AI, her tumor acquired PDGFRA and SMAD4, detected on day 1 biopsy of everolimus treatment. Repeat biopsy on day 28 revealed loss of PDGFRA and SMAD4 with emergence of PIK3CA and MLL2 mutations and loss of STK11. After 1 year on everolimus her tumor progressed and repeat breast biopsy revealed loss of the PIK3CA, STK11, and MLL2 events, with appearance of AKT1 and NF1 mutations. Interestingly, her tumor also acquired ESR1_c.1607T>G, MTOR_c.6104C>T, and NSD1_c.5938G>A mutations, all classified as VUS but were not previously encountered in her course. Further analysis and biologic relevance of these changes will be presented.

Conclusion: This small study suggests that ER-positive breast cancer is a dynamic disease with genomic evolution on endocrine therapy and mTOR inhibition. In some patients, this change occurs early on therapy, possibly through clonal selection, but may also be related to tumor heterogeneity. The significance of this change is not fully understood, but study of early on-treatment biopsies may help us better understand tumor response to therapy.
Title: RAD1901, a novel oral, selective estrogen receptor degrader (SERD) with single agent efficacy in an ER+ primary patient derived ESR1 mutant xenograft model

Body: Despite advances in the treatment of metastatic breast cancer, many women eventually relapse with more aggressive forms of endocrine-resistant disease. Mutations in the ESR1 gene encoding the estrogen receptor (ER) have recently emerged as a potential mechanism for the development of clinical resistance to conventional anti-estrogen therapies, such as fulvestrant. To overcome some of the pharmacokinetic limitations and intramuscular administration challenges associated with fulvestrant endocrine therapy and to combat the development of resistance, there is a significant need for the development of more durable and more effective ER-targeted therapies. Here, we begin to describe and characterize the preclinical efficacy of RAD1901, a novel, orally bioavailable small-molecule SERD, with significant therapeutic potential for treatment of breast cancer. RAD1901 selectively binds to and degrades the ER and is a potent antagonist of ER-positive breast cancer cell proliferation. Importantly, RAD1901 demonstrated profound tumor growth inhibition in MCF-7 xenograft models when compared to fulvestrant and tamoxifen. Importantly, RAD1901 also demonstrated marked single agent efficacy in a primary patient-derived xenograft (PDx) model harboring the ESR1 Y537S mutation indicating the utility of this SERD against clinically relevant ER mutants. Further biochemical binding studies and co-crystallization experiments of RAD1901 bound to the ER further confirms the ability of RAD1901 to bind to both mutant and wild type forms of the ER. RAD1901 is currently undergoing clinical testing in postmenopausal women with ER-positive advanced breast cancer.
**Title:** High prevalence of splicing variant AR-V7 in triple negative breast carcinoma

**Body:** The androgen receptor (AR) and its pathway have been implicated in tumorigenesis and progression of breast cancer. Anti-androgen therapy has shown efficacy in the metastatic breast cancer and numerous clinical trials are underway to study efficacy in various clinical settings. 15 splicing variants of AR (AR-Vs) have been described in prostate cancer. Structurally, AR-Vs have insertions of cryptic exons downstream of the exons that encode the DNA-binding domain or deletions of the exons encoding the ligand-binding domain, resulting in a disrupted AR open reading frame and expression of ligand-binding-domain-truncated AR proteins. In prostate cancer, some of the AR-Vs especially AR-V7 are associated with aggressive disease and resistance to anti-AR therapy. The AR-V prevalence in human breast cancer specimens has hitherto not been studied. We aimed at studying the expression of AR-Vs in breast cancer specimens and present the data on AR-V1, AR-V7, AR-V8, and AR-V567, in AR-positive triple negative (TNBC) and ER+/Her2- breast cancer.

**Design:** 98 cases of TNBC, 40 cases of ER+/Her2 breast cancer and 17 cases with reduction mammoplasty were abstracted from NYULMC pathology database and screened for AR expression by immunohistochemistry (IHC). IHC for AR was performed using antibody clone N-20 (Santa Cruz) at 1:100 dilution. Normal breast tissue was used as internal control and 10% nuclear staining was used for categorizing a tumor as AR positive. A subset of cases which over-expressed AR were macrodissected from formalin fixed paraffin embedded sections with total RNA extracted by using the PureLink® FFPE RNA Isolation Kit (Invitrogen). Reverse-transcription was performed by using the SuperScript® III Reverse Transcriptase Kit (Invitrogen). AR-V expression was presented as cycle number difference to housekeeping gene (delta CT) for real-time PCR or as absolute copy number for digital PCR.

**Results:** AR+ TNBC and AR+/ER+ cases ranged from stage 1A to IIIA. IHC for AR showed > 10% staining in 27 of 98 TNBC cases and in 39 of 40 ER+/Her2 cases.

Conclusion: We report expression of various spliced variants in TNBC, ER+/Her2- breast cancer. A statistically significant expression of AR-V7 is seen in TNBC. Since AR-V7 predicts for poor prognosis and lack of response to anti-AR therapy in prostate cancer, AR-V7 expression may be a useful biomarker to analyze response data in ongoing breast cancer clinical trials.
Title: Exploring bazedoxifene and palbociclib as potential therapeutic strategies for overcoming ESR1-mediated endocrine resistance

INTRODUCTION
Despite effective endocrine treatments, endocrine resistance remains a major clinical challenge. We and other groups have recently detected ligand-binding domain ESR1 mutations in metastatic estrogen receptor positive (ER+) breast cancers. Our preclinical studies showed that these mutations confer constitutive activity and relative resistance to tamoxifen and fulvestrant. In this study we sought to investigate therapeutic strategies to overcome resistance rendered by the ESR1 mutations. Since our previous studies showed relative resistance to tamoxifen or fulvestrant, we hypothesized that bazedoxifene, a high affinity third generation SERM/SERD could overcome resistance driven by the ER mutant resistance. Additionally, we hypothesized that inhibiting cyclin D1, a key ER transcriptional target gene and cell cycle regulator, is a second potential therapeutic strategy to circumvent resistance rendered by mutant ER. Therefore in this study we tested the effects of bazedoxifene, palbociclib and their combination on cell proliferation in the presence and absence of the ESR1 mutations.

METHODS
For this study we established doxycycline inducible MCF7 cell lines expressing the ER-LBD mutations (Y537S, Y537N and D538G) and WT-ER as control. Cell proliferation response to bazedoxifene, tamoxifen, fulvestrant, palbociclib and the bazedoxifene-palbociclib combination was evaluated.

RESULTS
Cells harboring mutant ER were relatively resistant to tamoxifen and fulvestrant, as expected, and remained sensitive to single agent bazedoxifene and palbociclib. The combination of bazedoxifene and palbociclib was found to be superior to the single agents and exhibits synergistic activity.

CONCLUSION
The combination of bazedoxifene and palbociclib inhibits mutant ER cell growth and other cell models of endocrine resistance and is a potential therapeutic combination.
Title: Non-coding RNAs derived from near the ESR1 gene acts as a transcriptional regulator during estrogen deprivation adaptation of ER positive breast cancer cells

Fujiwara S, Saitoh N, Tomita S, Abdalla MO Osama, Iwase H and Nakao M. Graduate School of Medical Sciences, Kumamoto University, Kumamoto, Japan and Institute of Molecular Embryology and Genetics, Kumamoto University, Kumamoto, Japan.

Body: Endocrine therapies that blocks estrogen production are effective for estrogen receptor (ER)-positive breast cancer. However, endocrine therapy treated patients eventually experience relapse after a long period of estrogen deprivation. The mechanism underlying acquisition of estrogen independent growth by ER positive breast cancer cells remains unclear. To understand such molecular mechanism, we used a cell model LTED (long term estrogen deprivation) which MCF7 cells were cultured under estrogen deprivation for 4-10 months. In LTED cells, we found that ER encoded gene ESR1 was up-regulated and ER overproduction was essential for estrogen-independent cell growth. We also revealed that RNA transcriptions of the ESR1 and several neighbor genes were co-induced from both coding and non-coding regions in LTED cells, using RNA-sequence. These highly transcribed regions were corresponded to active histone modifications and transcription factor bindings according to publically available genome-wide analyses data. Fluorescence in situ hybridization (FISH) analyses indicated that RNA from the chromatin domain region nearby ESR1 were co-localized and made foci in nucleus. We found non-coding regions that are particularly highly transcribed. FISH analyses indicated that RNAs from these regions might interact with the parental ESR1 gene locus. Recent studies have shown that non-coding RNAs are involved in transcriptional regulation and chromatin regulation. To understand the role of the non-coding RNA, we have generated MCF7 cells lines that lack the non-coding site, using CRISPR/CAS9 system. We found that mRNA transcription of multiple genes including ESR1 were impaired by the deletion. These findings suggested that these non-coding RNAs may be involved in chromatin regulation of the chromatin domain nearby ESR1.

In this study, we found non-coding RNAs that control transcription of chromatin domain genes in ER positive breast cancer cells. Such non-coding RNA mediated transcriptional regulation might be critical for endocrine therapy resistance adaptation.
Title: The evolution of the estrogen receptor (ER) complex conformation governs estrogen-induced apoptosis in antihormone-resistant breast cancer cells

Maximov PY Y, Sengupta S, Fernandes DJ J, Fan P, Curpan RF F, Rajan SS S, Greene GL L and Jordan VC. The University of Texas, MD Anderson Cancer Center, Houston, TX; Georgetown Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC; The institute of Chemistry, Romanian Academy, Timisoara, Romania and The University of Chicago, the Ben May Department of Cancer Research, Chicago, IL.

Body: Over the past decade new insights have been gained into the acquired resistance to tamoxifen and the Aromatase Inhibitors (AIs) with the discovery of the new biology of estrogen-induced apoptosis. However, it has also been learned that estrogens can be classified into planar class I and angular class II estrogens. Using model systems of long-term estrogen-deprived breast cancer cells in vitro (MCF-7:5C), it was previously shown that class I estrogens cause immediate apoptosis over a 3-4 day period. Paradoxically, class II estrogens actually block apoptosis caused by planar class I estrogens. To gain insight into this paradox we have successfully crystallized an angular class II triphenylethylene (TPE) estrogen bound to the ligand binding domain (LBD) of the ER and derived a new conformation for the TPE:ER complex (code 3Q97 in the PDB). Surprisingly, Helix 12 seals the LBD with the class II estrogen, but not the same conformation is observed with the planar class I estrogen 17β-estradiol (E2). There would seem to be no reason why the 3Q97 complex would not cause immediate apoptosis. To address this issue we have used Western blot analysis for protein and qRT-PCR for mRNA levels for the ER. ER parameters were monitored for up to 72 hours and results compared and contrasted between E2, the Class II estrogens, 4-hydroxytamoxifen (4OHT) and endoxifen (Endox). ER protein and mRNA levels with 4OHT or Endox accumulated and remained high throughout the study period. In contrast, the planar estrogen E2 produced a rapid decline in the protein and mRNA levels for the ER complex. The angular class II estrogens initially produced an accumulation of the ER protein complex, which decreased with time. Using a chromatin immunoprecipitation (ChIP) technique we demonstrated that the class II estrogens recruit only half of the ER to the estrogen-responsive genes promoters (TFF1 And BREB1) and less than half co-activator binding compared to E2. The TPEs were only partial agonists compared to planar estrogen. These results explain why the Class II estrogens induce delayed apoptosis. We conclude that, for the first time, we have observed the binding of a ligand to a receptor that changes conformation against time and evolves from an antagonist to an agonist conformation to trigger apoptosis. These observations have current relevance to the decryption of the protective effects of estrogen alone therapy against breast cancer incidence in the Women's Health Initiative (WHI) trial. Combination of anti-progranulin (GP88/PGRN) antibody and letrozole inhibits tumor formation of letrozole resistant breast cancer cell lines

Serrero G, Dong J, Yue B, Hicks D and Hayashi J. A&G Pharmaceutical Inc., Columbia, MD and Precision Antibody, Columbia, MD.

The 88 kDa glycoprotein GP88 (Progranulin, PCDGF, acrogranin) is the largest member of the granulin/epithelin family of growth modulators identified as a driver of tumorigenesis. GP88 (PGRN) was also shown to be overexpressed in invasive ductal carcinoma (IDC) whereas it was negative in benign tumors and normal mammary epithelial tissue, thereby establishing GP88 as a therapeutic and diagnostic target in breast cancer (BC). Our laboratory has developed validated tools to measure GP88 in tumor biopsies and biological fluids as well as blocking its action. We showed that GP88 was secreted and detected in the serum of BC patients at an increased level when compared to healthy subjects. Pathological studies with 530 cases of ER+ IDC with clinical outcomes showed that GP88 tumor expression was an independent prognostic indicator of recurrence in early stage BC patients. Training study followed by an independent validation study demonstrated that high GP88 tissue expression (GP88 3+) was associated with a 4-fold increase in risk of recurrence at 5 years. A neutralizing anti-GP88 antibody AG1 was expressed in a high yield CHO cell line was developed. The present study examined the effect of AG1 in letrozole resistant cell line AGLetR developed by long term selection in letrozole supplemented medium. This cell line showed decreased letrozole responsiveness in vivo and therefore constituted an excellent model for investigating letrozole resistance in vitro as well as in vivo. Here we report the results of studies investigating the effect of various doses of AG1 on LetR tumor development in combination with letrozole for AGLetR. We show that treatment with AG1 (10 mg/kg i.p.) in combination with letrozole was efficient to maintain long term responsiveness and inhibit tumor growth. Letrozole alone (5mg/kg) was unable to inhibit tumor growth and showed a doubling of tumor volume. Interestingly, long term combination treatment lead to tumor regression and inhibited tumor growth. These data suggest that inhibiting GP88 could provide a novel and alternative therapeutic strategy for patients with resistance to anti-estrogen therapy, being tamoxifen or letrozole.

Title: Estrogen-independent growth of ESR1-mutant breast cancer cells requires CDK4/6

Luo F, Le X, Jeselsohn R, Brown M and Garraway L. Dana Farber Cancer Institute, Harvard Medical School, Boston, MA; Broad Institute, Cambridge, MA and Beth Israel Deaconess Medical Center, Boston, MA.

Body: A recent breakthrough in cancer treatment has been the development of highly specific cyclin-dependent kinase 4/6 (CDK4/6) inhibitors. CDK4/6 inhibitors, such as palbociclib, prevent cell cycle progression from growth phase (G1) to the DNA synthesis (S) phase of the cell cycle. Palbociclib, however, is only approved for first-line treatment of patients with estrogen receptor positive (ER+) breast cancer in combination with an aromatase inhibitor, letrozole. Approximately 20% of metastatic breast cancer patients, harbor an activating mutation in the ligand-binding domain (LBD) of the estrogen receptor gene, ESR1, which confers resistance to estrogen deprivation. It is unclear whether tumors harboring these endocrine treatment-associated mutations will also respond to CDK4/6 inhibition. We have found that estrogen-independent growth of ESR1-mutant breast cancer cells requires CDK4/6. Thus, ESR1-mutant breast cancer cells are sensitive to CDK4/6 inhibition. Mechanistically, ERS1 LBD-mutant cells upregulate key mediators of the G1-S cell cycle transition. Furthermore, the sensitivity of ESR1-mutant breast cancer cells to CDK4/6 inhibition requires RB1. While cells expressing RB1 respond to CDK4/6 inhibition, knockout of RB1 via CRISPRs enables ESR1-mutant breast cancer cells to resist combined estrogen depletion and CDK4/6 inhibition. Our studies suggest that tumors harboring ESR1 LBD mutations and an intact RB1 will respond to combined CDK4/6 inhibition and estrogen deprivation.
Title: A neoadjuvant window trial of endocrine response in women with invasive lobular carcinoma

Body: Background:
Patients with invasive lobular carcinoma (ILC) would be expected to have favorable outcomes compared to patients with invasive ductal carcinoma (IDC) given that ILC is more often hormone receptor-positive (HR+), human epidermal growth factor receptor 2 (HER2)-negative, of lower grade, and displays decreased proliferation markers. Based on our preclinical studies showing differential hormone response in HR+ ILC vs. IDC and on recent studies suggesting differences in endocrine treatment response between patients with ILC vs. IDC, we designed a biomarker-driven, neoadjuvant window trial for newly diagnosed women with HR+, HER2-negative ILC. We hypothesize that Ki67 will be reduced by 85% in the fulvestrant arm compared with 60% and 75% reduction in the tamoxifen and anastrozole arms, respectively, and that Ki67 reduction will correlate with alterations in expression of ER and ER-regulated genes. Differential Ki67 effect will serve as a surrogate for outcome of patients with ILC on endocrine therapy.

Trial Design: This multicenter study (NCT02206984) will enroll 150 women with HR+ and HER2-negative ILC. A mandatory research breast tumor biopsy will be performed at baseline. Fifty patients will be randomized to each of three open-label treatment arms for 21 days: fulvestrant (two 250 mg IM injections on both day 1 and day 14), anastrozole (1mg orally daily), or tamoxifen (20 mg orally daily). Biomarkers of response will be assessed on baseline and post-treatment tumor tissue. Patients will proceed to definitive surgery on day 21 after study drug exposure, or they will undergo a second research breast core biopsy if further neoadjuvant treatment is planned.

Eligibility Criteria: Eligible patients include postmenopausal women with newly diagnosed, HR+, HER2-negative ILC (excluding pleomorphic subtype) measuring ≥ 1cm, with adequate organ function, ECOG PS ≥ 2, and agreeable to baseline research breast tumor biopsy.

Specific Aims: The primary endpoint is percent change from baseline to post-treatment Ki67 values in ILC tissue after 21 days of endocrine treatment. Comparisons across study arms will be made using a general linear model adjusting for institutional effect, with 80% power estimated for pairwise comparisons of \( \log_2 \) (% staining) between treatment arms, allowing for 10% attrition. Secondary endpoints include post-therapy Ki67, and change in ER and PR protein expression by IHC. Finally, planned correlative studies include evaluation of gene expression, epigenetic markers, and DNA sequence variants in ILC tissues in an effort to identify biomarkers of endocrine response and putative drivers of endocrine resistance in ILC.

Target Accrual: This study will be open to enrollment by August 2015 at the University of Pittsburgh. Additional sites will be opened through the Translational Breast Cancer Research Consortium (TBCRC). We anticipate an accrual rate of 8 patients per month.

Title: Spatial and temporal genomic heterogeneity of estrogen receptor and clinical impact in a patient with advanced breast cancer

Rizel S, Dvir A and Soussan-Gutman L. Davidoff Center, Rabin Medical Center, Petah Tikva, Israel and Teva Pharmaceutical Industries Ltd, Shoham, Israel.

Body: Endocrine therapy targeting Estrogen receptor alpha (ERα) is a key therapeutic strategy for hormone-driven breast cancer. Resistance to endocrine therapy may be intrinsic, arising from different clones or acquired by evolution influenced by selective pressure conditioned by therapy. Emerging evidence points to the role of acquired ERα mutations in driving resistance, when detected in the metastases but were absent from primary tumor.

Here we studied tumor genomic evolution in a patient who developed two distinct recurrent consequences. The first recurrence was located at the lung and developed 14 years from diagnosis. In the adjuvant setting, the patient was treated with chemotherapy and had no endocrine therapy incorporated. On initial recurrence, the patient was treated with aromatase-inhibitor which resulted in complete response and the site is free of tumor now for 5.7 years. However, 2 years into endocrine therapy with aromatase-inhibitor the patient developed a single hepatic metastasis and treatment was changed to fulvestrant for 8 months with slow ongoing progression. The patient had partial hepatectomy, cholecystectomy and metastatectomy 3 months after fulvestrant was stopped. Histology and immunohistochemical stains confirmed breast origin, ER +2, 100%, PR +3, 100%.

The endocrine therapy resistant hepatic lesion was sequenced by hybrid capture Next Generation Sequencing (NGS) and ERα (D538G) mutation was detected along with PIK3CA and GATA3 typical for hormone+ breast cancer. We have studied the primary tumor by same NGS method and detected only the PIK3CA and GATA3 mutations. In the lung lesions, responsive for endocrine therapy when sequenced by NGS the ERα (D538G) resistant mutation was absent.

Clinical data for treatment of ERα (D538G) mutation driving endocrine resistance is lacking. The patient could not tolerate tamoxifen and failed treatments with aromatase-inhibitor and chemotherapy, losing 14 kg in weight. Treatment with megestrol acetate 160 mg was initiated and patient achieved partial response confirmed by hepatic MRI and an improved performance status which is now ongoing for 8 months.

This case represents the first evidence of heterogeneous response to endocrine therapy explained by presence/absence of ERα (D538G) resistant mutation along with evidence for an active treatment in not an uncommon scenario.
Mechanisms of resistance to CDK4/6 inhibition in ER+ breast cancer

Estrogen receptor positive breast cancers show frequent deregulation of Cyclin D-CDK4/6 signaling. Combining CDK4/6 inhibitors with hormonal therapies produces clinical benefit, supporting drug approval of the first CDK4/6 inhibitor, Palbociclib, in combination with Letrozole or Fulvestrant. Due to the adaptive nature of cancers, development of drug resistance is common and resistance to CDK4/6 inhibitors can be expected. To understand potential mechanisms of resistance to palbociclib, ER+ breast cancer cells were made resistant to Palbociclib in vitro. Characterization of resistance models derived from T47D and MCF7 cell lines revealed different mechanisms of resistance to Palbociclib. Resistant T47D revealed loss of functional Rb through a large 3 prime genomic deletion of RB1. Palbociclib failed to inhibit proliferation of these cells confirming Rb inactivation as the primary mechanism of Palbociclib activity.

Palbociclib-resistant MCF7 cells retained Rb mRNA and protein expression suggesting direct loss of Rb function was not the mechanism of resistance. RNAseq and CNV analysis of several resistant MCF7 lines revealed distinguishing features of the resistant lines including up-regulation of E2F, TGFβ, WNT and NF-κB transcriptional networks. Also, proteomic analysis showed that prominent features of all the resistant MCF7 cells included elevated Myc expression as well as increased abundance of Rb, phosphorylated Rb, E2F1 and its downstream targets Cyclin E1, Cyclin A2 among others. Palbociclib treatment of resistant MCF7 lines showed that CDK4/6 inhibition still modulated phosphorylated Rb and E2F1 levels, but repressed levels were higher than compared to basal levels of vehicle treated parental MCF7 cells. Given the precedence for Cyclin E/CDK2 activity to redundantly regulate Rb function at the G1 checkpoint, Cyclin E1 expression was inhibited using shRNA. Results show that knockdown of Cyclin E1 protein in Palbociclib-resistant cells restores sensitivity to Palbociclib.

Palbociclib-resistant MCF7 transcriptomes also exhibited significantly decreased expression of Estrogen Receptor target genes. Resistant cells proved unresponsive to the ER antagonist Fulvestrant, suggesting a loss of dependence on ER signaling. Cyclin E1 dysregulation is also implicated in resistance to hormonal therapy and Cyclin E1 knockdown resensitized Palbociclib-resistant MCF7 cells to Fulvestrant treatment. The observations of cross resistance to CDK4/6 inhibitors and hormonal therapy highlight the co-dependence of Cyclin D-CDK4/6 and ER signaling in ER+ breast cancer. Continued studies are focused on describing the alterations driving increased Cyclin E1 expression in response to CDK4/6 inhibition and strategies to circumvent development of resistance via Cyclin E/CDK2 signaling.
Title: Characterization of resistance to the selective CDK4/6 inhibitor palbociclib in ER positive breast cancer

Body: Background: Dysregulation of the cyclin D-CDK4/6-Rb axis occurs in a substantial proportion of ER-positive (ER+) breast cancers and has been linked with endocrine resistance. Adding the CDK4/6 inhibitor palbociclib to endocrine treatment has led to a substantial improvement of the outcome of patients with ER+ metastatic breast cancer. However, with the increasing clinical use, acquired resistance to palbociclib is merging as a new major clinical challenge.

Methods: The ER+ cell lines T47D and MCF7 have been shown to be highly sensitive to treatment with palbociclib. Using long-term co-culture with increasing doses of Palbociclib, we generated MCF7 and T47D cell line clones with acquired resistance to Palbociclib. Three distinct resistant clones were selected for each cell line showing an IC50 shift from sensitive to resistant of approximately 300nM to 3μM for MCF7 and 400nM to 3.5μM for T47D, respectively. Resistant cell lines were characterized using RNA sequencing and mass spectrometry-based phosphoproteomics. Effects on selected target proteins (eg pAKT, pS6, pRB, RB or Cyclin D1) were confirmed using Western Blots. To modify resistance to palbociclib, a targeted in vitro drug-screen was performed using a range of inhibitors of the PI3K/AKT/mTOR and MEK pathways.

Results: Western blot analysis of resistant cell lines demonstrated sustained down-regulation of Rb and phospho-Rb in response to palbociclib, which was reversible after discontinuation of palbociclib. Mass spectrometry identified >6,000 peptides across parental and resistant cells corresponding to 4,757 phospho-peptides and 5,337 phosphorylation sites. Pathway analysis suggested increased activity in the P31K/AKT/mTOR pathway in resistant clones (including Akt1, p90S6K and mTOR), as well as changes in p53 and apoptotic regulation (e.g. phosphorylation of BAD). In addition, resistant clones showed multiple phosphorylation changes in the Rho/Rac pathway, suggesting changes in cytoskeletal organisation and a more invasive phenotype. Targeted drug screening showed a variable pattern across resistant clones with increased sensitivity to co-treatment of palbociclib with AKT inhibitors, PI3K alpha/delta inhibitors and/or MEK inhibitors in selected resistant clones, whereas pan-PI3K or PI3K beta/delta inhibitors showed limited efficacy in the selected clones.

Conclusions: Phosphoproteomic analysis of palbociclib-resistant ER+ breast cancer cell lines demonstrated up-regulation of PI3K/AKT/mTOR and anti-apoptotic pathways. Resistant cell lines were sensitive to inhibition of PI3K/AKT/mTOR and/or MEK pathways with distinct patterns of activity across resistant clones suggesting that co-treatment of CDK4/6 inhibitors and PI3K/AKT and/or MEK inhibitors warrants further investigation as potential new therapeutic strategies in palbociclib resistance.
Title: Downregulation of histone H2A and H2B pathways is associated with anthracycline sensitivity in breast cancer

Body: Background: Meta-analyses performed by the Early Breast Cancer Trialists Collaborative Group demonstrated a significant increase in disease free and overall survival through the addition of anthracyclines to polychemotherapy. Anthracyclines have, however, significant toxicities including cardiotoxicity and leukaemia. It is, therefore, imperative to identify those patients who will benefit from adjuvant anthracycline treatment; other patients could then be spared unnecessary toxicities and be considered for alternative adjuvant therapy. Several markers that may predict anthracycline benefit have been explored in patient cohorts (HER2, TOP2A, Ch17CEP and TIMP1) with limited success.

Methods: To identify markers that are clinically-relevant, we generated MDA-MB-231, MCF7, SKBR3 and ZR-75-1 breast cancer cell lines sensitive and resistant to epirubicin to identify pathways contributing to anthracycline resistance. A complementary approach including gene expression analyses to identify molecular pathways involved in resistance, and small-molecule inhibitors to reverse resistance were performed. RNA was extracted from patients in the BR9601 adjuvant trial evaluating the addition of epirubicin (E) to CMF and analysed through Nanostring technology. Log-rank analyses explored the predictive values of the signatures on distant relapse-free survival (DRFS). Cox-regression models tested independent predictive value on DRFS in the presence of treatment, age, tumour size, nodal status, ER status and grade, and treatment by marker interactions.

Results: Gene expression analysis identified upregulation of a histone gene module in all four cell lines which was validated by qRT-PCR. Histone deacetylase small-molecule inhibitors reversed resistance and were cytotoxic for epirubicin-resistant cell lines, with IC50's ranging from 0.1-3.69µM, confirming that histone pathways are associated with epirubicin resistance. Gene expression analysis of the 18-gene histone module in the BR9601 clinical cohort revealed that patients whose tumour had low expression had an increased DRFS (HR: 0.35, 95%CI 0.17-0.73, p=0.005) when treated with E-CMF compared with patients treated with CMF alone. Conversely, there was no apparent benefit of E-CMF vs CMF in patients with high histone module expression (HR: 0.96, 95%CI 0.58-1.59, p=0.87). After multivariate analysis and adjustment for HER2 status, nodal status, age, grade and ER status, the treatment by marker interaction was 0.35 (95%CI 0.13-0.96, p=0.042) for DRFS.

Conclusion: Histone gene expression was an independent predictor of anthracycline benefit in terms of DRFS. In vitro data demonstrated that resistance could be reversed with histone deacetylase small-molecule inhibitors. The histone signature identified could be a potential theranostic candidate for patients with early breast cancer.

Title: Investigating clonal dynamics in triple negative breast cancer chemoresistance

Echeverria GV V, Seth S, Moulder S, Symmans W, Chang J, Cai S, Heffernan T and Piwnica-Worms H. M.D. Anderson Cancer Center, Houston, TX and University of Texas Health Science Center, Houston, TX.

Body: Approximately 50% of triple-negative breast cancer (TNBC) patients have extensive residual disease following neoadjuvant chemotherapy (NAC). These patients have a four-fold increase in mortality risk and an increased risk of distant metastases within three years (1). Understanding the molecular basis of resistance to NAC is expected to provide opportunities to better treat patients in the primary setting. Extensive intratumoral subclonal heterogeneity has been well documented in primary, treatment-naïve TNBC (2). Subclonal populations harboring distinct molecular profiles may confound targeted therapy strategies, yet the functional impact of subclonal heterogeneity in TNBC resistance to therapy is unknown. We are implementing DNA barcoding to quantitatively track changes in subclonal architecture pre- and post-treatment in patient-derived xenograft (PDX) models of TNBC in order to design novel combination therapies. Such barcoding strategies have been used to monitor clonal dynamics in breast cancer PDXs with great sensitivity (3).

We have established an orthotopic PDX from a treatment-naïve TNBC patient (PIM1, procured from a patient later found to have chemoresistant disease). In order to model chemoresistance, we treated PIM1 with Adriamycin and cyclophosphamide (AC), standard of care NAC for TNBC patients, which resulted in partial response but left residual disease. To characterize subclonal dynamics in response to NAC, we transduced freshly isolated PIM1 cells with a lentiviral library expressing 25 million unique DNA barcodes (Cellecta) using conditions to ensure each transduced cell contained a single unique barcode. Transduced cells were selected with puromycin, then orthotopically implanted into immuno-compromised mice. High-throughput barcode sequencing revealed reproducible maintenance of greater than 60,000 unique barcodes in PDX tumors. Comparison of barcode distribution in tumors treated with vehicle or NAC will reveal whether NAC selects for a subpopulation of cells during the development of resistance. Future directions will include whole-exome and RNA sequencing to characterize genomic changes associated with alterations in barcode distribution in response to NAC treatment. Our ultimate goal is to identify novel combination therapies to eliminate subclones that contribute to chemoresistance in primary TNBC.

Title: Importance of TGFβ-SMAD3 axis in resistance to anti-HER2 drugs

Shimoda M, Chihara Y, Kagara N, Naoi Y, Shimomura A, Shimazu K, Kim SJ and Noguchi S. Osaka University Graduate School of Medicine, Suita, Osaka, Japan.

Body: **Aim:** The aim of this study was to elucidate the role of transforming growth factor β (TGFβ) in the resistance of HER2-positive breast cancer cells to anti-HER2 drugs including trastuzumab and lapatinib.

**Methods:** A HER2-positive breast cancer cell line, SKBR3, was cultured in the presence or absence of TGFβ for 14 days. Subsequently, TGFβ-treated cells were cultured for seven days with or without the anti-HER2 drugs. Sensitivity to trastuzumab and lapatinib was estimated by the WST-8 cell viability assay or absolute cell counts using In Cell Analyzer (GE Healthcare). Proportion of CD44+ CD24– breast cancer stem cells was estimated by flow cytometry of cells immunostained with anti-CD44 and anti-CD24 antibodies. For clinical study, 33 patients with HER2-positive breast cancer receiving neoadjuvant paclitaxel plus trastuzumab in our institution were analyzed. Among the cases, 27 biopsy samples obtained before any treatment from 27 patients who completed 12 cycles of weekly paclitaxel and trastuzumab were subjected to CD24 immunohistochemistry.

**Results:** SKBR3 cells cultured with TGFβ for 14 days exhibited decreased sensitivity to both trastuzumab and lapatinib. Time course study revealed that continuous stimulation for 14 days with TGFβ was required for the resistance to anti-HER2 drugs. Activation of SMAD3, a downstream target molecule of TGFβ, was enhanced over time, judged by the increase in phosphorylation and in nuclear translocation. During 14 day culture with TGFβ, proportion of CD44+ CD24– cells were dramatically increased, and mammosphere formation, another marker of breast cancer stem cells, was significantly enhanced compared to cells treated without TGFβ. Among four HER2-positive breast cancer cell lines, only SKBR3 cells showed increased proportion of CD44+ CD24– cells and resistance to the anti-HER2 drugs, while other two cell lines exhibited epithelial-mesenchymal transition (EMT) in response to TGFβ. To explore the possibility of targeting TGFβ-SMAD3 axis to overcome resistance to anti-HER2 therapy, we used SIS3, a specific inhibitor of SMAD3. Importantly, SIS3 completely restored the sensitivity to both trastuzumab and lapatinib of TGFβ-treated SKBR3 cells, with the decrease in the proportion of CD44+ CD24– cells. These in vitro results suggest that CD24 downregulation can be a surrogate marker of resistance to anti-HER2 therapy. To establish this, we evaluated the CD24 expression in tumor samples of breast cancer patients who received paclitaxel plus trastuzumab in the neoadjuvant setting. Weak CD24 expression in tumor cells in biopsy samples obtained before any treatment was significantly correlated with poorer response to the drugs.

**Conclusion:** These data clearly indicate the importance of TGFβ-SMAD3 axis in the acquired resistance to anti-HER2 drugs. Moreover, resistance to anti-HER2 therapy is associated with the property of breast cancer stem cells rather than EMT. Targeting TGFβ-SMAD3 axis warrants further investigation for overcoming resistance to anti-HER2 therapeutics.
Title: Whole exome analysis of HER-2 positive human breast cancers: Molecular mechanisms underlying response to neoadjuvant therapy with trastuzumab

La Ferla M, Aretini P, Scatena C, Menicagli M, Lessi F, Franceschi S, Cantini L, Bevilacqua G, Naccarato AG Giuseppe, Fontana A and Mazzanti CM Maria. Pisa Science Foundation - ONLUS, Pisa, Italy; Division of Pathology, University Hospital of Pisa, Pisa, Italy and University Medical Oncology Unit II, Azienda Ospedaliero-Universitaria Pisana (AOUP), Pisa, Italy.

Body: Background: HER2 receptor is overexpressed in 20–30 % of BC and it has been chosen to be an effective therapeutic target. Trastuzumab (Herceptin), a humanized monoclonal antibody, has been approved by FDA to be anti-HER2 therapy, but the mechanism by which Trastuzumab exerts its antitumor activity is not fully understood. Despite that almost 50% of HER2 Positive BC patients do not respond to Trastuzumab based therapy or become resistant during the therapy. An understanding of Trastuzumab resistance mechanisms would be a helpful tool in the development of rational drug combinations to circumvent resistance and allow better selection of patients likely to respond. The aim of this study is the correlation of the mutational profile of HER-2 positive patients with complete response and partial response to the neoadjuvant therapy with Trastuzumab and evaluation of possible molecular factors predictive of response.

Materials and Methods: We performed, so far, whole-exome DNA sequencing (Ion Proton system) to analyze primary FFPE biopsy and primary surgical removed tumors of HER2 positive BC patients specifically selected for different response to the neoadjuvant therapy with trastuzumab and all ER and PR negative: 3 Full Responders (FR) with a complete disappearance of the tumor mass after the therapy and 2 Partial Responders (PR) with a partial shrinkage of the tumor mass, which is then removed by surgery. More patient samples are in the process to be analyzed by whole exome analysis for a total of 20 patients (10 each group).

Results: We identified gene mutations in SYNE2, ANKRD44, CEP350, OR6C74, STRN3 and GIN1 genes present in the biopsy of PR patients and their presence rise in the post therapy samples. Interestingly these mutations rise in the post therapy samples while are nearly absent in the FR patients. On the other side we found some variants present in MACC1 and MAPK1 genes present in the FR samples and absent in the PR samples. Thanks to literature analysis we found that some of these variants are already associated with Trastuzumab resistance and sensitivity.

Conclusions: We found that some genes have a reduction/disappearance or an increase of the mutant allele after treatment. Our findings indicate a possible involvement of a combination of gene mutations associated with resistance to the Trastuzumab therapy for the PR patients. The final gold is the creation of a gene panel implicated in resistance and/or in the complete response to Trastuzumab. Moreover other genes which resulted differentially expressed between PR and FR HER2+ patients are in the process of being investigated. However functional studies, as well as association studies in a larger patient dataset are needed to explore our hypothesis.
Title: Changes in the tumor microenvironment develop acquired resistance to pegylated liposomal doxorubicin in breast cancer mouse model

Kai M, Liu YT, Saito Y, Ferrari M and Yokoi K. Houston Methodist Research Institute, Houston, TX.

Body: Pegylated liposomal doxorubicin (PLD) is one of the most widely used nanotherapeutics for the treatment of advanced/metastatic breast cancer. PLD accumulates in tumors utilizing so-called the enhanced permeation and retention (EPR) effect. Nevertheless, therapeutic efficacy and long term survival remain variable due to the development of acquired resistance. Elucidating the mechanisms of acquired resistance to PLD shall help developing new strategies to improve therapeutic outcome. It has been largely overlooked that the transport of therapeutics across biological barriers can significantly affect the efficacy of cancer therapies. Previously, we showed that the transport of PLD to tumors depends both on the tumor type and organ site. This effect is controlled by the extent to which endothelial cells (ECs) are covered by the collagen type IV (Col4) in the basement membrane, which in turn is influenced by the levels of MMP-9. Here, we have developed 4T1 tumor model which develops acquired resistance to PLD and spontaneous lung metastases. Our objective is to elucidate the resistant mechanism by evaluating the changes in the transport of PLD to the sensitive and resistant/metastatic tumors.

BALB/c mice bearing 4T1 cancers were treated with PLD intravenously when tumor volumes reached a size of approximately 100-200 mm$^3$. Tumor volumes in all mice decreased after initial PLD injections (sensitive). However, tumors started to grow again after 20 days and didn't respond to the second/third injections (resistant). Furthermore, 13 out of 14 mice developed spontaneous lung metastases. To elucidate the mechanisms of the resistance, mice bearing sensitive or resistant tumors were sacrificed after 24 hours of PLD injection, respectively. PLD accumulation in tumors was evaluated by imaging fluorescence of doxorubicin. Immunofluorescence staining was performed to evaluate the expression of ECs, Col4, MMP-9, and efflux pump associated p-glycoprotein (P-gp) in the primary tumors, and the expression of ECs and Col4 were also evaluated in lung metastases.

PLD accumulation was significantly decreased in the resistant tumors compared to the sensitive tumors, although P-gp expression was not increased in the resistant tumors. The amount of ECs and Col4 increased in the resistant tumors. Interestingly, ECs were covered more tightly by Col4 in the resistant tumors as compared with the sensitive tumors, which could decrease the EPR effect in the tumors. MMP-9 expression decreased in the resistant tumors, suggesting less degradation of Col4 in the basement membrane. Coverage of ECs by Col4 was similar between the metastatic lung tumors and uninvolved lung tissue as well as the resistant primary tumors, indicating the EPR effect is not increased in the metastatic tumors.

In summary, ratio of ECs covered by Col4 is higher in the resistant/metastatic tumors as compared to that in the sensitive primary tumors. This structural change in the tumor microenvironment, impeding the sufficient PLD transport to the tumors after the initial PLD therapy, can be a cause of acquired resistance/development of lung metastasis. These changes should be taken into account to develop strategies for overcoming the acquired resistance and metastasis.

Title: Abstract Withdrawn

Body:
Leptin is a potent adipokine that plays an important role in the progression of breast cancer and interferes with the action of tamoxifen. We investigated the molecular mechanism underlying the effect of leptin on tamoxifen resistance in breast cancer cells that express leptin receptor (ObRb), and evaluated the impact of ObRb suppression on tamoxifen treatment in MCF-7 and tamoxifen-resistant (TAM-R) cells. Leptin-induced signaling pathway activation was examined by qRT-PCR and western blotting. Chromatin immunoprecipitation assays were performed to further examine the binding of estrogen receptor (ER) α on the promoter of cyclin D1 (CCND1) gene. The effects of combined ObRb knockdown and tamoxifen treatment were evaluated in MCF-7 and TAM-R cells. We found the enhanced proliferation effects induced by leptin were related to extracellular signal-regulated kinase (ERK) 1/2 and signal transducers and activators of transcription (STAT) 3 signaling pathway activation and CCND1 upregulation. Leptin enhanced CCND1 gene transcription by inducing the binding of ERα to the promoter of CCND1 gene. ObRb knockdown significantly enhanced the inhibitory effects of tamoxifen on TAM-R cell proliferation and survival. This study suggested that Long-term endocrine therapy facilitates leptin and ObRb overexpression in breast cancer cells, which attenuates the inhibitory effect of tamoxifen by activating both the ERK1/2 and STAT3 signaling pathways and upregulating CCND1 gene expression. Combination therapy involving ObRb knockdown and tamoxifen treatment may be an alternative therapeutic option for tamoxifen-resistant breast cancer.
**Title:** t-Darpp enhances protein kinase A signaling through direct effects on PKA holoenzyme and indirectly influences cell metabolism, proliferation and apoptosis

**Body:** Trastuzumab has dramatically improved the adjuvant therapy of Her2-positive breast cancer. However, acquired resistance to trastuzumab frequently occurs. Breast cancer cells in vitro selected for trastuzumab resistance exhibit over-expression of t-Darpp, a truncated form of the 32 kDa dopamine and cAMP-regulated phosphoprotein (Darpp-32). t-Darpp over-expression has previously been demonstrated to confer trastuzumab resistance and to result in increased protein kinase A (PKA) activity and signaling. Phosphorylation of Darpp-32 at threonine 75 has been shown to promote inhibition (not activation) of PKA by a yet unknown mechanism. T75 phosphorylation on t-Darpp is required for its trastuzumab resistance activity but the role of T75 phosphorylation in PKA activation by t-Darpp is not known and the molecular mechanism by which t-Darpp enhances PKA activity has not been reported. We used cells stably over-expressing either wild type t-Darpp or a T75A mutant of t-Darpp. Using proximity ligation assays, we found that t-Darpp binds directly to the RI regulatory subunit of PKA leading to 75% less RI subunit bound to the catalytic subunit of PKA (PKAc), compared to parental cells. In contrast, the t-Darpp-T75A mutant does not bind RI and those cells have only 34% less RI bound to PKAc compared to parental. These results suggest a direct effect of t-Darpp on PKA activation by binding the regulatory subunit RI and thereby preventing RI from inhibiting PKAc. The T75 phosphorylation site appears to be required for this activity. Using enzymatic and caspase activity assays, we also show that cells over-expressing t-Darpp, but not t-Darpp-T75A, have increased proliferation, up to 4-fold more cellular ATP, and diminished apoptotic response to etoposide, relative to parental cell controls. So far, this data suggests a dual mode of t-Darpp action: modulation of cell metabolism (possibly via effects on ATP production) and direct effects on PKA holoenzyme. Ultimately, pro-apoptotic response is diminished. Further studies will determine whether PKA activation by t-Darpp is responsible for, or separately influenced by, the metabolic effects of t-Darpp.
Title: Understanding resistance mechanisms of PIK3α inhibition in breast cancer

Le X, Luo F, Treacy D, Wulf G and Garraway L. Dana-Farber Cancer Institute, Boston, MA and Beth Israel Deaconess Medical Center, Boston, MA.

Body: Breast cancer is the most common non-cutaneous cancer in women worldwide. PIK3CA is the most frequently mutated oncogene in all invasive breast cancers, with about one third of cases harboring activating mutations. Small molecule therapeutics targeting PI3K pathway has been developed and investigated for a decade. Everolimus (an mTOR inhibitor) is now successfully used in conjunction with hormonal therapy in patients with metastatic hormone-receptor positive breast cancers. Inhibitors of PI3Kα have shown promise as a single agent as well as in combination with hormonal therapies. The high rate of primary and acquired resistance; however, limits clinical usage of this class of drugs. There is an urgent need to understand the resistance mechanisms of PI3K inhibition and develop strategies to overcome the resistance in breast cancer. We took a genome-scale functional screening approach to identify resistance mechanisms to PI3K inhibition in breast cancer. We performed a whole-genome lentiviral open-reading frame (ORF) overexpression screen in a breast cancer cell line (T47D) in the presence of a PI3Kα inhibitor. We screened a total of 15,590 ORFs and identified 75 genes whose overexpression confers resistance to PI3K inhibition. Once we validate the hits, we plan to determine the mechanisms by which the genes confer resistance. We also plan to perform RNA-sequencing in patient samples with PI3Kα resistance to evaluate the clinical relevance of these genes and pathways.
Title: Are specific interactions of proteasome with Hsp72 responsible for resistance of triple negative breast cancer cells to proteasome inhibitors?

Gaczynska M and Osmulski PA A. The University of Texas Health Science Center at San Antonio, San Antonio, TX.

Body: Proteasome, the essential giant protease, is the hub of the ubiquitin-proteasome pathway critical for maintaining intracellular proteostasis. Inhibitors of the proteasome cause overload of cells with non-degraded protein debris and activate proapoptotic signaling. The effects are especially dramatic in fast metabolizing cancer cells; hence the proteasome inhibitors are used as anti-cancer drugs. There are two FDA-approved drugs directly blocking the proteasome activity, bortezomib and carfilzomib, and several others are in trials. So far, the high effectiveness of these drugs is limited to multiple myeloma and other hematological malignancies. Unfortunately, breast and other solid cancers are much more resistant to apoptosis triggered by attenuation of the ubiquitin-proteasome pathway than majority of blood cancers. The relatively low effectiveness of proteasome inhibitors has been noted even for cancers that have been identified in genome-wide screens as addicted to the proteasome activity, such as triple negative breast cancers. The source of the resistance, noted in cell culture, animal studies and clinical trials, remains unknown. Here we propose that, at least in part, the resistance can be tracked down to protein-protein interactions between the drug target, the proteasome, and a cytosolic heat shock protein, Hsp72 (inducible Hsp70). Indeed, high levels of Hsp72 have been observed in many cancers, including breast, and generally correlate with poor prognosis. The intracellular roles of the ubiquitous chaperone are undoubtedly very diverse, however we postulate a novel molecular action: direct protection of the proteasome from competitive inhibitors of its enzymatic activity. The hypothesis has been inspired by our recent work exploring the very effective ubiquitin-proteasome pathway in the naked mole rats. These small African rodents do not develop cancers and maintain unusually long lifespan and health-span. Interestingly, the proteasome in naked mole rats is exceptionally resistant to inhibition. We discovered that the resistance is bestowed by a cytosolic protein factor containing Hsp72 and Hsp40 chaperones (Biochim. Biophys. Acta-MBD 1842; 2060-2072; 2014). We partially purified the factor and tested its in vitro effectiveness with human proteasomes. The molecular mechanism beneficial for naked mole rats may be also protective for human cancer cells. We used pilifithrin µ, a specific small molecule inhibitor blocking the interactions of Hsp72 with other proteins, to test the hypothesis. We prepared lysates from cultured triple negative breast cancer cells MDA-MB-231. Such lysates are rich in proteasome activity and preserve interactions of the proteasomes with natural protein ligands. Interestingly, upon the treatment with pilifithrin µ proteasomes in lysates maintained their high activity while becoming significantly more sensitive to inhibition with bortezomib. The studies are in progress to assess the identity of a putative chaperone-based proteasome resistance factor in breast cancer cells.
Title: Overexpression of miR-200a confers chemoresistance by antagonizing TP53INP1 and YAP1 in human breast cancer

Yu S-J, Yang L, Hong Q and Shao Z-M. Breast Cancer Institute, Cancer Hospital, Shanghai Medical College, Fudan University, Shanghai, China.

Body: Introduction:
Emerging evidence suggests molecular and phenotypic association between treatment resistance and epithelial–mesenchymal transition (EMT) in cancer. Compared with the well-defined molecular events of miR-200a in EMT, the role of miR-200a in therapy resistance remains to be elucidated.

Methods:
Breast cancer cells transfected with mimic or inhibitor for miR-200a was assayed for chemoresistance in vitro. miR-200a expression was assessed by quantitative real-time PCR (qRT-PCR) in breast cancer patients treated with preoperative chemotherapy. Luciferase assays, cell proliferation assay were performed to identify the targets of miR-200a and the mechanism by which it promotes treatment resistance. Survival analysis was used to evaluate the prognosis value of miR-200a.

Results:
In this study, our results showed ectopic expression of miR-200a promotes chemoresistance in breast cancer cell lines to several chemotherapeutic agents, whereas inhibition of miR-200a enhances gemcitabine chemosensitivity in resistance cancer cells. Furthermore, overexpression of miR-200a was closely associated with poor response to preoperative chemotherapy and poor prognosis in breast cancer patients. Furthermore, knockdown of YAP1 and TP53INP1 phenocopied the effects of miR-200a overexpression, and confirmed that TP53INP1 is a novel target of miR-200a. Remarkably, TP53INP1 expression is inversely correlated with miR-200a expression in Breast cancer cell lines. Taken together, these clinical and experimental results demonstrate that miR-200a is a determinant of chemoresistance of breast cancer.

Conclusions:
Upregulated miR-200a enhances treatment resistance via antagonizing TP53INP1 and YAP1 in breast cancer.
DSS1 depletion is a promising strategy increasing chemosensitivity possibly independent of BRCA2 expression

Gondo N, Rezano A, Kuzushima K, Iwata H and Kuwahara K. Aichi Cancer Center Research Institute, Nagoya, Aichi, Japan; Aichi Cancer Center Hospital, Nagoya, Aichi, Japan and Faculty of Medicine, Universitas Padjadjaran, Bandung, Indonesia.

Background
DSS1 (deleted in split-hand/split-foot malformation 1) was originally identified as a BRCA2-associated protein, and its downregulation results in the degradation of BRCA2. Some reports demonstrated that BRCA2 overexpression was correlated with histopathological grade III in sporadic breast cancers, implicating the involvement of BRCA2 overexpression in the proliferation rate of breast cancer cells. Because DSS1 is a stabilizer of BRCA2, we investigated whether altered expression of DSS1 was associated with malignant advancement of sporadic breast cancers. By comparison of DSS1 mRNA level, we reported that the high DSS1 expression groups in breast cancer patients showed worse prognosis in relapse-free survival; however, DSS1 expression per se was not correlated with other clinical parameters including cellular proliferation or tumor grade. Therefore, we hypothesized that breast cancer cells highly expressing DSS1 might be resistant to anti-cancer drugs, and compared chemosensitivity in overexpression or underexpression of DSS1 in breast cancer cells.

Methods
We established MCF7 overexpressing DSS1 (MCF7/DSS1) by retroviral transfection. DSS1 or BRCA2 knockdown in MCF7 was performed using siRNA transfection. The susceptibility to the cytotoxic chemotherapy such as doxorubicin and paclitaxel in breast cancer cells was analyzed by flow cytometry to detect apoptosis.

Results
MCF7/DSS1 showed more resistant to cytotoxic drugs compared with GFP-control MCF7 transfectants (MCF7/GFP). The percentages of apoptotic cells in MCF7/DSS1 and MCF7/GFP treated by doxorubicin were 40.2% and 12.0%, respectively. Conversely, depletion of DSS1 in breast cancer cells resulted in enhanced chemosensitivity compared to control cells. Although DSS1 knockdown induced the downregulation of BRCA2, BRCA2 depletion itself did not show such enhancement of chemosensitivity.

Conclusion
Consistent with the cohort study of sporadic breast cancers, we demonstrated that high expression of DSS1 increased resistance of breast cancer cells to cytotoxic chemotherapy in vitro. Conversely, DSS1 knockdown increased the susceptibility to these drugs in spite that BRCA2 depletion did not affect chemosensitivity. These results indicate that DSS1 could be a molecular target to increase chemosensitivity, which is independent of BRCA2 expression.
Title: Notch3 as a predictor of GSI sensitivity in distinct subtypes of triple negative breast cancer

Shah D and Osipo C. Loyola University Chicago, Maywood, IL.

Body: Breast cancer is the second leading cause of cancer-associated death in women. Triple negative breast cancer (TNBC) accounts for 10-15% of breast cancer, lacks expression of ER, PR, and HER2 gene amplification. Due to lack of targeted therapy, TNBC has the worst prognosis. TNBC is a heterogeneous disease with six distinct subtypes. Current treatment includes combination of surgery, radiation therapy and chemotherapy. Notch signaling is increased in TNBC and predicts for worst overall outcome. The goal of the study is to identify novel Notch-biomarkers that predict sensitivity of subtypes of TNBC to Notch inhibition in both bulk and cancer stem cells.

Methods: Two subtypes of TNBC, Mesenchymal stem-like MDA-MB-231 and basal like MDA-MB-468 cells were used. Notch signaling was evaluated using both RNA-sequencing and quantitative real time PCR (q-RTPCR). Cancer stem cell markers were evaluated using Aldefluor assay, CD44 high/ CD24 low expression, and mammosphere forming assay. To study the effect of chemotherapy and Notch, MDA-MB-231 and MDA-MB-468 cells were treated with carboplatin or a pan Notch inhibitor- gamma secretase inhibitor (GSI) or combination of both and cell viability was measured using the trypan blue exclusion test.

Results: The RNA-seq and RT-PCR results showed that Notch3 is differentially expressed in the two cell lines. Notch3 was knocked down using siRNA and its effect on cell viability was assessed after GSI or carboplatin or combination treatment. MDA-MB-468 cells had higher Notch receptors and activity, most notably Notch3. MDA-MB-468 cells had high levels of Aldefluor whereas MDA-MB-231 cells showed higher levels of CD44 High/CD24 Low expression. MDA-MB-468 cells had higher mammosphere forming efficiency (MFE) compared to MDA-MB-231. Notch inhibition decreased MFE of MDA-MB-468 whereas it increased MFE of MDA-MB-231 cells. MDA-MB-468 cells have lower IC50 for carboplatin or GSI compared to MDA-MB-231 cells, as measured by cell viability assay. However, combination treatment lowered IC50 for GSI in MDA-MB-231 cells as compared to MDA-MB-468 cells. Since Notch3 levels were strikingly different between the two cell lines, we hypothesized that Notch3 levels are necessary for GSI sensitivity. Carboplatin treatment increased Notch3 in MDA-MB-231 cells and the increase in Notch3 could be the reason for lower IC50 of GSI during combination treatment as increased Notch3 would provide the substrate for gamma-secretase. In MDA-MB-468 cells, Notch3 knockdown significantly reduced cell viability and was similar to GSI, suggesting that GSI acts through Notch3. Furthermore, Notch3 knockdown and carboplatin treatment reduced viability comparable to carboplatin and GSI treatment, reinforcing that the GSI acts through Notch3 in TNBC. Using the Kaplan-Meier Plotter, high Notch3 predicted poor recurrence free survival post chemotherapy in patients with ER-, HER2-, basal breast cancer.

Conclusions: GSI acts through Notch3 in two TNBC subtypes and combination of chemotherapy with Notch inhibition results in a better outcome as compared to either drug alone. Future experiments would elucidate the role of Notch3 inhibition in targeting cancer stem cells post chemotherapy treatment in different subtypes of TNBC.
Title: Prognostic role and impact of multi-clonal ER and PgR expression in ductal carcinoma in situ: Results from the UK/ANZ DCIS trial

Thorat MA, Jones LJ, Levey PM, Elia G, Evagora CA, Bundel NJ, Fentiman IS, Forbes JF and Cuzick J. Background:
Majority of studies investigating prognostic role of ER and PgR expression in ductal carcinoma in situ (DCIS) have failed to show a significant relationship with recurrence. Branched evolutionary tumour growth and resulting intratumour heterogeneity is now increasingly acknowledged in a variety of cancers. DCIS offers the opportunity to investigate relevance of clonal populations in different ducts that may have evolved differently and may impact outcome differently. We investigated prognostic role of ER and PgR expression in DCIS and impact of clonal variation in ER/PgR expression using material from UK/ANZ DCIS trial.

Methods:
Formalin-fixed paraffin embedded tissues (FFPETs) were collected from patients enrolled in the UK/ANZ DCIS trial, a randomised 2X2 factorial design trial investigating role of tamoxifen, radiotherapy or both as adjuvant treatment in DCIS. A nested case-control design was used; cases (patients with recurrence) were matched by treatment arm and age to 2 controls each (no recurrence).

ER and PgR expression was evaluated on whole sections by immunohistochemistry using 1D5, PGR636 antibodies and EnVision™ FLEX + detection system (Dako). Assays were scored by Allred method (positive if expression >1%) and clonal method. Clonal method documented presence of ducts with complete lack of ER or PgR expression in otherwise ER or PgR positive (Allred method) DCIS. Analyses categorising such multi-clonal DCIS as ER or PgR positive as per current practice (standard) and categorising these as ER or PgR negative DCIS (clonal method) were performed.

Results:
Of 540 samples (180 cases, 360 controls), ER and PgR status was evaluable in 504 and 498 patients respectively. ER expression was absent (ER-) in 148 (29.4%), 356 (70.6%) were ER positive (ER+) with 39 (7.7%) of these displaying multi-clonal expression (ERmulti-clonal). PgR expression was absent in 163 (32.7%), 335 (67.3%) were PgR positive with 84 (16.9%) of these displaying multi-clonal expression.

ER- DCIS showed increased risk (Table) of in situ ipsilateral breast event (DCIS-IBE) and invasive ipsilateral breast event (I-IBE) (borderline significance). Prognostic discrimination was higher when ER status was determined by clonal method (ΔX² 1.57 for I-IBE and 9.05 for DCIS-IBE). Increases in the risk of I-IBE and DCIS-IBE were similar for ER- and ERmulti-clonal DCIS.

</table>
Lack of PgR expression was only associated with increased risk of DCIS-IBE and PgR status did not add to the prognostic information provided by ER status.

Conclusions:
ER expression is prognostic for recurrence in DCIS. ER+ DCIS with distinct ER- clones has a recurrence risk similar to ER- DCIS. ER scoring should take clonality of expression into account.
Title: Prognostic and predictive relevance of HER2 status in ductal carcinoma in situ: Results from the UK/ANZ DCIS trial

Thorat MA A, Wagner S, Jones LJ J, Levey PM M, Bulka K, Hoff R, Sangale Z, Flake II DD D, Bundred NJ J, Fentiman IS S, Forbes JF F, Lanchbury JS S and Cuzick J. Centre for Cancer Prevention, Wolfson Institute of Preventive Medicine, Queen Mary University of London, London, United Kingdom; Centre for Tumour Biology, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom; Blizard Institute Core Pathology, Blizard Institute of Cell and Molecular Science, Queen Mary University of London, London, United Kingdom; School of Medicine and Public Health, The University of Newcastle, Australia, Callaghan, New South Wales, Australia; Institute of Cancer Sciences, The University of Manchester, Manchester, United Kingdom; Guy's Hospital, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom and Myriad Genetics, Inc., Salt Lake City, UT.

Body: Background:
As compared to invasive breast cancer (IBC), HER2 is much more frequently overexpressed in ductal carcinoma in situ (DCIS). Unlike IBC, the prognostic significance of HER2 overexpression remains to be established in DCIS and large studies to investigate its predictive role are lacking. We investigated the prognostic and predictive relevance of HER2 protein and ERBB2 mRNA expression in DCIS using material from UK/ANZ DCIS trial.

Methods:
Formalin-fixed paraffin embedded tissues (FFPETs) were collected from patients enrolled in the UK/ANZ DCIS trial, a randomised 2X2 factorial design trial investigating role of tamoxifen, radiotherapy or both as adjuvant treatment in DCIS. ERBB2 mRNA expression was evaluated by reverse transcription followed by PCR on customized Taqman low-density arrays. ERBB2 mRNA expression was analysed as a continuous variable and also as a binary variable using a cut-off to reproduce HER2 expression distribution similar to that observed with immunohistochemistry (IHC). HER2 protein expression was evaluated by IHC using HercepTest™ and scored as per ASCO-CAP 2013 recommendations; HER2 equivocal (IHC2+) were grouped with HER2 negative (IHC 0 or 1+) for main analyses. Additional analyses using binary ERBB2 mRNA expression as a reflex test for HER2 IHC2+ were also performed.

Results:
HER2 protein expression was evaluable in 713 (181 events) of 755 available samples (DCIS absent or lost during assay in 42). ERBB2 mRNA expression was evaluable in 521 (134 events) of 704 available samples (DCIS absent or insufficient RNA in 51, assay failure in 132). Both results were available in 508 cases (130 events). Increase in ERBB2 mRNA expression (median 0.62; range 0.07-36.76) was associated with increased risk of in situ ipsilateral breast event (DCIS-IBE) [Hazard ratio (HR) = 1.07; 95% Confidence Interval (95%CI) 1.04-1.10; p < 0.0001] but not with increased risk of invasive ipsilateral breast event (I-IBE) [HR = 1.03; 95%CI 0.97-1.10; p = 0.3209]. HER2 positivity by IHC was similarly associated with increased risk of DCIS-IBE [HR = 2.90; 95%CI 1.91-4.40; p < 0.0001] but not with increased risk of I-IBE [HR = 1.40; 95%CI 0.81-2.42; p = 0.2313]. Reclassification of HER2 IHC2+ cases using binary ERBB2 mRNA expression (46 as negative, 16 as positive; 18 expression data unavailable) further improved prognostic discrimination of HER2 IHC [ΔΧ² (1d.f.) 5.51; p = 0.0189] for any recurrence. The effect of radiotherapy (RT) for reducing I-IBE was greater in HER2 positive (by ERBB2 mRNA expression) cases [HR = 0.24; 95%CI 0.07-0.83; p = 0.0237] as compared with HER2 negative cases [HR = 0.60; 95%CI 0.23-1.55; p = 0.2925]. Kaplan-Meier estimates of 10-year I-IBE rates with and without RT were 4.5% (2.5%-1.4%) and 15.8% (9.6%-25.3%) in HER2 positive DCIS; rates in HER negative DCIS were 5.2% (2.1%-2.4%) and 7.3% (4.3%-12.2%) respectively. The differential benefit of RT by HER2 status was also seen for reduction in DCIS-IBE.

Conclusions:
HER2 overexpression is associated with increased risk of DCIS-IBE but not of I-IBE. HER2 status is predictive of radiotherapy response with larger reductions in both I-IBE and DCIS-IBE seen in HER2 positive DCIS.
**Title:** PIK3CA mutations predict resistance to trastuzumab/pertuzumab and nab-paclitaxel in primary HER2-positive breast cancer – Massive parallel sequencing analysis of 293 pretherapeutic core biopsies of the GeparSepto study

Loibl S, Budczies J, Weichert W, Furlanetto J, Stenzinger A, Pfarr N, von Minckwitz G, Jackisch C, Schneeweiss A, Fasching P, Schmatloch S, Aktas B, Nekljudova V, Weber K, Untch M and Denkert C. German Breast Group, Neu-Isenburg, Germany; Charite University of Berlin, Berlin, Germany; University Hospital Heidelberg, Heidelberg, Germany; Sana Klinikum Offenbach, Offenbach, Germany; University Hospital Erlangen, Erlangen, Germany; Elisabeth Krankenhaus Kassel, Kassel, Germany; University Hospital Sen, Essen, Germany and Helios Kliniken Berlin-Buch, Berlin, Germany.

**Body: Background:** Phosphatidylinositol 3-kinase mutations (PIK3CA) are common in breast cancer (BC). Mutations are predominantly found in hot-spots located in the helical and kinase domains (exons 9 and 20). We recently demonstrated that PIK3CA mutations predict lower pathological complete response (pCR) to double blockade with trastuzumab/lapatinib in HER2+ve primary BC.

**Methods:** We evaluated PIK3CA mutations in 293/403 HER2+ve tumors of participants of the neoadjuvant GeparSepto (G7) study (Untch et al. SABCS 2014). The G7 study investigated the effect of exchanging paclitaxel for nab-paclitaxel prior to EC. All patients received trastuzumab and pertuzumab. The G7 study showed a significantly higher pCR rate in patients receiving nab-paclitaxel. HER2, hormone receptors (HR), Ki67 and tumor infiltrating lymphocytes (TILs) were centrally assessed prior to randomization. PIK3CA mutations in exons 9 and 20 were evaluated in formalin-fixed, paraffin embedded core biopsies taken before therapy using deep targeted massive parallel sequencing with a minimum coverage of 500 and a mean coverage of 6520 and 6346 per amplicon, (exon9 and exon 20). Only non-synonymous mutations in the coding region that were called at variant allele frequency ≥10% were taken into consideration. Only cases with a tumor cell content of ≥20% were included.

**Results:** In the G7 study, 396 patients with HER2+ve BC have been randomized from 06/2012 to 01/2014 and started treatment. From these 293 could be sequenced. Median age in the analyzed cohort was 49 years (range 22-75); most tumors were cT1-2 (89.9%); cN0 (54.4%); ductal invasive (88.7%), grade 3 (53.9%), HR+ve (69.6%), Ki67>20% (69.3%), LPBC-negative (83.2%). Overall, 22.2% of the tumors were found to have a PIK3CA mutation, 20.1% in HR+ve and 27.0% in HR-ve. Overall, the pCR rate was significantly lower in the PIK3CA mutant tumors compared to the wild type (wt) group (47.7% vs. 66.7%; p=0.009). This effect was seen both in the HR+ve (43.9% vs. 61.3%; p=0.052) and the HR-ve population (54.2% vs. 80.0%; p=0.029). There was also a significant difference in pCR according to PIK3CA mutation status dependant on the taxane. In the nab-paclitaxel group, pCR rates were significantly lower in patients with PIK3CA mutations compared to those without PIK3CA mutations (38.7% vs. 72.0%; p=0.001), whereas in the paclitaxel group, there was no significant difference between patients with and without a PIK3CA mutation (55.9% vs. 60.9%; p=0.690). The respective interaction could be demonstrated in univariate (p=0.039) as well as multivariate regression analysis (p=0.010) after adjusting for known baseline factors.

**Conclusion:** Patients with PIK3CA mutantHER2+ve BC have a significantly lower pCR rate compared to patients with wt tumors. In contrast to the results with double anti-HER2 blockade consisting of trastuzumab/lapatinib, the effect was evident irrespective of the HR status. In addition, PIK3CA mutation status was significantly associated with higher pCR following nab-paclitaxel.

The project has partly been funded within the EU-FP7 project RESPONSIFY No 278659 and the German Cancer Consortium (DKTK).
Title: Intrinsic subtype and therapeutic response among early stage HER2-positive breast tumors from the North Central cancer treatment group (Alliance) N9831 trial

Body: Importance: 20-25% of patients with early stage HER2-positive breast cancer develop tumor relapse after adjuvant trastuzumab. Identification of such patients is a key goal for clinical management decisions.

Objective: To assess molecular heterogeneity among early stage HER2-positive patients using the Prosigna™ algorithm, to define intrinsic subtypes, and to determine the clinical significance of such heterogeneity.

Design: The NanoString® platform was used to measure the abundance of the PAM50 subtype signature transcripts. Samples from the NCCTG (Alliance) N9831 trial were analyzed using the Prosigna™ algorithm to define intrinsic subtype and risk scores. Subtypes were evaluated for recurrence-free survival following chemotherapy with or without trastuzumab.

Setting: Samples were obtained from a multi-center randomized phase III trial of chemotherapy versus chemotherapy plus trastuzumab.

Participants: All tumors were centrally evaluated for HER2 positivity, defined as IHC 3+ and/or FISH >2.0; 1392 patients were evaluated for molecular subtype.

Intervention(s): Patients received adjuvant chemotherapy (doxorubicin plus cyclophosphamide followed by paclitaxel) (n=484) or chemotherapy plus trastuzumab (n=908).

Main Outcome Measure(s): The primary outcome was recurrence-free survival as a function of subtype and treatment.

Results: Patients with HER2-positive tumors with HER2-enriched features comprised about 70% of the sample cohort, and these individuals received significant benefit from adjuvant trastuzumab (HR=0.68, 95%CI: 0.52, 0.89, p=0.005), as did the relatively fewer patients (291/1392) with Luminal-type tumors (HR=0.52, 95%CI: 0.32, 0.85, p=0.01). The sample cohort contained a small number of patients with tumors having Basal-like features (97/1392), and the data suggest that these individuals may have received less benefit from trastuzumab, beyond that received from chemotherapy alone (HR=1.06, 95%CI:0.53,2.13, p=0.87).

Conclusions: The majority of HER2-positive tumors are classified as HER2-enriched or Luminal using the Prosigna algorithm, and patients with such tumors benefit from adjuvant trastuzumab. About 10% of HER2-positive tumors exhibit Basal-like genomic features, and such tumors appear to recur at fairly similar frequency irrespective of treatment with chemotherapy or chemotherapy plus trastuzumab. Patients with HER2-positive/Basal-like tumors may represent a cohort that should be considered for enrollment in trials to evaluate emerging novel HER2-targeted agents, other targeted therapies, or combinations of both approaches.

Support provided in part by CA129949 and CA15083.
**Title:** Non-amplification ERBB2 genomic alterations in 5,605 cases of refractory and metastatic breast cancer: An emerging opportunity for anti-HER2 targeted therapies

**Body:** Background: Non-amplification ERBB2 alterations (ERBB2 mut) in advanced/metastatic breast cancer (mBC) are not detected by IHC or FISH, but when detected by DNA sequencing assays can lead to clinical responses to anti-HER2 targeted therapy. We queried a database of more than 43,000 clinical cases to uncover the frequency, type and associated genomic alterations (GA) in mBC driven by ERBB2 mut and highlight clinical responses to small molecule drug and antibody-based anti-HER2 therapeutics.

Methods: DNA was extracted from 40 microns of FFPE sections from 5,605 mBC. Comprehensive genomic profiling (CGP) was performed using a hybrid-capture, adaptor ligation based next generation sequencing assay of up to 315 genes to a mean coverage depth of >600X. The results were analyzed for base substitutions, short insertions and deletions, selected rearrangements, and copy number changes.

Results: 698 (12.5%) of 5,605 mBC featured ERBB2 alterations. 596 (10.6%) featured ERBB2 amplifications and 137 (2.4%) featured ERBB2mut. 35 (0.6%) of total mBC had both ERBB2amp and ERBB2mut, which accounted for 5.0% of all ERBB2 altered mBC. The 137 ERBB2mut mBC cases had a median age of 61 years (range 29 to 93 years) and were sequenced to a mean depth of 600X. Samples utilized for CGP included 52 (38%) from the patient's primary BC and 85 (62%) from metastatic sites including bone/soft tissue/skin (12%), liver (20%), LN (14%), serous cavities (6%), lung (4%) and miscellaneous sites (6%). 71 (52%) mBC were submitted as carcinoma NOS, 44 (32%) as IDC, 22 (16%) as ILC and 1 (1%) as mucinous mBC. Of the 137 ERBB2mut cases, 8 featured more than 1 ERBB2 mut. There were 124 (85%) ERBB2 kinase domain mutations and 15 (10%) extra-cellular domain ERBB2mut. The most common genes co-altered in ERBB2mut mBC were TP53 (49%), PIK3CA (42%), CDH1 (37%), MYC (17%), and CCND1 (16%). The enrichment of ERBB2mut in CDH1 mut mBR was significant (p=0.0006) and associated with relapsed lobular mBC. Multiple case examples of kinase domain and extra-cellular domain ERBB2mut mBC responding to a variety of anti-HER2 targeted therapies will be presented.

Conclusions: In this large series of 5,605 mBC, 20% of the total ERBB2 alterations were non-amplification ERBB2mut not detectable by standard of care IHC and FISH slide-based HER2 tests. Given the demonstration of ERBB2mut driven mBC responsive to anti-HER2 targeted therapies in this study, expansion of clinical trials designed to detect these ERBB2mut cases with CGP and optimize the targeted therapies for these patients is strongly recommended.

Title: Objective measurement of HER2 (ERBB2) intracellular and extracellular domain spatial co-localization stratifies benefit from adjuvant trastuzumab

Carvajal-Hausdorf DE, Toki M, Schalper KA A, Pusztai L, Pysrri A, Kalogeras KT T, Kotoula V, Fountzilas G and Rimm DL L. Yale University, New Haven, CT; Yale University, New Haven, CT; Attikon University Hospital, Athens, Greece; Aristotle University of Thessaloniki, Thessaloniki, Greece and Aristotle University of Thessaloniki, Thessaloniki, Greece.

Body: Background: The ASCO/CAP guidelines consider chromogen-based immunohistochemistry (IHC) as the primary assay to determine HER2 status in breast cancer. U. S. Food and Drugs Administration (FDA) approved HER2 antibody assays target the protein's intracellular domain (ICD). Studies suggest that quantitative, domain-specific measurement of HER2 might predict benefit from trastuzumab therapy, further classifying traditional HER2-positive breast cancer. Here we define a method of simultaneous, objective measurement of HER2 ICD and extracellular (ECD) domains, and determine its effect on trastuzumab benefit in the adjuvant setting.

Methods: We measured co-expression of HER2 ICD and ECD using a proximity ligation assay (PLA) and quantitative immunofluorescence (QIF) in a HER2 standardization tissue microarray (TMA) with CLIA-lab defined HER2 status. Previously validated, standardized HER2 antibodies were used to detect ICD and ECD (CB11 and SP3, respectively). We determined the relationship between HER2 PLA scores, HER2 clinical status and domain-specific scores. Finally, we measured HER2 ICD/ECD PLA in 180 patients from a clinical trial of adjuvant chemotherapy followed by trastuzumab (HeCOG 10/05). Median cut-point was used to stratify patients according to HER2 PLA scores. Cut-points for HER2 ICD and ECD were obtained using Joinpoint software. All statistical tests were two-sided.

Results: In the standardization TMA, HER2 PLA levels were associated to HER2 CLIA status (P<0.0001). There was a good correlation between HER2 PLA scores and HER2 ICD and ECD (R²=0.57 and R²=0.54, respectively). In trastuzumab-treated patients from HeCOG 10/05, a similarly good correlation was observed between HER2 PLA scores and HER2 ICD and ECD (R²=0.41 and R²=0.3, respectively). In univariate analysis, HER2 PLA-low status was associated with ER-positive status (P=0.005). There was no association with age, histological grade, tumor size, lymph node status and TNM stage. Although all tumors were HER2-positive, HER2 PLA-high status was significantly associated with longer 5-year disease-free survival (DFS) (log-rank P=0.036, HR=0.32, 95% CI: 0.132-0.935). HER2 PLA status was superior to ICD status (log-rank P=0.67) and numerically comparable to ECD status (log-rank P=0.049, HR=0.31, 95% CI: 0.144-0.997) to predict benefit from adjuvant trastuzumab, as previously published by our group. HER2 PLA high status was independent predictor of better outcome in a Cox proportional hazards model including age, histological grade, ER status, tumor size, lymph node status and TNM stage.

Discussion: Using an objective, quantitative HER2 assay for synchronous, domain-specific measurement, we stratified benefit from adjuvant trastuzumab treatment in patients from a prospective cohort. Our results further support the concept that benefit from HER2 ECD-targeted therapies might be modulated by the presence of truncated HER2 protein variants and that tyrosine kinase inhibitors (ICD-directed) may be advantageous for a subset of HER2-positive patients. Furthermore, this technique that uses two antibodies has the potential to increase both sensitivity and specificity of the IHC assay to predict response to HER2 pathway inhibitors.
Title: The updated ASCO/CAP guidelines for HER2 testing create more uncertainty for clinicians

Chen J, Klein P and Shao T. Mount Sinai Beth Israel Medical Center, NY, NY.

Body: Background: Accurate assessment of the Human Epidermal Growth Factor Receptor 2 (HER2) status has been an integral part of clinical decision making in treatments of breast cancer. In 2007, American Society of Clinical Oncology (ASCO)/College of American Pathologists (CAP) published a series of guidelines on how to determine the status of HER2. The guidelines were updated in 2013 with the goal of reducing the numbers of false negative cases. The new guidelines are based on a combination of HER2:CEP17 ratio and average HER2 copy number. We sought to assess the overall effect of the new guidelines.

Methods: We retrospectively identified all cases of invasive breast cancer with HER2 testing done in 2014 from the pathology database of Mount Sinai Beth Israel, Mount Sinai St. Luke's and Roosevelt Hospitals. Our pathology department guideline is to perform initial testing for HER2 with immunohistochemistry (IHC) by the HercepTest (Dako) method. Those with IHC of 2+ would be followed by reflex HER2 dual probe FISH. The HER2:CEP 17 ratio and average HER2 copy number were then reviewed for each IHC 2+ case using the 2013 guidelines. These cases were then rescored using the 2007 guidelines. All equivocal cases as determined by the new 2013 guidelines (HER2:CEP17 ratio <2.0 with an average HER2 copy number ≥4.0 and <6.0 signals/cell) were further evaluated to determine whether repeat HER2 testing was performed as suggested by the new guidelines and whether HER2 directed therapy was recommended for patient.

Results: Among 853 cases identified in the database, 337 were IHC 2+. Using 2007 guidelines, 27/337 cases (8.0%) were amplified (HER2:CEP 17 ratio >2.2), 6 (1.8%) were equivocal (HER2:CEP 17 ratio 1.8-2.2), and 305 cases (90.2%) were non-amplified (HER2:CEP 17 ratio <1.8). Using the 2013 guidelines, 29/337 cases (8.6%) were amplified (HER2:CEP 17 ratio ≥2 or HER2 copy number ≥6), 23 (6.8%) were equivocal (HER2:CEP17 ratio <2.0 with an average HER2 copy number ≥4.0 and <6.0), and 284 (84.3%) were non-amplified (HER2:CEP 17 ratio <2 with an average HER2 copy number <4.0). The new guidelines resulted in change in HER2 status in 24 cases (7.1%): 2 cases changed from equivocal to amplified, 1 case changed from equivocal to non-amplified, but 20 cases changed from non-amplified to equivocal. Of the 23 equivocal cases determined using the 2013 guidelines, only 13 cases had repeat HER2 analysis. On repeat HER2 testing, one case was found to be HER2 amplified, 4 cases were non-amplified, and 8 cases remained equivocal. Only one equivocal case received HER2 directed treatment.

Conclusion: The 2013 ASCO/CAP guidelines for HER2 assessment identified a slightly increased number of patients eligible for HER2 directed therapy, but also resulted in a significant increase in the number of equivocal cases. The new guidelines appear to have generated more uncertainty for the clinician due to the rise in equivocal cases. Further studies are needed to determine whether patients with equivocal HER2 status would benefit from HER2 directed therapy.
**Title:** Quantitative HER family proteins assessment as prognostic and predictive biomarkers in the EGF30008 clinical trial

**Body:**

**Background**

Combined targeted strategy with letrozole (Le) and lapatinib (La) improves progression-free survival (PFS) in patients with metastatic breast cancer (MBC) co-expressing hormone receptor-positive (HR+) and HER2+ but not in HR+/HER2-negative (HER-) disease (Johnston J Clin Oncol 2009). However, among HER2+ tumors, quantitative levels of HER2 are heterogeneous with a broad dynamic range corresponding to approximately 163.7 to 17446.7 amol/µg as previously reported (Nuciforo SABCS 2014). In addition, within HER2- tumors, quantitative measurement of HER family proteins may identify those patients most likely to benefit from the addition of La to Le. In this retrospective study, we tested the prognostic and predictive ability of HER proteins quantification in clinically HER2+ tumor samples from the EGF30008 study.

**Methods**

Formalin-fixed paraffin-embedded primary tumor tissues sections from HER2+ MBC population were used. After laser microdissection, tissue lysates were prepared for selected reaction monitoring mass spectrometry (SRM-MS) analysis. Absolute quantitation was accomplished through simultaneous detection of endogenous target and synthetic labeled heavy peptide identical to analytical targets (EGFR, HER2, HER3). HER2 protein levels were correlated with PAM50 molecular subtypes, ERBB2 and ESR1 genes by nCounter. PFS and overall survival (OS) were analyzed by Kaplan–Meier and log-rank test. To determine whether HER2 protein levels were predictive of La benefit, we tested the interaction term of HER2 protein as a continuous variable by treatment arm in a Cox model.

**Results**

Within the HER2+ study cohort (n=219), 107 had an available tumor block; 84 cases had sufficient material for HER expression measurement by SRM-MS. Average HER2 levels were 2321.1 amol/µg (median, 817.6). HER2 levels were lower in Le+La (n=43; mean, 1761 amol/µg) compared to Le (n=41; mean, 2908 amol/µg) arms, although the difference was non-significant (p=0.108). No expression of EGFR and HER3 was observed. HER2 protein levels were significantly different among PAM50 subtypes with HER2-enriched (HER2E) tumors showing the highest expression followed by Basal-like, Luminal A, Luminal B, and Normal-like (p<0.001). A correlation between HER2 protein, ERBB2 (r=0.5, p<0.001) and ESR1 (r=-0.5, p=0.001) gene expression was found. In patients with disease that expresses HER2 protein levels above the median a trend towards worse PFS (2.9 vs 7.7 months, p=0.092) and OS (21 vs 39 months, p=0.071) were observed. A statistically significant interaction was observed between HER2 protein levels and La treatment for both PFS (p=0.049) and OS (p<0.001). HER2+ tumors with lower expression of HER2 benefited more from La than those with higher expression.

**Conclusions**

Levels of HER2 protein in HER2+ MBC are extremely heterogeneous. An association between HER2 protein and gene expression by nCounter was observed. HER2E tumors by PAM50 showed the highest levels of HER2 protein. Within the group of HER2+ MBC by standard IHC/FISH, tumors with high HER2 protein had a statistically non-significant worse outcome and do not seem to benefit from La. Further validation of these findings is warranted.

**Title:** Quantitative p95HER2 protein expression is predictive of trastuzumab response in HER2-positive metastatic breast cancer

Sperinde J, Bachmeier B, Weidler JM M, Lie Y, Chenna A, Winslow J, Engel J, Schubert-Fritschle G, Sommerhoff C, Petropoulos C, Bates M, Huang W and Nerlich A. Monogram Biosciences, Integrated Oncology, LabCorp, South San Francisco, CA; Institute of Laboratory Medicine, Ludwig-Maximilians-University, Munich, Germany; Formerly Monogram Biosciences, South San Francisco, CA; Munich Cancer Registry (MCR) of the Munich Tumour Centre, Institute of Medical Informatics, Biometry and Epidemiology (IBE), University Hospital of Munich, Ludwig-Maximilians-University, Munich, Germany; Institute of Laboratory Medicine, Ludwig-Maximilians-University, Munich, Germany and Munich Municipal Hospital, Munich, Germany.

**Body: Background:** Expression of p95HER2 (p95), a truncated form of the HER2 receptor that lacks the trastuzumab binding site but retains kinase activity, has been reported as a prognostic biomarker for poor outcome in trastuzumab-treated HER2-positive metastatic breast cancer (MBC). However, the ability of p95 to predict trastuzumab benefit has not been demonstrated due to the difficulty in obtaining the appropriate control group, namely HER2+ MBC patients not treated with trastuzumab. In the current study, the predictive value of p95 expression was tested in a cohort comprised of HER2-positive MBC patients treated before the availability of trastuzumab and trastuzumab-treated HER2-positive MBC patients.

**Methods:** The current cohort was derived from 206 HER2-positive MBC patients in the Munich Cancer Registry with a median follow up of 64 months. Cases were divided between those that received trastuzumab (n=115) and those that were treated before the availability of trastuzumab (n=91). Quantitative p95 protein expression was measured in formalin-fixed paraffin-embedded samples using the p95 VeraTag® assay (Monogram Biosciences), which is specific for the active M611 form of p95. Quantitative total HER2 protein expression was measured using the HERmark® assay (Monogram Biosciences). p95 and HERmark cutoffs were pre-specified (Duchnowska, Clin Cancer Res, 20:2805, 2014 and Huang, Am J Clin Pathol, 134:303, 2010). Analyses with p95 were restricted to samples with confirmed HER2 overexpression by HERmark. All hazard ratios (HR) were stratified by estrogen receptor status and grade.

**Results:** Consistent with previous training (Sperinde, Clin Cancer Res, 16:4226, 2010) and validation (Duchnowska, Clin Cancer Res, 20:2805, 2014) datasets, subjects treated with trastuzumab experienced a shorter time to progression (TTP) when p95 expression levels were above the cutoff versus below the cutoff (HR = 3.8, p = 0.019). However, only a trend was observed between p95 expression levels and overall survival (HR = 2.2, p = 0.20), possibly due to a lower frequency of events and relatively small sample size. The predictive value of p95 was assessed by determining the benefit of adding trastuzumab to chemotherapy treatment in subsets below and above the p95 cutoff. As expected, patients with p95 below the cutoff experienced significant benefit in TTP from adding trastuzumab (HR = 0.13, p<0.001), whereas patients with p95 above the cutoff experienced less benefit (HR = 0.70, p=0.47). p95 expression level was predictive of trastuzumab response with an interaction p-value of 0.015. The results for OS were similar, however trastuzumab benefit was less distinct between the two groups (interaction p = 0.18); HR = 0.23, p = 0.0013 below the p95 cutoff versus HR = 0.50, p = 0.14 above the p95 cutoff.

**Conclusions:** In this dataset, quantitative p95 expression was predictive of trastuzumab treatment benefit in MBC. Patients with high p95 expression may be particularly good candidates for dual HER2 blockade, as reported in the NeoALTTO trial (Scaltriti, Clin Cancer Res, 21:569, 2015), or other additional therapies.
Title: The association between the expression of progesterone receptor and clinical benefit of adjuvant trastuzumab in estrogen receptor-positive and HER2-positive breast cancer patients

Lee HW, Ahn SG, Park JT, Yang BS, Park S, Jeong J and Kim SI. Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea and Yonsei University College of Medicine, Seoul, Korea.

Body: 

**Background:** Previous studies have shown that progesterone receptor (PR) status has a prognostic value in hormone receptor-positive breast cancer. In this study, we evaluated the clinical significance of PR status in estrogen receptor (ER)-positive and HER2-positive breast cancer.

**Methods:** We retrospectively analyzed the data of ER+ and HER2+ breast cancer patients who underwent surgery at Gangnam Severance hospital and Severance hospital from 2002 to 2012. We excluded patients who had a history of previous cancer, received neoadjuvant chemotherapy, did not received adjuvant chemotherapy, and had contralateral breast cancer or metastasis at diagnosis. A total of 346 patients were identified. Among them, 155 patients (44.8%) received adjuvant trastuzumab.

**Results:** At a median follow-up of 59 months, median disease-free survival (DFS) and overall survival (OS) were 56 and 59 months, respectively. The DFS and OS showed no difference according to PR status in overall patients. Then, these patients were categorized into two groups: ER+/HER2+/PR+ and ER+/HER2+/PR-. In ER+/HER2+/PR+ patient, there was no difference of DFS or OS according to trastuzumab use. In ER+/HER2+/PR- patients, DFS was significantly better in patients who received adjuvant trastuzumab treatment compared to those who did not (p=0.009). We also analyzed influence of PR status on treatment outcome between patients who received adjuvant trastuzumab and those who did not. In patients who received adjuvant trastuzumab, there was no difference of DFS or OS according to PR status. However, in patients who did not receive adjuvant trastuzumab, ER+/HER2+/PR- patients showed worse DFS than ER+/HER2+/PR+ patients (p=0.006).

**Conclusions:** In patients with ER+/HER2+ breast cancer, we found that a prognostic value of PR only retained in those who did not receive adjuvant trastuzumab. Our findings suggest that the use of adjuvant trastuzumab may offer less clinical benefit for the patients with ER+/HER2+/PR+ breast cancer.
Title: High activation of PI3K pathway defined by PIK3CA mutation, PTEN, and INPP4B expression are associated with trastuzumab efficacy in HER2-positive breast cancer

Sueta A, Yamamoto Y, Takeshita T, Yamamoto-Ibusuki M and Iwase H. Kumamoto University Graduate School of Medical Science, Kumamoto, Japan.

Body: Background
Aberrations of phosphoinositide-3-kinase (PI3K) pathway are extensively found in many human cancers through several mechanisms, including mutation or amplification of PIK3CA and loss of phosphatase and tensin homolog (PTEN) and inositol polyphosphate 4-phosphatase-II(INPP4B). In breast cancer, a number of studies have suggested the putative mechanism of resistance to trastuzumab therapy in terms of PI3K pathway activation. We aimed to evaluate the predictive relevance of these biomarkers to trastuzumab efficacy in HER2-positive disease.

Patients and Methods
A total of 43 breast cancer patients with HER2-positive who received both neoadjuvant treatment and surgery at Kumamoto University Hospital between 2004 and 2012 were selected. The regimens of chemotherapy included anthracycline or taxane-containing drugs in combination with trastuzumab. Using pretreatment tumor tissues, PIK3CA mutations (E542K, E545K, and H1047R) were analyzed by direct dideoxynucleotide sequencing and digital PCR methods. Additionally, the expressions of PTEN, pAkt, and INPP4B were assessed by immunohistochemistry (IHC).

Results
The overall pathological complete response (pCR) rate was 60%. Direct sequencing detected PIK3CA mutations in 21% of all patients, whereas digital PCR detected them in 26 % when the cutoff point of the mutation was set at 1%. In some cases, it was difficult to differentiate mutant DNA from artifact by direct sequencing, but we could identify the mutation clearly using digital PCR. We found the correlation between the proportion of the PIK3CA mutation and the pCR rate; the pCR rates in the patients with PIK3CA mutations with cut-off of 1%, 10% and 20% were 55%, 29%, and 0%, respectively.

There were no significant correlations of clinicopathological features with PIK3CA mutations, copy number status, PTEN, and pAkt expression. Low INPP4B expression was associated with larger tumor size (P = 0.035), and higher nuclear grade (P = 0.031) compared to high expression.

We evaluated the contribution of biomarkers related to the PI3K pathway to the prediction of pCR by logistic regression models. In multivariate analysis, activation of the PI3K pathway due to either PIK3CA mutation or low PTEN expression were related to poorer response to trastuzumab (OR of predictive pCR was 0.11, P = 0.041). Similarly, high activation defined as PIK3CA mutation or low expression of PTEN or INPP4B tend to have lower pCR (OR was 0.14, P = 0.064).

Conclusions
1. Digital PCR has potential to complement the direct sequencing data, leading to more accurate measurement of the mutation frequency.
2. Our findings provide additional support for the recently published studies regarding activating mutation in PIK3CA in HER2-positive breast cancer, and further suggest that integrated biomarkers of PIK3CA mutation, PTEN, INPP4B are stronger predictors of trastuzumab response than either one alone.
**Title:** Homologous recombination deficiency (HRD) as a predictive biomarker of response to neoadjuvant platinum-based therapy in patients with triple negative breast cancer (TNBC): A pooled analysis

Telli ML L, McMillan A, Ford JM M, Richardson AL L, Silver DP P, Isakoff SJ J, Kaklamani VG G, Gradishar W, Stearns V, Connolly RM M, Loibl S, Elkin EP P, Timms K, Hartman A-R and von Minckwitz G. Stanford University School of Medicine, Stanford, CA; Dana-Farber Cancer Institute, Boston, MA; Massachusetts General Hospital Cancer Center, Boston, MA; Harvard Medical School, Boston, MA; UT Medicine Cancer Therapy and Research Center, San Antonio, TX; Northwestern University, Chicago, IL; Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins School of Medicine, Baltimore, MD, Germany; German Breast Group, Neu-Isenburg, Germany and Myriad Genetics, Inc., Salt Lake City, UT.

**Body:**

**Background:** TNBC patients with homologous recombination (HR) deficient tumors have significantly higher pathologic complete response (pCR, ypT0/is ypN0) rates when treated with platinum-based chemotherapy regimens than TNBC patients whose tumors are HR non-deficient. We performed a pooled analysis of 5 phase II studies that included patients with TNBC treated with neoadjuvant platinum-based chemotherapy to better estimate the pCR rates amongst HR deficient and HR non-deficient tumors.

**Methods:** Patients with TNBC and known HR deficiency status from the following clinical trials were available for analysis: PrECOG 0105 (N=72), NCT00148694/NCT00580333 (N=50), NCT01372579 (N=26), TBCRC 008 (N=18). Neoadjuvant chemotherapy regimens included 1) carboplatin, gemcitabine, iniparib, 2) cisplatin with or without bevacizumab 3) carboplatin, eribulin, 4) carboplatin, nab-paclitaxel, with or without vorinostat. HR deficiency status was defined as a high HRD score (42 or higher) and/or presence of a BRCA1/2 tumor mutation (tBRCA). Logistic regression models were used to adjust for study effects. The addition of data from the TNBC platinum-treated arm of GeparSixto (n=101) to this pooled analysis will be available at the time of presentation bringing the total sample size to 267.

**Results:** pCR was achieved in 51 patients (31%) and 104 patients (63%) were HR deficient (31 with high HRD score and tBRCA mutation, 67 with high HRD score only, and 6 with tBRCA mutation only). Patients with HR deficient tumors were more likely to achieve a pCR than those with HR non-deficient tumors: 44% vs. 8% (p<0.01). When adjusting for study effects in separate logistic regression models, patients with HR deficient tumors (OR=12.5), with tBRCA mutations irrespective of HRD score (OR=2.3), or with high HRD scores (OR=14.6) were more likely to have a pCR (see Table).

**Conclusion:** HR deficiency status is a robust predictor of pCR across different neoadjuvant platinum-based regimens. This pooled analysis suggests that HRD can be used to identify TNBC patients with a high probability of obtaining pCR with a platinum-based neoadjuvant chemotherapy regimen.

Title: Homologous recombination deficiency (HRD) as a predictive biomarker of response to preoperative systemic therapy (PST) in TBCRC008 comprising a platinum in HER2-negative primary operable breast cancer

Connolly R, Elkin E, Timms K, Goetz M, Boughey J, Zhang Z, Walsh B, Carpenter J, Storniolo A, Watkins S, Gabrielson E, Hartman A-R and Stearns V. Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD; Myriad Genetics Inc, Salt Lake City, UT; Mayo Clinic, Rochester, MN; University of Alabama at Birmingham, Birmingham, AL; Indiana University, Indianapolis, IN and Anne Arundel Medical Center, Annapolis, MD.

Body: Background:
Biomarkers to predict response to platinum-based therapy in early breast cancer are needed. HRD is a promising predictor of response to DNA damaging agents, such as platinums. We hypothesized that HRD (high HRD score $\geq 42$ and/or tumor BRCA [tBRCA] mutation) would predict pathological complete response (pCR) in patients with HER2-negative early breast cancer treated with PST comprising a platinum, regardless of estrogen receptor (ER) status.

Methods:
TBCRC008 was a multicenter placebo-controlled trial that investigated pCR (no invasive cancer in breast/axilla) following 12 weeks of preoperative carboplatin and albumin-bound paclitaxel with or without vorinostat in patients with ER-positive or triple-negative breast cancer (TNBC) (Connolly RM. JNM 2015). The pCR rate was similar in both arms (vorinostat 25.8%, placebo 29%). We performed an exploratory biomarker study correlating baseline tumor biopsy HRD status with pCR. The analysis population included all patients with available HRD and pCR data. We compared the proportion of patients with pCR by HRD status using Fisher's exact test. A subset analysis compared pCR proportions by high ($\geq 42$) vs. low (<42) HRD score in those patients who did not have tBRCA mutation. A logistic regression model included HRD status, ER status, treatment arm, tumor grade and use of additional anthracycline-based non-study chemotherapy prior to definitive surgery.

Results:
HRD status and pCR data were available for 48/62 patients (30 ER-positive, 18 TNBC). Of these, 46% of tumors were HR deficient (n=22/48, 33% ER-positive [10/30], 67% TNBC [12/18]). We observed a significantly higher pCR rate in patients with HR deficiency vs not (50% vs 7.7%, $p=0.002$) in the overall population. A similar trend was observed in ER-positive (30% vs 5%, $p=0.095$) and TNBC (66.7% vs 16.7%, $p=0.13$) patients. There was no significant difference when analyzed by treatment arm (vorinostat vs placebo). In a subgroup analysis (n=40) of patients without tBRCA (25 ER-positive, 15 TNBC), a significantly higher pCR rate was observed in those with high vs low HRD score (64.3% vs 7.7%, $p <0.001$). After adjusting for ER status, randomized treatment, use of AC treatment, and tumor grade, patients whose tumors exhibited HR deficiency had a greater than 6 fold increase in pCR compared to those without HR deficiency (adjusted odds ratio = 6.76, 95% CI = 0.85-53.99, $p=.072$).

Conclusion:
This is the first study to evaluate the predictive role of HRD status in patients with ER-positive, HER2-negative breast cancer treated with platinum-based therapy. Our results also support prior observations that HRD status is a promising predictive biomarker of response to platinum agents in TNBC. Further evaluation of this question is warranted in both TNBC and ER-positive breast cancer.
**Title:** Prosigna® intrinsic subtyping predicts response to neoadjuvant combination therapy in study that includes herceptin within HER2+ (IHC) patients

**Body:**

**Background:** The role of the HER2-enriched (HER2E) subtype determined by the Prosigna Assay in the neoadjuvant setting has remained largely uncharacterized. In this study, we examine whether Prosigna can identify a subgroup of HER2+ patients for whom combination neoadjuvant therapy that includes trastuzumab (Herceptin) is associated with a greater likelihood of pathological complete response (pCR).

**Methods:** In this single-arm retrospective analysis, 75 patients determined to be HER2+ by IHC were treated with a neoadjuvant regimen (NAC) consisting of 8-12 cycles of anthracyclines and taxanes as well as Herceptin. The Prosigna Assay was performed on the NanoString nCounter® Dx Analysis System at HU Virgende la Victoria de Málaga/CIMES-UMA. pCR was used as the endpoint for this study and was determined using the Miller & Payne scoring criteria.

**Results:** Mean patient age for this study population was 49 (±11.1yr) and all patients were determined to be HER2+ by IHC. The overall pCR rate in this patient population was 46.2%. Of the 75 patient samples analyzed for this study, 59 (78.6%) were HER2E, 4 (5.3%) were Luminal A and 12 (16.1%) were Luminal B, as identified by the Prosigna Assay. Of the 16 tumors classified as Luminal (A or B) by Prosigna within this HER2+ population, only 2 (12.5%) responders were observed. Categorical analysis revealed that Prosigna subtype predicted response to a NAC regimen combined with Herceptin (Odds ratio [Her2E vs. non-Her2E]=6.4, p=0.023). Further analysis of the Her2E subtype revealed that tumors with profile expression that correlated well with the prototypical Her2E centroid were significantly more likely to respond to combination NAC and Herceptin (Odds ratio [Unit increase of 1 in Her2E correlation]=88.2, p=0.004).

**Conclusions:** The results of this study indicate that HER2+ patients with greater correlations to the HER2E subtype have an increased likelihood of response to combination neoadjuvant regimens that included HER2-targeted therapy.
**Publication Number:** P3-07-15

**Title:** Prosigna® subtype correlation is a strong predictor of response to neoadjuvant chemotherapy (NAC) in early breast cancer (EBC) study

**Body: Background:** Prosigna's ROR score was demonstrated as a strong predictor of response to NAC in a representative cohort of EBC patients including HR+/HER2- N0-N1 patients. Given that the ROR score is partially derived from the correlation of the tumor's expression profile to that of the four prototypical intrinsic subtypes, we determined the relative strength of the association between each subtype correlation and the likelihood of response to NAC. **Methods:** We analyzed 294 FFPE breast cancer samples from pts treated with NAC (anthracyclines and taxanes) in a multi-center Spanish cohort. The Prosigna Assay was performed on the NanoString nCounter® Dx Analysis System at HU Virgen de la Victoria de Málaga/CIMES-UMA. Pathologic complete response (pCR) was used as the primary endpoint for this study and was determined using the Miller and Payne scoring criteria. **Results:** Mean patient age in this population was 50 (±11yr). Apart from targeted therapy, all patients received a standard neoadjuvant treatment regimen consisting of 8-12 cycles of anthracyclines and taxanes. 58% of patients were HR+/HER2- while 24% were classified as HER2+ and 18% were TNBC patients. Of the 311 pts samples previously tested, subtype correlation data was available for 294. Overall subtype concordance between IHC and Prosigna was 72% (K=0.66). The overall pCR rate in this population was 24.9%. Prosigna subtype breakdown in the full study population was 60 Luminal A, 118 Luminal B, 69 HER2-enriched and 47 Basal-like with response rates of 7.2%, 7.2%, 46.2% and 57.4%, respectively. We found that in all study populations, subtype correlation was a strong predictor of response to NAC. Tumors with expression profiles that correlated well with the Luminal prototypical centroids were found to be largely unresponsive to NAC (Luminal A Odds ratio=0.074 per unit increase, p<0.0001; Luminal B Odds ratio=0.059 per unit increase, p<0.0001). Conversely, higher HER2E and Basal-like correlations were associated with increased probability of response (HER2E Odds ratio=11.2 per unit increase, p<0.0001; Basal-like Odds ratio=9.0 per unit increase, p<0.0001). Increased proliferation-score (p-score) was also associated with increased probability of response to NAC (Odds ratio=3.43 per unit increase, p<0.0001). **Conclusions:** In a representative cohort of breast cancer patients, both the magnitude of the subtype correlation to the prototypical centroids as well as p-score, as determined by the Prosigna Assay, were strong predictors of response to NAC. This data underlines the importance of molecular testing for optimal systemic therapy indications in EBC.

Comparing surrogates of oncotype Dx recurrence scores in invasive ductal carcinoma: How complicated does it have to be?

Robertson SJ J, Petkiewicz SL L, Arnaout A, Clemons M, Gravel DH H and Pond GR R. EORLA, Ottawa, ON, Canada; University of Ottawa, Ottawa, ON, Canada; The Ottawa Hospital, Ottawa, ON, Canada and McMaster University, Hamilton, ON, Canada.

**Body: Background:** The Oncotype DX Recurrence Score (ODX) is commonly used to estimate recurrence risk and chemotherapy benefit in ER positive, node negative breast cancer but is associated with significant cost. The Magee score (MS), a free online calculation using numerical values of commonly assessed pathological features (ER, PR, Her2/neu, and Ki-67), has been validated as an ODX surrogate. This includes the MS using classic H scores (HMagee) or Surrogate H scores derived from total % positive cells and average intensity or our use of Surrogate H scores derived from Allred scores (SMagee). Also Gage et al (2015) used a simple algorithm based on tumor grade, PR >1% and ER>20%. Here we compare three methods of predicting ODX scores.

**Design:** 61 patients from The Ottawa Hospital with ER positive HER2/neu negative invasive ductal carcinoma (IDC), known ODX were assessed. Classic H scores (CH) were assessed using Image analysis. All cases had Ki67 (1000 cell hot spot score), tumor size, grade, and Allred scores available. Surrogate H scores (SH) were derived (average reported intensity x midpoint of reported Allred positive score range or absolute percentage if between 1-10%). The three MS were calculated with CH giving classic MS (HMagee) and with SH giving surrogate scores (SMagee). Each case was also categorized using rules published by Gage (2015): LOW predicted if Low Grade and PR positive (>1%), HIGH predicted if High Grade or Low ER (<20%). Agreement with classic ODX categories of low (<18), intermediate (18-30) and high risk (≥31) was assessed.

**Results:** ODX included 35 low, 20 intermediate and 6 high risk (Mean 17.4, sd=10). There was a good correlation between corresponding HMagee and SMagee 1-3(0.820, 0.73, 0.84). Concentrating on the theoretically best MS1 that includes Ki67 and all clinical variables (Table 1); HMagee1 predicted 32 cases as low grade with 78% accuracy and SMagee1 predicted 26 low grade with 92.3% accuracy. Of note, all intermediate ODX predicted low by MS were ODX 18-20. None of the MS falsely predicted high risk in low risk ODX. The one case of high ODX which MS predicted low (false negative) is controversial as an Allred ER&PR 8 tumor gave low ODX PR score. Using SMagee1 in this population would safely leave 32 (52.5%) in the intermediate category. Of note, all intermediate ODX predicted low by MS were borderline ODX 18-20. The Gage algorithm in our population is less useful with higher discordance rate and left 69% in the intermediate category.

Conclusions: In IDC, while simpler algorithms without proliferation markers do not perform as well; SMagee1 based on Allred, performs at least as well in prediction of ODX as an MS based on classic H score and can potentially save considerable time and money. In our hands the simpler Gage algorithm does not perform as well.
Body: Oncotype DX (OD) 21-gene breast cancer (BC) assay is used for testing of estrogen receptor positive (ER+) early stage BC and provides a low, intermediate or high 10-year risk recurrence score (LRS, IRS, HRS) for BC. Scores are used as guidelines to predict the probability of successfully adding adjuvant chemotherapy (AC) to endocrine therapy (ET) to reduce the risk of BC recurrence. In retrospective analysis of 2 clinical trials, patients (pts) with HRS benefited from addition of AC to ET, no benefits were shown for LRS, and benefits of AC for IRS were not clear. The OD assay has been utilized since 2004, but data on the impact of using assay results in clinical practice across the US are lacking. The TAILORx and RxPONDER prospective clinical trials which are using OD scores are ongoing (results will be available in 2017 and 2022, respectively) and may help clinicians better understand the predictive capabilities of the IRS OD score.

We analyzed the current impact of IRS OD score in a retrospective observational study of the National Cancer Data Base (NCDB) (which represents 75% of the US population) from 2010-2012. This time period encompasses the beginning of required recording of molecular assays and the latest data released by NCDB in 4/2015. Demographic and clinical variables of all pts with IRS results were analyzed using frequency statistics, chi-square and logistic regression analysis.

Data from 24260/27995 pts with IRS and documented AC information was analyzed. 11520=47.4% pts received AC. Age ranged from 20-90 (mean 58.4, median 59 years); 99.2% were ER+ and females, 2.7% were HER2+; 6143=25.3% had T1a, T1b or T3 tumors; 19791=81.5% were N0, 3684=15.1% N1; 17950=73.6% had ≥G2 tumors and 3389=14% had lymphvascular invasion (LVI).

Selected demographic and clinical characteristics of patients (pts) with -/+ chemotherapy (AC)

IRS OD result had poor PPV for the administration of AC (47.4%). AC administration was significantly associated with larger tumors, LN+, LVI, high tumor grade, higher TNM stage, younger age and black race (p<.001), but not with facility type (community/comprehensive/academic-research program), income, or education (p>0.05). Medicare pts were less likely to receive AC than ones with private insurance (p<.001).

Our data analysis reveals that additional guidelines for selection of pts for OD testing and new algorithms for AC administration in the IRS subsets are needed. The authors of this abstract solicit a call to action from interested parties on behalf of the patients affected by this conundrum.

Orucevic A, Heidel RE E and Bell JL L. The University of Tennessee Medical Center, Knoxville, TN.

Oncotype DX (OD), initially used for early stage estrogen receptor-positive (ER+), node-negative (LN-) invasive breast cancers (BC) and later also for ER+ and 1-3 LN+BC, provides a low, intermediate or high 10-year risk recurrence score (LRS, IRS or HRS) for BC. Based on the score, the addition of adjuvant chemotherapy (AC) to endocrine therapy is recommended for HRS; no benefit for LRS, and unclear benefits for IRS.

The test has been in use since 2004. Payment for OD was approved by the Centers for Medicare & Medicaid Services in 2006. Patient selection for OD use remains unclear, and data on utilization and impact of the assay in clinical practice across the US are lacking.

The utilization and impact of OD across the US is presented in a retrospective observational study of National Cancer Data Base (NCDB) patients (represents 75% of the US population) from 2010-2012. This time period encompasses the beginning of required recording of molecular assays and the latest data released by NCDB in 4/2015. Demographic and clinical variables of all patients that had OD results were analyzed using frequency statistics, chi-square and logistic regression analysis.

513080 patients had BC; 406525 were ER+. 86409 patients with known OD results were analyzed (23.7% of ER+). Patients age range from 19-90 (mean 58.8, median 59 years); 99.1% were females.

The OD is obtained in almost ¼ of ER+BC patients across the US. Its application across geographic and racial groups is fair. Factors influencing patient selection for OD test and AC administration upon obtaining IRS results require further study.
Title: Progesterone receptor positivity is an independent predictor of long-term benefit from adjuvant tamoxifen treatment of estrogen receptor positive breast cancer

Fohlin H, Nordenskjöld A, Fornander T, Löfdahl B, Skoog L and Stål O. Linköping University, Linköping, Sweden; Regional Cancer Center South East Sweden, Linköping, Sweden; Institute of Clinical Sciences, Sahlgrenska Academy, Sahlgrenska University Hospital, Gothenburg, Sweden; Southern Älvsborg Hospital, Borås, Sweden; Karolinska University Hospital, Stockholm, Sweden; Unilabs, St Göran Hospital, Stockholm, Sweden and Karolinska University Hospital, Karolinska Institute, Södersjukhuset, Stockholm, Sweden.

Body: Introduction: The expression of estrogen receptor (ER) and progesterone receptor (PgR) predicts the response to endocrine therapy of breast cancer. Nearly all PgR positive tumors are also ER positive. The independent predictive information of PgR has been questioned after an overview by the EBCTCG. However, the studies in the overview were performed before modern PgR immunohistochemistry (IHC) was developed.

Purpose: We aim to investigate the independent predictive value of PgR determined by IHC in ER positive tumors.

Materials and methods: Between 1976 and 1990 the Stockholm Breast Cancer Study Group conducted a randomized trial comparing adjuvant tamoxifen versus control. We evaluated 618 patients with ER-positive "low-risk" breast cancer (tumor size ≤ 30 mm and lymph node-negative) for whom PgR was determined by immunohistochemistry. The median follow-up was 17 years. Hazard ratios (HRs) and 95 % confidence intervals (CIs) were estimated using the Cox’s proportional hazards model.

Results: Patients with ER+/PgR+ tumors receiving tamoxifen had a reduced recurrence risk compared with those who were not treated with tamoxifen (HR= 0.40, 95% CI 0.27 – 0.59, p< 0.001). For patients with ER+/PgR- tumors the difference between tamoxifen vs. no tamoxifen treatment was not statistically significant (HR= 0.88, 95% CI 0.51 – 1.52, p= 0.65). P for interaction between the groups was 0.02.

Conclusion: Our results indicate that the PgR expression adds predictive value to the ER expression regarding benefit from tamoxifen treatment.
**Title:** A validated test for neoadjuvant clinical response to endocrine therapy in breast cancer that estimates accurately recurrence-free and overall survival

**Body:**

**Background:** Aromatase inhibitors (AIs) have an established role in the treatment of estrogen receptor alpha positive post-menopausal breast cancer. Recently we have developed and validated a microarray-derived 4-gene test (Edinburgh EndoResponse4) to predict response to AIs in the neoadjuvant setting. We have also demonstrated the translational potential of this test in predicting accurately clinical response when mRNA is measured for these genes by polymerase chain reaction (PCR) or the gene protein is measured by immunohistochemistry (IHC). There is a major clinical need for biomarkers to predict which patients are likely to recur on adjuvant endocrine therapy so alternative or additional treatments can be provided to reduce recurrence and improve outcome. The aim of this study was to determine if Endoresponse4 and IHC of these gene proteins could do this.

**Methods:** The original microarray assay used pre- and on-treatment (14-days) biopsies from 73 post-menopausal women with ER-rich breast cancer receiving 3 months of neoadjuvant letrozole prior to surgery with 10 years follow-up after adjuvant letrozole. Matched formalin-fixed paraffin embedded (FFPE) tissue sections from 42 of these patients were used for IHC and antibodies were optimised against 3 of the 4 proteins (where validated antibodies were available) using Envision technology. The ability of our test to estimate recurrence-free (RFS) and breast cancer specific overall survival (OS) using both PCR and IHC was then tested in a unique validation cohort of 140 post-menopausal women with ER-rich breast cancer treated with 2 weeks of neoadjuvant letrozole or anastrozole prior to surgery followed by adjuvant endocrine therapy and 10 years of follow up.

**Results:** Within our training cohort (n=73) using Kaplan-Meier analysis our 4-gene test predicted neoadjuvant clinical response and demonstrated a significant association with both RFS (P=0.029) and OS (P=0.009). This approach predicts outcomes within 2-weeks rather than 4-months of treatment required in other studies such as P024. Using IHC in the training cohort (n=42), two gene markers in combination (IL6ST at diagnosis and MCM4 after 2-weeks treatment) predicted both RFS (P=0.017) and OS (P=0.009) with great accuracy. The 140 patient group is being analysed and the findings are so far are consistent with the initial training cohort and indicate a significant association with outcomes.

**Conclusion:**
- A 4 gene model with clinical potential has been developed and validated to predict response to neoadjuvant aromatase inhibitors.
- This 4 gene model predicts for response and also predicts relapse free and overall survival.
- Proteins encoded by 2 of these 4 genes measured by IHC in an initial test set of 42 patients predict accurately both EFS and OS.
- A validation cohort (n=140) with over 10-years of follow-up will be available at SABCS 2015 to determine if this 2 biomarker test can predict outcome on adjuvant endocrine therapy.
2015 San Antonio Breast Cancer Symposium

Publication Number: P3-07-21

Title: Non-alcoholic fatty liver disease induced by selective estrogen receptor modulators is a protective factor for breast cancer survival

Body: Purpose: Non-alcoholic fatty liver disease (NAFLD) induced by selective estrogen receptor modulators (SERMs) treatment may be related to treatment efficacy for the antagonism of circulating estrogens. We conducted a retrospective study to investigate the relationship between survival outcomes and NAFLD in breast cancer patients treated with tamoxifen or toremifene.

Patients and methods: 785 eligible patients received tamoxifen or toremifene in Sun Yat-sen university cancer center from January 2005 to December 2009 were included in our study. All patients have at least one abdominal ultrasonography measurement at baseline and every year's follow-up. Patients who diagnosed NAFLD by ultrasonography during three-year's follow-up were classified into NAFLD cohort, others were classified into no-NAFLD cohort. Univariate and multivariate Cox regression was utilized to analyse the relationship between NAFLD and disease-free survival (DFS) and overall survival (OS).

Results: 158 patients had reported NAFLD in the first 3 years' follow-up. Patients who developed NAFLD had better DFS and OS than those not developing NAFLD. The 5-years DFS was 91.56% and 85.01% at NAFLD and no-NAFLD cohort (univariate hazard ratio [HR]: 0.59 [95%CI 0.37-0.96], P=0.034), respectively. The 5-years OS was 96.64% and 93.31% at NAFLD and no-NAFLD cohort (univariate HR: 0.39 [95%CI 0.16-0.99], P=0.047), respectively. Multivariate analysis revealed that NAFLD is an independent prognostic factor on DFS in breast cancer patients with SERMs treated. Women treated with SERMs experienced NAFLD in the first three-year's follow-up had a reduced risk of DFS of 42% (multivariate HR: 0.58; [95%CI 0.36-0.95], P=0.032) compared with patients without NAFLD.

Conclusion: NAFLD induced by SERMs seems to be associated with better survival outcomes and may therefore be helpful in predicting treatment responses in breast cancer patients treated with SERMs.
Title: RS1008805 polymorphism in CYP19A1 gene is related to the efficacy of hormone therapy in early breast cancer

Wang X, Shao X, Zheng Y, Shi L and Huang Y. Zhejiang Cancer Hospital, Hangzhou, Zhejiang, China.

Body: Purpose It has been suggested that genetic polymorphisms in CYP19A1 gene were related to aromatase activity as well as circulating steroid hormone levels in postmenopausal women. Therefore, it is biologically reasonable that CYP19A1 rs1008805 (A/G) polymorphism may be associated with clinical outcome for hormone therapy.

Methods Genotyping for CYP19A1 polymorphism rs1008805 was performed on 287 women with HR-positive early breast cancer. Associations were evaluated between CYP19A1 rs1008805 genotypes and disease-free survival (DFS).

Results Based on the analysis of the whole cohort, no significant differences were observed between rs1008805 genotypes and DFS, 5-year DFS rate. However, in postmenopausal women, rs1008805 genotypes were significantly associated with DFS and 5-years DFS rate (AA versus AG versus GG: 89.2 months versus 58.2 versus 32.7 months; 55.9% versus 47.8% versus 0%; P = 0.019). In addition, when the population was subgrouped into two cohorts, women carrying GG variant have a poorer DFS, 5-years DFS rate (GG versus AA or AG: 32.7 months versus 70.6 months; 0% versus 52.1%; HR, 3.613; 95% CI, 1.380-9.457; P = 0.005). Furthermore, being adjusted by patients features in multivariate analyses, GG genotype remained an independent prognostic factor for DFS (HR, 3.439; 95% CI, 1.251-9.456; P = 0.017). However, there was no significant differences in DFS and 5-years DFS rate between women harbor the minor allele and those with the homozygous common allele (AG or GG versus AA: 52.4 months versus 89.2 months; 41.0% versus 52.9%; HR, 1.288; 95% CI, 0.705-2.353; P = 0.408). In addition, there were no differences between rs1008805 polymorphisms and DFS among premenopausal women.

Conclusions The homozygous minor allele (GG) of CYP19A1 rs1008805 is significantly associated with worse clinical outcome of hormone therapy in postmenopausal HR-positive early breast cancer patients. If confirmed, genotyping for CYP19A1 polymorphisms rs1008805 may provide predictive information for better selection of endocrine treatment.
Title: CYP2D6 genotype and breast cancer recurrence in tamoxifen treated patients: An evaluation of the importance of loss-of-heterozygosity

Ahern TP, Hertz DL, Damkier P, Ejlertsen B, Hamilton-Dutoit SJ, Rae JM, Regan MM, Thompson AM, Lash TL and Cronin-Fenton DP. University of Vermont College of Medicine, Burlington, VT; University of Michigan College of Pharmacy, Ann Arbor, MI; Odense University Hospital, Odense, Denmark; Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark; Aarhus University Hospital, Aarhus, Denmark; University of Michigan Medical Center, Ann Arbor, MI; Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA; University of Texas MD Anderson Cancer Center, Houston, TX; Emory University, Atlanta, GA and Aarhus University, Aarhus, Denmark.

Body: Background: Tamoxifen therapy for estrogen receptor positive (ER+) breast cancer reduces recurrence risk by about half. Steady-state concentrations of endoxifen, a potent anti-estrogenic tamoxifen metabolite, are reduced in women whose CYP2D6 genotypes confer poor enzyme function. Many studies have measured associations between genetically impaired CYP2D6 function and tamoxifen resistance. It has been suggested that the subset of studies using DNA extracted from tumor-infiltrated tissue may have been susceptible to genotyping error induced by loss of heterozygosity (LOH); the putative non-differential genotype misclassification may have biased these studies’ estimates toward the null. We reviewed the clinical epidemiology studies conducted to date to assess the importance of loss-of-heterozygosity (LOH) at the CYP2D6 locus and its implications for assessing tamoxifen effectiveness.

Methods: We searched for the terms "tamoxifen" and "CYP2D6" in PubMed, including all papers and abstracts through 31 May 2015 on the association of CYP2D6 gene variants and the risk of breast cancer recurrence or mortality. We used a quantitative bias analysis (QBA) to evaluate the importance of genotype misclassification in studies that extracted DNA from tumor-infiltrated tissue. We conducted a random effects meta-analysis to evaluate all studies simultaneously, and within groups according to whether DNA was derived from tumor-infiltrated tissue or non-neoplastic tissue.

Results: Thirty-one studies investigated CYP2D6 genotype and breast cancer recurrence, yielding relative effect estimates ranging from 0.08 to 14. DNA was extracted from blood or non-neoplastic tissue in 21 of these 31 studies (68%), and from tumor-infiltrated tissue in the remaining 10 (32%). Our analysis of the association between variant/variant genotype compared with wildtype/wildtype genotype included 21 of the 31 studies. Sixteen (76%) of these 21 studies extracted DNA from blood or non-neoplastic tissue and five (24%) extracted DNA from tumor-infiltrated tissue. Genotype misclassification parameters for the QBA were estimated from six concordance studies. There was little difference between the effect estimates (EE) and 95% confidence/simulation intervals (95% CI/SI) before and after QBA (EE=1.71, 95%CI=1.24, 2.36, and 1.80 95%SI=1.28, 2.54, respectively). Studies using non-neoplastic DNA had higher variance than those based on tumor-infiltrated tissue DNA, half reported implausibly high EE, and many were susceptible to design and analysis errors that would bias estimates of association away from the null.

Conclusions: We found little relative bias in the summary estimates of association, either overall or when limited to the tumor-infiltrated tissue DNA studies. Three guideline panels, based on robust evidence, recommend against CYP2D6 genotype-guided tamoxifen therapy. Alternatives for optimizing the effectiveness of tamoxifen therapy, such as assuring adherence and persistence, are more likely to achieve clinically important benefits.
Title: The role of glucocorticoid receptor (GR) expression in predicting pathological complete response (pCR) to neoadjuvant chemotherapy in triple-negative breast cancer (TNBC)

Body: Background
Up to 40% of breast cancers have moderate to strong expression of GR, and activation of GR is associated with poor prognosis in ER-negative breast cancer. GR activation in breast cancer cells initiates anti-apoptotic signaling, contributing to chemotherapy resistance. We hypothesize that GR highly expressing TNBCs will have a suboptimal response to neoadjuvant chemotherapy.

Methods
We identified patients with triple-negative breast cancer (TNBC) who received neoadjuvant chemotherapy at the University of Chicago between 2002 and 2014 under IRB approved protocols. Those patients for whom pre-treatment and post-treatment tissue was available were included in this study. Unstained sections of formalin-fixed paraffin-embedded primary tumor were obtained. Percentage tumor cell GR expression was determined via immunohistochemical (IHC) examination using two different antibodies: the anti-GR rabbit monoclonal XP antibody (Cell Signaling, D8H2, 1:500 dilution) and the polyclonal rabbit anti-GR antibody (1:80). Staining was performed according to methods previously published by Belova et al. TNBCs were considered GR positive if greater than 10% of cancer cells stained moderately to strongly positive for GR.

Results
Fifty paired tissue samples were identified and pre- and post-treatment tissue was stained for GR using two anti-GR antibodies as above. Of these 50 cases, 80% had moderate to strong expression of GR using the XP antibody; results with the polyclonal ab will be compared. Percentage GR expression did not change in the setting of treatment. Work to correlate GR expression using the monoclonal versus the polyclonal antibody and clinicopathological features is ongoing.

Conclusions
To our knowledge, this is the first study attempting to evaluate percentage GR expression as a biomarker of response to neoadjuvant chemotherapy in TNBC. If higher GR expression correlates with a lower pCR rate in TNBC as hypothesized, then GR blockade in conjunction with chemotherapy may overcome chemotherapy resistance and lead to improved response to treatment in patients with GR expressing TNBCs.
Title: Improved clinical outcomes on enzalutamide observed in patients with PREDICT AR+ triple-negative breast cancer: prognosis or prediction?

Miller K, Krop I, Schwartzberg L, Abramson V, Garcia-Estevez L, Eakle J, Nanda R, Yardley D, Ademuyiwa F, Chan S, Crown J, Danso M, Gelmon K, Ma L, Martinez-Janez N, Gradishar W, Steinberg J, Tudor IC, Uppal H, Paton VE E, Parker J, Hudis CA and Traina TA A. Body: Background: A novel genomic signature that identifies androgen receptor (AR)-driven disease (PREDICT AR) is being developed for its ability to select patients (pts) who may benefit from enzalutamide (ENZA), a potent AR inhibitor. In a phase 2 study of triple-negative breast cancer (TNBC) pts treated with ENZA (NCT01889238) half of pts had PREDICT AR+ TNBC, with improved clinical outcomes in this sub-population. Because pts with hormonally driven (estrogen-receptor/progesterone-receptor[ER/PR]+) BC are thought to have a better prognosis, we investigated whether the outcomes observed in pts with PREDICT AR+ TNBC could be explained by prognosis alone.

Methods: PREDICT AR was assessed on advanced TNBC from 118 ENZA-treated pts. Because the duration of treatment (Tx) typically decreases with each subsequent Tx, exploratory analyses included median progression-free survival (mPFS) on ENZA vs duration of Tx prior to ENZA (used as a PFS surrogate) in pts who had received ≤1 prior Tx (data cutoff 24Mar15). Baseline characteristics by PREDICT AR status were also evaluated. An independent non-ENZA-Tx TNBC data set (after neo/adjuvant Tx) was probed for PREDICT AR status and clinical outcomes.

Results: ENZA-Tx pts with PREDICT AR+ TNBC (n=56; 47%) were older (66 years vs 52 years), had a longer disease-free interval (DFI) (37 vs 20 months), more bone involvement (57% vs 24%), were more likely to have had prior ER/PR+ BC (30% vs 8%), and a longer median duration on the first-line Tx (29 vs 19 weeks[wks]) vs pts with PREDICT AR- TNBC (n=62;53%).

Table 1. mPFS from ENZA-Tx pts and duration of prior Tx by PREDICT AR status and line of Tx.

<table>
<thead>
<tr>
<th>PREDICT AR Status</th>
<th>Tx prior to ENZA</th>

</tr>
</tbody>
</table>

The prevalence of PREDICT AR+ primary TNBC from the non-ENZA-Tx dataset was 51% (n=182). DFI after neo/adjuvant therapy was not statistically different (p=0.605) between pts with PREDICT AR+ vs PREDICT AR- TNBC, and pathologic complete response rates were 23% vs 38% in PREDICT AR+ vs PREDICT AR- TNBC, respectively.

Conclusion: mPFS in pts with PREDICT AR+ TNBC who received first-line ENZA was longer than first-line Tx duration in those who received prior Tx (32 vs 29 weeks). In pts with PREDICT AR+ TNBC who received second-line ENZA, mPFS was longer than the median duration of their first-line Tx (40 vs 34 weeks). This trend was not observed in pts with PREDICT AR- TNBC. Key demographic differences did not explain these outcomes, suggesting benefit from ENZA. Duration of first-line non-ENZA-Tx was shorter in pts with PREDICT AR- TNBC vs pts with PREDICT AR+ TNBC who received second-line ENZA (17 vs 34 weeks),
suggesting a better prognosis in pts with PREDICT AR+ advanced TNBC; however, PREDICT AR status was not associated with DFI following neo/adjuvant treatment for primary TNBC. PREDICT AR may identify a hormonally driven subset of pts with advanced TNBC who have a better prognosis and who may benefit from ENZA.

Title: Biomarker comparison between androgen receptor – Positive-triple-negative breast cancer (AR+ TNBC) and quadruple-negative breast cancer (QNBC)

Xiu J, Obeid E, Gatalica Z, Reddy S, Goldstein LJ J, Link J and Waisman J. Caris Life Sciences, Phoenix, AZ; Breastlink Medical Group, Orange, CA; City of Hope Medical Oncology, Duarte, CA and Fox Chase Cancer Center, Philadelphia, PA.

Body: Background: Quadruple-negative breast cancer (QNBC) is a subgroup of triple-negative breast cancer (TNBC) that lacks androgen receptor (AR) expression. While TNBC patients with AR expression have shown a promising response to AR-targeted therapies, QNBC patients' treatment options remain limited, with no targeted therapy. We investigated the biomarker profiles of large cohorts of AR+TNBC and QNBC to identify their molecular differences.

Method: TNBC tumors (defined as negative by IHC for ER, PR, Her2 and ISH for Her2) referred to Caris Life Sciences (Phoenix, AZ) between 2009 and 2015 were evaluated by board-certified pathologists with a combination of immunohistochemistry (AR, cKIT, cMET, EGFR, ER, ERCC1, Her2, MGMT, PD-1, PD-L1, PGP, PR, PTEN, RRM1, SPARC, TLE3, TOPO2A, TOPO1, TS and TUBB3), fluorescent/chromogenic in-situ hybridization (cMET, EGFR, Her2, TOP2A), and sequencing (Next-generation and Sanger). Tumors evaluated included a mix of primary tumors and metastases. QNBC tumors were defined as TNBC tumors that showed negative AR expression (<10% of cells staining).

Results: Among 2,071 TNBC tumors identified, 1,952 tumors had AR IHC performed, out of which 1,612 (83%) were QNBC and 340 (17%) were AR+ TNBC tumors. Tumor expression of PD-L1 (Ab: SP142, Spring Bioscience/130021, R&D Systems, cutoff used: 2+, 5%) was significantly higher in QNBC compared to AR+TNBC tumors (18% vs. 8%, p=0.01), while PD-1 (Ab: NAT105, Ventana) expression on tumor-infiltrating lymphocytes was comparable between the two cohorts (60% vs. 62%). QNBC tumors were significantly more likely to express proteins of cKIT (26% vs. 15%, p=0.01), EGFR (69% vs. 56%, p=0.03), TS (49% vs. 33%, p<0.0001) and TOPO2A (85% vs. 65%, p<0.0001) compared to AR+TNBC. TLE3 expression was significantly higher in AR+TNBC cohorts (48% vs. 32%, p<0.0001). Sequencing reveals that QNBC tumors carried significantly higher mutation rate of TP53 (71% vs. 55%, p<0.0001) while AR+TNBC tumors showed significantly higher mutation rates of PIK3CA (42% vs. 12%, p<0.0001), AKT1 (13% vs. 1%, p<0.0001) as well as ERBB2 (5% vs. 1%, p=0.0003).

Conclusion: Biomarker comparisons between two molecular subgroups of the TNBC tumors confirm the molecular heterogeneity of this aggressive type of breast cancer. Our biomarker results suggest that for AR+TNBC tumors, future clinical trial design can consider fluoropyrimidines, taxanes, and agents targeting PI3K/AKT/mTOR pathway as well as pan-HER inhibitors, and those agents may be combined with anti-androgen therapies. On the other hand, clinical trials for immune checkpoint inhibitors, TOP2A inhibitors, as well as agents that target cKIT and EGFR should be considered for QNBC tumors. Our findings highlight the molecular differences that should be considered in the design of future clinical trial strategies, warranting further investigation for improving targeted therapy and outcomes in TNBC.
**Title:** Distinct biomarker features in triple-negative breast cancer metastases to the brain, liver and bone

Xiu J, Gatalica Z, Reddy S, Waisman J and Link J. Caris Life Sciences, Phoenix, AZ; City of Hope Medical Oncology, Duarte, CA and Breastlink Medical Group, Orange, CA.

**Body:**

**Background:** Triple-negative breast cancer (TNBC) is characterized by its aggressive nature and accounts for a disproportionate number of metastatic disease cases and breast cancer-related deaths. Despite recent improvements, TNBC patients who develop metastatic diseases have limited treatment options. We investigated biomarkers from brain, liver and bone metastases collected from TNBC patients to identify therapeutic options and to examine molecular differences between the metastatic sites.

**Method:** Triple-negative breast cancer tumors referred to Caris Life Sciences (Phoenix, AZ) between 2009 and 2015 were tested with a combination of immunohistochemistry, fluorescent/chromogenic in-situ hybridization and sequencing (Next-generation and Sanger).

**Result:** 1570 TNBC tumors were analyzed, including 1297 tumors taken from breast, 54 from brain, 172 from liver and 47 from bone. Select biomarker frequencies of protein overexpression (IHC), gene amplification (ISH) and mutations (SEQ) are summarized in Table 1. Brain metastases showed the highest protein expression of TOP2A and PDL1; liver metastases showed the highest expression of AR and SPARC, as well as the highest mutation rate of PIK3CA. Bone metastases showed the lowest expression of TS, RRM1 and ERCC1. BRCA1 and BRCA2 mutation rates ranged from 0-11% in various specimen sites.

§: the group with the highest frequency of actionable results; £: p values are calculated from comparing the group with the highest frequency with the lowest frequency using two tailed Fisher-Exact test, further detailed statistical analysis will be presented; †: low levels predict response to associated drugs; Ns: non-significant, i.e., p >0.05; n/a: data not available due to low N

**Conclusion:** Distinct biomarker features identified in different metastatic sites in TNBC present the rationale to investigate differential treatment strategies. Based on biomarker results, etoposide, immune-modulatory agents may seem promising for brain metastases; anti-androgen therapies and nab-paclitaxel may be promising in treating liver metastases; while fluoropyrimidines, gemcitabine and platinum may be considered for TNBC patients with bone metastases.

Body: Background: The BRCA1-like copy number (CN) profile can be used as a biomarker to predict which stage III breast cancer patients benefit from myeloablative, DNA double-strand-break (DSB)-inducing chemotherapy. In addition, a BRCA1-like gene expression classifier, derived from the BRCA1-like CN profile, can predict which patient group will achieve an increased pathological complete remission rate on a standard neoadjuvant regimen complemented with carboplatin/veliparib. A non-myeloablative, dose-dense schedule of epirubicin, paclitaxel and cyclophosphamide (ETC) is used in the clinic to treat stage III patients. Since ETC contains an intensified dose of DNA DSB-inducing cyclophosphamide, we tested the BRCA1-like CN profile as a predictive biomarker for ETC benefit in the GAIN trial.

Methods: The GAIN trial was a prospective, multi-center, non-blinded, randomized phase III trial. Eligibility comprised histologically confirmed invasive breast cancer with at least one positive axillary or internal mammary lymph node and no signs of distant metastases. The allocated adjuvant treatment was intensified chemotherapy with sequential E (150 mg/m2), T (225 mg/m2) and C (2500, after amendment 2000 mg/m2) each 3 cycles every 2 weeks (ETC) or concurrent E (112.5 mg/m2) and C (600 mg/m2) for 4 cycles every 2 weeks followed by 10 cycles of weekly T (67.5 mg/m2) combined with 4 cycles of capecitabine (2000mg/m2) on day 1-14 in a 3-weekly cycle (EC-TX). Only the triple negative patients were used for these analyses. For samples with good quality DNA extracted from formalin-fixed paraffin-embedded tumor tissue, a library was prepared and sequenced on an Illumina HiSeq2000 platform. Copy number estimates were extracted from the sequence data by normalizing GC-content and mappability corrected read counts to the average read count. These CN profiles were classified as either BRCA1-like or non-BRCA1-like using a previously established shrunken centroid classifier with an established cut-off. Disease-free survival (DFS) and overall survival (OS) were estimated using the Kaplan-Meier method, the difference in survival was analysed using log-rank tests. Multivariate analyses were done by generating Cox regression models with important prognostic factors.

Results: Out of 424 triple negative patients, 166 patients with available tissue and a tumour cell content of at least 60% were analysed for BRCA1-like status and included in the analyses (classified as BRCA1-like: n=122). Based on clinicopathological characteristics, these patients were similar to the total group of triple negative participants. In the BRCA1-like patients, there was no significant difference in DFS or OS between ETC and EC-TX (log-rank tests n.s.). In accordance, Cox regression models confirmed these findings.

Conclusion: In contrast to the predictive value of the BRCA1-like profile in myeloablative chemotherapy, it could not predict survival benefit for a non-myeloablative, non-platinum-/veliparib-containing regimen in this study population. An intensified dose of cyclophosphamide resulted in similar outcomes in BRCA1-like patients as addition of capecitabine to standard chemotherapy. These results help to define the appropriate application of the BRCA1-like profile as a predictive biomarker.
Title: Role of germline BRCA status and tumor homologous recombination (HR) deficiency in response to neoadjuvant weekly paclitaxel followed by anthracycline-based chemotherapy

Body: Background: Both HR deficiency and BRCA mutation status predict response to platinum-based therapy and BRCA mutation status predicts docetaxel resistance. However, the association of either biomarker with response to the individual elements of either AC or taxanes (T) is unknown since T is commonly given concomitantly with or after anthracyclines (A). We evaluated the association of HRD and BRCA mutation status with response to neoadjuvant weekly T followed by AC or (F)EC in high-risk breast cancer.

Methods: We studied 140 high risk Stage I-III breast cancer patients (pts), enrolled in the breast cancer genome guided therapy study (BEAUTY), obtaining biopsies for DNA/RNA sequencing and MRI imaging to assess response to neoadjuvant weekly T (+trastuzumab+-/pertuzumab for HER2+ disease) followed by AC or (F)EC. Germline BRCA status and HR status of tumor samples (Myriad laboratories) were obtained. HR deficient tumor was defined as HRD score ≥42 or BRCA mutation. MRI response by changes in tumor size after 12 weeks of T was classified by WHO criteria. pCR was defined as ypT0/Tis ypN0. Both MRI response after T and pCR (after T and AC) were examined in terms of germline BRCA mutation (gBRCAmut vs. gBRCAwt) and tumor HR deficiency.

Results: Of 140 pts enrolled, 8 withdrew consent and 2 carboplatin treated pts were excluded. Germline data were available for 124/130 pts. 12 patients had BRCA deleterious germline mutations (4 BRCA1, 8 BRCA2). MRI partial (PR)/complete response (CR) rate to T was 47.3% (95% CI: 37.8-57.0%) in the BRCAwt group and 66.7% (95% CI: 34.9-90.1%) in the BRCAmut group. No MRI CR’s were observed in BRCA1 mut pts. In contrast, pCR rate was 50% in the 12 gBRCAmut pts (95% CI: 21.1-78.9%) and 31.3% in the 112 gBRCAwt pts (95% CI: 22.8-40.7%). HR deficiency status has thus far been determined for 74 pts: 26 pts have HD deficient tumors: 18 TNBC, 5 Luminal B, 2 ER-/HER2+; and 1 ER+/HER2+. Determination of HR deficiency is ongoing and will be reported for the full cohort in terms of 12 week MRI response to T and pCR to T+AC.

Conclusion: In the setting of neoadjuvant weekly T followed by AC, pCR rates were non-significantly higher in pts with BRCA1 mutations. While we observed no overall association between BRCA mutation status and response rates to taxanes; nearly all
MRI responses to taxanes (partial and complete) were observed in the BRCA2 group. Prospective studies are needed to validate these findings and to determine whether BRCA status can be used to select therapy. HR deficiency is uncommon in luminal A and HER2+, frequent in TNBC, and the association of HRD with both MRI response to taxanes and pCR will be reported at the meeting.
Molecular profiling comparison of BRCA1/2-mutated and BRCA1/2 non-mutated triple-negative breast cancer (TNBC)

**Body:** Background: Triple-negative breast cancer (TNBC) is one type of breast cancer that remains challenging because of its aggressive nature and the lack of effective targeted therapy for it. Molecular profiling has revealed different subtypes, indicating a potential for promising targeted therapy such as androgen blockade and PARP inhibition in some TNBCs. The purpose of this study is to identify differences in BRCA1/2 mutated and non-mutated TNBC to shed light on potential therapeutic options in both subtypes, utilizing a multiplatform approach.

**Methods:** A cohort of 386 triple-negative breast cancer specimens were tested via a multiplatform profiling service (Caris Life Sciences, Phoenix, AZ) consisting of gene sequencing (next generation sequencing [NGS]), protein expression (immunohistochemistry [IHC]) and gene amplification (fluorescence or chromogenic in situ hybridization [FISH or CISH]). Primary and metastatic specimens were evaluated. Tumor specimens with any BRCA1 and/or BRCA2 mutation (i.e. pathogenic or variant of unknown significance) were categorized as "BRCA1/2-mutated", while all others were considered "BRCA1/2 non-mutated".

**Results:** In our cohort, 16.3% (63/386) of specimens were BRCA1/2-mutated while 83.7% (323/386) had no BRCA1/2 alteration detected. Amongst the highest rates of protein expression in BRCA1/2-mutated and non-mutated specimens were biomarkers like TOPO1 (63.5% and 63.4%), EGFR (65.2% and 67.4%), and the immune checkpoint biomarker, PD-1 (65.1% and 61.9%), with non-statistically significant differences. Differences noted between BRCA1/2-mutated and non-mutated specimens were detected by IHC in AR (11.1% versus 22.0%, p=0.0585) and PTEN (47.6% versus 59.6%, p=0.0941), with both trending but not achieving statistical significance. The highest overall mutation rate in both BRCA1/2-mutated and non-mutated were TP53 (80.6% and 73.1%, p=0.2659). Differences were also noted between BRCA1/2-mutated and non-mutated specimens by NGS in APC (6.3% versus 1.9%, p = 0.0644) and PIK3CA (11.1% versus 25.8%, p = 0.0137), with PIK3CA being statistically significant.

**Conclusion:** Multiplatform tumor profiling identified differences in molecular profiles between BRCA1/2 mutated and BRCA1/2 non-mutated TNBC. Our findings raise the possibility for future investigation of potential combination therapeutic targeted therapy. Increased AR overexpression in BRCA1/2 non-mutated specimens is consistent with reports from other institutions. Further studies utilizing tumor profiling to elucidate the biological differences in in TNBC subtypes are warranted, to optimally include patients on clinical trials with specific targeted therapy and possibly improve treatment options.
2015 San Antonio Breast Cancer Symposium

Publication Number: P3-07-31

Title: Immune activation signatures identify a subset of ER+ breast cancers with increased pathologic complete response to neoadjuvant chemotherapy

Body: Background: Proliferation is the strongest predictor of response to neoadjuvant chemotherapy in estrogen receptor-positive (ER+) breast cancer. Evidence of immune activation has also been associated with improved response to neoadjuvant chemotherapy in breast cancer. We hypothesized that immune signatures may be associated with response independent of proliferation in ER+ breast cancers.

Approach: We compiled microarray expression data from breast cancer biopsies obtained prior to neoadjuvant chemotherapy on 465 ER-positive/HER2-negative patients by reported pathologic receptor status. We evaluated the association of 118 published gene expression signatures with response to neoadjuvant chemotherapy, based on study-defined pathologic complete response (pCR) versus residual disease (RD).

Results: Overall, 42 of 118 signatures were significantly associated with response to neoadjuvant chemotherapy in ER+ breast cancer (FDR-corrected p<0.05, simple logistic regression). Of those signatures that achieved significance, 52% (22/42) of signatures were proliferation-associated based on correlation to the 11-gene PAM50 proliferation index (Pearson's R^2>0.30, p<1e-10). Among signatures that were NOT proliferation-associated, 50% (10/20) were immune-related. Using unsupervised hierarchical clustering of all 118 signatures, these ten immune signatures formed a distinct cluster. Of the 10 signatures, nine were designed to reflect "immune activation" and were highly correlated with each other in ER+ tumors (R^2>0.4, p<0.001). The mean of each of these nine signatures was significantly higher in patients with pCR versus RD (FDR-corrected p<0.05, t-test). Patients with higher "immune activation" signatures had increased likelihood of pCR within multiple subgroups of ER+ breast cancer, including luminal B and non-luminal PAM50 subgroups, as well as intermediate- and high-proliferation ER+ breast cancers. For luminal A or low-proliferation breast cancers, "immune activation" signatures were not significantly associated with response, though very few patients achieved pCR in these two subgroups.

Conclusions: Gene expression signatures associated with "immune activation" identify a subset of ER+ breast cancers with higher rates of pCR to neoadjuvant chemotherapy. These "immune activation" signatures appear to be proliferation-independent and may provide additional predictive information to existing gene expression-based approaches for ER+ breast cancer.
Title: Tumour infiltrating lymphocyte (TIL) and chemokine gene signature predicts for benefit of anthracycline-containing chemotherapy in breast cancer patients

Braunstein M, Yao C, Lyttle N, Liao L, Boutros PC C, Twelves CJ J, Bartlett JMS MS and Spears M. Ontario Institute for Cancer Research, Toronto, ON, Canada; University of Toronto, Toronto, ON, Canada; University of Toronto, Toronto, ON, Canada; University of Toronto, Toronto, ON, Canada; Leeds Institute of Cancer and Pathology and Cancer Research UK Centre, St James' University Hospital, Leeds, United Kingdom; University of Toronto, Toronto, ON, Canada and Edinburgh Cancer Research Centre, Western General Hospital, Edinburgh, United Kingdom.

Body: Background: The contribution of immune cells has long been appreciated in tumour development and disease progression; however, their translational potential as cancer-associated prognostic and predictive markers was only recently recognized. High densities of tumour-infiltrating lymphocytes (TILs) correlate with improved clinical outcome in breast cancer; whether TILs also predict anthracycline benefit in all, or only a particular subgroup, of breast cancer patients remains largely unknown. Furthermore, since identification of TILs is generally based on H&E staining, it has not previously been possible to evaluate relative contribution of distinct T-cell types, and B cells, to patient outcome.

Methods: We assessed 290 patient samples from the BR9601 adjuvant breast cancer trial for the capacity of TIL contexture to predict for anthracycline (E-CMF) benefit over CMF. We immunoprofiled patient samples on the Nanostring platform to gain insight into the impact of lymphocyte populations predicting for anthracycline benefit. Our immunoprofiling panel included 38 genes representing TIL-gene signatures and chemokines that may be responsible for recruiting TILs to the tumour site.

Results: The analyses revealed two important findings. First, refinement of the 38-gene panel resulted in the generation of a novel 9-gene signature that includes cytotoxic T lymphocytes (CTL) and chemokine genes. Low CTL gene expression correlated with ER+ expression while high expression correlated with ER- expression (p<0.0001), consistent with the notion that high TIL densities are predominantly observed in non-luminal breast cancers. Second, in an univariate Cox regression analysis, this 9-gene signature was a predictive biomarker of anthracycline benefit with respect to breast-cancer specific OS (HR: 0.371, 95%CI 0.158-0.868, p=0.022) and DRFS (HR: 0.395, 95%CI 0.172-0.907, p=0.028); this effect was no longer significant after adjustment for other prognostic factors (OS HR: 0.437, 95%CI 0.166-1.150, p=0.094; DRFS HR: 0.488, 95%CI 0.185-1.287, p=0.147).

Conclusion: This study highlights the significance of assessing the entire tumour since TILs, tumour and stromal cells collectively engage in a complex interplay that contributes to disease development and progression. Importantly, it reveals that not only CTLs but also chemokines may be clinically relevant and should be validated as potential biomarkers of anthracycline benefit and as therapeutic targets.
**Title:** Prediction of the treatment response to neoadjuvant chemotherapy in breast cancer by subtypes using tumor-infiltrating lymphocytes

Kashiwagi S, Asano Y, Goto W, Morisaki T, Noda S, Takashima T, Onoda N and Hirakawa K. Osaka City University Graduate School of Medicine, Osaka, Japan.

**Body:** Purpose: Monitoring the host immunological response to cancer in the microenvironment of the interaction between tumor and the body plays an important role in predicting treatment response and outcomes. Recent interest has focused on the morphological evaluation of tumor-infiltrating lymphocytes (TILs) in breast cancer (BC) and on the evidence showing their clinical relevance. Meanwhile, no consensus has yet been reached on standard methods for pathological evaluation of TILs. Therefore, methods of evaluation have differed in reports to date showing the clinical relevance of TILs. An International Working Group (2014) announced recommendations for evaluating TILs in an effort to improve consistency and reproducibility. In this study, the clinical validity and utility of TILs in NAC were investigated based on this recommendation with a stratified analysis by BC subtypes. Changes in TILs after recurrence, which have seldom been reported to date, are also discussed.

Experimental Design: TILs was evaluated in 177 patients with breast cancer treated with NAC and subsequent curative surgery. All patients received a standardized protocol of NAC consisting of four courses of FEC100 (500 mg/m² fluorouracil, 100 mg/m² epirubicin, and 500 mg/m² cyclophosphamide) every 3 weeks, followed by 12 courses of 80 mg/m² paclitaxel administered weekly. Forty-five patients had HER2-positive breast cancer and were additionally administered weekly (2 mg/kg) or tri-weekly (6 mg/kg) trastuzumab during paclitaxel treatment. The correlation between TILs evaluated according to the standard method, and prognosis, including the efficacy of NAC, was investigated retrospectively.

Results: In the 96 high-TIL group, compared to the 81 low-TIL group, triple-negative breast cancer (TNBC) (p < 0.001) and HER2-enriched (p = 0.040) were significantly more frequent, and the pathological complete response (pCR) rate were significantly higher (p = 0.003). On multivariate analysis also demonstrated that high-TIL status was an independent factor to indicate significantly more favorable prognosis of the patients compared with low-TIL status (p = 0.036, HR = 0.45). Among the 61 TNBC and the 36 HER2-enriched patients, the pCR rate was significantly higher in the high-TIL group than in the low-TIL group (p = 0.013) (p = 0.014). On multivariate analysis also showed that high-TIL status was an independent factor to predict the favorable prognosis (p = 0.023, HR = 0.24) (p = 0.036, HR = 0.13). Biopsy specimens from local recurrence after successful NAC frequently showed decreased TILs.

Conclusion: TILs may be a biomarker to predict treatment response to NAC in patients with TNBC and HER2-enriched subtypes of BC. A decrease in TILs may also be associated with tumor recurrence.
Title: Predictive role of stromal tumor infiltrating lymphocytes (TILs) in patients with metastatic HER2-positive breast cancer (BC) treated with trastuzumab

Yoon JA, Yoo C, Lee HJ, Kim K-P, Kim J, Ahn J-H, Jung KH, Gong G and Kim S-B. Asan Medical Center, University of Ulsan College of Medicine, Song-pa gu, Korea and Asan Medical Center, University of Ulsan College of Medicine, Song-pa gu, Korea.

Body: Background: Prognostic significance of stromal TILs in metastatic BC has been suggested in various BC subtypes. However, predictive role of stromal TILs for the efficacy of trastuzumab has not been established in patients with HER2-positive BC. This study was performed to evaluate whether the stromal TILs are associated with the efficacy of trastuzumab in patients with metastatic HER2-positive BC.

Method: Between June 2006 and March 2013, a total of 60 women with recurrent or metastatic HER2-positive BC treated with trastuzumab were included in this retrospective analysis. In these patients, trastuzumab was administered either as single agent or combination with taxanes. Stromal TILs were assessed using immunohistochemistry in surgical specimen (n=39, 65%) and biopsy specimen of metastatic lesion (n=21, 35%) by the academic pathologist (HJL). Primary endpoint of this study was progression-free survival (PFS), and secondary endpoints were response rate and overall survival (OS).

Result: Median age was 54 year old (range, 36-76), and all patients had invasive ductal carcinoma. Hormone receptor was positive in 34 patients (57%) and 18 patients (30%) initially presented with metastatic disease. Nine patients (15%) received cytotoxic chemotherapy without trastuzumab before the administration of trastuzumab. Patients were grouped according to the TILs (< 10% [n=50] and >10% [n=10]), and there was no significant difference in age (p=0.68), histologic grade (p=1.00), metastatic sites (p>0.05), and number of lines of chemotherapy before the administration of trastuzumab (p=0.33) among patients with low and high stromal TILs. High TILs were more common in hormone receptor (HR)-negative tumor compared with HR–positive tumor (31% vs 6%; p=0.02). In overall, median PFS and OS were 15.0 months (95% CI, 9.7-20.2) and 35.0 months (95% CI, 29.8-40.2), respectively. Median PFS in patients with high stromal TILs were numerically longer than that in those with low TILs (22.0 months [95% CI, 9.6-34.4] vs 14.0 months [95% CI, 9.6-18.4]; p=0.057). There was no difference in response rates (p=0.43) and OS (p=0.94) according to the stromal TILs. FcR genotype was not significantly correlated with objective response rate, PFS and OS.

Conclusion: This study suggests that the stromal TILs might be associated with the clinical outcomes of HER2-targeted therapy in patients with metastatic HER2-positive BC. Our finding should be validated in future studies based on a large sample size.

Keywords: Breast cancer, tumor infiltrating lymphocyte. Trastuzumab, HER2.
Title: Tumour immune subtyping as a predictive biomarker for adjuvant endocrine therapy in early breast cancer

Body: Adjuvant endocrine therapy is one of the mainstays in the treatment of breast cancer. Approximately 75% of all patients is treated with either tamoxifen or an aromatase inhibitor (AI), without any predictive biomarkers besides the estrogen receptor. It is known, that the immune system plays a pivotal role in the treatment of breast cancer. Earlier, subtyping the local immune response has been shown to predict therapy efficacy for chemotherapy. The current study was performed to discover predictive relations between the local immune response and survival in two different cohorts treated with adjuvant endocrine therapy. Tumour tissue was collected from a cohort of 236 Dutch post-menopausal patients from the Intergroup Exemestane Study (IES-trial) who were randomized between 5 years of tamoxifen and 2.5 years of tamoxifen followed by 2.5 years of an AI (switch-scheme). The tumour tissue was stained for infiltration of CD8+ cytotoxic T-cells, FoxP3+ regulatory T-cells and CD68+ macrophages and the expression of different HLA-markers (classical HLA-I, HLA-E, HLA-G). These results were combined into three immune profiles (strong, intermediate, weak), and correlated to survival. Similar analyses were performed on a cohort of 2596 patients participating in the international TEAM trial, who were randomized between 2.5 years of tamoxifen followed by 2.5 years of an AI (switch scheme) and 5 years of AI.

In the IES-cohort, patients with a strong local immune response had a significant better recurrence free survival when treated with 5 years of tamoxifen (5-year RFS 89.5%) compared to the switch scheme (5-year RFS 76.5%) (p=0.003). In patients with a weak local immune response, RFS was improved for patients treated with the switch scheme (5-year RFS 100%) compared to tamoxifen monotherapy (5-year RFS 75.6%) (P=0.003). Similar trends were observed for overall survival, although not statistically significant (p-values of 0.051 and 0.109 respectively). In the TEAM-cohort, no statistical significant differences were observed between both treatments in either immunological subtype (strong immune subtype: 5-year RFS 87.2% for 5-years AI versus 82.8% for the switch scheme (p=0.495), weak immune subtype: 85.9% for 5-year of AI vs 82.2% for the switch scheme (p=0.343)).

This study is the first to show combined immunological markers as a predictive marker for endocrine therapy. A strong immune response predicts a benefit for tamoxifen monotherapy, whereas a weak response predicts a benefit for AI-containing therapy. Although the exact mechanism of this effect is not known, we hypothesize that it might be contributed to immunomodulatory capacities of AIs. If the effect observed in the IES-cohort is indeed contributed to the effect of AIs, it would be expected that there is no difference in the TEAM-cohort between both arms since they both contain AIs, which was indeed observed. Future studies will be directed towards validation of these findings in an independent cohort.
Title: Immune related gene expression signatures predict benefit of letrozole over tamoxifen in BIG 1-98

Willis S, Gray KP, Regan MM, Rae JM, Kammler R, Young B, Ditzel HJ, Lyng MB, Colleoni M, Viale G and Leyland-Jones B. Avera Cancer Institute, Sioux Falls, SD; IBCSG Statistical Center, Boston, MA; University of Michigan Comprehensive Cancer Center, Ann Arbor, MI; International Breast Cancer Study Group Coordinating Center Pathology Office, Bern, Switzerland; Institute of Molecular Medicine, University of Southern Denmark, Odense, Denmark; Breast Center, Kantonsspital, St. Gallen, Switzerland and European Institute of Oncology, Milan, Italy.

Body: Background: The prognostic significance of increased levels of CD8+ tumor infiltrating lymphocytes (TILs) in ER- breast cancer has been described. We sought to identify possible immune-related biomarkers for predicting benefit from letrozol (LET) or tamoxifen (TAM) for recurrence in ER+ breast cancer.

Patient and Methods: We used Illumina DASL Assay to measure gene expression in FFPE primary breast cancers from a subset of postmenopausal patients enrolled in the BIG 1-98 randomized phase 3 trial comparing 5 years LET (n=344) vs TAM (n=381) as adjuvant endocrine therapy. Gene sets (n=1910) that represent cell states and perturbations within the immune system from the Human Immunology Project Consortium were used in an exploratory analysis to identify possible predictive signatures.

Results: We identified five distinct gene signatures from previously reported laboratory experiments associated with immune cell differentiation that are highly predictive of benefit (reduced breast cancer recurrence risk) of LET over TAM, each with gene signature p-values <1E-5 and signature-by-treatment interaction p<1E-6. The signatures predict a similar pattern that patients at low-risk score benefit from LET and patients with high-risk score appear to have an advantage with TAM after 5 years. The gene signatures originate as a result of being differentially expressed in the following previously reported experiments. [RAP2A EEF2K TRAF3IP2 GPR37L1 DDX54] down regulated comparing TLR3 and TLR9 agonists in dendritic cells. [RPA1 DUSP4 NUDT18 ZFYVE28] up regulated in comparison of T follicular helper versus Th17 cells. [MAPK15 CCR4 SORCS2 RAMP1 SH3PXD2A] up regulated in regulatory T cell versus CD4+ T cells. [NDUFA6 GIMAP1 CPNE3 ST3GAL6 CCDC88A] down regulated in comparison of untreated CD8+ dendritic cells versus treated with IFNG. [GPN1 COX17 CUL2 CDSA] down regulated in naïve vs stimulated CD8 T cells after 48 hours. We further investigated the signatures using Hungarian Academy of Sciences (HAS) cohort (Gyorffy B 2010), which is a collection of smaller published affymetrix cohorts combined into a larger ER+, TAM treated cohort (n=700). One signature was not tested because two genes were not present in the affymetrix cohort. Three of the remaining four signatures gave informative prognostic results in the HAS cohort, and the signature associated with differentiation of CD8+ dendritic cells was highly prognostic with HR=0.36 (0.26-0.49) p=1E-11.

Conclusion: The role of selective estrogen receptor modulators on immune response has been well described, where TAM has been shown to prevent differentiation and activation of dendritic cells (Naibandian 2005). Similarly, it has been shown that MET inhibitors negatively regulate neutrophils suggesting that anti-MET drugs in cancer could impact immune response (Finisquerra 2015). These findings suggest that if TAM is a negative regulator of immune response why in the ATAC clinical trial, the combination therapy of anastrozole plus TAM were not significantly different from TAM alone were anastrozole was superior. With the increasing importance of understanding the role of immune response on outcome and the use of combination therapies the assessment of TILs in the neoadjuvant setting will be critical for guiding therapy.
Title: Quantitative analysis of T cell and macrophage immune markers in Her2-positive breast cancer

Body: Purpose/Objectives:

Her2-neu positive breast cancers have a good overall prognosis with the advent of Her2-directed therapies such as trastuzumab. However, despite the increased efficacy with Her-2-directed therapies 20-30% of patients still have local and/or distant failure despite being Her-2 amplified on pathology. The etiology of this local failure remains unknown. Recent evidence has suggested that there may be immune factors that contribute to the progression of breast cancer and the response to therapy so we undertook a study to examine the relationship between immune-based markers and traditional pathologic and clinical markers of outcome.

Materials/Methods:

Paraffin-embedded sections were generation and clinical records were reviewed for 88 patients, age ≥ 18 years, with pathologically-proven Her2-neu+ breast cancer who were treated at a single institution from 01/2001 to 12/2013. Single-color immunohistochemical staining was performed for CK5/6, CK14 and EGFR and scored by a breast pathologist. Adjacent sections were also then stained for CD45, CD4, CD8 and CD68 using a multi-color immunohistochemical approach. Slides were scanned using the Vectra Automated Quantitative Pathology Imaging System and analyzed using an in-house algorithm to quantitate the number of immune cells within the tumor, tumor margin and within 2 mm outside the tumor. We then compared the level of CK5/6, CK14, EGFR with the number of immune cells. The number of different immune cells were also analyzed with respect to other clinical parameters including age, tumor size, nodal status, hormone receptor status, time to progression, progression-free survival and overall survival.

Results:

At a median follow-up of 66.5 months, 20 (22.7%) patients had progressed. We found that the number of CD45+ leukocytes at the margin correlates with the expression of CK5/6 (p = 0.015) which predicted for local failure. Further, we found that the ratio of CD8 to CD4 cells within the tumor and margin highly correlates with the expression of the hormone receptors (p = 0.01).

Conclusions:

Our preliminary results suggest that immune markers may be important predictors of a basal-like phenotype as defined by CK5/6 expression in Her2+ breast cancers which itself correlated with significantly higher local failure. Further higher CD8 to CD4 ratios were highly correlated with hormone receptor expression, particularly PR expression suggesting that in the Her2+ population the more favorable prognosis for the "triple-positive" subtype of Her2+ cancers may be in part due to a more favorable immune microenvironment.
Title: Increment of neutrophil/lymphocyte ratio (NLR) can be one of the useful predictive markers for the metastatic breast cancer (MBC) with first line hormonal therapy (HT)

Miyamoto T, Fujisawa T, Morishita A, Yanagita Y and Kuwano H. Gunma Cancer Center, Ota, Gunma, Japan and Graduate School of Medicine, Gunma University, Maebashi, Gunma, Japan.

Body: [Introduction] Cancer microenvironment formed by the immune and inflammatory cells is noticed to be one of the factors for tumor growth, invasion or metastasis. To figure out the systemic inflammatory environment, the neutrophil / lymphocyte ratio (NLR) is a useful method and a simple indicator. We have some reports that NLR can predict the prognosis in many malignancies, including breast cancer, as I reported in SABCS 2014, however, NLR cannot be a predictive marker in major cancers, because the usage with anti-cancer agents will make NLR status out of order. In hormonal receptor positive metastatic breast cancer (HR+ve MBC), we choose hormonal therapy (HT) for the first line, mainly. HTs have little influence for NLR, therefore, the change of NLR, increment or decrement, can reflect the systemic inflammatory status and be a useful predictive marker for the HR+ve MBC with HTs.

[Purpose] I defined dNLR as the difference between NLR at the 2-3 months after HT and before HT. To evaluate the dNLR affects the Overall Survival (OS) and Progression Free Survival (PFS) of the patients of MBC or not.

[Patients] From 2003 to 2013, we have 299 MBC patients in our hospital. Out of them, 134 patients had HTs as first line, included 18 Stage4 patients at the first visit. Median Disease free survival (DFS) is 1497-day, the median OS after the recurrence is 1472-day. Average value of the NLR before HT is 2.62. The reasons of MBC are bone metastases (mets), pleural and pulmonary mets, liver mets, lymph node mets, central nervous system (CNS) mets, unresectable metastatic chest wall recurrence, or other.

[Results] By univariate analysis, DFS < 1000 (p<0.01) and liver mets (p<0.05) made a contribution to poor OS. dNLR>=0.5 (p<0.05), liver mets (p<0.05) and 2 or more organs involvements (p < 0.05) made a contribution to poor PFS. With multivariate analysis, for OS, only DFS < 1000 was an independent prognostic factor. And for PFS, only dNLR>=0.5 was an independent predictive factor. Poor OS factors by univariate analysis had no influence for PFS as well as poor PFS factors did not reflect the OS.

[Discussion] The dNLR was a predictive marker for HR+ve MBC which we can easily and simply examine by blood sample. Now we cannot reveal the relationship with dNLR and OS, however, this fact suggests that we can decide to stop the first line HT and select the second line therapy using with not only images or tumor makers but also dNLR. This can certainly contribute for good OS. It remains some questions between dNLR and other examinations, for example, which can detect the patient status earlier and more accurate? First, we need to accumulate further retrospective cases and plan the prospective study to make sure of the adequate treatment divided by dNLR.

[Conclusion] The dNLR>=0.5 is one of the independent predictive markers for HR+ve MBC with first line HT.
**Body: BACKGROUND:** Currently available therapeutic armamentarium for locally advanced and/or metastatic breast cancer (LA/MBC) allows an increasing tailored approach for each of the major tumor immunophenotypes. Nevertheless, there is scarce information about how these subgroups fare and how the alternative therapeutic approaches are actually being used during the disease course. CASCADE is an epidemiological, retrospective, and multicenter study aimed to retrieve demographic and clinical information from a representative cohort of LA/MBC patients treated within the Spanish National Healthcare System.

**MATERIALS AND METHODS:** Several strategies were used to identify patients diagnosed with LA/MBC for the first time between 01/2007 and 12/2008 in 13 Spanish public hospitals covering nearly 5'000'000 inhabitants (>10% of the national population) and followed throughout their metastatic lifetime until death, lost to follow-up, or until December 2013. Data collected included demographical and clinical information for each line of treatment. Descriptive statistics were applied to analyze the information.

**RESULTS:** We identified 443 LA/MBC patients. Median age at diagnosis was 59 years (CI95%: 49.5 - 71.6). Significant differences in dropout rates per line of treatment were found according to the tumor intrinsic immunophenotype. Patients reaching a 4\textsuperscript{th} line were: whole study population 38.4%, HER2-/HR+ 42.8%, HER2+/HR- 41.5%, HER2+/HR+ 39.5%, and Triple-negative 31.9%. Median Overall survival (OS) and per line Progression Free Survival (PFS) for each line of treatment by tumor subtype were:

**CONCLUSION**: Our study identifies differences in OS and PFS among BC immunophenotypes, with Triple-negatives faring the poorest. Among therapeutic families, chemotherapy clearly prevails along the disease lifetime, with hormone therapy being primarily used during the initial lines of treatment.
Pharmacogenetic study of exemestane and everolimus in metastatic breast cancer patients progressing on prior non-steroidal aromatase inhibitors

Background: Activation of the mTOR pathway has been observed in patients (pts) with metastatic breast cancer (MBC) progressing on endocrine therapy. BOLERO-2 trial demonstrated a significant increase in progression free survival (PFS) obtained with everolimus (EVE) and exemestane (EXE) versus EXE alone in pts refractory to a prior non-steroidal aromatase inhibitors (NSAI). However, there is large interindividual variability in toxicity and efficacy profiles of EXE-EVE treatment. Single Nucleotide Polymorphisms (SNPs) have been proposed to explain some of these differences. The objective of this study was to perform a pharmacogenetic analysis to identify SNPs associated with EVE toxicity and activity.

Methods: This is a prospective unicentric clinical trial for postmenopausal pts with hormone receptor-positive, HER2 negative, MBC progressing on prior NSAI, treated with EXE-EVE.

Blood samples were obtained from all pts, and 12 SNPs in key genes involved in EXE pharmacokinetics (ABCB1, CYP2C8, CYP3A4, CYP3A5) and pharmacodynamics (AKT1, AKT2, FGFR4, PHLPP2, PIK3R1, RAPTOR) were genotyped. EVE pharmacokinetics data was available for a subset of 37 pts. The association between the SNPs and EVE pharmacokinetic parameters were analyzed using U-Mann-Whitney test. A selection of clinically relevant toxicities (non-infectious pneumonitis (NIP), mucositis, hyperglycemia and hematological) was analyzed using binary logistic regression. Cox regression was used to analyze the association of SNPs with time to treatment modifications (reduction or interruption) due to toxicity, PFS and OS.

Results: 90 patients with median age of 62 yrs were included. At data cut off, a total of 77 pts had discontinued treatment. Major reasons for discontinuation were: disease progression (80%), adverse events (17%) and death (2%). Number of prior chemotherapy lines: 0; 50%, 1;18%, 2;10%, ≥3; 22%. 76% of pts experienced at least one adverse event related to EVE. CYP3A4 rs35599367 (CYP3A4*22 allele) heterozygous pts had higher EVE concentration in blood compared to wild type pts (P=0.019), in agreement with previous data.

Regarding EVE toxicities, ABCB1 SNP rs1045642 showed a higher risk of mucositis (HR=2.3, 95%CI=1.1-4.8, P=0.031; multivariable analysis), and PIK3R1 rs10515074 variant was inversely associated with hyperglycemia (HR=0.24, 95%CI=0.1-0.8, P=0.016; multivariable analysis). RAPTOR rs9906827 protected for NIP (HR=0.38, 95%CI=0.2-0.9, P=0.024; multivariable analysis). When analyzing the time to treatment modification due to any toxicity, we observed a trend for FGFR4 rs351855 and RAPTOR rs9906827 (HR=0.59, 95%CI=0.3-1.0, P=0.06 and HR=0.71, 95%CI=0.5-1.1, P=0.12; respectively, in multivariable analysis).

Regarding activity, RAPTOR rs9906827 was also associated with longer PFS (dominant model HR=0.48, 95%CI=0.3-0.8, P=0.006; multivariable analysis). No SNP was significantly associated with OS.

Conclusions: We found altered EVE pharmacokinetics for CYP3A4*22 carriers and protection for NIP and longer PFS for RAPTOR rs9906827. This study supports prospective trials for genetic testing prior to EXE-EVE therapy to stratify patients according to toxicity and efficacy risk profiles.
Title: Genomic alterations indicative of a luminal A subtype associate with clinical benefit to buparlisib and letrozole in endocrine-resistant ER+/HER2– metastatic breast cancer

Balko JM M, Hicks M, Berger MF F, Solit DB B, Bouvier N, Sanders ME E, Estrada MV V, Won H, Cantley LC C, Mayer IA A and Arteaga CL L. Vanderbilt University; Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College.

Body: Background: Activation of the phosphoinositide-3-kinase (PI3K) pathway has been associated with resistance to endocrine therapy in estrogen receptor-positive (ER+) breast cancer. Recently, we reported a Stand Up 2 Cancer (SU2C) Phase Ib trial of buparlisib, an oral, reversible, pan-PI3K inhibitor in combination with the aromatase inhibitor letrozole in patients with metastatic ER+/HER2– breast cancer (n=51) who had previously progressed on endocrine therapy. In this study, 31% of patients demonstrated clinical benefit (CR, PR and SD ≥6 months; Mayer et al. JCO 2014). Clinical activity was observed in patients with PIK3CA-wild type (PIK3CA-WT) and PIK3CA-mutant (PIK3CA-MUT) tumors. We performed targeted next-generation sequencing (tNGS) to identify somatic alterations associated with clinical benefit to the combination therapy.

Methods: tNGS was performed using Memorial Sloan Kettering-Integrated Mutation Profiling of Actionable Cancer Targets (MSK-IMPACT) in DNA extracted from tumors of 33 study patients (22 samples from archived primary/untreated and 11 from metastatic biopsies). Detected alterations were tested for association with clinical benefit (Fisher's exact test) and progression-free survival (PFS; log-rank test). For PFS analysis, patients were censored if they discontinued buparlisib for toxicity.

Results: The most commonly detected alterations occurred in PIK3CA (36%), TP53 (30%), MAP3K1 (27%), GATA3 (24%), CCND1 (24%), CDH1 (21%) and PTEN (21%). Additional alterations of note included FGFR1 amplification (15%), MYC amplification (12%), ESR1 mutations (6%) and ERBB2 mutations (6%). Probable inactivating mutations occurring in MAP3K1 (MAP3K1-MUT) were significantly associated with improved clinical benefit, regardless of other mutations (6/9 patients, 67%, P=0.044). PIK3CA-MUT tumors trended toward greater clinical benefit (7/12, 58%, P=0.067). Patients with coexisting PIK3CA-MUT and MAP3K1-MUT tumors derived the largest clinical benefit (5/7, 70% P=0.07) compared to patients with only PIK3CA-MUT (2/5; 40%, P=1.0) or only MAP3K1-MUT tumors (1/2; 50%, P=1.0). Only 2/19 (11%) patients with PIK3CA-WT/MAP3K1-WT cancers benefitted from treatment. Both MAP3K1 and PIK3CA alterations were each also associated with increased PFS (p=0.03 and p=0.009, respectively). Three of 5 (60%) patients with tumors with FGFR1 amplification achieved clinical benefit (including a MAP3K1-MUT tumor and a PIK3CA-MUT/MAP3K1-MUT tumor), suggesting that FGFR1 may preferentially signal via PI3K and/or FGFR1 amplifications are not associated with resistance to the combination of aromatase inhibitors and PI3K inhibitors.

Conclusions: Both MAP3K1 and PIK3CA are mutated at higher frequencies in luminal A breast cancer, suggesting that this alteration pattern (MAP3K1-MUT + PIK3CA-MUT) is a surrogate for low grade ER+ breast cancers with PI3K dependence. It is also possible that MAP3K1 mutations may predispose tumor cells to sensitivity to PI3K inhibition, but this speculation requires further investigation. Finally, patients with ER+/FGFR1-amplified cancers appeared to derive clinical benefit from combined therapy with letrozole and buparlisib.
Title: Predicting outcome and benefit to first-line bevacizumab in advanced/metastatic hormone receptor (HR)+/HER2-negative breast cancer (BC) treated with endocrine therapy: A correlative science study from the LEA phase III clinical trial (GEICAM/2006-11_GBG 051)

Prat A, de la Haba-Rodriguez J, Guerrero Á, García-Sáenz JA A, Morales S, Antón A, Muñoz M, Ramos M, Martínez-Jáñez N, Margelí M, Servitja S, Rojo F, Galván P, González S, Cruz J, Sánchez-Rovira P, Perelló A, Rodríguez-Martin C, Casas M, Carrasco E, Caballero R and Martín M. Body: Introduction: The role of bevacizumab in combination with chemotherapy in metastatic BC is controversial, and no biomarker exists as of today that predicts benefit to this agent. In the LEA clinical trial, a numerical, statistically non-significant benefit from the addition of bevacizumab to endocrine therapy (ET) was observed in the first-line metastatic setting (18.4 vs. 13.8 months of Progression-Free Survival (PFS), p=0.14). Here, we explored various gene expression-based predictors of outcome and benefit to bevacizumab.

Methods and materials: LEA trial randomized 380 patients with HR+/HER2- advanced disease to bevacizumab in combination with ET (ET+B) vs. ET alone. Primary endpoint was PFS. Expression of BC selected genes was evaluated in formalin-fixed paraffin-embedded (FFPE) primary tumors using the nCounter platform from patients randomized in Spain that consent for biomarker analyses. The following variables were evaluated: 1) research-based PAM50 intrinsic subtypes (categorical variable; Luminal A, Luminal B, HER2-enriched, Basal-like and Normal-like); 2) research-based PAM50 signatures (continuous variable; scores showing the distant of the gene expression values of an individual sample compared to the centroid gene values for each PAM50 intrinsic subtype); 3) risk of recurrence (ROR) groups (low, medium and high); 4) the 13-gene hypoxia/VEGF signature (continuous); and 5) Ki67 by immunohistochemistry (continuous). Uni- and multivariable Cox models for PFS were used to test the prognostic significance of each variable. To determine whether each variable is predictive of bevacizumab benefit, we tested the interaction term of each variable by treatment arm in a Cox model.

Results: Tumor samples from 103 patients were analyzed: 55 (53%) in ET+B arm and 49 (47%) in ET arm. Subtype distribution was as follows: 57 (55.3%) Luminal A, 32 (31.1%) Luminal B, 5 (4.9%) HER2-enriched, 1 (1.0%) Basal-like, and 8 (7.8%) normal-like. In a univariate analysis, Luminal B tumors had a poorer outcome using Luminal A as reference (13.8 vs. 21.3 months, respectively; hazard ratio, HR=1.80, 95% CI 1.10-2.95, p=0.019). Concordant with this finding, Luminal A signature was associated with a better outcome. Similarly, ROR-P high group showed a poorer outcome than ROR-P low group (8.5 vs. 19.4 months; HR=2.88, 95% CI 1.30-6.35, p=0.009). Neither VEGF-13 signature nor Ki67 were found to be associated with PFS. Similar findings were obtained after adjustment for treatment, age, previous ET, ECOG, visceral disease and number of metastatic sites. In terms of treatment benefit, the HER2-enriched signature was the only variable found predictive of bevacizumab PFS benefit in univariate (p=0.010) and multivariate (p=0.015) analyses.

Conclusions: In advanced HR+/HER2- disease, intrinsic subtype (i.e. Luminal A vs. B) independently predicts PFS following first-line ET. In addition, HR+/HER2-negative tumors with high expression of the HER2-enriched signature, a biomarker of estrogen-independence, benefit the most from bevacizumab. Further validation of these prognostic and predictive biomarkers is warranted.
Title: DNA methylation patterns correlating with outcome in patients treated with first-line bevacizumab for metastatic breast cancer

Gampenrieder SP P, Rinnerthaler G, Weinhäusel A, Pulverer W, Hugnagl C, Hackl H, Romeder F, Monzo Fuentes C, Hauser-Kronberger C, Mlineritsch B and Greil R. Salzburg Cancer Research Institute with Laboratory of Immunological and Molecular Cancer Research and Center for Clinical Cancer and Immunology Trials, Paracelsus Medical University Salzburg, Salzburg, Austria; Business Unit for Molecular Diagnostics, AIT – Austrian Institute of Technology GmbH, Vienna, Austria; Division of Bioinformatics, Biocenter, Innsbruck Medical University, Innsbruck, Austria and Paracelsus Medical University Salzburg, Salzburg, Austria.

Body: Background: Biomarkers predicting response to bevacizumab containing therapy in breast cancer are of urgent need for a personalized treatment approach. DNA methylation is involved in regulation of angiogenesis and development of treatment resistance and could therefore provide predictive information for bevacizumab efficacy.

Patients and methods: A genome-wide methylation profiling using the Illumina Infinium HumanMethylation450 BeadChip was performed in FFPE specimen of 36 patients with HER2-negative metastatic breast cancer treated with chemotherapy in combination with bevacizumab as first-line therapy (discovery set). Twenty-eight (78%) samples came from primary tumor and 8 (22%) from metastasis (2 lung mets., 1 pleural met., 1 liver met., 2 soft tissue mets., 1 ovarial met., 1 bone marrow infiltration). Based on progression-free survival (PFS) and breast cancer subtype (ER+ vs. triple-negative) patients were divided in responder (R) and non-responder (NR). By biostatistical methods differences in the methylation pattern between R and NR were detected. The 48 most interesting genes (e.g. because of their involvement in angiogenesis or carcinogenesis) showing a differential methylation status between R and NR are currently validated in two further metastatic breast cancer cohorts treated with (main set) and without bevacizumab (validation set), respectively. These validated results will be presented at the meeting.
2015 San Antonio Breast Cancer Symposium

Body: INTRODUCTION AND OBJECTIVES: Patients with advanced breast cancer (BC) and metastatic bone disease typically have elevated serum levels of bone turnover markers (BTMs). Potent antiresorptive agents, such as denosumab and zoledronic acid, can significantly reduce BTM levels (Stopeck et al. J Clin Oncol 2010). Prior studies have provided evidence that higher BTM baseline levels may be associated with worse clinical outcomes (Ali et al. Ann Oncol 2004). In this analysis, we assessed the association between BTM levels after treatment with antiresorptive agents and overall survival (OS), disease progression (DP) and disease progression in the bone (DPB) in patients with advanced BC and bone metastases.

METHODS: This post-hoc analysis included data from patients with BC and bone metastases enrolled in an international, blinded phase 3 trial who were randomized to receive either denosumab (120 mg SC) or zoledronic acid (4 mg IV, adjusted for creatinine clearance). The BTMs urinary N-telopeptide (uNTx) and bone-specific alkaline phosphatase (BSAP) were measured at study entry and at study month 3. The clinical outcomes of OS, DP, and DPB were compared in patients with BTMs above or below median levels at month 3 of antiresorptive therapy. These covariate analyses were based on Cox models stratified by treatment, prior SRE before month 3, prior bisphosphonate use, chemotherapy at randomization, and region (Japan or other countries).

RESULTS: A total of 1705 patients were measured for uNTx serum levels, with 895 patients ≥ and 810 < the median of 10.40 nmol/mmol at month 3. Similarly, BSAP levels were measured in a total of 1708 patients, with 855 patients ≥ and 853 < the median BSAP level of 10.89 ng/mL at month 3. Patients with uNTx levels ≥ the median at month 3 had a significantly reduced OS (by 54%) and a greater risk of both DP (by 21%) and DPB (by 23%) than patients with uNTx levels < median (see Table). Similarly, patients with BSAP levels ≥ the median level at month 3 had an increased risk for reduced OS (by 197%), DP (by 67%) and DPB (by 56%) compared with patients whose BSAP levels < median. After adjusting for risk factors suggestive of more advanced disease such as visceral metastases or > 2 bone metastases, the correlation between elevated BTMs and reduced OS and greater risk of DP and DPB was maintained.

CONCLUSIONS: Patients with BTM levels ≥ median at month 3 of antiresorptive therapy had generally worse clinical outcomes than patients whose BTM levels were < median. Assessment of uNTx and BSAP serum levels after treatment with antiresorptive therapy can add to our understanding of which patients with breast cancer and bone metastases are most at risk for decreased OS, or increased DP or DPB.

Title: CYPTAM-BRUT 3: Endometrial thickness cannot be used as a marker for tamoxifen metabolization in postmenopausal breast cancer patients

Body: Background:
Tamoxifen is commonly used for the treatment of all stages of estrogen receptor (ER) positive breast cancer (BC), the largest group of BC. In postmenopausal women, known endometrial side-effects are cystic appearance, hyperplasia, polyps and endometrial cancer. Tamoxifen is converted through several CYP450 enzymes into the active metabolite endoxifen. Patients with particular single nucleotide polymorphisms (SNPs) in those CYP450 enzymes (e.g. CYP2D6) have lower endoxifen concentrations and therefore could experience less benefit from tamoxifen. However, the clinical significance stays controversial in the literature as results remain contradictory. Our primary hypothesis is that women with lower endoxifen levels do not have the typical tamoxifen-induced increase in endometrial thickness.

The aim of this study is to test the association between endoxifen concentration and the increase in double endometrial thickness (DET).

Patients and methods:
CYPTAM-BRUT 3 is a prospective, multicentric study including postmenopausal women with an ER positive BC receiving tamoxifen in the adjuvant setting. Primary objective is the association between serum endoxifen levels and change in DET between baseline and follow-up after 3 - 6 months. Secondary objectives are investigating the relation between serum endoxifen levels and other endometrial changes (i.e. the presence of cysts/polyps), menopausal symptoms assessed with a questionnaire and serum levels of follicle-stimulating hormone (FSH) and sex hormone-binding globulin (SHBG). Other objectives are the association between the 'CYP2D6 tamoxifen activity score', based on SNPs and co-medication, and DET, other endometrial changes, FSH and SHBG. The CYPTAM-BRUT 3 study is a sub-study of the CYPTAM study in Leiden, The Netherlands, with survival as primary outcome.

Results:
144 women were included in 19 hospitals. There was no significant association found between endoxifen and change in DET (p=0.888), as for the association between endoxifen and the development of cysts/polyps (p=0.208). For the questionnaire items no correlation was found (p≥0.051). Changes of FSH and SHBG were in the range of what would be expected during tamoxifen treatment in the general population and there was no association with endoxifen (p=0.726 and p=0.181). In addition, no association was found between the CYP2D6 TAS score and DET (p=0.613), other endometrial changes (p=0.196), FSH (p=0.976) and SHBG (p=0.900).

Conclusion:
Our study is one of the first studies that prospectively investigated the relation between tamoxifen metabolization, in correlation with endometrial thickness and SNPs.

We can conclude that the typical increase in endometrial thickness seen in a significant proportion of postmenopausal women under tamoxifen cannot be used to predict that those women have a high endoxifen concentration or that women without an increased endometrial thickness have a significantly lower endoxifen concentration. The same conclusions can be made for the
other tamoxifen-induced changes as cysts and polyps, menopausal symptoms, FSH and SHBG. It may also apply to tamoxifen efficacy but further prospective studies looking at survival are needed to answer that question.

Title: Comprehensive profiling of metaplastic breast carcinoma reveals frequent over-expression of PD-L1

Body: Background: Metaplastic breast carcinoma (MBC) is a rare subtype of breast carcinoma less responsive to conventional chemotherapy relative to usual breast carcinomas (UBCs) such as ductal and lobular subtype. In molecular terms MBC usually clusters with triple negative breast cancer (TNBC), but MBCs portray a worse prognosis in comparison to TNBCs. Published studies investigating MBCs for specific biomarkers of therapy response are rare and limited by the methodological approaches.

Methods: This study included 132 patients with 38 histologically confirmed MBCs and 94 UBCs. Amongst the 94 UBCs, 44 were estrogen receptor positive, 33 were triple negative and 17 were HER2 positive. Direct sequencing analysis was performed on genomic DNA isolated from formalin-fixed paraffin-embedded tissue (FFPE) using the Illumina MiSeq Next Generation Sequencing platform (NGS). Immunohistochemistry for PD-L1 (SP142, Spring Bioscience), PD-1 (NAT105, Ventana) and EGFR (31G7, Life Technologies) was performed using automated procedures. Additionally, mutation analysis for *EGFRvIII* was performed on RNA extracted from FFPE tissue.

Results: At the genomic level, numerous cases of MBC had multiple genomic alterations with the most frequent genetic mutation in *TP53* gene (14/24), similar to the TNBC controls (17/33). *BRCA1* mutations were detected in 2/10 cases. Potentially actionable mutations were rare and included *PIK3CA* gene. Importantly, PD-L1 expression on cancer cells was detected in significantly higher proportion of MBCs (37%) than in the UBC cohort (6%) or TNBC control (14%) (p=3.7x10^-5 and p=0.03, respectively). PD-1 positive tumors infiltrating lymphocytes (TILS) varied greatly in MBC (0 to >50/mm²). Over-expression of *EGFR* was frequent in MBCs (62%); however no mutations in the gene including *EGFRvIII* were detected.

Conclusion: Comprehensive profiling of a large cohort of this rare carcinoma highlighted predominance of *TP53* mutations, wild type *EGFR* gene expression, a distinct increase in proportion of PD-L1 expression in carcinoma cells, and PD-1 expression in TILS. The latter properties can be exploited in clinical trials utilizing immune check point inhibitors.
Title: Prediction of complete pathologic response to veliparib/carboplatin plus standard neoadjuvant therapy in HER2 negative breast cancer: Exploratory protein pathway marker results from the I-SPY 2 trial

Body: Background: In the I-SPY 2 TRIAL, HER2- patients were randomized to receive standard chemotherapy or chemotherapy plus the oral PARP inhibitor veliparib in combination with carboplatin (V+C), which graduated in the HR-/HER2- arm. Exploratory analysis of protein signaling was performed to identify biomarker candidates that correlated with pCR in the HER2- population. We evaluated 110 key signaling proteins using reverse phase protein microarray (RPPA) data from pre-treatment LCM purified tumor epithelium.

Methods: Of 115 patients, 97 (V+C: 61 controls: 36) had RPPA and pCR data. RPPA data was correlated to pCR in both the treated and control patients using parametric (t-test) or non-parametric (Wilcoxon) statistical analysis, depending on data distribution. Only analytes whose pre-treatment levels were associated with response in the V+C but not in the control arm were identified (P<0.05). Markers are analyzed individually; p-values are descriptive and were not corrected for multiple comparisons. Results: 11 protein/phosphoprotein markers were significantly associated with pCR in the V+C arm but not in controls. Two were positive predictors of response: YAP S127 p= 0.03 and LC3B p=0.04. Negative predictors of response included Cyclin D1 p=0.001, and a number of phosphorylated RTKs: ROS Y2274 p=0.03, IGF1R Y1135/Y1136-IR Y1150/Y1151 p=0.03, ERBB4 Y1284 p=0.002, total HER2 p=0.04, and total IGF1R p=0.01. Moreover, a number of AKT-mTOR pathway proteins were found to be negative predictors of V+C response: ACC S79 p=0.005, p70S6K S371 p=0.01, and B-RAF S445 p=0.01.

Conclusion: Our sample size is too small to draw definitive conclusions and the results are exploratory. Coordinated RTK-mTOR pathway activation appears to be a hallmark signature of lack of response to veliparib in HER2- tumors. We also found that HER2 levels were correlated paradoxically with lack of response in this HER2- population, suggesting potential added clinical value of quantitative HER2 measurement techniques. Such exploratory results merit evaluation in larger trials with HER2- breast cancer patients.
Title: Residual cancer burden (RCB) with veliparib/carboplatin in the I-SPY2 trial

Liu MC, Symmans WF Fraser, Yau C, Chen Y-Y, Rugo HS S, Olopade OF F, Datnow B, Chen B, Feldman M, Kallakury B, Hasteh F, Tickman R, Ritter J, Troxel M, Mhawech-Fauceglia P, Duan X, Berry D, Esserman L and DeMichele A. Mayo Clinic, Rochester, MN; MD Anderson, Houston, TX; Buck Institute for Research on Aging, Novato, CA; University of California, San Francisco, CA; University of Chicago, Chicago, IL; University of San Diego, San Diego, CA; University of Pennsylvania, Philadelphia, PA; Georgetown University, Washington, DC; Swedish Medical Center, Seattle, WA; University of Minnesota, Minneapolis, MN; OHSU, Portland, OR; Keck Hospital of USC, Los Angeles, CA and Loyola University Health System, Maywood, IL.

Body: Background: I-SPY2 is a multicenter phase 2 trial in high risk stage II/III breast cancer (BC) using adaptive randomization within biomarker subtypes to evaluate novel agents added to standard neoadjuvant chemotherapy. The first regimen to graduate based on the predicted probability of a higher pCR rate within predefined subsets was veliparib/carboplatin + paclitaxel (VC+T→AC vs T→AC) in triple negative BC (TNBC). In TNBC the residual cancer burden (RCB) is prognostic, whether as a continuous index or grouped into classes, with pCR (RCB-0) and RCB-I classes having identical survival. Therefore, we evaluated the use of RCB to further discriminate between investigational and control arms. Methods: Site pathologists reported RCB for 99% of subjects in the primary efficacy analysis based on pCR (n=114/115). We compared the distribution of RCB reported as a continuous index in each treatment-subset combination to matched concurrently randomized controls using the Wilcoxon rank sum test for RCB index, and Fisher's Exact test for RCB classes (RCB-0/I vs RCB-II/III). The statistics are descriptive rather than inferential, and given the small sample size have no claim on generalizability. We modified the Bayesian model used to compute the estimated probability of success in a future, randomized, phase 3 trial of 300 subjects, if response were defined by either pCR or RCB-I (RCB0/I), or separately if it were defined by pCR alone. Results: VC+T→AC led to a significantly lower RCB index than T→AC in TNBC (p=0.0021), with a near-significant trend when those with pCR were excluded (p=0.06). There was no significant difference in RCB distributions in the other breast cancer subtypes treated. In TNBC, the odds ratio (OR) for achieving RCB-0/I in the VC+T→AC arm vs control was 8.2 (95% confidence interval (CI): 2.1–35), whereas the OR for achieving pCR was 4.56 (95% CI: 1.25–19.53). The simulations using response information from I-SPY2 to predict the probability of success for VC+T→AC for TNBC in a future phase 3 trial estimated this probability to be 0.99 if modeled using RCB-0/I as the response endpoint, and 0.90 if modeled using pCR as the response endpoint. Conclusions: Use of RCB index and classes provided additional insight into the effect of adding VC to T, appearing to magnify the improved treatment response that had been observed with pCR rates in TNBC. It will be important to test in randomized trials whether a decrease in the RCB index relative to controls, and/or increased rates of RCB-0/I class, are predictive of survival benefit in TNBC.
Title: Early and accurate prediction of pathological response by magnetic resonance imaging and ultrasonography in patients undergoing neoadjuvant chemotherapy for operable breast cancer

Kaise H, Ishikawa T, Miura D, Hasegawa Y, Horiguchi J, Hayashi M, Takao S, Kim SJ, Tanino H, Miyashita M, Konishi M, Shigeoka Y, Yamagami K, Suzuki M, Taguchi T, Akazawa K and Kohno N. Tokyo Medical University Hospital, Tokyo, Japan; Yokohama City University Medical Center; Toranomon Hospital; Hirosaki Municipal Hospital; Gunma University Hospital; Tokyo Medical University Hachioji Medical Center; Hyogo Cancer Center; Osaka University Hospital; Naga Municipal Hospital; Konan Hospital; Hyogo Prefectural Nishinomiya Hospital; Yodogawa Christian Hospital; Shinko Hospital; Niigata University Medical and Dental Hospital; Kobe Kaisei Hospital; National Hospital Organization Chiba Medical Center and University Hospital, Kyoto Prefectural University of Medicine.

Body: Background: Neoadjuvant chemotherapy (NAC) reduces tumor size, and increases the frequency of breast-conserving surgery in operable breast cancers. Response predictions to NAC are made based on diagnostic imaging. Although various studies have reported the optimal timing for diagnostic imaging, this still remains unclear.

Purpose: To identify the optimal timing of diagnostic imaging for the response prediction to NAC, and to evaluate the accuracy of response prediction.

Methods: We evaluated 146 cases enrolled in the JONIE-1 study (a randomized controlled trial comparing zoledronic acid plus chemotherapy with chemotherapy alone as a NAC in patients with HER2-negative primary breast cancer). The chemotherapy regimen was FEC100×4 courses followed by weekly paclitaxel 80×12 courses (± zoledronic acid). Statistical analysis of the association between the tumor reduction ratio and the histopathological response and the prediction of pathological complete response (pCR) was performed using JMP software. The maximum tumor diameter was evaluated using magnetic resonance imaging and ultrasound on each patient 3 times (before NAC, after FEC treatment, after NAC) and tumor reduction ratios were calculated.

Results: The average age of the patients was 49.8 years old. The menopause status was pre-menopause in 84 patients, and post-menopause in 58 patients. Regarding the subtype classification, 116 patients were of the luminal type (Lum) and 26 patients were triple negative (TN), and the Ki-67 labeling index had a median of 25% (1%-93%). Pathological examination demonstrated that 16 patients had pCR(11.3%, Lum; 9; TN: 7), and 126 patients had non-pCR (88.7%, Lum:107; TN:19). Seven patients had clinical-CR (4.8%, Lum: 4; TN: 3) at post-FEC, and 26 patients (17.8%, Lum: 20; TN: 6) at post-NAC. The prediction of pCR at post-FEC and post-NAC was evaluated by single variable analysis, resulting in an AUC (0.75645) p=0.0017 at post-FEC, and AUC (0.76563) p=0.0001 at post-NAC. The sensitivity / specificity / positive predictive value / negative predictive value were 0.625 / 0.873 / 0.385 / 0.948 at post-FEC, 0.250 / 0.976 / 0.571 / 0.911 at post-NAC, respectively. In TN cases, the values were 0.714 / 0.947 / 0.833 / 0.900 in post-FEC, and 0.429 / 1.000 / 1.000 / 0.826 in post-NAC.

Conclusions: Diagnostic imaging evaluation performed after FEC treatment was useful for the prediction of pCR. Furthermore, the reliability was high in Triple Negative Sub type, but is affected by the existence of residual tumors in Luminal type.
Title: Regulation of DNA methyltransferases via TRAF6 determines breast cancer response to decitabine

Body: Background: Tumorigenesis involves both genetic and epigenetic changes. Epigenetic alterations are reversible and are promising cancer therapeutic targets. Decitabine (5-aza-2'-deoxycytidine), a DNA methyltransferase inhibitor, is FDA approved for hematological malignancies. However, the effect of decitabine in breast cancer is not completely understood. Previous reports indicated that one decitabine mechanism involves regulation of protein levels for DNMT1, the major DNA methyltransferase that methylates hemimethylated CpG di-nucleotides in DNA. However, the E3 ligase involved in this process has not been identified. Whether decitabine also regulates DNMT3A and 3B in a similar fashion remains unclear. Therefore, our goals were to 1) understand mechanisms underlying decitabine action, 2) test the antitumor activity of decitabine in breast cancer models and 3) identify biomarkers associated with response to decitabine.

Methods and Results: Western blots of breast cancer cell lines showed that DNMT1, DNMT3A, and DNMT3B protein levels decreased following decitabine treatment without a reduction in mRNA levels. Bioinformatic analysis of DNA methyltransferase sequences revealed a potential TRAF6 binding motif, and the interaction with TRAF6 (TNF receptor-associated factor 6) was confirmed by IP. TRAF6 functions as an E3 ligase. To determine whether TRAF6 might be the E3 ligase responsible for the degradation of DNMTs after decitabine treatment, we knocked down TRAF6 by RNA interference or knocked out the TRAF6 gene by CRISPR/Cas9. Down regulation of TRAF6 attenuated DNMT ubiquitination and increased DNMT protein levels, suggesting that TRAF6 might mediate proteasome-dependent degradation of all three DNMTs. This was further confirmed by reconstituting the knockout cells with WT and a TRAF6-C70A mutant, followed by assessing DNMT protein levels. Global DNA methylation was also increased after TRAF6 depletion and was confirmed in TRAF6 knock out cells in which DNMT levels were unaffected by decitabine. Cell cytotoxicity and colony forming assays showed that TRAF6 knockout cells were resistant to decitabine, suggesting that a major decitabine mechanism of action is through the regulation of TRAF6 which, in turn, degrades DNMTs, leading to decreased global methylation. Finally, decitabine significantly induced TRAF6 at both mRNA and protein levels, a process that might create positive feedback leading to increased degradation of DNMT proteins upon decitabine treatment. Based on these results, we further hypothesized that levels of the three DNMTs might influence decitabine response. Using 18 breast cancer patient derived xenograft (PDX) models, we found a wide range of DNMT protein levels regardless of ER/HER2 status. DNMT levels in the PDX models were directly associated with sensitivity to decitabine treatment, confirming our hypothesis.

Conclusion: Our data showed that decitabine might be an effective agent for treating breast cancer and revealed a novel mechanism underlying decitabine treatment. Baseline DNMT protein levels may serve as a biomarker for predicting decitabine drug response.

Title: Identification of serum biomarkers associated with Akt inhibitor MK-2206-induced toxicity in a pre-surgical breast cancer (BC) trial

Body: Background: The PI3K/Akt/mTOR pathway is an important oncogenic driver in BC. A major hurdle in clinical Akt inhibitor development has been dose-limiting toxicities, such as rash. To facilitate the risk assessment of Akt inhibitor associated toxicity, we hypothesize that circulating biomarkers can be identified in proteins secreted by the tumor or tumor microenvironment and systemic response after treatment. Exosomes are small membrane bound vesicles containing proteins, mRNA, miRNA, and lipids that are secreted from host cells and remain viable after long-term storage of blood. In this study, we focused on identifying biomarkers associated with drug rash from serum exosomes in BC patients treated with the Akt inhibitor MK-2206.

Methods: In an open-label pre-surgical trial, 2 doses of weekly MK2206 were administered to patients (pts) with stage I-III invasive BC: first at day -9 and second at day -2 from surgery. Sera were collected before and after MK2206. 200 µL of serum was used to isolate total exosomes by precipitation and centrifugation, followed by trypsin digestion and multiplexing labeling analysis. The Orbitrap mass spectrometer was used to acquire LC-MS/MS data. 1,053 unique proteins were identified from the uniProt database. Maximum false discovery rate level (FDR) for predictive biomarkers was controlled at 26% (q<0.26). Analysis was conducted on pre-MK-2206 and post-MK-2206 treated sera from pts to develop a protein signature associated with rash and identify candidate biomarkers of MK-2206-associated rash.

Results: The study was discontinued after 12 pts were enrolled due to toxicity. Notably, an acneiform/maculopapular rash was observed in 5 pts. Unsupervised principal component analysis on the pre-MK-2206 specimens and the entire set of 1,053 proteins demonstrated that 4 of the 5 pts with rash formed a distinct cluster. 30 proteins were differentially expressed in pre-MK-2206 samples from pts who developed rash vs. no rash (q<0.26), with ≥1.5 fold difference in expression level in those with rash after MK-2206. Ingenuity pathway analysis revealed statistically significant over-representation of pathways involved in lipid metabolism (including MALRD1, AWAT2), nucleic acid synthesis (PPAT, ADSLL1), and protein synthesis (PPIB). 45 proteins were significantly different in post-MK-2206 samples (q<0.285). Lipid metabolism was the most significantly over-represented pathway in post-MK-2206 samples.

Conclusions: We demonstrated that mass spectrometry-based proteomic analysis of patient-derived serum exosomes is a promising approach to study drug-induced toxicity. We found significant changes of circulating proteins before and after MK-2206. Increased expression of different proteins involved in lipid metabolism appears to predict skin toxicity, commonly seen with PI3K/Akt pathway inhibitors. Since the PI3K/Akt signaling pathway plays a role in physiological regulation of lipid metabolism, lipid metabolic profiles of BC patients might be important for predicting the risk and controlling toxicity induced by Akt inhibitors. These toxicity-associated biomarkers should be validated and then assessed prospectively in clinical trials.
Chromosomal instability as a predictor of sensitivity to paclitaxel

Cavalcante LL L, Denu R, Zasadil L, Weaver BA A and Burkard M. University of Wisconsin, Madison, WI.

Body: Background: Paclitaxel is one of the most effective therapies for breast cancer, although many patients do not benefit. Our goal is to identify those who will benefit, by understanding how this drug contributes to chromosomal instability (CIN). CIN is the gradual gain/loss of whole chromosomes that can occur with mitotic errors as tumors proliferate. Some breast cancers inherently have CIN whereas others lack CIN. Previous work suggests low rates of CIN can promote tumor growth by creating genetic diversity. By contrast, high rates of CIN are lethal, apparently due to a high incidence of deleterious karyotypes. We hypothesize that paclitaxel operates by increasing CIN, and that this has preferential anticancer effects in tumors with preexisting low CIN. Methods: To assess rates of underlying CIN in human breast cancer, we performed 6-chromosome FISH on 354 human breast cancers and correlated with outcomes on a cohort with median 8.4 year follow-up. We measured the physiologic levels of paclitaxel that occur in human breast tumors. To do this, we treated 5 women with neoadjuvant paclitaxel 175mg/m2, performed tumor biopsy at 20 hours, performed LC to quantify intratumoral levels and analyzed mitotic spindles by IHC. Additionally, we performed timelapse videomicroscopy to analyze mitosis in fluorescently-labeled breast cancer cells in the laboratory after exposure to these levels. To evaluate whether CIN controls paclitaxel sensitivity we artificially introduced low levels of CIN into breast cancer cell lines by doxycycline-inducible expression of GFP-Mad1, a protein involved in the mitotic checkpoint, and tested whether this enhanced sensitivity to physiologic doses of paclitaxel.

Results: A total of 77% (270/349) of breast cancer have detectable underlying CIN, (average percentage of non-modal chromosomes averaged for 6 chromosomes) greater than the normals (n=11). CIN is higher in HER2+ and TNBC subtypes compared to HR+. CIN does not correlate with the proliferation marker, Ki67 (r2 = 0.04), which does not support the idea of a growth advantage. CIN greater than median levels correlated with worse breast cancer-specific survival (p=0.022 log rank), but no difference in OS or RFS. Paclitaxel in human breast cancer reaches a level mimicked by 5-50nM exposure in laboratory experiments. In the laboratory, breast cancer cells exposed to these levels exhibit multipolar divisions, and similar abnormal mitoses can be found in patient tumors. In breast cancer cells lacking CIN, chromosome analysis demonstrates that it can be artificially induced by conditionally expressing GFP-Mad1. Inducing GFP-Mad1 expression increases sensitivity to paclitaxel, demonstrating that CIN enhances taxane sensitivity.

Conclusions: These data support the idea that excessively high levels of CIN can be lethal to cancer cells and that paclitaxel enhances CIN. We predict that the anticancer effects of paclitaxel are marked in tumors with intrinsic CIN, as the enhanced levels are lethal. Thus CIN may be an effective biomarker to predict which women will benefit from taxane therapy. Ultimately, this could be applied in the clinic to substantially improve patient care by decreasing primary resistance or by reducing side effects associated with paclitaxel use.
Title: Insulin-like growth factor 1 receptor expression and polymorphism are associated with response to neoadjuvant chemotherapy in breast cancer patients: Results from the NEOZOTAC trial (BOOG 2010-01)

Body: Background
The insulin-like growth factor 1 (IGF-1) pathway is involved in cell growth, proliferation and cell cycle progression and associated with tumor genesis and therapy resistance. This study aims to elucidate whether variation in the IGF-1 pathway is predictive for pathologic response in early breast cancer (BC) patients taking part in the phase III NEOZOTAC trial, randomizing between 6 cycles of neoadjuvant TAC chemotherapy with or without zoledronic acid.

Method
Formalin-fixed paraffin-embedded (FFPE) tissue samples of pre-chemotherapy biopsies and operation specimens were collected for analysis of IGF-1 receptor (IGF-1R) expression using IHC (n=216) and for analysis of 8 candidate SNPs in genes of the IGF-1 pathway (n=184) using OpenArray® RealTime PCR. Optionally, blood samples were collected immediately before chemotherapy for determination of glucose, insulin, IGF-1, IGF-2 and IGF-BP3. Associations with patient and tumor characteristics and chemotherapy response according to Miller and Payne (MP) pathologic response were performed using chi square and logistic regression analyses.

Results
High IGF-1R expression was associated with estrogen receptor expression (P=0.001). During chemotherapy, a significant number of the tumors (47.2%) showed a decrease in IGF-1R expression, while in a small number of the tumors an upregulation was seen (15.1%). IGF-1R expression before treatment was not associated with pathological response, however absence of IGF-1R expression after treatment was associated with a better response in multivariate analyses (P=0.012) and patients with a decrease in expression during treatment showed a better response to chemotherapy as well (P=0.008). Moreover, the variant T allele of 3129G>T in IGF-1R (rs2016347) was associated with a better pathological response in multivariate analyses (P=0.032). In addition, high glucose and insulin levels were associated with positive lymph node status before chemotherapy in multivariate analysis (P=0.019) and (P=0.031), respectively.

Conclusion
Neoadjuvant chemotherapy induced changes in the IGF-1R expression in most of the tumors. Absence or diminished expression of IGF-1R after treatment was associated with a better pathological response. Additionally, we found a SNP (rs2016347) in IGF-1R as a potential predictive marker for chemotherapy efficacy in BC patients treated with TAC. These findings may help to select patients who might benefit from (co-)treatment with an IGF-1 pathway inhibitor.
Title: Predictive value of O6-methylguanine-DNA methyltransferase (MGMT) promoter gene methylation in triple-negative breast cancer patients receiving carboplatin

Fontanella C, Gehlhaar C, Denkert C, Schneeweiss A, Heppner B-I, Koch I, Blohmer J-U, Jackisch C, Lederer B, Fasching PA A, Müller V, Untch M, Aprile G, Puglisi F, Nekljudova V, Heppner F, von Minckwitz G and Loibl S. German Breast Group, Neu-Isenburg, Germany; University Hospital of Udine, Udine, Italy; Charité University of Berlin, Berlin, Germany; University Hospital Heidelberg, Heidelberg, Germany; Sana Klinikum Offenbach, Offenbach, Germany; University Hospital Erlangen, Erlangen, Germany; University Hospital Hamburg-Eppendorf, Hamburg, Germany; Helios Klinikum Berlin-Buch, Berlin, Germany and Charité Universitätsmedizin Berlin, Berlin, Germany.

Body: Background: The epigenetic profile of triple-negative breast cancer (TNBC) showed a wide prevalence of MGMT promoter methylation. Aberrant methylation of MGMT seems to be an independent predictor of poor survival in patients with basal-like breast cancer. Moreover, patients with MGMT-negative basal-like tumors who received cyclophosphamide had significantly improved DFS and OS compared with MGMT-positive tumors. However, the impact of MGMT methylation in the context of modern therapy concepts is not clear.

Methods: We retrospectively evaluated 174 TNBC tumors of patients enrolled into the neoadjuvant GeparSixto trial from 08/2011 to 12/2012. Patients were randomized to receive 18 weeks of neoadjuvant treatment with paclitaxel (80mg/m²/week) and non-pegylated liposomal doxorubicin (20mg/m²/week) with or without addition of carboplatin (AUC 2.0-1.5/week). Hormone-receptor status, HER2 status, and Ki67 were centrally confirmed prior to randomization. We defined pathological complete response (pCR) as ypT0/is ypN0. MGMT promoter methylation status was determined by PCR using EZ DNA Methylation Kit™ (Zymo Research); TNBC tumors were considered to be methylated if they had an average methylation ≥ 10%, some tumors were considered borderline due to high heterogeneity among CpG islands. We investigated the effect of MGMT methylation on pCR and its correlation with baseline characteristics.

Results: A total of 210 tumors from the TNBC cohort of the GeparSixto trial (n=315) were available with a tumor content >20%. In 174 tumors the methylation assay was performed successfully. The number of tumors with methylated MGMT was similar in carboplatin vs. non-carboplatin treated cohorts. In the carboplatin group 19.3% (17/88) of TNBC were methylated, 65.5% (58/88) unmethylated, and 14.8% (13/88) borderline. In the non-carboplatin group 20.9% (18/86) of TNBC were methylated, 62.8% (54/86) unmethylated, and 16.3% (14/86) borderline. In the entire cohort, there was no association between MGMT methylation status and pCR (p=0.522). Non-carboplatin cohort: 33.3% (6/18) of patients with methylated MGMT achieved pCR vs. 51.9% (28/54) of unmethylated and 51.9% (28/54) of patients with methylated MGMT achieved pCR vs. 51.9% (28/54) of unmethylated and 51.9% (28/54) of patients with methylated MGMT achieved pCR vs. 51.9% (28/54) of unmethylated and 51.9% (28/54) of patients with methylated MGMT achieved pCR vs. 51.9% (28/54) of unmethylated (p=0.079). Carboplatin cohort: 52.9% (9/17) of patients with methylated MGMT achieved pCR vs. 55.2% (32/58) of unmethylated and 76.9% (10/13) of borderline (p=0.320). In TNBC patients with methylated MGMT, the addition of carboplatin resulted in a 20% increased pCR rate (p=0.241).

Conclusion: In this study no statistically significant association between MGMT methylation and pCR was found. Patients with MGMT methylation seemed to have a lower possibility to achieve a pCR and the addition of carboplatin seemed to reverse this effect. However, a clear classification of the borderline MGMT samples and further studies in larger series of TNBC are warranted.
**Title:** Predictive value of tertiary lymphoid structure assessed by high endothelial venule count in neoadjuvant setting of triple-negative breast cancer

Song IH, Lee HJ, Park IA, Yu JH, Ahn J-H and Gong G. University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea.

**Body:**

**Background**

Tertiary lymphoid structure (TLS) is an ectopic lymph node-like structure characterized by lymphoid aggregation with high endothelial venules (HEVs), and is an important source of tumor-infiltrating lymphocytes (TILs). TILs have a strong prognostic and predictive significance, particularly in triple-negative breast cancer (TNBC). We previously analyzed expression of immune-related genes in pre-neoadjuvant chemotherapy (NAC) biopsy samples using NanoString assay and showed that gene expression of follicular helper T cell marker CXCL13, which is closely associated with TLSs, was an independent predictive factor for pathologic complete remission (pCR) in TNBC. However, measuring gene expression of biopsy sample is not easy to perform in daily pathology practice. Therefore, we evaluated TLSs by assessing hematoxylin and eosin (H&E) stained slides and immunohistochemistry, and investigated their clinical importance.

**Methods**

A total of 108 patients diagnosed with primary TNBC and treated with NAC (anthracycline, cyclophosphamide, and taxane) were included. The amounts of TILs and TLSs were histopathologically measured in H&E slides. Immunohistochemical studies were done in 55 cases with available tissue samples. The numbers of CD3-, CD8-, and CD20- immunopositive cells in tumor areas were counted by the image analyzer. MECA79- immunopositive HEV densities were calculated. Their relationship to CXCL13 gene expression by NanoString assay was also analyzed.

**Results**

The overall rate of pCR was 30.6% (33 of 108 tumors). Lower pre-NAC clinical T stage and higher level of TIL and TLS assessed by H&E slides were predictors of pCR in all cases. The mean number of MECA 79-immunopositive HEV in pre-NAC biopsy samples was 12 (range, 0-72). The amounts of TILs and TLSs, numbers of CD3-, CD8-, and CD20- positive cells, HEV density, and expression of CXCL13 showed good correlation with one another. Higher HEV density, CD20- positive cell number, and CXCL13 expression were predictors of pCR. Higher CD8- positive cell numbers and CXCL13 expression were associated with better disease-free survival rate.

**Conclusion**

The amount of TLSs assessed by H&E slides and MECA 79-immunopositive HEV densities was well correlated with level of TILs, numbers of CD3-, CD8-, and CD20-positive cells, and gene expression of CXCL13, and was significantly associated with pCR in TNBCs. Therefore, assessing HEV density by MECA 79 immunohistochemistry in pre-NAC biopsy samples might be an objective and valuable tool for predicting pCR of TNBC in routine pathology practice. Further investigation of mechanism of TLS development might help to improve immunotherapeutic strategy.
Title: Development of a 6-gene qPCR RUO-validated assay as a predictive biomarker for response of vantictumab (OMP-18R5; anti-frizzled) in HER2- breast cancer patients

Body: Background: We have developed a monoclonal antibody, vantictumab that blocks canonical WNT/β-catenin signaling through binding of five FZD receptors (1, 2, 5, 7, 8). This antibody inhibits the growth of several tumor types, including breast. Vantictumab reduces tumor-initiating cell frequency and exhibits synergistic activity with standard-of-care (SOC) agents (Gurney et al, 2012). To target breast cancer patients most likely to respond to vantictumab, we undertook a predictive biomarker study.

Methods: We have identified a 6-gene Wnt pathway-related signature, FBXW2, CCND2, RHOU, CTBP2, WiFi1, and DKK1, based on microarray gene expression data from 8 breast cancer patient derived xenograft (PDX) models with established in vivo response to vantictumab plus SOC. This signature successfully predicted the response of 8 additional and independent PDX breast tumors. We further developed a qPCR Research Use Only (RUO) assay for the 6 genes to be used on FFPE human breast tumor samples. Multiple assays targeting different regions spanning each mRNA transcript were tested and selected based on PCR efficiency, specificity and sensitivity. We compared assay sensitivity under different cDNA synthesis and pre-amplification conditions: random vs. gene-specific priming, number of pre-amplification cycles, pre-amplification reaction volumes, and cDNA synthesis kits. A repeatability study was performed to test assay performance. The pre-amplification and PCR were repeated over three separate days and across two independent labs.

Results: Our results showed that cDNA synthesis by gene-specific priming followed by 18 cycles of pre-amplification performed the best and the assay is robust with minimal starting FFPE RNA input. The results of the repeatability study were consistent among the different days and the different labs (<5% CV). Using the 6-gene qPCR RUO assay, the signature score from the microarray data was further refined using 12 PDX HER2- breast tumors with known in vivo response to vantictumab with SOC. The prevalence of the 6-gene signature was established using ~100 HER2- breast cancer samples.

Conclusions: A robust 6-gene RUO-validated assay was developed as a predictive biomarker for vantictumab in HER2- breast cancer. The assay is currently being evaluated in a Phase 1b study of vantictumab with paclitaxel in HER2- breast cancer.
Title: CD44v as a potential predictive biomarker for pathologic complete response in primary HER2+ breast cancer: Utility of adaptive response biopsy in preoperative therapy

Yamauchi T, Imamura CK K, Yamauchi H, Jinno H, Takahashi M, Kitagawa Y, Nakamura S, Lim B, Krishnamurthy S, Reuben JM M, Liu D, Tripathy D, Zujewski JA, Chen H, Takebe N, Saya H and Ueno NT T. Division of Medical Oncology, St. Luke's International Hospital, Tokyo, Japan; Keio University, School of Medicine, Tokyo, Japan; St. Luke's International Hospital, Tokyo, Japan; Keio University, School of Medicine, Tokyo, Japan; Showa University School of Medicine, Tokyo, Japan; The University of Texas MD Anderson Cancer Center, Houston, TX; The University of Texas MD Anderson Cancer Center, Houston, TX; The University of Texas MD Anderson Cancer Center, Houston, TX; Cancer Therapy Evaluation Program, National Cancer Institute, Rockville, MD and Division of Gene Regulation, Institute for Advanced Medical Research, Keio University, School of Medicine, Tokyo, Japan.

Body: Background: Preoperative dual anti-HER2 therapy with lapatinib and trastuzumab in combination with conventional chemotherapy demonstrates a higher pathologic complete response rate (pCR) than trastuzumab with chemotherapy in patients with HER2+ breast cancer. Preoperative chemotherapy has been reported to increase the fraction of cancer stem-like cells (CSCs) in breast cancer, but this effect has not been well validated in clinical setting. Cancer cells with the epithelial-mesenchymal transition (EMT) phenotype also exhibit stem cell–like properties with drug resistance. Our goal was to determine the quantitative values of various biomarkers in baseline and adaptive response biopsy specimens and in subsequent surgical specimens to predict pCR in patients treated with dual anti-HER2 therapy as demonstrated by reduction of CSCs, phosphorylated receptors and signaling kinases, and circulating tumor cells (CTC) with the EMT phenotype. Methods: Eighteen patients with operable primary HER2+ invasive breast cancer (≥T2 excluding inflammatory breast cancer, any N) were eligible. Patients received lapatinib (1000 mg PO daily) + trastuzumab (4 mg/kg at loading, then 2 mg/kg IV weekly) for the first 6 weeks, then lapatinib (750 mg daily) + trastuzumab (2 mg/kg IV weekly) + paclitaxel (80 mg/m2 IV weekly) for 12 weeks, followed by surgery (ClinicalTrials.gov Identifier: NCT01688609). Tumor and blood specimens were collected before (baseline), after the 6 weeks of dual anti-HER2 therapy (adaptive response biopsy), and at 18 weeks, after 12 weeks of dual anti-HER2 therapy + paclitaxel (surgical specimens). We measured CSC biomarkers CD44 variant (CD44v) and aldehyde dehydrogenase-1 in tumor tissues, EMT markers in CTCs (TWIST1, SNAIL1, SLUG, ZEB1, and FOXC2) in blood samples by quantitative RT-PCR, and the ratios of phosphorylated EGFR (pEGFR)/EGFR, pHER2/HER2, pERK/ERK, and pAkt/Akt in tumor tissues. All tissue and CTC biomarker levels at all three time points were evaluated for their association with response via Fisher's exact test, McNemar's test, and Wilcoxon rank sum test according to the variables. Results: Eight of 18 patients (44.4%) achieved pCR after dual anti-HER2 therapy + concurrent paclitaxel. All patients who achieved pCR showed reduction or disappearance of CD44v+ cells over the treatment course. Five of the 10 non-pCR patients showed consistent CD44v expression or enrichment after dual anti-HER2 therapy in both the adaptive response biopsy and the surgical specimens. None of the eight pCR patients had detectable CD44v in the 7-week adaptive response biopsy specimen (Fisher exact test, two-tailed, P = 0.0359). None of the other markers significantly predicted pCR. Conclusion: Persistent expression or enrichment of CD44v was suggested to be predictive for non-pCR in breast cancer patients treated with preoperative dual anti-HER2 therapy plus concurrent cytotoxic chemotherapy. A single evaluation of biomarkers before therapy is insufficient for prediction of clinical response. Application of the adaptive response biopsy during the course of preoperative therapy might play a significant role in the success of therapeutic strategies that target CSCs.
Title: Stem cell markers are overexpressed in tumorspheres cultured from circulating epithelial tumor cells (CETCs) in patients with breast cancer

Zimon D, Pizon M, Mayer V and Pachmann K. Transfusion Center, Bayreuth, Germany.

Body: Background:
Breast malignancies continuously shed tumor cells which may enter the circulation, spread to other tissue and initiate metastases, but only a small subpopulation among CETCs is capable of metastasis formation. The subpopulation of CETC capable of forming tumorspheres in vitro and carrying stem cells properties is assumed to have metastatic potential. The aim of this study was to characterize the pattern of expression of the tumorspheres as compared to CETCs.

Methods:
Blood samples were obtained from patients diagnosed with breast tumors. CETCs were enumerated with maintrac method and subsequently cultivated in stem cell-selective medium. The expression of stem cell marker genes EpCAM, Nanog, Okt4 Sox2, ALDH and CD133 were detected by RT-PCR in single CETCs and tumorspheres.

Results:
0.1- 10% of CETCs could form non-adherent tumorspheres under stem cell-selective conditions after a period of 14 days. Array qRT-PCR analysis revealed that putative stem cell markers, such as Oct4, Sox2, Nanog, EpCAM, ALDH1 and CD133 are overexpressed in relation to house-keeping genes RPL13a and GAPDH in tumor spheres in contrast to the significantly lower expression level of these stem cell markers in individually isolated CETCs. High expression level of pluripotency genes in tumorspheres was associated with aggressive tumor behaviour in terms of tumor progression and type of cancer.

Conclusion:
Thus, differential expression of stem cell markers in CETCs and tumorspheres substantiates the hypothesis that only a small population of circulating tumor cells possess the stem cell properties and are responsible for metastasis formation.
Title: Impact of high SPARC expression of a primary tumor as a strong risk factor for disease recurrence and overall survival in patients with triple-negative breast cancer

Zhu A, Yuan P, Du F, Ding X and Xu B. Cancer Hospital, Chinese Academy of Medical Sciences, Peking Union Medical College, Beijing, China.

Body: Background: SPARC (secreted protein acidic and rich in cystein) is a secreted glycoprotein that interacts with extracellular matrix protein and acts as a regulator of critical cellular functions such as proliferation and cell migration. An increasing number of studies have shown altered expression of SPARC in several malignancies. However, the role of this potential biomarker in breast cancer development and progression is controversial. Triple-negative breast cancer (TNBC) is known for its poor prognosis and high recurrence probability. There is a need for prognostic biomarkers to guide treatment decisions for this subtype.

Objective: To explore the association between SPARC and the prognosis of triple-negative breast cancer.

Methods: In this study, a total of 211 samples of triple-negative breast lesions from 2004 to 2008 were collected in Cancer Hospital, Chinese Academy of Medical Sciences. SPARC expression was evaluated by immunohistochemistry using an immunoreactive score (IRS) from patients with up to 10 years clinical follow-up data. The current study set out to examine both the expression of SPARC in primary tumor tissue and to demonstrate if a link existed between the levels of SPARC and the clinical outcome. Cox proportional hazards model was used to estimate HRs and 95%CI, stratified on tumor grade, TNM stage, lymph node status and vascular invasion.

Results: High SPARC expression (IRS≥3) was observed in 52.1% of all primary tumors. Patients expressing low levels of SPARC had better disease-free survival (DFS) (HR=0.632, 95%CI:0.405-0.987, P = 0.044) as well as overall survival(OS)(HR=0.576, 95%CI:0.351-0.946, P = 0.029) compared to those with high SPARC expression levels.Furthermore, the presence of high SPARC expression was an independent prognostic factor for both DFS (HR=1.67, 95%CI:1.04-2.69, P=0.034) and OS(HR=1.77, 95%CI:1.04-3.01, P=0.037) of triple-negative breast cancer patients, stratified on tumor grade, TNM stage, lymph node metastasis and vascular invasion, with adjustment for age, hormonal status, tumor size, adjuvant radiotherapy and adjuvant chemotherapy.

Conclusion: Our results suggest that the presence of higher SPARC expression could be an indicator of high aggressiveness and may be a strong prognostic factor for triple-negative breast cancer.
Title: Predictors of response and follow up biomarkers for metronomic chemotherapy with cyclophosphamide and celecoxib in advanced breast cancer patients

Perroud HA A, Alasino CM M, Rico MJ J, Menacho-Marquez MA A, Mainetti LE E, Queralt F, Pezzotto SM M, Rozados VR R and Scharovsky G. Institute of Experimental Genetics, School of Medical Sciences, National University of Rosario, Rosario, Santa Fe, Argentina; Rosario Institute of Oncology, Rosario, Santa Fe, Argentina; Argentinean Council of Science and Technology - CONICET, Buenos Aires, Argentina and Institute of Immunology, School of Medical Sciences, National University of Rosario, Rosario, Santa Fe, Argentina.

Body: Low-dose metronomic chemotherapy (MC) with Cyclophosphamide (Cy) and Celecoxib (Cel) has demonstrated to be effective and well-tolerated in advanced breast cancer patients (ABCP) but predictive markers of response or follow-up are lacking. Given the antiangiogenic properties of MC we analyzed several angiogenesis-related biomarkers and evaluated their potential role as predictors of response or treatment follow-up of ABCP treated with MC. Treatment plan: Patients received Cy 50 mg p.o./day + Cel 200 mg p.o./bid. Cellular parameters: Circulating endothelial cells (CEC) and Circulating progenitor endothelial Cells (CEP) were determined by Flow Cytometry. Serologic parameters: Serum levels of vascular endothelial growth factor (VEGF), VEGF-C, soluble VEGF Receptors 2 and 3 (sVEGFR-2, sVEGFR-3) and Thrombospondin-1 (TSP-1) were determined by ELISA. Blood samples were collected before and during treatment. Twenty patients were enrolled. Response Rate was 5% and Clinical Benefit (CB) 55%. Most of the patients showed prolonged stable disease (SD ≥ 24 weeks). Biomarkers were determined in all patients. Levels of CEC and CEP showed no clear trend variations during treatment. However, levels of CEC significantly increased at the time of disease progression in those patients who showed CB (P=0.014). Also baseline values of CEC and CEP showed marginally significant associations with Time To Progression. Serum VEGF concentration decreased during treatment (P=0.050) while sVEGFR-2 increased (P=0.005). VEGF-C, sVEGFR-3 and TSP-1 showed non-significant variations. VEGF/sVEGFR-2 ratio decreased during treatment (P=0.041), whereas VEGF/TSP-1, and VEGF-C/sVEGFR-2 ratios showed non-significant variations. Baseline values of VEGF, and VEGF/sVEGFR-2 showed negative and significant associations with TTP (P=0.0354 and P=0.0300, respectively) while sVEGFR-2 did not. When considering the two variables together, the goodness of prediction was not improved. To confirm the value of baseline VEGF and VEGF/sVEGFR-2 as predictors of response, we used the 50th percentile as a cutoff value to analyze the % of progression free survival. Patients with values lower than the 50th percentile for both biomarkers showed longer TTP (P=0.0001 and P=0.0008, respectively). The treatment had anti-angiogenic effect (VEGF decrease and sVEGFR-2 increase). The absence of variation in VEGF-C and sVEGFR-3 would indicate the lack of effect on lymphangiogenesis. Increased levels of CEC could be useful for detecting progression. If confirmed with a higher number of patients, baseline VEGF and VEGF/sVEGFR-2 values could be useful as early predictors of response.
**Title:** Association of overexpression of hypoxia inducible factor 1α with response to neoadjuvant chemotherapy in early stage breast cancer

Zhi WI Iris, Huang C-Y, Gabrielson E, Tully E, Cimino-Mathews A, Santa-Maria C, Jeter S, Kai C, Semenza G and Stearns V. Hematology/Oncology Fellowship Training Program, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD; Breast and Ovarian Cancer Program, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD; Division of Biostatistics and Bioinformatics, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD and Sun Yat-Sen Memorial Hospital., Yanjiang West Rd. #2, GuangDong, China.

**Body:**

**Background:** Hypoxia inducible factor 1 alpha (HIF-1α) is a master transcription factor involved in multiple oncogenic processes. In breast cancer, HIF-1α overexpression is associated with increased resistance to radiation therapy, chemotherapy, and inferior disease-free and overall survival. Patients who achieve a pathologic complete response (pCR) following neoadjuvant therapy have improved survival outcomes. Limited data are available regarding the association between HIF-1α expression and rates of pCR. We investigated the relationship between HIF-1α overexpression and pCR rates following neoadjuvant chemotherapy for early breast cancer.

**Methods:** Eligible women were those with HER2-negative, stage II-III breast cancer, who received anthracycline- and taxane-based neoadjuvant chemotherapy from 2002 to 2012, and were included in an institutional review board-approved Integrated Breast Cancer Research Database at Johns Hopkins. The database includes patient age, sex, menopausal status, breast cancer diagnosis, tumor histopathology, treatment history, laboratory data, and outcomes. Both diagnostic and surgical tissue blocks were retrieved from pathology archives. Whole section slides were prepared and analyzed by immunohistochemical staining with appropriate negative and positive controls. The intensity of cells positive for HIF-1α was estimated visually by a pathologist blinded to clinical data. A semi-quantitative scoring of nucleus expression was used to score HIF-1α expression: score 0 is defined as less than 1%, 1 is defined as 1-5%, 2 as 5-20% and 3 as >20% tumor cells positive for HIF-1α. Overall tumor HIF-1α negativity was defined as (0, 1) and positivity as (2, 3). We compared baseline HIF-1α status among responders (pCR defined as no invasive tumor in the breast or lymph nodes) and non-responders (no pCR) using Fisher's exact test, and evaluate the association between baseline and surgical specimens in those who did not achieve pCR using McNemar's test.

**Results:** A total of 122 women meeting the eligibility criteria underwent a definitive surgical procedure following neoadjuvant chemotherapy. Of those, 50 patients had no tissue blocks available at baseline and additional 16 patients' blocks did not contain sufficient tissue for analysis. Thus, tumors from 56 women were available for analysis. Median age was 50 (range 33-78), 54% were White and 35% Black; 41% and 59% of women had triple negative and hormone receptor-positive tumors, respectively; 71% women had Ki67>30%, and 80% were node-positive. Overall pCR was observed in 12 women (21%). We did not detect a significant association between HIF-1α score on the diagnostic specimen with pCR status ($p=0.627$). However, a positive HIF-1α score was significantly associated with positive lymph nodes ($p=0.01$). We observed a significant decrease in HIF-1α score following chemotherapy ($p<0.001$).

**Conclusions:** We did not observe a clear association between HIF-1α expression and response to neoadjuvant chemotherapy. However, HIF-1α expression on a diagnostic specimen was statistically higher than following chemotherapy and was associated with lymph node positivity. Our study is limited by its retrospective nature and a small sample size.
Title: Ki67 cut-off point to predict the benefit of adjuvant chemotherapy in ER+ HER2- breast cancer patients

Body: BACKGROUND: The benefit of chemotherapy for patients with estrogen receptor(ER)+ HER2- breast cancers is an ongoing question. The evaluation of the tumor's proliferation by Ki67 may guide the indication but no consensual predictive cut-off has been set yet.

MATERIALS AND METHODS: This study included women with a first ER+HER2- invasive breast cancer treated by primary surgery between 2003 and 2008. Data was collected prospectively. Ki67 cut-off was sequentially set each 1% from 5% to 30%. For each threshold, the interaction between Ki67 and adjuvant chemotherapy was integrated in a multivariate Cox model to determine when it became statistically significant in predicting distant-disease free survival (DDFS). Using different Ki67 cut-offs, we also compared DDFS of patients who had or not an indication of chemotherapy, depending on whether they actually received it or not.

RESULTS: Among the 3221 breast cancers, median Ki67 was 10%, with a mean of 15% (S.D = 14). Ki67 was an independent prognosis factor whether the cut-off was set to 14% or to 20% (p<0.001). The interaction between Ki67 and chemotherapy became significant only for a threshold of Ki67 above 20% (p<0.05). When adjuvant chemotherapy was not indicated according to St Gallen guidelines 2013 with a Ki67 cut-off set to 20%, DDFS was not significantly improved if patients did receive chemotherapy.

CONCLUSION: In ER+ HER2- breast cancers, a Ki67 level of expression >= 20% was predictive of benefit from adjuvant chemotherapy. A threshold at 14% was not as discriminant. Based on this large cohort study, we recommend the use of a cut-off at 20% to decide whether patientes with ER positive tumors should receive chemotherapy or not.
Title: Association between gene variants in SULT1A1 and UGT1A4 and disease outcomes in patients enrolled in SWOG S0226 and treated with anastrozole alone or in combination with fulvestrant for metastatic breast cancer

Body: Background: Anastrozole (A) blocks estrogen production by inhibiting the activity of CYP19 aromatase. Fulvestrant (F) blocks estrogen receptor (ER) signaling by competitive binding, leading to ER degradation by ubiquitination. SWOG S0226 ("Phase III Randomized Trial of Anastrozole versus Anastrozole and Fulvestrant (250mg LD) as First Line Therapy for Post Menopausal Women with Metastatic Breast Cancer," ClinicalTrials.gov Identifier:NCT00075764) demonstrated that combination of A+F is superior to A alone as first-line therapy for patients with ER positive metastatic breast cancer (Mehta et al, NEJM, 2012). Our functional preclinical studies have shown that single nucleotide polymorphisms (SNPs) in SULT1A1 and UGT1A4, drug conjugation enzymes that inactivate A and F, result in decreased enzyme activity toward these drugs (Edavana et al, DMD, 2013; Edavana et al Pharmgenomics Pers Med 2013). We therefore hypothesized that these SNPs will be associated with disease outcomes in S0226 patients due to altered drug levels.

Methods: Germline DNA was available for 295 (43.5%) patients enrolled in S0226 overall (157 on A and 138 on A+F). SNPs in SULT1A1 and UGT1A4 were determined either by direct sequencing or allele-specific PCR (TaqMan) assays.

Results: There was no difference in progression-free survival (PFS) or overall survival (OS) comparing patients with or without available germline DNA (p = 0.86 and 0.36, respectively). The SULT1A1 G902A allele (rs6839), which confers decreased mRNA and enzymatic activity, was associated with improved PFS (GG/GA vs. AA; HR 0.74, 95% CI 0.56-0.98, p=0.033) and OS (HR 0.70, 95% 0.50-0.98, p=0.039). In exploratory subset analyses of PFS, the SULT1A1 G902A association was similar across both treatment arms (A HR=0.75; 95% CI 0.51-1.10; A+F HR=0.73; 95% CI 0.48-1.11). For OS there was some evidence of a difference by treatment (A HR=0.60; 95% CI 0.38-0.96; A+F HR=0.82; 95% CI 0.50-1.32), though no significant interaction was evident (p=0.30).

The UGT1A4 G-163A promoter variant, which leads to decreased protein expression, was not associated with PFS (AA/AG vs. GG HR 0.88, 95% CI 0.68-1.14, p=0.33); however, this variant was associated with OS (HR 0.71, 95% CI 0.52-0.96, p=0.027). In subset analyses with OS, the difference was marginally stronger in the A arm (HR 0.63, 95% CI 0.42-0.97, p=0.035) compared to the A+F arm (HR 0.77, 95% CI 0.49-1.21, p=0.25), though the interaction was not significant (p=0.40).

Conclusion: SULT1A1 and UGT1A4 gene variants resulting in decreased enzyme activity were associated with better PFS, OS or both in patients enrolled in SWOG S0226. Planned validation studies correlating these SNPs with drug levels and disease outcomes in additional patient cohorts will establish their clinical utility in identifying patients who benefit from A and F alone or in combination.

Title: ER pathway activity as a predictive biomarker for neoadjuvant endocrine therapy

Body: Approximately 75% of all breast cancer patients is treated with endocrine therapy, based on stratification using estrogen receptor (ER) and progesterone receptor. To date, these classical biomarkers are the only ones available to predict the response to (neo)adjuvant endocrine therapy. Response to endocrine therapy depends on the presence of an active tumor-driving ER signalling pathway and, in the case of treatment with aromatase inhibitors (AI), also on aromatase-induced estradiol as the pathway activating ligand. Conventional nuclear staining for ER is not necessarily indicative of an estradiol-activated ER signalling pathway. We evaluated a recently described diagnostic computational model (Verhaegh, Cancer Research 2014) which identifies ER pathway activity based on tissue-derived target gene mRNA levels, for its clinical utility to predict neoadjuvant AI response in ER positive breast cancer patients.

Tumour tissue from pre-treatment biopsies and post-treatment resection material was collected from patients with early breast cancer (>2 cm and >50% ER expression) participating in the TEAM-IIA trial, which were treated with neoadjuvant exemestane for 3 to 6 months. Using Laser Capture Microdissection (LCM), tumour cells were isolated and the probability of ER pathway activity was assessed with RT-qPCR. In total, 77 FFPE samples were analysed (51 biopsies + 26 paired resection cases). In a preliminary analysis, results were correlated with clinical response based on palpation and mammography.

ER pathway activity significantly decreased during therapy (0.45 vs 0.27, two sided t-test p=0.001). Based on mammography, baseline ER activity in biopsy predicted therapy outcome after 3 months, with a higher probability of ER activity in responders, n=7, compared to non-responders, n=12, (0.73 vs 0.44, one sided t-test p=0.003). When therapy was continued up to 6 months, no correlation was found suggesting that other factors influence overall outcome of neo-adjuvant therapy. Baseline ER-pathway activity significantly predicted progressive disease by palpation at the end of therapy (mean treatment duration of 174 days, range 86-288 days) with a mean ER-pathway activity at biopsy of 0.53 vs 0.16 (p=0.01).

The significant difference in baseline activity with progressive disease indicates that low ER pathway activity could be used to predict low response rates. This is supported by the observation that all progressive disease cases at end of therapy had low baseline ER activity. Furthermore, baseline activity particularly predicted early radiological response based on mammography.

These preliminary results indicate that our ER pathway activity model could be able to predict response to endocrine neoadjuvant therapy. Further evaluation will be performed in order to assess the influence of post-treatment activity and other markers for response (Ki-67).

Body: Background: Eribulin is a non-taxane, microtubule dynamics inhibitor approved for the treatment of patients with locally advanced or metastatic breast cancer. To date, no biomarker exists to prospectively select patients who will derive the maximum benefit from this chemotherapeutic. In this study, we explored, in a prospective clinical trial, the efficacy and the association of pre-treatment expression of mRNA with response in patients with HER2-negative breast cancer treated with neoadjuvant eribulin. Results of the HR+ cohort are presented here.

Methods: SOLT1007 is a phase II, open-label, single-arm, exploratory pharmacogenomic study of single agent eribulin as neoadjuvant treatment for stage I-II HER2-negative breast cancer (n=100 HR+ and n=100 HR-negative). Patients received 1.4 mg/m² of eribulin mesilate intravenously on Days 1 and 8 every 21-day cycle, for 4 cycles. Baseline, C2D1, and post-treatment (surgical) formalin-fixed, paraffin-embedded tissue samples were collected and gene expression profiled. The PAM50 genes and 492 additional breast cancer-related genes were evaluated using the nCounter platform. Research-based intrinsic subtype and the Risk of Relapse based on subtype and proliferation (ROR-P) were evaluated using the Parker et al. JCO 2009 algorithm. The association of each signature and pathological complete response in the breast (pCRb) was evaluated using univariate logistic regression models. Genes found differentially expressed between screening and surgical specimens were identified using a paired two-class Significance Analysis of Microarrays.

Results: 92 evaluable patients were included. Mean age: 55.7. Mean tumor size: 3.7 cm. Mean Ki-67 %: 30.3. The overall pCRb rate was 5.4%. Distribution of the intrinsic subtypes was as follows: Luminal A (n=36, 39.1%), Luminal B (n=34, 37.0%), Basal-like (n=10, 10.9%), Normal-like (n=10, 10.9%) and HER2-enriched (n=2, 2.2%). pCRb rates differed significantly by subtype (p=0.009): Luminal B (11.7%, 4/34), HER2-enriched (50%, 1/2), Luminal A (0%, 0/36), Basal-like (0%, 0/10), Normal-like (0%, 0/10). pCRb rate differed significantly by ROR-P (p=0.018): ROR-P high (16.7%, 4/24), ROR-P med (1.9%, 1/52), ROR-P low (0%, 0/16). Ki67 % did not predict pCRb (p=0.406). Subtype change at surgery occurred in 48.3% (14/29) of Luminal B disease. 78.6% (11/14) of subtype changes in Luminal B disease were to Luminal A. Compared to screening biopsies, 136- and 141- genes were found up- and down-regulated in surgical specimens (False Discovery Rate <5%). The up-regulated gene list was enriched for response to hormone stimulus (e.g. ESR1, BCL2 and ERBB4), negative regulation of apoptosis (e.g. IL6, EGFR and PTEN) and angiogenesis (e.g. ANGPTL4, HIF1A and TGFBR2). The down-regulated gene list was enriched for cell cycle (e.g. CCNB1, RAD17 and MKI67), DNA-repair (e.g. BRCA1, BRCA2 and ATR) and microtubule cytoskeleton organization (e.g. AURKA, CENPA and KIF23).

Conclusions: From a response and biological perspective (i.e. induction of a Luminal A phenotype), patients with Luminal B disease might benefit the most from eribulin therapy. Strategies combining eribulin with endocrine therapy seem warranted in Luminal B breast cancer.
Title: Chemosensitivity and endocrine sensitivity predicted by MammaPrint and BluePrint in clinical luminal patients in the prospective NBRST study

Pellicane JV V, Whitworth P, Beitsch P, Baron P, Beatty J, Murray MK K, Dul CL L, Mislowsky AM M, Nash CH H, Richards PD D, Lee LL L, Stork-Sloots L, de Snoo F, Untch S, Gittleman M, Akbari S and Rotkis MC C. Virginia Breast Center, Bon Secours Cancer Institute, Richmond, VA; Nashville Breast Center, Nashville, Nashville, TN; Dallas Surgical Group, Dallas, TX; Breast & Melanoma Specialists of Charleston, Charleston, SC; The Breast Place, Charleston, SC; Akron General Hospital, Akron, OH; St. John Hospital & Medical Center, Detroit, MI; Coastal Carolina Breast Center, Murrells Inlet, SC; Northeast Georgia Medical Center, Gainesville, GA; Blue Ridge Cancer Care, Roanoke, VA; Comprehensive Cancer Center, Palm Springs, CA; Agenda Inc, Irvine, CA; Breast Care Specialists, Allentown, PA; Virginia Hospital Center, Arlington, VA and Northern Indiana Cancer Research Consortium, South Bend, IN.

Body: Background
Ideally classification by subtype predicts treatment response and overall outcome. BluePrint 80-gene functional molecular subtype is based on mRNA expression (as is intrinsic subtype) associated with intact translation to protein (unlike intrinsic subtype). BluePrint (BP) classifies patients into Luminal, HER2 or Basal-type. Presently subtype is approximated using conventional immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH) (“conventional subtype”) or assigned by gene expression profiling. The aim of the prospective NBRST study was to compare chemosensitivity as defined by pathological Complete Response (pCR), or endocrine sensitivity as defined by partial response (PR) using 80-gene functional subtype vs. conventional IHC/FISH subtyping. In this analyses we present the results of all IHC/FISH Hormone Receptor (HR) positive/Her2 negative patients.

Methods
The neo-adjuvant NBRST study enrolled over 1000 US patients between June 2011 and December 2014. Women aged 18–90 with histologically proven breast cancer, who were scheduled to start neo-adjuvant chemotherapy (NCT) or neo-adjuvant endocrine therapy (NET), and who provided written informed consent were included. Additional inclusion criteria were no excision biopsy or axillary dissection, no confirmed distant metastatic disease, and no prior therapy for breast cancer. Treatment was at the discretion of the physician adhering to NCCN approved or other peer-reviewed, established regimens. BluePrint in combination with MammaPrint classifies patients into four molecular subgroups: Luminal A, Luminal B, HER2 and Basal. pCR is defined as T0/isN0 and PR is according to RECIST and defined as at least a 30% decrease in the tumor bed.

Results
418 IHC/FISH HR+/Her2- T1-4, N0-3, patients were enrolled (median age 54, range 22-87). MammaPrint and BluePrint (MP/BP) classified 28% as Luminal A, 54% as Luminal B, and 18% as Basal-type. The distribution of locally assessed ER% in BP Luminal tumors was 2% ER 0-10%; 3% ER 11-50%; and 95% ER>50% compared to 45% ER 0-10%; 28% ER 11-50%; and 27% ER >50% in BP Basal tumors. Tumors classified as BP Luminal 370 (89%) received NCT and the overall pCR rate was 9%. There was a significantly higher (p<0.0001) pCR rate of 26% in BP Basal tumors compared to the pCR rate in BP/MP Luminal A and B tumors (3% and 6%). 43 (10%) patients received neo-adjuvant ET and 72% had a PR.

Conclusions
Molecular subtyping using MammaPrint and BluePrint classified 1 out of 5 pathological luminal patients as BP Basal-type with a significant higher response rate to NCT compared to BP Luminal patients. BP Luminal patients have an excellent partial response rate to NET.
Title: Population-based validation study of Adjuvant! for primary breast cancer patients in the Netherlands

Siesling S, van Kleef JJ, Bretveld R, Groothuis-Oudshoorn CGM GM, van der Palen J, Jobsen JJ J and Struikmans H. University of Twente, MIRA Institute for Biomedical Technology and Technical Medicine, Enschede, Overijssel, Netherlands; Netherlands Comprehensive Cancer Organisation, Utrecht, Netherlands; Medisch Spectrum Twente; Medical School Twente, Enschede, Overijssel, Netherlands; University of Twente, Enschede, Overijssel, Netherlands; Medisch Spectrum Twente, Enschede, Overijssel, Netherlands; MC Haaglanden, Den Haag, Zuid-Holland, Netherlands and Leiden University Medical Center, Leiden, Zuid-Holland, Netherlands.

Body: Background Adjuvant! is an online risk prediction tool that can support breast cancer patients and physicians in clinical decision-making regarding adjuvant systemic treatment. The aim of this study was to validate Adjuvant! on a Dutch population-based cohort of women diagnosed in 2003 and assess its calibration and discriminatory accuracy.

Methods All Dutch patients diagnosed with invasive primary breast cancer in 2003 in the Netherlands meeting the criteria of Adjuvant!; unilateral, unicentric invasive breast cancer, no evidence of metastatic or residual disease, pathologically staged I-III and no pT4 features, were included. Local treatment consisted of breast conserving therapy or ablative surgery and axillary staging. Adjuvant systemic treatment was given according to national guidelines. Patient, tumor and treatment characteristics were retrieved from the Netherlands Cancer Registry. Endpoints were ten-year overall survival, breast cancer specific survival and event free survival.

Findings A total of 8,195 patients were included. Out of all patients, 4,389 (53.6%) received some form of adjuvant systemic therapy. Throughout a ten-year follow-up, 2,156 (26.3%) patients died and 1,953 (23.8%) patients developed a recurrent disease (locoregional, distant or contralateral invasive cancer or DCIS). Ten-year observed overall survival was underestimated by -1.4% (95% CI -2.3 to -0.4, p=0.006), breast cancer specific survival was underestimated by -3.3% (95% CI -4.1 to -2.6, p<0.0001) and event free survival was underestimated by -3.5% (95% CI -4.5 to -2.6, p<0.0001). Discrimination was moderate for overall survival and breast cancer specific survival but poor for event free survival.

Interpretation Adjuvant! does not accurately predict breast cancer specific survival and event free survival in this Dutch population-based study. Dutch patients showed better ten-year survival rates than predicted by Adjuvant!. For specific patient groups, the model could be used to estimate overall survival. We conclude that Adjuvant! should be used with caution in clinical practice in the Netherlands but probably also in other countries and the US.
Purpose: Some studies suggest that telomere shortening due to repeated cell divisions may be associated with increased breast cancer risk and mortality. Obesity is also associated with increased breast cancer risk and mortality. Few studies have examined telomere length as a potential mechanism/biomarker mediating the obesity-breast cancer association. One study published of a diet, physical activity and support intervention in prostate cancer patients found a positive association between lifestyle changes and relative lengthening of telomeres, and another study of weight loss in healthy postmenopausal women observed no effect of weight loss on leukocyte telomere length. The purpose of our study was to examine the effect of a 6-month diet- and exercise-induced weight loss intervention vs. usual care on telomere length in 100 breast cancer survivors.

Methods: 100 breast cancer survivors with BMI ≥ 25 kg/m2 were randomly assigned to a weight loss counseling intervention with either telephone or in-person counseling (n = 67) or usual care group (n=33). Weight loss counseling included eleven 30-minute counseling sessions over 6 months, focusing on reducing caloric intake, increasing physical activity and behavioral therapy. Body composition (height, weight, and DEXA scans), physical activity and diet were measured at baseline and 6-months. Fasting blood samples were also collected at baseline and 6 months. Relative telomere length (T/S: telomere length/single copy of gene albumin) was measured by quantitative-polymerase chain reaction (qPCR) done on buffy coat extracted genomic DNA. Mean baseline to 6-month changes were compared between groups (intent-to-treat) using generalized estimating equations and Pearson correlation coefficients.

Results: Baseline characteristics were similar for women randomized to each group. Women were 59±7 years, with BMI 33.1±6.6 kg/m2 and were 2.9±2.1 years from diagnosis; 91% were non-Hispanic white, and 51% were diagnosed with Stage I breast cancer. Average 6-month weight loss was 6.2% and 2.0% for weight loss and usual care groups, respectively (p=0.0004). At baseline, higher % body fat was associated with shorter T/S (r = -0.31, P=0.012). After 6 months, women randomized to weight loss experienced a 4% T/S lengthening compared to a 5% T/S shortening in the usual care group (P=0.10) (Table 1).

CONCLUSION: Our results indicate that higher % body fat is associated with shorter leukocyte telomere length, and weight loss was associated with an increase in leukocyte telomere length, suggesting that telomere length may be a mechanism mediating the relationship between obesity and breast cancer risk and mortality.
Title: Comparison of strategies for weight loss maintenance among rural breast cancer survivors: The rural women connecting for better health randomized controlled trial

Body: Background: Breast cancer survivors who reside in rural areas represent one of the largest medically underserved populations of breast cancer survivors in the nation and have higher obesity prevalence compared to their urban counterparts. Given the evidence linking obesity with poor breast cancer prognosis, trials are needed to demonstrate ability to produce long-term weight loss maintenance in this hard-to-reach group. Group phone-based counseling via conference calls is a low-technology approach with excellent reach to rural areas. This treatment delivery approach capitalizes on the support benefits of in-person groups by allowing participants to interact in real time while also diminishing costs.

Methods: In this 2 phase trial, overweight and obese (BMI 27 to 45 kg/m2) rural breast cancer survivors (with initial stage 0-III disease) were randomized to one of two extended care interventions for weight loss maintenance (Phase 2) subsequent to an initial 6-month weekly group phone-based behavioral weight loss intervention (Phase 1). To be eligible for randomization for maintenance, participants must have lost ≥ 5% of their baseline weight during Phase 1. In Phase 2, participants were randomized to continued group phone-based counseling reduced in frequency to every other week during maintenance vs every other week mailed newsletters that followed the same content.

Results: 210 breast cancer survivors with a mean time since treatment of 3.5 years ± 2.4 years, mean age of 58.1 ± 9.9 years, and mean BMI of 33.9 ± 4.4 kg/m2 residing in a three state region of the rural Midwest were entered in the 6-month weight loss phase. Retention from baseline to 6 months (Phase 1) was 91%. Mean percent weight loss at 6 months for the total sample was 12.9% with 82% of enrolled participants ≥ 5% below baseline weight. 172 participants with a mean initial loss of 14.0% of baseline weight (12.8 ± 4.9 kg) were randomized to a maintenance intervention. Retention from 6 to 18 months (Phase 2) was 92%. Intent-to-treat analyses with imputation of missing data revealed participants in the group phone condition regained less weight (3.3 ± 4.8 kg) compared to participants in the newsletter condition (4.9 ± 4.8 kg; p = 0.03). Mean percent weight loss from baseline to 18 months did not significantly differ between the group phone condition (10.2 ± 7.5%) and the newsletter condition (9.2 ± 7.9%). However, at 18 months 75.3% of participants in the group phone condition remained ≥ 5% below baseline weight compared to 57.8% in the newsletter condition (p = .02).

Discussion: The initial group phone-based weight loss intervention exceeded typical weight losses reported in the literature with over 80% of enrolled participants achieving clinically meaningful weight loss. Continued group phone counseling was modestly better in sustaining weight loss at 18 months than a mailed newsletter. However, for both maintenance approaches, the majority of participants maintained a weight at 18 months that was 5% or more below baseline.
Title: Mobile phone multimedia messaging intervention for breast cancer screening

Lee HY Y, Le C, Ghebre R and Yee D. University of Minnesota, Twin Cities, Minneapolis, MN.

Body: Background. Korean American women have one of the highest breast cancer mortality rates and lowest breast cancer screening rates among American women. In response to the need to enhance breast cancer screening, this study aims to develop and test a 7-day mobile phone application (app)-based Mammogram (mMammogram) intervention designed to promote breast cancer screening among Korean American women. To date, mobile app technology has not been used for mammogram promotion.

Methods. Using FBM Model, we developed a mammogram intervention designed to increase knowledge of breast cancer screening, intent to receive mammogram, and the receipt of a mammogram. A series of focus groups were conducted to inform the development of the intervention. A randomized controlled trial was conducted with baseline, one week post-intervention, and 6-month follow-up testing among 120 Korean American women who were aged 40 and older and had not had mammograms within the last 2 years. The intervention group (60) received an individually and culturally tailored text messages via mobile app with health navigation services. The control group (60) received a brochure including information on breast cancer, screening guidelines, and a list of clinics that offer low-cost or free mammography without health navigation services.

Results. At one week post-test, statistically significant between-group differences were found; intervention subjects reported higher scores of knowledge in breast cancer and screening guideline than subjects in control group (mean differences: 1.70, p < 0.05). No statistical between group differences identified in intention to receive screening. However, significant between-group difference was found in the receipt of mammogram at 6-month follow-up test; 40.0% (24/60) of the intervention group received mammograms whereas 25.0% (15/60) of the brochure group received mammograms after intervention (p < 0.05). 100% of the participants expressed satisfaction with the intervention and 98.3% reported that they would recommend the program to their friends.

Conclusions. This study provides evidence of the effectiveness and feasibility of the mammogram intervention with health navigation services in promoting breast cancer screening. Mobile application-based intervention is a promising tool to increase both knowledge and receipt of mammograms. Given the widespread usage of mobile phone among minority populations, a mobile phone-based health intervention could be an effective method of reaching hard-to-recruit populations with high breast cancer burden, using individually tailored messages that cover broad content areas and overcome restrictions to place and time of delivery.
Title: Improving sleep to reduce breast cancer risk in shift workers

Gotay C, Aronson K, Campbell K, Demers P, Fleming J, Gelmon K, Goodfellow E, Munoz C, Neil-Sztramko S, Pollak M, Shen H and Spinelli J. The University of British Columbia, BC, Canada; Queen’s University, ON, Canada; University of Toronto, ON, Canada; BC Cancer Agency, BC, Canada; McGill University and BC Cancer Research Centre, BC, Canada.

Body: BACKGROUND: Shiftwork that involves circadian disruption has been designated as a 2A (probable) breast cancer carcinogen by the International Agency for Research on Cancer. Night shift workers experience many lifestyle disturbances including disrupted sleep. While the specific biological mechanisms that confer increased breast cancer risk are not yet clear, sleep disruption is hypothesized to have both direct (lowering melatonin levels) and indirect (obesity status) impacts on risk status. However, few interventions of any type have been reported for shift workers to potentially reduce their risk for breast cancer. An effective intervention to improve sleep quality would be one way to potentially reduce breast cancer risks in these women.

METHODS: 47 female shift workers aged 40-65 who had experienced high circadian disruption (rotating or permanent night shifts) at least 3 times per month for at least 2 years participated in a single arm study examining the impact of a sleep intervention on health behaviours and breast cancer risk. Over the course of 10 months, women received with a 10-session (plus 2 booster sessions), telephone-delivered sleep hygiene intervention. The program was adapted from a hospital-based sleep clinic protocol based on cognitive behaviour therapy (CBT) principles and aimed to improve sleep quality and quantity. Sleep quality was assessed by the Pittsburgh Sleep Quality Index (PSQI). Data were assessed at baseline and 6 and 12 months.

RESULTS: Mean age was 47 years, 68% were partnered, and 78% had diploma level education or higher. Participants were nurses (49%), emergency communications personnel (17%) and paramedics (13%), and others. At baseline, 79% had “poor” sleep quality (score above 5 on the PSQI), decreasing to 54% at 6 months and 49% at 12 months (p<0.001 for both changes between baseline and 6 months, and between baseline and 12 months, based on McNemar’s test). Significant correlates of better sleep included younger age, being married, and having more education, but not obesity (measured by body mass index). We also investigated chronotype, which characterizes sleep time preferences that reflect underlying circadian rhythms; individuals may be “morning types” or larks (preferring early awakenings and bedtimes), “evening types” or owls (preferring late nights and mornings), or intermediate. We found that our intervention was more significantly effective for larks (where 11% reported good sleep at baseline and 67% at 12 months) and intermediates (where 28% reported good sleep at baseline and 62% at 12 months) than for owls (where 15% reported good sleep at baseline and 18% at 12 months).

DISCUSSION: Most female shift workers in this study report impaired sleep quality. Our CBT-based sleep intervention led to significant improvements in sleep quality in 6 months, and these improvements were maintained at one year. This approach was more effective for some chronotypes than others, and “night owls” may require a different intervention. Sleep is a modifiable risk factor that is increasingly linked with cancer-related outcomes, including cancer incidence. Interventions to improve sleep quality such as the program used here offer a novel approach with the potential to reduce breast cancer risk.
The use of chemoprevention increases significantly with oncology trained providers and with application of a risk assessment model

Oseni T, Perkins S, Deutsch E and Soballe P. Naval Medical Center San Diego, San Diego, CA and Uniformed Services University, Bethesda, MD.

**BACKGROUND**
Large clinical trials have proven the efficacy of selective estrogen receptor modulators in reducing the risk of breast cancer in high risk women. However, despite these studies the use of chemoprevention in high risk women remains low. The goal of this study was to determine in a clearly identified high risk population, the utilization rate of chemoprevention and factors that affect its use, notably, surgeon training and the Gail model.

**METHODS**
This was a retrospective chart review of all women diagnosed with Atypical Ductal Hyperplasia (ADH) at our institution from 2008 to 2013. We examined the use of chemoprevention and screening recommendations after diagnosis. Other factors evaluated included family history, Gail model, surgeon specialty and menopausal status.

**RESULTS**
Ninety-four women with ADH were treated at our facility in the study time frame. The overall use of chemoprevention in our study population was 41.5%. Of those who were not on chemoprevention, 56.4 % were offered chemoprevention and declined. In addition, after the diagnosis of ADH, annual mammography was recommended for 75% of women. However, this was preferentially seen in women on chemoprevention (95% vs. 65%). Menopausal status and use of the Gail model were statistically significant in predicting annual screening after a diagnosis of ADH. The Gail score was calculated preferentially in women who chose chemoprevention. Prior breast biopsy, family history of cancer, first degree relative with cancer, age and menopausal status were not found to be statistically significant in the use of chemoprevention. Oncology training and use of the Gail model were found to be statistically significant in chemoprevention use.

**CONCLUSION**
The use of chemoprevention in high risk women is significantly improved with oncology training and the use of the Gail model. Concern regarding side effects continues to result in low utilization of selective estrogen receptor modulators. Education regarding newer agents for chemoprevention with minimal side effects may result in increased utilization of chemoprevention.

Intermittent fasting (IF) regimens have gained widespread attention in recent years for their possible role in human health and disease risk. In mice, IF schedules that are aligned with sleep-wake cycles appear to positively influence metabolic processes related to cancer risk and may have direct effects on carcinogenesis; however the impact of these regimens on cancer risk in humans remain unclear. We examined associations between nighttime fasting duration (a form of IF aligned with sleep-wake cycles) and (1) biomarkers demonstrated to be associated with breast cancer prognosis; and (2) long-term clinical outcomes in a sample of breast cancer survivors from the Women's Healthy Eating and Living (WHEL) Study. Dietary data were available for 3,061 non-diabetic women enrolled in the WHEL Study. Nighttime fasting duration was calculated using time-stamped 24-hour dietary recalls collected at the baseline, Year 1, and Year 4 study assessment periods. Approximately 3-4 dietary records were collected per subject at each assessment period, and these records were averaged to yield a single estimate of nighttime fasting duration per time point. Glycosylated hemoglobin (HbA1c) and C-reactive protein (CRP) levels were ascertained from blood specimen collected at baseline. Clinical outcomes recorded during the study follow-up include breast cancer events (recurrence or new primary) and mortality. Linear regression models examined the associations of nighttime fasting with baseline concentrations of HbA1c and CRP. Delayed-entry Cox proportional hazard models were used to assess the association between nighttime fasting duration, recorded at the baseline, Year 1, and Year 4 assessments, with clinical outcomes. These models used a counting process method to account for repeated measures. All models controlled for basic demographic factors, participant characteristics (BMI, comorbidity status, sleep duration), breast cancer characteristics (stage, grade, anti-estrogen use), and dietary variables (total calories, evening calories, eating frequency). Women fasted an average of 12.5 hours per night (SD=1.6 hours). There were 520 new breast cancer events, and 569 deaths during study follow up. HbA1c level was significantly and inversely related to nighttime fasting duration. Each 2-hour increase in the nighttime fasting duration was associated with a 0.2-unit decrease in HbA1c ($\beta=-0.21$; $p=0.03$ with HbA1c expressed as mmol/mol), and there was no evidence of mediation or effect modification by participant characteristics, e.g., BMI. No associations were observed between nighttime fasting duration and CRP. In longitudinal models, women who fasted less than 13.1 hours per night (bottom two tertiles of nightly fasting distribution) had roughly a 50% higher hazard for experiencing a breast cancer event, compared to women who fasted at least 13.1 hours per night (HR: 1.46; 95%CI: 1.11-1.93; $p<0.01$). Nighttime fasting duration was not associated with mortality. Findings suggest that increasing the length of the nighttime fasting interval could be a simple, feasible, and novel strategy to improve glucose control and reduce breast cancer risk. Randomized trials confirming the link between nighttime fasting duration and breast cancer risk are warranted.

Title: Early life residence, fish consumption and risk of breast cancer

Haraldsdottir A, Torfadottir JE E, Valdimarsdottir UA A, Aspelund T, Tryggvadottir L, Launer LJ J, Harris TB B, Gudnason V and Steingrimsdottir L. Unit for Nutrition Research, Faculty for Food Science and Nutrition, University of Iceland, Reykjavik, Iceland; Centre of Public Health Sciences, Faculty of Medicine, University of Iceland, Reykjavik, Iceland; Harvard School of Public Health, Boston, MA; The Icelandic Heart Association, Kopavogur, Iceland; The Icelandic Cancer Registry, Reykjavik, Iceland; Faculty of Medicine, University of Iceland, Reykjavik, Iceland and Laboratory of Epidemiology, Demography and Biometry, Intramural Research Program, US National Institute on Aging, Bethesda, MD.

Body: Introduction: Few studies exist on the effect of diet during different periods of life, on breast cancer risk later in life. Great differences existed in food consumption between the capital and rural areas in Iceland in the middle of the 20th century, with very high fish consumption in coastal areas.

Objectives: Our aim was to explore the effect of diet and residence during early life and midlife on breast cancer risk later in life.

Methods and data: We used data from the Reykjavik Study, a population-based Icelandic cohort of 10049 women born between 1907 and 1935, and examined the association of residence in early life, used as a proxy for dietary habits, and risk of breast cancer. To further explore this association, we also used food frequency data at different periods of life, including adolescence, from the AGES-Reykjavik cohort, a subgroup of the Reykjavik Study, established in 2002. Participants provided information on residence in early life. By linkage with the Icelandic Cancer Registry, information on breast cancer diagnoses was available throughout 2013. Adjustments were made for a series of potential confounders, including residence for dietary analysis.

Results: During a mean follow-up of 27.3 years, 744 women were diagnosed with breast cancer. We found a significant inverse association for breast cancer diagnosis among women who lived through the puberty period (20 years or more) in coastal villages compared with women residing in the capital area (HR = 0.74, 95% CI: 0.58, 0.94). In the subgroup analysis, we found that women with high fish consumption in midlife had lower risk of breast cancer in older age, compared with women with lower consumption, (OR = 0.60, 95% CI 0.38, 0.94). However, we did not observe a statistically significant association between high fish intake in adolescence and breast cancer (OR = 0.84, 95% CI 0.62 - 1.13).

Conclusions: Our results suggest that high fish consumption in early- to midlife may be associated with reduced risk of breast cancer.
Title: Combined effects of soy isoflavones and a high fat diet on the mammary gland in an animal model of diet-induced obesity

Kurrat A, Diel P, Blei T, Kluxen F, Mueller D, Pichotta M, Soukup S, Kulling S and Oden C. Institute of Cardiovascular Research and Sports Medicine, German Sports University Cologne, Cologne, Germany; Max Rubner-Institut, Karlsruhe, Germany, Karlsruhe, Germany and Clinic for Cattle, Endocrinology, University of Veterinary Medicine, Hannover, Germany.

Body: Scope: Obesity is a major risk factor for the development of breast cancer whereas isoflavone (ISO) exposure is discussed to reduce this risk. Aim of this study was to investigate effects of dietary soy ISO intake on proliferation and estrogenicity of ISO in the mammary gland of obese female Wistar rats.

Methods: Female Wistar rats (5 – 7 rats / group) grew up on low fat ISO-depleted diet (LF IDD) or ISO-rich diet enriched with a soy based commercial extract (LF IRD; ISO: 467 mg / kg diet). Starting postnatal day 83, ovariectomized (OVX) and intact animals received high fat diet for 12 weeks to induce obesity in the absence (HF IDD) or presence of ISO (HF IRD, ISO: 431 mg / kg diet). A special diet switch group (HF IRD switch OVX), grew up on LF IDD but switched to HF IRD after ovariectomy. This mimics the short term exposure to ISO in postmenopausal Western women who take ISO supplements. Two groups receiving LF diet either with or without ISO (LF IRD, LF IDD) lifelong served as control. From ablactation until the end of the experiment body weight and food consumption were monitored twice a week. After 12 weeks of HF diet animals were sacrificed. Body weight, visceral fat mass, and serum leptin were measured, and breast tissue was excised. Protein expression of proliferating cell nuclear antigen (PCNA) and progesterone receptor (PR) in breast tissue was analyzed by both immunohistochemistry (IHC) and Western Blot as markers for proliferation and estrogenicity of ISO, respectively.

Results: Analysis of ISO plasma levels revealed 1400 nM in LF IRD group and 300 – 700 nM in HF IRD groups. HF diet increased body weight, visceral fat mass and serum leptin levels compared to LF diet. In the mammary gland HF increased expression of proliferation marker PCNA and PR as compared to LF groups. Lifelong but not short term (HF IRD switch OVX) ISO exposure reduced body weight, visceral fat mass and leptin levels in HF OVX rats. In the mammary gland lifelong ISO exposure reduced PCNA expression in both LF and HF intact animals whereas in HF OVX animals lifelong ISO exposure increased PCNA expression compared to short term ISO exposure. PR expression increased in HF IRD OVX compared to HF IDD OVX.

Conclusion: The ISO plasma levels of the rats are comparable to the average ISO plasma levels as found in Asian population. Our results show that lifelong ISO intake reduces the risk to develop obesity in female rats. In the mammary gland lifelong ISO exposure decreases cell proliferation and shows estrogenicity by increasing PR expression. Effects of short term ISO exposure are less strong compared to lifelong ISO exposure. This supports the hypothesis that only lifelong but not short term ISO exposure can reduce the risk to develop breast cancer.
Title: Growth inhibitory effects of Cornus officinalis on a model for triple negative breast cancer

Telang NT T, Nair HB B and Wong GYC YC. Palindrome Liaisons Consultants, Montvale, NJ; Texas Biomadical Research Institute, San Antonio, TX and American Foundation for Chinese Medicine, NY, NY.

Body: Background: The triple negative breast cancer (TNBC) molecular subtype is characterized by the absence of estrogen receptor-α (ER-α), progesterone receptor (PR) and human epidermal growth factor receptor-2 (HER-2) expressions. TNBC is refractory to endocrine and to HER-2 selective therapy, while options for the treatment of choice involving high dose Anthracyclin/Taxol based conventional chemotherapy and/or small molecule inhibitor based targeted therapy are associated with systemic toxicity and acquired tumor resistance, leading to compromised efficacy. These limitations emphasize a need to identify efficacious non-toxic agents for secondary prevention/therapy of TNBC. Cornus officinalis (CO) is a Chinese herb of a nutritional nature in the form of a fruit. It is a major ingredient herb in some well-known Chinese herbal formulations for health management purposes. Growth inhibitory efficacy of CO in a model for ER positive Luminal A molecular subtype of clinical breast cancer is associated with abrogation of estradiol promoted growth via generation of anti-proliferative estradiol metabolites [Telang et al: Mol. Med. Rep. 5: 20-28, 2012]. The present study examines the growth inhibitory effects of CO, and identifies possible molecular targets for its efficacy in a pre-clinical cell culture model for TNBC.

Experimental model, Herbal Extract and Biomarkers: The human mammary carcinoma-derived ER-α negative, PR negative and HER-2 negative MDA-MB-231 cell line represents the model for TNBC. Non-fractionated aqueous extract from CO represents the test agent. Anchorage dependent growth, anchorage independent (AI) colony formation, cell cycle progression, cellular apoptosis and relevant pathway specific mechanistic assays represent the biomarkers for efficacy.

Results: Treatment of MDA-MB-231 cells with CO extract induces substantial dose dependent cytostatic growth arrest (IC50:0.1%; IC90:0.5%), and strongly inhibits AI colony formation. Within the cytostatic range CO inhibits G1 to S phase transition leading to G1 arrest that is accompanied by decreased expressions of Cyclin D1 and p-RB. Cellular apoptosis induced by CO is associated with modulation of the BAX-BCL-2 pathway, and up-regulation of the pro-apoptotic Caspase 3/7 activity.

Conclusions: These data provide a mechanistic evidence for efficacy of CO as a naturally occurring nutritional substance in a cell culture model for TNBC. The present study validates a mechanism based approach to prioritize efficacious non-toxic herbal extracts for secondary prevention/therapy of the TNBC molecular subtype of clinical breast cancer.
Title: A pilot feasibility study of the WISDOM study, a preference-tolerant randomized controlled trial evaluating a risk-based breast cancer screening strategy

Body: Background: For almost 30 years, annual mammograms for women over 40 have been a cornerstone of the US strategy to reduce breast cancer mortality. Introduction of the 2009 USPSTF screening guidelines, though based on a thorough review of the scientific literature, has triggered scientific debate and a stalemate. The solution is not to prolong the controversy with repetitious reviews of past studies, but rather to test and implement a personalized model that leverages advances in breast cancer biology, risk assessment, and imaging to provide screening recommendations based upon well-characterized measures of risk. Our WISDOM (Women Informed to Screen Depending On Measures of risk) study, a preference-tolerant randomized controlled trial funded through PCORI, will evaluate whether such a risk-based screening strategy, compared to annual screening, is as safe, is less morbid, enables prevention and is preferred by women. This upcoming pilot study will test the feasibility and technical implementation of the WISDOM trial, focusing on recruitment, enrollment, and randomization processes, a coverage with evidence development approach to enable rapid adoption, and patient experience and satisfaction. Findings will directly inform implementation of the full trial, slated to begin in fall 2015 throughout the Athena Breast Health Network, a research and care collaboration across the five UC Medical Centers and Sanford Health.

Trial Design: 225 participants will be recruited from Athena patients receiving care at UCSF. Participants must be female; between age 40 and 75; have had a normal mammogram at UCSF in the past 6 months; and in the Athena research cohort. Exclusion criteria are a breast cancer or DCIS diagnosis; inability to provide consent; or inability to speak English. After education about the trial, patients will be asked if they are willing to be randomized to either the risk-based or annual screening schedule; if not, they can self-assign to their preferred schedule. The randomized and self-assigned cohorts will receive the same interventions. The risk-based screening strategy will incorporate risk assessment based on the latest Breast Cancer Surveillance Consortium model along with established and recently validated genetic risk factors, co-morbidities, and breast density, and will be used to tailor individual recommendations for starting and stopping age, frequency, and screening modality. A saliva assay will be administered to participants in the risk-based arm to screen for genetic breast cancer risk factors (BRCA1 & BRCA2 + 9 additional genes + 81 single nucleotide polymorphisms).

Statistical Methods: Descriptive statistics for the proportion of women who are willing to be randomized, choose the risk-based arm in the self-assigned cohort, and are willing to accept their assigned or chosen screening schedule, as well as the distribution of participant anxiety scores, will be analyzed. This will inform statistical design for the full trial, including the number of women who should be approached to enroll 65,000 randomized participants and the sample size needed to measure anxiety and decision regret in the randomized cohort. Results from the pilot will be available September 30, 2015.
Differential response of inflammatory cytokines to omega-3 fatty acid supplementation based on menopausal status

Kimler BF F and Fabian CJ J. University of Kansas Medical Center, Kansas City, KS.

Background: High dose marine omega-3 fatty acid supplementation is currently undergoing assessment in early phase primary prevention trials. A potential mechanism of action is thought to be inflammation resolution. Since post-menopausal women may have higher systemic levels of pro-inflammatory cytokines, and hormones may affect response to fatty acids, we conducted two parallel pilot trials of eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) as Lovaza® supplementation in women at high risk for development of breast cancer. This post-hoc analysis examines whether five cytokines involved in inflammatory processes (HGF, MCP-1, NGF, PAI-1, TNF-alpha) are impacted by menopausal status.

Methods: Separate trials were conducted in pre-menopausal (N=36) or post-menopausal (N=35) women. Blood (fasting) and benign breast tissue (non-fasting, sampled by random periareolar fine needle aspiration) was acquired before and after intervention with 4 g Lovaza® daily for 6 months. In addition to standard risk and response biomarkers, panels of cytokines associated with inflammatory processes were assayed by Luminex® technology: HGF, insulin, MCP-1, NGF, PAI-1, resistin, TNF-alpha. For breast tissue, values were normalized to protein content.

Results: Thirty-four women in each trial completed the intervention and provided pre-study and post-study specimens. At baseline, higher values for post-menopausal compared to pre-menopausal women were observed for serum levels of MCP-1 (p=0.002, non-parametric Mann-Whitney test), PAI-1 (p=0.001), and TNF-alpha (p=0.019). The same was observed for off-study specimens. There was no statistically significant (non-parametric Wilcoxon signed rank test) effect of the intervention in either cohort for MCP-1 or PAI-1. However, for TNF-alpha, while there was no modulation observed in pre-menopausal women, there was a modest decrease (medians of 3.7 to 3.4 pg/ml; p=0.016) for post-menopausal women. An effect on TNF-alpha would not have been detected if the two cohorts had been combined.

For breast tissue, higher values for post-menopausal women at baseline were observed for HGF (p=0.029), MCP-1 (p=0.013), NGF (p=0.001), and TNF-alpha (p=0.001), but not PAI-1 (p=0.79). Off-study values were also typically higher in post-menopausal women. As with serum levels, there was a significant decrease in TNF-alpha values over the course of the study (p=0.042) in post-menopausal women but not pre-menopausal women. A decrease was also observed for HGF (p=0.002) and MCP-1 (p=0.001) for post-menopausal women but not pre-menopausal women.

Conclusion: This post-analysis suggests caution when admixing pre-menopausal and post-menopausal women in small clinical trials of omega-3 fatty acid supplementation, especially when assessing biomarkers of inflammatory processes. For trials with both, sufficient subjects should be enrolled that stratification prior to randomization is possible.
Title: Receipt of breast cancer risk assessment and personalized prevention information among women diagnosed with a benign breast lesion (BBL) in a one stop breast unit: A prospective assessment

Body: Background: Women's awareness about their personal breast cancer (BC) risk in the general population is generally low. Mass screening and mass prevention interventions have as yet been moderately efficient in breast oncology. "Personalized prevention" including risk communication, personalized screening and primary prevention recommendations is a promising. A personal history of BBL slightly increases subsequent BC risk.

Objectives: the main objective was to evaluate the acceptability of a mathematical tool- based breast cancer risk assessment and subsequent proposal of a personalized BC prevention program in a BBL population. Secondary objectives were to evaluate information receipt, awareness, satisfaction, and anxiety.

Methods: Women were eligible for the study if aged 40-74, were recently diagnosed with a benign breast lesion at the one stop breast Unit of the center, had no personal history of cancer or atypical lesions and were not BRCA carriers. Women were proposed a personalized risk assessment using a mathematical tool (BCSC score adapted to the French population-Ragusa et al) together with personalized information on risk, BC screening and prevention, release of a personalized program and evaluation of their receipt. The main end point was the proportion of women willing to have a risk assessment and personalized counseling. A cut-off point of 70% was considered critical to consider acceptability. Secondary end points were perceived BC risk, satisfaction, anxiety and distress levels at day 2 using standardized questionnaires, as well as adherence with the proposed programs.

Results: Of 150 women proposed BC risk assessment and personalized prevention information between 02/2014 and 03/2015, 129 (86%) accepted. Median age: 53.6 years. 33% had a low BC risk (< 1.1% at 5 yrs [mean risk of 50 yrs-old women in France]), 53% a moderate risk (1.1-1.66% at 5 yrs), while 14% were high risk (> 1.66% at 5 yrs). 87% had never had any previous information on BC risk. 3 pts required a genetic assessment.

Participants were globally very satisfied with physicians' and nurses' interpersonal skills, availability and provision of information (mean score > 4; range 2-5). The mean scores of clarity of the BC risk information (4.14±1;range 2-5) and screening program information (4.21±0.93; range 2-5) were high.

The mean score of perceived risk level was estimated to 33.5% (SD=21.9).

Mean scores of state anxiety (36.7±12.2; range 20-71), trait anxiety (39.5±8.9; range 23-59), depressive symptoms (3.4±3.3; range 0-12) and psychological distress indicated low levels of all. Higher level of state-anxiety was associated with lower scores of satisfaction with doctors and nurses human qualities (r = 0.26, p<.05) and with lower scores of clarity of information about screening program (r = 0.25, p<.05).

Conclusion: The receipt of breast cancer risk assessment and personalized prevention information among women diagnosed with BBL was high (86%). Information need is high given the low level of real risk awareness. Such population may benefit from personalized prevention. Anxiety and distress scores were low and satisfaction rates high.
Title: Telapristone acetate suppresses the expression of genes involved in cell proliferation, stem cell self-renewal, and anti-apoptosis in MNU-induced rat mammary tumors

Lee O, Clare SE E, Ivancic D, Scholtens DM M and Khan SA A. Northwestern University, Chicago, IL.

Body: Background: We previously reported that telapristone acetate (TPA), an anti-progestin, significantly suppressed mammary tumor formation and growth accelerated by progesterone (P4) and medroxyprogesterone acetate (MPA) in N-methyl-N-nitrosourea (MNU)-induced carcinogenesis model[1]. This suggests TPA holds promise for the prevention and treatment of human breast cancer. The purpose of this study is to identify the genes modulated by TPA in rat mammary ER/PR+ tumors, which may be translated into a therapeutic biomarker of TPA therapy in ER/PR+ breast cancer.

Methods: Rat mammary tumors from MNU carcinogenesis were used for study [1]. Treatment groups were: control, MPA, P4, MPA+TPA, and P4+TPA. Doses were 30mg of TPA and 25mg of P4 or MPA (90 day release pellets). Tumor epithelium was isolated by laser capture microdissection and RNA extracted. 100 ng of RNA per sample was used for targeted -gene expression profiling by nCounter Gene Expression analysis (Nanostring Inc.). 112 genes related to PR, GR, AR signaling were selected by MetaCore pathway analysis (Thomson Reuters, Inc.). The data was normalized by positive control and RNA content using nSolver. The genes significantly modulated by hormones and TPA were reported as means ± standard deviations (SD) for each group as well as a p-value for pairwise t-test comparison.

Results:

mRNA expression, log mean (log SD).

Compared to the control, P4 significantly reduced CHD5 expression, a tumor suppressor in a mouse model, and its down-regulation contributes to the development and progression of human breast cancer. Comparing the P4 and P4+TPA groups, the genes involved in cell proliferation and DNA repair (C-MYC, FANCA, Ki67, RFC3, and TK1), EZH2 (stem cell self-renewal), and anti-apoptosis (survivin) were significantly down-regulated by TPA. On the other hand, MPA induced the up-regulation of FKBP5 (androgen-regulated protein), PLZF (GR responsive gene), TEK (angiogenesis-regulating gene) and TNFSF11 (RANKL) compared to the control. Comparing the MPA and MPA+TPA groups, TPA significantly reduced the expression of EGFR, SNAI2 and endothelin-1 (EMT initiation or maintenance) and increased AR expression.

Conclusions: TPA inhibits P4/PR mediated cell proliferation, and increases apoptosis. The tumorigenic effect of MPA is likely through AR and GR rather than a PR specific manner. In addition to the PR, MPA binds with high affinity to AR and GR, and therefore has the potential to elicit actions distinct to those of P4, which does not bind AR.

Title: Weight maintenance initiated at midlife reduces mammary tumor incidence but metformin treatment does not mimic the effect

Cleary MP P, Mizuno NK K, Yang D-Q, Liao J and Grossmann ME E. University of Minnesota- Hormel Institute, Austin, MN.

Body: Weight gain and/or obesity are now considered to be risk factors for the development of postmenopausal breast cancer. Thus, weight loss and/or maintenance resulting from calorie restriction (CR) is recommended however success rates are infrequent. Metformin (MET) is a safe and effective treatment for type 2 diabetes mellitus and its use has been linked to reduced breast cancer incidence and mortality in comparison to other forms of diabetes treatments. Interestingly, MET's mechanism of action is considered to be similar to CR. The goal of the present investigation was to directly compare the effect of CR implemented at midlife with the administration of metformin on the development of mammary tumors (MT) in a relevant mouse model. Further, since these interventions would likely be used by obese women we studied both lean and obese mice. Female MMTV-TGF-α mice which develop MTs in the second year of life were fed ad libitum (AL) either a low fat (LF) (10.2% by calories) diet or a moderately high fat (HF) (33.5% by calories) diet from 10 until 30 weeks of age. At 30 weeks the mice on each diet were divided into AL, MET (250 mg/kg/bw/day) or CR (25% reduction in calories) subgroups and then followed until 90 weeks of age. HF-AL and HF-Met mice were significantly heavier than the other 4 groups whose weights were similar. The survival curves had an overall P value of P<0.0001 with LF-CR having the best survival of 100% while the HF-AL and HF-Met had the poorest survival with rates of 68% and 63% respectively. HF-CR mice had a significantly better survival rate compared to HF-AL and HF-Met (P<0.0001 for both). MT incidence (histologically confirmed) was significantly reduced in LF-CR (6%) compared to all other groups (45%-69%) (Chi-squared analysis). Tumor incidence in the HF-CR group (51%) was reduced compared to HF-AL (69%) and HF-Met (60%) mice but not significantly different due to adjustment for multiple comparisons, although the HF-CR vs HF-AL comparison was P<0.02. However, when the incidence rate for tumors detected by palpation prior to euthanasia was examined LF-CR mice did not have any MTs although the palpable incidence rates were not significantly different due to the need for multiple comparisons (LF-CR vs LF-AL was P<0.0097). The HF-CR group had significantly reduced palpable MT prior to euthanasia as compared to both HF-AL and the HF-Met (P<0.0002 and P<0.0001 respectively). Total tumor weight, grade and multiplicity were also examined for the effects of weight maintenance and MET. Presently the role of the AMPK pathway in these effects and serum measurements are being determined. In conclusion, the results to date indicate that weight maintenance during midlife can have a significant impact in delaying MT formation regardless of body weight status although the effects of MET are less dramatic.

Title: Preventive effect of metformin in combination with atorvastatin on 7,12-dimethylbenzanthracene induced breast cancer in high fat diet fed C57BL/6 mice

Ramdhave AS Satish and Nandave M. SPP School of Pharmacy and Technology Management, SVKM's NMIMS University, Mumbai, Maharashtra, India.

Body: Metabolic syndrome is a cluster of common clinical and biochemical abnormalities that includes insulin resistance, impaired glucose tolerance, central obesity and dyslipidemia. While the underlying mechanisms are not exactly understood, increasing evidence supports that insulin resistance causes perturbation of Insulin-like growth factor-1 (IGF1) axis which forms the core reason of carcinogenesis. IGF1 receptor (IGF-1R) overexpression has also been reported to stimulate transcription of the fatty acid synthase (FASN) gene, a key enzyme involved in neoplastic lipogenesis. Thus, we hypothesize that by modulating these metabolic syndrome linked abnormalities, we may attenuate cancer development. We investigated the effects of High Fat Diet (HFD: D12492) induced metabolic abnormalities on growth of 7,12-Dimethylbenzanthracene (DMBA)-induced breast cancer model. Preventive effect of Metformin (Met) in combination with Atorvastatin (Ato) on DMBA induced breast cancer in HFD fed mice was designed and assessed using the Chou-Talalay method. Female C57BL/6, aged 4-5 weeks were fed with HFD for 16 weeks to induce metabolic abnormalities and it was confirmed by various physiological, biochemical and histological parameters. From 16th week onwards, these female C57BL/6 mice were orally administered 0.2 ml olive oil containing 1 mg DMBA for 6 weeks. The preventive treatment of Met and Ato was initiated on the same day before first carcinogen dose. Met was administered at a dose of 50, 100 and 200mg/kg. Similarly Ato was administered at a dose of 6.25, 12.5 and 25mg/kg. The combinations were administered at a dose of Met 50mg/kg + Ato 6.25mg/kg, Met 100mg/kg + Ato 12.5mg/kg and Met 200mg/kg + Ato 25mg/kg. These test drugs were administered in drinking water for another 18 weeks. During the experiment, the animals were weighed weekly and palpated for the presence of mammary tumors. Tumor incidence, latency, frequency and tumor volume were also recorded. It was observed that the tumors from mice fed with only HFD were almost twofold the volume of mice fed with normal fat diet (NFD). These findings were correlated with the observation that mice fed with HFD had significantly elevated plasma glucose, insulin, IGF-1, triglyceride, cholesterol, LDL and FASN levels. Furthermore, Met and Ato individually at higher dose reduced the tumor volume by one fourth as compared to HFD group. Likewise, Met and Ato in combination at higher dose significantly attenuated the tumor volume to one tenth as compared to HFD group. Combination index (CI) was calculated with the computerized Chou–Talalay method and was found to be less than 1, demonstrating a synergistic effect of two drugs. Thus, our study suggests a potential role for this combination in the management of a metabolically defined subset of breast cancer.
Metabolic profiles in female Sprague-Dawley rats receiving either a standard (4% fat) or Western (20% fat) diet and changes in rats bearing mammary cancers
