Title: Targeting SET to disrupt oncogenic CIP2A feedforward loop shows therapeutic potential in triple negative breast cancer cells

Comprehensive Breast Health Center, Taipei Veterans General Hospital, Taipei, Taiwan; Show Chwan Memorial Hospital, Changhua City, Taiwan; Yang-Ming Branch of Taipei City Hospital, Taipei, Taiwan; Institute of Biopharmaceutical Sciences, National Yang-Ming University, Taipei, Taiwan and National Taiwan University Hospital, Taipei, Taiwan.

Body: Triple-negative breast cancer (TNBC) remains a difficult-to-treat cancer with a need for new therapeutic target. The serine/threonine protein phosphatase 2A (PP2A) functions as a tumor suppressor and enhancing PP2A activity by PP2A-activating agents is a promising anti-cancer approach. There are intrinsic inhibitors of PP2A including SET and cancerous inhibitor of protein phosphatase 2A (CIP2A), both of which interact and inhibit PP2A, playing oncogenic roles. Here we studied the tumor promoting effects of SET and CIP2A and discovered a potent linkage between SET and CIP2A-feedforward pathway in TNBC. We further demonstrated the anticancer activity of a novel SET/PP2A protein-protein interaction inhibitor, TD-19. Analyzing TCGA and clinical TNBC cohort, SET and CIP2A overexpressions correlated with worse survival in TNBC patients. Tumors from TNBC patients with higher SET expressions were significantly associated with higher Ki-67 and p-Akt expressions [Table 1]. Consistent with clinical results, TNBC cells with ectopic overexpression of SET and CIP2A showed significantly increased cell proliferation, migration and invasion, and colony-formation. Moreover, TD-19 demonstrated anti-tumor effects through inhibiting SET-PP2A interaction and CIP2A/PP2A/pAkt-mediated pathway in vitro and in a TNBC xenograft mouse model. Mechanistically, TD19 downregulated CIP2A mRNA via affecting Elk-1 amount in nucleus thereby decreased the binding of Elk-1 to the CIP2A-promotor. Furthermore, given that ERK-dependent phosphorylation of Elk-1 is essential for Elk-1 shuttling from cytoplasm to nucleus and PP2A controls ERK activation (phosphorylation), we hypothesized a CIP2A-feedforward loop consisting of pERK/pElk-1/CIP2A/PP2A may contribute to the oncogenesis in TNBC. Indeed, with TD19 treatment, SET/PP2A interaction was inhibited, PP2A activity was increased, and expressions of the CIP2A-feedforward loop members were suppressed. This loop was validated by knockdown of PP2A and ectopic expression of Elk-1. In addition, ectopic expression of SET increased pAkt, pERK, pElk-1 and CIP2A expressions, suggesting a positive linkage between SET and CIP2A feedforward signaling. Importantly, combining TD-19 with cisplatin demonstrated enhanced anti-proliferative and apoptotic effects in association with CIP2A downregulation in vitro. In summary, we discover a novel oncogenic CIP2A-feedforward loop in TNBC and targeting SET to disrupt oncogenic CIP2A feedforward loop shows therapeutic potential in TNBC.

Title: Abstract Withdrawn
Title: Targeting ERR-α regulated lactate metabolism eliminates drug-resistant breast cancer cells

Quayle L, Park S, McDonnell DP P, Ottewell PD D and Holen I. University of Sheffield, Sheffield, South Yorkshire, United Kingdom and Duke University, Durham, NC.

Body: Novel therapeutic strategies to eliminate chemo-resistant tumour cells responsible for the development of secondary lesions are essential in order to prevent breast cancer relapse. We have developed an in vitro model system enabling isolation of a putative metastasis-initiating breast cancer cell sub-population with a mitotically quiescent, drug-resistant phenotype. We hypothesise that this population is able to utilise oestrogen-related receptor-alpha (ERR-α)-regulated oxidative lactate metabolism and that inhibition of this critical survival pathway will result in elimination of tumour cells that have survived anti-cancer therapies.

Flow cytofluorometric monitoring of Vybrant® DiD retention identified a mitotically quiescent sub-population (~0.05%) in MDA-MB-231 human breast cancer cells grown under high glucose (11mM) conditions. DiD-retaining cells accumulated in the G₂/M phase of the cell cycle and were shown to be non-senescent following cytochemical analysis of β-galactosidase activity. Cytotoxicity assays with doxorubicin (0.40µM for 72 hours) demonstrated increased survival in the quiescent fraction (40.76%) compared with the rapidly dividing bulk cell population (1.63%, P ≤ 0.0001). Isolated drug-resistant cells contained a sub-fraction (~1%) that was able to form new clonal populations following cessation of treatment. Mitotically quiescent cells were cultured under high glucose (11mM) or glucose-depleted conditions with high lactate (22mM) in the presence of ERR-α inhibitors Cpd29 (10µM) or XCT790 (10µM). Colony formation was completely eliminated in Cpd29- and XCT790-treated samples compared to untreated controls. Drug-resistant sub-clones were isolated from the quiescent population following 72 hours treatment with doxorubicin (0.40µM) and were cultured under glucose-depleted conditions with high lactate (22mM) in the presence of ERR-α inhibitors Cpd29 (10µM) or XCT790 (10µM). In both instances, colony formation was completely prevented.

We provide the first evidence that blocking cellular energy production through inhibition of ERR-α regulated oxidative lactate metabolism can eradicate a chemo-resistant, quiescent breast cancer cell population. Our data suggest that ERR-α inhibitors may be used in combination with chemotherapy to eliminate minimal residual disease and reduce breast cancer recurrence.
Title: Treatment with a Jumonji demethylase inhibitor JIB-04 sensitizes resistant breast cancer cells to chemotherapeutic drugs in an in vitro model of intrinsic resistance

Singh B, Washburn LJ J, Kinne HE E, Milligan RD D and Lucci A. The University of Texas MD Anderson Cancer Center, Houston, TX.

Body: We have recently developed a usable model of panresistance in triple-negative breast cancer. We have shown that only 0.01% cells survive a metabolic challenge involving lack of glutamine in culture medium of SUM149 triple-negative Inflammatory Breast Cancer cell line. These cells, designated as SUM149-MA for metabolic adaptability, are resistant to chemotherapeutic drugs, and they efficiently metastasize to multiple organs in nude mice. The MA cells can survive a variety of challenges in the metastasis process because of their embryo-like nature and high adaptability. Epigenetic state is a key player in cancer evolution. Therefore, a variety of compounds are being developed that would target epigenome for anticancer therapy. We believe that the identification of potentially effective epigenetic drugs can benefit from their evaluation in a usable system of panresistant cancer cells such as our model system of MA cells. This is particularly true for the compounds that may affect cellular adaptability upon a long treatment rather than affecting cell proliferation or apoptosis in a short period. In this study we evaluated JIB-04, a pan-inhibitor of Jumonji family of histone demethylases, for its ability to affect intrinsic resistance in MA cells. First, we found that MA cells are more resistant to JIB-04 treatment in a comparative evaluation with the parental SUM149 cells line. A treatment with 125-250 nM JIB-04 for 18-20 days killed all parental cells but not all MA cells; at least 20 MA cells survived and formed colonies after a 14-days recovery. Next, we asked whether JIB-04 treatment would affect the intrinsic resistance of MA cells, e.g., sensitize them to treatment with chemotherapeutic drugs. In order to assess the most resistant cells in population, these experiments involved treatment of MA cells with 125 nM JIB-04 for 10 days followed by a recovery in drug-free medium for 7 days; then we treated the cells with 5 nM paclitaxel or 100 nM doxorubicin for 6-8 days followed by a recovery for 1-12 days. We found that JIB-04 pre-treatment sensitized MA cells and the parental SUM149-Luc cell line to both these chemotherapeutic drugs as assessed by a dramatic drop in the number of colonies as compared to those obtained after treatment of control cells with the same chemotherapeutic drugs. To consider how our results may apply in the context of evolving disease in patients who are not taking chemotherapeutic drugs, we asked whether JIB-04 treatment would alter expression of surface molecules on resistant breast cancer cells such that they can be destroyed by immune system. In this regard, we specifically found that JIB-04 treatment increased the expression of PD-L1 in MA cells. Published results from a clinical study suggest that PD-L1 expression on breast cancer cells renders them responsive to various therapies, not just immune checkpoint blockade targeting PD-L1. In conclusion, our results suggest a novel approach for evaluating potential anticancer agents such as JIB-04 that would halt cancer evolution and prevent development of resistance to currently offered therapies.

**Title:** ZBTB2 is a novel therapeutic target for cisplatin-resistance in metastatic breast cancer

Shin V, Siu MT, Cheuk I, Ho J, Chen J and Kwong A. The University of Hong Kong, Hong Kong; Cancer Genetics Centre, Hong Kong Sanatorium and Hospital, Hong Kong and Hong Kong Sanatorium and Hospital.

**Body:**

**Background:** Zinc finger and BTB/POZ domain containing proteins (ZBTB) belong to a class of DNA-binding proteins that involved in development, differentiation and carcinogenesis. Our earlier findings showed that ZBTB2 expression was upregulated in cisplatin-resistant cells when compared with naïve cells. Increase in ZBTB2 expression was associated with ABCG2 drug transporter in drug resistance. However, the molecular mechanism of ZBTB2 in drug resistance and breast cancer metastasis remain largely unclear.

**Methods:** A cisplatin-resistant triple-negative breast cancer (TNBC) cell line, MDA-MB-231/cis, was used to examine the involvement of drug transporter genes and the drug resistance pathway. Stem cell related genes were studied by RNA-sequencing. Characterization of ZBTB2 on cell proliferation, invasion and epithelial-mesenchymal transition (EMT) process were performed in ZBTB2 siRNA transfected cells. Stem-like cells properties were validated using aldehyde dehydrogenase (ALDH) activity, tumorsphere formation ability and stem cell markers. Metastatic animal model was used to study the genetic changes during metastasis and associated with the findings in clinical samples.

**Results:** ZBTB2 has a higher expression in TNBC than other breast cancer subtypes. Also, the ZBTB2 expression is more prominent in primary breast tumor tissues when compared with non-tumor counterparts from TNBC patients. Silencing of ZBTB2 significantly reduced cell proliferation, invasion and sensitized cells to cisplatin through induction of apoptosis. Induction of ZBTB2 has been associated with breast cancer metastasis in mice model, where higher expression was seen in metastatic tumors when compared with primary tumors from tumor xenografts. ABCG2 and some epithelial-mesenchymal transition (EMT) markers (Twist 1, Snai2 and MMP-9) have been increased in metastatic tumors. Further, RNA sequencing analysis showed that ABCG2, IL6ST and FGFR1 were upregulated in MDA-MB-231/cis cells and downregulated in ZBTB2 siRNA transfected cells. Silencing of ZBTB2 reduced ALDH activity and tumorsphere formation ability. Treatment with inhibitor of NFkB (Bay11-7085) further decreased cell proliferation in cisplatin-resistant cells when compared with siZBTB2 alone. Expression of Stat3 and b-catenin were reduced upon knockdown of ZBTB2.

**Conclusion:** Taken together, silencing of ZBTB2 sensitize cancer cells to cisplatin through regulation of EMT markers and stem-like cell properties in TNBC. These findings suggest a novel molecular pathway targeting ZBTB2/stat3/NFkB signaling to combat drug resistance in metastatic TNBC.
Title: Squalene epoxidase is a potential metabolic oncogene by amplification with clinical implications in breast carcinoma: An in silico pan-cancer study with in vitro evidence

Body: Background: The SQLE gene, located on chromosome 8q24.13 in humans, encodes squalene epoxidase, a rate limiting enzyme in the pathway of cholesterol synthesis. In the past, sporadic reports have suggested that SQLE expression may be under control of its copy dosage. Nonetheless, SQLE relevance in cancer has never been studied in detail, possibly due to a conceptual bias given by the physical proximity of SQLE to the well-known oncogene MYC.

Aims: In the present analysis, we investigated SQLE copy number (CN) – gene expression (GE) association in large, well annotated multi-cancer datasets, and focused on the clinical and pathological correlations of SQLE in breast cancer (BC). Using lasso penalized multiple regression, we generated a model in order to explain the variance in SQLE expression accounted for by methylation and transcription factor expression across the diversity of TCGA studied neoplasms. Finally, we aimed at assessing which effects, if any, SQLE inhibition would generate in BC in vitro models.

Patients/Methods: We downloaded and analyzed the processed data from the TCGA repository and from the METABRIC dataset. We assessed by array-CGH and q-RT-PCR a panel of BC cell lines portraying the diversity of SQLE behavior in that disease, and performed cytotoxicity assays with terbinafine, a SQLE inhibitor, as well as SQLE directed RNA interference experiments and duplication-time tests.

Results: Breast, ovarian, and colorectal cancers exhibited the tightest SQLE CN-GE correlation among 8,783 cases from 22 cancer types, with BC showing the strictest one. SQLE promoter hypermethylation and regulation by transcription factors seemingly play a greater role to control SQLE GE in other cancer types compared with BC.

SQLE was overexpressed in aggressive, locally advanced BC, and its overexpression subtended a worse prognosis independently of classical clinical and pathological variables. In our BC models, we observed that inhibiting SQLE caused cell demise in a copy-dosage dependent fashion, and increased replication time only in SQLE expresser cell lines, but not in those without endogenously transcribed SQLE.

Conclusions: Our in silico and in vitro results strongly suggest that SQLE may behave as a bona fide metabolic oncogene by amplification, and could potentially be a novel treatment target in BC and other cancer types.
Exercise and triple negative breast cancer: Unravelling the anti-neoplastic molecular factors through novel culture method

Dela Cruz MA, Roy P, Chowdhury S, Chan S and Roy HK K. Boston University Medical Center, Boston, MA.

Body: Background
Despite advances to ameliorate breast cancer survival, triple negative breast cancers (TNBCs) attribute to highly disproportionate mortalities due to its aggressiveness and poor therapeutic response (Bao et al., Cancer Medicine 2014). Despite the lack of target-specific drugs, chemotherapy is the mainstay treatment, warranting more efficacious measures against TNBCs. Studies have shown that physical activity intervention reduced breast cancer risk between 20-80% (Monnikohf et. al., Epidemiology 2007) as well as breast cancer related mortality by 34% (Ibrahim et al., Med Onc 2010). However, it is clear that such intervention uptake in the population may not be feasible given the longstanding public health drive to increase physical activity. Therefore it is imperative to identify the molecular factors that might be involved in cancer prevention and therapy with the long term goal of developing a supplement. Due to the recent epidemiological findings on exercise and breast cancer, we wanted to develop a system to comprehensively identify beneficial myokines using a cell culture system.

Methods
For this study we differentiated C2C12 myoblasts into myotubules. Myotubules were contracted in Krebs Ringer Buffer solution with the C-Pace EP Pacer for 8 hours. Buffer was collected and concentrated using Amicon Ultra-0.5 centrifugal filter tubes to produced an exercise/conditioned medium. To explore the effects of exercise on breast cancer cell lines MCF-7 (ER+) and MDA-MB468 (TNBC line) were treated with conditioned medium for 48 hrs. To explore the effects of exercise and chemotherapeutic efficacy MDA-MB468 cells were treated with doxorubicin, conditioned medium or both for 48 hrs. Protein was isolated and processed for immunoblot analysis. Cell cycle markers p21, pRb, cyclin D1, PCNA as well as apoptotic marker cPARP were assessed to reveal the effects treatment.

Results
Treatment of conditioned medium in MCF-7 revealed marked changes in both p21 (92% increase, p=0.05) and pRb protein expression (62% decrease, p<0.05) as well as a modest reduction in PCNA (24% decrease , p<0.02). Conditioned medium treatment in MDA-MB468 cells showed a reduction in cyclin D1 and PCNA expression (40%, p<0.01 and 30%, p<0.02) as well as an induction of cPARP expression (32%, p=0.09). Doxorubicin treatment increased p21 and cPARP protein expression (2.2-fold increase, p<0.01 and 80% increase, p<0.05 respectively). Treatment of conditioned medium and doxorubicin displayed a synergistic effect with a 3.65-fold increase in p21 (p<0.01) and 130% increase in cPARP (p=0.01).

Conclusions
We have developed a novel system that may enable, for the first time, mechanistic studies to elucidate the role of skeletal muscle/exercise in breast cancer prevention and chemotherapy. Our data indicates a secreted factor(s) from skeletal muscles that plays a role in anti-proliferative and pro-apoptotic effects, which are the hallmark of exercise's anti-neoplastic properties. Studies are ongoing to further understand, characterize and isolate this factor(s) for therapeutic purposes. Given the limited chemotherapeutic options and heterogeneity in TNBC, our exercise culture system sheds a promising light on novel drug development and chemo-sensitization.
Title: Dual inhibition of the MEK5 and PI3K pathways synergistically reduces proliferation and viability in triple negative breast cancer cells

Wright TD D, Raybuck C, Wendekier K and Cavanaugh JE E. Duquesne University Graduate School of Pharmaceutical Sciences, Pittsburgh, PA.

Body: Aberrations in the MAPK/extracellular signal-regulated kinase (MEK/ERK) and phosphoinositide-3-kinase (PI3K) pathways have been linked to increased proliferation and survival in triple negative breast cancer (TNBC) cells. It has been proposed that these survival characteristics are enhanced through compensatory signaling and crosstalk mechanisms. Promising combinations of MEK and PI3K inhibition have been evaluated in phase I clinical trials for various cancer types. However, these clinical trials have had limited efficacy and have yet to encompass the MEK5/ERK5 pathway, which has been shown to promote cell survival. The goal of this study was to examine the crosstalk between the MEK1/2, MEK5, and PI3K pathways and determine the most promising combination of the MEK1/2, ERK5, and PI3K inhibitors, U0126, XMD8-92, and LY294002, respectively, in a diverse panel of triple negative breast cancer cell lines: BT549, MDA-MB-231, and MDA-MB-468. Our results indicate that dual inhibition of the MEK5 and PI3K pathways significantly reduced proliferation (45.53%) in MDA-MB-231 TNBC cells. Also, the combination of MEK5 and PI3K inhibition was shown to be synergistic. In contrast, inhibition of ERK1/2 alone or in combination with PI3K or ERK5 inhibition yielded mixed responses. Additionally, treatment with LY294004 in MDA-MB-231 (ERK 5 KO) was more potent (IC_{50}= 2.5 uM) than treatment in the native MDA-MB-231 cell line (IC_{50}= 13.7 uM). These data suggest that crosstalk between these kinases occurs and dual inhibition of PI3K and ERK5 may be a novel therapeutic approach for treating TNBC.
Title: Biological functions of ER\(\beta\) in triple negative breast cancer and its utility as a novel therapeutic drug target

Body: Background: Triple negative breast cancer (TNBC) accounts for approximately 20% of all breast cancer diagnoses. It is the most aggressive form of breast cancer and clinical management is problematic due to lack of available targeted therapies. We have shown that approximately 30% of all TNBCs express estrogen receptor beta (ER\(\beta\)), a ligand binding transcription factor, and a potential drug target for patients with this form of the disease.

Methods: Using novel ER\(\beta\)-expressing TN cell lines developed in our laboratory, we assessed the impacts of ER\(\beta\) on proliferation, invasion, migration, and alterations in cell cycle progression following estrogen and ER\(\beta\)-specific agonist treatment. We also characterized the ER\(\beta\) transcriptome and cistrome in these models through microarray and ChIP-Seq, respectively. Finally, we determined the tumoral response of cell line xenografts and PDXs treated with 17\(\beta\)-estradiol.

Results: We found that both estrogen and multiple ER\(\beta\)-specific agonists elicit significant anti-tumor effects in ER\(\beta\)+ TNBC cell lines and tumor xenografts. Activation of ER\(\beta\) with estrogen and ER\(\beta\)-specific agonists resulted in inhibition of cell proliferation primarily through a G1/S phase cell cycle arrest. Substantial reductions in cell migration and invasion were also observed following treatment. Microarray studies revealed that ER\(\beta\) differentially regulated the expression of approximately 1000 genes following estrogen treatment. Of these genes, the most striking effects were observed in a family of small secreted cysteine protease inhibitors known as cystatins, which were highly induced following ER\(\beta\) activation. ChIP-Seq and ChIP-PCR identified ER\(\beta\) binding sites in the promoter region of each cystatin and demonstrated ER\(\beta\)-mediated alterations in chromatin marks and recruitment of PolII around these promoters. We found that cystatins directly interact with TGF\(\beta\) receptor 2 (TGF\(\beta\)R2) and block downstream TGF\(\beta\) ligand-mediated activation of the canonical signaling pathway. Depletion of cystatins from conditioned media or through siRNA-mediated silencing reduced the ability of ER\(\beta\) to elicit these anti-tumor effects. In vivo, estrogen treatment of mice harboring ER\(\beta\)+ TNBC cell line xenografts or PDXs resulted in increased tumoral expression and serum levels of cystatins, and suppressed tumor growth.

Conclusions: Our data demonstrated that estrogen and ER\(\beta\)-specific agonists elicit anti-cancer effects in ER\(\beta\)+ TNBC, both in vitro and in vivo. These effects are partially mediated by cystatins which can interact with, and inhibit, canonical TGF\(\beta\) signaling, a pathway known to drive TNBC progression. Given the lack of targeted therapies for TNBC patients, the present data suggests that estrogen or ER\(\beta\)-specific agonists offer a novel approach to manage this subset of patients.
Cytotoxic potential of the RG7388 MDM2-p53 binding antagonist and the GSK2830371 WIP1 inhibitor on MX-1 and MCF-7 human breast cancer cells

Manoharan V, Lunec J, Esfandiari A, Mahdi A, Wu C-E, Zanjirband M, Karunanayake EH Hamilton, Tennekoon KH Hemamala and De Silva S. Institute of Biochemistry, Molecular Biology and Biotechnology, University of Colombo, Colombo, Western, Sri Lanka; Northern Institute for Cancer Research, School of Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom and Chang Gung Memorial Hospital at Linkou, Chang Gung University College of Medicine, Taoyuan, Taiwan.

Body: Background
The tumor suppressor p53 is a central hub in molecular signaling pathways that control the integrity of the human genome. The p53 protein functions as a transcription factor and increases the expression of many cellular genes which contribute to activation of cell cycle arrest, apoptosis and DNA repair. MDM2 is another important p53 target gene, and the MDM2 protein is capable of binding directly to p53 and directing it for degradation through the ubiquitin-dependent proteolytic pathway. Inhibition of MDM2 stabilizes p53 and MDM2 inhibitors are being explored clinically as therapies. Stabilization alone may not be enough to increase the activity of p53, and posttranslational modification of p53 by phosphorylation has been proposed to be an important contributory mechanism by which p53 becomes functionally active. Therefore maintaining the phosphorylated status of p53 in tumor cells may help to enhance its growth inhibitory and pro-apoptotic role. Wild type p53 – induced phosphatase (Wip1) is a serine – threonine phosphatase which dephosphorylates central players in the DNA damage response, including p53 and may be an additional target to enhance p53-dependent treatments. Therefore this work was focused on the effect of MDM2 (RG7388) and Wip1 (GSK2830371) inhibitors on MX-1 and MCF breast carcinoma cell lines. These two cell lines were recorded to have wild type TP53 status as well as high expression of Wip1.

Trial design
RG7388 and GSK2830371 were tested for growth inhibition on MX-1 and MCF-7 breast cancer cell lines using the sulforhodamine B (SRB) assay. The results were further confirmed and mechanism explored by western blotting using extracted protein from drug treated cell lines. Contradictory evidence regarding the TP53 mutation status of the MX-1 cell line was clarified by direct sequencing of MX-1 DNA.

Results
The MCF-7 cells responded to both RG7388 and GSK2830371 with GI50 value of 0.034 µM and 2.92 µM respectively. The MX-1 cells did not respond to either drug. The results of western blotting showed there was no expression of p53 in the MX-1 cell line. Failure to respond to RG7388 and also no expression of p53 in western blotting made us suspicious about the TP53 status of the MX-1 cells. The direct sequencing results confirmed that there was a 5bp deletion in exon 4 of the TP53 gene of the MX-1 cells. The c.154_158delCAATG mutation creates a stop codon at the 54th aminoacid position and results in a truncated p53 protein (p.Gln52Valfs*3).

Conclusion
RG7388 and GSK2838371 showed cytotoxic effects on MCF-7 cells, whereas both RG7388 and GSK2838371 had no effect on the MX-1 cell line due to the truncated p53 and loss of p53 function. In conclusion, the potency of both drugs depends on the TP53 mutation status and they are likely to be mediated via p53-dependent growth inhibition and apoptosis. Further studies are needed to evaluate the combination effect of both drugs on TP53 wild type cell lines.

Title: TruRisk® based next-generation sequencing in BRCA1/2-negative breast and ovarian cancer families reveal high mutation prevalence in additional risk genes

Body: Background: 24% of familial breast cancer (BC) and/or ovarian cancer (OC) cases analyzed within the framework of the German Consortium for Hereditary Breast and Ovarian Cancer (GC-HBOC) are due to pathogenic BRCA1/2 mutations. However, the mutation prevalence of non-BRCA1/2 genes associated with familial BC and/or OC is largely unknown. Methods: Here, we present the first NGS data generated using the GC-HBOC-designed TruRisk® gene panel. In this study a cohort of 2028 BRCA1/2 and CHEK2 c.1100delC negative index cases was analyzed which comprises consecutive patients from BC families and BC/OC families complying the inclusion criteria of the GC-HBOC. Sequencing was performed on MiSeq, NextSeq, or HiSeq devices (Illumina) using customized SureSelect XT enrichment (Agilent). Data analysis was carried out using the SeqPilot software (version 4.2.2), SophiaDDM (Version 3.5.0.12-p5.0.0) as well as an in house bioinformatics pipeline (Cologne Center for Genomics, varpipe_v2.X). The analysis of copy number variations (CNV) based on NGS-data is currently in process and not yet included in the present mutation prevalence. Results: By focusing on 22 BC/OC associated genes (ATM, BARD1, BRIP1, CDH1, CHEK2, FAM175A, FANCM, MLH1, MRE11A, MSH2, MSH6, NBN, PALB2, PMS2, PTEN, RAD50, RAD51C, RAD51D, RINT1, STK11, TP53, XRCC2), we identified 71 different deleterious variants in 104 unrelated mutation carriers derived from 2028 BC and BC/OC families (8%). Interestingly, we identified a high prevalence of ATM mutations (n=29, 1.4%) in the familial cases. Additionally mutations in PALB2 (n=27), NBN (n=9), CHEK2 (n=14), BARD1 (n=9), BRIP1 (n=10), RAD51C (n=11) were frequently observed and we confirmed FANCM (n=17) as a novel BC predisposing gene. No mutations in MLH1, MRE11A, PTEN, RAD51D, STK11 and XRCC2 were identified in our collective. Conclusions: Due to the unexpectedly high mutation prevalence in familial cases, our study highlights the importance of these genes to be included in BC/OC routine diagnostics. In contrast we found low occurrence or absence of mutations for a subset of our gene selection which requires further investigation to optimize the gene panel for diagnostic purposes. Nevertheless this approach confirms the TruRisk® gene panel as a reliable tool for this comprehensive analysis.
Title: Multi-gene panel testing for hereditary cancer predisposition in unsolved high risk breast and ovarian cancer patients

Body: Background
Among women with an elevated risk of hereditary breast and ovarian cancer who previously tested negative for pathogenic mutations in BRCA1 and BRCA2, a subset remain at increased risk of having hereditary breast, ovarian or other cancers, and should be offered multi-gene panel testing. We tested three groups of women who were enrolled in the UCSF Cancer Genetics and Prevention Program: (i) 97 women with a personal history of bilateral breast cancer, (ii) 104 women with a personal history of breast cancer and a first-degree or second-degree relative with ovarian cancer, and (iii) 99 women with a personal history of ovarian, fallopian tube, or primary peritoneal cancer. All women previously tested negative for pathogenic BRCA1 and BRCA2 mutations by either limited or comprehensive testing.

Methods
We performed comprehensive next-generation sequencing using a panel of 19 genes developed by Color Genomics (a CLIA-certified laboratory) covering ATM, BARD1, BRCA1, BRCA2, BRIP1, CDH1, CHEK2, EPCAM, MLH1, MSH2, MSH6, NBN, PALB2, PMS2, PTEN, RAD51C, RAD51D, STK11, and TP53.

Results
Across the groups tested, 9% had pathogenic mutations in one or more of the genes analyzed (8% in genes other than BRCA1 and BRCA2). Among these women, Ashkenazi Jewish and Hispanic women had elevated mutation rates compared to those of other ethnicities. In addition, we identified two women with pathogenic mutations in two cancer susceptibility genes, which has significant implications for family testing. These results demonstrate the importance of genetic testing of genes other than BRCA1 and BRCA2.

Conclusions
Among women with an elevated risk of hereditary breast and ovarian cancer who have previously tested negative for BRCA1 and BRCA2 mutations, we propose that women with characteristics of any of the three groups above be considered for subsequent multi-gene panel testing. Additionally, ethnicity and the possibility of multiple mutations may be indications for additional testing in these women and in family members of carriers.
Title: Factors associated with genetic testing in a cohort of breast cancer survivors

Blaes AH H, McKay K, Riley D, Jatoi I, Rock J, Trentham-Dietz A, Chrischilles E and Klemp J. University of Minnesota; University of Iowa; University of Texas Health Science Center, San Antonio; University of Wisconsin and University of Kansas.

Body: Background: Approximately 35% of individuals with breast cancer meet guidelines for Germline genetic testing based on young age of onset, triple-negative subtype, and positive family history. While the national guidelines expanded opportunities for genetic testing, it is unclear how consistently these guidelines are being followed. It is also unclear which factors influence the decision to receive genetic testing or learn the results of testing. We present the results of a large multi-institution survey examining factors associated with the receipt of genetic testing, adherence to recommended guidelines for genetic testing and accessing results, in addition to evaluating correlates from the medical record compared to self-report.

Methods: The Greater Plains Collaborative (GPC) Clinical Data Research Network (CDRN) Breast Cancer Group conducted a comprehensive multi-site (7 cancer care delivery sites across the Midwest) survey, Share Thoughts on Breast Cancer Study. Inclusion criteria were women >18 years, with microscopically-confirmed ductal carcinoma in situ or invasive (but not metastatic) breast cancer, diagnosed January 2013 to May 2014, and with no prior cancer other than breast cancer. Questionnaire data were linked to tumor registry data for those who consented to access their medical record.

Results: 1235/1987 surveys were completed giving an overall response rate of 61.4%. Signed informed consent to utilize medical records was obtained for 852/1235 (69%). The median age of survivors at diagnosis was 59 years, 90.4% were white, 45.2% had a 4-year college degree or more, and 58.9% had private insurance. 486/1235 (39%) underwent genetic testing with 53 planning to in the future. 8% (39) reported having a deleterious mutation with 7% not knowing the results of their genetic testing. Among younger women with no family history of breast cancer, 74.8% of those under age 50 and 89.3% of those under age 45 reported receiving genetic testing. Of younger women with >1 relative with breast cancer, 86.7% (age <50 years) and 87.5% (age <45 years) reported receiving testing. Of those < 60 years with triple negative tumors, 75.0% reported getting genetic testing. Self-reported factors that correlated with genetic testing include younger age, higher family income (54% of those with household income >$100,000 were tested vs. 27% of those with household income <$20,000), higher education level (49% of those with 4 years of college or more were tested vs. 25% of those with high school or less), having private insurance (53% tested, vs. 26% of those reporting government or no insurance), and having had more relatives with breast cancer.

Conclusion: Our study demonstrates the feasibility of undertaking a comprehensive survey of breast cancer survivors from across the Midwest. Genetic testing rates of 39%, were consistent with national recommendations. However, there is still an opportunity to identify additional survivors who did not undergo testing within 2 years of their diagnosis, particularly those with lower education and poorly insured. There are ongoing efforts to determine why 7% of the cohort did not report knowing the results of their genetic testing.
Title: Trends in age of breast cancer diagnosis for women with pathogenic variants in genes associated with increased breast cancer risk

Body: Background: The National Comprehensive Cancer Network (NCCN) currently recommends consideration of genetic testing for appropriate, high risk individuals when it will impact medical management of the individual or at-risk family members. Established NCCN testing criteria are based on family history, the presence of multiple primary cancers, and age of diagnosis. For breast cancer, women diagnosed before age 50 are eligible for genetic testing with limited family history; however, these criteria were developed based on high-risk breast cancer genes, such as \(BRCA1\) and \(BRCA2\). The growing use of gene panels has extended testing to include genes associated with a 2- to 4-fold increased risk for breast cancer. Although NCCN guidelines now include medical management recommendations for these genes, it is unclear whether current criteria appropriately identify candidates for testing who have pathogenic variants (PVs) in genes with moderate breast cancer risk. Here, we investigated the age of breast cancer diagnosis in women carrying PVs in genes with high or moderate breast cancer risk.

Methods: Clinical testing was performed for 68,239 women with a personal diagnosis of breast cancer using a 25-gene hereditary cancer panel that includes genes with a high (\(BRCA1, BRCA2, PTEN, TP53\)) or moderate (\(PALB2, CHEK2, ATM, STK11, CDH1, NBN, BARD1\)) risk of breast cancer. The majority of women tested met current NCCN criteria for testing based on their personal and/or family cancer history. The proportion of women with a PV who were diagnosed <50 and <60 years of age was evaluated.

Results: Overall, 5,231 women diagnosed with breast cancer were found to carry a PV in a gene with high or moderate breast cancer risk. 70.2% of women with PVs in genes with a high breast cancer risk were diagnosed with breast cancer before age 50, compared to only 55.5% of patients with PVs in genes with moderate breast cancer risk (see Table). However, similar proportions of women with PVs in genes with a high (89.3%) and moderate (80.2%) breast cancer risk were diagnosed before age 60 (see Table).

Conclusions: Approximately half of the women with a PV in a moderate breast cancer risk gene identified here were diagnosed before age 50. This likely overestimates the proportion of moderate-risk PV carriers with early onset breast cancers, as current testing criteria are weighted towards diagnoses at young ages. Given that there are now medical management guidelines for patients who carry PVs in most of the moderate-risk breast cancer genes, it is important to consider whether current testing criteria developed for genes with a high breast cancer risk effectively identify women with PVs in moderate-risk genes.
The yield of germline genetic testing in breast cancer patients diagnosed prior to age 50

Madlensky L, De Rosa D and Forbes K. University of California San Diego, La Jolla, CA.

Body: Young breast cancer (BC) patients are more likely to carry a mutation in a cancer predisposition gene than women diagnosed later in life. Historically young BC patients were eligible for BRCA1/2 genetic testing, but now with the advent of larger panels, more extensive germline genetic testing is available. Little is known about the yield of panel testing in young BC patients. The goal of this study is to report on the testing outcomes of referrals to a single institution cancer genetics program for women who had a diagnosis of BC at or prior to age 50.

METHODS: Cases were identified from the cancer registry of a single institution. Women with invasive breast cancer or DCIS were included if their diagnosis was at or before age 50. Charts were reviewed to abstract data on age of diagnosis, type of testing offered, and results of genetic testing, as well as insurance status and family history of cancer.

RESULTS: A total of 386 young BC patients were referred for genetic counseling in 2011-2015. Of those, 287 (74%) attended a genetic counseling appointment. Many of the women not attending had previously had genetic testing with an outside provider; their test results were included in the table below. Of the 287 attending a genetics consultation, most were offered genetic testing (87.1%); most of those not offered testing had either already been tested but without genetic counseling, or did not meet current NCCN or their insurer's criteria for testing. Eighteen women were offered a panel but elected to have only BRCA testing due to concerns about variants of unknown significance (VUS). Of those tested, 15.4% had a pathogenic or likely pathogenic mutation identified. Of women who had only BRCA testing, 11.7% were positive and 4.4% had a VUS. Of those who had panel testing, 16.9% were positive and 19.3% had a VUS.

Other genes with positive panel results included 4 x TP53 mutations, 4 x CHEK2, 2 x PALB2 and 1x each of RAD51C, RAD51D, STK11, NF1, and PTEN. The three patients who tested positive for a hereditary cancer predisposition syndrome (STK11, NF1, and PTEN positive) had clinical features of their respective syndromes. The STK11 patient was previously known to have Peutz-Jeghers syndrome, while the NF1 and PTEN patients had subtler features of Neurofibromatosis type 1 and PTEN-Hamartoma Tumor Syndrome (Cowden Syndrome) respectively.

CONCLUSIONS: The yield of germline genetic testing in BC patients increases with younger age of diagnosis. Panel testing increases the yield of testing above that of BRCA1/2 alone, and enabled the formal diagnosis of a few individuals with hereditary cancer syndromes who did not have classic features of their syndromes. The VUS rate for panel testing remains significant, and some women elect to have BRCA1/2 testing only due to personal preference because of VUS rates. These data describing the yield of testing in BC patients diagnosed at a young age may be useful for genetic counseling of this patient population.

Title: Screening, management, cancer diagnoses, and outcomes of women with germline BRCA mutations in Israel: The Noga Clinic experience

Mor P, Levy-Lahad E, Beler U, Carmon M, Strano S, Hadar T, Olscha O, Rabinowitz R, Srebnik N, Simon E, Duchin R, Jackson M and Rabinovitch R. Medical Genetics Institute, Shaare Zedek Medical Center, Jerusalem, Israel; Obstetrics and Gynecology, Shaare Zedek Medical Center, Jerusalem, Israel; Breast Surgery, Shaare Zedek Medical Center, Jerusalem, Israel; Imaging Institute, Shaare Zedek Medical Center, Jerusalem, Israel; Obstetric and Gynecologic Ultrasound Unit, Shaare Zedek Medical Center, Jerusalem, Israel and University of Colorado Comprehensive Cancer Center, Aurora, CO.

Body: Background: Women with germline BRCA (gBRCA) mutations in the United States are typically diagnosed at the time of cancer diagnosis and most often undergo bilateral mastectomy. Israel's population of 8 million includes over 3 million Jews of Ashkenazi ancestry, of whom 2.5% would be expected to have gBRCA based on population studies. Cross-ancestral and -racial marriages in Israel continue to expand the population at risk for gBRCA mutations. Gene typing for any woman in Israel can be obtained without cost through either the national health care system or genetic screening studies. The Noga Clinic (NC) in Jerusalem was started in September 2007 for women with documented gBRCA mutations at risk for breast and/or ovarian cancer to counsel them on risk-reducing (rr) surgical interventions and provide rigorous screening to diagnose cancer at its earliest stages. Screening is performed in compliance with NCCN and international recommendations. This report presents information from that unique population and clinical experience.

Methods: Clinical records of women with at least one screening visit at NC through December 2015 were retrospectively reviewed. Women with a documented gBRCA mutation with or without a clinical history of breast/ovarian cancer were eligible for assessment every (q) 6 months (m): bilateral breast exam by an experienced breast surgeon (q6m), serum CA-125 (q6m), trans-vaginal ultrasound (q6m), bilateral mammography (q12m) and bilateral breast ultrasound (q12m) alternating with bilateral contrast enhanced MRI (q12m) beginning at age 25. Women are offered rr bilateral mastectomy (BMast); rr bilateral mastectomy is recommended by the age of 40. Cancer diagnoses and rr surgeries were recorded.

Results: 611 women have undergone at least one screening assessment at the NC, of whom 44 had a prior cancer diagnosis. Age at the time of initial gene testing ranged from 20-87y (median 38). Of those with recorded mutation data, 272 women (57%) had mutations in gBRCA1, 205 (43%) in BRCA2, and 1 in both. Mutation specifics will be presented in detail. For the 567 women without a prior cancer diagnosis, median age at first screening visit was 37y (range 21-87) and total follow up was 2,141 person-years (per person range 1-9y, median 3.3). Only 21 women (4%) elected rrBMast at a median age of 42y (range 26-60); none developed breast cancer. In the remaining individuals, 31 breast cancers were diagnosed (58% gBRCA1, 42% gBRCA2) from the initiation of screening at a median age of 51y (range 28-88); the majority were DCIS and diagnosed at a median screening follow up of 2.8y. No participant was treated with anti-endocrine chemoprevention. There have been no breast cancer deaths. 5 women were diagnosed with ovarian cancer (all gBRCA1) of whom 1 died of the disease. Methods of cancer detection will be presented.

Conclusion: This is the largest reported data set of women with gBRCA mutations without a prior breast or ovarian cancer diagnosis screened and followed over time. In this highly selected predominantly Jewish population in Israel, the great majority of women chose not to undergo rrBMast and have excellent outcomes when participating in regular and rigorous screening. Further follow-up is ongoing.
ATM mutations contribution to hereditary breast-pancreatic cancer

Gordon OK K, Childers K, McFarland R and LaDuca H. Providence Health & Services, Southern California, Burbank, CA and Ambry Genetics, Aliso Viejo, CA.

BACKGROUND: Germline mutations in PALB2, BRCA2 and STK11 are well established as increasing risk of both breast and pancreatic cancer. More recently, ATM and BRCA1 mutations have also been associated with risk, but literature is limited. We investigated the prevalence of pathogenic mutations and likely pathogenic variants (“mutations”) in BRCA1/2, PALB2, STK11 and ATM, comparing mutation occurrence in individuals with diagnoses of breast cancer alone to those with both breast and pancreatic cancer primaries. Prevalence of CDKN2A (p16) mutations was also evaluated in the breast–pancreatic cohort because of its contribution to hereditary pancreatic cancer.

METHODS: Clinical histories and test results were reviewed for patients undergoing multi-gene panel testing at one clinical laboratory between April 2012 and June 2015. The study population was limited to women with breast cancer only (n=27,573) and women with both breast and pancreatic cancer (n=97) without other primaries. Patients underwent comprehensive analysis of 5-49 genes, depending on the panel ordered. Demographic and clinical information was provided by clinicians on test requisition forms and pedigrees/clinic notes if provided. Gene-specific mutation frequencies were compared between women with breast cancer only and women with breast and pancreatic cancer using Fisher’s exact test.

RESULTS: Mutations were identified in BRCA1, BRCA2, PALB2 or ATM in 13 of the 97 breast - pancreatic cancer probands (13.4%) and 1,255 of the 27,573 breast cancer probands (4.6%). Gene-specific mutation frequencies and statistical comparisons may be found in Table 1. ATM mutations were significantly more likely to be identified in women with breast and pancreatic cancer compared to breast cancer alone (Table 1). Interestingly, no CDKN2A or STK11 mutations were identified in the breast plus pancreatic cohort, although this may have been limited by the small number of individuals tested for this gene. Of those 13 women with breast and pancreatic cancers who had identified mutations, 11 (85%) had diagnoses of breast cancer over age 50.

CONCLUSION: This exploratory study substantiates the association of deleterious germline ATM mutations with predisposition to both breast and pancreatic cancers. These results also suggest that mutations in ATM may account for a larger portion of inherited breast and pancreatic cancer kindreds than mutations in other well-described genes such as BRCA2, PALB2 and STK11. A personal history of breast and pancreatic cancer may warrant the expansion of current NCCN testing criteria as a single indicator for germline testing, and that pancreatic screening consortia (CAPS) consider inclusion of ATM mutations in screening recommendations.

Title: Abstract Withdrawn
Social media's impact on patient utilization of high-risk clinics for genetic counseling and testing services

Body: Background: The availability and variety of cancer genetic testing services have grown tremendously in past years; testing services now offer panels that analyze more than 75 cancer susceptibility genes with results available in just weeks. Engaging the high-risk population in conversations regarding the importance of hereditary cancer screening is a prerequisite to initiating genetic testing and appropriate cancer surveillance. It has been shown that population awareness of cancer genetic testing has increased, but few studies have explored factors that contribute to actual uptake of these services.

Methods: A 36-question research survey was adapted from Cycle 3 of the 2014 Health Information National Trends Survey by NCI and distributed online to patients who received genetic counseling at the Ruth Paul Hereditary Cancer Program at the George Washington University Medical Faculty Associates. All patients who presented to the clinic, including those with and without cancer diagnoses, were invited to complete the survey. The survey was divided into four sections: (1) how the patient usually seeks health information, (2) how the patient has used media and the internet to understand cancer genetics, (3) how often the patient visits health professionals, and (4) why the patient pursued testing at the high-risk clinic.

Results: Forty-five out of 68 consented individuals completed the online survey. Most patients searched the internet regarding genetic testing in the past (64% vs. 36% who did not) but felt that they learned the most about cancer genetic testing through their health care provider and their family members/friends (49% and 35%, respectively). Though most patients access social networking sites (78%), only 4% shared information and 11% received information regarding cancer genetic testing through one of these sites. Most patients (65%) felt that information obtained from social media regarding cancer genetic testing had no impact on their decision to make an appointment. One-third of respondents (33%) felt that Angelina Jolie's decision to have prophylactic surgery for her known mutation encouraged them to make an appointment while 53% felt it had no impact on their decision. Most patients received a referral from their healthcare providers (91%) to have genetic testing, though 48% of those patients had to ask their doctor about genetic testing before receiving the referral.

Conclusions: Many patients use social media and internet resources for education regarding cancer genetic testing. However, most individuals sought genetic counseling services in our Hereditary Cancer Program after discussion with their health care providers. Half of those patients were only referred after raising the topic with their provider. While online resources can raise awareness and educate about cancer genetic counseling, improving uptake and utilization of these critical resources will require education of health care providers.
Body: Introduction: Genetic testing is known to improve outcomes in high-risk women by finding cancers in the earliest most treatable stage or through prophylactic measures. However, these life-saving services may not be available to low-income women due to lack of insurance or access to genetic providers. To address this need, a collaboration between the Hereditary Cancer Clinic at Vanderbilt-Ingram Cancer Center (VICC) and the Robert E. Hardy Cancer Clinic at Nashville General Hospital at Meharry Medical College (MMC) was established in 2015 to systematically screen all MMC breast cancer patients for hereditary traits and refer them for genetic counseling (1). We hypothesized that high risk women could be accurately identified using this clinic based screening tool.

Methods: MMC clinic staff screened breast cancer patients using a 10-item Family Cancer Risk Assessment tool (RISK) that has been designed for use in a busy clinic environment (2). We tested the accuracy of the RISK by comparing the results to a 3-generation pedigree and the current NCCN guidelines for referral of patients to genetic services (3). The project was approved by the IRBs at each institution and study data were collected and managed using RedCap electronic data capture tools hosted at Vanderbilt University (4). Summary statistics and Chi-square for significance were performed.

Results: 73 breast cancer patients completed the RISK during their clinic visits and 41 (56%) had a high-risk score of 6 or more. All 41 patients have been referred for genetic counseling, with 18 (44%) women having completed a pedigree interview over the phone. 11 of these 18 patients (61%) were African-American; 5 (27.7%) were Caucasian; and one each (5% each) were of Asian and Hispanic ancestry. 9/18 were diagnosed ≤ 50 years (Mean entire group =50 yrs; range 36 -57). 5/18 (27.7%) had triple negative markers on pathology and 2/18 were ER+/PR+/Her2+, and the remainder had ER+/PR+/HER2- cancers. Among the 18 patients with full pedigrees, 17 (95%) patients met current NCCN guidelines based on pedigree analysis. The one outlier had a revised RISK score based on updated information obtained during the pedigree interview. Genetic testing was offered to 10 patients seen in VICC clinic and 1 declined testing. The other 8 patients either failed (n=4) or are awaiting an appointment (n=4). No deleterious mutations were seen in those tested. 4 VUSs (BRCA2, NBN, SMARCA4, and RAD51D) were found in 3 of the 9 tested patients. No significant differences were found in race, age or type of tumor.

Conclusion: Point of care risk assessment using the Family Cancer Risk Assessment screening tool is highly accurate for identifying patients at high genetic risk for hereditary breast cancer. While the tool was completed using pen and paper, it could easily be computerized for ease of administration and calculation of risk scores. This approach benefits the busy oncologist in identifying and referring appropriate patients for genetic testing.

Title: Contribution of germline mutations in cancer predisposition genes to tumor etiology in women diagnosed with invasive breast cancer before 40 years

Ellsworth RE E, Rummel SK K and Shriver CD D. Chan Soon-Shiong Institute of Molecular Medicine at Windber, Windber, PA and Murtha Cancer Center, Washington, DC.

Body: Background: Although breast cancer in young women (YW) accounts for <10% of diagnoses annually, tumors in young patients have more aggressive characteristics and higher mortality rates. The cost of breast cancer, including treatment costs, physical and psychosocial effects, and lost productivity, is higher in YW than older patients. Improved understanding of etiology of breast cancer in YW is critical to developing effective prevention strategies.

Methods: All patients diagnosed before 40 years were identified. Family history was classified as average (No first or second degree relatives with breast or ovarian cancer or 1 second degree relative with breast cancer diagnosed >50 years), moderate (1 first degree relative with breast cancer, 2 first or second degree relatives with breast cancer diagnosed >50 years or 1 first or second degree relative with ovarian cancer) or strong (>1 first or second degree relative with bilateral breast cancer, breast and ovarian cancer or male breast cancer, >2 first or second degree relatives with breast cancer before age 50, breast and ovarian cancer in different relatives, ovarian cancer at any age or >3 first or second degree relatives with breast cancer at any age). Genomic DNA was isolated from blood samples and targeted sequencing was performed using the TruSight Cancer panel (Illumina). Pathogenic mutations were identified using VariantStudio.

Results: Seven percent (132/1950) of patients enrolled in the CBCP were diagnosed <40 years. Of these, 7% had a strong family history. TruSight sequencing was completed for 63 women for whom genomic DNA was available: five patients had pathogenic BRCA2 mutations (1813dupA, 5849del4, 999del5, Q2491X, Y3098X), all ER+ tumors, and seven patients had BRCA1 mutations (187delAG, 448insA, 943ins10, E84X, Q1313X, E1535X) all in triple negative breast cancers (TNBC). A pathogenic CHEK2 I157T was detected in an African American woman with TNBC. Variants of unknown significant were also detected in APC, ATM, BRCA1, BRCA2, CHEK2, CDH1, ERCC4, FANCA and PMS2 and heterozygote mutations detected in autosomal recessive genes BLM and RECQL4.

Discussion: Pathogenic mutations were found in 21% of young women with breast cancer with an additional 22% harboring potentially pathogenic mutations. BRCA1 mutations were associated with triple negative breast tumors in individuals with moderate to strong family history and BRCA2 mutations were associated with ER+ tumors in young women without strong family histories. These data demonstrate that although genetic predisposition may account for 21-43% of tumors, >50% of tumors in young women are not attributable to genetic causes, and identification of those non-genetic factors is critical to reduce the burden of breast cancer in this population.
Title: BRCAsearch - results of population-based screening of BRCA1 and BRCA2 germline mutations in incident breast cancer in South Sweden

Body: Increasing evidence supports the benefit of identifying the BRCA1 and BRCA2 germline mutation status in early breast cancer. Germline mutations in these two genes are treatment predictive for the benefit of risk reducing surgical interventions of the contralateral breast and the ovaries and fallopian tubes, in early breast cancer (Metcalf 2014; Domchek 2010). Furthermore, they may possibly also be treatment predictive for the effect of certain types of medical interventions (Tutt SABCS 2014).

In order to provide the patient with the opportunity to take BRCA test results into account already when planning primary treatment, BRCA testing and cancer genetic counseling needs to be initiated and performed early during the diagnostic and treatment related process in newly diagnosed breast cancer cases. Special attention needs to be taken to the fact that the test results may affect not only the patient, but also her or his relatives. We have observed that the clinical efficacy of BRCA-screening criteria may be surprisingly low, leaving a substantial number of BRCA-carriers undetected in spite of intense contacts with health care providers (Unpublished results).

BRCAsearch (ClinicalTrials.gov Identifier: NCT02557776) is a population based study including new invasive breast cancer cases at three hospitals in the South of Sweden. Patients are invited to perform BRCA1 and BRCA2 germline mutation analysis at time of primary treatment after written study information and written genetic counseling, irrespective of family history, age or clinical phenotype. The primary end-points of the study include the rate of BRCA mutations in newly diagnosed breast cancer in South Sweden, the fraction of patients that accept inclusion in the study, and the rate of mutation positive patients that do not fulfill clinical criteria for BRCA mutation screening. Secondary end-points include the perception among patient of the intervention and testing procedures, the types of questions the patients present during the process and psychosocial outcome among carriers and non-carriers.

In May 2016 about 400 patients have been included in the study, whereof 333 have been analyzed for BRCA germline mutations. The accrual target of the study is 500 patients, which will be reached during the fall of 2016. At the meeting, the BRCA1 and BRCA2 mutation rates will be presented, as well as the acceptance rate of the study among patients approached, and the fraction of mutation positive patients that do not fulfill current BRCA1 and BRCA2 mutation screening criteria, and whose positive mutation status therefore would have been missed if clinical selection criteria had been applied.

The results of the study will be used to define selection criteria for BRCA-mutation screening in new breast cancer cases, and the design of screening procedures with an appropriate clinical effectiveness.

Title: Unhealthy lifestyle patterns are prevalent in unaffected BRCA mutation carriers & are associated with increased oxidative stress and telomere length alterations

Body: The lifetime-risk of breast-cancer is greatly increased in women carrying a deleterious mutation in the \textit{BRCA1} or \textit{BRCA2} genes. Recently, there has been increased penetrance of \textit{BRCA1} and \textit{BRCA2} mutations which may be due to lifestyle influences. There is a need to identify approaches to reduce the penetrance of \textit{BRCA} 1/2 mutations. Understanding how modifiable lifestyle-factors affect cancer-risk in \textit{BRCA}-mutation carriers may have implications for risk-reduction in this group. At the molecular level, oxidative-stress and telomere dysfunction are early events in cancer development and these processes may be considered surrogate markers of cancer-risk. It has been reported that \textit{BRCA}-mutation carriers are more susceptible to these pro-carcinogenic processes that non-carriers.

The aim of this pilot study was to objectively measure lifestyle factors in unaffected \textit{BRCA}-mutation carriers and to assess the impact of these lifestyle-factors on oxidative-stress profiles and telomere length.

Participants (n=75) were recruited from breast-cancer family-risk clinics and cancer-genetics clinics. Body-composition (BMI, waist-circumference), metabolic profiles and physical-activity (triaxial accelerometry) were measured for each participant. Serum levels of the oxidative-stress markers 8-oxo-7,8-dihydro-2'-deoxyguanosine (8-oxo-DG) and 4-hydroxynonenal (4-HNE) were measured in a subset of participants (n=30) by ELISA. Telomere length was measured in a subset of participants (n=30) by quantitative PCR (qPCR).

Participants demonstrated poor adherence to physical-activity guidelines with 94% not reaching physical-activity levels recommended by the American College of Sports Medicine. The majority of participants were overweight (39%) or obese (32%) with 73% exhibiting abdominal obesity. 21% of participants had the metabolic syndrome (MetS) at the time of study enrolment with the majority of participants (80%) presenting with at least one feature of the MetS. Circulating levels of 8-oxo-DG did not appear to be affected by body composition or MetS status, however, serum levels of the lipid peroxidation marker 4-HNE were significantly higher in participants with the MetS (p < 0.0001). Correlation of serum 4-HNE levels with individual features of the MetS and related parameters revealed significant direct correlations with waist circumference (p = 0.02), number of features of MetS (p = 0.0007), insulin (p = 0.02) insulin resistance score (HOMA-IR) (p = 0.01), HBA1c (p = 0.006), glucose (p = 0.048) and triglycerides (p <0.0001). Age-adjusted telomere length was not influenced by anthropometric measurements or MetS status in this group. Moderate physical activity levels were inversely associated with age-adjusted telomere length; particularly, among post-menopausal participants (p =0.009).

This work has provided compelling evidence that in this cohort of \textit{BRCA}-mutation carriers, unhealthy lifestyle-patterns are prevalent. In addition, these results suggest that the potential may exist to modify pro-carcinogenic processes in this cohort by modifying physical activity levels and targeting the metabolic syndrome and its component features lifestyle interventions and/or medication.
Title: Low-level gonosomal mosaicism of a de novo BRCA1 gene mutation – The origin of a constitutional mutation in a breast cancer family

Bülow L, Keupp K, Richters L, Pohl E, Wappenschmidt B, Zarghooni V, Reichstein-Gnielinski S, Maringa M, Giesecke J, Rhiem K, Hahnen E and Schmutzler R. Center for Familial Breast and Ovarian Cancer, Center for Integrated Oncology (CIO) and Center for Molecular Medicine Cologne (CMMC), Medical Faculty, University of Cologne and University Hospital Cologne, Cologne, Germany.

Body: Mosaicisms arise when specific cells within a developing organism mutate to result in two or more cell populations with distinct genotypes. In cases of gonosomal mosaicism a genetic variation is present in both somatic and germline cells. Here, we describe a large Turkish breast cancer family with four affected individuals. In the Index patient (II-1; age of onset 45 years), a heterozygous deleterious frameshift mutation, c.1310dupA, p.His437Glnfs*2 in BRCA1 was identified using the TruRisk® gene panel designed by the German Consortium for Hereditary Breast and Ovarian Cancer (GC-HBOC). Predictive genetic testing showed heterozygous carrier status in the daughter (III-1).

The mutation was also analyzed in peripheral blood of the affected mother (I-1; age of onset 45 years) of the index patient by Sanger Sequencing. Interestingly, Sanger sequence did demonstrate the presence of remarkable small peaks presenting the frameshift mutation similar to a mosaic pattern. A second and third independent blood draw within a time frame of four month was tested and a mosaic signal of approximately 10 % was reproducibly detected.

In order to exclude a potential allelic drop out, independent sequencing experiments via next generation sequencing (NGS; TruRisk® gene panel) were performed. Again, the mutation was present with an allele read frequency of 12 %. No other pathogenic mutations were detected in any of the other tested breast cancer susceptibility genes.

To further examine and underscore the presence of gonosomal mosaicism different tissues should be analyzed. As no tumor material or surrounding normal breast tissue was available primary skin fibroblasts were isolated from skin biopsy. Sequencing of cultured primary fibroblasts demonstrated the absence of the familial BRCA1 mutation. With NGS-based CNV analysis as well as MLPA analysis we excluded aberrant copy numbers of BRCA1 in blood and fibroblasts.

In conclusion, our data provide striking evidence for a BRCA1 mosaicism, which is not detectable in all body cells. Due to the inheritance of the BRCA1 mutation to the next generations (II-1 and III-1), we assume the presence of a gonosomal mosaicism in the affected mother (I-1).

Additionally, the history of breast cancer onset in the family indicates that the BRCA1 mosaic mutation carrier do not necessarily have a milder phenotype compared to full heterozygotes. In this context our results implicate the importance of using highly sensitive sequencing platforms in routine diagnostics to ensure the detection of disease causing low-level mosaic mutations.
Title: Beyond CHEK2 in breast cancer: Search for additional moderately penetrant risk gene variants by analyzing the oligogenic disease course in CHEK2 mutation carriers

Pohl E, Richters L, Hauke J, Ernst C, Kröber S, Niederacher D, Arnold N, Ramser J, Groß E, Gehrig A, Schmidt G, Dutrannoy V, Kast K, Hahnen E and Schmutzler R. Center for Familial Breast and Ovarian Cancer, Center for Integrated Oncology (CIO) and Center for Molecular Medicine Cologne (CMMC), Medical Faculty, University of Cologne and University Hospital Cologne, Cologne, Germany; University Hospital Düsseldorf, Heinrich-Heine University Düsseldorf, Düsseldorf, Germany; University Hospital of Schleswig-Holstein, Campus Kiel, Christian-Albrechts University Kiel, Kiel, Germany; Klinikum rechts der Isar, Technical University Munich, Munich, Germany; Institute of Human Genetics, University Würzburg, Würzburg, Germany; Institute of Human Genetics, Hannover Medical School, Germany; Institute of Human Genetics, Campus Virchow Klinikum, Charite Berlin, Berlin, Germany and University Hospital Carl Gustav Carus, Technical University Dresden, Dresden, Germany.

Body: In one third of all cases, breast cancer (BC) shows a familial aggregation, suggesting a genetic predisposition. Besides BRCA1/2, several highly or moderately penetrant risk genes could be identified, including CHEK2 (cell-cycle checkpoint kinase 2) which controls DNA repair upon DNA damage, cell cycle arrest, and apoptosis. The CHEK2 germline mutation c.1100delC is a European founder mutation causing a frameshift, premature protein truncation (p.T367Mfs*15), and loss of protein function. It has been shown that CHEK2 c.1100delC carriers are predisposed to estrogen receptor positive (ER+) breast tumors. As the absolute risk of BC and the probability of developing bilateral BC in CHEK2 c.1100delC mutation carriers seems to be higher in women with a BC family history (Cybulski et al., 2011), many previous studies were interested in identifying additional moderately penetrant risk gene variants explaining the CHEK2 specific phenotype. Although the multiplicative nature of risk effects due to CHEK2 mutation c.1100delC and additional moderate or low risk variants have been suggested in the past (Byrnes et al., 2008; Sokolenko et al. 2014), additional moderate risk genes in CHEK2 mutation carriers have not been studied so far.

Here we focused on 165 BRCA1/2 negative BC/OC index cases recruited by the German Consortium for Hereditary Breast- and Ovarian Cancer (GC-HBOC) which were heterozygous for one of the two European founder mutations (c.1100delC or delExon9/10). Samples were analyzed by targeted next generation sequencing using a 48 gene panel including confirmed BC risk genes like ATM, PALB2 or FANCM as well as Lynch syndrome causing genes and several putative novel risk genes which have been identified recently or are currently under investigation in national and international studies. We were able to identify a total of 9 patients (9/165; 5.5%) carrying at least one deleterious mutation in addition to the known heterozygous CHEK2 mutation of which one carried mutations in 2 genes (FANCL, p.S144Lfs*6 and PMS2, c.250+3_250+6del). Deleterious variants in the remaining patients were identified in ATM (p.I1581Nfs*5), FANCL (p.S144Lfs*6), FANCM (p.Q156*), GPRC5A (p.R61Sfs*59, 2 times), PMS2 (p.D414Rfs*44), RINT1 (p.Q356*) and XPC (p.C670*).

In summary, the results obtained with this selection of genes further supports the assumption that the increased cancer risk for CHEK2 mutation carriers with a family history of BC/OC is at least in part explainable by an oligogenic disease course. Preliminary data suggest an association of the presence of additional deleterious mutations and an earlier age of onset in CHEK2 mutation carriers. For instance the patient carrying two mutations in FANCL and PMS2 in addition to the CHEK2 c.1100delC variant showed a remarkably low age of onset (31 years). Analysis of missense and potential splice site variants in this cohort are mandatory to further validate these findings. Additionally, we could confirm panel diagnostics as a powerful tool to improve individual risk prediction and clinical care of CHEK2 mutation carriers.

Title: Clinical outcome of patients with advanced triple negative breast cancer with germline and somatic variants in homologous recombination gene

Body: Background: Variants in homologous recombination (HR) genes other than BRCA1/2 may cause a BRCA-like phenotype triple negative breast cancer (TNBC), which includes the sensitivity to platinums and DNA repair inhibitors. Evaluation of HR proficiency may influence the clinical management of TNBC. Our aim was to evaluate germline and somatic HR gene variants in advanced TNBC patients (pts) and clinical outcome.

Methods: Our cohort included advanced TNBC pts unselected for family history or age at diagnosis, enrolled in an institutional molecular screening program (NCT01505400). DNA from matched blood and FFPE tumor samples was assessed using a lab developed next generation sequencing Hereditary Cancer Panel (NGS-HCP) that includes all exons of 52 cancer predisposition genes, with 20 HR genes (Illumina MiSeq/NextSeq, germline coverage 100x, somatic coverage 500x). Medical records were reviewed for clinical outcome, pathology and prior germline BRCA1/2 testing results. All pts consented for research on banked samples and return of pathogenic germline variants was optional. Log rank test was used to determine time from surgery with curative intent to relapse (TTR) and overall survival from diagnosis to death (OS) differences based on presence of HR variants.

Results: We included 32 pts who consented for return of pathogenic germline variants and had sufficient DNA for NGS-HCP analysis. Median age at diagnosis was 45 years (range 21-80). Initial stages at diagnosis were: I (12.5%), II (62.5%), III (19%) and IV (6%). Germline HR variants were detected in 17 pts (53%) with a median number of variants per patient of 1 (range 0-6). Five pts had likely pathogenic or pathogenic variants in HR genes: BRCA1 (2), BRCA2 (1), FANCC (1) and FANCC + BML (1). Another patient had a BRCA1 pathogenic variant previously detected by Multiplex Ligation-dependent Probe Amplification but was not detected by NGS-HCP. 26 variants of unknown significance (VUS) were identified in 13 HR genes, including FANCA (6), FANCF (3) and BRCA1 (3). Only one patient had a somatic HR variant in FANCA not found in the germline. 30 pts (94%) had somatic TP53 variants. Sporadic somatic BRCA1/2 variants were not seen. BRCA1/2 variants present in the tumor were equivalent to those detected in blood of BRCA1/2 carriers. Median (m) TTR was 17 months (range 1-119) and mOS was 49 months (range 8-123). Presence of likely pathogenic or pathogenic germline variants was not associated with TTR (p=0.78) and OS (p=0.23). Presence of germline VUS, likely pathogenic or pathogenic variants also did not correlate with TTR (p=0.72) and OS (p=0.47).

Conclusions: In our cohort of pts with advanced TNBC, 12% had germline pathogenic variants in BRCA1/2, similar to the previously reported rate in early stage TNBC pts. Prevalence of likely pathogenic or pathogenic variants in non-BRCA HR genes was 6%. The presence of germline variants in HR genes was not associated with clinical outcome, however, the number of patients included was small and we had limited power to detect survival differences.
Investigation of HBOC germline mutations in women diagnosed with breast cancer in Trinidad and Tobago

Parkinson GT T, Chagpar AB B, Hofstatter EW W and Nunez-Smith M.  Yale School of Medicine, New Haven, CT.

Background: Trinidad and Tobago (T&T) is a southern Caribbean island with a population of approx. 1.3 million. According to WHO/PAHO, T&T has the 2nd highest breast cancer mortality rate in the region, and breast cancer continues to lead in incidence and mortality in cancers among female citizens. Notably, a large proportion of breast cancer cases in T&T appear to occur at a young age; with nearly 36% of breast cancers diagnosed under the age of 50. It is known that a younger age at diagnosis can be associated with Hereditary Breast and Ovarian Cancer syndrome (HBOC), characterized by germline mutations in tumor suppressor genes such as BRCA, PTEN and TP53. Yet, the prevalence of HBOC mutations remains unknown in T&T, as local health services for genetic counseling and testing in T&T currently do not exist. As such, our study aimed to determine the prevalence rate of HBOC mutations among women with breast cancer in T&T who met NCCN criteria for evaluation for HBOC syndrome; thus investigating whether there is a need to include genetic testing and counseling in local oncology management in T&T.

Methods: At the National Radiotherapy Center, the main oncology unit in T&T, female breast cancer patients, who met the NCCN criteria for further genetic counseling/testing, were recruited either through doctor referrals or chart reviews. We conducted interviews inquiring about their personal breast cancer diagnosis, risk factors for breast cancer, as well as any relevant family history. This was followed by the collection of saliva samples using Oragene kits, which were then analyzed by Color Genomics Inc. for 30 genes associated with hereditary cancers; including 19 HBOC associated genes such as BRCA1, BRCA2, TP53 and PTEN. Finalized results were returned to patients by genetic counselors from Color Genomics.

Results: 165 patients who met NCCN guidelines for HBOC counseling/testing were approached, of whom 150 agreed to participate. Due to funding and resource limitations, 60 samples were collected thus far; ages ranged from 19-56. The majority of women met NCCN criteria based on age of personal breast cancer diagnosis (40%), and/or family history of breast and/or ovarian cancer (60%). Preliminary results show that of 49 samples, 10 patients tested positive for deleterious HBOC germline mutations: 7 - BRCA1, 2 - BRCA2 and 1 - PTEN; thus far giving a prevalence rate of 20%.

Discussion: Therefore, our results found a strikingly high HBOC germline mutation prevalence rate of 20% among a cohort of female breast cancer patients meeting NCCN criteria in T&T. As we continue to finalize the incoming data on these patients, we hope to draw associations between their genetic status and their respective tumor markers, family history, and personal medical history. However, these initial results demonstrate the need to include genetic counseling and testing in the local oncology management in T&T, as the identification of HBOC mutations can influence treatment options, as well as help identify family members who are at high risk for cancer predisposition. Ultimately, this integration could help alleviate the country’s high incidence and mortality rates with respect to breast cancer, and save the public healthcare system significant financial resources.
Increasing participation in research - breast cancer (Inspire-BrC)

Background: Increasing Black patients' participation in cancer clinical trials is important because of the population's lower survival rate. Accrual for Blacks is the lowest of all groups at 0.5-1.5%. Our study aims to increase trial participation rates among Black breast cancer patients by testing the effectiveness of a culturally tailored video intervention on the decision to participate in a clinical trial.

Methods: We hypothesized that the intervention would increase clinical trial enrollment by 6 percentage points compared to our 2012 enrollment baseline of 6% (22/384). Self-identified Black patients with invasive breast cancer at 5 MedStar Hospitals watched a 15' video about clinical trials, targeting six cultural and attitudinal barriers to participation. The Attitudes and Intention to Enroll in therapeutic clinical Trials (AIET) pre-/post-/follow-up tests with 31 items was used to determine the impact of the video on three domains: actual trial enrollment; likely participation in trials; and attitudes toward trials. The pre-test was conducted at baseline; post-test immediately after video; and follow-up 7-21 days after the intervention. Participants were followed for 6 months to assess trial enrollment status. Descriptive statistics were used to describe study subjects with respect to basic characteristics; means and standard deviations for continuous variables; and frequencies and percentages for categorical variables. Repeated measures analysis of variance was used to examine whether the changes in attitudinal barriers were statistically significant over time. The primary outcome measure was the proportion of Black breast cancer patients who signed consent and/or enrolled in a therapeutic clinical trial.

Results: From Mar/2014 to Sept/2015, 279 patients were approached to join INSPIRE-BrC prior to discussion about therapeutic clinical trials; 52 declined participation. 208 signed consent and 200 completed it. Average age was 59 yrs (SD=12), 75% were stage I-III; 29% were married; 85% had 1 or more children; 29% attended some college or technical school; 53% had private insurance, 31% Medicare, 16% Medicaid; and 53% had a household income <$40,000/yr. A total of 41 INSPIRE-BrC participants (20.5%) signed consent and 29 (14.5%) enrolled onto a therapeutic study (one-sided p=0.027 vs H0: P=0.06). Pre-video, 52% of patients expressed that it was likely they would participate in a hypothetical therapeutic clinical trial; immediately post-video, 67% (p=<0.001) and 7-21 days after the intervention, 64% (p=0.003). Among 31 AIET items, 25 (81%) showed statistically significant and positive change after the intervention. Specifically, trust in the doctor increased and, suspicion in trials decreased (p<0.001). Further, patient views on fairness for treatment of poor people and Blacks became significantly more positive (p<0.001).

Conclusion: Study findings show that the video is a promising tool for rapid dissemination of a theory-driven, evidence-based model to enhance clinical trial accrual among Black cancer patients. The video also has the potential to positively change attitudes about clinical trial participation.

The study was supported by the Breast Cancer Research Foundation.
Title: Socioeconomic disparities in needle biopsy prior to breast cancer surgery across physician referral networks

Killelea BK K, Herrin J, Soulos PR R, Pollack CE E, Forman HP P, Yu J, Xu X, Tannenbaum S, Wang S and Gross CP P. Cancer Outcomes, Public Policy and Effectivemess Research Center, Yale School of Medicine, New Haven, CT; Yale School of Medicine, New Haven, CT; Johns Hopkins School of Medicine, Baltimore, MD; Yale School of Medicine, New Haven, CT; Yale School of Medicine, New Haven, CT; Section of Cardiology, Yale University School of Medicine, New Haven, Ct and Health Research and Educational Trust, Chicago, IL.

Body: Introduction

Although needle biopsy (NB) is recommended prior to breast cancer surgery, the use of NB has been shown to vary according to patient socioeconomic status (SES), operating surgeon, and geographic region. We hypothesized that surgeons who work in the same peer referral network (defined by patient sharing) might have similar practice patterns with regard to NB, and that the magnitude of SES disparities might vary across networks. We therefore examined: 1) SES disparities in the receipt of NB, 2) variation in NB across networks, and 3) whether the association between SES and NB varied across networks.

Methods

We used the SEER database and 5% Medicare sample to examine all patients with a new diagnosis of breast cancer from 2004 through 2006. We used Medicare claims to construct peer groups of physicians based on patient-sharing ties. Patients were assigned to peer groups based on the surgeon who performed their definitive surgery. We defined a patient as having low SES if she was in the lowest quintile of area-level income. We used hierarchical generalized linear models (HGLM) to assess the association between low SES and receipt of NB, including random effects for the surgeon, peer group, and Hospital Referral Region (HRR). We then allowed the low SES effect to vary across peer groups in order to determine whether the association between SES and NB varied across groups.

Results

In the full sample of 14,552 patients, 9,498 (65%) received needle biopsy. In bivariable analysis, patients in the lowest income quintile were less likely to receive NB compared to all other patients (59% vs 67%, p<.001). The majority of the variance (59%) in NB use was at the patient level, 22% was at the surgeon level, and 13.7% at the peer group level. The use of NB varied substantially across peer groups, with a median of 69% (interquartile range [51%, 84%]). Even after accounting for physician, peer group, and HRR variation, patients in the lowest stratum of SES were significantly less likely to have received NB compared to all other patient (OR = 0.88; p=.04). Finally, we found that the association between SES and NB varied significantly across referral networks (P<0.05)

Conclusions

Patients with low SES are significantly less likely to receive NB prior to breast cancer surgery, and moreover the magnitude of this SES-related disparity varies significantly according to which referral networks are providing care. Future policies to increase NB rates and standardize care for all breast cancer patients may consider the implications of how care for patients with low SES varies across surgical provider networks.
**Title:** Disparities in human epidermal growth factor receptor 2 testing completion: A population-based retrospective cohort study, 2010-2013

Schroeder MC C, Neuner JM M, Xia C and Thomas A. University of Iowa, Iowa City, IA; Medical College of Wisconsin, Milwaukee, WI and ProMedica Hematology/Oncology Associates, Sylvania, OH.

**Body:** *Introduction:* Human epidermal growth factor receptor 2 (HER2) is an established biomarker predictive for response to HER2-targeted therapies. Testing breast cancer specimens for HER2 protein overexpression or gene amplification is the standard of care. Earlier work showed inconsistent delivery of HER2 testing to some patient groups. We sought to understand current imbalances in HER2 testing. *Methods:* Our retrospective cohort analysis of Surveillance, Epidemiology and End Results Program data included women diagnosed with microscopically confirmed, first primary malignant breast cancer from 2010-2013. Women were categorized by race, stage, age, and whether they received HER2 testing. Those with unknown information in any of these variables were excluded. Descriptive analyses and multivariate logistic regression assessed the effect of these factors on the likelihood of not receiving HER2 testing. *Results:* The full cohort included 182,032 women, of which 3,551 (2.0%) did not undergo testing for HER2 (Table 1). The portion of HER2 untested tumors was higher for African American women (2.3%) and other non-white women (2.2%), women over age 70 (2.3%) and women with Stage I (2.3%) or Stage IV disease (5.0%). Within the African American cohort similar patterns were seen: age ≥70 (2.8%), Stage I (2.8%) and Stage IV (5.4%). The portion of women with untested tumors decreased from 2010 to 2013: 2.6% to 1.6% (p<0.001) for the full cohort, and 2.9% to 1.9% (p<0.001) for African Americans. On multivariate analysis, odds of not undergoing testing were highest for African American women (OR=1.27, p<0.001), women of age ≥70 (OR=1.26, p=0.001), and women with Stage IV disease (OR=4.07, p<0.001) (Table 2). Odds of not undergoing HER2 testing decreased over time (OR=0.60 for 2013 vs 2010, p<0.001). *Conclusion:* Persistent, and significant, disparities in completion of HER2 testing suggest that reasons for not testing extend beyond technical issues. While proportionally small, given the prevalence of breast cancer, addressing these disparities in HER2 testing may offer an opportunity to deliver life-prolonging, often well tolerated, therapy to significant numbers of patients. The improvements in delivery of HER2 testing seen over time are reassuring.

Title: Successful implementation of a novel breast cancer navigation program in Nuevo León, México

Mireles-Aguilar T, Tamez-Salazar JJ J, Villarreal-Garza CM M, Rodriguez y Silva M, Romero C and Pérez-Reyes P. MILC. Médicos e Investigadores en la Lucha Contra el Cáncer de Mama, Monterrey, Nuevo León, Mexico; Centro de Cáncer de Mama, Tecnológico de Monterrey, Monterrey, Nuevo León, Mexico and Secretaría de Salud del Estado de Nuevo León, Monterrey, Nuevo León, Mexico.

Body: Introduction: Although the overall incidence of breast cancer (BC) is lower in Latin America than in high-income countries, the mortality burden is greater, mainly due to presentation at more advanced stages. Advanced BC presentation has been directly associated to delays by the patient and provider. In Mexico, it has been previously shown that the longest delay occurs within the health system interval, with a median of 5 months. Navigation programs have been proved to be a valuable strategy to assist individuals in overcoming barriers for care across the cancer care continuum. However, its implementation has been limited to date in low-income settings.

Objectives: The aim of this project was to propose a novel BC navigation program to overcome different common barriers for access to accurate diagnosis and early treatment in a limited setting in Nuevo Leon, Mexico. The secondary objectives were to educate and involve medical students by being part of the navigation process and raising women awareness about BC.

Methodology: Through an alliance with the local Ministry of Health, during 18 months, we invited women who had their mammogram done in a referral mammographic center to participate in this Navigation Program. Two weeks after recruitment women were taken by a designated transportation to a specialized BC diagnostic unit, participated in a BC self-awareness educational session (increment in knowledge was measured by pre and post tests), received a clinical breast exam and were provided with their mammography report (interpreted by a breast radiologist). When appropriate, core biopsies were performed and onward referrals to a BC Treatment Center were provided. Along with this process, a Navigator Training Program took place as part of the medical students’ 5th year curricula in the ITESM Medical School, within their academic clinical practice (knowledge increment was measured by pre and post tests). This project was supported by Susan G. Komen Foundation.

Results: 1632 low-income uninsured women were navigated and 37 BC were diagnosed. All BC patients started treatment within 3 months from their initial mammogram. 55% were diagnosed at early stages (0-IIA) and 45% at II-B to IV stages (vs. 26% and 74%, respectively, from the overall report from the Ministry of Health in 2014). Patient BC awareness knowledge increased by 22%. 170 students participated in the navigation process, and their knowledge rose by 18% from baseline. The BC Navigation Training Program is now part of the official academic curricula of the ITESM Medical School.

Conclusions: Our Navigation Program was intended to break down medical care barriers to reduce delays and improve quality of care, by guiding Mexican women through the whole continuum of BC diagnosis and early treatment. This successful implementation resulted in shorter health system intervals and BC down staging. Well-designed patient navigation projects should be implemented in low- and middle-income countries to establish their value and feasibility. Due to a lack of educated patient navigators in these regions, health care professionals should be trained to provide navigation guidance through the complex health care systems frequently encountered in underserved settings.
Title: Genetic testing for HBOC among women with a personal diagnosis of breast cancer in patients with Medicaid as compared to patients with private insurance

Body: Introduction: National guidelines recommend that women diagnosed with early-onset breast cancer and/or a strong family history receive BRCA1/2 testing to guide treatment decisions. Among newly diagnosed patients, a positive test result will often prompt more aggressive surgical treatment to minimize the risk of second primary cancers. Currently, coverage for genetic counseling and testing for Hereditary Breast and Ovarian Cancer (HBOC) under the Medicaid expansion program of the Affordable Care Act has varied by state, where some states require a copayment for this service. Similarly, there is no mandate to cover risk-reducing surgery for patients found to carry a genetic mutation despite research showing cost-effectiveness. This analysis sought to determine whether genetic testing for HBOC among patients with breast cancer is different for those with Medicaid compared to those with private insurance.

Methods: A commercial laboratory database was analyzed for patients with a personal history of breast cancer who underwent testing with a 25-gene hereditary cancer panel from September 2013-February 2016. Patients were eligible for inclusion if they were between ages 18 and 64 at the time of testing and had not undergone previous genetic testing. A total of 17,020 patients with either Medicaid (N=4,313) or one of 5 private payers (N=12,707) were tested during this period. Descriptive statistics, including means for continuous variables and proportions for categorical variables, were calculated. Chi-square tests were used to test associations and differences of positive rates between insurance provider category. Two-tailed p-values are reported, and any p-value less than 0.05 is considered statistically significant.

Results: Medicaid patients had a median age of breast cancer diagnosis of 45 compared to 47 for patient with private insurance. Among women with Medicaid insurance, a higher proportion were of African (13.3% vs 6.4%) and Latin American ancestry (16.4% vs 5.3%). The mutation positive rate among patients with Medicaid was 13.0%, which was statistically higher than patients with private insurance (9.5%) (p<0.001). The positive rate was higher among Medicaid patients of all ancestries suggesting that this discrepancy was not due to ancestry difference among the two testing populations.

Positive rate by ancestry

Conclusions: Overall, the positive mutation rate among individuals with Medicaid insurance was higher than those with private
insurance, suggesting the testing requirements applied to this population may be more stringent than those applied to the private insurance population. Consistent genetic testing insurance criteria are necessary for all patients to receive care in line with guidelines following a breast cancer diagnosis.
Title: Impact of enrollment in clinical trials on survival of metastatic breast cancer patients

Body: Background: The number of patients worldwide with metastatic breast cancer (MBC) who participate in therapeutic clinical trials has remained so far low. One of the reasons is a lack of opportunity, whereas another is fear of health care providers and patients of poor outcome of the use of new drugs. We therefore investigated whether survival in patients with MBC who participated in first-line therapeutic clinical trials is worse than that in patients who received only standard care and never enrolled in a clinical trial. We hypothesized that first-line therapeutic clinical trials do not negatively affect survival outcome. Methods: We reviewed the records of 5501 patients with MBC treated at The University of Texas MD Anderson Cancer Center from January 2000 to December 2010. We extracted a first cohort of 285 patients enrolled in a therapeutic clinical trial for the first time for first-line systemic MBC treatment. The second cohort, referred to as the eligible control population, consisted of 367 patients without comorbidities who did not participate in a clinical trial at any stage of their disease; these patients lived in Harris County, in which MD Anderson is located, and thus could be potentially eligible for MD Anderson’s financial assistance program. To limit confounding factors, we excluded male patients and patients with known brain metastasis from both cohorts. Results: The median follow-up duration in our cohort was 7.16 years (95% confidence interval [CI], 6.53-7.64 years). We observed discrepancies in race (minorities were less represented in the clinical trial arm), estrogen receptor (ER) status (more ER-positive than ER-negative patients participated in clinical trials), and metastatic disease site (fewer patients with bone metastasis participated in clinical trials) between the two groups. Overall, we observed no significant differences in progression-free survival (PFS) or overall survival (OS) duration between the treatment arms. Specifically, in the clinical trial cohort, the median PFS duration was 7.00 months (95% CI, 5.72-8.71 months), and the median OS duration was 28.48 months (95% CI, 22.70-34.60 months). In the control cohort, the median PFS duration was 10.02 months (95% CI, 7.13-11.99 months), and the median OS duration was 28.71 months (95% CI, 24.41-31.31 months) \((P = .089 \text{ and } .335, \text{ respectively})\). Conclusion: In MBC patients, enrolling in first-line therapeutic clinical trials does not result in worse survival than does never enrolling in a clinical trial. This study should reassure health care providers in demonstrating that enrollment in a clinical trial does not negatively affect survival in MBC patients.
Title: Socio-demographic predictors for delay of treatment among a racially diverse, urban breast cancer population

Ko NY Y, Pattis G, Battaglia TA A, Wang C, Denis GV V, Hirsch A and Weinberg J. Boston University School of Medicine, Women's Health Unit, Boston, MA; Boston University School of Public Health, Boston, MA; Boston Medical Center, Boston, MA and Boston University School of Medicine, Boston, MA.

Body: Background:
Racial and ethnic disparity in breast cancer outcomes is a long-standing problem that continues to worsen. Recent evidence has underscored the importance of timely care, as delays in treatment can lead to decreased survival. We sought to understand predictors of delay to first treatment among a racially diverse cancer population.

Methods:
This is a retrospective study of breast cancer cases diagnosed between the years 2000 to 2014. Data was extracted from the cancer registry at Boston Medical Center (BMC), an urban safety net hospital. Inclusion criteria were any breast cancer diagnosis from 2000-2014, receiving first treatment at BMC, and disease stage 0-III. Cox Proportional Hazards regression analysis was performed to identify predictors of time to first treatment, defined as days from date of diagnosis to date of first treatment with surgery or neo-adjuvant chemotherapy. Covariates included age, sex, race, type of insurance, marital status, US birth, disease stage and year of diagnosis.

Results:
Patients were 99% female and with a mean age of 58 years (range 23-96). Among a sample of 1545 breast cancer cases, 1372 (89%) had surgery as first treatment and 173 (11%) had neoadjuvant chemotherapy. Median days to treatment was 45 days (IQR 27, 71). In the multi-variable adjusted models for both treatment groups, race, and insurance were significantly associated with delay. In the surgical group, Black race, public or no insurance, non-US born, later stage and unmarried status were associated with increased risk of delay. For example, Blacks were at higher risk for delay (HR= 1.2; 95% CI 1.37-1.04) compared to the Hispanic or White (reference) groups. Public insurance (HR = 1.19; 95%CI 1.37-1.04) and no insurance (HR = 1.43; 95%CI 1.85-1.09) was significantly associated with increased delay when compared to private insurance (reference). In patients with neoadjuvant chemotherapy as first treatment, additional significant predictors of delay were age and year of diagnosis.

Conclusion:
Race and insurance status were significant predictors of delay to first treatment in a population of diverse breast cancer patients seeking care at a safety net hospital. Intervention efforts need to target patients at greatest risk for treatment delays.
Title: Predictors of social support among newly diagnosed breast cancer patients seeking care at an urban safety net academic medical center

Ko NY Y, Festa K, Gunn C, Bak S, Wang N, Nelson K, Flacks J, Morton S and Battaglia TA A. Boston Medical Center Women’s Health Unit; Boston University School of Public Health and Medical Legal Partnership Boston.

Body:
Background: Disparities in breast cancer care are a worsening problem, requiring effective interventions that seek to address the delivery of high quality cancer care. Evidence from interventions designed to improve timeliness of care routinely identify lack of social support as one of the biggest barriers to care. And, social support is associated with adherence to treatment and survival. This study explores predictors of social support in a diverse population of cancer patients.

Patients and Methods: This is a secondary analysis of baseline preliminary data from participants enrolled in Project SUPPORT, a randomized controlled comparative effectiveness trial designed to evaluate the impact of patient navigation with or without legal support and services, among women diagnosed with Stages 0-4 breast cancer between 2014-2016. Upon enrollment (within one month of a cancer diagnosis) we administered the Medical Outcomes Survey (MOS) of social support to all participants. This validated survey tool addresses functional support, including an overall score (range 0-95) and 4 distinct domains: Emotional/Informational, Tangible, Affectionate and Positive Social Interaction. Using chi-squared and t-tests we compared MOS scores across socio-demographic variables: age, race, language, insurance, health literacy and marital status.

Results: Of the 103 participants, mean age is 54.5 (SD = 10.6); 56% Hispanic, 19% Black, and 22% White and 2% identified as other; the majority had public insurance 76%; 66% speak English, 21% Spanish and 13% Haitian Creole. Only 36% have adequate health literacy as measured by the BRIEF. Only 32% are currently partnered. The overall mean total score for social support is 75.8 (+/- 23.6), median of 78.9 (range 60.5 – 98.7). Participants scored lowest in tangible support (mean score 67.7 +/- 33.1) and highest in affective support (83.5 +/- 25.8). Non-White participants scored significantly lower across all domains (mean overall MOS score 73.3 +/- 2.6) when compared with Whites (mean overall MOS score 84.5 +/- 4.8, p value = 0.04). There were no differences in MOS scores by language, insurance, literacy or marital status.

Conclusion: This is the first study to describe social support scores (overall and specific domains) from the validated MOS survey tool among a racially diverse, urban cancer patient population. We found significant differences by race. Studies to identify risks for low social support can help inform future targeted interventions.

Title: Planning and implementation of two regional one-stop breast health centres within a large geographic health authority: Outcomes and quality improvements in health service delivery

Body: Interrogative examination of wait times for the pathway steps leading to diagnosis, surgical treatment, and oncology consultation for breast cancer within a geographically dispersed publically funded health authority led to advocacy for and establishment of two large one-stop Breast Health Centres (BHCs) within the largest urban cities. One year after publication of the 2000 EUSOMA guidelines for breast cancer diagnosis and treatment, regional breast cancer pathways and wait times did not meet guidelines. Population median wait time from date of first investigation to tissue diagnosis was 2.7 or 5.9 weeks (for clinical presentation or screen presentation respectively), 6.0/7.0 weeks to definitive surgical intervention, and 14.3/11.7 weeks to oncology consultation. Only 39% of patients were diagnosed initially via core needle biopsy. 5% of patients underwent immediate reconstructive surgery. Due to wait times for initial imaging (mammogram, ultrasound) at hospital facilities, baseline imaging was often performed at private imaging labs without needle diagnostic capability, and repeated again with a series of wait times at the hospitals - as the initial community images were not accessible to the hospital interventional radiologists. Smaller communities and their hospitals maintained shorter wait times in comparison to the large urban centres. Repeat population based measurement in 2009 indicated wait times were unchanged, and MRI guided biopsy was still not available within the region. Nursing support and patient education re breast cancer prognosis and treatment was not available until the time of oncology consultation.

BHCs were planned, funded by the Ministry of Health, established in physical conjunction with the breast screening programs, and became operational as of early 2012. During the first year of BHC operation, population median wait time from date of first investigation was 2.0 weeks for tissue diagnosis, 6.4 weeks for final definitive surgical intervention, and 9.4 weeks for oncology consultation. 90% of patients were initially diagnosed via initial core needle biopsy with IHC staining for ER, PR, and HER2. Patients served by the BHCs had nurse navigator support and education from time of presentation. The surgical team overcame regional surgical wait time barriers such as available admission beds by establishing the first comprehensive population-based outpatient mastectomy and reconstruction program in Canada with over 1200 performed to date. These wait times have been maintained in spite of increase in the HA population from 1.2 million to 1.6 million during the project timeline.
Title: Influence of winter season, driving distance, and time on receipt of breast conserving therapy among Iowa urban and rural patients

Wolf CL L, Frankova D and Franko J. Mercy Internal Medicine Residency, Des Moines, IA and Mercy Medical Center, Des Moines, IA.

Body: BACKGROUND: The distance to treatment centers has been reported as a factor influencing the choice of mastectomy over breast conservation therapy (BCT) among breast cancer patients, potentially enhancing disparities for rural patients. We analyzed the impact of crowfly and driving distance to the radiation center and winter season on patient choice of BCT versus mastectomy among breast cancer patients.

METHODS & SETTINGS: Our patient base included 3223 stage 0-3 breast cancer patients treated between 2002 and 2015. Treatment was provided at an established breast center serving urban, suburban, and rural patients in central Iowa.

RESULTS: Crowfly distance (19±22 miles, range 0-160, median 8.7) was consistently shorter as compared to true driving distance (25±27 miles, 0-205, 12.8). One-quarter patients drove over 33 miles (equivalent of 38 minutes). There was tight correlation between crowfly and driving distance (Spearman's rho=0.989, p<0.001) and time (0.985, p<0.001).

In univariate analysis, there was no significant difference in crowfly, driving distance, and driving time in minutes to the radiation center between BCT and mastectomy patients (19.3±22.5 vs 18.4±21.6 miles, p = 0.317; 25.1±27.5 vs 24.4±27.0 miles, p = 0.585; 29.9±25.3 vs 29.5±24.9 minutes, p = 0.664).

Receipt of BCT was not predicted by crowfly or true driving distance, driving time, or season. There was no interaction between distance, winter season, and drive time. Receipt of BCT was more likely with older age (OR=1.02 per year of age, p<0.001) and later year of treatment (OR=1.05, p<0.001).

CONCLUSION: Driving distance, time, and crowfly distance correlated tightly and do not influence patient choice of surgery type for breast cancer in our population. Despite a substantial rural population, driving distance, driving duration, and climate did not significantly influence patients' decisions for mastectomy versus BCT.
Body: Clinical trials offer breast cancer patients access to the most innovative treatments, high levels of care and hope for a better future. Yet, fewer than 5% of individuals with breast cancer participate in clinical trials nationally. Education is commonly identified as a target for intervention to increase rates of participation. In late 2015, the Cancer Support Community (CSC) conducted an online survey assessing cancer clinical trials to inform development of an educational program aimed to increase clinical trial awareness and participation. Results from this survey highlighting the experiences, beliefs, and preferences of breast cancer patients are reported here.

239 individuals with breast cancer (47.2% of CSC’s national online survey of cancer patients) responded to survey questions assessing their experiences, knowledge, beliefs, and preferences about cancer clinical trials. Most respondents were female (99.6%), Caucasian (84.9%), and averaged 59.6 years old (s.d. =9.7). 21.4% were diagnosed with metastatic breast cancer, and 22.4% had experienced a recurrence. 45% were currently receiving treatment and 75.2% were in remission. Nearly all (97.5%) had health insurance. 106 received treatment at an academic or comprehensive cancer center.

Most (87.5%) had heard of clinical trials pre-cancer, however, there was a wide range of beliefs about the purpose and potential benefits of and barriers to trial participation. While 35.8% had participated in trials, 57.9% had never considered participating in a clinical trial. 53.6% had discussed clinical trials with their healthcare team during treatment. Notably one quarter reported not discussing this at all. Of those having this discussion, 59.2% reported discussions were initiated by the physician, 13.6% by nurse or other healthcare provider, and 17.6% by the patient. During this discussion, only 19% felt that their goals and concerns related to clinical trial participation were meaningfully addressed. Not surprisingly, 95.9% reported more time with their doctors to discuss clinical trials would be “somewhat” or “very” helpful for aiding decision-making.

Respondents reported decision-making tools and resources that would be helpful to them. 97.4% reported that a website which included clinical trial information would be “somewhat” or “very helpful” in identifying clinical trials or aiding decision-making, yet such a resource was shared with only 27.0%. 70.5% reported that speaking directly with another patient who had participated in a clinical trial would be helpful; yet this was only offered to 8.8% of patients.

Based on these findings CSC with partner organizations is developing a series of products and programs to educate individuals who may be eligible for clinical trials. The survey data yields insight into the contents of a successful education and support program around clinical trials and highlights the necessity to provide a comprehensive program that addresses patient preferences for more time to discuss clinical trials with the oncology team and with other patients who had elected to participate in a clinical trial.
Title: Community breast navigation improves breast cancer screening in Hartford, CT

Banks RM M and Stevenson CE E. UConn Health, Neag Comprehensive Cancer Center, Farmington, CT.

Body: Purpose The Community Breast Navigation Program (CBNP) through UConn Health (UCH), in partnership with Susan G. Komen of CT and Community Health Services, Inc. (CHS) in Hartford, CT attempted to address disparities in breast cancer screenings by embedding a Community Breast Navigator (CBN) in the adult medicine clinic of CHS from September 23, 2015 until April 25, 2016. The CBN's principle roles are to provide breast health education, streamline screening scheduling, and follow-up to reschedule missed appointments. The program was implemented to combat barriers to access which cause low rates of mammogram screening. In the United States in 2013, only 37.1% of uninsured women received mammogram screenings compared to 70.4% of insured women. The community breast navigator aims to capture uninsured and underinsured women in an underserved community to improve mammography screenings and early detection of breast cancer.

Scope The objective of the CBNP is to service uninsured and underinsured African-American and Latino women age 40 and over. The mammograms and ultrasounds are offered free of charge to the patient. The costs of the screenings are paid by private donations to UCH. The patient is also offered a gas card or one-day bus pass to provide transportation assistance.

Methods The CBN educates women on the importance of maintaining breast health through breast screenings, clinical breast exams, and self-breast exams and contacts patient access and radiology departments at UCH to schedule screenings. The patient is reminded of the mammogram screening 1-3 days before the appointment. If the patient fails to attend the appointment the CBN contacts the patient and UCH to reschedule the screening.

Results Within 7 months at CHS, 57 (57.6%) of the 99 women referred in the study period received recommended breast screenings. 75.4% of women attended the breast screening with no cancelled appointments, 17.5% of women attended after one cancelled appointment, and 0.7% attended after two cancelled appointments. In CT in 2014, 54.1% of uninsured women received mammogram screenings; through the CBNP 62.2% of uninsured women received mammogram screenings, an improvement of 8.1% in our population. Also, transportation assistance was provided to 32% of patients.

Conclusion To decrease barriers and increase access the CBN scheduled and rescheduled breast screenings. Mammograms costing $478 for 2D and $518 for 3D imaging were offered at no cost and gas and bus vouchers were provided to patients. The CBNP addressed common barriers which are cost, transportation, and scheduling to improve mammography screenings and early detection of cancer. Not receiving breast screening was attributed to out-of-service phone numbers, unanswered phone calls and decisions to receive breast screening elsewhere due to the proximity or familiarity with another imaging center. This program should be modeled in health centers and underserved communities to improve mammography screening and close the gap between insured and un/under-insured patients. The most important concepts for the CBNP are to alleviate the patient's barriers and provide a seamless process to receive breast screening.
Title: Breast cancer provider delay after the 2011 triple disaster in Fukushima, Japan

Ozaki A, Leppold C, Tsubokura M, Sawano T, Tsukada M and Ohira H. Minamisoma Municipal General Hospital, Minamisoma, Fukushima, Japan.

Body: Introduction
Timely diagnosis and treatment is an indispensable part of breast cancer management. Delay of this process, also known as provider delay, can result in a deteriorated prognosis of affected patients. Although it has been suggested that disasters can impact cancer care and extend provider delay, there is little information available on long-term trends of breast cancer provider delay in post-disaster settings.
So-so district of Fukushima prefecture, Japan, experienced an earthquake, tsunami and the Fukushima Daiichi Nuclear Power Plant Accident in 2011. So-so district has areas falling within the mandatory, voluntary and non-evacuation ordered zones. Due to a long-term shortage of medical staff and closure of medical institutions post-disaster, patients with breast cancer may have experienced longer provider delay in this area.

Objectives
To compare provider delay of breast cancer patients and elucidate contributing factors to delay pre- and post-disaster, in an area severely affected by Japan's 2011 triple disaster.

Methods
We retrospectively investigated data of newly diagnosed breast cancer patients who undertook first medical consultation at the two main cancer centers in the non-evacuation ordered zone of So-so district from 2005 to 2016. Sociodemographic and clinical information was collected from medical records. The main outcome measure was median (days) from first medical consultation to start of breast cancer-specific treatment, pre- and post-disaster, using Mann-Whitney U test. Multivariate linear regression was then conducted to identify any factors which contributed to extended provider delay before and after the disaster.

Results
A total of 157 pre-disaster patients and 121 post-disaster patients were included in the study. There was no significant difference in the interval of median days of first medical consultation to start of first treatment pre- and post-disaster (40 vs. 39, p=0.82). Although diagnosis was made in a shorter interval post-disaster compared to pre-disaster (11 vs. 14, p=0.01) with significantly smaller median number of biopsies (1 vs. 1, p=0.001), this post-disaster improvement in diagnostic process was offset by deferred start of treatment after diagnosis (26 vs. 22, p=0.008). Among the pre-disaster patients, cancer detection by breast cancer screening program (p<0.001), being engaged in full-time job (p<0.042), and number of biopsies before diagnosis (p=0.005) contributed to longer provider delay in multivariate regression. However, consultation from other medical providers (p=0.03) was the only factor which significantly contributed to extended delay post-disaster, after controlling for multiple variables.

Conclusion
There was no significant increase in provider delay among breast cancer patients post-disaster. However, a median interval of 39 days from first medical consultation to start of treatment is much longer than other high-income countries, and shows much room for improvement in future.
Prophylactic contralateral mastectomy - A valid choice?

Whilst the data on patient satisfaction following prophylactic mastectomy and reconstruction in those with a high risk of breast cancer is mostly positive, surgical and nursing opinion regarding contralateral prophylactic mastectomy (CPM) without reconstruction for symmetry +/- risk reduction has a limited evidence base. Anecdotal experience of UK practice suggests opinion varies enormously. Some surgeons would offer CPM as a method of achieving symmetry whilst some would only perform this if the remaining breast was deemed "problematic" (eg very large or high residual risk). Some surgeons would not countenance removing a "Healthy breast" under any circumstances but would happily reduce a "healthy" breast to achieve symmetry or offer their patients a lengthy reconstruction with the potential complications attached.

This study was designed to assess the variance in opinion towards CPM in breast units across the United Kingdom from both surgeons and specialist breast care nurses and how this compared to views expressed by a cohort of breast cancer patients. 3 questionnaires were designed to canvas opinion from breast surgeons, breast care nurses and members of 3 patient groups who had a range of procedures including reconstruction. This was designed to explore attitudes to CPM as a method of achieving symmetry and potential barriers in those without a perceived high risk of breast cancer. The clinicians questionnaires were distributed to members of the Association of Breast Surgeons of Great Britain and Ireland and the patient questionnaire via 3 web groups.

Respondents: 325/340 patients, 80/709 nurses, 126/588 surgeons.

When the patients were asked, only 50% felt all surgical options were discussed and only 37% felt they were given equal weight. 34 patients had a bilateral mastectomy and 13 patients a prophylactic CPM whereas a further 15 (30%) and 4 (23.5%) respectively wanted one. Out of the patients who had a "healthy" breast removed 54% were to reduce risk and 46% were to achieve symmetry.

84% of surgeons felt that where appropriate breast conserving surgery and mastectomy were discussed equally but over 40% would never discuss or perform prophylactic mastectomy in either the immediate or delayed setting for any reason. 65% of nurses felt CPM should only be considered if broached by the patient and 23% didn't know what their surgeons views on the subject were.

From the nurses perspective if a patient requested a reconstruction 18% felt a psychologist should be involved which rose to 70% if a CPM was considered. For the 60% of surgeons who would perform this procedure 30% didn't involve anyone else in the discussions.

25% of surgeons would offer a CPM for those without a large remaining breast which rose to 40% (22% of nurses) if the breast size was larger. 38% would offer the procedure for a patient with a high genetic risk or a high level of worry independent of proven risk.

32% of surgeons and 16% of nurses felt that the pendulum had swung too far towards reconstruction being the gold standard of achieving symmetry.

Our finding support a heterogeneous approach to CPM in UK practice and that we should in fact be offering this procedure routinely to appropriate patients as an alternative to reconstruction to achieve symmetry independent of genetic or perceived risk.
Title: Women's experiences with a decision aid for neoadjuvant systemic therapy for operable breast cancer

Zdenkowski N, Herrmann A, Hall A, Boyle FM and Butow P. Calvary Mater Newcastle, Newcastle, NSW, Australia; University of Newcastle, Newcastle, NSW, Australia and University of Sydney, Sydney, NSW, Australia.

Body: Background: Neoadjuvant systemic therapy (NAST) is a treatment option for selected patients with highly proliferative and/or large operable breast cancer. Whilst survival outcomes are equivalent between up-front surgery and NAST, the decision about treatment sequence can be difficult due to complexity and perceived urgency of the decision. Patients may value the outcomes of these options, such as down staging and prognostication, differently. Involving patients in decisions about their healthcare reduces anxiety, increases quality of life and satisfaction with care. Decision aids can improve patient involvement in health care decisions, but one is not available for the decision about NAST.

Aims/Methods: We conducted a prospective, single-arm pre-post study to evaluate a custom-designed decision aid developed for women who have been offered NAST. Eligible patients were: female; aged ≥18 years; diagnosed with an operable invasive breast cancer; considered for NAST with curative intent. Here, we report on the grounded theory qualitative analysis of a convenience sample of 16 semi-structured phone interviews to explore patient experience with this decision aid.

Results: Participants' median age was 52 (IQR=41-63), median time since breast cancer diagnosis was 5 months (IQR=2-8). Most were married or living with a partner (81.3%) and had a University level degree (68.8%). Patients perceived the decision aid to be useful for becoming more informed and involved in deciding on NAST. Specifically, the decision aid enhanced patients' understanding of their type of breast cancer and the treatment options available to them by summarising and extending the information they received during the consultation with their doctor. Some women perceived the included graphs and statistics to be particularly helpful to understand potential risks and benefits of their treatment options. All patients described the provided information as reliable, relevant and tailored to their needs. They found the decision aid easy to understand and balanced (not in favour of NAST or surgery). The amount of the information provided was seen to be just right. Most women received the decision aid after the initial consultation with their surgeon and perceived this as the right delivery timing. Reading and rereading the decision aid at home in between two consultations allowed women to easily integrate the decision aid into their care. They appreciated the opportunity to reconsider their options after consulting their doctor. A number of women reported that their family members used the decision aid as well and thus became more informed and involved in the decision making process. Some women took the decision aid to the next consultation with their doctor to discuss their preferences and concerns further. All patients followed their doctors' treatment recommendation. The decision aid seemed to confirm but not change women's decisions on NAST.

Discussion: These initial results suggest that this decision aid is a useful tool to assist breast cancer patients' involvement in the decision about NAST. A quantitative analysis of the decision aid's acceptability, feasibility and efficacy will be reported subsequently.
Title: Use of real-time patient reported outcomes to improve performance in breast surgery

Whitacre EB B and Moore MN N.  Breast Center of Southern Arizona, Tucson, AZ and University of Arizona School of Public Health, Tucson, AZ.

Body: Background: Patient reported outcomes (PRO's) are important to the new health care delivery system but can be difficult to obtain, especially in real-time. The purpose of this project was to demonstrate that 1) An office based iPad patient survey mechanism can obtain PRO's effectively and efficiently; 2) Real time reporting of outcomes to a national database can identify potential gaps in care compared to a peer group of surgeons; 3) Rapid reporting can be used to assess the impact of changes in clinical practice.

Methods: The American Society of Breast Surgeons has a HIPAA secure quality-reporting program for breast surgery which has a parallel secure web site to collect PRO's for patients undergoing breast surgical procedures. Based on patient responses, the physician site reports aggregate PRO's for mastectomy, lumpectomy and breast biopsy, comparing each physicians results with his/her peers. The existing patient survey site utilizes an email invitation and response system, but has only a 34% response rate. Review of the existing data before beginning the project showed that the lowest score for the participating surgeon (EBW) was in response to the question following mastectomy: “During your office visit, did your surgeon or your surgeon’s staff discuss what to expect with care and recovery after surgery?” with an 83% positive response compared to 88% for the aggregate in 2014. To address this, the following clinical changes were made beginning in 2016: 1) Additional emphasis on the expected post op course during initial cancer talk with the patient, 2) a phone call by the surgeon 1-2 days before mastectomy to address any additional questions, 3) a phone call by the surgeon 1-2 days after surgery. In addition, in order to improve the patient response rate, the patient survey was adapted to an iPad, allowing patients to complete the survey in the office at the time of their post operative visit.

Results: The iPad system resulted in a 98% response rate compared to 34% for the email based system. Median time to complete the survey was less than 2 minutes and required no additional staff time, office space, or equipment (other than the iPad itself.) Most patients were very pleased with the iPad platform, although some older patients had difficulty seeing the screen or navigating the touch screen. The high response rate resulted in a very rapid change in the reported PRO's, showing within less than 4 months, that the clinical changes focusing on patient concerns over post operative mastectomy care were successfully addressed, with and increase from 83% to 94% satisfaction for that particular outcome measure.

Conclusion: This study demonstrates that an office based iPad patient survey, linked to a national quality database reporting surgical care, can be used to identify gaps in care, and can then be used to rapidly assess the impact of implemented clinical changes. This is not possible with other national web sites attempting to report quality (e.g. Physician Compare, Health Grades, Vitals), and should be considered for future programs to improve reporting and actionability of PRO's.
2016 San Antonio Breast Cancer Symposium

Title: Adapting evidenced based strategies for effective communication in cancer genetic counseling

Body: As genetics and genomics become part of mainstream Medicine, these advances have the potential to reduce or exacerbate health disparities. Hereditary breast and ovarian cancer risk services are becoming more accessible for low-income individuals, due to the Affordable Care Act of 2010, increased coverage by state Medicaid programs, and decreased costs of testing. Yet access alone is not sufficient to ensure high quality genetic counseling and appropriate testing. Gaps in effective communication are widely recognized as a major contributor to health disparities. The purpose of this study was to describe current communication between cancer genetic counselors and low-income English-, Spanish- and Cantonese-speaking patients in safety net settings, and to assess communication effectiveness from the patient and counselor’s perspectives.

Methods: Inductive qualitative methods were used, including observations and audio recording of cancer genetic counseling sessions (n=170), stimulated recall interviews with patients (n= 58), semi-structured interviews with observed genetic counselors (n=10) at two public hospitals.

Results: We identified a fundamental mismatch of patient information needs and information provided by counselors. Components of communication that contributed to this mismatch and resulted in ineffective communication include: (1) provision of information that lacks relevance for the patient; (2) provision of too much information; (3) conceptually difficult presentation of information; (4) imprecise and non-interactive discussion of screening and prevention options. Despite counselors’ awareness that they were not always effectively communicating with their limited English proficient and limited health literacy patients, they reported lacking effective tools to draw upon. To address these findings, we adapted evidenced based strategies developed in other medical settings, such as teach-back, plain talk, and proven risk communication methods, to the cancer genetic counseling context. In a pilot, counselors learned about these strategies in a four-hour workshop, and then spent two months practicing in clinic before we began observing them again. Preliminary results of the pilot indicate that counselors are able to apply these strategies to improve patient comprehension and engagement.

Conclusions: Our findings indicate a need to transform the standard model of genetic counseling communication to more effectively meet diverse patients’ informational and emotional needs. Particularly for pre-test counseling, counselors need to adapt to the communication needs of the increasingly diverse patients who now have access to hereditary breast and ovarian cancer testing, including the many with limited health literacy and limited English proficiency. Counselor training in communication tools proven effective for patients of low health literacy in other fields should be integrated into training curricula.
Title: Reliability and acceptance of e-based survey instruments for measuring patient reported outcomes (PRO) in breast cancer patients: First results of the ePROCOM study

Wallwiener M, Simoes E, Hartkopf AD, Taran F-A, Keilmann L, Sickenberger N, Stevanovic S, Belleville E, Ladra C, Schneeweiss A, Wallwiener D, Brucker SY and Graf J. University Hospital Tuebingen, Tuebingen, Germany and University Hospital Heidelberg, Hospital for General Obstetrics and Gynecology, Heidelberg.

Body: Introduction
Especially in oncology patients, Patient Reported Outcomes (PRO) play an increasingly important role to measure subjectively perceived health status and treatment effects. At the moment, paper-based surveys of PRO still predominate (pPRO); in recent years, data on patient-relevant endpoints is being increasingly collected electronically (ePRO). The aim of the study was to analyze the acceptance of an ePRO-survey tool in breast cancer patients within the PRAEGNANT multicenter trial. Furthermore, it should be considered, whether differences in response behavior between pPRO and ePRO can be identified (reliability check).

Materials and Methods
ePROCOM (Patient Reported Outcomes and Compliance Analysis) was conceptualized as a monocenter, randomized, parallel-group, cross-over study. Female patients with diagnosis breast cancer aged more than 18 years were included. We randomized the patients into one of two study arms. In study arm A the patients are first asked to use the electronic, web-based tool to document the patient questionnaire (EORTC QLQ C-30 and FACT-B). Afterwards the patients were asked to fill and evaluate the paper-based questionnaires accordingly, followed by evaluation of usability, acceptance and capability. In study arm B the course varies by meaning that paper-based evaluation will be followed by the assessment of electronic data capture.

Results
N=110 patients with breast cancer in adjuvant or neoadjuvant situation completing the study during an outpatient visit at the University Hospitals in Tuebingen and the National Cancer Centre Heidelberg (average age: 52.4). In most patients, there were no differences in terms of acceptance between pPRO and ePRO. Only in some older patients with a lower quality of life hurdles for ePRO could be identified, because of lower acceptance rates. We could not find significant differences in response behavior between pPRO and ePRO.

Discussion
Because no differences in response behavior could be identified, the tool can be define as reliable possibility to measure patient reported outcomes. E-PRO surveys appear to be suitable for use in breast cancer patients. However, there is a need of support in older and more ill patients, to participate form the technical capabilities of ePRO.
Title: Development and application of whole processing management for patients with breast carcinoma: A novel management strategy for breast health

Chen J, Yu K, Liu G, Shao Z and Wu J. Fudan University Shanghai Cancer Center, Shanghai, China and Fudan University Shanghai Medical College, Shanghai, China.

Body: The reformation on the management strategy of patients led by medical institutions could show the real value of medical services and match the needs of both patients and physicians. A novel patient management strategy, the whole processing management mode, was developed in Department of Breast Surgery, Fudan University Shanghai Cancer Center. Based on the online tools, the e follow-up Wechat public platform, the department provides several humanistic medical services in every aspects of breast health management, such as education, screening and diagnosis, multi-disciplinary comprehensive treatment and follow-up, including the remote medical reports reading. After the application of the novel patient management mode, regular appointments before seeing doctors, triage on-demand are realized. Between Jun-2015 and March-2016, a total of 7,668 person-time patients made the reservation for chemotherapy and over two thousand patients made the reservation for endocrine therapy prescription through the online approach. The total volume of out-patient clinic was 169,246 person-time in 2015, gained a 26.8% increase compared with in 2014. However, the queuing time for consultation was deceased by 28.8% in 2015. The doctor-patient relationship is extended online and the follow-up rate is improved. Between Jun-2015 and December-2015, a total of 823 patients online submitted the medical reports during follow-up period, among those, four patients were found disease relapse or metastasis and were call back to the hospital for further treatment. The novel mode may promote the cooperation among the multi-disciplinary comprehensive treatment teams, realize the hierarchical medical system among the department, and provide guarantee for the clinical and basic research based on the principle of precision medicine.
Title: Value-based approach to treatment of HER2-positive breast cancer: Examining the evidence

Nixon NA A, Hannouf M and Verma S. Tom Baker Cancer Center, Calgary, AB, Canada and Ivey School of Business, Western University, London, ON, Canada.

Body: Outcomes of HER2-positive breast cancer have improved significantly with use of targeted therapies. Survival in both early (EBC) and metastatic breast cancer (MBC) has improved along with gains in quality of life. With increasing costs of cancer care, it became imperative that health systems evaluate cost-effectiveness and value provided by new therapies.

Methods: We conducted a review of 'value' utilizing the ASCO 2015, ASCO 2016 (revised) and ESMO framework for all currently available HER2 targeted therapies. We performed a systematic review of cost-effectiveness analyses (CEAs) of these therapies across the neoadjuvant, adjuvant, and metastatic disease settings. We included economic evaluations from published literature and government agencies involved in drug-approval assessments from NICE (UK), pCODR (Canada), and PBAC (Australia).

Results: 22 studies evaluating 1-year of trastuzumab (H) in EBC were identified. Of these, 17 found the regimen cost-effective (CE). Three of 22 plus an additional 1 evaluated 9 weeks H, all of which found it CE. NICE and PBAC determined adjuvant H to be CE, consistent with clinical benefit (Table 1). There are currently no academic CEAs of neoadjuvant pertuzumab (P). It has been evaluated in drug-approval processes by NICE and pCODR, both finding cost-effectiveness highly uncertain. In MBC, 6 studies evaluating H for first line were identified. The combination with chemotherapy was CE in 3 of 4 studies, whereas monotherapy and combination with anastrozole were not. A total of 9 studies evaluating lapatinib for MBC were identified. While it was CE combined with capecitabine for second line, in all other combinations it was not. Two studies evaluating P for MBC did not find the regimen CE, despite significant clinical benefit. However, PBAC considers the regimen CE and pCODR recommended funding based on net clinical benefit, whereas NICE did not. No academic CEAs of trastuzumab emtansine (T-DM1) in the literature were identified however cost-effectiveness in second line has been evaluated by pCODR, NICE and PBAC. All groups found it not CE, even with very high clinical benefit (Table 1).

* = Not significant

Conclusion: While there is consistent value provided by Her2 targeted therapies, there is generally lack of support for these in MBC based on cost-effectiveness analysis. We need to work towards a model that integrates value, clinical benefit and cost to implement new therapies in cancer, including HER2 positive breast cancer.
Cost-effectiveness analysis of adding neoadjuvant chemotherapy with pertuzumab, in patients with HER2+ breast cancer in Spain

Abanell J, Ciruelos E, De la Haba J, Martín M, Muñoz-Molina B, De Salas-Cansado M and Colomer R. Hospital del Mar, Barcelona, Spain; Hospital Universitario 12 de Octubre, Madrid, Spain; Hospital Universitario Reina Sofía, Córdoba, Spain; Roche Farma S. A, Madrid, Spain; Hospital Universitario La Princesa, Madrid, Spain and Hospital Universitario Gregorio Marañón, Madrid, Spain.

OBJECTIVES: Given the increase resource constriction of the healthcare systems, efficiency analyses are become more frequent to give additional information to help decision makers in the adoption of new interventions that have already proved clinical value. The use of a neoadjuvant chemotherapy regimen including pertuzumab, trastuzumab and docetaxel (PTD) has demonstrated to improve pathological complete response (pCR) in patients with HER2+ breast cancer (BC). The objective of this study was to estimate the cost-effectiveness of PTD vs. TD in Spain.

METHODS: Clinical outcomes from the NeoSphere trial were combined with local data regarding the use of resources associated to patients’ follow-up and management of recurrences in a Markov model. Markov models are commonly used to represent the evolution of cancer patients, the effect on clinical outcomes and costs of alternative treatment strategies. In this study, patients with HER2+ BC were modeled through six different health states (event-free, locoregional-relapse, remission, metastatic-relapse [1L], metastatic-relapse [2L], and death) in two cohorts receiving PTD or TD. Long-term effects were estimated by fitting a log-logistic distribution (other techniques were also explored) to event free survival (EFS) data from the NeoSphere study (prevention of 5% relapses at 5 years) combined with utility estimates from the literature. Other transition probabilities as well as unit costs were also obtained from the literature and validated by a 15-oncologists Delphi panel, as well as the estimation of the patients follow-up and recurrences costs. The effectiveness was expressed in terms of quality adjusted life years (QALY) and the analysis was performed from the perspective of the Spanish National Healthcare System (NHS) over a lifetime horizon (a 3% annual discount rate was used for both costs and effects). Deterministic and probabilistic sensitivity analyses (PSA) were performed to assess the robustness of the model results and the influence of different input parameters.

RESULTS: PTD was associated to higher effectiveness than PT (14.007 and 13.447 QALY respectively) and lower lifetime costs (€141.070 € and €148.299 € respectively). PTD was also a dominant option over PT when pathological complete response results from the NeoSphere study were combined with EFS data from the CTNeoBC analysis to estimate long-term results. Both the deterministic and probabilistic sensitivity analyses confirmed the robustness of the results, showing that PTD was a dominant option in more than 90% simulations in the PSA.

CONCLUSIONS: Beyond the better long-term health outcomes, the combination of PTD would also result in lower lifetime costs for the Spanish NHS, showing that adding pertuzumab is a dominant strategy in HER2+ BC patients receiving neoadjuvant therapy.
Title: Evaluation of women with \textit{BRCA} mutations and breast cancer tested at an NCI designated comprehensive cancer center: A cost of illness estimation

Biskupiak JE E, Telford C, Yoo M, Unni SK K, Ye X, Deka R, Brixner DI I and Stenehjem DD D. College of Pharmacy, University of Utah, Salt Lake City, UT; AstraZeneca Pharmaceuticals, Gaithersburg, MD; Program in Personalized Health Care, University of Utah, Salt Lake City, UT and Huntsman Cancer Institute, Salt Lake City, UT.

Body: Objectives: Little is known regarding the impact of mutation status on the costs of breast cancer care. This study sought to estimate health care charges (all-cause, BC related, other cancer related and non-cancer related) among women with breast cancer (BC) and \textit{BRCA} mutations (\textit{BRCA}m) in terms of \textit{BRCA} status, HER2 expression status, ER/PR status, treatment patterns, serious adverse events related to the cancer or its treatment, and cancer treatment period.

Methods: Adult women with invasive BC diagnosed from 1995-2014 and tested for a \textit{BRCA}m were identified from the Huntsman Cancer Institute tumor registry (Salt Lake City, Utah) and via chart review. Patients with available charge data were included in the study. Patients were categorized by mutation status, receptor status and initial treatment setting. Charges were categorized as inpatient, outpatient and pharmacy (both anticancer and other medication) related charges as well as by type of service (diagnosis, surgery, reconstruction, radiation, office visit, and medication). Descriptive statistics were used to describe mean (SD) charges. Wilcoxon Rank-Sum test was used to compare health care charges.

Results: There were 816 women with BC who underwent \textit{BRCA} testing and had available charge data. There were 134 women with a \textit{BRCA}m vs 682 with \textit{BRCA} wild type (wt). Age at diagnosis was similar between the two groups, however, \textit{BRCA}m patients had more triple negative BC and higher histologic grade. Total breast cancer related mean (SD) charges were similar between \textit{BRCA}m vs \textit{BRCA}wt ($86,689 (75,937) vs $85,843 (97,304), p=0.19). Of this a similar amount was due to facilities/technical and pharmacy (41% each), while the remainder was physician/professional costs. Within pharmacy costs, similar amounts were due to chemotherapy (23%) and biologics (21%). However, while 58% received chemotherapy, only 8% received biologics. Patients seen initially in the neoadjuvant treatment setting (N=148) had higher breast cancer related mean charges than those in the adjuvant setting (N=553; $117,922 (102,108) vs $80,061 (90,010), p<.0001), while those seen initially in metastatic setting had a mean charge of $103,525 (135,029).There were 142 HER2+ (ER+/PR+/HER2+ or ER-/PR-/HER2+) and 521 HER2- (TNBC or ER-/PR+/HER2-) breast cancer patients (receptor status unknown in 153 patients). HER2+ patients had higher breast cancer related mean charges than HER2- patients ($155,858 (122,227) vs $69,883 (67,642), p<.0001). Further, anticancer treatment charges accounted for 53% ($82,890 (81,269)) of HER2+ costs and 11% ($7,929 (21,782)), p<.0001 of HER2- costs. Biologics accounted for 87% of the former and chemotherapy accounted for 78% of the latter charge.

Conclusions: Mutation status was not associated with higher breast cancer charges. Patients initially seen in the neoadjuvant setting had higher breast cancer charges than those seen in the adjuvant setting. Receptor status (being HER2+) was associated with higher breast cancer charges and this was driven by expenditure on biologics.
Title: Is 6 hour monitoring for administration related reactions after first administration of subcutaneous trastuzumab necessary? A single institution audit

Karmali S, Hughes N, Galiauskas R, Cook J, Murphy K, Bird BR R and Murphy CG G. Bon Secours Hospital, Cork, Ireland and University College Cork, Ireland.

Body: Background: Subcutaneous (sc) trastuzumab has demonstrated non-inferiority to intravenous (iv) trastuzumab and is preferred by patients and providers. Serious administration related reactions (ARRs) such as hypotension, respiratory distress etc. were not reported in the pivotal HannaH study. However, the summary of product characteristics (SPC) advises that patients should be observed for ARRs for 6 hours post the first injection (and 2 hours post subsequent injections), similar to the iv formulation.

Methods: We conducted an audit of patients commencing sc trastuzumab at our institution. Medical notes of each patient were reviewed to record adverse events reported on the day of first administration or at the subsequent visit. In addition all patients were interviewed by telephone and questioned regarding adverse events with first or subsequent injections.

Results: 39 patients were identified, 32 had received prior iv trastuzumab. Patients received a mean of 12 injections. In total patients received 470 sc trastuzumab injections, associated with a recommended 1,096 hours of observation as per SPC. 3 injections (0.6%) were associated with ARRs within 24 hours, all on the first cycle. 2 patients (5%) experienced injection site reactions immediately post injection and 1 patient had injection site pain during the injection. 1 patient experienced pyrexia and dry cough 24 hours post injection and was hospitalized for respiratory tract infection. No patient experienced a reaction between 2 and 6 hours post first injection. There were no serious ARRs.

Conclusions: ARRs related to sc trastuzumab are usually immediate, mild and self-limiting. Observing patients for 6 hours post first injection and 2 hours post subsequent injections represents an inefficient use of healthcare resources.
OBJECTIVES: The purpose of this study was to describe the economic impact of recurrences (locoregional or unresectable/metastatic recurrences [MR]) in patients with HER2+ breast cancer (BC) in Spain.

METHODS: A Delphi panel of 15 Spanish oncologists was carried out to define the clinical management (patients' flow and healthcare resources use) of locoregional recurrences (LR) and unresectable or MR in patients with HER2+ BC. Healthcare resources included medication, medical visits, lab and imaging tests, hospitalizations, surgery, adverse events management and treatment of specific metastases (e.g. bone metastases). Additionally, loss of productivity was also estimated. Local unit costs where used in combination with healthcare resources and workdays lost to estimate both the direct and indirect costs of LR and MR in HER2+ BC patients. A deterministic sensitivity analysis was performed to explore the robustness and assess the critical variables of the study.

RESULTS: The estimated distribution of recurrences in HER2+ BC patients was: 90% of MR, 7% of LR and 3% of LR followed by an MR. With respect to MRs, 31% of cases were estimated to receive up to 5 lines of treatment whilst 5% received no treatment (10%, 20% and 21% would receive 2, 3 and 4 treatment lines, respectively, with a median of 3 lines). Treatment regimens including trastuzumab were the most frequently used (in combination with pertuzumab and taxane in 1L, and with other combinations in 4&5L). In 3L, the most common treatment regimen was lapatinib-capecitabine. Total costs, including medical and indirect costs were €235,138, being the direct costs more than 88.7% (€208,682). Both direct and total costs were higher in patients being treated with a higher number of treatment lines, with figures ranging from €38,511 (1L) to €308,869 (5L) and €50,908 (1L) and €358,000 (5L) respectively.

CONCLUSIONS: HER2+ BC patients with a MR were estimated to receive a median of 3 treatment lines and almost one third receives 5 treatment lines. The direct and indirect costs of recurrences are high, with a calculated average total cost of €235,138. Using targeted therapies in earlier stages of HER2+ BC that achieve a reduction of recurrences would achieve significant cost savings in Spain.
**Title:** Saving in clinical trials: A possible challenge for improving health care for breast cancer patients

Taverniti C, Bonfadini C, Pradotto M, Cagnazzo C, Demartini P, Rossi L, Ignazzi G, Arizio F and Beano A. A.O.U. Città della Salute e della Scienza - Breast Unit, Torino, Turin, Italy; University of Turin - San Luigi Hospital, Orbassano, Italy; Istituto di Candiolo, Fondazione del Piemonte per l’Oncologia - IRCCS, Candiolo, Turin, Italy and AOU Città della Salute e della Scienza - CTO, Turin, Italy.

**Body:**

**Background:** The economic crisis that has characterized recent years has required a careful spending review worldwide and particularly in Italy Health Care System. This resulted in substantial cuts in terms of services and drugs prescriptions. For this reason, it becomes very important to adopt measures aimed to save health care costs, maintaining at the same time the highest standard of health care. The enrollment in clinical trials (CTs) may encourage this goal, making high-cost drugs available.

**Methods:** We compared the overall expenses for an oncology patient treated with standard therapy (reference: public hospital price list) to a similar patient enrolled in a CT. The cost comparison was made considering a patient affected by Her2 positive breast cancer in three different settings: neoadjuvant, adjuvant, and advanced/metastatic disease. We considered three categories of cost: diagnostic procedures; drug purchase; drug management. All analyses were performed considering an average treatment period and dose, calculated on a middleweight patient.

We take into account the absolute saving in Euro (€) and the percentage one.

**Results:** The data show a saving in all treatment lines, referring to the analyzed cost groups.

In neoadjuvant setting, the estimated patient standard cost is 92,829,00€; we calculated a saving of 92,451,00€ (93,74%), of which 1,226,00€ for diagnostic procedures charge (65%), 89,205,00€ for drug purchase (100%) and 2,020,00€ for drug management (116%).

In adjuvant setting, where the estimated standard cost is 25,527,00€, we observed a saving of 23,332,00€ (51%): 22,392,00€ (98% of drug purchase) and 940,00€ (54%) for drug management; no saving for diagnostic procedures.

Regarding the metastatic breast cancer treatment, we calculated a saving of 115,158,00€ (88%) compared to 115,571,00€, that means the estimated standard cost. In this case the saving is allocated as follows: 750,00€ for diagnostic procedures (64.5%), 113,508,00€ for drug purchase (100%) and 900,00€ for drug management (100%).

**Conclusions:** CTs are useful in order to save money in the overall patient management, allowing them to have access to expensive innovative drugs.

Moreover, we have to consider the additional fees provided by Sponsor for each enrolled patient.

This basic model of cost analysis could be used by Institutional Health Care stakeholders for spending review strategies. The public institutes with the characteristics of Comprehensive Cancer Center are essential to recruiting the needed study population for Sponsored CTs, and the cashed and saved money can be reinvested for improving Breast Cancer patients care.
Title: Determining the breast tumor margin through genomics of the cancer-stromal interaction

Dhage S, Ernlund A, Wang J, Axelrod D, Berman R, Roses D and Schneider R. New York University School of Medicine, New York, NY.

Body: Introduction: Data indicate that breast tumors can enact gene expression changes in the peri-tumoral stroma that remains after surgical removal of the tumor. This tumor adjacent normal tissue harbors genomic changes that reflect early transformation events as well as promote a tumor-nurturing environment making it highly receptive to future cancer development, tumor invasion, metastasis and recurrence. The physical and spatial extent at which abnormal genomic changes penetrate into the surrounding tissue has not been examined. We hypothesized that a genetically defined border exists between tumor altered, disease promoting stromal tissue and normal tissue based on tumor imprinted alteration in gene expression and distance from tumor. Methods: Samples of tumor and tumor-adjacent histologically normal tissue at 5 mm, 10mm, 15mm, and 20 mm were obtained from 33 patients undergoing mastectomy. Tissues were analyzed for genome-wide mRNA expression using microarrays. An unsupervised NMF analysis for data dimension reduction of tissue clustering, was performed. In order to define a subset of genes that have similar expression in tumor and at least one distance of normal tissue, we defined a tumor signature and a tumor-like gene signature. To define a tumor-like gene signature, pair-wise statistical analysis was performed to isolate genes with a 2-fold change in expression (p.value < 0.01) in at least one distance of normal tissue compared to tumor. Using tumor-like genes, hierarchical clustering was used to separate genes into 7 clusters based on average gene expression levels across tumor and each distance of normal and further examined for functional characterization using PANTHER gene analysis tools. Correlation studies examining each patient's gene expression in normal tissue compared to tumor were carried out. Results: The tumor signature is enriched in proliferative genes and pathways related to angiogenesis. The tumor-like signature is enriched with pathways that are tumor promoting such as disruption of basement membrane, migration, and angiogenesis. The gene signature in the 20mm region reveal that the cells have not been transformed but are highly plastic and in a state of flux between maintaining activities of normal cells, tumor suppression and are also pro-transforming of processes involved with proliferation, extracellular re-modeling and EMT. We found key tumorigenic pathways displayed a general decrease of gene expression at distances further from tumor and particularly the 20 mm region displayed an enrichment of pathways necessary for normal tissue maintenance. We found that 50% or more samples within 5mm, 10mm, and 15mm correlate well (R >0.5) with tumor expression compared to only 30% of 20mm tissues. Conclusion: Breast tissue devoid of tumor cells is genomically related to tumor, most significantly within 5mm. These genomic changes display a gradient from tumor truncating at 20 mm. The impact of the stromal cell gene profile and pre-malignant altered cells in the remaining stroma after surgery, may be defined by genetic alterations in abnormal stroma that resemble those in tumor particularly at a 5mm distance. This tumor-like signature may be important for making and personalizing surgical and adjuvant therapeutic decisions.
Title: Impact of primary surgery on short-term survival of older breast cancer patients in the UK

Bundred N, Lavelle K, Sowerbutts AM, Pilling M and Todd C. The University of Manchester, Manchester, United Kingdom.

Body: Introduction
Lack of surgery for older breast cancer patients may reduce cancer survival. Previous studies did not adjust for comorbidity and tumour characteristics which affect survival.

Methods
In a prospective cohort study investigating older patients’ treatment, survival analyses (mean 3.8 years, 95% CI: 3.69-3.83) was undertaken for 910 breast cancer patients aged ≥65 years diagnosed at 22 English hospitals from 1/7/10 to 31/12/12. Primary outcome was breast cancer specific survival. Independent variables included surgery, comorbidity, functional status and tumour characteristics recorded from patient interview (at diagnosis) and case note review. Data analyses included Cox’s multiple regression.

Results
Adjusting for tumour stage, comorbidity and functional status, women undergoing primary surgery (n=772) had a third of the hazard of breast cancer death compared to those who did not (n=138) (HR 0.36, 95% CI: 0.20-0.66, p=0.001). The number of observed breast cancer deaths exceeded those expected for participants who did not have primary surgery, were aged ≥85 years, steroid receptor negative or had a higher grade or stage tumour. In univariate analysis women aged ≥85 years had an increased hazard of breast cancer death compared to 65-69 year olds (HR 4.02, 95% CI: 1.61-10.01, p=0.003). Patients’ role in the treatment decisions did not alter whether they received surgery or not; those who were active/collaborative were as likely to get surgery as those who were passive (i.e. left the decision up to the Surgeon).

Conclusions
Surgery for older breast cancer patients reduces the hazard of cancer death by a third, independent of age, comorbidity and tumour characteristics. Surgeons must actively advise surgery for all elderly patients.

Cox's proportional hazards regression of breast cancer specific survival (unadjusted n=906)

Title: Abstract Withdrawn
Title: Use of an absorbable implant to mark the lumpectomy cavity: Initial report of 300 patients in a multi-center registry database

Kaufman CS S, Cross MJ J, Goyal S, Barone J, Devisetty K, Dehne NS S, Edmonson D, Gass JS S, Graham CL L, Hong RL L, Patton BJ J, Phillips RF F, Schonholz SM M, Smith LA A, Tafra L, Smith AB B and Dilworth J. University of Washington, Bellingham, WA; Breast Treatment Associates; Robert Wood Johnson / Rutgers University; Exempla St. Joseph Hospital; Staten Island University Hospital; William Beaumont Hospital; Womens and Infants’ Hospital; Georgia Breast Care; Virginia Hospital Center; Metro Surgical Associates; Noble Hospital; Lovelace Women's Hospital; Arizona Breast Cancer Specialists; Anne Arundel Health System; Karmanos Cancer Institute at McLaren Flint; Exempla St. Joseph Hospital and Highlands Oncology Group.

Body: Objective:
Increased use of oncoplastic procedures makes it difficult to distinguish the lumpectomy margins from seroma fluid. Many side effects of radiation therapy are due to overestimated treatment volumes due to seroma based planning. A novel 3-dimensional (3D) absorbable device sutured to the lumpectomy tumor bed allows greater precision in targeting of the margins while avoiding normal tissues. A multi-center clinical registry was established to assess use of this device over time. This initial report of the first 300 patients provides insight into patient selection, tumor characteristics, method of implantation and initial outcomes.

Methods:
A bioabsorbable 3D implantable marker with a fixed array of 6 titanium clips was sutured to the site of the excised breast cancer during lumpectomy with or without oncoplastic closure techniques. The framework of the implant resorbs slowly over time, while the clips remain permanently. The marker was utilized for boost or partial breast irradiation (PBI) planning or treatment targeting. To date the registry has accrued 300 patients from 12 centers. Data includes patient demographics, breast size, tumor characteristics, surgical and radiotherapy techniques, cosmesis and follow-up.

Results:
Data on 300 patients with median follow-up 10.4 months was analyzed. Median age was 64.4 years, 83% of women were postmenopausal and 10% had comorbidities. Breast size was evenly distributed between cup size B, C and >D. Cancer histology was in-situ (20%), invasive ductal (62%), invasive lobular (9%) and others (10%) measuring T1 (80%) and T2 (20%). Laterality and tumor location within the breast were typical. Most patients had oncoplastic rearrangement (74%) at the time of lumpectomy. Re-excision (including mastectomy for extensive disease) occurred in 14% of patients. Infections occurred in 2% of patients and in one patient the device was removed during surgical debridement of the postoperative infection. No devices have been removed during follow-up due to misplacement or patient-generated concerns. No cancer recurrences have been reported. In most cases, size of the device reflected size of the tumor with the 2X2cm (47%) and 2X3cm (32%) devices used most often. The device was utilized by radiation oncologists for boost or PBI planning or treatment. Data on ease of setup and boost planning is being collected. Early reports regarding cosmetic appearance show a trend for excellent or good cosmesis as judged separately by both physicians and patients (93% and 92%).

Conclusions:
A novel 3-dimensional absorbable device sutured into the tumor bed provides clarity in radiation targeting of tissues at greatest risk while sparing adjacent normal tissues mobilized during surgery. This initial report of a multi-center clinical registry on over 300 patients characterizes patient selection, treatment methods and follow-up. Ongoing collection of additional data, regarding radiation regimen, cosmesis and patient satisfaction, have been accumulated and provide insight regarding clinical attributes of this implantable marker.
Title: Multicentre observational study evaluating why mastectomies are advised by UK multi-disciplinary teams

Singh JK K, McEvoy K, Marla S, Wilcox M, Rea D, Hallissey MT T, Francis A and West Midlands Research Collaborative. University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; University Hospitals of Coventry and Warwickshire NHS Foundation Trust, Coventry, United Kingdom; Royal Wolverhampton Hospitals NHS Trust, Wolverhampton, United Kingdom and Independent Cancer Patients’ Voice, United Kingdom.

Body: Background: Marked variation in mastectomy rates exists across the UK. Identification of variation in practice is a key step towards standardisation of service. The rationale for advising mastectomy by multi-disciplinary teams (MDTs) has not been previously explored in the UK. The main aim of this multicentre observational study was to describe current practice in MDT decision-making for patients undergoing mastectomy. A secondary aim was to determine utilisation of neoadjuvant therapies.

Methods: A multicentre, protocol-driven, prospective cohort study, led by trainees of the West Midlands Research Collaborative was performed during July and September 2015. Data was collected securely using Research Electronic Data Capture. Inclusion criteria were: women >18 years undergoing mastectomy for in situ/invasive disease; presenting with symptomatic or screen detected disease; performed as a primary procedure or following failure of breast conserving surgery (BCS); with or without immediate breast reconstruction (IR).

Results: A total of 1776 patients (1823 mastectomies; 47 bilateral procedures) from 68 units were included. Median age was 63 years (range 20-99). In total 481 (26%) IRs were performed; median IR rate was 22% (range 0-67%). Mastectomy was advised by the MDT in 1402 (77%) cases. Reasons for advising mastectomy are shown in Table 1.

</tbody>
</table>

In total 153 patients with oestrogen receptor positive (ER+) tumours were offered neoadjuvant endocrine treatment (NET); 131 (86%) received treatment. A total of 293 post-menopausal women with uni-focal, ER+ tumours, >20mm were not offered NET; mastectomy was advised by MDTs in 202 patients and the rationale for advising mastectomy in 173 patients (86%) was large tumour to breast size ratio.

In total 104 patients with Human Epidermal Growth Factor Receptor 2 over-expressing (HER2+) tumours were offered neoadjuvant chemotherapy and trastuzumab (NACT); 89 (86%) received treatment. A total of 88 women <70 years old with HER2+ tumours, >20mm were not offered NACT; mastectomy was advised by MDTs in 75 patients and rationale for advising
masectomy in 45 women (60%) was large tumour to breast size ratio.

**Conclusions:** Although most mastectomies are advised for large tumour to breast size ratio, there is inconsistency in the utilisation of neoadjuvant therapies with many potentially eligible patients with large tumours not being given the opportunity to be downsized. Application of standardised recommendations for neoadjuvant treatment resulting in increased and appropriate use of neoadjuvant therapies could reduce the number of mastectomies advised by MDTs.
Title: Development and validation of a nomogram predicting pathological axillary status (ypN0 vs. ypN+) in a subgroup of patients converting from cN+ to ycN0 through neoadjuvant therapy (NAT) – A transSENTINA substudy

Liedtke C, Kolberg H-C, Kerschke L, Goerlich D, Bauerfeind I, Fehm T, Fleige B, Hauschild M, Helms G, Lebeau A, Schmatloch S, Schrenk P, Schwentner L, Staehler A, von Minckwitz G, Loibl S, Untch M and Kuehn T. University Hospital Schleswig-Holstein / Campus Luebeck, Germany; Marien-Hospital Bottrop, Germany; University Hospital Münster, Germany; Klinikum Landshut, Germany; University Hospital Duesseldorf, Germany; Helios-Klinikum Berlin-Buch, Germany; Spital Rheinfelden, Switzerland; University Hospital Tuebingen, Germany; University Hospital Hamburg-Eppendorf, Germany; Hospital Kassel, Germany; AKH Linz, Germany; University Hospital Ulm, Germany; German Breast Group, Germany and Klinikum Esslingen, Germany.

Body: Background: Particularly among patients converting from cN+ to ycN0 status through neoadjuvant therapy (NAT) the optimal method and extent of axillary staging is unclear. The aim of this analysis was to develop a nomogram predicting the probability of positive axillary status (ypN+) after PST among these patients based on clinical and pathological parameters.

Methods: Patients converting from cN+ to ycN0 due to PST included in a prospective study (SENTINA, Arm C) were included. Univariate and multivariate analyses were carried out to evaluate the association between 14 clinical/pathological parameters and pathological axillary status (ypN0 vs ypN+) using logistic regression models. Model accuracy, sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were assessed applying leave-one-out cross-validation (LOOCV) and ROC analyses. Different cut-points were evaluated. Calculations were performed using the SAS Software (Version 9.4, SAS Institute Inc., Cary, NC, USA.).

Results: Arm C contained 553 patients, 369 patients were evaluable with respect to the above parameters. Univariate analyses revealed a significant association between pathological axillary status and ER status (odds ratio (OR) 4.05, 95% confidence interval (95%CI) 2.81-5.83), PR status (OR 3.07, 95%CI 2.16-4.36), multifocality (OR 2.37, 95%CI 1.57-3.58), lymphovascular invasion (OR 8.61, 95%CI 5.12-14.46), detection of a SLN after NAT (OR .56, 95%CI .36-.87), detection method (IHC vs routine: OR .46, 95%CI .27-.78; IHC vs serial HE: OR .72, 95%CI .49-1.07; serial hematoxylin eosin (HE) vs routine: OR .639, 95%CI .39-1.04), clinical tumor size (OR 1.051, 95%CI 1.03-1.07) and pCR-status in the breast (ypT0 and ypTis vs others, OR .11, 95%CI .08-.17). A multivariate model was fitted including significant clinical parameters. Stepwise backward variable selection was carried out resulting in a model including ER status (OR 3.81, 95%CI 2.25-6.44), multifocality (OR 2.22, 95%CI 1.26-3.92), LVI (OR 9.16, 95%CI 4.68-17.90), detection of a SLN after NAT (OR .50, 95%CI .26-.95) and clinical tumor size (OR 1.03, 95%CI 1.01-1.06). In LOOCV, this model demonstrated an accuracy of 73% (sensitivity 73%, specificity 72%, PPV 75%, NPV 70%) using .5 as cut-off. Based on the performed ROC analysis an area under the curve (AUC) of 0.81 was calculated.

Conclusion: A model using ER status, multifocality, LVI, detection of a SLN after NAT and clinical tumor size was built to predict pathological axillary status (ypN+) with a high accuracy. If successfully validated based upon an independent dataset, this nomogram could allow advising patients for / against axillary surgery in case of clinical axillary conversion after NAT.
Title: Are there patients with T1-T2, node-negative breast cancer who are high-risk for locoregional recurrence?

Body: Background: Indications for post-mastectomy radiotherapy (PMRT) in T1-T2, node negative (N0) breast cancer patients with “high-risk” features are controversial based on lack of consensus as to what constitutes “high-risk”, and variable results of small retrospective studies. The EORTC 22922 and MA20 trials reporting improved 10-year disease-free survival with nodal irradiation included high-risk N0 patients but these patients were not analyzed separately and did not receive modern systemic therapy. We sought to evaluate long-term locoregional control in T1-T2N0 patients with high-risk features undergoing mastectomy in the contemporary era.

Methods: We retrospectively identified patients with T1-T2N0 breast cancer with ≥1 high-risk feature treated with mastectomy from 1/2006-12/2011. High-risk features were defined as age <40 years, multifocal/multicentric disease, lymphovascular invasion (LVI), medial or central tumor location, and high nuclear grade. The primary outcome of interest was rate of LRR.

Results: Among 672 patients meeting inclusion criteria, 187 (28%) had 1 risk factor: 21 (3%) were age <40 years, 132 (20%) were multifocal/multicentric, and 34 (5%) had LVI; 449 (67%) patients had ≥2 high-risk features, and 36 patients with unknown grade were excluded from risk analysis. PMRT was received by only 15 (2%) patients. Clinicopathologic characteristics of the 657 patients treated without PMRT are shown in Table 1.

*Unknown grade in 34 cases, excluded from risk analysis **Unknown receptor status in 26 cases

Sentinel node biopsy alone was performed in 98% of these patients. A median of 4 lymph nodes were retrieved (range 1-15). Adjuvant systemic therapy was received by 86% of patients. At median 5.6 years of follow-up, overall LRR rate was 4.7% (n = 31), with the majority (55%) of events involving the chest wall. Increasing tumor size was associated with LRR (HR 1.70, 95% CI
1.26–2.29, p = 0.006), while age, histology, grade, subtype, LVI, multifocality/multicentricity, and tumor location were not (all p > 0.05). Although rate of LRR increased from 3.8% to 9.4% with 1 vs. ≥4 high-risk features, a comparison of 1 vs. 2 vs. 3 vs. ≥4 risk factors was not significant by Kaplan-Meier estimation (p = 0.54).

**Conclusions:** A low LRR rate of 4.7% was seen in this large unselected cohort of T1-T2N0 cancers with "high-risk" features treated by mastectomy and systemic therapy without PMRT. While increasing tumor size was predictive, other features did not confer a higher risk of LRR either independently or together, and do not by themselves mandate the use of PMRT in this population.
Preclinical validation of a new tumor imaging agent targeting αvβ3 to detect breast tumor using NIR-light imaging

Surgery is still a essential step for breast cancer treatment. Complete tumor removal during surgery rely on surgeon's ability to differentiate tumor from normal tissue. To date, no intra operative method is available and reliable enough to help the surgeon delineate precisely tumor extension in the adjacent normal tissue. Thus, surgeons rely solely on pre operative imaging techniques to delineate tumor margins. Recent advances made in the field of non-invasive imaging and vectorized nano-size particles have revealed a remarkable potential for improved tumor-margin detection. AngiostampTM is a new fluorescent agent for intra operative imaging. This system provides strong binding on αvβ3 integrin-rich tumor neoangiogenesis. Our general hypothesis is that targeting αvβ3 integrin-rich breast carcinoma neoangiogenesis should provide improved delivery of diagnostic compounds and assist surgeons intra operatively using near-infrared imaging techniques.

We conducted preclinical studies to evaluate the distribution of angiostampTM in vivo in murine breast tumor model and to determine the expression of αvβ3 integrin on human breast specimens. The capacity of AngiostampTM to target αvβ3 integrin was assessed in 4T1 breast tumor model. After tumor implantation, mice were injected with AngiostampTM or a saline solution. Detection of the tumors was performed at different timepoints (early, progressive and established tumors, N= 24 mice/timepoint) using near infrared (NIR) imaging system (FluobeamTM) to detect fluorescence in tumor tissue. In parallel, the expression of αvβ3 integrins in normal breast tissue, benign lesions (N=20) and various tumors subtypes (N=120) was assessed by immunohistochemistry.

In mice injected with AngiostampTM, fluorescence was observed only within the tumors with low background. AngiostampTM labeled tumors at all timepoint. No false negative fluorescence was found as confirmed by histopathological analyses. In humans, the αvβ3 integrin are expressed in normal breast epithelial cells and benign metaplastic or proliferative epithelial lesions. However, due to the density of carcinomatous cells, the level of expression was much higher in breast cancer: 94% of invasive ductal carcinomas and 100% of invasive lobular carcinomas had a membranous staining (moderate to high intensity). Expression in breast cancer was not restricted to tumor subtypes neither hormone receptor expression nor SBR grade.

Based on this preclinical demonstration, AngiostampTM could allow a better intra-operative detection of tumor bed in breast cancer, increasing the efficiency of surgical procedure especially for infraclinic disease and decreasing the rate of second surgery. Preclinical development is ongoing and the first clinical trial is expected in 2017.

Title: Prediction of underestimation associated with flat epithelial atypia, atypical ductal hyperplasia and atypical lobular hyperplasia by needle biopsy: Experience in an Argentine breast unit

Body: INTRODUCTION: Flat Epithelial Atypia (FEA), Atypical Ductal Hyperplasia (ADH), and Atypical Lobular Hyperplasia (ALH) are well known non-obligate precursors of breast malignancy. Management of FEA, ADH and ALH after image-guided needle biopsy (NB) still remains controversial. The aim of this study was to evaluate the rate of malignancy underestimation associated to FEA, ADH or ALH diagnosis by image-guided NB, either core needle biopsies (CNB) or vacuum assisted breast biopsy (VABB). As a secondary objective, we attempted to identify clinical characteristics and imaging features associated with malignancy.

MATERIAL AND METHOD: We retrospectively reviewed all consecutive image-guided NB performed between January 2006 and April 2016 that resulted in a diagnosis of FEA, ADH or ALH which were subsequently submitted to surgical biopsy. All pathological reports were available. We compared the pathology specimens obtained from biopsy to those obtained from surgery. The rate of underestimation was calculated by means of specific mathematical equations.

RESULTS: Among 4715 patients who underwent image guided NB, 174 (3.7%) resulted in diagnosis of FEA, ADH and ALH. 49 patients were excluded because of loss in follow up. The diagnosis in the remaining 126 cases, were 45 (36%) FEA, 66 (51%) ADH, 9 (7%) ALH and 8 (6%) combined diagnoses. Of these, 16 (13%) were ultrasound-guided CNB procedures and 110 (87%) stereotactic VABBs. In thirty-six cases (28.3%) the diagnosis was upgraded to malignancy. For CNB specimens, we found underestimation in 10 of 16 procedures (62.5%) and at VABB there were 26 cases of underestimation out of a total of 110 biopsies (23%). Univariate analysis indicated that use of CNB (p=0.001), residual calcifications (p=0.008), and presence of ALH in NB specimens (p=0.08) were independent predictors of underestimation. The presence of a mass on ultrasound was more likely to be associated with malignancy, as 5 out of 10 lumps (50%) resulted in lesion upgrade. Neither age at diagnosis nor hormonal status were significant predictors for malignancy underestimation. The final pathological results of the underestimated NBs, distributed by lesion type were as follows: For FEA, we found 7 low grade DCIS, 1 high grade DCIS and 1 invasive tubular carcinoma. Among 20 cases of ADH, we encountered 15 low grade DCIS, 1 invasive tubular carcinoma, and 4 NST ductal carcinoma. In 5 cases originally diagnosed as ALH we upgraded to LCIS, we found 1 invasive lobular carcinoma, and 1 invasive ductal carcinoma. Finally, both of the combined lesions resulted in upgrade to invasive ductal carcinomas.

CONCLUSION: In our experience, we found that the diagnostic underestimation rate when using CNB is approximately three times than for VABB. Residual microcalcifications and presence of ALH on NB were found to be independent predictors of underestimation. In our country, surgical excision of FEA, ADH and ALH remains the standard of care. Further research is needed in order to establish which patients with atypical findings on initial biopsy will achieve benefit from surgery, and which might be suitable candidates for surveillance.
Title: A comparison of the micro-impulse radar SAVI SCOUT to the radioactive I125 seed in localization of non-palpable breast cancer for breast conserving therapy

Nolano SE E, Thalhiemer LO O, Yu E, Grujic E, Carter WB B and Frazier TG G. Barbara Brodsky Comprehensive Breast Center, Bryn Mawr Hospital, Bryn Mawr, PA.

Body: Breast conservation and primary radiation (BCT) is a widely used treatment for early stage breast cancer patients. Studies report a 20-40 percent re-excision rate to obtain clear margins. Current localization practices include needle, radioactive seed and intraoperative U/S. Seed localization has been found to decrease tissue volume excision and improve patient satisfaction. However, radioactive seed programs are difficult to implement due to cumbersome regulations by the Nuclear Regulatory Commission (NRC). SAVI SCOUT® is a new technology cleared by the FDA for tumor localization. This device utilizes non-radioactive, micro-impulse radar (radar) to provide surgical guidance. The aim of this study was to evaluate the SCOUT® and determine its equivalence to seed localization by comparing re-excision rates and specimen volume.

70 patients with clinical stage 0, I, or II breast cancer who were treated with BCT were included in this IRB approved review. 35 patients were compared using the SCOUT radar localization technique with 35 patients using the radioactive iodine 125 seed localization technique. All patients received a wide segmental resection. The tissue was oriented and assessed clinically (visualization and palpation) and radiographically (Kubtec's XPERT 40 Digital Specimen Radiography System) in the operating room. Additional margins were excised if deemed to be suspicious by the surgeon (unless the anterior margin was skin or the posterior margin was the pectoral muscle fascia). Final margin status for both groups was compared. A positive margin was any margin with tumor on ink. The total volume of the excised specimen plus additional margins was recorded by the pathologist. In all 70 patients, the targeted lesions, seed and/or reflectors were successfully removed. There were 420 margins assessed (6 for each specimen), using the additional margins excised as the final margin for evaluation of tumor on ink. Of the 210 final margins in the specimens excised using the seed, 5 margins (2.38%) in 4 patients were positive. 5 margins (2.38%) were also positive in 4 patients using the SCOUT. Nine patients in total returned to the operating room for re-excision. [One re-excision was performed as physician preference for close (<2mm) margins for DCIS.] 5/9 patients requiring re-excision were found to have residual disease. A total of 119 additional margins were excised from 51 patients at the initial operation. 68 margins from 26 patients (SCOUT) and 51 margins from 25 patients (seed). Of the 119, 5 margins were found to be positive. 3 margins 4.41% (3/68) in the SCOUT group and 2 margins 3.92% (2/51) in the seed group. The average volume resected from the SCOUT averaged 81.28 cm3 while the volume of the seed averaged 100.39 cm3 (p-value 0.209).

The use of SCOUT for non-palpable tumor localization was equivalent to seed localization when comparing margin re-excision rate and tissue volumes. We conclude that SCOUT is an excellent alternative in breast cancer localization and can be easily implemented in most hospitals for breast conservation therapy.
Title: Utility of LigaSure™ vessel-sealing device in axillary dissection for breast cancer surgery: A randomized single center study

Body: Introduction
Axillary lymph node dissection is standard therapy for patients with positive-node breast cancer, and can be performed with an electrocautery scalpel and suture ligation in most cases. However, knot slipping can occur during suture ligation and this can spread thermal damage to peripheral tissues. The LigaSure™ Small Jaw vessel-sealing system was developed as an alternative to suture ligatures, staplers, and other energy-dependent devices for sealing blood and lymphatic vessels, but its use in axillary dissection for breast cancer is limited. We prospectively compared the duration until drain removal after surgery, total lymph fluid drainage volume, intraoperative blood loss, and incidence of complications after axillary dissections, between this device and conventional methods.

Methods
This prospective randomized study was conducted at the Department of Breast and Endocrine Surgery at Tokai University School of Medicine, Kanagawa, Japan, between October 2011 and March 2015. Major eligibility criteria included (1) pathologically confirmed breast cancer diagnosis, (2) age ≥20 and ≤80 years, and (3) a signed informed consent form. The primary endpoint was duration until drain removal after surgery. The secondary endpoints were total lymph fluid drainage volume, intraoperative blood loss, and incidence of postoperative surgical complications. We defined the criterion for drain removal as a lymph fluid drainage volume of <40 mL/day for two consecutive days. The target accrual was 100 patients, with a two-sided error rate of 5%, and 90% power. The assumed duration until drain removal after surgery was 7.2 days in the control group (conventional use of an electrocautery scalpel and suture ligation) and 5.8 days in the study group (use of the LigaSure™ Small Jaw). This clinical study was approved by the Institutional Review Board of the Tokai University School of Medicine and is registered with UMIN (No. 000013034).

Results
Initially, 100 patients were assigned as eligible; however, two patients were later excluded because of the exclusion criteria. Of 98 patients, 49 were randomized to the study group, and 49 to the control group. The mean duration until drain removal after surgery was 5.2 days in the study group and 5.0 days in the control group (p=0.573). The mean total lymph fluid drainage volumes were 260.3 and 233.5 mL (p=0.502), and the mean intraoperative blood loss volumes were 17.8 and 18.0 mL (p=0.949), for the study and control groups, respectively. No significant differences were found between the two groups regarding drain removal duration, total drainage volume, and intraoperative blood loss volume. Both groups had low incidence rates of postoperative hematoma, wound infection, lymphedema, and pain, and had similar incidence rates of seroma formation after drain removal.

Conclusion
Our study results indicated that the use of the LigaSure™ Small Jaw in axillary dissection for breast cancer was as safe as conventional methods. However, using the LigaSure™ Small Jaw did not improve surgical outcomes such as duration until drain removal and total lymph fluid drainage volume compared with conventional methods.
van Bommel A, Spronk P, Vrancken Peeters M-J, Mureau M, Siesling S, Smorenburg C and van Dalen T. Leiden University Medical Centre; Dutch Institute for Clinical Auditing; Netherlands Cancer Institute / Antoni van Leeuwenhoek; Erasmus MC Cancer Institute / University Medical Centre; Comprehensive Cancer Organisation the Netherlands (IKNL); MIRA Institute for Biomedical Technology and Technical Medicine, University of Twente and Diakonessenhuis Utrecht.

Body: Background
Breast cancer treatment is a multimodality effort to optimize outcome as well as to achieve the optimal cosmetic result. Various treatment strategies can be used for the latter goal: upfront breast conserving surgery (BCS), BCS after neoadjuvant therapy (NAC), and ablative surgery combined with immediate breast reconstruction. The rate of BCS is frequently used as a quality and trend indicator. The aim of the present study was to analyse the combined efforts expressed as the rate of breast contour preserving procedures (BCPP) and compare it to the rate of BCS.

Material and methods
All invasive M0 female breast cancer patients diagnosed and operated in one of the 89 hospitals in the Netherlands between January 2011 – December 2015 were selected from the national NABON Breast Cancer Audit. BCPP (defined as ‘primary BCS’, ‘BCS after NAC’, or ‘ablative surgery combined with an immediate reconstruction’) was calculated for the years of diagnosis, age groups (<30, 30-39, 40-49, 50-59, 60-69 and ≥ 70 years) and the individual hospitals.

Results
A total of 61,309 patients were identified. The rate of upfront BCS remained stable during the study period (52%), while the BCPP rate increased over the years (63% to 71%) due to an equal increase in the proportions of patients receiving NAC with BCS and undergoing ablative surgery with immediate breast reconstruction. While upfront BCS (with and without NAC) rates increased with age (30% in patients aged <30 years to 67% in patients aged 60-69), the rate of BCPP was more or less stable in these age groups, as the rate of ablative surgery with immediate reconstruction showed an inverse relationship with age, decreasing from 44% in patients <30 years to 1% in patients ≥70 years of age.

The rate of BCS varied between hospitals in the Netherlands: 37% to 77%. Although BCPP is more often performed compared to BCS, the variation between hospitals remained (47% to 88%)

Table. Percentage of patients treated with Breast Conserving Surgery (BCS), BCS after neo-adjuvant therapy and immediate breast reconstruction with ablative surgery resulting in total percentages of Breast Contour Preserving Procedures (BCPP).

BCS: Breast Conserving Surgery; IBR: Immediate Breast Reconstruction; BCPP: Breast Contour Preserving Procedures

**Conclusions**

While the rate of BCS remained stable over recent years, the rate of BCPP has increased significantly. Including immediate reconstruction into the BCPP rate annihilates observed age-dependent differences of the BCS-rates, while institutional differences remained. All in all, combining different treatment strategies into one parameter (BCPP) provides a more appropriate measure of maintaining the breast contour than BCS alone.
Title: Breast-conserving surgery plus hormone therapy without irradiation in elderly women with early breast cancer

Inoue H, Hirano A, Ogura K, Hattori A, Yukawa H, Sakaguchi S, Matsuoka A, Tanaka N, Kodera A, Kamimura M, Fujibayashi M, Naritaka Y and Shimizu T. Tokyo Women's Medical University Medical Center East, Tokyo, Japan; Tokyo Women's Medical University Medical Center East, Tokyo, Japan and Tokyo Women's Medical University Medical Center East, Tokyo, Japan.

Body: Background
The meta-analysis of the Early Breast Cancer Trialists' Collaborative Group (EBCTCG) revealed that whole-breast irradiation after breast conserving surgery (BCS) decreased ipsilateral breast tumor recurrence (IBTR) and breast cancer-related death. However, elderly patients can find daily hospital attendance difficult, and their IBTR risk is low. A randomized control trial was performed in women aged ≥70 years with hormone-positive breast cancer to investigate the usefulness of breast-conserving therapy without irradiation (Hughes et al. N Engl J Med 2004). Since September 2001, we have offered BCS plus hormone therapy without irradiation in patients who satisfy the following criteria: age ≥60 years; pathologically node negative, hormone-positive breast cancer; a negative surgical margin; and no lymphovascular invasion. We assessed prognosis in patients who chose this option.

Patients and methods
Between September 2001 and December 2014, 219 patients met the inclusion criteria; 90 and 129 patients underwent BCS plus hormone therapy with or without irradiation, respectively. The cumulative IBTR incidence and overall survival (OS) for the groups was evaluated. A negative surgical margin was defined as a margin of ≥5 mm.

Results
The median ages at operation were 73 years (range, 60–88 years) and 65 years (range, 60–80 years) for the without and with irradiation groups, respectively (p <0.001). There were no significant differences in tumor size, lymph node metastasis, or adjuvant therapy between the groups. The median follow-up duration is presently 4.6 years. IBTR was observed in 5 (3.9%) and 1 (1.1%) patient(s) in the without and with irradiation groups, respectively (p = 0.192). The 5-year IBTR cumulative incidences were 0.9% and 2.2%, and the 10-year were 6.7% and 2.2%, for the without and with irradiation groups, respectively (p = 0.390). The 5-year OS rates were 93.8% and 98.5%, and the 10-year OS rates were 89.7% and 94.0 for the without and with irradiation groups, respectively (p = 0.205).

Conclusion
BCS plus hormone therapy without irradiation in elderly patients is an appropriate option.
Title: Clinicopathologic factors related to surgical margin involvement, reoperation, and residual breast cancer in primary operable breast cancer - An analysis of 2050 patients

Lai H-W, Chen S-T and Chen D-R. Changhua Christian Hospital, Changhua, Taiwan.

Body: Background: Positive or involved margins resulted in higher rates of local recurrence in breast cancer patients and often needs further operations. Identification of patients at increased risk for positive surgical margin may enhance clinical pre-operative decision-making.

Methods: A retrospective study with 2050 primary operable breast patients were enrolled in our current margin analysis study, and factors associated with positive surgical margin, re-excision, and residual cancer detection in the re-excision specimen were analyzed.

Results: Among them, 151 (7.4%) patients were found to have positive surgical margin involvement. The positive surgical margin involved rate was 11.3% (118/1042) in breast conserving surgery (BCS) patients, and 3.3% (33/1008) in mastectomy group (P<0.001). In multivariate analysis, the positive surgical margin involvement in BCS patients was associated with lower body surface area (BSA), larger tumor size (OR=1.377, CI=0.147~0.498), and pathologic multifocal (OR=3.766, CI=0.639~1.973). MRI use was associated with decrease margin involved rate in BCS patients (OR=0.530, CI=-1.102 ~-0.172). Among the 33 margin involved mastectomy patients, only 3(9.1%) received further excision. Among the 118 BCS patients with surgical margin involvement, 83(70.3%) received further re-excision. Patients with younger age, or DCIS (OR=2.165, CI=0.225~ 1.464) histologic subtypes were factors related to re-operation. Combined with MRI for pre-operative evaluation was associated with decreased re-operation (OR=0.302, CI=2.129 ~ -0.317)

. Among the 83 BCS patients with positive surgical margin and undergone further surgical excision, 44(53%) was found to have residual tumor in the re-excision specimens. Compared with no residual tumor in the second operation group, no difference in tumor size, lymph node status, pathologic multifocal, or MRI use were found. The only difference was that DCIS (71%, 22/31) histologic subtype was associated with higher residual tumor than other (42.3%, 22/52) type of breast cancer (P=0.021).

Conclusions: Lower BSA, larger tumor size, pathologic multifocal were associated with increased risk for positive surgical margin involvement. Combined pre-operative evaluation with MRI was associated with decrease surgical margin involvement and re-operation in BCS patients. Patients with DCIS had positive surgical margin involvement was associated with increased risk for re-operation and residual cancer found at re-excision.
Title: An update on trends in nipple-sparing mastectomy incision locations: A systematic review of the literature with pooled analysis

Santos PJF F, Daar DA A, Mowlds DS S, Wirth GA A and Lane KT T. University of California Irvine School of Medicine, Irvine, CA.

Body: Introduction: The incidence of nipple-sparing mastectomy (NSM) has greatly increased, owing to refinements in technique, increased surgeon comfort and the superior aesthetic outcome afforded by retention of the nipple-areola complex (NAC).¹ The indications for nipple-sparing mastectomy continue to broaden as the oncologic safety of nipple preservation is elucidated.² Incision location varies widely among surgeons and likely contributes to the complication profile associated with these procedures. While small studies have looked at complications associated with NSM,³ the preferred incision location has not been determined.

Methods: A systematic review was performed according to the Preferred Reporting Items for Systematic Review (PRISMA) guidelines. Search terms “nipple-sparing,” “nipple-areola sparing,” or “total skin-sparing” were used in PubMed and MEDLINE databases from January 2013 to October 2015. Studies were included if the mastectomy incision type was described and accompanied by the overall and/or respective complication profile. A pooled analysis was completed for the overall NAC necrosis rate as well as for necrosis by incision type.

Results: Of the 162 studies identified, 32 studies met the inclusion criteria, and a total of 4,986 nipple-sparing mastectomies were available for analysis. Incision types were divided into 6 categories: inframammary (2,030 NSMs, 40.7%), radial (1,247 NSMs, 25%), periareolar (922 NSMs, 18.5%), endoscopic (444 NSMs, 8.9%), mastopexy/previous scar (271 NSMs, 5.4%), and other (72 NSMs, 1.4%). Thirty different incision variations were used, in total. Among the 26 studies reporting overall NAC necrosis rates (3,831 NSMs), the pooled NAC necrosis rate was 9.3%. Seventeen studies reported their rates of necrosis by incision location (1,736 mastectomies): inframammary, 11.6%; radial, 13.8%; periareolar, 18.2%; endoscopic, 17.4%; mastopexy/previous scar, 5.7%; and other, 0.0%.

Conclusion: The inframammary incision has become the preferred NSM incision as it minimizes disruption of the blood supply to the NAC as evidenced by its superior complication profile. Many studies fail to report their complications as they relate to incision location. Consistent reporting in the literature is warranted as a means of further elucidating the short and long-term complication profiles associated with NSM incision location.

Title: 200 experiences of oncoplastic surgery with the omental flap reconstruction

Abe N, Sagawa N, Unesoko M and Zaha H. Nakagami Hospital, Okinawa, Japan.

Body: Background: There are several small case series about the omental flap for breast reconstructions. However, the long-term oncological safety and the clinical benefits remain uncertain, especially the flap is used as a part of oncoplastic breast surgery. We retrospectively studied 200 patients who underwent oncoplastic breast surgery using the laparoscopically harvested omental flap.

Methods: A retrospective chart review of 200 patients who underwent oncoplastic surgery using the omental flap at our institution from April 2002 to March 2016 was performed. All the omental flaps were laparoscopically harvested, and mainly used as a partial reconstruction immediate after breast-conserving surgery (BCS). Short- and long-term laparoscopy-associated complications, local recurrences and cosmetic outcomes were evaluated.

Results: Although 46 cases of nipple-sparing mastectomy or skin-sparing mastectomy were included, most of patients underwent partial breast reconstruction after BCS. The successful rate of laparoscopically harvesting of the omental flap was 99.5% (199 out of 200). The rate of complications was 12.0%. Laparoscopy-associated complications occurred in 4 cases (2.0%). The rate of positive margin was 6.5%. Local recurrence occurred in two cases (1.0%) during medial follow-up period of 78 months. In 24 patients (12.0%), the volume of the flap was insufficient. When applied to nipple-sparing mastectomy or skin-sparing mastectomy, volume luck occurred in 32.6% of patients. Cosmetic outcome was mostly satisfactory. Approximately 80% of patients scored good or excellent evaluated with 4 point scale by 3 health professions. The size of the reconstructed breast basically did not change even after radiation therapy. Donor-site scars were almost negligible just like those of laparoscopic cholecystectomy.

Conclusions: The laparoscopically harvested omental flap has minimal donor-site morbidity and deformity. The long-term oncological safety is also promising. Although there is a limit of adaptable volume, the omental flap is an attractive option in partial breast reconstruction after BCS.
Title: A multi-center prospective study of radiofrequency ablation therapy for small breast carcinomas

Kinoshita T, Ohtani S, Doihara H, Yamamoto N, Takahashi M, Fujisawa T, Aogi K, Hojo T, Asaga S, Yoshida M and Tsuda H. National Cancer Center Hospital, Tokyo, Japan; Hiroshima City Hiroshima Citizens Hospital; Okayama University Hospital; Chiba Cancer Center; Hokkaido Cancer Center; Gunma Prefectural Cancer Cente; Shikoku Cancer Center; National Cancer Center Hospital East and National Defense Medical College Hospital.

Body: Background: As the management of breast carcinoma evolves toward less invasive treatments, the next step is the possibility of removing the primary tumor without surgery. The most promising noninvasive ablation technique is radiofrequency ablation (RFA), which can effectively kill tumor cells with a low complication rate. Our preliminary studies of RFA followed by standard surgical resection have indicated that this technique is effective for surgical ablation of small (≤ 2cm) breast tumors without extensive intraductal components (EIC).

Methods: To determine if RFA is oncologically and cosmetically appropriate for the local treatment of primary breast carcinoma, this multi-center prospective study used RFA as the sole local treatment of breast tumors ≤ 1.5cm in size on ultrasound and MRI. Exclusion criteria include receiving of preoperative chemotherapy, or the presence of invasive lobular carcinoma or invasive ductal carcinoma with suspicious EIC. After confirmation that the standard baseline core biopsy for diagnosis and measurement of tumors markers (ER, PgR, HER-2/neu expression and the presence of the Ki-67 proliferative marker) have been obtained, consent will be obtained and the patient scheduled RFA. All patients received adjuvant radiation therapy. The use and choice of systemic therapy will be based on the information from the baseline core biopsy. The first primary endpoints of this study is successful tumor ablation, as evidenced by negative findings on vacuum-assisted or core biopsies and imaging studies after RFA. The second primary endpoints is the incidence of procedure related adverse events. Forty patients with small tumors that are clearly identifiable and measurable by ultrasound and MRI were enrolled. The response to ablation was evaluated with both vacuum-assisted or core biopsies and imaging studies every 3 months during the first year. The long-term outcomes were assessed using quality of life measurement scales and imaging studies every 6 months thereafter through year 5.

Results: Of the 58 patients who participated in this study, 55 completed the protocol. In 48 of the 55 (87%) treated patients, successful tumor ablation, as determined by negative findings on vacuum-assisted or core biopsies and imaging studies, was confirmed. The remaining 7 patients with biopsies positive for residual tumor underwent surgical resection. There were no local or distant recurrences in treated 55 patients with a median follow up of 47 (range 36-73) months.

Conclusions: RFA can be safely used alone in patients with small breast tumors, provided that local tumor control must be regularly assessed by image-guided vacuum-assisted or core biopsies after ablation. RFA has several potential advantages over lumpectomy for the treatment of early stage breast cancer.
Title: Technical skill of surgical residents may affect margin status of breast conserving operations

Komenaka IK K, Djenic B, Hsu C-H, Nodora J, Winton L, Bouton M and Martinez ME. Marciopa Medical Center; University of Arizona and University of California San Diego.

Body: Background: Quality of patient care and surgical outcomes have come under increased scrutiny. Numerous other studies have examined outcomes at teaching hospitals compared to non-teaching hospitals. The most important factor to determine early success of breast conservation is the attainment of pathologically negative margins. Few studies, however, have examined the effect of teaching residents on margin status. The current study was performed to evaluate the effect teaching residents on margin status after lumpectomy.

Methods: Retrospective review of all patients from July 2006-June 2015 was evaluated. A resident was usually considered the primary surgeon. If the resident was unavailable or unprepared to operate, the attending surgeon was the primary surgeon. As part of the routine evaluation of surgical residents, technical ability was classified as satisfactory or unsatisfactory for level of training. All evaluations of the technical ability of the residents were completed prior to the collection of the current data. The effect of surgical residents' participation and their technical ability to perform lumpectomy was evaluated to determine if there was an effect on margin status. Logistic regression analysis was performed to adjust for clinical variables known to affect margin status.

Results: Of 292 patients, 15% of patients had positive margins. The attending surgeon has positive margin rate of 10.7% vs 16% for Residents (p = 0.32). When technical skill evaluation was included, Residents with unsatisfactory technical skills had positive margin rate of 27% compared to 10.2% for residents with satisfactory skills (p = 0.002). In multivariate logistic regression analysis, operating surgeon remained significantly associated with positive margins. Operations done by residents with satisfactory technical skills or attending surgeon were less likely to have positive margins than those done by residents with unsatisfactory technical skills (OR 0.39, 95% CI 0.22-0.86; p = 0.03). Patients who underwent preoperative chemotherapy were also less like to have positive margins (OR 0.40, 95% CI 0.18-0.91; p = 0.04). In patients with at least 2 years of followup (mean follow up of 48 months) breast cancer specific survival was 94% and 2% had local recurrences as a first event.

Conclusions: Technically ability of residents may affect margin status after lumpectomy. With the increased use of surgical outcomes to measure quality of care in medicine, the importance of teaching surgical residents needs to be considered in future quality of care evaluation.
Title: Isolated sternal metastases: The place of surgical resection

Body: Background: Solitary sternal metastases from breast cancer are found in approximately 1.9 to 2.5 % of all advanced breast cancer cases. According to the latest AJCC classification, they are still considered as stage IV disease, but their prognosis is better in the absence of other foci of metastatic disease. Their treatment still remains controversial.

Material and methods: This is a monocentric retrospective study performed in our breast clinic and approved by our ethics committee. Twelve patients were included in this study between 2010 and 2015; 11 had a metachronous solitary sternal metastasis and 1 had a synchronous metastatic sternal lesion. Complete restaging was negative in all patients for other metastatic lesions. The extent of resection (different parts of the sternum and frequently also adjacent rib cartilages) necessary to obtain free margins was estimated preoperatively on MRI images focused with adequate sequences. All the patients underwent a large sternal resection and a chest wall reconstruction integrated in a multimodal approach. Characteristics of the patients and of the tumors were studied. The major outcomes studied were disease-free (DFS) and overall survival (OS).

Results: The mean interval between the initial diagnosis of breast cancer and the discovery of sternal metastasis was 115 months. After surgical resection, free margins were obtained in 10 patients. No post-operative complications were observed except for persistent thoracic pain in one patient with a medical history of chronic pain. Excellent cosmetic and functional outcomes were obtained without significant impairment of respiratory function. Ten patients received chemotherapy pre- or postoperatively. All the tumors expressed ER and/or PgR receptors, and endocrine therapy was administered in all patients. Mean duration of follow-up was 25 months (9-51 months). Three patients presented distant recurrences: 2 liver lesions and 1 cervical nodal recurrence with pericardic effusion. Out of these 3 patients, 1 died after 51 months. Currently the DFS of this small study is 75 % and the OS is 91.6 %.

Conclusion: Treatment of isolated sternal metastases of breast cancer must be based on a multidisciplinary strategy. Sternectomy and multilayered chest wall reconstruction (with different types of meshes and flaps) could be a curative approach in highly selected patients with no other metastatic lesions. In this group of patients, the good prognosis observed could be due to a different mechanism of dissemination, based on lymphatic rather than hematogenic diffusion. Longer follow-up and prospective studies are needed to confirm these encouraging results.
Title: Use of a 3-D bioabsorbable tissue marker in 61 patients over two years

Body: Background: Breast conservation surgery (BCS) may preserve the breast but many women have less than optimal cosmetic outcomes. Increasingly, this has been addressed by the use of oncoplastic reconstruction. Now, targeting radiation treatment for boost or partial breast irradiation (PBI) using the seroma has become more difficult due to the adjacent tissue rearrangement and resultant “benign” seromas. Since the radiation dose generated increases by the third power of the radius ($r^3$), there is a need to accurately focus radiation therapy to avoid chronic radiation side effects. We have used a 3-dimensional bioabsorbable tissue marker to accurately target the tumor bed while excluding inadvertent seromas caused by oncoplastic procedures. We report on tissue marker implantation on 61 consecutive breast conservation patients in regards to targeting, impact on cosmesis, imaging followup, ease of re-excision, as well as side effects and patient satisfaction.

METHODS: Consecutive lumpectomy patients who were candidates for targeted radiation therapy were considered for implantation with the 3-D bioabsorbable marker from May 2014 to June 2016. The tissue marker has a fixed array of 6 titanium clips and was sutured to the site of the excised breast cancer during lumpectomy. The framework of the implant resorbs slowly over time, while the clips remain permanently. All patients had oncoplastic reconstruction with total implant coverage. The marker was utilized for boost or partial breast irradiation (PBI) planning or treatment targeting. Data includes patient demographics, breast size, tumor characteristics, surgical and radiotherapy techniques, follow-up imaging, cosmesis and patient satisfaction.

Results: Data on 61 patients with median follow-up 12.7 months was analyzed (range 1.5–25.5). Median age was 62.4 years (range 33-74), 5 of women were postmenopausal and 15% had comorbidities. Cancer histology was in-situ (13%), invasive ductal (84%), invasive lobular (3%) of sizes T0 (13%), T1 (59%), T2 (25%), T3-4 (3%). Laterality and tumor location within the breast were typical. Re-excisions occurred in 11% of patients. No infections occurred in the postoperative period. One infection occurred with chemotherapy and another with repeated aspirations of oncoplastic area. No device was removed for infection, misplacement or patient-generated concerns. No cancer recurrences have been reported. Size of device used reflected size of the tumor; 2X2cm (44%), 2X3cm (34%) and 3X3cm (20%). The device was utilized by radiation oncologists for boost or PBI planning and treatment. Data on ease of setup and boost planning is being collected. Mammography at one year demonstrated marker clips coalescing as the bioabsorbable device dissolves. Evaluation of cosmetic appearance has shown good to excellent cosmesis as judged separately by both physicians and patients (92% and 94%).

Conclusions: Initial experience with 61 patients implanted with a novel 3-D absorbable device prospectively followed for an average of 12 months can be used in an array of breast cancer patients without device specific morbidity. Good to excellent cosmesis may be related to the addition of volume to the lumpectomy bed not seen with rearrangement of existing tissues.
Primary surgery in inflammatory breast cancer

Muzaffar M, Vohra N and Wong J. East Carolina University/Brody School of Medicine, Greenville, NC.

Background: Inflammatory Breast Cancer (IBC) is a rare but very aggressive variant of breast cancer accounting for around 1-5% of all breast cancer cases. Current standard of care is multimodality therapy with preoperative chemotherapy followed by modified radical mastectomy and adjuvant radiotherapy.

Method and Material: We searched the Surveillance Epidemiology and End results Registry to identify female patients diagnosed with Stage III IBC between 1988-2013. We performed descriptive and univariate analyses of the patients with IBC. Variables assessed included patient age, race/ethnicity, histologic subtype, tumor grade, hormone receptor status, surgery type.

Results: We identified 11604 women with IBC from SEER database diagnosed between 1988-2013. The median age was 57 yrs., 80 % (9273) of patients were white, 14.4 % (1667) blacks, and around 73% had nodal involvement. 32.4 % (3756) patients were diagnosed with IBC between 1988-2000, while 67.6 % (7848) between 2001-2013. We excluded patients with missing primary surgery information with 7586 patients remaining for analysis. The median age in this final cohort was 56 yrs., 80.4 % (6097) patients were white, and 13.7 % (1044) were black. The predominant tumor type was invasive ductal carcinoma, majority of the patients had grade 3 tumor 59.4 % (4504), grade 2 in 23.2 % (1757), 47.1% were estrogen receptor (ER) positive, 43% were ER negative, 53% were progesterone receptor negative, and 7% had HER 2 positive tumor. In this cohort 6.4 % (487) patients underwent partial mastectomy and 93.6 % (7099) underwent mastectomy. In the cohort undergoing breast conservation, 15% were during 1988-2000 and 84.4% during years 2001-2013 (p value=0.06).

Surgery in non-metastatic inflammatory Breast Cancer

<td>0.06</td>
</tr>
<tr>
<td>Mastectomy</td>
<td>411 (6.9%)</td>
<td>5959 (93.1%)</td>
<td></td>
</tr>
</tbody>
</table>

The median survival was 46 months among patients diagnosed between 1988-2000 and 61 months for 2001-2013 time period (p<0.0001). The median survival in patients undergoing partial mastectomy was 42 months versus 48 months among patients undergoing mastectomy (p=0.0001).

Discussion: IBC continues to be an aggressive breast cancer subtype, but survival has improved over last decade. The utility of partial mastectomy has increased in the last decade compared to 1988-2000. Mastectomy still remains the standard surgical option, but with more effective systemic therapeutic agents, better tumor responses are noted especially in Her 2 positive and triple negative IBC. Partial Mastectomy may be a viable option for patients achieving complete clinical response.
Should modified radical mastectomy be modified? A phase 1 study to evaluate infraradical mastectomy for invasive breast cancer

Colibion M, Lifrange E, Jossa V, Mutijima E, Crevecoeur A, Olivier F, Di Bella J and Jerusalem G. Clinique Saint Vincent Rocourt, Liège, Belgium; CHU Sart Tilman, Liège, Belgium and Senology Center, Liège, Belgium.

Background: Surgical procedures in breast cancer have become less aggressive. However, around one in three patients must undergo modified radical mastectomy (MRM). We evaluated if infraradical mastectomy (IFM), which preserves the skin and fat tissues surrounding the breast, is safe. IFM has the potential to preserve neck opening and by the way femininity of patients. Aesthetic results obtained after breast reconstruction are also expected to be improved.

Objective: The primary objective of this phase 1 trial is to evaluate the feasibility and safety of IFM.

Methods: Patients were recruited in two specialized breast clinics. We performed enucleation with a cold knife to the mammary gland after a water-assisted dissection of the periglandular space using a dedicated tool. In a second step we removed the peripheral skin and fat tissue which surrounded the gland to obtain a classical MRM. Fat tissue removed in the second step underwent a careful pathological examination (10 biopsies) in order to evaluate residual invasive or in situ breast cancer and atypical hyperplasia. We also evaluated which is the percentage of tissue and skin removed in the second step with regard to the global surgical specimen because that could be left in the future if the procedure is declared safe.

Results: A total of 35 patients (43 to 80 years old) were prospectively recruited from March 2015 to March 2016. The distribution of tumor type was: pTis 2.9%, pT1 45.7%, pT2 45.7% and pT3 5.7%. Pathological analysis of the periglandular tissue removed in the second step revealed: 0% invasive carcinoma, 1% focal ductal carcinoma in situ (DCIS), and 0% atypical hyperplasia. On average, the weight of an IFM was 37% lower compared to the weight of a MRM. Skin resection was reduced by 48% with IFM. No serious adverse event was observed.

Conclusions: Preliminary results are promising. Our phase 1 trial suggests that the procedure is safe concerning premalignant or malignant disease left after IFM. Moreover, a high quantity of skin and fat tissue is saved by IFM. We are now recruiting a second cohort of patients in order to confirm these results. In addition, we will also quantify the amount of mammary glands left around IFM compared to MRM by performing additional biopsies and quantitative evaluation by pathologists. Presurgical selection criteria have been modified for the second cohort in order to avoid residual DCIS left after IFM. After this second cohort, we plan to begin a large prospective randomized phase 3 trial with long-term disease-free survival and aesthetic results as the primary endpoints.
Title: Predicting residual disease in breast conservative surgery after neoadjuvant treatments in breast cancer patients using the margin index tool

Rubio IT T, Loinaz I and Esgueva-Colmenarejo AJ J. Hospital Universitario Vall d’Hebron, Barcelona, Spain.

Body: Background. The appropriate surgical margin after neoadjuvant treatment (NAT) is controversial. Margin index, a relationship of the margin obtained to the size of the tumor, is a reliable method for the prediction of residual disease after breast conservative surgery (BCS) in the adjuvant setting. Our aim was to apply the margin index to patients with NAT to predict residual disease.

Material and Methods. From a prospectively maintained database, patients with stage I - III with NAT who underwent BCS between July 2008 and December 2012 were included. Margin index was calculated as for the adjuvant setting: margin index = closest margin (mm)/tumor size (mm) × 100 considering the tumor size of the lumpectomy specimen. A receiver operating curve was created using the derived margin index and the presence or absence of residual disease in the re-excision specimen. Patients with pathologic complete response (pCR) (no invasive tumor) were excluded.

Results. Of the 206 patients, 63 (30.5%) had a pCR and were excluded. Of the 143 patients, 76 (53%) had an intraoperative re-excision depending on the surgeon or the intraoperative pathology report. Of the 76 patients, 23 (32%) had residual tumor in the intraoperative re-excision specimen. There were no statistically significant differences in residual disease regardless of who indicates intraoperative re-excision. (p= 0.56) Twenty-three patients (16%) underwent a second surgery for positive or close margins ( < 2mm). Residual disease, whether infiltrating or in situ or both, was found in 10 (43%) patients. The overall c index for the receiver operating curve was 0.76. A margin index > 5 had a sensitivity of 80% and a specificity of 63%.

Conclusion. Rates of re-excision after NAT in BCS patients are similar to the adjuvant setting. Margin index may be a valuable tool for determine residual disease after NAT in patients undergoing BCS. Further validation of this index is warranted in a larger cohort of patients after NAT to confirm these results.
Title: Non-liposuctive endoscopic axillary lymph node dissection in breast conservative surgery

Yang W, Zhang H and Wang H. Fudan University Affiliated Zhongshan Hospital, Shanghai, China.

Objective
Limiting surgical invasiveness is the main theme of breast surgery. Endoscopic axillary lymph node dissection (EALND) has been introduced since 1993 but not widely applied due to limited benefits as well as the controversy of liposuction that needed to create the working space in axilla. Progress of energy instruments brings the opportunity to new attempts to further enhance cosmetic outcomes and diminish complication rates. In this study, we report the preliminary outcomes of non-liposuctive EALND (NEALND) in breast conservative surgery.

Patients and methods
From Nov 2013 till June 2016, 143 patients diagnosed with cN+ breast cancer were categorized into two separate groups, the conventional ALND (CALND, 71 patients) and NEALND group (72 patients).

Inform consents were obtained from all patients. Number of lymph nodes harvested, tumor size, intra-operative bleeding, drainage volume, pain score (10 scale survey) were collected.

The breast symmetrical score (BSS) and patient satisfaction (4 scale survey) were used as variables to evaluate cosmetic outcomes.

Results
There was no statistical difference in intra-operative bleeding (NEALND: 31.33±20.22 ml, CALND: 38.00±18.21 ml, P=0.31) and first postoperative 3 day axillary drainage volume (NEALND: 62.30±32.42, CALND: 69.67±35.44, P=0.11). A slightly increased in the number of harvested lymph nodes was observed in the NEALND group in comparison with CALND (NEALND: 17.34±6.55, CALND: 14.68±5.85, P=0.03), there was no statistical difference reported for distant metastasis among two groups (NEALND: 2.68±3.59, CALND: 2.55±1.31, P=0.54). The pain score (NEALND: 3.79±1.51, open: 4.41±0.96, P=0.04) meanwhile breast symmetrical score was significantly superior in the NEALND group in comparison with CALND (NEALND: 0.098±0.091, CALND: 0.25±0.14, P=0.001). Patient satisfaction survey reported a slightly positive feedback (NEALND: 4.00±0.00, CALND: 3.77±0.54, P=0.02). In the CALND group, slight to moderate skew of nipple position towards the axilla was observed in many cases, suggesting the side effect of axillary scar contracture. The average operation time for NEALND was about 90 min in the first 20 cases, and then down to about 60 min, so the learning curve is suggested as 20 cases. All the patients are under follow up with no recurrence to date.

Conclusions
Efforts on minimizing surgical invasiveness are greatly developed in systemic treatment and non-surgical local control. However, surgery is the fastest and the most economical way to obtain pathological complete remission, and still has space to be completed. NEALND may be a feasible surgical alternative with minimal invasiveness, suitable to a category of patient demanding excellent cosmetic outcome. Evaluation of long-term survival, complication rates and cosmetic results are mandatory in order to further estimate the applicability of this type of surgical management in treatment of breast cancer.

Title: Oncoplastic breast surgery is oncologically safe in locally advanced breast cancer after neoadjuvant chemotherapy, an Egyptian experience

Youssef M, Namour A, Youssef O and Morsi A. National Cancer Institute, Cairo University, Cairo, Egypt and Royal Devon and Exeter NHS Foundation Trust, Exeter, United Kingdom.

Body: Background:
Oncoplastic surgery (OPS) has emerged as a new approach for extending breast conserving surgery (BCS) possibilities, reducing mastectomy and re-excision rates, while avoiding breast deformities. OPS integrates plastic surgery techniques for immediate reshaping after wide excision for breast cancer. This techniques is emerging and our experience in Egypt has been gradually increasing. Our aim was to extend the applicability of OPS into more advanced tumours following neoadjuvant chemotherapy.

Method:
A prospective feasibility cohort study of OPS after neoadjuvant chemotherapy was carried at the national Cancer institute – Cairo University and included 40 patients. We aimed to look at long term oncologic safety and cosmetic outcomes. The primary outcome was the local recurrence rate. Secondary outcomes included survival and margins obtained as well as cosmetic outcomes. Survival analysis was performed with Kaplan-Meir curves. Cosmetic outcomes were assessed using a modified Breast Q questionnaire (EORTC 10801).

Results:
40 patients were included in this study. All were diagnosed with locally advanced breast cancer between September 2012 and January 2015 at the National Cancer Institute – Cairo University. All were treated primarily with neoadjuvant chemotherapy (Anthracycline-based). The median age was 44.45 (Range 22- 65) years with median follow-up period of 42 (Range 24 – 60) months.

27.5% showed complete pathological response. 62.5% of patients had a level I OPS procedure, 10% had a level II procedure, and 27.5% had a volume replacement procedure with a Latissimus Dorsi flap.

The median resection margins with level I, level II, and volume replacement were 10 mm, 25 mm and 15 mm respectively. The difference in margins between level I and II was statistically significant (p = 0.028), so was the difference between the 3 types of procedures (p = 0.035).

Three patients (7.5%) had local recurrence and required mastectomy; at 11, 13 and 16 months respectively. One of those (2.5%) developed distant bone metastasis.

Cumulative disease-free survival (DFS) for the whole cohort was 90.2%. Overall survival (OS) was 100% as there was no mortality reported during the follow-up period. Cumulative disease-free survival for patients with level I surgery was 85.4% while for those with level II and volume replacement it was 100% with no statistically significant difference (p = 0.2) because of small number of events.

The cumulative disease-free survival when the median resection margin obtained was less than 20 mm was 86.3%, whereas when the median margin was equal or more than 20 mm, it was 100%. This difference was not statistically significant (p = 0.2).

The cosmetic outcomes ranged between excellent result (70%), very good (15%), good (10%) and poor results (5%) on a very simplified scale that was used for the purpose of the study.

Discussion:
Oncoplastic breast surgery didn't compromise oncologic safety in the patients included in the study. The local recurrence rate, the DFS and OS were all within acceptable ranges. It even allowed wider margins of resection which could be associated with better oncologic outcomes. At the same time, it gave a better cosmetic outcome and therefore higher patient satisfaction.
Title: Deep Infrared Imaging to identify venous impairment after breast cancer surgery

Body: INTRODUCTION
Breast cancer related lymphedema (BCRL) is commonly attributed to axillary lymph node dissection (ALND) and reduction of lymph flow. Impairment of the axillary vein seems to contribute also to BCRL, leading to a deep pitting edema of hand and forearm. When a patient with axillary vein impairment stands up, hand skin looks rapidly hyperaemic, due to a vasodilation of the capillaries. This vascular situation may result from removal of the fatty tissue containing lymph nodes, and disruption of the good emptying of the axillary vein. The orthostatic intermittent venous stenosis induces collateralizations which are derivative evidence of the axillary vein impairment. We highlight them using an original, cheap and easy procedure, based on a deep infrared imaging (DIRI) device.

MATERIAL AND METHODS
A total of 100 women were recruited, 50 BCRL patients and a control group composed of 50 healthy women. In all subjects, we performed visible light and DIRI pictures of the thorax, including neck, shoulders and upper arms. Images were mixed and screened by 3 blind operators. The operators screened for differences in thermograms, such as asymmetric and collateral trajectories.

RESULTS
The DIRI coupled with our reading grid seems to be specific and sensitive enough to identify BCRL patients with asymmetric collateralization of the axillary vein.

CONCLUSION
DIRI and its reading grid seems to be a useful tool in daily clinical practice to evaluate the hemodynamic changes of the axillary vein in BCRL patients. This evaluation gives us more insight in the (future) development and eventual treatment of BCRL.
Title: Early detection of secondary lymphedema after cancer treatments

Body: Introduction
The overall incidence of secondary lymphedema in oncological surgery is estimated at 15.5%. Most of filtrated fluid returns to circulation by the lymphatic system. Reducing the lymphatic capacity transport, lymph node dissection procedures shift the fluid balance exchange, leading, in a time-delayed manner, to the onset of a lymphedema. All patients undergoing an adenectomy are at the risk to develop a lymphedema. Complaints of heaviness, paresthesia or power loss in the ipsilateral arm are precursor signs of secondary lymphedema which are not enough considered to start a decongestive treatment. Currently, a lymphedema is diagnosed after it has clinically developed.

In order to start earlier decongestive treatment or preventive treatment, sensitive detecting tools can be helpful. Actually no instrument or method has demonstrated the capability to detect accurately pre-clinical signs of secondary lymphedema. Near infrared fluorescence lymphatic imaging (NIRFLI) could be the answer to this need.

Our experience based on almost thousand NIRFLI exams on healthy and lymphedema patients highlights that the superficial lymphatic system is completely different in healthy limbs compared to lymphedematous limbs. NIRFLI exams in oncological patients who are apparently free of secondary lymphedema, after surgery, present typical abnormalities of the lymphatic network. This study aims to confirm the possibility to detect secondary lymphedema at a subclinical stage. Detection may be performed using NIRFLI that allows realizing mapping of the superficial lymphatic network at different times after surgery in order to follow the patient at risk to develop secondary lymphedema.

Method
Breast cancer patients are recruited before surgery and after informed consent. They undergo NIRFLI exam before surgery, and 10 days, 3 months, 6 months, 1 year and 2 years after surgery. Images and videos are recorded and compared to the previous one in order to detect any change in the architecture of the superficial lymphatic system. Anamnesis, clinical examination of the operated area, precise volumetry and deep infrared imaging are performed at each session. The study started in January 2015, it was approved by the local ethical committee of the CHU St-Pierre – Université libre de Bruxelles (CE AK/13-12-119/4322Bis; EudraCT number: 2013-004237-32;NCT02415725).

Results
To date, 30 patients have been recruited. One patient presents changes in her NIRFLI, and presents also signs of lymphedema, one year after the treatment. The other patients do not show any changes in their NIRFLI, nor preclinical or clinical signs of lymphedema. No side effects consecutive to the NIRFLI exams were noted.

Conclusion
After almost thousand NIRFLI in lymphedema patients, we state that NIRFLI is a high resolution exam to visualise the architectural changes of the superficial lymphatic network. We observed in every lymphedema NIRFLI abnormalities and in every healthy subject normal NIRFLI patterns. When clinical context and subjective symptoms are present, even without clinical oedema, we always observed NIRFLI abnormalities. Because the onset of secondary lymphedema occurs with a delay after surgery (mean time 27 months), we expect to observe those changes in part of our recruited patient in the near future.

Title: Lipofilling of the axilla to reduce secondary lymphedema after axillary lymph node dissection

Body: Introduction
Upper limb lymphedema remains a frequent complication (3-60%) of axillary lymph node dissection (ALND) for breast cancer. Part of these lymphedema present lymphatic but also venous impairment. During surgery, adipose tissue surrounding the axillary vein is partially or completely removed and the axillary sheath can also be damaged. This anatomical disruption could reduce the local hemodynamic condition, with as a consequence an increased microvascular filtration at the distal part of the affected limb. Patients with a venous impairment after ALND present a pitting edema at the level of the hand and forearm and other clinical signs that allows us to identify them. In order to reduce their edema, we propose an original and simple surgical approach that could partially restore the axillary hemodynamic impairment.

Material and Methods
BCRL patients with positive clinical signs for axillary hemodynamic changes underwent lipofilling under the axilla vein. Patients remain without any treatment nor sleeves during 10 days after surgery. Precise volumetry was performed the day before, the day after and 10 days after surgery (CE AK/13-06-75/4276AD, EudraCT n° 2015-001565-37). After 10 days, patients restart previous physical treatment and we continued to evaluate limb volume by volumetry. Subjective symptoms as numbness, heavy arm, pain and tension of the skin were evaluated.

Results
48 BCRL patients underwent lipofilling surgery. Edema volume reduced significantly in the majority of patients. This reduction was already observed directly after surgery, and was maintained before restart of physical treatment. Subjective symptoms like heavy arm, numbness, and functional impairment of the upper limb in daily activities started to decrease directly after the operation. Most of the patients continued physical treatment, but felt that compression garments was not essential anymore to maintain edema at low level.

After 24 months of follow up, no complications were recorded.

Conclusion
In selected BCRL patients, lipofilling under the axillary vein improves local hemodynamic, reduces distal hyperfiltration and consecutively reduces part of the edema. Results of this pilot study need to be empowered by multicentric studies.
**Title:** International validation of the EORTC patient-reported outcome measure (PROM) in breast reconstruction (BRR): The EORTC QLQ-BRECON23 evaluating the psychometric properties and clinical effectiveness

**Body:** Introduction: PROMs are integral to assessing clinical effectiveness after BRR. The European Organization for Research and Treatment of Cancer (EORTC) BRR questionnaire (QLQ-BRR24) was developed for use alongside the EORTC PROMS: QLQ-C30 (cancer) and QLQ-BR23 (breast cancer).

Methods: Patients (n=438) from 28 centres across 9 countries covering 6 languages self-reported the: EORTC QLQ-C30, QLQ-BR23 and the QLQ-BRR24 before and after BRR including a debriefing questionnaire. Prospective patients (n=234) completed the QLQ-BRR24 at baseline (before mastectomy and BRR) and at 4-8 months post BRR (response to change analysis, RCA). Cross-sectional patients (n=204) were at 1-5 years after BRR evaluating long-term quality of life (QOL) effects and test-retest reliability through repeated completion of QLQ-BRR24 (2-8 weeks apart). Scale convergent validity was tested using Pearson's correlations. Hypothesis-testing and clinical interpretability used known-group comparisons evaluating effect size and minimally important clinical differences.

Results: Patient groups: implant alone (n=176), donor flap (n=166) and control (mastectomy or staged-delayed, n=96). Six HRQL scales: i) sexuality; ii) treatment side effects; iii) donor symptoms; iv) breast cosmetic; v) nipple cosmetic; vi) satisfaction with surgery and 4 stand-alone questions (well-fitting bra, loss or preserve nipple, satisfaction with donor scars) were psychometrically tested. 16.1% (70/434) of women reported confusing, difficult or upsetting items. These comprised sexuality, the 1-week time window, and “coming to terms with disease or treatment”. Five of the six QLQ-BRR24 multi-scales demonstrated good internal consistency (Cronbach's alpha: 0.76 - 0.93), except for treatment side-effects (arm tingling or fullness: Cronbach's alpha: 0.67). Test-retest reliability was good (intra-class correlations: 0.73 - 0.92). Low to moderate correlations (r <0.43) between the scales of QLQ-BRR24 and QLQ-C30 and QLQ-BR23 indicated different/distinct constructs of the QLQ-BRR24 complementing existing questionnaires. Breast cosmetic scale showed a large effect (Cohen's d=0.86, p<0.001) between DIEP and LD flaps, and moderately significant (p<0.05) effects for implant versus donor BRR, post-mastectomy radiotherapy and surgical complications. Most QLQ-BRR24 scales differentiated surgical complications. Sexuality and treatment side-effects showed small effect responsiveness. Well fitting bra was excluded based on weak EFA (<.3), floor/ceiling effects and counterintuitive differentiations within known group comparisons.

Conclusions: The internationally validated EORTC QLQ-BRECON23 evaluates effects of BRR in breast cancer patients, and complements the EORTC core breast cancer modules. Future studies should consider comparing it to the BREAST-Q, another questionnaire that assesses breast reconstruction outcomes.
Title: Post mastectomy breast reconstruction in elderly women: Complications and the impact of individual surgeons

Body: Purpose/Objective
In the United States over 40% of incident breast cancer diagnoses are in women over 65 years of age. Effective breast cancer treatments allow elderly patients to live long, healthy lives; questions regarding long-term quality of life are increasingly important. In women over 65, post-mastectomy breast reconstruction (PMBR) is uncommon with reported rates of 6-30%. The goal of this study is to report complication rates in elderly PMBR patients and to evaluate the impact of individual surgeons on PMBR in elderly patients.

Material/methods
We identified 19,417 Medicare beneficiaries diagnosed with localized breast cancer between 2005 and 2011 who underwent mastectomy. Medicare claims were used to identify PMBR, post-operative complications after PMBR (within 30 days of surgery), and long-term complications related to reconstruction (within three years following surgery). Mastectomy surgeon was identified from Medicare claims with surgeon characteristics identified through linkage to the American Medical Association (AMA) Masterfile.

Multi-level, multivariable logistic models clustered by surgeon and geographic area were used to determine the impact of surgeons on the likelihood of reconstruction. The intraclass correlation coefficient (ICC) and median odds ratio (MOR) were used to describe the relative impact of the individual surgeon. The ICC estimates the proportion of variability explained by the surgeon on PMBR rates. The MOR quantifies the likelihood of a patient having a different PMBR outcome if the patient were to change surgeons (or geographic area); it is directly comparable to odds ratios. Odds ratios (OR) were used to describe the impact of fixed demographic and clinical covariates.

Results
Among the entire cohort, 1,234 (6.4%) patients underwent PMBR. The post-operative complication rate was 8.4% and the long-term complication rate was 19.9%. Eighteen percent of the variability in PMBR use was attributed to the individual surgeon (ICC 0.181). The MOR for surgeon was found to be 1.85 (95% CI [1.70,1.99]), indicating that a patient had an 85% chance of having a different outcome (receiving or not receiving PMBR) if the patient saw a different mastectomy surgeon. The MOR for geographic area indicated that a patient had a 32% chance of having a different outcome if the patient saw a surgeon in a different geographic area (1.32, 95% CI [1.17, 1.47]). Patients who were Asian, single, older, of lower socioeconomic status, and underwent radiation therapy were less likely to undergo PMBR. Patients who had pre-operative MRI or received chemotherapy were more likely to undergo PMBR. Patients who were treated by female surgeons or plastic surgeons were significantly more likely to undergo PMBR. Overall, the individual surgeon was the most predictive of PMBR, except for the use of pre-operative MRI and mastectomy surgeon's specialty being plastic surgery.

Conclusion
A small minority of older women undergo PMBR despite having low post-operative and long-term complication rates. The individual surgeon and geographic area significantly influences whether older breast cancer patients will undergo PMBR. Future research should focus on surgeon characteristics that may influence a patient's decision to undergo PMBR.
Title: Does fat transfer increase the risk of breast cancer recurrence? A meta-analysis involving 2382 patients

Wazir U, Chehade HEH, Headon H, Oteifa M, Kasem A and Mokbel K. London Breast Institute, London, United Kingdom and Kuwait Cancer Control Centre, Al Sabah Medical District, Shuwaikh 70653, Kuwait.

Body: Introduction: Lipofilling is an increasingly popular technique for breast reconstruction following both mastectomy and breast conserving surgery. However, concerns remain over its oncological safety and its effect on cancer recurrence.

Methods: A systematic literature review and meta-analysis was carried out. Patients who had undergone mastectomy and patients who had undergone breast conserving surgery (BCS) were looked at separately in order to investigate whether the addition of lipofilling had a significant effect on locoregional recurrence rate.

Results: Eleven studies were used in the analysis yielding a total of 2382 patients. For patients undergoing mastectomy (mean follow up = 36.2 months: range=12-90) or BCS (mean follow up = 30.2 months: range = 12-60) , the addition of lipofilling was not found to significantly affect the locoregional recurrence rate.

Conclusion: This meta-analysis demonstrates that lipofilling is an oncologically safe procedure to be incorporated into breast reconstruction following either mastectomy or BCS for breast cancer. However a careful oncological follow up is recommended. In the future, more adequately- powered controlled clinical trials are needed in order to fully understand long term outcomes after lipofilling.
Title: Exclusive fat grafting breast reconstruction after mastectomy: Feasibility and complications on 54 patients

Body: Backgrounds: Autologous fat grafting has become a frequent, simply reproducible and low-risk technique in breast reconstruction. The potential risk of fat tissue transfer to the breast in oncologic patients remains to be discussed, but one must clearly distinguish the situation where there is a breast parenchyma left and where the whole gland has been removed, like in our study. Although lipotransfer has become very popular, only a limited number of case series have been reported up to date. The presented study describes an optimized treatment and complications for breast reconstruction after total mastectomy by lipotransfer alone.

Patients and methods: A retrospective study was performed in two French centers with five surgeons between February 2011 and June 2015, including 54 patients. Inclusion criteria were patients with prior breast cancer, treated by mastectomy and with a finished breast reconstruction with exclusive fat grafting. Exclusion criteria were prior reconstruction with implant or flap. We used two technics for liposuction: manual aspiration with syringes (pouret kit®) or waterjet assisted liposuction (body-jet®). The BRAVA® could be combined with the reconstruction. Our study had 2 main objectives: evaluate the factors influencing the number of surgical procedures and study the complications and carcinologic evolution. Statistical analysis was performed using stata 13.1 SE.

Results: We included 54 patients, 49 delayed reconstructions including two bilateral reconstructions and 5 immediate reconstructions. The morphologic data showed: a normal BMI for 70.3 % (38/54) patients and a bra cup A or B for 72.2 % (39/54). 39 patients had radiotherapy during the cancer treatment and the mean time between radiotherapy and reconstruction was 19 months. For the patients without radiotherapy, the mean time between mastectomy and reconstruction was 22 months. 6 patients (11%) were smoker or diabetic. We used manual aspiration in 37 patients (68.5 %) and hydro dissection in 17 patients (31.5%). 10 patients received BRAVA system in complement. We performed 231 fat grafting procedures with an average of 4.2 per patient. The mean total quantity of fat injected was 904 ml per patient with a mean quantity per procedure of 219 ml. The mean time between two procedures was 4.3 months. Only the prior radiotherapy treatment increases the number of procedures significantly (p=0.02) and the use of hydro dissection with bodyjet decreases the number of fat grafting procedures significantly (p=0.04). We observed one failure of procedure requiring an implant and three patients with metastatic disease without local recurrence with a mean follow of 5, 2 years. We also observed 3% of infectious complications (7/231) and 19 patients presented fat necrosis (34%). Of these 19 cases of fat necrosis, 6 (11 %) required a surgery.

Conclusion: Autologous fat grafting can be proposed as an alternative for total reconstruction after mastectomy with a low level of complications and no local recurrence in our study. Only anterior radiotherapy increases the number of procedures probably due to fibrosis and lack of cutaneous flexibility.
Title: Long term risk of explantation with Strattice™ assisted breast reconstruction, is it any different to submuscular reconstruction?

Wilson RL L, Kirwan CC C, Johnson RK K and Harvey JR R. University Hospital of South Manchester, Manchester, United Kingdom and University of Manchester, Manchester, United Kingdom.

Introduction

The most recent meta-analysis published, containing only studies from 2011 onwards, reports acellular dermal matrix (ADM) assisted breast reconstructions are associated with a significant increase in risk of infection, seroma and mastectomy flap necrosis but not implant loss when compared to submuscular reconstructions. We hypothesised that implant loss associated with ADM-assisted reconstruction did not exclusively occur within the first 30 days after surgery and studies with short-term follow-up may underestimate the risk. We aimed to determine with long-term follow-up at what time point explantation occurs after Strattice™ ADM-assisted reconstruction and if it differs from traditional submuscular implant based reconstruction.

Methods

A retrospective case note review was completed for all immediate implant based reconstructions performed between 1st January 2009 and 31st December 2015 in a single tertiary centre in England. Implant losses, the timings and causes of loss were determined.

Results

In total there were 510 immediate implant based reconstructions performed in 373 patients, of which 135 were submuscular and 375 ADM-assisted.

In the ADM group a total of 22 (5.9%) implants were lost as a complication of their primary surgery. 14 implants were lost due to infection and eight due to wound breakdown. Implants were lost over a range of 14-661 days, median 76 days. Implant loss occurred within 30 days in six (27%), <90 days in 13 (59%) and over 90 days in nine breasts (41%). There were seven unplanned explantations, six were changed to autologous reconstructions (three for cosmetic reasons and three as a result of radiotherapy damage); one patient had a completion mastectomy for recurrent cancer.

In the submuscular group a total of 11 (8.1%) implants were lost as a complication of their primary surgery. Six implants were lost due to infection and five due to wound breakdown. Implants were lost over a range of 12-274 days, median 49 days. Implant loss occurred within 30 days in four (36%), <90 days in seven (64%) and over 90 days in nine breasts (36%). There were a further six unplanned explantations, two for pain and four for cosmetic reasons.

Comparing the two groups there were no differences in total implant loss rate or time to implant loss.

Conclusions

Implant loss within the first 3 months of ADM-assisted breast reconstruction is 3.5%; however, implant loss can occur more than 90 days after ADM-assisted breast reconstruction. Patients and clinicians should be aware that the risk of explantation continues for up to two years post-operatively with an ADM-assisted reconstruction whereas with submuscular coverage there were no implant losses beyond nine months follow-up. There were no differences in explantation rates between submuscular and ADM-assisted breast reconstructions.
Title: A single-center report of 125 cases of incidental internal mammary lymph node biopsy in free abdominal flap breast reconstruction

Quan C, Huang N, Yang B, Zhang Y, Huang X, Chen J and Wu J. Fudan University Shanghai Cancer Center, Shanghai, China and Shanghai Shanghai Medical College, Shanghai, China.

Body: Objective
The aim of the current study is to determine the clinical value of incidental internal mammary lymph node biopsy in free abdominal flap breast reconstruction using internal mammary as recipient vessels and to investigate the risk factors of internal mammary lymph nodes metastasis.

Methods
The clinical data of all free abdominal flap breast reconstructions using internal mammary as recipient vessels performed from November 2006 to April 2016 in Department of Breast Surgery, Fudan University Shanghai Cancer Center were included into the study. The incidence of internal mammary lymph node biopsy and the rate of metastasis were described. The differences between groups were compared using $\chi^2$ test. Univariate and multivariate Logistic regression analysis was conducted to evaluate risk factors of internal mammary lymph node metastasis.

Results
A total of 125 patients met the inclusion criteria, 89 (71.2%) of whom adopted unilateral immediate breast reconstructions. 64.8% of them were diagnosed with primary invasive breast cancer, while 27.2% were carcinoma in situ. According to AJCC TNM staging system, the percentages of patients with stage 0, I, II, III were 27.2%, 26.4%, 27.2% and 8.0%.

62 (49.6%) patients had internal mammary lymph nodes harvested. 6.4% (4/62) of those who adopted internal mammary lymph nodes biopsies were diagnosed with internal mammary lymph nodes metastasis, all in immediate breast reconstructions. 72 (57.6%) patients cut off costicartilage (the second or third costicartilage) during the exposure of internal mammary vessels. The excision of costicartilage is not associated with the harvest rate of internal mammary lymph node ($P>0.05$). All of the 4 patients upstaged their TMN stage of tumor after internal mammary lymph node metastasis and adopted adjuvant chemotherapy and radiotherapy. Up to May 2016, no recurrence or distant metastasis was reported.

In Logistic regression analysis, larger invasive tumor size and axillary lymph node metastasis were found to have correlations with internal mammary lymph node metastasis (larger invasive tumor size: $P=0.029$; axillary lymph node metastasis: $P=0.004$), while tumor location or immunohistochemical subtype had no correlations. In addition, axillary lymph node metastasis was proved to be a independent risk factor of internal mammary lymph node metastasis ($P=0.036$) while tumor size was not.

Conclusions
Internal mammary lymph nodes found incidentally during internal mammary recipient vessel exposure for free flap breast reconstruction could provide surgeons with important information for further treatment. This approach for internal mammary lymph node biopsy revealed an appreciable success rate and should be promoted in clinical practice. The size of invasive tumor and the axillary lymph node metastasis were associated with internal mammary lymph node metastasis.
Title: Neoadjuvant radiotherapy in mastectomy and immediate autologous free flap reconstruction. Findings from the primary radiotherapy and DIEP flap (PRADA) pilot study

Thiruchelvam P, Hadjiminas D, Cleator S, Wood S, Leff D, Jallali N, James S and MacNeill F. Imperial College School of Medicine, London, United Kingdom and The Royal Marsden Hospital, London, United Kingdom.

Body: Background:
The need for post mastectomy radiotherapy (PMRT), may preclude reconstructive surgeons from offering patients immediate, autologous reconstruction. This is due to historical evidence suggesting high rates of short- and long-term complications as well as poorer aesthetic outcomes. As the indications for PMRT broaden this practice denies an ever-increasing number of women the benefit of an immediate reconstruction.

Aim:
This pilot study evaluates the safety of offering radiotherapy prior to mastectomy and immediate DIEP flap reconstruction.

Methods:
Women planned for neoadjuvant chemotherapy (NAcT), mastectomy (following unsuccessful breast conservation surgery (BCS) or upfront selection) and PMRT were offered a change in sequencing of RT at two academic breast surgery units in London, UK. Data was prospectively captured on 19 women, including: patient demographics, treatment details, tumour characteristics, oncological and post-operative outcomes. Operative parameters included unplanned return to theatre [RTT] <30 days, mastectomy skin flap necrosis, and evidence of wound infection at 5 days, 4 and 12 weeks post-operatively. All mastectomies, were performed by one of 3 breast surgeons (DH, FAM, DRL) using a circumareolar incisions with one patient undergoing a vertical pattern incision for skin reduction.

Results:
The cohort demonstrated a broad range of age, body mass index (BMI) and mastectomy weight [mean (range): age=46 years (28-72); BMI = 28.4 kg/m^2 (23-37.6) and specimen weight=678gm (257-1040)]. The mean time from completion of NAcT to neoadjuvant radiotherapy (NART) was 31.1 days (9-49 days), and time from completion of NART to mastectomy and DIEP was 17.8 days (13-24 days). There was one unplanned RTT at 72 hours for an evacuation of haematoma, 1 revision of micro-vascular anastomosis, 1 clinical fat necrosis requiring formal excision and 1 wound debridement and primary closure for poor wound healing (vertical pattern skin reduction). There were no flap failures and no mastectomy envelope necrosis. With a mean follow-up of 16.2 months, there were no loco-regional recurrences, 5 distant relapses with mean presentation at 13.7 months and 2 breast-cancer related deaths at 13.9 and 22.2months respectively.

Conclusion:
This pilot study suggests that mastectomy and DIEP reconstruction is surgically feasible within 4 weeks of completing NART. In this small cohort of oncologically high-risk women with altered sequencing of RT we did not observe flap failure or post-mastectomy skin flap necrosis. A larger multicentre study with aesthetic assessment, PROMS and translational aspects is planned.
Immediate breast reconstruction is highly accepted by breast cancer patients undergoing mastectomy when routinely offered- Recent experience of an Australian tertiary oncoplastic breast unit

Cheung DSM SM, Trinh L, Edirimanne S and Eslick G. Nepean Hospital, Sydney, Australia and University of Sydney, Sydney, Australia.

Body: Introduction:
Despite recommendations by breast cancer guidelines, that immediate breast reconstruction (IBR) should be offered to all breast cancer patients considered for mastectomy national IBR rates have been reported as low as 12% in Australia. We report our oncoplastic breast cancer unit experience on acceptance of IBR, where it is routinely offered for all the medical fit breast cancer patients.

Methods:
We retrospectively reviewed, prospectively collected data on IBR by 3 oncoplastic breast cancer surgeons from 1st of September 2014 to 31st of March 2016. Patients were considered to be unfit for IBR if they were American Society of Anesthesiologist (ASA) Score 4 or 5, have unstable psychiatric illness, inflammatory breast cancer or high metastatic cancer burden. All the patients who were fit for IBR were offered both prosthetic and autologous IBR options.

Results:
137 patients underwent mastectomy operation, of whom 27 were considered unfit for IBR. Of the remaining 110 patients, 84 (76%) accepted IBR. Of the patients who had IBR 64 (76%) had single stage prosthetic, 15 (18%) two stage prosthetic and 5 (6%) autologous reconstructions. Those who accepted IBR were younger compared to those who didn't have IBR (median age: 47 yrs vs. 67 yrs, p<0.001), and were more likely to be in current relationship (78.57% vs. 61.54%, p=0.06). All the three surgeons had high IBR acceptance rates (70.45%, 71.43%, 84.44%) and patient insurance status did not influence IBR acceptance rate (public 57% vs. private 65%, p=0.47). The majority of patients (25 of 26) who did not accept IBR stated that breast reconstruction was not important for their body image.

Conclusion:
Our recent data shows, in Australia, when routinely offered to breast cancer patients who are fit for reconstructive surgery by oncoplastic breast cancer surgeons, IBR is highly accepted. Younger patients and those who are in current relationship, were more likely to accept IBR, whereas, individual perception of insignificance of breast reconstruction for the body image was the main determinant of not accepting IBR.
Title: Quality of life assessed by BREAST-Q in patients with delayed immediate tissue expander based breast reconstruction with and without radiotherapy

Hamann M, Brunnbauer M, Scheithauer H, Hamann U, Pölcher M and Braun M. Red Cross Hospital Munich, Munich, Germany and LMU Munich, Munich, Germany.

Body: Introduction
Radiotherapy of the breast is known for having a negative impact on implant based breast reconstruction. Technical improvements, such as expander-implant based delayed immediate reconstruction (EIBR), seem to produce better results. The purpose of this study was to analyze the effects of prior radiotherapy (RT) and postmastectomy radiotherapy (PMRT) on patient-reported quality of life (QoL) in patients with EIBR compared to patients that underwent EIBR without any RT.

Material and methods
After a retrospective chart review, all patients with a history of EIBR at the Red Cross Hospital Munich were invited for a structured physical examination and interview. All operations were performed between 2008 and 2012 by two surgeons (H.U. and B.M.). To assess QoL, the BREAST-Q - post reconstruction module was used and results were compared between the following three cohorts: 1. patients without RT (n=65), 2. patients with PMRT (n= 27) and 3. patients with a history of breast irradiation before mastectomy (n=16). Patients with prior RT and a PMRT after local relapse were excluded.

Results
Of 161 patients eligible, 94 patients followed the invitation, 14 of them with bilateral EIBR. Baseline characteristics between participating and non-participating patients were comparable. The median follow-up time was 18.1 months. Most of the baseline characteristics (e.g. tobacco use, diabetes) were comparable between the cohorts. Application of (neo-) adjuvant chemotherapy was significantly more frequent in cohort 2. The category Satisfaction with the breast was numerically but not significantly better in cohort 1 than in cohort 2 (p 0.078) whereas the psychosocial well-being showed a trend in favor of cohort 2 (p 0.058). Satisfaction with breast was significantly better in cohort 1 than 3 (p 0.014) as well as Satisfaction with breast (implant only) (p=0.007). There was no difference for Satisfaction with outcome (p=0.666). Cohort 2 reached more points in all categories than cohort 3 although this difference was not significant. Of all patients, 92.7 %, 84.6 % and 78.6% (cohorts 1, 2 and 3) would undergo the operation again.

Conclusion
After short follow-up time, EIBR seems to be a feasible method for breast reconstruction resulting in a high QoL, even if PMRT is required. In patients with a prior RT, QoL is worse compared to the other groups. However, patients’ acceptance of EIBR is still high. Prospective studies and long-term follow-up are required for definitive conclusions.
Title: Shared decision-making approach in breast reconstruction in a developing country

Body: Background
In Mexico breast cancer is the leading cause of cancer mortality in women. The goal of reconstruction is restoration of patient's quality of life after cancer, including concerns about body image, sexuality, self-esteem and social life. Reconstruction is one of the most important determinants of long-term health. Autologous reconstruction has been found to offer a better satisfaction in the long term, even these findings, a paradigm shift toward implant reconstruction has been described previously. Shared decision making (SDM) is a collaborative process that allows patients and their providers to make health care decisions together. It takes into account the best clinical evidence available, as well as the patient's values and preferences. In medical treatments where several options have been found, SDM has been a useful tool, increasing patient's satisfaction and better outcomes. Through this process of informing and involving the patient, high-quality decisions that align with patient preferences are achievable.

Methods
Evaluation of particular case was made, with personalized approach depending on breast cancer stage and mastectomy type planned. On first consultation basic information about different techniques was offered: pros and cons on surgical time, recovery time, long term complications, sensation and physical appearance. We offered a second consultation if the patient wanted to go deeper in the information we presented, or even is she wanted to look out for more information on the internet and other sources. When an abdominal free flap was planned, we saw the patient in a second consultation to review the CT-angio, and to establish the definitive flap option.

For risk estimation we used www.brascore.org website, and talk about it with the patient. Then patient and plastic surgeon made decision on breast reconstruction technique. BREAST-Q questionnaires were applied in pre and postoperative setting.

Results
From 06/2014 to 06/2016 we performed 150 breast reconstructions with this SDM approach with the following techniques: 64% expander, 15% direct to implant, 11% DIEP flap, 6% latissimus dorsi flap, 3% Becker implant, 1% TRAM flap.

BREAST-Q questionnaires showed 100% think breast reconstruction is better than do not reconstruct, and 100% would recommend reconstructive surgery. 91.7% felt included in the decision process. Satisfaction with breast (preoperative vs postoperative) 66.21 vs 81.13, Satisfaction with outcome 85.06, Psychosocial well being 80.75 vs 88.35, Physical well-being 74.92 vs 68.73, Sexual well-being 66.66 vs 72.84, Satisfaction with information 86.86, Satisfaction with surgeon 98.73, Satisfaction with medical staff 96.2.

Analysis
Implant based reconstruction (82%) was prefered due to: simplicity, less overall risk, and giving more importance to cancer treatment and leaving reconstruction in second place. It could also be a short-term vision regarding benefits, in spite of shared information.

Aesthetic improvement of the abdominal area seems to be a factor to decide for autologous abdominal flap among young adult women (7%).

Possibility of pregnancy should be considered among young women. In our breast reconstruction program for young women with breast cancer, egg preservation is offered, so abdominal flaps should be delayed after a possible pregnancy.

Conclusions
We need to encourage SDM in breast reconstruction. We need information systems available to patients prior to breast reconstruction like educational meetings, giving healthcare professionals feedback, giving healthcare professionals learning materials, and using patient decision aids.

Shared decisions leads to better outcomes and high patient's satisfaction in breast reconstruction.
Risk factors affecting post-operative complication after immediate reconstruction with implant for operable breast cancer patients

Park SJ, Choi JH, Lee MH, Jung S-Y and Lee ES. Center for Breast Cancer, Research Institute and Hospital, National Cancer Center, Goyang, Gyeonggi, Republic of Korea.

Body: Purpose:
Immediate breast reconstruction (IBR) with implant after nipple-areola complex (NAC) sparing mastectomy is an increasing treatment for breast cancer patients. Old age, obesity, smoking history, large volume of implant and adjuvant oncologic therapies have been known as risk factors for post-operative complication after IBR. However, less is known about the risk factors after IBR with implant in Asian women with relatively low body mass index (BMI), small volume of breast and less history of smoking. We analyzed the risk factors for post-operative complications after IBR with implant in patients receiving NAC sparing mastectomy.

Methods:
We investigated a prospectively maintained database from 2012 to 2015 at National Cancer Center. A total of 278 breast reconstructions (230 unilateral, 24 bilateral) in 254 patients were performed by a single surgeon; 99.3% (276 of 278 breasts) were oncologic, and 0.7% (2 of 278 breasts) were prophylactic mastectomy. For each patient, we collected data on age, BMI, history of smoking and diabetes mellitus, volume of implant, adjuvant oncologic therapies, distances from tumor to nipple and skin, imprecise magnetic resonance image (MRI) finding (no discernible enhancing, non-mass enhancement, and multifocal tumor), and use of acellular dermal matrix (ADM).

Results:
Mean age was 44.8±7.6 years and mean BMI was 22.5±2.9 kg/m². Patients with smoking history was 4.3% (n=11). Mean implant size was 242.3±57.7mL. Patients underwent chemotherapy in 39% (n=99) and radiotherapy in 29.1% (n=74). Compared to western studies, our patients showed lower BMI, less history of smoking, and smaller size of implant insertion. Overall post-operative complication rate was 8.3% (n=23) and the complication rate was similar to the results of western studies; which included wound dehiscence (4.3%, n=12), infection (2.9%, n=8), and implant loss (2.9%, n=8). The use of ADM was independently associated with post-operative complications (30.0% in patients used ADM vs 6.6% in patients without ADM, respectively; OR, 6.016, 95% CI, 2.018-17.939; p=0.001). Other factors were not significantly related to post-operative complications.

Conclusions:
Our study is the largest study to investigate the risk factors for post-operative complications after IBR with implant in Asian countries. Compared to western studies, the patients had lower BMI, less history of smoking and smaller size of implant. Although known risk factors, such as smoking, obesity and size of implant, were not significantly associated with post-operative complication in our study, the incidence of post-operative complication was similar to that of western studies. These results might be caused by higher post-operative complication rate after use of ADM compared with western studies. Further study is warranted to evaluate the impact of ADM on post-operative complication on Asian countries.
Oncologic outcomes of immediate breast reconstruction after neoadjuvant chemotherapy in breast cancer patients: A matched case control study

Introduction: Although the indication for total mastectomy (TM) with immediate breast reconstruction (IBR) has been expanded, IBR after neoadjuvant chemotherapy (NACT) is still controversy. We assumed that TM with IBR after NACT is feasible surgical treatment in breast cancer patients. Methods: A retrospective review of breast cancer patients who underwent TM with IBR after NACT between 2008 and 2015 at a single center was conducted. These cases were matched by 1:5 to patients who underwent mastectomy alone after NACT. Matching variables included age, clinical T and N staging before NACT, response to NACT, and pathologic staging after NACT. Pathological stage was followed by seventh American Joint Committee on Cancer (AJCC) classification. Results: Overall, 31 patients were identified in the TM with IBR group (Study group) and 85 patients (Control group) were matched. In the study group, 13 (41.9%) patients underwent nipple-sparing mastectomy (NSM) and 18 (58.1%) underwent skin-sparing mastectomy (SSM). Median follow-up duration was 29.2 (7-31) and 38.8 (11-85) months for the study and control group, respectively. Median age was 37.0 (26-57) and 40.0 (24-56) years for the study and control group, respectively. The clinicopathologic characteristics of both groups are summarized in Table1.

Disease-free survival ($p=0.520$), local recurrence-free survival ($p=0.610$), distant metastasis-free survival ($p=0.795$), and over survival ($p=0.971$) did not differ significantly between two groups. **Conclusion:** TM with IBR after NACT is feasible surgical treatment option in breast cancer patients.
Title: Total mastectomy and immediate breast reconstruction for breast cancer: A ten-year Canadian single institution experience

Body: Fear of high local recurrence rate associated with immediate breast reconstruction (IBR) following total mastectomy for breast cancer might be a contributing factor to the low rate of immediate reconstruction performed in Quebec. The aim of this study was to demonstrate the oncological safety of total mastectomy with immediate breast reconstruction.

A retrospective chart review of all patients who underwent total mastectomy with immediate breast reconstruction at the University of Montreal Hospital Center between 2006 and 2015 was performed. 375 patients (420 cases) met the inclusion criteria. The mean age was 51.5 years (25-77). The median follow-up was 45.6 months (0.4-115.2). Clinical cancer staging was done according to the American Joint Committee on Cancer (AJCC) criteria. 349 cases (83.1%) were classified as Stage < cIIb and 71 cases (16.9%) as ≥ cIIb. 73 patients (19.5%) received neoadjuvant chemotherapy, 113 (30.1%) received adjuvant chemotherapy and 91 (21.7%) received postoperative radiotherapy. Only 4 patients (3.5%) had a significant delay in receiving adjuvant chemotherapy and 4 patients (4.4%) had a delay in initiation of radiotherapy. In total, there were 12 (2.6%) local recurrences and 29 (7.7%) distant recurrences.

The results of this study demonstrate a low rate of local recurrence that is comparable to the current literature. Total mastectomy in association with immediate breast reconstruction is therefore an oncologically safe approach for the treatment of breast cancer and should be more widely adopted by medical centers throughout Quebec.
Body: Introduction:
The harvest of the latissimus dorsi muscle for the realization of immediate breast reconstruction induces a large dorsal scar measuring up to 20 centimeters, while only the muscle is used. We present here the results of our experience of endoscopic harvesting of the latissimus dorsi muscle using 3D technology. Our main objective is to reduce the dorsal scar and second assess the functional consequences for patients.

Methods:
Between December 1st, 2015, and June 1st, 2016, there were 7 patients who underwent latissimus dorsi endoscopic harvesting, with 3D technology, for an immediate breast reconstruction after a skin-sparing or nipple sparing mastectomy.

Results:
4 patients had latissimus dorsi muscle with breast implant and 3 patients by latissimus dorsi muscle only. The age average was 55 years (range 45-70). The mean length of surgery was 250 minutes (range 150-380). The mean length of hospitalization was 7 days (range 4-12 days). One patient treated for local recurrence had skin necrosis because of previous radiotherapy. Donor site seroma was the main post surgery drawback. Patients on average benefited from 3 evacuations (range 1-5) of 850ml (range 640-1270ml). Acceptance of the reconstructed breast was good in six cases, and poor in one case. Only one patient reported discomfort at the donor site 1 month after surgery.

Conclusion:
The endoscopic 3D latissimus dorsi flap harvesting allows to reduce donor site scar. There is no significant difference concerning complications or post-operative pain and functional discomfort between the endoscopic and classic harvesting procedure.
Title: Prognostic significance of CD8+ tumor-infiltrating lymphocytes (TILs), CD4+ TILs and TILs in male breast cancer

Body: Background
Several studies have demonstrated that the presence and the amount of tumor-infiltrating lymphocytes (TILs) are a potential biomarker of prognostic significance in some solid tumors. Data suggests that high levels of TILs are associated with favorable prognosis. However, whether TILs have any indication for prognosis in male breast cancer (MBC) patients remains unknown. In this study, we investigated the relationship between the expression and degree of CD8+ TILs, CD4+ TILs, and TILs and evaluated the prognostic value of these three factors in MBC.

Methods
We retrospectively identified 110 male breast cancer patients diagnosed between 2000 and 2013 at Salah Azaïz Cancer Institute. Stromal (str) CD8+ and CD4+ TILs were evaluated immunohistochemically. Two pathologists independently evaluated TILs levels using H&E stained slides following 2014 International TILs Working Group guidelines. Kaplan Meier and univariate and multivariate Cox regression analysis were applied to determine the association of CD8+ TILs, CD4+ TILs and TILs with clinicopathological features and overall survival (OS).

Results
The median for presence of str-CD8+TILs was 7% (0%-40%), str-CD4+TILs was 2% (0%-20%) and str-TILs was 10% (1%-40%). Only 12% of MBC patients had high str-CD8+TILs and 11% had high str-CD4+TILs. Fifty three percent had low str-TILs and 47% had moderate str-TILs. No lymphocyte predominant breast cancer was identified. Regarding intrinsic molecular subtypes, TNBC subtype and HER2 enriched tumors compared with Hormone receptor positive tumors had higher median levels of str-CD8+TILs, str-CD4+ TILs and str-TILs at diagnosis. However, increased level of str-CD8+ TILs, str-CD4+TILs and str-TILs weren't associated with improved OS in IHC subtypes (p=0.597, p=0.498 and p=0.456 respectively). On univariate analysis, higher levels of str-CD8+TILs, str-CD4+ TILs and str-TILs were associated with better OS (p=0.035, p=0.043 and p=0.040 respectively). Multivariate analysis identified str-CD8+ TILs and str-TILs as independent prognostic factors for OS ([HR= 0.851 (0.706-0.997), p=0.000] and [HR= 0.69 (0.43-0.96), p=0.045] respectively) but not str-CD4+ TILs (p=0.276). A high level of str-TILs was correlated with high str-CD8+ (p = 0.025).

Conclusion
The level of TILs in male breast cancer is low, suggesting prominent immune regulation/suppression in this disease. Str-CD8+ T cells and str-TILs represent potential prognostic markers in male breast cancer patients.
**Title:** Immune characterization of inflammatory breast cancer and correlation to pathological complete response

**Body: Background:**
Treatment of inflammatory breast cancer (IBC) includes neoadjuvant chemotherapy (NAC) followed by mastectomy and radiation. Responses are limited however with low pathological complete response (pCR) rates and poor survival. Recent RNA expression studies suggest that activated T cell signaling pathways and immunomodulatory markers such as PD-L1 are associated with a higher pCR rate in IBC; however comprehensive studies of tumor infiltrating lymphocytes (TIL) and protein expression of immunomodulatory molecules are lacking. There is a critical need therefore to study molecular and immune determinants of therapeutic response in IBC, with the goal of identifying biomarkers and actionable strategies to improve treatment outcomes.

**Methods:**
Baseline core biopsies from 36 IBC patients, 22 with stage III and 14 with stage IV disease were evaluated. Of these, 21 stage III and 10 stage IV patients underwent mastectomy following NAC, the latter for palliative purposes. Tumor subtype distribution was 14 patients with HER2-/HR-, 6 with HER2+/HR-, 11 with HER2-/HR+, and 5 with HER2+/HR+ disease. TIL infiltration in the tumor stroma was quantified on H&E slides based on consensus guidelines as well as by immunohistochemistry (IHC) staining for CD8. PD-L1 expression in the TIL and invasive tumor was evaluated by IHC in tumors with >1%TIL.

**Results:**
Stromal TIL were found in the invasive tumor on pretreatment biopsies in 26 (72%) patients, with TIL percentages ranging from 1% to 60% (mean=11.6; sd=13.8); of note, 1 patient biopsy sample only had tumor emboli on the tissue block and therefore was not evaluable. Higher TIL infiltrate was noted in stage III versus stage IV disease (mean TIL 11.6% versus 3.5%, p=0.028). Mean TIL infiltrate was 11.5% in HER2-/HR-, 10.0% in HER2+/HR-, 10.4% in HER2+/HR+, and 3.6% in HER2-/HR+ tumors (p=NS). At mastectomy, 7/21 stage III patients and 1/10 stage IV patients achieved a pCR. Mean TIL was 13.4% in the pCR group versus 8.2% in the non-pCR group (p=0.37) CD8 and PD-L1 staining was performed on samples with >1%TIL (n=15, of which 14 samples were available for additional staining). An average of 42% of TIL stained positive for CD8 (range 10-80%). There was no significant relationship between %CD8 and pCR, stage, or receptor status. None of these 14 patients demonstrated membranous PD-L1 positivity but all had focal weak cytoplasmic staining in the lymphocytes.

**Conclusions:**
Differences exist in the presence of stromal TIL in distinct groups within IBC (stage III versus stage IV disease and across histologic subtypes) and may contribute to differential responses to therapy. When comparing these results to published non-IBC literature (FinHER trial), our IBC patient cohort had lower TIL infiltrate in several histologic subtypes (HER2-/HR- 11.5% vs 25%, p=0.015), HER2+/HR-(10% vs 20%, p=0.10), and HER-/HR+ disease (3.6 vs 7.5%, p=0.01); TIL was comparable for HER2+/HR+ disease. Additional studies are underway (including multiplex analysis of myeloid and lymphoid markers, T cell receptor sequencing, and molecular profiling) in pre-treatment and surgical samples to better understand mechanisms of treatment response and resistance.

Title: Nanotheranostics using plasmonic gold nanostars to target inflammatory breast cancer cells and tumor emboli

Shammas RL L, Fales AM M, Crawford BM M, Hollenbeck ST T, Vo-Dinh T and Devi GR R. Duke University School of Medicine, Durham, NC; Duke University, Durham, NC; Duke, Durham, NC and Duke, Durham, NC.

Body: Introduction: Due to the aggressive nature of inflammatory breast cancer (IBC) and insensitive imaging techniques, patients diagnosed with IBC have a poor prognosis. IBC's unique ability to form emboli leads to rapid growth and distant invasion. New therapies aimed at disrupting the formation of tumor emboli are needed. Gold nanostars (GNS) are unique nanoparticles that can be imaged in real time with high sensitivity, and are rapidly endocytosed into cancer cells. Due to their sharp spikes, GNS exhibit plasmonic properties, which strongly enhance the electromagnetic field upon laser excitation. In addition to their use as highly intense and stable fluorescent labels, these nanoparticles can be photothermally activated to trigger cellular ablation. The use of GNS as an imaging and therapeutic modality for IBC should be investigated.

Methods: IBC (SUM-149/SUM190), non-IBC (BT474M1/MD-MBA-231), and drug resistant isotype variant (rSUM-149) cell lines were incubated with GNS, stained with Hoechst33342, and imaged with multiphoton microscopy (MPM). The dose and time dependent effects of GNS on SUM-149 proliferation was assessed with MTT assays. Photothermal treatment was performed on GNS-labeled IBC, non-IBC, and drug resistant cancer cell lines. The effects of photothermal therapy on cell viability were assessed using fluorescein diacetate and propidium iodide. Using a tumor emboli model, SUM-149, rSUM-149, and SUM-190 tumor emboli were labeled with GNS on the 3rd day of embolic maturation. Emboli were sectioned, stained with H/E, and imaged with MPM to demonstrate the depth of GNS penetrance. The potential for photothermal ablation of the GNS-labeled tumor emboli was assessed using various laser intensities. Propidium iodide was used to examine emboli viability following treatment.

Results: In all cell lines, GNS displayed rapid cellular uptake without nuclear involvement. MTT assay showed that GNS concentrations of 0.15 and 0.20 nM caused decreases in cell proliferation at 6 and 12 hours. Proliferative capacity was unaltered at 24 hours for all concentrations, however this may be due to spectrophotometric interference with high intracellular GNS concentrations. Live/dead staining confirmed effective photothermal treatment in all cultures with a clear zone of cellular death. For tumor emboli studies, GNS allowed bright fluorescent monitoring of tumor emboli using MPM, and cross sectional imaging demonstrated GNS penetrance into the embolic core. Photothermal ablation of GNS-labeled tumor emboli was successfully demonstrated following laser irradiation. Cell death was confirmed with propidium iodide.

Conclusion: Gold nanostars provide a highly fluorescent intracellular label for cancer cell lines, and tumor emboli without significantly altering cell proliferation. Furthermore, the inherent optical properties of the GNS allows for a combined therapeutic application following photoactivation. This is the first study to demonstrate the nanothernostic application of GNS in IBC tumor emboli. Prior studies have shown the effectiveness of photothermal ablation in in vivo sarcoma models; we are currently extending our studies to an IBC mouse model.

Title: Long-term rates of breast preservation after breast-conserving therapy for ductal carcinoma in situ

Rakovitch E, Nofech-Mozes S, Hanna W, Gu S, Fong C, Tuck A, Sengupta S, Elavathil L, Jani P, Done S, Miller N, Youngson B, Bonin M, Chang M and Paszat L. Sunnybrook Health Sciences Centre, University of Toronto, Toronto, ON, Canada; Institute for Clinical Evaluative Sciences, Toronto, ON, Canada; Kingston General Hospital, Kingston, ON, Canada; University Health Network, Toronto, ON, Canada; Thunder Bay Regional Health Sciences Centre, Thunder Bay, ON, Canada; Henderson General Hospital, Hamilton, ON, Canada; Sudbury Regional Hospital, Sudbury, ON, Canada; London Health Sciences Centre, London, ON, Canada and Mount Sinai Hospital, Toronto, ON, Canada.

Body: Background: Despite evidence that radiotherapy (RT) after breast-conserving surgery (BCS) for ductal carcinoma in situ (DCIS) halves the risk of recurrence, the benefit of RT in the management of DCIS continues to be a matter of controversy. One argument against the use of RT after BCS is that patients who develop ipsilateral local recurrence (LR) can be salvaged with further breast-conserving surgery such that the omission of RT will lead to high rates of breast preservation while minimizing exposure to RT. Breast preservation is an important determinant of quality of life for women with early stage breast cancer and DCIS. Yet the management of LR and the impact of RT on the resultant long-term risks of bilateral breast preservation in a population of women with DCIS are unclear. We assessed the treatment of LR, the impact of RT on the use of salvage mastectomy and the long-term risks of bilateral breast preservation achieved in a population of women with DCIS treated with BCS alone or BCS+RT.

Methods: A population-based analysis of women diagnosed with DCIS from 1994-2003 treated with BCS alone or BCS+RT with pathology review. Treatment and outcomes, including the development of LR and contralateral breast events, were determined by administrative databases with validation by review of operative or pathology reports. Median follow-up was 10.2 years for cases treated by BCS alone, 11.6 years for those treated by BCS+RT. We used a propensity-adjusted Cox proportional hazards model to evaluate factors associated with the use of salvage mastectomy for LR and to evaluate factors associated with any mastectomy. We assessed the risk of long-term breast preservation by calculating the KM 10-year risk of ipsilateral mastectomy and any mastectomy.

Results: The population cohort includes 3303 women with pure DCIS; 1649 (50%) were treated by BCS alone, 1654 (50%) received BCS+RT. Women treated with RT had more high risk features of DCIS than those treated by BCS alone. LR developed in 343 (21%) women treated by BCS alone and in 257 (15.5%) women treated by BCS+RT (p<0.01). Most women who developed LR received salvage mastectomy, irrespective of age at diagnosis and histology. Salvage mastectomy was used in 57.4% (197/343) of cases that recurred after BCS alone and in 67.6% (173/257) that recurred after BCS+RT. The likelihood of receiving salvage mastectomy for LR was similar in patients initially treated by BCS+RT vs. those initially treated BCS alone. Most (90%) of mastectomies were performed for a LR. Overall, individuals initially treated by BCS+RT had a 29% lower probability of having a mastectomy at 10 years compared to those treated by BCS alone (HR=0.71, 95%CI: 0.60,0.84,p<0.0001). The 10 year mastectomy-free survival rates are 82.7% for women initially treated by BCS alone and 87.3% for those treated by BCS+RT (p=0.0096).

Conclusion: Women who received RT after BCS for DCIS experience a greater likelihood of long-term bilateral breast preservation. This is attributable to the lower risks of LR and that most local recurrences after breast-conserving therapy are treated by salvage mastectomy. Long-term breast preservation should be considered in discussions weighing the benefits and risks of RT after conservative surgery for DCIS.
Title: Gene expression differences between ductal carcinoma in situ with and without progression to invasive breast cancer

Doebar SC C, Sieuwerts AM M, de Weerd V, Martens JWM WM and van Deurzen CHM HM. Erasmus MC Cancer Institute, Rotterdam, Zuid-Holland, Netherlands; Erasmus MC Cancer Institute, Rotterdam, Zuid-Holland, Netherlands; Erasmus MC Cancer Institute, Rotterdam, Zuid-Holland, Netherlands; Erasmus MC Cancer Institute, Rotterdam, Zuid-Holland, Netherlands and Erasmus MC Cancer Institute, Rotterdam, Zuid-Holland, Netherlands.

Body: Background

The mechanism behind progression of ductal carcinoma in situ (DCIS) to invasive breast cancer (IBC) remains unknown. The aim of our study was to increase our understanding regarding molecular alterations driving DCIS progression by comparing gene-expression patterns between patients with pure DCIS and patients with synchronous DCIS and IBC.

Methods

In this retrospective study, we included patients with extensive pure DCIS (n=12), defined as > 5 cm, as a representation of biologically indolent lesions with limited invasive capacity. These cases were matched with patients with a limited DCIS component, defined as < 1 cm, and synchronous IBC (n=12), representing lesions with a high invasive potential. Matching was based on age and surrogate DCIS subtypes. Gene expression profiling, using 93 tumor-specific target genes, was performed to identify transcriptional differences between the DCIS components of these two groups. The identified genes were validated by immunohistochemistry.

Results

In total, for 9 genes there was a significant difference in gene expression between patients with pure DCIS and patients with DCIS and synchronous IBC. The majority of these 9 genes were significantly higher expressed in DCIS samples with IBC, including PLAU ($P=0.002$), COL1A1 ($P=0.006$), KRT81 ($P=0.009$), S100A7 ($P=0.015$), SCGB1D2 ($P=0.023$), KRT18 ($P=0.029$) and NOTCH3 ($P=0.044$), while EGFR and CXCL14 showed a significantly higher expression in pure DCIS ($P=0.015$ and $P=0.028$ respectively). Based on these 9 genes, unsupervised hierarchical clustering-analysis revealed distinct clustering of patients with pure DCIS and patients with DCIS and synchronous IBC. Immunohistochemical analyses are in progress.

Conclusion

This pilot study suggests that patients with pure DCIS have a significant different gene expression pattern as compared to patients with DCIS and synchronous IBC. If these results can be validated in an independent cohort, these differently expressed genes could be used to predict progression in individual patients diagnosed with DCIS. Furthermore, these genes may pinpoint driver pathway(s) that play an important role in the progression of DCIS to IBC.
Title: DCIS and the risk of breast cancer death - A case control study

Wadsten C, Garmo H, Fredriksson I, Sund M and Wärnberg F. Sundsvall Hospital, Sundsvall, Sweden; Umeå University, Umeå, Sweden; Uppsala University, Uppsala, Sweden; Regional Cancer Center, Uppsala-Örebro, Uppsala, Sweden; Cancer Epidemiology & Population Health, Kings College, London, United Kingdom and Karolinska Institutet, Solna, Sweden.

Body: Introduction
The risk of breast cancer death after a primary ductal carcinoma in situ (DCIS) is less than 2 % after 10 years. Whereas in situ recurrences do not influence survival, a 17-fold elevated risk of breast cancer specific mortality has been shown for invasive recurrences. Adjuvant radiotherapy (RT) effectively reduces recurrences after breast conserving surgery (BCS) for DCIS, but no studies have been able to demonstrate a survival benefit from adjuvant RT treatment or from choosing mastectomy instead of BCS. Here patient and tumour related risk factors for breast cancer death in women with a pure primary DCIS were studied.

Patients and methods
Women registered with a primary DCIS, between 1992-2012 in three of Sweden’s health care regions with a population of approximately 5.2 million, were enrolled in a nested case-control study. Out of 6,964 women with DCIS, 96 patients who later died from breast cancer were identified. Four controls per case (n=318) were randomly selected by incidence density sampling. We retrieved medical records and pathology reports and calculated OR with 95% CIs for various variables using conditional logistic regression.

Results
Of the 96 cases, 10 patients developed distant metastasis without a known local recurrence. In 56 patients death was preceded by an invasive ipsilateral recurrence and in 3 patients by a recurrent ipsilateral DCIS. Seven patients had invasive breast events in both the ipsilateral and the contralateral breast. Seventeen patients had contralateral invasive breast cancer and 3 patients contralateral DCIS.

Multifocality and tumour size over 25mm (OR 2.6 (1.6 to 4.2)), positive or uncertain margin status (OR 2.8 (1.6 to 4.9)) and detection outside screening (OR 2.1 (1.2 to 3.9)) increased the risk of breast cancer death in univariate analysis, when adjusted for age and year of diagnosis. Suspicion of micro-invasion and nuclear grade 3 was associated with a nonsignificant increased risk, OR 1.8 (0.6 to 5.0) and 2.6 (0.9-6.5), respectively. The risk was not affected by age or treatment. Tumour size and margin status remained significant in the multivariable analysis, when adjusted for treatment and for contralateral breast cancer (OR 2.0 (1.2 to 3.7)).

Conclusion
In the present study, large tumours and positive or uncertain margin status were significant risk factors for later breast cancer death after a primary DCIS. More extensive treatment was not related to a lower risk. The significance of tumour biology and nuclear grade will be further examined and evaluated.
Presentation of a Bayesian decision model for the treatment of ductal carcinoma in situ (DCIS) of the breast

Belda T, Giménez J, García JM, Tortajada S, Vila J and Estevan R. Virgen De Los Lirios Hospital, Alcoy, Alicante, Spain; Valencian Institute Of Oncology (IVO), Valencia, Spain; Polytechnic University of Valencia (ITACA), Valencia, Spain and La Fe Hospital, Valencia, Spain.

INTRODUCTION: Breast carcinoma (BC) is the most common cancer in women worldwide with an increasing incidence by 2% annually, representing a major health problem in developed countries. The National Health Systems are focused on early diagnosis to minimize the fatal consequences of the disease, conducting screening mammography in women aged 40 to 70 years. However, early diagnosis has dramatically increased the diagnosis of ductal carcinoma in situ (DCIS). Medical treatment decisions are based on Clinical Practice Guidelines (CPG), which provide physicians general recommendations to help obtain the best optimal patient care. Many studies have reported improper use in routine clinical practice as they do not take into account the uncertainty of the decision or the risks and benefits involved.

Thus, the increased frequency of patients diagnosed with DCIS secondary to breast screening programs and the deficits in the current making decision process based on GPC, are the main reasons we have taken into account to build a System Decision Support (SDS) for the treatment of patients with DCIS.

MATERIAL AND METHODS: The research centers involved in this study were the Valencian Institute of Oncology (IVO) and the Polytechnic University of Valencia and within the Institute for the Application of Information Technology and Advanced Communications (ITACA). Researchers from both centers have collaborated for the creation and validation the model.

RESULTS: A decision tree was developed based on the accepted treatment alternatives from the NCCN guidelines 2015 and the possibility of uncertain events resulting from treatment decisions. The usefulness was measured in recurrence-free survival. The optimal treatment decision was to administer Radiation therapy regardless of the status of estrogen receptors. For the decision to give hormone therapy, the optimal decision is to administer HT if the percentage of cells staining positive for estrogen receptor was high and not administer if the percentage was low. We found that the decisions obtained with the model are consistent with current recommendations and with accepted scientific evidence. We also made the computer adaptation of the model for easy use in routine clinical practice. We collected data from 266 patients treated at the IVO in the last 17 years, with a mean follow-up of 75 months. The patients had an overall survival of 99.25 % with a recurrence-free survival of 86.8 % after a median follow up of 75 months.

CONCLUSIONS: In this study we developed a decision treatment model for patients with DCIS based on Bayesian Decision Theory. The results were consistent with scientific evidence and clinical practice. Finally, we performed the computer implementation of the model in order to be used in routine clinical practice.

DISCUSSION: The model developed in the study is the first decision model that takes into account the uncertainty calculation based on the expected utility of each decision on recurrence-free survival for each patient.
Title: Claudin-4 expression is associated with disease free survival in breast carcinoma in situ: Mean follow up of 8.2 years

Duarte GM M, Almeida NR R, Tocchet F, Espinola J, Pinto T, Barreto CT T, Pinto GA A, Soares FA A, Marshall P and Paiva GR R. State University of Campinas, Campinas, SP, Brazil and AC Camargo Cancer Center, São Paulo, SP, Brazil.

Body: Introduction: Claudins are tight junction molecules that have been associated with breast cancer prognosis. The claudin-low intrinsic subtype of invasive carcinoma was recently described and associated with high grade carcinoma, low junction molecules expression and worse response to chemotherapy. However, it is not known whether the expression of claudins may provide clues as to carcinoma in situ prognosis. The aim of study was evaluate the association between claudin–4 expression and disease-free survival and histologic type of local recurrence in carcinoma in situ after longer follow up.

Methods: A tissue microarray (TMA) block was constructed from 137 pure carcinoma in situ paraffin blocks sampled from patients treated from 1999 to 2009. The TMA was submitted to immunohistochemical staining for claudin-4. A claudin-4 score calculated based on percentage and intensity of expression, categorized samples as: claudin-4-low or claudin–4-high. Clinical data, treatment data, local recurrence data and survival of each patient were reanalyzed from medical records. Kaplan-Meier curves, log-rank and Wilcoxon tests were used to analyze disease-free survival; qui-square and Fisher test were employed to compare others variables; a significance level of 5 % was used.

Results: Claudin-4 expression was evaluated in 86 samples, 88.4% were claudin-4-high and 11.6% claudin-4-low. Mean follow up was 8.2 years ( and local recurrence rate was 10.5 %. There was significant difference in the disease-free survival between claudin-4-high and claudin-4-low (4.9 x 1.9 respectively, p= 0.02); however there was no difference between both in histologic type of recurrence, invasive or in situ (p=0.44).

Conclusion: In our samples, claudin-4-high expression in carcinoma in situ was more frequent than low expression. Our data showed that claudin-4-low expression had a worse prognosis in carcinomas in situ (inferior disease-free survival) but it was similar to claudin-4-high in histologic type of local recurrence.
Title: LORIS trial of active monitoring for DCIS: How does the online pathology eligibility review process work?

Thomas J, Hanby A, Pinder S, Pirrie S, Rea D, Gaunt C, Young J and Francis A. Western General Hospital, Edinburgh, United Kingdom; University of Leeds, Leeds, United Kingdom; King's College London, London, United Kingdom; Cancer Research UK Clinical Trials Unit (CRCTU), Birmingham, United Kingdom and University Hospitals Birmingham, Birmingham, United Kingdom.

Body: Introduction
The LORIS Trial is a UK randomized clinical trial comparing active monitoring with surgery for low risk ductal carcinoma in situ (DCIS), defined as low or low-intermediate grade DCIS without comedo necrosis, as diagnosed on vacuum-assisted (wide bore) core needle samples. Because of the inconsistency of grading DCIS, we have underpinned this trial with a Central Histopathology Review (CHR) before randomisation. The process of the CHR for the first 22 months of a two year pilot study between July 2014 and May 2016 is reported here.

Patients and methods
Patients were eligible for CHR if they satisfied all of the eligibility criteria and had locally reported low or intermediate grade DCIS. Patients were identified at 28 pilot sites and were registered for potential trial entry following written informed consent before being subjected to CHR. CHR comprised online examination of digitally scanned histology slides of all material from all diagnostic biopsies and was performed by at least two of the three LORIS specialist breast pathologists. Histology slides were submitted using Royal Mail Safebox® to the University of Birmingham where they were digitally scanned and made available for review via the Leica digital image hub. The outcome of the review was reported in a separate secure online database by completion of a Central Pathology Review Form. Access to both online systems is password protected. Eligibility was confirmed if two pathologists agreed that there was low or low to intermediate grade DCIS and no comedo necrosis. A maximum of 7 calendar days from receipt of the diagnostic material was allowed for the central review process. The digital images of the histology slides are stored by the Leica system for future reference.

Results
100 patients were registered and their slides reviewed. 55 of these were deemed eligible by CHR; of these 38 have been randomised. 45 patients were deemed ineligible, most commonly due to grade being in the upper half of the intermediate category and/or comedo necrosis. In addition, 9 patients were deemed not to have DCIS and 1 patient had invasive disease. Grouping the grade categories as low and low to intermediate grade (low risk and eligible for randomisation) Vs intermediate to high and high cytonuclear grade (ineligible for randomisation) showed 91% agreement on grade category amongst the reviewing pathologists.

Results of the central review were made available to sites within 7 days for 97% of cases submitted. On average, central review was completed within 4 days. Average time between registration and randomisation was 3 weeks. The LORIS central review pathologists found online viewing and reporting of sections acceptable.

Conclusions
Central Histopathology Review using online viewing of digital slides provides timely and efficient pathology Quality Assurance in this clinical trial setting, with acceptable turnaround times and good agreement between reviewing specialist breast pathologists. This process will be continued in the main phase of the trial.
Title: Improved long-term outcomes of breast-conserving therapy for women with ductal carcinoma in situ

Warren LE, Chen Y-H, Halasz LM, Capuco A, Bellon JR, Brock JE, Punglia RS, Wong JS and Harris JR. Dana-Farber Cancer Institute/Brigham and Women's Hospital, Boston, MA; Dana-Farber Cancer Institute, Boston, MA; University of Washington, Seattle, WA and Brigham and Women's Hospital, Boston, MA.

Body: Purpose: Improved mammographic and surgical techniques and pathologic evaluation, particularly greater attention to achieving negative margins, have resulted in decreased local recurrence rates for patients with ductal carcinoma in situ (DCIS). This is an updated analysis of local outcomes after breast-conserving surgery (BCS) and adjuvant radiation therapy (RT) at a single institution in the modern era.

Methods and Materials: We retrospectively reviewed the records of 245 women treated for DCIS with BCS and RT between 2001 and 2007. Competing risk analysis was used to calculate local recurrence (LR) as a first event with the development of a second non-breast malignancy, contralateral breast cancer, and death as competing first events. The median age at diagnosis was 54 (range, 32-84) and 174 (93%) women had estrogen receptor (ER) and/or progesterone receptor (PR) positive disease. Ninety-five (39%) were grade III. Specimen radiograph during surgery was obtained for 223 women (91%) and post-operative mammogram for 102 (42%). Half underwent more than one excision. The institutional goal for margins during the study period was 3 mm or greater; final margins were >2 mm in 221 (90%). All received adjuvant radiation therapy to the whole breast (median whole breast dose: 4400; range, 4000 - 5220) and nearly all (99%) received a boost to the surgical cavity (median boost dose: 1600; range, 800 – 1800). Among patients with ER and/or PR+ disease, 105 (60%) received adjuvant hormonal therapy.

Results: At a median follow-up of 10.6 years, 4 patients had a LR (2 DCIS, 2 invasive ductal carcinoma) as a first event with a cumulative LR incidence of 0.0% and 1.5% at 5 and 10 years, respectively. The 5 and 10-year cumulative incidence of the competing first events is seen in the table below. Twenty women developed a contralateral breast cancer (CBC; 8 DCIS, 12 invasive carcinoma), 13 were diagnosed with a second non-breast malignancy (3 endometrial, 2 fallopian tube, 1 gallbladder, 1 leukemia and thyroid, 4 lung, 1 ovarian, and 1 uterine), and 7 died. Family history, age at diagnosis, and receipt of hormonal therapy were not significantly associated with the development of CBC on univariable analysis (all p>0.05).

Incidence of local recurrence and competing events

</tbody>
</table>

Conclusions: With longer follow-up, our rates of local recurrence following breast-conserving therapy for DCIS remain very low (1.5% at 10 years). The vast majority of patients had >2 mm margins, specimen radiographs, and received a tumor bed boost. The majority (60%) of patients with hormone receptor positive disease received adjuvant endocrine therapy. The 10-year incidence of CBC was higher than expected. Predisposing factors for the development of CBC are worthy of investigation.
Title: The role of sentinel lymph node biopsy in patients with ductal carcinoma in situ. An updated meta-analysis involving 9803 patients

Body: Background: Ductal carcinoma in situ (DCIS) is the predominant pre-invasive neoplasia of the breast. It was observed that omission of axillary dissection in those with pure DCIS had no adverse effect on survival or recurrence. Therefore, axillary dissection typically does not feature in the management of DCIS. However, it has recently been purported that in some cases of DCIS, the axillary lymph nodes may show evidence of invasive disease. Consequently, there may be a role for sentinel lymph node biopsy (SLNB) in patients with DCIS with a high risk of invasion.

Materials and Methods: Systematic literature review identified 48 studies (9803 DCIS patients who underwent SLNB). Separate analyses for patients diagnosed preoperatively by core sampling and patients diagnosed postoperatively by specimen pathology were conducted to determine the percentage of patients with axillary nodal involvement. Patient factors were analysed for associations with risk of nodal involvement.

Results: The mean percentage of positive SLNBs was higher in the pre-operative group (5.95% vs. 3.02%; p=0.0201). Meta-regression analysis showed a direct association with tumour size (p=0.0333) and grade(p=0.00839), but not median age nor tumour upstage rate.

Conclusions: SLNB should be considered in patients with a pre-operative diagnosis of extensive and/or high-grade DCIS after a careful multidisciplinary discussion in order to identify those patients who have unrecognised axillary spread.
Title: Resolution of DCIS in patients with early breast cancer receiving primary chemotherapy for invasive breast cancer

Body: Background
Ductal Carcinoma in Situ (DCIS) plays a pivotal role in surgical planning for patients who are to undertake primary chemotherapy. As DCIS is not thought to be responsive to chemotherapy, many women with large primaries or extensive DCIS on initial diagnosis will be planned for and undergo mastectomy. To investigate the role of chemotherapy in invasive breast cancer with concomitant ductal carcinoma in situ (DCIS), we examined patients who had primary systemic therapy for a primary invasive cancer with either radiologically or histologically proven DCIS to see if there were patients in whom there was no evidence of DCIS at resection.

Methods
This was a retrospective single centre study. Examining the records of all patients who had received primary chemotherapy between January 2010 and October 2014.

Patients were identified through the Guy’s breast cancer database and chemotherapy prescribing system. To fully assess the DCIS status, all patients were cross-referenced with the electronic notes on our electronic noting system (MOSAIQ), radiology on Patient Archiving and Communication System (PACS) and histology on our Electronic Patient Record (EPR).

Results
1526 patients were identified, of whom 156 underwent primary chemotherapy. Of these, 46 patients had a pre-chemotherapy biopsy confirming DCIS, of whom 30 also had radiological evidence of DCIS. A further 26 had micro-calcification on their initial imaging which was presumed to be DCIS.

Twelve of the 46 patients with biopsy proven DCIS at presentation did not have DCIS at resection. Of these 9 had a mastectomy, with 5 achieving a pathological complete response (pCR), of whom 4 had a complete radiological response (rCR).

Of the 26 who had micro-calcification pre-chemotherapy, 15 did not have DCIS in the resection specimen. Of these, 10 had a mastectomy, with 6 having a pCR of whom 3 also had rCR.

Conclusion
This retrospective study suggests that chemotherapy can influence DCIS, with 12 biopsy proven having a pCR post treatment. This may indicate that some patients may be spared mastectomy.

Although there were patients with radiological evidence of DCIS, without a confirmatory biopsy we cannot be sure that these were malignant. This highlights the need to ensure that all suspicious areas distant from the primary tumour should be biopsied before treatment.

In conclusion, for patients who have an excellent clinical and radiological response, even in the presence of DCIS at presentation, more intensive evaluation is indicated if conservative surgery is a possibility.
Body: Background: Ductal carcinoma in situ (DCIS) is considered to be a precancerous lesion that shares many genetic similarities with invasive ductal carcinoma (IDC). However, it remains unclear how DCIS might develop into IDC and whether the coexistence of DCIS has any clinical significance. There is limited data on whether coexisting DCIS in patients with IDC (IDC-DCIS) has any impact on patients' clinical presentation, tumor characteristics, prognosis and treatment selection. We aim to investigate differences in patients with pure IDC versus patients with IDC-DCIS.

Methods: We reviewed clinicopathologic data from the Breast Molecular Epidemiological Resource (BMER) database, which is a prospectively maintained breast cancer database from the University of Iowa. Missing information was supplemented by Iowa Cancer Registry database. Patients with a diagnosis of pure IDC and IDC-DCIS from 2009 to 2014 who underwent surgical resection of their breast cancer were included. We excluded patients with stage IV disease at diagnosis and those who underwent neoadjuvant therapy. Patients who had more than one tumor were only analyzed once using parameters of the largest tumor. Patient and tumor characteristics and treatment selection were compared between the IDC and IDC-DCIS groups. Student's t test was used for continuous variables and chi squared test for categorical variables.

Results: We observed that women with IDC-DCIS (n=226) had higher incidence of Her-2 positive cancers than those with pure IDC (n=95) (p=0.04). The IDC-DCIS group was more likely to be ER + and PR +, though these differences were not statistically significant. Another distinguishing characteristic between the two groups was that the IDC group contained more current smokers than the IDC-DCIS group (18.9% vs 10.6%, p<0.01). Patients with IDC-DCIS were more likely, than patients with pure IDC, to be under-staged based on clinical information. Clinical stage distribution in IDC-DCIS group was: 4% stage 0, 61.9% stage I, 28.3% stage II and 5.8% stage III. In contrast, the percentages of pathologic stage I, II and III were 54.5%, 35.4% and 10.2%, respectively (p=0.002). Similar analysis for patients with pure IDC showed no significant overall change from clinical to pathologic stage. Patients with IDC-DCIS tended to have higher total mastectomy rates than patients with IDC (37.2% vs 31.6%, p=0.34). Management of patients in either group were not significantly different in terms of radiation, chemotherapy, or hormonal therapy. There were 4 deaths (4.2%) in the IDC group and 12 deaths (5.3%) in the IDC-DCIS group (p=0.68).

Conclusions: Our study showed that active smoking may be a risk factor for the development of IDC without pre-existing DCIS. Patients with IDC-DCIS had higher rates of Her-2 positivity and significant differences between clinical and pathologic stages. Management and survival of both groups were similar.
Title: Microenvironment microarrays show that microenvironment mediated resistance mechanisms to lapatinib differ between basal and luminal HER2+ cells

Body: Cell lines represent a valuable model system for the study of breast cancer, as they capture the cellular diversity, mutational spectrum, expression subtypes, and genomic alterations that are observed in clinical specimens. However, like any model system, cell lines are imperfect, particularly when it comes to capturing the effects of the myriad of signals and interactions they encounter in their microenvironment (ME). We are utilizing a technology known as microenvironment microarrays (MEMA) to begin to unravel the consequences of interactions of breast cancer cells with the ME. MEMA consist of thousands of unique combinations of insoluble matrix proteins that are printed to form growth pads with ligands added to the media. Cells are grown on the MEMA spots and the effects of the specific ME that they are exposed to can be read out using immunofluorescent stains of interest. When combined with automated imaging and sophisticated image processing and analysis, the MEMA platform enables the identification of specific ME conditions that alter the phenotypes of cells. We have applied MEMA to understand both baseline responses to the ME as well as how the ME might mediate response to therapeutics. We performed a pilot experiment to investigate the effects of the ME on the response to the HER2-targeted inhibitor lapatinib. We found that HCC1954 cells continued to proliferate robustly in the presence of HGF when treated with 500 nM lapatinib. In contrast, AU565 cells were proliferative in the presence of NRG1 and lapatinib, but not HGF. Focused follow up studies showed that HGF is effective in rescuing only basal HER2+ cells, while NRG1 is effective in rescuing only luminal subtype HER2+cells. Rescue with the relevant growth factor was also observed in 3-d matrigel studies, showing this was not an artifact of the 2-d culture system. We investigated the effects of drug combinations using lapatinib plus drugs that target either MET (Crizotinib) or HER3-HER2 dimers (pertuzumab). These drug combinations were able to overcome the resistance mediated by HGF and NRG1 in basal and luminal cells respectively. We found the effectiveness of pertuzumab particularly interesting, given that lapatinib should still be inhibiting HER2 kinase activity. Parallel studies found that inhibitors targeting other kinase receptors such as IGF1R partially restored sensitivity to HER2 in the presence of NRG1, suggesting a role for such receptors in the resistance. Immunoprecipitation studies showed that IGF1R co-immunoprecipitated with HER2/HER3 when pertuzumab was absent, but that additional of pertuzumab abrogated the binding of IGF1R to HER3, suggesting the formation of HER2-dependent higher order structures that can signal even when HER2 is inhibited. These studies highlight the importance of understanding the effects of the ME on cancer cells, and demonstrate the differences between ME factors that can confer resistance to HER2 targeted inhibitors in basal and luminal HER2+ cells. These findings suggest that both subtype and ME composition may be important in determining response to combinatorial treatments and may be useful to inform clinical decision making.
**Title:** Paclitaxel induced mena- and TMEM-mediated pro-metastatic changes in the breast cancer microenvironment

**Body:**

**Background:** Breast cancer cell intravasation and dissemination occurs specifically at microanatomical structures that we call tumor-microenvironment of metastasis (TMEM), representing direct physical contact between a tumor cell expressing the actin-regulatory protein Mammalian-enabled (Mena), a perivascular Tie2\(^{hi}\)/Vegf\(^{hi}\)-expressing macrophage, and an endothelial cell (Harney et al. Cancer Discovery 2015). TMEM sites have been identified in mouse and human mammary carcinomas, and both TMEM density (Rohan et al. JNCI 2014) and invasive Mena isoform expression (Agarwal et al. Breast Cancer Res, 2012; Forse et al. BMC Cancer, 2015]) correlates with metastasis in early stage breast cancer. Since cytotoxic agents such as PTX induce influx of bone marrow-derived progenitors that differentiate into Tie2\(^{hi}\)/VEGF\(^{hi}\) macrophages in the primary tumor, we hypothesized that PTX may potentiate tumor cell invasion and metastasis by inducing the formation of TMEM sites and/or function.

**Methods and Results in humans:** We analyzed the effect of chemotherapy on TMEM and invasive Mena isoforms in 10 patients with localized breast cancer who had residual disease after neoadjuvant chemotherapy (NAC: weekly paclitaxel followed by dose-dense doxorubicin-cyclophosphamide [AC]), of whom 7 had more than 2-fold increase in TMEM density in residual disease compared with pretreatment. In a separate cohort of 5 patients, NAC produced an acute increase of up to 150-fold in invasive Mena isoforms after 1-2 doses of NAC.

**Methods and Results in mice:** After our preliminary data in humans, we evaluated effects of PTX in 4 different models, including 2 mouse models (PyMT-spontaneous & transplantation) and 2 patient-derived xenograft (PDX) triple negative models (HT17, HT33). Although PTX delayed primary tumor growth, tumors in PTX-treated mice had significantly more TMEM sites, circulating tumor cells (CTCs) and metastatic foci when compared to vehicle-treated animals. Using intravital imaging of MMTV-PyMT-Dendra2/Cfms-CFP mice, PTX induced influx of macrophages into primary tumors and intravasation of cancer cells at TMEM sites. Furthermore, PTX treatment significantly increased expression of Mena at the gene and protein levels, including invasive Mena isoforms. Deletion of the Mena gene completely abolished dissemination and metastasis in all cases, including those treated with PTX.

**Conclusions:** We show in mammary carcinoma mouse models and PDX models that although PTX delays tumor growth, it induces invasive Mena isoform expression and significantly increases the density of TMEM sites that are responsible for cancer cell intravasation, dissemination and metastasis. Thus, our data indicate that PTX paradoxically induces dissemination of breast cancer cells by promoting invasive Mena isoforms and TMEM-mediated cancer cell intravasation, suggesting that blockade of TMEM assembly and/or function could enhance the effectiveness of PTX and possibly other cytotoxic agents commonly used to treat early and advanced stage breast cancer.
**Title:** Effect of PD-1 and PD-L1 in the tumor microenvironment on overall survival of triple-negative breast cancer patients

**Body:**

**Introduction:** The programmed cell death-1 (PD-1) immune checkpoint is a normal regulator of the autoimmune response to inflammatory stimuli. Several cancers have taken advantage of this mechanism by harboring its ligand (PD-L1), thus activating the checkpoint to evade immune destruction. Increased expression of PD-L1 on tumor cells has been linked with worse outcomes in several cancers, including breast cancer. In triple-negative breast cancer (TNBC), expression of PD-L1 is increased compared to luminal cancers and as such, has become a favorable target for anti-tumor therapies. However, few studies evaluate the impact of PD-1 and PD-L1 expression on overall survival (OS) in TNBC. The aim of this study was to assess OS based on PD-1 and PD-L1 positivity and distribution in the tumor microenvironment.

**Methods:** All patients with newly diagnosed TNBC from 1999 to 2015 with adequate pathologic specimen were identified for evaluation. Surgical pathology specimens were stained by immunohistochemistry (IHC) for PD-1 and PD-L1. Those considered PD-1+ or PD-L1+ had a staining score of 3, 4, or 5. Patient and clinical characteristics of the adjuvant group were compared by PD-1 and PD-L1 status with Chi-Square and ANOVA, as appropriate; characteristics of the neoadjuvant population were described. OS was calculated using Kaplan-Meier method and compared by Log Rank test for PD-1, PD-L1 positivity and tumor microenvironment status.

**Results:** Fifty-two patients met inclusion; 38 had surgery prior to chemotherapy while 14 had neoadjuvant chemotherapy. There were 15 PD-1+ patients (39%) and 21 PD-L1+ (55%) patients in the treatment naïve cohort. No significant difference was found in the treatment naïve group between age, race, postmenopausal status, final stage, or pathologic characteristics (e.g. tumor size, mitotic rate, and grade) for all PD-1+ and PD-L1+ patients. Of the 21 PD-L1+ patients, staining was present in the tumor, tumor/non-tumor (mixed), and non-tumor microenvironment 42.9%, 33.3%, and 23.8% of the time, respectively (p=0.008). No significant difference was found in OS between PD-1+ and PD-1- patients (p=0.509) or PD-L1+ and PD-L1- patients (p=0.240). However, distribution of PD-L1 staining significantly associated with OS. Those demonstrating PD-L1 staining in the tumor had a significantly higher OS than those with PD-L1 staining in the non-tumor microenvironment (p=0.008). In the subset of PD-L1+ patients, those with staining in the tumor show a 10-year OS of 100% versus 60% for those with staining in non-tumor (p=0.006). In the neoadjuvant cohort, 14.3% of patients expressed PD-1 positivity, while 42.9% had PD-L1 positivity; the distribution of the PD-L1 staining in tumor 14%, mixed 29%, and non-tumor 50%. No difference in OS was found based on PD-1 or PD-L1 (p=0.660) positivity in the neoadjuvant cohort.

**Conclusion:** A large number of TNBC stain for PD-1 and/or PD-L1. The implications of this are yet to be determined. In this small cohort, pattern of staining had a significant impact on overall survival in treatment naïve patients. This finding will need to be validated on a larger cohort but may have important implications for treatment by defining patients who may benefit by checkpoint inhibitor therapy.
Title: Perioperative use of NSAID analgesic ketorolac may suppress early relapses in breast cancer: Perhaps transient systemic inflammation plays a role

Retsky MW W, Demicheli R, Forget P, Hrushesky W and Baum M. Harvard TH Chan School of Public Health, Boston, MA; Milan National Cancer Institute, Milan, Italy; Université Catholique de Louvain, Brussels, Belgium; University of South Carolina, Columbia, SC and University College London, United Kingdom.

Body: A bimodal pattern of hazard of relapse among early stage breast cancer patients has been identified in multiple databases from US, Europe and Asia. We are studying these data to determine if this can lead to new ideas on how to prevent relapse in breast cancer. Using computer simulation and access to a very high quality database from Milan for patients treated with mastectomy only, we proposed that relapses within 3 years of surgery are stimulated somehow near the time of surgery. Most relapses in untreated breast cancer are in this early category. We could identify both angiogenesis of dormant micrometastatic deposits (particularly for premenopausal node positive patients) and activation of single dormant cells. Retrospective data from a Brussels anesthesiology group suggests an unexpected mechanism. Ketorolac, a common NSAID analgesic used perioperatively in surgery produced far superior disease-free survival in the first 5 years after surgery. The expected prominent early relapse events in months 9-18 are reduced 5-fold. Transient systemic inflammation accompanying surgery could facilitate angiogenesis of dormant micrometastases, proliferation of dormant single cells, and seeding of circulating cancer stem cells (perhaps in part released from bone marrow) resulting in early relapse and could have been effectively blocked by the perioperative anti-inflammatory agent. If this observation holds up to further scrutiny, it could mean that the simple use of this safe, inexpensive and effective anti-inflammatory agent at surgery might eliminate early relapses. This may reduce breast cancer mortality by 25 to 50% at low cost and toxicity. The best responding subgroup may be triple negative breast cancer. These data suggest transient systemic inflammation (identified by IL-6 in serum) is the precipitating factor. CTC and cells released during surgery in the presence of transient systemic inflammation could account for the single cell activation that was prevented by perioperative NSAID. There are a number of mechanisms that could explain how the perioperative NSAID prevents surgery induced angiogenesis. We are pursuing a clinical trial in Nigeria (high incidence of triple negative breast cancer and early onset). What we describe is driven by a host response and may be a general effect not limited to breast. Breast cancer is a disease that runs its course in over a decade but it seems that most relapses are the result of events that occur in the week after surgery.

Title: Metabolic obesity, adipose inflammation and aromatase: Potential drivers of breast cancer risk in women with normal body mass index

Body: Background: Elevated body mass index (BMI) is associated with increased risk of postmenopausal breast cancer, which may be partly attributable to an inflammation-aromatase axis. Most individuals with elevated BMI harbor white adipose tissue inflammation (WATi), defined by the presence of crown-like structures in the breast (CLS-B). CLS-B are composed of a dead/dying adipocyte surrounded by CD68+ macrophages. This inflammation is associated with activation of NF-κB and elevated expression of aromatase, which could contribute to tumor development. Additionally, WATi correlates with several circulating changes, including hyperinsulinemia, which increase breast cancer risk. Although breast WATi correlates with rising BMI, it is also present in some normal BMI individuals. Beyond inherited germline syndromes, the etiology of breast cancer in individuals with normal BMI is not well understood. Here we examined the impact of breast WATi on breast aromatase expression and circulating factors in women with normal BMI.

Methods: Non-tumorous breast tissue and fasting blood were collected from 72 women with BMI < 25 kg/m² undergoing mastectomy at MSKCC. Breast inflammation was detected by the presence of CLS-B using CD68 immunohistochemistry. The primary objective was to determine if breast WATi in normal BMI individuals correlates with elevated aromatase levels in the breast, measured by qPCR, western blotting, immunofluorescence and enzyme activity. Secondary objectives included assessment of breast adipocyte size and circulating metabolic and inflammatory factors.

Results: Breast inflammation was present in 39% of women. Median BMI was 23.0 (range 18.4 to 24.9) in women with breast WATi versus 21.8 (range 17.3 to 24.6) in those without inflammation (P=0.04). Aromatase mRNA expression was positively correlated with WATi (CLS-B/cm²; P=0.002). Those with severe WATi had highest aromatase mRNA levels, compared to those with no or mild WATi (P=0.005). Aromatase protein, assessed by measuring adipose stromal cell-specific immunofluorescence or western blotting, and activity were also higher in CLS-B+ cases compared to CLS-B- (P<0.001). Breast WATi correlated with larger adipocytes (P=0.01) and higher circulating levels of C-reactive protein, leptin, insulin, and triglycerides (P<0.05). Insulin resistance, characterized by the homeostasis model (HOMA2-IR), correlated with breast WATi (P=0.004). Finally, leptin, a known inducer of aromatase and driver of cancer growth, correlated with higher breast aromatase levels (P=0.02) and larger adipocytes (P<0.01).

Conclusions: A metabolically unhealthy state occurs in women with inflamed breast adipose despite having a normal BMI. This subclinical inflammatory state is characterized by elevated aromatase in the breast, insulin resistance, and dyslipidemia. The presence of enlarged adipocytes in the breasts of normal BMI women with inflammation suggests a state of hyperadiposity which could not be predicted based on BMI alone. These findings indicate that normal BMI metabolic obesity may be associated with increased cancer risk. Our results suggest that objective measurements of adiposity rather than BMI may help to identify individuals at increased risk for disease.

Title: Prognostic value of molecular tumor infiltrating lymphocyte (mTIL) signatures in HER2-positive breast cancer patients in N9831 and FinHer/FinXX trials

Body: Background: While previous study showed that the enrichment of immune-related gene expression was associated with outcome in HER2+ patients receiving sequential or concurrent trastuzumab (H), stromal tumor infiltrating lymphocytes (sTIL) have not been consistently shown to associate with outcome in this group of patients. Given that TIL scoring may be subjective, we analyzed molecular signatures of different subsets of tumor infiltrating immune cell populations, using NanoString™ gene expression data to assess molecular TIL (mTIL) signature enrichment and intrinsic subtype as a function of relapse-free survival (RFS).

Methods: NanoString™ technology was used to quantify mRNA in samples from 1,280 patients in N9831, 168 patients in FinHer, and 170 patients in FinXX. In N9831, patients in arm A were treated with chemotherapy alone (AC-T), arm B received chemotherapy followed by sequential H (AC-T-H), and arm C received H concurrently with chemotherapy (AC-TH). In the FinHer trial, H was given concurrently for 9 weeks and either 1 year or 9 weeks in FinXX trial. Cox proportional hazard ratio (HR) was used to determine the association of each gene signature with RFS. Different immune subset signatures, including CD45, B-cells, CD8 T-cells, cytotoxic-cells, and T-cells were analyzed using algorithms developed by NanoString.

Results: In N9831, CD45, cytotoxic-cell, and T-cell signatures were significantly associated with improved RFS in patients receiving chemotherapy alone and AC-T-H. However, none of the mTIL signatures were significantly associated with outcome in patients treated with chemotherapy without concurrent trastuzumab. The 10-year Kaplan-Meier estimates for RFS in arm B patients with CD45 enrichment or no enrichment were 81.3% and 72.6%, respectively (HR 0.63 [95% CI, 0.42-0.93]; p = 0.02), and in arm C were 83.6% and 79.8%, respectively (HR 0.79, 95%CI 0.49-1.28; p = 0.34). Among patients with HER2-enriched subtype, all of the mTIL signatures were associated with improved RFS in arm A (AC-T) and B (AC-T-H) but remained non-significant in arm C (AC-TH). In patients with luminal subtypes, mTIL signatures were not significantly associated with outcome in patients treated with chemotherapy alone. Similar findings were observed in the FinHer and FinXX trials, in which, none of mTIL signatures were significantly associated with outcome among patients who received H.

Conclusion: This analysis sheds light on previous discrepancy between immune-related gene signature and sTIL findings. Our data also suggests that the poor prognosis associated with lack of infiltrating immune cells can be partly overcome by the concomitant administration of H with chemotherapy. mTIL signatures, specifically CD45, cytotoxic, and T cells, were prognostically associated with improved outcome in patients receiving chemotherapy without concurrent trastuzumab. Understanding the role of the immune system in response to H will require a higher degree of granularity than can be achieved by histological quantification of TILs. Further studies are needed to validate the significance of mTIL signatures as predictive or prognostic biomarker in HER+ patients.
Title: From monocyte re-programming to the expansion of tumor infiltrating lymphocytes for adoptive T cell therapy

Body: Tumor associated monocytes and macrophages are highly plastic cells reported to support cancer progression by promoting tumor angiogenesis and metastasis in patients as well as in a variety of experimental mouse models. Conversely, other studies have demonstrated the ability of tumoricidal monocytes to specifically destroy tumor cells. These contrasting biological activities, tumor development versus destruction, are mediated by macrophages with distinct functional polarization, ultimately dictated by microenvironmental cues. While much effort has focused on strategies to block the recruitment of circulating monocytes in tumor tissue, or in the depletion of tumor macrophages in vivo in tumor-bearing mice, newly emerging approaches designed to 'reprogram' tumor macrophages with anti-tumor properties are demonstrating promise for cancer immunotherapy. We show that tumor-associated TIE-2-expressing monocytes (TEM) are highly proangiogenic and immune suppressive cells critical for breast tumor vascularization and growth. By merging computational systems modeling and experimental approaches, we have uncovered treatments reprogramming pro-tumoral monocytes into immunologically potent cells capable of mediating an anti-tumor immune response. We report here that proangiogenic and suppressive functions of TEMs are similarly driven by TIE-2 and VEGF receptor tyrosine kinase and their ligands PlGF and Ang-2. These unraveled pathways and ligands, which underlie monocyte pro-angiogenic activity, have a strong predictive value for breast cancer patient relapse-free survival. Further, blocking of TIE-2 and VEGFR kinase activity induced TEMs reprogramming into cells with features of myeloid dendritic cells able to enhance anti-tumor T cell responses. Most importantly, this treatment when applied to the tumor microenvironment, allows for the first time the expansion in vitro of Tumor Infiltrating Lymphocytes (TILs) to numbers compatible with Adoptive Cell Therapy (ACT). ACT consists of the administration to cancer patients of autologous TILs expanded in vitro from patient tumors in large numbers and has proven to be exceptionally effective in metastatic melanoma. However, ACT is of limited clinical efficacy in various other cancer types including breast cancer and to date, to the best of our knowledge, no expansion of functional TIL has been reported for ACT purposes in breast cancer. We show here that the expanded TILs displayed mainly an effector memory phenotype, are specific for tumor antigens and kill autologous tumor cells in vitro in a MHC-dependent manner. Thus, this uncovered treatment combination represents the first intervention on the breast tumor microenvironment which overcomes TILs dysfunctions and provides for the first time the basis for ACT in breast cancer.
Title: Expression of LAG-3 in breast cancer, and its association with subtype and outcome

Burugu S, Gao D and Nielsen TO. Genetic Pathology Evaluation Centre, Vancouver, BC, Canada.

Aim: To investigate the expression and clinical value of the immune checkpoint marker LAG-3 in breast cancer patients

Background: Lymphocyte-activation gene 3 (LAG-3) is a recently discovered immune checkpoint biomarker that is targeted by agents currently being evaluated in early phase clinical trials. LAG-3 functions as a cell surface receptor expressed following T cell activation and negatively impacts T cell functions. This biomarker has not yet been evaluated in large series of breast cancers with long term treatment and outcome data, in the context of subtype and other immune biomarkers.

Methods: Two tissue microarray series (a training set with N=330 and a validation set with N = 2203 patients) were constructed from breast carcinoma primary excision specimens from University of British Columbia hospitals, linked to detailed clinical and pathological data. None of these patients had received neoadjuvant treatment. 4µm sections were stained with an antibody to LAG-3 (clone 17B4) by immunohistochemistry using a Ventana Discovery Ultra automated slide stainer. LAG-3+ stromal and intra-epithelial tumor infiltrating lymphocytes (TILs) were reported as absolute counts per tissue microarray core. Stromal TILs (sTIL) were defined as lymphocytes present in the stroma not in direct contact with tumor nest whereas intra-epithelial TIL (iTIL) were lymphocytes in direct contact with carcinoma cells. All descriptive and survival analyses were conducted using SPSS software.

Results: LAG-3+ sTILs were found in 16% of breast cancer cases in both the training set and the validation set; LAG-3+iTILs were present in 14 and 11%, respectively. In both the training set and the validation set, the presence of LAG-3 (iTILs or sTILs) was significantly (p<0.001) associated with high grade tumors, estrogen and progesterone receptor negativity, high Ki67 index and with the HER2+ and basal-like subtypes. In survival analyses of ER negative patients, in both sets patients with LAG-3 T cells (iTILs or sTILs) had a significantly improved disease-specific survival (p<0.05). As with other lymphocyte biomarkers, this association was not observed among ER+ patients.

Conclusions: LAG-3+TILs are present in breast cancer and are associated with major risk factors and hormone receptor negative subtypes. ER negative breast cancer patients have a better outcome if they contain LAG-3+ TILs, consistent with published data showing better survival among ER- breast cancer patients with immune infiltrates. More than a quarter of ER negative breast cancers contain TILs expressing LAG3, and may represent the most relevant subset to target with emerging checkpoint inhibitors targeting this T cell surface receptor.
Title: Analysis of breast cancer in young women in the department of defense (DOD) database

Body: Background: Women under the age of 40 account for approximately 7% percent of breast cancer patients. Breast tumors from young women are often ER-negative, occur in African-American patients, and have other indicators of high risk: yet, multivariate analyses demonstrated that young age is an independent predictor of poor outcome. Due to the unique nature of the patient population served by DOD, a disproportionate number of breast cancer cases in young women are seen. We compare the characteristics, treatment, and outcomes of young patients diagnosed with breast cancer with those of older patients.

Methods: The databases of the Military Health System Repository and the DOD Central Registration were used to identify female breast cancer patients treated at DOD facilities between 1998 and 2007. Information on demographics, breast cancer stage at diagnosis, definitive surgical treatments, systemic treatment, recurrence rate and overall survival was analyzed by age groups at the time of diagnosis (less than 40 years old, 40 to 49 years, and 50 years or older) using $X^2$ testing with significance defined as $p<0.05$.

Results: We identified 10,066 women who were diagnosed with invasive breast cancer at DOD facilities between 1998 and 2007, of which 11.3% (1139) were less than 40 years old at diagnosis. 53% of this young cohort were white, 25% were African-American and 8% were Hispanic (14% undisclosed). The percentage of breast cancer among African-American women in the young cohort was higher than in the older cohorts (19.3% in 40-49yo and 10.6% in ≥50yo). High-grade tumors were significantly more frequent in the younger cohort when compared to the older group (49.5% vs 34.7% and 25.2%, $p<0.001$).<40yo most commonly presented with Stage II disease (45.3%) at diagnosis, while older groups were mostly diagnosed with Stage I disease (41.6% and 52.4%). The most common subtype of breast cancer across ages was ER+ disease, however, <40yo group had proportionally less ER+ (49% vs 61% and 67.3%, $P<0.001$). There was a higher rate of bilateral mastectomies among the young women (18.4% vs 9.1% and 5.0%, $p<0.0001$). Independently of the stage of disease, chemotherapy was given significantly more frequently to <40y (90.43%) and 40-49yo (81.44%) than ≥50yo (53.71%). The 10-year overall survival of younger women was similar to the ≥50yo cohort, despite intensive treatment.

Discussion: This study is one of the largest retrospective studies of women under 40 years old with breast cancer. Younger women with invasive breast cancer had more aggressive tumors presenting at higher stages. In this group with good access to healthcare, younger women still had a similar overall survival rate to older women despite receiving more aggressive treatment and potentially having fewer comorbidities than the older group.
Title: Local recurrence in young women with invasive breast cancer; the prospective study of outcomes in sporadic and hereditary breast cancer (POSH)

Maishman T, Cutress RI I, Hernandez A, Gerty S, Copson ER R, Durcan L and Eccles DM M. Cancer Sciences Academic Unit and Southampton Clinical Trials Unit, Faculty of Medicine, University of Southampton and University Hospital Southampton Foundation Trust, Southampton, Hampshire, United Kingdom.

Body: Aim
To evaluate the surgical and clinical factors affecting local recurrence and other outcomes in young breast cancer patients using the POSH study.

Background
POSH (MREC:00/06/69) is a prospective cohort study of 3024 women aged 18-40 with breast cancer. Randomized controlled trials suggest equivalent survival between mastectomy and breast conserving surgery (BCS); however, very few young patients were included in these analyses. Emerging data also suggests a possible survival advantage for mastectomy in gene mutation carriers, and young age may be a predictor of higher rates of local recurrence.

Methods
Summary statistics were used to describe the cohort by surgical type (mastectomy or BCS). Study endpoints were in-breast ipsilateral local-recurrence interval, distant disease-free interval and overall survival. Cumulative hazard and Kaplan-Meier plots were used to describe survival data. Univariable and multivariable analyses were carried out using Cox proportional hazards models and flexible parametric survival (FPS) models (for any models with time-varying covariates).

Results
Of 2882 patients analysed, 1464 underwent mastectomy, 1395 BCS; and 23 had lymph node surgery only. Patients undergoing mastectomy had significantly larger tumours and higher proportions of positive Family History, positive estrogen receptor (ER+), progesterone receptor (PR+) and/or human epidermal growth factor 2 (HER2+) tumours. Local events only accounted for 15% of recurrences. Local recurrence varied over time by surgical type; local recurrence rate was similar at 18 months but higher for BCS compared to mastectomy at 5- and 10-years (18-months: 1.0% vs 1.0%, FPS-HR[95%CI]=1.43[0.89,2.32], p=0.348; 5-years: 5.3% vs 2.6%, FPS-HR[CI]=3.39[2.03,5.66], p<0.001; and 10-years: 11.7% vs 4.9%, FPS-HR[CI]=5.27[2.43,11.43], p<0.001, respectively). Similar results were found in the adjusted model and when restricting the analyses to patients with smaller tumours. Conversely, distant-metastases and death events were significantly lower for BCS but not after adjusting for prognostic factors. Chest-wall radiotherapy following mastectomy was associated with improved local recurrence interval (HR[CI]=0.46[0.24,0.86],p=0.015). Positive surgical margins, and the development of a local event, predicted for reduced distant disease free interval (HR[CI]=0.50[0.35,0.71],p<0.001; and 10-year FPS-HR[CI]=0.29[0.14,0.62],p=0.001, respectively).

Conclusions
In the short term, there is no difference in local recurrence between BCS and mastectomy in young women. Longer term, local recurrence is higher in BCS, but there is no difference in survival between surgical groups after adjusting for known prognostic factors. Surgical extent appears to be less important for distant relapse or death from breast cancer than completeness of excision or, where appropriate, chest-wall radiotherapy.

Body: Purpose
This study aimed to evaluate the uptake of fertility preservation, rate of pregnancy, pregnancy outcome and breast cancer outcome after diagnosis of early breast cancer in young women who were referred to Maastricht University Medical Center, from the regional hospitals in the Southeast part of the Netherlands.

Patients and methods
We prospectively registered the demographics of patients, who visited our university hospital for counseling on fertility preservation at diagnosis of stage I-III invasive breast cancer in the years 2008-2015. At baseline, tumor and treatment characteristics were registered. During follow-up information on fullfilled childwish and disease status was collected. To compare the fertility preservation group and the non-fertility preservation group independent samples Student t-tests and Chi-square tests were conducted.

Results
In total 128 women with a median age of 32 years (19 – 43) were referred for fertility preservation counseling before start of chemotherapy, with an increase in referral in the more recent years. Thirty-nine (30.5%) women chose for fertility preservation: in 26 patients embryos were frozen, in seven oocytes, and in one both embryos and oocytes. In four patients the procedure was not succesfull. Patients who had chosen for fertility preservation more often had a male partner (87.2% vs 70.8%, \( P = 0.05 \)) and had a smaller tumor size (median 19 versus 23 mm, \( P = 0.04 \)) at the time of diagnosis compared to those who did not chose for fertility preservation. During a median follow-up of 30.3 months (range 0 – 96.9), 27 (21.1%) patients had tried to conceive: 14 (35.9%) women in the fertility versus 13 (14.6%) in the non-fertility preservation group. All of these had recovery of ovarian function after chemotherapy-induced ovarian failure. Only two women used the cryopreserved embryos, both succesfull and combined with preimplantation genetic diagnosis of the embryos because of germline mutations in BRCA1-gene. Eight patients in the fertility preservation group and seven patients in the non-fertility preservation group became at least once pregnant. In the fertility preservation group, eight healthy babies were born, one baby had Morbus Hirschsprung, one women is pregnant at this moment and one woman had a miscarriage. Of the eleven pregnancies in the non-fertility preservation group, nine healthy babies were born and one woman had two miscarriages. Of the referred 128 women, nine (7.0%) had breast cancer recurrence, three in the fertility preservation group versus six in the non-fertility preservation group.

Conclusion
One third of referred patients choose for fertility preservation before start of chemotherapy. In all of these patients, the ovarian function recovered. However, two couples used their cryopreserved embryos for preimplantation genetic diagnosis and both became pregnant. Since the follow-up time is relatively short, more data are mandatory to make a statement on the effectiveness of fertility preservation techniques in young breast cancers patients.
HOHO study: How European and US young women cope with breast cancer and fertility concerns

Body: Background
The International Breast Cancer Study Group (IBCSG), in collaboration with Dana-Farber Cancer Institute, conducts the European (EU) cohort of the Helping Ourselves Helping Others (HOHO) study. HOHO is a prospective longitudinal cohort study investigating short and long-term treatment and fertility concerns in young women with breast cancer (BC): most previous studies have been retrospective.

Patients and methods
From Aug 2009-Jan 2016, 300 patients aged 18-40 yrs with early/advanced BC were enrolled within 6 mos of diagnosis in 18 Centers in Italy and Switzerland. Patients are surveyed every 6 mos the first 3 yrs and yearly for additional 7 yrs. 297 baseline surveys were evaluable. The baseline survey includes sociodemographic and treatment data, and a modified Fertility Issues Survey (including fertility concerns, preservation, outcome and impact on treatment decisions). Clinical data are collected yearly. We qualitatively compare the EU baseline data with the published US data (Ruddy et al, JCO 32:1151, 2014).

Results
Almost two thirds of women in both cohorts discussed future fertility with their doctors at diagnosis. Fertility concerns, desire for future pregnancy (both before disease onset and at time of survey) and steps to reduce infertility were all more common in the EU cohort. EU women were also more concerned about fertility when discussing treatment and about a possible relapse affecting their ability to care for future children.

Conclusion
Many young women with newly diagnosed BC have concerns about fertility, which may affect their treatment decisions. In the EU cohort fewer women had a stable relationship and children before diagnosis, potentially influencing their treatment decisions and encouraging fertility preservation. Concerns about a possible relapse could partly explain the decrease in their pregnancy desire after the disease. Differences between EU and US women seem to emerge: continued data collection will determine if they persist over time. The POSITIVE Trial (IBCSG 48-14/ALLIANCE 221405) will address safety and outcome of pregnancy after BC.

A prospective evaluation of clinical outcomes in women with pregnancy-associated breast cancer (PABC)

Background: Many studies suggest that women with PABC—breast cancer (BC) diagnosed during pregnancy or within 12 months post partum—have adverse outcomes compared to age matched women whose BC is not associated with pregnancy (non-PABC). However, it is unclear whether this is due to diagnostic delay alone or biological differences. Hence, we investigated whether PABC is independently prognostic for disease-free survival (DFS) and overall survival (OS) in a prospective database of young BC patients.

Methods: A prospective database of women ≤40 years of age diagnosed with BC between February 2008 and January 2015 was analyzed. Data regarding, stage at diagnosis, pathology, treatment, and clinical outcomes were available. Statistically significant differences in baseline characteristics and administered therapies in women with and without PABC were evaluated using the chi-square or Fisher’s Exact tests. Kaplan-Meier curves for DFS and OS in the PABC and non-PABC cohorts were compared using the log-rank test. A multivariate Cox proportional hazards model adjusted for age, nodal involvement and tumor size.

Results: Of 224 women in the database who provided consent for research, 32 (12%) had PABC. Mean age of the PABC and non-PABC patients respectively was 34 (range 27 to 39) and 37 (range 21 to 40) and the median follow-up was 40 months in both groups. PABC was more likely to be locally advanced at diagnosis (44% vs. 22%, p<0.01) and less likely to be hormone receptor positive (75% versus 85%; p <0.01). There was no significant difference in age at diagnosis, tumor grade, lymphovascular invasion, HER2 expression or administered treatments between the two groups. Among the 166 women with early stage BC (not locally advanced), PABC was associated with positive lymph node status in a univariate model [OR 3.2 (95%CI 1.2-8.4), p=0.02] but just missed significance in a multivariate analysis that adjusted for age and tumor size (p=0.06). Eight patients (22%) in the PABC group and 19 (10%) in the non-PABC group experienced local or distant disease recurrence; 3 patients (8%) in the PABC group and 11 (6%) in the non-PABC group died. The 3-year DFS in the PABC and non-PABC cohorts was 79% vs. 90% (p=0.22) and the 3-year OS was 97% in both groups.

Conclusion: Diagnostic delay could account for the higher rate of locally advanced disease in the PABC group. However, the lower hormone receptor expression and strong trend toward greater lymph node involvement independent of size suggest that women with PABC may have intrinsically worse disease biology. Event rates may still be too low to detect a statistically significant difference in recurrence risk. Further research is necessary to identify unique molecular features of PABC that may be amenable to targeting.
Title: Oncologic outcome of pregnancy associated breast cancer: A case-control study

Body: Introduction and Aims
Pregnancy-associated breast cancer (PABC) is defined as the diagnosis of invasive breast cancer during the gestational period, within one year of pregnancy or any time during lactation. A diagnosis of PABC has traditionally been attributed a poor prognosis. The aim of this study was to assess the long-term outcome of patients diagnosed with PABC compared to a cohort of age-matched control patients.

Methods
A single-institution retrospective chart review was performed in 188 patients with PABC treated between the years of 1992 and 2015. Non-PABC controls were selected to match based on age and year of diagnosis. Clinicopathologic features, surgical and adjuvant treatments received, and clinical outcomes were assessed. Patients who were stage IV at diagnosis were excluded. Overall survival was estimated using Kaplan-Meier methods and compared between cases and controls using a log-rank test stratified on matched pair.

Results
Out of 188 patients with PABC, 63 (34%) were pregnant at the time of diagnosis and 125 diagnosed within 1 year of pregnancy (average: 6 months post partum). The characteristics of the PABC and case-matched controls are listed in Table 1.

</table>

Figures are reported as percentages for categorical variables. OS: Overall survival
Important pathological differences were evident with PABC patients compared to the non-PABC controls. PABC cases were more likely to be high grade (p<.001), node positive (p=.039) and less likely to be estrogen or progesterone receptor positive (p=.003). The majority of both cases and controls received chemotherapy (18% neoadjuvant). In the patients who were pregnant at time of diagnosis, 19 received chemotherapy during their pregnancy, with the most common combination being AC followed by paclitaxel in the post-partum period. Five year overall survival was similar for both groups, 88% for PABC patients and 95% for non-PABC case controls (p=.746) with a median follow up of 5.1 years.

Conclusion
Diagnostic and therapeutic advances have improved the oncological outcome for breast cancer patients, but not all of these have been adapted for pregnant patients. The consistent finding of higher-stage tumors in these patients reinforces the importance of utilizing developments in systemic treatments, potentially through case registries, to evaluate outcomes. PABC is associated with more adverse features than non-PABC controls matched for age and year of diagnosis. However, PABC is not in itself an adverse prognostic factor for survival after correcting for pathologic features.

Title: PD-L1 is highly expressed in tumor infiltrating lymphocytes in pregnancy associated breast cancer

Blanco Jr LZ Z, Pincus JL L and Siziopikou KP P. Northwestern University, Section of Breast Pathology, Chicago, IL and Robert H. Lurie Cancer Center, Chicago, IL.

Body: Background: Pregnancy associated breast cancer (PABC), diagnosed during or after gestation, is typically triple negative, and is associated with a poor prognosis. Those diagnosed within two years have an even worse outcome. We previously assessed the immune microenvironment of invasive breast carcinomas in young women and reported that tumor infiltrating lymphocytes (TILs) were more prominent in PABC. Programmed cell death protein 1 (PD-1) is upregulated following activation of lymphocytes, while programmed death ligand 1 (PD-L1) is one of the primary ligands that it interacts with to inhibit T-cell activation and proliferation. PD-L1 may also be constitutively expressed on tumor cells as a result of oncogenic signaling or epithelial-mesenchymal transition. Emerging evidence suggests that the effect of the local immune system, particularly the interactions between PD-1 and PD-L1, is also key in breast cancer progression and in breast tumor responses to chemotherapy and targeted therapy. In this study, we assessed expression of PD-1 and PD-L1 in both TILs and tumor cells in PABC and in age-/stage-/grade-matched nulliparous women, and correlated their expression with clinicopathologic characteristics in this aggressive type of breast carcinomas.

Design: 21 patients diagnosed with PABC within two years of pregnancy (mean age=35.7, range=26-48) and 15 matched controls (mean age=37.5, range=29-51) were evaluated. Slides were reviewed and pathologic tumor characteristics, including TILs, were noted. Immunohistochemical stains for PD-1 and PD-L1 were performed. Extent (1=1-25% positive tumor cells, 2=26-50%, 3=51-75%, 4=76-100%) and intensity (1=weak, 2=moderate or 3=strong) of staining were assessed. A composite score (CS) was calculated by multiplying the extent by intensity (range=0-12; weak=1-3; moderate=4-8 and strong=9-12).

Results: The mean CS for PD-L1 in TILs was significantly higher in PABC (5.86) compared to controls (3.07), \( p = 0.03 \). Further, strong expression of PD-L1 in TILs was only observed in PABC (9/21, 42.9%); none of the controls had strong PD-L1, \( p = 0.01 \). The high expression of PD-L1 in PABC TILs was independent of tumor grade, hormone receptor and HER2 status, and other histologic features including lymph node metastasis. Expression of PD-1 in TILs was similar in both PABC and controls (mean CS 6.81 and 5.36, respectively). Immunoreactivity in the tumor cells themselves was rare with only two PABC and four control cases expressing PD-1 and PD-L1.

Conclusion: 1. TILs in PABC have significantly higher PD-L1 expression. 2. Strong expression of PD-L1 in TILs was only observed in PABC. 3. High PD-L1 expression in TILs was independent of the tumor characteristics in this series. 4. PD-1 is expressed similarly in TILs in both PABC and controls. 5. Rare cases may have PD-1 and PD-L1 expression in the tumor cells themselves. The results of our study showing significant expression of PD-L1 in PABC TILs add to the understanding of the role of the microenvironment in breast cancer progression. These complex interactions between tumors cells and the local immune system may predict response to therapy and investigation into the role of immune based therapies is under way in these aggressive breast carcinomas that affect young women.
Title: Phase II in-human dose escalation study of the optical molecular imaging tracer bevacizumab-800cw for molecular fluorescence guided surgery in primary breast cancer patients

van Dam GM M, Koller M, Qiu SQ Q, Linssen MD D, de Vries J, Jansen L, Kelder W, de Jong JS S, Jorritsma-Smit A, van der Vegt B, Robinson DJ J and Nagengast WB B. University Medical Center Groningen (UMCG), Groningen, Netherlands; Martiniziekenhuis, Groningen, Netherlands; University Medical Center Utrecht, Utrecht, Netherlands and Erasmus Medical Center, Rotterdam, Zuid-Holland, Netherlands.

Body: Introduction
Molecular Fluorescence Guided Surgery (MFGS) might be used for intraoperative detection of positive resection margins in breast conserving surgery (BCS) for the treatment of breast cancer. Currently, the presence of tumor positive resection margins can only be assessed ex vivo by histopathological analysis of the excised tissue, which takes up to 5 working days. The current study defined the optimal dose of the near-infrared (NIR) optical imaging tracer bevacizumab-800CW to enable intraoperative detection and image-guided pathology of tumor positive resection margins in breast cancer patients.

Methods
Molecular Fluorescence Guided Surgery during BCS was performed in subjects treated for primary breast cancer. The NIR optical imaging tracer bevacizumab-800CW targeting vascular endothelial growth factor A was administered intravenously three days prior to surgery in four escalating dose groups (4.5mg, 10mg, 25mg and 50mg). NIR fluorescent signals were detected real-time using an intraoperative fluorescence camera system (SurgVision BV). Standardized ex vivo analyses of tumor-to-normal ratios (TNR) were performed to define the optimal tracer dose using a BlackBox imaging system (SurgVision BV) for imaging fresh bread loaf slices, a NIR fluorescence flatbed scanner (Odyssey, Li-Cor) for imaging 10µm slices of formalin-fixed paraffin-embedded (FFPE) blocks, NIR Confocal Laser Endomicroscopy (CLE, Mauna Kea Technologies) and multi-diameter single fiber reflectance and single fiber fluorescence (MDSFR/SFF) spectroscopy quantification to enable correction for the influence of tissue optical properties on fluorescence in tumor and normal breast tissue.

Results
Currently, 12 subjects have been included and analyzed in four dosing groups. All tumors showed specific tracer uptake at macroscopic and microscopic level during ex vivo analyses, confirmed by histopathology. Quantification of NIR fluorescent signals showed higher TNRs by increasing doses up to 25mg. No further increase in TNR was seen in the 50mg dose group. CLE showed the feasibility of visualization of the tracer accumulation in tumor tissue compared to normal tissue at a microscopic level. MDSFR/SFF spectroscopy objectively confirmed the dose dependency up to 25mg.

Conclusion and future perspective
Intravenous administration of bevacizumab-800CW in doses up to 50mg is safe and highly tumor specific, showing a plateau of TNR at 25mg and 50mg. Further expansion of the dosing cohorts of 10mg and 25mg with additional seven patients per group will be performed to establish the optimal dose for MFGS during BCS for an upcoming phase III multicenter randomized controlled trial. By enabling MFGS during BCS the surgical treatment of primary breast cancer patients might be optimized by a reduced need for re-excision surgery and thereby reducing the risk of co-morbidity, psychological burden, poor cosmesis and healthcare costs.
Title: Diagnostic value of breast specific gamma imaging for breast cancer

Body: In this study, 422 female patients who presented with clinical indications and underwent ultrasound (US), mammography (MMG), and breast specific gamma imaging (BSGI) before surgery during the period from July 2013 to June 2015 were retrospectively reviewed. Twenty-two of the patients had no pathological report available and were excluded. These patients who presented with clinical indications underwent both ultrasound and mammographic examinations initially. If both US and MMG were positive, the patient was recommended for a BSGI examination for pre-surgical planning. A BSGI examination was also recommended for patients with negative or indeterminate mammographic findings.

The diagnostic results were compared with histological examination and the sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) for each modality were determined. Combinations of either two or three of the diagnostic results were also reviewed and the corresponding diagnostic indicators calculated. For these combinations, a positive indication on one of the two (or three) diagnostic tests were interpreted as a positive result. The sensitivity of US, MMG, BSGI, the combination of US and MMG, US and BSGI, MMG and BSGI, and the combination of all three together in the diagnosis of breast carcinoma were determined for the 400 patients included in the study and are listed in Table 1, column 1. The specificity, PPV, and NPV for each of these modalities and combinations of modalities were also determined and are shown Table 1, column 2-4.

The population was comprised of 243 patients with 245 malignant lesions and 157 patients with 189 benign lesions. The malignant lesions were primarily infiltrating ductal carcinoma (76%) and ductal carcinoma in situ (14%), with the remaining lesions (10%) being invasive lobular carcinoma, Paget’s disease and mixed carcinomas. The benign lesions were primarily fibroadenoma (39%), adenosis (40%) and papilloma (10%), with the remaining lesions (11%) being duct ectasia, inflammation or phyllodes. There were 79 false negative cases by MMG, however, when ultrasound and BSGI were combined, 73 out of 79 were accurately identified. Additionally, there were nine, seventeen and eighteen Ductal Carcinoma in situ (DCIS) misdiagnosed by BSGI, MMG, and ultrasound respectively, but through joint imaging of BSGI+MMG+US; 33 out of 35 were accurately judged.

BSGI is a useful adjunct modality for the diagnosis of breast carcinoma. It is also extremely useful for diagnosis of non-calcified DCIS, and circumvents limitations of mammography in identifying malignant lesion in dense breast. Moreover, it is helpful for improving the diagnosis accuracy of breast carcinoma when BSGI is combined together with MMG and US.
Title: Predictive value of FDG-PET/CT after neoadjuvant endocrine treatment in breast cancer

Body: Background: Neoadjuvant endocrine therapy (NET) has demonstrated efficacy in terms of clinical response and outcome in hormone-receptor positive (HR+) post-menopausal patients (pts) with breast cancer (BC) not eligible for primary breast conservative surgery (BCS). However, the monitoring of tumor response to NET is challenging and clinical response is the current gold standard. The aim of the present study was to investigate the contribution of the early metabolic response (eMR) at one month in FDG-PET/CT in a NET setting for post-menopausal pts with HR+, HER2- BC compared to morphological and pathological responses. We also aimed to evaluate the prognostic value of eMR.

Methods: This was a prospective and ancillary study of CARMINA 02, UCBG0609 (Cancer in press), a phase II clinical trial evaluating the efficacy of 4 to 6 months neoadjuvant anastrozole or fulvestrant. FDG-PET/CT exams were performed at baseline (M0), after 1 month of treatment (M1: eMR) and pre-Op (late metabolic response: lMR) in 11 pts (74.2 years ± 3.6) from 2007 to 2010. Pts were classified “metabolic responders” (mR) if SUVmax values decrease was ≥ 40% at M1 and “non-metabolic responders” (mNR) if otherwise; lMR was also assessed in mR and mNR groups defined at M1. We compared eMR to morphological response (clinical, breast US and MRI) at M1 and pre-op, to the pathological response according to Sataloff classification and to Ki67 score variation during treatment. Early metabolic response was also correlated with the PEPI (Preoperative Endocrine Prognostic Index) score and survival (overall survival, OS and relapse free survival, RFS).

Results: Main results are summarized in Table I. There was a significant difference between mR and mNR pts at M1 (eMR) and pre-op (lMR). One patient with a complete metabolic response at pre-op had the best pathological response (Sataloff TB). Also, mR pts had a better clinical response: 2 partial response (PR) in mR vs 1 in mNR group and 2 mNR patients were classified PD (progressive disease). There was a trend toward better survival for mR pts in OS and RFS (Kaplan-Meier p=0.18 and 0.06, respectively) and all the pejorative events occurred in the mNR group: 3 deaths and 3 metastatic progressions. Besides, no difference in eMR was observed regarding the histological subtype (ductal or lobular; p>0.05) nor the treatment group (p>0.05).

Table I: Metabolic, morphological and pathological response at M1, Pre-Op and on the surgical specimen.

Conclusions: These preliminary results showed the value of the early metabolic response in FDG- PET/CT in a NET setting...
compared to the morphological or the pathological responses alone. Early metabolic responders patients had better OS, RFS and PEPI scores.
Title: Assessing response in locally advanced breast cancer treated with neoadjuvant chemotherapy: Predictive and prognostic potential of volume-based metabolic variables with 18F-FDG PET/CT

Hospital Virgen de la Luz, Cuenca, Spain; Hospital General Universitario de Ciudad Real, Ciudad Real, Spain; Instituto de Matemática Aplicada a la Ciencia. Universidad de Castilla-La Mancha, Ciudad Real, Spain; Servicio de Oncología Médica. Hospital Virgen de la Salud, Toledo, Spain and Servicio de Oncología Médica. Hospital La Mancha Centro, Alcázar de San Juan, Ciudad Real, Spain.

Body: Aim:
To explore the usefulness of metabolic variables of breast tumours obtained in 18F-FDG PET/CT in the prediction of response to neoadjuvant chemotherapy (NC) and prognosis in locally advanced breast cancer (LABC).

Material and methods:
Prospective multicenter study including 60 patients with LABC and NC indication and a baseline 18F-FDG PET/CT. After breast tumor segmentation, SUV variables (SUVmax, SUVmean and SUVpeak) and volume-based variables as metabolic tumor volume (MTV) and total lesion glycolysis (TLG) were obtained. Univariate analysis was performed with the use of Kaplan-Meier and Cox proportional hazards models to study the potential of metabolic variables, molecular phenotypes of breast cancer specimens and histologic response to predict: disease-free status (DFs), disease-free survival (DFS) and overall survival (OS).

Results:
Sixty patients underwent NC. 14 were classified as pCR. 56 patients were free of recurrence during the follow-up. Median ± SD of DFS and OS was 43±15 and 46±13 months respectively. SUV and volume-based variables showed significant relations (p<0.005) with the histological response with higher values in responders compared to no responders (median, mean and SD of SUVmax, SUVmean, SUVpeak, MTV and TLG of 13.77, 13.34 and 5.79; 8.85, 8.35 and 3.73; 11.33, 10.7 and 4.88; 13.44, 26.60 and 34.58 and 96.39, 258.12 and 384.63 for responders vs 6.04, 7.84 and 5.26; 3.42, 4.77 and 3.20; 4.79, 6.06 and 4.08; 9.88, 13.63 and 12.48 and 33.78, 70.17 and 97.94 for non responders respectively).

MTV and TLG showed significant association with DFs (p=0.015 and p=0.038 respectively). Median, mean and SD of MTV and TLG for patients with DFs were: 8.90, 13.72 and 15.12 and 90.54 and 144.64 respectively. Median, mean and SD of MTV and TLG for patients with a non-DFs were: 16.72, 29.70 and 31.09 and 90.89, 210.98 and 382.80 respectively. No significant relations were observed with SUV variables and DFs.

Conclusion:
No significant relations were obtained for none metabolic variable with DFS and OS.

Conclusion:
In patients with locally advanced breast cancer, volume-based metabolic variables obtained with 18F-FDG PET/CT, differently to SUV based variables, were good predictors of neoadjuvant chemotherapy response and disease free status.
Title: In vivo, intraoperative margin detection utilizing the Lumicell margin assessment system

Body: ***This is a place-holder abstract***
In breast conserving surgery (BCS), obtaining tumor-free margins while excising minimal healthy tissue is critical for local control and maximizing cosmetic outcome. Currently, 20-40% of lumpectomy patients have positive margins that require surgical re-excision. Second surgeries increase discomfort, add emotional and cosmetic expenses to the patient, and add cost to the healthcare system.

This placeholder abstract will report the findings from Phase 2B of a two part Feasibility Clinical Study for the Lumicell Margin Assessment System, consisting of the LUM015 optical contrast agent and the LUM2.6 Imaging Device, for real-time, intraoperative detection of residual tumor in patients with breast cancer during lumpectomy surgery. Phase 2A results demonstrated that LUM015 is tumor selective, safe in humans, and 100% sensitivity for tumor detection. Of 15 study patients, 10 were injected with LUM015, and 2 (20%) had positive margins with “ink on tumor” on standard histopathology and underwent re-excision. In both cases, the LUM Imaging System correctly identified residual tumor in lumpectomy cavity walls during the initial surgery which was confirmed by pathology. Data from Phase 2A were analyzed to determine the parameters of the detection algorithm which will be assessed in Phase 2B using a LUM015 dose of 1.0mg/kg.

In Phase 2B, up to 50 patients will be evaluated to achieve 10 evaluable subjects with positive margins based on histological margin assessment from the initial shaved margin. The surgeon will use the LUM 2.6 Imaging Device to remove up to three shaved margin specimens from each tumor bed cavity surface identified as containing fluorescence above the abnormal tissue threshold. Final margin assessment for each lumpectomy surface will be assessed per standard of care by a pathologist by measuring the distance to the inked surface of each tissue shaving from invasive cancer or ductal carcinoma in situ (DCIS). Concordance between final pathology determination and the LUM 2.6 Imaging Device will be reported along with overall positive margin rate. As of June 13, 2016, 9 patients have been enrolled, 3 patients have already undergone standard of care surgery followed by removing therapeutic shaves when indicated by the Lumicell Margin Assessment System.

We anticipate having the results from the Phase 2B study completed by the submission deadline of October 1, 2016. We will report the results in terms of concordance between intraoperative imaging and pathology analysis. This study is registered with ClinicalTrials.gov, identifier NCT02438358.
Title: Diffuse optical tomography can predict pathologic complete response in patients with HER2+ or triple negative breast cancer undergoing neoadjuvant chemotherapy

Body: Background
Pathologic complete response (pCR) predicts clinical outcome in women who receive neoadjuvant chemotherapy (NACT) for breast cancer. Identifying who will have a pCR early during NACT has the potential to save patients months of ineffective chemotherapy and limit unnecessary toxicity; however, no method currently is standardly used. Diffuse optical tomography (DOT) uses near-infrared light to measure concentrations of oxyhemoglobin [HbO₂], deoxyhemoglobin [Hb], total hemoglobin [HbT], and oxygen saturation [SO₂%], and can assess tissue structure and vascularity. As it is inexpensive, fast, and does not require radiation or intravenous contrast no radiation nor IV contrast, DOT has the potential to become an integral part of NACT to predict responses to NACT. Given the particular significance for pCR in HER2+ and triple negative breast cancer (TNBC), we prospectively evaluated whether a 2 week change in DOT parameters could predict pCR after 5 months of NACT in these subtypes.

Methods
We conducted a prospective cohort study of women with stage II-IIIC breast cancer scheduled to receive NACT with 12 weeks of weekly taxol and four cycles of doxorubicin with cyclophosphamide (AC). We evaluated the associations between residual cancer burden (RCB: 0-3; pCR= RCB 0) and changes in DOT measures. Optical imaging was performed at baseline and before the following: Taxol #3, Taxol #5, AC #1, AC #2, and surgery. Correlation and t-testing were used to evaluate the relationship between 2-week DOT changes and pathologic response.

Results
In a prospectively accrued, longitudinal clinical study with DOT, at least 20 patients with HER2+ or TNBC were enrolled. For patients with these tumor subtypes, there was a significant association between pCR after 5 months of NACT (i.e. RCB 0) and change in the following DOT parameters comparing baseline to after 2 weeks of taxol: HBO (p=0.02), HBT (p=0.02), and S02% (p=0.03). No significant association was seen with HB (p=0.20) or water (p=0.85). When looking specifically at patients with TNBC (n=at least 8 patients), these associations were particulars strong between pCR and the following DOT parameters: HBO (p=0.004), HBT (p=0.009), and S02% (p=0.04). Additional patients are anticipated in this study are anticipated to complete NACT and will be reported at SABCS.

Conclusions
Optical imaging can provide imaging biomarkers to monitor breast cancer response to NACT. Early predictions of pathologic response to NACT can be made with high accuracy as early as two weeks after treatment initiation. These findings are specifically strong in TNBC, a group for whom pCR is predictive of clinical outcome.
Title: A liquid biopsy test for breast cancer detection provides consistent diagnostic results in patients over six months

Body: Current methods of breast cancer detection are often confounded by imaging limitations, such as lesion size, benign breast tissue, and dense breasts. These limitations result in unnecessary biopsies due to false positive findings based on imaging. Despite the increased ability to detect early breast cancer, the over-use of biopsy remains an issue. There is a critical need for new approaches to breast cancer detection that improve diagnostic accuracy when clinical assessment is challenging. Provista Diagnostics has developed Videssa® Breast - a blood-based proteomic test that measures serum protein biomarkers (SPBs) and tumor-associated autoantibodies (TAAbs). Patient biochemical data is combined with clinical data to generate a diagnostic score that correlates with either the absence or presence of breast cancer (Grades I through III). The ability of Videssa® breast to detect cancer (Invasive Breast Cancer and Ductal Carcinoma in situ) was evaluated using prospective, multi-center clinical trials. The Provista-001 study enrolled 351 women ages 25-49 and included a follow-up visit at 6 months with an additional blood draw. Eligible patients included women assessed as ACR BIRADS® 3 or 4 on imaging with no history of breast cancer or prior breast biopsy.

Serum samples from the initial visit and 6 month follow-up visit of Provista-001 were analyzed using Videssa® Breast to determine if diagnostic results for benign subjects were similar over the course of the study. Samples were analyzed for SPBs and TAAbs in order to determine whether analyte levels and diagnostic scores change over a 6-month period in patients diagnosed with a benign breast condition. Linear regression data for analytes shows overall high fidelity between the initial visit and follow-up. In addition, samples that were TAAb-positive for a given target at the initial visit tended to remain positive at follow-up. Sample background, deriving from unidentified immunological factors, can confound the analytical output when measuring TAAbs in serum. Interestingly, sample background was highly reproducible between both visits, suggesting that these values are related to inherent patient-specific factors. Overall, these data demonstrate high analytical reproducibility for in expression of independent Videssa® Breast biomarkers in patients diagnosed with a benign breast condition over the course of six months. Data for 236 women were compared between visits and demonstrated greater than 80% concordance in diagnostic status.

The ability of Videssa® breast to provide consistent diagnostic results over 6 months further supports use of the test as an adjunct to imaging for the early detection of breast cancer and provides physicians with an additional tool that can be used to inform the decision to biopsy or increase vigilance through active monitoring.
Specific detection of anti-Her2 PEGylated PrecisionMRX® nanoparticles measured using superparamagnetic relaxometry

Weldon CL L, Minser KE E, Gomez A, Anderson WH H, Karaulanov T, Hathaway HJ J, Huber DL L, Vreeland EC C and Paciotti G. Senior Scientific LLC, Albuquerque, NM; University of New Mexico Health Sciences Center and University of New Mexico Comprehensive Cancer Center, Albuquerque, NM and Center for Integrated Nanotechnologies, Sandia National Laboratories, Albuquerque, NM.

Body: Current methods for detecting solid tumors lack sensitivity and diagnose primary and metastatic lesions only after the tumor is well established. Superparamagnetic Relaxometry (SPMR) is a combination technology that utilizes superconducting quantum interference detectors (SQUID) to measure the magnetization of superparamagnetic, tumor-targeting magnetite (Fe₃O₄) nanoparticles. Conceptually, PEGylated Fe₃O₄ nanoparticles labeled with a tumor targeting moiety (i.e., a monoclonal antibody) are intravenously injected and specifically target solid tumors utilizing both passive (the EPR effect) and active (receptor-mediated) mechanisms. Subsequently, the Fe₃O₄ nanoparticles are magnetized by a low field magnetic pulse in the MRX™ instrument and only those particles that are bound to their target site are measured by the SQUID sensors. Unbound nanoparticles are not detected.

To demonstrate the utility of SPMR in detecting cancer we used PEGylated PrecisionMRX® nanoparticles that are covalently linked with a monoclonal antibody (mAb) targeting ERB-2 (anti-Her2). The particles were characterized for size (by dynamic light scattering), free and bound mAb (by ELISA), antibody potency (by bioassay) and stealth (in plasma interaction studies). In vitro, the anti-Her2 conjugated particles exhibited specific binding to ERB-2 overexpressing breast cancer cells (MCF-7/Her2-18). Specific binding was defined by the ability of the native mAb to competitively block the binding of the anti-HER-2 conjugated particles to ERB-2 antigen coated on ELISA plates or expressed on the cell surface. In addition, in ERB-2 negative cell lines, the anti-Her2 conjugated particles exhibited little to no binding.

In vivo, anti-Her2 conjugated PrecisionMRX exhibited significantly longer circulation times when compared to unPEGylated particles. Distinct magnetic dipoles were detected by the MRX instrument at the target site (the tumor) and site of nanoparticle elimination (the liver). These data were confirmed in excised organs showing significant magnetic moments in the liver, tumor, and spleen.

Analysis of the MRX SPMR data suggest that the technology can detect as few as 10,000 cancer cells in vivo by optimizing the nanoparticles for stealth and targeting.

This work was performed, in part, at the Center for Integrated Nanotechnologies, an Office of Science User Facility operated for the U.S. Department of Energy (DOE) Office of Science. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

Title: γ-glutamyl hydroxymethyl rhodamine green (gGlu-HMRG) is promising fluorescence probe for rapid diagnosis of breast cancer; The feasibility study of real time imaging for breast cancer examination -

Takamaru T, Akashi ST T, Kuwayama T, Sawada T, Hirota Y, Urano Y and Nakamura S. Showa University Koto Toyosu Hospital, Tokyo, Japan; Showa University, Tokyo, Japan and Graduate School of Medicine, The University of Tokyo, Tokyo, Japan.

Body: Background and Aim
To date, fluorescence imaging has been used gradually for real time diagnosis in various clinical situations. Evaluation of margin on surgical specimens is essential to decide whether additional resection should be performed for breast cancer surgery. In the same context, rapid assessment of biopsy specimen is crucial because when they do not contain any part of the lesions, re-examination should be need.

A fluorescence probe named γ-glutamyl hydroxymethyl rhodamine green (gGlu-HMRG) was rapidly activated by an enzyme, γ-glutamyltransferase (GGT). It was overexpressed in variety of cancers so promising for clinical use. The aim of this study is to examine the usefulness of the probe for breast cancer detection.

Material and Methods
We investigated the patients of breast cancer or benign disease who received examination consecutively from March 2015 to February 2016 in our hospital. The samples were obtained by core needle biopsy (CNB) or vacuum-assisted breast biopsy (VAB). We sprayed the probe on these samples immediately after examination and shoot images by CCD camera. To evaluate the fluorescence intensity along the time, we used a filtered CCD camera that could detect specifically gGlu-HMRG color (Discovery® INDEC Medical Systems Inc.). The images were automatically obtained every 30 seconds for 10 minutes after adding the probe on the specimens.

The average value of the image in each region of interest (ROI) was analyzed using image analysis program Image J (https://imagej.nih.gov/ij/).

We investigated the change of fluorescence intensity with the passage of time. We also compared the fluorescence intensity of malignant lesions with benign ones, and analyzed whether the fluorescence intensity could distinguish the malignant lesions from benign ones.

Result
We obtained 362 samples from 96 tumors. Fifty-six tumors with 215 samples were benign, while 40 tumors with 147 samples are malignant histologically.

The fluorescence was immediately observed after sprayed the probe. The intensity had been increasing in proportion to time. The malignant specimens were rapidly increasing; in contrast, the benign ones were slowly. For example, when it took 60 seconds after spraying the probe that the intensity increase up to some level in malignant specimens, while benign one took 240 seconds up to the same level on average.

Comparing the malignant lesions with benign ones after sprayed 120 seconds, the fluorescence intensity was higher in malignant specimens than benign ones (average fluorescence intensity; benign 0.9, malignant 2.3 p=0.0138). By ROC analysis whether the fluorescence intensity could distinguish the malignant lesions from benign, AUC, sensitivity and specificity was 0.63, 70% and 57%, respectively (cut off 0.2).

Conclusion
The probe was contributory to distinguish malignant and benign lesions and may be useful for the rapid diagnosis of CNB in practice. We are now trying to seek a more accurate probe to differentiate benign and malignant lesion as a next step.
Development of photoacoustic vascular imaging system for breast cancer

Toi M, Asao Y, Takada M, Kataoka M, Endo T, Kawashima M, Yamaga I, Nakayama Y, Tokiwa M, Fakhrejahani E, Torii M, Kawaguchi-Sakita N, Kanao S, Matsumoto Y, Yagi T, Sakurai T, Togashi K and Shiina T. Graduate School of Medicine, Kyoto University, Kyoto, Japan; Medical Imaging System Development Center, Canon Inc., Tokyo, Japan; Graduate School of Medicine, Kyoto University, Kyoto, Japan; Graduate School of Medicine, Kyoto University, Kyoto, Japan and Graduate School of Medicine, Kyoto University, Kyoto, Japan.

Background:
Tumor angiogenesis and hypoxia are associated with breast cancer growth and metastasis. Photoacoustic (PA) tomography is an optical imaging technology that visualizes distribution and oxygenation status of hemoglobin with high spatial resolution. Initially we developed a photoacoustic mammography (PAM) having a flat-shaped scanning detector that could detect breast tumors. Nevertheless, the flat-shaped detector array has the drawback of a limited view. Here we developed a novel PAM system with a hemispherical-shaped detector array (HDA), which enables us to identify microvasculatures non-invasively and allow the collection of nearly spatially isotropic three-dimensional reconstructed image of blood vessels. This non-invasive vascular imaging system may be able to characterize tumor angiogenesis and analyze the status of microcirculation. The aim of this study was to analyze the imaging findings of tumor-related vasculature in breast cancer patients.

Patients and method:
A PAM system with HDA has been generated in a cooperation project between Canon Inc., Japan, and Kyoto University. Twenty-two primary breast cancer patients, including 5 patients with non-invasive cancer and 17 patients with invasive cancer, diagnosed between December 2014 and December 2015 underwent the PAM imaging analysis. We also applied the breast deformation algorithm from the breast shape in a MRI image to that in a PA image in order to create a fusion image of the two modalities for the analysis. Features of peri- and intra-tumoral vasculature, and their oxygenation status were evaluated. The study protocol was approved by the institutional review board at Kyoto University Hospital (UMIN000012251). All patients provided informed consent to participate in this study.

Results:
The abnormal peri-tumoral vasculature was detected in 86% of all non-invasive and invasive disease cases. In invasive cancer cases, most tumor-related blood vessels were centripetally directed toward the tumor, and 93% of centripetal blood vessels appeared to be disrupted or rapidly narrowed at the tumor boundary. The centripetal blood vessel structure was frequently observed in invasive cancer compared with non-invasive cancer (61% vs 35%). PA images before and after preoperative chemotherapy were obtained in one case, where intra-tumoral blood vessels became finer after chemotherapy, reflecting normalization of intra-tumoral microcirculation induced by chemotherapy.

Conclusions:
A PAM system with HDA has provided a high-resolution vascular images of primary breast cancers. The morphological differences of peri-tumoral vasculature were observed between invasive disease and non-invasive disease. These results suggest the potential of PA imaging as a non-invasive tool to analyze tumor vasculature of human breast cancers and maybe be helpful for breast cancer diagnosis.

Title: Diagnostic performance of supplemental screening with molecular breast imaging in women with dense breast tissue

Redfern RE E, Shermis RB B, Chen JT T and Kudrolli H. ProMedica Toledo Hospital, Toledo, OH; Bowling Green State University, Bowling Green, OH and Gamma Medica, Inc, Salem, NH.

Body: Purpose: The aim of this study was to retrospectively assess the diagnostic performance of molecular breast imaging (MBI) as a supplementary screening tool for women with dense breast tissue. We had previously reported excellent cancer detection rates and positive predictive values, whereas in this report we present 1-year follow up data and present sensitivity, specificity and negative predictive values. Methods: Molecular Breast Imaging (MBI) was implemented in routine clinical practice at a large, community-based breast imaging center. Women 25 to 90 years of age with dense breasts and negative mammogram results who underwent subsequent screening with 300 MBq (8 mCi) $^{99m}$Tc-sestamibi MBI were retrospectively analyzed. Outcome measures included sensitivity, specificity, and positive and negative predictive values. Results: In 1,376 women with a complete reference standard, 17 (1.2%) were diagnosed with cancer. MBI detected cancer in 15 subjects such that 2 interval cancers occurred and were considered false negatives. Of those 17 cancers, 1 (5.9%) were ductal carcinoma in situ only, 13 were invasive tumors (76.5%); 1 (5.9%) patient was diagnosed with bilateral disease. Overall sensitivity of MBI in this sample was 88.2% (95% CI 63.6 – 98.5), while specificity was also high at 92.4% (95% CI 90.9 – 93.8). Positive predictive value for recall ($PPV_1$) was 12.7% (95% CI 7.3 – 20.1), while negative predictive value for recall ($NPV_1$) was calculated as 99.8% (95% CI 99.4 – 100.0). Conclusions: When incorporated into a community-based clinical practice environment, MBI demonstrated high sensitivity, specificity and negative predictive value. These results demonstrate the utility of MBI as a supplementary screening tool to mammography for women with dense breasts.
Eribulin induces vascular remodeling and reoxygenation in advanced breast cancer patients: A comparative study with bevacizumab

Ueda S, Saeki TS, Takeuchi H, Shigekawa T, Yamane T, Kuji I and Osaki A. International Medical Center, Saitama Medical University, 1371-1 Yamane, Hidaka, Saitama, Japan.

Body: Purpose: Eribulin mesylate (eribulin) is a first-in-class halichondrin B-based microtubule dynamics inhibitor. To understand the mechanism of vascular remodeling of eribulin, we compared optical hemodynamic and blood biomarker changes between eribulin and bevacizumab.

Methods: Patients with advanced breast cancer with stage III/IV were eligible for the study. Patients were assigned to receive either eribulin or single-agent bevacizumab. Diffuse optical spectroscopic imaging (DOSI) measured tissue concentrations of oxy-hemoglobin (O2Hb), deoxy-hemoglobin (HHb), total hemoglobin (tHb) and oxygen saturation (SO2) of breast tumors before and day 7 after the first infusion. Peripheral blood samples were obtained from the patients to measure plasma concentration of VEGF, bFGF, FLT-3L, EGF, G-CSF, TNFα, IL1b, IL4, IL6, IL8, IL10, IL12p40, and TGF-β1.

Results: Baseline DOSI measurement of all 29 patients (eribulin, n = 14 and bevacizumab, n = 15) revealed significantly higher tumor concentrations of O2Hb, HHb, and tHb than that in the normal breast tissue. Eribulin significantly decreased in HHb concentration and increased SO2 during the observation period. This trend was not observed for bevacizumab. Instead, bevacizumab significantly decreased the concentration of O2Hb and tHb. The blood biomarker study revealed that both eribulin and bevacizumab decreased plasma concentrations of VEGF and bFGF, but only eribulin suppressed the plasma concentration of TGF-β1.

Conclusions: Optical imaging technology revealed that eribulin, but not bevacizumab, induced tumor reoxygenation after the start of infusion. Eribulin had a potent anti-angiogenic properties as well as bevacizumab, while suppression of TGF-β1 observed by only eribulin could be associated with remodeling of the microvasculature through suppression of activated stromal cells.
Title: Increased tumor perfusion following treatment with trastuzumab as measured by contrast-enhanced ultrasound

Sorace AG G, Barnes SL L, Quarles CC Chad, McIntyre JO Oliver and Yankeelov TE E. The University of Texas at Austin, Austin, TX; St. Joseph’s Hospital and Medical Center, Barrow Neurological Institute, Phoenix, AZ and Vanderbilt University Medical Center, Nashville, TN.

Body: Introduction: The primary purpose of this study is to determine if the order of dosing in standard-of-care (SOC) combination therapy for HER2+ breast cancer has an effect on the perfusion characteristics within the tumor. Improving the intratumoral delivery of cytotoxic systemic therapy is a significant challenge in advancing cancer treatment. Knowledge of the vascular changes following SOC treatments could enable optimizing their order and timing, potentially leading to significantly improved response. Currently, one SOC regimen for HER2+ breast cancer treatment is doxorubicin administered for 3-4 cycles prior to trastuzumab. Our goal is to quantitatively map the changes in perfusion in response to different combinations of trastuzumab plus doxorubicin treatment through imaging in a murine model of HER2+ breast cancer.

Experimental Design: BT474 breast cancer cells ($1 \times 10^7$) were subcutaneously implanted into mice ($n=12$) and randomly assigned into three treatment groups: two doses of trastuzumab (10 mg/kg) followed by doxorubicin (1.5 mg/kg), doxorubicin prior to trastuzumab (same total drug dosage as group 1), and saline. After tumors reached ~225 mm$^3$, animals were imaged with contrast-enhanced ultrasound (CEUS) (VisualSonics Vevo 770, Definity microbubbles) before treatment (day 0), and on days 1, 3, 4, and 7. Treatment occurred on days 0, 3 and 4. Percent change (from baseline, day 0 scans) of the CEUS signal intensity quantified from the functional vasculature (surrogate for vessel perfusion) following contrast injection were measured for each animal for each day. Tumors were extracted on day 7, and sectioned, paraffin-embedded, and stained with CD31, alpha-SMA and H&E.

Results: Tumors treated with trastuzumab initially exhibited a significant increase in CEUS signal intensity (from the functional vasculature) on day 1 compared to tumors initially treated with doxorubicin ($p < 0.01$). Additionally, compared to the control tumors, tumors treated with trastuzumab prior to doxorubicin revealed a significant increase in perfusion (change in signal intensity of functional vasculature) of contrast agent on days 3 ($p = 0.01$), 4 ($p = 0.001$) and day 7 ($p < 0.01$). There were no significant differences in the doxorubicin treated first group and the controls on any of the days ($p > 0.25$). Qualitative differences were noted between control and treated groups for alpha-SMA, no apparent differences were noted in microvessel density.

Conclusion: Trastuzumab significantly improves a tumor's vascular perfusion in this HER2+ breast cancer model. Doxorubicin dosing prior to treatment with trastuzumab may potentially be hindering the intratumoral delivery of the subsequently delivered, targeted therapy. Improving the tumor's functional vasculature by altering the order of dosing of these combination therapies by giving trastuzumab prior to cytotoxic therapy has potential to enhance both the delivery and the effectiveness of these combination therapies. These data indicate a potential pathway to optimize therapeutic efficacy for individual HER2+ breast cancer patients.
Body: Purpose: The Imagio® breast imaging system, a diagnostic opto-acoustic (OA) imaging device bearing the CE Mark, is in the U.S. FDA Premarket Approval process. OA provides both functional (relative oxygenation/de-oxygenation) and anatomic (angiogenesis) information that is co-registered and temporally interleaved in real time with gray-scale ultrasound that may improve distinction between benign and malignant masses. OA imaging pathology correlation was performed to elucidate the histologic features of OA features of breast cancers.

Methods and Materials: A multicenter postmarket surveillance and clinical follow-up study was conducted in five Dutch sites in which 209 women with breast masses underwent OA prior to biopsy. Histopathology examination of the biopsies revealed 146 benign masses (mostly fibroadenomas) and 76 malignant masses (mostly invasive ductal carcinomas). For invasive ductal carcinomas, histologic grade and the features used to assess histologic grade (nuclear pleomorphism, tubule formation, and mitotic count) were assessed. For each mass, 5 pre-determined OA features, 3 internal features, and 2 external features were evaluated. The 3 internal scores (vessels, blush, and hemoglobin) and 2 external features (capsular boundary zone and peripheral boundary zone) were separately and collectively summed for testing relationships with traditional histopathology measures using a two-sided Jonckheere-Terpstra test of ordered outcomes. Distribution differences between benign and malignant masses were performed using a Wilcoxon Rank Sum test for each internal, external, and summed total internal, external, and total score.

Results: The mean differences were significantly higher for malignant vs. benign for internal vessels (p=0.0009), internal blush (p=0.0085), external boundary zone (p<0.0001), and external peripheral zone (p<0.0001), but not internal hemoglobin. Mean Total Internal Score, Total External Score, and Total Internal and External Score were all significantly higher (all p<0.01) for malignant vs. benign. Among invasive carcinomas, Total Internal Score and Total Internal and External Score were significantly higher for higher histologic tumor grade (p=0.04, 0.02), significantly higher Total External Score and Total Internal and External Score for higher tubule score (p=0.06, 0.03), slightly higher Total Internal Score and Total Internal and External Score for higher nuclear pleomorphism score (p=0.04, 0.05), and slightly higher Total Internal Score for higher mitotic score (p=0.03).

Conclusion: OA feature summary scores appear to differentiate between benign vs. malignant and correspond to histologic grade and scoring components of histologic grade. The U.S. investigational PIONEER pivotal study (n=2,095) may further confirm these results.
Title: Using ultrasound findings to predict high tumor-infiltrating lymphocytes in triple negative breast cancer

Inagaki M, Ota D, Tsuji M, Kobayashi Y, Mori M and Fukuuchi A.  Breast and Endocrine Surgery, Mitsui Memorial Hospital, Tokyo, Japan and Pathology, Mitsui Memorial Hospital, Tokyo, Japan.

Body: Purpose Previous clinical data showed that high tumor-infiltrating lymphocytes (TILs) indicated a good prognosis in triple negative breast cancer (TNBC) and suggested that TNBC with TILs responded well to immunotherapy. Breast ultrasound is a safe inspection method without any radiation exposure. Therefore, we investigated whether ultrasound findings can predict high TILs in TNBC.

Patients and Methods The TNBC patients who underwent surgery at Mitsui Memorial Hospital, Tokyo, Japan, from 2009 to 2015, including those who underwent neo adjuvant chemotherapy (NAC), were selected for this study. The pre-treatment ultrasound findings were used retrospectively, and we compared the shape, margin, homogeneity of internal echoes, posterior features, and growth pattern of the lesions. Regarding shape, we classified the ultrasound findings as “round”, “oval”, “lobulated”, “irregular”, and “other” in accordance with The Japan Associations of Breast and Thyroid Sonology. Similarly, we classified the margins as "circumscribed" or “well-defined and smooth”, "well-defined and rough", "indistinct" and "obscure”. We used “homogeneous” and “heterogeneous” internal echoes. In terms of posterior features, we used the “accentuation”, “not changing”, “attenuating” and “shadowing” categories. By referring to previous report, we classified four types of growth patterns, i.e., "growing along the mammary ducts", "expansive growth pattern", "irregularly shaped mass with retracting surrounding tissue" and "other". Two pathologists evaluated stromal TILs, which were located between the cancer nests, by surgical specimens or needle biopsies of those who underwent NAC. Then the TILs were classified into four groups: “absent”, “weak”, “moderate”, and “dense”. “Absent” indicated that there were no lymphocytes in the stroma. “Weak”, “moderate” and “dense” indicated that lymphocytes occupied about 1–40%, 40–75% and 75%–100% area in the stroma, respectively. We analyzed ultrasound findings and TILs with the χ² -square test.

Results A total of 97 lesions and 95 female TNBC patients were validated. The median age was 62 years old (range, 32–88 years). Of the total, 37 patients underwent NAC. The degree of “absent” TILs was 5 lesions, “weak” was 58, “moderate” was 22, and “dense” was 12 lesions. In the ultrasound findings, the shape categories “round,” “oval,” and “lobulated” were more “dense” TILs (n=12, 100%) than others (n=47, 55.3%) (p = 0.002). The "circumscribed" and "well-defined and rough" margins were found to be more “dense” TILs (n=11, 91.7%) than the other TILs (n=49, 57.6%) (p=0.020). “Accentuating” posterior echoes were more “dense” and “moderate” TILs (n=23, 67.6%) than “weak” and “absent” TILs (n=25, 39.7%) (p=0.009). The lesions with expansively growing pattern showed higher rate “dense” and “moderate” TILs (n=20, 58.8%) than “weak” and “absent” TILs (n=20, 31.7%) (p=0.010). There were no significant differences in internal echoes.

Conclusion We determined that ultrasound findings of round, oval or lobulated shape, accentuating posterior echoes and expansively growing pattern could predict the presence of high TILs. Thus, the safe, low-cost, and radiation-free ultrasound examination was recommended for predicting high TILs and prognosis.
Title: Test-retest fidelity of FDG SUVmax in bone and non-boney metastatic breast cancer lesions in local area network PET/CT scanners

Body: Background: Metabolic activity in lesions, measured by FDG-PET, is often used for assessing tumor aggressiveness and response to therapy. Patients may be scanned on different machines, so quantitative measurements should be reproducible. Reducing SUV variability in PET machines throughout a local network can aid in monitoring patient response to therapy and increase access to clinical trials.

Methods: Eighteen female patients with advanced or metastatic breast cancer underwent paired FDG PET/CT test-retest studies with 1-15 days between scans, and without interim change in treatment. Ten patients were studied in the same scanner and 8 patients were studied in 2 different scanners. Five different PET/CT scanners were used (2 GE DSTE, 2 Siemens (BioGraph 6 and mCT), 1 Philips Ingenuity TF). Each PET/CT scanner was calibrated using NIST-traceable reference sources to characterize and reduce variability. All of the images were interpreted by two separate reviewers. SUVmax values in lesions, corresponding normal tissue, and normal liver were collected. Linear mixed models with random intercept (patient effects) were fitted to compare differences in log(|SUVmax % difference|+.01) in multiple lesions per patient.

Results: SUVmax was assessed in a total of 130 lesions (75 bone). The median number of lesions per patient was 5 (range 1-17). Average SUVmax ranged from 1.0 to 18.2 (mean±SD = 6.0±3.2). The median SUVmax difference was 0.4 (8%) for 47 lesions imaged twice in the same scanner, and was 0.6 (13%) for 83 lesions imaged in two different scanners. In a multivariable linear mixed effects model, SUVmax for different scanners within the same institution did not differ more than for the same scanner (p=0.39), but repeat scans with different scanners and site personnel at had an average of 78% greater percentage difference in SUVmax than for the same scanner (p=0.009). In the same model, the average percent difference in SUVmax for bone lesions was estimated as 30% lower than for other sites (p=0.06, 95% confidence interval 0-50%). Examining normal liver uptake, the median SUVmean was 2.5 (range 1.9-3.1) with an median 6.5% difference between measurements (range 1.1%-23.7%) that did not appear to differ based on scanners used for repeat measurements (p=0.47).

Conclusions: The variability in quantitative FDG SUVmax between scans is modest, suggesting reliable reproducibility in appropriately calibrated settings. In our study, bone lesions had somewhat higher fidelity than other tumor sites. Additional studies will address variability in other cancer types. Careful calibration and monitoring of PET/CT scanners, and consistent imaging protocols are necessary in clinical trials that utilize quantitative PET/CT imaging in order to confidently interpret results.

Research Support: NIH grant U01-CA148131 and NCI-SAIC Contract 24XS036-004.
Title: Evaluation of contrast-enhanced ultrasonography for early prediction of response to neoadjuvant chemotherapy in triple negative breast cancer

Body: Objectives

We aimed to determine whether contrast-enhanced ultrasonography (CEUS) can predict the early effects of neoadjuvant chemotherapy on triple negative breast cancer.

Methods

The clinical responses of 20 consecutive patients with breast cancer (T1–2, N0–1, M0) to neoadjuvant chemotherapy between October 2012 and Feb 2016 were assessed using ultrasonography and contrast-enhanced ultrasonography before starting the therapy and after the treatment of 2 courses. Ascending slope (AS) of perfusion parameters for contrast-enhanced ultrasonography were created from time–intensity curves based on enhancement intensity and temporal changes to objectively evaluate contrast-enhanced ultrasonography findings. We investigated whether rate of change of ascending slope (ΔAS) and tumor size (ΔUS) could predict pCR.

Results

Eight (40.0%) of the 20 patients achieved pathological complete response. ΔAS were significantly higher (-25.5 ± 35.5 vs. 14.7 ± 33.2; P < 0.02) in patients who achieved pCR than in those who did not. On the other hand, ΔUS of pCR and non-pCR did not significantly differ among tumors (-40.8 ± 22.4 vs. -21.4 ± 20.6; P = 0.06). The AUC values for ΔAS and ΔUS were 0.792 (95% CI, 0.579 -1.000, P = 0.03) and 0.729 (95% CI, 0.501 - 0.957; p = 0.09), respectively. We set ΔAS and Δ US cut-offs for predicting pCR at -20.08 and -33.75 based on the ROC curves. Clinical and pathological characteristics of the 20 patients are summarized in

Clinical and pathological characteristics of patients with breast cancer.

Conclusion
\(\Delta A\)S assessed with CEUS can help the physician to early predict the probability of achieving pCR or not.
Title: Preoperative assessment of breast cancer survival using ultrasound diameter and shear wave elastography

Evans AJ J, Purdie C, Thompson AM M, Jordan L, Fuller-Pace FV V, Whelehan PJ J, Macaskill JE E and Vinnicombe S. Dundee University, Dundee, Scotland, United Kingdom and MD Anderson Cancer Centre, Houston, TX.

Body: Introduction: assessment of prognosis has traditionally been performed after surgical excision of breast cancer. However with the increased use of neoadjuvant chemotherapy (NACT) there is a need for pre-operative prediction of prognosis to aid treatment selection. Stiffness at shear wave elastography (SWE), an ultrasound technique, has been shown to correlate with histologic grade, independently predict nodal involvement and be associated with response to NACT. SWE is easy and fast to perform, is quantitative and has been shown to be highly reproducible. We therefore hypothesized that lesional stiffness and size at pre-operative US examination may be associated with breast cancer mortality and provide useful pre-treatment prognostic information.

Methods: consecutive patients undergoing breast ultrasound (US) for lesions subsequently shown to be invasive breast cancer between April 2010 and December 2011 underwent SWE had the US lesion diameter and mean stiffness (kPa) at SWE recorded prospectively. Patient's survival including cause of death was ascertained from local and national sources. Eight patients with metastases at presentation were excluded. Breast cancer specific survival (BCSS) was ascertained for 3 equal groups based on US size, mean kPa, and a combination using equal weighting of the 2 parameters. BCSS was assessed using Kaplan-Meier survival curves and statistical significance ascertained using the logrank test.

Results: 289 patients (mean age 63 yrs, 107 screen detected and 182 symptomatic lesions) constituted the study group. 20 breast cancer and 21 non-breast cancer deaths were recorded and mean follow-up in those alive was 4.8 years. Breast cancer survival for equal size groups based on a) stiffness were 98%, 91% and 89% (p=0.05) b) US size were 98%, 95% and 85% (p=0.001) and c) a combination of US size and stiffness were 99%, 97% and 82% (p<0.0001).

Conclusion: the combination of US diameter and mean stiffness at SWE provides powerful preoperative assessment of prognosis in women with breast cancer. This information could be used to inform decisions regarding NACT.
Body: Background
Imagio® is an opto-acoustic (OA) breast imaging system designed to concomitantly collect OA images together with diagnostic ultrasound (CDU). The device is intended to improve distinction between benign and malignant masses. In this interim analysis of the post-market surveillance MAESTRO study we report the results of 75 patients who had breast masses classified as BI-RADS 4a and 4b by CDU.

Aim
We assessed OA’s sensitivity, specificity, and its ability to downgrade benign masses and upgrade malignant masses based on the probability of malignancy (POM) and BI-RADS category.

Methods
Seventy-five patients with 78 breast masses were evaluated with OA prior to biopsy. For each mass, the radiologist scored 5 OA features, assigned a POM and BI-RADS category. OA sensitivity, specificity, and BI-RADS downgrade and upgrade percentages were assessed with and without contribution from a previously derived nomogram.

Results
The mean POM difference between malignant and benign masses was higher for OA (37%) than for CDU (27%). OA specificity was 43% without the nomogram and 68% with the nomogram. OA sensitivity was 97% with and without the nomogram. With OA 43% of benign masses could be downgraded and 47% of malignant masses could be upgraded in BIRADS category.

Conclusion
These results appear to confirm the previously reported ability of OA to improve the differentiation between benign and malignant masses compared to CDU alone, to potentially decrease negative biopsies, and to upgrade BI-RADS category in malignant masses. The MAESTRO study (n=200) may further confirm these results.
Title: Non-invasive and low-cost technique for early detection of clinically relevant breast lesions using a handheld point-of-care medical device (iBreastExam): Prospective three-arm triple-blinded comparative study for breast cancer screening in low resource setting countries

Somashekhar SP and Ashwin KR. Manipal Comprehensive Cancer Centre - Manipal Hospital, Bangalore, Karnataka, India.

Body: OBJECTIVE: To determine the clinical efficacy of a handheld point-of-care medical device that could potentially assist allied healthcare workers to perform standardized Clinical Breast Examination in low-resource settings.

MATERIALS AND METHODS: Nine hundred and eighty-nine healthy women visiting a tertiary Indian hospital, for annual health check were recruited for bilateral breast examinations. Additionally, 20 women attending the hospital with breast-related symptoms were also recruited as part of the opportunistic screening program. Each woman was examined by three independent methods, each blinded to the other two: iBreastExam (iBE), Clinical Breast Examination (CBE) by an expert clinician and Breast Imaging (mammography or breast ultrasound). Main Outcome Measures Sensitivity, Specificity, PPV, NPV for iBE and CBE were derived with Breast Imaging tests used as reference standard.

RESULTS: Out of 916 enrolled participants, 93 were confirmed by imaging to have at least one breast lesion. Clinical Breast Examination in comparison with imaging detected breast lesions with Sn = 65 %, Sp = 94 %, PPV = 52 %, NPV = 96 %, and iBreastExam reported Sn = 84 %, Sp = 94 %, PPV = 60 % and NPV = 98 %. In women below age 40 (314 participants), iBE detected breast lesions with Sn = 85 %, Sp = 93 %. All malignant lesions were identified by iBE, while one non-palpable malignant lesion was missed by clinician CBE.

CONCLUSION: The point-of-care Breast Imaging device (iBreastExam) performed with significantly better sensitivity, by 19 %, than CBE to detect breast lesions while reporting high specificity (94 %) and NPV (98 %). In younger women population under the age of 40 years, where the prevalence of dense breast is high, iBreastExam demonstrated high-performance characteristics. iBreast-Exam detected all malignant lesions in this study, while the clinician's CBE missed to detect a non-palpable malignant lesion. iBreastExam can be a promising tool to provide clinically effective and standardized breast examinations in low-resource settings to detect breast lesions at early stages. The device can also be an effective screening tool for younger women with dense breasts.

Title: Adjunct diagnosing with breast specific gamma imaging or ultrasound in symptomatic women with mammographic dense breasts: A single center retrospective and comparative analysis

Huang J, Zhang Z, Yu X, Wang X and Qiu F. Surgical Oncology, Hangzhou, Zhejiang, China.

Body: Background: Mammographic density breasts decrease the diagnostic accuracy of mammography (MMG). While ultrasound (US) or breast specific gamma imaging (BSGI) can detect breast cancer in mammographic dense breasts, but these modalities have not been directly compared in prospective trials. We conducted a retrospective and comparative analysis of adjunct diagnosis to compare, within the same participants, by BSGI and US in mammographic dense breasts.

Methods: Diagnosing with BSGI or US in women with mammographic dense breasts is a retrospective and comparative study recruiting symptomatic women with mammographic dense breasts. Eligible women had performed BSGI and US with independent interpretation of adjunct imaging. Outcome measures included sensibility, specificity, and diagnostic accuracy (assessed by the area under the receiver operating characteristic curve) of combined MMG plus BSGI versus MMG plus US. These were compared using McNemar's test for paired binary data in this comparative analysis.

Results: From April 2013 to April 2016, 364 symptomatic and mammographic dense women (median age ± SD, 51.12±10.92 years) recruited and had the final surgical pathology diagnosis, with 218 malignant diseases (59.89%) and 146 benign diseases (40.11%). Combined with BSGI or US can increase the sensibility, specificity and diagnostic accuracy of MMG. There is no difference for BSGI and US in enhancing the sensitivity of MMG diagnosis (Se-Difference: 3.21%, \( P=0.23 \)), but the diagnosis specificity of MMG joint BSGI was more superior than MMG plus US (Sp-Difference: 10.27, \( P=0.003 \)). ROC curve analysis of area under the curve showed that MMG plus BSGI has better diagnostic accuracy than MMG with US (0.90 vs. 0.83, \( P=0.0019 \)). For different breast cancer molecular classification, MMG plus US seems more sensitivity for the Luminal A subtype than that of MMG plus BSGI, but without significant (Difference: 3.28, \( P=0.687 \)). Other subtypes and the primary local tumor size of breast cancer did not affect the diagnostic sensitivity of MMG plus BSGI or US.

Conclusions: For the symptomatic women with mammographic dense breasts, MMG plus BSGI or US have similar diagnostic sensitivity, but the specificity and diagnostic accuracy of MMG plus BSGI was higher than MMG plus US. BSGI could potentially be the adjunct diagnosis modality in Chinese women with mammographic dense breasts.
Title: Can ultrasound replace sentinel lymph node biopsy in breast cancer staging of the axilla? Results from a single center retrospective review of axillary evaluation with conventional sonography and ultrasound elastography

Leong L and Upadhyaya V. Singapore General Hospital, Singapore.

Body:
Sentinel lymph node biopsy (SLNB) is the gold standard for axillary staging in clinically node negative breast cancer patients. Although generally safe and accurate, SLNB is an additional surgical procedure with occasional instances of false negatives and complications arising. Hence, there is interest in finding less invasive alternatives to SLNB. The aim of the study is to determine if ultrasound (US), together with adjunct US elastography (EI), has the potential to replace SLNB by evaluating its overall accuracy as well as the nodal disease burden in false negative cases.

Materials and methods
Axillary US evaluations in breast cancer patients performed in a single center institution over a 7 year period (2009-2015) were reviewed. Lymph nodes with histological assessments from percutaneous or surgical biopsies were included in the study. Cases which had histology obtained only after neoadjuvant chemotherapy were excluded. US assessment was based on the retrospective review of the attending radiologists' US reports. EI was based on the elastographic size ratio calculated from available elastographic images obtained before US percutaneous biopsy of lymph nodes. The sensitivity, specificity and false negative rates were correlated with histology as the gold standard. For false negative cases, the number of nodes involved and the size of the largest metastatic focus were recorded from available pathology reports.

Results
608 axillary US studies performed on 578 patients with invasive breast cancers were reviewed. 254 (41.8%) cases had nodal metastases and 354 (58.2%) had benign histology. Overall US sensitivity, specificity and false negative rates were 74.8%, 91.0% and 25.2% respectively.

Comparison of the diagnostic accuracy between conventional US and EI

Conclusion
US is fairly accurate in the evaluation of axillary nodal disease. Even in false negative cases, the nodal disease burden is low, potentially not affecting prognosis. Hence, axillary US staging has the potential to replace SLNB. Adding EI to conventional US evaluation will not significantly reduce the false negative rate but may help reduce unnecessary biopsies.
Title: Tomosynthesis as an alternative to magnetic resonance imaging (MRI) in assessing invasive lobular carcinoma (ILC) multifocality

Holt RE E, Topps A, Lim YY and Gandhi A.  University Hospital of South Manchester NHS Trust, Manchester, United Kingdom and  Manchester Academic Health Science Centre, Manchester, United Kingdom.

Body: Introduction
Invasive lobular carcinoma is associated with a higher rate of multifocality than other types of breast cancer. Breast MRI is commonly performed in patients diagnosed with ILC to assess for additional disease prior to formulating a management plan. MRI may be both time consuming and costly and can delay treatment. Recently tomosynthesis has become an adjunct in the assessment and diagnosis of breast cancer. It is readily available at the time of mammography therefore providing information at the one stop clinic. We proposed that it may be possible to use tomosynthesis to assess for multifocality in ILC in place of MRI.

Method
A retrospective review of all cases of ILC diagnosed at a single regional screening unit over a 3-year period was performed. Patients having surgery as primary treatment were included. Ninety-eight patients were identified, 29 having both MRI and tomosynthesis in addition to mammography and ultrasound scan as part of their assessment. Histological data was used to compare the two imaging modalities. Bland and Altman limits of agreement analysis was performed to assess the difference between MRI and tomosynthesis in these patients. An acceptable difference (the difference in values that is unlikely to influence management) was set at 5mm.

Results
The Bland and Altman limits of agreement analysis produced three graphs to demonstrate the difference between MRI and Tomosynthesis, MRI and histology size and Tomosynthesis and histology size. It shows that the average difference between MRI and Tomosynthesis = 3.8mm (95% limits of agreement: −19.2 to 26.8mm). The percentage of ‘acceptable’ differences (defined as ≤5mm) was 72% for MRI and tomosynthesis suggesting that there is good concordance between the two. Tumours measuring >30mm on MRI are perceived as smaller under Tomosynthesis.

The analysis demonstrated the average difference between MRI and histology values is -1.3 mm (95% limits of agreement = −33.2 to 30.6) compared with an average difference between Tomosynthesis and histology of -5.1 mm (95% limits of agreement = −27.7 to 17.5). The percentage of ‘acceptable’ differences (defined as ≤ 5 mm) was 48% for both MRI vs histology and Tomosynthesis vs histology, suggesting that neither is superior when compared to final histology results.

In three patients there were multifocal cancers identified on histology that had not been detected by any imaging modality. In one patient there were MRI images that suggested a second tumour which was not present on histological examination. The same is true for a patient diagnosed with a second cancer identified by tomosynthesis but not found in the specimen. A third patient was diagnosed with a second tumour by both image modalities but again not present on histology. In one case tomosynthesis detected a true second cancer that was not identified on MRI.

Conclusion
We believe this preliminary study suggests that tomosynthesis is equivocal to MRI for assessing multifocality in ILC. If confirmed the implications would be a shorter investigative pathway with reduced delays and costs. A larger multicle-centre trial to assess the use of tomosynthesis to replace MRI in patients with ILC is warranted.
Title: Breast ultrasound surveillance with image fusion technique in a short-interval follow-up for BI-RADS category 3 mass lesions

Nakano S, Fujii K, Kousaka J, Mouri Y and Ando T. Aichi Medical University, Nagakute-city, Aichi, Japan.

Body: PURPOSE: Breast ultrasound (US) is a diagnostic imaging modality that is now widely used as an adjunct to mammography for evaluation of breast abnormalities. In the Breast Imaging-Reporting and Data System (BI-RADS) lexicon, a solid mass with an oval shape, well-circumscribed margins and parallel orientation is classified as category 3 (BI-RADS category 3 mass lesions). This mass should have a risk of malignancy of < 2%. Surveillance breast US in short-interval follow-up for BI-RADS category 3 mass lesions is an acceptable alternative to biopsy. The surveillance US is recommended 6 month after initial lesion identification and then every year for at least 2 y. However, inconsistent reproducibility for US due to operator dependence is still a clinical issue. The aim of our study was to verify the utility of US using real-time virtual sonography (RVS) - to coordinate present US images with past US images reconstructed from previously acquired US volume data using magnetic tracking system – in a short-interval follow-up for BI-RADS category 3 mass lesions.

METHOD AND MATERIALS: We enrolled 20 women (23 lesions) with more than 24 months of follow-up after classification as BI-RADS category 3 during initial US. US surveillance was scheduled at 6, 12 and 24 months. Three-dimensional assessment of morphologic features was performed while serially checking past US volume data corresponding to the present US probe position. Measurement of the target lesion diameter was performed after the probe was adjusted to include the maximum diameter of a past US image at each visit.

RESULTS: RVS was technically successful in 100% of patients. All target lesions were detected, including two iso-echoic lesions. The mean target lesion diameters at baseline and at 6, 12 and 24 months were 8.2±4.2, 8.4±4.5, 8.1±4.5 and 8.3±5.0 mm, respectively. Statistical analysis using a Friedman test with multiple comparisons revealed no significant difference between the diameters at each time point (p = 0.785). RVS was used to directly compare the US morphologic characteristics and sized of lesions. Furthermore, the RVS data can be reproduced in their entirety for independent review at a later date by using stored US volume data.

CONCLUSION: Our results suggest that RVS is reproducible, operator-independent technique for comparison of US images of BI-RADS category 3 mass lesions obtained at different time points.
Title: PD-1-IRDye800CW as a novel probe for fluorescence molecular imaging and image guided intraoperative surgery in breast tumor mouse model

Du Y, Chi C, Yang X and Tian J. Chinese Academy of Sciences, Institute of Automation, Chinese Academy of Sciences, Beijing, China.

Body: Background: Breast cancer, especially triple-negative breast cancer (TNBC), characterized by lack of expression of estrogen receptor (ER), progesterone receptor (PR), and HER2/neu (HER2), are generally high-grade, aggressive tumors with poorer disease-specific survival than other breast cancer subtypes. Therefore, novel imaging and therapeutic strategies are needed to improve the management of TNBC. Programmed cell death (PD-1) is an immune inhibitory receptor expressed by activated T cells that play a pivotal role in tumor immune evasion. Previous studies showed that intratumoral expression of T-cell inhibitory molecule PD-L1 was associated with high histologic grade and TNBC. Therefore, PD-1 was suggested to be an attractive target for antibody-guided fluorescent tumor imaging of breast tumor. Aim: The aim of this study is to create a novel near infrared fluorescence imaging probe PD-1-IRDye800 CW, which may facilitate a targeted in vivo fluorescence imaging and guide the intraoperative surgery of breast tumors. Methods: The 4T1 breast tumor bearing Balb/c mice were used in this study. PD-1-IRDye800CW probes were injected intravenously, and the ratIgG-IRDye800CW was used as control. The fluorescence imaging was performed at different time points including 0, 1 h, 4 h, 8 h, 12 h and 24 h after probe injection. And the surgery was performed 8 h post-injection with the aid of fluorescence imaging guided surgical navigation system. Results: It showed that PD-1-IRDye800CW reached the tumor site 30 min after tail vein injection. The fluorescence signal gradually accumulated at the tumor region 1 h to 8 h post-injection and then the tumor signal decreased 12 h thereafter. While the IgG-IRDye800CW control mice, the fluorescence signal can also be detected in the tumor region 30 min after injection, and then the signal was restricted to the tumor and kidney regions 1 to 4 h post-injection. Thereafter, most of probe was urinated, and the signal in the tumor regions decreased after 8 h. The fluorescence signal intensities of PD-1-IRDye800CW and IgG-IRDye 800CW probes at the tumor regions were compared under the same fluorescence scale bar, and we found that the PD-1-IRDye800CW probe showed a specific targeting and stable signal at the tumor region. To confirm the in vivo observation, the tumors and major organs were dissected out 8 h post-injection, and we found that the fluorescence signal of the PD-1-IRDye800CW probe in the tumors was stronger than the control probe. Conclusion: Our data suggested that through specific binding to the PD-1 expressing tumor infiltrating lymphocytes (TIL), the PD-1-IRDye800CW probe achieved a targeted imaging of breast tumors in vivo. Furthermore, the PD-1-IRDye800CW can work as an intraoperative imaging probe for the guidance of breast tumor surgery. These findings reinforce the potential of PD-1-IRDye800CW for the theranostic applications in clinics in the future.

**Body: Introduction:** Tumoral masses are not only composed of malignant cells, but also enclose a more or less ample stromal micromilieu, which has been shown to influence the cancer cell behaviour. As aging induces accumulation of senescent cells in the body, this micromilieu is thought to be different in cancers occurring in old patients compared to the younger counterparts. More specifically, senescence-related fibroblastic features, such as the Senescence Associated Secretory Profile (SASP) and the induction of Autophagy, are suspected to stimulate tumor growth and progression.

**Materials and Methods:** We compared gene expression profiles in stromal fields of breast carcinomas by performing laser capture microdissection of the cancer-associated stroma from 8 old (≥80 years at diagnosis) and 9 young (< 45 years at diagnosis) triple negative breast cancer patients. Gene expression data were obtained by microarray analysis (Affymetrix). Differential gene expression and Gene Set Enrichment Analysis (GSEA) were performed.

**Results:** Differential gene expression analysis showed higher growth-, dedifferentiation- and migration-promoting gene expression in the stromal samples of older vs younger patients. GSEA confirmed the presence of a SASP, as well as the presence of Autophagy in the stroma of older patients.

**Conclusion:** We provide the first evidence in humans that older age at diagnosis is associated with a different stromal micromilieu in breast cancers. The SASP and the presence of Autophagy appear to be important age-induced stromal features.

Title: Stromal kinome screening identifies a novel regulatory kinase implicated in fibroblast-mediated progression of invasion in triple negative breast cancer tumours

Giamas G, Grothey T, Grothey A and Stebbing J. University of Sussex, United Kingdom and Imperial College, United Kingdom.

Body: Background:
The tumor microenvironment impacts the behaviour of surrounding epithelial cells and is thought to play a pivotal role in tumorigenesis while influencing treatment response. Still, the role of stromal cells-mediated paracrine signalling on tumor cells' fate and disease progression/remission remains largely unknown. Unravelling the significance of kinases in 'normal' stromal cells and deciphering the transmitted signals that result in reciprocal communications with tumor cells could lead to the identification of new combinatorial strategies for the treatment of breast cancer (BC). Considering the lack of effective therapies for triple negative BC patients (TNBC), we aimed to identify 'normal' fibroblasts-expressed kinases that modulate the invasive potential of TNBC tumor cells and characterise their mechanism(s) of action.

Methods / Results:
We performed a kinome siRNA screening in human mammary fibroblasts (HMFs). After silencing, HMFs were co-cultured with MDA-MB-231 TNBC cells using a 3D-matrigel assay, allowing cells to form spheroids. 3D cell invasion was measured at different time points using confocal microscopy (HMF and MDA-MB-231 were fluorescently labelled). Our screening revealed new kinases expressed in HMFs, whose inhibition was able to impede ('harmful' kinases) or promote ('protective' kinases) the invasion of MDA-MB-231 cells.
Mechanistic studies determined whether this effect was a result of direct interaction between cells, or if it was mediated via secretion of specific factors from stromal cells. Our data showed that the exosomes transmitted from normal fibroblasts (upon inhibition of the specific kinase) were responsible for the observed invasive phenotype of TNBC cells. Quantification/distribution of exosomes followed by mass-spectrometry determined the number, size and content of exosomes in the presence/absence of this kinase. Subsequent RNAseq and quantitative proteomics (SILAC) uncovered the alterations in signalling pathways and key proteins in TNBC cells, due to silencing of the specific kinase in normal fibroblasts. Xenograft BC orthotopic studies further demonstrated that co-injection of TNBC cells with knock-out normal fibroblasts (for the kinase under study), results in reduced tumor growth (primary & metastatic) compared to co-injection of TNBC cells with wild-type normal fibroblasts.
In a clinical setting, we examined the expression (mRNA/protein) of the kinase of interest on TNBC patients consisting of primary normal and cancer associated fibroblasts (CAFs) (>5cm or <5cm from primary tumor site respectively). We also analysed various GSE datasets containing matched normal/CAFs samples along with patients’ survival data and saw a reverse correlation of the expression of this kinase with overall and metastasis-free survival.

Conclusions:
Further understanding the biological complexity and contribution of the stromal cells in tumour development and expansion is of critical importance in our attempt to identify new putative targets for cancer treatment. Our work reveals a new 'undermining' kinase expressed in normal fibroblasts, inhibition of which can have beneficial effects for TNBC patients.

Title: Microenvironment induced DDR2 mediates stromal-cancer interactions and metastasis growth in breast cancer

Kleer CG G, Martin EE E, Anwar T, Arellano-Garcia C, Lama A, Medhora N, Chen Y-C, Yoon E, Ge C, Franceschi R and Gonzalez ME E. University of Michigan, Ann Arbor, MI.

Body: Background: Accumulating evidence suggests that mesenchymal stem/stromal cells (MSCs) are recruited to the tumor microenvironment and play roles in tumor progression; however the underlying mechanisms by which MSCs promote breast cancer migration and invasion, and their role in metastasis need further investigation. Studies have demonstrated that collagen plays an important role in breast tumorigenesis by activating signaling pathways. We hypothesize that MSCs may promote breast cancer progression through regulating collagen-induced signaling in breast cancer cells.

Methods: We isolated carcinoma-associated MSCs (CA-MSCs) from human breast cancer metastasis to lymph node (LNM) and liver (LM). A portion of each specimen was stained with H&E to confirm the diagnosis, and a portion was mechanically dissected and digested with collagenase. Adherent CA-MSCs were subcultured in MSC medium for up to 12 passages. CA-MSCs were subjected to multilineage differentiation assays and labeled with Ds-Red. COL 1 expression and its receptor discoidin domain receptor 2 (DDR2) were downregulated in the CA-MSCs-DsRED using specific shRNA. We established single culture and co-cultures of CA-MSCs with GFP labeled breast cancer cells (BCCs) MDA-MB-231 and MCF10CA1a which were used for Live Imaging Microscopy, IHC, RT-PCR, WB, immunofluorescence, 3D proliferation and invasion assays, and in vivo xenograft experiments.

Results: CA-MSCs had spindle morphology, normal karyotype, were nontumorigenic in vivo, and possessed tri-lineage differentiation ability (osteoblast, adipocyte, and chondrocyte). CA-MSCs exhibited high mRNA and protein levels of collagen I (COL1) and its receptor DDR2. ShRNA-mediated knockdown of COL1 or DDR2 in CA-MSCs induced a change in morphology towards epithelial, decreased expression of epithelial to mesenchymal transition (EMT) markers, and impaired migration. Co-culture of CA-MSCs with BCCs led to increased BCC proliferation, EMT, invasion, and increased DDR2 expression in BCCs compared to single cultures of BCCs, which was blocked by COL1 and DDR2 shRNA in CA-MSCs. Live imaging studies revealed that shCOL1 and shDDR2 was sufficient to completely disrupt the organized migration pattern of BCCs aligned with CA-MSCs. In vivo, xenografts derived from MDA-MB-231 cells co-cultured with shControl CA-MSCs exhibited increased collagen I deposition in the tumor microenvironment, increased tumor growth, and metastasis compared to the single cultures of MDA-MB-231 cells. Remarkably, shDDR2 in CA-MSCs rescued the phenotype and reduced tumorigenesis and metastasis.

Conclusion: We successfully isolated and characterized CA-MSCs, confirming their presence in human breast cancer metastasis. Our findings suggest that collagen I and its receptor DDR2 play a role in directional migration of breast cancer cells in alignment with CA-MSCs, a function that may be implicated in breast cancer invasion and metastasis. Downregulation of DDR2 reduced tumor growth and metastasis in vivo. Modifying the tumor microenvironment by manipulating collagen I and/or DDR2 levels in MSCs might be therapeutically useful in preventing or halting metastasis.
Title: Tumor infiltrating macrophages, lymphocytes and matrix metalloproteinase 9 (MMP-9) expression in breast cancer

Pelekanou V, Brown JR R and Rimm DL L. Yale University, School of Medicine, New Haven, CT.

Body: Background: Immune therapy has been highly successful in tumors with high lymphocytic infiltrate, but they only represent the minority of breast neoplasms. Macrophages rather than lymphocytes, are more prominent in mammary development and disease. Specific markers of breast tumor associated macrophages (TAMs) remain to be defined. Local interactions define their plasticity and activity, rendering in situ investigation important in their characterization. MMP-9 is an important regulator of breast cancer microenvironment that could mediate cross-talk between TAMs and tumor cells. Here we objectively measure CD68 and CD163 and also MMP-9 within each macrophage subtype to determine the relationship between macrophage expression, tumor infiltrating lymphocytes (TILs) and molecular subtypes in breast cancer.

Methods: Using a multiplexed quantitative immunofluorescence (QIF)-based assay for simultaneous detection of DAPI (all cells), Cytokeratin (epithelial cells, clone CK8/CK18), CD163 (M2 Macrophages, clone CD163-L-U), CD68 (pan macrophage marker, clone PG-M1), and MMP-9 (Matrix Metalloproteinase 9, clone D603H XP). We measured the levels of protein expression in breast carcinomas on two sets of Yale tissue microarrays (TMA) [YTMA201 (all breast cases, n=399) and YTMA149 (Triple Negative, n=160)]. Markers were measured using the AQUA method of QIF on TMAs at two-fold redundancy. Linear regression coefficients ($R^2$) were used to compare antibody QIF scores within cores from different areas of the tumors. Median cut-point was used to stratify patients for overall and disease specific survival (OS and DSS).

Results: Cases with high TILs, as shown by assessment of CD3, 8 and 20, generally show an inverse relationship with both CD68 and CD163, especially in ER+ cases. MMP-9 was then measured in both subtypes of macrophages. In ER+ tumors MMP-9 was expressed in CD163+ macrophages ($p=0.007$), while in TNBC it was found in CD68+/CD163- macrophages ($p<0.001$). In all cases MMP-9 was significantly higher in ER- cases (CD68+/CD163- $p=0.0001$), (CD163+ $p=0.01$). In ER+ cases high MMP-9 expression was associated with shorter OS ($p<0.0001$ in CD163+ cells). On the contrary, in TNBC high MMP-9 was associated improved DSS in the CD68 compartment ($p=0.007$).

Discussion: Using an objective, quantitative multiplex assay for synchronous measurement in tumor and microenvironment, we found an inverse relationship between TILs and macrophage infiltration, suggesting immune modulation by different cellular elements. Within the macrophage population, we found that MMP9 expression is a function of the breast cancer molecular phenotype. Most significantly, the ER status of the tumor is correlated with the macrophage subtypes that express MMP9. Efforts to determine the clinical value of these observations are underway to better determine the balance between pro- and antitumor immunity in breast cancer.
Body: Breast cancer is highly heterogeneous and associated with a myriad of risk factors. Women with high mammographic density have 2-6 fold higher risk of developing breast cancer and changes of tumor stroma are predictive of patient survival. Also, obesity at diagnosis is linked to 33% increase in risk of overall mortality in women with early-stage breast cancer. However, the cause for poor prognosis in obesity associated breast cancer is not fully understood. Studies show mechanical forces in the breast stroma as key regulators of mammary tumorigenesis. These mechanical cues are transduced through discoidin domain receptor-1 (DDR-1), which forms part of the arsenal of cell surface receptors that mediate cell-collagen interactions. DDR-1 expression is upregulated in breast cancer-associated stroma in several preclinical tumor models and has been linked with poor prognosis. However, little is known about how stromal DDR-1 contributes to tumorigenesis. Therefore, I aim to investigate the functions of DDR-1 in the tumor stroma of the breast and its precise role in breast cancer.

Findings: To address this, orthotopic injection of mesenchymal like-mouse mammary tumor cells (M-Wnt) were done in DDR-1 knockout (KO) mice and wild type (WT) mice, and tumor growth was monitored. I observed a significant reduction in tumor growth in KO mice vs WT. Immunohistochemistry of the tumors showed reduced expression of collagen-IA in KO. Given the association of obesity with cancer, I generated a cohort of High Fat diet (HFD) induced obese KO and WT mice for tumor studies. I observed enhanced tumor growth in both WT-HFD and KO-HFD mice vs the non-obese mice. Moreover, percent difference in tumor weight from KO and WT obese mice was higher than that from non-obese. To elucidate the causative factors, circulating plasma proteins were assessed for cancer biomarkers in these cohorts. Out of the 20 analytes checked, circulating Endothelin-1 (ET-1) was significantly increased in WT non-obese mice. ET-1 also positively correlated with the tumor volume measurements in these mice. Recent studies show ET-1 to be a pro-fibrotic factor. This is in line with the increased expression of Col-IA in WT tumors. Intriguingly, I did not observe an increase in plasma ET-1 in the obese WT mice. There were overall reduced circulating Leptin, IL-6 and G-CSF levels in KO-non obese, and this difference was more pronounced in KO-obese. G-CSF levels were significantly high in WT-HFD vs KO-HFD. To access the tumor microenvironment, RNA-Seq was done on tumors obtained from the above two cohorts. My RNA seq data confirmed abrogation of both ET-1 and IL-1β/IL-6 signaling axis in the KO. Additionally, RNA-Seq revealed significant upregulation of T-cell activation gene signatures in the KO mice. Immune suppressive TGF-β signaling genes were up-regulated in WT. High ECM protein gene expression in the WT tumors could contribute to reduce immune cell infiltration and immune suppression.

Summary: Host DDR-1 plays a definitive role in breast tumorigenesis. Increased Endothelin-1, ECM proteins, and immune suppression in the WT tumors are responsible for their enhanced tumorigenesis. The host DDR-1 dependent tumorigenesis gets further aggravated in case of diet induced obesity in ET-1 independent manner and, by enhanced immune-suppression.
Body: During cancer progression from an indolent stage to a clinically manifested disease, the surrounding microenvironment co-evolves into an activated state through continuous and dynamic paracrine communication between all constituent cell types that collectively sustain malignant growth. Hence, from a therapeutic perspective, tumors must be regarded as multi-cellular organs. Mesenchymal cells are highly plastic entities. Normal fibroblasts are described to counteract tumorigenesis by repressing cancer initiation. However, co-evolution of the malignant epithelium and its underlying stroma instigates activation of cancer-associated fibroblasts (CAFs) into a phenotype endorsing most, if not all, hallmarks of cancer progression.

Through translational studies using breast cancer patient cohorts, genetically engineered mouse models (including patient derived xenografts), and single-cell RNA sequencing, we delineate a previously unappreciated role for CAFs as determinants of breast cancer prognosis and treatment response through specification of the molecular subtype of breast cancer. Expression of paracrine growth factors mediating malignant cell-CAF crosstalk in breast cancer was found to be associated with a hormone receptor-negative state. Genetic targeting of the signaling networks governing the interactions between tumor cells and CAFs confirmed their functional importance by prompting a delay in tumor growth, impaired extra-cellular matrix deposition and reduced angiogenesis. Importantly, our work holds therapeutic implications, as genetic or therapeutic targeting of CAF subsets resulted in conversion of basal-like/triple-negative breast tumors into a luminal state that conferred sensitivity to endocrine therapy in previously impervious tumors. Additionally, to mechanistically explore the heterogeneity of mesenchymal cells in breast tumors, we have made use of single cell RNA sequencing of isolated CAFs as a guide to divide cells into transcriptionally similar groups. Distinct clusters of different CAF subtypes were identified and found to denote diverse functions in the tumor microenvironment.

In conclusion, therapeutic targeting of functional subsets of CAFs may be exploited as a refined strategy to improve patient benefit from established treatments by impinging on the stimulatory crosstalk between CAFs and their surrounding malignant microenvironment.
Title: Inhibition of cancer-associated fibroblast function by farnesoid X receptor activation: Experimental basis for a novel therapeutic strategy in breast cancer

Barone I, Vircillo V, Giordano C, Tarallo R, Rinaldi A, Bruno G, Bonofiglio D, Catalano S and Ando' S. University of Calabria, Arcavacata di Rende, CS, Italy; Centro Sanitario, University of Calabria, Arcavacata di Rende, CS, Italy and Laboratory of Molecular Medicine and Genomics, “Scuola Medica Salernitana”, University of Salerno, Salerno, SA, Italy.

Body: Background: Breast cancers are heterogeneous tissues comprised of multiple components, including tumor cells and microenvironment cells. Fibroblasts are the most abundant cell type in tumor-associated stroma (named as Cancer Associated Fibroblasts, CAFs), with multiple roles in tumor initiation and promotion through soluble secreted factors, extracellular matrix proteins, or direct cell-cell contacts. While the significance of CAFs is well recognized, the treatment of CAFs in clinical practice has not yet been established. Our previous studies have shown that activation of the nuclear Farnesoid X Receptor (FXR) in mammary epithelial cancer cells resulted in reduced proliferation, migration, and invasion 'in vitro' and tumor growth 'in vivo'. Here, we have investigated the role of FXR in CAFs to evaluate whether this receptor may affect their tumor-promoting features.

Methods: Human CAFs were isolated from biopsies of primary breast tumors (n=4) and characterized for expression of CAF markers. Immortalized CAFs were also used. FXR expression was evaluated by realtime RT-PCR, immunofluorescence and immunoblotting analyses. To assess the functional role of FXR in CAFs, we tested the effects of the synthetic FXR agonist GW4064 by using MTT proliferation, wound healing and Boyden chamber-based transmigration assays. RNA sequencing was used to compare the transcriptomes of vehicle- and GW4064-treated CAFs. Ingenuity Pathway Analysis (IPA) was used to calculate the activation z-score of molecular canonical pathways. The impact of FXR activation on tumor-promoting abilities of CAFs was tested in coculture experiments with human estrogen receptor -positive MCF-7 and -negative SKBR-3 breast cancer cells.

Results: We evidenced, for the first time, FXR mRNA and protein expression in CAFs. GW4064 treatment did not affect proliferation of CAFs; in contrast, it was able to significantly decrease their motility. Quantitative transcriptome profiling of CAFs treated or not with GW4064 revealed 1182 differentially expressed genes, of which 285 were upregulated and 330 were downregulated (fold change $\geq 1.5$) in response to GW treatment. In line with our previous experiments, IPA evidenced a marked reduction in the activity of RhoA signaling, signaling by Rho Family GTPases, regulation of actin-based motility by Rho showing activation z-score of -1, -0.83, and -0.82, respectively. A decreased Rho A GTPases signaling profile is consistent with the reduced migration capabilities of GW4064-treated CAFs, as these proteins are known to govern cell cytoskeleton organization, migration, and metastasis dissemination. Finally, MCF-7 and SKBR-3 breast cancer cells cocultured with GW4064-treated CAFs showed reduced anchorage-independent growth, suggesting how GW4064 exposure may also influence secretion of tumor-promoting soluble factors from CAFs.

Conclusions: The present and our previous studies propose FXR ligands as potential pharmacological tools that, targeting both cancer and activated stromal cells, may represent a more effective approach to treat breast cancer patients.
Mechanisms of CD8+ T cell immunosuppression in triple negative breast cancer

Gruosso T, Gigoux M, Bertos N, Zuo D, Manem V, Monette A, Lapointe R, Haibe-Kains B and Park M. Goodman Cancer Research Center, McGill University; Princess Margaret Cancer Centre, University Health Network and Laboratoire d'Immuno-Oncologie, ICM, Université de Montréal/CHUM Research Center (CRCHUM).

Body: Triple negative breast cancer (TNBC), defined as tumors lacking expression of the estrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor receptor 2 (HER2), are especially difficult to treat effectively. While ER+ and HER2+ breast cancer subtypes can be treated with Tamoxifen and Herceptin, respectively, there are no targeted therapies for TNBC patients. Furthermore, while only 20-30% of TNBC patients respond to chemotherapy in the neoadjuvant setting, overall outcome remains poor for non-responding patients. However, mounting evidence suggests that immune-checkpoint inhibitor immunotherapies may be especially promising for TNBC patients. We and others have shown that the presence of CD8+ T cells, a crucial component of the cytotoxic arm of the adaptive immune response, is a sign of good clinical outcome in TNBC patients. However, good outcome only correlates with CD8 +T cell invasion of the tumor parenchyma. Some patients had an accumulation of CD8+ T cells in the surrounding tumor-associated stroma, but not the tumor epithelia, and these patients responded as poorly as patients with no CD8 T cells at all. Yet how cancer associated fibroblasts (CAFs), the dominant cell type of the tumor-associated stroma, affects CD8+ T cell invasion into the tumor epithelia is still poorly understood. To identify potential stroma-dependent mechanisms which potentiate or inhibit CD8+ T cells invasion into the tumor epithelia, we performed gene expression profiling of laser-capture microdissected tumor-associated stroma (and matched epithelia) from 38 TNBC cases. Here we identify several stromal and epithelial canonical pathways as well as biomarkers that are associated with and may explain the accumulation of CD8 T cells outside of the tumor epithelia.
Title: Human breast cancer biopsies induce eosinophil recruitment and enhance adjacent cancer cell proliferation

Spencer BL L, Szalayova G, Ogodnik A, Rincon M and James T. UVM, Burlington, VT; Danbury Hospital, Danbury, CT and Department of Medicine, Immunobiology UVM, Burlington, VT.

Body: Previous research has demonstrated that chronic inflammation facilitates cancer progression and spread to other sites. The effect of acute inflammation in the microenvironment of the tumor that develops as a result of standard biopsy procedures has not been studied in detail. Recent studies demonstrated that acute inflammation in mouse models from a mammary biopsy increases the frequency of distal cancer metastasis. Core needle biopsies are the standard procedure for breast cancer diagnosis, but there have been no studies detailing the inflammatory response from the biopsy. The purpose of this study is to determine if core needle biopsies in breast cancer patients trigger an inflammatory response, determine the type of inflammatory response that occurs and study the potential effect of acute inflammatory response on tumor cells remaining. The biopsy wound site was identified in primary tumor resection samples from breast cancer patients. The inflammatory response adjacent and distant to the biopsy were studied via histology and immunohistochemistry. Tumor cell proliferation was studied as well. Our study demonstrated that diagnostic core needle biopsies trigger inflammatory cell recruitment at the site, and those cells remain over long periods of time. An unexpected increase in eosinophils were found to accumulate at the biopsy site. The biopsy also was shown to increase proliferation adjacent to the wound site. Overall, core needle biopsies used for breast cancer diagnosis induce a unique inflammatory environment at the site of the biopsy as well as the closely surrounding cells. Inflammation induced by the biopsy could lead to tumor cell progression or metastasis in breast cancer. These findings may be important for the clinical management of breast cancer.
Title: Prognostic and predictive marker in the tumor microenvironment of breast cancers

Wallon UM, Brady AL L, Isaac KM M, Ali ZA A, Gilman PB B and Shevade A. Lankenau Institute for Medical Research, Wynnewood, PA and Lankenau Medical Center, Wynnewood, PA.

Body: Background: Though genetic alterations initiates' tumor formation, extracellular signals from the tumor microenvironment can modify the growth and spread of cancer cells. We are studying a small modifier protein, tissue inhibitor of metalloproteinase-4 (TIMP-4) that can accelerate tumor growth and metastatic potential as seen in both cell culture, animal experiments and prospective studies of clinical subjects. TIMP-4 is synthesized by stromal cells and secreted into the tumor microenvironment. It binds to the membrane-bound tetraspanin CD63 on tumor epithelial cells and induces the activation of the tumor promoting PI3K/AKT pathway. This modifier has its strongest effect on the so-called triple-negative breast cancers (TNBC) and breast cancers with HER2 gene amplification.

Methods: Cell culture experiments using the human MDA-MB-468 (TNBC) and SK-BR-3 (HER2 amplified) cell-lines were used to assess the effects of elevated levels of TIMP-4 on downstream targets. Cells with or without human recombinant TIMP-4 added to the growth medium were used to determine the effects on growth, AKT activation, apoptosis and response to anti-TIMP-4 treatment. Tumor growth in nude mice with or without TIMP-4 containing slow-release pellets implanted into the mammary fatpad was followed for six-week period to assess response to anti-TIMP-4 therapy. Lungs, liver, spleen and mammary fatpads were collected and analyzed. Prospectively collected patient samples, in accordance with the IRB approved protocol, were tested for circulating levels of TIMP-4 and the cancer marker CA15-3, using commercially available ELISA kits, in samples collected prior to chemotherapy and at each treatment cycle.

Results: Augmentation of TIMP-4 levels in the cell culture medium of TNBC and HER2-amplified cells resulted in accelerated growth and increased activation of AKT as determined by Western blotting for pAKT\textsuperscript{Ser 473} and pAKT\textsuperscript{Thr 308}. Adding an anti-TIMP4 therapeutic antibody to TNBC cells grown in the presence of TIMP-4 resulted in reduced growth. HER2-positive cells grown under identical condition and treated with either an anti-TIMP-4 or a neutralizing ErbB2 antibody demonstrated no effects on growth. Only dual blockade of HER2 and TIMP-4 resulted in reduced growth. Using the anti-TIMP-4 therapy in animals resulted in stable disease with no signs of metastatic growths. Patients undergoing treatment for TNBC or HER2-positive breast cancer that had continuous elevated TIMP-4 levels while on treatment had a higher recurrence rate than patients with diminishing TIMP-4 levels in response to therapy. The TIMP-4 levels preceded and correlated better with disease progression than the traditional CA15-3 marker.

Conclusion: Together these clinical and laboratory data suggests that TIMP-4 could be a prognostic as well as a predictive marker. Our preliminary clinical data indicates that TIMP-4 might be a more reliable marker for recurrence/progression than CA15-3. Also, our cell and animal studies indicate that TIMP-4 could be therapeutic target for TNBC and HER2-positive breast cancer patients that test positive for this marker. Thus providing a targeted therapy for TNBC patients and HER2-positive patients that do not have full clinical benefit of HER2-targeted therapies alone.
Title: Fibroblasts isolated from the “normal-like” tissue adjacent to breast tumours suppress healthy epithelial progenitor cell proliferation while supporting tumour cell growth

Chatterjee S, Berdnikov A, Lee-Wing V, Safneck J, Buchel E and Raouf A. Research Institute in Oncology and Hematology, Winnipeg, MB, Canada; University of Manitoba, Winnipeg, MB, Canada; University of Manitoba, Winnipeg, MB, Canada and University of Manitoba, Winnipeg, MB, Canada.

Body: The tissue adjacent to breast tumors has been referred to as “normal-like” tissue despite exhibiting many alterations at epigenetic and gene expression levels consistent with enhanced proliferation and wound healing signatures. However, the influence of such alterations on the proliferation and differentiation of healthy breast progenitors is currently unknown. Fibroblasts are a major component of microenvironment for the healthy and malignant breast cells. We therefore, isolate fibroblast from primary breast tumors, tissue adjacent to tumors (TAT) and the healthy breast tissue and examine their ability to support proliferation of healthy and malignant breast cells. To characterize the TAT samples we first utilized clonal co-culture assays using breast cells obtained from the healthy breast tissue (reduction mammoplasty sample, RM) and the healthy fibroblasts. Our results suggested that the TAT samples surprisingly contained significantly decreased pool of progenitors compared to the RM samples. In order to study the underlying mechanism, we characterized fibroblasts derived from either the breast tumours (TAFs) or the TAT samples (TATF) or the RM normal samples (NAFs) and assessed their role on breast progenitor cell functions. Fibroblasts were isolated from the ER+ and ER- breast tumours and their adjacent breast tissue. We observed that matrigel co-cultures consisting of RM samples and NAFs led to a 5.5-fold expansion of the progenitors, whereas the co-cultures of TAT or the RM samples with either TAFs or TATFs failed to show expansion of epithelial progenitors. The comparative secretome analysis of the NAFs and the TATFs identified TGFβ as a candidate molecule primarily secreted only by the TATFs and not by NAFs. Interestingly, blocking TGFβ signaling restored both TAFs’ and TATFs’ ability to support the expansion of healthy progenitors in matrigel cultures. Lastly, we found that TAFs were able to enhanced breast cancer cell proliferation in vivo and in vitro but to a lesser extent than the TAFs. Our observations suggest that the tissues adjacent to breast tumours are transformed into a TGFβ-enriched environment that is supportive of breast tumour growth while suppressing the proliferation and differentiation potentials of the healthy breast progenitors. Our data also suggest that the use of TGFβ blockers may be important in reducing risk of local breast tumour recurrence.
**Title:** Cancer-associated fibroblasts release exosomal microRNAs that dictate an aggressive phenotype in breast cancer

**Body:** Cancer-associated fibroblasts (CAFs) are the major components of the tumor microenvironment. They may drive tumor progression, although the mechanisms involved are still poorly understood. Exosomes have emerged as important mediators of intercellular communication in cancer. They mediate horizontal transfer of microRNAs (miRs), mRNAs and proteins, thus affecting breast cancer progression. Differential expression profile analysis identified three miRs (miRs -21, -378e, and -143) increased in exosomes from CAFs as compared from normal fibroblasts. Immunofluorescence indicated that exosomes may be transferred from CAFs to breast cancer cells, releasing their cargo miRs. Breast cancer cells (BT549, MDA-MB-231, and T47D lines) exposed to CAF exosomes or transfected with those miRs exhibited a significant increased capacity to form mammospheres, increased stem cell and epithelial-mesenchymal transition (EMT) markers, and anchorage-independent cell growth. These effects were reverted by transfection with anti-miRs. Similarly to CAF exosomes, normal fibroblast exosomes transfected with miRs -21, -378e, and -143 promoted the stemness and EMT phenotype of breast cancer cells. Thus, we provided evidence for the first time of the role of CAF exosomes and their miRs in the induction of the stemness and EMT phenotype in different breast cancer cell lines. Indeed, CAFs strongly promote the development of an aggressive breast cancer cell phenotype.
Title: Obesity and breast cancer: The adipocyte-macrophage interaction as a mediator of metastasis

Connelly L, Yadav N, Barcikowski A, Imaizumi Y and Jacobs A. University of Hawaii at Hilo, Hilo, HI.

Body: Obese individuals with breast cancer have a poorer prognosis and higher risk of metastatic disease vs. non-obese patients. Prior research has largely focused on defining the interactions between adipocytes and tumor cells, but other cell types may also play a role. Adipose tissue in obese individuals is characterized by a significant infiltration of macrophages. We have therefore investigated the adipocyte-macrophage interaction as a possible mechanism whereby obesity promotes breast cancer metastasis.

We performed co-culture with both human and murine cells to determine whether adipocytes influence the expression of metastasis-promoting signals in macrophages. For the human system we co-cultured primary breast adipocytes with THP-1 macrophages. For the murine system we co-cultured 3T3-L1 differentiated adipocytes with J774.1 macrophages. We then assayed the mRNA levels and protein expression of metastasis-promoting genes.

In both systems we found that co-culture with adipocytes increased the expression of Vascular Endothelial Growth Factor A (VEGF-A) in macrophages. In examining a potential mechanism, we also show that media collected from cultured adipocytes (adipocyte-conditioned media) activates the transcription factor Egr-1 in macrophages. Since Egr-1 is a known regulator of VEGF-A expression, this is a potential mechanism whereby VEGF-A transcription is up-regulated. Treatment of human macrophages with Interleukin-6, Leptin and Insulin induced VEGF-A levels to a similar degree as co-culture, identifying these as adipocyte-derived signals that can possibly mediate this effect.

In summary we have found that the interaction between adipocytes and macrophages leads to the up-regulation of the pro-angiogenic signal VEGF-A in macrophages. Therefore this represents a potential mechanism whereby obesity could promote breast cancer metastasis.
**Title:** Stem cell and macrophage markers are enriched in normal tissue adjacent to inflammatory breast cancer

Reddy JP P, Atkinson RL L, Larson RA A, Burks JK K, Smith D, Debeb BG G, Ruffell B, Creighton C, Reuben JM M, Krishnamurthy S, Symmans WF F, Brewster A and Van Laere SJ J. MD Anderson Cancer Center, Houston, TX; University of South Florida, Tampa, FL; Baylor College of Medicine, Houston, TX and University of Antwerp, Belgium.

**Body:** *Introduction:* We hypothesized that normal breast tissue in inflammatory breast cancer (IBC) patients contains intrinsic differences, including increased mammary stem cells and macrophage infiltration, which may promote the IBC phenotype.

**Materials and Methods:** Normal breast tissue at least 5cm away from primary tumors were obtained from mastectomy specimens. This included an initial cohort of 8 IBC patients and 60 non-IBC patients followed by a validation cohort of 19 IBC patients and 25 non-IBC patients. Samples were immunostained for either CD44<sup>+</sup>CD49f<sup>+</sup>CD133/2<sup>+</sup> stem cell markers or the CD68<sup>+</sup> macrophage marker and correlated with IBC status. Automated quantitation of positive cells was employed for the validation cohort. We also examined the association between IBC status and previously published tumorigenic stem cell and IBC tumor signatures in the validation cohort samples.

**Results:** 8 of 8 IBC normal tissue samples expressed CD44<sup>+</sup>CD49f<sup>+</sup>CD133/2<sup>+</sup> stem cell markers in the initial cohort as opposed to 0/60 non-IBC normal tissue samples (p=0.001). Similarly, the median number of CD44<sup>+</sup>CD49f<sup>+</sup>CD133/2<sup>+</sup> cells was 25.7 in the IBC validation cohort as opposed to 14.2 in the non-IBC validation cohort (p=0.007). 7 of 8 IBC samples expressed CD68<sup>+</sup> macrophages in initial cohort as opposed to 12/48 non-IBC samples (p=0.001). In the validation cohort the median number of CD68<sup>+</sup> cells was 3.7 in the IBC cohort vs 1.0 in the non-IBC cohort (p=0.06). Normal tissue of IBC patients was positively associated with a tumorigenic stem cell signature (p=0.02) and with a 79-gene IBC gene signature (p<0.001).

**Conclusions:** Normal tissue from IBC patients is enriched for both mammary stem cells and macrophages. Further, normal tissue of IBC patients has higher association with both a tumorigenic stem cell signature and IBC-specific tumor signature. Collectively, these data suggest that normal tissue from IBC patients is distinct from non-IBC normal tissue and may support the hypothesis that a primed normal breast contributes to the development of IBC symptoms upon oncogenic insult. Validation of these results in additional normal tissue in cancer-free women would better determine causality.
Title: Joint influence by paracrine adipocyte signals and metabolic conditions on breast cancer

Rosendahl AH H, Bergqvist M, Lettiero B, Kimbung S and Borgquist S. Lund University, Faculty of Medicine, Clinical Sciences Lund, Lund, Sweden.

Body: Background: The growing global population of overweight and obese people represents a pressing public health concern. A higher percentage of body fat is linked to an altered metabolic state and an increased risk of chronic metabolic disorders and cancer. Although, the mechanistic explanations for how obesity affects the development, progression and prognosis of cancer is incompletely mapped.

Purpose: To investigate the joint influence by adipocytes and metabolic pressure on breast cancer cell expansion.

Experimental Design: In vitro differentiated 3T3-L1 adipocytes were exposed to metabolic glucose$^{low/high}$ and insulin$^{low/high}$ pressure in order to mimic normal, pre-diabetic, overt diabetic and late diabetic conditions. Adipocyte-conditioned medium was collected and paracrine effects by adipocyte-derived factors on estrogen receptor (ER)-positive (T47D, MCF-7) and ER-negative (MDA-MB-231) breast cancer cell proliferation, molecular adaptations, and cell motility were subsequently analyzed using sulforhodamine B, Western immunoblotting and migration assays.

Results: Under normal metabolic conditions, adipocytes stimulated the growth of ER+ (1.1-2.0-fold; $P<0.001$) and to a greater extent, ER- breast cancer cells (3.1-fold; $P<0.001$), compared with controls. The joint effects by adipocyte paracrine signals and higher metabolic pressure (overt or late diabetic conditions), further enhanced the proliferative response in both ER+ and ER-cells (1.3-3.5-fold; $P<0.01$), compared with controls. Furthermore, adipocyte-derived factors induced morphological changes, protrusion extensions and cell migration in the low invasive T47D cells. Additional acquisition of molecular epithelial-mesenchymal transition features were observed in breast cancer cells following co-culturing with adipocyte-derived factors.

Conclusion: These study results support the hypothesis that paracrine signals by adipocytes significantly stimulate the proliferation and induction of a more motile phenotype of human breast cancer cells, which is further enhanced under obesity-associated metabolic conditions.
Body: Background: FAPα is a transmembrane serine protease expressed on cancer associated fibroblast that promotes tumour growth and invasion. In patients (pts) with poor outcome and survival FAPα is highly overexpressed. FAPα is also expressed in stroma across all breast cancer subtypes without association with clinicopathological factors. Pts without Complete Pathological Response (pCR) after Neoadjuvant Chemotherapy (NC) had poor outcome. We analysed the relationship between the expression of FAPα in stroma (fibroblast) and in epithelial breast cancer cells of pts without pCR after NC (taxanes, antracycines and trastuzumab in Her2+).

Methods: 60 pts were included. ER, PR and Ki67 were studied by IHQ (Ventana) and Her2 by FISH (PathVysion). FAPα expression was determined by IHQ (polyclonal, Ventana). St Gallen guidelines for subtype of breast cancer were used.

Results: 53 pts had tissue. Median age 47 years (range 29-68). Median tumour size 43mm and 10 (18.9%) were multifocal. 37 (69.8%) had positive axillary nodes. 47 were ductal invasive carcinomas. 33 (62.3%) were grade 2 and 20 (37.7%) grade 3. 44 pts (83%) had ER+ (20 luminal B), 17 (32%) Her2+ and 6 (11%) triple negative(TN). Median Ki67 was 22% (p25-75:15-38%). Miller-Payne response was 1.9% G1 (1pt), 43.4% G2 (23 pts), 41.5% G3 (22 pts) and 13.2% G4 (7 pts). The recurrences were 2 local and 12 distant (26.4%). Median FAPα in residual epithelial breast cancer cells after NC was 85% (p25-75:30-95%) and in the stroma 20% (p25-75:10-62%). Median epithelial FAPα was 55% in TN, 85% Her2, 72.5% luminal A and 92.5% in luminal B. Median stromal FAPα was 52.5% in TN, 20% Her2, 15% luminal A and 15% in luminal B. There is not association between stromal FAPα and clinicopathological features, but a higher epithelial FAPα was found in tumours with higher ER, PR and Ki67. In luminal B subtype, stromal FAPα was smaller in pts with relapses (median 7.5%) than without relapses (median 30%).

Conclusions: Stromal FAPα in residual cancer after NC is higher in TN breast cancer but without association with relapses in our small sample. However, in luminal B subtype stromal FAPα is smaller in pts with relapses.
Body: Background: Tartrate-resistant acid phosphatase (TRACP or ACP5) is a metalloprotein enzyme that belongs to the acid phosphatase family and is mainly expressed by osteoclasts. It is a classic marker for bone resorption and osteoclast differentiation. TRACP expression is a useful serum marker for extensive bone metastasis. Recent studies have reported that TRACP promotes the invasion and distant metastasis of melanoma and breast cancer cells through the modulation of focal adhesion kinase (FAK) phosphorylation and epithelial cell migration. Therefore, TRACP has received considerable attention as a newly discovered proinvasion metastasis driver associated with different malignancies. Additionally, TRACP overexpression is indicative of the poor prognoses cancer patients and suggests that TRACP may have an important role in promoting tumor metastasis. Its detail mechanism in modulating cancer metastasis remains unknown. We have previously demonstrated the serum TRCAP 5a is a valuable marker in assessing disease activity, severity or systemic macrophage (inflammatory) burden. It has recently been found that up-regulation of TRACP promoted cancer cell invasion and lung metastasis, whereas TRACP knockdown inhibited these processes.

Aims: No studies have previously addressed the question of extracellular effects of TRAP. The aim of this study was to evaluate if TRACP binds to and is endocytosed by cancer cells. We also aim to determine if extracellular TRACP affect oncogenesis or cancer progression, alter the cancer cell expressions of angiogenesis or adhesion molecules, or direct the treatment resistance or cancer prognosis.

Results: Knockdown of TRACP significantly attenuated FoxM1-enhanced invasion and lung metastasis. Extracellular TRACP in culture media influenced the tumor invasion upon endocytosis. Significant increased invasion/migration was observed upon higher concentrations of TRACP. Tumor growth was significantly enhanced when the tumor xenografting previously primed with polarized M2Ø or TRACP protein, by enhanced metalloproteinase (MMP-9) and angiogenic factor (VEGF-A) expression

Conclusions: TRACP or M2Ø-secreted TRACP could promote cancer growth and modulated the tissue and microenvironment and create pre-metastatic condition by cell adhesion/angiogenesis signaling alteration. TRACP-targeting strategy is plausible in breast cancer metastasis treatment.
A hierarchy of cancer associated fibroblasts in situ and in circulation promote breast cancer metastasis

**Background:** Metastasis is the primary cause of breast cancer mortality. Interactions between cancer cells and non-cancer cells of the tumor microenvironment (TME) are pivotal in governing tumor initiation, progression, and metastasis, and cancer associated fibroblasts (CAFs) are critical orchestrators of these interactions. We recently identified circulating CAFs (cCAFs) as a novel circulating biomarker associated with metastatic breast cancer. We established CAF cell lines from dissociated luminal A, ER- Her-2 amplified, and triple-negative/basal-like (TN) breast tumors. We demonstrated that “aggressive” CAFs differentially secrete miRNAs that contribute to ER-negativity, activated growth factor signaling, and induction of EMT in breast cancers compared to “indolent” CAFs. We hypothesized that a hierarchy exists within CAFs regarding their ability to facilitate tumor progression and metastasis. Here we demonstrate that CAFs derived from aggressive TN breast tumors differ from those derived from more indolent Luminal A breast tumors in secretion of cytokines and chemokines that can confer differential effects on the behavior of breast cancer cells. We also demonstrate that “aggressive” CAFs more potently facilitate tumor progression and metastasis than “indolent” CAFs. We additionally evaluated if “aggressive” and “indolent” CAFs differ in their ability to mobilize CTCs and circulating CAFs into circulation.

**Methods:** Conditioned media (CM) from “aggressive” and “indolent” CAFs was analyzed for chemokine/cytokine expression. Luminal A breast cancer cells (MCF-7) or primary tumor cells from an aggressive TN tumor (DT28) were injected into the mammary fat pad of 6-8 week old female NSG mice, either alone or in combination with CAF19-I or CAF23-A. Tumor progression was monitored and mice were examined for metastasis at necropsy. Tissues were harvested for histology and blood was collected by cardiac puncture. Plasma was analyzed for cytokine/chemokine expression and blood was processed for enumeration of circulating tumor cells (CTCs) and cCAFs.

**Results:** “Aggressive” CAF CM had significantly higher levels of a number of factors, including IL-8, SDF-1, and CXCL1, compared to “indolent” CAF CM. MCF-7 cells co-injected with “aggressive” CAFs formed tumors much faster than those co-injected with the “indolent” CAFs or without CAFs. While DT28 cells readily form tumors and metastasize in the NSG model, fewer DT28 cells do not form metastases in the timeframe that this same lower number of DT28 cells co-injected with “aggressive” CAFs demonstrated robust tumor growth and developed metastases in liver and pancreas. DT28 cells co-injected with “indolent” CAFs did not exhibit metastases.

**Conclusion:** The data presented here further demonstrate that there is a hierarchy within CAFs regarding their ability to facilitate tumor growth and metastasis, and that this may largely be mediated by secreted soluble factors. “Aggressive” CAFs may retain their programmed role in circulation and accelerate metastasis more than “indolent” CAFs. We suggest that targeting CAFs in situ and in circulation and disrupting their interactions with breast cancer cells could provide novel strategies to combat breast cancer and breast cancer metastasis.
Title: A paradigm shift for insulin-like growth factor-1 receptor function in triple negative breast cancers

Obr AE E and Wood TL L. Rutgers University-New Jersey Medical School, Newark, NJ.

Body: Loss of insulin growth factor (IGF) signaling in the mammary gland at puberty leads to delayed elongation and defects in terminal end bud (TEB) proliferation. Moreover, IGF signaling is essential for epithelial mesenchymal interactions in mammary bud morphogenesis. We have generated and characterized a mouse line containing both MMTV-Wnt1 and MMTV-dnIGF-1R (kinase dead-IGF-1R) transgenes (referred to subsequently as bigenic mice) that leads to increased mammary tumor initiation and metastasis. Recent analyses of TCGA human datasets support the relevance of our model in human triple negative breast cancers (TNBCs) that have reduced IGF-1R expression and increased expression of Wnt1 and the Frizzled co-receptor Lrp6. We have identified alterations in a number of target genes that potentially regulate metastasis in the bigenic primary tumors including increases in interleukin-6 (IL-6), Nanog, Slug, and decreases in E-cadherin expression as assessed by Qiagen specific qPCR and single gene qPCR. Furthermore, a subset of anti-inflammatory chemokines and cytokines were assessed by a targeted qPCR array revealing increases in interleukin-4, interleukin-10, and C-C motif chemokine ligand-2 and decreases in tumor necrosis factor-alpha and interleukin-1 in the bigenic tumors suggesting a tumor associated macrophage phenotype. By flow cytometry analysis, the ratio of CD4+ T cells to CD8+ T cells is increased in the bigenic tumors suggesting a tumor promoting immune microenvironment. However, increased expression of IL-6 in the bigenic tumors is specific to the luminal tumor cells, and inhibition of IGF-1R in the MCF7 human breast cancer cell line results in increases in both IL-6 and Slug expression suggesting the tumor cells activate EMT and a pro-tumorigenic microenvironment in response to decreased IGF-1R. Taken together, our data suggest IGF-1R acts as a negative regulator of mediators that promote invasion and metastasis in TNBCs.

References:
Body: **BACKGROUND.** The epithelial-mesenchymal transition (EMT) is a developmental program that cancer cells often activate to acquire a highly plastic phenotype that promotes invasion, metastasis, but also chemoresistance and cancer stem cell generation. As readers of epigenetic marks, bromodomain and extra-terminal (BET) proteins BRD2, BRD3 and BRD4 participate in the regulation of multiple transcriptional programs implicated in cancer progression. We sought to unravel the roles of BET proteins in EMT in breast cancer.

**METHODS.** Cell line models of the different subtypes of breast cancer were used in this study (luminal A: MCF-7, T47D, basal-like: MDA-MB-231, SUM149PT). BET expression was modulated by using RNA interference or plasmid-mediated overexpression. Small molecule JQ1 was used to inhibit BET proteins. The expression of 84 key EMT genes was monitored by PCR using a Qiagen kit. We also monitored EMT by measuring the expression of epithelial and mesenchymal markers by immunoblot and immunofluorescence staining.

**RESULTS.** Despite their homology, we report that BET proteins differentially regulate EMT. Based on an EMT PCR array, we identified a BRD2-specific transcriptional profile that promotes EMT, whereas BRD3 and BRD4 signatures repress this program. These individual signatures are unidentifiable upon pan-BET inhibition using JQ1, reinforcing the necessity to target each BET member separately to better understand their functions. Upon BRD2 depletion, basal-like breast cancer cells, which present a mesenchymal phenotype, exhibit a reduced expression of mesenchymal markers (N-cadherin, vimentin) and re-express epithelial markers (E-cadherin, cytokeratins). Moreover, a large panel of EMT master transcription factors is downregulated in BRD2-depleted cells, including the Snail and ZEB families or Twist. Interestingly, we found that BRD3 or BRD4 depletion leads to the opposite phenotype: an increase of mesenchymal marker expression and repression of the epithelial markers. In luminal A breast cancer cells which present an epithelial phenotype, BRD2 overexpression leads to the expression of mesenchymal markers. Similar results were obtained by depleting BRD3 or BRD4 in these cells, confirming the differential roles of BET proteins in EMT regulation.

**CONCLUSION.** Taken together, our results establish that BRD2 positively regulates EMT, whereas BRD3 and BRD4 repress this program. BET proteins possess separate and opposite biological functions, reinforcing the relevance of an individual targeting instead of a pan-BET inhibition using JQ1. We hypothesize that BET proteins modulate EMT through the regulation of its master transcription factors. We propose that the balance of BET proteins present at the promoters of the EMT genes is a novel mechanism of regulation of this program in breast cancer cells.
Title: Obesity-induced EMT in luminal A breast cancer cells

Hayden A, Quach D, Galvan G, Patodia R, Brenner A and deGraffenried L. The University of Texas at Austin, Austin, TX and The UT Health Science Center at San Antonio, San Antonio, TX.

Body: Introduction: Obesity is associated with a worse prognosis in breast cancer, including the less aggressive ER+ luminal A subtype, but the mechanisms by which it promotes disease progression are unclear, making treatment difficult. Obese breast cancer patients have a higher risk of a more aggressive disease compared to lean patients, which is associated with treatment resistance and metastasis. The mechanisms promoting obesity-driven metastasis are not understood, but several studies have indicated that obesity is associated with a “stem-like” phenotype. A “reprogramming” occurs, transforming stationary, epithelial cells to motile, malignant cells that exhibit a more aggressive phenotype than their stromal counterparts. Our data suggest that in vitro exposure of luminal A breast cancer cells to obese conditions may induce an epithelial to mesenchymal transition (EMT), which is characterized by a more stem-like phenotype, resistance to treatment (chemo, hormone and radiation), as well as greater metastatic potential. This has let us to hypothesize that one critical mechanism by which obesity promotes a more aggressive disease is through inducing an EMT reprogramming, resulting in a more stem-like phenotype.

Methods and Results: Both in vitro and translational approaches will be done to determine if obesity induces epigenetic reprogramming associated with a more stem-like phenotype. MCF-7 ER+ breast cancer cells exposed to 2% sera from obese (BMI ≥30) postmenopausal women demonstrated a significant increase in expression of both SNAIL1 and TWIST transcription factors (9-fold and 4-fold, respectively) which are implicated in EMT and potentially stem-cell programming, compared to those exposed to sera from lean women. Current studies are underway to determine if this is observed in other ER+ luminal A cell lines, including T47D, and whether induced changes in these transcription factors results in changes in signaling pathways associated with EMT, including TGFβ, which can activate the PI3K–AKT, ERK MAPK, p38 MAPK and JNK pathways and WNT signaling, which promotes EMT by stabilizing β-catenin. Additionally, the luminal A cell lines will be assessed for changes in other factors known to modulate breast cancer cell programming, including KLF4, OCT4, SOX2, and NANOG.

Conclusions: Our earlier studies have demonstrated that obesity promotes a more aggressive disease even in luminal A disease. The mechanisms for this remain unclear. Our exciting preliminary findings suggest that obesity might induce a reprogramming of the luminal A well-differentiated cell to a more stem-like phenotype. Our results will lay an important foundation for understanding how obesity modulates breast cancer disease progression, whether this programming may provide therapeutic target to improve response and overall survival in the obese patient.
Title: Eribulin impairs TGF-β type I receptor localization and signaling in BT-549 cells

Kaul R, Risinger AL L and Mooberry SL L. University of Texas Health Science Center at San Antonio, San Antonio, TX and Cancer Therapy & Research Center at San Antonio, San Antonio, TX.

Body: Microtubule targeting agents (MTAs) continue to be some of the most valuable drugs used to treat breast cancer. While decades of research have shown that these drugs cause mitotic arrest in cells by suppressing the dynamic instability of microtubules, recent evidence demonstrates that the ability of MTAs to disrupt microtubule-dependent transport of key signaling components, including proteins and microRNAs, in interphase cells likely contributes to their anticancer actions. TGF-β signaling is a driver of oncogenesis and epithelial-to-mesenchymal transition (EMT) that involves multiple protein trafficking and intracellular signaling events. Ligand mediated activation of the cell surface TGF-β receptors leads to downstream signaling in the canonical and the non-canonical pathways that collectively lead to the expression of proteins implicated in EMT, including Snail and Slug. Additionally, TGF-β type 1 receptor (TGF-βR1) undergoes constant cycling from the plasma membrane to the cytosol, a microtubule-dependent process. We tested the hypothesis that a short-term treatment of breast cancer cells with eribulin or 3 other clinically relevant MTAs would differentially disrupt interphase microtubules and alter the transport and downstream signaling of TGF-βR1. BT-549 cells were treated for 2 h with concentrations of MTAs that cause comparable disruption of the interphase microtubule network; 100 nM was used for the destabilizers, eribulin or vinorelbine and 1 µM was used for the stabilizers, paclitaxel or ixabepilone. The results show that TGF-βR1 was extensively localized along the stabilizer-induced microtubule bundles, a phenomenon not observed with destabilizer-treated cells. The downstream consequences were further assessed. The expression of Snail and Slug were evaluated in cells pretreated with MTAs followed by TGF-β stimulation. Eribulin and vinorelbine significantly inhibited the TGF-β-induced expression of Snail and Slug while stabilizers did not alter their expression levels. We hypothesize that eribulin and vinorelbine are inhibiting the non-canonical TGF-β signaling pathway since they had no effect on the localization and expression of Smad2/3, proteins involved in the canonical pathway. Eribulin induced inhibition of TGF-β signaling is consistent with previous studies that show that a 7 day treatment reversed TGF-β-mediated EMT in breast cancer cells1. Data from patients shows that eribulin decreases the plasma concentration of TGF-β within 7 days of treatment initiation2. Our data suggest that eribulin rapidly inhibits non-canonical TGF-β signaling indicating that this is a potential mechanism for the eribulin-mediated EMT reversal. This information, together with previously published reports, suggest that eribulin has multiple effects leading to inhibition of TGF-β signaling. These studies begin to shed light into the diverse mechanisms of action of MTAs.

Diet, development and predisposition to breast cancer: The impact of sugar derived metabolites (AGEs) on pubertal mammary gland development

Krisanits BA A, Nogueira LM M, Findlay VJ J and Turner DP P. Medical University of South Carolina, Charleston, SC.

The mammary gland is one of the few organs that continues to develop postnatally through stages including puberty, pregnancy, lactation, and involution. The gland is composed of epithelial and stromal cells that include fibroblasts, adipocytes, endothelial cells, nerve cells, and macrophages. Terminal end bud (TEB) structures are found exclusively in the pubertal developmental stage. The formation of TEBs and side branching drives mammary gland epithelial cell invasion into the mammary fat pad, continuing until the entire fat pad is filled. Pubertal mammary gland morphogenesis integrates a balance of epithelial cell proliferation, differentiation, and apoptosis. Several studies have shown that the interaction between mammary epithelial and stromal cells is crucial for the proper postnatal development of the mammary ductal tree. Interestingly, studies have shown that processes important in mammary gland development are often deregulated during breast cancer tumorigenesis. Thus, understanding the complex signaling network as well as the interactions between the different cell types during mammary gland development will be vital for elucidating the mechanisms underlying breast cancer progression and metastasis.

Glycation is the non-enzymatic glycosylation of sugar moieties to biological macromolecules such as protein and DNA which produces reactive metabolites known as advanced glycation end products (AGEs). AGE content in the Western Diet has consistently increased over the last 50 years due to increased consumption of sugar laden and cheap processed/manufactured foods which are high in reactive AGE metabolites. AGE containing food can lead to the accumulation of AGEs in the body overtime leading to pro-inflammatory and pro-oxidant effects when signaling through receptor for advanced glycation end products (RAGE). Leading too many complications associated with diseases including diabetes, Alzheimer's, heart disease and cancer. Preliminary data in our lab has shown that AGEs also have an effect on phosphorylation and signaling of estrogen receptor α (ERα), a key receptor and signaling pathway in the regulation of mammary gland development during puberty. This observation, together with the links between diet, mammary gland development and immune cell recruitment lead us to examine the biological effects of a diet high in AGEs on pubertal mammary gland development in mice. We observed a significant disruption of normal pubertal mammary gland development in mice fed a high AGE diet when compared to mice fed a control diet. Mice fed the high AGE diet showed increases in TEB number as well as width, length and area. We also observed an increase in ductal branching and a decrease in ductal extension. Future studies will assess the role of macrophage recruitment to the developing gland, specifically around the TEBs based on its reported role in normal TEB function. We also plan to assess ERα signaling in mice fed the high AGE diet based on the reported role of estrogen signaling in ductal elongation.
Conditional inactivation of the 25-hydroxyvitamin D-24-hydroxylase (Cyp24a1) in the mouse mammary epithelium alters mammary gland development

Sheng L, Turner AG G, Tarulli GA A, Barratt K, Kremer R, Morris HA A, Callen DF F and Anderson PH H. Adelaide Medical School, University of Adelaide, Adelaide, SA, Australia; Dame Roma Mitchell Cancer Research Laboratories (DRMCRL), Adelaide Medical School, University of Adelaide, Adelaide, SA, Australia; School of Pharmacy and Medical Sciences, University of South Australia, Adelaide, SA, Australia and McGill University Health Centre, Montreal, QC, Canada.

The biologically active form of vitamin D (1,25(OH)\(_2\)D) regulates proliferation, differentiation, and apoptosis in diverse cell types. We have previously identified anti-proliferative activities of 1,25(OH)\(_2\)D in human breast tissue, as well as 1,25(OH)\(_2\)D target gene expression consistent with reports that elevated vitamin D levels may protect against cancer. In mouse studies, vitamin D signaling modulates normal mammary gland development, including ductal outgrowth and branching, and protects against tumorigenesis. Degradation of 1,25(OH)\(_2\)D is initiated by the enzyme Cyp24a1 in target tissues, providing critical local control of 1,25(OH)\(_2\)D bioactivity. In vitro, blockade of Cyp24a1 activity potentiates the anti-proliferative effects of 1,25(OH)\(_2\)D. However, the extent to which endogenous Cyp24a1 activity within the mammary epithelium regulates local 1,25(OH)\(_2\)D levels to modulate normal mammary gland development, with possible implications for cancer, has not been investigated. We generated a novel mouse model with conditional knockout of the Cyp24a1 gene specifically in the mammary epithelium (MMTV-Cre x Cyp24a1\(^{lox/lox}\)). Ablation of Cyp24a1 activity in the mammary epithelium does not alter either gland or body weight at 4, 6 or 10 weeks of age. Preliminary analyses of mammary gland whole mounts indicate that virgin knockout mice form fewer terminal end buds compared to glands from wild-type littermates at 4 and 6 weeks of age (\(P<0.05\)). Moreover, the width of the ducts proximal to the central lymph node of knockout mice was less than that of wild-type mice at 4 and 10 weeks of age (\(P<0.05\) and \(P<0.01\), respectively). In addition, the number of secondary and tertiary branching points is reduced in mammary glands from knockout mice at 6 weeks of age (\(P<0.05\) and \(P<0.01\), respectively). In summary, our findings suggest that Cyp24a1 activity within epithelial cells plays a crucial role to modulate postnatal mammary gland development, presumably by limiting the local accumulation of 1,25(OH)\(_2\)D.
Title: Patient derived DCIS mouse-intraductal (MIND) models recapitulate the full spectrum of human patient pathology and histologic features including progression to invasion in a subset of cases

Body: Introduction: The 20-year breast cancer mortality rate following a DCIS diagnosis is ~3%. Radiation and anti-hormonal therapy of DCIS has not resulted in improved overall survival, which argues against the non-selective use of such therapies in DCIS management. However, some DCIS cases do progress to invasive cancer, and these patients may benefit from treatment. A study of 80 DCIS patients followed for up to 30 years reported a 43% progression rate. Notably, progression was not predicted by grade, as 39% of even low-grade DCIS ultimately progressed to invasive cancer. Clearly, there is a need to identify which DCIS lesions are likely to progress. We have developed a novel mouse xenograft model (mouse-intraductal; MIND) to study the molecular basis of DCIS progression and enable identification of suitable biomarkers that predict invasive progression.

Methods: MIND involves injection of epithelial cells derived from patient breast lesions into the mammary ducts of immunocompromised mice. Serial sections of mouse mammary glands containing DCIS xenograft lesions were examined at time intervals of 3-14 months post-engraftment by histology using hematoxylin and eosin (H&E) and immunohistochemistry using anti-human cytokeratin 5/19, smooth muscle actin, ER, PR, p53, Ki67 and HER-2.

Results: Intraductal injection of cells derived from breast lesions of 28 patients into 133 mice resulted in a successful engraftment rate of 60%. Among these, 12 pure DCIS samples were injected into 35 different mice to create MIND xenografts. As early as three months post-engraftment, the DCIS xenograft cells showed multilayered in situ growth consisting of atypical neoplastic cells with prominent and vesicular nuclei. DCIS MIND xenografts exhibited the full spectrum of human DCIS histologic features, including similar biomarker expression (ER, PR, Ki67, HER-2 and p53) at long-term follow-up after engraftment (up to 12 months). Most remarkably, a subset of xenografts representing 5 patients (5/12; 42%) showed progression to invasion 6-12 months post-engraftment in the absence of any external genetic manipulations. This rate is very similar to that reported for human DCIS progression in untreated patients. MIND DCIS xenograft lesions that progressed showed disruption of basement membrane and myoepithelial layer by the invasive cells, retraction of basement membrane, and micro-invasion. MIND DCIS lesions were enriched in small capillaries, and in some cases clusters of invasive cells appeared inside nearby blood vessels.

Conclusion: The MIND xenograft is a viable model for human DCIS progression that recapitulates histologic features of human DCIS, as well as reported rates of progression to invasion. The availability of this innovative model provides a valuable tool for the discovery of new biomarkers to identify DCIS with invasive potential. The identification of high risk DCIS will ultimately help patients and clinicians choose the best course of therapy and avoid the morbidity and costs associated with unnecessary treatment.
Title: The mammary ducts create a favourable microenvironment for xenografting of luminal and molecular apocrine breast tumours

Bonnefoi H, Richard E, Grellety T, Velasco V, MacGrogan G and Iggo R. Bergonie Cancer Institute, INSERM U1218, University of Bordeaux, Bordeaux, France.

Body: There is a paucity of models for hormone receptor positive (HR+) breast cancer because of the difficulty of establishing xenografts from these tumours. We show that this barrier can be overcome by injecting human tumour cells directly into the mammary ducts of immunodeficient mice. Tumours from 31 patients were infected overnight with a lentiviral vector expressing tdTomato and injected through the nipple into the mammary ducts of NOD-SCID-IL2RG/-/- mice. Tumours formed in the mice in 77% of cases after the first injection (6/8 luminal A; 15/20 luminal B and 3/3 molecular apocrine). Four luminal A and one molecular apocrine graft were tested in secondary and tertiary grafts: all were successfully passaged in secondary and 4/5 in tertiary grafts. None of the samples engrafted when injected subcutaneously. The morphology, oestrogen receptor (ER), progesterone receptor (PR), androgen receptor (AR) and Ki-67 profiles of the clinical samples were maintained in the tertiary grafts. We also show that the intraductal approach can be used to test the response to targeted therapy with fulvestrant and palbociclib, using a genetically defined ER+ model. Fulvestrant was ineffective in this model but palbociclib inhibited tumour growth and prevented conversion of DCIS into IDC. We conclude that the mammary ducts create a microenvironment that is uniquely favourable to the survival and growth of tumours derived from mammary hormone-sensing cells. This approach opens the door to testing genomically-targeted treatment of HR+ tumours in precision medicine programs.
**Background:** Patient-derived xenograft (PDX) models of breast cancer replicate the diverse histologic and molecular features of patient tumors and provide a renewable source of human tumor tissue; however, collection of tissue by core needle biopsy is problematic due to patient discomfort, bleeding risk, and the limited number of passes a patient can tolerate. In addition, FDA guidelines caution that multiple core needle biopsies could lead to an overestimation of the true pCR rate in neoadjuvant trials.

**Methods:** To support the neoadjuvant molecular diagnostic and drug development program in TNBC, a pilot study was conducted to determine if fine needle aspiration (FNA) could be used for building PDX models. Prior to engraftment, FNA samples were analyzed for cell number and viability.

**Results:** Six PDX models were successfully generated from eight individual tumor samples. These models retain histologic and molecular features of the original patient tumors as determined by immunohistochemistry, RNA expression profiling, and deep whole-exome and targeted gene sequencing. In addition, the tested PDX models recapitulate the responses to therapies across multiple chemotherapeutic agents.

Based on this success, we have standardized the use of FNAs to generate PDX models both pre- and post-therapy in two ongoing neoadjuvant clinical trials:

1. MDACC 2014-0185 (PI Stacy Moulder, 360 patients), 'Improving outcomes in TNBC using molecular triaging and diagnostic imaging to guide neoadjuvant therapy'
2. MDACC 2014-0045 (PI Jennifer Litton, 20+ patients), 'A pilot study of BMN673 as a neoadjuvant study in patients with diagnosis of invasive breast cancer and a deleterious BRCA mutation'

</table>

To date, treatment-naïve primary tumor samples from 67 patients enrolled onto these neoadjuvant trials, and 16 matched non-responsive post treatment tumor samples have been analyzed for cell count and viability (table above) prior to being engrafted into the humanized mammary fat pads of NOD/SCID mice.

**Conclusion:** We have demonstrated success in using FNAs to build PDX models that recapitulate the biology and clinical course of the original tumor. In our pilot study, we successfully generated six PDX models using FNA for TNBC, including some harboring deleterious BRCA1/2 mutations. Because of the high concordance in histologic, genomic, and clinical attributes, we are now using this approach to develop a rich resource of pre- and post-treatment PDX models for the investigation of therapeutic resistance.
Title: Triple negative breast cancer patient-derived xenografts: Molecular characteristics and sensitivity to emerging therapies

Body: Background: Patients with triple negative breast cancer (TNBC) that have significant residual disease following neoadjuvant therapy have a poorer prognosis. The difficulty in developing improved treatment strategies for these patients is compounded by the molecular diversity of this pathology. Thus, preclinical efficacy testing with models representing the molecular heterogeneity of TNBC may not only improve efficacy testing but also has the potential to facilitate biomarker discovery to inform patient selection.

Methods: We generated 28 hormone receptor-low/HER2- patient-derived xenografts (PDXs) from 26 patients; the majority from residual disease following neoadjuvant chemotherapy. We characterized the tumors from the patients and the matched PDXs by targeted exome sequencing, RNA sequencing, and Reverse Phase Protein Arrays. We established single agent sensitivity for a set of PDXs to standard TNBC therapies as well as emerging targeted therapies targeting PARP, mTOR, PI3K and MEK1/2.

Results: PDXs maintained DNA/RNA profiles similar to the patients' tumors. Our PDX set exhibits a diverse set of potential driver alterations and is comprised of PDXs representative of all TNBC molecular subtypes. The PDXs varied in their sensitivity to standard chemotherapeutics. PI3K, mTOR and MEK inhibition caused tumor growth inhibition in several PDX models but were unable to cause tumor regression as single agent. In contrast, talazoparib caused dramatic regression in 5 out of 12 PDXs tested, including 3 PDXs from patients whose tumors had progressed on neoadjuvant anthracyclines and/or paclitaxel. Four of these talazoparib sensitive PDXs were derived from patients not harboring BRCA1/2 germline alterations; three had somatic alterations in genes linked to DNA damage repair (ATM, BRCA2, PTEN). The comparison of PARP sensitivity with molecular profiles will be presented.

Conclusions: TNBC PDXs represent molecular tumor heterogeneity as well as heterogeneity in response to targeted therapeutics. PDXs represent an opportunity for biomarker discovery as well as for rationale combination therapies to enhance the efficacy targeted therapies.
**Title:** Treatment of ESR1 mutant and PIK3CA mutant patient-derived breast cancer xenograft models reveals differential anti-tumor responses to estrogen receptor degraders and PI3K inhibitors in vivo

**Body:** The phosphoinositide 3-kinase (PI3K) pathway is a key driver of hormone receptor (HR)–positive breast cancer growth and survival. It is estimated that 40-45% of HR+ breast cancers harbor oncogenic mutations in the PIK3CA gene, which encodes the p110α isoform of PI3K. Taselisib (GDC-0032) is a mutant-selective PI3K inhibitor that demonstrates enhanced potency in PIK3CA mutant breast cancer cells and is being developed as a treatment for metastatic breast cancer that targets PIK3CA-mutant, HR-positive, HER2-negative patients. Activating mutations in the ESR1 gene were recently described in metastatic breast cancer. These mutations confer hormone independent growth and may be associated with resistance to aromatase inhibitors. Drugs that selectively bind and antagonize the Estrogen Receptor alpha (ERα) protein and target it for degradation, such as fulvestrant, are referred to as selective estrogen receptor degraders (SERDs). Preclinical activity of the orally bioavailable SERD, GDC-0810, has not been well characterized in ESR1 mutant PDX models. Therefore, our aim was to evaluate the efficacy and pharmacodynamic responses to agents that target ERα and PI3K as monotherapies and in combination, in ESR1 and PIK3CA mutant HR+ breast cancer patient-derived xenograft (PDX) models. We hypothesized that mutational status of ESR1 and PIK3CA may predict the responsiveness of HR+ PDX models to SERDs and PI3K inhibitors in vivo. Characterization of seven PDX models included authentication of hormone receptor status by immunohistochemistry (IHC) and determination of ESR1 and PIK3CA genotype and allele frequency by exome sequencing. For a subset of models that utilize estrogen for growth, mice were supplemented with 17β-estradiol, and cells or tumor fragments were implanted into the fat pad of intact female NOD-SCID or NOD-SCID-IL2Rgamma null mice and treated with fulvestrant, GDC-0810, or taselisib. Both fulvestrant and GDC-0810 were efficacious in ESR1 wild type (WT) and mutant PDX models but to variable degrees ranging from tumor stasis to growth delay, with GDC-0810 resulting in superior single agent activity at relevant clinical exposure in the WHIM20 and WHIM43 ESR1 mutant models. PIK3CA mutations (E542K, E545K, M1004V, and H1047R) were confirmed in six PDX models and PI3K pathway activation verified by strong pS6RP IHC staining. Taselisib induced tumor growth inhibition and tumor regressions in models harboring PIK3CA mutations, and models with no detectable expression of WT p110α were the most sensitive. In the WHIM43 (ESR1 D538G, PIK3CA M1004V), HCl-011 (ESR1 WT, PIK3CA E545K) and HCl-013 (ESR1 Y537S, PIK3CA H1047R) PDX models, combining fulvestrant and taselisib treatment further enhanced tumor growth inhibition with respect to either treatment alone. Our studies demonstrate the diverse anti-tumor responses of HR+ PDX models to SERDs and the PI3K inhibitor taselisib in the context of clinically relevant ESR1 and PIK3CA mutations. Pharmacological and genomic characterization of additional PDX models may aid in strengthening associations between genotype, drug sensitivity and predictive biomarkers of response.

Title: Consistent dosing-time dependent tolerability of everolimus (EV) in a pilot study in women with metastatic breast cancers (MBC) and in a mouse chronopharmacology investigation

Giacchetti S, Li XM, Ozturk N, Cuvier C, Machowiak J, Arrondeau J, Chang-Marchand Y, Espié M, Okyar A and Lévi F. Breast Disease Unit, Hopital Saint Louis, Assistance Publique-Hopitaux de Paris (AP-HP), Paris, France; 1INSERM U935, Team “Cancers Chronotherapy and Optimization of Hepatic Function”, Villejuif, France; Université Paris-Sud, Orsay, Villejuif, France; 3Istanbul University, Faculty of Pharmacy, Beyazit-Istambul, Turkey; University Paris Diderot, Paris 7, Paris, France and Cancer Research Unit, Warwick Medical School, Coventry, United Kingdom.

Body: Background
The molecular circadian clock regulates mTOR activity, the main target of EV. EV use is hampered by adverse events in MBC patients (pts). Knowing the optimal timing of EV oral intake could improve tolerability, thus compliance and treatment efficacy.

Objective: To assess the relevance of EV timing for side effects in MBC pts, and to determine the impact of EV timing for body weight, circadian rest-activity pattern, and liver circadian clock in mice.

Materials and methods:
From 2013 to 2014, 19 MBC pts were treated with EV 10mg plus hormonotherapy at St Louis hospital Breast Cancer unit. Morning or Evening oral intake was prescribed by the medical oncologist in charge of each patient for both EV and hormonotherapy. Side effects were compared according to EV timing. We further investigated whether oral (po) EV timing mattered mice regarding tolerability. EV (5-20 mg/kg/day x 14 days) was administered through oral gavage at 4 circadian times, 6 hours apart to different groups of synchronized male or female B6D2F1 mice (n=32/sex). Body weight change and lethal toxicity were the endpoints. EV effects were further determined on clock gene Per2 expression in the liver of Per2::luciferase (Per2::luc) mice. Per2::luc expression was monitored in freely-moving mice every minute for 3 days before, 5 days during and 3 days after daily EV at one of two timepoints using Real Time-Biolumicorder (RT-BIO, Geneva, Sw). Periods and amplitudes of Per2::luc rhythms were determined with spectral analysis.

Results:
Nine pts took EV in the morning and 10 in the evening for a median duration of 7.5 months (1.3-19.2 m). Median age was 59 (39-85), median delay between metastatic disease and EV treatment was 52.5 months. Pts had a median of 3 prior lines of treatment for MBC. EV was associated with exemestane (13 pts), or tamoxifen (6 pts). Evening EV was associated with higher occurrence of edema (6 vs 2 pts), fatigue (9 vs 2 pts), and pneumonia (3 vs 0 pts). Equitoxic doses of EV were twice as high in female as compared to male mice. EV timing at the beginning of the light (rest) span resulted in a lethal toxicity rate of 25% in female mice receiving 20 mg/kg/d and 50% in male mice dosed with 10 mg/kg/d). In contrast all the mice treated with EV at the beginning of the dark (activity) span survived, irrespective of dose level. Maximum body weight loss ranged from 5% following EV timing near activity onset to 12% after EV delivery near rest onset, both in males (5 mg/kg/d) and females (10 mg/kg/d) (ANOVA p<0.001). The circadian expression of liver Per2::luc was abolished following EV dosing near rest onset. Per2::luc remained rhythmic in mice receiving EV at the beginning of the activity span.

Conclusion: Tolerability was largely improved by the delivery of EV near the onset of the activity span both in women with MBC and in male or female mice. Morning administration of EV could minimize metabolic alterations and fatigue in humans. This timing should further avoid circadian disruption in the liver molecular clocks thus ensure better treatments tolerability.
Body: Background: Approximately 200,000 women are diagnosed with breast cancer each year and 75% develop estrogen receptor (ER) positive tumors. Obesity is a risk factor for ER-positive breast cancer, particularly after menopause, and affects 40% of US women. Obese women are more likely to be diagnosed with advanced tumors, lymph node involvement, and less likely to respond to endocrine therapy compared to lean women. Mechanisms underlying the poorer prognosis of obese women are unclear, but epidemiological studies highlight roles for weight gain and metabolic dysfunction in breast cancer prognosis. While endocrine therapies provide considerable benefit, many obese women still experience breast cancer recurrence. Activation of growth factor receptors, including FGFR1, may contribute to endocrine therapy resistance. In this study, we describe a mouse model of obesity and breast cancer patient-derived xenograft tumors (PDX). Only the obese environment led to growth factor receptor activation, despite amplification of FGFR1. Our study highlights a role for FGF ligands, produced by adipose tissue during weight gain, in supporting FGFR1-driven tumor progression after estrogen withdrawal.

Methods: ER-positive, FGFR1-amplified breast cancer PDX tumors were established in ovariectomized lean and obese mice in the presence of estradiol (E2). To simulate the hormonal environment of postmenopausal women on aromatase inhibitors, E2 was removed from half of the mice in each adiposity group and the study was terminated 3 weeks later. Weight gain, body fat percentage, and adipose tissue as well as tumor characteristics were analyzed. A phospho-receptor tyrosine kinase array identified activated growth factor receptors in tumor lysates and results were confirmed using immunohistochemistry and the Aperio Digital Pathology system. A PDX-derived cell line was used for in vitro studies to confirm the role of ligand-activated FGFR1 in tumor cell proliferation.

Results: Prior to estrogen withdrawal (EWD), obese mice were heavier and had higher body fat percentage than lean mice. This trend was accelerated after EWD, with obese mice gaining more weight due to body fat accumulation. EWD induced excess fat deposition in visceral depots in both lean and obese mice; however, obese mice also gained fat in mammary adipose tissue. Excess mammary fat deposition in obese mice was associated with elevated production of FGF1. EWD led to tumor regression in lean, but not obese mice, measured by changes in tumor volume and Ki67 labeling. Compared to lean, tumors from obese mice had higher levels of phosphorylated FGFR1, without changes in total FGFR1.

Conclusions: Weight gain and metabolic dysfunction have been implicated in the link between obesity and breast cancer. In our study, we show that EWD promotes weight gain and mammary adipose tissue expansion in obese mice and identify a potential role for adipose-derived FGF1 in tumor progression after hormone withdrawal. Activation of growth factor receptors may underlie increased breast cancer recurrence observed in obese, postmenopausal women and could help identify patients that might benefit from FGFR-directed therapies.
Characterization of an estrogen-dependent murine model of human estrogen receptor-positive breast cancer bone metastasis

Introduction: Breast cancer patients with estrogen receptor-positive (ER+) tumors have the highest rate of developing clinically evident osteolytic bone metastasis. However, much of our knowledge of breast cancer bone metastasis has been derived from ER- murine xenograft models, as robust pre-clinical models of ER+ bone metastasis are currently lacking. Thus we sought to develop and characterize a murine xenograft model of breast cancer bone metastases using an estrogen-dependent ER+ MCF-7 cell line.

Methods: 28-day-old female nude mice were implanted with the following 60-day extended-release 17β-estradiol (E2) pellets: 0.72, 0.36, 0.18, 0.10, or 0.05 mg; with or without 1x10^5 MCF-7 cells (ATCC) inoculated via the left cardiac ventricle. Non-estradiol-supplemented female nude mice were also inoculated with either MCF-7 cells or a well-characterized, bone-tropic human ER- MDA-MB-231 cell line (referred to as MDA-SA), used as a comparison model. Radiographs and dual-energy X-ray absorptiometry’s (DXAs) of hind femurs and tibias were obtained weekly to assess osteolytic lesion formation and BMD, respectively. Statistical significance was analyzed using one-way ANOVA with Tukey’s post-hoc testing.

Results: Using E2 doses previously reported in the literature to promote MCF-7 orthotopic tumors and bone metastases (0.72 mg 60-day 17β- E2 pellets), bone metastases developed with 100% incidence (n = 13) by day 28 in the MCF-7 model, with osteolytic lesion area increasing to 10.3±0.8 mm^2 by day 42 (as compared with 100% incidence on day 21 in non-estrogen-supplemented mice inoculated with MDA-SA (n=8) with osteolytic lesion area of 10.7±2.0 mm^2). However, histologic assessment of hind limbs of MCF-7 tumor bearing mice suggested that this estrogen dose stimulated a significant increase in bone mass. Therefore, the estrogen-dependency of bone metastasis formation and changes in BMD were explored. Bone metastasis incidence was estrogen-dependent; falling to less than 100% in mice with E2 doses less than 0.72 mg (50-75%, n = 4-12). BMD of distal femurs of mice supplemented with estradiol was significantly greater than naïve controls on day 28 (average increase of 65.3%, p<0.05), and was not dose dependent over the range of doses tested (0.05-0.72 mg pellets).

Conclusion: Despite a marked increase in bone density, ER+ MCF-7 cells formed radiographically detectable osteolytic lesions with 100% incidence by day 28 in 0.72 mg 60-day 17β- E2 supplemented nude mice. It is possible that estrogen-stimulated increases in BMD contributed to the longer time required to achieve ER+ osteolytic lesion sizes comparable to those in standard ER- models. However, lower doses did not mitigate effects of estrogen on BMD in these 1-month-old mice, while lowering the incidence of bone metastasis formation. While further optimization is planned, intracardiac inoculation of MCF-7 cells in female nude mice provides a robust model of estrogen-dependent ER+ breast cancer bone metastases.

Title: Synergistic effect of EGFR1 inhibitor and paclitaxel in newly patient derived metaplastic carcinoma cell line which harbored EGFR gene amplification

Chung P-H, Chen TW-W, Chang D-Y, Lin C-H, Huang S-M and Lu Y-S. National Taiwan University Hospital, Taipei, Taiwan.

Body:

**Background**
Metaplastic breast cancer (MBC) is a rare but aggressive subtype of invasive breast cancer, which is generally resistance to conventional chemotherapy. The majority of MBCs do not express the estrogen receptor, progesterone receptor and negative for HER-2/neu over expression. Thus, targeted treatment options to treat MBCs are also limited. Cancer cell lines are important tools used for us to test the therapeutic efficacy of anticancer agents. However, few in vitro systems for studying MBC are developed. Here we report a newly established novel MBC cell line using the recently developed conditionally reprogrammed cell method and search for effective therapeutic regiments to treat MBCs.

**Methodology**
The tumor tissue used for cell line establishment was obtained from a 40 year-old Taiwanese female, who was diagnosed with T2N2aM1 metaplastic carcinoma of breast cancer (with squamous metaplasia). The MBC tumor tissue was first digested by collagenase/ dispase mixture. After digestion, the MBC tumor cells were cultured in F medium with irradiated 3T3-J2 fibroblasts supplemented by 5 uM ROCK inhibitor (Liu et al., Am. J. Pathol. 2012). Subsequently, the MBC tumor tissue cells were passaged and propagated in these conditions until the majority of culture is tumor cells. The MBC tumor cell line was further passaged in DMEM/F12 medium without feeder cells and ROCK inhibitor. Finally, the MBC cell line (MBC-1) was characterized using DNA sequencing, immunofluorescence, Western blotting and viability assays.

**Results**
The genomic DNA of MBC1 was examined using DNA sequencing, and the MBC-1 maintained known patient's tumor mutation at the TP53 locus (p.V73fs*76). The MBC cell line also harbored EGFR gene amplification as the patient's tumor, according to quantitative PCR assays. To evaluate tumorigenicity, the MBC cell line was injected subcutaneously into immunocompromised mice, and the MBC tumors formed four weeks after injection. The MBC-1 stained positively using pan-cytokeratin antibody and negative of vimentin, confirming the epithelial origin of the cell line. To explore the possible effective treatment options, the cell line was incubated with different targeted therapy and chemotherapy agents, and the MBC cell line was relatively resistant to most of targeted therapy and chemotherapeutic agents. However, EGFR inhibitors (gefitinib and afatinib) could partially inhibit growth of the MBC cell line. We hypothesis that the inhibitory effect could act through inhibiting the amplified EGFR receptors. To further enhance the effect of EGFR inhibitors in the MBC-1, we combine the EGFR inhibitors with chemotherapy agents, and discovered that EGFR inhibitor and paclitaxel were synergistic across the range of concentration tested. The study on downstream mechanism of the synergism is ongoing.

**Conclusions**
We have successfully established a novel metaplastic carcinoma cell line with EGFR amplification from a patient using the conditionally reprogrammed cell method. Based on the preclinical study in the cell line, we found that combining EGFR inhibitor and paclitaxel could be a promising strategy to treat MBC with EGFR amplification.
Title: Rates of successful engraftment in breast cancer xenograft models based on tissue type: Primary vs relapsed disease

Body: 

Purpose: As we have published expertise in breast cancer xenograft models and clonal dynamics, our aim was to explore rates of engraftment based on type of tissue for attempted xenografting (primary vs relapsed/metastatic disease) and clinical breast biomarker subtype.

Methods: Tissue from patients (pts) enrolled in a locally advanced/metastatic study and a breast tumour tissue repository (ie. resectable primaries) between Sept. 2008 and July 2015 underwent xenografting using NodScid/IL2rgKO (NSG) mice. Xenografts were passaged when tumour volume reached 1 cm$^3$. Mice with no engraftment after 12 months (mos) were sacrificed. Pt charts were reviewed to determine biomarker status (hormone receptor [HR], HER2), date and type of tissue collection for xenografting. Prediction of successful engraftment based on tissue type and biomarker status was performed using nominal logistic regression.

Results: A total of 70 tissue samples with known engraftment status were included in the analysis: 51 from primary breast tumour, 10 from relapsed disease (dz) with ≤ 1 line of therapy in the advanced setting and 9 from relapsed dz with > 1 line of therapy in the advanced setting. Tumours from pts treated with > 1 line of therapy were more likely to engraft compared to primary or recurrent dz with ≤ 1 line of therapy (89%, 35%, and 40% respectively; p=.008). HR- primary tumours were more likely to engraft compared to HR+ primary tumours: 71% of HR-/HER2- (triple negative) and 67% of HR-/HER2+ tumours versus 4% of HR+/HER2- and 38% of HR+/HER2+ tumours; p<.0001. Combining all tissue types, HR- tumours were more likely to engraft compared to HR+ tumours: 76% of HR-/HER2- and 67% of HR-/HER2+ tumours versus 37% of HR+/HER2+ and 22% of HR+/HER2- tumours; p=.0007. Table 1 shows the rate of engraftment for each tissue type and biomarker status. Combining these 2 variables predicts engraftment in 80% of cases.

Conclusion: This preliminary study highlights potential differences in successful xenoengraftment based on biomarker status at diagnosis and type of tissue, primary vs relapsed tumour, the latter suggesting that the underlying biology of primary or first relapsed recurrent disease is distinct from more refractory disease, and warrants further exploration. This work is ongoing. (Funded by CBCRA, BCCF)

Title: Differential regulation of microRNAs and integrins influences metastatic potential: Comparison between locally invasive BT-474 and metastatic MDA-MB-231 xenografts

Lawrence PV Varun, Desai K, Prabhu JS S, Korlimarla A, Nair MG G and Sridhar TS. St. John's Research Institute, Bangalore, Karnataka, India.

Body: Background: Generation of BT-474 and MDA-MB-231 xenografts in immunocompromised mice provides one means of dissecting the molecular events involved in local invasion versus distant metastasis. Recently, Glunde et al. have shown an interdependence of genes involved in cell-cell and cell-matrix adhesion (E-cadherin and integrin β1) and extra-cellular matrix degradation (MMP-2 and 9) in allowing cells to metastasize. Further, Fite et al. have identified a set of microRNAs (miRs) up-regulated by E-cadherin (a pre-EMT marker) and down-regulated by Vimentin (post-EMT marker) in acquiring an invasive phenotype. We have performed a detailed analysis of integrins, matrix metallo-proteases and key miRs to better understand the molecular events underlying these disparate behaviours.

Methods: We injected BT-474 (N=5) and MDA-MB-231 (N=5) cells orthotopically into SCID mice. Xenografts were assessed for local growth rate and monitored for distant metastasis. The implanted tumors as well as the distant metastatic foci were harvested. Markers involved in local invasion, distant metastasis and tumor-stroma interactions including miRs were compared between BT-474 and MDA-MB-231 cell lines and their xenografts by q-RT-PCR, immunofluorescence and immunohistochemistry.

Results: As expected BT-474 xenografts showed a higher rate of tumor growth when compared to MDA-MB-231. Histological examination of BT-474 tumors confirmed only locally invasive tumor growth with infiltrated blood capillaries and vessels; no macro and microscopic metastases were observed in the organs collected. On the contrary, MDA-MB-231 xenografts showed highly undifferentiated tumor growth and frank lung metastasis and extra-pulmonary tumor growth in one of the five mice injected despite slow rate of local growth. Expression of matrix metalloproteases – MMP-2 & 9 was more than 30 fold upregulated in MDA-MB-231 xenografts as compared to BT-474. Elevated level of E-cadherin was observed in BT-474 but was absent in MDA-MB-231.

The most interesting differences were seen in the levels of miRs and cell-surface integrins. High levels of miR-18a, miR-93 and miR-182 were observed in BT-474 implants when compared to MDA-MB-231 which had a much lower level of these miRs. On the contrary, higher levels of integrin β3, and β1 were observed in MDA-MB-231 tumors when compared to BT-474. Integrin β6 was absent in both. The reciprocal relationship between these markers is being examined and compared between locally invasive tumors and metastatic triple negative breast cancers from our case series of human specimens (N=250).

Conclusion: miRs and integrins known to be involved in invasion are differentially regulated in tumors that are locally invasive compared to ones with distant metastasis. The level of the key targets of these miRs as well as additional integrins is being examined. Understanding the epigenetic regulations leading to metastasis via tumor-stroma interaction might help in discerning differential tumor behaviour.
Murine radical mastectomy model for preclinical study of adjuvant systemic therapies

Katsuta E and Takabe K. Breast Surgery, Roswell Park Cancer Institute, Buffalo, NY.

Background:
Current standard of care of breast cancer is removal of primary tumor followed by systemic adjuvant therapy to reduce recurrence and to prolong survival. However, vast majority of the preclinical studies that use murine models evaluate the drug response of primary tumors either in mammary pads or subcutaneous tissues. Lately it has been shown that the genetic profiles of metastatic lung tumors are significantly different from that of their primary mammary tumors, let alone subcutaneous tumors. Therefore we hypothesized that the responses of metastatic tumors rather than primary mammary tumors need to be evaluated for a systemic therapy. However there are few reports of murine mastectomy models used for preclinical study.

Methods:
Murine mammary adenocarcinoma 4T1-luc2 cells were inoculated into #2 right mammary fat pad under direct vision as previously described (Katsuta et al, JSR 2016). The tumor burden was quantified by bioluminescence IVIS imaging system. Novel platinum drug, Triplatin, or Vehicle was administrated every 4 days for 3 times from the day after inoculation. Amount of lung metastases were quantified ex vivo by IVIS imaging. Then we compared the growth of metastatic tumors between two methods of radical mastectomy; midline incision method and Halsted incision method, which were performed 8 days after inoculation. Triplatin or Vehicle was administered 2 days after mastectomies.

Results:
First we compared the two methods of chest mammary tumor removal; midline incision method and Halsted incision method. There was no significant difference in weight of resected tumors between these two techniques (p=0.751), however, the bioluminescence in midline incision model was significantly higher than Halsted incision model at the first day after operations (p=0.003). Only 1 out of 7 cases (14%) after Halsted incision method developed local recurrence, whereas all (100%) the animals that underwent midline incision method developed recurrence within 30 days after operation (p<0.001). No mice developed respiratory failure due to wound closure of wide skin defect. We then examined the effect of Triplatin on chest mammary tumor and lung metastasis. There was no significant difference in bioluminescence from chest mammary tumors between treatment group and non-treatment, however, ex vivo bioluminescence of lung metastases demonstrated that treatment group mice had significantly less tumor burden in lung than non-treatment group. Utilizing Halsted incision method with less local recurrence, we found that lung metastases were significantly less in treatment group than non-treatment group in live animals monitored by bioluminescence.

Conclusion:
We have established an improved murine chest mammary tumor resection model. Effects on metastases, as opposed to primary tumor should be evaluated for the preclinical study of adjuvant systemic therapy, since they may not be the same.
Title: Profiling miRNA in high risk post-operative early breast cancer patients to detect possible association to correlation with immune system antitumor response

Tzschaschel MLJ L J, Rack B, Majunke L, Trapp EK K, Mahner S, Fasching PA A, Fehm T, Schneeweiss A, Friedl TWP WP, Polasik A, Janni W and Alunni-Fabbroni M. Ludwig Maximilians Universitaet Muenchen Klinik und Poliklinik fuer Frauenheilkunde und Gerburtshilfe, Munich, Germany; University Hospital Erlangen, Friedrich-Alexander, Erlangen, Germany; Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany; National Center for Tumor Diseases, University Hospital Heidelberg, Heidelberg, Germany and University Hospital Ulm, Ulm, Germany.

Body: Aims: Identifying which patient will be the one who develops metastasis or relapses is still an unsolved problem in breast cancer research. Circulating free nuclei acids such as microRNA (miRNA) are very promising cancer biomarkers to detect those patients. Aim of this study was to unravel an association among whole blood miRNA profiling, circulating tumor cells (CTCs) and clinical outcome in early breast cancer (EBC) patients and to test the utility of miRNAs as prognostic and diagnostic markers in post-operative patients.

Methods: 48 high risk EBC patients, a subsample of the German SUCCESS A trial, were included in this retrospective study together with 18 aged-matched healthy donors (HDs) as controls. Peripheral blood was drawn post-operatively before (T0), after (T1) and two years after (T2) chemotherapy directly in Tempus Blood RNA Tubes (ThermoFischer Scientific) to stabilize and isolate total RNA. miRNAs were quantified by qPCR and their relative expression was calculated according to the 2^(-DCt) method. CTCs were detected by immunocytochemistry. Data were analyzed using non-parametric statistical tests and p-values below 0.05 were considered significant.

Results: 8 different miRNAs, either with oncogenic (miR-10a, -19a, -21, -22) or tumor suppressive (miR-20a, -127, -155, -200b) properties, in most of the cases linked to immune system regulation (miR-19a, -20a, -21, -127 and -155) were tested. miR-19a, miR-21, miR-22 and miR-127 showed the most promising results as prognostic markers in our tests. They could differentiate patients from HDs (Patients vs. HD: miR-19a at T0, p=0.004), T1 (p<0.0001), miR-21 at T0 (p=0.001), T1 (p=0.004), miR-22 at T1 (p=0.012), T2 (p=0.034)). Additionally they correlated with the post-operative detection of CTCs (miR-127) and the late development of metastasis (miR-19a). Kaplan-Meier analysis indicated a borderline association between a longer progression free survival and higher miR-19a levels (HR= 2.808, 95% confidence interval [CI] =0.904, p=0.074.)

Conclusion: We found a panel of miRNAs that could discriminate post-operative patients from HDs and could predict patients' outcome. We suggest that whole blood miRNA profiling could unravel a correlation with the activation of the immune system, leading to an efficient antitumor response and a better clinical outcome. These findings could open new perspectives in immune oncology and personalized therapy already in the early phase of the disease.
Title: Expression of miR-18a and miR-210 in normal breast tissue as candidate markers of breast cancer risk

Wang J, Shidfar A, Costa FF F, Scholtens D, Bischof JM M, Sullivan ME E, Ivancic D, Soares MB B and Khan SA A.  Feinberg School of Medicine, Northwestern University, Chicago, IL.

Body: Purpose: miRNAs are non-coding RNAs that are abnormally expressed in breast cancer, with critical roles in cancer due to their regulation of large gene networks. miRNA expression in benign high-risk breast tissue has never been evaluated, but it may provide information about early dysregulation events that contribute to breast cancer risk. The contralateral unaffected breast (CUB) of women with unilateral breast cancer is in high-risk for the second primary cancer. Thus, we examined miRNA expression profiles in tumor and the matching CUBs to seek potential miRNA biomarkers for breast cancer risk.

Methods: FFPE tissues of breast cancer and their matching CUB tissues were sectioned. The areas of tumor and normal ductal epithelium were outlined and then dissected using laser microdissection system. Total RNA was extracted for miRNA profiling studies. Expression profiles of 754 mature miRNAs were examined using TaqMan Low Density Arrays assays in 30 paired breast cancer and CUB samples (15 with ER+ tumors, 15 with ER- tumors) and 15 reduction mammoplasty (RM) controls, matched by age, race and menopausal status. ANOVA test was performed to examine the differential expression among groups and pairwise comparison with Sidak adjustment was used for multiple comparison. Seven candidate miRNAs were then examined in an independent CUB sample set (20 with ER+ tumors, 20 with ER- tumors) and 20 RM controls. Further independent validation was performed using qRT-PCR in 80 benign breast biopsy (BBB) samples: 40 from women who subsequently developed breast cancer (cases) and 40 from those who did not (controls). Logistic regression analysis and receiver operating characteristic (ROC) analysis were performed using combinations of the expression of multiple miRNAs to establish models discriminating cases from controls.

Results: Seven miRNAs (miR-18a, miR-210, miR-214*, miR-124, miR-193a-3p, miR485-3p and miR-671-3p) were found to be differentially expressed in breast cancer and CUB samples vs. RM samples in the discovery sample set. Among them, miR-18a and miR-210 were validated in a second, independent CUB sample set. The expression of miR-18a and miR-210 were significantly higher in tumor (regardless ER status) compared to CUBs and RM controls. The expression levels in CUBs were significantly higher than in RM. We then examined miR expression in case BBB samples, and confirmed that expression of miR-18a and miR-210 were increased compared with controls. ROC analysis using miR-18a and miR-210 discriminated high-risk cases from standard-risk controls with OR 2.44, P = 0.022.

Conclusion: The expression of miR-18a and miR-210 were elevated in breast cancer, in matched CUBs, and in BBB predating cancer diagnosis. These data provide strong support for the hypothesis that miR-18a and miR-210 expression in BBB is an indicator of increased risk of breast cancer. Given the high expression in tumors, they are also potential cancer detection biomarkers.

Title: Dynamic regulation of a microRNA-mRNA network during breast cancer metastasis reveals an essential tumor-promoting role for miR-203

Bishopric NH H, Speransky S, Kajan D, Laderian B, Iorns E, Clarke J and Lippman ME E. University of Miami Miller School of Medicine, Miami, FL.

Body: BACKGROUND: Metastasis represents a critical turning point from curable to incurable breast cancer. Alterations in gene expression underlie aspects of this transition and are coordinated both genetically and epigenetically.

HYPOTHESIS: Epigenetically controlled microRNA-mRNA regulatory networks underlie the ability of breast cancer cells to metastasize and acquire treatment resistance.

METHODS: Human MDA-MB-231 and MDA-MB-436 breast cancer xenograft primary tumors and corresponding lymph node, liver, lung and diaphragm metastases were generated by inoculation of cell lines into the mammary fat pad of NSG mice. Human-specific gene expression profiling was performed using microarrays with qPCR validation. MicroRNA targets were validated by 3’UTR mutagenesis-luciferase assays. Lentiviral shRNA and miRNA mimic constructs were stably transduced into the same cell lines and growth properties were assessed in vitro and in vivo. Mice were euthanized when tumors achieved 10% of body weight or at day 100, whichever came first.

RESULTS: A common set of 18 mRNAs was differentially regulated at all 4 metastatic sites relative to primary tumors. Of these, 17 were downregulated, and 13 of these were strikingly enriched for microRNA binding sites. In the same tissues, we identified 21 microRNAs that underwent downregulation during primary tumor growth relative to parental cell cultures, but were highly upregulated at all 4 metastatic sites. 18 of these had at least one target among the downregulated genes, and 6 had multiple targets in the same 13 mRNA 3’ UTRs. One, miR-203, previously described as a tumor suppressor, directly targeted two of the repressed genes, TWF1 and APBB2. MiR-203 levels positively correlated with primary tumor size in METABRIC ($p=0.0096$). MiR-203 overexpression blunted in vitro tumorigenic properties, modestly reduced primary tumor growth rates, and prevented metastasis formation. Remarkably, knockdown of miR-203 also reversed multiple tumorigenic properties of both cell lines, including proliferation, migration, and growth in soft agar, and conferred a fibroblastic morphology on MDA-MB-231 cells. In addition, primary miR-203KD xenograft tumors grew extremely slowly and underwent partial involution between days 80-100. Residual miR-203KD tumors and metastases at day 100 demonstrated re-gain of miR-203 expression through loss of the shRNA silencing vector.

CONCLUSIONS: A small group of microRNAs displays biphasic expression during cancer growth. At least one of these, microRNA-203, is required for metastatic growth, but also inhibits metastasis formation when expressed at high levels. Our findings suggest opposing roles for the same microRNA at different stages of breast cancer progression, and support the existence of dynamic, context-sensitive epigenetic mechanisms that adapt breast cancer cells to thrive at remote sites. These mechanisms may serve as targets for intervention during the evolution of metastatic disease.
Detecting early breast cancer by the combination of five serum microRNAs and its possibility of prediction of pathological complete response in neoadjuvant chemotherapy

Shimomura A, Shiino S, Kawauchi J, Takizawa S, Sakamoto H, Shimizu C, Takeshita F, Niida S, Kinoshita T, Tamura K and Ochiya T. National Cancer Center Hospital, Tokyo, Japan; Toray Industries, Inc., Kamakura, Japan; National Cancer Center Research Institute, Tokyo, Japan and National Center for Geriatrics and Gerontology, Nagoya, Japan.

Background: It is recently reported that microRNAs (miRNAs) are stably present in serum and potentially useful in the diagnosis and evaluation of treatment of cancer.

Materials and Methods: Serum samples of breast cancer before treatment (n=1280) between 2008 and 2014 were obtained from National Cancer Center Hospital and controls (n=3348) were obtained from collaborative institutes. Additionally, the serum sample of patients who received neoadjuvant chemotherapy (NAC) and surgery between last chemotherapy administration and surgery were collected. A comprehensive quantitative expression analysis of miRNA was performed using the by DNA chip “3D-Gene® (Toray Industries Inc.)” Clinicopathological data was retrieved from medical records. Pathological complete response (pCR) was defined as the absence of residual invasive and in situ cancer of the resected breast specimen and all sampled regional lymph nodes.

Results: Serum samples before treatment of breast cancer patients (n=74), non-cancer controls and patients with other cancers were used (n=2007) in a training set. The rest except for samples after NAC were used in a test set. The formula with the combination of five miRNAs (miR-1246, miR-1307-3p, miR-4634, miR-6861-5p, and miR-6875-5p) was found to be able to detect breast cancer (BCmiR set). BCmiR set had a sensitivity of 97.3%, specificity of 82.9% and accuracy of 89.7% in the test cohort. BCmiR set could detect breast cancer in the non-invasive stage (sensitivity of 98.0% for Tis).

In the breast cancer patients, 91 patients received NAC and surgery. Median age of NAC patients was 49 years (range 28-77). Forty-two patients were hormone receptor-positive (HR+) and HER2-negative (HER2-), 24 were HR+ and HER2-positive (HER2+), 11 were hormone receptor-negative (HR-) and HER2+ and 14 were HR- and HER2-. pCR was observed in 19 (20.9%) of NAC patients. pCR in each subtypes were 3 (7.7%) in HR+ and HER2-, 6 (33.3%) in HR+ and HER2+, 4 (57.1%) in HR- and HER2+ and 3 (27.3%) in HR- and HER2-. Serum after NAC were obtained from 19 pCR patients and 71 non-pCR patients. When we applied BCmiR set to the serum samples after NAC, the average diagnostic index (cut-off value=0) in pCR patients was significantly lower than that in non-pCR patients (pCR, -0.30±0.84; non-pCR, 0.31±1.15; p=0.03). In fact, 57.9% of pCR patients were classified into non-breast cancer. However, 40.8% of non-pCR patients were misclassified into non-breast cancer.

Conclusion: The combination of five miRNAs (BCmiR set) measured from serum can be used to detect breast cancer. BCmiR set has potential to predict pCR in patients who received NAC. The further analysis to predict pCR is underway and further results will be presented in the symposium.
Title: MicroRNA-27b mediates deregulation of energy metabolism in breast cancer

Eastlack SC C, Alahari SK K, Dong S and Cole JT T. Louisiana State University Health Sciences Center, New Orleans, LA and Ochsner Medical Center, Jefferson, LA.

Body: MicroRNAs (miRNAs) are a class of small, non-coding RNA which participate in gene regulation by targeted silencing of specific mRNA transcripts. Recently, it has become clear that dysfunctional miRNA expression is an important contributor to the deregulation of key signaling pathways underlying carcinogenesis. MicroRNA-27b is an example of one such pro-oncogenic miRNA, and correspondingly, its expression has been found to be upregulated in breast cancer cells and tissues. In this regard, several targets of miR-27b have previously been verified, and implicate miR-27b in multiple neoplastic processes including migration, invasion and metastasis. In order to enable future development of miRNA-based cancer therapies, the putative targets of each miRNA must be mapped more comprehensively. Such awareness is necessary in order to make informed choices regarding whether a miRNA-based therapy is likely to be effective and what side-effects should be anticipated. Therefore, this project seeks to further establish the role of miR-27b in the context of breast cancer, specifically by identifying novel target transcripts under its control. Using target prediction algorithms and breast cancer cell culture models, initial evidence has implicated Pyruvate Dehydrogenase Protein X (PDHX) to be a probable target. As a structural component of the Pyruvate Dehydrogenase Complex, the role of PDHX in linking the end products of glycolytic reactions with subsequent oxidative phosphorylation pathways is indispensable. However, a hallmark of cancer cell metabolism is the propensity to consume glucose aerobically, which liberates additional carbon skeletons for use in biosynthetic reactions that are crucial for tumor growth. In this way, miR-27b overexpression appears to sever the link between glycolysis and subsequent catabolic pathways, thus conferring a pro-growth advantage to the cancer cells. Expression profiling of PDHX using both breast cancer cell lines and human breast tissues (which overexpress miR-27b) reveal that PDHX levels are indeed significantly reduced, thus supporting the notion that miR-27b alters cancer cell metabolism specifically by targeting this gene in breast cancer. Improving the current understanding of miR-27b's functions will lay the necessary ground work to evaluate its potential as a novel target for cancer therapy. Similarly, the awareness of the expression status of miR-27b and its targets in breast cancer tumors will further efforts to find suitable miRNA tissue biomarkers to enhance screening and prognosis. In this way, microRNA-based approaches offer the distinct potential to improve cancer detection as well as treatment, making them a dynamic method to improve management of breast cancer patients in the future.
Title: MicroRNAs associated with acquired taxane resistance in a breast cancer cell line model

Taylor KJ J, Chong T, D'Costa A, Yao C, Gourley C, Cameron DA A, Bartlett JMS MS and Spears M. Edinburgh Cancer Research Centre, University of Edinburgh, Edinburgh, United Kingdom; Ontario Institute of Cancer Research, Toronto, ON, Canada and University of Toronto, Toronto, ON, Canada.

Body: Background: Acquired chemoresistance remains the major cause of therapeutic failure in the treatment of breast cancer. Improved knowledge of the transition from drug sensitive to resistant breast cancer will pave the way for novel preventative and therapeutic strategies. MicroRNAs (miRNA) are endogenous, small non-coding RNAs that regulate gene expression by targeting the 3'UTR region of messenger RNAs. There is a growing body of evidence to suggest miRNAs may be involved in the development of chemoresistance and may play a role in the regulation of drug resistance pathways.

Methods: An in vitro model of paclitaxel resistance was developed through the generation of resistant MDA-MB-231 cell lines by serial culture in escalating doses of taxane until resistance was achieved. The chemoresistant model was used to compare differential miRNA expression with the sensitive, parental line using the Nanostring® platform, analysing 800 human miRNAs. Confirmation of differential expression was performed by QRT-PCR.

Results: This analysis resulted in 30 significantly altered miRNA (1.5 fold, p value < 0.05) at 25nM paclitaxel and 48 significantly altered miRNA at 50nM paclitaxel. The top up-regulated miRNA cluster in MDA-MB-231 25PACR is hsa-miR-548l (fold change: 2.89, p value: 0.016) and top down-regulated was hsa-miR-449a (fold change: -4.1, p value: 0.001). In MDA-MB-231 50PACR the top up-regulated miRNA cluster is hsa-miR-193a-5p (fold change: 3.746, p value: 0.008) and the top down-regulated miRNA cluster is hsa-miR-135a (fold change: -4.085, p value: 0.001). To explore the molecular mechanisms of the differentially expressed miRNAs in paclitaxel resistance, targets were predicted by in silico analysis. Pathways and networks designated by miRNA targets included the cell cycle, PI3K/Akt pathways and focal adhesion.

Conclusion: In this study we identified candidate resistance-associated miRNAs which were differentially expressed between in vitro derived paclitaxel resistant MDA-MB-231 and the sensitive parental line. Further validation to ascertain their role in the transition to a chemoresistant phenotype is currently ongoing.
Title: Reduced expression of miR-200c-3p contributes to cell migration and invasion in paclitaxel-resistant breast cancer cell

Wang X, Chen J, Chen Z, Huang J and Ye W. Zhejiang Cancer Hospital, Hangzhou, Zhejiang, China.

Body: Background: miRNAs are a class of small noncoding RNA molecules that regulate gene expression by degradation of target mRNAs or inhibition of translation. Metastasis is one of the major problems that give obstacles to improve the clinical outcome of breast cancer. However, the underlying molecular mechanism of breast cancer metastasis remains largely unclear. Emerging studies have demonstrated that miRNAs play an important part in tumor invasion and metastasis. In the present study, we aimed to investigate the role and mechanism of miR-200c-3p in regulating the migration and invasion of paclitaxel-resistant breast cancer cells, and identify potential targets for breast cancer treatments.

Material and methods: Paclitaxel-resistant breast cancer cell line MCF-7/Tax was established by stepwise selection in increasing concentration of paclitaxel. The 50% inhibitory concentration and cell viability were measured by the MTT assay. The expression level of miR-200c-3p in MCF-7/Tax and the parental MCF-7 cells was assessed by quantitative real-time RT-PCR. Gain-of-function and loss-of-function study on cell migration and invasion abilities were carried out by transfection of miR-200c-3p mimics or inhibitors respectively. The molecular target of miR-200c-3p was verified by dual-luciferase reporter assay.

Results: Paclitaxel-resistant breast cancer cell line MCF-7/Tax was established. Compared with parental MCF-7 cells, expression of miR-200c-3p determined by real-time RT-PCR was significantly down-regulated in paclitaxel-resistant MCF-7/Tax cells. The ability of migration and invasion of paclitaxel-resistant MCF-7/Tax cells was obviously increased as compared to parental MCF-7 cells. In addition, we found that up-regulation of miR-200c-3p expression inhibited the migration and invasion of MCF-7/Tax cells, while down-regulation of miR-200c-3p expression increased the migration and invasion of MCF-7/Tax cells. Dual-luciferase reporter assay demonstrated that SOX2 was one of the direct targets of miR-200c-3p in breast cancer.

Conclusions: Our results indicate that reduced expression of miR-200c-3p plays a crucial role in cell migration and invasion of paclitaxel-resistant breast cancer cell, and miR-200c-3p may suppress the cell migration and invasion possibly partially through SOX2. Our findings suggest that miR-200c-3p may serve as a promising therapeutic target for breast cancer metastasis.

Background
MicroRNAs (miRNAs) are important regulators of cellular function and have been associated with both aging and cancer, while the impact of chemotherapy on miRNAs has barely been studied.

Patients and Methods
To examine whether chemotherapy accelerates the aging process, we have monitored age-related circulating miRNAs in 89 older breast cancer patients (≥70y), receiving adjuvant chemotherapy (N= 46; chemo group, ChG) or no chemotherapy (N= 43; control group, CoG). Patients and associated blood samples belonged to the cohort of our recently published study (Brouwers et al., Oncotarget. 2016.) All patients underwent geriatric assessment at inclusion (T0), after 3 months (T1) and 1 year (T2). At each timepoint we analysed the serum expression of nine age-related miRNAs (miR-20a, miR-30b, miR-34a, miR-106b, miR-191, miR-301a, miR320b, miR374a, miR-378a).

Our primary aim was to assess miRNA changes during the study period, including differences between groups. Secondary endpoints included association of microRNAs with: chronological age, clinical geriatric assessment parameters and aging biomarkers assessed in the above-mentioned study. We then investigated the predictive role of miRNAs at T0 on: decline in functionality and quality of life, toxicity and unexpected hospitalization during or after chemotherapy. We also performed clustering of patients according to specific miRNA signatures.

Results
Except for miR-106b, which appeared to behave slightly different in ChG compared to CoG, all other miRNAs underwent moderate fluctuations during the study course with no significant differences between both groups. Also within the older cohort, several age-related miRNAs significantly (p<0.05) correlated with clinical aging/frailty (miR-106b, miR-191, miR-301a, miR-320b, miR-374a), as well as with other biomarkers of aging. In particular, miR-106b, miR-374a and miR-378a were associated with IL-6 (slope= -0.34, -0.30 and 0.30 respectively, p<0.05), whereas miR-301a and miR-378a showed a relevant correlation with MCP-1 (slope= -0.18 and 0.27 respectively, p< 0.05).

Moreover, based on their ‘aging miRNA’ profiles, patients clustered into two distinct groups, cluster A (CA) and cluster B (CB), exhibiting significantly different results for several biological/clinical aging parameters. CA (N=43, miR-20a, miR-30b, miR-191, miR-301a and miR-374a underexpressed, miR-378a overexpressed) was characterized by older age, higher geriatric risk profile, as well as elevated IL-6, TNFα and MCP-1 levels compared to CB (N=45, inverse expression pattern). Moreover, 31.9% of CA patients but only 7.4% of CB patients experienced decline in quality of life after chemotherapy (p=0.051).

Conclusions
These results further corroborate our recent findings, stating that adjuvant chemotherapy does not significantly boost aging progression in elderly breast cancer patients. Our data also endorsed specific age-related miRNAs as promising aging/frailty biomarkers in oncogeriatric populations.
Title: Differential expression of microRNAs (miRNAs) in HER2 negative breast cancer (BC)

Pascual T, Gámez-Pozo A, Camara-Jurado M, Manso LM M, Pérez-Campos A, Trilla L, Fresno-Vara JA A and Ciruelos EM M. Hospital La Princesa, Madrid, Spain; Instituto de Genética Médica y Molecular (INGEMM), Hospital Universitario La Paz-IdiPAZ, Madrid, Spain; Hospital Severo Ochoa, Leganes, Madrid, Spain and Hospital 12 de Octubre, Madrid, Spain.

Body: Background:
MiRNAs are non-coding single-stranded RNAs that control gene expression by directing their target mRNAs for degradation and/or posttranscriptional repression. Compared to mRNA signatures, miRNAs have better and stronger biomarker properties with 20 times more power in biomarker studies as compared to mRNAs (when comparing 20,000 mRNAs to ~1,000 miRNAs). Global downregulation of miRNAs has emerged as a common theme in human breast tumors and has been shown to contribute to oncogenesis. Hormone receptor (HR) status is one of the most important factors influencing BC outcome. Several data indicate the extensive alterations in miRNAs regulation upon estrogen pathway and suggest the utility of considering miRNAs expression in the understanding the development of cancer disease, invasiveness, metastasis and treatment failure.

Our aim was to identify differential expression miRNAs in HER2 negative BC. We previously reported a set of miRNAs deregulated in HR+/HER2- BC vs. Triple negative BC (TNBC). In this work we have validate these differences in a new cohort of BC patients.

Methods:
Total RNA was extracted samples extracted from primary breast cancer FFPE tissue. MicroRNAs expression was analyzed by RT-qPCR using TaqMan Arrays from Applied Biosystems. Normalization was performed using de DTc method with two housekeeping miRNAs identified previously identified using NorMean. MicroRNA expression values in each group were compared by the Mann Whitney test.

Results:
121 patients with early HER2 negative BC were included in the present study. All patients showed absence of nodal involvement at the time of diagnosis. The median age at diagnosis was 56 years, 89 cases (74%) had positive estrogen receptor and 53 cases (44%) grade 3. miR-20a, miR-19a, miR-106a, miR-18a and miR-135b expression were significantly higher in TNBC samples, whereas miR-190b, miR-375, miR-449a, miR-342, miR-149, miR-193b, miR-214, miR-30a* and miR-30e* were significantly more expressed in ER+/HER2- samples. No significant differences were found in miR-139-5p expression between both groups.

Conclusions:
We have validated fourteen miRNAs that are differentially expressed between ER+/HER2- and TNBC breast cancer subtypes. Altered expression of miRNAs could be a potential therapeutic tool and promising biomarker in personalized treatment.
Title: Epithelial mesenchymal transition associated with high miR-221 and integrin β6 leads to poor prognosis in hormone receptor positive HER2 negative breast cancers

Prabhu JS S, Kaul R, Korlimarla A, Desai K, Gangadharan C, Rajarajan S, Nair MG G, Alexander A, Kaluve R, Manjunath S, Correa M, Prasad MSN, Patil S, Srinath BS and Sridhar TS. St Johns Research Institute, Bangalore, Karnataka, India; St Johns Medical College Hospital, Bangalore, Karnataka, India; St Johns Medical College, Bangalore, Karnataka, India and Shankara Cancer Hospital and Research Center, Bangalore, India.

Body: Background: MicroRNA mediated molecular alterations are involved in the initiation and progression of cancer. Altered expression of multiple microRNAs is associated with endocrine resistance in hormone receptor positive HER2 negative (HR+/HER2-ve) cancer. The role of miR-221 in inducing epithelial to mesenchymal transition (EMT) is well documented especially in cell line model systems. However, the detailed mechanism of specific microRNAs in intrinsic and acquired resistance to endocrine therapy needs to be worked out. In addition, more needs to be done in the documentation of these mechanisms in human breast cancer specimens with complete clinical documentation and long-term follow-up. In this study, we have evaluated the clinical significance of miR-221 and its mechanistic role in EMT using human specimens and cell line models.

Materials and Methods: Formalin fixed paraffin embedded tumor from 129 HR+/HER2-ve breast cancer patients with a median follow up of 63 months were used for estimation of miR-221 by quantitative real time PCR. Expression levels of genes which are direct targets of miR-221 and related genes in EMT were analysed from these tumors. Survival between miR-221 high and low groups was compared by Kaplan Meier survival curves and prognostic relevance was estimated by Cox proportional hazard model.

Cell line experiments to investigate the role of miR-221 in inducing EMT through integrin β6 are underway in both wild type and tamoxifen resistant MCF-7 cell lines (A gift from Prof Ben Ho Park, Johns Hopkins University School of Medicine).

Results: A significant elevated level of miR-221 was observed in small proportion (14%) of HR+/HER2-ve tumors. miR-221 expression had an inverse correlation with both ER protein and ESR1 mRNA levels within HR+/HER2-ve tumors. Tumors with high levels of miR-221 showed significantly higher expression of integrin β6 which is a robust marker of EMT. Patients with high expression of miR-221 had a poorer survival in Kaplan Meier analysis. Results of interrogation of EMT mediated through integrin related pathways involving miR-221 in cell line models will be presented.

Discussion: The association between miR-221 and integrin β6 in HR+/HER2-ve breast cancer with endocrine resistance suggests a potential link between an epigenetic regulator and a mediator of tumor-stromal interaction. The other mediators involved in this pathway are being investigated. miR-221 could be potentially used as a marker for identification of a poor prognostic subtype within HR+/HER2-ve breast cancers.
Title: MicroRNA-367a promotes tumor growth and stemness potential by targeting FBXW7 in breast cancer

Body: Increasing studies showed that MicroRNAs (miRNAs) participate in the carcinogenesis and progression of breast cancer, but the specific mechanism of miRNAs in breast cancer needs to be further explored. In this study, we found that miR-367a was significantly up-regulated in breast cancer tissue samples and cell lines, compared to paired normal tumor-adjacent samples and MCF-10A. Meanwhile, Kaplan–Meier analysis demonstrated high miR-367a expression was evidently correlated with poor prognostic features of breast cancer. Overexpression of miR-367a remarkably promoted proliferation, cell cycle, inhibited apoptosis ratios and stem-like capacity of breast cancer cells in vitro, while silencing the expression of miR-367a dramatically reversed these cellular events. In addition, in vivo studies showed that knockdown of miR-367a inhibited tumor growth of breast cancer, moreover, F-box and WD repeat domain-containing 7 (FBXW7) was identified as a direct target gene of miR-367a, as miR-367a directly bound to the 3'untranslated region of FBXW7. Notably, alterations of FBXW7 levels abrogated the effects of miR-367a on breast cancer cell proliferation, cell cycle, apoptosis and stemness potential. In conclusion, evidence from this study demonstrated that miR-367a may serve as a novel prognostic indicator for breast cancer patients and exerts tumor promotion, at least in part, by inhibiting FBXW7.

Key words: miR-367a, FBXW7, breast cancer, tumor growth, stem-like capacity.
Title: IsomiRs and tRNA fragments are race-dependent regulators in breast cancer

Rigoutsos I, Telonis AG G, Loher P, Jing Y and Londin E. Computational Medicine Center, Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA.

Body: For a long time, it was believed that each microRNA (miRNA) precursor arm produces one consequential mature miRNA (the “archetype” miRNA). This product is the sequence that one finds listed in databases such as miRBase. We now know that each arm produces clouds of isoforms (isomiRs) that include the archetype and contribute to the functional role of the miRNA locus from which they arise.

By analyzing the transcriptomes of healthy individuals from the 1000 Genomes Project (1KG) we showed that isomiR expression is constitutive and depends on a person's sex, population origin, and race. Using the breast cancer (BRCA) datasets from The Cancer Genome Atlas (TCGA) repository we extended our findings to the disease context and showed that isomiR expression also depends on a patient's race and on BRCA subtype.

We have tested several isomiRs from two different oncogenic miRNA loci. In particular, we selected isomiRs that are differentially abundant between White (Wh) and Black or African American (B/Aa) Triple Negative Breast Cancer (TNBC) patients. Transient transfection of each isomiR in MDA-MB-468, a cell line model of TNBC in B/Aa patients, and BT-20, a cell line model of TNBC in Wh patients, led us to two observations: 1) within a cell line, isomiRs from the same locus downregulated largely distinct collections of mRNAs; and, 2) across cell lines, isomiRs from the same locus downregulated largely distinct collections of mRNAs. The findings suggest that distinct isomiRs from the same miRNA locus target different mRNAs in Wh and in B/Aa TNBC patients.

With regard to tRNAs, the conventional understanding was that the genomic loci encoding them produce a precursor transcript which is processed to give rise to the mature tRNA used in codon translation. Early efforts showed that, in addition to the full-length mature tRNAs, tRNA fragments (tRFs) are also produced from both the precursor and the mature tRNAs. These tRFs were initially thought to be degradation products.

Our analyses of transcriptomes from the 1KG showed that tRFs in healthy individuals are constitutive and their profiles depend on race, sex, and population origin. Our findings extended to the disease context: using TCGA BRCA transcriptomes, we showed that tRF expression also depends on a patient's race and on BRCA subtype. We also discovered a new category of tRFs, the “internal tRFs” or i-tRFs that are wholly internal to the mature tRNA. Our analyses show that i-tRFs are responsible for much of the difference we observe across individuals.

We examined experimentally several tRFs with abundances that differ between Wh and B/Aa TNBC patients. Transient over-expression of these tRFs in the MDA-MB-468 and BT-20 cell lines led to findings analogous to those we made for isomiRs: 1) within each cell line, each tRF downregulated largely different groups of mRNAs; and, 2) the same tRF downregulated largely different groups of mRNAs in the two cell lines. The findings suggest that distinct tRFs can have distinct mRNA targets that differ between Wh and B/Aa TNBC patients.

These findings suggest that isomiRs and tRFs are regulatory molecules with previously unrecognized roles that depend on a patient's race.
Title: Integration of transcriptomic, proteomic and drug response data in triple negative breast cancer cell lines and PDX models

Mills CE E, Hafner MA A and Sorger PK K. Harvard Medical School, Boston, MA.

Body: Drug response screens on panels of cell lines aimed at identifying markers of sensitivity or resistance have been limited in their successes. Unfortunately, the recent release of many such studies has been accompanied by concerns surrounding reproducibility. Since then, several publications have addressed these concerns by pointing out sources of variability and by suggesting better experimental methods as well as more robust analytical approaches. In the presented profiling effort, we integrated the latest advances in drug response measurement and focused on data diversity and quality rather than on breadth. We selected 32 breast cancer cell lines with a strong bias towards triple negative lines as well as 4 cell lines established from relevant patient-derived xenografts. We used high content microscopy to assay the phenotypic responses of the cell lines to a panel of 34 drugs made up largely of kinase inhibitors currently in the clinic along with some standard of care chemotherapeutics. The microscopy based drug response assay allowed us to measure drug potency, and to quantify the efficacy of the drugs in terms of growth inhibition and cell death. For the same cell lines, we used RNAseq to measure basal mRNA expression levels and shotgun mass spectrometry to measure endogenous protein levels.

The completeness and controlled conditions under which these data sets were collected provide confidence in their integration. The complementarity of these multi-omics data has allowed us to address questions about the landscape of, particularly triple negative, breast cancer cell lines. Such questions include: where do the patient-derived lines lay among the established cell lines? and how different are the landscapes defined by drug response phenotypes, mRNA expression, and protein levels? We used network-based algorithms to identify eigenstates of signaling pathways related to genomic events, and further explored these states in the TCGA data.

At the level of drug response, we have focused on important questions related to the clinical use of kinase inhibitors. In particular, we compared various CDK inhibitors in an effort to identify markers that are informative of response potency and efficacy. We have also looked at variability of the responses of the cell lines studied to multiple PI3K inhibitors that either target specific isoforms or all isoforms. Overall the data set that has been collected is a valuable resource for understanding drug response in triple negative breast cancer, and the transcriptomic and proteomic factors that influence it.
Title: Mathematical modeling of the unfolded protein response pathway in breast cancer cells

Shajahan-Haq AN N, Demas DM M, Clarke R and Baumann WT T. Georgetown University Medical Center, Washington, WA and Virginia Tech, Blacksburg, VA.

Body: Over 70% of all breast cancers are estrogen receptor positive (ER+) and are treated with endocrine therapies such as aromatase inhibitors or ER-disruptors as part of the standard of care. However, endocrine resistance remains a major clinical challenge for the successful treatment of this disease. ER+ breast cancer cells can escape endocrine therapy-mediated cell death through adaptations in the unfolded protein response (UPR), an evolutionarily conserved cellular stress response pathway that is linked to many other pathways (autophagy, metabolism, anti-oxidant response). To better understand how the UPR pathway promotes endocrine resistance, we built a mathematical model from quantitative measurements of key UPR signaling molecules following treatment of ER+ MCF7 cells (endocrine sensitive, estrogen dependent) with dithiothreitol (DTT). DTT disrupts or prevents protein disulfide bonding and is a potent inducer of the UPR. The same measurements were also made in two MCF7-derived resistant cell lines: LCC1 (sensitive to ER-disruptors, estrogen independent) and LCC9 (resistant to ER-disruptors, estrogen independent). Determining the (minimal) changes to the MCF7 mathematical model needed to adequately capture the data from the resistant cell lines allows us to create specific hypotheses for how the UPR adapts to help produce resistance to endocrine therapies. These hypotheses, in turn, can lead to drug targets for reversing resistance.
Title: Tumor suppressor control of the cancer stem cell angiogenic niche

Crowe D, Kramer K and Wu J. University of Illinois, Chicago, IL.

Body: Mammary stem cells (MSC) expansion is associated with aggressive human breast cancer. The nuclear receptor peroxisome proliferator activated receptor γ (PPARγ) is a breast cancer tumor suppressor, but the mechanisms of this suppression are not completely characterized. To determine if PPARγ regulates MSC expansion in mammary cancer, we deleted PPARγ expression in the mammary epithelium of an in vivo model of basal breast cancer. Loss of PPARγ expression reduced tumor latency, and expanded the CD24+/CD49fhi MSC population. PPARγ null mammary tumors exhibited increased angiogenesis which was detected in human breast cancer. In vivo inhibition of a PPARγ regulated miR-15a/angiopoietin-1 pathway blocked increased angiogenesis and MSC expansion. PPARγ bound and activated a canonical response element in the miR-15a gene. PPARγ null tumors were sensitive to the targeted anti-angiogenic drug sunitinib but resistant to cytotoxic chemotherapy. Normalization of tumor vasculature with sunitinib resulted in objective response to cytotoxic chemotherapy. Chemotherapy treated PPARγ null mammary tumors exhibited luminal phenotype and expansion of unipotent CD61+ luminal progenitor cells. Transplantation of chemotherapy treated luminal progenitor cells recapitulated the luminal phenotype. These results have important implications for anti-angiogenic therapy in breast cancer patients.

Title: Estrogen induced apoptosis can be mimicked by targeting unfolded protein response

Sengupta S, Sevigny C and Clarke R. Georgetown-Lombardi Cancer Center, Georgetown University, Washington, DC.

Body: Estrogen signaling is considered to promote growth in estrogen receptor positive (ER+) breast cancers and its actions can be blocked by antagonists like tamoxifen or by inhibiting the synthesis of estrogen by aromatase inhibitors. Both of these classes of drug are used to treat ER+ breast cancers in the clinic. Paradoxically, before the discovery of tamoxifen and aromatase inhibitors high dose estrogen (HDE) was the choice of endocrine therapy to treat post-menopausal breast cancers. Recent clinical trials have observed 30% clinical benefit rate with high as well as low doses of estrogen-therapy in aromatase-inhibitor resistant breast cancers. Despite its clinical success, the precise underlying mechanism of estrogen-therapy by which it triggers the tumor regression remains unknown. Studies in the laboratory have indicated that unfolded protein response (UPR) and apoptotic pathways may play important role in estrogen-induced apoptosis. Using MCF7:5C cells, which can proliferate independent of estrogen and are hyper-sensitive to estrogen as evident by induction of apoptosis, we demonstrate that increased global protein translational load as the trigger for estrogen-induced apoptosis. This subsequently leads to endoplasmic reticulum (EnR) stress and activates the protein kinase-RNA-like endoplasmic reticulum kinase (PERK) pathway of UPR. Our results also suggest that sustained phosphorylation of eukaryotic initiation factor 2-alpha (eIF2-α), a downstream target of PERK activation, may be crucial in estrogen-induced apoptosis. Phosphorylation of eIF2-α attenuated global translation but preferentially allowed high expression of transcription factors, including, activating transcription factor 4 (ATF4) and C/EBP homologous protein (CHOP). ATF4 and CHOP are known to activate apoptosis. Notably, we were able to recapitulate this phenotype by pharmacologically inhibiting the regulatory subunits of the protein phosphatase 1, GADD34 (growth arrest and DNA damage inducible protein) and CReP (constitutive repressor of eIF2α phosphorylation), that are responsible for de-phosphorylation of eIF2-α. This was evident in MCF7:5C cells as well as another estrogen-independent breast cancer cell line LCC9 that is resistant to both tamoxifen and fulvestrant but does not undergo estrogen mediated apoptosis. We further observed that the combination of 4-hydroxy-tamoxifen (4OHT) and pharmacological inhibitors of GADD34 and CReP potentiated its apoptotic action in both LCC9 and MCF7:5C cells. These results not only enhance our understanding of the apoptotic mechanism of estrogen but also provides crucial evidence that estrogen-induced apoptosis can be mimicked by manipulating the unfolded protein response even in breast cancer cells that are not susceptible to estrogen mediated apoptosis.
Title: Transmembrane protein 33 (TMEM33) induces apoptosis via UPR signaling and autophagy in breast cancer cells

Body: Breast cancer is the most common cancer diagnosed in women. Endoplasmic reticulum stress (EnR stress) and the related unfolded protein response (UPR) are activated in breast cancer cells and can promote cell survival and endocrine resistance. TMEM33 is a novel transmembrane protein that resides in the endoplasmic reticulum (EnR) and has been shown to activate the PERK and IRE1α branches of the UPR. However, the underlying mechanism of action of this EnR resident protein TMEM33 and the cellular functions that it regulates remain largely unknown. In this study, we show that overexpression of TMEM33 induces robust cell death in breast cancer cells. TMEM33 overexpression strongly activates UPR associated pro-death JNK-p53 signaling. We also observed a significant inhibition of the downstream survivin, which blocks cell death activation by binding to caspases and inhibiting their activation. We further show that the blockage of JNK activation with either an inhibitor or overexpression of survivin, protects cells against TMEM33 induced apoptosis. In addition, we show that TMEM33 overexpression induces autophagy in breast cancer cells. Inhibition of autophagy with using either the inhibitor chloroquine or knockdown of the Atg5 gene, further sensitizes breast cancer cells to the effects of TMEM33 overexpression. Cell death induced by TMEM33 is also decreased by overexpression of the autophagy gene Beclin 1. The findings in this study demonstrate that the novel EnR resident protein TMEM33 induces cell death by activating IRE1α-JNK-p53-survivin signaling in breast cancer cells. Concurrently, autophagy is also activated by TMEM33, and functions as a pro-survival mechanism. Cell fate reflects the balance between the pro-death and pro-survival activities as regulated by TMEM33.
Title: Pterostilbene enhances TRAIL-induced apoptosis in TRAIL-resistant triple negative breast cancer cells

Wu Y-C, Wang H-C, Chen C-J, Liu L-C and Way T-D. China Medical University Hospital, Taichung, Taiwan; School of Medicine, College of Medicine, China Medical University, Taichung, Taiwan and College of Biopharmaceutical and Food Sciences, China Medical University, Taichung, Taiwan.

Body: Triple-negative breast cancer (TNBC) is refractory to commonly used chemotherapeutic agents, as a result it leads to relatively poor prognosis. TNF-related apoptosis-inducing ligand (TRAIL) is currently in clinical trials as a treatment for cancer. Unfortunately, patients develop resistance to the TRAIL, therefore, agents that can sensitize cells to TRAIL are urgently needed. Pterostilbene (PTER), a natural dimethylated analog of resveratrol, is known to have diverse pharmacologic activities. In the present study, we investigated whether PTER affect TRAIL-induced apoptosis and its mechanism in TRAIL-resistant TNBC cells. First, our results indicated that PTER induced apoptosis in TNBC BT-20 cells. Next, we found that PTER enhanced TRAIL-induced apoptosis in TRAIL-resistant TNBC BT20 and MDA-MB-468 cells. We demonstrated that PTER induced both death receptor (DR)-5, DR4 and decreased decoy receptor (DcR)-2 expression. PTER also decreased the expression of anti-apoptotic proteins survivin, Bcl-xL and c-FLIPs/L, but had minimal effect on the expression of Bcl-2. PTER caused the cleavage of bid protein and enhanced the expression of pro-apoptotic Bax. Moreover, we found that PTER induced DR4 and DR5 expression through the reactive oxygen species (ROS) –mediated activation of extracellular signal-regulated kinase 1/2 (ERK 1/2) and p38 mitogen activated protein kinase (p38 MAPK). Overall, our results show that PTER can potentiate TRAIL-induced apoptosis through the ROS–mediated activation of ERK 1/2 and p38 MAPK leading to DR4 and DR5 induction and down-regulation of anti-apoptotic proteins.
A genetic model of mammary gland fibrosis and cancer risk

Wu J and Crowe D. University of Illinois, Chicago, IL.

Body: Ductal cells of the mammary gland arise from mammary stem cells (MSC) and consist of estrogen receptor negative (ER-) luminal cells and a small ER+ luminal population. Luminal cells are maintained by the proliferation of ER- luminal progenitor (LP) cells, which are expanded in basal subtype breast cancer. Human breast LP cells exhibit telomere DNA damage, which is associated with mammographic density and increased cancer risk. Short telomeres resulting from the DNA damage response correlate with aggressive breast cancer phenotypes. Telomeric repeat factor 2 (TRF2) binds to telomeres and protects them from the DNA damage response. TRF2 expression is reduced in most human breast cancers but the phenotypic advantages of this genetic alteration are unknown. To determine the effects of telomere DNA damage on mammary gland function and tumor phenotype, we deleted TRF2 expression in mammary gland epithelium. Mammary glands lacking TRF2 expression exhibited increased telomere DNA damage response, histopathological and functional degeneration, and prominent ductal fibrosis. MSC from TRF2 deficient glands were unable to completely regenerate mammary glands following transplantation to cleared fat pads. TRF2 deficient mammary tumors also demonstrated telomere DNA damage response but exhibited rapid onset and increased proliferation. Tumor derived LP cells underwent expansion but exhibited high telomere DNA response and failed to form tumors following transplantation. In contrast, the severely depleted MSC population was highly tumorigenic and maintained telomeres via the ALT mechanism. Telomere DNA damage response in mammary tumors resulted in p53 dependent ER+ cellular differentiation and sensitivity to anti-estrogen therapy. Our results provide a new in vivo model for exploring mechanisms of mammographic density, stem cell differentiation, cancer risk, and therapeutic sensitivity.
Title: Independent validation of EarlyR gene signature in BIG 1-98: A randomized, double-blind, phase III trial comparing letrozole and tamoxifen as adjuvant endocrine therapy for postmenopausal women with hormone receptor-positive, early breast cancer

Buechler S, Gray KP, Gökmen-Polar Y, Willis S, Thürlimann B, Kammler R, Leyland-Jones B, Badve SS and Regan MM. University of Notre Dame, Notre Dame, IN; IBCSG Statistical Center, Dana Farber Cancer Institute, Boston, MA; Indiana University School of Medicine, Indianapolis, IN; Avera Cancer Institute, Sioux Falls, SD; International Breast Cancer Study Group Coordinating Center and Pathology Office, Bern, Switzerland; Breast Center, Kantonsspital, St. Gallen, Switzerland and Swiss Group for Clinical Cancer Research SAKK, Berne, Switzerland.

Body: Background: EarlyR is a prognostic gene signature score in ER+ breast cancer (BC) computed from the expression values of ESPL1, SPAG5, MKI67, PLK1 and PGR using a novel algorithm. EarlyR has been validated in multiple cohorts profiled on Affymetrix and Illumina microarrays. This study sought to verify prognostic features of EarlyR in a cohort of BIG 1-98.

Patients and Methods: Illumina DASL assay was used to measure gene expression in FFPE tissue of primary BC from a case-cohort sampling subset of postmenopausal women in BIG 1-98 treated with adjuvant endocrine therapy (letrozole or tamoxifen). Chemotherapy treatment was at the discretion of individual physicians and patients. Among the 1218 patients centrally reviewed with sufficient RNA material for the DASL assay, 1174 with ER+ status and assessed for EarlyR are included in the analytic cohort. EarlyR scores and pre-specified risk strata (≤25=low, 26-75=intermediate, >75=high) were computed, while blinded to clinical data. The analysis endpoints included distant recurrence free interval (DRFI) defined as time from randomization to BC recurrence at a distant site within 8 years and BC free-interval (BCFI) defined as time from randomization to first invasive BC recurrence at a local, regional or distant site or invasive contralateral BC within 8 years. Weighted proportional hazards models (univariate and multivariate, stratified by treatment assignment) were used to adjust for Kaplan-Meier, hazard ratio estimates and Wald test statistics to obtain unbiased analyses and to give consistent estimates.

Results: The distribution of the EarlyR risk groups was 67% low, 19% intermediate and 14% high risk in this ER+ cohort. EarlyR was prognostic for 8-year DRFI (P-trend=0.008). Patients with high EarlyR risk score (>75) had significantly increased risk of distant recurrence within 8 years (univariate HR=1.73, 95%CI: 1.14-2.64) compared to low EarlyR risk group (≤25). The estimated 8-year DRFI (95%CI) is 84%(80%-88%) for high risk vs. 91%( 89%-92%) for low risk, corresponding to an absolute DRFI risk reduction of 7% (low vs high). EarlyR is also prognostic of 8-year BCFI in ER+ (P-trend=0.002) with the estimated 8-year BCFI (95%CI) 79%(75%-84%) for high risk vs. 88%(86%-89%) for low risk. Consistent results were observed in ER+, HER2- (P-trend=0.01 for DRFI, P-trend=0.004 for BCFI), in ER+, LN- (P-trend=0.05 for DRFI, P-trend=0.03 for BCFI) and ER+, LN+ (P-trend=0.08 for DRFI, P-trend=0.03 for BCFI) subsets.

Conclusions: This study confirmed the prognostic significance of EarlyR using FFPE tissue from the BIG 1-98 trial. In analyses of all ER+ patients and subsets LN-, LN+ and HER2-, EarlyR classifies 65%-70% of patients as low risk, 11-16% as high risk, and < 20% as intermediate risk. In these subsets, the size of the low risk group is larger and the size of the intermediate risk group is smaller than those reported for commercially available signatures. EarlyR identifies a set of high-risk patients with relatively poor prognosis who may be considered for additional treatment. The clinical utility of EarlyR requires further study.
Title: Serum-triglycerides among triple negative breast cancer patients as a biomarker of poor outcome

Lofterød T, Mortensen ES S, Nalwoga H, Wilsgaard T, Frydenberg H, Risberg T, Eggen AE, McTiernan A, Aziz S, Wist EA A, Reitan JB B, Akslen LA A and Thune I. Oslo University Hospital, Oslo, Norway; University Hospital of North Norway, Tromsø, Norway; University of Bergen, Bergen, Norway; UiT The Arctic University of Norway, Tromsø, Norway; University Hospital of North Norway, Tromsø, Norway; Fred Hutchinson Cancer Research Center, Seattle; Haukeland University Hospital, Bergen, Norway and UiT The Arctic University of Norway, Tromsø, Norway.

Body: Background: Obesity and related metabolic imbalances, including increased activity of free fatty acids, may promote tumor growth and metastasis. Fatty acids are mainly stored as triacylglycerols. Yet, the role of serum-triglycerides on breast cancer prognosis is still undefined.

Methods: A population based survival study among 575 breast cancer patients identified within the Tromsø study during 1979-2008, was conducted. Pre-diagnostic serum triglycerides, high density lipoprotein-cholesterol, total cholesterol, height and weight were measured. Histopathological and clinical data were obtained from medical records, and hormone receptor, HER2 status, and Ki-67 were re-analyzed on tissue microarray blocks. Multivariate Cox proportional Hazard regression models were used to study the associations between patient characteristics including s-triglycerides, and breast cancer survival.

Results: Among 575 women with invasive breast cancer (stage 1-3), a total of 87 women were diagnosed with triple negative breast cancer (TNBC). Patients diagnosed with TNBC, compared to non-TNBC, were likely to be younger at diagnosis (55.3 vs 57.9 years, \(p=0.061\)), they had larger tumors (29.7 mm vs 22.5 mm, \(p=0.001\)), and higher Ki-67 (31.1% vs 15.9%, \(p<0.001\)). After a mean follow-up of 8.4 years, TNBC patients with above median levels of s-triglycerides (> 0.98mmol/L) compared to TNBC patients with below median levels of s-triglycerides (\(\leq 0.98\)mmol/L) had 3.0 times higher risk for breast cancer recurrence or breast cancer specific death (HR 3.02, 95% CI 1.21-7.55), and 3.4 times higher overall mortality risk (HR 3.41, 95% CI 1.38-8.45). Among the TNBC patients, women with above median s-triglycerides had 15% lower 5-year disease-free survival (76% vs 91%) and 18% lower 5-year overall survival (74% vs 92%) compared to women with below median s-triglycerides.

Conclusions: Our results strongly support s-triglycerides as an important biomarker for breast cancer outcomes among triple negative breast cancer patients.

Multivariate Cox proportional Hazard regression model. Adjusted for BMI and age at attendance (continuous), age at diagnosis (continuous), breast cancer stage at diagnosis (categorical), and current smoking (categorical). Abbreviation: CI, confidence interval; n, number of cases; TNBC, triple negative breast cancer
Title: Estrogen receptor-positive breast cancer in \textit{BRCA1} mutation carriers shows a BRCAness profile, suggesting sensitivity to drugs targeting homologous recombination deficiency

Body: \textit{Background}
As estrogen receptor (ER)-positive breast cancer in \textit{BRCA1} mutation carriers arises at an older age with less aggressive tumor characteristics than ER negative \textit{BRCA1} mutated breast cancer, it has been suggested that these tumors are 'sporadic' and not \textit{BRCA1}-driven. With the introduction of targeted treatments specific for tumors with a non-functioning \textit{BRCA1} or \textit{BRCA2} gene, the question whether the \textit{BRCA} genes are impaired in the tumor, is highly relevant. Therefore, we performed genomic profiling of \textit{BRCA1}-mutated ER+ tumors.

\textit{Methods}
Genomic profiling, \textit{BRCA1} promoter methylation assessment, and loss of heterozygosity (LOH) analysis were done on 16 \textit{BRCA1}-mutated ER+ tumors. Results were compared with 57 \textit{BRCA1}-mutated ER- tumors, 36 \textit{BRCA2}-mutated ER+ associated tumors, and 182 sporadic ER+ tumors.

\textit{Results}
The genomic profile of \textit{BRCA1}-mutated ER+ tumors was different from \textit{BRCA1}-mutated ER- breast tumors, but highly similar to \textit{BRCA2}-mutated ER+ tumors. In 83% of the \textit{BRCA1}-mutated ER+ tumors, loss of the wildtype \textit{BRCA1} allele was observed. Clinicopathological variables in \textit{BRCA1}-mutated ER+ cancer were more similar to \textit{BRCA2}-mutated ER+ and sporadic ER+ breast cancer than to \textit{BRCA1} mutated ER- cancers.

\textit{Conclusions}
As \textit{BRCA1}-mutated ER+ tumors showed a BRCAness copy number profile and LOH, it is likely that the loss of a functional \textit{BRCA1} protein plays a role in tumorigenesis in \textit{BRCA1}-mutated ER+ tumors. Therefore, we hypothesize that these tumors are sensitive to drugs targeting the \textit{BRCA1} gene defect.
Title: Breast cancer subtype, age and lymph node status as predictors of local recurrence following breast-conserving therapy

Body: Purpose/Objectives: Advances in breast-conserving therapy (BCT) have yielded local control rates comparable or superior to those of mastectomy. Here, we sought to identify risk factors associated with isolated local recurrence (LR) following BCT. Materials/Methods: This study included a multi-institutional cohort of 2,233 consecutive breast cancer patients who underwent BCT between 1998 and 2007. Patient characteristics and disease parameters were stratified by age, subtype and nodal status. Biologic subtype was approximated by receptor status and tumor grade. No patients received HER2/neu-directed therapy. The association of clinicopathologic features with LR was evaluated using Cox proportional hazards regression models. Results: At a median follow-up of 106 months, 69 LR events (3.1%) were observed. Among the overall cohort, 10-year freedom from LR was 95.9%. On univariate Cox regression analysis, risk factors associated with LR included subtype other than luminal A (hazard ratio [HR] for luminal B = 3.01, HER2 = 6.29, triple negative [TNBC] = 4.72; p<0.001 for each), younger age (HR of oldest versus youngest quartile = 0.43; p=0.005), regional lymph node involvement (HR for 4-9 involved nodes = 3.04; >9 nodes = 5.82; p<0.01 for each), positive resection margins (HR = 2.43; p=0.005), and high-grade disease (HR = 5.37; p <0.001). Presence of LVI (HR = 1.56; p=0.06) or 1-3 involved nodes (HR = 1.55; p=0.07) approached significance. Multivariate Cox regression demonstrated an association with LR among those with non-luminal A subtypes (HR for luminal B = 2.64, HER2 = 5.42, TNBC = 4.32; p<0.001 for each), younger age (HR for age >50 = 0.56; p=0.01), and any nodal disease (HR=1.06 per involved node; p<0.004).

Conclusions: BCT yields favorable outcomes for the large majority of patients, although increased LR was observed among those with non-luminal A subtypes, younger age, and increasing lymph node involvement. Risk factors for LR following BCT appear to be converging with those following mastectomy in the current era.
Title: Extracellular vesicles from young women's and postpartum breast cancer display unique proteomic content, alter breast cancer aggressive behavior, and influence immune cell function

Borges VF F, Jordan KR R, Hall JK K, Schedin T, Hansen K and Schedin P. University of Colorado Denver, Anschutz Medical Campus, Aurora, CO and Oregon Health Science University, Portland, OR.

Body: Background: Young women's breast cancer [YWBC] affects 27,000 US women age ≤45 annually. Half of these cancers occur within 5-10 years of a prior childbirth, a postpartum breast cancer [PPBC], incurring a 3 fold increased risk for metastasis and death. Recently, extracellular vesicles [EV] have been identified in human circulation, released from cancer cells, that have paracrine and autocrine effects, alter the tumor microenvironment and establish metastatic niches. EVs isolated from breast cancer lines increase proliferation and invasion of other breast cancer cells in vitro. However, the impact of EVs isolated from primary breast cancer patients on tumor invasion, metastasis and their role in tumor immune suppression is largely unknown. We hypothesized that EVs from YWBC/PPBC patients may contain unique pro-metastatic cargo, influence aggressive breast cancer cell behavior and may demonstrate the ability to alter immune cell function.

Method: We isolated EVs using size-exclusion chromatography [SEC] from the plasma of 10 unaffected young women and 20 YWBC patients balanced for parity, age, subtype and stage. We compared the breast cancer-specific EV proteins within various clinical groups of YWBC and PPBC to identify significant proteomic differences by parity, sub-type, stage, and disease recurrence. We determined the functional impact of these EVs on tumor cell motility and proliferation, and analyzed the effect of breast cancer derived EVs on immune cell phenotype, function, and T cell proliferation assays.

Results: Of the 582 proteins, 22 proteins are significantly increased in the EVs of YWBC compared to unaffected donors. The protein set includes breast cancer antigens [MUC 1, 2, 5b], transcriptional regulators [Myc target protein], enzymes [catalase, MMP inhibitor 1], and signaling molecules [Annexin 1, latent TGFβ binding protein 1], among others. Several identified proteins specifically track with those YWBC cases with subsequent metastases. Furthermore, 8 unique proteins track with PPBC, including cartilage oligomeric matrix protein, a novel breast cancer biomarker that correlates with increased invasiveness, and decreased recurrence-free survival. EVs isolated from the plasma of newly diagnosed YWBC increase breast cancer invasion and EVs derived from breast cancer are engulfed by the majority of monocytic immune cells, including dendritic cells, classical and activated monocytes, but not by lymphocytes. Specifically, CD14+ monocytic myeloid derived suppressor cells engulfed the EVs while the CD15+ granulocytic subset did not. Once engulfed, phenotypic changes occur in the EV containing monocytes and a significantly reduction in T cell stimulation in standard mixed-lymphocyte reactions is observed.

Conclusion: EVs isolated from YWBC & PPBC cases have unique protein content and increase breast cancer invasiveness, which suggests potential mechanistic roles for EVs as increasing metastatic risk and provides novel candidate biomarkers. We identified an immunomodulatory effect of breast cancer EVs on human monocytes that may contribute to immunosuppression in breast cancer and a role for EVs as directly modulating the host and tumor microenvironment.
Title: Quantification of HER2-driven signaling (HER2$_S$) inhibition of four different anti-HER2 drugs tested ex vivo in live primary HER2-negative breast cancer cell samples with abnormal HER2 signaling activity

Body: Background: A new functional cellular analysis platform, the CELx HER2 Signaling Profile (CELx HSP) Test, uses a label-free impedance biosensor to measure HER2 signaling activity in live tumor cells. A recently completed study quantified HER2-driven signaling activity in epithelial cell samples extracted and cultured from fresh breast tissue specimens obtained from 34 patients with HER2-negative breast cancer (DAKO 0 or 1+). Of the cell samples tested, 7 of 34 HER2-negative breast tumor patients (20.5%; 95% CI=10%-37%) were found to have abnormal HER2 signaling activity (HER2$_S$+). The current study set out to: 1) evaluate the primary cells with abnormal HER2-driven signaling with four HER2 signal inhibitors - pertuzumab, lapatinib, neratinib, afatinib; and 2) evaluate the same four HER2 signal inhibitors with 9 HER2-positive cell lines. The objective was to quantify the percentage of HER2-driven signaling activity each drug could inhibit ex vivo in the primary cell samples and cell lines. Comparing the results between the HER2-negative primary cells and the HER2-positive cell lines was also of interest. The anti-HER2 drug, trastuzumab, was not studied because its primary mechanism of action does not appear to be direct mediation of HER2-driven signaling.

Methods: Epithelial cells from the 7 HER2-negative tumor specimens with abnormal HER2-driven signaling (HER2$_S$+) and the 9 HER2-positive cell lines were obtained. Real time live cell response to NRG1, a specific HER2/HER3 agonist, with or without a HER2 targeted drug (pertuzumab, lapatinib, neratinib, afatinib) was measured and quantified using an xCELLigence RTCA impedance biosensor (ACEA Biosciences, San Diego, CA). Clinically relevant concentrations of the HER2 drugs were used. From these responses, the percentage inhibition of the HER2-driven signaling activity initiated by NRG1 by the HER2 drugs was determined. Results: Each of the HER2 drugs inhibited an average of at least 69% of the HER2-driven signaling activated by NRG1 stimulation in the HER2-negative primary cell samples; the highest level of inhibition was found with the two irreversible covalent dual RTKi's, afatinib and neratinib. All of the HER2 drugs inhibited a greater percentage of HER2-driven signaling in the HER2-negative primary tumor cells than in the HER2-positive cell lines.

Conclusions: These findings provide strong evidence that HER2 signal inhibitors are effective in blocking abnormal levels of HER2-driven signaling (HER2$_S$+) ex vivo in live primary cells from breast cancer patients with normal expression levels of HER2. These results suggest a new group of breast cancer patients, HER2-negative with abnormal HER2 signaling (HER2-/HER2$_S$+), may benefit from the addition of HER2 signal inhibitors to current combination therapeutic regimens. Additional studies to confirm these findings are underway.
**Title:** CCND1 amplification in early breast cancer patients: Correlation with subtypes and prognosis

Hanf DC C, Fasching PA A, Villalobos IE E, Gasparyan A, Wachter D, Santiago A, Guzman R, Weihbrecht S, Hanf V, Hartmann A, Beckmann MW W and Press MF F. University Hospital Erlangen, Comprehensive Cancer Center Erlangen-EMN, Erlangen, Germany; Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA; Breast Center Klinikum Fuerth, Fuerth, Germany and Institute of Pathology, University Hospital Erlangen, Erlangen, Germany.

**Body:**

**Background:** Mechanisms of progress and recurrence of early breast cancer (BC) have gained importance since several targeted therapeutic options in metastatic breast cancer have been introduced over the last years, especially in hormone receptor positive BC. This study investigates the amplification of cell cycle regulator cyclin D1 gene (CCND1) amplification as one possible progression mechanism.

**Patients & Methods:** Patients from an unselected cohort of early BC patients were included into this study. A tissue microarray (TMA) was available for n=832 patients with early breast cancer. CCND1 amplification was assessed after FISH (Abbott Vysis LSI CCND1 SpectrumOrange/CEP11 SpectrumGreen Probes Kit). A CCND1/CEP11-ratio ≥ 2.0 was considered as amplification. Staining was successful in 545 tumor cores. Amplification results were correlated with clinical patient and tumor characteristics and survival analyses were performed with regard to distant disease free survival and overall survival.

**Results:** CCND1 amplification was found in 13.6% of patients. Triple negative, luminal A like, luminal B like and HER2 positive tumors were amplified in 7.5%, 7.8%, 18.6% and 15.7% respectively (p = 0.010). CCND1 amplification was significantly associated with a higher grading and a higher body mass index. Furthermore an amplification was seen more frequently in lobular BC and ductal BC than other histological subtypes. Survival analysis showed a reduced DDFS for patients with CCND1-amplification. 5 year DDFS rates were 90.6% for non-amplified tumors and 86.0% for amplified tumors (p, log-rank =0.066 ). 5 year OS rates were 93.0% for non-amplified tumors and 90.1% for amplified tumors (p, log-rank =0.119).

Adjusted for age, tumor size, nodal status and molecular subtype, cox regression showed HR of 1.3 (95% CI: 0.76-2.5, p=0.46) for DDFS and a HR of 1.33 (95% CI: 0.7-2.53, p=0.38) for OS.

**Conclusion:** With a 13.6% prevalence in all breast cancer patients, mainly present in luminal B like cancers, CCND1-amplification is a genetic aberration associated with an unfavorable prognosis. Within hormone receptor positive women CCND1 amplification might play a role in treatment resistance mechanisms in early breast cancer patients.
**Title:** Use of an aptamer library based next generation omics platform for the development of a novel trastuzumab predictive assay

**Body:**

**Introduction:** Previous attempts to use individual aptamers as diagnostic reagents have failed to consistently achieve performance comparable to antibodies. Here we report a novel systems biology approach using poly-ligand aptamer libraries to identify responders and non-responders to trastuzumab-based regimens in metastatic breast cancer.

**Methods:** To overcome the fundamental limitation of the individual aptamer binding affinities, large libraries (10⁶ species) were created so that potentially thousands of aptamers could bind to each of a multitude of targets related to the whole cellular changes in response to trastuzumab therapy. A set of breast cancer patients, which received trastuzumab mono- or combined therapy for at least 7 months were classified as “Responders” (R); cases with particular regimen discontinued in the period not exceeding 5 months were classified as “Non-Responders” (NR). A library of 2x10¹² unique 90-mer ssDNA oligodeoxynucleotides (ssODN) was trained on FFPE tissue of both R and NR patients. Partitioning of aptamer libraries was done by microdissection of the tumor tissue, after incubation of aptamer library with the entire tissue section, to drive selection pressure toward cancer cells. A total of 10 cases of R and NR, 6 Her2+ cases each, were used to train separate aptamer libraries, with 1 positive and 2 counter selection cases per enrichment. Enriched libraries were screened on 20 R and 20 NR cases (11 Her2+ cases each) by adopting modified immunohistochemistry protocol. Each library was used as an independent reagent (similar to an antibody in IHC) across all 40 cases to evaluate the efficacy of the aptamer library to distinguish differences between the R and NR groups. Staining (DAB chromogen) profiles were scored from 0 to 3+ (nuclear and cytoplasmic staining) by a pathologist without any knowledge of the clinical outcomes. Initial validation was done by t-test using raw histological scores. Four libraries showed significant p-values between groups of responders and non-responders, a classification algorithm was constructed and evaluated using area under the receiver-operator characteristic curve (AUC). The datasets of two best-performing libraries were combined into one model using logistic regression to further improved the classifier performance.

**Results:** Of seventeen trained libraries, eight were evaluated and four showed significant correlation to clinical benefit with a minimum accuracy of 75% for each library when evaluated independently. Furthermore, two libraries showed exceptional performance (ROC curve AUC of 0.86 and 0.77). Combination of the profiling data from these two libraries using logistic regression resulted in an AUC of 0.985. A prospective validation of aptamer histochemical theranostic testing has been initiated.

**Summary:** Enriched aptamer libraries appear to distinguish trastuzumab responsiveness in metastatic breast cancer. This technology could be used as an additional technique beyond FISH testing to determine sensitivity to anti-HER2 agents. The demonstrated platform is applicable to virtually any disease where the safe and effective use of corresponding drug is yet to be improved.
Title: The immune response in triple negative breast cancer

Gillgrass AE E, Pond GR R, Levine MN N, Whelan TJ J, Hassell JA A and Bane AL L. McMaster University, Hamilton, ON, Canada.

Body: Background: Triple Negative Breast Cancer (TNBC) is often associated with a poor prognosis. However TNBC is a heterogeneous group of tumors and while some patients have a poor prognosis others appear to do well long-term. There are currently no clinical or pathologic tumor features that distinguish poor from good outcome. Some TNBCs have infiltration with immune cells and the degree of this infiltration correlates with prognosis.

Objectives: 1) To comprehensively examine immune factors associated with outcome in a cohort of TNBC patients, and 2) to develop an immune gene signature that can stratify patients into low and high risk groups.

Methods: We profiled RNA from 22 TNBCs (10 who had experienced a recurrence) from our institutional cohort using the PanCancer Immune Profiling Panel from NanoString. This panel consists of an extensive list of 770 genes designed to evaluate the immune microenvironment of tumors. The genes fall into a number of functional categories including; 1. Genes that identify specific immune cells, 2. Cytokines that promote an effective immune response and others that are associated with immunosuppression, 3. Chemokines, which attract immune cells into the tumor, 4. Genes that assess both the activation and inhibition of immune cell function, 5. Genes that identify tumor specific antigens. Analysis was performed in the nSolver Advanced Analysis Program.

Results: Using unsupervised hierarchical clustering of genes that were highly differentially expressed, the tumors were classified into 3 immune groups with distinct clinical outcomes. Group 1 ('Immune Excluded'), consisted of tumors with the lowest levels of expression of the immune markers assessed, suggesting that these tumors have a low or absent immune infiltrate; 7 of 7 patients in this group recurred. Group 2 ('Immune Activated') contains tumors that had the highest levels of anti-tumoral immune cell genes and their activation markers. This we interpret to represent a tumor group with a robust anti-tumor immune response; 0 of the 6 patients in this group recurred. In comparison Group 3 ('Immune Low') had moderate to low levels of expression of the majority of immune genes assessed. This we interpret to represent a group of tumors with limited immune cells present; 3 of 9 patients in this group recurred. Lastly, when comparing scores for immune cells, patients that recurred had lower scores for cytotoxic cells, CD8 T cells, Th1 cells and B cells.

Conclusion: In this pilot study high expression of anti-tumoral immune genes correlated with good outcome, whereas lower/absent expression of these genes correlated with poor outcome. We are currently extending these findings to our entire cohort of 180 TNBC patients.
2016 San Antonio Breast Cancer Symposium

Publication Number: P4-12-10

Title: Prognostic relevance of caspase 8 polymorphisms for breast cancer

Wimberger P, Jan Dominik K, Agnes B, Kurt S, Rainer C, Rainer K, Winfried S and Hagen B. Medical Faculty and University Hospital Carl Gustav Carus, TU Dresden, Germany, Germany;  German Cancer Consortium (DKTK), Dresden and German Cancer Research Center (DKFZ), Heidelberg, Germany; Institute of Pathology and Neuropathology, University Hospital Essen, University of Duisburg-Essen, Germany; West German Cancer Center, University of Duisburg-Essen, Germany and Institute of Pharmacogenetics, University Hospital Essen, University of Duisburg-Essen, Germany.

Body: Background: The minor allele of two caspase 8 polymorphisms, namely CASP8 -652 6N InsDel (rs3834129) and CASP8 Asp302His (rs1045485), were repeatedly associated with reduced breast cancer susceptibility. Contrarily, the presence of the -652 6N Del or the CASP8 302His variant was reported to be an unfavorable prognostic factor in colorectal cancer or neuroblastoma. However, prognostic relevance of these genetic variants for breast cancer is completely unknown and is therefore addressed by the current study.

Methods: Genotyping was performed by pyrosequencing. Caspase 8 mRNA expression was quantified by comparative RT-qPCR.

Results: We observed an allele-dose dependent association between CASP8 -652 6N InsDel and caspase 8 mRNA expression in breast cancer tissue, with homozygous deletion carriers showing lowest relative caspase 8 expression (p=0.0131). Intriguingly, the presence of the -652 6N Del or the 302His variant was shown to be a negative prognostic factor for breast cancer in terms of an allele-dose dependent influence on overall survival (OS, p=0.0018, p=0.0150, respectively). Moreover, both polymorphisms were independent predictors of OS after adjusting for co-variats (p=0.007, p=0.037, respectively). Prognostic relevance of both polymorphisms was independent from ER or Her2/Neu receptor status and a combined analysis of diplotypes revealed an additive influence on OS (p=0.0002).

Conclusion: This is the first report, showing negative and independent prognostic impact of the CASP8 -652 6N Del and the 302His variant for breast cancer. Our data provide rationale to further validate clinical utility of these polymorphisms for breast cancer and to extend this investigation to a broad scope of other malignancies.
Up-regulation of SPARC is associated with breast tumor progression and epithelial SPARC expression is correlated with poor survival and MMP-2 expression in patients with breast carcinoma

Lee JS, Kim G-E, Park MH and Yoon JH. Chonnam National University Medical School, Gwangju, Republic of Korea and Chonnam National University Medical School, Gwangju, Republic of Korea.

Background: Secreted protein acidic and rich in cysteine (SPARC) plays a crucial role in the process of tumor invasion and metastasis in many cancers. Matrix metalloproteinases (MMPs) degrade the extracellular matrix and participate in several key processes of invasion and metastasis. The aims of this study were to evaluate the potential involvement of SPARC in the progression of breast tumor and to determine its association with outcome variables and MMPs expression in patients with breast carcinoma (BC).

Materials and Methods: SPARC expression was examined in 8 pairs of BC tissues and surrounding normal tissues at mRNA and protein levels by quantitative real-time PCR (qRT-PCR), RNAscope in situ hybridization (ISH), Western blotting, and immunohistochemistry techniques. Immunohistochemical staining of SPARC on tissue microarray was done in 26 normal breasts, 76 ductal carcinoma in situ (DCIS), and 198 BC samples. In addition, we performed immunohistochemical staining for MMP-2 and MMP-9 in BC.

Results: SPARC expression at mRNA and protein levels by qRT-PCR and Western blotting was significantly increased in BC tissues compared to the surrounding normal tissues (p < 0.05 and p < 0.01, respectively). RNAscope ISH and immunohistochemistry of SPARC confirmed that SPARC expression was increased in BC tissues compared with their normal tissues and its expression was more pronounced in the stromal compartment than in epithelial compartment. SPARC expression was different among the normal, DCIS and BC groups and epithelial SPARC expression increased progressively from normal breast through DCIS to BC (p < 0.001). In patients with BC, high epithelial SPARC expression was associated with worse disease-free and overall survival (p = 0.002 and p = 0.048, respectively) and independently predicted worse disease-free survival (p = 0.002). Epithelial SPARC expression was significantly correlated with MMP-2 expression (p < 0.05).

Conclusion: Our results suggest that up-regulation of SPARC contributes to breast tumor progression. SPARC expression may be a useful biomarker for the prognostic prediction in patients with BC. SPARC can control extracellular matrix degradation through up-regulation of MMP-2.
**Title:** Quantitative *in vivo* imaging of intratumoral heterogeneity to assess tumor response to trastuzumab treatment in a preclinical model of HER2+ breast cancer

Syed A, Quarles CC, McIntyre JO, Barnes SL L, Yankeelov TE E and Sorace AG G.  University of Texas, Austin, TX and Vanderbilt University, Nashville, TN.

**Body: Introduction:**
Intratumoral heterogeneity is associated with variable treatment response and poorer patient prognosis. Initial changes in intratumoral cellular and vascular heterogeneity after treatment could serve as an early metric for treatment response and be used to guide and optimize therapy for improved patient outcome. Quantitative, noninvasive imaging can characterize, in 3D, tumor response to treatment by evaluating longitudinal alterations in heterogeneity. Our goal is to quantitatively image the changes in intratumoral cellular and vascular heterogeneity in response to trastuzumab in a murine model of HER2+ breast cancer.

**Experimental Design:**
Data from two independent cohorts of mice were used in this study. Mice were implanted subcutaneously with BT474 breast cancer cells (1×10^7) and randomly assigned to trastuzumab treated (10 mg/kg) or saline control groups. After tumors reached ~225 mm^3, intraperitoneal injections of trastuzumab or saline were given on days 0 and 3. In the first cohort of mice (n=14), quantitative dynamic contrast enhancement magnetic resonance imaging (DCE-MRI) assessed tumor response on days 0 (prior to treatment), 1 and 4. In this study, we focused on the calculated extravascular extracellular space, measured using DCE-MRI parameter, ν_e. In the second cohort of mice (n=10), ^18F-fluoromisonidazole positron emission tomography (FMISO-PET) imaging was utilized to assess tumor hypoxia on days 0 (prior to treatment), 1, 3, 4, and 7 through changes in standardized uptake value (SUV). Longitudinal changes in heterogeneity were assessed using voxel based histogram analysis of ν_e or SUV. Statistical analysis (R Studio) compared histogram analyses (full-width half-maximum, range, kurtosis, and standard deviation) of control and treated groups. Tumor size measurements obtained at the conclusion of the experiment were used to validate imaging findings of tumor response to treatment.

**Results:**
DCE-MRI revealed increased heterogeneity in extravascular extracellular space after trastuzumab treatment, as quantified by a significant increase in the FWHM of ν_e voxel distributions at day 4 post-treatment (p=0.03). Additionally, the FMISO-PET data showed a significant decrease in hypoxic regional heterogeneity in treated tumors, as quantified by percent change (normalized to baseline) in standard deviation and range of SUV tumor voxel distributions on days 3 (p=0.02), 4 (p=0.01), and 7 (p<0.001) compared to saline controls.

**Conclusion:**
Trastuzumab improved oxygen delivery throughout the tumor as quantified by decreased hypoxia heterogeneity (narrowing of distributions) of the FMISO-PET SUV map. Likewise, the increased heterogeneity (widening of distributions) of the DCE-MRI ν_e parametric map, reflects a more heterogeneous cellularity interpreted to arise from enhanced cell death following trastuzumab treatment. Ongoing analysis of heterogeneity of corresponding histology slides will be used to validate the imaging measures of heterogeneity. DCE-MRI and FMISO-PET reveal quantitative longitudinal changes in tumor cellular and vascular heterogeneity, and may be able to predict response and guide therapy for patients with HER2+ breast cancer.
**Title:** High intratumoral and stromal S100A8 expression is prognostic of poor outcome in breast cancer

**Body:**

**Background:** S100A8 and S100A9 are members of a family of calcium binding proteins that regulate inflammatory response, and are biomarkers of inflammatory diseases. S100A8/A9 preferentially form heterodimers that interact with their receptor, RAGE, to activate signaling pathways (ERK1/2 MAPK, JNK, and NF-κB) and stimulate tumor cells. Elevated expression of S100A8/A9 has been observed in cancers of the bladder, esophagus, colon, ovary, and breast. S100A8/A9 are expressed intratumorally by cancer cells and in the stroma by infiltrating immune and myeloid cells as well. We investigated the associations of elevated expression of intratumoral and stromal S100A8 with survival outcomes in breast cancer.

**Methods:** Tissue microarrays (TMA) were constructed from breast cancer specimens from patients with stage I-III breast cancer treated at the University of Michigan Comprehensive Cancer Center between 2004-2006, ensuring a minimum of 10-year follow-up. Each patient was represented on the TMA by representative regions of non-necrotic tumor and distant normal tissue. Automated Quantitative Immunofluorescence (AQUA) was performed for S100A8 protein, and samples were scored for intratumoral and stromal S100A8 expression. S100A8 staining was assessed as a continuous value and by exploratory dichotomous cutoffs. Associations with disease-free survival (DFS) or overall survival (OS) and S100A8 expression, either as continuous value or based on the exploratory cutoffs, were determined using the Kaplan-Meier method and Cox proportional hazards models.

**Results:** In the entire patient cohort, high intratumoral S100A8 expression, as a continuous measure, was a significant prognostic factor for OS (univariable hazard ratio [HR] 1.26, 95% confidence interval [CI] 1.02-1.56, p=0.036), and for DFS (multivariable HR [95%CI] = 1.24 [1.01-1.53], p = 0.043). Exploratory analyses demonstrated optimal cutoffs of intratumoral and intrastromal staining that greatly separated survival curves. We evaluated whether the prognostic significance of S100A8 expression is different in breast cancer patients based on hormone receptor status and determined that neither intratumoral nor stromal S100A8 expression were significantly associated with outcomes.

**Conclusions:** Elevated intratumoral and stromal expression of S100A8 are significant indicators of poor outcome in breast cancer patients. These data further support a biological role for S100A8 signaling in mammary carcinogenesis and aggressive tumor behavior. Evaluation of S100A8 protein expression might provide additional prognostic information beyond traditional breast cancer prognostic biomarkers. Further validation is necessary to investigate these findings.

Title: Folate receptor alpha (FOLR1) expression in triple-negative breast cancer (TNBC)

Cui X, McIntire PJ J, Ginter PS S, Irshaid L, Chen Z and Shin SJ J.  Weill Cornell Medicine, New York, NY.

Body: Background Folate receptor alpha (FOLR1) has been identified as a potential prognostic and therapeutic target in breast cancer. The limited studies evaluating the role of FOLR1 in breast cancer have shown that FOLR1 protein expression is enriched in triple-negative breast cancer (TNBC). Newly developed anti-FOLR1 therapy could potentially be used for patients with TNBC for whom few therapeutic options exist. We sought to evaluate FOLR1 protein expression in a cohort of patients with TNBC to determine its prevalence and prognostic value. Design Immunohistochemistry was performed for FOLR1 (26B3.F2, Biocare, RTU) on tissue microarray (TMA) slides consisting of 62 primary TNBC. Membranous staining in ≥5% of cells was deemed positive in a given case. Statistical analyses correlating FOLR1 protein expression with clinicopathologic parameters and clinical outcome [disease-free survival (DFS) and overall survival (OS) (range: 16 to 196 months, mean: 111 months)] were performed. Results 62 cases of primary TNBC from 61 patients were studied. All patients were female and the mean age was 55 years (range 30 to 91 years). Histologically, almost all tumors were invasive ductal carcinoma (94%; 58/62) and grade 3 (89%; 55/62). Most were pT1 tumors (71%; 44/62) or pT2 (27%; 17/62). For the majority of patients, the nodal status was N0 (61%; 38/62) or N1 (24%; 15/62) and the stage was 1 (53%; 33/62) or 2 (32%; 20/62). Most cases were negative for FOLR1 (84%; 52/62). FOLR1 expression did not correlate with any clinicopathologic parameters, DFS or OS (P>0.05). Conclusion Similar to other studies, we found no correlation with FOLR1 expression and common clinicopathologic parameters and clinical outcome in TNBC. While FOLR1 expression has been previously reported to confer poor prognosis in breast cancer (all types), our findings suggest that in TNBC specifically, FOLR1 expression is not prognostically significant.
Title: Triple-negative breast cancers (TNBCs) rich in infiltrating stromal plasma cells have improved disease-free survival and overall survival

McIntire PJ J, Cui X, Ginter PS S, Irshaid L, Chen Z and Shin SJ J. Weill Cornell Medicine, New York, NY.

Body: Background Tumor-infiltrating lymphocytes (TILs) have emerged as a prognostic indicator in patients with TNBC. Furthermore, lymphocyte-predominant breast cancer (LPBC), defined as those containing ≥50% stromal TILs has been shown to be associated with better prognosis. While cell-mediated immunity has received much of the credit for anti-tumor responses, the International TILs Working Group recommends that the assessment of stromal density of TILs should incorporate all mononuclear cells including plasma cells. Very little is known about the role of humoral immunity, particularly the role of plasma cells in the anti-tumoral response in breast cancer. We sought to evaluate the prognostic value of plasma cells in the setting of stromal TIL assessment of TNBC. Design Morphologic assessment of TILs was performed on a representative H&E slide of 76 cases of primary TNBC. For each case, the stromal density of TILs was estimated and then classified as LPBC or non-LPBC using a cutoff of ≥50% for the former. Also, the plasma cell intensity defined as the mean percentage of stromal plasma cells of five 40x high power microscopic fields of TILs was recorded at 5% increments. Statistical analyses were performed using disease-free survival (DFS) and overall survival (OS) (range: 16 to 196 months, mean: 110 months) as primary endpoints. Results Plasma cell intensity was dichotomized at 12.5% and predictive of OS [21, 95% confidence interval (CI) .05-.93, \( P = 0.0401 \)]. A positive dose related response trended toward significance for each 5% increase in plasma cell intensity (.97, 95% CI .93-1.01, \( P = 0.1168 \)). Disease-free survival also trended positively towards significance (.39, 95% CI .13-1.20, \( P = 0.0991 \)). When comparing LPBC, tumors rich in plasma cells (>12.5% of TILs) trended towards longer DFS (.17, 95% CI .02-1.62, \( P = 0.1226 \)) when compared to plasma cell poor LPBC. Conclusion In addition to the cell-mediated immune response in TNBC, our findings suggest that humoral immunity may also play a role in predicting recurrence and survival in these patients. Our findings suggest that inclusion of an additional parameter of plasma cell intensity may be prognostically valuable in TIL assessment of TNBC.
Title: Prospective association between breast cancer risk and an individual dietary index based on the British Food Standards Agency nutrient profiling system

Deschasaux M, Julia C, Zelek L, Kesse-Guyot E, Gourlet V, Lécuyer L, Méjean C, Ducrot P, Peneau S, Latino-Martel P, Fézeu L, Fassier P, Hercberg S and Touvier M. Sorbonne Paris Cité Epidemiology and Statistics Research Center (CRESS), Inserm U1153, Inra U1125, Cnam, Paris 13 University, Nutritional Epidemiology Research Team (EREN), Bobigny, France; Avicenne Hospital, APHP, Bobigny, France and Avicenne Hospital, APHP, Bobigny, France.

Body: Background: The Food Standards Agency Nutrient Profiling System (FSA-NPS) constitutes the basis for the Five-Colour Nutrition Label suggested in France to be put on the front-of-pack of food products. At the individual level, a dietary index (FSA-NPS DI) has been derived and validated and corresponds to a weighted mean of all FSA-NPS scores of foods usually consumed by the individual, reflecting the nutritional quality of his/her diet. Our aim was to investigate the association between the FSA-NPS DI and breast cancer risk in a large cohort.

Methods: This prospective study included 46,864 women aged over 35y from the NutriNet-Santé cohort (2009-2015) who completed at least three 24h dietary records during the first 2y of follow-up (median follow-up: 4.0y). 555 incident breast cancers were diagnosed. FSA-NPS DI was computed for each subject using the following nutrient content for 100g of each foods and beverages consumed: energy, total sugar, saturated fatty acid, sodium, fruits and vegetables (%), fibres and proteins. Higher values of the FSA-NPS DI correspond to a lower nutritional quality of the diet. Associations were characterized by multivariate Cox proportional hazards models.

Results: The FSA-NPS DI was directly associated with breast cancer risk (HR_{1-point increment}=1.06 (1.02-1.11), P-trend=0.005; HR_{Q5vs.Q1}=1.52 (1.11-2.08), P-trend=0.002). These associations were similar after the exclusion of cases diagnosed during the first year of follow-up.

Conclusions: In this prospective study, a higher FSA-NPS individual score was associated with an increased breast cancer risk. These results suggested that unhealthy food choices may be associated with a 52% increase in breast cancer risk (FSA-NPS DI ≥7.7 (Q5) vs. <4.1 (Q1)), supporting the public health relevance of developing front-of-pack nutrition labels based on this score.
Title: Long-term effects of weight loss on breast cancer biomarkers in postmenopausal women

McTiernan A, Duggan C, Tapsoba JdD, Mason C and Wang C-Y. Fred Hutchinson Cancer Research Center, Seattle, WA.

Body: Background: Obesity increases risk for postmenopausal breast cancer, and is associated with elevated blood levels of inflammation-related marker C-reactive protein (CRP), insulin, glucose, and the angiogenesis-related biomarker vascular endothelial growth factor (VEGF). The long-term effect of weight loss on these breast cancer risk biomarkers is unknown. This study aimed to test the 30-month effect of weight loss on breast cancer biomarkers in postmenopausal overweight/obese women, who had completed a randomized control trial test of behavioral weight loss and/or exercise compared to control.

Methods: From 1/2005-7/2008, women (N=438) were randomized to 1 of 4 arms: reduced calorie weight loss diet (D; N=118); moderate intensity aerobic exercise (E; 225 minutes/week) (N=117); both interventions (D+E; N=116); or control (C, no intervention; N=87). The D intervention goals were: 1200-2000 calories/day, dietary fat < 30% of calories, and ≥ 10% loss of initial weight. The E goal was ≥ 45 minutes of moderate-intensity exercise 5 days/week. The D+E interventions were identical to those for D and E. A total of 157 women returned for a 30-month blood draw (18 months after end-of-study).

Analysis: We compared the average changes in outcomes from baseline to 30 months in weight loss (combining D and D+E groups) vs. no weight loss (combining C and E groups), according to the intention-to-treat principle, using generalized estimating equations (GEE). As a secondary, pre-planned analysis, we combined data for all women regardless of randomization group, and divided them into four categories based on change from baseline to 30 months: 1) gained weight or remained weight stable; 2) lost < 5% of baseline weight; 3) lost 5% - <10% of baseline weight; and 4) lost ≥ 10% of baseline weight. We then compared 30-month analyte changes by these 30-month weight loss groups, with category 1 as referent.

Results: Mean 30-month weight changes from baseline were: D+E, - 7.7%; D, - 6.3%; E, -1.9%; and C, -3%. CRP was 22.5% lower than baseline for women randomized to a diet group, compared with a 4% reduction from baseline in women in a non-diet group (p=0.07). Insulin was 33% lower in women randomized to diet, while it was 20% lower in women not randomized to a diet group (p=0.10). Women who lost 5% - <10% of baseline weight at 30-months experienced an 18% (p<0.001) decrease in CRP compared to baseline, while those who lost ≥ 10% had a 56% lower CRP level (p<0.001). VEGF decreased to a similar amount (14% -15%) in women who lost <10% of baseline weight; and decreased by 26% in those whose 30-month weight decreased by ≥ 10% (p<0.002). Compared with baseline levels, insulin decreased by 16% in those who lost < 5% of baseline weight. In contrast, insulin levels decreased by 31% and 44% (each p=0.004), in those whose 30-month weight loss was 5% - <10% lower than baseline and ≥ 10% lower than baseline, respectively. Glucose levels increased in women whose weight loss was < 5%, but remained stable in those whose 30-month weight was ≥ 5% lower than baseline (each p=0.04).

Conclusions: Long-term weight loss of at least 5% may have biological effects relevant to breast cancer prevention in overweight or obese postmenopausal women.
Title: Changes in the gut microbiome of post-menopausal women 2 weeks after initiating a structured weight loss intervention

Body: Background
Change in the relative composition of the gut microbiome at the phyla level, particularly decreases in *Bacteroidetes* and increases in *Firmicutes* species, has been associated with both obesity and increased risk for breast cancer. It is unclear how rapidly the microbiome changes in response to a reduced calorie and fat diet during a weight loss intervention. As a planned sub-study of a clinical trial with a structured behavioral weight loss intervention with randomization to high dose omega-3 fatty acids or placebo (NCT02101970; clinical trials.gov), we evaluated changes in the gut microbiome after 2 weeks of dietary intervention.

Methods
46 post-menopausal women at increased risk for breast cancer with a BMI > 27 kg/m² had a baseline 3 day food record, DXA, and blood and breast tissue sampling for biomarkers. They were then started on a reduced fat and calorie diet (~1200 kcal/day from 2 portion-controlled entrees, 3 low calorie high protein shakes, and 5 servings of fruits/vegetables daily), recommendation to exercise 225 minutes per week, and a weekly behavioral intervention. Fecal samples were collected at baseline, after 2 weeks of diet but prior to study agent, and after 6 months of weight loss intervention. Stool samples were stored at -20°C until brought to the clinic, and then at -80°C until DNA extraction. Bacterial taxonomic classification was performed using real-time PCR and 16S pyrosequencing using specific 16S rRNA primers. Baseline Healthy Eating Index (HEI) was calculated from the 3 day food record; fruit and vegetable servings were obtained from weekly food logs.

Results
42 women completed the 6 month weight loss intervention. At baseline, median BMI was 31.0 kg/m² and HEI was 58 (range 28-90) with 12 and 23 servings of fruits and vegetables per week. Median relative weight loss at 6 months was -11.9 % (0 to -22.7 %). When dichotomized to relative losses of <10% vs >10% (which we have previously shown to be associated with significant improvement in blood and breast tissue risk biomarkers [Fabian Cancer Prev Res 2013]), women with 6 month >10% loss had favorable change in the two major stool phyla at 2 weeks with a median 10% increase for *Bacteroidetes* and 8% decrease for *Firmicutes*. Conversely, women with <10% loss showed a decrease (median -11%) in *Bacteroidetes* and an increase (median 16%) for *Firmicutes*. Fruit and vegetable consumption also differed between the weight loss groups. The >10% loss group had higher baseline consumption of vegetables and continued this after starting the diet. The more adherent a woman was to dietary recommendations in the first weeks of dietary intervention, the more likely she was to lose >10% weight by 6 months.

Conclusions
Favorable modulation of the gut microbiome early in a weight loss intervention is associated with subsequent substantial weight loss. Microbiome assessment after 6 months of weight loss intervention is in progress.

Supported by a grant from the Breast Cancer Research Foundation and pilot funds from National Cancer Institute Cancer Center Support Grant P30 CA168524.
Title: Efficacy of *dipsacus asperoides* (DA) in a model for triple negative breast cancer

Telang NT, Nair HB B and Wong GYC YC. Palindrome Liaisons Consultants, Montvale, NJ; UT Health Science Center, San Antonio, TX and American Foundation for Chinese Medicine, New York, NY.

**Body: Background:** The triple negative breast cancer (TNBC) is characterized by the absence of estrogen receptor-α (ER-α), Progesterone receptor (PR) and human epidermal growth factor receptor-2 (HER-2). This molecular subtype responds only to conventional cytotoxic chemotherapy and to small molecule based targeted therapy. These therapeutic options are associated with long-term systemic toxicity and acquired tumor resistance leading to compromised efficacy. These limitations emphasize identification of efficacious non-toxic agents for secondary prevention/therapy of TNBC. *Dipsacus asperoides* (DA) is a Chinese herb of a nutritional nature. The root of this herb represents an ingredient that is commonly included in the traditional Chinese herbal formulations for health management purposes. The present study examines the growth inhibitory effects of DA and identifies possible mechanistic leads for their efficacy in a preclinical cell culture model for TNBC.

**Experimental Model, Herbal Extract and Biomarkers:** The human mammary carcinoma derived ER-α-, PR- and HER-2- MDA-MB-231 cell line represents the model for TNBC. Non-fractionated aqueous extract from DA represents the test agent. Anchorage dependent growth, anchorage independent (AI) colony formation, cell cycle progression and relevant pathway specific mechanistic assays represent the quantitative biomarkers for efficacy.

**Results:** Treatment of MDA-MB-231 cells with DA extract induces a dose dependent cytostatic growth arrest (IC$_{50}$: 0.0015%, IC$_{90}$: 0.0030%), and strongly inhibits AI colony formation. Within the cytostatic concentration range, DA treatment inhibits cell cycle progression via progressive G2/M arrest, suggesting abrogation of the G2/M checkpoint affecting DNA damage repair pathway. The induction of cellular apoptosis by DA is indicated by a dose dependent up-regulation of pro-apoptotic Caspase 3/7 activity.

**Conclusion:** These data identify potential mechanistic leads for the efficacy of DA in the present model. The present study validates a mechanism based approach to prioritize efficacious non-toxic herbal extracts for secondary prevention/therapy of the TNBC molecular subtype of clinical breast cancer.
**Title:** POWER-remote: A randomized study evaluating the effect of a remote-based weight loss program in women with early stage breast cancer

**Background:** The majority of women diagnosed with breast cancer are overweight or obese, and gain weight after diagnosis. The Practice-based Opportunities for Weight Reduction (POWER) study reported that, in an obese population with cardiovascular risk factors, a scalable remote weight loss intervention with web support was equally effective to an in-person intervention (Appel NEJM 2011). We adapted the remote intervention for breast cancer survivors.

**Methods:** We conducted a phase II single-blind trial in which women with stage 0-III breast cancer and a BMI ≥25 were randomized to a remotely-delivered weight loss intervention with a study specific website (POWER-remote) or to self-directed weight loss. Participants were stratified by menopausal status and concomitant hormone therapy use. Weight was assessed at baseline, 6 and 12 months. The primary objective was to compare the proportion of women who lost ≥5% of their baseline body weight after 6 months in the POWER-remote and the self-directed arms. A sample size of 80 patients yielded approximately 93.6% power to detect a difference in weight loss response of 19.0% in the self-directed arm and 38.2% in the POWER-remote arm with a one-sided type I error of 10%. We obtained blood samples for correlative studies including inflammatory biomarkers and assessment of telomere length at baseline and 6 months.

**Results:** From 2013-2015 we enrolled 96 women; 84 were evaluable for the primary analysis. Both cohorts had similar baseline characteristics including menopausal status, race (77% Caucasian and 20% African American in entire cohort), and BMI (average mean 32 kg/m2). The majority (93%) of patients received endocrine therapy, and 55% had completed chemotherapy. At 6 months 43.1% (95% CI 29.3–57.8) of women randomized to POWER-remote had lost ≥5% of their baseline body weight, compared to 11.1% (95% CI 3.7–24.1) in the self-directed arm, p<0.001. A significant difference continued at 12 months, and was observed in all subgroups (Table 1). Biomarker analysis will be presented at the meeting.

Conclusions: Sustained weight loss over 1 year is feasible in breast cancer survivors who undergo a remotely delivered weight loss intervention. Weight loss was observed irrespective of endocrine therapy or chemotherapy. These data will be used to design a new trial with a physical activity component.
Title: Cost-effectiveness of pre-implantation genetic diagnosis for BRCA mutation carriers

Lipton JH H, Wong WWL WL, Warner E, Greenblatt EM M, Lee EK K and Chan KKW KW.  Sunnybrook Odette Cancer Centre, Toronto, ON, Canada;  School of Pharmacy, University of Waterloo, Kitchener, ON, Canada and  Mount Sinai, Toronto, ON, Canada.

Body: Introduction: Management of BRCA mutation carriers is very expensive due to preventive surgeries and/or screening tests, as well as greater likelihood of cancer treatment. The related cancer burden and costs continue from generation to generation. One relatively new option for male or female BRCA mutation carriers, who wish to have children, is pre-implantation genetic diagnosis (PGD) of in vitro fertilized embryos. PGD eliminates the mutation from the descendants of these carriers. The purpose of this study was to model the cost-effectiveness of PGD.

Methods: We developed a Markov Model using TreeAge Pro 2016 and compared incidence of cancers, cancers-related death, costs, quality adjusted life-years (QALY), and incremental cost-effectiveness ratio (ICER) in the 2nd generation associated with conventional management of BRCA mutation carriers vs. PGD using a U.S. third-party payer's perspective with a lifetime horizon at a discount rate of 3% per year. In the model, health states were implemented to reflect the natural history of breast and ovarian cancer for women, and prostate cancer (and breast cancer in BRCA2 mutation carriers) for men. Model data were obtained from published literature. Costs were determined from published data and insurance payment schedules.

Results: Our preliminary results show that for BRCA1 mutation carriers, the PGD with IVF strategy is associated with an increase of 0.29 QALYs and costs an additional $292.68 per person, translating to an ICER of $1,014.25/QALY when compared with “No PGD”, making it highly cost-effective. For BRCA2 mutation carriers, the PGD with IVF strategy is associated with an increase of 0.17 QALYs and costs an additional $4,916.88 per person, translating to an ICER of $28,436.10/QALY when compared with “No PGD”, making it cost-effective.

Conclusion: PGD for both BRCA1 and BRCA2 mutation carriers reduces cancer burden, increases QALYs and, is very cost-effective in the 2nd generation cohort, making this an attractive option from the perspectives of patients and public payers. Our estimates are conservative because the cost-effectiveness of PGD will likely improve further if subsequent generations are included in the model, given the expected further reduction in cancer burden and associated cost-savings in subsequent generations.
Title: Investigating the use estrogen receptor β agonists in the prevention of breast cancer using a transgenic mouse model
Samayoa C, Krishnegowda NK K, Vadlamudi RK K and Tekmal RR R. University of Texas Health Science Center at San Antonio, San Antonio, TX.

Body: Breast cancer is the most common cancer among women worldwide. In the United States, 1 in 8 women will develop breast cancer during her lifetime, and in 2016 over 240,000 new cases will be diagnosed. Incidence rates differ by geographic location, with women living in Asia having the lowest rates. However, after migrating to the U.S and adopting a western diet their rates increase. This highlights the importance of lifestyle, including diet, in modulating breast cancer risk. Soy has been previously implicated as the dietary component contributing to the reduced breast cancer rates in Asian women. Compounds that can selectively activate Estrogen Receptor β have been identified in plants, including soy. Given the tumor-suppressive properties of ERβ, it may be possible to use these agonists in the chemoprevention of breast cancer.

The objective of this study was to investigate the utility of using ERβ agonists in the prevention of breast cancer using a transgenic mouse model. MMTV-HER2/neu mice develop premalignant lesions at 4-5 months, and tumors starting at month 7 due to overexpression of the Her2/neu proto-oncogene. MMTV-HER2/neu mice were treated with 2 different ERβ agonists, S-equol or LY500307, for 3 months and evaluated for branching, hyperplasia and differential gene expression. When compared to controls, ERβ agonist-treated mice exhibited a significant decrease in branching and ductal hyperplasia, with no change in body weight. Differential gene expression analysis revealed 218 modified genes in response to S-equol treatment, and 258 genes modified by LY500307 treatment, with an overlap of 36 genes. Pathway analysis identified an enrichment for chemokines signaling pathways, particularly TNF, in the reversal of hyperbranching resulting from treatment with ERβ agonists.

Although previous studies have demonstrated crosstalk between ER's non-genomic signaling and growth factor signal transductions pathway, this is the first study to demonstrate the impact of ERβ activation on HER2/neu mediated pre-neoplastic changes. Our study suggest that ER β agonist treatment may be a valuable therapeutic option for the chemoprevention of breast cancer in women at increased risk.
**Title:** Regulation of miRNA-29c and its gene targets in preneoplastic progression of triple negative breast cancer

Bhardwaj A, Tachibana K, Ganesan N, Rajapakse K, Singh H, Gunaratne P, Coarfa C and Bedrosian I. UT M.D. Anderson Cancer Center, Houston, TX; Baylor College of Medicine, Houston, TX and University of Houston, Houston, TX.

**Body: Introduction:** Little is understood about the early molecular drivers of the triple negative breast cancer making identification of women at risk and development of targeted therapy for prevention a significant challenge. **Methods:** Here, by deep sequencing of TNBC- cell line based breast cancer progression system we have identified miRNA-29c and its functional gene targets to be potentially involved in the normal to preneoplastic transition during TNBC progression. We have used cell line based functional assays that are relevant in early tumorigenesis such cell proliferation (ki67), and colony formation assay to study the growth inhibitory potential of these miRNA and their gene targets. To identify direct gene targets of miRNA-29c, we cloned the 3'untranslated region containing miRNA-29c binding sites from predicted gene targets in a luciferase reporter vector, pmiRGLO and studied the potential of miRNA-29c overexpression on the repression of luciferase reporter activity indicating their direct gene regulation. **Results:** Our deep sequencing results and their further validation by QPCR revealed miRNA-29c to be lost during the TNBC progression, and its forced expression to inhibit cell proliferation and colony formation of preneoplastic (MCF10AT1) and ductal carcinoma in situ (MCF10DCIS) cells. We found miRNA-29c to directly bind in 3'UTR of TGIF2, CREB5, AKT3 and CDK6 and regulate their expression as shown by our luciferase assays. We also found miRNA-29c binding to 3'UTR of these gene targets to be functionally relevant as TGIF2, CREB5 and AKT3 were able to rescue the inhibition in cell proliferation and colony formation assay caused by loss of miRNA-29c in preneoplastic cells. Further confirming the relevance of these miRNA-29c gene targets and pathways in TNBC tumorigenesis, inhibition of PI3K, which is upstream of AKT3, inhibits cell proliferation in MCF10AT1 and DCIS cells. We also examined the regulation of tumor suppressor miRNA-29c to study the mechanisms responsible for its loss during breast cancer development. We found c-myc and EZH2 driven epigenetic mechanism as well as DNA methylation in part to cause the loss of miRNA-29c during TNBC progression. Consistently, we found a pan HDAC inhibitor and a DNA methylation inhibitor to relieve the suppression of miRNA-29c. **Conclusions:** Together, these results indicate that loss of miRNA-29c plays a central role in preneoplastic development of breast cancer and efforts directed at inhibition of its target pathways or rescue of miRNA-29c itself may provide novel opportunities for prevention of TNBC.
Title: Molecular mediators of mammographic density

Ironside A, Hawkesford K, Gomm J, Haywood L, Goulding I, Wang J, Lamaziere A, Poirot M, Silvente-Poirot S, Chelala C and Jones JL. Centre for Tumour Biology, Barts Cancer Institute, London, United Kingdom; Centre for Molecular Oncology, Barts Cancer Institute, London, United Kingdom; Sterol Metabolism and Therapeutic Innovations, Cancer Research Center of Toulouse, INSERM UMR 1037, Toulouse, France and Sorbonne Universités-Université Pierre et Marie Curie-Paris 6, Paris, France.

Body: Introduction
Mammographic density (MD), created predominantly by increased stromal tissue, is a major risk factor for breast cancer, though little is known about the biological mechanisms mediating it. Tamoxifen prevents breast cancer in a subset of high-risk women via mechanisms that appear dependent on reduction of MD. Animal models suggest tamoxifen remodels the mammary stroma to a tumour-inhibitory phenotype. This study aims to analyse the effect of tamoxifen on human breast fibroblast function and identify pro-tumourigenic pathways contributing to the density-associated risk.

Methods
Primary human breast fibroblasts from normal, high risk or breast cancer patients were treated with hydroxytamoxifen (100nM-5μM), the active metabolite of tamoxifen. Fibroblast function was analysed by measuring: proliferation, expression of stromal proteins fibronectin and collagen 1; effects on TGF-β signalling via SMAD phosphorylation and upregulation of the myofibroblast marker SMA. Genome wide analysis was performed using RNA-Seq. Significantly deregulated pathways were validated by quantitative real time PCR, western blotting and mass spectrometry.

Results
Fibroblasts from 25 patients were treated with hydroxytamoxifen. All patients showed reduced proliferation with treatment. 62% of patients showed reduced fibronectin expression. Collagen 1 expression and TGF-β-mediated upregulation of SMA and fibronectin were consistently inhibited by tamoxifen.

RNA-Seq analysis revealed downregulation of Wnt signalling, an established pro-fibrogenic and pro-tumourigenic pathway, and other stromal signalling pathways including matrix/receptor interaction, focal adhesion signalling and collagen formation. Intriguingly, there was significant modulation of many metabolic pathways, including components of the microsomal anti-oestrogen binding site (AEBS).

Binding of tamoxifen to the AEBS inhibits cholesterol epoxide hydrolase (ChEH) enzyme activity, promoting an anti-tumourigenic phenotype. The effects of tamoxifen on fibroblasts could be replicated using tesmilifene, a commercially available inhibitor of ChEH. Mass spectrometry analysis confirmed an altered cholesterol metabolite profile in the tamoxifen treated fibroblasts.

Conclusion
These data indicate that tamoxifen can directly remodel the mammary stromal microenvironment, generating a less ‘reactive’ stroma. Thus, tamoxifen impacts on multiple pathways, many independent of the oestrogen receptor, to create a tumour-inhibitory microenvironment. This offers exciting potential for patient monitoring and alternative breast cancer prevention strategies.
Evaluation of miracle mouthwash (MMW) plus hydrocortisone or prednisolone mouth rinses as prophylaxis for everolimus-associated stomatitis: Results of a randomized phase II study

Jones VE E, McIntyre KJ J, Paul D, Wilks ST T, Ondreyco SM M, Sedlacek SM M, Melnyk Jr. AM M, Oommen SP P, Wang Y and O'Shaughnessy JA A. US Oncology Research, Inc., The Woodlands, TX; Yakima Valley Memorial Hospital/North Star Lodge, Yakima, WA; Texas Oncology, Dallas, TX; Rocky Mountain Cancer Centers, Denver, CO; Texas Oncology, San Antonio, TX; Arizona Oncology, Glendale, AZ; Texas Oncology, Abilene, TX; Texas Oncology, Fort Worth, TX; McKesson Specialty Health, Inc., The Woodlands, TX and Texas Oncology/Baylor-Charles A. Sammons Cancer Center, Dallas, TX.

Background: Oral stomatitis is a frequent adverse event (AE) associated with mTOR-inhibitor therapy, and can impact adherence. In BOLERO-2, patients (pts) with hormone receptor-positive (HR+) metastatic breast cancer (MBC) treated with exemestane plus everolimus (EVE), the incidence of all-grade (G) stomatitis or related AEs was 67%, with 24%/8% of pts developing G2/G3 stomatitis or related AEs, respectively (Perez et al ASCO 2013 Abs 7029). In BOLERO-2, 24% of pts required EVE dose reduction for stomatitis (Rugo et al Ann Oncol 2014;25:808). This study evaluated 2 steroid-based mouth rinses for the prevention or amelioration of oral stomatitis in pts with MBC treated with EVE.

Methods: This prospective randomized phase II study enrolled postmenopausal pts (planned accrual=100) with HR+ MBC within the US Oncology Network who were initiating therapy with an aromatase inhibitor plus EVE (10 mg/day)(AIE). Pts were randomized 1:1 to prophylactic therapy with 1 of 2 oral rinses (ARM 1: MMW 480 ml recipe: 320 mL oral Benadryl, 2 g Tetracycline, 80 mg Hydrocortisone, 40 mL Nystatin suspension, water; or ARM 2: Prednisolone (P) 15mg/5mL oral solution, 1.8% alcohol). Pts were instructed to swish/expectorate 10 ml of the assigned rinse 4x daily starting with D1 of EVE treatment, for a total of 12 wks. The primary objective was to determine the incidence of G≥2 stomatitis or related oral AEs during the first 12 wks of treatment. Based on a historical estimate that ≥37% of pts receiving AIE develop G≥2 stomatitis, 50 pts for each arm were required to detect a reduction of the incidence of G≥2 stomatitis from 37% to <20%, with alpha = 0.05, 80% power, and a 1-sided test. Secondary objectives included assessment of AEs (all grades), determination of the percentage of pts requiring dose interruption/reduction of EVE or discontinuation of therapy due to toxicity, and evaluation of the impact of the oral rinses on the duration and severity of stomatitis.

Results: As of 5/30/2016, a total of 104 pts have been randomized and 100 pts have received treatment (49 MMW; 51 P). Median age was 61 yrs (range 31-82 yrs). The incidence of stomatitis and related oral AEs (any grade) during the first 12 wks was 29% (n=14/49) and 27.5% (14/51) in the MMW and P arms respectively. The incidence of G2 oral AEs was 12% (6/49) and 8% (4/51) with MMW and P respectively. There was only 1 G3 oral AE (MMW arm), and no G4 events. There was 1 EVE dose reduction (MMW) and 4 EVE dose delays (3 MMW, 1 P) during the first 12 wks of treatment. No pts stopped the steroid mouth rinse therapy due to mouth rinse-related toxicity. Conclusion: These prospective data provide evidence of a reduced incidence of mTOR-associated oral AEs with prophylactic use of a steroid mouth rinse. The 29%/27.5% incidence of all-grade and 12%/8% incidence of G2 oral AEs, with only 1 G3 event, compare favorably with the 67% and 24%/8% incidence of all-grade and G2/3 stomatitis, respectively, in BOLERO-2. These data also show the safety and tolerability of these 2 steroid mouth rinses. Prophylactic use of steroid mouth rinses substantially decreases the incidence of G2/3 stomatitis and the need for EVE dose modifications.

Title: YSC's "shady pink elephant" end of life series

Esser MR R, Rowe J, Schapmire T and Lewis S. Young Survival Coalition, New York, NY and University of Louisville, Louisville, KY.

Body: Background
Young Survival Coalition (YSC) is the premier organization dedicated to the critical issues confronted by young women diagnosed with breast cancer. Young women diagnosed with metastatic breast cancer (YWMBC) in particular, face unique concerns. As a result of a large survey to its metastatic constituency from September 2013 through February 2014, YSC gained important information about the lack of knowledge and education when it comes to end of life (EOL) planning and decisions. The survey was a result of YSC's Research Think Tank, which included a metastasis work group that identified the psychosocial needs of YWMBC as a priority.

Based on the results of this survey which showed 71% of YWMBC had not made EOL plans, YSC decided that offering education and tools regarding EOL was an important intervention to offer. In doing so, young women affected by breast cancer, young adult cancer survivors, co-survivors and healthcare providers will be better prepared to have difficult conversations by allowing stigma to be removed, intentions to be shared, and plans to be made, all to honor the young woman's wishes.

Methods
YSC created a three part end-of-life series called the “Shady Pink Elephant.” (hereinafter “Series”) Each part featured a subject matter expert and was offered as a Facebook event where the speaker was live-streamed and recorded. YSC also offered free continuing education credits for nurses and social workers. The recorded events are stored on YSC's YouTube channel as enduring material. The three parts include: (a) The Research and Benefit of Introducing Palliative Care Early; (b) Let's Have Dinner and Talk about Death; and (c) The “Nuts and Bolts” of End of Life Planning. YSC collaborated with the University of Louisville and received IRB approval to study the entire series as intervention. The study is in process and will conclude later in 2016.

Results
Nine participated in Series Part One of the live event. For Series Part Two, 31 participated in the live event. In the third and final part, 33 participated in the live event. The three parts housed on YSC's YouTube channel have been viewed a total of 747 times to date: 411 views for part one, 156 views for part two and 180 for part three. Thirty-three sought continuing education credit. Fourteen social workers and 5 nurses contacted the approving organization to receive continuing education credit for Series Part One, and 10 social workers and 1 nurse contacted the approving organization to receive continuing education credit for Series Part Three.

Conclusions
Live-streamed, recorded Facebook events are a novel and forward-thinking mode of programmatic offering. YSC learned through this process that live-streamed events are a feasible way to offer programming that reaches a larger and broader audience of young women affected by breast cancer and their loved ones.
Title: Design, implementation and evaluation of a smoking cessation intervention for patients undergoing breast cancer surgery

Nolan M, Ghosh K and Warner DO O. Mayo Clinic, Rochester, MN.

Body: Introduction:
Smoking is a risk factor for poor outcomes following breast reconstructive surgery, including wound dehiscence and infection. Women who would choose to have reconstructive surgery after mastectomy for breast cancer are unable to do so if they have not quit smoking. The specific aims of this project are to 1) design and implement an intervention to assist these patients in quitting and 2) evaluate its efficacy.

Methods:
Baseline data regarding current practices was collected via a chart review of 75 smoking breast cancer surgery patients from 1/1/2012-12/31/13. Charts were analyzed for documentation of smoking status, quit advice, resources provided and used, and smoking status at follow-up. Formative research informed the design of an Ask-Advise-Refer intervention for all new breast cancer patients seen at Mayo Clinic.

Intervention Design:
Smoking patients were identified prior to their initial Breast Cancer evaluation at Mayo Clinic, Rochester, during a standard intake call. Smoking status was documented by the rooming assistant to alert the physicians of smoking status, and physicians asked these patients about their smoking behavior, discussed the risks of smoking both for surgical procedures and breast cancer, and offered a Nicotine Dependence Consultation with a tobacco treatment specialist in an “opt-out” strategy that emphasized the importance of smoking cessation as part of the breast cancer treatment process. The advice and referral was documented in the medical record. Evaluation of the intervention was performed via a chart review of patients seen after one year of implementation.

Intervention Evaluation Results:
Breast clinic physicians documented smoking status in all patients seen after implementation. Referral to the Nicotine Dependence Center for cessation counseling increased from 29% (22/75) to 74% (20/27). Among those referred, attendance at the consultation increased from 41% (9/22) to 75% (15/20), suggesting stronger provider encouragement of cessation services. 30-day abstinence rates for those who attended a consult prior to 5/1/16 were 46% (6/13), which is consistent with baseline data.

Conclusions:
An Ask-Advise-Refer intervention for new breast cancer patients seen at Mayo Clinic, Rochester, who report current smoking, has been associated with higher rates of provider counseling on tobacco dependence, referral to available services, and patient attendance at referrals. Attending a referral greatly increases a patient's chances of quitting smoking for at least 30 days compared to average spontaneous quit rates in this population. This model is low-cost, time-efficient for providers, and applicable to most practice settings. Finding ways to make this intervention self-sustaining and applicable to multiple other practices could greatly improve our patient's health outcomes.

Title: Global Cancer Institute online tumor boards to improve global patterns of clinical practice for breast cancer

St. Louis J, Bukowski A, Paulino E, Ferreyra ME E, Nunes J, Mejia G, Duarte C, Ruiz R, Touya D, Polo S, Chavarri-Guerra Y, Moreno J, Georgieva N, Tsoyko T, Obayedullah Baki M, Luna HC C and Goss PE E. The Global Cancer Institute, Boston, MA; Massachusetts General Hospital Cancer Center, Boston, MA; Instituto Nacional do Câncer, Rio de Janeiro, RJ, Brazil; Harvard Medical School, Boston, MA; Marie Curie Hospital, Buenos Aires, Argentina; Hospital Erasto Gaertner, Curitiba, Brazil; Hospital Clinico Viedma, Cochabamba, Bolivia; Institution Nacional de Cancerologia, Bogota, Colombia; Instituto Nacional de Enfermedades Neoplásicas, Lima, Peru; Hospital de Clinicas, Montevideo, Uruguay; INCAN, Guatemala City, Guatemala; Instituto Nacional de Ciencias y Nutrition Salvador Zubiran, Mexico D.F., Mexico; Instituto Oncologico Nacional, Panama City, Panama; MHAT Nadezhda, Sofia, Bulgaria; Lviv State Oncological Regional Centre, Lviv, Ukraine; Obayedullah-Ferdousi Cancer Foundation, Dhaka, Bangladesh and National Kidney and Transplant Institute, Quezon City, Manila, Philippines.

Body: Background: The Global Cancer Institute (GCI) breast cancer multi-disciplinary tumor boards (MTBs) are live, online telemedicine discussions of breast cancer patient case scenarios between breast cancer specialists in low- and middle-income countries (LMICs) and expert breast cancer specialists in the United States (US). In the US MTBs are routinely held in most cancer centers and have been shown to improve patient outcomes and patient and family quality of life. GCI launched breast cancer MTBs in 2012 with the goals to improve breast cancer patient care in underserved populations globally, to establish an online platform to allow live communication and collaboration among oncologists, and to serve as an educational tool for oncologists.

Methods: During our MTBs case scenarios are presented by global oncologists for discussion and input by a panel of both community/tertiary care expert breast oncologists from our global network. During each MTB, three cancer centers present challenging breast cancer patient scenarios. Patient scenarios are presented in English, according to a standard PowerPoint template. After presentation guideline - or clinical trial-based discussions are held for each case. As the patient cases originate from oncologists in LMICs, optimal and best locally available clinical care in rural and remote settings are discussed. For educational purposes the MTBs and the associated YouTube panel discussions are archived online and can subsequently be viewed by practicing oncologists and trainees globally. Links to relevant international guidelines, published and ongoing clinical trials, and other educational resources are also provided to all MTB attendees.

Results: Since its initiation in 2012, the GCI MTBs have engaged a network of 370 oncologists in LMICs and 20 expert panelists from nine cancer centers in the United States. Together the oncologists in LMICs represent 28 tertiary cancer centers and 116 community oncologists in 19 countries across Latin America, Eastern Europe, Asia, and Africa.

Conclusions: GCI breast cancer MTBs are a powerful educational and networking tool for oncologists in LMICs to improve their patterns of clinical practice, conduct multi-disciplinary discussions and access research collaborations. GCI invites oncologists throughout Latin America, Europe, Asia, and Africa to join our tumor boards and further expansion of its MTB network. GCI currently surveys oncologists in our network before and after attendance of MTBs to measure modifications in oncologists’ practice and adherence to international clinical practice guidelines.

Title: Results of the continuing education program in oncoplasty and breast reconstruction of the Brazilian Society of Mastology at Araujo Jorge Hospital in Goiania

Paulinelli RR R, Filho JWCM C M, Ribeiro LFJ J, Freitas-Junior R and Urban CA A. Hospital Araujo Jorge, ACCG, Goiania, GO, Brazil; Federal University of Goias, Goiania, GO, Brazil; Positivo University, Curitiba, PR, Brazil and Hospital Nossa Senhora das Graças, Curitiba, PR, Brazil.

Body: Oncoplastic and reconstructive surgery is an important part of the treatment of breast cancer. In Brazil there is a specialization in Mastology since 1978, fully dedicated to manage all diseases of the breast. There are 2 years of specific residence training, after specialization in General Surgery or Gynecology. Incorporation of the reconstructive surgery is not uniform among all Breast Units around Brazil. Therefore, the Brazilian Society of Mastology has created an official program of continuing education. **Objective**: To evaluate the effectiveness of a Hands On Educational Program in Oncoplasty and Breast Reconstruction of the Brazilian Society of Mastology at the Hospital Araújo Jorge, in Goiânia, in 2015. **Materials and Methods**: Twelve mastologists were selected as trainees, based on the curriculum score. The program was divided into 10 monthly modules of two days (24h), with 25% of theory and a 75% of surgery. Activities were coordinated by two local and two invited teachers. The effectiveness was measured via an on-line questionnaire. To measure the improvement in medical practice it was used the modified classification of Urban and Lebovic, for the complexity of the reconstructive procedures. They were considered as class 1: monolateral partial reconstructions, esthetic incisions, periareolar de-epidermization, local reshaping; class 2: bilateral procedures, nipple-areolar reconstruction, lipofilling, breast augmentation, mastopexy; class 3: reconstruction with expanders or implants; class 4: myocutaneous flaps. Statistical analysis was performed by SPSS. It was significant a p<0.05. Results: Twelve mastologists participated, with a mean age of 42.92 (+10.27). They performed 213 procedures, in 88 patients, using the main techniques for breast reconstruction. All students declared themselves satisfied with the course and they would indicate it to others. At the beginning, most students had some experience in local flaps. Half of the students referred trouble in finding other colleagues that could perform the reconstructions. At the end, most students declared themselves confortable to perform partial or total reconstruction of the breast with local flaps, mammaplasties, fat grafting, expanders and implants. Most of them were comfortable to resolve their own complications. More than a third were safe in performing miocutaneous flaps. All mastologists said to be interested in continuing technical improvement in different ways.

Conclusion: The current program in Goiania benefited many patients and brought a great contribution to the training of the participants.
Title: A school-based breast health (BH) educational program to increase breast cancer awareness in a rural Mexican community: A qualitative comparative analysis of students’, relatives’ and teachers’ perceptions

Soto-Perez-de-Celis E, Rojo-Castillo MP and Chavarri-Guerra Y. Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Tlalpan, Mexico City, Mexico and Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Tlalpan, Mexico City, Mexico.

Body: Background: In order to increase breast cancer awareness, we implemented a school-based educational program for female adolescents in a rural Mexican community, aimed at increasing knowledge and promoting intergenerational transmission of information to their female relatives. Here we report the perspective of the students, their female relatives and the school teachers on the program's impact on the adolescents and their community, as well as the major emergent themes related its implementation.

Methods: Adolescents enrolled in a public rural Mexican middle school were invited to participate in the program. They received age-appropriate, culturally sensitive sessions from expert educators focused on transmitting BH knowledge in their household. The students’ opinions of the program were evaluated using open ended questions immediately after its completion. The opinion of the students’ female family members and of the school teachers were recorded four months after the intervention using open ended surveys and semi-structured interviews. The interviews were conducted at the school by two oncologists who designed and implemented the program and were recorded in video and audio formats. Data was coded using a narrative research approach, and a constructivist paradigm was used to explore emerging themes. NVivo software was used for qualitative data analysis.

Results: The surveys were answered by 126 students, 185 family members and 18 teachers. Seven teachers then participated in semi-structured interviews. The following major themes were identified as related with the BH educational program by students: (1) the importance of breast self-examination; (2) the power obtained through knowledge and learning; and (3) the importance of disseminating the obtained information. The following major themes were identified by female relatives: (1) the importance of disease prevention; (2) knowledge to perform self-examination and seek medical attention and (3) empowerment through information. An analysis of the teachers’ opinions identified the following major themes: (1) the program aided in discussing intimate topics; (2) the relevance of disseminating information in the community; (3) training other teachers and survivors for implementation; and (4) the importance of the acquisition of new knowledge. The relevance of obtaining and disseminating new knowledge was a common emerging theme among the three groups. Interestingly, both the students and their relatives highlighted the power of knowledge in empowering women and allowing them to prevent diseases and take care of their own health.

Conclusions: Obtaining feedback from the relevant stakeholders and promoting active participation of the community is essential for the implementation of successful school-based education programs in cancer. We identified relevant themes related to BH education which could be useful for designing and implementing future programs. Providing adolescents from underserved populations with new knowledge and tools to take care of their health can empower them and aid them not only in preventing disease but in disseminating that knowledge in their communities.
Title: First posts: A content analysis of an online breast cancer community user's initial postings

Body: Introduction: Online breast cancer communities provide users with both information and emotional support. Members of these communities include both patients and caregivers. We aimed to characterize the differences in content between patients' and caregivers' first posts.

Methods: 20189 posts were downloaded from a public online breast cancer community. Posts were sorted by user name and date to identify unique posters and coded for user demographics and content. Descriptive statistics (e.g. chi-square test) characterized differences between patients and caregivers in terms of topics and content.

Results: Of the 1827 unique posters, 83% were identified as the patient (n=1277, 70%) and 13% were identified as a caregiver (n=230). 835 (69%) patients had been previously diagnosed with breast cancer. Chemotherapy was the most common topic among cancer patients.

Breast Cancer Patients' Topics of Conversation

<td>“I was allergic to some of the chemo meds”</td>
</tr>
<tr>
<td>Radiation</td>
<td>255 (31)</td>
<td>Patients discussing the decision for radiation, or their experiences with it.</td>
<td>“I wanted to answer your query about radiation…”</td>
</tr>
<tr>
<td>Estrogen Modulating Therapy</td>
<td>156 (19)</td>
<td>Patients discussing the decision to take estrogen modulating medications (e.g. Tamoxifen) or their experiences with it.</td>
<td>“I don't know if I'm going to take this with all the side effects I read.”</td>
</tr>
<tr>
<td>Surgery</td>
<td>55 (7)</td>
<td>Patients discussing surgical options for breast cancer treatment (not reconstruction) or experiences with the procedures.</td>
<td>“I don't want them to leave half of my breast with a chance for a new diagnosis”</td>
</tr>
<tr>
<td>Reconstruction</td>
<td>49 (6)</td>
<td>Patients discussing reconstruction options or experiences with the procedures.</td>
<td>“I recently had a TE recon and it went fine but a week later i developed an infection…”</td>
</tr>
</tbody>
</table>

Patients tended to seek information about physical concerns more often than psychosocial concerns.

Thematic Content of Posts: Patients v. Caregivers

<table>
<thead>
<tr>
<th>Domain</th>
<th>Patients n(%)</th>
<th>Caregivers n(%)</th>
<th>Chi-Square p-value</th>
<th>Explanation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discussing Physical Issues</td>
<td>234 (29)</td>
<td>25 (11)</td>
<td>&lt;.001</td>
<td>Discussing physical symptoms as a result of cancer or treatment.</td>
<td>“I was allergic to some of the chemo meds”</td>
</tr>
<tr>
<td>Seeking Emotional Support</td>
<td>113 (14)</td>
<td>34 (15)</td>
<td>&lt;.001</td>
<td>Poster discusses feeling upset, or directly asks for support.</td>
<td>“Thanks for listening to my pity party…”</td>
</tr>
<tr>
<td>Discussing Psychosocial</td>
<td>89 (11)</td>
<td>21 (9)</td>
<td>.165</td>
<td>Poster mentions psychological issues including depression or anxiety, or with</td>
<td>“I also found help through the use of an antidepressant…”</td>
</tr>
</tbody>
</table>

In contrast, caregivers used the community significantly more often as a source of emotional support ($p<.001$), although they also sought information on how to best support patients.

Conclusion: First post content varied depending on if the poster was a patient or a caregiver. Patients' first posts were often information-seeking about physical concerns, whereas caregivers tended to use the forum as a source of emotional support. By analyzing the frequency of topics and content of posts, clinicians may better understand the educational needs of patients and caregivers.
Title: Waiting for Treatment: Addressing Inequities in access to essential medications for metastatic breast cancer

Faucette C. Canadian Breast Cancer Network (CBCN), Ottawa, ON, Canada.

Body: Introduction:
Of the women in Canada diagnosed with breast cancer each year, 5% will have an initial diagnosis of metastatic breast cancer and many more will recur with metastatic disease. Despite global advancements in metastatic breast cancer, access to new drugs in Canada remains inequitable.

Objective:
To examine the present situation in Canada for drug approval and decision-making by provinces and territories around new metastatic drugs and to assess processes in the system causing the greatest lags, the range in wait times for new treatments by province and the jurisdictions most affected by wait time delays.

Methodology:
- A bilingual survey in spring 2015, focusing on access to metastatic treatments across Canada. 98 women responded to the survey from all Canadian jurisdictions except Yukon.

Results:
Systemic Delays:
Patients endure 1-2 years for drugs to be approved for sale in Canada and further delays in access through the pCODR, pCPA and provincial drug assessment processes. The longest delays occur at the provincial review stage.

Inequitable Access to Treatments across Provinces:
Lack of firm deadlines for the provinces to list a drug on their formulary once a drug has been approved pricing negotiated. Often a 2-year time lag or longer between provinces in making reimbursement decisions, resulting in inequitable access across the country.

Line Sequencing Access Delays:
Further limitations on access created by the restrictions that provinces place on when drugs can be used in the course of treatment. Formularies often cover older drugs that are less costly, and as such it is a challenge to secure coverage of newer therapies.

Conclusion:
Wait time delays create a significant barrier to patients receiving optimal treatment and care. Metastatic patients are forced to endure wait time delays of 2-4 years before accessing new treatments. These delays occur at nearly every stage of the approval process, with the greatest waits occurring at the provincial level.
Lags in treatment access across the country also have an impact on standards of care. Patients in provinces with timely approvals, have access to more treatment options than those in provinces where patients must wait for new treatments to be added to the formulary.
Lengthy wait times for new treatments complicate a patient's prognosis. Slowing the progression of their disease and maintaining a better quality of life is of critical concern and metastatic patients with urgent treatment needs cannot wait for new treatments to become publicly accessible. For these patients, expedited access to a diversity of treatment options can make all the difference in ensuring optimal health outcomes and improved quality of life.
Title: Peer navigation for people affected by hereditary breast, ovarian and related cancers: Results from the first six months

Rezende LF F, Cohen S, Rose D and Friedman SJ J. FORCE - Facing Our Risk of Cancer Empowered, Tampa, FL.

Body: People affected by hereditary breast, ovarian, and related cancers (HBOC) due to a mutation in BRCA, or another gene that increases cancer risk, have unique support and information needs and face medical decisions that differ from survivors of sporadic breast cancer and from people at average risk for these cancers. Finding peers to talk to can be challenging, especially for people living outside of metropolitan areas.

FORCE (Facing Our Risk of Cancer Empowered) developed our Peer Navigation Program to provide personalized, expert-reviewed resources and 1:1 support for people affected by HBOC, including breast cancer survivors and people at high risk for breast cancer due to a mutation in BRCA or another gene that increases cancer risk.

The program utilizes a custom database that matches individuals seeking support with trained Peer Navigators who have faced similar medical challenges and decisions. Users complete an intake form, providing basic demographic, medical, and geographic information in order to match them as closely as possible to a peer volunteer. The user selects from 21 specific topics of interest to them. This generates a personalized, expert-reviewed resource guide on each selected topic, which individuals can use to make informed, shared decisions with their healthcare providers.

Trained Peer Navigators conduct one-hour phone calls with program users to discuss the personalized resources and provide non-judgmental emotional support. Our goal is to match users and complete the navigation process within one week from the time they submitted their intake form. After a navigation session, both the Peer Navigator and the program participant are asked to fill out an evaluation.

All Peer Navigator volunteers undergo a written and telephone interview to assure their readiness to help others. Once they pass this screening process, they complete a series of online VolunteerFORCE Academy training webinars and complete a profile form providing information about their demographics, personal and medical situation, and medical decisions.

Volunteers receive training on the following: FORCE 101, HBOC 101, Active Listening Skills and Peer Navigation instructions. All webinars have been reviewed and approved by a member of FORCE's Scientific Advisory Board and our Vice President of Education. The webinars stress several important themes, including: encouraging users to discuss information with medical experts, avoiding dispensing of personal or medical advice, and maintaining a non-judgmental perspective.

We have 104 trained peer navigators, both male and female, ranging in age from 21 – 73. Both cancer survivors, as well as high-risk individuals are represented. Peer volunteers come from diverse backgrounds and geographic locations, and have made a variety of medical decisions about genetic testing, cancer screening, chemoprevention, and risk-reducing surgeries.

The program launched in April 2016. We will present results from post-call evaluation surveys completed from April 1, 2016 through September 30, 2016. Data on most commonly requested topics, user satisfaction, ease of use, and intention to use the information in shared decision-making with their health care provider will be presented.
Title: Measuring what is important to patients in clinical trials: Hearing the patient's voice

Body: Patients who participate in clinical trials are important to clinical research and contribute to the advancement of medical discoveries. However, typical clinical trials do not always capture information that is important to patients: how they feel, function and survive. The only way to accurately measure how a patient feels or functions is to ask them. This can be done through the administration of health related questionnaires that are filled out by the patient without interpretation from anyone else; these are referred to as Patient Reported Outcomes (PROs). Although, PRO assessments have been used in clinical trials for the past 30 years through the collection of global quality of life (QOL) and later health related QOL (HR-QOL) measurements, the information has been too broad and has not been precise enough to use in drug approvals, descriptive drug label information or to inform other patients.

There is an effort to change the paradigm of PRO assessment to measure the information most relevant to patients in clinical trials. This includes measuring treatment toxicity, symptom burden and physical function. This is relevant information that other patients want to know about a specific treatment for a specific disease to help them in their treatment decision making. The voice of the patient is critical to assess these items, through PRO measurements. In order to ensure that PRO questionnaires are filled out during a clinical trial, there are ways to make them more acceptable to patients by involving patients in their development (what questions are asked/how many questions are asked/when they are given to patients/how they are given to patients).

Patients can inform study teams on the acceptability, understandability and relevance of the questions being asked. Patients can be a key contributor to clinical trial development by identifying the questions that are most important to them and the best way to ask these questions during a clinical trial.

Patient advocacy and educational organizations like Cancer Information & Support Network (CISN) are advocating for changes in PRO collection in clinical trials. Based on information collected from many survivors, caregivers and advocates, a patient-centric clinical trial development model will be proposed. The model includes the involvement of patients as key stakeholders early in clinical trial development to incorporate PROs into clinical trials that are acceptable for patients to complete and the outcomes are meaningful and matter to future patients.

Title: The advocates in science (AIS), a research advocacy program of Susan G. Komen®

Spears PA A, Finestone S, Jernigan C, Johnson P, Johnson J, Durham K, Wright K and Sabelko KA A. Susan G. Komen, Dallas, TX.

Body: Susan G. Komen® has a longstanding commitment to ensure that the unique and valuable perspectives of breast cancer patients, survivors, and co-survivors are integrated into the scientific dialogue and decisions impacting Komen's progress toward ending breast cancer. Komen established the Advocates in Science (AIS) Program to build a cadre of skilled, knowledgeable and broadly-networked breast cancer research advocates and engage patient advocates throughout the research process, where they provide a real-world understanding of what matters most to patients and a sense of urgency to find more-effective ways to prevent, diagnose, treat, and ultimately cure breast cancer.

The AIS Program, overseen by an AIS Steering Committee, takes a multi-pronged approach to research advocacy that includes the following components:

**Involvement in Komen's Research Grant Strategy and Peer Review:** Through the AIS Program, Komen matches advocates to Komen activities that best fit their training, experience and preference. A few of our most experienced breast cancer advocates serve on Komen advisory boards, providing strategic guidance and input on the research grant focus, and many others participate as advocate reviewers of our research grants.

**Engagement of Advocates in Komen-funded Research Projects:** Advocate involvement is required in most Komen-funded grants and strongly encouraged in all other Komen-funded research projects. Through the Program, Komen has created several tools – some aimed toward advocates and others targeted toward researchers – to facilitate effective advocate engagement in research projects.

**Education & Training:** Komen is committed to developing the next generation of breast cancer research advocates and strengthening the skills and knowledge of all AIS members. The AIS Program provides opportunities for advocates to learn more about breast cancer research and strengthen their research advocacy skills through a variety of educational sessions and rigorous training programs. These sessions/programs vary in format, from online tools, webinars, face-to-face meetings, and peer-to-peer mentoring.

**Communication:** The AIS Update keeps advocates up-to-date on recent scientific advances in breast cancer; Komen's research and its impact; and upcoming educational and participation opportunities for advocates both within Komen and nationally. Engaging patient advocates is increasingly being recognized as a fundamental factor in developing, implementing, and overseeing research that more effectively meets patients' needs. With its rich and growing experience in research advocacy, Komen is one of the pioneers of “patient-centric” research programs. Through the AIS Program, Komen continues to build a cadre of knowledgeable and experienced research advocates who bring the patient voice to Komen's — and other organizations'—research programs, in all areas of breast cancer research from the bench to the bedside to the curbside and back.

AIS members are also active in their communities and serving as bridges between advocates, scientists and Komen Affiliates to enhance understanding and excitement about research; foster greater support for research and its funding; build stronger researcher<->community connections; and energize hope for finding cures.
Title: Male breast cancer— infusing a little blue into the sea of pink

Wagner H and Boyages J. A Man's Pink (Male Breast Cancer Advocacy Organization), Brooksville, FL and Macquarie University, Sydney, NSW, Australia.

Body: Male breast cancer (MBC) is a rare disease dominated by a sea of pink. Issues faced by men with this disease include delayed diagnosis, lack of male-specific information, stigma about having a "female disease" and often under-treatment. MBC is often treated as a female breast cancer but differences between the two are starting to emerge. Men are often older at diagnosis and sometimes considered "too old" for more aggressive treatments such as chemotherapy. Drugs such as aromatase inhibitors may not be as effective in men as in women but are often prescribed. Drugs such as tamoxifen can cause side-effects such as weight gain, hot flushes, loss of libido and impotence.

Support for patients with MBC is less advanced than that for female breast cancer. A Man's Pink, a MBC advocacy organization, mission is to promote MBC awareness, increase early detection, optimize and increase the survival rates for men diagnosed with breast cancer. Male Breast Cancer: Taking Control (BC Publishing, Boyages, 2015) empowers patients to understand their diagnosis and treatment. Apart from incidence data, prognosis and treatment options, this talk will focus on how a website (www.malebreastcancer.ca) dedicated to MBC can help dismiss some of the myths and help overcome stigmata for men facing difficulties at diagnosis, treatment and recovery.

Our goal is to promote awareness to assist with earlier diagnosis and treatment to improve survival rates and the journey for men in their battle with breast cancer.
Title: Non-metastatic and metastatic breast cancer patients' priorities when considering a treatment decision

Body: Introduction: Health care value is of increasing importance in light of rising health care costs. Several frameworks have been developed to measure value in cancer care. Yet, the patient perspective of value is not fully understood or integrated into such measurement. Understanding patient priorities when deciding upon treatment would contribute to effectively measuring and communicating value. To contribute further to patient perspective on value, we examined patient priorities when deciding upon treatment between non-metastatic breast (BC) and metastatic breast (MBC) cancer patients. We focused on these populations to explore if differences exist among populations likely to experience differences in care and related costs due to differing trajectories. Methods: From April-May 2016, 221 BC and 91 MBC survivors in the online Cancer Experience Registry answered questions about treatment decision-making. Using a 5-point Likert scale (not at all to very much), respondents rated the importance of (1) financial cost of care, (2) length of life (LoL), (3) quality of life (QoL), and (4) impact on family, when making a treatment decision. They also ranked the same factors in order of importance (1 most to 4 least important). Finally, they considered two factors at a time indicating which had greater impact on their decision. Chi$^2$, independent t-tests and Wilcoxon rank-sum tests were used to investigate differences between BC and MBC. If there were no significant differences, combined results are presented. Results: Participants were median age 56 y; 88% non-Hispanic white. Characteristics differed significantly between BC and MBC: 41% and 31%, respectively, working full-time; 8% and 31% on disability; 35% and 50% income<$60K; and median time since diagnosis 3 y and 4.5 y. The greatest proportion of registrants (80%) indicated QoL was “very much” important when deciding upon treatment followed by LoL (59%), family impact (56%), and cost (23%). The mean (±SD) rank score of factors corroborated the order of importance: QoL (1.6±0.9); LoL (2.1±1.0); family impact (2.3±1.0); and cost (3.1±1.2). When making pairwise comparisons between QoL, LoL, and cost, 40% of BC survivors indicated LoL was much more important than cost vs. 52% among MBC (chi$^2$=4.1, p=0.042), and 61% of BC indicated QoL was much more important than cost vs. 72% among MBC (chi$^2$=3.6, p=0.058). Conclusion/Implications: When considering treatment, BC and MBC patients prioritized QoL suggesting the need for conversations with clinicians to focus on QoL among other factors. Both BC and MBC patients gave less priority to cost than other factors. Interestingly, MBC patients placed an even greater emphasis than BC patients on QoL and LoL relative to cost. Given the rising cost of care, healthcare teams may also need to prompt discussions around potential financial toxicity particularly among a population likely to be faced with long-term costs such as MBC. Future research should explore how to develop, evaluate and implement evidence-based tools that enhance doctor-patient communication around QoL and cost.
Title: Young women with early stage breast cancer and their supportive care needs: Results from a regional survey

Ratcliffe J, Hodgson N, Rana P, Levine M and Sussman J. McMaster University, Hamilton, ON, Canada and Hamilton Health Sciences, Juravinski Cancer Centre, Hamilton, ON, Canada.

Body: Background
Approximately 18% of all newly diagnosed breast cancer cases in Canada occur in women less than 50 years of age. Young women with breast cancer (YWBC) may experience unique physical and psycho-social issues yet there is a lack of data outlining their specific needs and concerns across the trajectory of care. This study described the unmet supportive care needs of YWBC at a regional cancer centre in southern Ontario, Canada.

Objectives
1. To describe unmet supportive care needs of young women (<45 years) with early stage breast cancer in a representative region by using the Supportive Cancer Needs Survey (SCNS-SF34).
2. To describe the level of satisfaction with information to support cancer treatment decision making and causes of distress among YWBC (<45 years) in a representative region.

Study Design
This study used a prospective survey design that was administered to consenting YWBC. The Supportive Care Needs Survey (SCNS-SF34) was used to measure respondents' need for cancer support and care. This instrument captures needs through 34-items that cover five domains: psychological needs, health system and informational needs, physical and daily living needs, patient care support needs and sexuality needs. In addition, an original 26-item survey questionnaire was administered. Survey items were developed from the recurring themes of an earlier project that informed 4 levels of inquiry: demographics, decision making/ informational support, disease and treatment characteristics, and causes of distress.

Results
Fifty-one patients were approached by a member of their circle of care. Of these patients, 35 completed the survey resulting in a 69% response rate. The majority of respondents were between the ages of 33 and 40 (48.6%), were diagnosed within 6 to 12 months of study entry (60.0%); had a university degree (51.4%); were married (82.9%) and (65.7%) have young children.

The three most common Moderate to High Unmet Supportive Care needs (rated 4 or 5 on a 5-point Likert scale) were: “Worries of those close to you” (34.3%), “Fears about the cancer spreading” (34.3%), “Anxiety” (28.6%) all of which reside in the psychological domain. Overall respondents agreed or strongly agreed to statements regarding their level of satisfaction with information to support cancer treatment decision making provided by their oncology team. Respondents did score lower in satisfaction with the information their oncology team provided regarding fertility. In terms of psychosocial support, 40% percent of respondents reported they had met with a social worker and 17% reported attending a breast cancer support group.

Conclusion
The results highlight that the supportive care needs of many YWBC are unmet, particularly those related to psychological burden and fertility concerns. Early identification and appropriate referral to fertility specialists and/or supportive care social workers could improve current practice. Further research is needed to explore how barriers to fertility and supportive care needs of young adults with cancer may best be overcome.
Title: A meta-analysis of cognitive impairment in breast cancer survivors treated with chemotherapy

Bernstein LJ J, McCreath GA A and Rich JB B. Princess Margaret Cancer Centre, Toronto, ON, Canada; University of Toronto, Toronto, ON, Canada and York University, Toronto, ON, Canada.

Body: Background: Cognitive impairment in women with breast cancer has long been attributed to chemotherapy, but the evidence for this has been inconsistent, and more recent research suggests that additional cancer- and treatment-related factors also impact cognition. To systematically evaluate and describe “chemobrain,” a multilevel meta-analysis of objective cognitive function in breast cancer survivors treated with chemotherapy was conducted to estimate the magnitude of impairment across 9 cognitive domains and explore moderating variables.

Method: PubMed, Embase, CINAHL, Cochrane CENTRAL, Scopus, and PsycINFO were searched from their inception to May 2016 to identify studies that compared the cognitive performance of survivors treated with chemotherapy to a control group or to their own prechemotherapy testing. Multilevel modelling was used to account for the interdependence among effect sizes obtained within the same study.

Results: Seventy-seven studies involving 3417 cancer patients treated with chemotherapy yielded 1548 effect sizes. Cross-sectional comparisons revealed worse overall cognitive performance in survivors treated with chemotherapy relative to healthy controls \((d = -0.27, \text{95\% CI } [-0.32, -0.21])\) but not disease-specific controls \((d = -0.07, \text{95\% CI } [-0.14, 0.00])\). Relative to all controls, cognitive impairment in survivors treated with chemotherapy was observed in tests assessing language \((d = -0.25)\), executive function \((d = -0.21)\), processing speed \((d = -0.15)\), delayed recall \((d = -0.15)\), and attention/concentration \((d = -0.14)\), but not in visual/spatial perception, immediate recall, recognition memory, or psychomotor domains. Because patients and controls were not well matched in many studies on age, education, and IQ, which are known to impact cognitive test performance, group differences in these variables were explored as moderators of observed cognitive deficits in post hoc analyses. Results showed that chemotherapy patients and controls performed equivalently when the controls were 6 years older or had 1 less year of education. Longitudinal comparisons showed improved postchemotherapy performance relative to prechemotherapy baseline, but practice effects were not accounted for in these comparisons.

Conclusion: Breast cancer survivors treated with chemotherapy show subtle yet diffuse cognitive impairment. Their cognitive performance was equivalent to that of women in comparison groups who were 6 years older, which suggests that chemotherapy accelerates cognitive aging. Results from breast cancer patients who were not treated with chemotherapy, however, indicate that chemotherapy is not the only determinant of cognitive dysfunction. Group differences in age and education moderated the magnitude of cognitive impairment. The cognitive reserve framework, which posits that individuals differ in the degree of neural disruption they can withstand before exhibiting cognitive deficits, should be considered in future studies in order to better understand moderating effects on cancer-related cognitive dysfunction. In particular, both cross-sectional and longitudinal studies should ensure that comparison cohorts are closely matched on age, education, and other relevant cognitive reserve variables.

Title: Psychosocial distress monitoring in a multidisciplinary, inner city breast center

Castaldi M, Elrafei T and Soliman C. Jacobi Medical Center, Bronx, NY.

Body: Objective: Beginning in 2015, all Commission on Cancer–accredited cancer programs must have developed and implemented a process to screen for psychosocial distress and provide appropriate psychosocial care. At our institution that serves uninsured and underrepresented minority populations, we integrated a distress tool on a continuum, rather than as a onetime event. We reviewed the initial screening tools from our breast center to determine how psychosocial distress differs throughout treatment in order to identify pivotal times during course of treatment and to prioritize intervention strategy.

Methods: NCCN distress thermometer was administered to each patient with review of stressors to complete at 4 different intervals after diagnosis with breast cancer. Newly diagnosed breast cancer patients were asked to complete distress screening at various phases of their cancer care: shortly after diagnosis at surgery office visit, after surgery at first chemotherapy cycle, third medical oncology office visit, and last chemotherapy cycle. The tools were administered by patient navigators and referred to social work with a distress score of 5/10 or higher. Tools were then scanned into the medical record and collected by the social worker. We reviewed the collected distress tools and compared the data based on the where the patient was in course of treatment. Identifying stressors were grouped into 4 categories: practical, family, emotional, and physical.

Results: in April 2015, the implementation and preparation of distress screening was begun. Between August 2015 and April 2016, 94 distress tools were completed by patients in our breast center. 42.5 % patients had a distress score of 5 or above at their initial screen at surgical consultation, 31.8 % at their first cycle of chemotherapy, 53.3% at third medical oncology office visit, and last chemotherapy cycle. The tools were administered by patient navigators and referred to social work with a distress score of 5/10 or higher. Tools were then scanned into the medical record and collected by the social worker. We reviewed the collected distress tools and compared the data based on the where the patient was in course of treatment. Identifying stressors were grouped into 4 categories: practical, family, emotional, and physical.

Results: in April 2015, the implementation and preparation of distress screening was begun. Between August 2015 and April 2016, 94 distress tools were completed by patients in our breast center. 42.5 % patients had a distress score of 5 or above at their initial screen at surgical consultation, 31.8 % at their first cycle of chemotherapy, 53.3% at third medical oncology office visit and 50 % at completion of chemotherapy, triggering a social work intervention. The most common stressors were emotional, worry and fear, (44%) at initial assessment and physical, fatigue and tingling in hands and feet, (100%) at last chemotherapy cycle, with family stressors 33.3 ?, and practical matters 28%. The least common stressor was treatment decision or need for treatment change. Mean stress levels were 8/10 for surgical patients and 6/10 for patients seeing medical oncology. Although 4 screens were performed, the spectrum of stressors did not change significantly over continuum of care other than all patients reporting fatigue with a score of 5 or higher at completion of chemotherapy. All patients had psychosocial barriers to care that caused stress regardless of phase of cancer care.

Conclusion: Patients are at their peak stress levels at the time of diagnosis in consultation with the surgeon. As they move along their treatment plan, stress levels decrease, but the stressors seem to remain the same, except for physical stress being highest at end of chemotherapy. We recommend timing of the administration of the distress tools be based on capturing peak stress (at time of diagnosis) and then again at completion of chemotherapy to monitor for stress reduction. Addressing psychosocial barriers seems to be paramount in lowering distress scores in our underrepresented, minority breast cancer population.
Efficacy of screening and treatment of breast cancer patients reporting high level of distress

Background: Cancer patients (pts) are burdened by symptoms related to the disease itself or to the toxicities of treatment. A recent meta-analysis has shown that anxiety is the most common mental health issue among cancer survivors [Mitchell AJ, 2013]. The ASCO clinical oncology guideline adaptation recommends all health care providers routinely screen for the presence of emotional distress and symptoms of anxiety from the point of diagnosis onward [Andersen BL, 2014]. Consensus-based recommendations have been published to help cancer centers meet the American College of Surgeons Commission on Cancer’s accreditation requirement to screen for distress [Pirl, 2014] At our comprehensive community cancer center we perform distress screening using the M.D. Anderson Symptom Inventory (MDASI), composed of 27 questions. Pts who report moderate and severe levels of distress (≥5) on the MDASI are identified and referred for therapeutic interventions offered by the facility’s integrative oncology services.

Materials and Methods: The MDASI is an assessment tool that captures pts’ perceived symptom burden for real-time clinical intervention, taken at the point of no intervention (baseline) and every 21 days or greater. The 27-question MDASI is comprised of the M.D. Anderson Symptom Inventory (MDASI), a validated 19-item assessment instrument, with a Symptom Inventory Tool (SIT) added by our center of 8 questions and a free-text box. Symptoms are rated “at the worst” on an 11-point numeric scale ranging from 0 (“none present”) to 10 (“as bad as you can imagine”), as experienced by the patient in the past 24 hours.

Results: Over a ten-month period (9/1/2014 to 6/30/2015), 247 breast cancer (BC) pts completed the MDASI at intake and again ≥ 21 days after. Analysis of their initial surveys identified 69 pts (27.9%) who rated their distress as ≥ 5 (1st MDASI mean = 6.83), scores which would have initiated a support system response with referrals to integrative medicine services for intervention. Second MDASI results from these 69 BC pts revealed an average 2.29 distress score reduction (2nd MDASI mean = 4.48), with 51 pts (73.9%) reporting a decrease in distress, 7 pts (10.1%) having no change, and 11 pts (15.9%) reporting increased distress. More specifically, the group with decreased distress levels documented a mean distress score of 3 on their 2nd MDASI, averaging a significant 4-point diminution of distress for three-fourths of the BC pts heavily burdened by this symptom. The integrative services most utilized by these pts were Nutrition Therapy (100%), Spiritual Care (96.1%), Mind-Body Counseling (82.4%), Rehabilitation Therapy (41.2%), Acupuncture (35.3%), and Massage Therapy (35.3%).

Conclusions: Distress is a relevant symptom reported by cancer pts. This study demonstrates that early intervention in BC pts using integrative oncology approaches reduced distress in 74% of cases.
Return to work after breast cancer diagnosis: An observational prospective study of 125 patients in South America

Background: Breast cancer is the most common cancer in women. While its incidence has been increasing, recurrence and mortality rates have been decreasing. Because of that, cancer can now be regarded as a transient shock that does not prevent the survivors to live normal lives, including returning to their workplace. From a social perspective, long periods of sick leave have a strong economic impact. From the patient perspective, prolonged sick leave can cause financial difficulties and emotional distress. In United States and Europe, RTW rates vary among breast cancer patients from 24-66% after 6 months and 53-82% after 36 months of diagnosis. Factors associated with the decision to return to work are: age, chemotherapy, sequelae related to cancer therapy and support from the employer and coworkers. However, these findings vary among the different populations studied, suggesting that other factors may also interfere with the decision to return to work. Data on RTW after breast cancer diagnosis is not available in South America nor in developing countries – where the workforce tends to be relatively younger than average. The primary objective of this study was to evaluate RTW rates on months 12 and 24 after breast cancer diagnosis, and to evaluate factors associated with the decision to return to work.

Methods: Prospective, observational study evaluating RTW rates in patients diagnosed with breast cancer, > 18 and <57 years old (in Brazil women can retire at age 60) and under remunerated work for at least 03 months at the time of diagnosis. Patients with metastatic disease were excluded. Based on previously data, we estimated that 125 patients would be required to achieve the primary endpoint. Each patient was followed for 02 years. On months 6, 12 and 24 they answered a telephone interview and the FACT-B questionnaire. Disease characteristics and treatment were collected from electronic medical records. After completion of all third row of interviews (by september, 2016) we will perform univariate and multivariate analysis by logistic regression method to determine the independent predictors of return to work.

Results: Between july, 2012 and september, 2014, 125 patients were enrolled. The median age was 45.1 (range 25-57). Half of the patients (52.9%) were married at the time of diagnosis, and 96.9% received support from their life partner. Most of them reported that they liked their job (93.8%) and received support from their employer (61.5%), but only 29.1% reported adjustment offering, so that they could keep working during treatment. Almost half of patients (47.6%) had stage II disease, 75.4% and 19.7% were HR and Her 2 positive, respectively, and 92.6% received chemotherapy as part of their treatment. Overall, 22.1% and 28.8% of patients returned to work, at 6 and 12 months after breast cancer diagnosis, respectively.

Conclusion: Twelve months after breast cancer diagnosis, less than 30% of the patients had returned to work. By september, 2016, we will have completed the “24 month” interviews and will present RTW rates at that time and also correlative analyses of factors that affected the RTW in this population.
**Title:** Fertility concerns in young women after diagnosis of breast cancer: Experience of a breast cancer unit in México

**Body: Background**

Nearly 30% of all new breast cancer diagnoses occur in pre-menopausal women and about 7% of diagnoses occurring in women aged 40 years or less. Breast cancer treatment can increase the risk of early menopause and infertility. It is the major source of distress and concern form many young breast cancer patients who have no finished their families and have plans for childbearing.

**Methods**

As part of multidisciplinary approach in the Breast Cancer Unit at Centro Oncologico Estatal ISSEMYM an evaluation psychosocial aspects of sexuality, fertility and menopause after diagnosis of breast cancer has been implemented. We conducted an exploratory study to better understand fertility concerns, the role of fertility in the treatment decisions and chemotherapy acceptance in a cohort of young women newly diagnose breast cancer evaluated in a Breast Cancer Unit. We invited eligible women to participate, fertility concerns was the primary end point

**Results**

A total of 52 women were evaluated. Of these, we exclude 2 patients they have stage IV disease at re staging. Thus 50 women were included in the analyses. Median age at diagnosis was 36 years (range 23 to 40 years). 86% had children already at the time of breast cancer diagnosis. Only 4 participants (8%) reported that before their breast cancer diagnosis, they wanted to have future or additional children. Whereas forty six (92%) did not. Of these patients 85% don't want to have children because of prior decision and 20% because fear of cancer recurrence. Forty nine patients would agree to receive chemotherapy (98%) and 51% would accept a risk of infertility of 76-100%. This acceptance was dependent on already having children. 68% would accept it only for ≥20% gain in cure.

**Conclusion**

Our study represents one of the first prospective evaluations of fertility concern in young women with recently diagnosed breast cancer in a Public Hospital in México. For the majority of young patients with breast cancer, cure remains their first priority. Most of the women have child before diagnosis and only 8% want to have additional children.
Title: Implications of financial modeling in breast cancer clinical research from 1990 to 2010

Body: SUMMARY: Over the past two decades significant progress has been made in breast cancer treatment resulting in a substantial improvement in patients' outcome. But we have to think about who promotes all this research and the consequences of the type of funding. This project aims to evaluate the implication of finance in clinical research and the variance according to the type of funding.

OBJECTIVES: To evaluate the financial evolution of breast cancer clinical trials in the past two decades, regarding the phase of development design of the studies, the collaboration between Academy (Acad) and Industry (Ind), the sample size, the study results and the statistical analyses conducted.

METHODS: A systematic review was performed using MEDLINE to identify breast cancer randomized clinical trials published between January 1990 and December 2010. Studies that involved chemotherapy, endocrine and/or targeted therapies, where the primary endpoint was considered adequate to support a drug approval in oncology according to the FDA and EMA (U.S. Food and Drug Administration and European Medicines Agency, respectively), were included.

RESULTS: Data were evaluated 2,211 and 472 met selection criteria comprised in the methodology. During the first decade Acad was the main breast cancer research promoter being replaced by the Ind. throughout the second decade (p <0.0001). Thirty-nine percent of the studies evaluated were phase III (39% Acad, 61% Ind), 15% were phase II (30% Acad, 70% Ind) and the remaining 47% were not classified by authors (65% Acad 35% Ind). As for the primary endpoint, 25% of the phase III trials evaluated progression free survival, 15% overall response rate, 1% time to progression and only 5% examined overall survival. Sixty-five percent of the trials were national (60% Acad 40% Ind) and 35% international (25% Acad 75% Ind). Single-center studies accounted for 11% of the trial (65% Acad 35% Ind). Most of the national trials were developed by the US. Fifty-four percent of the studies were conducted by research groups (67% supported by Ind. and 33% Acad.). The Ind sponsored 26% of the studies in the first decade and 50% during the second. The median number of patients enrolled by research groups was 892 in contrast with 409 included by other organizations. The primary endpoint was achieved in 19% of the Acad trials and 21% of the Ind trials. Only 53% of the studies declared intention to treat based analysis in their statistical workout.

CONCLUSIONS: There is a significant tendency towards the promotion of research by the pharmaceutical industries during the last two decades, leading a change in the clinical trials design and the endpoints.
Body: Background: The landscape of treatment options and associated prognosis for patients with metastatic breast cancer (MBC) is rapidly evolving. In response to these advances in therapy, numerous organizations have invested considerable resources into developing evaluation frameworks seeking to clarify the value of new therapies. While some of these frameworks foster patient-provider shared decision making, others are more payer focused, and all are limited in their incorporation of patient perceptions of value and evidence on treatment aspects most meaningful to patients.

Objectives: 1) To identify the attributes of treatment that patients with MBC value most, and 2) to explore the alignment between patient valuation of treatment attributes and healthcare provider perceptions of what patients value.

METHODS: Four 90-minute focus groups were conducted: two with patients (aged <50 years and aged ≥50 years) and two with healthcare providers (oncologists and oncology nurses) who treat patients with MBC. Using semi-structured discussion guides tailored to each participant group, patient and provider perceptions of the factors most important to patients when considering treatment were explored as well as various sources of perceived value in cancer care. Discussions were audio recorded and transcribed. Thematic analysis identified attributes patients with MBC consider when making treatment decisions, and concordance between patients and healthcare providers was assessed.

Results: A total of 24 patients and providers (n=5 patients <50 years, n=5 patients ≥50 years, n=7 oncologists, and n=7 nurses) participated in four different focus groups. The factors of greatest importance to patients included: impact of treatment side effects on daily life, depth of treatment response, longevity of life, and the value of hope in traversing their illness and achieving survival landmarks and goals. In contrast, oncologists focused predominantly on clinical considerations, such as treatment effectiveness and managing side effects. Oncology nurses noted similar clinical factors as oncologists, but also aligned more closely with patients on humanistic elements informing treatment decision-making.

Conclusion: This analysis reveals that while patient and healthcare provider assessments of value in treating MBC are well-aligned with respect to clinical factors such as managing side effects and depth of treatment response; patients also prioritize emotional and psychological factors, -- like having hope and avoiding suffering -- in addition to clinical factors. Moving forward, patient-centered value frameworks for MBC will need to address this gap between what providers and payers value and patient goals and priorities.
2016 San Antonio Breast Cancer Symposium

Title: Collateral damage from metastatic breast cancer – Preliminary results

Love SM M, Bernstein L, Obidegwu A, Ottenbacher A, Eshraghi L and Clague J. Dr. Susan Love Research Foundation, Encino, CA; Beckman Research Institute, City of Hope Comprehensive Cancer Center, Duarte, CA; 2M Research Services, Fort Worth, TX and Beckman Research Institute, City of Hope, Duarte, CA.

Body: BACKGROUND: Historically, research efforts have focused on developing new treatments, education, and support programs for metastatic breast cancer (MBC) patients. Less emphasis has been placed on understanding quality of life (QoL) issues for this underserved population. However, when faced with a metastatic diagnosis, managing, and minimizing the collateral damage resulting from sequential and often continuous treatments is critical to improving quality of life. Through this preliminary analysis, our aim is to understand the unique experience of MBC and identify potential areas of critical need.

METHODS: The Health of Women (HOW) Study™ is an online study for women and men, with and without a history of breast cancer, aimed at identifying causes of breast cancer. The (HOW) Study periodically releases new questionnaires and is currently comprised of ten questionnaires collecting information on personal and family health history, lifestyle, environmental exposures, breast cancer diagnosis and treatment, and QoL. Over 53,000 people are enrolled in (HOW), of which, 11,508 have completed the QoL questionnaire. Areas covered included chronic conditions, symptoms, moods and feelings, reproductive health, daily activities, patient-provider communication, and social and financial concerns. QoL measures were compared between participants with no history of breast cancer (NoHx), with non-metastatic breast cancer (non-MBC), and with MBC.

RESULTS: Of the 11,508 respondents, 3,965 reported a diagnosis of breast cancer—of those, 205 were metastatic. The majority were female (99%) and non-Hispanic White (95%). MBC were younger (28%<50 years, 65% 50-69 years) than non-MBC (20%<50 years, 69% 50-69 years; p<0.05). Overall, participants with MBC reported a lower QoL (20% excellent, 10% poor) than non-MBC (41% excellent, 3% poor) and NoHx participants (44% excellent, 2% poor; p<0.05). MBC and non-MBC participants did not differ on hot flashes, vaginal problems or fertility concerns. However, MBC participants were more likely than non-MBC participants to report: 1) Symptoms — including digestive, mouth and nose, hair and skin, eye, pain, fatigue and night sweats — significantly affecting their lives; 2) Problems with concentration, mood swings, anxiety, depression, memory, and sleeping; 3) Attributing each symptom and/or problem to their breast cancer treatment; 4) Problems performing daily activities; 5) Better communication with their clinical team; 6) Severe financial concerns including difficulty with medical expenses, losing one's job and/or health insurance, not meeting the financial needs of one's family and not being able to pursue career of choice; and 7) Severe social concerns including feeling dependent, isolated, and being treated differently (all p-values<0.05).

CONCLUSIONS: Participants with MBC had a considerably diminished QoL compared to non-MBC and NoHx participants. We identified key areas of concern and multiple areas of collateral damage not standard in research assessment. Our next steps are to use these data to develop a formal, qualitative questionnaire that includes newly identified collateral damage issues, and expand our sample of MBC. The combined data will guide us in developing recommendations for improving the QoL for people with MBC.
Villareal-Garza CM M, Platas A, Castro-Sánchez A, Miaja M, Bargalló-Rocha E, Martinez-Cannon BA A, Vega Y, Fonseca A, Ramos-Elias P, Márquez-Pérez CJ J, Bukowski A, Goss P, St. Louis J, Chapman J-A, Partridge A, Meneses A and Mohar A. Instituto Nacional de Cancerología, Mexico City, CDMX, Mexico; Program for Young Women with Breast Cancer, Mexico City, CDMX, Mexico; Breast Cancer Center, Tecnologico de Monterrey, Nuevo León, Monterrey, Mexico; MILC, Medicos e Investigadores en la Lucha Contra el Cáncer de Mama, Nuevo León, Monterrey, Mexico; MGH-Avon Breast Cancer Program, Massachusetts General Hospital Cancer Center, Boston, MA; (Retired) Canadian Cancer Trials Group, Queen's University, Kingston, ON, Canada and Dana-Farber Cancer Institute, Boston, MA.

**Body: Background:** Despite high rates of breast cancer in young women from low-and-middle-income countries (LMICs), their needs and concerns are not systematically studied or addressed. Understanding the characteristics of young women with breast cancer (YWBC) and the issues they face is of great relevance to the medical community, in order to tailor clinical interventions and supportive care for this unique and understudied patient population. The Mexican cohort “Mujer Joven y Fuerte” (Young and Strong Woman) has the goal of comprehensively characterizing and assessing the needs of YWBC in Mexico using patient- and physician-based surveys. **Methods:** A prospective cohort of newly diagnosed YWBC was established in November 2014 at two Mexican cancer centers in Mexico City and Monterrey. Eligible women answer web-based surveys on relevant topics including physical activity, genetics, psychosocial needs, and fertility. Clinicians complete pre-specified surveys using the US NIH BOLD Task Force common data elements registering clinical/pathologic characteristics and outcomes. Patients are evaluated at diagnosis, after 6 months, and annually for 5 years. Sub-studies assessing changes in cognition, sexual function and satisfaction, quality of life and depression/anxiety are being conducted, and biologic samples are stored for future research. **Results:** 96 YWBC with median age at diagnosis of 34 (21-41 y) were accrued to our pilot phase. 26% were single and 25% childless. 43% had higher education and 28% were employed. 90% presented with a self-detected mass. Clinical stage at diagnosis was distributed as follows: stage 0: 2%; I: 15%; IIA: 13%; IIB: 17%; III: 47%, and stage IV: 6%. The most frequent molecular subtype was HR+/HER2- (47%), followed by HER2+ (26%) and triple negative (21%). First follow-up results will be available shortly. **Conclusions:** To our knowledge, this represents the first prospective cohort of YWBC in Latin America. We are expanding this project to other centers in the region. Our findings will help develop culturally tailored interventions aimed at improving the psychosocial and medical outcomes of this vulnerable patient population.
Title: Patient-reported cosmetic outcomes in older breast cancer survivors: A population-based survey study

Swanick CW, Lei X, Xu Y, Shen Y, Goodwin NA, Giordano SH, Hunt KK, Jagsi R, Shaitelman S, Peterson SK and Smith BD. The University of Texas MD Anderson Cancer Center, Houston, TX and The University of Michigan, Ann Arbor, MI.

Background: For older women with breast cancer, local therapy options may include (1) lumpectomy followed by whole breast irradiation (Lump+WBI), (2) lumpectomy followed by brachytherapy (Lump+Brachy), (3) lumpectomy followed by endocrine therapy alone without radiation (Lump alone), (4) mastectomy without radiation (Mast alone), or (5) mastectomy followed by radiation (Mast+RT). For many patients, several of these options are acceptable based on current guidelines, but little is known about the impact of treatment choice on long-term cosmetic outcomes. We surveyed a population-based cohort of older breast cancer survivors treated with 1 of these 5 options to assess patient satisfaction with cosmetic outcome.

Methods: We used nationally comprehensive Medicare claims to identify women age ≥67 diagnosed with non-metastatic breast cancer in 2009, treated with 1 of these 5 treatment options, and still alive in 2015. From this cohort, 1650 patients (330 patients per local therapy) were randomly selected. Of these, 397 opted out, and the remaining 1253 potential participants were mailed a survey that included the CanSORT Satisfaction with Breast Cosmetic Outcomes instrument (5-point scale, higher score indicates greater satisfaction) and the Breast-Q Satisfaction with Breast instrument (0-100 Rasch transformed score, higher score indicates greater satisfaction). Multivariable linear regression models were used to assess the association of local therapy with each outcome, adjusting for age, race, comorbidity, chemotherapy, patient-reported BMI, bra cup size, smoking, income, and education. Spearman’s correlation assessed the relationship between the 2 outcomes. All analyses incorporated sample and response weights.

Results: We received completed surveys from 498 women (30% response rate). The median age was 73 years (range, 67-87 years). The interval from diagnosis to survey was 6 years for all patients. Among patients with evaluable CanSORT responses (n=439), the weighted mean score by treatment group was 3.64 for Lump+WBI, 4.01 for Lump+Brachy, 3.83 for Lump alone, 3.28 for Mast alone, and 3.25 for Mast+RT. In multivariable analysis with Lump+WBI as the referent, the adjusted CanSORT mean score was 0.37 points higher for Lump+Brachy (P=0.009), 0.35 points lower for Mast alone (P=0.035), and 0.33 points lower for Mast+RT (P=0.048). Among patients with evaluable Breast-Q Satisfaction responses (n=418), the weighted mean score by treatment group was 60.9 for Lump+WBI, 68.8 for Lump+Brachy, 66.7 for Lump alone, 58.8 for Mast alone, and 52.0 for Mast+RT. In multivariable analysis with Lump+WBI as the referent, the adjusted Breast-Q Satisfaction score was 7.4 points higher for Lump+Brachy (P=0.03) and 7.8 points lower for Mast+RT (P=0.04). Higher comorbidity predicted worse cosmetic outcome in both models; no other variables were associated with both outcomes. The 2 outcomes were highly correlated (Spearman’s coefficient=0.8, P<0.0001).

Conclusion: In this nationally representative cohort, satisfaction with cosmetic outcome (as measured by 2 distinct instruments) was higher for patients treated with Lump+Brachy and lower for those treated with Mast+RT compared to Lump+WBI. These results may be used to inform patient treatment decisions.
Title: Results of an educational program delivered through e-learning, focused on nursing for primary breast cancer patients

Abe K, Iseki C, Suzuki M, Kokufu H, Arahori Y, Ohno T, Kanazawa M and Takeishi Y. Chiba University Graduate School of Nursing, Chiba, Japan; National Hospital Organization Chiba Medical Center, Chiba, Japan; Kumamoto University Graduate School of Life Science, Kumamoto, Japan; Kushiro City General Hospital, Hokkaido, Japan; Chiba University Hospital, Chiba, Japan; Tohoku University Hospital, Miyagi, Japan and Hiraka General Hospital, Akita, Japan.

Body: Aim: An educational program delivered through e-learning was conducted, focusing on nursing for primary breast cancer patients. This paper investigates the results of the program, clarifying changes in levels of understanding before and after the program, and evaluations of the program by nurses who participated. Methods: The content of the education program, which consisted of 24 lessons, each lasting 15-20 minutes, including case studies, covered concerns raised in questions by patients and families about diagnosis, multimodal treatment and nursing for primary breast cancer. Instructors were Certified Nurses in Breast Cancer Nursing and Certified Nurse Specialists in Cancer Nursing, and PowerPoint presentations with video and audio material were created. A dedicated website was created, and 1417 participants took the on-demand program, which was provided from September 2015 to March 2016. Survey participants were the first 500 nurses registered for the course to respond. A questionnaire created by the researchers was sent by post to respondents. Responses were anonymous with identifying information code, and questionnaires were sent with a return envelope before the program (within 2 weeks of registration) and after the program (within 1 month of the end of the program), with return of the questionnaire signifying consent to participate. The questionnaire comprised 24 items on level of understanding of breast cancer nursing, aligned to program content, plus 11 items on evaluation of the program. Responses were selected from a 5-point scale, where 1 meant “strongly disagree” and 5 meant “strongly agree”. Analysis: Responses were quantified, and mean scores for each item were calculated. In addition, respondents were divided into two groups, namely, those with less than 3 years of breast cancer nursing experience (Group A) and those with 3 or more years’ experience (Group B), and were compared using the Mann-Whitney U test. SPSS Statistics V22.0 was used. Ethical considerations: The study went through Research Ethics approval at the researchers’ institute of affiliation. Results: A total of 126 people replied to both the pre-program and post-program questionnaire, and of these, the responses of 106 nurses (Group A: 34 nurses, Group B: 72 nurses) who were not qualified as Certified Nurses or Certified Nurse Specialists were used for analysis. Median age was 41.0 years (Group A: 38.5 years, Group B: 42 years), and median number of years of breast cancer nursing was 4.6 years. In terms of program evaluation, “I could study when it was convenient for me” scored 4.63, while “It will be useful for breast cancer nursing from now on” scored 4.57. In terms of comparison of level of understanding before and after the program, understanding improved on all 24 items, and was significant on 19 items. Comparison of the 2 groups showed significant difference on 2 items, “support for changes in body image” and “communication with the patient”, with changes in level of understanding in Group A being greater. Discussion: The study suggests that participants’ understanding of breast cancer nursing increased and improvements in clinical practice can be expected through e-learning materials that facilitate effective learning.
Body: Research Biopsies in Oncology – Patient Willingness, Perceptions, Understanding, and Experience: An Integrative Review.

Background
Tumors are classified into subsets based on molecular alterations to select personalized therapies, and research biopsies are essential to advance personalized medicine. However, research biopsies can be associated with complications, results might not directly benefit the patient particularly on-treatment biopsies obtained for evaluation of pharmacodynamics effect, and mandatory requirement can impact patient enrollment in clinical trials. Understanding patient perceptions and experiences surrounding research biopsies may highlight areas for improvement and could expand participation in clinical trials.

Objectives
The purpose of this integrative review explores and summarizes the current literature on oncology patient perceptions, willingness and experience of research biopsies evaluates data to determine potential implications for practice improvement, patient experience, and clinical trial participation.

Methods
Articles from January 2010-February 2016 were retrieved via a systematic search restricted to English of MEDLINE/Ovid. Search terms included breast cancer, cancer, research, biopsy, perceptions and attitudes. Inclusion criteria were studies that included patients with cancer and had information on patient willingness, perceptions, understanding, attitudes, and/or experience around research biopsies. Abstracts were independently reviewed for inclusion by two authors. For each selected manuscript, the following information was abstracted: primary author, sample and setting, results, conclusion, and assessment of strength of evidence level and quality using John Hopkins Nursing Evidence Based Practice (JHNEBP) Rating Scales.

Results
The search resulted in 175 unique studies. 17 abstracts were selected for full manuscript review. From these, 8 were excluded for not meeting inclusion criteria. The 9 selected studies ranged in sample size from 10-362 and all articles were rated IIIA-B evidence level. The majority of studies (66.7%) focused on breast cancer patients. Studies exploring patient willingness to undergo research biopsies (N=8) revealed variability in patient willingness to undergo research biopsies and identified research biopsies identified as a potential barrier to clinical trial participation. Studies exploring patient understanding of the risks and benefits of research biopsies (N=3) revealed overall poor understanding among patients. One study explored anxiety surrounding the research biopsy procedure, suggesting significant anticipatory anxiety is a significant concern. Issues surrounding informed consent were raised in several studies.

Conclusions
Research biopsies can be associated with significant anxiety, potentially impact enrollment in clinical trials, and consequently there is a need for development of strategies to improve patient experience and education. While a separate consent for research biopsies may be onerous, tailored educational materials, focus groups, as well as development of alternate strategies such as liquid biopsies, are essential to ensuring advancement in cancer care and outcomes.

Key Words: cancer, research, biopsy, perceptions, attitudes.
**Title:** Evaluation of a multidisciplinary cancer team quality in a breast cancer unit (BCU) in México

**Body: Background:**
The optimal management of patients with breast cancer (BC) requires the expertise of specialists from different disciplines. This has led to the evolution of multidisciplinary teams (MDTs), allowing all key professionals to jointly discuss individual patients and to contribute independently to clinical decisions. Data regarding BC MDTs in Latin-American countries are limited. The purpose is to assess the MDT performance in a Breast Cancer Unit in México.

**Methods:**
We conducted a prospective longitudinal study to evaluate the participation of MDT for breast cancer patients in Breast Cancer Unit at Centro Oncologico Estatal ISSEMYM. An assessor use a validated observational tool to rate quality and team decision-making for every patient discussed. Data were collected from a prospective observation of 150 breast cancer cases review during 3 months study period, in the Breast Cancer Unit meeting by a MDT. BCMDT (Breast Cancer Multidisciplinary Team) was integrated by medical, surgical and radiation oncologists, radiologist, pathologist, geriatrician and pharmacist. The information presented (patient case, radiological, pathological, comorbidities) and team member contribution and decision of further investigation or treatment as appropriate as well as MDT coordinators leadership role were analyzed. These tasks usually occur in a weekly meeting.

**Results:**
There were 150 breast cancer patients studied. The majority of the time for each case was taken up with information presentation, and often discussion occurred concurrently with presentation of information. The most common barriers to reaching clinical decisions were inadequate radiologic information (2 %) inadequate pathologic information (7%), and additional complementary studies needed (5%). The MDT had the ability to reach clinical decision in the 86% of cases. All members were present in the 98 % of sessions. The mean of participant was 12 in each meeting and the average time taken per patient was 3 minutes.

**Conclusion:**
This is an effort to collect information regarding BC MDTs from a Latin-American country and provides objective information of frequency, composition, function, and working mechanism of a BC MDT. The intervention of a MDT in the Breast Cancer Unit is efficacious and can improve decision making.
**Title:** Diagnosing cognitive impairment ("chemo brain") in breast cancer survivors

Razaq WA A, Tanaka T, Carlson B, Wenger M, Friedman J, Benbrook D and Craft M. Stephenson Cancer Center at Oklahoma University Health Sciences, Oklahoma City, OK.

**Body:**

**Background:**
Cognitive complaints ("chemo brain") are reported frequently after breast cancer treatment but little is known about its incidence and causes. Before we can intervene we need to be able to diagnose it properly. Mini Mental state examination (MMSE) can detect advanced Alzheimer's but won't help in detecting mild cognitive disturbances. We used Montreal Cognitive Assessment for Telephone (MoCA-T) and full scale Montreal Cognitive Assessment for Telephone (MoCA) to diagnose mild cognitive impairments in patients having normal MMSE.

**Methods:**
20 breast cancer survivors aged 50 years or older completed MoCA-T and MoCA, a year after they completed their treatment for breast cancer, describing the impact of their treatment regimen on their short term memory and ability to think and concentrate. On Day 5, they underwent a standardized laboratory protocol that assessed both behavioral and electroencephalographic (EEG) indicators of memory consolidation.

**Results:**

**Patient characteristics:**
20 postmenopausal breast cancer survivors aged 50 or above participated in the study a year after they completed their therapy. We are reporting preliminary results of 10 patients. Patients had stage I-III disease (stage I – One patient, Stage II – five patients, and stage III- four patients). All of them received various chemo regimens e.g. Cytoxan, methotrexate, 5-FU (CMF), Taxol, Trastuzumab (TH), Adriamycin (AC), taxotere, carboplatin (TCH). 8/10 patients received adjuvant radiation. 1/10 patient underwent reconstruction later. 7/10 patients received hormonal therapy with aromatase inhibitors.

**Results of MoCA –T and MoCA:**
MoCA-T, tests attention and concentration, executive functions, memory, language, conceptual thinking, calculations, and orientation. Possible scores range from 0-22 and scores <18 indicate mild cognitive impairment. The MoCA has possible scores from 0-30 and a score >26 is normal but <19 is indicative of cognitive impairment.

5/10 patients had abnormal MoCA and 3/10 patients had impaired MoCA-T signifying that almost 50%patients develop mild cognitive impairment after breast cancer treatment. During memory consolidation, EEG contained less theta and frequent bursts of alpha waves which is commonly seen in patients with neuropathic pain and insomnia.

MoCA-T and MoCA results for the patients

Conclusions:
The study signifies that mild cognitive impairment from breast cancer treatment (or “chemo brain”) was frequently reported and MoCA-T and MoCA tests were able to show even mild cognitive impairment in these patients. We are compiling our full data for EEG but the early results show that the patients had less theta but had frequent bursts of alpha waves, a pattern seen commonly in patients with insomnia and neuropathic pain. They retain fewer items and take more time responding to items as compared to normal people. We need more studies to diagnose and treat mild cognitive impairment (“chemo brain”) in breast survivors as most of these patients are still working and can be a valuable part of the community.
Title: Efficacy results of a phase 1b study of ONT-380, an oral HER2-specific inhibitor, in combination with capecitabine (C) and trastuzumab (T) in HER2+ metastatic breast cancer (MBC), including patients (pts) with brain metastases (mets)

Body: Background: ONT-380, a potent, highly selective, orally available small molecule inhibitor of HER2, has been associated with clinical benefit and minimal EGFR-type toxicities in single agent and combination studies of pts with HER2+ MBC, including pts with brain mets. In this Phase 1b study, ONT-380 was evaluated in combination with C and/or T in pts with HER2+ MBC who had been treated with T, a taxane, and ado-trastuzumab emtansine (T-DM1). During doublet dose escalation, ONT-380 300 mg PO BID was well tolerated and responses were seen in combination with either C or T alone; no maximum tolerated dose (MTD) was reached. ONT-380 300 mg PO BID was then studied in combination with both C and T as triplet therapy in order to provide dual blockade of HER2 in combination with cytotoxic chemotherapy. Safety and efficacy results of the triplet cohort are reported here.

Methods: ONT-380 300 mg PO BID was administered with C (1000 mg/m^2 PO BID 14 days of a 21-day cycle), and T (8 mg/kg IV loading; then 6 mg/kg IV once every 21 days). Prior treatment with T, a taxane, and T-DM1 were required; prior pertuzumab, lapatinib, or neratinib were permitted; prior capecitabine exposure was prohibited. Pts with asymptomatic brain mets (treated or untreated) were also eligible. Assessments included safety and tumor response by RECIST 1.1 and Modified CNS RECIST 1.1.

Results: Enrollment was complete as of December 2015. Interim safety and efficacy results as of May 27, 2016 are reported here, with mature data to be presented at the meeting. 27 pts were treated with ONT-380 + C + T: median age 50 y, 56% ER/PR+, 44% ER/PR, 47% PS 0, 53% PS 1. Pts received a median of 3 prior HER2 agents: 100% prior T and TDM-1, 74% prior pertuzumab, 37% prior lapatinib. 11 pts had brain mets at baseline, including 7 patients with untreated or progressive brain mets. Most toxicities were Gr 1. The most common adverse events (>40%) were diarrhea, nausea, palmar-plantar erythrodysaesthesia (PPE), vomiting, and fatigue. Gr 3 events included PPE (11%), diarrhea (11%), fatigue (11%), and reversible increase in AST/ALT (7%). Dose reductions of ONT-380 were required in 6 pts, with 4 of these patients having continued disease control >6 months at the reduced dose. In 24 pts with measurable disease at baseline, ORR was 58%, with best responses of 1 CR, 13 PR, 6 SD, and 4 PD, and clinical benefit rate (SD ≥ 6 mos, PR, CR) in all 27 pts was 67%. Median PFS as of this data cut was 6.3 m (95% CI: 4.1-n/a). Median time on treatment for all 27 pts was 6.2 mo (range 1.4-21.4 mo), with 12 pts still active.

Conclusion: ONT-380 in combination with C and T exhibits an acceptable well tolerated safety profile and shows evidence of responses and long-term disease control in pts who have received contemporary standard of care treatment for HER2+ MBC with both pertuzumab and T-DM1, including pts with brain mets. Based on these encouraging data, a randomized placebo-controlled Phase 2 study (HER2CLIMB) is now enrolling to further evaluate the activity of ONT-380 in this population, including pts with brain mets.
Title: Pertuzumab and trastuzumab plus standard neoadjuvant anthracycline-containing and anthracycline-free chemotherapy regimens in patients with HER2-positive early breast cancer: Efficacy analysis of a phase II cardiac safety study (TRYPHAENA)

Schneeweiss A, Chia S, Hickish T, Harvey V, Eniu A, Waldron-Lynch M, Eng-Wong J, Kirk S and Cortés J. National Center for Tumor Diseases, University Hospital, Heidelberg, Germany; British Columbia Cancer Agency – Vancouver Centre, University of British Columbia, Vancouver, Canada; Royal Bournemouth Hospital, Bournemouth University, Bournemouth, United Kingdom; Regional Cancer and Blood Centre, Auckland City Hospital, Auckland, New Zealand; Cancer Institute "I Chiricuta", Cluj-Napoca, Romania; Roche Products Ltd, Welwyn Garden City, United Kingdom; Genentech, Inc, South San Francisco, CA and Ramón y Cajal University Hospital, Madrid & Vall d’Hebron Institute of Oncology (VHIO), Barcelona, Spain.

Body: Background:
The multicenter, open-label Phase II TRYPHAENA study (NCT00976989) showed that neoadjuvant pertuzumab (P) + trastuzumab (H) + chemotherapy (anthracycline-containing or anthracycline-free) was generally well tolerated with low rates of symptomatic left ventricular systolic dysfunction (LVSD, the primary endpoint), in patients (pts) with HER2-positive, operable, locally advanced or inflammatory breast cancer. All three arms were highly clinically active: total pathologic complete response in the breast and axilla (tpCR; ypT0/is, ypN0) rates were 55–64%. We now report long-term disease-free survival (DFS), progression-free survival (PFS), overall survival (OS), and cardiac safety.

Methods:
Pts were randomized 1:1:1 to six 3-weekly neoadjuvant treatment cycles. Arm A: H + P (cycles 1–6) + fluorouracil, epirubicin, cyclophosphamide (FEC, cycles 1–3) + docetaxel (T) (cycles 4–6), Arm B: FEC (cycles 1–3) followed by T + H + P (cycles 4–6), Arm C: T + H + P + carboplatin (cycles 1–6). Adjuvant H was then given to complete 1 year of treatment. Doses: P 840mg loading and 420mg maintenance; H 8mg/kg loading and 6mg/kg maintenance; T 75mg/m², up to 100mg/m² if tolerated (Arms A and B); fluorouracil 500mg/m²; epirubicin 100mg/m²; cyclophosphamide 600mg/m²; carboplatin area under the plasma concentration–time curve 6. A preplanned descriptive analysis of DFS (time from surgery until disease progression or death), PFS (time from randomization until disease progression or death, equivalent to the common definition of event-free survival), and OS (time from randomization until death from any cause) was conducted 5 years after randomization of the last pt.

Results:
Median follow-up was balanced across arms (61.1 months in Arm A; 61.8 months in Arm B; 60.9 months in Arm C); 3-year Kaplan–Meier (KM) survival estimates and 95% CIs are shown in the table.

For all three arms combined, the hazard ratio for DFS in pts who achieved tpCR versus those who did not achieve tpCR was 0.27 (95% CI 0.11–0.64). During post-treatment follow-up, 2/72 (2.8%) pts in Arm A, 3/75 (4.0%) in Arm B, and 4/76 (5.3%) in Arm C had LVSD (any grade). Of the pts with LVSD, only 1 pt experienced an event indicative of symptomatic LVSD (assessed as NYHA class II and grade ≥3). Also during this period, 8 pts in Arm A (11.1%), 12 (16.0%) in Arm B, and 9 (11.8%) in Arm C experienced LVEF declines to <50% and ≥10% from baseline.

Conclusions:
The 3-year DFS and PFS rates were similar between treatment arms and were comparable to rates previously observed in the neoadjuvant NeoSphere study. Pts who achieved tpCR had improved DFS compared with those who did not achieve tpCR, supporting previous findings of an association between pCR and long-term outcomes (Cortazar et al, Lancet 2014).
combination of P, H, and standard anthracycline-containing or anthracycline-free chemotherapy regimens was generally well tolerated and no new safety signals were identified with 5 years follow-up.
Title: A randomized phase II study of Ki-67 response-guided preoperative chemotherapy for HER2-positive breast cancer

Takahashi M, Nishiyama Y, Hara F, Naito Y, Baba M, Sasaki M, Sato M, Watanabe K, Uemura Y, Yamaguchi T and Mukai H. NHO Hokkaido Cancer Center, Sapporo, Hokkaido, Japan; Kumamoto Shinto General Hospital, Kumamoto, Japan; NHO Shikoku Cancer Center, Matsuyama, Ehime, Japan; National Cancer Center Hospital East, Kashiwa, Chiba, Japan; University of Tokyo, Tokyo, Japan and Musashino Red Cross Hospital, Musashino, Tokyo, Japan.

Body: As for the HER2-positive breast cancer, there are many cases to be effective for neoadjuvant chemotherapy in comparison with other intrinsic subtypes. However, pCR is not provided by neoadjuvant chemotherapy in all cases. [Aim] This study evaluated the effectiveness of a therapeutic strategy that switches chemotherapy, based on Ki-67 tumor expression after initial therapy, relative to that of standard chemotherapy in patients with HER2-positive breast cancer. [patients and methods] Patients were randomly assigned to the control arm or the Ki-67 response-guided arm (Ki-67 arm). Primary tumor biopsies were obtained before treatment, and after three once-weekly doses of paclitaxel and trastuzumab to assess the interim Ki-67 index. In the control arm, paclitaxel and trastuzumab was continued for a total of 12 doses, regardless of the interim Ki-67 index. In the Ki-67 arm, subsequent treatment was based on the interim Ki-67 index. Early Ki-67 responders continued to received paclitaxel plus trastuzumab for a total of 12 doses, while early Ki-67 non-responders were switched to epirubicin plus cyclophosphamide every 3 weeks for three cycles with once-weekly trastuzumab for a total of 12 doses. The primary endpoint was the pathological complete response (pCR) rate. [Results] When 237 patients were enrolled, an interim analysis was conducted in 200 patients. There was almost linear correlation between the Ki-67 reduction rate at interim assessment and the pCR rate. The pCR rate in Ki-67 early non-responders in the Ki-67 arm (23.6%; 95% CI, 12.4 to 34.9) was inferior to that in the control arm (44.1%; 31.4 to 56.7; p=0.025). A strong correlation was not found between the Ki-67 reduction rate and the clinical response rate (Spearman’s correlation coefficient 0.22).

[Conclusions] The pCR rate in the Ki-67 arm was inferior to that in the control arm. A therapeutic strategy that switches chemotherapy, based on Ki-67 tumor expression after initial therapy, was not effective. The standard chemotherapy protocol remains as the recommended strategy for patients with HER2-positive breast cancer.

Title: Preliminary safety and efficacy of first-line pertuzumab combined with trastuzumab and taxane therapy for HER2-positive locally recurrent/metastatic breast cancer (PERUSE)

Bachelot T, Puglisi F, Ciruelos E, Peretz-Yablonski T, Schneeweiss A, Easton V, Lindegger N, Restuccia E and Miles D. Centre Léon Bérard, Lyon, France; University Hospital of Udine, Udine, Italy; Hospital Universitario 12 Octubre, Madrid, Spain; Hadassah-Hebrew University Medical Center, Jerusalem, Israel; National Center for Tumor Diseases, University Hospital, Heidelberg, Germany; F. Hoffmann-La Roche Ltd, Basel, Switzerland and Mount Vernon Cancer Centre, Middlesex, United Kingdom.

Body: Background:
First-line (1L) docetaxel+trastuzumab+pertuzumab (THP) for HER2-positive metastatic breast cancer (MBC) significantly improved progression-free survival (PFS) and overall survival in the phase III CLEOPATRA trial, and led to the approval of this regimen. PERUSE (NCT01572038) was designed to assess the safety and efficacy of investigator's choice of taxane+HP for 1L locally recurrent (LR)/MBC, and allows exploration of safety and efficacy in a larger population.

Methods:
PERUSE is a multicenter, single-arm phase IIIb study. Patients (pts) with Eastern Cooperative Oncology Group performance status ≤2 and no prior systemic therapy for LR/MBC (except endocrine therapy) receive T, paclitaxel (PAC), or nab-PAC plus H (8 mg/kg→6 mg/kg every 3 weeks [q3w]) and P (840 mg→420 mg q3w) until disease progression (PD) or unacceptable toxicity. The primary endpoint is safety. Secondary endpoints include best overall response (BOR) and PFS.

Results:
The safety/ITT population includes 1436 pts at data cutoff (1 Apr 2016). Median follow-up was 17.2 mo (range, <1–41.4). The median pt age was 54 years (range 23–87), 64% had hormone receptor-positive disease, 27% received adjuvant H, and 75% had visceral disease. Pts received T, PAC, nab-PAC, H, and P for a median of 3.8 mo (range <1–24.2; n=791), 4.2 mo (<1–36.6; n=618), 3.9 mo (<1–17.3; n=73), 16.0 mo (<1–45.9; n=1435), and 16.1 mo (<1–45.9; n=1436), respectively.

Most pts discontinued taxanes for 'other' reasons (25%), adverse events (AEs; 16%), PD, or investigator decision (15% each); H, for PD or AEs (46% and 7%); and P, for PD or AEs (46% and 8%).

Grade ≥3 treatment-emergent AEs (TEAEs) of interest are shown in table 1. Serious TEAEs were reported in 282 (36%) pts on T, 185 (31%) on PAC, and 21 (32%) on nab-PAC. Preliminary efficacy by taxane is shown in table 2.

**Conclusion:**
The preliminary findings of this large, single-arm study suggest that safety and efficacy of 1L taxane+HP for HER2-positive LR/MBC are in keeping with the results of the phase III CLEOPATRA study. There was less febrile neutropenia with PAC/nab-PAC+HP compared with THP, and preliminary PFS was similar to that seen in the CLEOPATRA study for all taxane+HP combinations.
Title: Neoadjuvant non-pegylated liposomal doxorubicin plus paclitaxel, trastuzumab and pertuzumab in patients with HER2+ breast cancer – Final results of the SOLTI OPTI-HER HEART study

Body: INTRODUCTION
Targeting HER2 by dual blockade with trastuzumab (T) and pertuzumab (P) in a taxane-based regimen is an active neoadjuvant treatment (NAT) of HER2+ early breast cancer (EBC). Addition of an anthracycline could further enhance this response, but potential cardiac toxicity is a concern. The Opti-HER HEART trial (NCT01669239) aims to optimize neoadjuvant treatment while minimizing cardiac risk, by combining T+P with a taxane and non-pegylated liposomal doxorubicin (NPLD).

MATERIAL AND METHODS
Phase II open-label, single-arm study of six 21-day cycles of NPLD (50mg/m2 D1), paclitaxel (80mg/m2 D1,8,15), T (4mg/kg C1D1, followed by 2mg/kg weekly), and P (840mg C1D1, followed by 420mg C2-6D1) as NAT for patients (pts) with stage II-IIIB HER2+ BC. Primary objective was to evaluate cardiac safety of the combination, measured by the incidence of type A (symptomatic congestive heart failure ) or type B [asymptomatic reduction of Left Ventricular Ejection Fraction (LVEF) value: ≥10% absolute decrease and LVEF<50%, LVEF<40% or any absolute decrease ≥20%] events, during NAT. Eighty-three pts were required to reject with 80% confidence the null hypothesis that the combination increases the incidence of cardiac events above the historical control of 18% (3% type A; 15% type B).

RESULTS
Between June 2013 and January 2015, 83 pts with HER2+ EBC (stage II 78%, stage III 22%) and adequate cardiac function (LVEF≥55%) were enrolled. Mean age was 50 years, N+ 47%, hormone receptor (HR) positive 71% and median baseline LVEF 66%. Eighty-five percent of pts completed 6 cycles of NAT, whereas 15% discontinued NAT due to toxicity. Adverse events (AEs) leading to dose adjustments/temporary interruptions and discontinuation of at least 1 drug occurred in 70% and 21% of pts, respectively. Primary objective was met with an incidence of cardiac events during NAT of 4% (95%CI 1-10, 3pts, all type B). Cardiac events until study completion (1 year) were 8% (all type B). All (but 2 cases with no follow-up data) were reversible and only 1 pt presented an asymptomatic LVEF<40%. Neutropenia (45%) was the most frequent hematological toxicity (G3/4 34%; febrile neutropenia 6%), less frequent in the 71% of pts that received primary G-CSF prophylaxis (G3/4 25% vs. 67%). Common non-hematological toxicities were diarrhea (74%; G3 7%), asthenia (78%; G3 11%) and neurotoxicity (52%; G3/4 10%). Pathological complete response (pCR) in breast+axilla (ypT0/is ypN0) was 60% (87% in HR-) and 69% in breast (91% in HR-).

CONCLUSIONS
The neoadjuvant combination of T+P, paclitaxel and NPLD does not increase the risk for cardiac events in HER2+ BC pts. Since cardiac toxicities may present later, long-term cardiac monitoring is essential. Efficacy in terms of pCR was remarkable, being higher to historical values of combinations with dual anti-HER2 blockade and one of the highest reported among HR-HER2+ BC. This regimen administered with primary G-CSF prophylaxis and cardiac function monitoring may be an effective and secure option for early and locally advanced HER2+ pts with good cardiac function.
Body: Background

Our recent randomized, multicenter phase III GeparSepto study (Untch M et al. Lancet Oncol 2016) found that substituting nab-paclitaxel for standard solvent-based paclitaxel significantly improved the pathologic complete response (pCR) rate in patients receiving a sequential regimen of taxane, epirubicin and cyclophosphamide as neoadjuvant treatment for high-risk primary breast cancer. Patients with HER2-positive tumors (32.8%; n=396) also received a combination of pertuzumab and trastuzumab: the present analysis focuses on efficacy and safety data from these HER2+ patients treated with the dual-blockade.

Methods

Patients with histologically confirmed early breast cancer (n = 1206) received either weekly paclitaxel 80mg/m² or weekly nab-paclitaxel 150/125mg/m², according to randomization), followed by four cycles of epirubicin 90 mg/m² plus cyclophosphamide 600 mg/m² q3w, with concurrent trastuzumab 6 mg/kg (loading (LD) dose 8 mg/kg) and pertuzumab 420 mg (LD 840 mg) q3w for those with HER2-positive tumors. The primary endpoint was pathologic complete response (pCR), defined as ypT0 ypN0.

Results

The GeparSEPTO trial included 396/1206 (32.8%) HER2+ primary breast cancer patients. 27.0% in the HER2-positive and 34.1% in the HER2-negative group had HR-negative disease. Baseline characteristics were otherwise comparable between HER2+ and HER2- patients. Higher rates of pCR were seen in HER2+, compared to HER2- tumors (57.8% vs 22.0%). The highest overall pCR rate was observed in the HER2+/HR- cohort with 71.0%; 66.7% with Pac and 74.6% with nab-Pac. In HER2+/HR+ pCR rate was 52.9% ; 49.4% with Pac and 56.4% with nab-Pac. Using the definition ypT0/is ypN0 for pCR; pCR rates were generally higher especially in the HER2+ cohort (66.2% (ypT0/is ypN0) vs 57.8% (ypT0 ypN0)) compared to 25.2% (ypT0/is ypN0) vs 22% (ypT0 ypN0)) in patients with HER2-negative tumors. The HER2+ patients experienced a significantly higher incidence of grade 3-4 adverse events 85.4% vs 78.0% in the HER2-cohort, p=0.003); grade 3-4 hematologic AEs 74.0% (HER2+) vs 69.5% (HER2-); p=0.120 with grade 3-4 anaemia 2.5% vs 0.9%; p=0.034); any grade thrombopenia 28.5% vs 21.8%; p=0.012) and febrile neutropenia 6.3 vs 3.3%; p=0.023. Any grade 3-4 non-haematological toxicities occurred in 38.4% vs 30.1%; p=0.005), with grade 3-4 diarrhea occurring in 7.6% vs 0.9%; p<0.001 of the patients. This had no impact on compliance. LVEF decreases from baseline were uncommon (7.6%) with 2.0% (HER2+) versus 0.4% (HER2-) of patients showing decreases to <50% along with a ≥10% decrease from baseline.

Conclusion

This is the largest cohort of patients with HER2-positive early breast cancer receiving a dual HER2-targeted neoadjuvant therapy of pertuzumab and trastuzumab, together with nab-paclitaxel or paclitaxel followed by epirubicin and cyclophosphamide. HER2+ patients experienced more noteworthy toxicity. The pCR rate were higher in the HER2+ cohort receiving the dual blockade and was highest in patients with in HER+/HR- particularly if nab-paclitaxel was substituted for paclitaxel. The trial is financially supported by Celgene and Roche.
Title: Preliminary safety and efficacy of first-line pertuzumab combined with trastuzumab and taxane therapy in patients ≥65 years with HER2-positive locally recurrent/metastatic breast cancer: Subgroup analyses of the PERUSE study

Miles D, Schneeweiss A, Peretz-Yablonski T, Ciruelos E, Puglisi F, Easton V, Lindegger N, Restuccia E and Bachelot T. Mount Vernon Cancer Centre, Middlesex, United Kingdom; National Center for Tumor Diseases, University Hospital, Heidelberg, Germany; Hadassah-Hebrew University Medical Center, Jerusalem, Israel; Hospital Universitario 12 Octubre, Madrid, Spain; University Hospital of Udine, Udine, Italy; F. Hoffmann-La Roche Ltd, Basel, Switzerland and Centre Léon Bérard, Lyon, France.

Body: Background:
First-line (1L) docetaxel+trastuzumab+pertuzumab (THP) is approved for HER2-positive metastatic breast cancer (MBC), based on superior progression-free (PFS) and overall survival vs TH in the phase III CLEOPATRA trial. Predefined CLEOPATRA subgroup analyses suggested that THP use should not be limited by patient (pt) age: toxicity was increased but efficacy was similar in pts ≥65 vs <65 years. PERUSE (NCT01572038) examined investigator's choice of taxane+HP for HER2-positive locally recurrent (LR)/MBC. We report preliminary safety and efficacy in pts ≥65 and <65 years.

Methods:
In this multicentre, single-arm phase IIIb study, pts with ECOG PS ≤2 and no prior systemic therapy for LR/MBC (except endocrine therapy) receive investigator's choice of T, paclitaxel (PAC), or nab-PAC + H (8→6 mg/kg q3w) + P (840→420 mg q3w) until disease progression/unacceptable toxicity. The primary endpoint is safety. Secondary endpoints include PFS, estimated using the Kaplan–Meier method.

Results:
At data cutoff (1 Apr 2016), 1436 pts were included in the safety/ITT populations. 312 pts (22%) were aged ≥65 at study entry; they were more likely to have comorbidities than the <65 group (91% vs 69%, including vascular disorders [56% vs 22%]; most commonly hypertension [51% vs 17%]) and be ECOG PS 1–2 (50% vs 38%).
Proportions of pts with visceral and hormone receptor-positive disease were similar (78% vs 74% and 65% vs 64%, respectively). Median duration of chemotherapy was similar but median exposure to antibodies was shorter in the ≥65 vs <65 group: H 11.7 mo (range <1–45.8) vs 17.5 mo (<1–45.9); P 11.6 mo (<1–45.8) vs 17.8 mo (<1–45.9).
Interruptions/discontinuations due to treatment-emergent adverse events (TEAEs) were more common in pts ≥65 compared with pts <65 with respect to taxanes (50% vs 35%), H (41% vs 26%), and P (38% vs 23%).
TEAEs related to taxanes, H, and P were generally similar in pts aged ≥65 and <65 (93% each, 67% vs 62%, and 71% vs 70%, respectively).
Serious TEAE rates and most common grade ≥3 TEAEs of interest are shown in table 1.

</table>
Preliminary median PFS at the time of this analysis was 23.2 mo in the <65 group (95% CI 20.7–25.3; median follow-up 18 mo) and 14.7 mo in the ≥65 group (95% CI 12.8–20.2; median follow-up 14 mo); 511/1124 (45%) and 116/312 (37%) pts were censored, respectively.

**Conclusion:**
Preliminary findings with 1L taxane+HP in this large cohort of LR/MBC pts show that pts aged ≥65 years had more comorbidities and poorer PS at study entry compared with those aged <65, and that serious TEAEs were noted more frequently. Treatment exposure and PFS were shorter for pts aged ≥65.

**Title:** A phase I/II of S-222611, a reversible EGFR and HER2 inhibitor, combined with trastuzumab +/- chemotherapy in patients with HER2-positive metastatic breast cancer

Rafii S, Macpherson I, Baird R, Saggese M, Spiliopoulou P, Kumar S, Italiano A, Bonneterre J, Campone M, Cresti N, Posner J, Takeda Y, Arimura A and Spicer J. Sarah Cannon Research Institute UK, London, United Kingdom; Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom; Cambridge Cancer Centre, Cambridge, United Kingdom; Institute Bergonie, Bordeaux, France; Centre Oscar Lambret, Lille, France; Institut de Cancérologie de l’Ouest, Nantes, France; Northern Centre for Cancer Care, The Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle, United Kingdom; Shionogi & Co. Ltd., Osaka, Japan and King’s College London, Guy’s Hospital, London, United Kingdom.

**Body:** Background: S-222611, an oral, reversible EGFR and HER2 inhibitor, has been shown to be well-tolerated as monotherapy at a dose of 800mg daily with good anti-tumor activity in patients previously treated with other anti-HER2-based regimens. This study evaluated the tolerability and safety of daily oral administration of S-222611 (S) in combination with trastuzumab (T), trastuzumab + vinorelbine (T+V) and trastuzumab + capecitabine (T+C) in HER2-positive (HER2+) metastatic breast cancer (MBC) with or without brain metastases.

Methods: This study was performed as a 3+3 dose escalation followed by expansion to examine the tolerability and safety of S in combination with T, T+V and T+C in Arms A, B and C, respectively. S was administered orally once daily, starting at a dose of 400mg in Arm A, and 200mg in Arms B and C. The dosing of T was 8mg/kg loading followed by 6mg/kg or fixed dose of 600mg subcutaneously every 21 days as recommended. V was administered at 60mg/m\(^2\) orally on Day 1 and 8 of a 21-day cycle, and C 1000mg/m\(^2\) orally daily for 14 days followed by a 7-day rest period. All patients had HER2+ MBC and were required to have progressed following at least one prior line of anti-HER2 therapy. Prior treatments with V and C were permitted. Anti-diarrhea prophylaxis with loperamide was not required.

Results: A total of 45 patients were enrolled. All patients had received prior anti-tumor regimens including T (n=45), T-DM1 (n=26), pertuzumab (n=9) and lapatinib (n=12). The clinically recommended doses of S at which most adverse events were manageable, were determined as: 600mg in Arm A, 200mg in Arm B and 400mg in Arm C. Dose limiting toxicities included Grade 3 diarrhea for Arm A; and Grade 4 neutropenia, Grade 3 Hypokalemia and Hypophosphatemia for Arm B. As of 13 May 2016, treatment is ongoing in 2 patients. No other Grade 4 AEs related to S-222611 have been observed. Grade 3 bilirubin elevation was observed in 5/45 patients, probably due to transporter (UGT1A1) inhibition, while no G3/4 liver dysfunction was reported. RECIST partial responses (PR) were observed in 6 of 9 patients in Arm A and 5 of 9 patients in Arm C, at respective clinically recommended doses. Nine of 45 patients had brain metastases; 4 of these patients showed RECIST PR including an intracranial tumor response in one patient (400mg in Arm C) who had prior treatments with paclitaxel, T+C, T-DM1 and V after diagnosis of BM.

Conclusions: The clinically recommended doses of S-222611 combined with T, T +V and T+C were determined for further clinical studies. Clinical benefit (PR and SD ≥6 month) was seen with each combination even in heavily pre-treated HER2+ MBC patients.

**Summary of the safety and efficacy of S-222611 (S) combination.**

Title: Cardiac biomarkers for early detection and prediction of trastuzumab and/or lapatinib-induced cardiotoxicity in patients with HER2 positive early breast cancer (BIG 1-06)

de Azambuja E, Bradbury I, Ewer M, Campbell C, Zardavas D, Ameels H, Baselga J, Huober J, Izquierdo M, Bozovic-Spasojevic I, Maetens M, Harbeck N, Pusztai L, Piccart M, Rodeheffer R and Sutter T. Institut Jules Bordet, Bruxelles, Belgium; Frontier Science (Scotaland) Ltd., United Kingdom; MD Ancerson Cancer Center, Houston; Breast International Group, Brussels, Belgium; BReast European Adjuvant Study Team, Brussels, Belgium; Memorial Sloan Kettering Cancer Cencer, New York; Breast Center, University of Ulm, Ulm, Germany; OGD, Novartis Pharma, Switzerland; Institute for Oncology and Radiology of Serbia, National Cancer Research Center, University of Belgrade, Belgrade, Serbia; Breast Cancer Research Laboratory, Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium; Brustzentrum, Frauenklinik der Universität München, Munich, Germany; Mayo Clinic, Rochester and Swiss Cardiovascular Center, Inselspital, Bern University Hospital, Bern, Switzerland.

Body: Background: Anti-HER2 agents are associated with an increased risk of cardiotoxicity, occurring mostly during treatment and being generally reversible. To date, no cardiac biomarkers have been validated as predictive markers of cardiotoxicity in patients (pts) receiving anti-HER2 therapies. We evaluated high sensitivity (HS) troponin T (TnT) and N-terminal pro-brain natriuretic peptide (NT-proBNP) in pts treated with neoadjuvant anti-HER2 therapies to evaluate if early elevation of cardiac biomarkers predicts early or late cardiac events.

Material and Methods: 455 pts were randomized to receive either lapatinib (154 pts), trastuzumab weekly (149 pts), or lapatinib with trastuzumab for a total of 6 weeks (152 pts). After this biological window, pts continued on the same targeted therapy plus 12-weekly paclitaxel until definitive surgery. After surgery, patients received adjuvant FEC (3x) followed by the same HER2 therapy as in the neoadjuvant phase for further 34 weeks (to complete 52 weeks in total). Eligible pts had an LVEF ≥50%. Cardiac biomarkers were centrally tested in plasma samples collected at baseline, week 2 (W2) and at surgery. Elevated biomarker was defined as either TNT >0.015 µg/L or NT-proBNP >125 pg/mL. The small number of pts and rarity of marker elevations allowed only descriptive analyses.

Results: At a median follow-up of 3.8 years, 280 pts had cardiac biomarkers tested at baseline (61.5%) and NT-proBNP was elevated in 39 pts (13.9%) while TNT was elevated in only 1 pt (0.35%). From those 39 pts with NT-proBNP elevated at baseline, only 1 pt experienced a cardiac event. Also, hypertension was presented in 14 pts (24.5%) with elevated NT-proBNP.

Serial measurements were available in 173 pts (61.7%) and NT-proBNP was elevated in 25, 10 and 21 pts at baseline, W2 and at surgery, respectively, while among 171 pts (61%) TNT was elevated in 1, 1 and 5 pts, respectively. There were 13 cardiac events in 11 pts in the entire trial. Five of these pts had a measurement of cardiac biomarkers at baseline (non-elevated NT-prBNP and TNT were observed in 4 and 5 pts), 9 of them had a measurement at week 2 (non-elevated NT-prBNP and TNT were observed in 8 and 9 pts) and 3 of them at surgery (non-elevated NT-prBNP and TNT were observed in 3 and 3 pts), respectively. The following table show the low specificity of the cardiac biomarkers.

During adjuvant phase, 13 pts experienced LVEF drop to <50% and none had either NT-proBNP elevated or TNT at surgery. **Conclusions:** Despite the small sample size, we demonstrated that cardiac biomarkers are rarely elevated in pts receiving anti-HER2 therapies, which is probably due to the absence of myocyte necrosis with respect to TNT, and the lack of chamber dilation in the case of NT-proBNP after exposure to these drugs. In addition, few cardiac events were present in this population not previously exposed to anthracycline-based chemotherapy; therefore the use of cardiac biomarkers in this population may be unnecessary.
Title: Characterization of neratinib-induced diarrhea in patients with early-stage HER2+ breast cancer: Analyses from the phase III ExteNET trial

Mortimer J, Di Palma J, Jahanzeb M, Schmid K and Ye Y. City of Hope Comprehensive Cancer Center; University of South Alabama; University of Miami; University of Nebraska Medical Center and Puma Biotechnology Inc..

Body: Background: ExteNET is an ongoing randomized placebo-controlled phase III trial designed to investigate the efficacy and safety of 12 months’ treatment with neratinib in women with stage I–III HER2+ breast cancer after completion of adjuvant trastuzumab. At 2 years after randomization, a significant improvement in invasive disease-free survival was evident with neratinib vs placebo (stratified hazard ratio 0.67, 95% CI 0.50–0.91; P=0.0091) [Chan et al. Lancet Oncol 2016]. Neratinib was generally well tolerated with a low incidence of grade 3/4 events; diarrhea was the most common adverse event (grade 3, 39.8%, grade 4, 0.1%). We reviewed the safety data related to this study in order to better characterize the occurrence of neratinib-induced diarrhea (NID) and its impact on health-related quality of life (HRQoL).

Methods: Patients received neratinib 240 mg once daily or placebo for 12 months. Antidiarrheal prophylaxis was not dictated by the protocol, but investigators were advised to treat diarrhea early. Adverse events were monitored until 28 days after the last dose of study drug, and graded according to NCI-CTCAE, v3.0. Patient-reported HRQoL questionnaires (Functional Assessment of Cancer Therapy–Breast [FACT-B], v4; EuroQol 5-Dimensions [EQ-5D]) were completed at baseline and 1, 3, 6, 9 and 12 months. Descriptive analyses of FACT-B and EQ-5D scores by maximum grade of diarrhea were performed in patients with post-baseline HRQoL assessments. ClinicalTrials.gov: NCT00878709.

Results: Of 2840 women randomized, 2816 (1408 per group) received at least one dose of study drug and were evaluable for toxicity. Diarrhea was more common with neratinib than placebo (all-grade: 95.4% vs 35.4%; grade 3: 39.8% vs 1.6%; grade 4: 0.1% vs 0%). Median time to onset of any grade NID was 2 (IQR 2-4) days. Most grade 3 NID occurred early in the course of treatment with a reduction in frequency thereafter; 28.6% of patients had grade 3 events during month 1 decreasing to approx. 6% or less after month 3. For those experiencing grade 3/4 NID, the median number of events was 2 (IQR 1–3) with a median cumulative duration of 5 (IQR 2–9) days. NID resulted in dose reductions in 26.4%, dose holds in 33.9%, drug discontinuation in 16.8%, and hospitalizations in 1.4% of patients. In the neratinib group, FACT-B and EQ-5D scores decreased with increasing severity of diarrhea (Table); the changes in scores were not considered to be clinically meaningful.

MID, minimally important difference; SD, standard deviation; VAS, visual analogue scale.

Conclusion: NID has a distinct clinical pattern, with a high incidence of grade 3 events in the first month and a dramatic decrease thereafter. In the absence of antidiarrheal prophylaxis, patients with severe diarrhea experience a median of 2 events lasting for a cumulative duration of 5 days. Loperamide prophylaxis given early in the course of treatment is currently being investigated in the prevention of NID with promising early results.
Title: T-DM1 in HER2 positive advanced breast cancer patients: Real world practice from a multicenter observational study

Body: Background: T-DM1 showed remarkable activity in metastatic HER-2 positive breast cancer (mBC) and it was recently approved for clinical use in patients (pts) who previously failed Trastuzumab- and Taxanes-based therapies. Currently, little is known on the performance of T-DM1 in a “real life” scenario. Therefore, we investigated effectiveness and safety of T-DM1 in Italian daily practice.

Methods: Pts baseline characteristics and clinical outcome of pts with HER-2 positive mBC treated with T-DM1 between 2013 and 2015 at 20 Italian Institutions were retrospectively collected and analyzed.

Results: 300 pts were included in our analysis. Median age was 51 years (27-78); visceral metastases were present in 204 (68%) pts and brain metastases in 86 (29%). It is noteworthy that 111 (37%) pts received T-DM1 as pure second line, 83 (28%) as third line and 96 (32%) as further lines. Moreover 10 (3%) pts had T-DM1 as first line because disease recurrence occurred during or adjuvant trastuzumab of within 6 months of its completion. The overall response rate (ORR) was 40%, global disease control rate (gDCR) 64%, median progression-free survival (PFS) 7.0 months (C.I.95%: 5.6-8.4) and overall survival (OS) at 2 years 63%. Pts with 1, 2 and 3 or more metastatic site had OS at 2 years of 87%, 67% and 46%, respectively (p<0.0001). When T-DM1 was given as second line the PFS was 8.0 months and beyond second-line was 6.8 months. Interestingly, for 38 (13%) pts who progressed after Pertuzumab-plus trastuzumab and taxanes as first line treatment, ORR and gDCR were similar to pertuzumab-naïve patients (38% and 62%, respectively) However PFS was 5.0 months (C.I.95%: 4.3-5.7) compared to 9.0 (95% C.I. 5.5-12.4) achieved in pts not receiving a previous pertuzumab-based treatment. Most frequent grade ≥3 toxicities were thrombocytopenia (2.6%), alopecia (2.1%), hypertransaminasemia (2.2%), neutropenia (1.3%), asthenia (1.3%) and diarrhea (0.4%).

Conclusions: To our knowledge, this is the first real life, multicenter retrospective analysis evaluating efficacy and safety of T-DM1 in pretreated HER-2 positive mBC pts. We observed remarkable results in terms of PFS and OS, especially when T-DM1 was given early in the course of metastatic disease. Shortened PFS in patients progressing after pertuzumab suggest further analyses to better define possible molecular mechanisms of cross-resistences between two molecules. As a whole there was no evidence of significant or unexpected toxicities. Although these findings should be taken with caution due to the retrospective analysis and the different lines of previous treatment considered, we confirmed the potential therapeutic role of T-DM1 across a heterogeneous population of HER-2 positive mBC patients. The final analysis will be presented to the meeting.
Title: Preference of trastuzumab administration route (intravenous or subcutaneous) in patients in the Czech Republic. Cross-sectional study on 429 patients

Petrakova K, Melichar B, Bortlicek Z and Hejduk K. Masaryk Memorial Cancer Institute, Brno, Czech Republic; Palacky University Medical and Teaching Hospital, Olomouc, Czech Republic and Institute of Biostatistics and Analysis, Faculty of Medicine, Masaryk University, Brno, Czech Republic.

Body: Background: Trastuzumab is the treatment for HER2-positive breast cancer in the metastatic, adjuvant, and neoadjuvant settings. Trastuzumab is available in intravenous (i.v.) and subcutaneous (s.c.) application form. PrefHer study published in 2013 described patients' preference for use of subcutaneous trastuzumab. Our aim was to find out and describe if any preference exists in real clinical practice in the Czech Republic.

Objectives: To analyse reasons for preference of s.c. or i.v. application of trastuzumab in patients with HER2-positive breast cancer in real clinical setting in the Czech Republic.

Methods: A questionnaire based data collection from patients treated in Comprehensive Cancer Centres between January 2015 and July 2015.

Results: We received 429 questionnaires from patients. Data analysis has been conducted in 301 (70.2%) patients' questionnaires after quality control for questionnaires completeness. Out of the 301 patients there were 151 who had ≥ 11 i.v. applications, 137 patients with 3-10 i.v. applications and 13 patients with only 2 i.v. applications. Majority of patients were treated in adjuvant setting (62.8%, n=189), 21.9% (n=66) received neoadjuvant treatment and 15.3% (n=46) patients were treated for advanced disease. Only 33 patients had experience with ≥ 11 s.c. applications, 222 patients with 3-10 s.c. applications and 46 patients with 2 s.c. applications. Subcutaneous form was given in 74.8% (n=225) in adjuvant setting, in 20.3% (n=61) in advanced setting and in 5.0% (n=15) in neoadjuvant setting. Pain related to trastuzumab application was assessed – 52.2% (n=157) patients stated that s.c. application is less painful, 34.2% (n=103) did not see difference and 13.6% (n=41) patients felt that i.v. form is less painful. When assessing site reactions majority (62.4%, n=184) of patients did not see difference between application forms, 20.0% (n=59) patients preferred s.c. form and 17.6% (n=52) preferred i.v. form. Lower anxiety related to trastuzumab application was reported with s.c. form (46.0%, n=137). Only 6.0% (n=18) patients reported lower anxiety with i.v. application and 48.0% (n=143) did not see any difference. Vast majority (92.7%, n=279) patients described s.c. form as more comfortable, 4.7% (n=14) patients did not see difference and only 2.7% (n=8) described i.v. form as more comfortable. Overall 95.0% (n=286) patients preferred s.c. application form of trastuzumab. The main reasons are time savings (86.7%, n=261) and better comfort (71.8%, n=216). Only 10 patients (3.3%) favoured i.v. application form. The main reason for i.v. preference is lower pain and lower incidence of complications (2.0%, n=6). The remaining 5 patients (1.7%) had no preference of any application form.

Conclusion: Patients treated in Comprehensive Cancer Centres in the Czech Republic prefer subcutaneous application form of trastuzumab. The main reasons for their preference are time savings and better application comfort.
Title: Comparative toxicity and effectiveness of trastuzumab combined with anthracycline versus platinum chemotherapy regimens for adjuvant therapy of HER2+ breast cancer in older women

Body: Rationale: The combination of chemotherapy and the monoclonal antibody trastuzumab is the standard of care for systemic adjuvant therapy of HER2-positive breast cancer, substantially improving patient outcomes. Two regimens have been widely adopted for use in the United States, adriamycin/cyclophosphamide/paclitaxel/trastuzumab (ACTH) and docetaxel/carboplatin/trastuzumab (TCH). While other options are available in the neoadjuvant and low-risk settings, ACTH or TCH remain standard of care for many women with early-stage HER2+ disease. No head-to-head comparison of these regimens has been conducted in a clinical trial, and the clinical trial data have limited generalizability due to the exclusion of older women and the low representation of minorities and those with significant co-morbidities.

Research Objectives: We used SEER-Medicare data from 2005-2013 to conduct a comparative effectiveness study of ACTH vs TCH among patients over 65 receiving trastuzumab-based adjuvant chemotherapy. An intent-to-treat analytic design was applied and propensity score matching was used to account for selection bias and to balance cohort characteristics between treatment arms. Outcomes included toxicity-related hospitalization, survival, and regimen completion (receiving ≥270 days of trastuzumab). Toxicity was evaluated using inpatient and emergency room claims for chemotherapy-related adverse events in the first six months of therapy, as well as all-cause hospitalization over the same period. Data from 1077 patients with HER2+ disease were analyzed and the propensity-matched sub-sample included 416 women.

Results: Over time there was a significant shift in regimen use between ACTH vs TCH, with 88% of patients in 2005 receiving ACTH compared to only 15% by 2011. Using the propensity score-matched patients, we found no difference between regimens in healthcare utilization for chemotherapy-related adverse events or all cause hospitalization. (RR=0.99, 95% CI 0.64-1.51) Patients receiving TCH were significantly more likely to complete trastuzumab (89% for TCH vs 77% for ACTH). There was no difference between regimens in five year breast cancer-specific survival or overall survival. Results of a sensitivity analysis limited to patients who completed trastuzumab were similar to the primary analysis.

Conclusions: Among older women with HER2+ breast cancer receiving multi-agent regimens with similar levels of medical comorbidity, ACTH compared to TCH did not appear to be associated with a higher rate of serious adverse events or hospitalizations, but was associated with a lower rate of completion of adjuvant trastuzumab. Ability to evaluate cardiotoxicity in this claims-based analysis was limited. We did not detect a difference in five year survival outcomes for ACTH compared to TCH. In the context of limited evidence in older patients, there appears to be little difference between the two regimens in terms of either toxicity or efficacy.
Title: A randomized phase II trial of trastuzumab + capecitabine versus lapatinib + capecitabine in patients with HER2-positive metastatic breast cancer previously treated with trastuzumab and taxanes: WJOG6110B/ELTOP

Takano T, Tsurutani J, Takahashi M, Yamanaka T, Sakai K, Ito Y, Fukuoka J, Kimura H, Kawabata H, Tamura K, Matsumoto K, Aogi K, Sato K, Nishio K, Nakagawa K and Saeki T. Toranomon Hospital, Tokyo, Japan; Kindai University, Osaka, Japan; NHO Hokkaido Cancer Center, Hokkaido, Japan; Yokohama City University, Kanagawa, Japan; Cancer Institute Hospital, Tokyo, Japan; Pathology Institute, Toyama, Japan; Kanazawa University, Ishikawa, Japan; National Cancer Center Hospital, Tokyo, Japan; Hyogo Cancer Center, Hyogo, Japan; Shikoku Cancer Center, Ehime, Japan; Tokyo-West Tokushukai Hospital, Tokyo, Japan and Saitama Medical University, Saitama, Japan.

Body: Background: In patients with HER2-positive metastatic breast cancer (MBC) who progressed on trastuzumab (H)-based therapy, both continuing H beyond progression and switching to lapatinib (L) in combination with chemotherapy are valid options. However, it is unclear which strategy is more effective and how we can select a proper strategy in each patient.

Methods: We conducted an open label, multicenter, randomized phase II trial to comparatively evaluate efficacy and safety of H + capecitabine (X) (HX) or L + X (LX) in women with HER2-positive MBC who were previously treated with taxanes and progressed on H-containing regimens. Patients treated with more than two chemotherapy regimens for MBC were excluded. Those treated with pertuzumab and/or T-DM1 were allowed to enroll in this study. Patients with brain metastases were also included if they are asymptomatic. Patients received H (4mg/kg loading then 2mg/kg weekly or 8mg/kg loading then 6mg/kg every 3 weeks) and X (2500 mg/m$^2$/day on days 1-14 every 3weeks) in HX arm and L (1250 mg/day) and X (2000 mg/m$^2$/day on days 1-14 every 3weeks) in LX arm until progression or intolerable toxicity. The primary endpoint was progression-free survival (PFS) and secondary endpoints included overall survival (OS), objective response rate (ORR), proportion of subjects progressing with brain metastases as site of first progression, and safety. We also assessed biomarkers in tumor tissues and circulating cell-free DNA.

Results: Between May 2011 and December 2014, 86 patients (43 in HX arm and 43 in LX arm) were enrolled in this study. Median age was 58 years (range 34-81), ECOG performance status was 0 (63%), 1 (35%), or 2 (2%), 63% had hormone receptor-positive disease, 15% had brain metastases, 56% had relapsed after primary surgery, and 23% had received adjuvant or neo-adjuvant trastuzumab. Median follow-up time was 44.6 months. Median PFS was 6.1 months in HX arm and 7.1 months in LX arm (hazard ratio 0.81 90% CI 0.55-1.21; p=0.39), median OS was 31.0 months in HX arm and not reached in LX arm (hazard ratio 0.58 95% CI 0.26-1.31; p=0.18), ORR was 40% in HX arm and 41% in LX arm (p=1.00), disease control rate was 73% in HX arm and 92% in LX arm (p=0.038), and proportion of subjects progressing with brain metastases as site of first progression was 5% in HX arm and 5% in LX arm. Grade 3-4 toxicities included hand-foot syndrome (21% in HX arm and 21% in LX arm) and diarrhea (9% in HX arm and 16% in LX arm). In subgroup analyses, PFS benefit in LX arm compared to HX arm was significantly larger among patients who had received previous systemic treatment for metastatic disease for less than 1 year (interaction p=0.007). Subgroup analyses by biomarkers will be presented at the meeting.

Conclusions: In women with HER2-positive MBC previously treated with trastuzumab and taxanes, lapatinib + capecitabine tended to yield better PFS and OS than trastuzumab beyond progression + capecitabine, although they were not statistically significant.
Title: Trastuzumab IV versus SC: A time, motion and cost assessment in a lean operating day care oncology unit

Body: Purpose:
Primary endpoint: quantification of the active healthcare professional (HCP) time associated with the standard intravenous (IV) infusion of trastuzumab (Herceptin®) compared to the subcutaneous (SC) administration in the treatment of patients with HER2-positive early breast cancer.

Secondary endpoints: quantification of the preparation and administration related costs (HCP time, consumables and drug wastage), patient chair time and the total time spent in the day care unit for both routes of administration.

Patients and Methods:
A local observational project was conducted in the LEAN Operating Day Care Oncology Unit of the Antwerp University Hospital (Belgian registration number: B300201525036).

Independent observers measured the duration of each trastuzumab IV and SC related task that HCPs undertook and recorded patient time in the chair and the day care unit. The type and quantity of medical consumables used with each route were also registered. A total of 105 patient episodes were recorded (40 IV, 65 SC) from October 2015 until May 2016.

The recorded active HCP time corresponded to the active preparation and administration time of the medication. Total preparation and administration time was calculated as the mean sum of task times, both for IV and SC formulations. The cost of each route of administration was calculated as the mean cost of HCP time plus the mean cost of consumables used. Drug wastage that occurred with the IV formulation was also taken into account. The total active HCP time was quantified by the Hospital's Human Resources department. Consumables were quantified using hospital pharmacy data and online sources. Patient chair time was measured as the actual time spent on the chair. The total time spent in the day care unit was calculated as the time between the patient's registry and the time the patient left the hospital.

Results: The mean active HCP time for preparation and administration of IV was 64 minutes compared to 14 minutes for SC. The mean cost for preparation and administration was €303,12 for IV (€33,8 of HCP time, €23,56 of consumables and €245,76 of drug wastage) versus €10,39 for SC (€7,68 of HCP time and €2,71 of consumables). Mean patient chair time and the total time spent in the day care unit for IV was 133 and 165 minutes respectively, and 11 and 50 minutes for SC.

<table>

</tbody>
</table>

SC administration of trastuzumab resulted in a HCP time saving of 50 minutes (versus IV) with a total cost saving of €292,73 per administration. This leads to a potential saving of €5,269,16 over a full course of adjuvant treatment (18 cycles).

Conclusion: Substituting IV with SC administration of trastuzumab leads to a substantial reduction in active HCP time. As a
result, the overall costs consisting of HCP time, consumables and drug wastage are also reduced. Additionally, the reduced patient chair and unit time could provide increased capacity within existing resources in a LEAN Operating Day Care Oncology Unit.
Phase III trial to evaluate patient’s preference for subcutaneous versus intravenous trastuzumab administration in patients with HER2 positive advanced breast cancer (ABC) under IV trastuzumab (IV-t) treatment for at least 4 months. ChangHER-SC study (GEICAM/2012-07)

Ciruelos EM M, Montaño Á, Rodríguez CA A, González-Flores E, Lluch A, Garrigós L, Quiroga V, Antón A, Malón D, Chacón JJ I, Velasco M, Gonzalez-Cortijo L, Jolis L, Pascual T, Amigo Y, Casas M, Cámar MC, Carrasco E and Casas A. Hospital Universitario 12 de Octubre, Madrid, Spain; Hospital Universitario Virgen del Rocio, Seville, Spain; Hospital Universitario de Salamanca-IBSAL, Zaragoza, Spain; Hospital Universitario Virgen de las Nieves, Granada, Spain; Hospital Clínico de Valencia, Instituto de Investigación Sanitaria INCLIVA, Universitat de València, Valencia, Spain; Hospital del Mar, Barcelona, Spain; Institut Català d’Oncologia Badalona-HU Germans Trias i Pujol, Badalona, Barcelona, Spain; Hospital Universitario Miguel Servet, Zaragoza, Spain; Hospital Universitario de Fuenlabrada, Madrid, Spain; Hospital Virgen de la Salud, Toledo, Spain; Hospital de Mataró (Consorti Sanitari del Maresme), Mataró, Barcelona, Spain; Hospital Universitario Quirón de Madrid, Madrid, Spain; Hospital General de Granollers, Granollers, Barcelona, Spain; GEICAM, Spanish Breast Cancer Group, Madrid, Spain and Hospital Universitario Virgen del Rocio, Seville, Spain.

Body: Background: Patients with HER2-positive ABC, receive anti-HER2 treatment for several months or even years. IV-t is administered weekly or 3-weekly, mandating patients to visit the hospital on a regular basis to receive infusions. This has inconveniences for patients and increase treatment costs. Subcutaneous administration could improve convenience of trastuzumab therapy. This study was designed to evaluate patient's preference for IV-t or SC trastuzumab (SC-t) in ABC patients.

Methods: This is a phase III, open label, multicenter study inpatients with HER2 positive ABC, receiving IV-t for at least 4 months and without evidence of disease progression. Patients received 600 mg of SC-t, either from a vial or from a single injection device (SID), every 3 weeks for 4 cycles. Before starting SC-t, patients received an additional IV-t cycle. Patients were randomized 1:1 to arm A, receiving 2 cycles of SC-t with vial followed by 2 cycles with SID or arm B, receiving the opposite sequence. After cycle 4, patients decided to continue with IV-t or SC-t till disease progression. Stratification criteria were the associated therapy (Chemotherapy, Hormone-therapy or none) and its administration route (IV, oral or none). Patients completed a questionnaire of experiences and preferences at three time points: before starting SC-t, after cycle 2 and after cycle 4. Health Care Professionals completed a satisfaction questionnaire every 5 patients. The primary objective was to evaluate patient’s preference for IV-t or SC-t (after cycle 2) and, secondary objectives were, to evaluate patient’s preference between the two SC-t administrations (vial or SID) after cycle 4, Health Care Professional satisfaction, associated costs of the administration options (Time and Motion pharmacoeconomic study) and safety.

Results: From September-13 to July-15, 166 patients were randomized (81 arm A, 85 arm B) in 26 Spanish sites from GEICAM. Median age was 60 years (35-93), 88% of patients were postmenopausal and 123 and 42 had an ECOG PS of 0 and 1, respectively. The median duration of prior IV-t for ABC was 1.8 years (range: 0.3-14). Patients received a median of 2 previous lines of Chemotherapy and/or Hormone-therapy (range: 1-9). Twenty patients were receiving pertuzumab at inclusion. According to patient questionnaires completed after cycle 2, 137 patients preferred the SC-t (66 arm A, 71 arm B), 11 the IV-t (6 arm A, 5 arm B), 11 didn't have a preference (4 arm A, 7 arm B), and 7 didn't answer (3 progressed, 2 withdrew participation before cycle 2 and 2 unknown reason). Three of the 11 patients choosing IV-t were receiving IV treatment as accompanying therapy; after cycle 4 five of these 11 patients finally continued with SC-t, 5 with IV-t and 1 progressed. From the 11 patients without any preference 7 received SC-t, 2 receive IV-t and 2 progressed; from the 137 patients preferring SC-t, 125 actually received it, 3 received IV-t and 9 progressed.

Conclusions: Our study shows that 82.5% of patients preferred the SC-t over the IV-t. Treatment choice was not influenced by the accompanying therapy.
Title: **BELIS: Safety and tolerability of at home administration of trastuzumab (Herceptin®) subcutaneous for the treatment of patients with HER2-positive early breast cancer**

Cocquyt VF F, Martinez-Mena CL L, Martens MT T, D'Hondt RG G, Graas M-PL L, Evron E, Fried G, Ben-Baruch NE E, Dijkstra AC C and Van De Walle EI I. UZ Gent, Belgium; CHU St Pierre, Belgium; AZ Turnhout, Belgium; AZ Damiaan, Belgium; Clinique Saint-Joseph, Belgium; Assaf Harofeh, Israel; Rambam Medical Center, Israel; Kaplan Medical Center, Israel and Roche.

**Body: Background:** Trastuzumab (Herceptin®; H) is a standard component of adjuvant treatment in patients with HER2+ early breast cancer (eBC) and is supported by all major treatment guidelines. The efficacy and safety of Herceptin intravenous (H IV) and Herceptin subcutaneous (H SC) have been shown to be comparable. The main advantage of SC administration is its shorter administration time. Administration at home for selected patients will allow greater independence and may lead to an improved quality of life. In this study, we assessed the safety and tolerability of H SC administered at home by a healthcare professional (HCP) in patients with HER2+ eBC.

**Methods:** Patients with HER2+ eBC who previously completed 6 cycles of H IV could be included in the study to receive 12 additional cycles of H for a total of 18 cycles. The 12 additional 3-week cycles consisted of 3 cycles of H IV in the hospital (6 mg/kg; cycles 7 to 9; period 1); 3 cycles of H SC in the hospital (600 mg; cycles 10 to 12; period 2); and 6 cycles of H SC administered in the home by a HCP (600 mg; cycles 13 to 18; period 3). Patients are being followed for a total of 24 months after their last treatment. Safety is being assessed from the adverse events (AEs) reported during the study. Patient-reported outcomes were obtained from validated questionnaires for: the satisfaction and quality of the treatments and care, and for symptom severity (0 [absent] to 10 [worst]). HCPs also reported on their experiences with both treatments.

**Results:** A total of 102 patients were treated in the study between November 2013 and July 2015 and will be followed for safety and efficacy through July 2017. The primary analysis reported here was done after the last 4-week post-treatment follow-up was completed (September 2015). Patient mean age at baseline was 54.4±12.3 (SD) years. A total of 91 (89%) patients reported 549 AEs: 535 (97%) of these were grade 1 or 2 and 194 (35%) were considered treatment related. The proportions of patients with at least one related AE were 7% for H IV period 1, 32% for H SC period 2, and 47% for H SC period 3, which was twice as long as periods 1 or 2. A total of 8 serious AEs were reported in 8 patients (2 each in periods 1 and 2; 4 in period 3). Prior to the first at-home SC administration (cycle 13), 99% of patients were satisfied to a large or very large extent with the IV and SC treatments at the hospital. At cycle 17, 100% of patients were satisfied to a large or very large extent with the SC treatment at home, and 100% of patients thought treatment at home was beneficial to a large or very large extent. In all 3 treatment periods, maximum mean scores were 3.0–3.8 for the most severe symptoms (fatigue, disturbed sleep, and numbness or tingling). All HCPs considered both administration routes to be fairly easy or very easy, and SC administration to be quicker and require fewer preparation resources.

**Conclusions:** The safety analyses and patient-reported outcomes recorded in this study indicate that H SC administered by a HCP at home instead of at the hospital was not associated with any new safety signals and was considered beneficial by the patients and HCPs.
**Title:** Pre-clinical antitumor activity, tumor localization, and pharmacokinetics of MP0274, an apoptosis inducing, biparatopic HER2-targeting DARPin®

**Body:** Background: HER2 positivity is an important predictive factor for treatment with anti-HER2 agents in several cancers. However, currently available monoclonal antibody and tyrosine kinase inhibitor drugs rarely achieve full disease control. We have developed a new HER2-targeting molecule with a unique pro-apoptotic mode of action that may provide additional benefit to patients. The DARPin® MP0274* binds to two distinct non-overlapping HER2 epitopes and to human serum albumin for half-life extension. As previously shown**, in vitro, MP0274 induces apoptosis and inhibits proliferation of cells expressing HER2 (IHC3+, IHC2+ and IHC1+) and potently inhibits HER2/HER3 downstream signaling. To support clinical development of MP0274, we tested the potency of MP0274 in several HER2 expressing patient-derived xenograft (PDX) models and investigated tumor localization. In addition, pharmacokinetics (PK) analysis was performed in cynomolgus monkeys.

**Methods:** Antitumor activity of MP0274 was tested in breast and gastric HER2 expressing PDX mouse models and was compared to standard of care therapies. Tumor localization of MP0274 was studied using an Indium-111 labeled version of MP0274 in a human ovarian adenocarcinoma (SKOV-3) xenograft model by whole-body SPECT/CT imaging. The PK of MP0274 was studied in cynomolgus monkeys (MP0274 is cross-reactive with cynomolgus HER2).

**Results:** In breast and gastric cancer PDX models, MP0274 showed superior efficacy compared to trastuzumab and lapatinib and equivalent efficacy compared to trastuzumab plus pertuzumab as measured by relative tumor volume. The imaging study with SPECT/CT demonstrated that MP0274 localizes effectively to the HER2-expressing human tumor within 24 h. The PK study in cynomolgus monkeys showed a half-life of ≥5 days at doses of 5 and 10 mg/kg while at the lowest dose tested (1 mg/kg) MP0274 had a terminal half-life of 0.4 days. The PK results are indicative of target-mediated clearance that becomes saturated at doses above 1 mg/kg.

**Conclusions:** MP0274, with its unique pro-apoptotic mode of action, demonstrates excellent activity in preclinical PDX models, fast localization to tumor and a long half-life in cynomolgus monkeys. MP0274 was well tolerated in all studies. These results suggest that MP0274 has the potential to provide additional clinical benefit to patients with HER2-expressing tumors. A GLP repeated dose toxicology study is ongoing and a phase I clinical trial is in preparation.

* DARPins are small repeat proteins, designed to bind targets with high affinity and specificity, which can be combined in a modular fashion to produce multi-functional agents.

Title: Systematic review of clinical trials for monoclonal antibody biosimilars in HER2-positive breast cancer

Body: Background: A number of proposed trastuzumab (TRAS) biosimilars are now in development for HER2-overexpressing breast cancer treatment. The purpose of this study was to systematically collate all published clinical data to assess the weight of available evidence for TRAS biosimilars in HER2-positive (+) breast cancer (BC), and to identify additional studies, not captured in the scientific literature, to support informed decision-making by healthcare stakeholders, as well as to raise awareness of ongoing developments within the field. Methods: MEDLINE®, Embase® and ISI Web of Science® were searched from inception to Sept 3, 2015. Conference proceedings (n=17) were searched from 2012 to Jul 31, 2015. Studies disclosing potential use of proposed biosimilars in the treatment of HER2+ BC were screened and categorized by originator and study type (English language only). To assess data strength and validity, risk of bias assessments were conducted. The ClinicalTrials.gov (CT.gov) registry was searched to identify any planned/ongoing/complete biosimilar trials in HER2+ BC. Results: On the analysis cut-off date, a total of 7 clinical studies (12 publications) were identified for proposed biosimilars of TRAS. The biosimilars identified for TRAS with published clinical data were BCD-022, CT-P6, FTMB and PF-05280014. For BCD-022, a pharmacokinetics (PK)/safety study in HER2+ BC (N=46) evaluating BCD-022 compared to TRAS, demonstrated equivalence between the two treatments. A PK/safety study (N=174) and comparative safety/efficacy study (N=475) of CT-P6 in HER2+ BC patients both provided evidence of PK equivalence, safety, and efficacy of the proposed biosimilar in this patient population. Bioequivalence of FTMB (versus TRAS) was also reported based on the results of a PK/safety study (N=118) in healthy subjects. For PF-05280014, a PK/safety study (N=105) in healthy volunteers demonstrated equivalence with TRAS. One published comparative safety/efficacy study protocol for PF-05280014 versus TRAS was identified for first-line treatment of patients with HER2+ BC (estimated [E]:N=690), and a second PK/efficacy/safety protocol for neoadjuvant BC treatment (E:N=220) was also published. A number of other planned studies were identified in CT.gov. These included 4 comparative safety/efficacy studies in HER2+ BC evaluating ABP 980 (E:N=808), CT-P6 (N=383/N=532), SB3 (E:N=806) and 2 PK/safety studies (BCD-022 [E:N=206], CT-P6 [E:N=174]) in women with BC. Two studies investigating PK and safety in healthy volunteers were also identified (PF-05280014 [E:N=162], SB3 [E:N=109]). Conclusions: This systematic review provides an unbiased synthesis of available evidence for proposed TRAS biosimilars in HER2+ BC, including data to support clinical similarity. The available clinical data for the 4 proposed biosimilars (BCD-022, CT-P6, FTMB and PF-05280014) investigated in a total of 918 healthy subjects or patients indicated highly comparable PK, safety, or efficacy profiles, versus TRAS. Additional data are required to fully evaluate the clinical similarity for proposed TRAS biosimilars, and the completion of several ongoing comparative trials are expected to provide further assurance of safety and efficacy in specific patient populations.
**Title:** Lapatinib after pertuzumab and ado-trastuzumab emtansine in metastatic HER2-positive breast cancer

Báez-Vallecillo L, Singareeka Raghavendra A, Hess K, Moulder SL L, Tripathy D, Valero V and Murthy RK K. The University of Texas MD Anderson Cancer Center, Houston, TX.

**Body:**

**Background:** Lapatinib (L) is approved in combination with capecitabine for patients with trastuzumab-resistant HER2-positive metastatic breast cancer (MBC) and in combination with letrozole for HER2-positive and ER/PR-receptor-positive MBC for whom hormonal therapy is indicated. However, there are no data on the activity of L in patients who received prior pertuzumab (P) and ado-trastuzumab emtansine (TDM-1), now included as standard first and second line therapies. The goal of this study was to assess the efficacy of L in routine clinical practice in a contemporary patient population that received prior P and/or TDM-1.

**Methods:** We identified all patients with trastuzumab-resistant HER2-positive MBC who received L-based therapy (n=570) between 2003 and 2016 through a departmental database at MD Anderson Cancer Center and reviewed the medical records of each patient to confirm treatment sequencing and outcome. Of these patients, we identified a target cohort who received L after prior P or TDM-1 (n=34). Analysis used Kaplan-Meier statistics.

**Results:** Of the 34 patients identified as the target cohort with prior P and/or TDM-1 exposure, 29 patients were available for outcome analysis since 5 patients were started on L-based treatment within 4 months of this analysis. In the comparison cohort (n=536) who had received L-based therapy without prior P and/or TDM-1 exposure, 445 patients were available for outcome analysis. In [Table 1], we display the patient characteristics and results. Clinical benefit rate (CBR), defined as complete or partial response or stable disease ≥ 6 months, was 58% (95% CI, 39%, 79%) for the target cohort and 78% (74%, 84%) for the comparison cohort. In the target cohort, nearly 25% (n=8) had received > 3 lines of therapy and in the comparison cohort only 10% (n=71) had received > 3 lines of therapy. The median duration on L was 4.9 months (range 0.7-19.2) in the target cohort and 5.6 months (range 0.0-82.3) in the comparison cohort. In both cohorts, median TTP and OS were longer in patients with de novo disease compared to patients with disease recurrence.

**Conclusions:** In the target cohort with prior P and TDM-1, nearly one third of patients received L for ≥ 6 months and over half the patients obtained clinical benefit for ≥ 6 months with no significant toxicity. This suggests clinically relevant benefit to L in a contemporary population of patients who have received prior P and TDM-1. However, clinical benefit and median duration on L were decreased in the target cohort versus the comparison cohort, which may reflect heavier pretreatment.

Title: Her2 is not a cancer subtype but rather a driver found in all intrinsic subtypes and highly enriched in molecular apocrine tumors

Daemen A and Manning G.  Genentech, Inc., South San Francisco, CA.

Body: Her2-enriched (Her2E) breast tumors defined by molecular profiling are discrepant from Her2-amplified tumors defined by clinical assessment – over half of all Her2-amplified tumors are not Her2E, while one-third of Her2E tumors are not Her2-amplified. We explored this discordance using genomic profiles of 4,000 breast tumors. We find clear support that Her2 amplification is a discrete cancer driver event and not a subtype, with little genomic impact other than in expression of genes on the amplicon. Many Her2-amplified tumors clearly belong to the basal, luminal A, or luminal B subtypes.

After accounting for the Her2 amplicon, most tumors classified as Her2E appear to be molecular apocrine, expressing high levels of androgen receptor and low to moderate levels of ER. The high rate of Her2 amplification in this group (63%) suggests that additional growth drivers are required for molecular apocrine tumors.

Her2 amplification is also a driver across subtypes of several non-breast tumor types. Her2 is amplified in 2% of 5,400 non-breast tumors, spanning 23 tumor types. The Her2 region in non-breast cancers shows a similar range of amplification and breadth of the amplicon, and a comparable rate of overexpression of genes within the amplicon for most Her2A tumors.

These discoveries reveal therapeutic opportunities for combining anti-Her2 therapy with endocrine or anti-androgen agents for breast cancer, and for expanding anti-Her2 therapy to other tumor types.

Title: Oncogenic potential of ERBB3 mutations in human mammary epithelial cells

Mishra R, Yuan L, Solomon T and Garrett JT T. James L. Winkle College of Pharmacy, University of Cincinnati, Cincinnati, OH.

Body: Activation of the HER (ErbB) family of receptor tyrosine kinase signaling is common in patients with metastatic breast cancer. HER2, a member of ErbB family is over-expressed in 25% of breast cancers. A recent large-scale genomics study reported that HER3 (ErbB3) mutations play a significant role in the development of acquired resistance in breast cancer patients. We are examining the role of HER3 mutations in the context of HER2-driven and ER-driven breast cancers, both in vitro and in vivo. We introduced a series of HER3 mutations (F94L, G284R, D297Y, D313H, K329T, T355I, L792V, E1261A), identified in breast cancer patients, using site-directed mutagenesis. Mutant HER3 constructs were subcloned into the Gateway-compatible lentiviral expression vector pDONR223-ErbB3 which were subsequently subcloned into the Gateway-compatible lentiviral pLX302 destination vector. Stable cell lines were generated in MCF10A and MCF10A/HER2 and ER+ MCF-7 and T47D breast cancer cells using lentiviral transduction. We confirmed the presence of HER3 constructs by digestion with BsrGI restriction enzyme and v5-tagged protein expression. We evaluated the oncogenic potential of these cell lines using various cell based assays. Out of the above listed mutations, T355I mutation was transforming in the breast cancer cell lines. In parallel experiments, we tested the effect of knocking down HER3 in tumor cell lines that harbor endogenous HER3 mutations. The HER3 K742E mutation occurs endogenously in the IGROV-1 (ovarian) and P262H & V104M in SNU-407 (colorectal), A232V in SNU-1040 (colorectal), N126K and R667H in HCT-15 (colorectal) cancer cell lines. We transfected the cells with either HER3 or control siRNA and determined that each cell line had a reduction in proliferation with knockdown of HER3. These data further suggest the potential for these HER3 mutations to be oncogenic. Furthermore, we investigated the signal transduction pathways in wild-type (wt) and mutant (mut) HER3 in ER+ MCF-7 and T47D as well as MCF10A and MCF10A/HER2 breast cancer cells using clinically relevant inhibitors against ER and HER2. In ongoing experiments, the wt and mut ER+ MCF-7 and T47D stable cells are subjected to ER specific inhibitors, fulvestrant or 4-hydroxytamoxifen. In separate experiments, MCF10AHER2 cells are being treated with the HER2 inhibitor, lapatinib and HER2-mediated transformation is being assessed by colony formation, cell migration/invasion and three-dimensional growth assays. We are also investigating the signaling pathways responsible for the oncogenic transformation of these cell lines. Accordingly, cell lysates prepared from MCF-7 and T47D or MCF10A/HER2 are being analyzed for Akt, Erk, and ErbB activation. These studies will provide the first systematic assessment of how mutations in HER3 affect response of HER2+ or ER+ breast cancers to clinically relevant inhibitors, using a library of naturally occurring HER3 mutants.
Title: A retrospective evaluation of cardiovascular recovery and oncologic outcomes associated with interrupted and continuous adjuvant trastuzumab in the setting of mild left ventricular dysfunction

Gibson JD D, Yao RJR R, Davis MK K and Simmons CE E. Vancouver Fraser Medical Program, University of British Columbia, Vancouver, BC, Canada; University of British Columbia, Vancouver, BC, Canada and British Columbia Cancer Agency, Vancouver, BC, Canada.

Body: Background: Trastuzumab is a monoclonal antibody that targets the HER2 receptor. In the adjuvant setting, 12 months of trastuzumab therapy has been shown to significantly reduce the risk of cancer recurrence. However, treatment with trastuzumab may also be associated with a decline in left ventricular (LV) function that, in most cases, will recover after trastuzumab therapy is stopped. When severe or symptomatic left ventricular dysfunction (LVD) occurs, trastuzumab is generally held with the intention of restoring cardiac function. It is less clear how to manage trastuzumab to optimize both cancer therapy and cardiovascular care when mild, asymptomatic drops in LV function are observed. The intention of this study was to assess how trastuzumab was managed immediately after the development of mild LVD in a non-trial setting and evaluate these outcomes.

Methods: Patients who received adjuvant trastuzumab therapy for breast cancer between September 2005 and September 2010 in British Columbia were identified. Heart function imaging data for these patients were subsequently reviewed to identify those who experienced either a drop in LV ejection fraction (LVEF) to 40-49% or a greater than 15% drop in LVEF relative to their pre-chemotherapy baseline to a final LVEF ≥50%. The charts of patients who met these inclusion criteria were then reviewed for demographic information, comorbidities, trastuzumab dosing regime, subsequent cardiac events, and breast cancer outcomes.

Results: A total of 171 patients were included in this study. 121 (70.8%) patients had an immediate hold in their trastuzumab therapy while the remaining 50 (29.2%) continued with their next scheduled dose. The number of patients who experienced a cancer relapse event in the therapy interruption and continuation groups were 21 (17.4%) and 5 (10.0%), respectively (P = 0.25). Cardiovascular events in the therapy interruption group included a subsequent drop in LVEF to <40% in 11 (9.1%) patients, long-term congestive heart failure (CHF) in 2 (1.7%) patients, and 1 (0.9%) death related to CHF. Cardiovascular events in the therapy continuation group included a subsequent drop in LVEF to <40% in 3 (6.0%) patients and long-term CHF in 1 (2.0%) patient. 24 (19.8%) patients in the therapy interruption group had a final LV function measurement that had fallen more than 10% below their baseline value while 12 (24.0%) patients in the therapy continuation group met this criterion (P=0.54). The mean numbers of adjuvant trastuzumab doses administered in the therapy interruption and continuation groups were 11.3 and 14.3, respectively. Finally, mean follow up times for the therapy interruption and continuation groups were 5.6 and 5.8 years, respectively.

Conclusions: Continuing trastuzumab immediately after the development of mild LVD did not appear to be associated with an increased risk of long-term cardiovascular events. However, holding trastuzumab immediately after the development of mild LVD appeared to be associated with a 7.4% absolute risk increase in breast cancer recurrence. While these results are not statistically significant, they are concerning and warrant further investigation.
Title: Development of mathematical prediction models to identify disease-free survival events for HER2-positive primary breast cancer patients treated by neoadjuvant chemotherapy and trastuzumab

Takada M, Sugimoto M, Masuda N, Iwata H, Kuroi K, Yamashiro H, Ohno S, Ishiguro H, Inamoto T and Toi M. Kyoto University Hospital, Kyoto, Japan; Institute for Advanced Biosciences, Keio University, Tsuruoka, Japan; Osaka National Hospital, Osaka, Japan; Aichi Cancer Center, Nagoya, Japan; Tokyo Metropolitan Cancer and Infectious Diseases Centre, Komagome Hospital, Tokyo, Japan; Tenri Hospital, Tenri, Japan; Breast Oncology Center, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan; Graduate School of Medicine, Kyoto University, Kyoto, Japan and Faculty of Health Care, Tenri Health Care University, Tenri, Japan.

Body: Background)
The addition of trastuzumab to standard neoadjuvant chemotherapy (NAC) doubles the pathological complete response (pCR) rate in patients with HER2-positive primary breast cancer. Patients who achieved pCR after NAC with trastuzumab showed a better prognosis compared to those without pCR. However, it is still difficult to predict the likelihood of recurrence after surgery at an individual patient-level. The aim of this study was to develop a mathematical model to predict disease-free survival (DFS) events such as recurrence for patients treated with NAC and trastuzumab. Because brain metastasis (BM) often occurs in HER2-positive cancer patients and it is a particular event for those, we planned to develop a specific model for BM as well.

Patients and Methods)
Data of 776 HER2-positive primary breast cancer patients from the multicenter cohort study (JBCRG-C03) were used in the analysis. All patients had received NAC plus trastuzumab between 2001 and 2010. Two prediction models using a machine learning method (alternating decision tree algorithm) were developed using age, body-mass index, menopausal status, clinical stage, histological type, ER/PgR status, histological/nuclear grade, type of surgery, pathological response, adjuvant radiation therapy, and adjuvant hormonal therapy. The model A (DFS) predicted the probability of any disease recurrence, death by any cause, or secondary malignancy within 5 years after starting treatment. The model B (BM) predicted the probability of occurrence of BM within the 5 years. First, bias-controlled virtual datasets were generated for the training of the models using a resampling method. Second, the models were optimized by cross-validation (CV). Finally, the developed models were validated using the original dataset. The area under the receiver operating characteristics curve (AUC) was calculated to assess the discrimination ability of the models.

Results)
The DFS and BM event was observed in 118 and 30 patients, respectively. The AUC values for the model A and model B were 0.833 (95% CI, 0.798–0.868, P < 0.001) and 0.927 (95% CI, 0.905–0.949, P < 0.001), respectively. The sensitivity and specificity at the cut-off value of 50% were 72.0% and 78.4% for the model A, and 100% and 83.7% for the model B, respectively. Patients predicted as “low-risk” by the model A showed a significantly better 5-year DFS rate than “high-risk” patients (91.2% vs 53.8%, P < 0.001). Patients predicted as “low-risk” by the model B showed a significantly better 5-year BM-free survival rate than “high-risk” patients (100% vs 76.1%, P < 0.001). The discrimination ability of these models were maintained for both ER/PgR-positive and ER/PgR-negative subgroups, and also for both pCR and non-pCR subgroups.

Conclusions)
Our models showed high accuracy for predicting DFS events and BM in HER2-positive primary breast cancer patients treated with NAC and trastuzumab. These two models would help to realize accurate prediction of DFS events and to optimize the postoperative surveillance plan. The identification of high-risk patients for recurrence including BM may be useful for selecting a patient-subpopulation who requires new therapeutic approach.
Title: The importance of hormone receptor status on biomarker expression and the efficacy of lapatinib plus capecitabine therapy after progression on trastuzumab in HER2 positive recurrent and advanced breast cancer

Arima N, Nishimura R, Toh U, Tanaka M, Saimura M, Okumura Y, Saito T, Tanaka T, Teraoka M, Shimada K, Koga T, Kurashita K, Todoroki H, Ueo H, Ohi Y, Toyoshima S, Mitsuyama S and Tamura K. Kumamoto Shinto General Hospital, Kumamoto, Japan; Kumamoto Shinto General Hospital, Kumamoto, Japan; Kurume University School of Medicine, Kurume, Fukuoka, Japan; JCHO Kurume General Hospital, Kurume, Fukuoka, Japan; Kitakyushu Municipal Medical Center, Kitakyushu, Fukuoka, Japan; Kumamoto City Hospital, Kumamoto, Japan; Saitama Red Cross Hospital, Saitama, Japan; Fukuoka University, Fukuoka, Japan; Sagara Hospital, Kagoshima, Japan; Shimada Breast Clinic, Kitakyushu, Fukuoka, Japan; Hirose Hospital, Fukuoka, Japan; Urasoe General Hospital, Urasoe, Okinawa, Japan; National Hospital Organization Kokura Medical Center, Kitakyushu, Fukuoka, Japan; Ueo Breast Cancer Hospital, Ooita, Japan; Sagara Hospital, Kagoshima, Japan; Kitakyushu Municipal Medical Center, Kitakyushu, Fukuoka, Japan and General Medical Research Center School of Medicine, Fukuoka University, Fukuoka, Japan.

Body: Background: Anti-HER2 treatment using trastuzumab (Tmab) has contributed to improving the clinical outcome of HER2-positive breast cancer patients. However, some patients do not respond to Tmab therapy and the combination of Lapatinib and capecitabine (LC) is an effective treatment option after progression on Tmab. Hormone receptor status is also an important factor for deciding if the patient should be treated with endocrine therapy as well. The aim of this study was to investigate the clinical significance of hormone receptor status in biomarker expression and to evaluate the efficacy of lapatinib therapy.

Materials and Methods: Eighty patients with HER2 positive breast cancer refractory to Tmab were enrolled in this prospective trial (KBC-SG 1107) between December 2011 and March 2014. The following treatment began after enrollment; lapatinib 1250-mg tablets were administered orally once daily and capecitabine (2000 mg/m2 per day) on days 1 to 14 every 21 days until disease progression or until severe adverse events. Total HER2 (H2T), p95HER2 (p95), and total HER3 (H3T) expression levels were quantified in formalin-fixed paraffin embedded samples using VeraTag assays. ER and progesterone receptor (PgR), PTEN and p95 expressions were evaluated using immunohistochemistry (IHC) and PIK3CA mutation using direct sequencing. Statistical analyses were performed using SPSS (ver. 21). A two-sided P<0.05 was considered a statistically significant difference.

Results: The ER- and PgR-positive rates were 55.0% and 33.8%, respectively. The response rate to LC was 30% (CR: 1 case; PR: 23 cases), the clinical benefit rate was 51.3% and the median progression-free survival (PFS) was 174.5 days. Both ER and PgR negativity significantly correlated with higher H2T (cutoff: 13.8), p95HER2 (cutoff: 2.8) and PTEN expression levels (cutoff: H score of 100). Lower H2T expression levels and PIK3CA mutation rates were often observed in the non-responders (both: p=0.087). The ER and PgR status did not correlate with response. A high p95 and PTEN expression significantly correlated with longer PFS in ER and/or PgR positive cases (p=0.02 and 0.03), respectively. The overall survival (OS) after LC significantly correlated with the number of recurrence organs (p=0.0002) but not with the p95 and PTEN expression levels.

Conclusion: LC therapy was effective in Tmab-refractory HER2 positive breast cancer. Moreover, the biomarker expression differed depending on the ER/PgR status and a high p95 and PTEN expression correlated with longer PFS in ER and/or PgR positive cases. Further study is necessary to validate these findings.

Title: Population pharmacokinetics (PK) and exposure-response (E-R) analysis of trastuzumab emtansine (T-DM1) in patients with HER2+ metastatic breast cancer (MBC) who have received at least two prior regimens of HER2-directed therapy

Body: Background:
TH3RESA was a Phase III randomized study to evaluate the efficacy and safety of trastuzumab emtansine (T-DM1) compared to treatment of physician's choice (TPC) in patients with HER2+ MBC who have progression after at least two regimens of HER2-directed therapy. Population pharmacokinetic (PK) and exposure-response (E-R) analyses were performed to characterize T-DM1 PK as well as E-R relationship for key efficacy and safety endpoints in the population.

Methods:
Post-hoc analysis based on historical T-DM1 population PK models was performed to assess whether PK is consistent with historical data. E-R analyses with OS and PFS were conducted using Cox proportional hazard (CPH) models with exposure metrics (model-predicted Cycle 1 C<sub>min</sub> and AUC<sub>ss</sub>) included in the model. Logistic regression models were used for binary endpoints of overall response rate (ORR) and key safety endpoints with exposure metrics included as continuous variable only. To supplement the E-R analysis for OS and PFS, case matching analyses were conducted to compare OS and PFS in the lowest exposure quartile (Q1) vs. higher exposure quartiles (Q2-4) to their corresponding matched control.

Results:
Historical T-DM1 population PK model well described T-DM1 PK in TH3RESA study. In CPH analyses with OS and PFS, hazard ratios (HR) of both efficacy endpoints consistently decreased with increasing T-DM1 exposure.

</table>
The E-R relationship is supported by case matching analyses, where T-DM1 treated patients were stratified by model-predicted Cycle 1 $C_{\text{min}}$. HRs of OS and PFS for patients at Q2–4 versus their matched TPC patients (HR (95%CI): 0.58 (0.44, 0.78) for OS; 0.47 (0.36, 0.62) for PFS) were numerically smaller than that of T-DM1 treated patients at Q1 versus their corresponding matched TPC patients (HR (95%CI): 0.96 (0.63, 1.47) for OS; 0.92 (0.64, 1.32) for PFS). For ORR, an E-R trend was also noted. On the other hand, no E-R relationship was identified with key safety endpoints.

**Conclusion:**
T-DM1 PK in TH3RESA patient population is similar to historical data. Although an E-R relationship was observed for efficacy, the results need to be interpreted with caution given the potential confounding association between risk factor and PK. No E-R relationship was observed for the safety endpoints examined.
Title: Plasma chemokine profile of HER2+ breast cancer (BC) patients treated with docetaxel (D) and carboplatin (C) in combination with trastuzumab (T) and/or lapatinib (L) in the neo-adjuvant setting

Collins DM M, Madden SF F, Gaynor N, Gallagher WM M, O'Donovan N and Crown J. Molecular Therapeutics for Cancer, National Institute for Cellular Biotechnology, Dublin City University, Dublin, Ireland; RCSI Population Health Sciences, Royal College of Surgeons in Ireland, Dublin, Ireland; UCD School of Biomolecular and Biomedical Science, UCD Conway Institute, University College Dublin, Dublin, Ireland; St. Vincent's University Hospital, Dublin, Ireland and All-Ireland Clinical Oncology Research Group (ICORG), Dublin, Ireland.

body: Background: Chemokines (chemotactic cytokines) are key regulators of the immune response, attracting immune cells to sites of inflammation, activating adhesion molecules, promoting extravasation and influencing T-cell subset polarization. Recent clinical data has shown a strong correlation between tumor infiltrating lymphocytes (TILs) and response to T therapy in HER2+ BC while the combination of chemotherapy, T and L has proven superior to chemotherapy and T alone in the neo-adjuvant setting (NeoALTTO). This preliminary study examines the levels of 40 circulating chemokines in 32 HER2+ BC patient plasma samples from ICORG 10-05 (neo-adjuvant DCT, DCL or DCTL) to investigate differences in chemokine profiles between treatment arms and patient's response to treatment.

Methods: Pre-treatment blood samples were collected before commencement of chemotherapy; post-treatment samples were collected two weeks prior to surgery. All patients received G-CSF concurrent with treatment. A panel of 40 chemokines and chemokine-associated cytokines were assessed by Luminex xMAP multiplex assay. Matched patient samples were run in single replicates and analysed together (n=32) or by comparing DCT (n=12) and DCTL (n=14) treatment arms (using a paired Mann-Whitney test and adjusting for multiple testing using Bonferroni correction). DCL (n=6) was omitted from the arm comparison due to low numbers. In addition, principle components analysis (PCA) was used to explore any trends within the data based on patient response (pathological complete response (pCR, n=15), partial response (PR, n=12), and non-response (NR, n=4)). 12 non-age matched healthy volunteer controls were also included in the PCA.

Results: PCA shows a clear separation between pre- and post-treatment samples. 30 of the 40 chemokines examined were significantly differentially expressed (adjusted p-value of <0.05) post-treatment across all treatment arms. When comparing DCT and DCTL, nine chemokines were significantly altered post-therapy in both arms with two chemokines, CCL24 (p=0.039) and IL-16 (p=0.039), increased in DCT only and ten chemokines, CCL11 (p=0.009), CX3CL1 (p=0.004), CXCL1 (p=0.024), IL-2 (p=0.043), IL-6 (p=0.034), IL-8 (p=0.004), CXCL11 (p=0.004), CXCL16 (p=0.004) and TNF-alpha (p=0.004) altered in DCTL only. PCA identified no trend between pre- and post-treatment chemokine levels and response.

Conclusions: DCT and DCTL produce statistically different alterations in the plasma chemokine profiles of HER2+ BC patients. Pre- or post-treatment levels of the chemokines examined are not collectively predictive of patient response to treatment. Further work is required to elucidate the relevance of DCT- and DCTL-specific chemokine alterations to response.
Title: Trastuzumab improves outcomes of New Zealand women with HER2+ stage I-III breast cancer

Lawrenson R, Lao C, Harvey V, Campbell I, Brown C, Seneviratne S, Edwards M, Scott N, Elwood M, Sarfati D and Kuper-Hommel M. The University of Waikato; The University of Waikato; Auckland Breast Cancer Registry; Waikato Breast Cancer Registry; The University of Waikato; University of Colombo; Waikato District Health Board; Waikato District Health Board; University of Auckland; University of Otago and Waikato District Health Board.

Body: Introduction
HER2 status has been routinely ascertained for stage I-III breast cancer since late 2005. Trastuzumab was first funded in New Zealand for use in HER2+ breast cancer in July 2007. This observational study aims to compare the difference in outcome between women with HER2+ stage I-III breast cancer who received trastuzumab as adjuvant therapy versus those who did not. Differences in presentation, treatment and outcomes between Māori and NZ European were studied.

Methods
The combined Waikato and Auckland Breast Cancer Registries have clinical details of 12377 women diagnosed with breast cancer between June 2000 and May 2013. 9506 women with breast cancer were tested for HER2 receptor status. Proportion of women with HER2+ (FISH amplified or IHC 3+), stage I-III breast cancer were examined by age, ethnicity and stage. Differences in use of trastuzumab for women with stage I-III breast cancer with a tumour size equal or larger than 1 cm and aged less than 75 years were assessed by ethnicity and year of diagnosis. Patients who had inflammatory breast cancer or developed metastatic disease or local recurrence within 3 months after diagnosis were excluded. Kaplan-Meier method and Cox proportional hazards model were used to examine the breast cancer-specific survival between women treated with trastuzumab and chemotherapy and those treated with chemotherapy without trastuzumab.

Results
1454 patients with early invasive breast cancer were HER2+. The proportion of cases with HER2+, stage I-III breast cancer increased with stage (stage I-III: 11.5%-26.9%), but decreased with age (<40 years to 80+ years: 28.8%-9.7%). Māori women were more likely to have HER2+ cancers than NZ European (17.8% versus 14.9%; p=0.02). Among the eligible patients, 605 women received trastuzumab and chemotherapy within 12 months for stage I-III breast cancer, and 275 had chemotherapy without trastuzumab. A small proportion (10.2%, 34/333) of women diagnosed in 2000-2005 received trastuzumab as part of a clinical trial. The proportion of women who received trastuzumab increased to 60.3% in 2006-2009 and to 87.1% in 2010-2013. 46.2% of Māori women were treated with trastuzumab compared to 55.9% of NZ European (p=0.040). The cancer-specific survival estimated with Kaplan-Meier method is shown in Table 1. Women treated with chemotherapy without trastuzumab were 2.7 times (95% CI: 1.9-3.9) more likely to die of breast cancer compared to those treated with trastuzumab and chemotherapy, after adjustment for stage, tumour size and hormone therapy.

Table 1. Breast cancer-specific survival between women with HER2+ stage I-III breast cancer who received trastuzumab as adjuvant therapy versus those who did not

Conclusions
Trastuzumab improved the breast cancer-specific survival of women with HER2+ stage I-III breast cancer. Māori women were more likely to have HER2+ cancer and less likely to be treated with trastuzumab. Rates of treatment with trastuzumab and the adjusted survival between Māori women and NZ European women were not significantly different.

Title: HER2-associated lipogenic phenotype as a potential therapeutical target in breast cancer patients

Ravacci GR R, Santos JR R, Brentani MM M, Tortelli T, Dale I, Logullo AF F and Waitzberg DL L. Medical School - University of São Paulo, São Paulo, SP, Brazil; Cancer Institute of São Paulo, São Paulo, SP, Brazil and Federal University of São Paulo, São Paulo, SP, Brazil.

Body: Lipogenic phenotype (genetic program activation involved *inde novo* fatty acid –FA-synthesis and key metabolic regulators) is associated to oncogenic transformation and malignancy. We hypothesize that in HER2 overexpressing breast cancer cells, HER2 function is affected by cell membrane lipid profile, mainly lipid rafts, necessary to HER2 location and activation within the cell membrane. Therefore, metabolic lipid imbalance could be a potential factor and marker associated to HER2 expression. To evaluate if cell lipogenesis and membrane lipid composition are affected by HER2 overexpression, we used an oncogenic transformed cell line engineered to overexpress HER2 receptor (HB4aC5.2), but identical to their parental strain (HB4a) in all other aspects. Several lipid related molecules including synthesis-FASN, uptake-CD36, transport-FABP4 and FA storage-DGAT by RT-PCR; and lipogenic regulatory pathways (mTOR, DEPTOR, SREBP1 and PPARγ) were evaluated in both cells. Lipogenic contribution to lipid rafts formation was evaluated by gas chromatography and confocal microscopy. The influence of HER2 overexpression and lipogenic phenotype on proteins activated by HER2 (AKT, ERK1/2 and FASN) was analyzed by western blot. Next, HB4a and HB4aC5.2 cells were treated, alone or in combination with DHA (omega-3 polyunsaturated fatty acid), by Trastuzumab (anti-HER2), and GW9662 (anti-PPARγ) for 72h, and all above experiments were repeated. Cell death was analyzed by flow cytometry. *In vitro* results were confirmed in Primary tumor and adjacent tissue samples from a cohort of 182 European breast cancer patients through metabolomics analysis. Statistical analysis was performed by MetaboAnalyst software (*p* <0.05). In HB4aC5.2 cells, the HER2 overexpression was associated with a lipogenic phenotype, which increase in cholesterol and saturated FA synthesis for the lipid rafts formation, suggesting that large amounts of HER2 require cell membrane changes to favor rafts saturation and formation, when compared to HB4a. Lipid rafts were associated with survival and proliferation signals hiper activation (*p*<0.001). Cell lipogenesis was independent ofmTOR/SREBP/PPARγpathway and occur concomitantly to DEPTOR (mTOR inhibitor) increased expression. Moreover, GW9662 or Trastuzumab treatment did not influence lipogenesis in cell culture. In HB4aC5.2 cells, only DHA treatment decreased the lipogenic phenotype, DEPTOR expression, saturated FA synthesis, disrupted lipid raft, inhibited HER2 signaling, and induced apoptosis (*p*<0.001). In addition, when added to Trastuzumab DHA potentiated cell death. In tumor tissue samples an increased FA synthesis was observed, such as palmitic acid, sphingolipids and phosphatidycholines saturated FA enriched, synthesis of cholesterol, suggesting an increase of lipid rafts when compared to normal breast adjacent tissue. Our results indicate that lipogenic phenotype is associated with HER2 superexpression in breast cancer cells, and it seems important to promote survival and proliferation, through lipid rafts increase. DHA modulation increased death in tumor cells, suggesting that cell membrane lipogenesis and lipid composition may represent a treatment target. Lipogenic phenotype confirmation in tumor tissue samples strengthens this hypothesis.
**Title:** Long-term survival in HER2-positive metastatic breast cancer: The first blow is half the battle

**Body:** Introduction: Metastatic breast cancer (MBC) is considered an incurable disease. However, long-term survival is increasingly observed in HER2-positive disease since the introduction of trastuzumab. We explored factors associated with long-term survival in a retrospective series at our Institute.

**Methods:** All patients with histologically proven HER2-positive (3+ score by IHC or HER2 amplification) MBC treated starting first-line trastuzumab-based palliative therapy between January 2003 to January 2013 were included. Patients were identified from the Institute's tumor registry and data were collected from patient records. The primary endpoint was overall survival. Kaplan-Meier survival estimates were calculated and multivariable survival analyses were performed to identify independent prognostic factors. Radiologic complete response (CR) was a secondary endpoint.

**Results:** We identified 113 patients with a median age at diagnosis of MBC of 52 years (range 27-82). Median follow-up for MBC was 39 months (range 2-148 months). Thirty-eight percent presented with synchronous metastases; 62% had recurrent disease of whom 42% had received prior trastuzumab as part of (neo-)adjuvant treatment. First-line palliative treatment consisted of trastuzumab plus vinorelbine (56%), a taxane (28%), capecitabine (10%), other chemotherapy (3%), or endocrine therapy (2%), and resulted in a CR in 27 patients (24%). In addition, one patient achieved CR to third-line therapy. Most patients with CR had received trastuzumab with a taxane (57%) followed by vinorelbine (32%). Fourteen out of 28 patients with CR are still alive without evidence of disease at a median follow-up of 91 months (range 23-148 months), of whom 8 still receive trastuzumab. Fourteen patients had disease relapse (8 on maintenance trastuzumab, 6 after discontinuation). Overall, 35 patients (31%) survived more than 5 years. Factors associated with long-term survival in univariable analyses were oligo-metastatic disease (1-3 distant metastases), synchronous metastases, no skin or brain metastases, no prior (neo-)adjuvant trastuzumab, first-line palliative treatment with trastuzumab and taxanes, and achieving a radiologic CR on treatment (see table 1). Achieving CR and the absence of skin metastases remained significant factors in multivariable analyses.

**Conclusion:** Thirty-one percent of patients with metastatic HER2-positive MBC survive over 5 years. Long-term response is particularly seen in patients who achieve a complete radiologic response on first-line treatment. This finding supports a strategy to administer the most effective agents as first line treatment, as is often but not always applied in clinical practice.

Title: Updated safety results from the first multicenter, open-label, phase IIIb study investigating the combination of pertuzumab with subcutaneous trastuzumab and a taxane in patients with HER2-positive metastatic breast cancer (SAPPHIRE)

Woodward N, De Boer RH H, Redfern A, White M, Roberts W, Truman M and Beith J. Mater Misericordiae Cancer Services/Mater Research Institute and the University of Queensland, Brisbane, QLD, Australia; Royal Melbourne Hospital, Parkville, VIC, Australia; Fiona Stanley Hospital, Murdoch, WA, Australia; Monash Cancer Centre, East Bentleigh, VIC, Australia; Roche Products, Pty. Limited, Dee Why, NSW, Australia and Chris O'Brien Lifehouse, Camperdown, NSW, Australia.

Body: Background: Pertuzumab targets the human epidermal growth factor receptor 2 (HER2) through an independent epitope to that of trastuzumab. Improved efficacy with acceptable toxicity has been shown, in metastatic breast cancer (mBC) for pertuzumab in combination with intravenous (IV) trastuzumab and docetaxel.1 This study aimed to assess the safety, tolerability and efficacy of combining IV pertuzumab with subcutaneous (SC) trastuzumab and a taxane, as 1st-line therapy in patients (pts) with HER2+ mBC. We present safety data with 19 months (mo) of median follow-up.

Methods: SAPPHIRE (NCT02019277) is a multicentre, open-label, phase IIIb study. Primary objective: safety and tolerability of IV pertuzumab + SC trastuzumab and investigator’s choice of taxane. Pts ≥18 years with confirmed HER2+ mBC and ECOG PS 0-2 were included. The incidence and severity of adverse events (AEs), serious (S) AEs and AEs leading to premature discontinuation of study treatment were analyzed by taxane group.

Results: 50 pts enrolled in the study. Taxanes of choice: nab-paclitaxel (NP; n=36), docetaxel (D; n=13) and paclitaxel (P; n=1).

As of March 4th 2016, 34 pts had withdrawn from study; median follow-up= 19mo (range: 6-27). 28(56%) pts received >18 cycles of study medication. All patients experienced AEs with 326 AEs in the D group and 675 in the NP group; the majority being grade 1-2. The most common AEs were diarrhea, fatigue, peripheral neuropathy, alopecia, and rash. Grade 3+ AEs (n=77) were reported in 30 (60%) pts, 20 in the D group (8 pts; 62%) and 57 in the NP group (22 pts, 61%). The most common grade 3+ AEs in the D group were febrile neutropenia (4 pts, 31%) and neutropenia (3 pts; 23%); and in the NP group neutropenia (3 pts; 8%), anemia, diarrhea, cellulitis, peripheral neuropathy, LVEF decreased and pulmonary embolism each reported in 2(6%) pts. SAEs (n=44) were reported in 25(50%) pts, 11 (8 pts; 62%) in the D group and 33 (17 pts; 47%) in the NP group. The most common SAEs in the D group were febrile neutropenia (4 pts, 31%) and pyrexia (2 pts, 15%); and in the NP group: pyrexia (5 pts, 14%), cellulitis (2 pts, 6%) and pulmonary embolism (2 pts, 6%). AEs of suspected cardiac disorders (n=12) were reported in 7(14%) pts; atrial fibrillation, cardiomyopathy, myocardial ischemia, and dyspnea each reported in 1(2%) pt; and LVEF decreased, palpitation, hypertension each reported in 2(4%) pts. AEs leading to study drug discontinuation (n=6) were reported in 6(12%) pts [LVEF decreased (3), drug hypersensitivity, syncope and blister]. AEs leading to chemotherapy discontinuation (n=24) were reported in 10(20%) pts. 4(8%) pts died on study (disease progression).

Conclusion: No new safety signals have been reported in this study. Of further clinical interest is the finding that no cases of febrile neutropenia were reported in the NP taxane group compared to 4 in the D group. The safety profile remains consistent with the CLEOPATRA,1 PERUSE2 and HannaH3 studies, indicating the combination is safe and tolerable.

2.Bachelot, et al. JCO 2014;32:5s(abstr#548)
Introduction: The addition of Trastuzumab (T) to chemotherapy (CT) revolutionized HER2-positive breast cancer (BC) and changed its natural history. We reviewed the efficacy of T outside clinical trials in a cancer comprehensive center.

Methods: Ambispective and descriptive study was conducted in Catalan Institute of Oncology (ICO-Barcelona). Estimates of progression-free survival (PFS) and overall survival (OS) were obtained with the Kaplan-Meier method and compared with LogRank test. The association of clinic-pathological variables and outcome was studied by $\chi^2$ and Cox proportional hazard analysis.

Results: 430 consecutive early HER2-positive BC patients (pts) were treated with adjuvant/neoadjuvant T and CT from Jan 2005 to Dec 2012. Pt basal characteristics are reported in Table 1. Neoadjuvant treatment was administrated in 230 pts (54%) and in 200 (46%) in adjuvancy. Pathological complete response (pCR) in breast and nodes (ypT0/isypN0) was achieved in 48% of pts, with higher rates in hormone receptor (HR)-negative pts (62 vs 37% p=0.0005). Median duration of T: 10.6 months (m). 28% pts treated with neoadjuvant T+CT who achieved a pCR did not receive adjuvant T. Treatment discontinuation: 38 pts (8.8%): 27 pts due to cardiac toxicity and 4 relapsed during adjuvant T. In 87% pts, neoadjuvant CT was based on anthracyclines (A) and taxanes. Adjuvant CT: A and taxanes in 57.4%; 14% pts FAC, 15.4% A-CMF and 12% TCH. At a median follow-up of 70m (3-135), 44 pts (10.4%) had relapsed: 33 pts with distant M1, 9 pts with only loco-regional disease and 2 pts contralateral HER2-positive BC. M1 location: 46% visceral, 34% bone/lymph nodes and 20% in central nervous system (CNS). PFS was 23.4m (0-88); median OS was not reached; estimated 10 years-OS was 86.5%. Pts treated with A and taxanes had a significantly better OS compared to those treated with other CT (113 vs 98m, p = 0.009). Kaplan-Meier curve showed numerically higher relapses at 10 years in HR-positive pts (83 vs 90% p = 0.8). Pts with pCR had significantly better OS (113 vs 104m, p = 0.006). Pts with CNS-metastases had a significantly worse OS (13 vs 26m, p = 0.02) and those with HR-negative (49 vs 24m, p = 0.033).

Conclusion: In everyday clinical practice, recurrences after adjuvant/neoadjuvant trastuzumab in HER2-positive BC were less than described in the T-pivotals trials, with 10% of recurrences at a median of FU of 70m. In our series, estimated 10 years-OS was 86.5%. Pts treated with A and taxanes had a significantly better OS as well as those pts who achieved a pCR. On the contrary, pts with CNS M1 and those with HR-negative had worse prognosis.

Title: HER2 activity regulates the pro-trastuzumab immune tumor microenvironment

Tagliabue E, Forte L, Regondi V, Ghirelli C, Aiello P and Triulzi T. Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy.

Body: It is well known that trastuzumab activity against HER2-positive breast carcinomas (BCs) depends also on immune cells. Our genomic analysis of 53 HER2-positive BCs indicated that those exquisitely sensitive to treatment are addicted to this oncoprotein and are enriched in immune pathways and T-cells infiltration, raising the hypothesis that HER2 regulates immune cells recruitment. The aim of this study was to investigate how HER2 activity contributes to mold tumor microenvironment. Gene expression profile analysis of 53 HER2-pos BCs showed that trastuzumab-sensitive tumors express significantly higher levels of chemokines involved in immune cells recruitment (IFNγ-related CXCLs and CCLs) and higher levels of immune checkpoint ligands (PD-L1, PD-L2) than tumors that do not benefit from trastuzumab. Immunohistochemistry analysis on FFPE tumor specimens showed a significant positive association between tumor cell positivity for CXCL9, CXCL10 and CCL2 and trastuzumab sensitivity. In vitro analysis in HER2-positive BC cell lines revealed that while IFNγ-related chemokines (CXCL9 and CXCL10) are not directly regulated by HER2 signaling, CCL2 was significantly up-regulated both at mRNA and protein levels by HER2 stimulation with EGF/HRG and down-modulated by HER2 inhibition with trastuzumab. The EGF-induced increase in CCL2 expression was abrogated by the concomitant treatment with PI3K inhibitor but not with MEK inhibitor, indicating that HER2 regulates CCL2 expression via the PI3K pathway. HER2 signals derived from cell stimulation with EGF/HRG caused also the upmodulation of PD-L1/PD-L2 both at mRNA and protein levels while their inhibition with trastuzumab reduced their levels. Overall, our results support the notion that the activated HER2 oncogene concomitantly induces the expression of CCL2 and PD-L1/PD-L2 regulating infiltration of pro-trastuzumab immune cells and their suppression. Thus, it is likely that activity of trastuzumab in therapy-responsive tumors derives from its ability in relieving suppression of recruited antitumor effector immunity. Supported by Italian Association for Cancer Research (AIRC).
Title: Phase II study of gemcitabine, trastuzumab, and pertuzumab for HER2-Positive metastatic breast cancer after prior pertuzumab-based therapy

Body: Background: The combination of taxanes with trastuzumab (H) and pertuzumab (P) for first line treatment of HER2-positive metastatic breast cancer (MBC) is associated with improved progression-free survival (PFS) and overall survival (OS). Treatment per physician's choice with anti-HER2 therapy after second line therapy is associated with a median PFS of 3 months. While continued use of H in therapeutic combinations after progression on H-based therapy is common, the efficacy of continuing HP-based treatment after progression on P-based therapy is unknown.

Methods: This is a single arm phase II trial of gemcitabine (G) with HP. Eligible patients had HER2-positive (IHC 3+ or FISH ≥ 2.0) MBC with prior HP-based treatment and ≤ 3 prior chemotherapies. Patients received G (1200 mg/m²) on days 1 and 8 of a q3 week (w) cycle, and H (8 mg/kg load → 6 mg/kg) and P (840 mg load → 420 mg) q3w. The primary endpoint is PFS at 3 months. Secondary endpoints include OS, safety and tolerability. An exploratory endpoint is to compare PFS by RECIST criteria versus 18-F FDG-PET response criteria. Using a Simon optimal 2-stage design, 21 patients were enrolled in stage 1. The successful 3-month PFS rate for stage 1 was set at 57% to allow accrual to stage 2 for a total of 45 patients. The study therapy will be considered successful if at least 27/45 (60%) patients are progression free at 3 months.

Results: As of June 9, 2016, 28 patients are enrolled; 21 are evaluable at 3 months and 7 have not had 3-month evaluation. At 3 months, 16/21 (76%) are progression free; 5 patients have progressed. The 3 month-PFS results for evaluable patients will be updated. There are no cardiac or febrile neutropenic events to date. Initially, 5 of 22 (23%) patients required G dose reduction (4 due to grade 3 neutropenia and 1 due to grade 3 vomiting) and the study was amended to lower initial G dose to 1000 mg/m².

Conclusions: The preliminary 3 month-PFS is 76% (95% CI 55% to 89%) in evaluable patients, and updated data will be presented. These findings suggest clinical benefit when P is continued beyond progression.
Title: Phase II trial of pertuzumab, trastuzumab, and nab-paclitaxel in patients (pts) with HER2 overexpressing (HER2+) locally advanced or inflammatory breast cancer (LABC) or untreated stage IV metastatic breast cancer (MBC)

Body: Background: Pathologic complete response (pCR) to HER2-targeting neoadjuvant therapy (NT) predicts for improved survival (Cortazar et al, Lancet, 2014). The addition of pertuzumab to trastuzumab and docetaxel increased pCR rates, and, as first line treatment for MBC led to longer overall survival ([OS] Swain et al, NEJM 2015). Avoidance of anthracyclines in the adjuvant setting for HER2+ BC reduced the risk of secondary hematologic malignancies without a detriment to OS (Slamon et al, NEJM, 20111). Finally, nab-paclitaxel (nab) might provide an advantage over other taxanes via decreased use of steroids and may lead to increased response rates (RR). We designed a study of pertuzumab (pert), trastuzumab (trast), and nab, testing the feasibility and efficacy of this regimen in the LABC and metastatic breast cancer settings.

Materials and Methods: Pts with Stages II-III LABC received six cycles of NT with pert (day 1 q 21 days), trast, and nab 100 mg/m^2 (both given IV, weekly). Pts with untreated MBC received the same regimen until progression, toxicities, or patient or physician preference led to stopping therapy. Primary endpoints included pCR (LABC) and RR and progression-free survival (PFS) in MBC. Forty pts with LABC and 25 pts with MBC were to be accrued. The study was designed to test whether the pCR rate of Neosphere (Gianni et al, Lancet Oncol, 2012, > 45.8%) and the PFS rate of CLEOPATRA (median of > 18.5 months) can be matched or exceeded. Procurement of serial samples for assessment of tumor gene expression, circulating tumor cells, miRNA, and serum DNA profiling for exploratory biomarker analysis was carried out.

Results: Twenty-two of 28 already enrolled pts with LABC (clinical stage II:15, stage III: 7) completed NT. The median age was 53 (34-77). The pCR rate was 86% (6/7) for hormone receptor negative (HR-) and 40% (6/15) for HR+ pts, with an overall pCR of 55%. Three pts without pCR following NT had residual BC with a HER2 negative phenotype. Eighteen of 22 pts required nab dose modifications. The most frequent toxicities following NT included elevated liver function tests:27%, peripheral neuropathy:23%, hematological toxicities:17%, diarrhea:18%, infusion reactions:18%. In the MBC cohort there were 13 of 16 enrolled pts with > 2 months of follow-up. The median age was 47 (31-65), 62% had HR+ disease. A CR rate of 4/13 (31%) and confirmed RR of 77% were observed. The median number of cycles with pert, trast, nab was 9 (3+ to 41); 11 of 13 pts required dose modifications or delays (3 of the delays were due to primary breast surgery performed upon response to treatment). At a median follow-up of 19 months, PFS and OS estimates are 63% (95% CI 0.09-0.93), and 89% (95% CI 0.61-1.0).

Conclusion: The non-anthracycline-containing regimen of pertuzumab, trastuzumab, and nab-paclitaxel induced a high pCR rate in HER2+ BC. PFS is encouraging in MBC. Outcome of the fully accrued cohorts inclusive of residual cancer burden scores in the LABC cohort, and correlative data with exploratory biomarker analysis will be presented.
Title: Splenic enlargement and bone marrow hyperplasia in patients receiving trastuzumab-emtansine for metastatic breast cancer

Kosmin M, Makris A, Jawad N, Miles D and Padhani AR R. Mount Vernon Cancer Centre, Northwood, Middlesex, United Kingdom and Paul Strickland Scanner Centre, Northwood, Middlesex, United Kingdom.

Body: Introduction
Trastuzumab emtansine (T-DM1) is an antibody-drug conjugate used for treatment of human epidermal growth factor receptor 2 (HER2)-positive metastatic breast cancer. An association between T-DM1 and splenic enlargement was noted anecdotally on sequential whole-body MRI (WB-MRI) examinations. A retrospective analysis of WB-MRI examinations of patients on T-DM1 was undertaken to investigate the hypothesis that an increase in splenic volume is due to either a generalised hyperplasia of the bone marrow and reticulo-endothelial system and/or an increase in portal venous pressure.

Methods
12 patients underwent 29 serial WB-MRIs before and during T-DM1 therapy. Splenic volume, portal vein diameter, bone marrow muscle-normalised signal intensity (nSI), water diffusivity (apparent diffusion coefficient, ADC) and fat fraction were measured. Changes in splenic volume were analysed, and correlations between the measured variables were obtained.

Results
An increase in splenic volume was observed in 92% of patients. Mean splenic volume increased from 144cm$^3$ (95%CI 110-177cm$^3$) to 209cm$^3$ (95%CI 161-257cm$^3$) on T-DM1 therapy (p=0.006). Increase in splenic volume correlated with treatment duration ($r^2=0.71$). Increase in normal bone marrow signal was seen (nSI 3.5 to 4.8, p=0.12), along with a decrease in fat fraction (64.3% to 57.3%, p=0.12), and reduced ADC (655µm$^2$/s to 543µm$^2$/s, p=0.11). No consistent changes to portal vein diameter were seen.

Discussion
An increase in splenic volume was consistently observed in patients on T-DM1 therapy. This was unrelated to portal vein changes but correlated with bone marrow hyperplasia. Caution should be applied when assessing metastatic disease in bone to avoid incorrectly attributing T-DM1-related changes in normal bone marrow to disease progression.
Body: Background
Preclinical and clinical studies suggest that trastuzumab resistance in HER2 amplified breast cancer (HER2+ BC) is mediated by cross-activation of alternative signaling pathways. Computational analysis and pooled whole-genome RNAi screens in HER2 transformed BC cell lines identified the IL6/JAK2/STAT3 axis as a master regulator pathway. The combination of trastuzumab plus ruxolitinib, a JAK1/JAK2 inhibitor, demonstrated synergistic tumor growth inhibition in mouse xenografts of HER2 transformed BC cell lines. These data provide the rationale for studying the efficacy of ruxolitinib and trastuzumab in a clinical trial.

Design
This is a multi-center, open-label, phase I/II trial of ruxolitinib plus trastuzumab in patients (pts) with HER2+ metastatic BC (MBC) who have progressed on ≥2 HER2-directed therapies in the metastatic setting (including trastuzumab, pertuzumab and T-DM1). The phase I is an adaptive design with 10 pts, using the time-to-event continual reassessment method to determine the recommended phase II dose. Phase II will be a non-randomized, open-label trial with 30 evaluable pts. The duration of a treatment cycle is 21 days, with trastuzumab given on Day 1 and ruxolitinib taken orally twice daily continuously. The primary endpoint of phase I is to determine the maximum tolerated dose of the drug combination. The phase I dose range for ruxolitinib is 10-25 mg BID (dose level 0: 20 mg BID). Response is assessed by imaging every 9 weeks. Blood samples and optional tissue biopsies are obtained for biomarker analysis at the following time points: pre-treatment, on-treatment C2D1, and at progression.

Results
Phase I started accrual in the fall of 2014. The trial has accrued 12 patients, with 9 evaluable and 3 non-evaluable patients. Of the evaluable patients, the mean age was 55.9 (range 32-69). Of these, 7 were postmenopausal (78%) 5/9 (56%) were estrogen receptor positive, and all had measurable disease. The mean number of prior lines of therapy in the metastatic setting was 5.6 (range: 3-8), including a mean of 3.2 (range: 2-5) prior regimens containing HER2 targeted therapies. As of 6/12/16, 2 patients remain on therapy. As this is an adaptive design, efficacy and drug tolerability will not be mentioned in this abstract to not bias the ongoing analysis. However, we anticipate that by SABCS 2016, 10 evaluable patients will have completed the DLT period – at which point, complete data will be presented.

Conclusion
Ruxolitinib plus trastuzumab is a novel, non-chemotherapy containing regimen. The phase I analysis is ongoing. We plan on reporting full safety/tolerability and efficacy data once 10 evaluable patients have completed the phase I (9/10 have currently completed DLT period). Given an early signal in HER2+ breast cancer, in this heavily pretreated population we will proceed directly to a phase II trial with the combination.
Title: Cardiac safety of dual anti-HER2 therapy in the neoadjuvant setting for treatment of HER2-positive breast cancer

Body: Background: Trastuzumab and pertuzumab are approved for the treatment of HER2-positive breast cancer in the neoadjuvant setting. However, limited cardiac safety data is available when used in combination with doxorubicin-based chemotherapy. At a single center we retrospectively report the cardiac safety of dose-dense doxorubicin and cyclophosphamide (AC) followed by paclitaxel, trastuzumab, and pertuzumab (THP) in the neoadjuvant setting followed by adjuvant trastuzumab-based therapy.

Methods: Patients treated with neoadjuvant dose dense AC followed by THP from September 1, 2014 to March 1, 2015 were retrospectively identified. Patients then had breast surgery and completion of anti-HER2 therapy for 1 year. The primary outcome was cardiac event rate, defined by New York Heart Association (NYHA) class III/IV or cardiac death. The secondary outcome was significant asymptomatic decline in left ventricular ejection fraction (LVEF) of 10%-15% from baseline to below the lower limit of normal, or ≥ 16% from baseline. Patients underwent LVEF monitoring at baseline prior to AC, prior to initiation of THP, and serially during 1 year of anti-HER2 therapy (neoadjuvant to adjuvant phases).

Results: Fifty-seven patients were included in the study. The median age was 46 years (range 26-68 years). The median number of cycles of trastuzumab and pertuzumab in the neoadjuvant setting was 6 (range 3-8) and 6 (range 2-8), respectively. In the adjuvant setting, 56 (98%) patients received trastuzumab with pertuzumab with a median cycle number of 12 (range 1-13). Two of 57 (3.5%) patients developed NYHA class III/IV heart failure after 5 and 9 months of trastuzumab, leading to permanent discontinuation of anti-HER2 treatment. Additionally, 7 (12.3%) patients developed a significant LVEF decline (without severe HF symptoms). The median LVEF was 65% (range 55-75%) at baseline and 64% (range 53-72%) after AC. There was a reduction in median LVEF to 60% (range 35-70%), 60% (range 23-73%), 61% (range 25-73%), and 58% (range 28-66%) at 3, 6, 9, and 12 months (+/- 6 weeks) of trastuzumab-based therapy.

Conclusion: In patients with HER2-positive breast cancer treated with neoadjuvant dose-dense AC and THP followed by completion of anti-HER2 therapy in adjuvant setting, the overall rate of NYHA Class III/IV heart failure was comparable to rates reported in trials of sequential doxorubicin and trastuzumab. Our findings do not suggest an increased risk of cardiotoxicity when pertuzumab is added to trastuzumab following a doxorubicin-based regimen.
Body: Background: In metastatic breast cancer, the CDK4,6 inhibitor palbociclib associated with fulvestrant proved superior to fulvestrant alone in HER2-negative breast cancer (NEJM 2015). In HER2-positive tumors, the dual blockade of the receptor plus an aromatase inhibitor led to a 21% rate of pCR in a neoadjuvant setting in ER+ cancers (J Clin Oncol 2013). In preclinical studies concomitant inhibition of CDK4,6 and trastuzumab led to synergistic antitumor activity (Cancer Cell 2016). The extent of early change and the persistence of Ki67 down-regulation are robust markers of the effects of endocrine treatments in hormone receptors positive breast carcinomas in the setting of neoadjuvant endocrine therapy (Ann Oncol 2012).

Methods: In this exploratory Phase II trial (NCT02530424), women with invasive unilateral non metastatic ER-positive breast cancer expressing HER2 and suitable for neoadjuvant therapy were treated with every 3 wks trastuzumab and pertuzumab for 6 cycles combined with palbociclib 125 mg po q.d. x 21 q. 4 wks and fulvestrant i.m. 500 mg, both given for 5 cycles (HPPF). The primary endpoint was characterization of Ki67 changes from baseline before therapy, at 2 weeks and at surgery.

Results: A total of 23 patients with centrally confirmed HER2 and ER positive breast cancer were recruited for this study. Ki67 was also assessed centrally. At baseline 30% of cases were classified as locally advanced, 43% as cN0 and 78% had Ki67 values > 20%. Objective clinical response was documented in 96% of patients and pCR (absence of invasive cells in breast and axillary nodes) was documented in 22% (pCR in breast only was 26%). The geometric means of Ki67 expression assessed at baseline, after 2 weeks of treatment and at surgery were 30.8 (SD 15.1), 3.9 (SD 15.9) and 9.2 (SD 16.6) respectively. The mean change in Ki67 values from baseline to after 2 weeks was -24.5 (paired t-test: P < 0.0001) and -13.9 (P = 0.008) from baseline to surgery. Treatment was fairly well tolerated. No serious adverse events > grade 3 were reported. The most frequent G 3 adverse events were neutropenia (26% of patients) and gastrointestinal disorders (17%).

Conclusions: Neoadjuvant triple targeting of ER, HER2 and Rb in HER2+/ER+ breast cancer treatment caused a significant and rapid decrease of Ki67 that was of larger magnitude after 2 weeks than at surgery irrespective of the recorded objective clinical response. The good tolerability, the rapid effect on Ki67, the consistent clinical response, and the rate of pCR with this chemotherapy-free approach support further clinical testing and additional molecular characterization.

**Title:** In vitro and in vivo activity of HER2-targeted antibody-liposomal doxorubicin conjugate MM-302 in HER2-intermediate tumors

Geretti E, Espelin C, Adiwijaya B, Coma S, Koncki Z, Sumner P, Dumont N, Garcia G, Bloom T, Janovsky J, Reynolds J, Campbell K, Moyo V, Molnar I, LoRusso P, Krop I, Miller K, Ma C, Munster P and Wickham T. Merrimack Pharmaceuticals Inc., Cambridge, MA; Yale Cancer Center, New Haven, CT; Dana-Farber Cancer Institute, Boston, MA; Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN; Washington University School of Medicine, St. Louis, MO and Helen Diller Family Comprehensive Cancer Center, San Francisco, CA.

**Methods:** In vitro binding and viability studies were performed with MM-302, PEGylated liposomal doxorubicin (PLD) and T-DM1 in a panel of cell lines at different HER2 expression. MM-302 showed an acceptable safety profile and promising activity in a Phase 1 study in HER2-positive (IHC 3+ or 2+ and HER2 FISH amplified) metastatic breast cancer (NCT01304797), and it is now being evaluated in a Phase 2 trial in the same setting (NCT02213744). A substantial percentage (~30%) of breast cancer patients show positive HER2 IHC (1+/2+) without HER2 gene amplification (“HER2 intermediate”). This population is not eligible for treatment with currently approved HER2-targeted therapies. The goal of this work is to evaluate preclinical activity of MM-302 in HER2 intermediate models.

**Results:** MM-302 efficiently bound to and induced tumor cell death across a panel of cell lines at different HER2 expression. In vivo evaluation showed increased HER2-mediated uptake of MM-302 over PLD in tumor cells in IHC 1+, 2+, and 3+ tumors but not in IHC 0 tumors. As expected, uptake of T-DM1 into HER2 intermediate models was negligible, and T-DM1 mainly localized in the periphery of the tumors and within the stromal cells. Treatment with MM-302 resulted in increased anti-tumor activity in the IGROV1 xenograft model, and in a significantly higher inhibition of T47D metastatic spread to lungs, ovaries, adrenal glands and liver relative to both PLD and T-DM1.

The preclinical findings were in line with observations on post-treatment biopsies from MM-302 Phase 1 study NCT01304797. HER2 expression within individual samples was found to be heterogeneous, ranging from ~1 x 10^5 to over 1 x 10^6 HER2 receptors per cell. Evaluation of MM-302 uptake in tumor cells at different HER2 levels within the same sample revealed that the magnitude of MM-302 tumor cell uptake was comparable across the range of HER2 expression from ~1 x 10^5 to over 1 x 10^6 HER2 receptors per cell.

**Conclusions:** Our data suggest that MM-302 effectively targets tumor cells expressing various levels of HER2 in preclinical models as well as in patient tumors. Hence, in addition to investigating activity in HER2-positive patients, MM-302 development may be extended to patients with intermediate HER2 expression (HER2 IHC 1+/2+; FISH-negative), who are ineligible to currently approved HER2-targeted therapies, and who represent a significant unmet medical need.

Title: Primary analysis of BERENICE: A phase II cardiac safety study of pertuzumab, trastuzumab, and neoadjuvant anthracycline-based chemotherapy in patients with locally advanced, inflammatory, or early-stage, unilateral, and invasive HER2-positive breast cancer

Swain SM M, Ewer MS S, Viale G, Delaloge S, Ferrero JM, Verrill M, Colomer R, Vieira C, Werner TL L, Douthwaite H, Bradley D, Waldron-Lynch M, Eng-Wong J and Dang C. Georgetown University Medical Center, Washington, DC; The University of Texas MD Anderson Cancer Center, Houston, TX; European Institute of Oncology, University of Milan, Milan, Italy; Institut Gustave Roussy, Paris, France; Centre Antoine Lacassagne, Nice, France; Northern Centre for Cancer Care, Newcastle upon Tyne, United Kingdom; Hospital Universitario La Princesa, Madrid, Spain; Instituto Português de Oncologia Francisco Gentil (IPOFG), Porto, Portugal; Huntsman Cancer Institute, University of Utah, Salt Lake City, UT; Roche Products Ltd, Welwyn Garden City, United Kingdom; Clinical Science, Global Product Development, Welwyn Garden City, United Kingdom; Product Development – Oncology, Genentech, Inc., South San Francisco, CA and Memorial Sloan-Kettering Cancer Center, New York, NY.

Body: Background: Neoadjuvant pertuzumab (P)+trastuzumab (H)+standard chemotherapy (CT) significantly increases pathologic complete response (pCR) rates v H+CT. However, anti-HER2 therapy following anthracyclines can cause heart failure, and data are limited or lacking on combining P+H after epirubicin or doxorubicin. We report cardiac and overall safety as well as total pCR (tpCR) rates with widely used but understudied anthracycline-containing regimens.

Methods: BERENICE (NCT02132949), a non-randomized, open-label, phase II study, enrolled patients (pts) with centrally confirmed HER2-positive, locally advanced, inflammatory, or early-stage, unilateral, and invasive breast cancer, Eastern Cooperative Oncology Group performance status ≤1, and baseline left ventricular ejection fraction (LVEF) ≥55%. In the neoadjuvant period, Cohort A pts received four q2w dose-dense doxorubicin+cyclophosphamide cycles (60 mg/m²/600 mg/m² with granulocyte-colony stimulating factor support as needed) followed by 12 qw paclitaxel doses (80 mg/m²) + four q3w P+H cycles (P 840 mg, then 420 mg; H 8 mg/kg, then 6 mg/kg). Cohort B received four q3w fluorouracil/epirubicin/cyclophosphamide cycles (500 mg/m²/100 mg/m²/600 mg/m²) followed by four q3w docetaxel cycles (75 mg/m² escalated to 100 mg/m²) + four q3w P+H cycles. Surgery was performed after cycle 8 for both cohorts. The primary objective was to evaluate cardiac safety during the neoadjuvant period, assessed by incidence of 1) New York Heart Association (NYHA) Class III/IV heart failure and 2) significant LVEF declines (≥10% from baseline with a value of <50%). Secondary objectives included assessments of adverse event (AE) rates and tpCR (ypT0/Tis ypN0; NX was considered non-tpCR). Results are descriptive; no statistical hypothesis testing was planned.

Results: Four hundred one pts were enrolled between Jul 2014–Aug 2015. Clinical cutoff was Mar 3, 2016. Demographics and baseline characteristics were generally balanced between cohorts; 64.3% v 61.7% of pts had centrally confirmed hormone receptor (HR)-positive disease and 95.0% v 93.0% had T1–T3 primary tumors. Three pts in Cohort A and none in Cohort B experienced NYHA Class III/IV heart failure during neoadjuvant treatment (table). Thirteen pts in Cohort A v four in Cohort B had significant LVEF declines (table). One Cohort B pt's LVEF decline was prior to anti-HER2 treatment. AE and serious AE (SAE) rates were well balanced between cohorts. The most common AEs were nausea, diarrhea, and alopecia. The most common SAE was febrile neutropenia. tpCR rates were similar between cohorts (table).

**Conclusion:**
Cardiac and general safety of the two anthracycline-containing regimens in BERENICE were as expected and were consistent with the known P+H+CT profiles. Both regimens were active, and tpCR rates were high.

Title: MetaPHER phase IIIb multicenter, open-label, single-arm safety study of subcutaneous trastuzumab in combination with pertuzumab and docetaxel in patients with HER2-positive advanced breast cancer: First results

Kümmerl S, Abraham J, Martin M, Crepelle-Fléchais A, Swat A, Nüesch E, Shing M and Tondini CA A. Kliniken Essen-Mitte, Essen, Germany; Velindre Cancer Centre, Cardiff, United Kingdom; Hospital General Universitario Gregorio Marañón, Madrid, Spain; Global Product Development, F. Hoffman-La Roche Ltd, Basel, Switzerland; Global Product Development Biometrics, F. Hoffman-La Roche Ltd, Basel, Switzerland; Global Pharma Development, Genentech, Inc, South San Francisco, CA and ASST Papa Giovanni XXIII, Bergamo, Italy.

Body: Background: MetaPHER investigates fixed-dose subcutaneous trastuzumab (Herceptin® [H SC]) in combination with intravenous (IV) pertuzumab (PERJETA® [P IV]) plus docetaxel (D IV). The MetaPHER study treatment regimen is based on CLEOPATRA (phase III; NCT00567190), which demonstrated a significant progression-free and overall survival benefit in patients (pts) with HER2-positive metastatic breast cancer (BC) following first-line treatment with IV trastuzumab (Herceptin® [H IV]) plus P IV plus D IV. Fixed-dose H SC was non-inferior to H IV in terms of pathological complete response and serum trough concentration, and had a comparable safety profile to H IV, in pts with HER2-positive early BC in HannaH (phase III; NCT00950300). Furthermore, PrefHer (NCT01401166) results showed compelling patient preference for H SC vs H IV (88.9% vs 9.6%) in the HER2-positive early BC setting. To date, limited data exist for H SC in combination with P IV and D IV; we report the first results of safety and tolerability from MetaPHER for this combination in pts with HER2-positive advanced BC.

Methods: MetaPHER enrollment is ongoing at >100 sites in 12 countries. Females aged ≥18 years with metastatic or locally recurrent HER2-positive BC previously untreated with non-hormonal anticancer therapy, an Eastern Cooperative Oncology Group performance status of 0 or 1, and left ventricular ejection fraction (LVEF) ≥50% receive fixed-dose H SC 600 mg/5 mL q3w, P IV (840 mg loading dose, then 420 mg at subsequent cycles q3w), and D IV (at least 6 cycles with a recommended initial dose of 75 mg/m² q3w; possible escalation to 100 mg/m² q3w and continuation of D IV after Cycle 6 at the investigator’s discretion). Study treatment is given until disease progression, unacceptable toxicity, withdrawal of consent, death, or predefined study end, whichever occurs first. The primary endpoint is safety and tolerability of H SC in combination with P IV and D IV in pts with HER2-positive advanced BC. Adverse events (AEs) and serious AEs (SAEs) were graded per National Cancer Institute – Common Terminology Criteria for Adverse Events (NCI-CTCAE) version 4.0. Results are descriptive.

Results: 150 pts were enrolled and received a median of 4 treatment cycles by the data cutoff date of June 23, 2016. Safety data are shown in the table.

Conclusion: MetaPHER's first report of H SC with P IV and D IV as first-line treatment for pts with HER2-positive advanced BC is consistent with the known safety profile for H IV with P IV and D IV from CLEOPATRA, and no new safety signals were identified.
Title: Evaluation of veliparib (V) and temozolomide (TMZ) in a phase 2 randomized study of the efficacy and tolerability of V+TMZ or carboplatin (C) and paclitaxel (P) vs placebo (Plc)+C/P in patients (pts) with BRCA1 or BRCA2 mutations and metastatic breast cancer

Diéras V, Han HS, Robson ME, Palácová M, Marcom PK, Kelly, Jager A, Bondarenko I, Citrin D, Campone M, Tell L, Domchek SM, Friedlander M, Kaufman B, Ratajczak C, Coates A, Bonnet P, Qin Q, Qian J, Giranda VL, Shepherd SP, Puhalla S and Isakoff SJ. Institut Curie, Paris, France; Moffitt Cancer Center, Tampa, FL; Memorial Sloan Kettering Cancer Center, New York, NY; Masarykův Onkologický ústav, Brno, Czech Republic; Duke University, Durham, NC; Erasmus MC Cancer Institute, Rotterdam, Netherlands; Dnepropetrovsk City Hospital, Dnepropetrovsk, Ukraine; Midwestern Regional Medical Center, Zion, IL; Institut de Cancérologie de l'Ouest, Saint Herblain, France; Stanford University School of Medicine, Stanford, CA; University of Pennsylvania, Philadelphia, PA; Prince of Wales Hospital, Sydney, NSW, Australia; Sheba Medical Center, Tel Hashomer, Israel; AbbVie, Inc, Chicago, IL; University of Pittsburgh Cancer Institute, Pittsburgh, PA and Massachusetts General Hospital, Boston, MA.

Body: Background: V is a potent, poly(ADP-ribose) polymerase (PARP) inhibitor that obstructs DNA damage repair. BRCA1/2 tumors are defective in homologous recombination, which leads to more error-prone mechanisms of DNA repair and increased sensitivity to PARP inhibition. V enhances the antitumor activity of alkylating agents such as TMZ in preclinical models. In addition, V+TMZ showed promising activity in a single-arm phase 2 study in pts with BRCA1/2 mutations. This phase 2 trial (NCT01506609) investigated the efficacy and tolerability of V+TMZ (or V+C/P) compared to Plc+C/P in pts with locally recurrent or metastatic breast cancer harboring a BRCA1 or BRCA2 mutation. Results from the primary analysis for the V+TMZ arm vs Plc+C/P are presented, and the V+C/P vs Plc+C/P results will be presented separately.

Methods: Male and female pts aged ≥18 years with histologically confirmed locally recurrent or metastatic breast cancer were randomized 1:1:1 to: 1) V 40 mg BID D1–7 + TMZ 150–200 mg/m² QD D1–5, 28-D cycle; 2) V 120 mg BID D1–7 + C AUC 6, D3 and P 175 mg/m², D3, 21-D cycle; 3) placebo BID D1–7 + C/P. Key eligibility criteria included known deleterious BRCA1/2 mutation, ≤2 prior chemotherapies for metastatic disease, no prior platinum agent, and no CNS metastases. Randomization was stratified by hormone receptor status, prior cytotoxic therapy (yes vs no), and ECOG PS (0–1 vs 2). The primary endpoint was progression-free survival (PFS) per RECIST 1.1 by independent review. Overall survival (OS), objective response rate (ORR), and safety/tolerability were also evaluated.

Results: A total of 290 pts (284 BRCA+ per central lab) were randomized (V+TMZ, n=94 [91 BRCA+]). Baseline demographics and disease characteristics were comparable among treatment arms; 41.3% of pts had triple-negative breast cancer (TNBC) and 31.7% had received ≥2 prior regimens. Median study drug exposure was 6 cycles for the V+TMZ arm and 10 cycles for the Plc+C/P arm. Median PFS, median OS (interim), and ORR for V+TMZ were inferior to Plc+C/P (PFS 7.4 vs 12.3 mo, OS 19.1 vs 25.0 mo, and ORR 28.6% vs 61.3%). In pts with TNBC, median PFS was 5.5 (3.1–8.5) mo; 8.4 (6.8–10.6) mo for pts with non-TNBC. Treatment-emergent adverse events (AEs) of interest occurring differentially with V+TMZ are shown in Table 1. Grade ≥3 AEs in ≥30% of pts in the V+TMZ arm were thrombocytopenia (48%) and neutropenia (37%).

Conclusions: V+TMZ provided durable responses, with less neutropenia, alopecia, and neuropathy than Plc+C/P; however, PFS, OS, and ORR were inferior in the TMZ arm compared to C/P.

Title: Palbociclib in combination with endocrine therapy in treatment-naive and previously treated elderly women with HR+, HER2– advanced breast cancer: a pooled analysis from randomized phase 2 and 3 studies

Rugo HS S, Turner NC C, Finn RS S, Joy AA A, Verma S, Harbeck N, Moulder S, Masuda N, Im Y-H, Zhang K, Kim S, Sun W, Schnell P, Huang-Bartlett C and Slamon D. University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA; Institute of Cancer Research and Royal Marsden Hospital, London, United Kingdom; David Geffen School of Medicine, Los Angeles, CA; Cross Cancer Institute, University of Alberta, Edmonton, AB, Canada; University of Calgary, AB, Canada; Brustzentrum der Universität München (LMU), Munich, Germany; University of Texas, MD Anderson Cancer Center, Houston, TX; National Hospital Organization Osaka National Hospital, Osaka, Japan; Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; Pfizer Inc, San Diego, CA; Pfizer Oncology, La Jolla, CA; Pfizer Inc, New York, NY and Pfizer Inc, Collegeville, PA.

Body: Background: At least 40% of breast cancers are diagnosed in women ≥65 y old and most are hormone receptor-positive/human epidermal growth factor receptor 2-negative (HR+/HER2-). Palbociclib (PAL) is an oral, small-molecule inhibitor of cyclin-dependent kinases 4 and 6. Randomized studies of PAL combined with endocrine therapy (ET) demonstrated significantly improved progression-free survival (PFS) in patients (pts) with treatment-naive and previously treated advanced breast cancer (ABC).

Methods: We evaluated the efficacy of PAL+ET vs ET alone in pts aged ≥65-74 and ≥75 y across multiple pivotal randomized phase 2 and 3 studies. Safety and pharmacokinetics (PK) data (blood samples collected from pts in phase 1/2 [PALOMA-1] and phase 1 studies [NCT00141297 and NCT00420056]) for PAL+ET were pooled and compared across age groups. Pts who had not received treatment for ABC were randomized to receive PAL+letrozole (LET) or LET alone/with placebo (PBO; PALOMA-1, open-label/PALOMA-2, double-blind). Pts who had progressed on prior ET were randomized to receive PAL+fulvestrant (FUL) or PBO+FUL (PALOMA-3, double-blind). The primary endpoint for these studies was investigator-assessed PFS. Safety assessments and blood counts occurred at baseline and every 2 weeks for the first 2 cycles and on day 1 of subsequent cycles.

Results: Among 872 pts treated with PAL+ET, 221 (25%) were aged ≥65-74 y and 83 (10%) were ≥75 y (PAL+LET: n=528, 162 and 56, respectively; PAL+FUL: n=347, 59 and 27). Median (range) treatment durations were 440 (1-1615) d, 502 (1-1615) d, and 459 (21-1404) d, respectively. Improvement in efficacy endpoints was seen with PAL+ET vs ET across all age groups (Table 1). Incidence of adverse events (AEs), serious AEs and discontinuations due to AEs were similar in the overall population (99%, 19%, 3%) and in pts aged ≥65-74 (99%, 25%, 5%) and ≥75 y (100%, 30%, 6%). Incidence of all grades and grade 3/4 neutropenia were also similar across age groups (overall: 67% and 54%; ≥65-74 y: 64% and 51%; ≥75 y: 77% and 60%). PK analysis showed no clinically relevant differences between arithmetic means, medians, and geometric means of the apparent oral clearance across age groups.

Conclusions: PAL in combination with ET is an effective and well-tolerated treatment option for elderly pts with HR+/HER2-endocrine-sensitive and -resistant ABC. A dose adjustment based on age is not required.

Title: A randomized, double-blind, phase 2 study of ruxolitinib (RUX) or placebo (PBO) in combination with capecitabine (CAPE) in patients (pts) with advanced HER2-negative breast cancer (ABC) and elevated C-reactive protein (CRP), a marker of systemic inflammation

O'Shaughnessy J, DeMichele A, Ma C, Richards P, Yardley DA A, Wright G, Kalinsky K, Steis R, Diab S, Kennealey G, Geschwindt R, Jiang W and Rugo H. Baylor University Medical Center, Texas Oncology, US Oncology, Dallas, TX; University of Pennsylvania, Philadelphia, PA; Washington University School of Medicine, St Louis, MO; Oncology & Hematology Associates of Southwest Virginia, Inc, Salem, VA; Sarah Cannon Research Institute and Tennessee Oncology PLLC, Nashville, TN; Florida Cancer Specialists, St Petersburg, FL; Columbia University Medical Center, New York, NY; Northside Hospital, Inc, Atlanta, GA; Rocky Mountain Cancer Centers, Aurora, CO; Incyte Corporation, Wilmington, DE and University of California, San Francisco, CA.

Body: Background: Systemic inflammation is associated with poor prognosis in pts with ABC. The JAK/STAT pathway is a key regulator of inflammatory signaling, associated with tumorigenesis, cell survival, and progression. We evaluated the efficacy and safety of RUX, a JAK1/JAK2 inhibitor, plus CAPE in pts with HER2-negative ABC and high systemic inflammation defined by the modified Glasgow Prognostic Score (mGPS). Methods: In this double-blind phase 2 trial, pts were randomized 1:1 to 21 day cycles of RUX+CAPE or PBO+CAPE: RUX 15 mg or PBO PO BID for 21 d; CAPE 1000 mg/m^2 PO BID for 14 d. Key inclusion criteria were systemic inflammation by mGPS of 1 or 2 (ie, CRP >10 mg/L), ECOG performance status ≤2, ≤2 prior chemotherapy regimens, and no prior CAPE. The primary endpoint was overall survival (OS); key secondary endpoints were progression-free survival (PFS), objective response rate (ORR; complete [CR] + partial response [PR]) per RECIST v1.1, clinical benefit rate (CBR; CR + PR + stable disease for ≥6 mo), duration of response, and safety. Treatment differences in OS and PFS were analyzed by the log-rank test; HRs and CIs were analyzed by the Cox proportional hazards model. Results: Baseline characteristics were similar between pts randomized to RUX+CAPE (n=76) vs PBO+CAPE (n=73): mGPS status (1, 82.9% vs 83.6%), hormone receptor (HR) status (positive, 67.1% vs 63.0%), and number of prior chemotherapy regimens for ABC (0, 50.0% vs 50.7%; 1, 38.2% vs 34.2%; 2, 9.2% vs 13.7%). Median treatment durations were 85 d with RUX in the RUX+CAPE group and 65 d with PBO in the PBO+CAPE group. Median OS was 11.2 mo with RUX+CAPE vs 10.9 mo with PBO+CAPE (HR, 0.932; 95% CI, 0.59–1.46; P=0.762). Median OS was 6.1 mo with RUX+CAPE vs 5.5 mo with PBO+CAPE in HR-negative pts and 11.7 mo and 12.2 mo in HR-positive pts. Median PFS was 4.5 mo with RUX+CAPE and 2.5 mo with PBO+CAPE (HR, 0.737; 95% CI, 0.49–1.12; P=0.151). Median PFS was 2.1 mo with RUX+CAPE vs 2.2 mo with PBO+CAPE in HR-negative pts and 6.1 mo and 4.1 mo in HR-positive pts. ORRs were 28.9% and 13.7% (P=0.024) in the RUX+CAPE and PBO+CAPE arms, respectively. The CBRs were 13.2% and 6.8%, respectively (P=0.278). Worsening of hematologic toxicity was higher and rates of grade 3/4 palmar-plantar erythrodysesthesia (PPE) were lower (1.4% vs 12.7%, respectively) with RUX+CAPE (Table).

*Most common all-grade (≥35%) or grade 3/4 (≥5%) events in the RUX+CAPE arm (safety group). †Laboratory abnormalities.

**Conclusion:** These data support the prognostic capabilities of the mGPS. The addition of RUX to CAPE for pts with ABC and high systemic inflammation was associated with an improved ORR compared with PBO+CAPE, but did not improve OS or PFS.
Title: First-line ribociclib plus letrozole in patients with de novo HR+, HER2– advanced breast cancer (ABC): A subgroup analysis of the MONALEESA-2 trial

O'Shaughnessy J, Petráková K, Sonke GS S, André F, Conte P, Arteaga CL L, Cameron DA A, Hart LL L, Villanueva C, Jakobsen EH H, Lindquist D, Souami F, Li X, Germa C, Hirawat S and Hortobagyi GN N. Texas Oncology-Baylor Charles A. Sammons Cancer Center and US Oncology Network, Dallas, TX; Masaryk Memorial Cancer Institute, Brno, Czech Republic; Netherlands Cancer Institute and BOOG Study Center, Amsterdam, Netherlands; Gustave Roussy, Villejuif, France; University of Padova and Istituto Oncologico Veneto, IRCCS, Padova, Italy; Vanderbilt-Ingram Cancer Center, Nashville, TN; Edinburgh Cancer Research Centre, University of Edinburgh, Edinburgh, United Kingdom; Florida Cancer Specialists/Sarah Cannon Research Institute, Fort Myers, FL; University Hospital of Besançon, Hospital Jean Minjoz, Besançon, France; Lillebaelt Hospital, Vejle, Denmark; Arizona Oncology, US Oncology Network, Sedona, AZ; Novartis Pharma AG, Basel, Switzerland; Novartis Pharmaceuticals Corporation, East Hanover, NJ and University of Texas M.D. Anderson Cancer Center, Houston, TX.

Body: Background: Around 15,000 US patients per year are diagnosed with de novo ABC. Due to the absence of prior systemic treatment for breast cancer, tumors of patients with de novo ABC may exhibit a different disease biology, which could result in different tumor responses compared with patients who have relapsed breast cancer. Ribociclib is an orally bioavailable cyclin-dependent kinase (CDK) 4/6 inhibitor. Results from MONALEESA-2, a double-blind, placebo-controlled, randomized Phase 3 trial (NCT01958021), demonstrated that first-line therapy with ribociclib + letrozole significantly improved progression-free survival (PFS) vs placebo + letrozole in patients with hormone receptor-positive (HR+) human epidermal growth factor receptor 2-negative (HER2–) ABC. Many patients with de novo ABC receive endocrine therapy in the first line and in subsequent lines; here we present results from the MONALEESA-2 study in a subpopulation of patients with de novo ABC.

Methods: Postmenopausal women (N=668) with HR+, HER2– ABC who had no prior systemic therapy for ABC were randomized 1:1 (stratified by liver and/or lung metastases) to receive ribociclib (600 mg/day; 3-weeks-on/1-week-off) + letrozole (2.5 mg/day; continuous) or placebo + letrozole. Patients with de novo ABC were eligible. Additional eligibility criteria included measurable disease or ≥1 predominantly lytic bone lesion, Eastern Cooperative Oncology Group performance status ≤1, and adequate bone marrow/organ function. Prior CDK4/6 inhibitors or systemic therapy for ABC were prohibited. Patients may have received ≤14 days of letrozole or anastrozole for ABC. The primary endpoint was locally assessed PFS; a predefined subgroup analysis evaluated PFS in patients with de novo ABC.

Results: In total, 227 patients with de novo ABC were enrolled. Patients with de novo ABC were equally distributed with 114 (34%) and 113 (34%) in the ribociclib + letrozole and placebo + letrozole arms, respectively. Median duration of exposure to study treatment in the ribociclib + letrozole vs placebo + letrozole arms was 14.1 vs 12.8 months. Treatment was discontinued in 84 (37%) patients with de novo ABC (ribociclib + letrozole vs placebo + letrozole, n [%]; 34 [30%] vs 50 [44%]). Reasons for treatment discontinuation (ribociclib + letrozole vs placebo + letrozole, n [%]) included disease progression (21 [18%] vs 41 [36%]), patient/physician decision (5 [4%] vs 6 [5%]), and adverse events (6 [5%] vs 3 [3%]). PFS was increased in patients with de novo ABC who received ribociclib + letrozole vs placebo + letrozole (hazard ratio=0.448 [95% confidence interval: 0.267–0.750]). The 12-month PFS event-free probability in patients with de novo ABC was 82% in the ribociclib + letrozole arm vs 66% in the placebo + letrozole arm.

Conclusions: The combination of ribociclib + letrozole significantly improved PFS compared with placebo + letrozole in postmenopausal women with HR+, HER2– de novo ABC at diagnosis and therefore may become an important treatment option in the de novo ABC setting.

Title: Treatment postprogression in women with endocrine-resistant HR+/HER2- advanced breast cancer who received palbociclib plus fulvestrant in PALOMA-3

Turner NC C, André F, Cristofanilli M, Verma S, Iwata H, Loi S, Harbeck N, Ro J, Colleoni M, Zhang K, Huang Bartlett C, Giorgetti C and Slamon D. Institute of Cancer Research and Royal Marsden Hospital, London, United Kingdom; Institut Gustave Roussy, Villejuif, France; Robert H Lurie Comprehensive Cancer Center, Feinberg School of Medicine, Chicago, IL; University of Calgary, Calgary, AB, Canada; Aichi Cancer Center Hospital, Nagoya, Japan; Peter MacCallum Cancer Centre, East Melbourne, VIC, Australia; Brustzentrum der Universität München (LMU), Munich, Germany; National Cancer Center, Goyang-si, Republic of Korea; Istituto Europeo di Oncologia, Milan, Italy; Pfizer Inc, San Diego, CA; Pfizer Inc, New York, NY; Pfizer Inc, Milan, Italy and University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA.

Body: Background: Palbociclib (PAL) plus fulvestrant (FUL) demonstrated significant improvement in progression-free survival (PFS) vs placebo (PBO) plus FUL in women with HR+/HER2- advanced breast cancer (ABC) whose disease had progressed on prior endocrine therapy (ET). Because the effectiveness of standard therapies after progression on PAL is unknown, it is important to understand whether the benefits of PAL with respect to PFS extend to subsequent treatments.

Method: Pre-, peri-, and postmenopausal patients (pts) with HR+/HER2- ABC who had relapsed/progressed on prior ET were randomized 2:1 to PAL (125 mg/d oral [3 wk on drug, 1 wk off]) + FUL (500 mg/mo intramuscular, per standard of care) or PBO+FUL. One prior line of chemotherapy (CT) for ABC was allowed. For 9 mo immediately after participation in PALOMA-3, pts were assessed every 3 mo for information on poststudy progression and treatment; the type of treatment, its duration, and sites of progression were analyzed.

Results: As of Oct 2015, with a median follow-up of 15.8 mo for PAL+FUL and 15.3 mo for PBO+FUL, 333 PFS events were observed (200 and 133, respectively). Median PFS was 11.2 vs 4.6 mo (hazard ratio [HR], 0.497 [95% CI, 0.398–0.620]; P<0.0001). In both treatment arms, the most common sites of disease progression were the liver (149 [43%] and 94 [54%]) and bone (55 [16%] and 43 [25%]). 1 pt in each treatment arm developed new brain metastasis. The most commonly used postprogression regimens were capecitabine (n=57 [28.8%]), paclitaxel (n=22 [11.1%]), and exemestane (n=34 [17.2%]). Median time to subsequent CT (from randomization to the start of the first CT treatment poststudy) was longer with PAL+FUL (252 d) than with PBO+FUL (132 d). This was also observed in pts with visceral disease who never received CT in the advanced setting at study entry (median 208 and 125 d, respectively). 252 pts had subsequent disease progression, treatment discontinuation on immediate subsequent therapy, or died. Proportionally fewer pts in the PAL+FUL vs PBO+FUL arm discontinued next-line treatment (33% vs 46%), indicating that PAL does not adversely affect the efficacy of subsequent treatments. Analysis of the time to end of next-line treatment showed that the HR between the 2 treatment arms was 0.623 ([95% CI, 0.482–0.805]; 1-sided P value=0.0001) in favor of PAL treatment (Table 1).

Conclusion: The current analysis demonstrated that the treatment effect of PAL+FUL was retained in the most immediate line postprogression and that progression after PAL has no effect on the therapeutic benefit from subsequent treatments.

Title: Long-term safety of palbociclib in combination with endocrine therapy in treatment-naive and previously treated women with HR+ HER2– advanced breast cancer: A pooled analysis from randomized phase 2 and 3 studies

Diéras V, Rugo HS S, Gelmon K, Finn RS S, Cristofanilli M, Loi S, Colleoni M, Lu D, Gauthier E, Huang-Bartlett C, Turner NC C and Schnell P. Institut Curie, Paris, France; University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA; British Columbia Cancer Agency, Vancouver, BC, Canada; David Geffen School of Medicine, Los Angeles, CA; Robert H. Lurie Comprehensive Cancer Center, Feinberg School of Medicine, Chicago, IL; Peter MacCallum Cancer Centre, East Melbourne, VIC, Australia; Istituto Europeo di Oncologia, Milan, Italy; Pfizer Inc, La Jolla, CA; Pfizer Inc, Collegeville, PA; Institute of Cancer Research and Royal Marsden Hospital, London, United Kingdom and Pfizer Inc, New York, NY.

Body: Background: Palbociclib (PAL) is a selective and reversible oral cyclin-dependent kinase 4 and 6 inhibitor. Large randomized phase (ph) 2 and 3 trials showed significant improvement in progression-free survival (PFS) when PAL was combined with endocrine therapy (ET) vs ET alone in treatment (trt)-naive and previously treated hormone receptorâ/opposite human epidermal growth factor receptor 2â/negative (HR+ HER2–) advanced breast cancer (ABC) patients (pts). The median PFS with PAL+ET is >2 years as a first-line therapy for ABC and 11.2 mo in endocrine-resistant ABC. We evaluated the long-term safety in PALOMA-1, -2, and -3.

Methods: We analyzed the tolerability of PAL in combination with ET in 3 randomized trials. Pts untreated for ABC were randomized to receive PAL+letrozole (LET) vs LET alone in PALOMA-1 (ph 2, open-label; 1:1) or randomized to receive PAL+LET vs placebo (PBO)+LET in PALOMA-2 (ph 3, double-blind; 2:1). PALOMA-3 included pts who progressed on prior ET, randomized to receive PAL+fulvestrant (FUL) or PBO+FUL (ph 3, double-blind; 2:1). Safety assessments, including a complete blood count, were done at baseline, on D1 of each cycle, and on D14 of the first 2 cycles. We evaluated adverse events (AEs) by 6-mo intervals (out to 36 mo) and cumulatively (12-, 24-, and 36-mo time points), and assessed latency (event onset) of pertinent adverse drug reactions (ADRs) in all pts treated in PALOMA-1, -2, and -3.

Results: A total of 1352 pts were pooled for this analysis; 872 pts received PAL+ET (527 pts, PAL+LET; 345 pts, PAL+FUL). Median duration of trt was 421 days in PALOMA-1 (January 2015), 603 days in PALOMA-2 (February 2016), and 330 days in PALOMA-3 (July 2015). PAL+LET was received by 119 pts as first-line trt in PALOMA-1 and 2 for 24–<30 months and 11 pts were treated for >36 mo. PAL+FUL was received by 140 pts for >12 mo as second-line trt in PALOMA-3. The most commonly reported ADRs across all studies were neutropenia, fatigue, nausea, anemia, and leukopenia. The 6-mo-interval analyses of the most common (>15%) AEs (by preferred term [PT]) from PALOMA-1, -2, and -3 indicated that these AEs were reported with the highest frequency during the first 6-mo interval and typically decreased in incidence over time to 30–<36 mo; the most common hematologic AEs (clustered PTs) are shown (Table). The cumulative incidence of AEs after the first vs the second and third years showed similar frequencies of most AEs, including the most common ADRs.

Conclusions: Based on these long-term safety analyses, there is no evidence of specific cumulative or delayed toxicity resulting from prolonged trt with PAL+ET for HR+ HER2– ABC. This supports the ongoing investigation of PAL+ET in early breast cancer (NCT02513394).

Table. Pooled hematologic AEs: all grades and all causality clustered PTs reported for ≥10% of PAL+ET (LET/FUL)-treated pts

**Sponsor:** Pfizer.
**Body:** Background: Androgen receptor (AR) expression has been observed in up to 77% of human epidermal growth factor receptor 2–positive (HER2+) breast cancer (BC). References: 1. Enzalutamide (ENZA) is a potent AR inhibitor approved for patients (pts) with metastatic castration-resistant prostate cancer. In vitro, ENZA enhances antitumor activity of trastuzumab in HER2+ AR+ cell lines and inhibits proliferation in trastuzumab-resistant HER2+ cell lines. 2. Methods: Pts with metastatic or locally advanced BC that was HER2+ AR+ by local or central laboratory assessment were enrolled in a single-arm, Simon 2-stage phase 2 study (NCT02091960). Key eligibility criteria included availability of a tissue sample, presence of measurable or evaluable disease per RECIST v1.1, progression on prior trastuzumab and ≥1 prior line of anti-HER2 therapy as the most recent regimen. Brain metastases and history of seizure were exclusionary. Evaluable pts were those with centrally confirmed nuclear AR expression ≥10% by immunohistochemistry who received ≥1 dose of ENZA and had ≥1 postbaseline tumor assessment. Pts received ENZA 160 mg daily and trastuzumab 6 mg/kg every 21 days until disease progression. The primary objective was clinical benefit rate at 24 weeks (CBR24), defined as complete or partial response (CR or PR) or stable disease (SD) for ≥24 weeks in evaluable pts. Additional endpoints included safety and progression-free survival (PFS). CBR24 in ≥3 of 21 evaluable pts was required to continue to stage 2 and enrollment of up to 66 evaluable pts total. This design yields a 1-sided type 1 error of 5% and 90% power when the true response is 25%.

**Results:** Here we present results from stage 1 (data cutoff: Mar 23, 2016), with 22 evaluable pts enrolled (pts 21 and 22 enrolled simultaneously); 18 had received ≥4 prior lines of therapy. Median duration of ENZA exposure was 144 days (range, 22-495), mean number of complete trastuzumab infusions was 6.5. CBR24 was 27.3% (95% confidence interval [CI], 10.7-50.2); 2 confirmed PR and 4 SD ≥24 weeks. Median PFS was 108 days (95% CI, 56-144). All pts experienced ≥1 adverse event (AE) any grade; 5 pts experienced AEs grade ≥3. ENZA-related AEs were reported in 16 pts (72.7%), the most common (in ≥10% of pts) were fatigue (22.7%), nausea (18.2%), diarrhea (13.6%) and arthralgia (13.6%). Serious AEs were reported in 6 pts (27.3%; 2 each of infection and back pain, 1 each of abdominal pain, nausea, vomiting, pyrexia, urinary retention and pulmonary edema). Two pts discontinued due to drug-related AEs: 1 related to both drugs, 1 related to trastuzumab. One on-study death from pulmonary edema was reported, which was not considered related to either drug.

**Conclusion:** Stage 1 met its primary objective. No new safety signals were identified, and the safety profile in this study was similar to that in men with prostate cancer and women with other BC subtypes treated with ENZA. These results are encouraging for a heavily pretreated population with advanced HER2+ AR+ BC. Enrollment in stage 2 continues with the combination of ENZA and trastuzumab.

A phase 2 open label study of everolimus in combination with endocrine therapy in resistant hormone receptor-positive HER2-negative advanced breast cancer

Yardley DA A, Blakely L, Hemphill B, Joseph M, Liggett W, Daniel B, Castrellon A, Shastry M, Finney L, DeBusk L, Hainsworth JD D and Burris III HA A.  Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN;  Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Chattanooga, TN;  Memorial Cancer Institute, Hollywood, FL and  Sarah Cannon Research Institute, Nashville, TN.

Body: Background: Therapies targeting estrogen receptor (ER) signaling are standard for patients (pts) with hormone receptor positive (HR+) (ER and/or progesterone receptor [PR] positive) metastatic breast cancer (MBC). Dysregulation of the mammalian target of rapamycin (mTOR) pathway has been associated with endocrine therapy (ET) resistance. BOLERO-2 demonstrated that the addition of the mTOR inhibitor, everolimus (EVE), to exemestane doubled the PFS in HR+ HER2- MBC pts who previously progressed on nonsteroidal aromatase inhibitor therapy. The premise of this phase 2 trial in HR+ MBC is that the addition of EVE to the last ET on which the disease progressed may restore sensitivity to ET and extend the benefit of the anti-estrogen therapy.

Methods: Pts ≥18 yrs with HR+, HER2- unresectable, locally recurrent, or MBC refractory to ET in either the adjuvant or advanced/metastatic setting. 0-1 chemotherapy (chemo) regimens for MBC were permitted. Post-/ pre-/peri-menopausal women were eligible with ovarian function suppression permitted. Additional eligibility requirements include: no prior mTOR inhibitor therapy, measurable or evaluable disease, ECOG ≤2, adequate bone marrow and organ function. EVE (10 mg PO daily) was administered on a 4-wk cycle in combination with the same dose and schedule of the last ET to which their disease became resistant. Disease assessments were performed every 2 cycles and treatment continued until disease progression or unacceptable toxicity. Blood samples and archival tumor were collected respectively for the VeriStrat Assay and for the Foundation One molecular profiling platform.

Results: 48 pts were enrolled; data from 26 pts is presented. Median age 63.5 yrs (range, 36-81) with 46% ≥ 65 yrs. 14 (54%) pts had received chemo in the adjuvant setting, 9 pts (35%) received chemo for MBC, and 4 pts (15%) received chemo in both settings. All pts had at least 1 prior hormonal therapy; 9 pts received ≥ 3 hormonal agents. EVE was combined with tamoxifen (27%), AIs (61%), and fulvestrant (12%). Median time on treatment was 18.6 wks (range 1-48.9 weeks). 5 pts (19%) remain on treatment and 21 (81%) have discontinued therapy due to: disease progression - 17, toxicity -2, and other causes - 2. 23 pts were evaluable for response. 1 pt on fulvestrant plus EVE had a PR and 18 pts (78%) had SD as best response, with SD > 6 mos in 7 pts, for a clinical benefit rate (CR+PR+ SD ≥ 6 months) of 35%. With a median follow up of 11 mos (range 2-16 mos), the median PFS was 6.6 months (range 3.6-9.4); the median OS has not been reached. Treatment-related adverse events consisted mostly of stomatitis, rash and fatigue with few G3 events: stomatitis 3 pts, rash 2 pts, and 1 each of fatigue, edema, and neutropenia. G1 pneumonitis was present in 2 pts. There were no G4 events or treatment related deaths.

Conclusions: In HR+ HER2- advanced/MBC patients who progressed on prior ET, the addition of EVE to the ET to which their disease became resistant, resulted in 1 PR and 7 pts with SD > 6 mos. The results of the full study population will be presented. Modulation of the mTOR/AKT/PI3K pathway with EVE may extend the benefit of ET, even after tumor progression on ET alone.
Evaluation of the effects of palbociclib (PAL) + letrozole (LET) on QTc

Ruiz A, Gauthier E, Durairaj C, Huang X, Hoffman J, Finn RS S, Moulder S, Joy AA A, Ettl J, Rugo HS S and Wang D. Pfizer Inc, La Jolla, CA; University of California, David Geffen School of Medicine, Los Angeles, CA; University of Texas, MD Anderson Cancer Center, Houston, TX; Cross Cancer Institute, University of Alberta, Edmonton, AB, Canada; Frauenklinik und Poliklinik Klinikum rechts der Isar, Technische Universitaet Muenchen, Muenchen, Germany and University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA.

Body: Background: PAL, an oral cyclin dependent kinase (CDK) 4/6 inhibitor, is under investigation in multiple oncologic clinical trials and is currently approved for use in multiple countries in patients with hormone receptor positive (HR+), human epidermal growth factor receptor 2 negative (HER2–) advanced breast cancer (ABC).

International Conference on Harmonization guidance recommends that all new drugs be evaluated for effects on cardiac repolarization in a well-controlled clinical study. For drugs for which such evaluation cannot be conducted in healthy volunteers (eg, most non-adjuvant anticancer agents), collection of robust corrected QT (QTc) interval data from a dedicated QTc study (hybrid thorough QT/QTc study) in patients [pts] is required in the registration dossier. The phase 3 PALOMA-2 study (N=666) confirmed the superior clinical benefit of PAL+LET vs placebo (P) + LET in postmenopausal women with estrogen receptor positive/HER2– ABC who have not received any prior systemic anticancer therapies for ABC. One of the secondary objectives of the study was to evaluate the effects of PAL+LET on QTc.

Methods: 12 lead (with a 10 second rhythm strip) tracings were performed in triplicate ∼ 2 min apart but within 10 min for all 3 ECGs. On the day preceding the initiation of treatment (Day 0), triplicate ECGs were obtained at time 0, 2, 4, 6, and 8 hrs (baseline). On Cycle 1 Day 14, when PAL concentrations were at steady-state, triplicate ECGs time-matched to baseline ECGs collected on Day 0 (±35 min) were obtained following PAL or P dosing. All ECGs were sent to a central laboratory for blinded manual adjudication and these data were used for analysis. ECG measurements included PR interval, QT interval, RR interval and QRS complex. The QT interval was corrected for the effect of heart rate using Fridericia's correction (QTcF), Bazett's correction (QTcB), and a study-specific correction factor (QTcS).

Approximately 60 pts were to be included for QTc evaluation to ensure 40 evaluable pts in the PAL+LET arm (2:1 randomization) of PALOMA-2 and thus, to establish noninferiority between post-baseline and baseline (∆QTc) at all 5 QTc sampling timepoints on Cycle 1 Day 14 with 90% power. The test was based on a 1-sided difference in means t test for paired ∆QTc (α= 0.05). The difference in means between ∆QTc under the alternative hypothesis is 10 ms, assuming a noninferiority margin of 20 ms and the standard deviation of the paired differences equal to 16 ms based on PALOMA-1 study. If the upper bounds (UB) of 1-sided 95% confidence intervals (CI) of ∆QTc for all 5 QTc time points were <20 ms, the post-baseline QTc will be considered noninferior to baseline and PAL+LET effect on QTc will be concluded to be not of clinical relevance.

Results: A total of 77 pts were enrolled for intensive QTc assessment in PAL+LET arm. No pts had a post-baseline absolute maximum QTcF, QTcS or QTcB ≥500 ms or a ∆QTc ≥60 ms during the intensive QTc assessment period. A random effect analysis of the mean ∆QTc data demonstrated that the UB of the 1-sided 95% CI for QTcF, QTcS, and QTcB were <8 ms at all 5 QTc sampling time points.

Conclusion: PAL+LET does not have a clinically relevant effect on QTc.

Title: Combined targeted therapies for advanced triple negative breast cancer: A phase II trial of nab-paclitaxel and bevacizumab followed by maintenance targeted therapy with bevacizumab and erlotinib

Body: Background: Chemotherapy remains the mainstay of therapy for patients with metastatic triple negative breast cancer (TNBC). We hypothesized that the addition of biologic agents targeting key pathways (bevacizumab targeting angiogenesis and erlotinib directed against EGFR) may prolong progression free survival (PFS) and offer a novel treatment strategy free from chemotherapy for patients with metastatic TNBC.

Methods: Patients with TNBC receiving initial therapy for metastatic disease were eligible for this multicenter phase II trial (NCT00733408) conducted at an academic center and affiliated, community practice sites. Induction therapy included nab-paclitaxel 100 mg/m² IV Qweek (wk) and Bevacizumab 10 mg/kg IV Q2wks x 24 weeks. Patients free of progression at 24 wks began maintenance therapy with bevacizumab 10 mg/kg IV Q2wks and erlotinib 150 mg po daily until progression with radiographic assessment every 8 wks. Primary objective was PFS with secondary objectives of response rate, overall survival (OS) and safety. All eligible patients were included in the analysis of PFS and OS. Response was evaluated among patients with measurable disease by RECIST 1.1 with central review. Patients with inadequate disease assessments were coded as non-responders. Kaplan-Meier method was used to estimate PFS and OS with patients censored at date of last tumor assessment (PFS) or date of last follow up (OS).

Results: From April 2009 – December 2015, 58 patients (median age 54, range 33-83) were enrolled; 56 (97%) had measurable disease, and all had metastatic TNBC by local assessment. 33 (57%) patients completed induction; 22 (38%) came off study during induction; 3 (5%) continue on maintenance therapy. 4 patients discontinued therapy prior to first assessment. As of June 8, 2016, 53 patients (91%) have progressed. Median follow up for surviving patients is 14.5 months (range 4.1-65.4). Median PFS is 7.7 months (95% CI 5.7, 9.5). Of 56 patients with measurable disease, 38 (66%) had partial response (PR); 10 (17%) with stable disease for clinical benefit rate (CBR) of 86%. Median OS is 18.2 months (95% CI 16.3, 24.5). Most common grade 3-4 toxicities during induction were neutropenia [17 (29%), 1 grade 4], fatigue [13 (22%), all grade 3], leukopenia [7 (12%), all grade 3], and neuropathy [7 (12%), all grade 3]. Rash was most common ≥ grade 3 toxicity during maintenance [4 (7%), grade 3]. One patient experienced clinical CHF during maintenance month 16 requiring bevacizumab discontinuation. Conclusions: Nab-paclitaxel and bevacizumab followed by maintenance targeted therapy with bevacizumab and erlotinib was well tolerated. While the observed PFS did not meet pre-specified criteria of interest, the majority of patients experienced clinical benefit (86%) with 30 (57%) receiving maintenance targeted therapy. Correlative studies are ongoing. Supported by Genentech (OSI4266s), Celgene (AX-CL-BRST-PI-003828) and Janssen.
Title: Ribociclib + fulvestrant in postmenopausal women with HR+, HER2– advanced breast cancer (ABC)

Tolaney SM M, Forero-Torres A, Boni V, Bachelot T, Lu Y-S, Maur M, Pasolo A, Motta M, Pan C, Dobson J, Hewes B and Chin Lee S. Dana-Faber Cancer Institute, Boston, MA; University of Alabama at Birmingham Hospital, Birmingham, AL; START Madrid-Centro Integral Oncológico Clara Campal Hospital, Madrid, Spain; Centre Léon Bérard, Lyon, France; National Taiwan University College of Medicine, Taipei, Taiwan; University Hospital of Modena and Reggio Emilia, Modena, Italy; San Raffaele Hospital, Milan, Italy; Novartis Institutes for BioMedical Research, Cambridge, MA; Novartis Pharmaceuticals Corporation, East Hanover, NJ and National University Cancer Institute, National University Health System, Singapore.

Body: Background: Endocrine therapy (ET) is the treatment backbone for hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2–) ABC, but efficacy is limited by ET resistance. The cyclin-dependent kinase (CDK) 4/6–cyclin D (CCND1)–retinoblastoma (Rb) and phosphatidylinositol 3-kinase (PI3K)/mammalian target of rapamycin (mTOR) pathways have been implicated in ET resistance. CDK4/6 and PI3K/mTOR inhibitors act synergistically with ET in preclinical and clinical studies of HR+ breast cancer. Ribociclib (LEE011; CDK4/6 inhibitor) + fulvestrant ± alpelisib (BYL719) or buparlisib (BKM120) in HR+, HER2– ABC is being investigated in a Phase Ib/II study (NCT02088684). Here, we present results from the ribociclib + fulvestrant combination, with intermittent and continuous ribociclib dosing.

Methods: Postmenopausal patients (pts) with HR+, HER2– ABC refractory to aromatase inhibitors received ribociclib intermittently (600 mg/day, 3-weeks-on/1-week-off; Arm A) or continuously (400 mg/day; Arm B; following Arm A safety evaluation) + fulvestrant (500 mg; Cycle 1 Day 1 and 15; subsequent cycles Day 1). Primary objective: dose-limiting toxicities (DLTs) to confirm the recommended Phase II dose of ribociclib + fulvestrant. Secondary objectives: safety, pharmacokinetics, and preliminary antitumor activity (RECIST v1.1); biomarkers that may correlate with response were also assessed.

Results: As of March 10, 2016, 24 pts received ribociclib + fulvestrant (Arm A, n=13; Arm B, n=11); 4 pts in Arm B were ongoing; median duration of exposure was 7.4 (Arm A) and 4.5 (Arm B) months. Median number of prior regimens: 4 (Arm A) and 3 (Arm B). Treatment discontinuation (n; Arm A, Arm B) was due to disease progression (11, 4), physician decision (1, 2), and adverse events (AEs; 1, 1). DLTs in Cycle 1 (n; Arm A, Arm B) were Grade [G] 3 pulmonary embolism (1, 0) and G3 aspartate aminotransferase elevation (0, 1). The most common G3/4 drug-related AE (Arm A, Arm B) was neutropenia (62%, 36%); 5 pts had QTcF prolongation >60 ms (n; 4, 1).

</table>

Best overall responses (BORs; n; Arm A, Arm B): partial response (PR; 3, 1), stable disease (SD; 9, 6), and neither complete response nor progressive disease (NCRNPD; non-measurable disease; 1, 4). Overall response rate: 23% (Arm A) and 9% (Arm B); disease control rate (BOR of complete response, PR, SD, or NCRNPD): 100% in both arms. Next-generation sequencing data (n; Arm A, Arm B) were available for 16 pts (7, 9): 5 pts had CCND1 alterations (PR [1, 0], SD [2, 1], and NCRNPD [0, 1]); 11 pts had PIK3CA alterations (PR [1, 0], SD [3, 4], and NCRNPD [1, 2]); 2 of these pts had both CCND1 and PIK3CA alterations (SD [1, 0] and NCRNPD [0, 1]).

Conclusions: Ribociclib + fulvestrant has a manageable safety profile and shows preliminary clinical activity in pretreated pts with HR+, HER2– ABC. Both ribociclib intermittent and continuous dosing schedules were well tolerated. Clinical responses were
observed in tumors with and without CDK4/6–cyclin D–Rb and PI3K/mTOR pathway alterations.
**Title:** Everolimus plus trastuzumab and paclitaxel as first-line therapy in women with HER2+ advanced breast cancer: Overall survival results from BOLERO-1

Yardley D, Hurvitz S, Jiang Z-f, Toi M, Burris H, Buyse M, Slamon D, Makhson A, Elsaid A, Lerzo G, Hellerstedt B, Nuzzo F, Sohn J, Manzyuk L, Cabaribere D, Lincy J, Weimann A, Noel-Baron F, Pacaud L and Andre F. Pascale, Dipartimento di Senologia, Napoli, Italy; Severance Hospital, Yonsei University Health System, Seoul, Korea; Russian Cancer Research Centre, Moscow, Russian Federation; Translational Research in Oncology (TRIO), Paris, France; Novartis Pharma AG, Basel, Switzerland and Institut Gustave Roussy, Université Paris Sud, Villejuif, France.

**Body: Background**

Everolimus (EVE), an mTOR inhibitor has shown activity in HER2+ advanced breast cancer (ABC) in both preclinical and clinical studies. In the pivotal BOLERO-1 trial (NCT00876395), the progression-free survival (PFS) was not significantly different between the EVE + trastuzumab (TRAS) + paclitaxel (PAC) combination and placebo (PBO) + TRAS + PAC in the full HER2+ population (EVE, 15.0 mo vs PBO, 14.5 mo; HR=0.89; 95% CI: 0.73-1.08; p=0.1166). Although not reaching protocol defined level for statistical significance, the hormone receptor negative (HR-) subpopulation appeared to benefit from EVE, with a 7.2 mo PFS benefit vs PBO arm (EVE, 20.3 mo vs PBO, 13.1 mo; HR=0.66; 95% CI: 0.48-0.91; p=0.0049). The final exploratory overall survival (OS) analysis from the study is presented here.

**Methods**

In this phase 3 randomized trial, 719 women with HER2+ ABC without prior TRAS or chemotherapy in the metastatic setting were randomized 2:1 to receive either EVE (10 mg/d) or placebo (PBO) and weekly PAC+TRAS, stratified by visceral metastasis (lung, liver, peritoneal or pleural: yes vs no) and prior adjuvant or neo-adjuvant treatment with TRAS (yes vs no). As the primary objectives (PFS on full population and on HR- subpopulation) of BOLERO-1 were not met, the key secondary endpoint of OS was not formally statistically tested. However, given the results of PFS, in particular in the HR- subpopulation, a change to the OS analysis plan was made by introducing one final exploratory OS analysis at the time of study termination.

**Results**

At data cutoff (Dec 31, 2015), the median duration of exposure was 40.8 weeks (range: 0.6-320.4) in the EVE arm and 48.1 weeks (range: 1.1-308.0) in the PBO arm. After a median follow-up of 60.3 mo, 350 deaths were recorded in the full population, 238 (46.9%) in the EVE arm and 112 (46.9%) pts in the PBO arm. In the full population, the median OS was comparable in the EVE vs PBO arms (48.6 mo vs 50.0 mo respectively; HR = 1.13; 95% CI: 0.90-1.42). In the HR- subpopulation, 138 deaths were recorded; 88 (42.3%) pts in the EVE arm and 50 (48.5%) pts in the PBO arm. In the HR- subpopulation, the median OS in the EVE arm was longer compared to PBO arm (57.0 mo vs 41.6 mo respectively; HR = 0.83; 95% CI: 0.59-1.19). Stomatitis, diarrhea, alopecia, cough, rash, pyrexia, neutropenia, and fatigue were the most frequent adverse events (AEs) reported in EVE arm (≥35%). AEs leading to dose interruption and/or change were reported in 441 (93.4%) pts in EVE arm and 165 (69.3%) pts in the PBO arm respectively. Overall, AEs leading to treatment discontinuation were reported in 262 (55.5%) pts in EVE arm and 98 (41.2%) pts in PBO arm. Serious AEs were reported in 171 (36.2%) pts in the EVE arm and 40 (16.8%) pts in the PBO arm respectively. On treatment AE related deaths were reported for 3.6% pts in the EVE arm and 0% pts in the PBO arm.

**Conclusions**

The median OS was similar in the EVE vs PBO arms for overall population. However, a prolongation of 15.4 mo in median OS of HR- subpopulation was observed in the EVE arm vs PBO arm in this exploratory analysis. Pts in the EVE arm had a manageable safety, consistent with the safety profile of EVE and no new safety signals were identified.
**Title:** Single agent palbociclib with or without trastuzumab for the treatment of Rb+ advanced breast cancer

**Body: Background:** The Cyclin D/CDK4/6/Rb axis is dysregulated in breast cancer (BC). Palbociclib (P) is an oral agent that specifically inhibits CDK 4/6 and is FDA approved for hormone-receptor positive (HR+) disease in combination with letrozole or fulvestrant. We performed a Phase II, multi-disease, basket trial of single agent P in patients (pts) with retinoblastoma positive (Rb+), advanced cancer. We now report the full expansion cohort in BC, including a subcohort of pts with HER2+ disease.

**Methods:** Pts with Rb+ BC were eligible for enrollment if they had measurable metastatic disease, adequate organ function and ECOG PS $\geq 1$, with no limit on number of prior therapies. Pts were stratified on HER2-status, with a planned HER2-positive (HER2+) cohort, with or without trastuzumab (T). Pts with active brain metastases were excluded. Pts received P 125mg for 21 days on, 7 days off of each 28 day cycle. The protocol was amended on May 12, 2014 to allow concomitant T (given every 3 weeks 6mg/kg) for pts with HER2+ disease. Toxicity was assessed every 28 days. Response was assessed every 2 cycles using RECIST 1.0 guidelines.

**Results:** A total of 62 pts were enrolled: 46 (74.2%) HR+/HER2-, 12% HER2+ (19.3%), and 4 (6.5%) ER/PR/HER2-. 10 of the 12 pts with HER2+ disease received T. As of June 10, 2016 one HER2+ patient (pt) remains on study who is also receiving T. Median age is 58 (range 34-88). Median prior lines of therapy is 6 (range 1-15). Response rates, progression free survival (PFS) and overall survival (OS) are depicted in Table 1 and are stratified by HER2 status and receipt of concomitant T.

* 1 pt not evaluable for response. HR: hormone receptor; T: trastuzumab; PR: partial response; SD: stable disease; PD: progressive disease; CBR: clinical benefit rate; mo: months; NA: not available

The most common adverse event was Grade 3 or 4 (G3/4) neutropenia (ntp) which occurred in 30 (48%) pts. There was one episode of febrile ntp in a pt who was progressing and had received 13 prior therapies. Other G3/4 events were leucopenia (n=10, 16.1%) thrombocytopenia (n=9, 14.5%), anemia (n=3, 4.8%).

**Conclusions:** P is well tolerated in heavily pretreated pts. Grade 3/4 ntp occurred in 48% of pts and required dose reduction without necessity to add growth factor support; febrile ntp was uncommon. Single agent activity is modest (22% in the overall population) in this heavily pretreated cohort. 3 of the 4 partial responses observed were in pts with HER2+ disease 2 of whom received concurrent T. Prolonged stable disease was observed in 9 pts, 8 of whom had HR+ disease. Given the response rate of 30% in those with HER2+ disease receiving T, and PFS of 6.7 months, further investigation into this combination is warranted. Biomarker studies are underway.
Title: Sacituzumab govitecan (IMMU-132), an anti-Trop-2-SN-38 antibody-drug conjugate (ADC) for the treatment of relapsed/refractory, metastatic triple-negative breast cancer (mTNBC): Updated results

Bardia A, Diamond JR R, Mayer IA A, Isakoff SJ J, Abramson V, Starodub AN N, O'Shaughnessy J, Kalinsky K, Moroose R, Shah N, Juric D, Shapiro GI I, Guarino M, Ocean AJ J, Messersmith WA A, Berlin JD D, Wegener WA A, Sharkey RM M, Goldenberg DM M and Vahdat LT T. Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA; University of Colorado Cancer Center, Aurora, CO; Vanderbilt-Ingram Cancer Center, Nashville, TN; Indiana University Health Center for Cancer Care, Goshen, IN; Texas Oncology-Sammons Cancer Center, Dallas, TX; Columbia University-Herbert Irving Comprehensive Cancer Center, New York, NY; University of Florida Health Cancer Center, Orlando, FL; The Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA; Helen F Graham Cancer Center, Newark, DE; Weill Cornell Medicine, New York, NY and Immunomedics, Inc., Morris Plains, NJ.

Body: Background. mTNBC has an aggressive course with limited effective therapy options and a median progression-free survival (PFS) of 2-4 months (mos) with standard therapy. Sacituzumab govitecan (IMMU-132) is an ADC targeting Trop-2, an antigen present in many epithelial cancers, including TNBC, and delivering SN-38, a topoisomerase I inhibitor as its therapeutic moiety. IMMU-132 was awarded Breakthrough Therapy designation by FDA based on its previously reported activity in relapsed/refractory mTNBC patients. Here we present updated results from the mTNBC cohort of an ongoing phase I/II study (ClinicalTrials.gov, NCT01631552).

Methods. mTNBC patients (pts) received IMMU-132 10 mg/kg on days 1 and 8 every 21 days. Trop-2 expression was not required for enrollment, but available tumor specimens underwent immunohistological (IHC) testing. Efficacy was assessed locally by RECIST 1.1; ORR, PFS and overall survival (OS) were determined for all pts. Pharmacokinetic parameters were estimated in select pts with adequate blood sampling. Immunogenicity to IMMU-132 was examined in all pts.

Results. We previously reported preliminary efficacy results in 51 mTNBC patients. Here we present data on 69 patients with data cutoff June 5, 2016. Median age was 56 years (31-81) and a median of 5 prior therapies (range 1-12), with 66 evaluable for response; ORR was 29% (19/66) 2 confirmed complete (CR) and 17 confirmed partial responses (PR). The median intention-to-treat PFS is 5.6 mos (95% CI, 3.6-7.1 mos) and median OS is 14.3 mos (95% CI, 10.5-18.8 mos). PRs included 2 pts whose tumors did not respond to anti-PD-L1 therapy. The duration of response in the 19 confirmed responders (8 continuing therapy) is 11.5 mos (95% CI = 7.6 to 12.7). The clinical benefit rate (CR+PR+SD>6 mos) for the 66 assessable patients is currently 45.5%. The majority (88%) of archival tumor specimens were moderately (2+) to strongly (3+) positive by IHC for Trop-2, precluding using Trop-2 expression as a selection criterion. Among current adverse events, grade ≥3 drug-related toxicities included neutropenia (35%), leukopenia (16%), anemia (13%), vomiting (9%), diarrhea (10%), and febrile neutropenia (4%). Clearance kinetics in 8 pts showed IMMU-132 and IgG had a terminal half-life of 15.3 ± 2.7 h and 86.5 ± 40.5 h, respectively, with area under the curve for free SN-38 (unbound) only 3% of the total amount of SN-38 (e.g., IgG bound). Thus, most SN-38 remains bound to the conjugate, and is released at a rate predicted from in vitro serum stability studies. No pt developed anti-IMMU-132 antibodies.

Conclusion The Trop-2-targeting ADC, IMMU-132, delivering cytotoxic doses of SN-38, shows high objective and durable tumor responses with manageable toxicity in heavily-pretreated pts with mTNBC in this updated cohort, supporting further development in this population with an unmet medical need.
First-line ribociclib + letrozole in patients with HR+, HER2– advanced breast cancer (ABC) presenting with visceral metastases or bone-only disease: A subgroup analysis of the MONALEESA-2 trial

Burris HA A, Chan A, Campone M, Blackwell KL L, Winer EP P, Janni W, Verma S, Burdaeva O, Alba E, Favret AM M, Mondal S, Miller M, Germa C, Hirawat S and Yap YS. Sarah Cannon Research Institute, Nashville, TN; Breast Cancer Research Centre WA & Curtin University, Perth, Australia; Institut de Cancérologie de l’Ouest – René Gauducheau Centre de Recherche en Cancérologie, Nantes, France; Duke University Medical Center, Durham, NC; Dana-Farber Cancer Institute, Boston, MA; Universitätsklinikum Ulm, Ulm, Germany; Tom Baker Cancer Centre, Calgary, Canada; Arkhangelsk Clinical Oncology Dispensary, Arkhangelsk, Russian Federation; Hospital Universitario Virgen de la Victoria, IBIMA, Málaga, Spain; Virginia Cancer Specialists, Arlington, VA; Novartis Pharmaceuticals Corporation, East Hanover, NJ and National Cancer Center Singapore, Singapore.

Body: Background: Patients with ABC who present with visceral metastases have a worse outcome than patients with non-visceral disease, while patients with bone-only disease tend to have a better prognosis. Ribociclib (LEE011) is an oral, selective inhibitor of cyclin-dependent kinase (CDK) 4/6. In a Phase 3, placebo-controlled, randomized trial (MONALEESA-2; NCT01958021), first-line ribociclib (R) + letrozole (L) significantly prolonged progression-free survival (PFS) vs placebo (P) + L in patients with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2–) ABC, with a hazard ratio of 0.556 (95% confidence interval [CI]: 0.429–0.720; p=0.00000329) at the interim analysis cut-off date (Jan 29, 2016). Here, we present subgroup analyses in patients with visceral metastases, and those with bone-only disease.

Methods: Postmenopausal women with HR+ HER2– ABC were randomized 1:1 to receive R (600 mg/day; 3-weeks-on/1-week-off) + L (2.5 mg/day; continuous) or P+L, stratified by the presence of liver and/or lung metastases. No prior CDK4/6 inhibitors or systemic therapy for ABC were allowed. Eligible patients had Eastern Cooperative Oncology Group performance status ≤1, baseline alanine/aspartate aminotransferase levels <5× upper limit of normal (ULN) or <2.5× ULN for patients with or without liver metastases, respectively, and ≥1 predominantly lytic bone lesion at baseline for patients with bone-only disease. Locally assessed PFS was analyzed for all patients (primary endpoint), and for predefined patient subgroups.

Results: Overall, 668 patients were randomized; 393 had visceral metastases and 147 had bone-only disease.

In patients with visceral metastases: Median PFS was not reached in the R+L arm (95% CI: 19.3–not estimable [NE]) vs 13.0 months (95% CI: 12.6–16.5) in the P+L arm, with hazard ratio 0.535 (95% CI: 0.385–0.742). Median duration of exposure was 12.0 and 13.0 months (R and L, respectively) in the R+L arm, and 12.1 and 12.2 months (P and L, respectively) in the P+L arm.

In patients with bone-only disease: Median PFS was not reached in the R+L arm (95% CI: NE–NE) vs 15.3 months (95% CI: 13.8–NE) in the P+L arm, with hazard ratio 0.690 (95% CI: 0.381–1.249). Median duration of exposure was 12.1 and 12.6 months (R and L, respectively) in the R+L arm, and 12.7 and 12.9 months (P and L, respectively) in the P+L arm.

Conclusions: First-line R+L was well tolerated and significantly prolonged PFS vs P+L in postmenopausal women with HR+, HER2– ABC, both in patients with visceral metastases and those with bone-only disease.

Keywords: Advanced breast cancer; CDK4/6 inhibitor; Letrozole; Ribociclib
Title: Safety of the combination of everolimus plus exemestane in the Italian cohort of patients enrolled in the expanded access “BALLET” study

Body: Background: The expanded access “BALLET” study has been designed to evaluate the safety of EVE plus EXE combination in hormone receptor-positive (HR+), human epidermal growth factor-receptor-2-negative (HER2-) metastatic Breast Cancer (mBC). The Italian population was predominantly enrolled in trial.

Patients and methods: Patients have been included according to the inclusion and exclusion criteria provided previously in the BALLET study. The aim of our analysis was the safety everolimus and exemestane analysed in two sets of population: a subpopulation including only patients who never received chemotherapy in metastatic setting (416 patients – 36.1% of the safety population) and a subpopulation including only patients who received at least one chemotherapy in metastatic setting, whatever the line of treatment (735 patients – 63.9%).

Results: One thousand two hundred seventy nine (1279) Italian female patients were screened, 1153 (90.1% of the screened set) out of these were included in the analysis and 1151 (90.0% of the screened set) were included in the safety population. 1116 (97.0% of the safety population) prematurely discontinued the study drug and the main reasons reported were disease progression (39.1%), local reimbursement of everolimus (31.1%) and adverse event(s) (16.1%). The mean duration of study treatment exposure was 158.3±106.79 days (median 139.5) for exemestane and 153.9±108.48 days (median 135.0) for everolimus with a treatment compliance (higher than 90%) of 94.4% and 58.6% and (lower than 60%) of 0.1% and 15.1% for exemestane and everolimus, respectively. 92.5% of patients of the safety population (91.1% and 93.3% patients without and with chemotherapy respectively) experienced at least one adverse event: gastrointestinal disorders” (67.3% vs. 64.6% in without and with chemo group); general disorders (48.6% vs. 48.3%); metabolism and nutrition disorders (35.6% vs. 37.4%) and skin and subcutaneous tissue disorders (32.2% vs. 27.5%). The incidence of everolimus related adverse events was higher (83.9%) when compared to those which occurred with exemestane. The most commonly reported adverse event was stomatitis (51.3% of patients) with 22.5% Grade 1; 18.2% Grade 2; 10.5% Grade 3; 0.2% Grade 4. The 49.7% of the patients experienced at least one stomatitis related to everolimus. No relevant difference was observed between the two groups of patients without and with chemo in metastatic setting.

Conclusions: The administration of chemotherapy before starting EVE plus EXE combination did not affect the safety profile of EXE/EVE in the treatment of mBC. The stomatitis is the most frequent and relevant adverse event to be clinically focused on.
Phase Ib safety, efficacy, and molecular analysis of ribociclib (LEE011) plus letrozole for the treatment of ER+, HER2– advanced breast cancer

Munster P, Ismail-Khan R, Garcia-Estevez L, Mayer IA A, Becerra C, Hamilton E, De Boer R, Wardley AM M, Im S-A, Teixeira L, Wang Y, Su F, Germa C, Hirawat S and Juric D. University of California San Francisco, San Francisco, CA; H. Lee Moffitt Cancer Center, Tampa, FL; Centro Integral Oncológico Clara Campal, Madrid, Spain; Vanderbilt-Ingram Cancer Center, Nashville, TN; Texas Oncology-Baylor University Medical Center-US Oncology Research, Dallas, TX; Sarah Cannon Research Institute and Tennessee Oncology, Nashville, TN; The Royal Melbourne Hospital, Melbourne, Australia; The Christie NIHR/CRUK Clinical Research Facility, Manchester, United Kingdom; Seoul National University College of Medicine, Seoul, Korea; Hopital Saint Louis and University Paris Diderot, Sorbonne Paris City, Paris, France; Novartis Pharma AG, Basel, Switzerland; Novartis Pharmaceuticals Corporation, East Hanover, NJ and Massachusetts General Hospital Cancer Center, Boston, MA.

Background: Aromatase inhibitors are the standard first-line treatment for patients (pts) with estrogen receptor-positive (ER+), human epidermal growth factor receptor 2-negative (HER2–) advanced breast cancer (aBC). However, resistance via disruption of the cyclin D–cyclin-dependent kinase (CDK)4/6–inhibitor of CDK4–retinoblastoma pathway is common. The oral, selective CDK4/6 inhibitor ribociclib has demonstrated synergistic activity with letrozole in preclinical models of ER+ breast cancer. This Phase Ib study investigated ribociclib plus letrozole in ER+, HER2– aBC (NCT01872260).

Methods: Postmenopausal pts with ER+, HER2– aBC received ribociclib (600 mg/day; 3-weeks-on/1-week-off) plus letrozole (2.5 mg; continuous). The primary objective of the expansion phase was to evaluate safety and tolerability. Secondary and exploratory objectives included efficacy, pharmacokinetics (PK), and biomarkers.

Results: As of October 30, 2015, 47 pts received ribociclib plus letrozole: 19 pts in the initial enrollment and 28 pts in the expansion phase. In the initial enrollment, 17/19 pts (89%) were previously treated for aBC (PT group); in the expansion phase, 27/28 pts (96%) were treatment-naïve for aBC (first-line group). All 19 PT pts and 10 first-line pts (62% of all pts) have discontinued treatment. Common (>5% of pts) treatment-related Grade 3/4 adverse events included neutropenia (43%), neutrophil count decreased (11%), and white blood cell count decreased (6%). Complete response (CR) was observed in 1 pt (4%) in the first-line group. In the PT and first-line groups, 1 pt (5%) and 10 pts (36%) had a partial response (PR), 7 pts (37%) and 4 pts (14%) had neither CR nor progressive disease (PD), 7 pts (37%) and 10 pts (36%) had stable disease (SD), and 4 pts (21%) and 3 pts (11%) had PD, respectively. Among pts with measurable disease, overall response rate (ORR; CR + PR) was 9% (95% confidence interval [CI]: 0–41%) for 11 PT pts and 46% (95% CI: 26–67%) for 24 first-line pts, and clinical benefit rate (CR; CR + PR + SD ≥24 weeks) was 18% (95% CI: 2–52%) for 11 PT pts and 79% (95% CI: 58–93%) for 24 first-line pts.

Ribociclib PK data were consistent with single-agent data and indicated no drug–drug interaction with letrozole. Notable genetic alterations detected by next-generation sequencing included PIK3CA mutations (4/10 PT pts [40%]; 14/22 first-line pts [64%]) and ESR1 mutations (2/10 PT pts [20%]). Responses were observed in pts harboring PIK3CA mutations (1 CR [first-line pt], 1 unconfirmed CR [first-line pt], 3 PR [1 PT pt, 2 first-line pts], and 3 unconfirmed PR [first-line pts]). Progression-free survival data for ribociclib plus letrozole, in addition to updated ORR and CBR, will be presented at the symposium.

Conclusions: The combination of ribociclib plus letrozole demonstrated encouraging clinical activity, particularly in pts treatment-naïve for aBC, with an acceptable safety profile that is in line with CDK4/6 inhibition. These results, which are consistent with the positive results of the MONALEESA-2 study (NCT01958021), provide additional safety and efficacy evidence for the use of ribociclib plus letrozole for the first-line treatment of postmenopausal aBC.
Title: Time on treatment of everolimus versus endocrine monotherapy or chemotherapy for early-line treatment of HR+/HER2-metastatic breast cancer: A retrospective chart review study in the US

Li N, Ohashi E, Koo V, Xie J, Hao Y and Tang DH H. Analysis Group, Inc., Boston, MA; Analysis Group, Inc., Los Angeles, CA and Novartis Pharmaceuticals Corporation, East Hanover, NJ.

Body: Background:
Among postmenopausal women with hormone receptor-positive, human epidermal growth factor receptor-2-negative (HR+/HER2-) metastatic breast cancer (mBC) whose disease progressed on a non-steroidal aromatase inhibitor (NSAI), everolimus-based therapy (EVE), different endocrine monotherapies (ET mono), and chemotherapies (CT) are commonly used. Time on treatment is an outcome primarily determined by a therapy's combined efficacy and safety profile. This study assessed the real-world time on treatment (TOT) among patients receiving these treatments in early-line (i.e., 1st and 2nd) settings.

Methods:
A nationwide sample of postmenopausal HR+/HER2- mBC patients treated by community oncologists in the US was included in this retrospective chart review. Eligible patients for this study were required to fail NSAI and then receive EVE, ET mono or CT (index therapy) as an early-line therapy for mBC between July 1, 2012 and April 15, 2013. TOT was measured from index therapy initiation to physician-reported treatment discontinuation and compared among treatment groups using Kaplan-Meier analyses with log-rank tests and Cox proportional hazards models adjusting for the line of therapy and baseline characteristics including recurrent or de novo disease status, age, race, insurance type, Charlson comorbidity index, sites of metastases (e.g., bone, any other visceral site), ECOG performance status, previous CT treatment in the mBC setting, and duration from the initiation of the last adjuvant ET to mBC diagnosis.

Results:
A total of 145 patients treated with EVE, 217 patients treated with ET mono, and 102 patients treated with CT were included in the analysis. Baseline characteristics among the three treatment groups were similar, although EVE-treated patients had higher burden of metastases relative to ET mono-treated patients, but lower burden relative to CT-treated patients. TOT was longer among EVE-treated patients than ET mono- and CT-treated patients (log-rank tests: p=0.01 and p<0.01). For patients who completed their index treatment, the median TOT among EVE, ET mono, and CT treatment groups were 8.9, 5.7, and 6.1 months, respectively. After adjusting for baseline characteristics, EVE was associated with significantly longer TOT compared with ET mono [hazard ratio (HR) = 0.62, 95% confidence interval (CI): 0.45 – 0.85] and with CT (HR = 0.32, 95% CI: 0.22 – 0.46).

Conclusions:
This real-world US chart review study of postmenopausal women with HR+/HER2- mBC showed that patients receiving EVE in line 1 or 2 experienced significantly longer TOT than those receiving ET mono or CT.
Title: Efficacy and safety of everolimus plus exemestane in HR+, HER2– advanced breast cancer progressing on/after prior endocrine therapy, in routine clinical practice: 2nd interim analysis from STEPAUT

Steger GG G, Bartsch R, Pfeiler G, Petru E, Greil R, Helfgott R, Egle D, Öhler L, Lang A, Tinchon C, Haslbauer F, Redl A, Hennebelle M, Mraz B, Winiger-Candolfi I and Gnant M. Internal Medicine I/Division of Oncology, Austria; Medical University of Vienna, Austria; Comprehensive Cancer Center, Medical University of Vienna, Austria; Medical University of Graz, Austria; Medical University of Salzburg, Austria; Hospital Sisters of Charity, Linz, Austria; Medical University of Innsbruck, Austria; St. Josef Spital, Vienna, Austria; Hospital of Rankweil, Austria; LKH Hochsteiermark, Leoben, Austria; Hospital of Vöcklabruck, Austria; Softwaremanufaktur Grünberg & Redl GmbH, Austria; Novartis Pharma GmbH, Vienna, Austria; Novartis Pharma AG, Basel, Switzerland and Surgery and Comprehensive Cancer Center, Austria.

Body: Background
STEPAUT, an Austrian non-interventional study evaluated the safety and efficacy of everolimus (EVE) + exemestane (EXE) in patients (pts) with hormone receptor-positive (HR+), human epidermal growth factor receptor-2 negative (HER2–) advanced breast cancer (ABC) recurring/progressing on/after prior nonsteroidal aromatase inhibitors (NSAIs) in routine clinical practice. Results of the 1st interim analysis (IA) were consistent with BOLERO-2 data. Here we present results from the 2nd pre-planned IA.

Materials and Methods
STEPAUT, with a planned enrolment of 300 pts, included postmenopausal pts, aged ≥ 18 yrs with HR+, HER2– ABC treated with EVE+EXE, progressing on/after NSAIs. Primary endpoint was progression-free survival (PFS); secondary endpoints included response per RECIST v1.1 and safety.

Results
The 2nd IA included 225 pts with a median age of 65 yrs. At the time of data cut-off: 9 May, 2016, 147 pts had discontinued study treatment, mainly due to disease progression and adverse events (AEs). Median duration of follow-up was 6.5 months (range 0–26.3 months), 172 pts (95%) had ECOG PS 0-1 and 52% of pts had visceral metastasis. A majority of pts (n=109, 54%) received the approved EVE dose of 10mg as the start dose, while 91 pts (45%) received half of the approved EVE dose i.e. 5mg. Median PFS values for different subgroups are shown in table 1 below. Overall, 57 pts (28%) required therapy interruption while 37 pts (18%) had EVE dose reduction from 10 to 5mg. A decreasing trend in AE frequency irrespective of EVE dose was observed during treatment period. The majority of AEs were of mild to moderate severity; most frequent AEs (all grades) were stomatitis, mucositis (48.0%), exanthema, rash (22.2%), and dyspnea, cough (22.2%). Frequent grade 3 or 4 AEs were stomatitis, mucositis (4.4%), weight loss, reduced general condition (2.7%), and inappetence, nausea (2.2%). Median time to first occurrence of stomatitis was 0.5 months; 8 pts (5%) discontinued therapy due to stomatitis and/or rash. Serious AEs constituted 10% of all AEs.

**Conclusions**

Real-world data from STEPAUT support EVE+EXE as a suitable treatment option for HR+, HER2− ABC recurring or progressing on/after prior NSAIs. Overall safety profile was also consistent with previous reports. Of note, occurrence of stomatitis and/or rash did not negatively influence PFS. Furthermore, a lower start dose of EVE 5mg did not seem to affect PFS negatively as long as the dose was adjusted to 10mg after a short period of time, thus supporting the administration of the approved EVE 10mg/day dose in the routine clinical setting.
Title: NCI9782: A phase 1 study of talazoparib in combination with carboplatin and paclitaxel in patients with advanced solid tumors

Background: Poly(ADP-ribose) polymerase (PARP) enzymes are involved in DNA repair and activated by DNA strand breaks. DNA damage from carboplatin is associated with activation of PARP. Preclinical data indicate that PARP inhibition potentiates the anti-tumor effect of platinum chemotherapy. Talazoparib (T) is an oral, selective PARP inhibitor with a single agent maximum tolerated dose (MTD) of 1mg orally qd. Primary dose-limiting toxicity (DLT) was thrombocytopenia. This phase I study combines T with the commonly used chemotherapy regimen of carboplatin (C) and paclitaxel (P).

Methods: Two dosing schedules are being investigated. In both schedules, C is administered on day 1 and P on days 1, 8, and 15 of a 21-day cycle. T (100-1000mcg) is dosed once daily for days 1-7 (schedule A) or days 1-3 (schedule B) starting on day 1. A 3+3 design is used for dose escalation. Key eligibility criteria include age ≥18 with a measurable or evaluable solid incurable malignancy. Patients (pts) must have tumor type that is expected to respond to C + P or have BRCA germline or somatic mutation. Stable, treated brain metastases are allowed. No prior C for metastatic disease is allowed. Pts must have platelets>150 and no need for anticoagulation. After 4-6 cycles of combination therapy, pts may continue the combination, change to C and intermittent T without P or change to T alone with continuous daily dosing. Each schedule will have a 6 subject dose expansion at the MTD. The starting dose level for schedule B will be the MTD from schedule A.

Results: Schedule A cohort results are reported: 11 pts (median age 59 [range 39-68]; 8 female; 3 male) have been enrolled. Pts had breast (6), ovarian (2), pancreatic (1), and SCC of oropharynx (1) and concurrent ovarian and pancreatic (1). Five pts are BRCA2+ and 3 pts are BRCA1+. Dose level 3 on schedule A (T 350mcg with C AUC 6 and P 80mg/m$^2$) exceeded the MTD with 2 of 3 pts experiencing hematologic dose limiting toxicities (DLTs) including 1 pt with grade (gr) 3 neutropenic fever and gr 4 thrombocytopenia and another pt with grade 3/4 neutropenia lasting > 7 days. Most common AEs include neutropenia (grade 3-4: 7), anemia (grade 3-4: 3), and thrombocytopenia (grade 3-4: 4). Results from expansion of dose level 2 (T 250mcg with C AUC 6 and T 80mg/m$^2$) will be presented. The 11 pts were on study a median of 9 weeks (range 9-36+). Four pts have discontinued study therapy: 1 due to need for anticoagulation for PE, 1 for prolonged cytopenias, and 2 for disease progression. Of the 8 pts with measurable disease evaluated for response to date, 4 had SD, 1 had a cPR, 1 had radiographic CR, and 2 with PD. A pt with BRCA 1+ triple negative breast cancer has maintained a prolonged PR (36+ weeks) even after dose reductions to T 100mcg with C AUC 3. One pt with ovarian cancer (BRCA WT) has radiographic CR (CA 125 remains mildly elevated) after 15+ weeks of therapy.

Conclusion: PARP inhibition with talazoparib days 1-7 in combination with carboplatin and paclitaxel leads to DLT of myelosuppression. However, clinical responses are seen even with lower dose combinations.
Cobimetinib (C) combined with paclitaxel (P) as a first-line treatment in patients (pts) with advanced triple-negative breast cancer (COLET study): Updated clinical and biomarker results

Body: Resistance to standard taxane-based chemotherapy is common in triple-negative breast cancer (TNBC). Mutations and gene amplifications in the MAPK pathway that upregulate MAPK signaling are present in many TNBC tumors. Upregulation of the MAPK signaling pathway can result in degradation of the pro-apoptotic protein BIM and upregulation of anti-apoptotic proteins, including BCL-2, BCL-XL, and MCL-1, thus promoting cell survival and desensitizing tumor cells to the pro-apoptotic effects of taxane chemotherapy. Updated data on clinical safety and efficacy are presented along with biomarker data evaluating the effects of treatment on induction of apoptosis.

The COLET study (ClinicalTrials.gov ID, NCT02322814; EudraCT number, 2014-002230-32) consisted of a safety run-in (n∼12) followed by a blinded 1:1 randomized expansion stage (n∼90) to C + P or placebo (PBO) + P. The safety stage is complete and the randomized stage is enrolling pts. Two additional cohorts investigating the effect of adding atezolizumab will be recruiting and are out of scope of this submission. Pts in cohort I were treated with P 80 mg/m² on days 1, 8, and 15 and C/PBO 60 mg/day on days 3–23 of each 28-day cycle until disease progression or unacceptable toxicity. Gene expression and apoptotic index were measured by RNA-Seq and TUNEL staining, respectively, to assess the biologic activity of C + P. Sixteen women (median age, 55.5 years) were enrolled in the safety run-in stage. At data snapshot (April 22, 2016), all 16 pts had received ≥1 dose of study treatment. Median time on treatment was 116 days (range, 7-336) for C and 84 days (range, 0-351) for P. Fifteen (94%) pts had ≥1 adverse event (AE); 5 (31%) pts had grade 1/2 AEs and 10 (63%) pts had grade 3 AEs (Table). No pts experienced grade 4–5 AEs. Among the 16 safety run-in patients, responses to date include partial response (PR; n = 8 [50.0%]), stable disease (SD, n = 4 [25.0%]), and progressive disease (n = 2 [12.5%]), as well as 2 pts with no post-baseline tumor assessment. Six pts maintained a PR at ≥20 weeks and three maintained a PR at ≥40 weeks. To date, matched pre- and on-treatment biopsies were evaluable for 2 pts, 1 with a PR and 1 with SD. In the patient who attained a PR, increased expression of pro-apoptosis genes, including BIM, was observed; but this was not seen in the patient experiencing SD. The PR patient also had an increase in apoptotic index. Updated biomarker data will be reported. This is the first study to evaluate C + P in TNBC. The safety profile of C + P is consistent with that of known safety profiles. Efficacy and safety will be further evaluated in the ongoing randomized stage.

Title: Phase II trial of selinexor for metastatic triple negative breast cancer

Body: **Background:** XPO1 (also known as CRM1) is the exclusive nuclear exporter of multiple tumor suppressor proteins (TSP) including p53, p21, BRCA1/2, pRB, FOXO. XPO1 inhibition forces nuclear accumulation of TSPs, thus inducing apoptosis in cancer cells. Selective Inhibitors of Nuclear Export (SINE) compounds are novel, small molecule, slowly reversible inhibitors of XPO1. SINE compounds showed potent cytotoxicity in the majority of TNBC cell lines in vitro and xenografts.

**Methods:** Eligible patients had measurable metastatic TNBC, received at least one prior line of chemotherapy in the setting of metastatic disease (including anthracycline and taxane), and had an ECOG PS 0-1. Selinexor was given at 60 mg orally twice weekly (day 1 & 3 of each week), three of each four-week cycle. The primary objective of this study was to determine the clinical benefit rate (CBR, defined as complete response + partial response + stable disease (SD) ≥12 weeks) from Selinexor in patients with TNBC. This study used a Simon two-stage design (null hypothesis CBR 5%, alternate hypothesis CBR 20%)

**Results:** Ten patients with a median age of 60 years (range 44-71) were enrolled between 7/2015 and 1/2016. The median number of prior chemotherapy lines was 2 (range 1-5). A planned interim analysis for the first stage per protocol was performed. Three patients had SD and 7 had progressive disease. The median duration of SD was 84 days (range 17-130 days) and all patients experienced progressive disease with a median PFS of 38 days (range 17-130 days). Based on these results, the error probability of observing no response among the first 10 patients is 0.107 under the alternative hypothesis, i.e., P of response =20%, using the Exact binomial test. This false negative error rate is under the planned type II error 0.20, which is consistent with the predefined stopping rule of the study: the study would be halted if no patient achieved objective response (complete or partial response) in the first 10 eligible patients (stage I).

The most frequent grade 1 and 2 observed adverse events that were possibly related to Selinexor were nausea 30% (all grade 1), vomiting 50% (40% grade 1), constipation 50% (40% grade 1, 10% grade 2), diarrhea 20%, anorexia 30%, thrombocytopenia 30%, blurred vision 30%. No grade 4 toxicity was noted. Grade 3 toxicity included reversible encephalopathy (10%), irritability (10%), and thrombocytopenia (10%).

**Conclusion:** Selinexor was well tolerated in patients with advanced TNBC but did not result in objective responses in this patient population. Further combination studies can be explored.

Title: A retrospective study about re-biopsy at disease progression on T-DM1

Body: Background:
T-DM1 is an antibody-drug conjugate, which consists of trastuzumab, DM1, and linker. It has been established as standard of care for human epidermal receptor (HER) 2-positive metastatic breast cancer (MBC). At the first step, trastuzumab has to combine with extracellular domain of HER2. Then T-DM1 is delivered into HER2-positive cancer cells, and DM1 is released. After that, antitumor activity of DM1 can be exerted. In this way, T-DM1 works on HER2-positive cancer cells with high specificity. This retrospective study is aimed to examine whether HER2 status at disease progression on T-DM1 is related to efficacy of T-DM1.

Patients:
We identified 23 patients who started treatment with T-DM1 between February 2014 and March 2016 at our department. The data cut-off date was April 30, 2016.

Methods:
We retrospectively reviewed the medical records of these 23 patients and investigated the following items: patient characteristics, time to failure (TTF), objective response, and results of re-biopsy. TTF were analyzed by the Kaplan–Meier method. The definition of HER2-positive was immunohistochemistry 3+, or FISH >2.2.

Results:
There were 23 patients who started administration of T-DM1 for MBC at our department in this period. All patients had HER2-positive MBC which was diagnosed as HER2 positive by examination of samples from primary tumor. At the time of data cut-off, five patients had continued T-DM1 therapy, and 18 patients had finished it due to disease progression in 15 patients and adverse events in three patients. Re-biopsy was conducted to 13 (87%) of 15 patients who experienced disease progression during TDM-1 therapy. Samples of re-biopsy were acquired from the site that showed progression during T-DM-1 therapy. Re-biopsy revealed that HER2 status had changed to negative in six (46%) patients (Negative group), and had remained positive in seven (54%) patients (Positive group). Patient characteristics are shown in table.

</tr>
</tbody>
</table>

Median TTF was 65.5 days (95% CI: 34-NA) in Negative group, 126 days (95%CI: 70-140) in Positive group, and 196 days (95%CI: 93-594) in all patients. Proportion of progressive disease (PD) was 83% (five in six patients) in Negative group, 43% (three in seven patients) in Positive group, and 39% (nine of 23 patients) in all patients.

Conclusions:
In 46% of patients who received re-biopsy, HER2 status changed to negative. There was a trend that TTF was shorter and PD rate was higher in Negative group than in Positive group. We demonstrated that some of patients who experienced PD during
T-DM1 therapy had HER2-negative MBC, and in these patients efficacy of T-DM1 was likely to be insufficient. In such a case that
disease progression occurs in a few months of T-DM1 therapy, we have to consider whether its HER2 status remains positive or
changes to negative.
Title: Can surrogate pathological subtyping replace molecular subtyping? Outcome results from the MINDACT trial

Cardoso F, Slaets L, de Snoo F, Bogaerts J, van 't Veer LJ J, Rutgers EJ J, Piccart-Gebhart MJ J, Stork-Sloots L, Russo L, Dell'Orto P and Viale G. Breast Unit, Champalimaud Cancer Center, Lisbon, Portugal; European Organization for Research and Treatment of Cancer, Brussels, Belgium; Medical Affairs, Agenda, Amsterdam, Netherlands; Helen Diller Family Comprehensive Cancer Center, University of California, San Francisco; Netherlands Cancer Institute, Amsterdam, Netherlands; Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium and European Institute of Oncology (IEO) and University of Milan, Milan, Italy.

Body: Background
Molecular subgroups within early breast cancer (EBC), such as Luminal A, Luminal B, HER-2+, Basal-like may help to best to identify patients for specific treatment regimens. Controversy exists as to which methodology is best at identifying these molecular subgroups. Immunohistochemistry (IHC) may be used as a surrogate method to stratify patients. Molecular subtyping gene expression based tests, such as BluePrint, measure a greater number of genes than pathological criteria. ER, PgR, HER-2 and Ki67 are measured individually at the protein level, while BluePrint is designed to capture the functional underlying biologic pathway regulated by these receptors.

Methods
The MINDACT trial is an international, prospective, randomized, phase III trial which has proven the clinical utility of MammaPrint in selecting EBC patients who can safely avoid chemotherapy. Here we present the results of a preplanned MINDACT sub-study to compare outcome based on molecular subtyping (MS) to surrogate pathological subtyping (PS) as endorsed by 2013 St. Gallen Consensus. MS data were obtained by MammaPrint (MP) and BluePrint classifying patients in the following subtypes: Luminal A (MP Low Risk); Luminal B (MP High Risk); HER2-type; and Basal-type. ER, PgR, HER2 and Ki67 protein status were centrally assessed by IHC/FISH. The primary hypothesis was that among PS Luminal patients, patients with HER-2+ or Basal-type tumors by MS would have a decreased DMFS compared to MS Luminal patients. At \( \alpha = 5\% \) with 220 events, the study has 80% power to demonstrate this for \( HR = 2.44 \).

Results
The table depicts classification of tumors according to PS versus MS for all patients (n=5,806).

<td>5806</td>
<td></td>
</tr>
</tbody>
</table>

Most pronounced differences: MS classified 54% as Luminal A among the Luminal B by PS. MS classified 38% as Luminal (A and B) and 5% as Basal-type among the HER-2+ by PS. MS classified 5% as Luminal (A and B) among the TN cases by PS. MS identifies 63% of patients as Luminal A, while PS identifies 47%; 5yr DMFS for both methods was \( \geq 96.0\% \).

PS Luminal cancers that were classified as HER-2+ or Basal-type by MS had a lower 5yr DMFS (88.0% for HER-2+ and 90.2% for Basal), albeit non-significant, than those who were also Luminal by MS (95.9%): \( HR = 1.40 \), 95% CI = 0.75-2.60.
In PS TN cancers, MS identified 24 out of 500 patients (5%) as Luminal-type with excellent prognosis (5yr DMFS of 100% versus 71.4% for MS HER-2+ or 90.1% for MS Basal-type).

Among the PS Luminal patients, Ki67 cut at 20% identified patients with ki67 low (69%), with 5yr DMFS ≥ 96.0% (better compared to the 14% cut-off).

**Conclusions**

1) MS was able to re-stratify 16% of patients to a low risk Luminal A-type group with an excellent outcome. 2) Among TN EBC, 5% were classified as Luminal by MS and had an excellent outcome. 3) Albeit limited by low numbers of patients in each subgroup, this study suggest that MS is better correlated with outcome. 4) The observed subtype discrepancies may have an impact on treatment decision making. 5) Centrally assessed Ki67 labeling index of 20% may be the best cut-off for surrogate differentiation between Luminal A and B.
2016 San Antonio Breast Cancer Symposium

Publication Number: PD7-02

Title: Identification of breast cancers with an indolent disease course: 70 gene indolent threshold validation in a Swedish randomized trial of tamoxifen vs. not, with 20 year outcomes

Body: Importance: The frequency of cancers with indolent behavior has increased with screening. We asked whether an ultralow risk threshold on a multigene classifier would identify women whose cancers had an indolent course over 2 decades of follow-up, and which features were most predictive of outcome.

Methods: An ultralow risk threshold of the FDA-cleared MammaPrint 70-gene expression score was set to predict long-term absence of breast cancer-specific mortality in the absence of systemic therapy. The Stockholm Tamoxifen (STO) trial conducted between 1976 and 1990, where postmenopausal women with clinically detected node-negative breast cancers <3cm were randomized to receive tamoxifen versus not, was used for validation. Immunohistochemistry markers (n=727) and Agilent microarrays for MammaPrint risk scoring (n=652) were performed from formalin-fixed paraffin-embedded primary tumor blocks. Recursive partitioning was performed using the rpart package in R to select variables and construct a regression tree that best predicts 20-year breast cancer specific survival. Input variables include: age, period of diagnosis, grade, hormone receptor status, HER2 and Ki67 status, 70-gene risk categories (high, low but not ultra, or ultralow), treatment arm and tumor size; and cross-validation was used to select the final regression tree model.

Results: In this trial conducted in the era before mammographic screening, 58% and 42% were MammaPrint low and high risk, respectively, while 15% were above the ultralow threshold. In the tamoxifen treated arm, women with tumors above the ultralow threshold had no deaths at 15 years and their 20-year disease-specific survival rates of 97%; whereas if untreated, their survival rates were 94%. Recursive partitioning identified the ultralow threshold classification as the first primary split in the model. Once the indolent tumors were partitioned out, among women with tumors below the ultralow threshold, the next most prognostic feature was size, where patients with tumors >20mm have worse breast cancer specific survival. The last split in the model divides the patients with tumors ≤20mm into 70-gene high risk vs low but not ultralow risk groups.

Conclusions and Relevance: A threshold of the 70-gene MammaPrint assay can identify patients with indolent disease whose long-term risk of death from breast cancer after surgery alone is exceedingly low. This threshold emerged as the most prognostic variable, followed by tumor size, and mammaprint high vs. low but not ultralow in our recursive partitioning analysis. This suggests that finding indolent tumors early at a small size may not have much impact on patient outcome. Determining the presence of an ultralow risk breast cancer may prevent overtreatment. Conversely, once the indolent tumors are taken out of consideration, both biology and size impact outcome, and finding these tumors at a small size is likely still important and supports screening in this postmenopausal node negative population.
A model using grade and hormone receptor staining defines groups at low vs. high risk for distant metastasis: Comparison to the 21-gene recurrence score

Background: The 21-gene recurrence score (RS) combines breast cancer (BC) expression of multiple genes into a single number which is prognostic for BC recurrence. We previously showed that a model using standard pathology data (AAMC Risk Groups) has substantial overlap with RS Risk Groups. The present study compared the recurrence rate of AAMC Risk Groups to that of RS-based Risk Groups as defined by the TAILORx trial and OncotypeDX (ODX) assay.

Methods: From a prospective registry of BC treated at MD Anderson Cancer Center (2/2005 – 5/2015), we selected cases tested with ODX. Cases were excluded for: other cancer in the past 5 years, T4 stage, node positivity, missing grade, missing ER%, ER&PR<1% or HER2 positivity. Three methods were used to categorize distant metastatic risk: ODX and TAILORx Risk Groups were defined using RS, and AAMC Risk Groups were defined using grade and ER/PR level (Tables). For each method, the proportion of patients experiencing metastasis was calculated within Risk Groups.

Results: 1296 cases were included, with a mean follow-up of 3.5 years (25% had ≥4.9 years of follow-up). 82 cases (6.3%, 95% CI 5.1 – 7.8%) experienced distant metastasis, with a mean time-to-metastasis of 2.7 years. The proportion of patients experiencing distant metastasis was similar between the AAMC Low Risk Group (1.5%) and the TAILORx (3.2%) and ODX (2.4%) Low Risk Groups.

The AAMC Low Risk Group was less than half the size of the ODX Low Risk Group. Of the 5 recurrences in the AAMC Low Risk Group, 1 was ODX Low Risk and 4 were ODX Intermediate Risk; 2 had 1% PR staining. Of the 17 recurrences in the ODX Low Risk Group, 1 was AAMC Low Risk and 5 (all grade 3) were AAMC High Risk; 3 had PR staining < 10%. The proportion of patients experiencing distant metastasis was similar between the AAMC High Risk Group (17.4%) and the TAILORx (16.4%) and ODX (18.2%) High Risk Groups.

The number of patients in the AAMC High Risk Group was greater than the ODX High Risk Group.

**Conclusions:** AAMC Low and High Risk Groups were prognostic of the likelihood of distant metastasis, and performed similarly to TAILORx and ODX Low and High Risk Groups. If RS were omitted for AAMC Low and High Risk cases, 44% [(329+235)/1296] of cases in the present cohort could have been spared ODX testing. The AAMC Risk Groups, using standard pathology data, can reliably identify a large number of patients unlikely to benefit from ODX testing and thus provide substantial cost savings.
A novel nomogram model can predict oncotype DX results thus reducing healthcare expenditures

Orucic A, Bell JL and Heidel RE E. University of Tennessee Medical Center, Knoxville, TN.

Body: Oncotype DX (ODX) is a commercially available 21-gene recurrence score (RS) assay for breast cancer (BC), which has both prognostic and predictive recurrence value for estrogen receptor-positive (ER+)/HER2-negative (HER2-)/lymph node-negative (LN-) BC. ODX is currently endorsed for use by ASCO, the NCCN, and others for routine guideline application. The RS predicts benefit of adding adjuvant chemotherapy to hormonal manipulation. ODX is costly, a factor which contributes to the test being performed in only ~1/3 of ER+BC in the USA. Disparities of its use in the US and other developed countries were recently published by us and others. The need for finding an accurate widely applicable, readily available surrogate for ODX is apparent. This study serves to develop and validate nomograms which can be used in place of ODX.

National Cancer Data Base (NCDB) analysis from 2010-2012 of ODX tested ER+/HER2-/LN- patients (pts) with 6-50mm tumor size was used to create nomograms for predicting a high or low ODX RS test results. Analysis of NCDB ODX tested pts in 2013 was used for external validation. Age, tumor size, grade, progesterone receptor (PR) status, lymph-vascular invasion (LVI), and the four most frequent BC histologic types were chosen as variables for creating nomograms based on the published methods (JCO, 26(8):1364-70, 2008). Logistic regression was used to generate the scores and predicted probabilities. The predictive accuracy of the regression model was yielded using a Receiver Operator Characteristic (ROC) analysis and model fit was analyzed by plotting the predicted probabilities against the actual probabilities.

Nomograms predicting a high- or low-risk ODX RS test results were created based on results from 27,719 ODX tested pts (2012-2012) and were validated on 12,763 ODX tested pts (2013) (table1).

Note: actual nomogram to be published in manuscript
Grade and PR status were shown to be the highest predictors for a low- or high-risk ODX RS. The ROC curves for the probabilities of a low- or high-risk RS showed excellent agreement between the nomogram prediction and actual observation with high, acceptable C-indexes-.89 for both internal and external validation cohorts.

We created and validated nomograms that accurately predict for a high- and low-risk ODX score based on the large, National Cancer Data Base which is comprised of >1500 Commission on Cancer accredited facilities. These nomograms may serve to select pts for which further ODX testing is not necessary and may be an excellent surrogate for BC pts for which ODX testing is not available.
**Title:** How 21-gene recurrence score assay is being used to individualize adjuvant chemotherapy recommendations in ER+/HER2 -node positive breast cancer -A national cancer data base study

Peethambaram PP P, Hoskin TL L, Heins CN N, Habermann EB B and Boughhey JC C. Mayo Clinic, Rochester, MN.

**Body:**

**Introduction:**

The 21-gene Recurrence Score (RS) assay has been shown in retrospective studies to predict benefit of adjuvant chemotherapy (AC) in node positive (N+) breast cancer (BC) patients (pts). This study evaluates the trends and patterns of use of RS assay in N+, ER+/HER2-breast cancer and the impact of RS on decision to use AC in a real-world multi-institutional database.

**Methods:** Pts with T1-T4c, N1mi-N3, ER+/HER2- BC diagnosed between 2010 and 2013, included in the National Cancer Data Base were analyzed. Pts who received neo-AC were excluded. Analyses included Cochrane-Armitage tests for trends and multivariable logistic regression assessing factors influencing RS testing and AC recommendations based on RS.

**Results:** Among 73,049 pts, RS was obtained in 20.6%, increasing from 14.9% in 2010 to 24.4% in 2013 (p<0.001). RS testing was most common in N1mi (43.6%) and N1 (22.0%) and rare in N2/N3 (3.3%) BC. Of the 12,540 BC with quantitative RS results, 61.1% were low RS, 32.3% intermediate RS and 6.6% high RS. AC recommendation was less frequent in pts with RS testing compared to pts not tested (50.4% recommended AC vs 80.9%, p<0.001). In pts with N1mi/N1 BC, recommendation rates for AC were higher with higher RS (see table), however in N2/N3 BC, AC was recommended in the majority (71-88%) regardless of RS. Most pts (>85%) with RS 26-30 or high risk RS were recommended AC regardless of N stage. For pts with low risk RS, recommendation for AC increased significantly with increasing N stage (see table). On multivariable analysis, in pts with low risk RS, AC was more likely to be recommended in those with N1/N2+ stage (OR 2.3 and 9.1 vs N1mi), T2 and T3/T4 tumors (OR 1.3 and 2.2 vs T1 tumors), poorly differentiated tumors (OR 1.6) and younger age (OR 3.4 and 1.7, respectively, for <40 and 40-49 vs 50-59) (all p<0.001). Among pts with RS 18-25, AC was more likely to be recommended in those with higher tumor grade, younger age but the effect of N stage was less pronounced. Histology (IDC vs ILC) did not influence AC recommendation in any RS subset.

**Conclusions:** RS was obtained in about one fifth of pts with N+ ER+/HER2- BC, predominantly for N1mi and N1 disease. Overall, RS testing decreased frequency of recommendation of AC in N+ BC pts. The RS influenced use of AC particularly in N1mi and N1 pts, likely avoiding overtreatment of those with low risk RS and RS 18-25. Prospective data regarding RS to direct AC in N+ BC are awaited.
Title: SEER study of breast cancer-specific mortality in patients with poorly differentiated tumors treated based on recurrence score results

Petkov VI I, Miller DP P, Howlader N, Baehner FL L, Penberthy L and Shak S. National Cancer Institute, Bethesda, MD and Genomic Health, Inc., Redwood City, CA.

Body: Introduction: The SEER Program of the NCI is an authoritative source of cancer incidence and survival statistics. Linking the 21-gene assay Recurrence Score® (RS) results to the SEER Registries (N=44,825) demonstrated very low 5-year breast cancer-specific mortality (BCSM) with RS <18 across many key clinical-pathological subgroups, such as age, nodal status, tumor grade, and size (npj Breast Cancer. 2016;2:16017). Given the large sample size and specific interest in outcomes as a function of tumor grade, further stratification of patients with poorly differentiated tumors was performed to determine BCSM when examined by both tumor grade and tumor size.

Methods: Patients were eligible if node negative (N0), HR+, HER2-negative (by RT-PCR), had no prior malignancy, had poorly differentiated (G3) tumors, and were diagnosed between Jan 2004 (test available in Jan 2004) and Dec 2011 (SEER survival updated through 2012). BCSM was defined according to pre-existing robust methodology (J Natl Cancer Inst. 2010;102:1584). RS was categorized according to the cutpoints of 18 and 31 established in the NSABP B-14 study. Five-year BCSM was estimated using actuarial methods.

Results: Among 6,666 eligible patients with G3 tumors, 4,683 had tumors ≤2 cm and 1,983 had tumors >2 cm. Median age was 57 years; 99.1% were female. Median follow-up was 39 months. The proportion of patients with RS <18 was 29% among those with tumors ≤2 cm and 25% among those with tumors >2 cm, somewhat lower than the overall population. For RS <18, 5-year BCSM was 0.3% (G3; ≤2 cm) and 1.4% (G3; >2 cm); reported chemotherapy use was 10% and 16%, respectively. 5-year BCSM for all groups are provided in Table. An additional year of BCSM follow-up in N0 G3 disease, as well as results for patients with node positive (micrometastases or 1-3 positive nodes) G3 disease, will be available for presentation.

Conclusions: Although patients with poorly differentiated tumors have worse prognosis in general, the RS identifies a sizable proportion of patients who can expect good outcomes without chemotherapy and its associated toxicity.
**Title:** Discovery of molecular predictors of late breast cancer specific events (BCSE) in ER+, node+ breast cancer – new transcriptome expression whole gene analysis of the phase III adjuvant trial SWOG S8814

Albain KS, Crager MR, Barlow WE, Baehner FL, Bergamaschi A, Rae JM, Ravdin PM, Tripathy D, Gralow JR, Livingston RB, Osborne CK, Ingle JN, Pritchard KI, Davidson NE, Carey LA, Cherbavaz DB, Sing AP, Shak S, Hortobagyi GN and Hayes DF. Loyola University Chicago Stritch School of Medicine, Maywood, IL; Genomic Health, Inc., Redwood City, CA; Cancer Research and Biostatistics, Seattle, WA; University of Michigan, Ann Arbor, MI; NA, San Antonio, TX; The University of Texas MD Anderson Cancer Center, Houston, TX; University of Washington, Seattle Cancer Care Alliance, Seattle, WA; University of Arizona Cancer Center, Tucson, AZ; Baylor College of Medicine, Houston, TX; Mayo Clinic, Rochester, MN; Sunnybrook Odette Cancer Centre and the University of Toronto, Toronto, ON, Canada; University of Pittsburgh Medical Center, Pittsburgh, PA and University of North Carolina at Chapel Hill, Chapel Hill, NC.

**Body:** BACKGROUND: Unique genes and pathways were identified for prognosis on tamoxifen (T, 5 yrs) and prediction on CAF-T vs T in S8814 using whole transcriptome RNA-Seq from archival FFPE tissue. (Albain, et al; Cherbavaz, et al; SABCS 2015) Discovery was robust for early DFS events but sparse for late. The aims of this new analysis were to 1) utilize a new endpoint BCSE for gene discovery of late events, prognosis and prediction and 2) add intronic counts to the previous exonic results to define whole genes impacting on late BCSE.

METHODS: Charts of patients (pts) on CAF-T (212) vs T (142) were reviewed to define the BCSE endpoint (local/regional, contralateral, distant). Deaths without BC were treated as competing risks. BCSE models (including metagenes) of late prognosis and prediction used cumulative incidence functions. Consolidated intronic regions counts within genes were added to exonic regions counts. Using these “whole gene” (WG) counts, association of gene expression with time to BCSE was assessed by Cox regression. A multiple WG score (MWGS) for BCSE prognosis beyond 5 yrs (to 12.5 yrs) was constructed and evaluated for 1-3 and 4+ node (N) groups. False discovery rate was controlled at 10%.

RESULTS: More exons and WG were discovered for prognosis on T alone over 12.5 yrs with the BCSE endpoint than DFS. For prognosis of late BCSE after 5 yrs, more genes were discovered using WG (n=111) than by exons (n=9). There were significantly fewer genes for late BCSE on CAF-T (8, WG; 0, exons). The functions of WG prognostic for late BCSE were: cell cycle/proliferation-26 genes, chromosome segregation/mitotic spindle-22, DNA repair/maintenance-10, transcriptional/translational control-5, cell adhesion/migration-4, immune-3, diverse/unknown-32 and growth factor/hormone receptor signaling-9 (this group was only found by WGs, not exons). Of these 111 WG, a MWGS prognostic for late BCSE on T used 57 previously discovered genes pre-specified for this analysis. Probability of BCSE beyond 5 yrs for low vs high MWGS was 8% vs 21% in N1-3+ and 17% vs 42% in N4+. Late prognosis on T differed by low vs high risk defined in a metagene model: cumulative BCSE at year 10 was 0% vs 47% (low vs high risk, p=0.001). Prediction of 10-yr incidence of BCSE varied by risk level by treatment in a metagene model: low risk- CAF-T=47%, T=0% (p=0.045); high risk- CAF-T=35%, T=45% (p=0.027).

CONCLUSIONS: Gene discovery for prognosis of late BCSE is enhanced with a novel WG transcriptome expression approach. Use of chemotherapy (CT) before T significantly attenuated gene discovery, so that molecular tools for decisions on extending endocrine therapy (ET) may not be reliable in a setting of prior CT. Some pts on ET for 5 yrs may not require either longer ET or CT, given a N+ cohort was defined with no BCSE observed over 12.5 yrs. For prediction of CT benefit, CAF-T appeared to be inferior to T in a low risk metagene model for BCSE. In sum, these results add more evidence that ET alone may be sufficient (perhaps better) in select N+ settings. Validation in SWOG S1007 (RxPONDER) is planned.

SUPPORT: NCI CA180888, 180819, 180821, 180820, 180863; in part, Genomic Health, Inc.
Body: **Background:** African American breast cancer patients have lower relative frequency of hormone receptor (HR)-positive/HER2-negative disease and higher subtype-specific mortality. However, few population-based studies have RNA-based subtyping data, and racial differences in the biology of HR-positive/HER2-negative tumors are not well understood.

**Methods:** Using data and biospecimens from the Carolina Breast Cancer Study (CBCS) Phase 3 (2008-2013), we classified approximately 1,000 invasive breast cancers according to PAM50 subtype and two risk of recurrence scores (ROR-P and ROR-PT). Relative frequency of Luminal A, Luminal B, Her2-enriched, and Basal-like subtypes and ROR scores (low/medium/high) were compared by race (blacks vs. whites) and age (≤50 years vs. >50 years), overall and among HR-positive/HER2-negative cases.

**Results:** Black women of all ages had significantly higher relative frequency of Basal-like breast cancer (36 and 31% in blacks vs. 18 and 15% in whites; younger and older, respectively) and lower frequency of Luminal A breast cancer (26 and 34% in blacks vs. 43 and 52% in whites; younger and older, respectively). Frequency of Luminal B and HER2-enriched breast cancer did not vary by race or age. Among clinically HR-positive, HER2-negative cases, Luminal A subtype comprised only half of the cases among black women, and was significantly less common than among white women (51% vs 60% in whites, p<0.05). Black women with HR-positive/HER2-negative disease also had significantly higher ROR scores (ROR-P medium or high 82% vs. 66% in whites, p=0.01; ROR-PT medium or high 85% vs. 69% in whites, p<0.01).

**Conclusions:** Multi-gene assays highlight disparities in frequency of aggressive, poorer prognosis tumor subtypes and implicate differences in tumor biology as an important contributor to mortality disparities among HR-positive/HER2-negative patients.
Tumor subtype and survival differences between Hispanic and non-Hispanic white breast cancer patients in the California cancer registry

Martinez ME Elena, Cress R, Gomez S, Rodriguez D, Cook LS Sue, Schwab R, Nodora JN N, Porter P and Li C. University of California, San Diego, La Jolla, CA; Fred Hutchinson Cancer Research Center, Seattle, WA; Cancer Prevention Institute of California, Fremont, CA; Public Health Institute, Sacramento, CA and University of New Mexico, Albuquerque, NM.

Body: Background: Prior studies show that Hispanic breast cancer patients are more likely than non-Hispanic white (NHW) women to be diagnosed with triple negative tumors but data on other subtypes are limited. Published data on survival differences between Hispanics and NHW breast cancer patients are inconsistent and vary depending on the covariates included in the multivariate models. We assessed differences in the distribution of the major tumor subtypes of breast cancer, as well as subtype-specific survival, between Hispanic and NHW patients according to nativity, and age and stage at diagnosis.

Methods: We used data from the population-based California Cancer Registry to include female invasive breast cancer cases diagnosed between 2004 and 2013 with follow-up through December 31, 2013, resulting in 90,236 total cases (69,693 NHW and 20,543 Hispanics). Tumor subtypes were classified into four categories: hormone receptor positive and HER2 negative (HR+/HER2-), HR+/HER2+, HR-/HER2+, and triple negative (HR-/HER2-). Logistic regression was used to estimate differences in distribution of subtype between Hispanic and NHW women. Cox proportional hazard models were used to estimate differences in survival for Hispanics and NHWs by subtype, adjusting for clinical and sociodemographic characteristics.

Results: Compared to NHW patients, Hispanic women were more likely to be diagnosed with tumors that were HR+/HER2+ (OR=1.22; 95% CI, 1.16-1.29), HR-/HER2+ (OR=1.37; 95% CI, 1.29-1.47), and triple negative (OR=1.27; 95% CI, 1.21-1.34) than HR+/HER2-. Foreign-born Hispanics had a higher odds of having HER2+ than HR+/HER2- tumors compared to NHW women (OR=1.29 for HR+/HER2+ and OR=1.50 for HR-/HER2+); these differences were less pronounced among U.S.-born Hispanics (OR=1.04 for HR+/HER2+ and OR=1.16; 95% CI, 1.06-1.26 for HR-/HER2+). In age-adjusted models, Hispanic women had higher breast cancer mortality than NHW women (HR=1.23; 95% CI, 1.17-1.30), which was consistent across all tumor subtypes. However, the mortality differences disappeared after adjustment for clinical, sociodemographic characteristics, and marital status.

Conclusions: Hispanic women were more likely than NHWs to be diagnosed with triple negative breast cancer as well as tumors overexpressing HER2 than HR+/HER2- tumors. This pattern held true when stratified by nativity, although higher ORs for HER2+ tumors among foreign-born than U.S.-born Hispanic women were observed. Within each subtype, Hispanics had 20%-30% higher mortality than NHW, which appeared to be explained by a combination of sociodemographic and clinical factors.
Title: Differences in the mutational landscape in African Americans and Caucasians with triple negative breast cancer

Ademuyiwa FO O, Tao Y and Luo J. Washington Uni Sch of Medcn, St. Louis, MO.

Body: Background- Triple negative breast cancer (TNBC) occurs at a higher frequency in African American (AA) premenopausal women compared with Caucasians. It is unclear if the biology and clinical outcome of TNBC is different in AA versus Caucasians. In this study, we sought to evaluate differences in the molecular pathology of TNBC in a large cohort of AA and Caucasians.

Methods- Using publicly available data from The Cancer Genome Atlas, we identified all patients with TNBC who had information on race. We analyzed the differences in clinical characteristics and tumor somatic mutations by race from whole exome sequencing using student's t test or one-way ANOVA for continuous variables and chi square or Fisher's test for categorical variables. Exome sequencing was performed with coverage of ≥70% and at a depth of 20x.

Results- A total of 1104 primary breast cancer patients were identified, of which 178 (16%) had TNBC. Overall, TNBC was more frequent in AA than in Caucasians (33.3% versus 14.9%; p value <0.001). More AA than Caucasians were classified as basal-like from PAM50 gene expression analysis (34.8% versus 16.1%; p value 0.001). No differences in the TNBC cohort were observed, 91% of AA were basal-like versus 81% of Caucasians (p value 0.842). Median tumor somatic mutation counts were higher in AA (39.5) versus Caucasians (34) (p value 0.022). However, no racial differences in the mutation counts in TNBC were observed (AA=56, Caucasians=60, p value 0.399). Somatic mutation analysis revealed racial differences in specific high prevalence (>5%) genes in all patients- [TP53 alterations: 46% in AA versus 27% in Caucasians; p value <0.001, PIK3CA alterations: 23% in AA versus 34% in Caucasians; p value 0.019, and MLL3 alterations: 12% in AA versus 6% in Caucasians; p value 0.028]. The TNBC patients did not have any specific high prevalence (>5%) genes associated with racial differences. AA with breast cancer had a shorter time to progression (TTP) (hazard ratio 1.62, p value 0.014) and worse disease free survival (DFS) than Caucasians. However, racial difference in TTP or DFS were not observed in the TNBC patients.

Conclusion- The mutational landscape of breast cancer may be different between AA and Caucasians, but appears to be similar in both races in the cohort with TNBC. Our findings have 2 implications: racial disparities in breast cancer may largely be due to differences in those with hormone receptor positive disease, and secondly, the higher frequency of TNBC in AA is unlikely due to differences in molecular features, but other modifiable factors.
Title: Racial differences in the molecular landscape of breast cancer

Lynce F, Xiu J, Nunes MR, Swain SM M, Gatalica Z, Isaacs C and Pohlmann P. Lombardi Comprehensive Cancer Center, MedStar Georgetown University Hospital, Washington, DC; Caris Life Sciences, Phoenix, AZ; MedStar Washington Hospital Center, Washington, DC and Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC.

Body: Background: African Americans (AA) have a higher mortality associated with breast cancer (BC) when compared to Caucasians (CC). This has been attributed to diverse factors that include access to care, reproductive factors and different somatic genomic profiles. We aimed to compare the racial mutational landscape of 565 BC samples.

Methods: DNA from formalin-fixed paraffin-embedded samples was sequenced using the Illumina NextSeq (Agilent SureSelect XT, 592 gene selected based on COSMIC database) and MiSeq (TruSeq, 47 gene) for mutation and gene amplification analyses. Protein expression was evaluated by Immunohistochemistry (IHC). The exome aggregation consortium database was assessed for known ethnicity associations.

Results: Tumor samples from 118 AA and 447 CC female patients were included in this analysis. AA were younger (median age 56 vs 58y, p<0.005) and had higher proportion of triple negative BC (TNBC) (32% vs 17%, p<0.001). 50.3% of the samples were obtained from primary tumors and the remainder from metastatic sites. This was similar in AA and CC (48.8% vs 51.8% primary tumors, pNS). The two genes with highest mutation prevalence were TP53 and PIK3CA. AA had fewer PIK3CA mutations (14.7% vs 28.2%, p<0.03). Within HR+/HER2+ and HR+/HER2- subtypes there was a similar trend in the number of PIK3CA mutations but it was no longer significant. The remainder mutation analysis did not differ between races. In terms of protein expression there were significant differences in the androgen receptor (AR), RRM1, EGFR and TS expression (table). AR positivity defined as ≥10% was less frequent in AA (40.0% vs 60.4%, p<0.001 and when adjusted for age, p<0.005) and associated with PIK3CA mutations in both AA and CC (p<0.01 and p<0.007). AR expression in TNBC was positive in 17.8% of CC and 5.4% of AA (pNS). Copy number variation (CNV) data assessed by NextGen revealed significantly higher gene copy number in AA compared to CC in CCND1 (16% vs 4%, p=0.04), FGF19 (16% vs 1.3%, p=0.01) and FGF4 (16% vs 3%, p=0.02). When only TNBC was considered, RRM1, TOPO1 and TUBB3 expression was significantly higher in AA than CC (table) and there were no differences in the mutational analyses. Evaluation of other BC subtypes (HER2, HR positive) is currently underway.

Conclusions: In this large cohort of AA who underwent genomic profiling there were relatively few differences in the mutation analysis compared to CC. The only significant difference seen was the lower number of PIK3CA mutations in AA, which had been previously reported in a cohort of 105 AA from the TCGA data (Keenan et al. JCO 2015). Protein expression by IHC revealed lower expression of AR in AA, even after adjustment for age, which could have therapeutic implications. Some of the racial differences found in the molecular landscape of BC including PIK3CA mutations, AR, EGFR expression and CNV may contribute to a more aggressive tumor biology in AA.

Title: Comparative analysis of the genomic landscape of breast cancers from women of African and European ancestry

Body: Objectives: Paucity of data on populations of African Ancestry in clinical trials continues to limit our ability to design and implement innovative solutions to narrow the breast cancer survival gap amongst Africans, African Americans, and European Americans. We have developed a cross-continent research infrastructure to examine the spectrum of genomic alterations in breast tumors from West Africa and subsequently, to compare them to tumors from African American women and women of European Ancestry in The Cancer Genome Atlas (TCGA) database.

Methods: Consecutive women with breast cancer presenting for treatment at the University College Hospital, Ibadan and at Lagos State University Teaching Hospital, Lagos, Nigeria gave informed consent and were recruited to the West African Breast Cancer Study (WABCS) between 2013-2016. Tumor-normal pairs were subjected to exome and/or high-depth (90x) genome sequencing. High confidence somatic mutations (substitutions, insertions/deletions and structural variants) were obtained by using multiple variant callers. Furthermore, 1,089 exomic and 80 genomic breast tumor-normal pairs from TCGA were harmonized with WABCS samples, resulting in a cohort of 147 West Africans (147 exome; 40 genome), 154 African Americans (154 exome; 31 genome), and 776 Caucasians (776 exome; 43 genome).

Results: Across the exomes, genes commonly altered in breast cancer in TCGA are also altered in women of African ancestry, but the mutational spectrum is quite different, demonstrating overrepresentation of tumors with aggressive phenotypes. Overall, TP53 (65%), ERBB2 (27%), and GATA3 (17%) showed statistically significant higher alteration frequencies in West Africans and African Americans. In contrast, PIK3CA (24%) was less frequently mutated. Of note, GATA3 mutation was statistically significantly more frequent in Nigerians (39%) and African Americans (16.7%) compared to Caucasians (10.5%), in ER-positive cancers. Analysis on Structural Variants (SV), on the other hand, has shown that the genome-wide SV counts among three populations are comparable in ER-negative cancers, while Nigerians have significantly more SV counts compared to African Americans (P=0.0013) or European Americans (P=2.9x10^-5) in ER-positive cancers. Similarly, genome-wide substitution patterns in ER+ and ER- cancers varied widely by race/ethnicity. In ER- cases, West Africans carried the highest proportion of canonical APOBEC-associated substitutions, particularly C>T transitions. Conversely, European Americans with ER+ disease showed a higher proportion of C>T than both West Africans (Welch t-test P = 0.044) and African Americans (Welch t-test P = 0.011). Mutation signature analyses highlighted multiple APOBEC signatures, with notable contribution differences across ancestry and ER status. A signature likely corresponding to DNA damage repair correlated with the proportion of genetic ancestry, being most prevalent in European Americans and least common in Nigerians, particularly in ER-negative cancers, with African Americans showing a degree of this signature’s contribution in between the two populations (linear model adjusted for age, P=1.0x10^-10).

Conclusions: Overall, our data suggests mutation spectra differences in across race/ethnicity and geography. Identification of molecular characteristics such as higher rates of HER2 enriched tumors and higher rates of GATA3 mutations in ER positive tumors are beginning to reveal the genomic basis of race-associated phenotypes and outcomes in breast cancer. Population differences in frequency and spectrum of mutations should now inform the design of innovative clinical trials that improve health equity and accelerate Precision Oncology care in diverse populations.
Title: Multiple-gene panel testing for hereditary cancer risk reveals a racial/ethnic disparity in genetic information

Body: Background: Multiple-gene germline sequencing panels are increasingly used to evaluate hereditary cancer risk. However, little is known about the results of such testing in racially/ethnically diverse populations.

Methods: Patients who presented to the Stanford University Clinical Cancer Genetics Program from 1/1/2013 to 12/31/2015 and underwent multiple-gene panel testing were included in the cohort (N=1,483). Information on demographics, personal and family history of cancer, and tumor characteristics was collected at time of clinic visit. Odds ratios and 95% confidence intervals were calculated for mutation status by different patient and tumor characteristics, including race/ethnicity. Results were compared using the chi-square test and considered significant if P<0.05 after Bonferroni correction for multiple hypothesis testing.

Results: Most patients (92%) were female. Patients were 51% Non-Hispanic White (NHW), 19% Asian, 14% Hispanic, 10% Ashkenazi Jewish, 5% other, and 1% unknown. Eighty-nine genes were tested in at least one patient; panel size ranged from six to 62 genes, with a median of 25 genes. The frequency of pathogenic or likely pathogenic mutations was 15% for any panel-tested gene, 5.5% for BRCA1/2, and 5.3% for other breast cancer-associated genes; mutation frequencies were similar between NHW, Asian, Hispanic, and Ashkenazi Jewish patients. Variables significantly associated with the carriage of a pathogenic BRCA1/2 mutation included personal or family history of ovarian cancer and personal history of triple-negative breast cancer (TNBC). No variable was significantly associated with the presence of a pathogenic mutation in the other breast cancer genes. The odds ratios for carrying a BRCA1/2 mutation with personal history of ovarian cancer (4.1 [2.2-7.3]), family history of ovarian cancer (3.1 [1.9-4.9]), and TNBC relative to other breast cancer subtypes (6.0 [2.9-12.4]) did not differ significantly between NHWs and non-Whites. The frequency of variants of unknown significance (VUS) in any panel-tested gene was higher in non-Whites (36%) than in NHWs (27%) (P=2E-4), with the highest odds ratio relative to NHWs among Asians (2.0 [1.5-2.7], vs 1.3 [0.9-1.7] among Hispanics and 1.2 [0.8-1.7] among Ashkenazi Jews). The odds ratio of finding a VUS for non-Whites compared to NHWs was similar for any panel (1.5 [1.2-1.9]), for BRCA1/2 (1.3 [0.8-2.3]), and for other known breast cancer-associated genes (1.5 [1.1-1.9]).

Conclusions: In this diverse cohort tested for hereditary cancer risk with multiple-gene panels, frequencies of pathogenic mutations were similar between racial/ethnic groups. By contrast, frequencies of VUS were significantly higher among non-Whites compared to NHWs. This higher VUS rate renders multiple-gene panel testing less informative for non-White patients. Efforts toward VUS re-classification, particular among non-Whites, are urgently needed to address this genetic information disparity.
Title: DCIS biological risk profile predicts risk of recurrence after breast conserving surgery in a Kaiser Permanente NW population

Bremer T, Whitworth P, Leo M, Barry T, Goldstein N, Ganders C, Francisco M, Leesman G, Linke S, Patel R, Pellicane J and Weinmann S. PreludeDx, Laguna Hills, CA; Center for Health Research, Kaiser Permanente Northwest, Portland, OR; NeoGenomics, Aliso Viejo, CA; Nashville Breast Center, Nashville, TN; Good Samaritan Cancer Center, Los Gatos, CA and Bon Secours Cancer Institute, Richmond, VA.

Body: Background: Patients with DCIS and their physicians need tools that provide better information about the individual patient's biological risk profile to help make treatment decisions. Prelude and the Kaiser Permanente Northwest Center for Health Research (KPCHR) validated a biological risk signature based test to assess ipsilateral breast event (IBE) risk after breast conserving surgery (BCS) with radiation (+RT) or without radiation therapy (-RT).

Methods: The Prelude DCIS test was independently validated in a retrospective cohort from the Kaiser Permanente Northwest (KPNW) integrated healthcare system in patients diagnosed with DCIS from 1990-2007 and treated with BCS±RT (n=608). KPCHR performed central pathology review to identify patients meeting study eligibility criteria with formalin fixed paraffin embedded (FFPE) tissue samples (n=475); KPCHR also reviewed medical records to collect patient, treatment, and outcome data. FFPE patient samples were provided to Prelude for testing. REMARK guidelines were followed.

A panel of biomarkers (HER2, PR, Ki-67, COX2, p16/INK4A, FOXA1 and SIAH2) were assayed by the Prelude CLIA lab and scored by board-certified pathologists (n=455). Prelude's DCIS test was executed independently using biomarker and clinicopathologic data while blinded to patient outcome data. The risk results were provided to KPCHR under a Data Transfer Authority. KPCHR biostatisticians executed a predefined and co-developed statistical analysis plan. IBE rates were assessed using Kaplan-Meier survival analysis. Hazard ratios (HR) were determined using Cox proportional hazards analysis, with RT as a covariate.

Results: The Prelude DCIS test score was statistically associated with total IBE as a continuous linear variable (0-10 unit scale) on a per unit basis, HR of 1.12, 95% CI [1.03, 1.23], p=0.01. The DCIS test score (0-10) corresponded to recurrence risks ranging from 10% to 42% (≤2, >7) for patients treated with BCS-RT and ranging from 4% to 11% (≤2, >7) for patients treated with BCS+RT. Patients treated with BCS ±RT with an elevated test score (≤3 vs >3) had a higher recurrence risk, n=455, HR=1.87 [1.03 - 3.38], p=0.04. In patients treated with BCS-RT in this sample, patients with a higher DCIS signature had an elevated recurrence risk, n=78, HR=2.37, 95% CI [0.82, 6.85], p=0.11. The 10-year contralateral breast event rate was 4%, 95% CI [2%, 6%]. Median follow-up time was 10.4 years.

Discussion: Patients diagnosed with DCIS and treated with BCS ±RT, were stratified into clinically relevant low and elevated risk groups (≤3 vs >3) in an independent validation of the Prelude DCIS test. Patients in the elevated risk group had substantially higher likelihood of 10-year total IBE. The number of patients treated with BCS -RT was limited and while the stratification by risk group for BCS -RT was in the expected direction, it did not reach statistical significance. Two additional validation studies are scheduled to be completed in 2016.

Title: Scalp cooling alopecia prevention trial (SCALP) for patients with early stage breast cancer

Body: Background
Adjuvant chemotherapy decreases the risk of breast cancer recurrence. However, it is associated with distressing side effects, including alopecia. Women consider chemotherapy-induced alopecia as one of the most severe side effects. In many countries, scalp cooling is used to prevent chemotherapy-induced alopecia. It causes cutaneous vasoconstriction, which reduces blood flow to hair follicles during peak plasma concentrations of the drug and may reduce cellular uptake of these agents. It also results in reduced biochemical activity, which makes hair follicles less susceptible to the damage of chemotherapy. There are no randomized trials assessing this approach with modern scalp cooling and success rates in non-randomized trials have varied.

Methods
We conducted a multi-center randomized non-blinded controlled prospective trial to evaluate the safety and efficacy of the Orbis Paxman Hair Loss Prevention System (OPHLP). Women with stage I-II breast cancer planned to receive neoadjuvant or adjuvant anthracycline- or taxane- based chemotherapy for at least four cycles were eligible. Participants were randomized in a 2:1 ratio to scalp-cooling or no cooling. Scalp-cooling was done using the OPHLP 30 minutes prior to, during and 90 minutes after each chemotherapy. The primary efficacy endpoints were hair preservation, defined as CTCAE 4 alopecia <2 (assessed by an independent and blinded evaluator), and device safety. We planned to enroll 235 patients to provide 85% power to detect a 20% difference in hair preservation (i.e. 15% with no cooling and 35% with scalp-cooling). Secondary endpoints included wig/scarf use and quality of life assessed by the EORTC QLQ-30, HADS and BIS. Participants will be followed for 5 years post-study for time to first recurrence, overall survival, site of first recurrence, and incidence of isolated scalp metastasis. One interim analysis was planned to allow the study to stop early for efficacy (superiority) after 95 and 47 patients were enrolled to cooling or no cooling, respectively, and have been evaluated for the primary endpoint. To maintain the overall type 1 error rate, an O'Brien-Fleming spending function has been used to set the superiority boundaries (interim boundary was calculated as p=0.0061 (or Z=2.509)).

Results
This is the first prospective randomized trial with modern scalp cooling in the world. At the time of the interim analysis, 95 patients in the cooling group and 47 patients in the no cooling group were evaluable and had completed 4 cycles of chemotherapy. Among them, 48 (50.5%) out of 95 in the cooling group and 0 (0%) out of 47 in the no cooling group had hair preservation. The one-tailed p-value from the Fisher's exact test is <0.0001, which crosses the superiority boundary (p=0.0061). Thus, on 9/26/2016, the DSMB decided to stop the study early and release the results. Our trial shows that scalp cooling using OPHLP is highly effective in hair preservation and should become available for patients who receive chemotherapy for early breast cancer. These data and secondary endpoint analysis data will be presented. We are seeking FDA approval for the OPHLP.
Women in the UK arm of the International Breast Cancer Intervention Study (IBIS-1) were randomised to placebo vs. tamoxifen (20mg/day). A total of 292 were excluded (breast cancer, death, or other cancer), leaving 3987 to be included in the analysis (2000 placebo arm, 1987 tamoxifen arm). Adherence was calculated using data from six monthly clinical visits during the trial. Adherence (<4.5 years, ≥4.5 years) was calculated using the Kaplan-Meier estimator. Our main objective was to investigate the effect of menopausal side effects experienced during the first six months on adherence overall and by treatment arm. All analyses were adjusted for age, Tyrer-Cuzick risk, smoking, hormone replacement therapy use, menopausal status, baseline symptoms, and treatment. Overall, 66.8% of women were adherent for at least 4.5 years (placebo: 71.5% vs. tamoxifen: 62.1%, p<0.001). Highest drop-out rates were found within the first 12 months of follow-up, and a significant difference in adherence between treatment arms was observed thereafter (p<0.05). A low number of women experienced nausea/vomiting (5.0%) and headaches (7.0%), while higher proportions reported gynaecological symptoms (irregular bleeding/vaginal dryness/vaginal discharge, 13.8%) and hot flushes (31.5%). Women reporting nausea/vomiting (OR=1.82 [95% CI, 1.35-2.47], p<0.001) and headaches (OR=1.41 [1.08-1.84], p=0.01) were significantly more likely to be non-adherent at 4.5 years. Long-term adherence was not significantly affected for those who reported hot flushes (OR=1.10 [0.94-1.30], p=0.2) or gynaecological symptoms (OR=1.18 [0.99-1.41], p=0.07) compared with their counterparts. Nausea/vomiting was significantly associated with non-adherence in both the placebo (OR=1.82 [1.16-2.87], p=0.009) and tamoxifen (OR=1.84 [1.22-2.76], p=0.004) arms. Headaches were associated with non-adherence in the placebo arm (OR=1.70 [1.16-2.50], p=0.006), while gynaecological symptoms were only significant in the tamoxifen arm (OR=1.30 [1.05-1.63], p=0.02). The majority of side effects were of mild or moderate severity and we observed significant trends for lower adherence with increasing severity for all symptoms (p<0.05 to <0.001).

In the IBIS-I trial, we observed a significant effect of common menopausal symptoms on long-term adherence. These effects were largely similar between tamoxifen and placebo arms, suggesting women are attributing age-related menopausal symptoms to preventive therapy. To ensure women experience the full benefit of preventive therapy, interventions are required to support the management of menopausal symptoms and to promote adherence. The higher rate of drop-out in the early months of the trial suggests early intervention may be an effective way to promote long-term adherence.
Title: Low-fat dietary pattern and breast cancer overall survival in the women's health initiative dietary modification randomized controlled trial

Chlebowski RT T, Aragaki AK K, Thomson CA A, Anderson G, Manson JE E, Simon MS S, Rohan TE E, Snetselar LG G, Lane D, Barrington WE E, Vitalins M, Womack C, Qi L, Hou L, Thomas F and Prentice RL L. Los Angeles BioMedical Research Institute at Harbor-UCLA Medical Center, Torarnce, CA; Fred Hutchinson Cancer Research Center; University of Arizona; Brigham and Women's Hospital; Karmanos Cancer Institute; Albert Einstein College of Medicine; Stony Brook University; University of Texas Health Science Center; University of California at Davis, Davis; University of Iowa, Iowa City/Davenport; Northwestern University Feinberg School of Medicine and University of Tennessee Health Science Center.

Body: Introduction: Among 48,835 postmenopausal women randomized in the Women's Health Initiative Dietary Modification (WHI DM) primary prevention trial, 1,767 women were diagnosed with breast cancer during the 8.3 years of dietary intervention. While differences were not statistically significant, there were fewer breast cancers diagnosed in the low fat dietary group women (HR 0.92 95% CI 0.84-1.01, P=0.09) with somewhat lower breast cancer mortality (HR 0.77 95% CI 0.48-1.22) than seen in control group women (JAMA 2006; 295:629). These findings were recently updated, and after 10.9 years (mean) post-diagnosis follow-up, breast cancer overall survival among these 1,767 women measured from diagnosis was greater in the dietary group (10 year survival, 82% vs 78%, 168 (2.24%) versus 319 (2.71%) deaths; HR 0.80 95% CI 0.66-0.97, P=0.02) (AACR Annual Meeting 2016, abstract CT0433, Clinical Trials Plenary Session). We now report low-fat dietary pattern influence on breast cancer overall survival in subgroups defined by breast cancer characteristics.

Methods: The WHI DM trial, conducted at 40 US clinical centers, from1993-1998 enrolled 48,835 postmenopausal women, aged 50-79, without prior breast cancer, with normal mammogram and dietary fat intake >32% of total energy. Participants were randomly assigned to a dietary intervention group (40%, n=19,541) with goals of fat intake reduction to 20% of energy and increased fruits, vegetables and grain intake, or a usual diet control group (60%, n=29,294). As previously reported, the dietary modification program reduced fat intake, increased fruit, vegetable and grain intake and was associated with modest weight loss (all P< 0.001). The current secondary analysis outcome is breast cancer overall survival in subgroups defined by breast cancer characteristics for cases diagnosed during the dietary intervention period. Because of possible selection prior to breast cancer diagnosis, these analyses do not compare randomized outcomes. Therefore, careful attention is paid to control of risk factors for breast cancer in the analysis.

Results: The examined subgroups included histology (ductal, lobular, other), estrogen receptor (ER) status (positive vs. negative by local laboratory), progesterone receptor (PR) status, HER2 status, triple negative (yes/no), stage (local, regional or distant), grade (well, moderately, poorly differentiated), tumor size (<1, 1- 2, >=2 cm), and nodal involvement (none, 1-3, 4+). None of the tests of interaction in subgroups were statistically significant. All subgroup hazard ratios (HR) were less than one except for ER negative cancers, triple negative cancers and those with 4+ positive lymph nodes. The results are suggestive of no influence of the low-fat dietary pattern on triple negative cancers (HR 1.64 95% CI 0.73-3.70 for triple negative vs. HR 0.73 95% CI 0.56-0.95 for other breast cancers, interaction P=0.06).

Conclusion: Compared to a usual diet control group, women randomized to a dietary intervention group providing a low-fat dietary pattern had a significantly increased overall survival following a breast cancer diagnosis with the possible exception of those developing triple negative cancers.
Title: Impact of pre-operative exercise on breast cancer gene expression

Body: Background: Exercise is linked to a lower risk of developing and dying from breast cancer, but the biological mechanisms through which exercise could impact breast cancer are unclear. In animal models, exercise impacts tumor formation and progression, but there are few data regarding direct effects of exercise on tumor tissue in humans. The Pre-Operative Health and Body (PreHAB) Study was a randomized window of opportunity trial designed to explore the impact of exercise on molecular pathways in women with breast cancer.

Methods: Inactive women with Stage I-III breast cancer were enrolled through Dana-Farber Cancer Institute and Yale University prior to surgery. Participants were randomized 1:1 to an aerobic and strength training exercise intervention or mind body control intervention and participated in the interventions between enrollment and the time of surgery. Tumor tissue was collected at enrollment and surgery; samples were reviewed by a breast pathologist and were macrodissected to include sections of tumor with at least 10% cellularity. Capture RNA-sequencing of the transcriptome coding regions was performed using the Illumina Truseq RNA access platform.

Results: 49 women were randomized (27 exercise and 22 control). At baseline, mean age was 52.6, BMI was 30.2kg/m2 and exercise was 49 min/wk. Mean time between enrollment and surgery was 4.2 weeks. Participants in the exercise arm significantly increased exercise vs. controls (increase of 203 vs. 23 min/wk, p<0.0001). Transcriptomic analysis was performed on the tumors from the pre and post intervention biopsies from 32 patients (16 exercise and 16 control). Quality Control analysis of the RNA-sequencing data showed an average read depth of 25 million reads per sample, mapping ~79% to exonic regions. Principal Component Analysis revealed no read bias or batch effects and unsupervised clustering showed that pre- and post-operative samples clustered together by patient. Differential gene expression analysis by DEseq2 revealed a limited number of individual genes with significant changes after the intervention. KEGG pathway analysis, however, of 214 KEGG pathways using the bioconductor package GAGE (Generally Applicable Gene-Set Enrichment for Pathway Analysis) demonstrated upregulation of 13 unique pathways between the baseline biopsy and surgical excision in exercise participants and none in mind body participants (q<0.1). The top ranked upregulated pathway was cytokine-cytokine receptor interactions (q=6.93E-05, set size=238 genes). Il6, CCL3 and other cytokines are among the genes upregulated in this pathway. Analysis also demonstrated downregulation of 13 unique pathways (q<0.1) including cell cycle, RNA transport and DNA replication pathways, in exercise participants over the intervention period.

Conclusions: A pre-operative exercise intervention led to alterations in gene expression in tumor tissue in women with breast cancer. Validation in additional data sets and an analysis of which cellular compartments within the tumor are responsible for the changes is needed. These findings demonstrate that exercise may have a direct effect on breast tumor tissue in humans, providing new insights into the biologic mechanisms through which exercise could lower the risk of developing and dying from breast cancer.
2016 San Antonio Breast Cancer Symposium

Title: Randomized, placebo-controlled trial of duloxetine for aromatase inhibitor (AI)-associated musculoskeletal symptoms (AIMSS) in early stage breast cancer (SWOG S1202)

Henry NL, Unger JM, Schott AF, Fehrenbacher L, Flynn PJ, Prow D, Sharer CW, Lew DL, Moseley A, Fisch MJ, Moinpour C, Hershman DL and Wade III JL. University of Michigan; Kaiser Permanente, Northern California; Metro Minnesota CCOP/Minnesota Oncology; William R. Bliss Cancer Center; Phoenixville Cancer Center; AIM Specialty Health; Fred Hutchinson Cancer Research Center; Heartland NCORP and Columbia University.

Body: Background: Adherence to AI therapy for adjuvant treatment of hormone receptor-positive breast cancer is poor, primarily because of AIMSS. Premature discontinuation of AI therapy can lead to increased likelihood of breast cancer recurrence. Duloxetine (dulox) is a serotonin norepinephrine reuptake inhibitor that is FDA-approved for treatment of multiple chronic pain disorders. Phase II data from an open label trial of dulox for treatment of AIMSS demonstrated a 61% improvement in pain. We hypothesized that treatment of AIMSS with dulox would improve average joint pain compared to placebo (plac).

Methods: Postmenopausal women with stage I-III breast cancer who had been taking AI therapy for between 3 wks and 36 mo were enrolled. To be eligible, patients were required to have average pain of ≥4/10 using the Brief Pain Inventory (BPI) that developed or worsened since AI therapy initiation, and not have any contraindications to dulox therapy. Patients were randomized 1:1 to dulox 30 mg daily for 7 d then 60 mg daily for 11 wks then 30 mg daily for 7 d, or to matching plac, stratified by baseline pain (4-6 vs 7-10) and prior taxane use (yes vs no). Pain, depression, and quality of life (QoL) were assessed after 2, 6, and 12 wks of therapy, as well as at the 24 wk time point. The primary analysis used linear mixed models to examine average pain through 12 wks by arm, adjusting for the stratification factors and assessment time. Clinically significant change in average pain was defined as a ≥2-point decrease from baseline.

Results: 299 patients were randomized between June 2013 and October 2015, 10 of whom were ineligible. 127 dulox-treated and 128 plac-treated patients were evaluable for the primary analysis. No sizeable imbalances in baseline factors were noted by arm. Seventeen pts reported grade 3 adverse events (AEs) (dulox: 12/138 (8.7%), plac: 5/141 (3.5%)), and 40 pts discontinued treatment because of AEs (dulox: 21 (52.5%), plac: 19 (47.5%)). Mean observed average pain, the proportion of pts experiencing clinically significant change in average pain from baseline, and percent reduction in average pain all indicated greater improvement for dulox compared with plac through 12 wks, but were similar by arm at wk 24 (12 wks after completion of intervention; see Table). In multivariable linear mixed model analysis, the BPI average pain was reduced on average by 0.82 points more on dulox compared to plac over the first 12 wks (95% CI -1.24 to -0.40, p=0.0002). Similar patterns were observed for worst pain, pain interference, joint pain, stiffness, and functioning, and QoL.

Conclusions: Treatment with duloxetine was superior to placebo for the treatment of AIMSS among women with early stage breast cancer, was well tolerated, and was associated with improvements in QoL. Clinicaltrials.gov NCT01598298.
Title: Aromatase inhibitors and endothelial function: Is there an association with early cardiovascular disease?

Body: Background: As more women are cured from their breast cancer, survivors with early stage breast cancer are at greater risk of dying from cardiovascular disease than their breast cancer. Aromatase inhibitors (AI) have been shown to reduce breast cancer-related mortality in women with estrogen receptor (ER)-positive disease which makes up 75% of all breast cancer cases. The use of AIs has been associated with higher rates of hypertension, hypercholesterolemia, angina pectoris and ischemic cardiovascular disease. In the aging population taking AIs, little is known about the direct impact of AIs on endothelial function, a predictor of cardiovascular disease. Endothelial dysfunction identified by reactive hyperemia using Endo-PAT has been associated with an increased risk of cardiac adverse events, independent of Framingham risk score.

Methods: At the University of Minnesota in 2014-2015, 25 healthy postmenopausal women and 36 postmenopausal women with locally advanced breast cancer and prescribed an aromatase inhibitor were identified. Subjects with a history of hypertension or hyperlipidemia were excluded. Consented subjects underwent biomarker analysis and pulse wave analysis using the HDI/Pulse Wave CR-2000 Cardiovascular Profiling System and pulse contour analysis using the Endo-PAT2000 system. Biomarkers and functional test markers were compared between cases and controls using T-tests and Wilcoxon Rank-Sum tests. Results: Mean age (61.7 vs 58.8 years), body mass index (27.4 vs 26.2 kg/m^2), race (93% vs 92% Caucasian), and tobacco use (100% nonsmokers) were similar between cases and controls, respectively. Mean systolic blood pressure (BP) was elevated in cases (128.3 mmHg vs 114.5 mmHg, p=0.0006). There were no differences in lipid profiles. Median ultrasensitive estradiol levels were reduced in cases (2 vs 15 pg/mL, p<0.0001). Median high sensitive C-reactive protein was significantly elevated in cases (4146 vs 1406 ng/L, p=0.05). There were no differences seen in markers of hemostasis or endothelial damage, including circulating endothelial cells, vascular cell adhesion molecule, P-selectin. Median large artery elasticity (12.5 vs 15.1 ml/mmHg, p=0.02), small artery elasticity (5.2 vs 6.7 ml/mmHg, p=0.04), and endoPAT ratio (0.8 vs 2.6, p<0.0001) were significantly reduced in breast cancer survivors on AIs as compared to controls. There was no correlation between use of chemotherapy, radiation therapy, type of AI, or duration of AI use and endothelial function among the cases. When adjusting for differences in BP, endoPAT ratio continued to remain significantly decreased in breast cancer survivors (0.8 vs 2.6, p<0.0001).

Conclusion: Postmenopausal women with breast cancer on AIs have reductions in endothelial function, a predictor of adverse cardiovascular disease (acute coronary syndrome, chest pain, myocardial infarction, cardiac death). With the growing trend that longer duration of endocrine therapy is needed, further work is needed to confirm these findings.
Title: BRCA1 methylation status, silencing and treatment effect in the TNT trial: A randomized phase III trial of carboplatin compared with docetaxel for patients with metastatic or recurrent locally advanced triple negative or BRCA1/2 breast cancer (CRUK/07/012)

Tutt A, Cheang MCU, Kilburn L, Tovey H, Gillett C, Pinder S, Lanchbury J, Abraham J, Barrett S, Barrett-Lee P, Chan S, Gazinska P, Grigoriadis A, Kernaghan S, Hoadley K, Gutin A, Harper-Wyne C, Hatton M, Owen J, Parker P, Roylance R, Shaw A, Smith I, Thompson R, Timms K, Wardley A, Wilson G, Harries M, Ellis P, Ashworth A, Perou C, Bliss J, Rahman N, Brown R and On Behalf of the TNT Trial Management Group and Investigators. Institute of Cancer Research, Breast Cancer Now, London, United Kingdom; Institute of Cancer Research Clinical Trials & Statistics Unit (ICR-CTSU), London, United Kingdom; King's College London School of Medicine, London, United Kingdom; Myriad Genetics, Inc, Salt Lake City, UT; Velindre NHS Trust Cancer Centre, Cardiff, United Kingdom; The Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom; Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom; Breast Cancer No2 Unit, Guys & St Thomas NHS Trust, Kings College London; Lineberger Comprehensive Cancer Center, The University of North Carolina at Chapel Hill, Chapel Hill, NC; Maidstone and Tunbridge Wells NHS Trust, Maidstone, United Kingdom; Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom; King's College London School of Medicine and Francis Crick Institute, London, United Kingdom; University College London Hospitals NHS Foundation Trust, London, United Kingdom; Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; The Royal Marsden NHS Foundation Trust, London, United Kingdom; BME Cancer Communities, Nottingham, United Kingdom; The Christie NHS Foundation Trust, Manchester, United Kingdom; UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA; The Institute of Cancer Research, London, United Kingdom and Imperial College London, London, United Kingdom.

Body: Background
TNT previously reported that patients(pts) with advanced triple negative breast cancer(TNBC) and germline BRCA1/2(gBRCA+) mutations are more likely to respond to carboplatin(C) than to docetaxel(D), and have longer progression-free survival with C. Here, we report results from a pre-planned biological analysis to test whether BRCA silencing or methylation status confer sensitivity to platinum.

Methods
Pts eligible for TNT had ER-, PgR-, HER2- BC or were known gBRCA+(any ER/PgR/HER2). Pts were randomized to C(AUC 6 q3wk) or D(100mg/m2 q3wk) for 6-8 cycles or until disease progression if sooner, with crossover possible on progression. Blood and archival tissue samples were requested for BRCA1/2 genotyping, central analysis of TN and DNA repair deficiency biomarkers. Primary endpoint was intention-to-treat objective response rate(ORR) up to cycle 6. BRCA1 mRNA level was estimated from whole-genome total RNA sequencing(RNA-Seq). BRCA1 methylation analysis was quantified by bisulfite sequencing. A methylation score for the sample was computed as percentage of methylated reads relative to total number of reads that were either methylated or not methylated for CpG sites. A sample with a score >10% was considered methylated(BRCA1 meth). a BRCA1 mRNA level "silenced" subgroup(BRCA1 silencing) was defined as value of log2(mRNA)<8.4, based on bimodal distribution.

Results
212 and 191 pts' samples were assessed for BRCA1 methylation and mRNA levels. 33 pts (15.6%) were found to be BRCA1 meth. Pts with BRCA1 meth had a better response to D (42%, 95%CI: 20, 64) than C (21%, 95%CI: -0.1, 43) absolute difference (C-D) -21% (95%CI: -52, 10); p=0.28), but not statistically significant. There was no evidence of a difference when gBRCA+ tumours were excluded.

31 pts (16%) had BRCA1 silencing. Concordant with BRCA1 meth, pts with BRCA1 silencing had a better response to D (65%, 95%CI: 42, 87) than C (29%, 95%CI: 4.9, 52) absolute difference (C-D) -36% (95%CI: -69, -3.3); p=0.07), with an odds ratio 0.22 (95%CI: 0.035, 1.2) in favor of D, interaction with treatment not significant (p=0.066).

19 pts with BRCA1 meth and BRCA1 silencing had a better response to D (60%, 95%CI: 30, 90) than C (22%, 95%CI: -5.0, 49) absolute difference (C-D) -38% (95%CI: -79, 2.9) in favor of D (p=0.17), and the interaction was not significant (p=0.15).

Further exploratory analyses examining any relationship between a response to C and new cutpoints for BRCA1 meth or BRCA1 mRNA level did not suggest any evidence of a signal.
Conclusion
Our data did not support a priori hypotheses that *BRCA1* methylation or silencing would be associated with a greater response to C than D, which is consistent with other reports in ovarian cancer. As *BRCA1* methylation will not always lead to significant silencing or be the only cause of low *BRCA1* gene expression, exploratory analysis is investigating the interaction of BRCA silenced group with D sensitivity. RNA-seq is ongoing and results from the final database will be presented.
Title: The efficacy and safety of the addition of ibandronate to adjuvant hormonal therapy in postmenopausal women with hormone-receptor positive early breast cancer. First results of the TEAM IIB trial (BOOG 2006-04)

Body: Background:
Results of clinical trials concerning adjuvant bisphosphonates for the prevention of (bone) metastases in patients with early breast cancer are conflicting. A recent large meta-analysis, however, suggests that bisphosphonates reduce the incidence of (bone) metastases and improve skeletal-related events in early breast cancer patients. Subgroup analyses show that postmenopausal women seem to benefit the most. In this subgroup a modest overall survival benefit was observed with the addition of adjuvant bisphosphonates to standard adjuvant systemic therapy (EBCTCG, Lancet, 2015). TEAM IIB, a randomized phase III study (ISRCTN17633610), prospectively investigates the value of the addition of ibandronate to adjuvant hormonal therapy in postmenopausal women with hormone-receptor-positive breast cancer.

Methods:
Postmenopausal women with stage I-III breast cancer and an indication for adjuvant hormonal treatment were randomized to receive at least 5 years of hormonal therapy (tamoxifen followed by at least 2-3 years exemestane, or in case of high risk at least 5 years of exemestane) with or without ibandronate 50mg orally, once daily for three years. Primary endpoint was disease-free survival (DFS). Secondary endpoints included time to and rate of bone metastases, other sites of recurrence, overall survival and safety. The study was amended because of slower than anticipated accrual and the sample size calculations were amended accordingly in June 2009. To detect a hazard ratio (HR) of 0.615 with a 2-sided alpha of 0.05 and a power of 0.8, 139 DFS-events were required in the intention-to-treat population.

Results: Between February 2007 and May 2014, 1116 patients were enrolled in 37 hospitals in the Netherlands of whom 40% had positive axillary lymph nodes and 56% of all patients received (neo)adjuvant chemotherapy (>95% anthracyclines, 69% taxanes). Baseline characteristics were well balanced. At September 9, 2016, 143 DFS events had been reported. Median follow-up was 4.6 years and 80 patients were still on ibandronate treatment. Adherence to 3 years ibandronate was 67%, 21 patients randomized to receive ibandronate never started. 19 patients, of whom 9 in the control group were excluded because of major ineligibility.

In the ibandronate treated group 3-year DFS was 94.4% versus 90.8% in the control group (HR 0.84; 95% confidence interval [CI] 0.60-1.17). In total, 48 patients in the ibandronate versus 45 in the control group died, of whom 18 (37,5%) versus 28 (62,2%) of breast cancer. 3 years after randomization 1.6% of ibandronate treated patients developed bone metastases versus 4.6% in patients who were treated with adjuvant hormonal therapy only (HR 0.76; [CI] 0.43-1.32). 14 (29,2%) versus 9 (20%) of patients died because of secondary malignancies respectively.

There was no significant difference in creatinine clearance during the first three years after randomization. 36 Serious adverse events (SAEs) were reported in the ibandronate group versus 51 in the control group. Of patients randomized to ibandronate 4 developed osteonecrosis, but without residual complaints.

Conclusion: So far, at a median follow-up of 4.6 years there is no statistically significant benefit from adding ibandronate to adjuvant hormonal treatment in postmenopausal women with hormone-receptor positive early breast cancer. However, since hazard rates are in favor of ibandronate longer follow-up is warranted before final conclusions can be drawn.
**Title:** DBCG 07-READ: A randomized phase III trial comparing six cycles of docetaxel and cyclophosphamide (DC) to three cycles of epirubicin and cyclophosphamide followed by three cycles of docetaxel (EC-D) in patients with early breast cancer

**Body:**

**Background:**
DBCG 07-READ was designed to compare sequential EC followed by D with DC in patients with early, TOP2A normal breast cancer as a retrospective evaluation of the DBCG 89D trial suggested that these patients would not benefit from an anthracycline.

**Methods:**
This is a multicenter open-label randomized phase III trial. Three groups of women were eligible following completely resected unilateral invasive TOP2A normal (TOP2A gene to centromere 17 ratio of 0.8 to 2.0) breast cancer by mastectomy or breast conserving surgery in combination with axillary clearance or a negative sentinel node biopsy; 1: Age 18 to 39 years; 2: Age 40 to 75 years and estrogen receptor (ER) negative (<10% positive) and/or HER2 positive tumor; and 3: Age 40 to 59 years and ER ≥ 10% positive and either node positive, ductal carcinoma and grade II-III, or tumor size > 20 mm. Eligible patients were required to have a Charlson Comorbidity (CC) Index ≤ 2 and to be without signs of distant metastasis. Patients were randomized to receive 6 cycles of DC (docetaxel 75 mg/m2 and cyclophosphamide 600 mg/m2) every 3 weeks or 3 cycles of EC (epirubicin 90 mg/m2 and cyclophosphamide 600 mg/m2) followed by 3 cycles of D (docetaxel 100 mg/m2) every 3 weeks. In case of a CC Index of 1 or 2 chemotherapy was administered at a reduced dose-intensity. Adjuvant endocrine treatment, trastuzumab and radiotherapy were administered according to the guidelines of the DBCG. The primary endpoint was disease-free survival (DFS), and secondary endpoints were overall survival (OS) and distant disease-free survival (DDFS).

**Results:**
Between July 2008 and December 2012 we (12 DBCG centers) randomly assigned 2006 eligible patients to DC (N=1008) or EC-D (N=998). Patient and tumor characteristics were balanced by treatment groups. The median estimated potential follow-up is 5.4 years and the 5-year DFS was 88.0%; 95% CI 85.8 to 90.0 in the EC-D arm and 87.9%; 95% CI 85.7 to 89.9 in the DC arm. No significant difference in the risk of DFS events HR=1.03; 95% CI 0.80 to 1.32; p=0.84 or mortality HR=1.11; 95% 0.79 to 1.56; p=0.55 was observed in the intent to treat analysis. Patient-reported toxicity will be compared for the two chemotherapy regimens.

**Conclusion:**
The READ trial gives evidence to support no outcome benefit from anthracycline in patients with TOP2A normal early breast cancer.
Title: The PI3K inhibitor, taselisib, has enhanced potency in PIK3CA mutant models through a unique mechanism of action

Body: Alterations of the phosphoinositide-3 kinase (PI3K)/Akt signaling pathway occur broadly in cancer via multiple mechanisms including mutational activation of the PIK3CA gene. The dysregulation of this pathway has been implicated in tumor cell growth and survival, thus PI3K is a promising therapeutic target with multiple inhibitors in clinical trials. Taselisib (GDC-0032), a novel, oral, selective inhibitor of p110alpha, sparing inhibition of p110beta, is more potent against cancer cells bearing mutations in the PIK3CA gene than those with wildtype PIK3CA. The mechanism leading to this enhanced mutant selectivity is revealed in these preclinical studies.

Uniquely among PI3K inhibitors, taselisib has a gain of potency in PIK3CA mutant SW48 isogenic cells compared to wildtype SW48 parental cells. Pathway inhibition and increased apoptosis are associated with the enhanced activity observed in PIK3CA mutant cells. In PIK3CA mutant cell culture-derived and patient-derived xenograft (PDX) models taselisib induces tumor regressions. In comparison to other clinical-stage PI3K inhibitors, taselisib confers superior anti-tumor activity in PIK3CA mutant xenografts when treated at a Maximum Tolerated Dose (MTD) in vivo.

We have discovered that taselisib has a dual mechanism of action, both blocking kinase signaling and inducing down-regulation of the mutant p110alpha protein level in a dose-dependent and time-dependent manner. Taselisib treatment leads to the specific degradation of mutant p110alpha without significant change in wildtype p110alpha protein in cultured cells and in mutant xenograft models including PDX. Other clinical PI3K inhibitors, including PI3Kalpha selective and pan-PI3K inhibitors are unable to induce degradation of mutant p110 alpha.

The taselisib-induced degradation of mutant p110a protein is ubiquitin-mediated and proteasome-dependent. These unique mechanistic effects of taselisib are most pronounced when comparing signaling suppression and p110a protein levels at 24 hours vs. 1 hour of drug exposure in PIK3CA mutant cell lines. This discovery indicates that PI3K inhibitors which trigger degradation of mutant p110a protein can more effectively suppress the signaling pathway in response to feedback, and may result in greater activity and improved therapeutic index.
Comprehensive comparison of prognostic signatures for breast cancer in TransATAC

Centre for Cancer Prevention, Wolfson Institute of Preventive Medicine, QMUL, London, United Kingdom; Institute of Cancer Research, London, United Kingdom; BrustZentrum Klinik St. Anna, Lucerne, Switzerland; SividoN Diagnostics, Cologne, Germany; NanoString Technologies, Seatlle, WA; Massachusetts General Hospital, Boston, MA; bioTheranostics, San Diego, CA; Genomic Health, Redwood City, CA and NHS Greater Glasgow and Clyde, Glasgow, United Kingdom.

Background: A number of prognostic signatures have been developed for the prediction of breast cancer recurrence in the past decade. We have developed two signatures (Clinical Treatment Score (CTS), four immunohistochemical markers (IHC4)) and validated four prognostic signatures (Oncotype Dx Recurrence Score (RS), PAM50-based Prosigna (ROR), Breast Cancer Index (BCI), and EndoPredict (EPclin)) in the TransATAC cohort. Here, we compare the prognostic performance of these six signatures for distant recurrence (DR) in years 0-10, and specifically in years 5-10 after treatment cessation.

Methods: 1231 postmenopausal women with hormone receptor positive and HER2-negative breast cancer had at least one test performed. Of these, 818 women had data on all six signatures available. IHC4, RS and BCI (linear) are molecular only signatures whereas CTS, ROR and EPclin include clinicopathological factors. The primary endpoint was DR and the primary objective was to compare the prognostic value of the six signatures in terms of DR for years 0-10, 0-5, and 5-10. Secondary objectives included the comparison of the prognostic performance for node-negative and node-positive patients separately and the additional prognostic performance of each signature to the others. Likelihood ratio statistics (LR-χ²) were used to assess the prognostic information of each signature alone or in combination with other signatures.

Results: Median follow-up for this analysis was 9.94 years (IQR 8.01-10.09) and a total of 126 DR were recorded. 818 women with HER2-negative disease for whom data of all six signatures were available were included in this analysis. For all patients, CTS and EPclin were the most prognostic signatures in years 0-10 (CTS: LR-χ²=124.9; EPclin: LR-χ²=116.2) and years 5-10 (CTS: LR-χ²=59.6; EPclin: LR-χ²=56.8) in the univariate analysis. The other four signatures performed similarly well in years 0-5, but of those only BCI and ROR provided substantial prognostic information in years 5-10 (BCI: LR-χ²=25.3; ROR: LR-χ²=43.8). In multivariate analyses comparing the added information of the molecular signatures over CTS, IHC4 and BCI provided the most information (IHC4: ∆LR-χ²=19.0; BCI: ∆LR-χ²=19.8). In node-negative patients (72.3%), the ROR showed the most prognostic value in years 0-10 (LR-χ²=48.6) and years 5-10 (LR-χ²=31.3) whereas the RS was least prognostic in this patient group. For patients with node-positive disease (27.7%), the CTS and EPclin were the most prognostic and the other four signatures provided much less prognostic information for this patient population (data not shown).

Conclusion: Overall, the CTS and EPclin were the most prognostic signatures for DR and also added significant prognostic value to the other scores in women with HER2-negative disease, primarily due to the incorporation of nodal status in these signatures. For women with node-negative disease, the ROR, BCI, and EPclin signatures provided most prognostic value whereas for those with positive nodes CTS and EPclin were most prognostic. Our analyses showed that the inclusion of clinic-pathological factors into gene signatures is highly important for deriving an accurate prognostic assessment, particularly in node-positive patients.
Title: Double blinded validation study to assess performance of IBM artificial intelligence platform, Watson for oncology in comparison with Manipal multidisciplinary tumour board – First study of 638 breast cancer cases

Somashekhar SP, Kumarc R, Rauthan A, Arun KR, Patil P and Ramya YE. Manipal Comprehensive Cancer Centre, Manipal Hospital, Bangalore, Karnataka, India.

Body: Background:
IBM Watson for Oncology (WFO) developed in collaboration with Memorial Sloan Kettering Cancer Centre is a cognitive computing system able to extract structured data from free text documents using natural language processing (NLP). It is a technology platform that uses NLP and machine learning to reveal insights from large amounts of unstructured data. Currently WFO provides treatment options only for breast, lung and colorectal cancers. In the present study we try to evaluate concordance of WFO treatment recommendations with Manipal multidisciplinary tumor board (MMDT), a quaternary health care centre for 638 breast cancer cases.

Materials and Methods:
MMDT treatment recommendation and relevant clinic-pathological data of 638 breast cancer cases both localised (514) and metastatic (124) disease which were treated in last 3 years was collected and the collected data of all the patients was entered in WFO. The treatment recommendations & the time required to enter the data and the time taken by WFO to give recommendations after analyzing the data was recorded. Treatment recommendation by WFO came in three categories with colour coding green, orange and red. Green is the RECommended standard treatment (REC), Orange is For Consideration (FC) and Red is Not RECommended (NREC). Concordance between MMDT and WFO was analysed for all cases as per stage and receptor status.

Results:
Of the treatment recommendations given by MMDT, WFO provided 46.4% in REC, 26.1% in FC, 21.5% in NREC. Nearly 73% of the MMDT treatment recommendations were in WFO REC and WFO-FC group. However 6% of the treatment provided by MMDT was not available with WFO. Treatment recommendations from WFO were concordant with MMDT in nearly 80% of time in non-metastatic and 45% in metastatic disease. In subset analysis of breast cancer with respect to receptor status the WFO-REC treatment was high with triple negative disease with 67.9% and least with Her 2 neu negative disease with 35%. Across all subsets with respect to receptor status concordance was better with non-metastatic disease over metastatic disease which was statistically significant. The mean time taken to collect the data and enter was 20 minutes which gradually decreased with acquaintance after 10 cases to 12 minutes. Metastatic disease took longer time (5-7 minutes more) over localized disease in all the groups. WFO took a median of 40 seconds to capture, analyze and give the treatment recommendations.

Conclusions:
WFO-REC and WFO-FC together were in 73 % of time concordant with the MMDT treatment recommendations. However with respect to metastatic disease and hormone positive Her 2 neu –ve disease there still needs to be lots of improvement from WFO. WFO is a step towards personalized medicine. It should be kept in mind that WFO will be only an assisting tool and it will never be able to replace the patient-doctor relationship which is a very essential component of treating a patient suffering with cancer. WFO will be a reliable artificial intelligence tool for every cancer center and its multidisciplinary tumor board and will change the quality of care in oncology.
Title: A phase II study of PD-L1 and CTLA-4 inhibition and immunopharmacogenomics in metastatic breast cancer

Body: Background
A hallmark of cancer is its ability to evade the immune system, however, it can be harnessed to detect and destroy cancer cells through inhibition of immune checkpoints such as CTLA-4 and PD-L1. This strategy has complementary and non-redundant mechanisms resulting in immune activation and antitumor synergy; progression free survival benefit has already been demonstrated in melanoma. A critical barrier in developing immunotherapies, however, is the identification of predictive biomarkers of response to therapy. Immunopharmacogenomic biomarkers, such as mutational burden, neoantigen profiles, and T cell receptor sequencing will elucidate the molecular interface between cancer and immune system, and may predict those most likely to benefit.

Methods
A single arm Phase II study was designed to determine the efficacy of PD-L1 and CTLA-4 inhibition and effects on immunopharmacogenomic dynamics in patients with metastatic breast cancer. The primary endpoint of this proposal is to investigate the response rate of the PD-L1 inhibitor, durvalumab, and the CTLA-4 inhibitor, tremelimumab, in metastatic breast cancer; secondary endpoints will examine the T cell receptor repertoire clonality, tumor mutational burden and neoantigen profiles. A total of 30 patients will be enrolled and treated with durvalumab 1500mg IV and tremelimumab 75mg IV monthly for 4 doses, then durvalumab 750mg every 2 weeks for 18 doses to complete 1 year of therapy with the option to renew therapy for an additional year; biopsies and blood at baseline and 2 months will be collected to assess immunopharmacogenomic biomarkers. Patients are eligible if they have triple negative or ER-positive breast cancer and have progressed on at least one line of chemotherapy and standard endocrine therapy if applicable. This is the first study to investigate immunopharmacogenomic biomarkers of response to dual checkpoint blockade in patients with metastatic breast cancer.
2016 San Antonio Breast Cancer Symposium

Publication Number: OT3-01-02

**Title:** CNIO-BR-008 trial: Reversion of T-cell exhaustion caused by chronic treatment with hypoxia-inducing antiangiogenic treatment by durvalumab in HER2-negative breast cancer: A pilot proof-of-concept trial

Quintela-Fandino M, Manso L, Mouron S, Lopez-Acosta JF F, García-Saenz JA A, Holgado E, Pascual-Martínez T, Medicina L, Guerra J, González-Cortijo L and Mañes S. CNIO - Spanish National Cancer Research Center, Madrid, Spain; H12O - Hospital 12 de Octubre, Madrid, Spain; HSCC - Hospital Clínico San Carlos, Madrid, Spain; HRYC - Hospital Ramón y Cajal, Madrid, Spain; HLP - Hospital La Princesa, Madrid, Spain; HUF - Hospital Universitario Fuenlabrada, Madrid, Spain; HQ - Hospital Quiron, Madrid, Spain and CNB - Centro Nacional de Biotecnología, Madrid, Spain.

**Body:** Background: The role of immune checkpoints in tumor progression is less relevant in breast cancer than in other malignancies. However, in preclinical experimentation we found a niche for immune checkpoint inhibitors. In an immunocompetent model of HER2-negative breast cancer (MMTV-PyMT) we observed that antiangiogenic agents may induce either a tumor normoxic or hypoxic adaptation. Normoxic adaptation leads to a therapeutically exploitable dependence on mitochondrial metabolism (Cell Rep 2016; 15: 1-14). Hypoxic adaptation (usually caused by monoclonal antibody type antiangiogenics) induces an increase in PGE2 and PGA synthesis, followed by a switch of the tryptophan metabolism from 5HIAA to kynurenine that culminates in differentiation of naive T-cells to Tregs and expression of PD-L1 in the hypoxic areas. The exhausted T-cell response observed in this model can be restored with PD-L1 inhibitors. We sought to prove the relevance of T-cell exhaustion an its reversibility by the anti-PD-L1 antibody durvalumab in patients receiving chronic bevacizumab (Bev).

**Trial design**
Single-arm, prospective, multicentric, phase II open-label trial. Patients receiving Bev maintenance after a chemotherapy+Bev regimen administered in the first line of metastatic disease that experience disease progression (PD) during maintenance will be candidates. The treatment will start by adding durvalumab (10 mg/kg q2w) to the ongoing Bev (15 mg/kg q3 w). Patients will undergo serial tumor biopsies, tumor-cfDNA sequencing (baseline and progression), and immunophenotyping (baseline and q4w). RECIST/I-RECIST and NCI CTC AE V4.03 criteria will be used for assessing disease response and toxicity.

**Elegibility criteria**
Women >18 year old diagnosed of HER2-negative advanced breast cancer; 2) have received chemotherapy plus Bev for the first line treatment and experienced PR, CR or SD, 3) followed by maintenance with three-weekly Bev in monotherapy for at least 6 weeks before diagnosis of PD. 4) Concurrent hormonal therapy is allowed for ER+ patients, but reception of previous immunotherapy is precluded. 5) Adequate organ function defined according to standard parameters.

**Specific aims**
Primary:
1) To determine the relative percentages of innate and adaptive immune cell subpopulations and ascertain the status of T-cell function and polarization by multiparametric flow cytometry in patients with acquired resistance against Bev
2) To assess the reversibility of the abnormalities evidenced in (1) by durvalumab
3) To determine the disease control rate of the combination, and its relationship with (1) and (2)
Secondary:
4) To determine potential tumor neoantigens generated by chronic tumor hypoxia secondary to the antiangiogenic treatment.

**Statistical methods**
The sample size is calculated on the basis of the expected change in the Treg percentage in peripheral blood (10%), with an alpha and beta errors of 5% and 20% respectively. The minimum number of patients necessary to observe a 10% decrease is 25. Changes in lymphocytes will be compared with intra-subject measurements and Z-scores.

**Accrual:** 2 of 25 (target accrual) patients have been recruited.

**Contact info:** mquintela@cnio.es.
Title: A phase I trial of the safety and immunogenicity of a DNA plasmid based vaccine (WOKVAC) encoding epitopes derived from three breast cancer antigens (IGFBP2, HER2, and IGF1R) in patients with breast cancer

Childs JS, Higgins DM, DeShong K, Heckman-Stoddard BM, Wojtowicz ME, Stanton SE, Bailey HH, Wisinski KB and Disis ML. University of Washington, Seattle, WA; University of Wisconsin, Madison, WI and NCI, NIH, Bethesda, MD.

Body: Background: Three proteins insulin like growth factor binding protein 2 (IGFBP2), human epidermal growth factor receptor 2 (HER2), and insulin like growth factor receptor-1 (IGF1R) are overexpressed in pre-invasive and high risk breast lesions and are associated with progression to invasive breast cancer. These proteins are immunogenic and elicit both humoral and cellular immunity in breast cancer patients. It is hypothesized that immunization with a plasmid vaccine (WOKVAC) targeting antigens from these proteins will be safe and immunogenic. WOKVAC has been designed to include extended sequences of the immunizing antigens that are predominantly associated with eliciting Type I immune responses. Type I immunity results in immune cells called T-cells secreting high levels of inflammatory cytokines (called Th1) that stimulate tumor destruction as well as the generation of cytotoxic T-cells that can directly kill the tumors.

Trial design: Phase I dose escalation study of 3 doses of WOKVAC admixed with 100mcg of GM-CSF. Patients will be assigned sequentially to one of three arms (10 patients/arm): Arm 1=150mcg, Arm 2=300mcg, Arm 3=600mcg. Each dose arm will have a staggered enrollment to assess toxicity. If the Arm 1 dose is determined to be safe, Arm 2 patients can be enrolled. If the Arm 2 dose is safe and immunologically more efficacious than Arm 1 then Arm 3 patients can be enrolled. Study treatment includes 3 monthly vaccines, two evaluations at 1 and 6 months post vaccine and a 5 year follow-up to collect reports from the patient's primary oncologist. Toxicity is assessed at baseline through the end of the study. Serial blood draws for immunologic monitoring is done.

Eligibility criteria: Patients with non-metastatic, node positive, HER2 negative breast cancer that is in remission and defined as no evidence of disease. Patients must have a good performance status, be at least 28 days from last cytotoxic chemotherapy and/or radiotherapy and 28 days from any use of systemic steroids.

Specific aims: (1) Determine safety of 3 escalating doses of WOKVAC, (2) Determine the most immunogenic dose, (3) Determine whether a WOKVAC Th1 polyepitope plasmid based vaccine elicits a persistent memory T-cell and (4) Determine whether WOKVAC vaccination modulates T regulatory cells and myeloid derived suppressor cells.

Statistical methods: (1) Safety will be assessed per NCI CTCAE v. 4.0, (2) Immunogenicity will be defined by the magnitude of the Th1 IFN-gamma antigen specific immune response. Successful immunization is a protein specific IFN-g precursor frequency greater than 1:20,000 PBMC for each antigen or 2 fold increase if baseline immune response (3) The IGFBP2, HER2, and IGF1R specific IFN-g/IL-10 ratios by ELISPOT will be evaluated to determine that a predominantly Th1 immune response is stimulated, and (4) Humoral immune response will be measured by ELISA and serum antibody avidity for IGFBP2, HER2, and IGF1R to determine an avidity index (AI) before and after vaccination.

Targeted Accrual: 30 patients

Title: VADIS trial: Phase II trial of the nelipepimut-S peptide vaccine in women with DCIS of the breast

Mittendorf EA A, Plitas G, Garber J, Crew K, Heckman-Stoddard B, Wojtowicz M, Vornik L, Peoples GE E and Brown PH H. The University of Texas MD Anderson Cancer Center; Memorial Sloan Kettering Cancer Center; Dana Farber Cancer Insitute; Columbia University; National Cancer Institute and Cancer Insight.

Body: Background: Our group has been investigating vaccination strategies in breast cancer. Specifically, we have been evaluating HER2-derived peptide vaccines including nelipepimut-S+GM-CSF administered adjuvantly to breast cancer patients who have been rendered disease-free with standard of care therapy but are at high risk for recurrence. Early phase clinical trials showed an approximately 50% reduction in relative recurrence risk in vaccinated patients. Based on these data, nelipepimut-S+GM-CSF is being evaluated in a phase III registration trial. Having shown the vaccine to be safe, effective in stimulating an antigen-specific immune response and potentially having clinical efficacy in the setting of secondary prevention, the current study was initiated to evaluate vaccination in DCIS patients. This trial represents an initial step to move the vaccine into the primary prevention setting.

Trial Design: Phase II, randomized, single-blind study. Patients will be randomized 2:1 to receive vaccine or GM-CSF alone. After enrollment, patients will receive 3 inoculations administered every other week preoperatively followed by surgery then completion of the vaccination series (3 additional inoculations) in the adjuvant setting.

Eligibility: The trial will enroll pre- or post-menopausal women with a diagnosis of DCIS made by core biopsy. The area of radiographic abnormality must measure at least 1 cm. Because the vaccine is a MHC class I, CD8+ T cell-eliciting vaccine, it is HLA restricted, and patients must be HLA-A2+ to enroll. Participants must also have an ECOG performance status <2, adequate cardiac, kidney and liver function and be willing to comply with all study interventions and follow-up procedures.

Specific Aims: The trial's primary endpoint is to evaluate for nelipepimut-specific CD8+ T cells in the peripheral blood of vaccinated patients compared to patients receiving GM-CSF alone. Secondary endpoints include evaluating toxicity; determining the immune response in vivo by DTH, in vitro by evaluating for epitope spreading to other tumor antigens, and importantly in the tumor by assessing the degree of lymphocytic infiltration in surgically resected specimens. The extent of HER2 expression, Ki67 and cleaved caspase 3 in the resected specimen will also be assessed.

Statistical Methods: A total of 108 DCIS patients will be consented and screened for eligibility. 48 (45%) are expected to be HLA-A2 positive. These 48 patient will be randomized 2:1 to vaccine or GM-CSF alone groups. Accounting for 10% attrition rate and for an approximately 5% non-evaluable sample rate, we expect to have 40 evaluable patients, 27 in the vaccine group and 13 in the GM-CSF alone group, that have baseline, pre-surgery, and post-surgery measures of nelipepimut-S-specific CD8+ T cells. We will have 82% power to detect a significant increase in nelipepimut-S-specific CD8+ T cells in the vaccine group versus the GM-CSF alone group.

Contact Info: The study is accruing at four sites to include Columbia University, Dana Farber Cancer Institute, MD Anderson Cancer Center and Memorial Sloan Kettering Cancer Center. Additional information can be obtained from the overall study PI, Dr. Elizabeth Mittendorf (eamitten@mdanderson.org). NCT0236582.
Title: Functional MRI signatures of immune response to targeted breast cancer therapy

Gadi VK, Stanton S, Dintzis SM M, Calhoun KE E, Hippe DS S and Partridge SC C. University of Washington, Seattle, WA and Fred Hutchinson Cancer Research Center, Seattle, WA.

**Body: Background:** Emerging data has shown that the immune system participates in both tumor development and tumor elimination and control. In breast cancer, activation of the immune system may mediate the effects of several anticancer drugs. In HER2+ and triple negative breast cancers, even 10% increases in tumor infiltrating lymphocytes (TILs) predict improved prognosis to adjuvant chemotherapy. Furthermore, the monoclonal antibody trastuzumab is known to increase peripheral Th1 immunity in women with HER2+ breast cancer, which may be reflected by increased TILs. An imaging approach to measure and monitor immune response would provide an essential non-invasive tool to select appropriate therapies based on an individual's response. Dynamic contrast-enhanced (DCE) MRI, reflecting blood flow and capillary permeability, and diffusion weighted (DW) MRI, reflecting cellularity, hold unique potential to provide quantitative imaging markers of therapy-induced immune response in breast tumors.

**Trial Design:** We propose to use trastuzumab to invoke immune response in patients with HER2+ tumors. Each subject will undergo a multiparametric MRI exam (with DCE and DW-MRI) and tissue sampling before and after a single dose of targeted anti-HER2 therapy with trastuzumab, prior to surgery. Pretreatment tissue will be obtained from the diagnostic core biopsy, and post-trastuzumab tissue will be collected from a research biopsy or the surgical excision, requiring at most a single additional biopsy. A variety of quantitative parameters will be extracted from the MRI scans. Whole tumor characterization will be performed, to calculate histogram-based metrics and second order textural features. Functional MRI features will be compared with histologic assessment of TILs, VEGF expression, and other immune response markers in tumors treated with HER2-targeted therapy. After the study window, patients will undergo standard of care treatment at the discretion of their physician.

**Specific Aims:** The primary objective will be to identify quantitative MRI markers of immune response to HER2-targeted treatment. We will implement a high-resolution multiparametric MRI approach and determine whether early changes on MRI after a preoperative run-in dose of trastuzumab correlate with tumor immune response markers as measured by histologic assessment.

**Statistical Methods:** The magnitude of response will be determined for individual MRI and histologic markers following one cycle of trastuzumab, and Pearson and Spearman correlation coefficients will be used to assess associations between changes in MRI and histologic markers. With 50 patients, we will have 80% power to detect a significant correlation between MRI and histologic markers as small as \( r = 0.39 \) (\( R^2 = 15\% \)), based on a 2-sided test of the null hypothesis \( r = 0 \) at the 0.05 significance level.

**Accrual:** Three patients have been accrued to date, with a target of 50 HER2+ patients. Patients may consent to either 1) preoperative run-in of a single cycle of anti-HER2 treatment or 2) neoadjuvant targeted anti-HER2 only treatment regimen (e.g., co-enrollment in TBCRC 026 or comparable trial), either of which allows for monitoring at pre and post 1 cycle of anti-HER2 treatment.

Title: A phase I/IIa study of the whole-cell vaccine BriaVax™ in metastatic or locally recurrent breast cancer patients (NCT00095862)

Wiseman CL L and Lacher M. Briacell Therapeutics, Berkeley, CA.

Body: BACKGROUND: BriaVax™ (formerly SV-BR-GM-1) is a breast cancer cell line transfected to release GM-CSF. Under FDA BB-IND 10312, the vaccine was tested in 3 metastatic breast, 1 metastatic ovarian cancer patients refractory to previous therapy. Patients received 20 million viable cells ID at 4 sites 48-72 hours after low-dose cyclophosphamide, 300 mg/m^2. Mean cell count was 22.8 x10^6 (18.8-27.6). Mean viability was 90.6%, (84-94%). Interferon-alpha (10,000 u) was injected into each inoculation site after 48 and 96 hrs. The protocol permitted 3 inoculations at 2 week intervals, then, if not showing clearly progressive disease, 3 more inoculations monthly. All patients were stable after 3 injections (2 months). However, Pt A002 enjoyed complete tumor regression of a progressing lung metastasis and near-complete response of multiple breast lesions (see below). Nonetheless, she relapsed widely 3 months after finishing the sixth and final injection per protocol. After obtaining FDA permission inoculations resumed. All metastases, including CNS, again showed prompt but subtotal regression after 3 immunizations (see Wiseman C and Kharazi A; The Breast Journal 2006). Toxicity was minimal and the overall survival of the 4 patients was 35 months.

TRIAL DESIGN: 9 patients will be accrued, toxicity (and also response) will be reviewed; unless there are prohibitive serious adverse events, 15 more patients will then be accrued.

ELIGIBILITY: Inclusion Criteria: Patients must have histological confirmation of breast cancer with recurrent and/or metastatic lesions via investigational site. Patients with new or progressive breast cancer metastatic to brain will be eligible if they meet other conditions. Patients must be 18 years of age or older, have expected survival of at least 4 months, adequate performance status (ECOG 0-2). Patients may be maintained on hormonal therapy provided there is clear evidence of tumor progression and have provided written informed consent.

Exclusion Criteria: Concurrent or recent chemotherapy (within 3 weeks), XRT within 3 weeks, may have had immunotherapy in the past (off within 3 weeks), or general anesthesia/major surgery (within 3 weeks). Patients must have recovered from all known or expected toxicities from previous treatment and passed a treatment-free “washout” period of 3 weeks before starting this program (8 weeks for persons receiving nitrosourea or mitomycin). History of clinical hypersensitivity to GM-CSF, interferon, yeast, beef, or to any components used in the preparation of the experimental vaccine. Additional criteria to be provided on request.

SPECIFIC AIMS: To evaluate the number, frequency, duration, and relation of toxicity events to BriaVax™ (formerly designated as SV-BR-1-GM), as defined by CTCAE and additional tests; to evaluate tumor response and durability; to assess immune responses to vaccine; to archive blood and urine for future analysis; to measure quality of life with the SF-36 questionnaire.

For further information, call the Briacell Corporate Office (US) at 888-485-6340

Acknowledgments: Dr. Gerhard Bauer, Dr. Saeid Babaei, the St. Vincent Medical Center, and Dr. George Peoples for advice and guidance.
Title: POSITIVE: A study evaluating pregnancy and disease outcome and safety of interrupting endocrine therapy for young women with endocrine-responsive breast cancer who desire pregnancy (IBCSG 48-14/BIG 8-13)

Body: Background
Young breast cancer (BC) patients often face the disease before completing their family planning. The best available retrospective evidence suggests that pregnancy after BC does not negatively impact disease outcomes in patients with endocrine-responsive BC and is safe for offspring. However, given the possibility of prolonged adjuvant endocrine therapy (ET) (5-10 yrs), it is not feasible to wait until completion of therapy in many of these women and thus there is a need to explore the safety of temporary interruption of ET to allow pregnancy. To date, no prospective study has been conducted in young women attempting future pregnancy.

Trial Design
Young patients with endocrine-responsive early BC and pregnancy desire will interrupt ET for up to 2 yrs to attempt pregnancy. As resumption of menses and conception depends on many factors, e.g. patient’s age and adjuvant treatment received, the 2-yr interruption period is approximate, intended to include treatment wash-out (3 mos) conception (~3-6 mos), delivery (~9 mos), breast feeding (~6 mos). Patients will be strongly advised to resume ET as soon as pregnancy attempts are concluded and to complete the planned 5-10 yrs ET.

Major Eligibility Criteria
* Histologically-proven stage I-III endocrine-responsive BC.
* Age ≥ 18 and ≤ 42 years at enrollment.
* Adjuvant ET (SERM alone, GnRH analogue plus SERM or AI) for ≥18 mos but ≤30 mos, stopped within 1 mo prior to enrollment.
* Patient wishes to become pregnant.
* Premenopausal status at BC diagnosis.

Specific Aim
To assess the risk of BC relapse associated with temporary interruption of ET to permit pregnancy and to evaluate pregnancy success and offspring outcome.

Statistical Methods
A true risk of BC recurrence of 2% per year is assumed for patients who do not interrupt ET. With 500 patients enrolled in 4.0 yrs and an additional 1.6 yrs of follow up, there will be approximately 1600 patient-yrs of follow up and a median follow up of approximately 3 yrs at the time of the primary analysis, anticipated to occur 5.6 yrs after enrolment of the first patient. If the true risk of BC recurrence is 2% per yr, we anticipate 31 BC recurrences and an estimated 3-yr breast cancer free interval (BCFI) event of 5.6% (95% CI 4.0% to 7.9%).

Translational Research will investigate different ovarian function and uterine parameters; and circulating tumour DNA. FFPE tissue of the primary tumour will be collected to integrate different parameters related to biology of BC arising in young women. All material will be banked centrally.

Psycho-oncological Companion Study on fertility concerns, psychological well-being and decisional conflicts is mandatory in the US and open to interested centers elsewhere.

Accrual: Target: 500; Actual: 39 (30 Apr 2016)
Psycho-oncological Companion Study Accrual: Target: 200; Actual: 29 (30 Apr 2016)

Title: ENDEAR: A randomized international phase 3 study comparing the efficacy and safety of enzalutamide in combination with paclitaxel chemotherapy or as monotherapy vs placebo with paclitaxel in patients with advanced diagnostic-positive triple-negative breast cancer

Dent R, Schmid P, Cortes J, Kim S-B, Andre F, Abramson V, Cardoso F, Colleoni M, Morris P, Steinberg J, Tudor IC, Uppal H, Paton VE E, Peterson A and Traina TA A. National Cancer Centre Singapore, Singapore; Brighton and Sussex Medical School, Brighton, United Kingdom; Vall d’Hebron Institute of Oncology, Barcelona, Spain; Ramon y Cajal University Hospital, Madrid, Spain; Asan Medical Center, Seoul, Korea; Institut Gustave Roussy, Villejuif, France; Vanderbilt-Ingram Cancer Center, Nashville, TN; Breast Unit, Champalimaud Clinical Centre, Lisbon, Portugal; Istituto Europeo di Oncologia, Milan, Italy; Memorial Sloan Kettering Cancer Center, New York, NY; Astellas Pharma, Inc., Northbrook, IL and Medivation Inc., San Francisco, CA.

Body: Background: Enzalutamide (ENZA), a potent androgen receptor (AR) inhibitor, demonstrated clinical activity in patients (pts) with advanced triple-negative breast cancer (aTNBC) (NCT01889238). TNBC with AR-driven biology has been previously confirmed; however, using immunohistochemistry (IHC) to identify this pt subset is suboptimal for AR-directed treatment. A novel binary genomic signature (Dx + or –) that identifies AR-driven disease was developed for its potential to select pts who may benefit from ENZA. Clinical outcomes in a phase 2 trial utilizing a genomic signature (Dx) showed improvement in Dx+ vs Dx– subgroups with ENZA being well tolerated; fatigue was the only grade ≥3 AE with a ≥5% incidence (Table).

Data cutoff date, Sep 15, 2015. NR=not reached; Tx=treatment.

Preclinically, ENZA + paclitaxel (PAC) has been shown in an MBA-MB-453 xenograft model to significantly reduce tumor volume compared to either single agent. Phase 1b dose-finding studies of ENZA + taxane combinations have shown the combination to be generally well tolerated.\(^2\,^3\) The aim of this phase 3 study is to evaluate and compare the clinical benefit and safety of ENZA + PAC or ENZA vs PAC alone in pts with Dx+ aTNBC.

Methods: ENDEAR is an international, double-blind, randomized, placebo-controlled, 3-arm phase 3 study in pts with Dx+ aTNBC who previously received 0-1 prior regimen for advanced disease. A total of 780 pts will be randomized (1:1:1) to 1 of 3 treatment arms: (A) ENZA + PAC; (B) placebo + PAC; (C) ENZA monotherapy followed by PAC at time of disease progression on ENZA monotherapy. Randomization will be stratified by the number of prior systemic therapies in the advanced disease setting (0 vs 1 line), prior taxane use in the neo/adjuvant setting (yes vs no), and geographic region of enrollment. Archival tissue samples are required for diagnostic assessment. Pts must have either measurable or evaluable disease; brain metastases and seizure history are exclusionary. PAC 90 mg/m\(^2\) (dose reduction allowed) will be given intravenously weekly for ≥16 weeks; ENZA 160 mg/day or placebo will be given daily until progression or other discontinuation criteria are met (crossover prohibited). The primary endpoint is progression-free survival (PFS) as assessed by an independent review; the key secondary endpoint is overall survival (OS). Assessment of tumor response will be done every 8 weeks. A hierarchical testing plan will control for multiplicity across PFS and OS. A stratified log-rank test will be used to compare the treatment groups: arm A vs B and arm C vs B. The primary analysis will be performed when ≥360 PFS events occur in arms A and B. Recruitment is ongoing.

Title: Long-term follow-up of TEXT and SOFT trials of adjuvant endocrine therapies for premenopausal women with HR+ early breast cancer

Body: Background
First results of the TEXT and SOFT international phase III trials were practice-changing, indicating that: i) 5y adjuvant exemestane+ovarian function suppression (E+OFS) reduces recurrence risk relative to tamoxifen(T)+OFS or to T alone, ii) T+OFS reduces recurrence risk vs T in women who are at sufficient risk to warrant chemotherapy (CT) and remain premenopausal afterwards, and iii) T alone remains appropriate for some premenopausal women. However, median follow-up (FU) was only 5.5y and <5% pts had died. FU is immature given the long natural history of HR+ disease and EBCTCG overviews showing overall survival (OS) improvements for T vs no-T emerged during 5-15y. It is crucial to establish if changing standard adjuvant endocrine therapy from T improves survival and if there are associated late toxicities.

Trial Design and Aims
Premenopausal women had invasive early breast cancer (BC) assessed as ≥10% ER and/or PgR.
SOFT was designed to determine the value of adding OFS to T, and the role of E+OFS in two cohorts: women who remained premenopausal after completion of neo/adjuvant CT, and women for whom adjuvant T alone was considered suitable treatment. SOFT compares 5y of T to T+OFS or E+OFS. OFS was GnRH analog triptorelin x5y, oophorectomy or ovarian irradiation. Median age was 43y; 35% had N+ disease. 53% enrolled after prior neo/adjuvant CT.
TEXT was designed to determine the role of adjuvant E in premenopausal women receiving OFS from the start of adjuvant therapy, comparing 5y of E+OFS vs T+OFS. Patients enrolled at start of all adjuvant therapy; 60% had CT concurrent with triptorelin after entry. Median age was 43y; 48% had N+ disease.
Secondary objectives include effects on OS, late side effects of early menopause and late toxicities.

Accruals
TEXT: 2672 women, Nov03-Mar11
SOFT: 3066 women, Dec03-Jan11

Statistical Methods
The primary endpoint, invasive disease-free survival, is time from randomization to invasive local, regional, or distant relapse, contralateral BC, second non-BC malignancy, or death. Secondary endpoints are BC-free interval, distant recurrence-free interval and OS. Primary results were reported in 2014, after ~5.5y median FU; 30% pts were still on 5y treatment and >90% continued in FU.

Long-term FU
Updated results are planned for FU through Dec16, with ~8y median FU. Pts finished 5y treatment by Apr16. Yearly visits continue; data collection includes weight, performance status, menstrual status, pregnancy attempts, GYN procedures, late AEs (cardiovascular, bone fracture), extended adjuvant therapy, invasive recurrence at first and subsequent sites, second non-BC malignancy, in situ cancers, OS.
FU through 2020 is planned, for min and median FU of 10 and 12y, roughly doubling the numbers of endpoints events since the first report. This will be critical to determine whether short-term treatment benefits persist for late recurrence, improve power to detect treatment effects on distant recurrence and OS endpoints with lower event rates occurring later in FU, and define associated late toxicities and side effects of early menopause. A consortium to fund long-term FU is being pursued.
Title: A randomized controlled trial comparing acupuncture versus usual care for the treatment of aromatase inhibitor-induced arthralgia (AIIA) in women with early-stage breast cancer

Body: BACKGROUND: The increase in breast cancer (BC) survival is largely due to the benefits of hormonal therapy, such as tamoxifen and aromatase inhibitors (AIs), for the treatment of hormone-sensitive breast cancer. Recent clinical trials have demonstrated that AIs are more effective than tamoxifen at reducing BC recurrences. However, BC patients receiving AIs have a higher incidence of osteoporosis, bone fractures, and musculoskeletal symptoms, particularly joint pain and stiffness. The incidence of AIIA in the ATAC trial was 27.8% in patients taking anastrozole versus (vs) 21% in patients taking tamoxifen (Baum M, Lancet 2002). The arthralgia associated with AIs can be so debilitating that it contributes to a significant percentage of non-compliance and discontinuation of systemic treatment. Patients with cancer often show interest in complementary and integrative modalities for symptom management (Vickers AJ, Lancet 2001), of which Acupuncture (Ac) is one of the most utilized therapies.

ELIGIBILITY: Subjects must be female ≥18 years, have undergone mastectomy or breast-sparing surgery, and must have recovered from all pain-related effects of the surgery and radiotherapy with a minimum washout period of 30 days prior to registration. Patients should have ER and PR positive BC and be actively taking a 3rd-generation AI (Anastrozole, Letrozole, or Exemestane) for at least the 30 days prior to registration and plan to continue for at least one year after registration. ECOG PS ≤2 and platelets counts > 50,000/uL. Patients must not have received topical analgesic with exception of oral NSAIDS drugs ≤14 days to registration.

TRIAL DESIGN: This is a 12-week, two arm randomized (1:1) trial evaluating the benefit of Ac in BC patients experiencing AIIA. AIMS: The aim of this study is to investigate the effectiveness of an integrative approach using Ac vs usual care (UC) treatment consisting of NSAIDs for the management of the AIIA. Primary endpoint is to compare the difference of Brief Pain Inventory-Short Form (BPI-SF) score at baseline vs week 8 between Ac and UC groups. Secondary endpoints are a) to compare the difference of BPI-SF score at baseline vs week 12 between Ac and UC groups, b) to compare the difference in AI adherence between Ac and UC groups and c) to compare the difference in patient initiated AI discontinuation between Ac and UC groups.

STATS/TARGET ACCRUAL: This is a randomized controlled phase II study with the goal to compare reduction in BPI-SF score for patients treated with Ac vs UC alone. Patients are randomized 1:1 between the two arms. Prior work has indicated a 2-point BPI-SF score reduction as clinically meaningful. A sample size of 56 patients yields a study with 90% power and a one-sided significance level of 0.025 to determine a difference in pain reduction ≥2. These calculations are based on the assumptions of normal distribution of the improvement in BPI-SF score and a standard deviation that is conservatively calculated to be 2.3. An additional 6 patients will be accrued to account for attrition.
Title: NCI-2016-00367: A phase IIB study of neoadjuvant ZT regimen (enzalutamide therapy in combination with weekly paclitaxel) for androgen receptor (AR)-positive triple-negative breast cancer (TNBC)

Fujii T, Lim B, Helgason T, Hess KR, Gilcrease MZ, Willey JS, Tripathy D, Litton JK, Moulder S, Krishnamurthy S, Yang W, Reuben JM, Symmans WF and Ueno NT. The University of Texas MD Anderson Cancer Center, Houston, TX; The University of Texas MD Anderson Cancer Center; The University of Texas MD Anderson Cancer Center; The University of Texas MD Anderson Cancer Center and The University of Texas MD Anderson Cancer Center.

Body: BACKGROUND: Approximately 50% of TNBC expresses AR by immunohistochemical (IHC) staining. Luminal androgen receptor (LAR) subtype is heavily enriched in hormonally regulated genes, yet negative for ER by IHC. LAR is associated with low pCR rates and long survival. Preclinical data have shown that taxanes inhibit translocation of AR from the cytoplasm to the nucleus where AR is activated. Combining paclitaxel with enzalutamide may inhibit the AR pathway synergistically thereby increasing pCR rates. We hypothesized that patients with AR-positive TNBC who have chemo-insensitive disease (CID) after initial anthracycline-based chemotherapy treated with ZT would have higher RCB-0 and RCB-I rates than those who receive conventional taxane-based chemotherapy. Our team developed a clinical trial to identify patients with CID (ARTEMIS: A Randomized, TNBC Enrolling trial to confirm Molecular profiling Improves Survival). In the ARTEMIS trial, treatment-naïve patients with localized TNBC undergo a pretreatment biopsy and then begin anthracycline-based chemotherapy. Molecular testing results and radiographic response assessment are used to identify CID and will guide the second phase of neoadjuvant chemotherapy (NACT) to overcome CID.

PRIMARY OBJECTIVE: To determine RCB-0 and RCB-I rates of patients with TNBC who have CID to initial anthracycline-based chemotherapy and who received ZT.

TRIAL DESIGN AND STATISTICAL METHODS: Patients with CID from the ARTEMIS trial can enroll in the 12-week ZT (paclitaxel, 80 mg/m² intravenously per week; enzalutamide, 160 mg orally per day). We will define pCR (RCB-0) or RCB-I as a response, using a Simon optimal 2-stage design with alpha=beta=10% and then setting the threshold for an acceptable pCR or RCB-I rate at 20%. We will enroll 12 patients into the first stage. If no patients experience pCR or RCB-I, we will stop the study after the first stage. If at least 1 patient experiences pCR or RCB-I, we will enroll 25 more patients for a total of 37 patients. We would declare the treatment worthy of further study if at least 4 of the 37 patients experience pCR or RCB-I. This design has a 54% probability of early termination after the first stage if the true pCR or RCB-I probability is 5%. Because patients with CID have a very low chance (5%) of achieving pCR with additional chemotherapy, improving pCR rates to 20% in this patient population would be clinically meaningful.

BRIEF ELIGIBILITY CRITERIA: Inclusion criteria: Primary invasive TNBC patients who have CID under the ARTEMIS trial; AR+ ≥1% nuclear staining by IHC; and adequate physical, organ, bone marrow, and cardiac functions. Exclusion criteria: Pregnant or lactating patients, history of colitis or absorption abnormality, known or suspected brain metastasis or leptomeningeal disease, or history of seizure.

CORRELATIVE SCIENCE: Enumeration of circulating tumor cells (CTCs) and expression of CTC-related gene transcripts will be measured to correlate CTC characteristics and/or gene profiles related to the AR pathway and treatment response to ZT.
Title: Femara plus ribociclib or placebo as neo-adjuvant endocrine therapy for women with ER+, HER2-negative early breast cancer - The Feline trial

Khan QJ J, Prochaska LH H, Mohammad J, Yuan Y, O'Dea A, Bardia A, Wisinski K, Hard M, Baccaray S, Makhoul I, Wagner J, Laura S, Ma C and Sharma P.  University of Kansas Medical Center, Kansas City, KS; University of Miami Health System, Miami, FL; City of Hope, Duarte, CA; Massachusetts General Hospital, Boston, MA; University of Wisconsin, Madison, WI; University of Arkansas for Medical Sciences, Little Rock, AR and Washington University Medical School, St. Louis, MO.

Body: Background:
In early ER+ breast cancer, neo-adjuvant (NA) endocrine therapy (ET) may identify a subset of patients with endocrine sensitive disease with excellent outcomes without chemotherapy. In patients receiving a NA aromatase inhibitor, on-therapy, short term (day 14) Ki-67 of <10% and post NA pre-operative endocrine prognostic index (PEPI) 0 at surgery are associated with low relapse rates without chemotherapy. Ribociclib, a novel CDK4/6 inhibitor is active in ER+ metastatic breast cancer. We hypothesize that ribociclib+letrozole as NA ET for stage II-III breast cancer will increase the number of women with a PEPI 0 at surgery.

Trial Design:
Randomized, placebo-controlled, multi-center, phase II, investigator initiated trial of NA letrozole +/- ribociclib in postmenopausal women with ER+, HER2-, breast cancer. Subjects will be randomized 1:1:1 to letrozole 2.5 mg daily + placebo, letrozole 2.5mg daily + ribociclib 600mg daily on D1-21 of a 28 day cycle (intermittent dosing), or letrozole 2.5mg daily + ribociclib 400mg daily (continuous dosing). Treatment will be continued for 6 months followed by surgery. Research core biopsies and blood will be collected at baseline, at day 14, and at surgery. A Ki67 >10% at day 14 will result in discontinuation of the subject from the protocol as this may be an early indicator of resistance to endocrine therapy. An MRI will be done after 2 months of therapy to assess response/progression. Primary endpoint is a PEPI score of 0 at surgery.

Key Eligibility Criteria:
Postmenopausal (natural or surgical) women with stage II/III ER+, HER2- breast cancer. Must have a palpable breast mass of at least 2 cm. Multicentric/contralateral invasive disease not allowed. Ipsilateral/contralateral DCIS is allowed. Inflammatory breast cancer is excluded.

Specific Aims:
Primary objective: To determine if ribociclib+letrozole as a 24 week NA ET increases rate of PEPI score of 0 at surgery compared to letrozole. Secondary objectives: To determine if ribociclib+letrozole as a 24 week NA ET increases the proportion of tumors with complete cell cycle arrest compared to letrozole; to determine if ribociclib in combination with letrozole for 24 weeks results in improved 5 year RFS compared to letrozole; to examine differences in response rates between the two ribociclib containing arms vs letrozole.

Statistical Methods:
The two ribociclib containing arms (n=80) will be combined for analysis against placebo + letrozole (n=40). Assuming that addition of ribociclib will increase the rate of PEPI 0 by 20%, and setting Type I error rate at 10% and Type II error rates at 20% in the final analysis, a sample size of 80 women in the treatment arm (40 in each arm) and 40 women in the control arm are needed to show significance.

Patient accrual and target accrual:
Participating sites include The Univ of Kansas Med Ctr, City of Hope National Med Ctr, Massachusetts General Hospital, University of Miami Sylvester Comprehensive Cancer Ctr, University of Arkansas for Medical Sciences, and University of Wisconsin. The trial has accrued 16 patients with a target accrual of 120 patients. Accrual should be complete in 2/2017.

**Body:**

**Background:** Delaying/overcoming resistance to ET in HR-positive HER2-negative BC patients (pts) is a major need to further improve safe and efficacious treatment options. F is a selective estrogen receptor (ER) downregulator currently indicated for the treatment of HR-positive metastatic BC in postmenopausal women with disease progression following anti-estrogen therapy. In FIRST trial F 500mg improved median time to progression (TTP) over anastrozole (23.4 vs 13.1 months, respectively) in untreated metastatic BC. P is a selective reversible inhibitor of cyclin-dependent kinase 4/6. FDA granted its accelerated approval based on progression-free survival (PFS) in combination with letrozole for postmenopausal women with ER-positive and HER2-negative advanced BC as initial ET (PALOMA-1). In another study, after progression to ET, P in combination with F resulted in longer PFS than F alone (PALOMA-3). The high median TTP achieved with F alone (FIRST) coupled with the significant benefit of adding P to F (PALOMA-3) suggest that F 500mg in combination with P in the first-line setting may significantly improve long-term disease control.

**Trial Design:** This is an international, randomized, double-blind, multicentre phase II study comparing F 500mg in combination with P vs F 500mg plus placebo as first line therapy in postmenopausal women with HR-positive, HER2-negative metastatic BC who have received ≥5 years of adjuvant ET for early disease and remained disease free for >12 months following its completion or have “de novo” metastatic disease. HR and HER2 status will be based on central testing on the most recent tumour biopsy. Patients will be randomized 1:1. The primary objective is to compare the efficacy of both treatment arms in terms of PFS at 1 year according to Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1 by investigator assessment. As secondary efficacy objectives, PFS, Objective Response Rate (ORR), Clinical Benefit Rate (CBR), Overall Survival (OS), and 1-year and 2-year survival probabilities, have been considered. Other secondary objectives include the comparison of safety, tolerability and health-related quality of life between the treatment arms. As exploratory objectives, the identification of promising biomarkers related with response to study therapy and primary/acquired drug resistance. Pts will be stratified by the site of disease (visceral vs non-visceral) and disease presentation at study entry (recurrent disease vs metastatic “de novo”). With a sample size of 190 pts, the analysis would have 80% power to detect a difference between both treatment arms, assuming PFS proportions of 0.545 and 0.695, respectively. This study is sponsored by GEICAM and Cancer Trials Ireland (formerly ICORG) is also participating. Recruitment started in February 2016 with 14 pts included. Analysis of the primary endpoint is planned for Q1 2018. ClinicalTrials.gov identifier: NCT02690480.
Title: Open label, phase 2 safety, efficacy, and pharmacokinetic study of pre-surgical intramuscular and intraductal fulvestrant in women with invasive breast cancer or DCIS undergoing mastectomy or lumpectomy

Feldman S, Gomberawalla A, Alonso A, Rea J, Quay S and Lawrence R. Columbia University Medical Center, New York, NY and Atossa Genetics, Seattle, WA.

Body: BACKGROUND: Breast cancer (BC) is the leading cause of cancer in women in the United States and the second leading cause of cancer-related death. Currently available options for prevention are oophorectomy, bilateral mastectomy, or medical therapy, such as tamoxifen, raloxifene or aromatase inhibitors. None of these options for prevention are without significant side effects with low patient uptake. This study proposes fulvestrant instilled directly into the breast via the nipple orifices as intraductal therapy. Providing a local therapy into the ducts could reduce the morbidity associated with prevention while potentially better targeting the carcinoma cell. Building on prior studies with cytotoxic agents, this study utilizes the pure anti-estrogen fulvestrant to be injected in up to 5 ducts to determine its effect on BC as well as the safety of this method of administration.

TRIAL DESIGN: An open-label, non-randomized PK study of pre-surgical fulvestrant in women scheduled for mastectomy or lumpectomy. Eligible subjects will be undergoing mastectomy or lumpectomy. The first 6 subjects will be treated with the standard dose of 500 mg intramuscular fulvestrant to establish the reference PK curve. The subsequent 24 subjects will receive fulvestrant by intraductal instillation. Subjects where at least 1 suitable duct is identified will undergo nipple aspiration in order to facilitate duct identification and intraductal infusion of a fulvestrant. A maximum of 5 ducts will receive intraductal infusion of fulvestrant. Across all ducts, the total dose will not exceed 500 mg (10 mL). Subsequent to mastectomy or lumpectomy subjects will undergo serial blood draws to determine fulvestrant blood concentration levels and tissue drug levels.

ELIGIBILITY: Female, age ≥ 18, mastectomy/lumpectomy scheduled within 30 days, Stage 1/2, ER+ low grade invasive BC or DCIS, ECOG scale 0-1.

Primary Objective: The safety and tolerability of intraductal administration of fulvestrant in women with Stage 1 or 2 invasive ductal carcinoma or DCIS, prior to mastectomy or lumpectomy.

Secondary Objectives: The pathological effects, specifically changes in Ki67, ER/PgR expression between pre-fulvestrant biopsy and post-fulvestrant surgical specimen.

STATISTICAL METHODS: Aim of this study is to assess safety and tolerability in subjects receiving intraductal fulvestrant. In addition this trial aims to characterize the PK of this alternative route of administration, and compare the intraductal PK profile to that of standard intramuscular administration. Finally, the 6 study subjects who receive intramuscular fulvestrant will be qualitatively compared with the main study cohort of 24 subjects who receive intraductal fulvestrant. Change in Ki67 labeling index will be compared between the two time points (baseline or time of diagnostic biopsy v. time of the surgically excised specimen collection).

Title: Phase II pre-surgical window trial of telapristone acetate (TPA) in early breast cancer and DCIS patients: Distribution of TPA in plasma, normal breast tissue and tumors

Lee O, Muzzio M, Ivancic D, Rogers C, Allu S and Khan SA A. Northwestern University, Chicago, IL and Illinois Institute of Technology Research Institute, Chicago, IL.

Body: Background: In vitro and preclinical data support the notion that anti-progesterone therapy will have activity against both estrogen and progesterone receptors (ER/PR) positive and negative breast cancer, but biomarkers of efficacy may differ in different types of breast cancer. We have conducted a pre-surgical window trial of oral telapristone acetate (TPA, CDB-4124) treatment in early breast cancer patients. This first ever trial of oral TPA for breast cancer and DCIS patients will provide us pilot biologic data that will help select the right population and the right biomarkers for future trials. Here we report distribution of TPA in plasma and breast normal tissue and tumors collected at surgery.

Methods: Our trial was a 1:1 randomized, double-blind, and placebo-controlled pre-surgical window trial of oral TPA 12mg (Proellex, CDB-4124, Repros Therapeutics Inc.) treatment for 2-10 weeks. 70 pre and postmenopausal women undergoing surgery for Stage 0-II breast cancer were recruited to the study. The surgical samples of 61 patients were used to determine the concentrations of TPA and its mono-demethylated metabolite (dTPA, CDB-4453) in plasma and matched normal tissue and tumor by Liquid chromatography–tandem mass spectrometry at the Illinois Institute of Technology, while maintaining the blind for the primary endpoint of cell proliferation. Statistical significance and analysis were calculated by Wilcoxon matched-pairs signed rank test and non-parametric Spearman correlation.

Results: We found that 32/61 women displayed detectable plasma concentrations of TPA and dTPA (median with IQR) 109ng/mL (71.3, 216) and 46.5 ng/mL (34.2, 73.7), respectively. TPA concentration was 2.3 times higher than dTPA in plasma (p<0.0001). The normal and tumor tissue samples of these 32 women were further analyzed. In normal tissue samples, the concentrations of TPA and dTPA were 283 ng/g (70.7, 326) and 51.0 ng/g (24.4, 122), respectively. TPA concentration was 5.5 fold higher than dTPA in normal tissue (p<0.0001). In tumors, the TPA and dTPA concentrations were 137 ng/g (31.1, 278) and 36.4 ng/g (17.3, 68.7), respectively. TPA concentration was 3.8 fold higher than dTPA in tumors (p<0.0001). Interestingly, TPA and dTPA were more abundant in normal tissue than in tumors (p=0.0005 for TPA, and p=0.0013 for dTPA). We found that TPA and dTPA was highly correlated in plasma (r=0.492, p=0.0042). Plasma TPA concentration was highly correlated with normal tissue concentration (r=0.61, p=0.0003) but non-significantly correlated with tumor concentration (r=0.32, p=0.147). However, the normal and tumor tissue concentrations of TPA and dTPA were highly correlated (r=0.71, p=0.0002 for TPA and r=0.556, p=0.0072 for dTPA).

Conclusions: Plasma TPA concentrations reflect concentration in normal breast tissue better than in tumors. However, within the breast, TPA concentration in normal and tumor tissue is correlated. Our trial is to be unblended shortly, and we plan to relate these results to the proliferative rates in tumor and normal tissue. The variability observed in plasma and tissue concentrations also suggests that pharmacogenomics studies may be appropriate in the future.
Title: MADELINE: A prospective observational study of mobile app-based patient reported outcomes in advanced breast cancer

Body: BACKGROUND: There have been few studies evaluating the day-to-day effects of advanced breast cancer (ABC) and its treatment on patients in a real-world setting. Palbociclib is a novel CDK4/6 inhibitor approved in the US for hormone-receptor positive, human epidermal growth factor receptor negative (HR+, HER2-) ABC/metastatic breast cancer (MBC) in combination with letrozole as initial endocrine based therapy in postmenopausal women or with fulvestrant in women with disease progression following endocrine therapy. With the introduction of this first-in-class drug it is important to understand the experiences of patients initiating ABC therapies including palbociclib in real-world settings and to document the management of these therapies. A smartphone-based mobile application has been developed to collect patient-reported outcome (PRO) data to assess the impact of ABC and associated treatment on symptoms, functioning and quality of life (QOL) as reported by patients. The application is further designed to provide patients initiating palbociclib with a virtual community to connect to others enrolled in the study for peer support. Additionally, clinical data on therapy management (e.g. dose modifications, interruptions, discontinuations, adverse event management and monitoring) will be obtained from patients’ medical records to explore the association between patient reported functioning and neutropenia.

Study Design: A prospective, observational, non-interventional study. PROs collected via a mobile application and clinical data via case report forms completed by investigator.

Eligibility Criteria: Women with HR+/HER2– ABC receiving palbociclib in combination with letrozole or fulvestrant as per US label (Group 1) or approved therapies for ABC other than palbociclib (Group 2). No comparison is intended between the 2 groups.

Specific Aims: The primary goals are to describe changes in patients’ general health status as measured by monthly administration of the 12-Item Short Form Health Survey, describe changes in patients’ psychological distress as measured by monthly administration of the Center for Epidemiological Studies Depression Scale, and describe the extent to which ABC and its treatment are associated with changes in patients’ lives in terms of symptoms, functioning and QOL as measured by daily and weekly administration of targeted patient-reported questions. Additionally, for patients who are employed at baseline, time lost from work in relation to breast cancer and its treatment will be quantified. Data from patients’ medical records will be used to document changes in therapy as well as the incidence, severity, and duration of neutropenia. The association between patient reported functioning and neutropenia will also be assessed. Finally, real-world monitoring patterns will be assessed.

Statistical Methods: Descriptive statistics will be used to summarize all endpoints. Meta-data regarding use of virtual community resources will be explored for relationships to PRO data.

Present Accrual and Target Accrual: Approximately 450 patients from up to 30 US sites will be enrolled. Study duration will be approximately 12 months assuming 6 months of recruitment. It is expected the study will start enrollment Q3 2016.

Sponsor: Pfizer.
Maximising recruitment and retention of patients into UK-ANZ POSNOC trial

Goyal A, Coleman RE E, Dodwell D, Fallowfield L, Jenkins VA A, Mann B, Reed MW W and POSNOC Trial Management Group. Royal Derby Hospital, Derby, United Kingdom; Weston Park Hospital, Sheffield, United Kingdom; St James Hospital, Leeds, United Kingdom; SHORE-C, Falmer, United Kingdom; Royal Melbourne and Royal Women's Hospital, Victoria, Australia and Brighton and Sussex Medical School, Brighton, United Kingdom.

Body: The success of a clinical trial is often dependant on whether recruitment targets can be met in the required time frame. Surgeons want to gather robust evidence but may experience considerable discomfort in relation to their clinical instincts and concerns about patient eligibility and safety. The ongoing POSNOC study design is pragmatic to maximise recruitment. A patient information DVD is used as an adjunct to patient information leaflet. The protocol allows for either axillary radiotherapy or axillary node clearance. Here we report recruitment and retention of participants into POSNOC, the associated barriers and challenges, and various strategies employed to overcome these barriers.

A total of 368 participants were recruited till May 2016. A total of 90% (331) of participants were recruited via non intra-operative pathway, and 10% (37) from intra-operative pathway. The most common known reasons for non-participation of eligible women were - woman wanting axillary treatment and clinician/MDT deciding woman needs axillary treatment. The mean randomisation yield from screening was 30% (range 6 to 100%). The highest recruiting sites were Derby, Manchester, Oxford, Belfast and Bristol.

The screening logs identified barriers as: fewer than estimated eligible women, clinicians not offering trial to all eligible patients and patient acceptability.

To reach recruitment targets in a timely fashion, a multifaceted approach is being employed. a) Protocol amendments to widen the inclusion criteria, b) 250 patients to be recruited by Australia and New Zealand sites, c) additional 50 sites to be opened in the UK, d) encourage OSNA centres to follow the non intra-operative pathway, e) communication workshops, f) POSNOC poster in breast units to raise awareness, g) questionnaire survey - sites to identify local issues and their perceptions about recruitment, h) social media - POSNOC WhatsApp group i) newsletters and briefings, j) competitions, k) tips to maximise recruitment document that includes a template script of one way to introduce the study l) regional telephone conferences for research nurses, m) investigator meeting.

The success of these strategies remains to be assessed and shall be reported separately.
Challenges faced across borders to open European academic multicentre projects: The ET-FES program part of the ERA-Net TRANSCAN JTC 2011

Body: Background
The activation of international non-profit clinical trials funded by the European Commission (EC) is challenging given the cross-borders regulations and the need to follow specific timelines according to EC rules. We report here the logistic procedures and challenges faced by 4 academic centres from 4 different countries from the European Union (EU) for the activation of such program in metastatic breast cancer (MBC).

Materials and Methods
The primary objective of the ET-FES program is to validate the use of a new radiotracer 18F Fluoroestradiol (FES), targeting estrogen receptors, as a tool to better predict endocrine responsiveness in MBC, with PET/CT. The trial is sponsored by EO Galliera (Genoa, Italy) and brings together Italy, Spain, France and Germany. In 10/2012, ET-FES was approved for funding from EC under the Seventh Framework Programme after the first ERA-NET TRANSCAN Joint Transnational Call (JTC) for Proposals (2011) on validation of new biomarkers for personalized cancer medicine.

Results
The official start of the program was set up on 06/2013 by the Italian Ministry of Health. Time to institutional review board and to competent authority (CA) approvals were 1.5 and 11, 2 and 5, 3 and 16, and 13 and 14+ months in Italy, France, Spain and Germany respectively. Overall, no blocking comment was raised by the ethical committees; only minor clinical and methodological issues were raised in Germany and Spain. Issues from CA were raised in all countries except France (12, 21 and 23 queries in Italy, Spain and Germany respectively), on quality aspects of 18F-FES investigational medicinal product dossier. At the sponsor level, time to final agreement signature with Advanced Accelerator Applications, the 18F-FES manufacturing company, required 13 months. First patient could be enrolled in Italy 14 and 22 months after ethical committee approval and after the official start of the ET-FES project respectively.

Conclusions
As of May 2016, of 310 patients expected, only 28 have been enrolled from Italy. From a regulatory viewpoint and acknowledging that 18F-FES does not have yet any marketing approval in the EU, the ET-FES program approval process was timely completed at the ethical committee level in Italy, France and Spain. Time to CA approval varied across countries and was timely achieved only in France, due to requirements varying from CA to CA, stressing the serious lack of harmonized procedures although intended by the 2001/20/EC directive. Regarding sponsor's responsibilities (i.e. Italy), the administrative procedures needed to activate this type of EU projects remain critical, appealing for more tolerant time span in order to satisfy all the legal aspects on contracts by public bodies, according to national rules and laws. One needs to be very conscious of these timelines when applying to EU/EC calls, especially when the time allowed for the conduction of research is limited (3 years here), unless jeopardizing the entire multicentre and multinational effort.
2016 San Antonio Breast Cancer Symposium

Publication Number: OT3-04-01

Title: BRE12-158: A phase II randomized controlled trial of genomically directed therapy after preoperative chemotherapy in patients with triple negative breast cancer (TNBC)

Schneider B, Miller KD D, Badve S, O'Neil B, Helft P, Chitambar C, Falkson C, Nanda R, McCormick M, Danso M, Blaya M, Langdon R, Lippman M, Paplomata E, Walling R, Thompson M, Robin E, Aggarwal L, Shalaby I, Canfield V, Adesunloye B, Lee T, Daily K, Ma C, Erban J, Radhakrishnan N, Bruetman D, Graham M, Reddy NA A, Lynce FC C and Radovich M. Indiana University Simon Cancer Center; Medical College of Wisconsin; University of Alabama Birmingham; University of Chicago; Meritus Center for Clinical Research; Virginia Oncology Associates; Memorial Cancer Center; Nebraska Methodist Hospital; University of Miami; Winship Cancer Institute of Emory University; Community Regional Cancer Care; Aurora Health Care; Community Healthcare System; Fort Wayne Medical Oncology and Hematology; Joe Arrington Cancer Research and Treatment Center; Mercy Clinic Oklahoma Communities; IU Health Arnett; IU Health Goshen Center for Cancer Care; Pinnacle Health Cancer Center; University of Florida; Washington University at St. Louis; Tufts Medical Center; University of Cincinnati; Erlanger Health System; Community Hospitals of Anderson and Madison Co and Georgetown University.

Body: Background: About 1/3 of patients with TNBC who receive preoperative therapy will experience a pathological complete response (pCR). Patients with residual disease have a markedly inferior overall survival (OS) compared to those who experience pCR. Recently, the CREATE-X trial demonstrated an improvement in disease free survival (DFS) and OS for post-neoadjuvant capecitabine; although the addition of capecitabine to standard therapy has not previously improved outcome across other non-selected adjuvant or neo-adjuvant trials. Prior data have also demonstrated that the residual tumors are genomically diverse and that these genetic changes are reflected at time of relapse.

Trial Design: This trial is a randomized phase II trial to determine whether a genomically guided therapy in the setting of incomplete response to standard neoadjuvant therapy will improve outcomes compared to standard of care. DNA from archived tumor samples collected at the time of surgery will be extracted and sequenced. The sequencing data will be interrogated for known genomic drivers of sensitivity or resistance to existing FDA approved agents. A cancer genomic tumor board (CGTB) will consider the genomic data along with the patient's prior treatment history, toxicities, and comorbidities and select the optimal therapy. Participants with a CGTB recommendation will be randomized to Experimental Arm A (genomically directed monotherapy) or Control Arm B (standard of care). Participants may have no CGTB recommendation either because sequencing did not identify a matched drug or because the drug was contraindicated and will be assigned to Control Arm B.

Eligibility criteria: Patients must have histologically confirmed TNBC with completion of all definitive local therapy and no evidence of metastatic disease. There must be significant residual disease characterized by >2cm primary tumor, or lymph node positivity or RCB classification II or III. An FFPE tumor block with tumor cellularity >20% is required. All patients must have completed preoperative chemotherapy including a taxane or anthracycline or both.

Specific aims: The Primary Aim is to compare 2-year DFS with a genomically directed therapy vs. standard of care. Secondary Aims include 1-year DFS, 5-year OS, collection of archival specimens for correlative studies, and to describe toxicities. Exploratory Aims are to describe the evolution of genomically directed therapies during the course of the study and to evaluate the drug specific effect on efficacy and toxicity.

Statistical methods: In order to detect an improvement in the fraction of patients free from disease at 2-year from 40% in the control Arm B to 63.2% in the genomically directed Experimental Arm A (corresponding to an HR=0.5), 136 participants will have 80% power to detect a difference in DFS using a two-side log-rank test with 0.05 level of significance.

Present accrual/target accrual: 38 accrued of 136 to be randomized.
DETECT III and IV – Individualized CTC-based therapy of metastatic breast cancer

Polasik A, Schramm A, Friedl TWP WP, Rack B, Trapp E, Fasching PA A, Taran F-A, Hartkopf A, Schneeweiss A, Müller V, Aktas B, Pantel K, Meier-Stiegen F, Wimberger P, Janni W and Fehm T. Gynecology and Obstetrics, University Hospital Ulm, Ulm, Germany; Gynecology and Obstetrics, Klinikum der Ludwig-Maximilians-Universität, Munich, Germany; Gynecology and Obstetrics, University Hospital Erlangen, Erlangen, Germany; Gynecology and Obstetrics, University Hospital Tübingen, Tübingen, Germany; University Hospital Heidelberg, Ulm, Germany; Gynecology and Obstetrics, University Hospital Hamburg-Eppendorf, Hamburg, Germany; Gynecology and Obstetrics, University Hospital Essen, Essen, Germany; University Hospital Hamburg-Eppendorf, Hamburg, Germany; Gynecology and Obstetrics, Heinrich-Heine-Universität, Düsseldorf, Germany and Gynecology and Obstetrics, University Hospital Dresden, Dresden, Germany.

Background: Circulating tumor cells (CTCs) are found in patients with early and metastatic breast cancer (MBC), and both their prognostic and predictive value has been described already. There is growing evidence that CTC phenotype may differ from the primary tumor. However, CTC targeted therapy is not used in clinical routine, and treatment decisions often still are based on the primary tumor's phenotype without considering CTC-characteristics. The aim of the DETECT studies is to investigate and evaluate the role of presence and phenotype of CTC for guiding therapeutic decisions in women with HER2-negative MBC.

Trial design and eligibility criteria: In a joint screening for DETECT III and IV, women with HER2-negative MBC are tested for CTCs and their HER2-phenotype. CTC detection is performed by the FDA-approved CellSearch System® (Janssen Diagnostics, Raritan, USA).

Patients with HER2-positive CTCs are randomized in the multicenter Phase III study DETECT III to a physician's choice chemotherapy or endocrine therapy with or without additional HER2-targeted treatment with lapatinib.

Women with only HER2-negative CTCs are recruited to the multicenter open-label phase II study DETECT IV. Postmenopausal women with hormone-receptor positive MBC are treated with everolimus and a physician's choice endocrine therapy in DETECT IVa. Patients with hormone-receptor positive MBC and an indication for chemotherapy and patients with triple-negative MBC receive mono-chemotherapy with eribulin in DETECT IVb.

Treatment efficacy will be evaluated based on the early available CTC clearance rate (in DETECT III and DETECT IVa) and progression-free survival (in DETECT IVb) respectively, as the primary endpoint; secondary objectives will be to estimate disease control rate, progression-free (DETECT III and IVa) and overall survival, toxicity and tolerability of treatments with lapatinib, everolimus and eribulin, and quality of life.

Specific aims: Changes in CTC-dynamics during therapy and their HER2-phenotype may influence following therapy decisions. The DETECT studies evaluate the prognostic and predictive role of CTCs as well as the efficacy of CTC based therapy to enable the establishment of a more personalized therapy for patients with MBC that might lead to prolonged progressive free survival and/or improved quality of life. The accompanying translational research programs investigate various markers for molecular characterization of CTCs and prediction of therapy response.

Present accrual and target accrual: More than 1550 patients with HER2-negative MBC have already been screened within the DETECT study program. Thus, it is the worldwide largest study concept with therapy decisions resulting from CTC-testing and CTC-phenotypization.

Contact: For further information on the DETECT study program please contact www.detect-studien.de or studienzentrale.ufk@uniklinik-ulm.de.
Title: The impact of the 21 gene recurrence score (RS) on chemotherapy prescribing in estrogen receptor (ER) positive, lymph node positive early stage breast cancer in Ireland

Keegan NM M, Milewski M, Kelly CM M, Murphy V, Chao C, Walsh J, Kennedy MJ John, O'Connor M, Murphy C, O'Reilly S, Keane M, Duffy K, Hennessy B and Morris PG G. Beaumont Hospital, Dublin 9, Ireland; Mater Misericordiae University Hospital, Dublin 7, Ireland; Cancer Trials Ireland, Dublin 2, Ireland; Genomic Health, Ireland; St James's Hospital, Dublin 8, Ireland; University Hospital Waterford, Waterford, Ireland; Bon Secours, Cork, Ireland; Cork University Hospital, Ireland; University College Hospital Galway, Ireland; Letterkenny General Hospital, Ireland and AMNCH and St Vincent's University Hospital, Dublin, Ireland.

Body: BACKGROUND
For Estrogen Receptor (ER) positive, early stage breast cancer, the 21 gene Recurrence Score (RS) has clinical use both as a prognostic tool and to predict chemotherapy benefit. The availability of this tool in Ireland has led to a reduction in the use of adjuvant chemotherapy for women with lymph node (LN) negative disease. However, the RS is not routinely funded for patients with LN positive (LN+) breast cancer in Ireland. In addition, there are limited international data on the use of this tool in the preoperative setting. In this prospective observational study, we are investigating whether access to the 21 gene RS leads to a reduction in the receipt of chemotherapy for patients with ER+, LN+ breast cancer, and to correlate the 21 gene RS with response to preoperative systemic therapy.

TRIAL DESIGN
This is a national, multi-site, prospective, observational study that will examine the impact of the 21 gene RS on chemotherapy recommendations in both the neoadjuvant and adjuvant setting. Prior to and following tumor testing with the 21 gene RS, Physicians will complete a questionnaire which details type and strength of systemic therapy recommendations.

ELIGIBILITY
Cohort 1 (postoperative) will include patients with ER+ tumors of any size with involvement of 1-3 lymph nodes (N1 including micrometastases). Cohort 2 (preoperative) will include patients with ER+, T2-T4 tumors with biopsy proven nodal metastases. Both cohorts will have ECOG PS 0 or 1 and be fit for consideration of chemotherapy as determined by the Investigator.

SPECIFIC AIMS
The primary endpoint is the percentage reduction in the number of patients for whom treating physicians recommend chemotherapy after testing with 21 gene RS. Secondary endpoints include the correlation between the 21 gene RS and residual cancer burden score, as well as pathological, clinical and radiological response rates. The economic impact of the 21 gene RS in ER+, LN+ will also be assessed.

STATISTICAL METHODS
The sample size is based on similar decision impact studies conducted in other countries. Physician recommendations for chemotherapy pre 21-gene RS and recommendations post 21-gene RS testing will be compared and percentage change estimated with 95% confidence intervals. For secondary endpoints, the Pearson correlation coefficient (rho) will be used to examine the strength of the correlation between the 21 gene RS category and response. A budget impact model will be used to estimate the cost reduction in adjuvant chemotherapy as a result of 21-gene RS testing.

PRESENT ACCRUAL AND TARGET ACCRUAL
Target accrual is 75 in each of the neoadjuvant and adjuvant cohorts to total 150 patients. Supported by Genomic Health.
2016 San Antonio Breast Cancer Symposium

Publication Number: OT3-04-04

Title: 21-gene recurrence score® in patients with primary metastatic ER+ HER2- breast cancer

Body: Background and Purpose
Results from the 21-gene Recurrence Score (RS) are prognostic and predictive for recurrence in early breast cancer independent of clinical-pathological parameters. Prognostic information and distribution of RS in primary metastatic breast cancer (PMBC) was reported in a previous study by King et al but remains ultimately unclear in ER+ HER2- patients. We hypothesize that there is a prognostic correlation between RS and TTP/OS in PMBC independent of clinical-pathological parameters, and the objective of the study is to evaluate the test for that cohort.

Patients and Trial Design
Between 2004 and 2014, 150 patients with first diagnosis of ER+/HER2- PMBC were enrolled in a multicenter, prospectively collected database. Pretreatment breast tumor samples will be analyzed by using 21-gene RS. Minimum follow-up will be 24 months.

Methods and Statistical Analysis
Patient characteristics, time to first progression (TTP), overall survival (OS) and treatment modalities will be described. The association between RS risk groups and both TTP and OS will be assessed by Kaplan-Meier estimates and compared with the log-rank test. Multivariate Cox regression models will be utilized to adjust for covariates. Additionally, assessing correlation of RS results using RS cut offs of 18 and 30 and additionally of 11 and 25 as well as analysis of quantitative ER from Oncotype DX assay for patients treated first-line with endocrine therapy are planned.

First results are expected to be presented in 2017.

2. Agendia Inc, Irvine, CA

Measuring the Impact of MammaPrint on treatment in Breast Cancer Patients: A Prospective Registry (IMPACt)

Background:
Gene expression profiling in breast cancer offers the potential to improve prognostic accuracy, treatment choice, and health outcomes in women diagnosed with early-stage breast cancer. Numerous gene-profiling assays are now available, which can be applied to a single tumor specimen to provide physicians with a more complete basis for treatment decisions.

- MammaPrint is a 70-gene profile to estimate whether patients are at high or low risk of developing metastases within the first 10 years after curative surgery.
- BluePrint is an 80-gene molecular subtyping profile that discriminates between three breast cancer subtypes: Luminal, HER2, and Basal

Trial design:
IMPACt is a prospective, case-only, study to measure the impact of MammaPrint on treatment decisions in breast cancer patients. The primary objective will be to measure the impact of MammaPrint on treatment decisions in stage I and II Hormone Receptor (HR)-positive, HER2-negative breast cancer patients. As a secondary objective, the impact of MammaPrint on treatment will be assessed in patients with T1a/bN0/1 (up to 1 LN) Triple Negative or HER2-positive breast cancer. Baseline clinical data and physician chemotherapy intention before knowing the MammaPrint result will be entered in CRF 1. After completion of CRF1, the MammaPrint result will be released. CRF2 will be completed after the final treatment decision has been made. This CRF will capture physician chemotherapy intention after the MammaPrint result and the impact of these results.

Eligibility:
The study will include women aged ≥18 years with histologically proven invasive stage I-II, HR-positive, and HER2-negative breast cancer, OR, T1a/bN0/1 (up to 1 node) triple negative or Her2-positive breast cancer who signed informed consent.

Objectives:
Primary objective:
- Assess the impact of MammaPrint and BluePrint on chemotherapy + endocrine versus endocrine alone treatment decisions in HR-positive, HER2-negative breast cancer patients.

Secondary objectives:
- Assess the impact of MammaPrint and BluePrint on treatment decisions in T1a/b, N0/1 (up to 1 node) triple negative or Her2-positive breast cancer patients
- Compare clinical subtype based on IHC/FISH ER, PR, HER2 and Ki-67 (if available) with BluePrint molecular subtype

Statistical methods:
A sample size of 331 patients is required to detect a 25% overall treatment change (5% significance and 95% power) in stage I and II HR-positive, HER2-negative patients. In addition at least 50 T1a/bN0/1 (up to 1 LN) Triple Negative, and at least 50 T1a/bN0/1 (up to 1 LN) HER2-positive breast cancer patients will be enrolled. A McNemars test will be performed for the comparison of the two proportions of treatment intentions (before and after), both expressed as a percentage.

Accrual: The study started accruing in November 2015. Approximately 15-20 institutions in the United States will participate.
Contact information: Hatem.Soliman@moffitt.org.
Title: Three-monthly dynamic evaluation of CEA and CA15-3 (followed by 18-FDG PET) vs usual practice in the follow-up of early breast cancer (BC) patients (pts): A prospective randomized trial (KRONOS-patient-oriented new surveillance study, Italy)

Zamagni C, Gion M, Mariani L, Stieber P, Quercia S, Rubino D, Bernardi A, Cacciari N, Fini A, Lenzi M, Minichillo S, Pizzirani C, Pagliaro M, Tomasini S and Barbieri E. SSD Oncologia Medica “Addaríi”, Policlinico S. Orsola-Malpighi, Bologna, Italy; Centre for the Study of Biological Malignancy Markers, Venezia, Italy; Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy and Institute of Clinical Chemistry, University of Munich, Munich, Germany.

Body: Background: Current guidelines for BC surveillance in asymptomatic pts recommend annual mammography and periodical physical examination. These recommendations arise from two trials conducted in the 1980’s: since then no other randomized controlled trials (RCTs) have been conducted on BC follow-up. However our knowledge on BC biology, diagnosis of metastases and treatment has improved. The aim of this prospective RCT is to verify if the serial measurement of CEA and CA15.3 (followed by 18-FDG PET) can anticipate the diagnosis of breast cancer recurrence compared to control arm. If this intermediate end-point will be met a subsequent extension trial will investigate the impact of the earlier diagnosis of distant metastases on survival. Methods: Pts diagnosed with stage I-III BC, who underwent adequate surgery are eligible. Special histologies and low-risk cases according to St. Gallen criteria are excluded. We will include pts at the beginning of the follow-up after the conclusion of primary treatment (cohort 1), and pts that have concluded without relapse the first 5 years of follow-up (cohort 2). Eligible pts will be randomized in a 1:1 ratio to follow-up according to local practice (control arm) or to three-monthly serial dosing of CEA and CA15.3 and subsequent imaging studies (18-FDG PET) only in case of an increase of CEA and/or CA 15.3 greater than a critical difference (CEA +100% and/or CA15.3 +75%) compared to baseline (experimental arm). The following stratification factors will be used: node negative vs positive, HER2 negative vs positive, ER positive vs negative. Eight-hundred pts will be enrolled over 3 years. For such a calculation, we made the assumption of a 20% 5-year incidence of relapse. The target reduction of 3 months in restricted mean survival time (RMST) between the two arms implies a median time of diagnostic anticipation, conditional on having breast cancer recurrence, of 10 months. The follow-up will continue until 10 years from surgery. The first patient was enrolled on 23rd October 2014, up to now 434 pts have been enrolled. The present trial was approved by the Ethical Commitee of S. Orsola-Malpighi Hospital and is registered on clinicaltrials.gov (NCT02261389).
Background: Breast cancer incidence is increasing throughout the world. Despite remarkable risk reducing effects demonstrated in preventive randomised endocrine trials; primary preventive strategies are scarcely part of clinical routine. Putative reasons for reluctance may be inadequate tools for identification of women at high risk of breast cancer and reluctance to prescribe pharmaceuticals with considerable side effects in the preventive setting.

Trial Design: A randomized, double blinded, six-armed placebo controlled dose determination study to investigate the optimal dose of tamoxifen with the most favorable side effect spectra. To reduce the number of participants, costs and to shorten the trial period; change in mammographic density will be used as clinical outcome. After randomization and baseline mammography, women will be treated with placebo, 1mg, 2.5mg, 5mg, 10mg or 20mg of tamoxifen for six months where after a subsequent mammogram is performed.

Eligibility criteria: 1) Attending the national Swedish mammography screening program, 2) Having a measurable mammographic density, i.e. ≥4.5 % density (volumetric) measured by Volpara.

Specific aims: The primary aim is to identify the minimum dose of tamoxifen non-inferior in its ability to reduce mammographic density and with fewer side effects compared to 20 mg of tamoxifen. Secondarily, to study the associations between different doses of tamoxifen and changes in circulating levels of a number of proteins, lipids, hormones, and tamoxifen metabolites, including the impact of polymorphisms in the CYP2D6 gene. A translational aim is to study molecular changes in the healthy breast tissue as a result of tamoxifen exposure.

Statistical Methods: Previous studies have shown that ~ 50% of women treated with 20mg of tamoxifen have a reduction in density and respond to therapy. We therefore use the median density decrease in women treated with 20mg tamoxifen as the predefined response threshold. The primary efficacy endpoint is thus the proportion of responders that reaches this threshold. We will test for non-inferiority after treatment with placebo, 1mg, 2.5mg, 5mg, and 10mg compared to the group of women treated with 20mg tamoxifen. Per definition 50% of the women in the 20mg group are responders. The non-inferiority margin is defined to be 16.7 percentage points; that is the fraction of responders is not less than one third of the treated individuals (50% minus 16.7% = 33.3%). The null hypothesis is thus that the proportion of responders in women treated with placebo, 1mg, 2.5mg, 5mg, and 10mg is 33.3% or higher. Power calculations have determined a need of 1200 participants corresponding to 200 participants in each treatment arm.

Present accrual and target accrual: The trial will start recruiting as of September 2016. Eligible women are identified from the Swedish mammographic screening cohort, i.e. women age 40-74 years invited for biennial screening.

Title: A randomized trial evaluating bioimpedance spectroscopy vs. tape measurement in the prevention of lymphedema following breast cancer treatment

Body: Background: Breast cancer related lymphedema (BCRL) represents a common treatment associated complication following surgery, radiation and/or chemotherapy. Increasing data has demonstrated the ability of new diagnostic modalities to detect BCRL in the subclinical phase of the process allowing for early intervention.

Trial Design: This 2-group stratified randomized clinical trial evaluates the effectiveness of bioimpedance spectroscopy (BIS) for early detection and prevention of BCRL compared to tape measurement (TM). Baseline assessments are made preoperatively. Two-months post-op, patients are censored out if they have developed any of the exclusion conditions, did not have a mastectomy, axillary dissection, >6 sentinel nodes removed, radiation therapy, or taxane. Remaining patients are randomized within site to either BIS or TM; monitored at 3 to 6-month intervals up to 36-months post-op for a change over baseline specified to trigger a compression sleeve & gauntlet intervention. Cohort trigger thresholds are change of ≥10 L-Dex units or 5 to <10% volume. If the intervention is triggered, measurements by the other method are taken before initiating the 4-week intervention. Post intervention, patients are monitored only with TM. Volume change of ≥10% results in study removal and physician referral. At the 2 study endpoints (36 month visit or volume change of ≥10%) measurements are taken with each method.

Eligibility Criteria: Inclusion criteria: ≥ 18 with histologically confirmed stage I-III breast cancer (BC) or DCIS with planned surgery. Exclusion criteria include history of BC therapy or lymphedema.

Specific Aims: The primary hypothesis is that subclinical detection of BCRL with BIS and early intervention will reduce the rate of lymphedema progression (as measured by referral to complex decongestive physiotherapy) compared to TM. Secondary outcomes include BCRL risk factors, quality of life, and time to treatment.

Statistical Methods: Sample size and powering were based on the hypothesis that BIS would reduce progression rate by 20%. A rate of 50% progression in the TM group was used as the standard. 1100 patients will be enrolled to result in randomized groups of 100 (Total N=200) Statistics include relative risks with respective bootstrapped 95% C.I. and Cochran-Mantel-Haenszel tests.

Present Accrual and Target Accrual: Overall, the study target or expected enrollment as of the end of March 31, 2016 was 690 participants, 534 were actually enrolled (actual accrual 77% of target). Accrual at the study sites ranged from 15 to 104% of target.

Title: Influence of exercise or educational programs on long-term physical activity by patients after surgery for primary breast cancer: A randomized trial

Kawada K, Taira N, Hatono M, Takahashi Y, Miyoshi Y, Nogami T, Iwamoto T, Motoki T, Sien T, Matsuoka J, Doihara H, Ikeda M, Ogasawara Y, Takabatake D, Yoshitomi S, Kiyoto S, Yamamoto S, Mizota Y and Oka K. Okayama University Hospital, Okayama, Japan; Fukuyama City Hospital, Fukuyama, Hiroshima, Japan; Kagawa Prefectural Central Hospital, Takamatsu, Kagawa, Japan; Kochi Health Science Center, Kochi, Japan; Japanese Red Cross Okayama Hospital, Okayama, Japan; Shikoku Cancer Center, Matsumoto, Ehime, Japan; National Cancer Center Hospital, Chuo-ku, Tokyo, Japan and Faculty of Sport Sciences, Waseda University, Shinjuku-ku, Tokyo, Japan.

Body: [Background]
Past studies revealed that a moderate to high level of physical activity after diagnosis of breast cancer reduces both the risk of breast cancer-related death and death from all causes. Furthermore, some randomized studies suggested that exercise programs improve the percentage of patients who complete the chemotherapy and quality of life, and decrease fatigue, and adverse events. The issues to be determined include defining an established uniform exercise program and the efficacy of a long-term exercise program after breast cancer surgery.

[Object] To elucidate the efficacy of a long-term exercise program and to verify the safety and feasibility of a uniform exercise program using an existing social resource after primary therapy of breast cancer.

[Method] Subjects: The subjects included patients who had completed treatment for primary breast cancer, including surgery and/or adjuvant chemotherapy. Patients with metastatic breast cancer were excluded.

Randomization & intervention: The patients were randomly assigned to three groups.

The first group followed an exercise program at Curves® that involved 30 minutes of exercise, including aerobics, weight training, and stretching 3 times a week for 4 months. The second group was given life-style guidance at least once that patients participate in a lecture program about recommended exercise at this point and the importance of weight control after diagnosis of breast cancer using a brochure. The third group served as controls that the patients receive a brochure used same one in the second group. The variables included age and weight.

Outcome: The primary endpoint is level of physical activity at 1 year after randomization, and the secondary endpoints are the percentage of those completing the exercise program, patient reported outcomes (QOL, cancer or treatment associated symptoms, fatigue, depression, and anxiety), body mass index, bone density, and level of lymphedema.

Period of research: The study will last 2 years beginning March 2016.

Sample size: We plan to enroll 400 patients to detect 20% difference with 90% power.

Additional study: Some biochemical markers in the blood will be evaluated to determine the mechanism of the effect of exercise on the human body.
Title: Positive behavior change and weight loss in breast cancer survivors on hormonal adjuvant therapy: An energy balance research in cancer (EnBaR) prospective study

Body: BACKGROUND: Observational studies have repeatedly linked obesity to increased cancer incidence, recurrence, and mortality, leading to cancer treatment guidelines that call for maintenance of a healthy body weight, regular physical activity (PA) regardless of body mass index (BMI), and modest weight loss for overweight and obese cancer survivors (CS). Despite these recommendations, newly published reports suggest that more than 70% of CS are overweight or obese, and only 1/3 engage in the recommended levels of PA. Although trials have demonstrated that energy balance (EB) interventions are feasible in CS, it has been concluded that ongoing behavioral support is needed to implement and sustain changes in weight and PA. Through the subsequent Energy Balance Research (EnBaR) the incorporation of a weight management and PA program focused on ongoing behavioral support for breast cancer survivors (BCS) as an effective method for implementation of lifestyle modifications will be investigated.

TRIAL DESIGN: This is a single-arm prospective observational study investigating if implementation of an EB Program for BCS is an effective intervention for producing lifestyle behaviors. Eligible subjects must be female BCS ≥18 years with BMI ≥25 who are initiating hormonotherapy (HT) as their only oncology treatment modality. Subjects will consult with a Registered Dietitian (RD) to establish goals based on specified interventions for reducing overall BMI at the time of initiating their prescribed HT. Subjects will subsequently receive telephone calls from the RD at bi-monthly intervals to discuss the established points of intervention, answering questions proposed by the RD from a set intervention measurement scale. Patients will also report for body composition analysis performed by the RD via InBody at Baseline, Day 90, and Day 180. InBody is a validated tool that utilizes direct segmental multi-frequency bioelectrical impedance analysis (DSM-BIA) to provide a highly accurate report of an individual’s body composition.

AIMS: Determine change in Percent Body Fat (PBF) and BMI during adjuvant hormone treatment for breast cancer patients.

STATS/TARGET ACCRUAL: To assess % change in BMI and PBF between baseline and 180 days, one-sample $t$-tests will be used. Assuming an average (avg) baseline BMI of 33.7 with a standard deviation of 8.5; a sample of 120 patients will yield 89.4% power using a two-sided $t$-test to detect a 13% reduction in BMI to an avg of 29.32 and 82.8% power to detect a 12% reduction to an avg BMI of 29.656. Similarly, a $t$-test will have 83.7% power to detect a 12% decrease in % change in PBF assuming an avg baseline PBF of 41.36 with a standard deviation 10.5. The power calculations were accomplished by generating simulations of size 10,000 replications conducted at the 0.025 significance level using the TTEST procedure of SAS 9.4 [SAS Institute Inc., Cary, NC, USA]. The calculations assume a linear correlation of 0.5 between the baseline and Day 180 measurements and are Bonferroni corrected to maintain a familywise error of 0.05 for the primary analysis. All statistical analyses will be conducted using SAS 9.4. Statistical significance will be defined as $p < 0.05$. 

2016 San Antonio Breast Cancer Symposium

Publication Number: OT3-07-03
Title: A randomized study comparing MoistHer to topical lidocaine for female breast cancer survivors with dyspareunia

Body: **BACKGROUND:** Problems related to sexual function are known to affect quality of life in female breast cancer survivors (BCS). A leading symptom of sexual dysfunction reported by BCS is dyspareunia, defined as moderate to severe penetrative pain with intercourse that results in reduced frequency of intercourse or abstinence. Dyspareunia in females is most commonly caused by vaginal dryness and primarily treated with estrogen therapy, a contraindication for many BCS. A recent trial found that estrogen-deficient BCS with dyspareunia who applied topical lidocaine to the vulvar vestibule (VV) prior to penetrative intercourse (PI) reported decreased pain during PI and improvement of sexual distress (Goetsch MF, JCO 2015). Identification of additional non-hormonal therapies to target the VV prior to PI may therefore provide treatment options for the improvement of sexual dysfunction in BCS with dyspareunia.

**TRIAL DESIGN:** This is a double-blind, randomized trial to evaluate the benefits of applying natural lubricant MoistHer (MH) to the VV prior to PI in female BCS with dyspareunia. Subjects must be female ≥18 years BCS without active treatment (except for hormonotherapy), in a stable heterosexual partnership for ≥5 years, and report ≥ 3 months of consistent pain with PI. Patients with a history of pelvic pain, pelvic floor myalgia, vulvar dermatoses, or vaginismus will be excluded. Subjects will be randomized 1:1 to blinded home therapies of either MH or Topical Lidocaine (TL) for application to VV. MH is a commercially available vaginal moisturizer made of emu oil, tocopherol, safflower oil, and aloe extract and will be supplied by manufacturer Dromeo Inc. TL will be a 4% aqueous lidocaine hydrochloride solution prepared by research pharmacist (RP). Both MH and TL will be dispensed by RP in identical unmarked bottles. Subjects will agree to apply study liquid to VV and attempt PI at least twice per week for 4 weeks while maintaining a study diary to record pain scores. Outcomes will be measured via Sexual Function Questionnaire (SFQ), Female Sexual Distress Score-Revised (FSDS-R), and a rating of pain during PI on a scale of zero (no pain) to 10 (worst pain) via Numerical Rating Scale (NRS), to be completed by subjects at baseline, 2 weeks, and 4 weeks.

**AIMS:** Primary endpoint is pain with PI, to be reported as a score on the NRS. Secondary endpoints are improved quality of sexual life and resumption of PI, to be measured by the SFQ and FSDS-R.

**STATS/TARGET ACCRUAL:** A total of 50 patients will be recruited and randomized to receive either MH or TL at a 1:1 ratio (25 per group) using the Pocock-Simon dynamic allocation method. This sample size will achieve 94% power to detect at least 1.5 points NRS mean difference between treatments. NRS change will be compared between the two arms using a two-sample t-test (Pooled Standard error or Satterthwaite approximation as appropriate). Secondary outcomes include the SFQ and FSDS-R for which a longitudinal analysis of subscale scores will be conducted using a generalized linear mixed-effects model with fixed effects for treatment group and time. All statistical analyses will be conducted using SAS 9.3 [SAS Institute Inc., Cary, NC, USA]. Statistical significance will be defined as p < 0.05.
Title: A randomized study of personalized music therapy for patients with early stage breast cancer receiving chemotherapy

Body: BACKGROUND: A review of the literature identifies high levels of anxiety and depression as adverse effects of oncology diagnosis and treatment, even for patients with curable cancers such as early stage breast cancer (ESBC). Studies have reported that music therapy yields remarkable, multi-dimensional benefits on an individual's mood and state of mind. The purpose of this trial is to evaluate the impact of personalized music therapy (PMT) in reducing anxiety and other adverse mental health symptoms experienced by patients receiving chemotherapy treatment for ESBC.

ELIGIBILITY: Females ≥ 18 years diagnosed with ESBC (Stage I-III) initiating intravenous chemotherapy as their only oncology treatment modality who report anxiety ≥ 4 on a numerical rating scale of 0-10.

TRIAL DESIGN: This is a 4-week, two-arm, randomized (1:1) trial evaluating the anti-anxiety benefits of PMT for women with ESBC initiating intravenous chemotherapy. The patients randomized to the experimental group will participate in 30-minute PMT sessions conducted by a Licensed Musical Therapist (LMT). Initial PMT will occur within 1 hour of the patient's first chemotherapy infusion (C1D1), then once weekly for the remaining 3 weeks of the trial. Patients randomized to the control group will be referred to the medical oncologist for standard of care (SOC) anxiety treatment. Outcomes will be measured via the Generalized Anxiety Disorder Assessment (GAD-7), the Center for Epidemiologic Studies Depression Scale (CES-D), the Pittsburgh Sleep Quality Index (PSQI), and the Symptom Inventory Tool-M.D. Anderson Symptom Inventory (SIT-MDASI) to be completed by both cohorts at baseline and regular intervals for the duration of the study.

AIMS: The primary endpoint is to determine the impact of PMT during chemotherapy treatment on patient reported anxiety (GAD-7). Secondary endpoints will determine the impact of PMT during chemotherapy treatment on patient reported depression (CES-D), sleep disturbances (PSQI), and quality of life (SIT-MDASI).

STATISTICAL METHODS/TARGET ACCRUAL: Patients will be randomized to receive either PMT or SOC using the Pocock-Simon dynamic allocation method to balance tumor stage between the arms. With 30 patients in each arm and approximate target accrual of 60, the study achieves 80.0% power to detect a 0.65 standard deviation unit effect size of the change in scale measure between baseline and 4 weeks at the 0.05 significance level using a one-sided two-sample t-test. GAD-7 change will be compared between the two arms using a two-sample t-test (Pooled Standard error or Satterthwaite approximation as appropriate). The secondary outcomes include CES-D, PSQI, and SIT-MDASI for which a longitudinal analysis of subscale scores will be conducted using a generalized linear mixed-effects model with fixed effects for treatment group and time. All statistical analyses will be conducted using SAS 9.3 [SAS Institute Inc., Cary, NC, USA]. Statistical significance will be defined as p < 0.05.
**Title:** Adding whole-body MRI to body CT scans when evaluating response to systemic anti-cancer therapies alters treatment decisions in metastatic breast cancer

Kosmin M, Makris A, Joshi PV, Ah-See M-L and Padhani AR. Mount Vernon Cancer Centre, Northwood, Middlesex, United Kingdom and Paul Strickland Scanner Centre, Northwood, Middlesex, United Kingdom.

**Body: Introduction**
Accurate evaluation of disease extent and response to systemic anti-cancer therapy (SACT) is key to the clinical management of patients with metastatic breast cancer. By identifying disease distribution and response (particularly progression prior to symptomatic deterioration), imaging aids therapy choices and may maximise quality of life. Whole body MRI (WB-MRI) has increased accuracy for detecting liver and bone disease in breast cancer; however, its potential impact on patient management is largely unexplored. Thus, the purpose of this study was to evaluate the added value of WB-MRI with standard of care CT scans for clinical decision making in routine practice for patients with metastatic breast cancer.

**Methods**
All patients with metastatic breast cancer who had undergone WB-MRI between 1st April 2009 and 31st March 2016 were screened for this study. Those who had undergone a CT scan of the chest, abdomen and pelvis (CT-CAP) within 14 days of a WB-MRI date were eligible. Original radiology reports for the WB-MRI and CT-CAP were reviewed to establish the extent of reported disease and the SACT response assessment. Contemporaneous medical notes were reviewed to establish the impact of the paired imaging findings (and clinical review) with regard to therapy decisions per time point.

**Results**
210 pairs of WB-MRI and CT-CAP scans in 101 patients were eligible for analysis. The median age of the studied patients was 56 years (range 23 to 84 years). 46 examination pairs were baseline studies; 164 were undertaken for response assessments (1st line SACT = 46; 2nd line = 27; ≥3rd line = 58; no information = 33).

In 140 cases (66.7%) there were differences between the extent of disease reported by the WB-MRI and CT-CAP. Of these, 112 (80.0%) were due to the WB-MRI reporting additional sites of disease not evident on CT-CAP, mostly skeletal lesions. CT-CAP showed more disease in 10.0%, mostly lung lesions. 10.0% had some lesions evident only on WB-MRI and other lesions evident only on CT-CAP.

Of the 164 scan pairs performed for SACT response assessment, there were differences in the reported response to therapy in 46 cases (28.0%). 89.1% of disagreements were due to WB-MRI showing evidence of either disease progression (67.4%) or partial response (21.7%) that was reported as stable disease on CT-CAP.

Decisions to change SACT in response to disease progression reported by either/both imaging methods were made in 80 cases. Of these, treatment changes were made due to progression reported only on WB-MRI in 23 (28.8%) cases.

**Discussion**
This is a retrospective analysis of the real world use of WB-MRI and CT-CAP in the clinical practice of metastatic breast cancer, evaluating their impact on clinical care on a per time point basis. WB-MRI identified additional sites of disease (mostly bone) in over half of patients, which affected SACT decisions in a significant proportion of cases. In many cases, SACT changes would not have been made at the same time point without WB-MRI information. Further research is required to test the hypothesis that earlier identification of disease progression by WB-MRI leads to improved quality of life and patient outcomes.
Title: Characteristics of physician detected breast cancer

Malmgren JA A, Atwood MK K and Kaplan HG G. HealthStat Consulting Inc, Seattle, WA and Swedish Cancer Institute, Seattle, WA.

Background: Clinical breast examination (CBE) conducted as a part of a routine or annual physical exam is no longer recommended by the American Cancer Society. The U.S. Preventive Services Task Force has not issued any guideline on use of CBE stating there is not enough evidence to recommend for or against the practice.

Methods: A retrospective cohort study was conducted of all physician detected breast cancers (BC) stage 0-IV (N=641) in a dedicated institutional breast cancer registry research database from 1990-2014 (n=12081). Method of detection was chart abstracted at time of diagnosis. Categories are 1) physician or health care professional detection (PhysD) of a palpable lump or abnormality at routine examination prompting a BC work up and diagnosis; 2) patient detection (PtD) of breast symptoms such as a palpable lump, pain, swelling or bleeding which prompted a doctor visit and subsequent BC diagnosis; and 3) mammography detected (MamD) disease discovered by routine mammogram in the absence of complaints or known physical findings. Patients with 'other' or 'missing' diagnosis method were excluded (n=214). Bivariate, multivariate and survival analysis were used to compare characteristics and disease specific survival (DSS).

Results: Over the 25 year time period 5% of breast cancers were PhysD (n=641), 38% PtD (n=4556) and 60% MamD (n=6852). Percentage of PhysD BC decreased from 9% to 3% over time as relative incidence of MamD BC increased with the number per year remaining constant (20-40 cases/year). On average PhysD BC cases were older than PtD BC and younger than MamD BC cases [mean age PtD = 53 years, PhysD = 58 years, MamD = 60 years, p<.001] with significantly more PhysD cases age 75 and older [PtD = 8%, PhysD = 15%, MamD = 12%, p<.001]. PhysD BC was 56% stage II-IV vs. 23% MamD BC but less than PtD BC (69%) (p<.001). PhysD BC was more likely to be hormone receptor negative (15%) and more likely to be triple negative (ER-/PR-/Her2neu-) (11%) than MamD BC (6% for each) (p<.001). Mean tumor size of PhysD BC was significantly larger than MamD BC and significantly smaller than PtD BC [MamD BC = 1.69 cm (95% CI = 1.62, 1.76), PhysD BC = 2.55 cm (95% CI = 2.39, 2.70), PtD BC = 3.23 (95% CI = 3.16, 3.31) p<.001]. Histology for PhysD BC cases was 7% less ductal and 3% more lobular than either PtD or MamD BC. PhysD BC was less likely to be seen on subsequent mammography (21%) than PtD BC (17%) (p<.001). In a multinomial regression model, PhysD BC differed significantly by age, stage and HR status when compared to PtD and MamD BC (p<.001). In disease specific survival analysis of the invasive BC cases, the PhysD cases had significantly better DSS than the PtD cases but worse DSS than the MamD BC cases [5 year DSS: PtD = 92%, PhysD = 95%, MamD = 98%; 10 year DSS: PtD = 85%, PhysD = 92%, MamD = 95% (p=.004 PhysD vs. PtD, p<.001 PhysD vs. MamD).

Conclusions: Clinically detected breast cancer consistently presents as a small but significant portion of the breast cancer population. Physician detected breast cancer is less often seen on subsequent mammogram even after presentation of a palpable mass. While the percentage is modest the cost is minimal. CBE should continue to be taught and practiced by primary care physicians.

Title: Evaluating the feasibility of a web-based preference-tolerant randomized trial of risk-based vs. annual breast cancer screening: WISDOM study pilot

Body: Background: The WISDOM Study (Women Informed to Screen Depending on Measures of risk) aims to examine the effectiveness of personalized breast cancer screening and to bring objective recommendations to the current mammography screening debate. The WISDOM Study is a 100,000 woman randomized trial with a preference-tolerant design that will determine if risk-based screening (RBS) vs. annual screening, is as safe, less morbid, enables prevention and is preferred by women. A pilot was conducted to test the logistics of online participation and examine the acceptance of the study design and approach.

Methods: Women were recruited from the UCSF site of the Athena Breast Health Network, a clinical care-research cohort of 110,000 women from the 5 University of California Medical Centers and Sanford Health. The pilot recruited women via email who were 40 -74 years of age with no history of breast cancer and a normal mammogram in the past year. Those interested visited the WISDOM Study website (wisdomstudy.org), signed up, elected randomization or self-selection, provided electronic consent using DocuSign (eConsent), and completed genetic testing (RBS arm). The Breast Cancer Surveillance Consortium (BCSC) model (standard risk factors, ethnicity, and breast density) in addition to genetic testing (9 genes and 75 SNPs) was used to calculate breast cancer risks that informed the start and frequency of screening for women in the RBS arm. BCSC was also used in the annual screening arm but did not inform mammography screening recommendations. The pilot used a mixed method approach (using enrollment data, Exit Survey data, individual interviews and focus groups) to assess enrollment preferences, randomization acceptance and overall study workflow.

Results: The online electronic enrollment process and patient engagement portal was successfully implemented. In total, 639 women were invited, 235 registered (34%), and 171 (27%) consented to the pilot. Of these, 74% (127) elected to be randomized, and 26% chose to self-assign (66% chose annual screening (29)). Mean age was 56 years and the ethnic breakdown of the cohort was: 79% White, 10% Asian, 7% Latino, 3% Black, 1% other. 92% of those in the risk-based arm of the study completed genetic testing and were given results; only one genetic mutation was identified and occurred in CHEK2. Within the RBS arm (78), mammography recommendations were: 61% no further mammography until the age of 50, 22% biennial, 11% annual, and 6% every 6 month alternating MRI and mammogram. Exit Survey data illuminated confusion in study arm names (risk-based vs. annual), randomization acceptance (74%), annual arm preference in the self-selection group (66%), eConsent satisfaction (90%), enrollment process ease of use (88%), and website content, navigation and appearance satisfaction (66%). The pilot concluded in May 2016 to allow for refinements prior to the full trial.

Conclusion: Our pilot demonstrates that the majority of women are willing to be randomized and participate in an online screening study to answer the important question on optimal breast cancer screening. The pilot study results will inform implementation of the 100,000 women WISDOM Study which launches in fall of 2016.
Title: Study on over-diagnosis of high-precision breast cancer screening – Consideration from epidemiological point of view

Takebe K and Arai T. Takebe Breast Care Clinic, Takamatsu, Kagawa, Japan.

Body: <Introduction>
In breast cancer screening, it has been attempted to combine US with MMG. For relatively small breasts and dense breasts, there is the opinion that this combination is useful. On the other hand, the problem of over-diagnosis of breast cancer screening has been raised. We’ve been breast cancer screening with US/MMG combination method since 2005. The results were examined from the epidemiological point of view.

<Subjects and Methods >
Breast cancer discovery rate through US/MMG screening at our facility from 2005 to 2014 was considered. The medical examination was performed on 35,353 women. Kagawa Prefecture, in which our facility is located has had 100 percent breast cancer registration for more than 10 years. We have compared the breast cancer registration of 2013 with our examination results.

<Results>
Asymptomatic breast cancer detection rate in our breast cancer screening was 0.6%. % of the detected cancer was DCIS. Low-grade DCIS (Van Nuys 1 and 2) accounted for three-quarters of DCIS. In invasive carcinoma, 10 mm or less of luminal A type was 17%, other luminal types 19%, non-luminal types 5% and unclassified 6%. If our facility's highly precise breast cancer medical examination were performed throughout Kagawa Prefecture, DCIS would be found in 860 cases, 10 mm or less of luminal A type found in 276, other luminal type found in 320 and non-luminal type found in 70 cases per year. Compared to the Kagawa Prefecture breast cancer registered in 2013, DCIS was 6.6 times larger than the registered data, 10 mm or less of luminal A 2.9 times larger, other luminal types 1.1 times larger, and non-luminal types 1.2 times larger. The differences between the registered data and our findings for DCIS and 10mm or less of luminal A type are remarkable.

<Conclusion>
With the US/MMG combination method, the detection rate of DCIS and 10 mm or less of luminal A type have been excessive. Many type of DCIS and tiny luminal A type must exist latently. When performing a high-precision breast cancer screening, it is necessary to note such over-diagnosis. Furthermore, it is also necessary to re-examine the pathology diagnostic criteria of DCIS.
Title: Biology and long-term prognosis of screening detected non-palpable breast cancer by ultrasound in hospital-based Chinese population (2001-2014)

Body: Background: Milestone studies showed that ultrasound (US) was an effective primary screening test for breast cancer both in the western world and in China [PMID: 26712110, 26715161, and 25668012]. Ultrasound has been officially designated to be the initial imaging test for breast cancer screening in Beijing and several other cities in China, due to its improved sensitivity in Chinese women who usually have denser breasts and develop breast cancer earlier than Caucasian counterparts. Study showed that it would take 40 years to screen each woman in the target age group once [PMID: 26808342]. The mainstay modality of breast cancer screening in China is the hospital-based opportunistic screening among asymptomatic self-referred women. However, there is little data about the tumor biology and long-term survival of the US-detected non-palpable breast cancer (NPBC) in hospital-based Chinese population.

Methods: From January 2001 to December 2014, 3,786 asymptomatic women with positive (BI-RADS 4 and 5) initial screening US underwent biopsies in Peking Union Medical College Hospital, and 572 NPBC in 556 women were diagnosed. Women without dense breasts (defined as BI-RADS category C and D) also received screening mammography (MG) after physical examination and ultrasound. 788 patients with positive (BI-RADS 4 and 5) mammogram (MG) and normal US (BI-RADS 1, 2 and 3) underwent MG-guided biopsies and another 127 NPBC were diagnosed in 126 women. The clinicopathological features, treatment choice, 10-year disease-free survival (DFS) and overall survival (OS) were reviewed and compared between the US-detected and MG-detected NPBC. Prognostic factors of NPBC were identified.

Results: Overall, US could detect more invasive NPBC (83.4% vs 54.3%, p<0.001), lymph node positive cancer (19.1% vs 10.2%, p<0.001) and multifocal cancer (19.2% vs 6.3%, p<0.001). In invasive NPBC, US detected more low grade cancer (21.4% vs 10.2%, p=0.001), multifocal cancer (20.7% vs 2.9%, p<0.001), Her2 negative cancer (77.6% vs 62.3%, p=0.001) and larger tumor (pT1c+pT2, 53.3% vs 37.6%, p<0.001). There was no significant difference in immunophenotype/subtype, treatment methods, DFS or OS between US- and MG-NPBC among ductal carcinoma in situ (DCIS), invasive and all NPBC.

§ Kaplan-Meier survival curves between each two subgroups would be displayed in the poster.

Conclusion: Compared to MG, US detected more invasive NPBC with positive lymph node in hospital-based asymptomatic self-referred Chinese women, who could achieve comparable 10-year DFS and OS as MG-detected NPBC. US could serve as the feasible initial imaging modality in hospital-based opportunistic screening Chinese women.
Title: The impact of the introduction of breast cancer screening on a symptomatic breast cancer unit

Body: Background:
Breast screening with mammography remains the gold standard and is funded in Ireland for women aged 50–64. Several issues including overdiagnosis, overtreatment, false negative mammography, the presence of mammographically occult and interval cancers and has led to much controversy. The symptomatic breast cancer unit deals with all breast cancers and would be expected to be impacted by the National Breast Screening Programme (NBSP), established in 2008.

Aim:
We aim to assess the impact of the introduction of the NBSP on diagnosis of symptomatic invasive breast cancers in the screening population (50 – 64) compared to those 10 years younger (40 – 49) and 10 years older (65 – 75).

Method:
All symptomatic invasive breast cancers between January 2008 & January 2014 were reviewed. Patients were categorised by age (40 – 50, 50 – 64, 65 – 74). Tumour size, grade, subtype and lymph node status were determined. Disease progression was also recorded. Nottingham Prognostic Index (NPI) was calculated for all. Benign disease and non-invasive cancers were excluded.

Results:
A total of 956 patients between 40 and 75 had invasive breast cancer identified between January 2008 and January 2014. 403 of these were between the age of 50 – 64 and eligible for breast screening. A progressive reduction in patient numbers was identified in this age group biennially (Jan 08 – Jan 10: 151, Jan 10 – Jan 12:138, Jan 12 – Jan 14:114). There was no significant change in tumour grade (p=0.775). Favourable outcomes such as fewer nodal metastasis, a reduction in size, a lower NPI, and less aggressive disease progression were recorded in subsequent biennial groups when compared with the initial group.

Conclusion:
While the outcome may be multifactorial, it is clear that the size, stage and prognosis of the patient group eligible for screening has improved. It can be deduced that this may be attributable to breast cancer screening.
Title: An optimized 92-gene assay for the molecular diagnosis of triple-negative breast cancer

Sullivan PS S, Soifer HS S, Liu J, Zhang Y, Schnabel CA A and Brachtel EF F. University of California, Los Angeles, Los Angeles, CA; Biotheranostics, Inc., San Diego, CA and Massachusetts General Hospital, Harvard Medical School, Boston, MA.

Body: Background: Triple negative breast cancer (TNBC) often presents as high grade, poorly differentiated tumors resulting in a more aggressive disease for which accurate and timely diagnosis is critical to treatment selection or clinical trial enrollment. Furthermore, the high rate of distant metastases and absence of breast-specific immunohistochemical markers that contribute to diagnostic uncertainty may delay or limit treatment modalities that can lead to poorer outcomes. The 92-gene assay is an RT-PCR-based cancer classifier that previously demonstrated 80% accuracy for the diagnosis of breast cancer. In this study, blinded validation of an optimized algorithm and assay specifically developed to improve performance in TNBC is described.

Methods: To increase clinical scope for the diagnosis of TNBC, formalin fixed paraffin embedded specimens (N=103) representing a range of breast tumor histologies (e.g. TNBC, adenoid cystic, neuroendocrine, metaplastic, lobular, mucinous, DCIS) were added to the tumor reference database. A revised computational algorithm was constructed by the integration of machine learning techniques. For validation, tumor specimens (N=160) of TNBC (57%) and non-breast tumors (43%) were blindly tested using a 92-gene cancer classifier (CancerTYPE ID®, Biotheranostics, Inc). Tumor type predictions were reported as rank-order probabilities based on the degree of similarity to the tumor reference database. Assay sensitivity based on concordance of the main tumor type prediction with the reference diagnosis established by clinicopathologic review was analyzed.

Results: Assay results included 85 breast carcinomas (TNBC) (53%), 23 Salivary gland carcinomas (14%), and 52 carcinomas (33%) representing 11 other tumor types. For performance in TNBC, the 92-gene assay demonstrated an overall sensitivity of 93% (CI, 86-98), and sensitivities of 96% [95% CI, 89-99] and 80% [95% CI, 52-96], in primary and metastatic tumors, respectively (P=0.085). Additional performance characteristics are shown in Table 1.

Table 1

</tr>
<tr>
<td>Overall performance</td>
<td>160</td>
<td>140</td>
<td>0.88 (0.81-0.92)</td>
</tr>
</tbody>
</table>

Conclusions: An optimized 92-gene assay specifically modified to increase performance for the molecular diagnosis of TNBC showed strong accuracy in this blinded study. These findings support use of the 92-gene cancer classifier to aid in the diagnosis of primary or metastatic TNBC. With more refined tumor characterization, TNBC-specific chemotherapy regimens or clinical trial therapies may be pursued with the potential for improved patient outcomes.

Title: Breast implant associated anaplastic large cell lymphoma (BIA-ALCL) – The UK experience and first reported case of neoadjuvant brentuximab

Johnson L, O'Donoghue J, Stark H, Collis N, Lennard A, Butterworth M, McLean N, Youssef M, Gui G, Lyburn I, Bristol J, Hurren J, Smith S, Jacklin R, Cunningham D and MacNeill F. The Royal Marsden Hospital, London, England, United Kingdom; Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle Upton Tyne, United Kingdom; Lothian University Hospitals NHS Trust, Edinburgh, United Kingdom; Northumbria Healthcare NHS Foundation Trust, Northumberaland, United Kingdom; Gloucestershire Hospitals NHS Foundation Trust, United Kingdom; Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom and Broomfield Hospital, Chelmsford, United Kingdom.

Body: Introduction
The incidence of BIA-ALCL is on the rise. It is a recognised rare risk of breast implants. It commonly presents with a sudden, dramatic seroma around an implant, or occasionally a breast mass. Diagnosis is based on cellular morphology and staining positive for CD30 and negative for anaplastic lymphoma kinase (ALK).

The aetiology and management of BIA-ALCL remains unclear. Clemens et al. suggest the conventional Ann-Arbor staging system and aggressive local and systemic treatments may not be appropriate. In the majority of cases, BIA-ALCL is confined to the seroma or the inner aspect of the capsule, so total capsulectomy alone may be sufficient. Systemic therapy may only be required in the minority where disease extends beyond the capsule. We present the UK BIA-ALCL data using the new specific staging system.

Results
We report 11 cases of BIA-ALCL from seven regional centres. Treatment was multidisciplinary between breast/plastic surgery and haemato-oncology and based on best available evidence and expert opinion. Mean lead-time from implant to diagnosis was 10 years.

Using the new classification, eight Stage I cases that presented with recurrent seroma were treated successfully with implant removal and total capsulectomy. Four patients had bilateral breast augmentation (BBA); two had bilateral risk-reducing mastectomies (RRM) with implant reconstruction; two had a unilateral mastectomy and implant reconstruction for breast cancer, one of which had previously received adjuvant chemo-radio- and endocrine therapy.

All but one patient with bilateral implants had surgery to remove both implants and ipsilateral total capsulectomy. Of these, three also had contralateral capsulectomy and the pathology was benign. One patient had unilateral capsulectomy and bilateral exchange of implants.

Three patients presented with Stage IIA disease. One had previous RRM and implant reconstruction and presented with a mass. Treatment was CHOP+ (Echelon2 trial), radiotherapy and implant removal, she remains well at two years. One patient with previous BBA following a routine implant exchange developed a BIA-ALCL mass at the drain site. She was treated with local excision, adjuvant CHOP and radiotherapy. She is well at four years.

The third patient had BBA and presented with a mass adjacent to the implant and progressed rapidly through neoadjuvant CHOP to develop life threatening chest wall/thoracic cavity involvement. She achieved complete pathological response with six cycles of Brentuximab followed by bilateral total capsulectomy and implant removal. This is the first reported case of neo-adjuvant antibody therapy in BIA-ALCL.

Discussion
Our data support the published literature demonstrating the majority of BIA-ALCL is stage I/II and can be safely managed with surgery alone. Chemotherapy was targeted at patients with more advanced local disease. Brentuximab, a monoclonal antibody is not licenced for BIA-ALCL but is used in refractory in ALCL. BIA-ALCL related death, although rare, is due to uncontrolled local disease progression.

Conclusion
BIA-ALCL cases must be staged according to the new system to avoid overtreatment. Brentuximab should be considered first line therapy for locally advanced BIA-ALCL.

Publication Number: P5-03-03

Title: A blood-based proteomic Videssa® breast assay performs comparably in women with dense and non-dense breasts

Body: Breast density is associated with reduced imaging sensitivity and specificity for breast cancer (BC). Women with dense breasts are at a four- to six-fold increased risk of developing BC. A biochemical approach that is not affected by density would provide an additional tool to health-care professionals who are managing women with dense breasts and suspicious imaging findings. Videssa® Breast, a combinatorial proteomic biomarker assay, comprised of Serum Protein Biomarkers (SPBs) and Tumor –Associated Autoantibodies (TAAbs) integrated with clinical characteristic data to produce one diagnostic score that reliably detects BC was recently developed as an adjunctive tool to imaging. The goal of this study was to determine whether the diagnostic performance of Videssa® Breast was impacted by breast density.

Provista-001 enrolled 351 participants under the age of 50 years with no prior history of breast biopsy, and Provista-002 cohort one enrolled 210 participants under the age of 50 years with no history of breast biopsy within six months; all participants were assessed as BI-RADS 3 or 4. Breast density status was retrospectively obtained for participants; the four American College of Radiology breast density categories (a, b, c, and d) used for clinical reporting were applied. Serum was collected and tested with Videssa® Breast. Women were categorized into Dense, which included categories c and d, and Non-dense, which included categories a and b, groups.

To understand the performance of Videssa® Breast in women with dense breasts, the clinical sensitivity, specificity, NPV and PPV were evaluated in the dense and non-dense groups from the comprehensive Provista-001 and Provista-002 set (n=545). Of these 545, breast density information was available for 454; 62.6% (n=284) were categorized as having dense breasts and 37.4% (n=170) were categorized as having non-dense breasts. The sensitivity of Videssa® Breast in the non-dense and dense groups was 92.3% and 88.9%, respectively, and the specificity in the non-dense and dense groups was 86.6% and 81.2%, respectively. No significant differences were observed in the sensitivity (p=1.0) or specificity (p=0.1783) of Videssa® Breast in detecting BC in participants with non-dense breasts compared to those with dense breasts. The NPV in both groups exceeded 99%; the PPV was similar across groups.

In summary, this study demonstrates that Videssa® Breast has comparable performance in women with dense and non-dense breasts. Videssa® Breast demonstrates high sensitivity and specificity for detecting BC (Grades I through III), irrespective of density status. Videssa® breast provides an additional tool for health-care providers when women with dense breasts present with challenging imaging findings. In addition, Videssa® breast provides assurance to a woman with dense breasts that she does not have BC, potentially reducing further anxiety in this higher risk patient population.
Title: To excise or not?: Scoring system for predicting malignancy in patients diagnosed with intraductal papilloma at ultrasound-guided core needle biopsy

Body: Background: The management of benign intraductal papillomas on core biopsy is controversial. The aim of this study was to determine factors that predict under-evaluation of atypical lesion or malignancy in patients diagnosed with benign papilloma at ultrasound-guided core needle biopsy (CNB), and to develop a prediction algorithm for scoring the possibility of a diagnosis upgrade to atypical lesion or malignancy based on clinical, radiological and pathological factors.

Methods: The study enrolled patients diagnosed with benign papilloma at ultrasound-guided CNB who subsequently underwent surgical excision of the lesion. Multivariate analysis was used to identify relevant clinical, radiological and pathological factors that may predict malignancy.

Results: A total of 520 CNBs led to a diagnosis of benign papilloma (including benign and atypical papillary lesion), of which 452 CNBs were benign papilloma without atypia. Of the 250 lesions in 234 women were underwent subsequent surgical excision, 44 (17.6%) were diagnosed with atypia or malignancy. Multivariate analysis revealed that bloody nipple discharge, size on imaging ≥15 mm, BIRADS≥4b, peripheral location, and a palpable lesion were independent predictors of atypical lesion or malignancy. A scoring system was developed based on logistic regression models and beta coefficients for each variable. The area under the ROC curve was 0.830 (95% CI: 0.665-0.996), and the negative predictive value was 100% for a score ≤4.

Conclusions: A scoring system to predict malignancy in patients diagnosed with benign papilloma at CNB was developed based on five factors: bloody nipple discharge, size on imaging ≥15 mm, BIRADS≥4b, peripheral location, and a palpable lesion. This system was able to identify a subset of patients with lesions likely to be benign, indicating that imaging follow-up rather than surgical excision may be appropriate.
Title: Development of a panel of serum-based protein biomarkers for the non-invasive detection of breast cancer in BI-RADS category 4 patients

Chapman KB B, Copeland K, Kidd J, Qiu L, Sheibani N, Tam O, Friedman L, Korn R, Fiorica J, Lourenco A, Suthers S and Hesterberg L. OncoCyte Corporation, Alameda, CA; Boulder Statistics, Boulder, CO; Scottsdale Medical Imaging, Scottsdale, AZ; Sarasota Memorial Hospital, Sarasota, FL; Rhode Island Hospital, Providence, RI and Mercy Clinic Oncology, Oklahoma City, OK.

Body: Background: Current breast cancer screening guidelines call for annual mammography for asymptomatic women age 45 to 54 and once every two years for women age 55 and older. Women with suspicious screening mammograms are recommended for a diagnostic mammogram and may also undergo MRI or ultrasound. Ultimately, suspicious findings unresolved by imaging typically result in the recommendation of a breast biopsy. Approximately 10% of suspicious diagnostic mammograms are recommended for breast biopsies and 67% to 95% of these biopsies yield negative results. With the goal of reducing the number of patients with benign pathology undergoing invasive biopsies, we conducted a screen for serum protein biomarkers and identified a novel panel for the non-invasive detection of breast cancer.

Methods: Serum samples were collected at two sites from women with suspicious diagnostic mammogram findings (primarily BI-RADS category 4) undergoing biopsy for the evaluation of a potential malignancy. Serum samples from 100-patients (50 benign pathology and 50 malignant pathology) were evaluated on the SOMAscan Assay 1.3k, which measures levels of 1,310 different protein analytes. Statistical screening methodologies, such as individual t-tests with control for false discovery, were used to identify markers with the potential to distinguish benign from malignant pathology. The candidate markers were further studied and combined using generalized linear modeling to develop three potential diagnostic models. K-fold cross validation was used to guard against over fitting of the models.

Results: A 15-marker model resulted in an AUC of 0.92 with a sensitivity of 90% and specificity of 76%. Two 6-marker models (with 4 markers in common) each resulted in AUC of 0.85, yielding a sensitivity of 90% with a specificity of 56% or 64%.

Conclusions: This study reveals a novel panel of serum protein biomarkers that may allow for the non-invasive and sensitive detection of breast cancer in BI-RADS category 4 patients. A multicenter study is underway to further refine and validate this panel in a larger set of prospectively collected patient samples.
Title: Clinical value of $^{89}$Zr-trastuzumab PET in HER2-positive breast cancer patients with a clinical dilemma

Schröder CP P, Bensch F, Brouwers AH H, Lub-de Hooge MN N, de Jong JR R, van der Vegt B, Sleijfer S and de Vries EG G. Universital Medical Center Groningen, Groningen, Netherlands; Universital Medical Center Groningen, Groningen, Netherlands; Universital Medical Center Groningen, Groningen, Netherlands; Universital Medical Center Groningen, Groningen, Netherlands and Erasmus MC Cancer Institute, Rotterdam, Netherlands.

Body: **Background:** Information on human epidermal growth factor receptor 2 (HER2) is essential for management of metastatic breast cancer (mBC). In patients suspected of HER2-positive mBC, standard work up may fail to clarify whole body HER2 status. We aimed to assess whether $^{89}$Zr-trastuzumab PET can support treatment decisions in patients posing this clinical dilemma.

**Methods:** $^{89}$Zr-trastuzumab PET was performed as described earlier (Gaykema et al, Clin Cancer Res 2014) in patients in whom standard work up with bone scan, FDG PET, CT and if feasible a biopsy, failed to evaluate HER2 status of their disease. $^{89}$Zr-trastuzumab PET was defined positive, when at least a dominant part of the tumor load showed substantial tracer uptake (Gebhart et al, Ann Oncol 2015), when tumor tracer uptake in single lesions (except brain) was ≥ normal liver uptake or when brain metastases had a tracer uptake > background. Circulating tumor cell (CTC) analysis prior to tracer injection was performed using the CellSearch System (Janssen Diagnostics LLC) and CTC HER2 status was assessed immunofluorescently. Questionnaires about treatment decisions were completed before, directly after and ≥3 months after $^{89}$Zr-trastuzumab PET.

**Results:** Twenty patients were enrolled: 8 with two primary cancers (HER2-positive and HER2-negative BC or BC and non-BC), 7 with metastases inaccessible for biopsy, 4 with prior HER2-positive and HER2-negative metastases, 1 with primary BC with equivocal HER2 status (average 4.23 HER2 gene copies/nucleus). $^{89}$Zr-trastuzumab PET was positive in 12 patients, negative in 7 and equivocal in one patient. In 15/20 patients $^{89}$Zr-trastuzumab PET supported treatment decision. The scan altered treatment of 8 patients, increased physicians' confidence without affecting treatment in 10, and improved physicians' understanding of disease in 18 patients. Ten patients had 1-99 CTCs, 6 with HER2 expression. There was no correlation between HER2 expression by CTCs and $^{89}$Zr-trastuzumab PET results or subsequent treatment decision.

**Conclusion:** $^{89}$Zr-trastuzumab PET, but not CTC analysis, supports clinical decision making in BC patients in whom standard work up fails to evaluate HER2 status. (Funded by the Dutch A Sister's Hope).
Title: The measurement of gait speed: An easy way to select older patients with breast cancer for an adapted therapeutic decision making

Pamoukdjian F, Bricou A, Boudabous H, Sebbane G and Zelek L. Avicenne Hospital, HUPSSD, Bobigny, France and Jean Verdier Hospital, HUPSSD, Bondy, France.

Background: Despite recommendations about the adaptation of therapeutic decision making by the International Society of Geriatric Oncology, there is no guidelines concerning breast cancer in older patients for whom a therapeutic decision making should be adapted. Currently, the G8 index ≤ 14/17 is recommended for patients aged 70 and over before a therapeutic decision making to select patients with a potential frailty. Moreover, gait speed (GS) at the threshold of 1 m/s has been reported in a recent review to identify complications associated with frailty in older outpatients. Indeed, these patients could experience poor outcomes with cancer treatments. For these patients, it is expected that they could not have a standardized decision. We aimed to assess the geriatric profil of older patients with breast cancer for whom a therapeutic decision making was adapted.

Methods: 64 outpatients with breast cancer aged 65 and over were prospectively and consecutively included between November 2013 and April 2016, in two teaching hospitals in a Paris suburb (France). All patients had a G8 index, measurement of gait speed over a short distance (4m) and a multidimensional geriatric assessment before therapeutic decision making. An adapted therapeutic decision making was defined if it not followed treatment recommendations based on tumor characteristics (pTNM, grade, status of hormonal receptors, HER2 status, Ki67 index). A univariate and multivariate analysis by using a logistic regression with a stepwise procedure were performed in all patients with an adapted therapeutic decision. Two models were created to assess the value of G8 index and GS. All variables with \( P < 0.20 \) were included in both multivariate models. All tests were two sided significant at 0.05. Informed consent was obtained from studied patients prior inclusion. This study was approved by a local committee ethic.

Results: 67% (n=43) of patients had an adapted treatment with a mean age of 82.6 +/- 5.7 years (67-95). Of these patients, 33 had an invasive ductal carcinoma, 23 lymph nod extension, 11 metastatic disease. The mean tumor size was 30.4 +/- 15.4mm. 37 patients had a SBR ≥ 2, 39 positive hormonal receptors, 5 positive HER2 status. The mean KI67 index was 24.2 +/- 20%. 37 received hormonotherapy, 18 surgery, 16 radiotherapy, 5 chemotherapy. Most of these patients (53.5%) had ECOG-PS ≤ 1, 39 G8 index ≤ 14 and 36 GS < 1 m/s. In the first model, GS < 1 m/s was the only variable significantly and independently associated with adapted treatment (aOR=5.65, 95%CI: 1.78-19.31, \( P=0.003 \)). In the second model, at least one severe comorbidity (CIRSG grade III, aOR=4.52, 95%CI: 1.30-17.84, \( P=0.02 \) and cognitive impairment (MMSE<24/30, aOR=4.60, 95%CI: 1.32-17.97, \( P=0.01 \)) were the only variables significantly and independently associated with adapted treatment. In the two models, G8 index was not significantly associated with adapted treatment.

Conclusion: A slow gait speed < 1 m/s could be used as a screening test to select older patients with breast cancer for an adapted therapeutic decision making.
Title: Use of natural language processing on mammography and pathology findings to supplement BI-RADS to improve clinical decision making in breast cancer care

Puppala M, He TC, Ogunti R and Wong STC TC. Houston Methodist Hospital, Houston, TX.

Body: Breast Imaging Reporting and Data System (BI-RADS) is a standard system used by clinicians to describe mammogram findings and sort the results into categories numbered 0 through 6; this makes accurately communicating about these test results and following up after the tests much easier. For example, the BI-RADS 4 score is given to lesions that carry a risk of malignancy between 2 and 95% such that a majority (69 to 95%) of BI-RADS 4 lesions are biopsied. Our goal is to create a better risk estimate score to stratify patients by developing a more accurate threshold for biopsy.

To accomplish this goal, we defined the personal risk factors, relevant descriptors in the mammography and pathology findings for every patient with BI-RADS 3, 4, or 5 risk score. Clinical data were sourced from the Methodist Environment for Translational and Outcomes Research (METEOR) data warehouse at the Houston Methodist Hospital. METEOR data warehouse contains 135,280 unique patient mammogram reports dating from January 1, 2006 to May 30, 2015. Manual abstraction from this large number of free text reports is not feasible due to the constraints on time and labor costs, and risk of human-error during manual extraction. We developed a natural language processing (NLP) tool called Methodist hOspital Text Teaser (MOTTE) to extract defined clinical parameters and derive the desired meaning from the volumes of free text reports automatically. MOTTE is a rule-based software tool programmed in Java, Structured Query Language (SQL) and an open source machine learning toolkit, OpenNLP. MOTTE combines regular expressions and algorithms to identify where in the dictionary keywords and phrases related to a concept are found.

Mammography findings from January 2006 to May 2015 were extracted including breast density as well as the presence of mass, calcifications, architectural distortion, asymmetric density, and calcification characteristics. A total of 717 patients with BI-RADS 5 mammograms who underwent breast biopsy within 3 months of the abnormal mammogram report date were identified using MOTTE, which also extracted personal history, family history, and subtype information (ER, PR, and HER2 status) of those patients. Clinical data including age, race, height, weight, and body mass index (BMI) were extracted from the METEOR data warehouse for those 717 patients. The extracted data were verified and validated with 99% accuracy by assessing a random 10% of records against a gold standard of manual chart review, which was completed by the clinical coauthors. MOTTE surpasses the manual method in terms of consistency, time, cost, and data preparation. Our ongoing study is to apply the MOTTE to extract distinct characteristics of BI-RADS 4 scored patients. The finding would help to refine biopsy recommendations and create a predictive model to drive evidence-based biopsy decision-making in breast cancer care.
Title: A high specificity and sensitivity qPCR Assay for HER2, ER and PR gene expression in breast cancer patients

Rinker KD, Fuh KF, McIntyre JB, Shepherd RD, Wang H-y, Morris D and Lee H. University of Calgary, Calgary, AB, Canada; Optipharm Inc, Wonju, Gangwon, Republic of Korea; Yonsei University, Wonju, Gangwon, Republic of Korea and Alberta Health Services, Calgary, AB, Canada.

Body: Introduction: For breast cancer patients, the reliable assessment of human epidermal growth factor receptor 2 (HER2), estrogen receptor (ER) and progesterone receptor (PR) expression levels is a key determinant for patient stratification and treatment. These markers are currently scored by immunohistochemistry (IHC), with Her2 equivocal samples progressing to in situ hybridization (fluorescent or silver, FISH or SISH, respectively) of DNA amplification. However, FISH/SISH are not quantitative, and may take weeks to deliver an analysis. Further, FISH/SISH do not address the possibility of Her2 gene transcription being an important factor in the Her2 status of a tumour. We developed a novel qPCR assay, the T3 qDx Breast Tumour Profile Test, to enable quantitative assessment of HER2, ER and PR gene expression in a single analysis.

Objective: In this study, we evaluated the performance of the T3 qDx assay in 118 patients in Alberta, Canada, to determine the relationship to a previous 390 patient study conducted in the Republic of Korea. Additionally, the assay was optimized to standardize template input and optimize PCR chemistry for each marker. A comparison of qPCR and digital PCR was made for samples with range of Her2 scores, but focusing on equivocal samples for which the qPCR results disagreed with FISH/SISH. This step was conducted to identify whether transcript levels were independent of either Her2 protein or DNA copies in this sample population.

Materials and Methods: 118 breast cancer FFPE tissue samples obtained between 2005 and 2010 and banked in Calgary, Canada were used in this study. 1mm core punches were made, and RNA was extracted using the RecoverAll TM Total Nucleic Acid Isolation Kit. cDNA was synthesized using the qScript™ cDNA Synthesis kit and stored at –80°C until analysis. HER2, ER and PR expression were quantified using the T3 qDx Breast Tumour Profile Test. qPCR was carried out on a ViiA 7 Real Time PCR Instrument, and relative gene expression calculated using B2M as the reference gene. Digital PCR (dPCR) was performed on a QuantStudio 3D instrument, with copy number determined vs. RNase P. Finally, Her2 test performance was compared to Luminex and an off-the-shelf TaqMan assay for 61 corresponding patient samples.

Results and Discussion: Our results show concordances of 97.2% and 98.1% respectively for unequivocal HER2 and hormone receptor status determined by IHC/FISH (SISH), meeting the minimum concordance threshold of 95% for molecular assays mandated by the American Society of Clinical Oncology/College of American Pathologists. For patients with equivocal HER2 IHC status, the assay showed 86.2% concordance. 75% of the samples with a FISH/SISH score of 2+ were also positive by dPCR. Among the 25% of samples with discordant FISH/SISH and dPCR results, 66% agreed between qPCR and dPCR, while 33% had disparate qPCR and dPCR results. The assay also showed higher specificity and sensitivity than Luminex and an off-the-shelf TaqMan assay for Her2 determination. Taken together, these results indicate that a qPCR approach for determining Her2, ER and PR status can be successful, and that a subset of tumours (~8%) may have transcriptional regulation of Her2 levels that differ from gene amplification findings.

Title: Development of a novel HER2 testing strategy, using image-based cell-sorting to isolate pure cell populations from FFPE upstream of FISH

Body: Fluorescent in Situ Hybridization (FISH) guidelines defined by American Society of Clinical Oncology (ASCO) and the College of American Pathologists for determining HER2 status are set to improve accuracy and usefulness as a diagnostic marker in breast cancer. Despite these guidelines, many factors can influence HER2 testing results such as sample preparation, assay-conditions and interpretation of test results due to heterogeneous breast cancer samples. In this multi-site study, sample preparation was carried out using the DEPArray™ to recover pure tumor cell populations from formalin-fixed, paraffin-embedded (FFPE) breast tumor samples. We then compared HER2/CEP17 ratios obtained from the DEPArray™ processed samples from each laboratory to routine FISH on tissue sections.

Methods: Eight breast FFPE tumor tissue biopsies were obtained from commercial tissue banks. From the paraffin tissue blocks, four consecutive tissue curls (each 50 microns thick) were prepared. One curl from each of the 8 patient samples was distributed to four different laboratories for analysis following DEPArray™ based sample preparation. After an initial disassociation of each curl into a single-cell suspension, intact cells were sorted and then recovered based on cytokeratin/vimentin/DAPI staining using the DEPArray™. Cytokeratin+/Vimentin-/DAPI+ tumor (~250) and Cytokeratin-/Vimentin+/DAPI+ stromal (~250) recovered cells were then deposited onto glass slides prior to standard dual-color HER2/CEP17 FISH analysis for comparison to conventional HER2 FISH result.

Results: Serially sectioned breast tumors from 8 negative/positive cases: 7 infiltrating ductal carcinoma (IDC) and 1 metastatic carcinoma were studied. All four sites demonstrated 100% concordance between FISH results compared to the conventional HER2 FISH result. Overall, >60% of DEPArray™ isolated cells were recovered from FFPE samples that ranged from 1-15 years of age and reported to contain 60% to 80% tumor content. The use of pure sorted cells permitted the accurate determination of HER2 amplification status in only the tumor cells while the stromal cells consistently yielded a more normalized ratio of HER2 to centromere 17.

Conclusion: The preliminary results of this multi-site study demonstrate that use of DEPArray™ for sorted pure populations is reproducible as well as reliable method for subsequent analysis of HER2 by FISH on FFPE derived tumor cells. Given that traditional FFPE-based HER2 FISH results may be influenced by the tissue sectioning procedure, tissue heterogeneity and/or the scattering of few HER2 amplified tumor cells among normal stromal cells. The DEPArray™ allows analysis of immunofluorescence images and DNA content to isolate and recover pure and intact cell populations. This isolation of pure cell populations prior to FISH analysis is attractive for achieving precise determination of HER2 status on equivocal cases. A more formal analytical validation of this approach through CLIA is currently underway.

Title: Abstract Withdrawn
Title: Serum thymidine kinase 1 activity as a pharmacodynamics marker of cyclin-dependent kinase 4/6 inhibition in patients with early stage breast cancer receiving neoadjuvant palbociclib

Liu N, Thomas S, Luo R, Hoog J, Suh EM M, Bergqvist M, Neumüller M, Guo Z, Vij K, Sanati S, Ellis M and Ma C. Washington University School of Medicine, St. Louis, MO; Biovica AB, Uppsala, Sweden and Baylor College of Medicine, Houston, TX.

Background: Thymidine kinase 1 (TK1) is a fundamental enzyme in DNA synthesis. TK1 expression is E2F-dependent and peaks in the S-phase of the cell cycle. In preclinical studies, inhibition of cyclin-dependent kinase (CDK) 4/6 led to dose-dependent reduction of TK1 activity in cultured media. We hypothesized that serum TK1 could serve as a non-invasive surrogate marker of cell proliferation in patients (pts) receiving CDK4/6 inhibitors. In this study, we examined serum TK1 activity from breast cancer (BC) pts enrolled on a neoadjuvant study of palbociclib (Palbo) plus anastrozole (A), for changes induced by Palbo, and correlated with changes in tumor Ki67.

Methods: In this phase II neoadjuvant study, 50 pts with clinical stage II or III estrogen receptor positive (ER+) HER2- BC, received A (in combination with goserelin if premenopausal) alone for 28 days in cycle 0 (C0), followed by the addition of Palbo (125 mg daily on days 1-21) on cycle 1 day 1 (C1D1) for 4 28-day cycles (C1 to C4) unless C1D15 tumor Ki67>10%, in which case pts went off study. Following completion of cycle 4, A was continued for another 3-5 weeks to allow Palbo washout prior to surgery, except in 8 pts who received an additional 10-12 days of Palbo immediately prior. Blood and tumor biopsies were collected at 4 time points: baseline, C1D1, C1D15, and surgery. Serum TK1 activity was measured using the highly sensitive Divitum™ assay according to the Divitum™ Instructions for use (Biovica, Sweden). Tumor Ki67 IHC was performed at the Washington University AMP laboratory using the CONFIRM anti-Ki67 rabbit monoclonal antibody (clone 30-9), and pathologist-guided image analysis.

Results: There was no statistically significant difference in TK activity between baseline and C1D1 serum samples (Table 1). However, serum TK activity decreased significantly from C1D1 to C1D15 following the addition of Palbo and increased significantly from C1D15 to surgery following Palbo washout (Table 1), indicating a significant effect of Palbo on TK activity. At C1D15, TK activity was below the detection limit of 20 Du/L in 44 of 48 pts, and was at low levels (24, 26, 26, and 58 Du/L) in the remaining 4 pts, indicating a profound effect by Palbo. Interestingly, the TK activities of the 4 pts with tumor Ki67 >10% at C1D15 were all below 20 Du/L, suggesting the possibility of tumor cell proliferation independent of CDK4/6 inhibition.

The sensitivity and specificity of change (increase/decrease) in serum TK activity to predict tumor Ki67 (increase/decrease) induced by Palbo were 83% (19/23, 95%CI: 66-99%) and 93% (26/28, 95%CI: 83%-100%), respectively. The Kappa statistic was 0.761 (P<0.001), indicating substantial agreement between the two tests.

Conclusions: Serum TK1 activity may serve as a pharmacodynamics marker of CDK4/6 inhibition and further investigation is warranted.

Title: Activation of ERβ in triple negative breast cancer results in cell cycle arrest

Reese JM M, Bruinsma ES S, Monroe DG G, Goetz MP P and Hawse JR R. Biochemistry and Molecular Biology, Rochester, MN; Molecular Pharmacology and Experimental Therapeutics, Rochester, MN and Oncology, Rochester, MN.

Body: Background: Triple negative breast cancer (TNBC), which comprises approximately 20% of breast cancer diagnoses, lacks estrogen receptor alpha, progesterone receptor and Her-2 expression. However, we have identified that 30% of TNBC patients express estrogen receptor beta (ERβ), a nuclear hormone receptor and potential therapeutic target. Here we examine the effects of ERβ in triple negative breast cancer cell lines.

Methods: Cell lines that stably express ERβ were used to perform microarray analyses following five days of estrogen treatment. Ingenuity pathway analysis was conducted on differentially expressed genes to determine alterations in biological pathways. The effects of ERβ on cell cycle progression and apoptosis was determined. Cell cycle-related expression changes were confirmed with RT-qPCR and western blotting. The impact of siRNA mediated gene silencing of CDK1 on TNBC cell proliferation was assessed as was the ability of ERβ to elicit anti-proliferative effects in the setting of CDK1 knockdown.

Results: We have shown that estrogen or ERβ-specific agonist treatment causes decreased proliferation of ERβ+ TNBC cells. This inhibitory effect is not due to programmed cell death but rather a G1/S phase cell cycle arrest as indicated by flow cytometry experiments. Microarray data and ingenuity pathway analysis revealed a number of down regulated genes involved in cell-cycle progression. Specifically, estrogen treatment of ERβ positive TNBC cells was shown to result in suppression of cyclin-dependent kinase 1 (CDK1) and Cyclin B, effects that were confirmed following ERβ-specific agonist treatment at both the mRNA and protein levels via RT-qPCR and western blotting, respectively. Knockdown of CDK1 in ERβ+ TNBC cells using siRNA resulted in decreased proliferation and diminished the anti-proliferative effects observed following estrogen or ERβ-specific agonist treatment.

Conclusions: Our data demonstrate that estrogen and ERβ-specific agonists cause cell cycle arrest in ERβ positive TNBC. These effects are due to ERβ-mediated suppression of multiple genes involved in cell cycle progression including CDK1 and Cyclin B. Following knockdown of CDK1, estrogen or ERβ-specific agonist treatment displayed minimal impact on cell proliferation. Therefore, ERβ's effects on proliferation may primarily be mediated by blockade of CDK1 and Cyclin B. Regardless of ERβ, our data suggest that inhibition of CDK1 activity may have therapeutic benefit in a subset of TNBC patients, an area of study that has yet to be explored.
Title: Physico-biochemical regulation of EMT by microtubule associated protein 7 (MAP7)

Choi DS, Dave B, Rosato RR R and Chang JC C. Houston Methodist Cancer Center, Houston, TX.

Body: Background: We previously reported about 500 cancer stem cell (CSC) specific gene signatures from patient tumor samples. After screening with shRNAs for the 500 genes affecting mammosphere forming ability, we identified microtubule-associated protein 7 (MAP7) as one of the top candidate genes, which may serve as a target for breast CSCs. Although MAP7 is a predominant epithelial microtubule binding protein, only limited number of reports suggests that MAP7 may be a regulator of microtubule dynamics during cell division and a cofactor of Kinesin-1 in compartment transport in cells. However, little is known about how MAP7 supports epithelial cancers, especially breast cancer. Previously, we have reported that the mammosphere forming cells exhibit treatment resistance and high metastatic potential, which are intrinsic characters for CSCs displaying epithelial mesenchymal transition (EMT). We hypothesize that MAP7 supports breast cancer progression by promoting CSC self-renewal and survival through regulation of EMT.

Objectives: Here, we aim to show that MAP7 is an essential regulator of breast CSCs and to elucidate mechanism behind EMT regulation by MAP7 in breast CSCs.

Methods and Results: On Oncomine database analysis, MAP7 was up-regulated in most epithelial cancers, when compared to the corresponding normal tissues. Similarly, its expression in breast cancer was 2-fold higher than in the normal breast tissue (p<0.05), but without significant variances in the expression across the breast cancer subtypes. Gene silencing of MAP7 significantly reduced CD44+/CD24- breast CSC populations and mammosphere forming efficiencies of MDA-MB-231, HCC1937, and MDA-MB-468 breast cancer cells. Furthermore, the silencing of MAP7 expression compromised invasive potential of MDA-MB-231 cells by 50% and significantly altered the cell membrane mechanics of MDA-MB-468 cells, as indicated by a high-content image analysis for cell shapes and cell adhesion efficiency. More importantly, delivery of siRNA in vivo inhibited the growth of BCM2147 patient-derived tumor, and limiting dilution assay demonstrated that the tumor initiation potential of BCM2147 can be eliminated by MAP7 silencing. Through confocal microscope analysis of images of fluorescent immunostaining and co-immunoprecipitation assays, MAP7 showed polarized-expressions in spindle-shaped cancer cells and was co-localized with Focal Adhesion Kinase (FAK). Moreover, MAP7 silencing inhibited the phosphorylation of FAK by inactivating p130CAS and JSAP1, the upper stream and the down-stream regulators of FAK.

Conclusion: We have showed the ectopic expression of MAP7 in breast tumors and other epithelial tumors, suggesting MAP7 may be involved in tumorigenesis and critical for the survival of tumor cells. Moreover, our results suggest that MAP7 is a key element for survival and self-renewal of breast CSCs through polarization of cells and activation of FAK, required for the initiation of EMT. To that end, here we report that MAP7 is essential for breast cancer growth by supporting CSC survival and self-renewal.
Title: NEDD9 promotes breast cancer metastasis by regulating mitochondrial functions

Iida J, Dorchak J, Slavik J, Clancy R, Cutler ML and Shriver CD. Chan Soon-Shiong Institute of Molecular Medicine at Windber, Windber, PA; Uniformed Services University of the Health Sciences, Bethesda, MD and Walter Reed National Military Medical Center, Bethesda, MD.

Body: NEDD9 has been characterized as a metastasis-promoting gene in various cancer cells including breast. We previously reported that NEDD9 promotes malignant phenotypes of breast cancer cells through distinct and non-overlapped domains. For example, the FAT (Focal Adhesion Targeting) domain of NEDD9 promotes cancer cell growth, while the SH-domain facilitates cell migration. These results suggest that NEDD9 promotes tumor metastasis by enhancing dissemination and growth in the tumor-host microenvironments through distinct and non-overlapped domains. Thus, targeting functions of NEDD9 is a promising approach for breast cancer therapies.

In order to further characterize NEDD9-mediated breast cancer growth, we performed yeast-two hybrid (Y2H) screening to identify proteins that associate with the FAT domain of NEDD9. Using the FAT domain constructed in pGBKKT7 (Clonetech, CA) as a bait to screen library of human fibroblast (Clonetech, CA), we identified several proteins that associate with the domain. They are small GTPases (i.e. RAB11a and ARF4), cytoskeletal proteins (i.e. Nexilin), and cytosolic proteins (i.e. HAX-1). Among of these potential partner proteins, we focused on the interaction between NEDD9 and HAX-1 in breast cancer cells.

Co-immunoprecipitation assays confirm the molecular complex of NEDD9-HAX-1 in both SK-Br3 and SUM149 cells. Importantly, p130cas, which harbors similar domain structures with NEDD9, was not precipitated with NEDD9, suggesting a specific interaction between NEDD9 and HAX-1. Given the fact of NEDD9 as a key metastasis promoting gene, these results suggest that NEDD9-HAX-1 plays a key role breast cancer metastasis by facilitating growth in microenvironments.

While the biological function are not clear at present, previous studies demonstrated that HAX-1 localizes in mitochondria in breast cancer cells. Indeed, we demonstrated that NEDD9 was found in both cytosol and mitochondria fractions in malignant breast cancer cell MDA-MB-231, but not non-metastatic HCC38. These results suggest the presence of NEDD9-HAX1 complex in mitochondria and this complex may facilitate breast cancer metastasis. In addition to HAX-1, several mitochondrial proteins such as EFG1, DCTN6, and MMADHC were found in the Y2H screening system as described above. These results suggest that NEDD9 facilitates breast cancer metastasis through regulating multiple pathways including signaling pathways and mitochondrial functions, thus serving as a promising therapeutic target for cancer patients including breast.

Title: Upregulated purinergic signaling enhances cell proliferation in human and murine breast carcinomas

Mele M, McWhan K, Henningsen M, Vahl P, Jensen V, Johansen T, Pedersen H, Christiansen P and Bødtkjer E. Randers Regionshospitalet, Randers, Denmark; Aarhus University Hospital, Aarhus, Denmark; Aarhus University Hospital, Aarhus, Denmark; Randers Regionshospitalet, Randers, Denmark and Aarhus University Hospital, Aarhus, Denmark.

Body: The composition of the extracellular tumor microenvironment differs from that of most other tissues and is thought to provide cancer cells with a growth and survival advantage compared to normal cells. In solid tumors, the extracellular concentration of ATP can be elevated to ~100 µM and extracellular pH can be as low as 6.5. In the current project, we investigate the consequences of purinergic signaling in human and murine breast carcinomas: we study intracellular Ca\textsuperscript{2+} signals and associated changes in cell proliferation during stimulation with extracellular nucleotides.

We employ biopsies of human and murine primary breast carcinomas and compare them with matched normal breast tissue. Human biopsies are obtained with written informed consent from patients undergoing breast conserving surgery at Aarhus University Hospital or Regional Hospital Randers in Denmark. Murine biopsies are from mice overexpressing unactivated ErbB2 specifically in the breast tissue. We isolate epithelial organoids (~150 µm diameter) from tissue biopsies by partial digestion with collagenase III. Organoids loaded with the Ca\textsuperscript{2+}-sensitive fluorophore Fura-2 are studied by fluorescence microscopy. In separate experiments, cell proliferation is quantified by detecting newly synthesized DNA using immunofluorescence imaging of organoids incubated with the thymidine analogue bromodeoxyuridine (BrdU).

We find that intracellular Ca\textsuperscript{2+} responses during stimulation with extracellular ATP are elevated 2- to 10-fold in breast carcinomas from mice and humans, respectively, compared to matched normal breast tissue. We observe similar differences between breast cancer tissue and normal breast tissue in response to stimulation with the P2Y\textsubscript{2}/P2Y\textsubscript{4}-agonist UTP, whereas virtually no rise in the intracellular concentration of Ca\textsuperscript{2+} is observed in response to the P2X7-agonist 3’-O-(4-benzoyl)benzoyl-ATP. Application of cyclopiazonic acid – an inhibitor of the sarcoplasmic/endoplasmic reticulum Ca\textsuperscript{2+}-ATPase – also cause exaggerated intracellular Ca\textsuperscript{2+} responses in breast cancer compared to normal breast tissue. Consistent with the elevated Ca\textsuperscript{2+} responses, stimulation with 100 µM ATP or 100 µM UTP increases the rate of cell proliferation (i.e., fraction of BrdU-positive cells) by ~2-fold in the breast cancer tissue.

In conclusion, we find that purinergic signaling is upregulated in human and murine breast carcinomas compared to normal breast tissue. Activation of purinergic receptors – most likely P2Y\textsubscript{2} and/or P2Y\textsubscript{4} – enhances cell proliferation in breast cancer tissue. We propose that the high ATP levels in the tumor microenvironment promote breast cancer development or progression and that the associated signaling pathways represent promising targets for therapy.
Vitamin K dependent gamma-carboxylation in breast cancer

Welsh J, Beaudin S and Tenniswood M. University at Albany, Rensselaer, NY.

The secreted protein periostin (PN) is strongly linked to breast cancer aggressiveness and serum PN is a promising marker of disease activity. However, the regulation and function of PN in relation to the cancer phenotype has yet to be clearly defined. PN is one of the rare proteins (<15 in mammalian systems) that is subject to the post-translational addition of \( \gamma \)-carboxylated glutamatic acid (GLA) residues. However, no studies have addressed whether \( \gamma \)-carboxylation of PN has functional relevance in breast cancer, despite evidence that the proteins that catalyze \( \gamma \)-carboxylation are expressed in normal mammary gland. Using publically available datasets we found that GGCX, VKORC1 and VKORC1L1 (genes that mediate \( \gamma \)-carboxylation) are overexpressed in 24% of breast cancers. Furthermore, survival of patients whose tumors overexpress these genes is significantly worse than that of patients whose tumors do not overexpress these genes. Follow-up studies utilized the Human Protein Atlas to examine expression of GGCX, VKORC1 and VKORC1L1 proteins in normal breast and invasive ductal carcinomas (IDC). Normal ductal epithelial cells showed intense staining for GGCX, patchy moderate staining for VKORC1 and diffuse low signal for VKORC1L1. All cases of IDC exhibited strong staining for GGCX, 80% had moderate-intense staining for VKORC1 and 77% had diffuse but low staining for VKORC1L1. Staining for all 3 proteins was localized only in tumor cells indicating that stromal cells are unlikely to contribute to protein \( \gamma \)-carboxylation. Next we explored expression of the \( \gamma \)-carboxylation pathway genes using in vitro models of epithelial-mesenchymal transition (EMT) and tumor progression. The EMT model consists of human mammary epithelial cells immortalized with telomerase and SV40 (HMLE cells) that constitutively express GFP (control), TWIST, SNAIL or TGF\( \beta \). Relative to control cells, GGCX, VKORC1 and VKORC1L1 were up-regulated in HMLE-TWIST cells, GGCX and VKORC1 were up-regulated in HMLE-SNAIL cells and VKORC1 was up-regulated in HMLE-TGF\( \beta \) cells. These data suggest that \( \gamma \)-carboxylation may be triggered early in breast cancer oncogenesis. In the tumor progression model, we found up-regulation of GGCX and VKORC1 in HMLE+RAS cells relative to HMLE cells. Introduction of SV40 alone did not alter expression of these genes. In HMLE-TWIST and HMLE-RAS cells with the highest expression of GGCX, VKORC1 and VKORC1L1, PN was up-regulated 200-300-fold, supporting the concept that PN may be a relevant target for \( \gamma \)-carboxylation during EMT and tumor progression. In summary, available genomic and proteomic data suggest that the vitamin K dependent pathway genes GGCX, VKORC1 and VKORC1L1 are present in normal mammary gland but up-regulated in a subset of invasive breast cancers that are characterized by poor overall survival. Genes in this pathway are also up-regulated in mammary epithelial cells expressing triggers of EMT (particularly TWIST) or oncogenes such as RAS. Since the only known function of these genes is in \( \gamma \)-carboxylation, studies to confirm PN as a GGCX substrate and to identify additional \( \gamma \)-carboxylated proteins and their functions in breast cancer are clearly warranted. Our limited understanding of this ancient, conserved pathway may be masking an important therapeutic opportunity.
Title: The role and regulation mechanism of HOXB5 in human breast cancer cells

Kim JM, Lee J-Y and Kim MH. Yonsei University College of Medicine, Seoul, Korea.

Body: HOX genes are transcription factors that play important roles in body patterning and cell fate specification during normal development. Among of these, HOXB5, is involved in a variety of developmental processes, particularly during the enteric nervous system (ENS) development, and thus, abnormalities in HOXB5 function during embryo stages lead to Hirschsprung’s disease. Importantly, many HOX genes, including HOXB5, are expressed not only during embryogenesis but also in adults and are dysregulated in various cancers. In a previous study, we found aberrant overexpression of HOXB5 in breast cancer tissues and cell lines and demonstrated that HOXB5 is important in the regulation of cell proliferation in breast cancer cells. Also, HOXB5 induces invasive potential through epithelial-mesenchymal transition (EMT). The relationship between HOXB5 and phenotypic changes in MCF7 breast cancer cells has been studied, however, HOXB5 functions as a transcription factor and its involvement in signaling pathways remain unclear. In this study, we selected putative downstream target genes of HOXB5, such as interleukin (IL)-6, Snail2 and epidermal growth factor receptor (EGFR) by PCR array analysis. These genes have been reported to be involved in cancer progression, which is characterised by increased growth speed and invasiveness of the tumor cells. Here, we discovered that HOXB5 transcriptionally upregulates the promoter activity of these genes. Chromatin immunoprecipitation (ChIP) analysis to confirm direct binding of HOXB5 to the promoter region is now ongoing. Since we found that HOXB5 induces EGFR protein expression and SRC phosphorylation, we will further investigate signaling pathway components to understand the underlying molecular mechanisms of HOXB5 action in breast cancer.
Title: Talazoparib antitumor effects in BRCA-deficient breast cancer models

Body: Background: BRCA1 and BRCA2 functions are essential for the DNA double-strand break repair process in living cells with DNA damages. Therefore, germline pathogenic mutations in BRCA1/2 increases the risk of developing cancer.\(^1\). Poly(ADP-ribose) polymerase (PARP) enzymes are proteins responsible for DNA single-strand break repair. Persistent inhibition of PARP-dependent DNA repair in BRCA-deficient breast cancer cells leads to increased DNA damages resulting in cancer cell death. Talazoparib is a novel and potent, orally bioavailable, small molecule PARP inhibitor. Talazoparib’s dual mechanism of action inhibits PARP enzyme activity and effectively traps PARP on DNA, preventing DNA repair, resulting in cell death in BRCA1/2-mutated cells.\(^3\) In tissue culture studies, talazoparib is more potent at trapping PARP on DNA to induce cancer cell death compared to other PARP inhibitors.\(^4\) Previous studies have demonstrated talazoparib inhibited growth in tumors harboring BRCA1/2 gene mutations. In the MX-1 breast cancer model with BRCA1-deficiency, talazoparib inhibited cell growth in vitro and induced regression in solid mouse xenografts.\(^5\) Here, we demonstrate antitumor effects of talazoparib monotherapy in a panel of breast cancer cells and patient-derived breast cancer models with pathologic BRCA1/2 mutations.

Method: A panel of human breast cancer cell lines was treated with talazoparib to determine its cytotoxic effects. BRCA1/2 mutations status was correlated to talazoparib cytotoxic effects. At the molecular level, BRCA1/2-mutant and wild type breast cancer cell lines were treated with dose-escalating talazoparib to also assess the relationship between PARP-DNA trapping complex formation and treatment response. Patient-derived breast cancer xenograft models were used to assess talazoparib monotherapy on tumorigenesis. Immunohistochemistry assays were performed to determine Ki-67, gH2AX and caspase 3 marker expression following talazoparib treatment.

Results: Cytotoxicity was observed in 50% (7/14) cell lines at IC50 values that are achieved in the clinic. BRCA1/2 alterations were detected in 21.4% (3/14) of cell lines sensitive to talazoparib treatment. In 14 patient-derived breast cancer xenograft models selected for this study, 57.1% (8/14) responded to talazoparib monotherapy. Of these, 35.7% had mutations in the BRCA1 (28.6%) and BRCA2 (7.1%) genes. Stable disease was observed in 14.2% (2/14). One stable model had BRCA1 mutations. Tumor regression was observed in 42.8% (6/14) of the models treated with talazoparib monotherapy. Importantly, 66.7% (4/6) of patient-derived breast cancer models that regressed on talazoparib monotherapy had mutations in BRCA1/2 genes.

Conclusions: Cytotoxicity was observed with talazoparib monotherapy in breast cancer cell lines and in patient-derived xenograft tumor models harboring BRCA1 or BRCA2 mutations. Our data demonstrate therapeutic potential of talazoparib monotherapy in breast cancer associated with pathologic BRCA1/2 mutations.

Title: Androgen receptor signaling regulates survival to ionizing radiation in breast cancers

Yard BD D and Abazeed ME E. Cleveland Clinic Taussig Cancer Institute, Cleveland, OH.

Body: Background: Radiotherapy administered following breast-conserving surgery significantly reduces the risk of local recurrence and breast cancer mortality. However, a key limitation to radiotherapy has been the lack of biomarkers that reliably predict response to treatments. There is an urgent need to identify patients with tumors that are resistant to radiotherapy and to improve therapeutic efficacy in these patients. To advance genotype-directed radiotherapy in breast cancer, we identified determinants of survival by leveraging genomic data with a novel and validated high-throughput platform for measuring radiation sensitivity and discovered an association between androgen receptor (AR) expression and resistance to radiotherapy.

Methods: We profiled 28 breast cancer cell lines using our recently validated high-throughput assay to measure survival. Survival curve analyses permitted quantitative assessment of radiosensitivity. Gene Set Enrichment Analysis (GSEA) was used to correlate radiosensitivity with genomic features of the profiled cell lines. Cell growth and death were measured by CellTiter-Glo® and colony formation assays, respectively. DNA damage was measured by neutral comet assays. γ-H2AX was measured by Western immunoblot. Mouse xenografts were prepared by the orthotopic injection into the mammary gland of female NOD scid gamma mice.

Results: GSEA nominated several pathways that are known to confer resistance to DNA damage. However, some of the most correlated and intriguing gene sets were associated with AR signaling. We showed that AR mRNA levels were directly correlated with radiation survival (Pearson's r=0.48). To test the interaction between androgen signaling and radiation survival, we employed the AR-positive triple-negative breast cancer cell line MDAMB453. Re-supplementation of steroid deprived media with dihydrotestosterone (DHT) prior to radiation resulted in a dose dependent rescue of cell growth, while treatment with the potent AR antagonist enzalutamide sensitized the cells to radiation. Similar results were observed for other AR-positive cell lines (HCC202, ZR7530, CAMA1, and BT474) independent of ER and ERBB2 status. To assess whether androgen ablation cooperates with ionizing radiation in-vivo, MDAMB453 xenografts were exposed to either enzalutamide, radiation, or the combination of enzalutamide and radiation. The combination of enzalutamide (15mg kg\(^{-1}\) or 25mg kg\(^{-1}\)) and ionizing radiation suppressed tumor growth more potently than either enzalutamide or radiation alone. Using neutral comet assays immediately following radiation exposure, we determined that incubation of MDAMB453 and BT474 cells with enzalutatmide resulted in an increased number of double-strand breaks while treatment with DHT reduced DNA damage. Additionally, γ-H2AX levels remained elevated in enzalutamide treated cells following radiation treatment. Taken together, these data indicate that AR signaling protects breast cancer cells from DNA damage.

Conclusion: Integration of high-throughput radiation survival profiling with large-scale cancer genomic data indicates that androgen signaling is associated with radiation resistance in breast cancers. Radiotherapy of AR-positive breast cancers may be improved by neoadjuvant and concomitant anti-androgen therapy.
Title: A solution to the APOBEC mutation paradox in breast cancer

Body: Breast cancer has a major genetic component, and individual tumors can have thousands to tens-of-thousands of mutations. Large proportions are cytosine mutations in TCA and TCT trinucleotide motifs. A variety of studies have attributed this mutation signature to the APOBEC family of DNA cytosine deaminases, with previous literature favoring APOBEC3B as the most likely enzyme to be responsible (from a total of nine active family members). However, breast tumor genomic DNA sequences from patients with a naturally occurring germline deletion of the entire APOBEC3B gene still show an intact APOBEC mutation signature.

To resolve this paradox, we tested the hypothesis that the only other functionally dimorphic APOBEC family member, APOBEC3H, may be responsible. First, we performed an unbiased genetic analysis of TCGA data sets and showed that APOBEC3B-null tumors with this mutational bias have at least one copy of the haplotype-I variant of APOBEC3H, despite weak genetic linkage between these two genes (n=14/14). Remarkably, breast tumors without APOBEC3B and APOBEC3H haplotype-I showed no evidence for an APOBEC mutation signature (n=3/3). The proportion of APOBEC signature mutations between the cohort with and the cohort without APOBEC3H haplotype-I was highly significant (p<0.00001 and lower), indicating that these two enzymes alone may be fully responsible (and casting serious doubt on the potential role of APOBEC3A). Second, although deemed inactive in prior studies, we discovered that APOBEC3H haplotype-I has robust activity in biochemical assays with mutation of TCA-containing single-stranded DNA and in cellular assays with hypermutation of HIV-1 cDNA and mutation of a genomic DNA eGFP reporter gene. Third, the subcellular localization APOBEC3H haplotype-I and other expressed variants of this enzyme differed with only the latter showing significant nuclear localization in a panel of cell lines. The genomic mutagenicity and localization of APOBEC3H haplotype-I is attributable to a glycine at position 105, whereas other variants of this enzyme that have an arginine at this position, suggesting a general molecular mechanism. These studies combine to offer a parsimonious solution to the APOBEC mutation paradox with APOBEC3B and APOBEC3H haplotype-I, together, accounting for the strong “APOBEC mutation signature” observed in many breast cancers.
Title: Abstract Withdrawn
Preclinical characterization of VX-984, a selective DNA-dependent protein kinase (DNA-PK) inhibitor in combination with doxorubicin in breast and ovarian cancers

Background: The efficacy of chemotherapeutic agents such as doxorubicin, which cause lethal DNA double-strand breaks (DSBs), is diminished by efficient repair of the damaged DNA in cancer cells. DNA-PK is a key regulator of the non-homologous end joining (NHEJ) pathway, which is responsible for repairing DSBs. Studies of nonselective inhibitors of DNA-PK have shown that cancer cells depend on DNA-PK for survival following treatment with DSB-inducing agents. However, a comprehensive characterization of DNA-PK inhibition has been hampered by a lack of selective inhibitors. Here we describe VX-984, a potent and selective inhibitor of DNA-PK, and its preclinical profile in combination with doxorubicin both in vitro and in vivo.

Methods: VX-984 was examined as a single agent and in combination with doxorubicin or pegylated liposomal doxorubicin (PLD) in a panel of breast cancer cell lines and in mouse xenograft models, respectively.

Results: In vitro, inhibition of DNA-PK by VX-984 enhanced the cytotoxic activity of doxorubicin in established breast cancer cell lines and in primary ovarian tumor explants. Notably, mean Bliss DE >10% (strong synergy) were observed for doxorubicin in the presence of VX-984 in 22 of 35 breast cancer cell lines and 21 of 44 ovarian cancer cell lines in a broad cancer cell line screen. Further, the efficacy observed with VX-984 was associated with increased DNA damage as measured by phosphorylated histone H2AX (gamma-H2AX) and phosphorylated Kruppel-associated protein (pKAP1) in DU4475, MDA-MB-436 and MDA-MB-468 breast cancer cell lines, which is consistent with diminished DSB repair. In vivo, VX-984 significantly enhanced the efficacy of PLD in ovarian cancer patient-derived xenograft models and in cell line xenograft models.

Conclusions: These data provide evidence that inhibition of DNA-PK by VX-984 enhances the efficacy of doxorubicin in preclinical models and support the use of VX-984 in combination with DSB agents such as anthracyclines including PLD for the treatment of breast and ovarian cancers. VX-984 is currently in a Phase 1 clinical trial in combination with PLD. Sponsored by Vertex Pharmaceuticals Incorporated.
Title: Comprehensive analysis of the DNA damage repair and maintenance pathways that regulate TNBC sensitivity to replication stress

Redwood AB B, Cai S, Jeter-Jones S, Tu Y and Piwnica-Worms H. MD Anderson Cancer Center, Houston, TX.

Body: Agents that induce replication stress, such as inhibitors of Chk1 or ATR, are advancing in clinical development and are being tested for treatment of various solid tumors, including triple-negative breast cancer (TNBC). While the preclinical data are encouraging, additional studies are needed to predict with precision (i) which patients will most likely benefit from these inhibitors, (ii) the genetic and proteomic contexts in which these inhibitors will provide maximum therapeutic benefit as a single agent, or require additional sensitization via combination with a targeted- or chemotherapeutic agent, and (iii) exactly which targeted/chemotherapeutic agent will provide maximum therapeutic benefit for combination with replication stress inducers. To address these challenges in TNBC, we have attempted to gain a comprehensive understanding of how the DNA damage response pathways regulate TNBC cell survival in response to Chk1 inhibitors, by performing high throughput loss-of-function screens.

Chk1 serves an essential function during S-phase by preventing stalled replication forks from collapsing. In addition, when cells are exposed to agents that induce single strand DNA breaks or induce replication stress, Chk1 becomes activated to turn on the S- and G2-checkpoints to temporarily arrest cell cycle progression. Thus, tumor cell death due to Chk1 inhibition can occur in at least two ways. One is through replication catastrophe due to massive replication fork collapse and de-repression of late-origin firing, which results in enhanced DNA damage. The second is by mitotic catastrophe whereby cells with DNA damage bypass the S- and G2 checkpoints and move prematurely into mitosis without repairing the damage. Thus, the response of tumor cells to Chk1 inhibition as a single agent or with chemotherapy is expected to vary depending on the proficiency of DNA repair pathways and ability to sustain DNA synthesis. Chk1 inhibitors (Chk1i) have been shown to sensitize a wide variety of cancer cells to various chemotherapeutic agents, including cisplatin, irinotecan and a number of antimetabolites.

We have identified genes whose loss induce death of TNBC cells in the presence of (1) CHK1i alone, (2) chemotherapy alone or (3) CHK1i plus chemotherapy. In addition, given the role of TP53 as the most frequently mutated gene in TNBC, we also determined whether distinct vulnerabilities could be identified in TNBC cells that are p53-proficient versus p53-deficient. Thus, we have also identified the top synthetic lethal interactions that are either common to both p53-proficient and p53-deficient TNBC, or unique to p53-deficient TNBC; we are currently performing in vitro studies to validate the identified mechanisms. We anticipate these studies to be applicable to other agents that induce replication stress and cell cycle checkpoint bypass. Ongoing in vivo preclinical studies, which utilize patient-derived xenografts (PDXs) of TNBC to validate these findings are expected to impact patient selection for clinical trials, and also allow us to predict which chemotherapeutic agents will be most effective for combination with different cell-cycle checkpoint inhibitors.
PTEN immunohistochemistry is a predictor of mismatch repair status in breast cancer

Fusco N, Gambini D, Runza L, Lopez G, Ercoli G, Despini L and Bosari S. Fondazione IRCSS Ca’ Granda - Ospedale Maggiore Policlinico, Milan, Italy; University of Milan, Milan, Italy; Fondazione IRCSS Ca’ Granda - Ospedale Maggiore Policlinico, Milan, Italy and Breast Surgery Unit, Fondazione IRCCS Ca’ Granda - Ospedale Maggiore Policlinico, Milan, Italy.

Body: Phosphatase and tensin homolog (PTEN), a potent downregulator of the PI3K-Akt pathway, has been shown to mediate the interaction between poly (ADP-ribose) polymerases (PARPs) and the mismatch repair (MMR) complex in endometrial and ovarian cancer. Drugs inhibiting PARPs (iPARPs) are currently considered promising therapeutic tools in a subset of PTEN-defective tumors. Regrettably, the frequency and significance of MMR alterations in breast cancer is debated, and their relationship with PTEN status has not been investigated in the breast. Furthermore, many of the studies on the DNA damage response and its therapeutic implications in breast cancer focus on inherited syndromes (e.g. Lynch syndrome and hereditary breast-ovarian cancer syndrome).

Aims: We sought to explore the interplay between PTEN and the MMR system and to define whether PTEN immunohistochemistry (IHC) is a predictor of MMR proficiency in non-familial breast cancers.

Methods: 373 cases of non-familial breast cancers, including a representative number of no special (n=295) and special types (n=78), carefully characterized from clinical and pathological standpoints, were reviewed and used to construct 14 tissue microarrays (TMAs). For each case, a mean of 4.5 tumor tissue cores (range 3 to 6 cores) was sampled, incorporating distinct topographic areas of the tumor, as well as matched non-neoplastic breast tissue. Taken together, 1876 spots were generated. Each TMA was subjected to IHC for PTEN and the DNA MMR proteins MLH1, MSH2, MSH6 and PMS2. In order to minimize human-related biases, each stained slide was digitalized and two pathologists blindly analyzed each tumor spot using a dedicated software able to segment and randomize TMA cores. The pattern of expression was therefore annotated manually on a digital database using a specific add-on module to reconstruct the original topography.

Results: According to clinicopathologic surrogate definition of intrinsic subtypes, PTEN protein loss or heterogeneous expression was more frequent in estrogen receptor negative cancers. Furthermore, 100% of the MMR-proficient luminal B-like (HER2+) and triple-negative breast cancers displayed strong and diffuse homogeneous PTEN expression, while PTEN-positive status identified MMR-proficient luminal A-like and luminal B (HER2-) like tumors with accuracy rates of 89.3% and 92.7%, respectively (p=0.001, Fisher's exact test).

Conclusions: The present study is the first to investigate PTEN protein loss in a large set of non-familial breast carcinomas based on their DNA MMR status by IHC. Here, we demonstrated that PTEN strong and homogeneous expression by IHC is able to capture the vast majority of MMR-proficient non-familial breast cancers. Our findings broaden the understanding of the biology underpinning these tumors, suggesting that PTEN is likely play a role in the development of MMR alterations. Given that PTEN-defective breast cancers have the propensity to develop additional somatic alterations in the MMR system, our results suggest that IHC for PTEN and MMR proteins may be emplyed as an ancillary study to define new subclasses of sporadic breast cancers potentially eligible for iPARPs therapies.
Title: BRCA1 promoter hypermethylation, but not BRCA1 expression, is associated with basal-like features and good prognosis in triple negative breast cancer

Body: Purpose: BRCA1 gene mutation is closely associated with familial hereditary breast cancer. Decreased expression of BRCA1 could be detected in certain types of sporadic breast cancer without BRCA1 mutations. Aberrant hypermethylation of DNA promoter CpG islands is one of the mechanisms by which tumor suppressor gene expression and function could be lost. We investigated BRCA1 methylation status and BRCA1 immunohistochemistry (IHC) expression and their clinic-pathological significance in triple negative breast cancers (TNBC).

Patients and methods: We analyzed BRCA1 promoter hypermethylation using a methylation specific PCR assay and BRCA1 IHC expression using the MS110 monoclonal antibody and Garg and Meisel scoring classification. Their clinicopathological and prognostic implications were analyzed in a TMA of TNBC samples from European patients.

Results: To date, 123 TNBC have been analyzed. 25 tumors (20%) presented a BRCA1 promoter hypermethylation. BRCA1 IHC expression was retained, equivocal and lost in 73 (59%), 17 (14%) and 33 (27%) cases respectively. No significant correlation was found between promoter hypermethylation and protein expression (p=0.28). A significant association was found between promoter hypermethylation and basal staining (CK5/6 and/or EGFR IHC staining), while using either a 10% or 1% cut-off for basal definition (p= 0.04 and 0.03, respectively). No significant association was found between BRCA1 expression and a basal phenotype. With a median follow-up of 6.3 years (range [0.01 – 11.8]), 35 relapses and deaths occurred (71.2% 5-years RFS and 77.8 5-years OS). RFS was significantly associated with T and N stage, and a trend was seen for a better prognosis of BRCA1 promoter hypermethylated tumors (5-years RFS: 84% vs. 68%, p=0.07). OS was significantly associated with T and N stage, and adjuvant chemotherapy.

Conclusion: BRCA1 promoter hypermethylation is associated with basal-like features and seems to be associated with a better prognosis in TNBC. BRCA1 IHC expression is not a good surrogate marker for evaluation of the methylation status of the tumors, and did not appear associated with prognosis in our series. The data will be updated for the meeting in term of number of analyzed tumors in order to strengthen the statistical analysis.

Title: Cyclin d1 binding to chromatin and the induction of chromosomal instability requires the fuzzy domain

Body: The cyclin D1 gene encodes the regulatory subunit of a holoenzyme that phosphorylates and inactivates the retinoblastoma (Rb) and the nuclear respiratory factor 1 (NRF1) proteins to regulate nuclear DNA synthesis and mitochondrial biogenesis. Cyclin D1 is required for oncogene-dependent growth and genetic ablation of the murine cyclin D1 gene resulted in resistance to Ras or ErbB2-induced mammary tumorigenesis and APC-induced gastrointestinal tumorigenesis. Cyclin D1 overexpression occurs in human breast, prostate, lung, and gastrointestinal malignancies and its abundance is induced at the level of transcription, translation and through post-translational modifications. Cyclin D1 plays a key role in transcriptional regulation inducing gene expression governing chromosomal instability (CIN) and cell-cycle progression. Cyclin D1 is also known to bind TF regulatory regions in chromatin immuno-precipitation (ChIP) assays. Genome wide analysis of cyclin D1 occupancy using ChIP-Seq identified binding sites including both the coding and non-coding genome with enrichment for genes regulating CIN and the G2/M phase (Top2A, AurkB, Cenpp, Mlf1p, Zw10, Ckap2) consistent with enrichment of cyclin D1 at G2/M and the finding that cyclin D1 induces CIN. We sought to identify the molecular mechanisms governing the recruitment of cyclin D1 in the context of local chromatin to promote CIN. In order to define the domain of cyclin D1 involved in aneuploidy and tumorigenesis, we transduced and assessed the induction of aneuploidy in MEF cells using cyclin D1 wt (wt), cyclin D1 C-terminus domain (C4), cyclin D1 mutant lacking of the E-box motif (∆E) or ctrl. We also searched for potential histone protein interaction motifs in cyclin D1 and determined the epigenetic motif recognized by cyclin D1 using a histone peptide array. The recognition of an epigenetic code by cyclin D1 may facilitate genome wide expression changes during cell-cycle progression and tumorigenesis. We finally identified a “fuzzy” domain of cyclin D1 which is required to local chromatin access for regulatory promoter regions governing and promoting CIN.
Recurrence in breast cancer is mainly due to metastases and drug resistance in a fraction of primary tumors cells which are also known as cancer stem cells or tumor initiating cells. We found that Ganglioside GD2 identifies breast cancer stem cell (BCSCs) in triple negative breast cancer (TNBC) and that GD2 biosynthesis is tightly regulated by enzyme ST8SIA1 (GD3 synthase) in GD2+ cells. We have reported that ST8SIA1 is highly expressed in TNBC and its expression is highly correlated with p53 mutations primary tumors (Yan et al, SABCS abstract 2016). Here we hypothesize that ST8SIA1 has a functional role in BCSC mediated tumorigenesis in TNBC. To test the hypothesis, we deleted ST8SIA1 in SUM159 cells using CRISPR-Cas9 technology. As expected, deletion of ST8SIA1 in SUM159 cells reduced GD2+ cells from 17±1.5% to 0.3±0.1%. However, cell proliferation assay revealed no significant difference between ST8SIA1-KO and Cas9 control cells. In contrast, in-vitro tumorigenesis by soft-agar assays revealed a complete loss of colony formation in ST8SIA1-KO cells, whereas Cas9 control cells produced 30±10 colonies out of 1000 cells plated. To investigate tumor initiation potential, ST8SIA1-KO- or Cas9 control-SUM159 cells were transplanted in mammary fat pad of NSG mice. Cas9 control cells produced tumors within 1-2 weeks and reached the maximum allowed size by IACUC (1.5cm) within 3-4 weeks. In contrast, ST8SIA1-KO cells failed to produce any tumors even 15 weeks after injections. In addition, survival analysis by log-rank test revealed that most of the cas9 control cell injected mice died within 4 weeks after cell implantation whereas no deaths were observed in ST8SIA1-KO cells injected mice even 100 days after tumor implantation. These data indicate that loss of ST8SIA1 in TNBC cells depletes GD2+ BCSCs and inhibits in-vitro and in-vivo tumorigenesis.

To investigate gene expression changes due to loss of ST8SIA1 in CRISPR knockout cells, we analyzed mRNA expression in ST8SIA1-KO- and Cas9 control-SUM159 cells by RNAseq analysis (done in triplicates for each cell type). At p<0.05 and fold change >2, we found 1502 genes down-regulated and 842 genes up-regulated in ST8SIA1-KO- compared to cas9 control- cells. Ingenuity pathway analysis revealed that several stem cell associated signaling pathway including, wnt, stat3, NFκB, nanog and IL8 whereas tumor suppressor PTEN and p38 MAPK signaling were activated in ST8SIA1-KO- compared to cas9 control- cells. In specific, proteins associated with stem cell function including NOTCH3, PDGFRB, PDGFRA, VCAM1, CXCR4, CXCL12, SOX2, Wnt5a were down regulated in ST8SIA1-KO cells whereas DKK1 which acts as an antagonist for wnt-β-catenin signaling, was up-regulated in ST8SIA1-KO cells. These findings were validated by flow cytometry and western blot analysis using specific antibodies. In conclusion, our data suggests that deletion of ST8SIA1 in TNBC cells depletes BCSCs and inhibits tumorigenesis in-vitro and in-vivo. Development of specific inhibitors of ST8SIA1 could be of potential therapeutic value for patients with TNBC.
Title: GD2-mediated FAK signaling regulates breast cancer stem cell function in triple negative breast cancer

Nguyen K, Sun JC C, Hortobagyi GN N, Andreeff M and Battula VL. The University of Texas MD Anderson Cancer Center, Houston, TX.

Body: Ganglioside GD2 identifies breast cancer stem cells (BCSCs, Battula et al., JCI, 2012) and expression of GD2 is tightly regulated by GD3 synthase (GD3S). GD3S is highly expressed in GD2+ cells and inhibition of GD3S inhibits tumor formation and metastasis of breast cancer cells. However, the mechanism of GD2-mediated regulation of BCSC function is not known. Here we hypothesize that GD2 regulates signaling pathways involved in cell adhesion, migration and invasion of breast cancer cells. To identify these signaling pathways, antibody micro-arrays were used with 850 validated antibodies specific to total or phosphorylated proteins. Interestingly, focal adhesion kinase (FAK) was the most significantly phosphorylated protein in GD2+ compared to GD2- cells (S910 and S722). In addition, expression of FAK downstream mediators including Csk, PKCq, PKCl/I, Pyk2, and p38MAPK, was up-regulated in GD2+ compared to GD2- cells. Western blot analysis of FACS sorted SUM159 cells also revealed increased phosphorylation of FAK >80% at Y397 and >25% at Y861 in GD2+ compared to GD2- cells. FAK downstream targets including paxillin, p130 Cas, pERK were also up-regulated in GD2+ cells compared to GD2- cells indicating definitive activation of FAK signaling in GD2+ BCSCs. To investigate the functional role of GD2 in FAK mediated functions, we genetically deleted GD3S using the CRISPR knock-out system in SUM159 cells. only <1% GD2expression compared to >20% in parental cells was observed. GD3S-KO cells grew 5-10% slower in cell culture mostly because of the reduction (15±5%) in adherence. Trans-well assays revealed 3-5 fold reduction in migration and invasion of GD3S-KO compared to parental cells. These data indicate that GD2 and GD3S are not only the markers of BCSCs but also regulators of their function. Finally, we tested the effect of FAK inhibitor (PF-573228) against GD2+ BCSCs and GD3S-KO SUM159 cells. PF-573228 treatment decreased the number of mammospheres generated by GD2+ cells 3-4 fold in a dose dependent manner (100nM-1µM). In addition, treatment of PF-573228, inhibited migration and invasion of GD2+ cells 2 and 3 fold, respectively. However, treatment with PF-573228 on GD3S-KO cells further reduced their ability to migrate and invade by over 70% compared to untreated cells. In addition, GD3S-KO cells failed to form any mammospheres when cultured under low adherence conditions (p<0.00001), whereas the parental cells formed 15-20 mammospheres per 1,000 cells plated. In conclusion, our data demonstrate that FAK signaling is activated in GD2+ cells but that FAK inhibition alone may not be sufficient to inhibit BCSC function. Combined FAK and GD3S inhibition may exert highly synergistic effects against BCSCs.
Title: Transition from a pre-malignant lesion to cancer does not require stemness of the cancer-originating cells in the lesion

Bu W and Li Y. Baylor College of Medicine, Houston, TX.

Body: The precancerous lesion is the final step before malignancy, and is thus a key step to cancer prevention. Precancerous lesions are heterogeneous harboring distinct subsets of cells from stem cells to differentiated cells. Whether the stem cells or other subsets in these precancerous lesions are responsible for the eventual cancer remains unanswered. Here, we report that in the precancerous lesions of the MMTV-Wnt1 model of basal-like breast cancer, there exist the stem cell-enriched keratin 6a+ subset and more differentiated WAP+ cell subset. We demonstrate that both mutated Ras and B-Raf can robustly transform both cell subsets into cancer. These data suggest that multiple cell subsets in precancerous early lesions can evolve into cancer. This finding indicates that cancer prevention should target both self-renewing cells and other cell subsets in developing precancerous lesions in high-risk individuals.
Title: BRCA1-IRIS overexpression promotes and maintains the tumor initiating phenotype in TNBC cells: Implications for breast cancer early lesions

Sinha A, Paul BT T and ElShamy WM M. University of Mississippi Medical Center, Cancer Institute, Jackson, MS; University of Connecticut Health Center, Farmington, CT and University of Mississippi Medical Center, Cancer Institute, Jackson, MS.

Body: Introduction. Tumor-initiating (TIC) phenotype is potent inducer of dissemination of cancer cells from early lesions showing self-renewal, multi-lineage differentiation, chemo-resistance, and are defined as CD44+/CD24-/ALDHA+. Here, we demonstrate that BRCA1-IRIS overexpression (IRISOE) promotes TNBC formation by enhancing basal, EMT and TIC phenotype. In regards to TIC phenotype, we show that IRISOE elevates CD44 expression and ALDHA activity while prevents CD24 surface presentation. We present a novel pathway for CD24 internalization and confirm these data in animal model and tumor samples. Finally, we evaluated in pre-clinical models the ability of IRISOE to promote dissemination from early lesion and potential utility of IRIS inhibition to deplete TICs in TNBCs.

Methods. We used western blot, qRT/PCR, immunofluorescence (IF) and IHC to establish association of IRISOE with basal, EMT and TIC phenotype. FACS analysis to determine IRISOE effect on the TIC phenotype. 2D and 3D culture to evaluate the utility of IRIS inhibition + a ligating anti-CD24 antibody on TICs. In vivo mice models to study early dissemination, metastasis formation and the effect of IRIS peptide on TIC tumor growth. Finally, patient cohort to correlate IRISOE to BRCA1 expression, stem and dissemination biomarkers in breast cancer patients.

Results. We demonstrate an association between IRISOE and high basal and EMT phenotype. IRISOE leads to significant increase in basal biomarkers (EGFR, CK5, CK17, CDH3) and EMT markers (N-cadherin, vimentin, fibronectin, FOXC2, twist and snail). Within a cohort of breast cancer patients (n=326), including subcohort of TNBC patients (n=72), IRISOE was associated with loss of BRCA1. Association between IRISOE and increase in TIC phenotype, in vitro and in vivo was documented. We propose EGFR-c-Src-cortactin signaling pathway induced by IRISOE to be involved in CD24 internalization and thus TIC phenotype. In support of that both western blot and IF analysis showed that while IRIS silencing in TNBC cells led to complete re-direction of cytoplasmic CD24 to the membrane, silencing of members of this pathway led to partial effect. Conversely, their overexpression also partially reversed the effect of IRIS silencing on the TIC phenotype. IRISOE could also induce tumorigenesis and metastasis in non-tumorigenic luminal A, MCF7 cells by enhancing TIC phenotype in them. Not only that, mice injected with low numbers of MCF7/IRISOE cells generate larger tumors, most likely, due to enhanced interactions with the stroma, an effect most likely not possible when large number of cells is injected instead. These tumors also showed high dissemination in the form of increased CTCs and DTCs in the blood and bone marrow, respectively. Inhibiting IRIS with specific peptide led to 80% regression of tumors developed using TICs in NSG mice and the effect was even more dramatic on the Sox2+ population remained within these tumors.

Conclusion. This study reveals that IRISOE cells acquire TIC, basal and EMT phenotypes along with lack of BRCA1 expression and possess high dissemination and metastasis ability. Our results support inhibiting IRIS in TNBC patients to prevent early dissemination and metastasis.
**Title:** A novel non-canonical Notch1-IKKα-mTORC2-AKT pathway maintains survival in triple negative breast cancer cells and cancer stem-like cells

Hossain F, Peng Y, Pannuti A, Backus K, Golde T, Osborne B and Miele L. LSUHSC, New Orleans, LA; Loyola University Chicago; University of Mississippi; University of Florida and University of Massachusetts Amherst.

**Body:** Triple negative breast cancer (TNBC) is a heterogeneous group of clinically aggressive breast cancers. TNBC patients have high risk of recurrence and metastasis, and current treatment options remain limited. There is strong evidence for the involvement of Notch signaling in TNBC and in breast cancer stem-like cells (CSCs). Notch1 is highly expressed in Basal-like 1 (BL1) and especially Mesenchymal-Stem-Like (MSL) TNBCs. Expression of Notch1 and its ligand Jagged1 correlate with poor prognosis. Treatment of TNBC with dual mTORC1/2 inhibitors leads to resistance through activation of Notch1. Expression of Notch1 protein correlates with pAKT and nuclear NF-κB in TNBC. Here, we demonstrate that Notch1 promotes cell survival in MDA-MB-231 cells, representative of MSL TNBC, in part by activating NF-κB. Notch activation by Jagged1-expressing stromal cells enhances transcription of the anti-apoptotic gene cIAP-2 (BIRC3), a known NF-κB target. This event is dependent on recruitment to the cIAP-2 promoter of NF-κB subunits, IKKα and Notch1. Short term exposure of MDA-MB-231 cells (MSL, PTEN wild-type), but not MDA-MB-468 cells (BL1, PTEN-null) to recombinant Jagged1 leads to rapid AKT phosphorylation. This is suppressed by dual mTORC1/2 inhibitors, AKT inhibitors and IKKα inhibitors but not Everolimus (mTORC1-selective inhibitor). Rapid AKT phosphorylation downstream of Notch1 requires mTORC2, PI3K and IKKα, and contributes to NF-κB activation. These observations support a model where canonical and non-canonical mechanisms downstream of Notch1 trigger rapid AKT phosphorylation and NF-κB activation in PTEN wild-type TNBC cells. Both arms of this pathway require IKKα. CSCs derived from MDA-MB-231 cells have increased Notch1, pAKT and pIKKα expression. Combined pharmacological inhibition of Notch and AKT or Notch and IKKα completely blocks secondary mammosphere formation. These data and published literature suggest that: 1) IKKα connects the Notch and mTORC2/AKT pathways in some TNBC subtypes; 2) IKKα is also required for nuclear Notch1-mediated NF-kB activation and may be a critical node in the Notch signaling network; 3) A feedback mechanism may exist in some TNBC cells between mTORC2/AKT and Notch1; 4) The non-canonical Notch-IKKα-AKT pathway has a potential therapeutic role in targeting CSCs of selected TNBC subtypes.
Title: DYRK2 contributes to the generation of breast cancer stem cells through KLF4

Body: <Introduction>
Cancer stem cells (CSCs) have been defined by the potential to self-renew and to differentiate. CSCs pose a major hurdle in the treatment of cancer. However, the mechanisms by which cells acquire CSC properties such as drug resistance remain unclear. Dual-specificity tyrosine-regulated kinase 2 (DYRK2) is a protein kinase that phosphorylates its substrates on serine/threonine. Initially, we found that DYRK2 phosphorylates p53 at Ser 46 to regulate apoptotic cell death in response to DNA damage. Recently, we have shown that DYRK2 controls Snail degradation in breast cancer and ovarian serous adenocarcinoma. We also found that knockdown of DYRK2 in luminal-type breast cancer MCF-7 cells increased the cancer stem cell population. Kruppel-like factor 4 (KLF4) is one of the Yamanaka factors. It has been reported that pluripotent stem cells from mouse embryonic or adult fibroblasts are induced by introducing four factors, Oct3/4, Sox2, c-Myc, and Klf4. This finding led us to determine if KLF4 is indispensable for the maintenance of CSCs. The aim of this study is to clarify whether DYRK2 regulates CSCs through KLF4 in breast cancer.

<Methods>
Cell lines: MCF-7 (human mammary carcinoma: ATCC) cells were grown according to standard protocols. We established stable DYRK2-depleted cells. MCF-7 cells were transfected with pSuper-puro vector (pSuper control) or pSuper-puro DYRK2 shRNAs (shDYRK2) with puromycin to isolate stable cell lines. In turn, we established both stable DYRK2- and KLF4-depleted cells. shDYRK2 cells were transfected with pSuper-neo vector (pSuper-neo control) or pSuper-neo KLF4 shRNAs (shKLF4) with puromycin and G418. Knockdown of DYRK2 or KLF4 was confirmed by real-time RT-PCR and immunoblotting. The depleted cells were compared with the control cells using real-time RT-PCR, immunoblotting, flow cytometric analysis, mammosphere assay, xenograft models and immunohistological staining.

<Results>
We analyzed the population of breast cancer stem cells by flow cytometric analysis and in vitro mammosphere assay. The results showed that knockdown of DYRK2 was associated with the increase of CD44+/CD24- cells. While pSuper control cells formed mammospheres, they did in a lesser extent compared to shDYRK2 cells. In real-time RT-PCR and immunoblotting analysis, stable DYRK2 depletion in MCF-7 cells induced KLF4 accumulation. We then investigated the effect of KLF4 on stemness by flow cytometric analysis and in vitro mammosphere assay. The results showed that knockdown of KLF4 in shDYRK2 cells reduced the proportion of CD44+/CD24- cells. Whereas shDYRK2/shKLF4 cells formed mammospheres, they did in a lesser extent compared to shDYRK2/pSuper-neo control cells. Moreover, the scale of the mammospheres formed in shDYRK2/shKLF4 cells was significantly smaller, as compared with that in shDYRK2/pSuper-neo control cells. In xenograft models, the loss of KLF4 protein expression significantly decreased tumor formation. Immunohistological staining of fifty-nine samples from surgically treated breast cancer patients showed an inverse correlation between DYRK2 and KLF4 expression.

<Conclusion>
These findings revealed that DYRK2 contributes to the generation of breast cancer stem cells through KLF4.
Title: The role of inducible nitric oxide synthase in the stemness of triple negative breast cancer

Mehibel M, Simoes BM M, Telfer B, Williams KJ J and Stratford IJ J. Experimental Oncology Group, Manchester Pharmacy School, The University of Manchester, Manchester, Greater Manchester, United Kingdom; Breast Cancer Now Research Unit, Institute of Cancer Sciences, University of Manchester, Manchester, Greater Manchester, United Kingdom and Hypoxia and Therapeutics Group, Manchester Pharmacy School, The University of Manchester, Manchester, Greater Manchester, United Kingdom.

Body: Background
Breast cancer comprises a highly heterogeneous group of malignancies, which despite advances in diagnosis and therapy, collectively remain the second leading cause of death in western women. Triple negative breast cancer accounts for 15-20% of all breast cancer cases and is associated with an overall poor prognosis. It is noteworthy that these TNBCs tend to harbour more cancer stem cells (CSCs).

Increased inducible nitric oxide synthase (NOS2) expression has been reported in breast cancer where it was found to directly correlate with the traditional prognostic markers including tumor grade, P53 status, and tumor microvascularization as well as poor breast cancer specific survival. Nitric oxide (NO) signalling has various oncogenic effects in cancer cells which include evasion of apoptosis, enhanced proliferation and chemotherapeutic resistance. There is also some evidence that nitric oxide plays a role in stem cell biology.

Our aim was therefore to evaluate whether nitric oxide confers stem cell properties to breast cancer cells and whether pharmacological inhibition of NO production in these tumors could be a promising strategy in successful targeting of breast cancer stem cells.

Method
To achieve this goal, basal-like human breast cancer cell lines with different levels of nitric oxide were studied by sorting breast cancer cells using flow cytometry. Three methods for identifying putative cancer stem cells were used: i) qRT-PCR to investigate the expression of cancer stem cell markers (ALDH1, Sox2, Oct4, Nanog) ii) culture of mammary cells in anchorage independent conditions (mammosphere assay) and iii) co-expression of NOS2 and stem cell markers in tumor xenografts. In parallel, cells were engineered to constitutively overexpress the NOS2 gene and the effect of pharmacological inhibition of nitric oxide release on stemness characteristics of these cells was assessed.

Results
Basal-like breast cancer cell lines, producing high levels of nitric oxide, show enhanced stem cell properties as defined by mRNA expression level of the cancer stem cell markers ALDH1, Nanog and Oct4. Within each basal-like cell line studied, the NO\textsubscript{high} subpopulation showed higher levels of mammosphere forming efficiency (MFE) compared with the NO\textsubscript{low} cells. Furthermore, pharmacological inhibition of nitric oxide in the NOS2 overexpressing cells led a significant reduction in the mammosphere forming efficiency of the cells and in MDA231 tumor xenografts, there was an obvious co-localization between NOS2 expression and the stem cell marker ALDH1A1.

Conclusion
Our study suggests that nitric oxide can be a promising determinant of breast cancer stem cell activity in basal-like cell lines and we propose that drugs modulating expression and/or activity of NOS2 may be used to reduce heterogeneity in tumors and could be of therapeutic potential.
Title: Stem cell-like transcriptional reprogramming in metastatic resistance

Body: Whether an aggressive phenotype is promoted through adaptation or resistance to target inhibition remains poorly understood. Here, complementary studies in human tumors, xenograft models and cell lines reveal transcriptional reprogramming that supports metastasis in response to PI3K/mTOR inhibition. This feature is driven by stem cell-like transcription factors. These factors functionally cooperate to promote transcriptional up-regulation of key mTOR pathway components and of metastasis mediators. Their expression is also associated with stem cell-like and metastasis signatures in tumors, and their depletion impairs the metastatic potential of breast cancer cells.

Title: MiR-146a functions as suppressive non-coding gene via indirect upregulation of Let-7 to promote asymmetric division and inhibit the self-renewal ability of breast cancer stem-like cells

Sun X, Du N, Li G, Zhang J, Zhang J, Xiao G, Wang J, Tang S-C and Ren H. Cancer Center, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, Shaanxi Province, China; The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, Shaanxi Province, China; Breast Cancer Program and Interdisciplinary Translational Research Team, Georgia Regents University Cancer Center, Augusta, GA and Tianjin Medical University Cancer Institute and Hospital, Tianjin, China.

Body: MiR-146a plays as diverse roles in systemic malignancies, stimulating the tumor growth or blocking the tumor proliferation. However, its roles in breast cancer stem-like cells are barely known. We first identified the suppressive role of miR-146a in stem cells' renewal, promoting the asymmetric division of stem-like cells, and the expression of miR-146a was positively related with Let-7b level in vitro and in clinical specimens. Previous studies of Let-7 revealed its suppressive functions in stem-like cells expansion, and miR-146 was predicted to target and bind to the 3'UTR of LIN28, a negative regulator of Let-7 maturation. By using luc-assay and western, results showed that miR-146a increased the Let-7b level through degrading Lin28, and Lin28 is required for miR-146a induction of stem cells arresting and more asymmetric stem cells division. Moreover, Let-7 controlled Wnt signaling pathway activity is governed and strengthened by miR-146a, contributing to decrease the ratio of stem-like cells, forcing stem cells dividing asymmetrically. MiR-146a in turn formed negative feedback loop with Let-7 via the repression of NF-kB and Snai1 caused by Let-7b. Our results suggested the possible miR-146a/LIN28/Let-7/Snai1 signaling pathway in restraining the symmetric cells division, which was referred to the self-renewal capacity of breast cancer-stem like cells, and this axis helps to prohibit long–term tumor resistance and recurrence.
Title: The ectopic FOXA1 expression correlates to the luminal breast cancer stem cells

Body: Background: It is known that ER-positive breast cancer constitutes approximately 70% of all breast cancer and the particular population of these, called as luminal A breast cancer can lead to late recurrence, possibly due to the presence of dormant tumor cells. It is also argued that there are many similar biological characteristics between dormant cells and cancer stem cells (CSCs). So we hypothesized that some part of CSCs would be involved in the late recurrence of luminal type breast cancer and looked for the factors correlating late recurrence by comparing CSC-enriched population and other population.

Materials and Methods: We used the MCF-7 and HCC1500 human breast cell lines. Moreover, we isolated the BC#1 breast cancer cell from metastatic pleural effusion of a breast cancer patient (79 years old, ER+, PgR+, HER2 score 0). These cells are cultured in the adhesion culture condition or the mammosphere culture condition. The immunohistochemical characteristics such as ER, PgR, HER2, Cytokeratin (CK) 8, CK5/6 status of these cells were confirmed. The analysis of the ALDH activity and the CD44+/24- expression as the CSC marker were carried out using flow cytometry. The expression of target genes was analyzed using quantitative RT-PCR. Protein expression was determined by western-blotting. To assess the self-renewal potential of CSCs and the proliferation of immature cancer cells, we used mammosphere formation assay and colony formation assay. To investigate the effects of 4-hydroxytamoxifen (4-OHT) on mammosphere formation assay, 1µM of 4-OHT added to the medium in the particular experiment.

Results: BC#1 was confirmed as luminal type by immunohistochemistry and qRT-PCR. The expression tendency between two CSC markers are almost same and correlated to the mammosphere formation capacity. We also confirmed that mammosphere culture have an increased ALDH-positive population compared with adherent culture cells. Using flow cytometry, we divided the cell lines and isolated cells into two populations, ALDH-positive and negative. By qRT-PCR analysis, ALDH-positive population showed higher expression of FOXA1 (ER expression related gene) than ALDH-negative population. In addition, we found the significantly higher expression of FOXA1 gene, and RPRM gene (p53 induced G2/M arrest related gene) in mammosphere culture samples than in adhesion culture samples. In terms of the effects of 4-OHT, 4-OHT resistant mammosphere samples showed significantly increased FOXA1 gene expression level. Finally, we established shFOXA1 MCF-7 cells to investigate the relationship between self-renewal potential and FOXA1 expression. We found that colony formation in shFOXA1 MCF-7 cells decreased compared with control while there is no significant difference in the number of mammospheres.

Conclusion: CSC-enriched population showed higher FOXA1 expression and our results suggested that the expression of FOXA1 correlate to the proliferation of immature breast cancer cell rather than the induction of self-renewal potency of CSCs. Moreover, there is no report argued about the correlation between CSCs and G2/M arrest related gene like RPRM so that the biological mechanism should be investigated in future.

Title: RAD51AP1 is a novel prognostic marker and therapeutic target for breast cancer

Thangaraju M, Kolhe RB B and Pathania R. Augusta University, Augusta, GA; Augusta University, Augusta, GA and Augusta University, Augusta, GA.

Body: Background: Ionizing radiation is one of the most effective therapeutic strategies for the treatment of breast cancer and is considered as a more appropriate therapy for patients with high-risk of recurrence. Despite substantial benefits are achievable with this treatment, especially for ductal carcinoma and early invasive cancer, the critical barrier in using this treatment strategy is that tumor cells develop radioresistance, which in turn progress into advanced invasive cancer. Breast cancer stem cells (BCSCs), a subpopulation of cells within the tumor with a characteristic feature of self-renewal, play a critical role in radioresistance and treatment failure. BCSCs exhibit increased DNA repair activity by increasing RAD51AP1 for their prolonged survival and to evade from the radiation therapy. We explored the expression profile of RAD51AP1 in BCSCs, human normal and various subtypes of breast tumor tissues and cell lines and response to chemo- and radiation- therapy.

Methods: Gene expression (RNA and protein) profile was assessed using semi-quantitative and real-time PCR (qPCR) and western blot analyses. RAD51AP1 expression and its prognostic value in large cohort of human samples were analyzed by TCGA, GOBO, and Kaplan-Meier plotter integrative bioinformatics interface analyses. Breast cancer stem cell (BCSC) status was analyzed by FACS using CD24 and CD49f cell surface marker. Cell death was analyzed by propidium iodide (PI) stained cell cycle analysis.

Results: We found that tumor propagating CD49f+CD24+ cells activate RAD51AP1 more promptly than non-tumorigenic CD49f−CD24− cells and confer chemo- and radiation- therapy resistance. RAD51AP1 inactivation facilitates chemo- and radiation-therapy response by depleting CD49f−CD24+ cells with significant activation of apoptotic cell death signaling. RAD51AP1 expression was significantly higher in BC, especially in the basal triple-negative and HER2-positive BC subtype, than in normal mammary tissue. Further, RAD51AP1 expression is highest in grade III histological tumor types and negatively associated to overall disease-free survival. RAD51AP1 levels across different BC cell lines showed that triple-negative breast cancer (TNBC) cell lines expressed highest level of this gene than other sub types.

Conclusion: Overall, our findings provide evidence that BCSCs utilize DNA repair signaling for their self-renewal and RAD51AP1 play a critical role in BCSC self-renewal and maintenance. Further, RAD51AP1 expression profile can be used as a prognostic marker to monitor disease progression and chemotherapy response.
**Title:** Identification of a cancer stem cell-specific function for the histone deacetylases, HDAC1 and HDAC7, in breast and ovarian cancer

Ince TA A, Witt AE E, Lee C-W, Lee TI I, Azzam DJ J, Wang B, Caslini C, Petrocca F, Grosso J, Jones M, Cohick EA A, Gropper AB B, Wahlestedt C, Richardson AL L, Shiekhattar R and Young RA A. **Body:** Tumors are comprised of a highly heterogeneous population of cells, of which only a small subset of stem-like cells possess the ability to regenerate tumors in vivo. These cancer-stem-cells (CSCs) represent a significant clinical challenge as they are resistant to conventional cancer therapies and play essential roles in metastasis and tumor relapse. Despite this realization and great interest in CSCs, it has been difficult to develop CSC-targeted treatments due to our limited understanding of CSC biology.

Multiple signaling pathways involved in the regulation of CSCs have been identified. However, the regulation of CSCs is unlike the reversible short-term changes in cellular phenotype induced by various extracellular factors, or the permanent changes induced by mutations. The hierarchical differentiation of CSCs to nsTCs is long-lasting over many cell generations but it is also reversible, that is more akin to tissue differentiation, which suggests that epigenomic factors such as histone modifications may also be involved in the regulation of the CSC phenotype.

Here, we present evidence that specific histone deacetylases (HDACs) play essential roles in the breast CSC phenotype. HDACs are chromatin-modifying enzymes that are involved in regulation of differentiation, autophagy, apoptosis, migration, mitosis, and angiogenesis. There are 11 different HDAC genes with tissue-specific expression. Utilizing a novel breast CSC model, composed of isogenic BPLER (CSC) and HMLER (nsTC) cell line pairs, we discovered that among the 11 family members, only HDAC1 and HDAC7, are specifically over-expressed in breast CSCs when compared to non-stem-tumor-cells (nsTCs). Furthermore, we determine that HDAC1 and HDAC7 are necessary to maintain breast CSCs, and that over-expression of HDAC7 is sufficient to augment the CSC phenotype. Interestingly, while HDAC1 and HDAC7 have been implicated in the regulation of normal pluripotency and ES cells, their role in the regulation of malignancy in particular with breast and ovarian CSCs have not been appreciated before.

We also demonstrate that HDAC inhibitors (HDACi) targeting HDAC1 and HDAC7 such as MS275 and MGCD0103 can be used to preferentially target breast and ovarian CSCs. So far, the limited clinical studies have been completed with these HDACi, predominantly in Leukemia and Lymphomas. Our results indicate that these drugs should be tested more extensively in solid tumors. Furthermore, in standard trial design with cytostatic and cytotoxic drugs, the reduction in tumor size has been one of the main metrics for monitoring patient response. However, CSC targeting drugs may not cause a rapid reduction in tumor size. Since the CSC-specific actions of these HDACi (MS275 and MGCD0103) were previously unknown, CSC biomarkers were not used in patient selection or for measuring patient response. Our results suggest that biomarkers such as HDAC1 and HDAC7 are particularly compelling as a supplement to tumor size measurements for patient selection and monitoring therapy response. Since we found that the regulation of HDAC7 is predominantly occurring at the protein level, it would be feasible to use HDAC7 immunohistochemistry to stratify patients in future clinical trials.

Title: Abstract Withdrawn
Title: Improving the AJCC breast cancer staging system by incorporating tumor biomarkers

Body: BACKGROUND: The current American Joint Committee on Cancer (AJCC) breast cancer staging system provides important prognostic information, however its use is limited by the lack of data incorporating prognostic and predictive biological markers. In this study we sought to determine the relationship between stage, breast cancer subtype, grade and outcome in a large population-based cohort, and to develop a risk score point-based system incorporating biological factors to the current AJCC staging system.

METHODS: Patients diagnosed with primary breast cancer stage I-IV, between 2005-2008 were identified in the California Cancer Registry. For patients with stage I-III disease, pathological stage was recorded. For those with stage IV, clinical stage was used. 5 year-breast cancer specific survival (BCSS) and overall survival (OS) rates were determined for each potential TNM combination according to breast cancer subtype. Cox proportional hazard models were used to identify independent predictors of outcome. A risk score point-based system (range 0-3 points) was created to complement the current anatomic AJCC staging system. One point was assigned for each one of the following tumor characteristics: hormone receptor (HR)-negative status, HER2-negative status and grade 3. Survival probabilities between groups were compared using log-rank test. Multivariable analysis models according to stage and risk score were performed for BCSS and OS.

RESULTS: A total of 43,938 patients were included. The 5-year BCSS and OS for each TNM combination differed according to breast cancer subtype. The best outcomes were seen among HR-positive patients followed closely by those with HER2-positive and HR-positive tumors with the worst outcomes observed among patients with triple negative tumors. In a multivariable model, after adjusting for stage, treatment variables and other important confounders, ER negative status (OR 2.14; 95%CI 1.98-2.30), HER2-negative status (OR= 1.24; 95%CI1.14-1.34) and grade 3 (OR=2.03; 95% CI 1.88-2.20) were independent predictors of BCSS. Our risk score system separated patients into 4 risk groups within each stage category (all P<0.05). Similar results were seen for OS. The results in the table show that combining stage and risk score provides improved prognostic information.

Title: Predictors of aggressive end-of-life care in women metastatic breast cancer

Body: Background: Despite recommendations against aggressive end-of-life (EOL) care, a high percentage of patients with metastatic breast cancer (MBC) receive aggressive EOL care. MBC is a heterogeneous disease with a wide variation in survival. EOL care may differ by the patients' long-term course of care. We performed a population-based analysis to evaluate patterns and predictors of aggressive EOL care and associated costs among women with MBC.

Methods: The Surveillance, Epidemiology, and End Results-Medicare database was used to identify female patients with MBC diagnosed between 2002 and 2011. Aggressive EOL care in the last month of life was identified using claims data. Specifically: ≥2 emergency department (ED) visits, ≥2 hospital admissions, >14 days hospitalized, admission to the intensive care unit (ICU), admission to hospice within 3 days or less before death, and receipt of intravenous (IV) chemotherapy in the last 14 days of life were evaluated. Direct healthcare costs in the last month of life were calculated from Medicare claims. Patients were categorized into prognosis quartiles based on survival time from diagnosis. Multivariable analysis was performed to identify patient characteristics associated with aggressive EOL care and characteristics associated with high direct healthcare expenditures in last month of life in women with hormone-receptor (HR)+ and HR- MBC. High expenditures were defined as median costs >75th percentile. Factors associated with high expenditures were evaluated using linear regression.

Results: We identified 5,064 eligible patients. Of these, 2,156 (42.6%) received at least one measure of aggressive EOL care in the last month of life. The most frequent aggressive EOL care received in the last month of life were ICU admissions (17.3%) and >1 ED visits (14.1%). Median cost of care in the last month of life was $7,973. Predictors of aggressive EOL care included year of diagnosis (OR 1.04, 95% CI 1.02-1.06), black race as compared to whites (OR 1.50, 95% CI 1.25-1.79), being married compared to single (OR 1.15, 95% CI 1.01-1.32), and a Charlson comorbidity score of ≥2 compared to no comorbidities (OR 1.52, 95%CI 1.32-1.75). Predictors of not receiving aggressive EOL care included age >74 compared to ages 70-74, receiving care in the Midwest compared to the East (OR 0.82, 95% CI 0.70-0.96), and best prognosis compared to worst prognosis (OR 0.46, 95% CI 0.39-0.55). Predictors of high last month of life expenditures were similar in both the HR+ and HR- subsets: receipt of more aggressive EOL care was also associated with higher expenditures in both HR subsets (OR 5.02, 95% CI 3.88-6.49; OR 5.43, 95% CI 3.41-8.65, respectively). Median last month of life expenditures were unchanged from 2002-2012 for the whole population ($7,658 to $5,910, p=0.93), but rose significantly in patients in the worst prognosis quartile ($9,236 to $16,926, p<0.0001)

Conclusion: Patients with MBC frequently received aggressive EOL care. Women with poor prognosis were more likely to receive aggressive EOL care and have higher expenditures in the last month of life. Given the rising costs of cancer care, efforts should be made to identify patients early for EOL interventions to reduce costs, particularly in women with a poor prognosis.
Title: Overview of breast cancer mortality trends in the world

Pizot C, Boniol M, Boyle P and Autier P. University of Strathclyde Institute of Global Public Health, Lyon, France and International Prevention Research Institute, Lyon, France.

Body: Background: Since the 1990s, important changes in the detection and management of breast cancer have taken place. We analysed breast cancer mortality trends from 1989 to 2012 in 47 countries with data available for most years since 1987.

Methods: Breast cancer deaths and populations were extracted from the WHO mortality database. Age-standardised mortality rates were computed using the World standard population over the period 1987-2012 for women of all ages and for women aged <50 years, 50-69 years and ≥70 years. Percent changes in mortality trends were assessed over the period 1989-2012. Mortality rates are reported per 100,000 women. We constituted groups of comparable countries that are located in same region, have similar economic status and same mortality rates in 1987-89.

Results: Annual breast cancer mortality rates in 1987-89 ranged from 2.6 in South Korea to 29.3 in England and Wales (median rate of 18.5). In 2010-12, mortality rates ranged from 5.1 in South Korea to 18.4 in Denmark (median rate of 14.8). From 1989 to 2012 (23 years), declines in breast cancer mortality were observed in 39 out of 47 countries. Mortality changes ranged from a -45% reduction in England and Wales to a 79% increase in South Korea (median change of -28%). Mortality declines were more pronounced in countries with high mortality in 1987-89. In groups of comparable countries, sharp contrasts in mortality changes were observed, for instance -21% reduction in France against -37% reduction in Spain, or 5% increase in Latvia against -17% reduction in Slovakia. Although the mortality rates in 1987-89 were 20.9 in Australia and 27.4 in New Zealand, a mortality reduction of -38% was observed in both countries. Of note, in these groups of comparable countries, reductions in mortality were the same in countries that introduced mass breast screening around 1990 than in countries where breast screening was introduced in 2005 or after. Regarding age groups, the largest declines in mortality were observed in women less than 50 in all the countries except New Zealand and Hong Kong, and only three countries had an increased mortality in this age group (Brazil, Colombia, South Korea). Mortality changes in young women ranged from -59% reduction in Slovenia to 32% increase in South Korea (median change of -45%). Mortality changes in young women were not different in countries where breast screening before age 50 has always been uncommon (e.g., Norway, England and Wales) or is widespread since the late 1980’s (e.g., the USA, Sweden). In women aged 50-69 years, mortality changes ranged from -49% reduction in England and Wales to 111% increase in South Korea (median change of -27%). In women aged 70 years or more, mortality changes ranged from a -33% reduction in the Netherlands to a 151% increase in South Korea (median of -11%).

Conclusions: Huge disparities in changes in breast cancer mortality rates are observed around the World, and across age groups. Downward trends in breast cancer mortality prevail in most of Europe, North America, Oceania, and in few countries of Latin America and Asia. The situation in high income Asian countries is not easy to interpret because access to efficient therapies is commonplace. There seems to be no discernible influence of screening on mortality trends.
Title: Prospective family cohort analyses of gene-environment interactions in breast cancer: Body mass index

Terry MB, Dite GS S, Phillips K-A, Andrulis IL L, John EM M, Daly MB B, Buys SS S and Hopper JL L.  Columbia University Mailman School of Public Health, New York, NY;  The University of Melbourne, Carlton, Victoria, Australia;  Peter MacCallum Cancer Centre, Melbourne, Victoria, Australia;  Mount Sinai Hospital, Toronto, ON, Canada;  Cancer Prevention Institute of California, Fremont, CA;  Stanford University School of Medicine, Stanford, CA;  Fox Chase Cancer Center, Philadelphia, PA and University of Utah School of Medicine, Salt Lake City, UT.

Body: It is becoming possible to better identify women at increased genetic risk of breast cancer, but it is not known whether associations with risk factors are the same for women with different genetic susceptibilities. If there is a difference in disease associations by genetic risk, prevention and screening measures can be better targeted to appropriate groups of women. If there is no difference and the study is well-powered, advice to women regarding specific risk factors can be confidently given to women across the spectrum of genetic risk.

We examined this issue of gene-environment interaction for body mass index (BMI), a potentially modifiable risk factor, and used multi-generational family cancer history to derive a proxy measure of a woman's underlying genetic risk. This issue is complicated because the BMI risk association depends on time of life and potentially by menopausal status. Higher BMI has been found to be associated with an increased risk of breast cancer for post-menopausal women, especially for those 15 years or more post-menopause or aged 60 years or older. In contrast, for pre-menopausal women, young women and even adolescent girls, greater BMI has been found to be associated with a decreased risk of breast cancer.

For these analyses, we studied 11,700 participants from 5,400 families enrolled in the Breast Cancer Family Registry (North America and Australia) and the Kathleen Cuningham Foundation Consortium for Research into Familial Breast Cancer (Australia). These prospective cohorts, enriched for familial risk of breast cancer, were established in the 1990s and now have had up to 20 years follow up (mean follow-up 10.5 years; standard deviation 4.4 years). There were 540 incident breast cancers with a mean diagnosis age of 57.2 years (standard deviation 12.1 years).

We used Cox proportional hazards models to investigate whether the associations between risk of breast cancer and BMI, measured by hazard ratios (HRs), differed by underlying genetic risk, defined as the 5-year risk of breast cancer estimated by the Breast and Ovarian Analysis of Disease Incidence and Carrier Estimation Algorithm (BOADICEA) adjusted for age and continent. First, we found that the strength and direction of the association of BMI with risk depended on age at baseline ($p=0.004$). This strong interaction was not changed after adjusting for menopausal status ($p=0.5$). The change from decreased risk to increased risk was gradual over adult life with no apparent perturbation attributed to menopausal status.

Second, we found that there was a strong association with genetic risk ($p<0.001$), and this was unchanged after adjusting for the age-dependent association with BMI.

Third, we found no evidence for an interaction between BMI as a function of age at baseline and genetic risk ($p=0.8$). Our finding of a lack of an interaction with genetic risk is important because it supports, at least for BMI, current practice that assumes that breast cancer risk factors relevant to women in the general population also apply to women of higher genetic risk. In terms of potentially reducing absolute risk, increased BMI could be more important for women at higher genetic risk. This demonstrates the power of a cohort enriched for women at increased genetic risk.
Title: Impact of a decision-support tool on the utilization of colony-stimulating factors and incidence of febrile neutropenia among patients with breast cancer

Body: Background:
Following the 2012 American Society of Clinical Oncology's Choosing Wisely campaign recommendation against the routine use of colony-stimulating factors (CSFs) for the primary prevention of febrile neutropenia (FN) in patients with \( \leq 20\% \) risk, an evidence-based clinical decision-support tool (CSF decision tool) was implemented to promote risk-appropriate CSF use in breast cancer patients receiving chemotherapy by a national payer in the United States (US). We hypothesized that there should be no change in pre- and post-implementation FN rates if the CSF decision tool had promoted appropriate FN risk stratification among breast cancer patients.

Methods:
A retrospective observational cohort study design was used to analyze data from a national payer administrative claims database of nearly 40 million lives geographically spread across the US. The CSF decision tool was first implemented in 2014, with a staggered implementation across states (July 1, 2014 - November 1, 2014). Study subjects were female patients, aged \( \geq 18 \) years, who initiated chemotherapy for breast cancer in the time periods before or after the implementation of the decision tool (July 1, 2014 through March 30, 2015). Patients were assigned to case (defined as patients in the states where the CSF decision tool had been implemented) or control (defined as patients in states where the CSF decision tool had yet to be implemented) cohort. Patients in each cohort were followed up to 6 months after the first chemotherapy dose in the pre- and post-implementation periods. The outcomes were changes in the incidence of FN and CSF use rates, respectively. Rates of FN and CSF use were compared between the cohorts using difference-in-differences models; generalized estimating equations were used to adjust for differences in baseline risk factors including age, history of neutropenia or infections.

Results:
The final study population comprised 7,224 patients: 4,001 and 3,223 in the case and control cohorts, respectively. There was a higher proportion of patients who were 65 years or older in the case cohort compared to the control (22% vs 18%, \( p < 0.001 \)). Otherwise, the cohorts were comparable in FN risk factors at baseline in pre- and post-implementation periods.
In adjusted regression results, pre- and post-implementation FN rates were not significantly different for both case (5.38% to 5.65%) and control (5.07% to 5.13%) cohorts, \( [p=0.778] \). Use of CSF in the pre- and post-implementation periods decreased from 75% to 69% in the case cohort compared with a reduction from 72% to 71% in the control cohort: an absolute difference of 5.4% decrease in CSF use associated with the implementation of the decision support tool \( [p= 0.006] \).

Conclusion:
Despite a modest reduction in CSF use, we found no evidence of an increase in FN rates after the implementation of the CSF decision tool. Given the lack of impact of the Choosing Wisely campaign on inappropriate CSF use; our findings suggest that beyond the educational efforts and media campaigns, a greater reduction in unnecessary CSF use can be achieved through the use of clinical decision algorithms to reduce practice variation and improve adherence to national guideline recommendations.

Title: Baseline (BL) characteristics, treatment (tx) patterns, and outcomes in patients with hormone receptor (HR)+ vs HR– HER2+ disease from the SystHERs registry

Cobleigh M, Yardley DA A, Brufsky A, Rugo H, Swain S, Kaufman PA A, Tripathy D, Mayer M, Hurvitz S, O'Shaughnessy J, Mason G, Chu L, Antao V, Beattie M, Yoo B and Jahanzeb M. Sammons Cancer Center, Texas Oncology, US Oncology; Inflammatory Breast Cancer Research Foundation; Genentech, Inc. and University of Miami Sylvester Comprehensive Cancer Center.

Body: Introduction

HR+ metastatic breast cancer (MBC) generally has a more indolent course than HR– MBC. Less is known about differences in BL characteristics and disease outcomes by HR status in HER2+ MBC in the modern tx setting where patients (pts) may recur after adjuvant therapy. SystHERs is an ongoing, prospective, observational cohort study of HER2+ MBC pts. Here we describe BL characteristics, tx patterns, and outcomes by HR status and MBC diagnosis type.

Methods

SystHERs enrolled pts aged ≥18 years and within 6 months of MBC diagnosis. Locally-determined HR status was captured at initial diagnosis and/or disease recurrence; HR+ was defined as ER+ and/or PR+ disease in primary (early BC) or MBC. Tx data are shown for pts ≥9 months from MBC diagnosis to capture the completion of chemotherapy and the addition of hormonal therapy during maintenance tx. Median overall survival (OS; Kaplan-Meier) and the hazard ratio (Cox regression) were estimated.

Results

As of Feb 2016, data were available for 872 eligible pts with known HR status; 70% had HR+ disease and 50% had de novo MBC. Median follow-up from MBC diagnosis was 16.5 months (range, 0.4–49.4 months). Clinically important BL demographics and disease characteristics with noticeable differences are presented in Table 1. More black (vs white) pts were observed to be HR–. More recurrent (vs de novo) pts were observed to be HR+.

MBC tx choices may be influenced by adjuvant tx. Table 2 shows the most common first-line tx regimens in de novo vs recurrent pts with HR+ HER2+ disease and ≥9 months from MBC diagnosis. Among these pts, 60% de novo and 56% recurrent pts received any hormonal therapy. The most common first-line tx regimen for pts with HR– disease was chemotherapy + HER2-targeted therapy (92%).

There were 88 (15%) and 55 (21%) deaths in the HR+ and HR– groups, respectively. Median OS was not reached for either group, but the hazard ratio favored pts with HR+ disease (log-rank $P=0.026$; hazard ratio 0.683; 95% CI 0.488–0.957).

**Conclusions** In SystHERs, 70% of pts with HER2+ MBC had HR+ disease. A higher percentage of recurrent pts had HR+ disease vs de novo pts, perhaps suggesting selective elimination of HR– clones during adjuvant tx. While black pts are known to be more likely to develop HR– HER2– BC, our results show that HR– HER2+ disease is also more common in black pts, suggesting a proclivity for this population to develop HR– MBC regardless of HER2 status. In these early results, survival was higher in pts with HR+ HER2+ MBC.
Title: Abstract Withdrawn
Title: Stage-at-presentation and time-to-treatment for American Indian patients diagnosed with breast cancer

Algan O, Campbell JE E and Algan SM M. College of Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, OK; Biostatistics and Epidemiology, College of Public Health, University of Oklahoma Health Sciences Center, Oklahoma City, OK and College of Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Body: Purpose: To review the stage of presentation and time-to-treatment for American Indian (AI) patients diagnosed with breast cancer (BC) and compare them to White (W), Black (B), Asian (AS) and Hawaiian/Polynesian (HP) population across the US and by geographic region using a large national database.

Methods: The NCDB, a joint project of the American Cancer Society and the Commission on Cancer, is a comprehensive national database that registers approximately 70% of cancer patients in the US. Data for patients with BC was extracted from the NCDB 2013 PUF file (2004-2013). Categorical data were compared using the chi-square test. Time-to-treatment (TtT) analysis was performed in patients with non-metastatic breast cancer. All interval parameters were evaluated as continuous variables and compared using ANOVA analysis.

Results: Table 1 shows the number of patients, median age and stage at presentation by race. The median age was lowest for AS and largest for W patients. Compared to W patients, AI patients were less likely to present with stage 0/I disease and more likely to present with stage II/III disease. Similarly, AI patients were 25% more likely to present with metastatic disease when compared to W patients. Table 1 also shows the mean intervals (in days) from diagnosis to treatment. This analysis revealed significant differences amongst the races, with AI patients tending to have the second shortest TtT. Evaluation of the interval to treatment amongst the 9 geographic regions also revealed significant differences. The West North Central and East South Central regions had the shortest TtT and the Pacific and North East regions had the longest. For AI patients, the shortest TtT occurred in the West North Central and South Atlantic while the longest TtT occurred in the North East and West South Central regions. In general, the magnitude of these differences was under 20%, but varied greatly depending on the variables and regions evaluated. These differences were statistically significant (p-value < 0.01).

Conclusion: AI patients presented with later stage disease and longer interval to treatment for all modalities compared to White race, but did better overall than Black patients, both for stage at diagnosis and time to treat. There was considerable regional variation in time intervals across all races. Efforts to improve outcomes should be focused on addressing regional variations in time to treat, and in earlier diagnosis of breast cancer for at risk populations.

Title: Urinary arsenic metabolites and risk of breast cancer molecular subtypes in northern Mexican women

López-Carrillo L, Gamboa-Loira B and Cebrián ME E. Instituto Nacional de Salud Publica, Cuernavaca, Morelos, Mexico and Centro de Investigación y Estudios Avanzados del Instituto Politécnico Nacional, Mexico, Ciudad de Mexico, Mexico.

Body: Background/Aim: For many years, the presence of arsenic (As) in drinking water of some areas in Northern Mexico has been a major concern. As levels have ranged from 71 to 600 µg/L. We have recently reported that women residing in Northern Mexico, with higher urinary monomethyl arsenic acid percentage (%MMA) had an increased breast cancer (BC) risk (MMA% ORQ5vs.Q1=2.63; 95%CI: 1.89, 3.66; p for trend <0.001) (López-Carrillo et al., 214).

Breast tumor subtypes with distinctive biology and treatment responses are defined by the immunohistochemical expression of estrogen and progesterone receptors (HR) and human epidermal growth factor receptor 2 (HER2). Epidemiological evidence suggests that BC risk factors (i.e. breastfeeding, parity, menarche, etc.) may vary by tumor pathology. We assessed if %MMA is associated with a particular BC molecular subtype.

Methods: A population based case–control study was performed from 2007 to 2011 in five states of Northern Mexico. Incident cases were identified from main public tertiary hospitals in the study area. A total of 499 patients with histopathologically confirmed BC and molecular subtype status available information were identified. Controls were healthy women, with no history of cancer, matched 1:1 by age.

Tumor marker information for estrogen receptor (ER), progesterone receptor (PR) and HER2 was obtained from medical records. ER+ and PR+ was based on >=1% cell staining. HER2+ status was determined when at least 30% of protein overexpression was observed in the tumor cell. Cases were assigned to one of three tumor marker categories: HR+ (ER+ and/or PR+ and HER2-), HER+ (regardless of ER or PR status) and TNBC (ER-, PR-, and HER2-).

Urinary concentrations (µg/L) of species As³+, As⁵+, MMA⁵+, DMA⁵+, and arsenobetaine (AsB) were determined by high-performance liquid chromatography ICP-MS. Detection limits were As³+: 0.12; As⁵+: 0.20; MMA⁵+: 0.12; DMA⁵+: 0.08; AsB: 0.08. Results were reported by g of creatinine. Total As was calculated by using both the sum of iAs, MMA, DMA plus or minus AsB concentration (TAs or TAs-AsB, respectively). iAs was calculated as the sum of trivalent (As³+) and pentavalent (As⁵+). %iAs, %MMA and %DMA species were estimated using TAs-AsB as denominator.

Using logistic regression models, the associations between BC molecular subtypes and MMA% and DMA% was estimated according to the observed quintile distribution among controls. Based on the median value of each quintile a lineal trend was assessed accordingly.

Results. The mean age of cases and controls was around 54 years with 51 years of residence in the study zone. In the entire population, TAs ranged from 0.47 to 303.29 µg/L (0.45 to 1683.83 µg/g creatinine). HR+ BC patients were 57%, HER2 23% and TNBC 20%. These figures are similar to those reported among other groups of Mexican cancer patients. After controlling by key BC factors, %MMA remained as a significant risk factor for BC only for HR+. HER2+ and TNBC tumors were not significantly associated with urinary As metabolites.

Conclusion: Our results suggest that increased BC risk related to As exposure is not mediated by HER2 expression. This is the first report on As exposure and breast cancer subtypes which requires further confirmation.
Title: HER2 status remains the primary predictor of improved survival in patients with BCBM over the past 2 decades (1996-2015)

Narloch JL L, Harnden K, Broadwater G, Bercedis PL L, Terry H, John K, Peter FE E, Grace KJ J and Kimberly BL L. Clinical Research Training Program, Duke University Medical Center, Durham, NC; Duke University Medical Center, Durham, NC; Duke Cancer Institute, Durham, NC; Duke University Medical Center, Durham, NC and Duke University Medical Center, Durham, NC.

Body: BACKGROUND: Brain metastasis is a complication in advanced breast cancer (ABC) and is associated with poor prognosis. Incidence of breast cancer brain metastasis (BCBM) is increasing with advances in therapy, allowing patients to survive long enough to develop CNS metastasis. Improved outcomes have been documented in ABC over the past decades, largely related to the use of trastuzumab in HER2+ ABC. However, it remains unclear whether survival has improved in HER2-ABC in patients with BCBM. This study asks: has the improvement in systemic and radiotherapies for HER2- breast cancer impacted survival in patients with breast cancer brain metastasis.

OBJECTIVES: 1) To estimate whether date of BCBM diagnosis is associated with overall survival (OS) in patients diagnosed between 1996-2015. 2) To estimate whether OS of this patient population depends upon other demographic and clinical factors.

METHODS: This is a retrospective chart review of patients with diagnosis of BCBM between 1996-2015. Data collection includes: age at BCBM diagnosis, ethnicity, ER/PR/HER2 status, date of BCBM diagnosis, date of primary breast cancer diagnosis, date of death/last clinical follow-up, and treatment. Kaplan-Meier analysis and the log-rank test compared OS (time from diagnosis of BCBM until death or last clinical FU) between groups diagnosed in 5-year cohorts (1996-2000, 2001-2005, 2006-2010, 2011-2015). A univariate proportional hazards model was used to regress OS on date of diagnosis. A multivariate proportional hazards model was used which included the subset of patients diagnosed with BCBM in 2001 and later. This model adjusted for additional factors: race, time to development of BCBM diagnosis, age at the time of BCBM diagnosis, year of diagnosis as a continuous factor, ER, PR, while testing the significance of HER2 status. A p-value < 0.05 was significant.

RESULTS: A total of 165 patients with BCBM were included in this analysis, with a median age of 53.8 (SD 13.0) at time of BCBM diagnosis. Most patients were Caucasian (66%; 109/165) or African-American (29%; 48/165). Although statistical significance was not attained, greater median overall survival was seen for patients diagnosed with BCBM in more recent 5-year cohorts (2011-2016, 9.5 months; 2006-2010, 8 months) than patients in older cohorts (2001-2006, 3.6 months; 1996-2000, 5.3 months), p=0.3. Date of diagnosis of BCBM as a continuous variable is predictive of overall survival (HR 0.83 [95% CI: 0.71-0.97] comparing 5-year intervals, p=0.016). After adjusting for the covariates listed above, HER2 positive status is predictive of overall survival (HR 0.34 [95% CI: 0.34-0.56]; p<0.0001).

CONCLUSIONS: While survival has improved by 5.9 months over the past two decades, it remains highly dependent on HER2 status. Novel therapies for BCBM are greatly needed for ER+ and triple negative subtypes. Final results will include an expanded analysis to incorporate additional cases and three other categorical covariates measured during follow-up: whether the patient received radiotherapy, surgery, and/or medical therapy after diagnosis of brain metastases.

GRANT FUNDING: TL-1 CTSA Pre-Doctoral Training Grant (5TL1TR001116-03).
**Title:** Phyllodes tumours of the breast: The British Columbia cancer agency experience

**Body:**

**Background**
Phyllodes tumours (PT) of the breast are uncommon fibroepithelial lesions for which optimal management remains unclear. This population-based study reports treatment and outcomes for patients with PT and evaluates characteristics that influence outcome.

**Methods**
Data were analysed on 183 patients with newly diagnosed PT referred to the BC Cancer Agency from 1999-2014. Follow-up was obtained from chart and death records and letters to general practitioners. Five-year Kaplan-Meier (KM) local recurrence (LR) and survival were compared between cohorts with benign (n=83), borderline (n=50) and malignant PT (n=49) histology. Subtype was unknown in 1 patient who did not receive surgery due to severe comorbidity. Univariate analysis was performed using Cox regression modeling.

**Results**
Median follow-up was 65 (range 0.5-197) months. Median age was 48 (range 14–87) years. Median tumour size was 4 (range 1-23) cm. Heterologous sarcomatous differentiation was seen in 15 and malignant epithelial transformation in 11 patients. Local excision was performed in 163 (89%) and mastectomy in 19 (10%) patients. Margin status after local excision were: negative (>1mm, n=121, 74%), close (≤1mm, n=21, 13%), positive (tumour touching ink, n=20, 12%), or unknown (n=1, 1%). Margin status after mastectomy were negative (n=14, 74%) or close (n=5, 26%). Tumour borders were pushing (n=62, 34%), intermediate (n=22, 12%), infiltrative (n=38, 21%) or unknown (n=60, 33%). Eleven patients with malignant PT received radiation therapy as part of initial treatment. In these cases median tumour size was 8 cm and heterologous sarcomatous differentiation was present in 46% compared to 4 cm and 16% in malignant cases who did not receive RT.

LR occurred in 16 cases (5 benign, 4 borderline and 7 malignant). Distant metastases (DM) occurred in 7 patients with malignant PT leading to 6 cause specific deaths.

Five-year KM outcomes among women with benign, borderline, and malignant PT were: LR 6% vs 9% vs 21%, \( P=0.131 \); overall survival 96% vs 100% vs 82%, \( P=0.002 \); and disease free survival 94% vs 91% vs 67%, \( P<0.001 \). DM-free and cause specific survival at 5 years for malignant cases were 82% and 88% respectively.

Five-year KM LR among women with negative vs close vs positive margins were 8% vs 6% vs 37%, \( P<0.001 \). Corresponding rates for intermediate vs pushing vs infiltrative borders were 6% vs 6% vs 33%, \( P=0.006 \).

On univariate analyses, large tumour size, postmenopausal status, malignant classification, necrosis, positive margins, and infiltrative borders were factors associated with increased risk of any type of relapse (all \( P\leq0.014 \)). Positive margins and infiltrative tumour border were associated with increased LR (all \( P\leq0.006 \), and the latter remained significant in exploratory analyses after adjusting for margin status and PT classification. Advanced age at diagnosis and large tumour size were predictors of DM (all \( P\leq0.001 \).)

**Conclusion**
In this population-based series, 5-year outcomes among women with PT are comparable to those reported in the literature. Exploratory analysis suggests that infiltrative tumour borders may be used in conjunction with margin status to assess LR risk. While close margin was not associated with increased LR, re-excision is warranted for cases with positive margins.
Title: Synchronous bilateral breast cancer compared to unilateral breast cancer: A population based study

Yadav S and Zakalik D. Beaumont Health, Royal Oak, MI; Nancy and James Grosfeld Cancer Genetics Center, Beaumont Cancer Institute, Beaumont Health, Royal Oak, MI and Oakland University William Beaumont School of Medicine, Rochester, MI.

Body: Introduction: The clinical presentation and outcome of synchronous bilateral invasive breast cancer compared to unilateral breast cancer is not well studied. In this study, we present a population based comparison of tumor characteristics and survival between invasive unilateral and bilateral breast cancer.

Methods: Data from National Cancer Institute- Surveillance, Epidemiology and End Results (SEER) was analyzed to identify women who had a diagnosis of invasive ductal carcinoma (ICD-O-3: 8500/3) between the years 2000 and 2013. Women who were diagnosed with an invasive contralateral breast cancer within two months of initial diagnosis were classified under synchronous bilateral breast cancer group. Women who developed a contralateral breast cancer between three to twelve months of diagnosis were excluded. All women who did not develop a second breast cancer, or developed it after twelve months of initial diagnosis were classified under unilateral breast cancer group. Patients with an in-situ breast cancer diagnosis in the contralateral breast within twelve months of diagnosis of invasive ductal carcinoma were excluded. Patients with metastatic disease and unknown stage at presentation were excluded. Tumor characteristics and survival were compared between the two groups using the index case only. Mann-Whitney U test was used for continuous variables while Chi-square test was used for categorical variables. Kaplan-Meier curves and Cox proportional hazard regression models were used to compare survival. All data analysis was performed using SPSS 21.

Results: A total of 414,766 patients met our inclusion criteria. Of these, 3,590 patients were in the synchronous bilateral breast cancer group, while 411,176 were in the unilateral breast cancer group. Compared to unilateral breast cancer patients, bilateral breast cancer patients were slightly older (62 Vs 59, p<0.05) and were more likely to have higher T, N or overall stage at presentation. Their tumors were also more likely to be estrogen or progesterone receptor positive (p<0.05). Patients with bilateral breast cancer also had higher rates of mastectomy (63.3% Vs 39.1%, p<0.05). Patients with bilateral breast cancers had a significantly worse survival compared to patients with unilateral breast cancer (Table 1). In a multivariate Cox proportional hazard regression, adjusting for age at diagnosis, T-Stage, N-Stage, overall stage, hormone receptor status, type of surgical treatment and radiation therapy, bilateral breast cancers had a mortality hazard ratio of 1.48 (95% CI: 1.35 – 1.62, p<0.001) compared to unilateral breast cancers.

Conclusions: Our study demonstrates that bilateral breast cancer has a worse prognosis compared to invasive unilateral breast cancer. These findings have important implications for patients, and contribute to our understanding of the unique outcomes of bilateral breast cancer which will guide treatment and follow up.

Title: Real-world treatment patterns and survival among triple negative breast cancer patients versus patients with other breast cancer subtypes in early stage breast cancer

DaCosta Byfield S, Abushamaa AM M, Becker LK K, Shepherd SP P, Ricker JL L and Bonnet P. Optum, MN and Abbvie, IL.

Body: Background: It is generally accepted that outcomes of breast cancer (BC) patients (pts) differ by tumor characteristics, but relatively few studies have examined treatment patterns and outcomes in early stage disease by hormone receptor (HR) and HER2 status.

Methods: This retrospective study used physician-reported clinical information (date and stage at diagnosis, HER2 and HR status) for commercially insured BC pts from the Optum Oncology Management Registry linked with the Optum Research Database (medical and pharmacy claims from a national US health plan) and death data from Social Security Administration files from 01/2008 to 6/2014. Pts diagnosed with early stage breast cancer (ESBC) were examined. The index date was diagnosis of BC. Adult pts (≥18 yrs old) had to have known HR and HER2 status, continuous enrollment in the health plan from initial diagnosis for ≥6 months, surgery and systemic cancer therapy. Neo-adjuvant and adjuvant therapy (initial phase of care) based on timing of claims for NCCN-recommended therapy were examined, as well as survival and development of metastasis (based on claims with ICD-9 codes 196.0x, 196.2x, 196.5x-199.0x) after initial phase of care during the study period. Differences across the HR/HER2 subtypes were examined using t-test for continuous variables and chi-square test for categorical variables.

Results: Among 6,881 ESBC pts identified, 15% (n=1038) were TNBC pts, 65% HR+/HER2-, 14% HR+/HER2+ and 6% HR-/HER2+. Mean (median) age was 52 (53) years. Treatment patterns and outcomes vary by tumor subtype (Table).

Conclusions: The most common neo-adjuvant and adjuvant chemotherapy agents received were similar across HER2 subtypes and regimens for HR+ and HER2+ patients also included hormonal or HER2 targeted agents. TNBC pts had the shortest length of initial phase of care (mean 10 mths), though this cohort had the second highest percentage of patients receiving systemic neo-adjuvant therapy. Development of distant metastasis and mortality during the study period were highest for the HR-/HER2- patients, at 7.5% and 2.2% respectively. Development of novel targets and therapies for TNBC may significantly benefit patients with this BC subtype, in both neo-adjuvant and adjuvant setting to improve outcomes.
Title: Breast cancer in the Bahamas: Revisiting the adequacy of national screening guidelines

Deleveaux S, Curling D and Francis W. University of the West Indies School of Clinical Medicine and Research, Nassau, Bahamas; Princess Margaret Hospital, Nassau, Bahamas and Princess Margaret Hospital, Nassau, Bahamas.

Body: Background: The Bahamas is an island nation shown to have a high incidence of early onset breast cancer. In addition, recent research has revealed that the Bahamian population has a high prevalence of a founder mutation to the BRCA1 gene. Despite the population differences between the Bahamas and the United States, the screening guidelines for breast cancer in the Bahamas reflect those of the United States. This study provides data that suggests that the current breast cancer screening guidelines in the Bahamas do not capture cases in the age groups most at risk and are in need of revision.

Methods: We performed a retrospective review of all cases submitted to the Princess Margaret Hospital cancer registry from 1998-2012. We divided the patients into 10 year age cohorts and determined the frequency of breast cancer in each group. For comparison, data for the United States was obtained using the Surveillance, Epidemiology, and End Results (SEER) 18 registries, including all cases of breast cancer from 1998-2012 further stratified into age groups and ethnicity.

Results: The average age of diagnosis of breast cancer in the Bahamas from 1998-2012 was 54 years, compared to an average age of diagnosis in the United States overall population of 61 years and among the black American ethnicity, 58 years (2008-2012 data). The age group with the highest percentage of incidence in the Bahamas is the 40-49 age group consisting of 27% of those diagnosed from 1998-2012. During the same time period, the age group with the highest incidence of breast cancer in the United States was the 50-59 age group in the overall population (24.8%), as well as in the black population (26.7%). By beginning screening at age 40, according to screening guidelines during the study period, the United States was able to capture 95.3% of breast cancer cases in the overall population and 92.8% of breast cancer cases in the black population. Using similar guidelines, the Bahamas captured only 83.6% of breast cancer cases. For comparison, if screening began at age 30 in the Bahamas during the study period, 97% of breast cancer cases would have been captured.

Conclusions: The data in this study demonstrates significant differences in the incidence of breast cancer between age group cohorts in the population of the Bahamas compared to the population of the United States. Furthermore, it suggests that the screening guidelines in place in the Bahamas may be insufficient at capturing an adequate percentage of the population at risk for breast cancer. A significant increase in capture of those with breast cancer in the Bahamas may be achieved by reducing the age to begin screening below the age of 40.
Title: Breast cancer in octagenerians: A community hospital experience

Gadiyaram V and Caldwell D. Morton Plant Mease Hospitals, Clearwater, FL.

Body: Background: Breast cancer incidence increases with age. However Elderly patients are undertreated and underdiagnosed affecting their overall survival with limited availability of clinical trial data.

Patients and Methods: We used the data from our cancer registry to evaluate the cases of breast cancer diagnosed between the years 2005-2010 with follow up data available to date to examine the method of diagnosis (mammogram vs palpable abnormality), Age at diagnosis, Stage at diagnosis, Type of surgery (BCT Vs Mastectomy), Receptor status (ER/PR/Her 2 neu) and treatment's received (Hormonal therapy, Radiation therapy and chemotherapy) and average survival after the diagnosis of breast cancer. Data regarding the causality of death was not readily available as part of the registry data.

Results: A total of 495 breast cancer cases diagnosed in the years between 2005-2010 were identified. Median age at diagnosis was 85 with ages ranging from 81-102. Out of the 495 patients 55% were diagnosed with a mammogram and 41% by palpable abnormality. Patients were diagnosed at Stage 0, 1, 2, 3, 4 (12%, 45%, 7%, 3%). 55% underwent Lumpectomy and 31% underwent Mastectomy. 82% and 18% ER negative. Her 2 data was only available in 59 patients, out of those tested only 4 Her 2 positive. Radiation (34%), Chemo (6%), Hormone (34%), Radiation/Chemo 2%, Radiation/Hormone 18%, Chemo/Hormone 2%, 41% didn't proceed with any treatments. Median survival was 54 months and Average survival was 56 months. Median survival 54 months and average survival was 56 months, With 203 patients alive at the end of 5 years with mortality of about 62%. However we do not have the data of causality of death in these patients.

Conclusion: Even though Surgery was performed in most the patients, Only 50% or lesser number of patients had Adjuvant treatment with Endocrine, Radiation and chemotherapy. Based on the data even though most patient were diagnosed with early stage breast cancer, had significantly poor survival with median survival of about 54 months. With Survival dramatically dropped from 84 months to 48 months in patient 85+ years of age.

Title: Treatment patterns and resource utilization among patients with HR+/HER2– metastatic breast cancer in a privately insured US population

Body: Background
Hormone receptor positive (HR+)/HER2– tumors are the most common subtype among patients with metastatic breast cancer (MBC). Several newer therapeutic options have become available over the last decade, but little is known about the real-world treatment patterns and health care resource use (HCRU) in privately insured women with HR+/HER2– MBC.

Methods
An analysis of Truven MarketScan databases containing medical and drug utilization and productivity data from nearly 350 US payers was conducted. Patients aged 18-64 years with an ICD-9 diagnosis code of breast cancer along with ≥2 claims for secondary malignancy between 2007 and 2013 were selected. HR+/HER2– patients were identified based on receipt of endocrine therapy (ET) and absence of HER2-targeted therapies. Use of cancer-directed treatments following MBC diagnosis was analyzed. Treatment characteristics were examined by line of therapy (LOT). Average monthly all-cause and MBC-related HCRU were descriptively assessed.

Results
A total of 5,563 women with HR+/HER2– MBC (mean [SD] age, 54 [7.8] yrs) met the selection criteria. Overall, 97% of the total sample received ≥1 cancer-directed treatment. The most common treatment was ET (85%), followed by chemotherapy (CT) (70%), radiation (62%), and surgery (11%). Treatment patterns for CT alone and ET alone, including the top regimens by LOT, are presented in Table 1. Among those receiving a second LOT, nearly 44% switched to CT in the second line after having received ET alone in the first line. During the study follow-up, 56% of patients had ≥1 all-cause inpatient admission, 49% had ≥1 all-cause emergency department visit, and 9% had a hospice admission.

</tbody>
</table>
Conclusions
A substantial decrease in the use of ET, with simultaneous increase in the use of CT, was observed as patients progressed to subsequent LOTs. Nearly half of those receiving ET alone in the first LOT switched to CT in the second LOT, suggesting a need for more effective non-CT treatments to bridge unmet therapeutic needs in this patient population.
Title: Treatment patterns and resource utilization among elderly Medicare patients with HR+/HER2− metastatic breast cancer

Goyal RK, Carter GC, Nagar SN, Smyth EN, Price GL, Huang Y-J, Bromund JL, Li L, Schilder JM, Davis KL and Kaye JA. RTI Health Solutions, Research Triangle Park, NC; Eli Lilly and Company, Indianapolis, IN and RTI Health Solutions, Waltham, MA.

Body: Background
Therapeutic advances in metastatic breast cancer (MBC) over the last decade have led to several novel agents for the treatment of patients with hormone receptor positive (HR+)/HER2− MBC. However, current literature has little data on real-world treatment patterns and health care resource use, particularly among elderly women with HR+/HER2− MBC in the United States Medicare population.

Methods
A retrospective analysis of patients aged ≥66 years diagnosed with MBC during 2007 to 2011 was conducted using the SEER-Medicare database. Patients' HR and HER2 status was obtained from the SEER registry data. For patients with no HER2 data available, HER2− disease was determined based on the absence of HER2-targeted therapies within 12 months of diagnosis. Health care utilization and treatment patterns after MBC diagnosis were examined. Use of cancer-directed therapies, including chemotherapy (CT) and endocrine therapy (ET), were descriptively analyzed by line of therapy (LOT).

Results
A total of 3,622 women with HR+/HER2− MBC (mean [SD] age, 77 [7.3] years) were included. Over 90% of women received ≥1 cancer-directed treatment after MBC diagnosis, with ET being the most common (77%), followed by CT (50%), radiation (48%), and surgery (19%). Treatment with ET alone trended downward across LOTs, from 74% in the first LOT to 36% in the fourth LOT, with a corresponding increase in treatment with CT alone from 21% to 46% (Table 1). Among those receiving a second LOT, nearly 26% switched to CT in the second line after having received ET alone in the first line.

**Conclusions**

ET was the most common first-line treatment for elderly women with HR+/HER2– MBC in this study period. However, as patients progressed from first to fourth LOT, the proportion of patients treated with ET decreased substantially.
2016 San Antonio Breast Cancer Symposium

Publication Number: P5-08-20

Title: A real-world evidence study to define the prevalence of endocrine therapy-naive hormone receptor-positive locally advanced or metastatic breast cancer in the US

Nunes AP P, Green E, Dalvi T, Lewis J, Jones N and Seeger JD D. Optum Epidemiology, Waltham, MA; MedImmune, Gaithersburg, MD and AstraZeneca, Cambridge, United Kingdom.

Body: BACKGROUND
The recently completed FALCON trial (NCT01602380) compared the efficacy of the selective estrogen receptor degrader (SERD) fulvestrant 500 mg with anastrozole in postmenopausal women with hormone receptor (HR)-positive locally advanced or metastatic breast cancer (LA/MBC) who had received no prior endocrine therapy (ET). To better understand the size of the US population to which the results of the FALCON trial are applicable, this study estimated the proportion of postmenopausal patients with HR-positive, human epidermal growth factor receptor (HER)2-negative LA/MBC who had received no prior ET, using data from a US medical record database.

METHODS
This observational study retrospectively analyzed data from the Optum Electronic Health Record Database, obtained from provider groups across the US. Women over 40 years of age with breast cancer diagnoses (January 2008–March 2015) were included, provided they had at least 12 months of recorded medical history prior to index, and at least one recorded physician office visit in that time. Incident (newly diagnosed) and prevalent (previous diagnosis of early or advanced breast cancer) cases were identified. Free-text clinical notes were reviewed using natural language processing to identify a target patient population of postmenopausal women with HR-positive, HER2-negative LA/MBC who had received no prior ET (similar to the FALCON entry criteria); additionally, diagnostic codes or treatment history were also used to identify HR status in the absence of confirmation from the free-text notes. The results of this analysis were extrapolated to estimate the size of the target population at a national level, using statistics from the National Cancer Institute's Surveillance, Epidemiology and End Results (SEER) database. Results are presented descriptively.

RESULTS
Overall, 63,962 women with breast cancer were identified, of whom 11,831 had discernible information on menopausal status, HER2 status, HR status, and disease stage. Of these, 1,923 patients were identified with postmenopausal, HR-positive, HER2-negative (or unknown) LA/MBC. Within this population of patients, 70.7% (1,360/1,923) had not previously received ET (88.5% [920/1,040] incident cases; 49.8% [440/883] prevalent cases), representing 11.5% (1,360/11,831) of the total breast cancer population with known menopausal status, HER2 status, HR status, and cancer disease stage information. The proportion of patients with postmenopausal, HR-positive, HER2-negative LA/MBC who had received no prior ET in this sample was extrapolated using US national estimates of the size of the postmenopausal, HR-positive, HER2-negative LA/MBC population taken from SEER. This approach suggests a 5-year limited-duration prevalence of postmenopausal patients with HR-positive, HER2-negative LA/MBC who have received no prior ET of approximately 50,000 cases and an annual incidence of about 15,000 patients.

CONCLUSIONS
These real-world data provide an estimate of the number of postmenopausal patients with HR-positive, HER2-negative, LA/MBC in the US who have not previously received ET. This population corresponds to the recently completed Phase 3 FALCON trial of fulvestrant compared with anastrozole.
Title: The effect of family history on screening procedures and prognosis in breast cancer patients – Results of a large population-based case–control study on breast cancer

Seiffert K, Thoene K, zu Eulenburg C, Rudolph A, Schmalfeldt B, Flesch-Janys D, Chang-Claude J and Witzel I. University Medical Center Hamburg-Eppendorf, Hamburg, Germany; University Medical Center Hamburg-Eppendorf, Hamburg, Germany; University Medical Center Hamburg-Eppendorf, Hamburg, Germany and German Cancer Research Center (DKFZ), Heidelberg, Germany.

Body: Background:
Patients with a first- or second-degree family history of breast or ovarian cancer participate more frequently in breast cancer screening procedures. A benefit of additional screening visits has been documented in high-risk patients with (e.g. BRCA 1, BRCA 2 gene mutations). However, the potential benefit of additional screening examinations in moderate risk patients (patients with a history of breast cancer in one or two family members) remains unclear.

Methods:
Patients were recruited in 2002–2005 within a large population-based case–control study on breast cancer in Germany (3,813 cases and 7,341 age-matched healthy controls). Univariate and multivariate analyses were performed to evaluate the effect of family history on breast cancer risk, participation in screening procedures, tumor size and prognosis.

Results
A higher breast cancer risk was observed in patients with a positive family history (1 affected family member: OR 1.32, p<0.001). Patients with a 1st degree positive family history received a higher number of mammograms (MG) (>10 MG: 42.7% vs. 24.9%, p<0.001) and showed a higher rate of imaging-detected tumors (mammogram or ultrasound) (45.8% vs. 31.9%, p<0.001) compared to patients without positive family history. Positive family history (OR 1.45 pT1 vs. ≥pT2, p<0.001) and higher number of mammograms (≥10 mammograms: OR 2.29 pT1 vs. ≥pT2) were associated with smaller tumor size at initial diagnosis. Additionally, there was a significant association between mammogram regularity (HR 0.72, p<0.001) and imaging-assisted tumor detection (HR 0.66, p<0.001) with improved overall survival. However, no significant association between a positive family history of breast cancer and survival could be seen.

Discussion:
 Patients with a family history of breast cancer participated more frequently in screening procedures and had a higher rate of image-detected tumors with smaller size at initial diagnosis, compared to patients without affected family members. Breast cancer screening procedures were significantly associated with improved survival.
Impact of delay neoadjuvant chemotherapy on pathologic complete response in locally advanced breast cancer evidence of the real world in Mexico

Cabrera P, Muñoz W, Gutierrez L, Ramirez MT, Albarado A, Lara F and Mohar A. National Cancer Institute of Mexico, Mexico City, Mexico.

Background:
Several studies suggest that delay on initiation adjuvant systemic therapy has subtype specific effects on survival. Many patients need neoadjuvant chemotherapy (NAC) for locally advanced breast cancer (LABC) in middle income countries. The optimal timing from breast cancer (BC) diagnosis to initiation of NAC is unknown and is not known if this interval impacts in pathological complete response (pCR) and survival.

We evaluated the relationship between pCR (defined as no invasive disease in breast and lymph nodes) and the implications in survival outcomes from LABC diagnosis and initiation of NAC.

Methods:
Data were collected retrospectively from database on National Cancer Institute for locally advanced breast cáncer (II-III) treated with NAC within six months of their diagnosis and completed treatment between January 2007 to December 2015. We evaluated data’s of 934. Time between biopsy result and start of chemotherapy was calculated. Patients were grouped into those who had pCR vs. no pCR, those who started treatment within 28 days and those who started after 28 days and the expression of hormonal receptors and Her2 by immunohistochemistry. We evaluated the results with the Pearson’s X2 and Fisher’s exact test.

Results:
We evaluated data’s of 934 woman. Overall pCR rate for our population was (311) 33%. The patients who initiated their treatment before 28 days the pCR rate was 40% and in the group who initiated NAC after 28 days the pCR was 27% with p= 0.0001, independently of the immunohistochemistry pattern expression. The median overall survival for the patients who initiated NAC before 28 days is 111 months compare with the patients who initiated NAC after 28 days was 101 months with a p= 0.52. For disease free survival in patients who began NAC before 28 days and achieved pCR were 92.2 months and for the group after 28 days were 89.9 months (p=0.033).

If we divided the group in triple negative patients by immunohistochemistry (183) ER negative, PR negative, HER2 negative, the patients with less than 28 days have 49.5% of pCR and the patients who initiated NAC after 28 days have pCR 37% (p=0.044). In the group with triple positive 70 patients (ER positive, PR positive, HER2 positive) those who began the NAC before 28 days achieved pCR 45% and those after 28 days have pCR 39% (p=0.40). The patients with ER positive and HER2 negative 475, before 28 days achieved pCR 26% and those after 28 days pCR was 11% (p=0.0001). And finally the patients with ER negative and HER2 positive have a pCR of 64% if the NAC initiated before 28 days and the pCR was of 52% if the NAC started after 28 days (p=0.15).

Conclusions: As in the adjuvant treatment, the time between biopsy and initiation of neoadjuvant chemotherapy has an impact on the pCR rates and survival of patients with breast cancer locally advanced treated at National Cancer Institute of Mexico in the context of a real world scenario.

Title: The share thoughts on breast cancer study: A Greater Plains collaborative cohort characterization project

Chrischilles EA A, Gryzlak B, McDowell BD D, Connolly DW W and Waitman LR R. University of Iowa, Iowa City, IA and Kansas University Medical Center, Kansas City, KS.

Body: Background. The Greater Plains Collaborative (GPC) is a new clinical data research network in PCORNet, the National Patient-Centered Clinical Research Network sponsored by the Patient-Centered Outcomes Research Institute to conduct patient-centered outcomes research and comparative effectiveness research. The Phase I GPC network brought together a diverse population of 10 million people across 1300 miles covering seven states with a combined area of 679,159 square miles. Using input from community members, breast cancer was selected as a focus for cohort building activities. Objective. To test the GPC's integrated data sources, technical components, and governance by demonstrating the ability to select, characterize, and achieve at least a 50% response rate for a cohort of breast cancer patients from across the GPC. Methods. Each participating medical center extracted, transformed and loaded North American Association of Central Cancer Registries (NAACCR)-formatted data from their institution's tumor registry into its Informatics for Integrating Biology and the Bedside (i2b2) research warehouse. The GPC i2b2 research warehouse is fully de-identified with re-identification possible when accompanied by an approved IRB protocol. From these data, each medical center selected a cohort of all patients age 18 or older diagnosed with breast cancer between January 2013 and May 2014. De-identified data files were submitted to the GPC Honest Broker who applied eligibility criteria and selected a random sample of 250 eligible patients from each center's file. Eligible patients were women with microscopically-confirmed ductal carcinoma in situ or invasive (but not metastatic) breast cancer diagnosed during the study period. Women who had previously been diagnosed with cancer per tumor registry records were excluded as were women known to be deceased at the time the sample was selected. The sample of patients plus a list of up to 10 replacement patients was provided to each center for re-identification and mailing. Patients participated in designing the study materials. Results. IRBs at 7 of 8 collaborating medical centers ceded IRB review to the University of Iowa IRB pursuant to the GPC reliance agreement. Upon patient advice to ensure a representative cohort, a mailed questionnaire with patient incentive was employed. All study materials were mailed in a single packet containing a cover letter from the participating medical center, a 21-page questionnaire, medical record consent and $10 incentive. Questionnaires were mailed over a six-week period beginning June 19, 2015 and one remailing to nonrespondents was conducted 4 weeks after the initial mailing. A total of 1,986 patients were invited and 1,235 (62.2%) responded. Signed consent to obtain information from medical records was obtained for 852 (69%). The survey dataset for consented subjects was linked to the research warehouse to obtain tumor and treatment data and diagnosis and procedure codes from billing sources. Conclusion. The GPC's integrated data sources, honest broker-mediated approach to extract data and apply standardized clinical criteria, IRB reliance model, and patient study design partners were implemented successfully.
How do real-world treatment patterns compare to guideline recommendations for first-line metastatic breast cancer patients in US community clinics?

Body: Background:
Treatment (txt) guidelines are based on trial data from a small minority of patients (pts). Linked electronic health records (EHRs) are a novel approach to examine txt patterns and outcomes in larger and more generalizable populations. Given the increasing importance of real world data and real world outcomes, we utilized linked EHRs from a network of US community clinics to examine how real world txt patterns compare to metastatic breast cancer (mBC) txt guideline recommendations.

Methods:
The Flatiron database provides real world clinical data collected from EHRs used by US cancer care providers. The Flatiron network comprises ~15% of US cancer pts and is geographically and demographically diverse.
Using EHR from Jan 2016 mBC database, we evaluated first-line (1L) txt patterns in mBC by molecular subtype. Pts were selected if they received mBC txt within 60 days of mBC diagnosis between 01Jan2011-31Dec2015, had ≥2 visits within the Flatiron Network on or after 01Jan2013, and were ≥18 years (yrs). Analyses were conducted to describe pt and clinical characteristics and 1L txt by HER2 and/or hormone receptor (HR) status.

Results:
Among 2509 mBC pts identified, 58.9% were HR+/HER2-, 17.7% HER2+, 11.6% HR-/HER2- (triple negative, TNBC), 7.4% HER2 equivocal, and 4.3% 'not done/unknown HER2 status'. Txt patterns in the latter two groups were not analyzed. Selected pt and disease characteristics by subtype are shown in Table 1. Median follow-up since mBC diagnosis was 1.1 yrs (range 0-5 yrs). The 1L mBC txts by subtype are shown in Table 2. Pts with HR+/HER2- subtype were treated primarily with hormonal therapy (68%) and/or chemotherapy (chemo) (35%). Among HER2+ pts, the 1L mBC txt patterns include trastuzumab+pertuzumab with chemo (31%), trastuzumab with chemo (22%), trastuzumab with hormonal therapy (9%), ado-trastuzumab (4%), lapatinib with chemo (3%), and lapatinib with hormonal therapy (1%). For TNBC, the majority received chemo (95%), such as paclitaxel (21%), nab-paclitaxel (13%) and docetaxel (12%).

Conclusion:
This study advances our current understanding of real world 1L patterns of care by molecular subtype among mBC pts and how these compare to guideline recommendations. While the majority of pts are receiving therapy per guidelines, up to 22% of HER2+ of pts are not receiving targeted therapy in 1L mBC.

**Title:** The association between smoking and breast cancer characteristics and outcome

**Body:**

**Background:** Smoking is associated with an increased incidence of hormone receptor positive breast cancer. Data regarding worse breast cancer outcome in smokers are accumulating. Current literature regarding the impact of smoking on breast cancer characteristics is limited. The aim of this study was to evaluate the impact of smoking on the characteristics and outcome of estrogen receptor positive, human epidermal growth factor receptor 2 (HER2) negative early breast cancer.

**Methods:** This was a retrospective single center study. All patients diagnosed from 4/2005 through 3/2012 and treated in our institute for early, estrogen receptor positive, HER2 negative breast cancer, whose tumors were sent for Oncotype DX analysis were included. Medical records were reviewed for demographics, clinico-pathological parameters, treatment and outcome. Patients were grouped and compared according to smoking history (present or past smokers vs. never smokers) and status (current vs. former and never smokers). Heavy smokers (pack years $\geq 30$) were analyzed separately.

**Results:** A total of 671 patients were included. 28.7% had a history of smoking, 17% were current smokers and 11.5% were heavy smokers. Smoking had no impact on tumor size, nodal involvement and Oncotype DX recurrence score. Angiolymphatic and perineural invasion rates were higher in current smokers than in the rest of the cohort (11% vs. 5.1%, $p=0.023$, 9% vs. 3.45%, $p=0.013$, respectively). Smoking had no other impact regarding histological characteristics. Five-year disease free survival and overall survival rates were 95.7% and 98.5%, respectively. Smoking had no impact on outcome.

**Conclusions:** In patients with estrogen receptor positive, HER2 negative, early breast cancer, smoking had no clinically significant influence on tumor characteristics and outcome. As the study was limited to a specific subgroup of the breast cancer population in this heterogeneous disease and since smoking is a modifiable risk factor for the disease, further research is required to clarify the possible impact of smoking on breast cancer.

Title: Treatment patterns for breast cancer brain metastasis

Haraldsson B, Leone JP P, McDowell BD D and Chrischilles EA A. University of Iowa, Iowa City, IA and University of Iowa Hospitals and Clinics, Iowa City, IA.

Body: Background: There is sparse data on how mainstay treatments for brain metastasis (BM) are used in clinical practice and whether their usage has changed over time. Our population-based study presents the rates of surgical resection, radiation therapy, and chemotherapy in a large cohort of women with breast cancer BM. Methods: Women diagnosed with breast cancer between 1973 and 2013 were identified from the NCI linkage between the SEER program and Medicare claims data. Identification of BM was via ICD-9 diagnosis codes for secondary CNS malignancy on claims, and was defined as at least one inpatient claim and/or two or more outpatient claims. Treatment was defined as any claim filed with a procedure code for surgical resection of a BM, chemotherapy, and BM-directed radiation therapy. We excluded women without continuous Medicare coverage for a year before to 60 days after their first BM claim and women diagnosed with primary cancer other than breast cancer. Results: The proportion of women receiving treatment after BM claim increased from a low of 50.4% in 1992 to 66.8% in 2013 (p<0.0001). Further analysis of this period revealed rates of surgical resection rose from 7.8% to 11.5%, radiation therapy rose from 39.7% to 54.8%, and chemotherapy rose from 11.9% to 22.2% of women (p<0.002). We used adjusted logistic regression to explore associations between patient/tumor characteristics and treatment. Younger age and fewer comorbidities were associated with increased odds of receiving any of the three treatments. Compared with ER-/PR-, a woman whose index cancer was ER+/PR+ had lower odds of receiving any of the three treatments. Women with extracranial metastasis had greater odds of radiation or chemotherapy and lower odds of resection compared to women with BM only. Receiving any care at an Academic Medical Center (AMC) was associated with greater odds of resection, and lower odds of radiation and chemotherapy.

Conclusions: We found that the proportion of women with breast cancer BM who received treatment has increased over time. Further, logistic regression revealed multiple noteworthy contrasts, including a positive relationship between care at an AMC and...
surgical resection, while women who received care at an AMC had lower odds of radiation or chemotherapy.
Title: Treatment patterns and clinical outcomes in patients with hormone receptor (HR)+ HER2+ metastatic breast cancer and low vs high levels of HR positivity from the SystHERs Registry

Jahanzeb M, Tripathy D, Rugo H, Swain S, Kaufman PA A, Mayer M, Hurvitz S, O'Shaughnessy J, Mason G, Yardley DA A, Bruisky A, Chu L, Antao V, Beattie M, Yoo B and Cobleigh M. University of Miami Sylvester Comprehensive Cancer Center; University of Texas MD Anderson Cancer Center; University of California San Francisco Helen Diller Family Comprehensive Cancer Center; Washington Cancer Institute, MedStar Washington Hospital Center; Norris Cotton Cancer Center, Dartmouth-Hitchcock Medical Center; AdvancedBC.org; UCLA Jonsson Comprehensive Cancer Center and Translational Research in Oncology; Baylor Charles A. Sammons Cancer Center, Texas Oncology, US Oncology; Inflammatory Breast Cancer Research Foundation; Sarah Cannon Research Institute and Tennessee Oncology, PLLC; University of Pittsburgh Cancer Institute; Genentech, Inc. and Rush University Medical Center.

Body: Introduction In 2010, the cutoff for HR positivity in breast cancer was established as ≥1% of cells staining HR+, previously having varied from 1% to 10%. The impact of this change on treatment patterns and outcomes is poorly understood. SystHERs is a prospective, observational cohort registry of patients (pts) with HER2+ metastatic breast cancer (MBC) that commenced enrollment in 2012. To our knowledge, SystHERs is the largest registry to collect and analyze data for the HER2+ subgroup. We report baseline characteristics, treatment patterns, and early outcomes by %HR+ (1–9% vs 10–100%).

Methods SystHERs enrolled pts aged ≥18 years and within 6 months of HER2+ MBC diagnosis. For pts with locally-determined HR+ disease, defined as HR+ in primary or metastatic tissue, %HR+ is the highest percentage of ER+ or PR+ tissue in early breast cancer or MBC. The percentage of ER+ or PR+ cells was not reported for pts considered HR– by the investigator. Median overall survival (OS; Kaplan–Meier) and hazard ratios (Cox regression) were estimated.

Results As of Feb 1, 2016, data were available for 872 eligible pts with known HR status, of whom 608 (70%) had HR+ disease. Of the 608 pts, 53 (9%) had 1–9%HR+ and 496 (82%) had 10–100%HR+; %HR+ was not reported for 59 pts. Baseline characteristics were similar between %HR+ subgroups (Table 1).

As shown in Table 2, the 1–9%HR+ subgroup was less likely to receive first-line hormonal therapy (26%) than the 10–100%HR+ subgroup (56%). 87% and 79% of pts received chemotherapy, respectively. Median time from MBC diagnosis was 16.5 months (range, 0.4–49.4 months). Median OS was not reached at the data cutoff. The number of deaths was 13 (25%) in the 1–9%HR+ subgroup, and 68 (14%) in the 10–100%HR+ subgroup (log-rank P=0.025). The OS hazard ratio (0.514, 95% CI 0.283–0.931) favored the 10–100%HR+ subgroup. OS did not differ significantly between pts with 1–9%HR+ vs HR– disease (log-rank P=0.582, hazard ratio 1.185, 95% CI 0.647–2.169).

</table>

Conclusions These preliminary observational data suggest potential differences in treatment patterns and survival outcomes in low vs moderate/high HR+ expressers, with the former being less likely to receive hormonal therapy (26% vs 56%). Furthermore, low HR positivity was associated with poorer OS and was similar to OS observed in pts with HR– disease.
Title: Incidence of germline BRCA1- and BRCA2-mutated breast cancer in the US

Body: Background: Breast cancer is the most common cancer and second leading cause of cancer death among women in the United States (US). Inherited mutations in germline breast cancer susceptibility gene 1 and 2 (gBRCAm) are associated with increased risk of developing cancers, including breast cancer. No published reports of gBRCAm incidence within an unselected US breast cancer population are available based on a comprehensive literature review (CLR). The main objective of this analysis is to estimate the incidence of gBRCAm breast cancer in the US.

Methods: For this analysis the Surveillance, Epidemiology, and End Results (SEER) Program 18 registries captured incidence of breast cancer by stage, age and gender. The size of the US population was based on United Nation's population projections and standardized to the 2010 population. Age-specific gBRCAm distribution and gBRCAm-specific hormonal subtype for estrogen-receptor and progesterone-receptor (ER/PR), and human epidermal growth factor receptor-2 (HER2) estimates were determined from a CLR. Tumor cells negative for ER/PR and HER2 are referred to as triple-negative breast cancer (TNBC).

Results: In 2016, it is projected that approximately 250,000 individuals will be diagnosed with invasive breast cancer (all genders). Median age range of the population with invasive breast cancer is 65-69 years and 99% are females. Majority (72%) of female invasive breast cancer cases are ER/PR+ whereas 11% of cases are TNBC. Corroborating with current publications, gBRCAm is estimated at 5% for individuals less than 50 years old and 1% among all ages. Median age range of the gBRCAm cohort is 40-44 years. After applying currently available gBRCAm specific literature parameters, the majority (55%) of gBRCAm diagnoses are TNBC.

Conclusion: In the US, patients with gBRCAm represent a small proportion (1%) of all breast cancer tissues evaluated. Majority of gBRCAm patients are diagnosed with TNBC (55%) and are younger (median age range 40-44 years) than overall breast cancer population. Age differences noticed in gBRCAm may have been due to disparity in genetic screening practices among breast cancer population in the US rather than a reflection of gBRCAm expressions. These estimates of gBRCAm incidence are driven by limited reports on an unselected population of breast cancer gBRCAm cohort; therefore sensitivity analysis is required to assess the robustness of these estimates.

Title: Trends in age shifting and decreasing mortality of female breast cancer in Taiwan with emerging molecular subset of unmet medical need: A 30-year cohort observation from Taipei Veterans General Hospital

Lin Y-S, Tseng L-M and Liu C-Y. Taipei Veterans General Hospital, Taipei, Taiwan and Taipei Veterans General Hospital, Taipei, Taiwan.

Body: Background: Over the past thirty years, Taiwan has become a modern Asian country with an increasing incidence of breast cancer. We hypothesized that the epidemiological and demographic features of breast cancer patients in Taiwan have changed by using cohort study based on data collected from past three decades. However, despite improvement in prognosis of most breast cancer subtypes, we found that one subtype of luminal B type her-2 negative did not show significant improvement in overall survival and disease free survival from our cohort comparison.

Methods: Patients with primary breast cancer diagnosed between 1979 and 2010 were identified from the cancer registry database at Taipei Veterans General Hospital, Taiwan. Three periods of time were divided (1979 to 1988, 1989 to 1998, and 1999 to 2010) and compared to determine the epidemiological changes in female breast cancer in Taiwan.

Results: From 1979 to 2010, data from a total of 8417 breast cancer patients were collected. The ratio of breast cancer patients aged ≤35 years decreased from 13.3% in 1979 to 1988, to 10.6% in 1989 to 1998, and to 5.2% during 1999 to 2010. In the period of 1979 to 1988, 55.7% of patients were aged ≤50 years, and in the period of 1999-2010, only 45.7% of breast cancer patients were aged ≤50 yrs. From 1979-1988, ductal carcinoma in situ (DCIS) was rarely diagnosed (0.2%), and the ratio of patients who initially presented with DCIS increased to 2.9% in 1989 to 1998, and to 11.8% in 1999 to 2010. Patients diagnosed with stage I breast cancer also increased from 16.7% in 1979-1988 to 28.4% in 1999-2010. Patients diagnosed and treated in 1999-2010 (5-year overall survival: 81.7%) had a much better outcome than patients treated in 1979-1988 (5-year overall survival: 66.3%).

Conclusions: The epidemiological features of female breast cancer in Taiwan have changed over the past thirty years. A molecular subtype of luminal B type Her-2 negative was characterized as an emerging group with unmet medical need.
Title: Utilization of oncotype DX for breast cancer in different facility types in Louisiana

Loch M, Li X, Mumphrey B, Garcia A and Wu X-C. LSU Health Science Center, New Orleans, LA.

Body: Background: Oncotype DX, a 21-gene recurrence score, is the most validated prognostic assay that may identify both women most and least likely to benefit from adjuvant chemotherapy. It was added to the ASCO guidelines in 2007 and the NCCN guidelines in 2008 for use in node negative, hormone receptor (HR)+, HER2- breast cancer patients who will undergo 5 years of endocrine therapy. We explored its utilization in different cancer care settings to assess differences in the tool’s utilization.

Methods: We analyzed data from the Louisiana Tumor Registry, one of the NCI funded SEER registries for cases of HR+ HER2- localized breast cancer from 2010-2012 and explored differences in utilization of the Oncotype DX by facility type – teaching hospital cancer program (THCP), community hospital comprehensive cancer program (COMP), community hospital cancer program (CHCP), commission on cancer program (COC) and public hospital program. Chemotherapy administration data was collected on the 2011 cases with chemotherapy data collected from a CDC funded special project Enhancing Cancer Registry Data for Comparative Effectiveness Research (CER). Hospital sites were identified by the location where patients underwent surgery. Demographic and clinical factors were adjusted for using multivariate logistic regression.

Results: Of the patients who did have the Oncotype DX, 39.2% were white, 32.3% black. Women over 70 were much less likely (29.3% vs. >45% in women <70) to have the test. Patients who received surgery at public hospitals had the lowest chance (16.7%), whereas those who received surgery at COMP were most likely to have the test (43.1%) and at teaching hospitals, 31.8% had the test. The odds of not using Oncotype DX were significantly higher in public hospitals as compared with teaching hospitals even after adjusting for demographic and clinical factors (OR=2.44; 95% CI: 1.39-4.27).

Title: Triple negative breast cancer and factors associated with its treatment in the US – A population study using central cancer registry data

Wu M, Thompson T, Ryerson B, Miller J and Singh S. Centers for Disease Control and Prevention, Atlanta, GA.

Body: Background
Triple receptor-negative breast cancer (TNBC) is characterized by the lack of expression of all the three protein biomarkers, estrogen receptor, progesterone receptor and human epidermal growth factors receptor 2. Large population-based studies on TNBC epidemiology and treatment in the US were generally limited due to lack of routinely data collection on these biomarkers until recent years.

Purpose
This study compared TNBC incidence characteristics to the other subtypes of the breast cancer, examined and documented general treatment status and factors associated with the treatments among TNBC patients in the US.

Methods
We used the NPCR and SEER combined data. All women in the US with a primary invasive breast cancer diagnosed in 2011 and 2012 were included. TNBC age-specific and standard incidence rates, incidence rate ratios by demographic and geographic variables as well as incidence distribution by tumor and clinic characteristics were compared to other subtype of breast cancer. Summary treatment status by staging on TNBC were examined. Regression analysis on factors associated with treatments were also performed.

Results
TNBC indicated demographic, geographic variations, and poor aggressive tumor and clinic-pathologic features compared to other subtypes. 93% women with early stage TNBC had surgery. 31% women with mastectomy chose to undergo contralateral prophylactic mastectomy. Radiation therapy were received or recommended for 64% women with breast conserving surgery (BCS). Chemotherapy were received or recommended for 77% of stage I-IV TNBC women. Among stage I-III patients, sentinel lymph node biopsy was less likely preformed for those aged>=70, Non-Hispanic African-American, Hispanic, living in Southern Region, and less SES advantage; however, patient's SES status had no impact on surgery type; and there was no association of insurance status and radiation therapy among BCS patients.

Conclusions
Current treatment practice for TNBC in the US is generally concordance with the recommended breast cancer care. However, treatment disparities existed within the limited treatment options, and factors associated with the disparities also varied. More effective treatment options and treatment equality are warranted to improve overall care of this subtype.
Title: Plasma osteoprotegerin and the risk of breast cancer in BRCA1 and BRCA2 mutation carriers

Kotsopoulos J, Oden L, Akbari M, Singer C, Sun P, Salmena L and Narod S. Women's College Research Institute, Women's College Hospital, Toronto, ON, Canada; Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada; Karolinska Institutet, Stockholm, Sweden; Medical University of Vienna, Vienna, Austria and University of Toronto, Toronto, ON, Canada.

Body: Background: There is emerging evidence to suggest that progesterone-mediated upregulation of the receptor activator of nuclear factor κB (RANK)/RANK ligand (RANKL) signaling pathway plays a critical role in mammary gland epithelial cell proliferation, mammary stem cell expansion and carcinogenesis. Of relevance for women at a high risk of developing breast cancer due to an inherited BRCA mutation, are recent findings showing that circulating levels of osteoprotegerin (OPG) (an endogenous decoy receptor for RANKL and thus inhibitor of RANK/RANKL-mediated signaling) are lower in women with a BRCA1 or BRCA2 mutation compared to non-carriers. Whether low OPG concentrations contribute to the high breast cancer risk in this population is unknown. If so, a therapeutic intervention that mimics the action of OPG might be used for primary prevention. We evaluated the relationship between plasma OPG and breast cancer risk among women with a BRCA1/2 mutation in a prospective study.

Methods: Baseline blood samples were available from 199 BRCA1/2 mutation carriers with no previous history of cancer. Plasma OPG concentrations were measured using a commercial enzyme-linked immunosorbent assay (ELISA) and categorized dichotomously as high vs. low based on the median of the entire cohort. The cumulative incidence of breast cancer by baseline plasma OPG concentration was estimated using Kaplan-Meier survival analysis.

Results: Over a mean follow-up period of 6.6 years (range 0.2-17.6 years), 19 incident cases of primary invasive breast cancer were observed in the cohort. Women who developed breast cancer had significantly lower mean baseline OPG concentrations (83.6 pg/ml [range 4.1-165.6 pg/ml]) compared to the OPG concentrations of women who did not develop breast cancer (107.9 pg/ml [6.7-541.9]) (P = 0.03)(Table 1). BRCA mutation carriers with low baseline OPG concentrations (< 90 pg/ml) had a significantly higher risk of developing breast cancer compared to those with high baseline OPG concentrations (≥90 pg/ml). After ten years of follow-up, the cumulative incidence of breast cancer among women with low OPG concentrations was 23% compared to 7% among women with high OPG concentrations (P-log rank test = 0.01). There was no evidence of effect modification by menopausal status or BRCA mutation type.

Plasma OPG concentrations among BRCA mutation carriers who did and did not develop breast cancer

Conclusions: Our preliminary data suggest that low OPG concentrations are associated with an increased risk of breast cancer in BRCA1 and BRCA2 mutation carriers. These data support the potential for targeting of the RANKL pathway as a plausible cancer prevention strategy among women with germline BRCA mutations. Additional analyses with a larger sample size are underway.

**Title:** Breast cancer risk prediction using a polygenic risk score in women of African ancestry: Findings from GWAS in breast cancer in the African diaspora

Wang S, Qian F, Zheng Y, Ogundiran T, Ojengbede O, Zheng W, Blot W, Nathanson KL L, Hennis A, Nemesure B, Ambs S, Olopade OI I and D. Center for Clinical Cancer Genetics & Global Health, University of Chicago; University of Chicago; College of Medicine, University of Ibadan; Center for Population and Reproductive Health, College of Medicine, University of Ibadan; Vanderbilt Epidemiology Center, Vanderbilt-Ingram Cancer Center, Vanderbilt University; University of Pennsylvania; Chronic Disease Research Centre and Tropical Medicine Research Institute, University of the West Indies; State University of New York at Stony Brook; Laboratory of Human Carcinogenesis, National Cancer Institute and University of Chicago.

**Body:**

**Background:** Multiple common susceptibility loci for breast cancer (BC) have been identified/confirmed in Caucasian women. Combination of these SNPs into a polygenic risk score (PRS) could improve risk stratification and provide guidance for preventive and screening strategies. However, due to differences in allele frequencies of genetic variants, tumor characteristics between women of African and European ancestries, we sought to evaluate the association of PRS with BC in a large consortium of African women.

**Methods:** The GWAS in BC in the African Diaspora (ROOT consortium) included 3686 participants of African ancestry from Nigeria, USA, and Barbados (1657 cases, 2029 controls). PRS was constructed from the published odds ratios (ORs) from 90 susceptibility loci for BC. Logistic regression was used to examine its association with overall BC risk as well as associations by hormone receptor status, family history and other clinical features.

**Results:** One unit change in the PRS was associated with an OR of 1.13 (95% CI: 1.01-1.28, P=0.042) for overall BC risk, 1.15 (95%CI: 0.95-1.41, P=0.160) for ER+ BC risk, and 1.17 (95%CI: 0.95-1.44, P=0.133) for ER- BC risk. The ORs for developing BC by percentiles of the PRS, relative to women in the middle quintile, showed weak linear trend.

</tr>
<tr>
<td>&gt;95</td>
<td>1.10 (0.79-1.52)</td>
</tr>
</tbody>
</table>

**Note:** Odds ratios are for different percentiles of the PRS relative to the middle quintile (40% to 60%). Odds ratios were adjusted for study site and the first ten eigenvectors from principal components analysis.

The discriminative accuracy of the PRS, as measured by the C-statistic, was 0.524 (95% CI: 0.505-0.542) for overall BC, 0.511 (95% CI: 0.479-0.543) for ER+ BC, and 0.513 (95% CI: 0.481-0.545) for ER- BC. There was a statistically significant interaction between PRS and age, the association between PRS and overall BC risk were stronger in two age groups (aged <40 years and ≥60 years). The PRS was also more strongly associated with PR+ (OR=1.26, 95%CI: 1.01-1.58) compared to PR- (OR=1.08, 95%CI: 0.95-1.44) BC. Association between PRS and BC were similarly non-significant across different strata of family history of BC, BMI, alcohol consumption, oral contraceptive use, menopausal, ER and HER2 status.

**Conclusion:** BC PRS obtained from prior GWASs conducted in Caucasian women didn't provide a comparable degree of risk...
stratification for African Americans. Additional studies are needed to identify SNPs specific to women of African ancestry that could provide improved risk prediction. Further studies can also combine the PRS with lifestyle/environmental factors.
Title: Associations between breast cancer subtypes and mutations in cancer predisposition genes identified by clinical genetic testing of breast cancer patients

Body: Clinical genetic testing of individuals with a personal or family history of breast and ovarian cancer using panels for \( BRCA1/2 \) and other candidate cancer predisposition genes has become routine clinical practice. Several of the genes on hereditary cancer testing panels have been strongly associated with specific subtypes of breast cancer. In particular, individuals with germline mutations in \( BRCA1 \) predominantly develop estrogen receptor (ER)-negative and triple negative (TN) (estrogen receptor negative, progesterone receptor negative, HER2 negative) breast tumors. In contrast, \( CHEK2 \) and \( ATM \) mutations have been associated with ER-positive breast cancer. In this study, associations between mutations in panel genes and breast cancer subtypes were evaluated. A cohort of 60,000 breast cancer patients tested for germline cancer predisposing mutations using hereditary cancer gene panels was utilized. Information on personal and family cancer history, age of diagnosis, tumor pathology, and ethnicity of patients was obtained from test requisition forms or by follow up with ordering health care providers. Mutations in each gene were combined into four histological subtypes (triple negative; HER2 positive; ER-positive,HER2-positive; and ER-positive,HER2 negative). Associations for each subtype were estimated by case-control analyses comparing the frequencies of pathogenic mutations in each subtype with frequencies from non-TCGA controls from the Exome Aggregation Consortium (ExAC) database. In addition, case-case analyses were conducted to assess enrichment of gene mutations in specific breast cancer subtypes. Among the observed associations between genes and breast cancer subtypes, mutations in \( CHEK2 \) and \( ATM \) were highly enriched in luminal breast cancers and \( BARD1 \) was specifically associated with TN breast cancer. Refining the spectrum of pathological correlates with mutations in hereditary breast cancer genes will aid gene specific cancer risk management, and may accelerate the development of novel gene-specific therapeutic interventions.
**Title:** Assessment of breast cancer risk among atomic-bomb survivors based on ATM polymorphisms, radiation dose, and age at exposure

**Body:** RERF’s epidemiological study on atomic bomb survivors has found increased incidence of several types of cancers with increased radiation dose. A great deal of inter-individual variation in susceptibility to radiation-associated breast cancer could not be explained solely by radiation dose, suggesting the possibility of partial involvement of DNA repair capacity. Of 11 known single nucleotide polymorphisms (SNPs) of the DNA repair gene ATM, we selected a particular SNP (located in the 5' untranslated region and therefore thought to be associated with ATM gene expression) and examined the association with radiation-associated breast cancer in the context of an RERF A-bomb survivor cohort study. A follow-up survey of 3,040 female members of the RERF Immunogenome Study Cohort during 1981-2009 identified a total of 108 breast cancer cases. ATM genotypes (ATM-G/G, -G/A, and -A/A) were determined by the TaqMan assay method for all cohort members. Relative risks (RRs) of breast cancer were estimated for radiation dose, the ATM genotypes, and the combined categories of dose levels and genotypes. As a result, RR of breast cancer significantly increased with increased radiation dose (RR = 1.46/Gy, 95% CI: 1.19-1.80). A-bomb survivors with ATM-G/G homozygote revealed a significantly-increased RR of breast cancer (RR = 1.74, 95%CI: 1.18-2.56), using as a reference the risk of those with ATM-A/A homozygotes combined with ATM-G/A heterozygotes. When dividing the subjects into two groups by age at exposure (under 20 years of age and over 20), RR of breast cancer significantly increased with radiation dose in the group aged less than 20 years at exposure (RR = 1.65/Gy, 95% CI: 1.29-2.11), but no significant increase in RR by genotype was observed. In the group aged over 20 years at exposure, there was no significant increase in RR of breast cancer by dose, but RR of breast cancer significantly increased among ATM-G/G homozygotes, using as a reference the risk of ATM-A/A homozygotes combined with ATM-G/A heterozygotes (RR = 2.28, 95%CI: 1.28-4.06). In all analyses, no interaction between RR of breast cancer and combinations of radiation dose and genotype was detected. These findings suggested that the ATM genotypes and radiation dose might affect the risk of breast cancer among A-bomb survivors and that the significance of such impact might differ by age at exposure.
Title: A model with polygenic risk score and mammographic density predicts interval cancers

Shieh Y, Hu D, Huntsman S, Ma L, Gard CC C, Leung JWT WT, Tice JA A, Cummings SR R, Kerlikowske K and Ziv E. University of California, San Francisco; New Mexico State University; University of Texas MD Anderson Cancer Center; San Francisco Coordinating Center and San Francisco Veterans Affairs Medical Center.

Body:
Introduction:
Interval breast cancers present with clinical symptoms following a normal screening mammogram. They are associated with unfavorable biological features and with dense breasts. Models predictive of aggressive phenotypes may facilitate tailored screening for women at elevated risk of interval cancers. Polygenic risk scores (PRS) represent the cumulative effects of multiple single nucleotide polymorphisms (SNPs) and can be used to risk-stratify women. In prior reports, PRS is preferentially associated with screen-detected rather than interval cancers. We investigated methods to refine the PRS to preferentially predict interval cancers, and tested the performance of the PRS in joint models with mammographic breast density (MBD).

Methods:
We used data from 1058 breast cancer cases from The Cancer Genome Atlas (TCGA) as the discovery set for our PRS. We selected 107 SNPs from genomewide association studies of breast cancer risk for testing against tumor status at last follow-up in TCGA. Presence of tumor indicated recurrence, progression, or positive margins after resection. Women with tumor present at <100 days of follow-up were excluded. Suggestive associations (p<0.2) were used to construct a PRS, calculated as the sum across all SNPs of the per-allele log-odds ratio multiplied by the number of risk alleles for each SNP. We tested the performance of the PRS in a nested case-control dataset with 471 cases (102 interval cancers, 369 screen detected) and 496 controls from the California Pacific Medical Center Research Institute cohort. Logistic regression was used to evaluate the association between PRS, MBD and interval cancers. Area under the receiver operating characteristic (AUROC) curve was used to measure discrimination.

Results:
Of 107 SNPs, 23 had suggestive associations with presence of tumor at last follow-up in TCGA. The 23-SNP PRS discriminated between women with interval cancers and controls, with AUROC 0.57 (95% CI 0.51-0.63). With the inclusion of MBD in the model, the AUROC was 0.68 (95% CI 0.62-0.74). Women in the highest PRS quintile had an unadjusted 2.07-fold odds (95% CI 1.05-4.07) of developing interval cancers compared with women in the lowest quintile; adjustment for MBD did not change the point estimate. The PRS also discriminated between women with interval and screen-detected cancers, although the findings did not reach statistical significance (AUROC 0.55, 95% CI 0.48-0.61). With the inclusion of MBD in the model, the AUROC was 0.63 (95% CI 0.57-0.69).

Discussion:
A PRS associated with presence of tumor at last follow-up was independently predictive of interval cancers relative to controls. Models with PRS and MBD discriminated between interval and screen-detected cancers, although MBD provided most of the predictive power. Our findings are limited by the size and low number of recurrences in TCGA. It is possible that tumor status largely reflects treatment received, and may only partially represent the biological pathways of interval cancers. Our results suggest that SNPs may potentially identify women at risk for developing interval breast cancer, although further validation is required.
Title: Ovarian reserve and response to controlled ovarian hyperstimulation (COH) in breast cancer women with and without BRCA mutation

Body: Background: 6300 new cases of breast cancer arise in young women under 40 each year in France. Some of them are BRCA 1 or 2 mutation carriers. Most of them receive a potentially gonadotoxic chemotherapy while they have not yet completed their family. Since 2011, a systematic proposal of ovarian reserve follow-up and fertility preservation by oocyte freezing is provided to each young early breast cancer (BC) patients (pts) of our program (NCT 01614704). Preliminary results were presented at the SABCS in 2013. We now investigate the impact of BRCA mutation on the ovarian reserve and the ovarian response to simulation.

Methods: 115 young BC pts were systematically referred to a reproductive medicine centre before starting chemotherapy. Inclusion criteria were age 18 to 38, histologically confirmed invasive breast carcinoma, absence of metastases. According to their personal and familial history, genetic counselling was performed and if the patient met the criteria and agreed, BRCA genes were analysed. Pts in an adjuvant setting and who were asking for fertility preservation underwent COH during the interval between complete surgery and start of adjuvant chemotherapy. Ovarian stimulation protocol consisted in a conventional antagonist protocol with recombinant FSH starting on day 2 of the menstrual cycles. The GnRh antagonist was started on day of the COH and the final oocyte maturation was achieved by an injection of triptorelin 0.2 mg when at least 3 follicles reached 18 mm of diameter. All pts gave their informed consent for COH, egg/embryo freezing and follow-up.

Results: 115 pts achieved pre-treatment AMH and AFC assessment. 60 (52,1%) were eligible for COH in order to cryopreserve egg or embryos. BRCA analysis was performed in 83 pts. 23 did not meet the criteria or refused. 9 analyses are still in process. 17 (20.4%) pts were positive for BRCA mutation (BRCA1: 13; BRCA2: 4) and 66 were not. In the mutation carriers group (n=17), median age was 32 years (Range 25-37). Median initial AMH levels and AFC were 23 pmol/l (5.1–223) and 20 (6-100), respectively. Eight pts underwent COH. Median duration of stimulation was 9,5 days (8-13) with a median cumulative dose of gonadotropins of 2875 UI (1200-5450). The median number of vitrified oocytes was 5,5 (0-15). Two patients chose frozen embryo preservation (1 and 2 eggs respectively). In the non-carriers group (n=66), median age was 31 years (24-37). Median initial AMH levels and AFC were 23.4 pmol/l (0.8-136) and 24 (1-68). 27 pts underwent COH. Median duration of stimulation was 10 days (7-14). Dose of gonadotropins was 2700 UI (1365-5600). The median number of vitrified oocytes was 6 (0-18). The 3 patients chose eggs preservation (0.0 and 3 eggs respectively). There was no significant difference in the two groups.

Discussion/ Conclusion: Few studies stated that BRCA1 mutation may be associated with reduced ovarian reserve in healthy BRCA mutation carriers. Meirow and al concluded that both healthy and BC BRCA mutation carriers demonstrated normal ovarian response in vitro fertilization cycles. Our results show that ovarian reserve of BRCA 1/2 mutations BC carriers do not differ from that of non-carriers. Response to COH seems similar in both groups too.
Title: Impact of germinal center-associated nuclear protein polymorphisms on breast cancer risk and prognosis in a Japanese population

Body: Background: Germinal center-associated nuclear protein (GANP) is a phosphoprotein which is involved in mRNA export and the regulation of DNA recombination. We have previously demonstrated that deficiency of GANP led to spontaneous development of mammary gland tumors in a mouse model. In addition, we found that decreased GANP expression in human breast cancer tissue was an independent prognostic factor. Here, we conducted a case-control study and a retrospective cohort study to investigate whether single nucleotide polymorphisms (SNPs) of GANP are associated with sporadic breast cancer risk and prognosis in a Japanese population.

Subjects and Methods: Six hundred-ninety-four breast cancer cases and 1,376 age- and menopausal status-matched controls were selected within the framework of the Hospital-based Epidemiologic Research Program at Aichi Cancer Center. Cases and controls were genotyped using an Infinium iSelect custom array (iCOGS, Illumina Inc., San Diego, CA, USA). We assessed 13 SNPs at the GANP locus, 2 SNPs (rs2839178 and rs11702450) were selected for further analysis by considering linkage disequilibrium. Conditional logistic regression methods were used to estimate odds ratios (ORs) and 95% confidence intervals. In addition, the survival impact of the two SNPs was retrospectively analyzed using the 694 breast cancer cases. To evaluate the effect of SNPs on overall survival (OS) and disease-free survival (DFS), multivariate Cox proportional hazards modeling was applied.

Results: Compared to the AA genotype of rs2839178, the GG genotype showed statistically significant associations with breast cancer risk (OR: 0.48, 95%CI:0.30–0.76, $P = 0.002$). In prognostic analysis, compared to those with the genotype AA at rs2839178, patients with AG or GG showed longer DFS (HR: 0.71, 95%CI: 0.49–1.04 and 0.42, 0.13–1.42, respectively, $P$ for trend = 0.04). The GG genotype of rs2839178 also showed a positive tendency for longer OS although it was not statistically significant (HR: 0.69, 95%CI: 0.44–1.08, $P = 0.11$). We did not find that rs11702450 was associated with either breast cancer risk or prognosis.

Conclusion: This is the first study to investigate the association between GANP SNPs and breast cancer risk and prognosis. The direction of association with DFS was consistent with that of susceptibility. These results demonstrate that GANP SNPs presumably prevent the occurrence and malignant advancement of sporadic breast cancers.
Molecular evaluation of Peruvian patients with hereditary breast cancer reveals a novel germline mutation in \textit{BRCA1}

**Body: Background**

Breast cancer is the leading cancer in women worldwide, while in Peru is the second most frequent cancer with a high incidence of triple negative breast cancers (21%). There is no previous information about \textit{BRCA1/BRCA2} mutations in Peruvian high-risk breast cancer patients. Prior studies from International diagnostic laboratories only presented results of our population as a pooled Hispanic data. Our aim was to characterize mutations in \textit{BRCA1/BRCA2} genes in Peruvian patients with breast cancer with hereditary patterns.

**Methods**

We evaluated mutations in \textit{BRCA1/BRCA2} genes by Sanger sequencing and large genomic rearrangements by multiplex ligation-dependent probe amplification (MLPA) in 18 families with hereditary breast cancer criteria identified at the Breast Unit of Oncosalud-AUNA (Lima-Peru). Molecular analysis was done in the facilities of Genetics and Molecular Biology Center at the San Martin de Porres University (Lima-Peru).

**Results**

Sequencing identified 4 pathogenic mutations in 4/18 families, three previously detected (\textit{BRCA1}: c.302-1G>C y c.815_824dup10; \textit{BRCA2}: c.5946delT) and a novel germline mutation in exon 15 of \textit{BRCA1} (c.4647_4648dupAA, ClinVar SCV000256598.1) producing a frameshift variant. MLPA revealed 2 amplifications in exon 7 (duplication and triplication) in \textit{BRCA1} in unrelated patients with potential pathogenic effects, one of this co-existed with the \textit{BRCA2}: c.5946delT mutation. In addition, three variants of uncertain significance were found (c.140G>T, in exon 5 of \textit{BRCA1} and c.464G>A and c.938C>T in exon 5 and 10 of \textit{BRCA2}, respectively).

**Conclusions**

After a comprehensive evaluation we found an alteration rate of 27.8% (5/18) in \textit{BRCA1/BRCA2} in families with criteria for hereditary breast cancer. We reported \textit{BRCA1} c.4647_4648dupAA as a novel mutation. Further studies including a larger sample size of Peruvian patients should evaluate the prevalence or founder effect of this mutation in our population.
Title: Functional \textit{IGF1R} variant predicts preeclampsia protection from invasive breast cancer: Novel California teachers study findings

Powell M, Von Behren J, Neuhausen S, Reynolds P and Benz C. Zero Breast Cancer, San Rafael, CA; Cancer Prevention Institute of California, Berkeley, CA; Buck Institute for Research on Aging, Novato, CA and Beckman Research Institute of City of Hope, Duarte, CA.

Body: Many studies have reported lower breast cancer risk in women who develop hypertension in pregnancy with a meta-analysis reporting hazard ratios of 0.86 for preeclampsia and 0.83 for gestational hypertension. Our prior work in the Marin Women's Study (MWS) demonstrated both a lower breast density and a lower risk of breast cancer in women with pregnancy-induced hypertension (PIH) if they possess the TT genotype of \textit{IGF1R} SNP rs2016347.

Breast cancer in MWS women with PIH by IGF1R genotype

The current study was designed to validate and expand upon these findings in the larger California Teachers Study (CTS) which consists of $>130,000$ female educators. From original participants a case-control study was established in 2012 consisting of all non-Hispanic white women with DNA samples that became cases since entry into the study (N = 2030) and controls without invasive or in situ breast cancer (N = 1552). The current study nests within this case control study. All participants with a self-reported history of preeclampsia were selected (81 cases/56 controls). \textit{IGF1R} SNP rs2016347 was assessed by Taqman assay.

Results: Women with the TT genotype had an odds ratio (OR) of 0.38 when compared to the GG genotype after adjusting for potential confounders. Stratification by HR+/HR- cases and by age of first birth (AFB) resulted in statistically significant adjusted OR's of 0.26 for HR+ positive cases and 0.15 for women with AFB <30. Both showed significant trend effect for number of T alleles as shown below:

*p < .05

Overall in the CTS, the adjusted hazard ratio for women with vs without preeclampsia was 0.94 (0.81, 1.08).

Conclusions: These results suggest significant breast cancer protection in women with preeclampsia that possess the TT genotype, specifically in those women with AFB <30, and for the development of HR+ breast cancer. The overall OR for all
women with the TT genotype was low at 0.38 but did not reach statistical significance. This analysis in a second cohort again demonstrates a lower risk of breast cancer in women with a hypertensive disorder of pregnancy possessing the same IGF1R variant. Recent studies have associated the rs2016347 T allele with lower normal tissue expression of IGF1R mRNA, better survival in HR+ breast cancer, and improved pathological response to neoadjuvant chemotherapy. The protective T allele creates a new microRNA (miR-432) binding site within the IGF1R 3'UTR, offering a potential functional explanation for reduced mammary gland expression of this cancer-associated growth factor. This may interact with alterations of growth and metabolic factors characteristic of preeclampsia to imprint the immature gland with a lasting protective effect from later life breast tumorigenesis. If mechanistically substantiated, these findings could lead to a novel breast cancer prevention strategy.
Title: Adherence to healthy lifestyle behaviors in a predominantly Hispanic population of women undergoing screening mammography

Background: The American Cancer Society (ACS) established 2012 guidelines focusing on healthy lifestyle behaviors for the prevention of cancer and other chronic diseases. In our study, we compared adherence to the ACS guidelines for cancer prevention across a spectrum of breast cancer risk in a predominantly Hispanic population of women undergoing screening mammography.

Methods: We conducted a cross-sectional study in Washington Heights, NY among non-smoking women with a body mass index (BMI) \( \geq 18.5 \) kg/m\(^2\) undergoing routine screening mammography. Participants completed a self-administered questionnaire on demographics, breast cancer risk factors, and lifestyle factors, including adherence to ACS guidelines for physical activity (\( \geq 2.5 \) hours/week of moderate physical activity), consumption of fruits and vegetables (\( \geq 5 \) servings/day), alcohol intake (\( \leq 1 \) serving/day), and self-reported height and weight (BMI of 18.5-24.9 kg/m\(^2\)). We calculated a composite ACS adherence score, where each of the four main components were scored 0 for non-adherence, 1 for partial adherence, and 2 for complete adherence (range, 0-8), with scores of 6 to 8 representing optimal adherence. High breast cancer risk status was based upon a \( \geq 1.67\% \) 5-year risk of invasive breast cancer according to the Gail model or meeting family history criteria for \( BRCA \) genetic testing. Logistic regression models were used to examine the association between demographics, breast cancer risk status, and health behaviors.

Results: From Nov 2014-Dec 2015, 18,681 presented for screening, 2846 (15%) were approached for enrollment, 2345 consented, and 1977 were evaluable for this analysis. The mean age was 58.8 years (SD 10.9), over three-quarters identified as Hispanic, nearly 40% had not graduated high school, 24% met high-risk criteria for breast cancer, and only 8.3% had optimal adherence to ACS guidelines for lifestyle behaviors. In multivariable analysis, older women, racial/ethnic minorities, and those with lower educational levels were less likely to adhere to ACS guidelines. After controlling for known confounders, breast cancer risk status was not associated with adherence to lifestyle factors.

Conclusion: Our findings indicated that there is a significant difference in adherence to ACS guidelines for cancer prevention based upon age, race/ethnicity, and educational level. Our study has identified a population of women who may be targeted for lifestyle modification and screening mammography may provide a teachable moment to discuss strategies for preventing breast cancer and other chronic diseases.

Title: African Americans have more aggressive invasive lobular carcinoma subtypes and inferior early outcomes: SEER 2010-2013

Thomas A, Altekruse S, Avery TP P, Melin SA A, Howard-McNatt MM M and Schroeder MC C. University of Iowa, Iowa City, IA; National Cancer Institute, Bethesda, MD and Wake Forest University, Winston-Salem, NC.

Body: Introduction:
African Americans (AA) present more frequently with triple negative breast cancer (TN) and other aggressive breast cancer subtypes. Invasive lobular (ILC) breast cancer most commonly presents as estrogen receptor (ER)+, progesterone receptor (PR)+ and HER2-, though less frequently the more aggressive ER- or PR- luminal, TN or HER2+ subtypes occur. For women presenting with ILC 2010-2013, we report by race, differences in disease subtype, grade and stage at presentation and 2-year outcomes.

Methods:
We conducted a retrospective cohort analysis using Surveillance, Epidemiology and End Results Program. Women diagnosed with first primary malignant lobular breast cancer from 2010-2013 were included. Subtypes were categorized into four exclusive groups: ER+ and PR+ HER2-, ER+ or PR+ HER2-, TN and HER2+. Two-year survival was compared across race, and a multivariate cox model assessed overall survival.

Results:
ILC occurred less frequently in non-whites (Table 1). AA and other non-whites were younger at diagnosis than whites (p<0.001). AAs and other non-whites were less likely to have ER+ and PR+ HER2- disease (OR 0.85, p= 0.019 and OR 0.79, p=0.003 respectively). AAs had ILC of significantly higher grade and presented with more advanced stage disease than other race categories (p<0.001 for both). On multivariate analysis, survival was inferior for AA relative to whites (HR 1.32, p<0.010). Other non-whites had better survival than whites (HR 0.58, p=0.008). For AAs 2-year survival by disease subtype was: ER+ and PR+ HER2- (91.3%), ER+ or PR+ HER2- (90.5%), TN (59.5%), HER2+ (84.0%). For these subtypes, the proportion of women presenting with Stage IV ILC was 8.1%, 10.8%, 22.6% and 15.9% respectively.

Conclusion:
In this large, recent ILC cohort there were significant racial disparities in disease biology at presentation, with non-whites having more aggressive ILC subtypes, but only AAs having higher grade ILC. Short-term survival outcomes were inferior for AAs. Whether AAs presenting with advanced stage disease more frequently is due to biology or access to care is unknown. Further study of disease biology and healthcare delivery disparities could offer improved outcomes for AAs with ILC.

Title: Abstract Withdrawn
Title: Spectrum of hereditary breast and ovarian cancer gene variants in an African American cohort

Shah PD, D'Avanzo, Maxwell KN, Bradbury AR, Van Den Akker J, Kim S, Gil E, Simon MS, Nathanson KL and Domchek SM. Basser Center for BRCA, Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA; Color Genomics, Burlingame, CA and Karmanos Cancer Institute, Wayne State University, Detroit, MI.

Body: Background: Few reports describe the spectrum of mutations in breast and ovarian cancer predisposition genes found specifically in African Americans. Methods: 560 women who self-identified as African American (AA) from the University of Pennsylvania and Wayne State University were included in this IRB-approved, case-control study. Cases (n=218 with a personal history of breast and/or ovarian cancer) and controls (n=342 without breast or ovarian cancer) underwent germline genetic testing using the Color Genomics 19-gene breast and ovarian cancer risk panel. The subset of AA patients diagnosed with breast cancer ≤40 (n=185) was compared to an institutional cohort of white patients with breast cancer diagnosed ≤40 (n=189). Results: Of 218 AA cases, 70 had pathogenic or likely pathogenic (P/LP) mutations (BRCA1: n=36; BRCA2: n=24; TP53: n=3; RAD51D: n=2; ATM: n=2; CHEK2: n=2 and MSH6: n=1). Forty-two of 218 patients (19%) had at least one variant of uncertain significance (VUS). Of 342 AA controls, 5 women had P mutations in 5 distinct genes: BRCA2, ATM, BRIP1, PALB2 and PMS2. 55 control patients (16%) had at least one VUS. Many of the 75 P/LP mutations (cases, 70 mutations; controls, 5 mutations) in the full AA cohort were unique variants. In the 135 patients who had BRCA1/BRCA2 sequencing prior to testing under this protocol, the Color Genomics platform identified all 56 pathogenic mutations. Among AA patients diagnosed with breast cancer ≤40 (n=185), the incidence of TP53 and ATM pathogenic mutations was similar to the white, early-onset breast cancer cohort (n=189): TP53, 1% in both cohorts; ATM = 1% in AA patients and 2% in whites. However, no patients in the AA, early-onset cohort had germline CHEK2 mutations, compared to 4% of white, early-onset breast cancer patients (p=0.007). Conclusions: Taken together, the results of this study demonstrate the importance of considering germline mutation testing in the AA population. Examination of mutations and disease phenotypes within the AA population may facilitate understanding of the clinical risk associated with variants of uncertain significance. Further comparative data between the AA and white cohorts will be presented.
Title: Time differences in breast cancer diagnosis among minorities in a large referral academic center

Body: Background: Breast cancer (BC) is the most common malignancy and leading cause of cancer death in women. BC incidence is lower in Hispanic (H) (91.9/100,000) compared to non-Hispanic Whites (NHW -128.1/100,000) and Non-Hispanic Black (NHB - 124.3/100,000) population; however, mortality rate is higher in NHB (31/100,000) compared to NHW (21.9/100,000) and H (14.5/100,000). Diagnosis delay is a plausible factor that may explain differences in BC clinical outcomes among different race/ethnicity subgroups.

Objective: To compare time to diagnosis (TTD) by race/ethnicity in women with breast cancer diagnosed at Montefiore Medical Center from 2004 to 2012.

Methods: Patients with breast cancer and available race/ethnicity information diagnosed between 2004 and 2012 were categorized into 4 race/ethnicity groups: NHB, NHW, H or Asian. Dates of screening mammogram, diagnostic mammogram and biopsy were obtained. TTD was defined as the time difference between abnormal mammogram and biopsy dates.

Results: 919 patients had ethnicity information, 302 (32.8%) were H. TTD was longer in H compared to non-Hispanics (35 vs 31 days, z=2.2, p=0.02). Race and ethnicity information was available for 834 patients with a mean age of 62 years (SD:12.4). Of these, 252 (30.2%) were H and 387 (46.4%) were NHB. NHW had the shortest TTD (30 days), the highest frequency of Stage I (70%) and lowest frequency of high-nuclear grade (15.6%). NHB had a TTD of 31 days and higher frequency of triple negative disease (18.9%). TTD was significantly longer in H compared to NHW (35 vs 30 days, z=2.3, p=0.02), and there was a non-significant longer TTD when comparing H versus NHB (35 vs 31 days, z=1.9, p=0.0574). TTD between NHB and NHW was not different (31 vs 30 days, z=1.4, p=0.14).

Conclusions: The longer TTD in H vs Non-Hispanics was driven by the TTD in NHW. NHW had shorter TTD and more favorable pathological features which could lead to lower mortality rate. There was no difference in TTD between NHW and NHB but the latter had higher frequencies of triple negative disease. Correlation between TTD and mortality in our population will help to clarify the clinical effect of TTD differences among race/ethnicity subgroups.

Introduction: Although only about 5-7% of breast cancers occur in women under 40 years of age, multiple studies have shown that these cancers are more aggressive. In addition, issues related to genetic testing and fertility preservation are of particular importance for AYA patients with breast cancer. This retrospective analysis aims to describe various biologic and treatment related factors of an urban AYA population with breast cancer and the differences amongst these factors stratified by African American (AA) versus non-AA race. We will look at factors including stage at diagnosis, hormone receptor status, prevalence of BRCA1/2 mutations, time from diagnosis to treatment, enrollment in clinical trials, and fertility preservation.

Methods: A retrospective study of a population of AYA women with breast cancer seen at two hospitals in Washington D.C. from 2006 to 2015 was performed. Data was collected on age, BRCA1/2 test results, stage at diagnosis, hormone receptor status, time from diagnosis to treatment, enrollment in clinical trial, fertility preservation, and pregnant or breastfeeding status at time of diagnosis. Fisher exact test was used to test the association between two categorical variables. Wilcoxon rank sum test was used to compare time to treatment and stage at presentation between AA and non-AA patients.

Results: A total of 161 AYA patients were evaluated. 54 were identified as AA and 107 as non-AA (88 Caucasians, 13 Asian, 6 Hispanics). Median age was 32 years (20-39) overall; 32 years (23-39) for AA and 33 years (20-39) for non-AA. While the rate of genetic testing was high, significantly fewer AA AYA underwent testing compared to non-AA (74% versus 87% respectively, (p=0.050)) and 10% of AA versus 22% of non-AA were found to have a BRCA1/2 deleterious mutation (p=NS). Clinical trial participation was lower for AA compared to non-AA (57% vs. 76%, p=NS) for those where clinical trials were discussed/offered. Fertility preservation was pursued by 10% of AA vs. 35% of non-AA (p=0.001). Of note, 61% of AA and 34% of non-AA had children at the time of diagnosis (p=0.001). While AA (31%) presented more often with advanced stages of cancer compared to non-AA (19%) this was not statistically significant. Triple negativity was similar in AA AYA (25%) vs. non-AA (22%). The median time to treatment initiation did not vary between AA and non-AA (37 days vs. 36 days, p=NS).

Conclusion: In this retrospective study of an urban population of AYA women with breast cancer, there were no delays in treatment initiation or significant differences between AA and non-AA. When compared to non-AA, AA had a statistically significant lower rate of genetic testing and fertility preservation, although the latest could have been affected by a higher number of nulliparous in non-AA. Encouragingly, the clinical trial participation of AYA who had previously discussed clinical trials with their physician was very high.
Body: Introduction: In New Mexico, Hispanic women have a 1.7-fold increased risk of breast cancer-specific death compared to non-Hispanic white women. In previous studies, race/ethnic minority women have had larger survival disparities in estrogen receptor positive (ER+) than ER- disease, suggesting some aspect of ER may mediate survival outcomes. We thus conducted an extensive assessment of ER quantitative measures.

Objective: To determine whether ER percent positive and intensity differs by ethnicity, and to evaluate whether that potential difference might account for a proportion of survival disparities.

Methods: We conducted a population-based case-cohort study of first invasive breast cancer diagnosed in white females from 1997-2009 in six NM counties, identified through Surveillance Epidemiology End Results (SEER). We selected 15% of breast cancer cases and all breast cancer deaths through 2012. After IRB approval, pathology reports and tissue microarrays served as sources of ER, PR, and Her2 information. Tumors were classified according to modified intrinsic subtypes based on immunohistochemistry. Data were analyzed using Cox proportional hazards models adapted for case-cohort with weighted estimates (cohort weighted by 6.67x), and estimated hazard ratios (HR) and 95% confidence intervals (CI) using the robust variance and alpha=.05. The proportional hazards assumption was verified by Schoenfeld residuals. All analyses were adjusted for age. Interaction was assessed by inclusion of main effects and a product term (subtype* exposure).

Results: ER and intrinsic subtype information was available for 76% of the cohort (867/1143) and 70% of breast cancer deaths (689/991). Median follow up was 7.8 years. In analyses stratified by intrinsic subtype, Hispanic women experienced elevated mortality relative to non-Hispanic whites for luminal A (HR 1.9;95% CI 1.4-2.6), Luminal B (HR 2.9;95% CI 1.5-5.7), and TN tumors (HR 1.9;95% CI 1.0-3.6) but not Her2+ER- disease (HR 1.1;95% 0.3-3.4).

Overall ER Quantitative measures: Among ER+ women, breast cancer mortality decreased with increasing ER+ staining, measured by percent (p-trend=.004) or quartile (p-trend=.002). After adjustment for ER percent(ER%), women with increased ER intensity (score>2) had reduced mortality, relative to score=1 (HR 0.6;95% CI 0.4-.1.0). Results did not differ by Luminal A or B subtype (p interaction>.05).

Ethnicity-specific ER quantitative measures: ER% distribution did not differ by Hispanic ethnicity. However, among Hispanic women, interaction terms for ER%+ (p=.04) or quartile (p=.08) by subtype in relation to breast cancer survival suggest that Hispanic women with increasing ER staining have a reduced risk of mortality in Luminal A but not Luminal B tumors. Such differences were not evident among non-Hispanic white women. In multivariate models, inclusion of ER%+ and staining intensity did not alter Hispanic survival disparity overall, but mediated 8.6% in Luminal B.

Conclusion: After inclusion of ER%+, ER staining intensity is an independent risk factor for breast cancer survival. Differences in ER quantitative measures appear to account for only a small proportion of survival disparities. Survival gaps in ER+ breast cancer may be attributable to host or other tumor factors.
Title: Prospective cross-sectional-study on participation in mammography screening according to immigration background and education status

Kuehnle E, Oeztuerk T, Siggelkow W, Luebbe K, Moser A, Noeding S, John J, Noesselt T, Busch C, Arfsten M, Lemster S, Hilleman P, Doerk T and Park-Simon T-W. Hannover Medical School, Hanover, Lower-Saxony, Germany; Diakovere Henriettentifft, Breast Center, Hanover, Lower-Saxony, Germany; Klinikum Hanover Nordstadt, Cooperativ Breast Center KRH, Hannover, Lower-Saxony, Germany; Helios Klinikum Hildesheim, Breast Center, Hildesheim, Lower-Saxony, Germany; Kreiskrankenhaus Stadthagen, Breast Center Schaumburg, Stadthagen, Lower-Saxony, Germany and Sana Klinikum Hameln-Pyrmont, Breast Center, Hameln, Lower-Saxony, Germany.

Body: Introduction

Although the health of immigrants is an important issue in national health care policy there is a serious shortage of data in many countries. Most studies lack information on educational status which is a major limitation. In this prospective cross-sectional-study we analyzed the influence of immigration background and educational status on the participation in mammography screening programs in Lower-Saxony, Germany.

Material and methods

Data collection was conducted from 2012-2016 in six certified breast cancer centers using a personal questionnaire and data from the patients' medical records. Stratification into subgroups was carried out according to first and second generation immigrants and country of origin.

Results

1547/2129 primary breast cancer cases were analyzed. The percentage of patients with a history of immigration in our study cohort was 17.7%. The majority of them were citizens of EU27 Member states. First generation immigrants (n= 146), second generation immigrants (n=129), natives (n= 1272). No significant difference was seen in sex, age, tumor stage, histology, grading, Ki-67, Her2/neu-status, and hormone receptor status. A 100% participation rate in the mammography screening program was seen in patients with no school graduation. The lowest participation rate (85.5%) was seen in the group of native Germans with a college graduation and in first generation immigrants with a high school graduation (86.7%). Detailed statistical analysis will be presented on the poster.

Conclusion

No difference was seen between immigrants and native Germans with regard to tumor biology. In first-generation immigrants mammography screening was well accepted despite cultural and linguistic differences. Participation rate decreased with higher education level in all groups. High school graduates with immigrant background participated more frequently in breast cancer screening than native high school graduates. These findings mainly relate to immigrants from EU27 Member states rather than immigrants from non EU countries.
Predictors of breast density among Black and Hispanic women presenting for mammographic screening

Oppong BA A, Dash C, Li Y, Makambi K, Coleman T and Adams-Campbell L. MedStar Georgetown University Hospital, Washington, DC; Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC; Georgetown University, Washington, DC and Capital Breast Care Center, Washington, DC.

Background: Increased breast density has been associated with elevated breast cancer risk and complicating mammographic interpretation. Although previous studies have investigated population variations in breast density, Black and Hispanic women are often underrepresented in these analyses. Moreover, it is unclear how breast density differs between these ethnicities. We report on the mammographic density distribution of Black and Hispanic women having breast cancer screening at the Capital Breast Care Center (CBCC) and analyze factors associated with high breast density.

Methods: Retrospective data from electronic medical records at a population-based mammography screening center were abstracted. From 2010 to 2014, data from women undergoing their first breast cancer screening were reviewed. Patient demographics including race, age at screening, education and menopausal status were abstracted in addition to body mass index (BMI) and Breast Imaging-Reporting and Data System (BI-RADS) density category: 1- “fatty”, 2- “scattered fibroglandular densities”, 3- “heterogeneously dense” and 4- “extremely dense”. Logistic regression was used to investigate factors associated with breast density.

Results: Density categorization was recorded for 1747 women over the five-year period, with 855 (49%) Black and 892 (51%) Hispanic. Patient characteristics associated with high density (categories 3 and 4) were younger age, Hispanic ethnicity, nulliparity, premenopausal status, and BMI < 30 kg/m². On multivariate logistic regression, Hispanic ethnicity, premenopausal status, and BMI < 30 kg/m² were predictive of high mammographic density.

Conclusion: In a sample of women presenting for mammographic screening at CBCC, Hispanic women were more likely to have higher breast density compared to Black women. After controlling for ethnicity, postmenopausal and obese women were less likely to have dense breasts. Additional investigation is needed to further study the impact of obesity on breast density in underserved minority women.
Title: Self-evaluation of duration of adjuvant chemotherapy side effects in breast cancer patients: A prospective study

Galizia D, Martinello R, Cagnazzo C, Foresto M, Gallizzioli S, Longo V, Berchialla P, Solinas G, Calori A, Volpone C, Parola G, Teddi G, Ballari A and Montemurro F. Candiolo Cancer Institute-FPO (IRCCS), Candiolo, Italy; AOU Città della Salute e della Scienza Torino, Presidio Sant'Anna, Turin, Italy; University of Turin, Turin; Ospedale Maggiore della Carità, Novara, Italy; Ospedale Cardinal Massaia, Asti, Italy; Azienda Sanitaria Locale Verbano, Cusio, Ossola, Verbana, Italy; Azienda ASO Santa Croce e Carle, Cuneo, Italy and AOU Città della Salute e della Scienza Torino, Presidio Molinette, Torino, Italy.

Body: Background: Collection and analysis of chemotherapy-related side-effects (CSE) is critical in the management of cancer patients (pts) both in experimental trials and in the clinical practice. Usually, most of the available conventional systems like the National Cancer Institute (NCI) Common Terminology Criteria for Adverse Events (CTCAE) capture CSE severity but not their duration. Recently we observed that self-evaluation of CSE incidence and severity by a CTCAE v4.0-based questionnaire was feasible and potentially more informative than doctor reports in pts undergoing standard adjuvant chemotherapy (ACT) for operable breast cancer (Montemurro et al., JAMA Oncol 2; 445-452, 2016). Our questionnaire had also a section for reporting, for each of the considered CSE, day of onset, duration and whether it was still present at the time of the visit. Here we report the analysis of patient self-evaluation of CSE duration.

Methods: The study prospectively enrolled 604 pts receiving ACT for operable breast cancer between January 2011 and October 2013 at 11 sites in Italy. CTCAE v4.0 definitions of grade of severity for nausea, vomiting, constipation, anorexia, dysgeusia, diarrhea, fatigue, pain, paresthesia, and dyspnea were translated into Italian and rephrased. Questionnaires were administered after the first and third cycle of chemotherapy. At each time-point, information on CSE was extracted from the medical charts and compared to patient questionnaires.

Results: Overall 1177 questionnaires were collected, 596 after cycle 1 and 581 after cycle 3 of ACT. A median of 82% of the fields was completely filled-in. 594 and 573 pts-questionnaires had a corresponding MD-questionnaire. Comparison of CSE duration after cycle 1 of chemotherapy as self-assessed by pts versus that reported by doctors is summarized in the table

*5% trimmed mean, ** Student T test for paired samples

For all CSE, patient reported longer duration than doctors did. Comparisons of reports after cycle 3 were similar.

Conclusions: Self-reporting of CSE duration is feasible in patients receiving ACT after breast cancer surgery by using a CTCAE-derived questionnaire. Because doctors tend to underestimate both incidence and duration of CSE, patient-reported outcomes should be incorporated into the clinical practice because of the potential to provide a better estimate of the total burden.
of CSE.
Supporte by a grant of the Rete Oncologica Del Piemonte e della Valle d'Aosta.
Title: Impact of pre-operative exercise and mind-body interventions on patient-reported outcomes in women with newly diagnosed breast cancer

Body: Background: Breast cancer diagnosis has a number of adverse psychological effects. The Pre-Operative Health and Body (PreHAB) Study tested the impact of exercise and mind-body interventions upon mood, quality of life, and patient-reported outcomes in women with newly diagnosed breast cancer.

Methods: Women with newly diagnosed Stage I-III breast cancer were enrolled through Dana-Farber Cancer Institute and Yale University breast cancer clinics prior to surgery. Participants were randomized 1:1 to an aerobic and strength-training exercise intervention, comprised of twice-weekly meetings with an exercise trainer and home based aerobic exercise, or to a self-directed mind-body relaxation intervention, comprised of a book and CD focused on relaxation and visualization. Participants engaged in the interventions between enrollment and surgery. The EORTC QLQ C-30, Hospital Anxiety and Depression Scale, and Perceived Stress Scale were collected at enrollment and prior to surgery.

Results: 49 women were randomized (27 exercise and 22 control). Mean time between enrollment and surgery was 4.2 weeks. At baseline, patients reported moderate levels of anxiety, stress, insomnia, and lack of appetite, as well as diminished emotional and cognitive functioning (Table). Exercise participants significantly increased minutes of weekly exercise vs. mind-body participants (increase of 203 vs. 23 min/wk, p<0.0001). Mind body participants engaged in the intervention on average 69% of days during the intervention period. Pre-post changes demonstrated that participation in the mind-body intervention led to improvements in emotional and cognitive functioning and a reduction in anxiety and stress, and participation in the exercise intervention led to improvements in global quality of life, insomnia, appetite, and stress (Table). Women in the mind-body group experienced a significantly greater improvement in cognitive functioning as compared to women in the exercise group.

Conclusions: Women with newly diagnosed breast cancer reported a number of physical and psychological symptoms in the pre-operative period. Exercise and mind-body interventions demonstrated promising benefits in improving functioning and reducing symptoms. More work is needed to develop pre-operative programs to help reduce the distress imparted by a cancer diagnosis in the critical time between diagnosis and surgery.

Body: <Background>
The information presented herein extends our recent study of TTT (Trial for Triplet Antiemetic Therapy). One of our main clinical questions has been whether a 2nd generation serotonin receptor antagonist (5-HT3ra) would be superior to 1st generation 5-HT3ra when administering triplet antiemetic therapy for the prevention of chemotherapy induced nausea & vomiting (CINV), since a prior Japanese trial demonstrated palonosetron to be superior to granisetron for controlling the delayed phase of CINV induced by highly emetogenic chemotherapy (HEC) and to doublet antiemetic therapy including dexamethasone for anthracycline and cyclophosphamide containing regimens (AC).

<Objectives>
In this study, we assessed the efficacies of 1st and 2nd generation 5-HT3ra agents for use as triplet antiemetic therapy for AC, by monitoring CINV, focusing especially daily CR in the delayed phase.

<MATERIAL AND METHOD>
Between 2012 and 2015, 491 women with breast cancer receiving AC were recruited from 11 institutions in Japan, and randomly assigned to either single-dose palonosetron (0.75mg) or granisetron (40µg/kg) prior to chemotherapy on day 1, both with dexamethasone (9.9 mg intravenously) and aprepitant (125mg orally) on day 1 followed by additional doses (80mg orally) on days 2 and 3. Age, institution and habitual alcohol intake were used as stratification factors. The primary endpoint was a complete response (CR). Statistical analysis was done by Mantel-Haenszel Method. This trial was registered with UMIN000007882.

<RESULTS>
All 491 patients were included in efficacy analyses (ITT): 246 patients in the palonosetron group and 245 in the granisetron group. We previously reported that the difference in CR during the delayed phase, i.e. 24 hours after the administration of AC, did not reach statistical significance (53.8% vs 58.5%) in MASCC 2016. However, daily CR in the palonosetron group was much higher than that in the granisetron group after 48 hours.

<CONCLUSIONS>
Palonosetron showed better efficacy in controlling CINV during the late period of the delayed phase, i.e. 48 hours after AC administration, than granisetron as triplet antiemetic therapy for AC.

<Considerations>
The pattern of CINV reportedly shows two peaks including an acute phase caused by serotonin and a delayed phase caused by substance P, though the pattern of CINV with triplet antiemetic therapy administration might be different if the suppression of each of these peaks were to be achieved more efficiently. CINV may not be divided into two phases in the future, or the borderline area between the acute and delayed phases may require revision. The analysis of the late period of the delayed phase was ad hoc in this trial. However, when conducting studies related to CINV, it might be worthwhile to revise the borderline area between the two phases of CINV to facilitate elucidating the mechanisms underlying this potentially debilitating side effect of chemotherapy.
**Title:** Technology as a change agent for improving breast cancer quality care

**Body:**

**Background:** With rapid advances in research, clinicians often struggle to remain current with evolving care guidelines and to implement current national quality standards (NQS) relevant to breast cancer management. Adherence to NQS is driving reimbursement for cancer services, but clinical workflow processes and IT solutions are lacking to effectively document adherence. The Carevive Care Planning System™ (CPS), an evidence-based, patient assessment and care planning software, is designed to close gaps in quality cancer care by marrying clinical and patient-reported data with evidence-based algorithms to help centers improve and document their adherence rates to quality care standards.

**Methods:** This study enrolled 30 non-metastatic breast cancer patients presenting to an NCI-designated comprehensive cancer center for no greater than their second medical oncology visit, and compared provider adherence to quality metrics for these patients with 30 matched historical controls who were seen prior to the study intervention. All were planned for chemotherapy treatment. The two part study intervention included 1) Provider participation in certified continuing medical education (CME) on evidence-based assessment, decision-making, and management strategies for breast cancer and 2) Use of the Carevive CPS with intervention subjects, each of whom completed a electronic survey assessing current symptoms and concerns prior to their visit, and then received a provider-approved care plan including tailored recommendations for symptom management and referrals. The primary aim was to compare provider adherence to select quality metrics between historical controls (pre-test) and post-intervention subjects.

**Analysis/Results:**

Patient enrollment began in July 2015 and an earlier report of control data showed improved provider knowledge post-CME and opportunities to improve adherence. Median age and distribution of race, ethnicity, breast cancer stage, and HER2/ER status was not statistically different between the groups. Provider adherence to quality standards from pre to post-test is shown below:

</tbody>
</table>

**Conclusions:** Provider adherence to quality metrics for emotional wellbeing increased from pre- to post- intervention, but did not for pain assessment and management. This was largely due to ceiling effect, but opportunities exist for continued improvement in pain management, at least in documentation. The Carevive CPS plus CME has the potential to allow institutions an patient-centered and user-friendly approach to both improve and document adherence to quality metrics.
Title: Examining bone degeneration as a side effect of treatment in premenopausal breast cancer patients

Kim M and Kim HJ. Asan Medical Center, College of Medicine, University of Ulsan, Seoul, Pung Nap Dong, Republic of Korea.

Body: **Background:** Although it is widely known that adjuvant treatments cause osteoporosis in postmenopausal women, the effect of treatment and the exact degree of bone loss in premenopausal women is not well understood. For this reason, this study examined the relationship between the changes of bone mineral density (BMD) and the types of treatment in premenopausal breast cancer patients.

**Method:** This retrospective study looks at preoperative and annual spine bone densitometry tests conducted on breast cancer patients during their observational period following initial treatment for their diagnosis. 461 premenopausal patients who received treatment from January 2006 to April 2007 were the study cohort because of the availability of bone mineral density (BMD) data (L-spine and femur T scores) for a two-year period. The data from the patients were separated into groups according to their treatment plans: observation, adjuvant chemotherapy, adjuvant chemotherapy followed by use of Tamoxifen, and GnRHa (Gonadotropin Releasing Hormone agonist) followed by Tamoxifen.

**Results:** Of the 461 patients, 21 received no treatment aside from surgery, 75 received only Tamoxifen, 34 only chemotherapy, 166 chemotherapy and Tamoxifen, and 165 Zoladex and Tamoxifen. The no treatment group demonstrates the standard annual change in BMD. At first year, the chemotherapy only group and tamoxifen after chemotherapy group showed significant bone loss in the first year (p<0.005, both). The patients who received tamoxifen alone or tamoxifen with goserelin showed decrease BMD but not significant. After 2 years, tamoxifen with goserelin group showed significant decreased BMD in both spine and femur (p<0.001, p=0.001, both). Chemotherapy group showed partial recovery from the first year bone loss. **Conclusion:** The patients who received chemotherapy or GnRHa as treatment showed the greatest degree of bone degeneration but at different periods. However, Tamoxifen used along with these treatments seemed to lessen the extent of bone degeneration. Significant bone loss from hormone treatment occurred two years after surgery as compared to one year for chemotherapy.
Title: BEAUTY and the breast: Is adjuvant chemotherapy the right time for a beauty boost? Results of a randomised controlled trial

Background:

Beauty treatments (BT) commonly offered at the hospital meet a great success among patients (pts) as well as a favorable public image. However, their precise modalities and benefits have not been assessed so far. Breast cancer (BC) pts are a group of special interest in this field.

Methods:

A total of 400 pts treated with adjuvant chemotherapy (CT) after surgery for primary BC were randomized to receive BT during the course of their CT or no BT (control).

Pts had to fill in 3 questionnaires (quest.) before initiation of CT (T0) and after their last CT (T1): EORTC QLQ C30, BR23 (BC specific quest.) and Body Image Scale (BIS).

Primary outcome was improvement in the Body Image scale of BR23 (BRBI) and in BIS. BRBI was analyzed in 2 categories (Poor BRBI < 75, and Good BRBI >= 75).

Statistical analyses were based on comparison of mean scores and adjusted on use of BT and score before CT. A qualitative assessment of pts’ experience was performed at each cycle through an ad hoc quest.

Results:

Pts characteristics were similar in both groups: median age (50 years), T, N, and mastectomy rate (40%). A total of 1120 BT were administered.

Based on QLC-BR23 data, it was expected that 26% of BC pts would have a Poor BRBI. In our study, 50% of pts had a Poor BRBI at T0, correlated to younger age (<50), mastectomy and axillary lymph node dissection.

At T1, approximately 70% of pts had a Poor BRBI, similar in both groups (with and without BT) (p = 0.68). The majority of pts (86%) with Poor BRBI before CT did not improve after CT. For 46% of pts with a Good BRBI prior to CT, BRBI turned Poor after CT.

Table 1 shows the results of the scores at T0 and T1 and their statistical comparison.

Analyses of the qualitative assessment of pts’ perception showed the perceived added-value and limits of BT at this stage of the BC care pathway.

Conclusion:
In our randomized study, 50% of women had a degraded body image before CT. CT induced an observed further degradation leading to very low scores, without any effect of BT. The qualitative assessment of pts' perceptions revealed the specific needs of pts in terms of BT at this stage of their pathway.
Our study highlights the underestimation of pts-perceived body-image at this critical phase of their disease and generates hypothesis for further designing and tailoring of BT as an impactful supportive tool for BC pts.
Title: Pharmacokinetics of eflapegrastim in a phase 2 open-label dose-ranging study in breast cancer patients receiving TC regimen

Vacirca JL L, Papai Z, Horvath Z, Makharadze R, Reddy G, Song T, Koli P and Schwartzberg LS S. North Shore Hematology/Oncology Associates, East Setauket, NY; State Health Center, Budapest, Hungary; University of Debrecen, Oncology Clinic, Debrecen, Hungary; Cancer Center of Adjara Autonomous Republic, Batumi, Georgia; Spectrum Pharmaceuticals, Irvine, CA and West Cancer Center, Memphis, TN.

Body: Background: Eflapegrastim (SPI-2012/HM10460A) is a novel, long acting recombinant human granulocyte colony-stimulating factor (rhG-CSF). Eflapegrastim consists of an rhG-CSF conjugated to the recombinant E coli derived Fc fragment of IgG4 via a polyethylene glycol linker. Eflapegrastim is in clinical development for the treatment of chemotherapy induced neutropenia in cancer patients.

Methods: Pharmacokinetics (PK) of eflapegrastim was investigated in an open label, dose-ranging Phase 2 study in breast cancer patients receiving docetaxel + cyclophosphamide (TC) chemotherapy. The study consisted of 4 arms. Patients in Arms 1 through 3 received subcutaneous doses of 45, 135, or 270 µg /kg of eflapegrastim and patients in Arm 4 received 6 mg pegfilgrastim (Neulasta®) on Day 2 of each 21-day chemotherapy cycle. Serum samples were collected from a subset of eflapegrastim patients at pre-specified time-points and analyzed for eflapegrastim by a validated enzyme-linked immunosorption assay (ELISA). Pharmacokinetic analyses were conducted on serum concentration-time profiles after dosing in Cycle 1. The serum concentrations for samples collected in Cycle 3 were compared with the corresponding concentrations in Cycle 1. Pharmacokinetic analyses were not conducted for pegfilgrastim patients.

Results: The PK profile of eflapegrastim was investigated in 11 patients, including 3 patients in the 45 µg/kg treatment arm, 4 patients in the 135 µg/kg treatment arm, and 4 patients in the 270 µg/kg treatment arm. Following single eflapegrastim doses of 45, 135, or 270 µg/kg, peak serum concentrations increased in a dose proportional manner. The summary of pharmacokinetics of eflapegrastim is presented in the Table below.

Pharmacokinetic Parameters of Eflapegrastim in Patients Following Single Subcutaneous Doses in Cycle 1

AUC = area under the concentration-time curve; Cmax = maximum serum concentration; h = hour; NC = not calculated; SD = standard deviation; t1/2 = half-life; Tmax = time to maximum serum concentration; a) Expressed as median and range; b) Expressed as harmonic mean and pseudo SD

Pharmacokinetic Parameters of Eflapegrastim in Patients Following Single Subcutaneous Doses in Cycle 1

The maximum serum concentrations of eflapegrastim in Cycle 3 increased with the dose of eflapegrastim. The serum concentrations of eflapegrastim in Cycle 3 were generally lower than those in Cycle 1, but the profile was similar to Cycle 1.

Conclusions: The Cmax and AUC(0-312) of eflapegrastim increased in a dose proportional manner following subcutaneous administration. The half-life of eflapegrastim ranged from 31.5 to 81.0 hours, which is consistent with the half-life of other long-acting myeloid growth factors.

Title: Immunogenicity of eflapegrastim in a phase 2 open-label dose-ranging study of eflapegrastim in breast cancer patients receiving TC regimen

Vacirca JL, Papai Z, Agajanian R, Horvath Z, Makharadze R, Ibrahim E, Koli P, Reddy G, Tedesco KL L, McGregor K and Schwartzberg LS S. North Shore Hematology/Oncology Associates, East Setauket, NY; State Health Center, Budapest, Hungary; The Oncology Institute of Hope and Innovation, Downey, CA; University of Debrecen, Oncology Clinic, Debrecen, Hungary; Cancer Center of Adjara Autonomous Republic, Batumi, Georgia; Beaver Medical Group, Highland, CA; Spectrum Pharmaceuticals, Irvine, CA; New York Oncology Hematology (US Oncology/McKesson Specialty Health), Albany, NY; Samaritan Hematology and Oncology Associates, Corvallis, OR and West Cancer Center, Memphis, TN.

Body: **Background:** Eflapegrastim (SPI-2012/HM10460A) is a novel, long-acting recombinant human granulocyte colony-stimulating factor (rhG-CSF). Eflapegrastim consists of an rhG-CSF conjugated to a recombinant E. coli derived Fc fragment of IgG4 via a polyethylene glycol linker. Eflapegrastim is in clinical development for the treatment of chemotherapy induced neutropenia in cancer patients.

**Methods:** Immunogenicity of eflapegrastim was investigated in an open label, dose-ranging Phase 2 study in breast cancer patients receiving docetaxel + cyclophosphamide (TC) chemotherapy. The study consisted of 4 arms. Patients in Arms 1 through 3 received subcutaneous doses of 45, 135, or 270 µg/kg eflapegrastim and Arm 4 received 6 mg pegfilgrastim (Neulasta®) on Day 2 of each 21-day chemotherapy cycle. Blood samples for immunogenicity analysis were collected before the start of each chemotherapy cycle (Day 1) and at the End-of-Study Visit. Samples were tested in a screening assay for Anti-Drug Antibodies (ADA) to eflapegrastim by a validated enzyme linked immunosorption assay (ELISA). Positive samples from the screening assay were further tested in a confirmatory assay for antibodies binding to eflapegrastim or G-CSF. Samples found positive in the confirmatory assay were further tested in a validated cell based neutralizing antibody assay.

**Results:** Serum samples from 143 patients in the study were tested for ADA to eflapegrastim and G-CSF. Preexisting antibodies binding to eflapegrastim or G-CSF were detected in 9 out of 143 (6.3%) patients. One out of the 27 patients (3.7%) in the Pegfilgrastim Arm who was negative prior to dosing was positive for ADA in the G-CSF confirmatory assay. Two out of 100 patients (2.0%) treated with eflapegrastim, who were negative prior to dosing, demonstrated treatment-induced formation of ADA in the G-CSF confirmatory assay. However, the responses in these patients were transient (ie, not consistently positive at all the sampling times) and the assay response values were low and only slightly above the plate-specific cut points. None of the patients tested were positive for G-CSF neutralizing antibodies. A formal assessment of the impact of serum ADA on the PK of eflapegrastim was not performed since PK was examined in only a limited number of patients and all of those patients were negative for ADA both at study initiation and post-dose.

**Conclusion:** No neutralizing antibodies against eflapegrastim or G-CSF were detected in patients administered eflapegrastim in this study.
Title: Sustained efficacy of eflapegrastim in breast cancer patients in a phase 2, open-label, dose-ranging study

Vacirca JL L, Agajanian R, Papai Z, Horvath Z, Makharadze R, Ibrahim EN N, Choi MR, Song T, Tedesco KL L, McGregor K and Schwartzberg LS S. North Shore Hematology/Oncology, East Setauket, NY; The Oncology Institute of Hope and Innovation, Downey, CA; State Health Center, Budapest, Hungary; University of Debrecen, Oncology Clinic, Debrecen, Hungary; Cancer Center of Adjaran Autonomous Republic, Batumi, Georgia; Beaver Medical Group, Highland, CA; Spectrum Pharmaceuticals, Irvine, CA; New York Oncology Hematology (US Oncology/McKesson Specialty Health), Albany, NY; Samaritan Hematology and Oncology Associates, Corvallis, OR and West Cancer Center, Memphis, TN.

Body: Background: Eflapegrastim is a distinct biologic that uses the innovative proprietary long-acting protein/peptide discovery technology (LAPSCOVERY™) and consists of a novel, modified recombinant human G-CSF conjugated to the Fc fragment of IgG4 via a polyethylene glycol linker. A Phase 2 study of 3 doses of eflapegrastim vs pegfilgrastim was conducted in breast cancer patients receiving docetaxel + cyclophosphamide (TC) chemotherapy.

Methods: This was an open-label, global, multicenter, dose-ranging study designed to compare the safety and efficacy of eflapegrastim relative to a fixed dose of pegfilgrastim as a concurrent active control. The study included 4 treatment arms: 3 dose levels of eflapegrastim (45 µg/kg, 135 µg/kg, and 270 µg/kg) vs pegfilgrastim (6 mg). The primary objective of the study was the Duration of Severe Neutropenia (DSN) during Cycle 1. The results for the primary objective, along with demographics and safety, were described in a previous presentation (SABCS 2015 P1-10-05). The secondary endpoints included DSN in Cycles 2-4, absolute neutrophil count (ANC) in Cycles 1-4, the overall incidences of febrile neutropenia (FN) and hospitalization rates.

Results: A total of 147 evaluable patients were enrolled. Patient and tumor characteristics were comparable across all 4 treatment arms. Median age was 59.0 years (range 32 to 77 years); most patients were <65 years (68%), Female (98%), and White (95%). The DSN for the 135 µg/kg and 270 µg/kg was non-inferior to pegfilgrastim during all cycles and the DSN for patients treated with 45 µg/kg was non-inferior during Cycles 2 and 3 (Table 1). The ANC was dose proportional across all 4 cycles. The incidence of FN and hospitalization rates was low in all arms and there were no significant differences between the Eflapegrastim and Pegfilgrastim Arms (Table 2).

**Conclusions**: In breast cancer patients treated with TC, the non-inferiority of DSN of 135 µg/kg and 270 µg/kg eflapegrastim, compared to pegfilgrastim in Cycle 1, was sustained through Cycles 2-4 and the ANC profiles were comparable in Cycles 1-4. In addition, the overall incidence of FN and hospitalizations was comparable between the eflapegrastim arms and the pegfilgrastim arm.
Title: Evaluation of the relationship between psychological distress and risk for breast cancer

Vennard K, Crocker A, Ogheneruona A, Cuke M and Wood M. University of Vermont Medical Center.

Body: Women at increased risk for breast cancer (due to family history or having a pathogenic germline mutation in a cancer causing gene) have greater distress levels, which can impact quality of life and screening behavior. The goal of our study was to evaluate distress related to different risk factors for breast cancer and examine the stability of this distress over time. Methods: Women at increased risk for breast cancer who enrolled in the High-Risk Breast Program (HRBP) at the University of Vermont Medical Center were eligible for participation. Women with strong family history, a genetic mutation or atypia on biopsy (benign breast disease, BBD) who completed the Impact of Event Scale (IES) at least once were identified. The IES is a self-reported measure designed to measure subjective distress within the past seven days in relation to a stressor. The scale is based on a two-factor intrusion-avoidance model. Linear regression was used to examine change in distress over time and to compare distress levels between risk groups. Both risk measures and distress scores were examined using bivariate plots and normal probability plots. Pearson correlation coefficients and least squares regression coefficients were obtained along with 95% confidence intervals. In addition to treating the risk estimates as continuous measures, these estimates were grouped into low or average risk (<=2%) over five years, moderate risk (2%-4%) over five years, and high risk (>5%) over five years. Using the ordinal classification into three risk groups, analysis of variance was conducted to detect group differences in average psychological distress using a 5% significance level.

Results: The cohort comprised 344 women at increased risk for breast cancer due to a strong family history (80%), a genetic mutation (9%) or benign breast disease (16%). Mean IES score was 16.8 (CI 15.5, 18.2), and indicates high distress levels in this cohort. IES scores decreased over time (p<0.001 and p=0.003 after 4 and 8 years, respectively). Scores did not differ between the overall group and either women with a strong family history (p=0.06) or women with BBD (p=0.8). Women with genetic mutations had higher IES scores than those without (p=0.023). IES scores were positively associated with the number of risk factors an individual had (1, 2, or 3 risk factors: p=0.003).

Conclusion: We demonstrated that distress is similar among different risk categories and that distress decreases over time; patterns not previously recognized. Women with benign breast disease have IES scores similar to women with strong family histories of breast cancer. Women with multiple risk factors are also noted to have higher scores. Women with genetic mutations appear to have the highest distress levels. These findings further our understanding of cancer related distress. Targeting women with highest distress levels may improve both quality of life and screening adherence.
Title: A phase I safety study of topical calcitriol (BPM31543) for the prevention of chemotherapy-induced alopecia (CIA)

Body: Background: Chemotherapy induced alopecia (CIA) may lead to significant psychosocial and quality of life issues. Currently there are no FDA approved oral or topical agents available to prevent CIA. In murine studies, topical calcitriol reduced CIA, due to arrest of cell cycle in healthy hair follicles, and reduction in the sensitivity of follicular epithelium to chemotherapy.

Methods: A prospective dose escalation study is being performed in up to 31 women with breast cancer, gynecologic cancer and sarcomas. Each patient is applying 1mL of BPM31543 to her scalp bid, ≥ 5 days prior to initiation of taxane-based chemotherapy for at least 3 months or until the completion of chemotherapy. The study cohorts are: 5/10/20/60/80µg/mL. The first 5 cohorts are completely enrolled and the final cohort is currently being enrolled. Each patient undergoes pk analysis, adverse event (AE) monitoring, patient self-assessment diaries (1-10 scale), and blinded photographic assessments. Efficacy and pK data are still being collected and analyzed for the patients on study, but will be available by December.

Results: Twenty-four subjects have been enrolled so far (evaluable at this time, n = 13). Pk data (n = 16; 5-40µg/mL) showed inter-individual variability, but no significant dose-dependent increase in systemic absorption (range, < 20-110 pg/mL). Treatment-related AEs (probably/possibly) were mild/moderate in nature and included scalp pain (n = 1; 5 µg/mL), elevated vitamin D levels in 1 patient (20µg/mL) and passage of renal calculus in another (n = 1; 40µg/mL). All subjects reported changes in overall hair fullness, thickness, and volume of hair during chemotherapy. At the 5/10 µg/mL dose level, ≥ 75% hair loss was reported in 85% of patients. At the ≥ 20 µg/mL dose level, ≥ 75% hair loss was seen only in 43% of patients. Hair loss/ thinning caused all subjects to change their hair style (onset, week 2; peak, weeks 5-6).

Conclusions: Data have shown that the twice daily application of BPM31543 in patients receiving taxane-based chemotherapy was safe and well-tolerated. Efficacy data from the preliminary analysis was promising and led to the amendment of the study to evaluate two additional higher dose cohorts: 60 and 80 µg/ml.
Title: MOCHA: An institution-based care coordination app for post-hospitalization breast cancer patients

He T, Ogunti R, Yu X, Puppala M, Chen S, Mancuso J and Stephen W. Houston Methodist Hospital, Houston, TX.

Body: Purpose: Hospitals face many challenges in effective care coordination for post-surgery breast cancer patients, especially with scarce resources and limited availability of nurse navigators for care transition and post-hospitalization follow up. Mobile health provides an inexpensive and convenient means of real time care monitoring and communication between patients and care providers. Nevertheless, most current health apps focus on individual consumers and gather information from their daily lives, but do not integrate with clinical workflow or capture physiological and activity data into electronic medical record for real-time monitoring, patient surveillance, and professional care. To fill this gap, we have developed and implemented MOCHA (MethOdist Hospital Cancer Health Application), a coordinated care mobile app for post-hospitalization breast cancer patients from the perspective of a primary care institution. Methods: MOCHA supports both iOS and Android platforms and contains two main modules: health care monitoring and data communication, designed together with the physicians and nurses of the Houston Methodist Cancer Center. The Health care monitoring module aims to support real-time monitoring of the post-discharge medical state of breast cancer patients. Physicians can monitor the daily food intake and activities for patients and provide advice to patients in real-time. The data communication module was developed to safely exchange the care coordination data with the hospital electronic medical record or data warehouse. Communication between the patient and the physician can be via an in-house protocol or an open data exchange standard Fast Healthcare Interoperability Resources (FHIR), that describes data format and elements for exchanging electronic health records. Our communication module uses https-based protocol to exchange the structured data with the FHIR resource server. Implementation: To validate the MOCHA app, we collaborated with the oncologists and dietitians at the Houston Methodist Cancer Center, who provided breast cancer patients for post-surgery care coordination. Our app exchanges health care data in real time with our hospital's clinical data warehouse. MOCHA searches Nutritionix food database for nutritional information and uses personal trackers such as Fitbit for patients' daily activities with their authorization. The app sends patients' daily burned calories into our clinical data warehouse. During the evaluation period, the physician communicates with cancer patients daily. In addition, every patient has a bi-weekly physical examination, and all examination results are shown in the app. After the experimental evaluation, the physician will access the data warehouse and analyze the test data in order to improve the quality of care coordination. The experimental clinical evaluation is ongoing, and we will report the results once the study is completed. Conclusion: MOCHA app provides health care monitoring and secure communication functions with interface with clinical data warehouse. The technical evaluation shows that the proposed methods are robust and efficient in support of care coordination for post-surgery cancer patients.
Experience in the ABC Medical Center of Mexico City 2010-2015 using scalp-cooling system (DigniCap) for prevention of alopecia induced by chemotherapy

Background: Alopecia is one of the secondary side effect with the most emotionally impact for patients undergoing chemotherapy (CTX). The DigniCap System is the first scalp cooling system used to minimize alopecia. Methods: The objective of this study was to evaluate in a retrospective trial the efficacy of DigniCap preventing alopecia in consecutive patients treated in ABC Medical Center from December 2010 to January 2015. Patients receive different chemotherapy regimens, with different modalities, neo, adjuvant and for metastases in first and second line, as in many clinical stages with breast cancer (BC), were evaluated with the visual scale of Dean (score 0: 0-25%, 1: 25-50%, 2: 50-75%, 3: 75-100%) with photographs of the before and after treatment. Results: 120 pts with BC in stages I-V were treated with a taxane and antracyclins regimen of chemotherapy, 66 pts receive 12 treatment weekly of paclitaxel (T)l and 4 adriamycin/cyclophosphamida (AC) every 21 days, 28 pts 6-8 cycles every 21 days AC-Taxol, 22 pts (18%) suspended the treatment because of the loss of more than 50% of hair at the 2nd and 3rd chemotherapy cycle. 98 pts actually finished the treatment (72%). Of these, 82 pts (84%) had no loss or a minimal loss of hair (Dean score 0-1), 16 pts (16%) had a 50% of hair loss (Dean score 3). 8pts receive more than one regimen of chemotherapy. In the tracing any metastases or side effects were presented with the use of DigniCap. Conclusions: The use of DigniCap minimize alopecia in a 84%, including pts with more than one chemotherapy regimen, in a a safety level.

Title: Physicians perceptions of estrogen agonist/antagonists in menopausal health: An opportunity to address a triad of concerns in menopause and breast cancer survivorship

Krychman M and Portman D. Southern California Center for Sexual Health and Survivorship Medicine Inc, Newport Beach, CA and Sermonix Pharmaceuticals, Columbus, OH.

Body: Introduction: Estrogen agonists/antagonists (Selective Estrogen Receptor Modulators, SERMS) are a class of medications, which are gaining popularity in menopause health care as they can effectively address a variety of symptoms and offer a non-hormonal alternative. In particular, bone and genitourinary health both suffer from the ramifications of menopause as well as breast cancer treatment. Chemoprevention is also a medical concern in the at risk population. Breast chemoprevention efficacy, and prevention and treatment of osteoporosis as well as improvement of vulvovaginal health are dependent on estrogen receptor activity in the menopause and would be useful targets for treatment of menopausal women, for breast cancer patients and those with genetic predisposition to cancer syndromes who may undergo prophylactic surgeries or face decades of premature menopause and hypoestrogenism. To understand clinician awareness, we conducted an online internet survey to assess the current treatment practices for the use of SERMS for postmenopausal patients, specifically concerning the symptoms of osteoporosis/osteopenia and vulvovaginal atrophy (VVA). Methods: A self-administered Internet survey was conducted for physicians who were potential prescribes of SERMS. One hundred and eight (n=108) physicians were included (OB/GYN n= 53; PCP n= 55). The eligibility criteria included: Primary specialty of OB/GYN or Gynecology for “OB/GYNs,” Family Practice, General Practice or Internal Medicine. Physician participants had at least two and not more than 30 years of practice experience. Clinicians were currently in a community-based practice and were known to treat a minimum number of postmenopausal patients per month for both osteopenia/osteoporosis and vulvovaginal atrophy (VVA). Results: Physicians in this study saw an average of 100-250 postmenopausal patients per month. Although not statistically significant, OB/GYNs reported a higher monthly average volume of postmenopausal patients (186 patients) versus PCPs (140 patients.) SERMs were prescribed on average for a small percentage of patients though physicians anticipated that this would increase in the future. Nearly half of the physicians (48%) reported that the number of their postmenopausal patients who are receiving prescriptions for medications for prevention of osteoporosis is increasing. A novel SERM under investigation, had features perceived as uniquely favorable by a large majority of clinicians and included: Reducing vertebral fracture by 42% and non-vertebral fracture by 26% (76%), and 80% reduction in incidence of ER+ breast cancers at 5 years (74%), no significant drug-drug interactions (72%), and supported by a 5-year placebo-controlled study (70%). Conclusions: Clinicians are aware of the class of SERMS, use is likely to increase and agree that they may be of therapeutic benefit for menopausal women that have multiple post-menopausal health issues. There was recognition of a triad of concerns and the need for concomitant breast cancer chemoprevention, VVA improvement, and maintenance of bone health. Agents that target the estrogen receptor selectively may meet the goals of many clinicians in at-risk patient populations.

Title: Rolapitant for the prevention of chemotherapy-induced nausea and vomiting in breast cancer patients receiving multiple cycles of emetogenic chemotherapy

Schwartzberg L, Navari R, Arora S, Powers D, Jordan K and Rapoport B. The West Clinic, Memphis, TN; Indiana University School of Medicine - South Bend, South Bend, IN; TESARO, Inc., Waltham, MA; Martin-Luther-University Halle-Wittenberg, Halle, Germany and The Medical Oncology Centre of Rosebank, Johannesburg, South Africa.

Body: Background: Patients (pts) with breast cancer often receive highly emetogenic chemotherapy, such as anthracycline plus cyclophosphamide (AC). Additionally, young age and female gender are risk factors for chemotherapy-induced nausea and vomiting (CINV) in response to emetogenic chemotherapy. We assessed the ability of the long-acting neurokinin-1 receptor antagonist (RA), rolapitant, in the prevention of CINV over multiple cycles in pts with breast cancer.

Methods: This is a post hoc analysis of the prevention of CINV in a subset of pts with breast cancer from 3 similarly-designed, randomized, placebo-controlled phase 3 trials in which pts received a single oral dose of 180 mg rolapitant or placebo before chemotherapy. All pts received an oral 5-HT₃ RA + dexamethasone (active control). The regimens were cisplatin-based (n=36), AC-based (n=681) or other (n=166; carboplatin, cyclophosphamide, etc). Pts who completed cycle 1 could continue the same antiemetic treatment in multiple cycles. Endpoints for cycle 1 of chemotherapy included complete response (CR; no emesis and no use of rescue medication) and no emesis, and no nausea (maximum visual analogue scale [VAS] <5 mm), in the overall (0–120 h), acute (<24 h), and delayed (>24–120 h) phases. On days 6-8 of each subsequent chemotherapy cycle, pts self-reported the incidence of emesis or nausea interfering with normal daily life.

Results: In cycle 1, CR in both the overall (62.9% rolapitant, 55.1% control; p=0.018) and delayed (66.7% rolapitant, 59.7% control; p=0.032) phases were higher with rolapitant vs control. Rolapitant also improved no emesis rates in the overall (74.4% rolapitant, 62.6% control; p<0.001) and delayed (77.2% rolapitant, 68.5% control; p=0.004) phases. Although less pts were available for follow up over multiple cycles, a numerically greater proportion of rolapitant-treated pts than control pts reported no emesis (cycles 2-6) and no interfering nausea (cycles 2-5) (table). The incidence of treatment-emergent adverse events (TEAEs) was similar for rolapitant (85.2%) and control (83.2%) during cycles 1-6. The most common TEAEs occurred at comparable rates in the rolapitant and control arms: fatigue (28.5% and 29.4%, respectively), alopecia (28.5% and 31.2%, respectively), and constipation (20.0% and 20.9%, respectively).

Conclusions: Rolapitant added to 5-HT₃ RA and dexamethasone therapy improved CINV control and was safe and well-tolerated in pts with breast cancer receiving multiple cycles of emetogenic chemotherapy, mostly AC and carboplatin, historically a high-risk population for CINV.

* Unstratified Cochran-Mantel-Haenszel test for between rolapitant and control difference in response rate.
Title: Do patients and nurses outside clinical trial prefer subcutaneous trastuzumab over conventional intravenous infusion? 
Instituto Oncologico Nacional experience

Castillo-Fernandez O, Cabreja A, Arauz E, Bellido D, Lim M, Lopez R and Montano L. Instituto Oncologico Nacional, Panama, Panama and Centro Oncologico de Panama, Panama, Panama.

Body: Background
In the PrefHer study, subcutaneous administration of trastuzumab was preferred over intravenous administration (iv). In 2014 our hospital approved subcutaneous (sc) trastuzumab for use in patients with early or metastatic Her 2 positive breast cancer. The aim of this study was to evaluate patients (pts) and nurses’s preferences in our institution.

Methods
Patients with Her2 positive breast cancer and nurses who had received or administered both sc and iv trastuzumab were interviewed to evaluate their preference. Preference for sc was compared with a linear chi squared test.

Results
55 pts were interviewed. Median age was 53 years (30-83). 30 patients in adjuvant/neoad setting and 25 pts in the palliative setting. 41 pts (74.5%) preferred sc 95% CI (63-86) , 3 pts (5.5%) preferred iv 95% CI (-0.5-11.5) and 11 pts (20%) did not have preference 95% CI (9.4-20%) p< 0.0001. 72% of pts considered that sc trastuzumab was more convenient (p<0.0001).

11 nurses experienced with both iv and sc trastuzumab administration answered the questionnaire. Median age 41 years (30-55). 10/11 nurses preferred sc administration, 1/10 indicated no preference. All nurses considered that sc was the most convenient administration method for the patients and is highly recommended. The main reason for patients and nurses preference was that sc administration saved time.

Conclusion
Patients and nurses prefer s.c over iv trastuzumab. Our results are consistent with PrefHer study. Incorporation of sc trastuzumab could improve quality of care in patients with Breast Cancer Her 2 positive.
Title: Body image in women with breast cancer using a scalp cooling system to reduce chemotherapy induced alopecia

Cigler T, Melin SA A, Klein P, Hurvitz SA A, Melisko M, Moore A, Park GD D, Bageman E, Ver Hoeve ES S and Rugo HS S. Weill Cornell Medical College, New York, NY; Wake Forest School of Medicine, Winston Salem, NC; Icahn School of Medicine at Mount Sinai, New York, NY; University of California Los Angeles, Los Angeles, CA; University of California San Francisco Helen Diller Comprehensive Cancer Center, San Francisco, CA; Target Health Inc., New York, NY and Dignitana AB, Lund, Sweden.

Body: Background: Most women consider hair to be an important part of body image. Alopecia is an emotionally traumatic side effect for breast cancer patients undergoing adjuvant chemotherapy. The DigniCap® Scalp Cooling System is the first scalp cooling system cleared by the US Food and Drug Administration to reduce the likelihood of chemotherapy induced alopecia.

Methods: Quality of Life (QOL) data were collected as part of a prospective clinical trial evaluating the clinical performance of scalp cooling in women with early stage BC receiving adjuvant chemotherapy. The study's primary endpoint was hair loss as evaluated by patient self-assessment. Treatment success was defined as ≤ 50% hair loss. QOL was evaluated by the EORTC-QLQ-BR23 (BR23) administered at baseline, last chemotherapy cycle, and one month later. For BR23, 4 response categories were collapsed to 2 categories (Not at all/A little bit and Quite a bit/Very much) for analysis. QOL was compared between those with success vs. failure of scalp cooling.

Results: 101 patients were evaluable for the primary endpoint: Success was seen in 67 (66.3%) pts. QOL at study entry was comparable between pts with scalp cooling success or failure for each item in the BR23 questionnaire. Results reported as percentages of patients in each group who answered either quite a bit or very much to body image-related questions on the BR23 questionnaire are displayed in Table 1.

Conclusions: Women with breast cancer using scalp cooling during chemotherapy who had hair preservation experienced improved quality of life, according to self-assessment of body image, compared to women who had significant hair loss.
Title: Trajectory of patient (Pt) reported physical function (PF) during and after neoadjuvant chemotherapy in the I-SPY 2 trial

Shah M, Jensen R, Yau C, Straehley I, Berry DA A, DeMichele A, Buxton MB B, Hylton NM M, Perlmutter J, Symmans WF Fraser, Tripathy D, Yee D, Wallace A, Kaplan HG G, Clark A, Chien AJ Jo, I-SPY 2 Investigators, Esserman LJ J and Melisko ME E.  University of California, San Francisco, San Francisco, CA;  Georgetown Lombardi Comprehensive Cancer Center, Washington, DC;  Berry Consultants, Austin, TX;  University of Pennsylvania, Philadelphia, PA;  Gemini Group, Ann Arbor, MI;  MD Anderson Cancer Center, Houston, TX;  University of Minnesota, Minneapolis, MN;  University of California, San Diego, San Diego, CA;  Swedish Medica Center, Seattle, WA and  QuantumLeap Healthcare Collaborative, San Francisco, CA.

Body: Background
Patients (pts) receiving chemotherapy for breast cancer experience toxicities impacting short and long-term quality of life (QOL). Within I-SPY 2, a trial adaptively randomizing stage II/III breast cancer pts to neoadjuvant chemotherapy +/- an investigational agent, we are collecting pt reported outcome (PRO) data to understand the impact of investigational agents on QOL. This PRO sub-study provides a unique opportunity to study QOL longitudinally and explore how pt and tumor characteristics, exposure to investigational therapies, and surgical outcome impact QOL.

Methods
Pts enrolled in this trial receive paclitaxel (T) +/- an investigational agent for 12 weeks followed by 4 cycles of doxorubicin and cyclophosphamide (AC). Surveys include the EORTC QLQ-C30 and BR-23, and PROMIS measures for QOL metrics including but not limited to physical function (PF), anxiety, and depression. Surveys are administered pre-chemotherapy to 2 years post-surgery. PF data from the EORTC and PROMIS instruments was analyzed for 238 pts at 5 sites (UCSF, UCSD, U of Pennsylvania, U of Minnesota, and Swedish Cancer Center). 48 pts completed baseline, inter-regimen (between T and AC), pre-operative and post-surgery surveys. Of the 48 pts 32 completed a 6-month follow up (FUP) and 31 completed a 1-year FUP survey. A linear mixed effect model, adjusting for HER2 status and treatment type was used to evaluate changes in PF over time. Sample size is small and statistics are descriptive rather than inferential.

Results
Median age of pts in this analysis was 50 (range 27-72).

Table 1 shows PROMIS & EORTC PF scores in this cohort.

</table>
At baseline, mean PROMIS PF scores were higher than the US average (mean = 50) but declined as expected throughout treatment. HER2+ patients experienced a similar degree of recovery as HER2- pts post-surgery despite adjuvant treatment with Herceptin. Analysis of post-operative PROMIS PF indicated an average score within the U.S. general population (mean =50) but did not return to higher functioning seen at baseline levels (mean 52.5, p-value < 0.05). Analysis of the EORTC PF sub-scale demonstrated a similar trend; however, the baseline and post-operative difference was not significant (p-value=0.15 for both FUP). Finding supports PROMIS PF ability to measure high functioning cancer patients.

**Conclusions:** Among a subset of pts who completed all surveys in the I-SPY 2 QOL substudy, PF did not return to baseline at 6-12 months post-operatively. Through transition to an electronic platform of data collection we hope to improve compliance with survey completion. We continue to analyze other QOL measures and plan to correlate QOL data with treatment arm, adverse events, comorbidities, and response to neoadjuvant treatment.
Title: Sexual functioning among breast cancer survivors and their partners: A pilot study

Makhoul I, Pennisi A, Ochoa D, Klimberg S, Henry-Tillman R, Mack K, Hutchins L and Sherman AAC AC. University of Arkansas for Medical Sciences, Little Rock, AR.

Body: Introduction: Although a number of studies have examined sexual difficulties among breast cancer survivors, few have focused on multiple dimensions of sexual functioning or partners’ attitudes and difficulties. This pilot study sought a more comprehensive examination of sexual functioning among couples after breast cancer.

Methods: Patients who were at least 6 months post-treatment and were involved in committed relationships were recruited during routine clinic visits. Those who accepted to participate in the study were handed by the investigator a stamped self-addressed envelope (to the research office of the Cancer Institute) containing two questionnaires, for the patient and for her partner, and a cancer information sheet. No identifiable information was collected. Thus, the IRB did not require a written consent form.

Results: 200 patients were invited to participate in the study. 120 were in a stable relationship but only 100 accepted to take the envelope. The rest of the patients were single (76) or separated after their diagnosis (4; 2%). 38 couples participated by returning their completed questionnaires; they had been partnered for an average of 34.9 (14.3) years. Mean time since diagnosis was 40.4 (22.4) months, and mean age was 58.1 (11.5). 71.05% were currently receiving hormonal therapy.

Among the patients, 63.2% reported that they were sexually active and, retrospectively, reported that their sexual relationship had been satisfying prior to diagnosis. Currently, however, a large subgroup of patients (30.4%) reported markedly limited sexual satisfaction ("a little bit" or "not at all"). Additionally, 30.4%-to-43.5% reported low sexual interest; 69.6% reported significant problems with lubrication; 52.2% reported limited orgasm; and 30.4%-to-60.9% had difficulties with vaginal discomfort.

Among partners, 67.6% reported that they were sexually active. Their sexual relationships prior to diagnosis were recalled as having been highly satisfying. Currently, none of the sexually active partners reported low satisfaction, though a few (8.3%) had not been active in the past month. Few partners reported low sexual interest (0% - 4.2%). Marked erectile difficulties were reported by 16.7% to 20.8%, and 25.0% reported difficulties with orgasm.

The top 3 factors that patients endorsed as interfering with their current sexual functioning ("quite a bit" or "very much") were (1) pain (41.7%), (2) fatigue (37.5%), and (3) feeling unattractive (20.8%). Fewer participants endorsed concerns about breast tenderness (16.7%), hot flashes (12.5%), surgical scars (12.5%), their partners' reactions (16.7%), and their partners' own sexual difficulties (12.5%). For partners, the factors most commonly viewed as disrupting the sexual relationship were the patient's vaginal dryness (32.0%), the patient's fatigue (28.0%), and the partner's own sexual problems (20.0%).

Conclusion: Our results suggest that a large proportion of breast cancer survivors experience difficulties in multiple dimensions of sexual functioning. Contrary to a popular belief, separation rate after the diagnosis of breast cancer was low (2%) and most patients and their partners identified vaginal dryness and fatigue (not the breast surgery) as the major factors interfering with their sexual functioning.
Title: Randomized trial of exercise intervention vs. usual care for breast cancer patients with aromatase inhibitor to prevent and improve the aromatase inhibitor induced arthralgia

Body: Purpose: Arthralgia sometimes occurs in the breast cancer patients treated with aromatase inhibitors (AIs). It is one of the most important reasons for poor AIs adherence.

Background; The HOPE study previously demonstrated that exercise was effective in improving AI-induced arthralgia in breast cancer patients. However, recruitment to this study was limited to severe cases (Criteria; physically inactive, >6 months AT treatment, >2 months arthralgia). To assess if these findings were more generalizable to all breast cancer contexts we conducted a randomized trial of exercise intervention using wider eligibility criteria that the hope study to assess the impact on AI induced arthralgia in breast cancer patients.

Methods: We examined Japanese breast cancer patients operated at Nahanishi Clinic, Okinawa, Japan. Following the informed consent the patients were randomly assigned to a 3:1 ratio to exercise intervention or usual care. Eligibility criteria included receiving an AI for 0-4 years, no metastases, any arthralgia level and any exercise habits. Following randomization participants could choose from 3 types of exercise including strong (120-150 minutes per week of walking or running), intermediate (gentle calisthenics (daily NIPPON HOSO KYOKAI: NHK broadcast exercise) and weak (going up the stairs- frequency). Arthralgia was assessed using the Brief Pain Inventory (BPI), in which the patients completed a baseline, 6month and 12 month BPI assessment. Primary endpoint was BPI change at 12 months.

Results: Among 227 women screened, we randomized 108 women, with 80 to exercise intervention (46 of strong, 19 of intermediate and 15 of weak) and 28 to usual care. Base line BPI were well balanced between exercise intervention and usual care. Overall exercise intervention reduced BPI scores relative to control. The BPI changes of worst pain, least pain, average pain and pain right now were 0.09, -0.25, -0.14 and 0 for exercise intervention group and 0.21, 0.46, 0.07 and 0.61 for usual care group, respectively. There was a statistically significant difference of AIs adherence between exercise intervention group (99%) and usual care group (92%) (P=0.03).

Conclusion: Exercise intervention tends to improve the AI-induced arthralgia and has a positive effect on AIs adherence.
Title: Can a supervised exercise program compared to usual care prevent aromatase inhibitor-induced musculoskeletal pain in women with breast cancer?

Sanmugarajah J, Allan S, Bagchi R and Laakso E-L. Gold Coast University Hospital, Gold Coast, Queensland, Australia and Menzies Health Institute/Griffith University, Gold Coast, Queensland, Australia.

Body: Background: Aromatase Inhibitors (AIs) are commonly prescribed as hormone therapy for post-menopausal women with estrogen receptor-positive breast cancer. A number of authors have reported AI side effects that include increased risk for developing osteoporosis, joint pain, weight gain and depression. For example, 30-40% of post-menopausal women treated with AIs experience mild to severe joint pain. Although the exact causes of AI-induced joint pain are unknown, the side-effects are most likely due to low estrogen levels in the body. Denysschen et al. (2014) reported a significantly lower number of painful joints, reduced depressive symptoms, increased muscle strength, and improvement in quality of life in patients with AI-induced joint pain after an 8 week upper and lower body resistance exercise program.

Objective: To investigate whether a supervised exercise program could reduce or prevent musculoskeletal pain in patients with breast cancer undergoing AI therapy.

Methods: Twenty participants with breast cancer have thus far been randomised to either: (a) usual care and advice regarding benefits of regular exercise; or (b) usual care + 12 week supervised and home-based exercise program consisting of upper and lower body resistance exercises with self-selected aerobic exercises. Participants accrued 150 mins / week of moderate intensity aerobic exercise at 60-70% HRmax on 5 or more days of each week including 2 supervised sessions / week. Initial exercise intensity is individualized and generally begins at 55% to 60% of HRmax (15 to 30 minutes per session) and progresses to 60% - 70% of HRmax by week 6. Strength training consisted of 2 supervised sessions per week, of two sets of 10 to 12 repetitions of eight different strength exercises at 60% to 75% of estimated one repetition maximum. On at least 3 other days, using the same dosing principles participants executed 4 lower and 4 upper body resistance exercises at home using resistance bands. The primary outcome measures were pain (brief pain inventory; BPI) scores and grip strength (JAMAR dynamometer (kg)) measured at baseline, 3, 6 and 12 months. Two-way repeated ANOVAs were undertaken to evaluate differences between groups and factors.

Results: Mean pain scores across 12 months were largely maintained (p>0.05) for participants undertaking the exercise program compared to control participants whose mean BPI scores progressively increased from baseline through to 12 month follow-up. In the exercise group, mean pain scores increased by one BPI unit between baseline and 12 month follow-up. In the control group, mean pain scores increased by five BPI units between baseline and 12 month follow-up. A clinically significant difference in BPI scores is a change of two or more BPI units (Mease et al, 2011). Grip strength measures were significantly different (P<0.001) between groups at each time point with a trend towards improved grip strength between baseline and 6 months in the exercise group. Grip strength decreased in both groups between 6 and 12 months. Conclusion: By managing physical performance and pain as side effects of AIs, a 12 week supervised exercise program may contribute to preventing non-adherence with or withdrawal from AI therapy.

Title: Sociodemographic and economic factors are essential determinants of weight gain between before and after cancer diagnosis: Results from the prospective population-based NutriNet-Santé cohort

Body: Background: While many cancer patients are affected by weight loss, others tend to gain weight, which may impact prognosis and risk of recurrence and of second cancer. The aim of this prospective study was to investigate weight variation between before and after cancer diagnosis and socio-demographic, economic, lifestyle and clinical factors associated with moderate-to-severe weight gain.

Methods: 1051 incident cases of first primary cancer were diagnosed in the NutriNet-Santé cohort between 2009 and 2015. Weight was prospectively collected every 6 months since subjects’ inclusion (i.e. an average of 2y before diagnosis). Mean weights before and after cancer diagnosis were compared with paired Student's t-test. Factors associated with moderate-to-severe weight gain (≥5% of initial weight) were investigated by multivariable logistic regression.

Results: Weight loss was observed in men (-3.54kg in those who lost weight, p=0.0002) and in colorectal cancer patients (-3.94kg, p=0.0012). Weight gain was observed in breast and skin cancers (2.83kg, p=0.047, and 2.96kg, p=0.03 respectively). Women (OR=1.99[1.18-3.35]), younger patients (OR=1.78[1.05-3.03]), those with lower education (OR=2.17[1.07-4.37]), those with excess weight before diagnosis (OR=1.53[1.02-2.30]) and those who stopped smoking after diagnosis (OR=4.60[2.06-10.25]) were more likely to experience moderate-to-severe weight gain. In breast cancer patients, induced menopause was associated with weight gain (OR=4.12[1.76-9.67]), but no association was detected for tumor characteristics or treatments.

Conclusion: This large prospective cohort provided original results on weight variation between before and after cancer diagnosis, highlighting different weight trajectories. Socio-demographic and economic factors appeared to strongly influence the risk of weight gain, illustrating social inequalities in health.
Background: The rate of obesity is increasing in many countries worldwide. Most populations are not aware of steady weight gain with age. In addition, obesity is increasingly being recognized as a risk factor for breast cancer. Some studies have also demonstrated that weight gain after diagnosis is associated with increased risk for recurrence. The current study was performed to evaluate weight gain in a population of patients seen at a safety net institution. Additionally, patients also gave their opinion on weight loss strategies.

Methods: A retrospective review of all breast cancer patients seen at the county, safety net institution from July 2001 to June 2014 who had at least 2 years of follow up were evaluated for change in weight. For the question on weight loss strategies, all patients from May 2014 to May 2015 were included. Sociodemographic, clinical, and treatment variables were evaluated.

Results: From July 2001 to June 2014, 225 breast cancer patients had follow up prior to January 2013. Of these patients 59% gained weight after their diagnosis of breast cancer. Overall these patients gained an average of 2 kg after their diagnosis. Starting in January 2013, patients were given a simple message, “avoiding gaining weight” after their diagnosis. For 115 patients with follow up after January 2013, only 35% gained weight and on average, this group of patient lost 4 kg from diagnosis. Patients who initially gained weight were provided with basic weight loss strategies.

From May 2014 to May 2015, 1198 consecutive patients were seen. The average age was 45 years. 12% were non-Hispanic White. Only 30% of patients stated that their primary care provider discussed weight maintenance or weight loss as part of their routine health care. 40% of patients did feel that a permanent change was necessary to facilitate weight loss. However, fewer than half (44%) the patients felt that exercise was necessary. Dietary beliefs were varied, with the most commonly held belief was that vegetarian/vegan diet was necessary (28%). Patients rarely cited commonly recommended weight loss strategies: lower caloric intake (9%), eat frequently (0.3%), adequate fiber (0.1%), adequate protein (0.6%), enough sleep (0.1%), don't eat late (0.1%), no fast food (2%), avoid soda (1%), drink more water (1%). 6% of patients felt a low/no carbohydrate diet was important. By contrast, older strategies or popular ideas: low fat (8%), no flour/wheat/gluten (4%) were also felt to be important. 7.3% stated they did not know any strategy. 5% patients recommended stopping eating altogether to lose weight.

Conclusions: Similar to population wide data, breast cancer patients treated at a safety net institution tend to gain weight with follow up. Also similar to most populations, the population was not aware of recommended weight loss strategies and most do not feel that exercise is an important component of weight maintenance. As with the rest of the US population significant effort will be necessary to help patients avoid weight gain after diagnosis. Making patients aware of their weight may help patients avoid gaining weight.
Title: Abstract Withdrawn
2016 San Antonio Breast Cancer Symposium

Publication Number: P5-13-04

Title: Voice of cancer patients: Analysis of patient concerns regarding pregnancy and fertility preservation in patients with breast cancer

Aggarwal S, Sharma R, Sharma R, Gupta A, singh D and Aggarwal A. Santa Clara Valley Medical Center, San Jose, CA; Scry Analytics, San Jose, CA and Scry Analytics inc, Gurgon, Haryana, India.

Body: Breast cancer accounts for one third of all cancers seen in reproductive-age women. Adjuvant chemotherapy regimens used for treatment commonly affect fertility and cause premature ovarian failure. Fertility preservation in young cancer survivors is recognized as a key survivorship issue by the American Society of Clinical Oncology and the American Society of Reproductive Medicine. Many patients share their experiences in online forums, which contain millions of freely shared messages that can be used to analyze concerns regarding pregnancy and fertility preservation. However, this data is unstructured and difficult to analyze. We organize it using methods from Big Data Science (BDS) and analyze it by creating a Decision Support System (DSS) and an interface that can be used by patients and by providers to understand concerns of these patients.

Method:
We collected 5.8 million unique messages (by 170,000 users) from 20 unrestricted breast cancer forums that provide clinically relevant information. We next built custom ontologies for breast cancer, treatment, pregnancy and fertility and supportive therapies. We then created a DSS using methods from BDS, including topic modeling, information retrieval, and natural language processing to extract relevant information from these messages.

To use this system, a user provides disease-related parameters, key questions and the treatment. The DSS then gives messages discussing a similar cohort of patients that have similar parameters and are going through similar treatments.

Results:
Of 170,000 patients, only 5,109 patients reported their age and 1,604 patients reported their age below 45 years. 2,378 patients posted 6,377 messages discussing pregnancy and fertility related issues during Breast-Cancer treatment, and of these, 907 reported their age below 45.

Their specific concerns included:
· Does pregnancy increase the risk of recurrence (31 messages from 24 patients)
· Chances of successful pregnancy in patients who are 30 to 39 years old
· Risk of birth and genetic defects (23 messages from 21 patients)

Fertility options being discussed:
· Freezing embryos, eggs, or ovarian tissues. (169 messages from 138 patients)
· Artificial Insemination, hormone assisted pregnancy, or ovarian stimulation- in vitro fertilization (55 messages from 43 patients)
· Use of GNRH to preserve fertility during chemo with Lupron (291 messages) and Zolodex (391 messages)

Other findings include:
· 893 messages talked about stopping tamoxifen early, mostly within first 1.5 to 3 years so as to try the pregnancy option and 116 patients said that they stopped tamoxifen early.
· 83 patients talked about a successful pregnancy. Only 40 patients discussed getting fertility experts involved early.

Conclusion:
· This interactive system reliably provides meaningful insights from patient’s point of view to their treatment, their concerns, and suggestions for supportive therapy. It also gives insight into unmet needs where more resources and research should be focused.
· Fertility preservation is a major concern in pre-menopausal patients. It should be addressed early on to prevent patients taking harmful decisions such as cutting short their hormonal therapy.
· Fertility counseling seems to be underutilized.
**Title:** Effect of aromatase inhibitor (AI) therapy on sleep and activity patterns in early stage breast cancer

Bhave MA A, Kidwell K, Lyden AK K, Alsamarraie C and Henry NL. University of Michigan, Ann Arbor, MI.

**Body:**

**Background:** AIs are commonly used for treatment of postmenopausal women with hormone receptor-positive breast cancer for 5-10 years. However, women often experience side effects including musculoskeletal pain and sleep disturbances that lead to treatment discontinuation and worse healthcare-related outcomes. There is a need to understand the impact of adjuvant AI therapy on sleep and activity patterns in treated patients and associations with treatment adherence. This study examines objective and subjective changes in sleep patterns and daytime function in patients starting AI therapy using actigraphy and questionnaires.

**Methods:** 49 postmenopausal women with hormone receptor-positive breast cancer who completed local surgery and chemotherapy and were planning to start AI therapy were enrolled. Patients completed 10 consecutive days of actigraphy and validated questionnaires to assess pain, sleep quality, fatigue and physical function at baseline and after three months of AI therapy. Changes in actigraphy parameters after 3 months of AI therapy were examined using paired T-tests and associations between actigraphy measures and patient-reported outcomes were examined using Pearson's correlations.

**Results:** 42 patients completed the baseline assessment and 22 patients completed the 3 month assessment. 20 patients were excluded due to incomplete actigraphy data (n=3), discontinuation of AI therapy (n=5) or withdrawal from the study per patient preference (n=12) prior to the 3 month assessment. Total 24 hour activity, average activity per minute and maximum activity over a 24 hour period worsened after 3 months of AI therapy (all p-values <0.05).

Changes in actigraphy variables and questionnaires after 3 months of AI therapy

*p-value from t-test

There was a trend towards worse sleep efficiency after 3 months. Patient-reported physical function also decreased after 3 months of AI therapy (p-value <0.05), but pain severity remained unchanged. Worsening patient-reported fatigue after 3 months of AI treatment correlated to a decrease in average activity per minute (r=-0.55, p-value <0.05) and maximum activity over a 24 hour period (r=-0.61, p-value <0.05).

**Conclusions:** Daytime activity and sleep patterns are negatively affected by AI therapy and are associated with worsening fatigue. Future research is needed to better understand the relationship between fatigue and daytime activity, which may lead to interventions to improve tolerance and adherence to AI therapy.
Title: Factors associated with follow up medical care among women with early stage breast cancer

Hershman DL L, Quyyumi F, Accordino MK K, Buono DL L, Neugut AI I, Hillyer GC C and Wright JD D. Columbia University Medical Center, New York, NY.

Body: Introduction: In patients with early stage breast cancer treated with curative intent, optimal follow-up guidelines vary widely among national organizations. NCCN guidelines suggest patients should be followed by a medical oncologist (MO) every 3-6 months and by a radiation oncologist (RO) every 6-12 months for the first 5 years. These recommendations are not evidence based and have an unknown effect on cancer outcomes. We sought to evaluate the patterns of follow-up care and predictors of discontinuation of follow-up care.

Methods: Using the Surveillance, Epidemiology, and End Results (SEER)-Medicare linked dataset, we evaluated patients diagnosed with stage I and II breast cancer who underwent surgery from 2002-2007 with follow-up to 2012. Patients who died in the 5-year period following diagnosis were excluded. We evaluated patterns of follow-up visits for the 5 years after diagnosis among surgeon, MO and RO. We defined discontinuation of follow-up care as >12 months without a visit claim from any of the three providers. We performed a Cox-proportional hazards multivariate analysis to determine factors associated with discontinuation of follow-up care. Patients were censored if a new cancer was diagnosed.

Results: A total of 35,484 stage I and II breast cancer patients were included in the analysis. In addition to the surgeon, 77.5% saw a MO, and 57.8% saw RO in the first year. The mean number of total physician appointments for years 1-5 were 9.4, 3.3, 2.4, 2.0 and 1.7, respectively. During the 5 years, 13,908 (39.6%) patients discontinued follow-up visits. The discontinuation rate averaged about 12% per year for years 2-5. Discontinuing physician visits increased with increasing age. Patients who saw all 3 physicians in year 1 were less likely to discontinue follow-up visits (OR = 0.54, 0.51-0.57). Patients were more likely to discontinue physician visits if they were hormone receptor negative (HR = 1.41, 1.33-1.49), were black (HR = 1.14, 1.06-1.22) or Hispanic (HR = 1.36, 1.17-1.58) compared to white, lived in a rural as opposed to urban setting (HR = 1.12, 1.05-1.18), were unmarried (HR = 1.16, 1.12-1.20), had a higher comorbidity score (HR = 1.15, 1.10-1.21), or were in a lower SES quintile (HR = 1.08, 1.02-1.15). Women who had a mastectomy (vs lumpectomy) (HR = 0.83, 0.80-0.87) and those who were receiving chemotherapy (HR = 0.55, 0.52-0.59) or radiation therapy (OR = 0.60, 0.57-0.62) were less likely to discontinue physician visits.

Conclusions: Clinical practice guidelines for surveillance of breast cancer after primary treatment are based on expert opinion and have an unclear effect on long-term outcomes. Coordination of follow-up care may reduce discontinuation. More research is needed to determine the optimal follow-up for maintaining adherence to therapy, reducing over-testing and encouraging secondary cancer screening guidelines.
Conditional disease-free survival among patients with breast cancer

Background: Conditional disease-free survival (CDFS) reflects changes over time. Because traditional disease-free survival (DFS) is estimated from the date of diagnosis, it is limited in the ability to predict risk of recurrence in patients who have been disease free. In this study, we determined CDFS of breast cancer patients and estimated the prognostic factors for DFS.

Method: We retrospectively reviewed clinical data of 7587 consecutive patients who underwent curative surgery for breast cancer between January 2004 and December 2013 at Samsung Medical Center. Univariate and multivariate analyses were performed to identify risk factors for DFS, which was computed using the Kaplan–Meier method. CDFS rates were based on cumulative DFS estimates.

Results: Median follow-up duration was 20.44 months. Three-year DFS was 93.46 percent at baseline. Three-year CDFS survival estimates for patients who had been disease free for 1, 2, 3, 4 and 5 years after treatment were calculated as 92.84, 92.37, 93.03, 89.41, and 79.64 percent, respectively. Three-year CDFS increased continuously each year after 1 year of DFS in hormone receptor (HR)-negative patients but decreased each year in HR-positive patients.

Conclusion: In HR-positive patients who are disease free after 3 years, continuous care including surveillance and metastases workup should be considered, although this is not recommended in the current guidelines. On the other hand, the social costs may be reduced in HR-negative patients by extending the surveillance interval. Further studies are needed to identify indicators of DFS prognosis in breast cancer patients.
Title: The perception of chronic pain among breast cancer survivors

Bao T, Seluzicki C, Li Q and Mao J. Memorial Sloan Kettering Cancer Center, New York, NY and Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA.

Body: Introduction: Breast cancer treatments may result in acute pain that, if untreated or undertreated, may lead to chronic pain. Twenty to thirty percent of patients who undergo mastectomy experience post-mastectomy pain syndrome, and up to 50% of breast cancer survivors taking aromatase inhibitors (AI) report aromatase inhibitor associated arthralgia (AIAA). The rates, experiences, and risk factors of the effects of breast cancer treatment on breast cancer survivors' perceptions of chronic pain are not well defined.

Methods: We conducted a cross-sectional survey among postmenopausal, hormone receptor-positive, breast cancer survivors who were currently taking or had previously taken an AI. The main outcome variable was the patient's perception of living with chronic pain. Variables including breast cancer treatment, socioeconomic and clinical factors, symptom burden, pain (measured by the Brief Pain Inventory [BPI]), and pain-related coping (measured by the Pain Catastrophizing Scale [PCS]) were measured. Univariate and multivariate logistic analyses were performed to identify the risk factors associated with patients' perceptions of living with chronic pain.

Results: Among 561 participants, 62 (11.1%) reported that they perceived themselves as living with chronic pain prior to their breast cancer diagnosis and 172 (30.8%) reported living with chronic pain during the past 6 months at the time of the survey. Compared with patients who did not perceive chronic pain, patients with the perception of chronic pain had significantly higher pain severity (4.15±0.17 vs. 1.54±0.09) and interference (3.47±0.2 vs. 0.97±0.08); higher pain medication usage (percentage of patients taking at least one pain medication over the past 7 days: 85.47% vs. 57.36%); and higher levels of negative coping with pain, including rumination (4.08±0.31 vs. 2.28±0.16), magnification (2.27±0.2 vs. 1.15±0.08), and helplessness (4.63±0.37 vs. 1.64±0.13). Among participants, 369 (65.78%) reported taking at least one pain medication over the past 7 days. In a multivariate analysis, age (<56 or >70), higher BMI (>30), prior chemotherapy, currently experiencing AIAA, and the presence of chronic pain before cancer diagnosis were identified as risk factors associated with the perception of living with chronic pain.

Conclusion: One in three breast cancer survivors considered themselves to be living with chronic pain, and two-thirds developed such perceptions following their cancer diagnosis. Both chemotherapy and AI use were risk factors for perceptions of chronic pain. Those women who had chronic pain experienced greater pain severity, daily interference, and more negative coping. Better understanding of the risk factors and symptom burden associated with chronic pain perceptions among this population may allow for more targeted interventions to reduce chronic pain and its negative sequelae, including premature termination of AI treatment.
Title: Development and implementation of a patient-centered, nurse practitioner-led survivorship intervention for breast cancer

Post KE E, Moy B, Furlani CM M, Smith BL L, Strand EA A, Taghian AG G and Jeffrey P. Massachusetts General Hospital, Boston, MA.

Body: Background: Despite a call for action to improve survivorship care, there is no consensus about the optimal model of care delivery. Challenges include time and resources required for an independent survivorship clinic and conflicting evidence regarding the value of survivorship care plans (SCP). In this context, we sought to develop and evaluate the feasibility of a model of nurse practitioner (NP) led survivorship visits (“bridge visits”) within the breast cancer clinic following completion of initial therapy.

Methods: Patients received a NP-led Survivorship Bridge visit (NPSBV) following treatment for early stage breast cancer. Using an embedded care design, oncology NPs met with patients within six months after treatment and collaborated to create a SCP. We conducted a cross-sectional self-administered paper survey evaluating patient satisfaction with the NPSBV and overall care and a parallel survey of patients presenting for routine follow-up as a control population.

Feasibility was defined as greater than 75% NPSBV attendance rate and no difference in satisfaction with care compared to control patients. Differences between groups were assessed with chi-square test and two-tailed p value at 0.05 percent.

Results/Conclusion: Overall, 117 of 166 surveys were returned for a 71% response rate (RR). Among the NPSBV patients, 72 of 109 surveys were returned (66% RR). Of the control patients, 45 of 57 surveys were returned (79% RR). 64% of NPSBV patients were aged 55 or older, 96% were White, 4% were Asian and 1% identified as Hispanic or Latino. In the control group, 50% were aged 55 or older, 83% were White, 9% Black, 6% Asian, 1% other and 2% identified as Hispanic or Latino.

Satisfaction with care was high for both groups. 95% of participants reported that their providers always had respect for what they had to say, 94% reported that providers always spent enough time with them and 94% reported that they always trusted their providers with their medical care. NPSBV patients were more likely to report that their team “always” cared as much as they do about their health compared to control patients (91% vs. 80%, p = .0060). There were no other significant differences between groups.

The NPSBV met feasibility with a 99% attendance rate and had high acceptability and satisfaction rates. 94% reported that the NPSBV provided easy to understand information. 94% reported that the NPSBV helped to explain the follow up plan, 97% reported it provided helpful information on lifestyle/wellness and 99% reported that they would recommend the NPSBV to other patients. However, 4% felt that their emotional/spiritual needs were not met by the NPSBV and 14% felt that their emotional/spiritual needs were only somewhat met. Further, 18% felt that the NPSBV only somewhat resolved baseline concerns regarding breast cancer survivorship care (BCSC).

Implications: A patient-centered NPSBV for breast cancer survivors is feasible and associated with high patient satisfaction. Findings will guide the refinement and implementation of this embedded care design for BCSC delivery. Future studies should evaluate how survivorship interventions can impact baseline concerns and how best to tailor survivorship interventions to each individual.
A patient centered intervention for adaptation of cancer risk reduction guidelines in breast cancer survivors

Thomas PS S, Klimitchek A, Nelson B, Damani S and Bevers TB B. University of Texas MD Anderson Cancer Center, Houston, TX.

Background: Cancer survivors are susceptible to cancer recurrence and other cancers and this is an opportune time to focus on cancer prevention. The American Institute of Cancer Research (AICR) and the American Cancer Society estimate that modifications to the behaviors of diet and physical activity in addition to maintaining a normal body mass index (BMI) can help reduce cancer incidence by one third. The AICR and the American College of Sports Medicine (ACSM) have established guidelines on nutrition and physical activity respectively for cancer risk reduction. Cancer patients' transition to survivorship is an ideal time for them to make lifestyle modifications and adopt these guidelines. Although studies have evaluated structured exercise regimens and nutritional interventions, data is lacking on how to best achieve long term lifestyle changes in this population. By introducing a patient-centered intervention that utilizes motivational interviewing to our breast cancer survivors, we plan to increase the rate of adherence to the AICR and ACSM guidelines through tailored counseling focused on patient-driven lifestyle modifications.

Methods: Breast cancer survivors 5 years out from their diagnosis seen in the survivorship clinic were also scheduled to be seen by a health education specialist (HES) for a baseline visit. One year follow up visits were scheduled with the HES for reassessment of their nutrition and physical activity goals. All patients completed a survey of questions assessing their adherence to the nutritional and physical activity guidelines on cancer risk reduction at baseline and at 1 year follow up visit. Anthropometric measures including height, weight, BMI, pulse, respirations, and blood pressure were collected at each visit with their provider. Baseline demographic data was collected on all participants including age, race/ethnicity, cancer stage, previous cancer treatment(s), and comorbid conditions. Frequency of interactions (i.e clinic visit, telephone call, or secure message) with the HES were extracted from the medical record.

Results: From October 6, 2014 to May 31, 2016, 200 breast cancer survivors were seen in the survivorship clinic and by a HES. Fifty women who completed a baseline and 1 year follow up survey were selected to assess their adherence to the AICR and ACSM guidelines on cancer risk reduction. Sixty percent of patients decreased their BMI, 5% maintained their BMI, and 35% had an increase in BMI after one year follow up. There was an increase in the percentage of patients adhering to all of the guidelines after one year of follow up in comparison to baseline. There were notable increases in adherence to physical activity guidelines with 24% of survivors achieving at least 150 minutes of moderate exercise each week at baseline assessment and 34% of survivors meeting this guideline at the 1 year follow up visit.

Discussion: Through our intervention with a HES in our survivorship clinic, we were able to see trends toward increased adherence to the AICR and ACSM guidelines. Further analysis is ongoing to assess the frequency of interactions with the HES and their adherence to the guidelines. This analysis will give us a better understanding of the ideal target population for this intervention.
Publication Number: P5-13-12

Title: Symptom burden, unmet need for assistance, and psychosocial adaptation among longer term breast cancer survivors

Body: Introduction:
Advances have improved survival among breast cancer (BC) patients and 89% can expect >5 year survival. The price for this survival, however, may be physical and psychosocial symptoms that persist many years into the survivorship trajectory. Unmet needs for symptom management and the relationships between unmet needs, symptom burden, and psychosocial adaptation remain unclear. We examined these relationships among longer term BC survivors.

Method:
Eligibility included non-metastatic BC survivors diagnosed > 3 years prior and attendance at a survivorship-focused appointment. Nineteen common symptoms of disease and treatment were evaluated and participants reported unmet need for assistance for each symptom they experienced. Psychosocial adaptation was assessed through the Hospital Anxiety and Depression Scale (HADS).

Results:
103 primarily white (72%), middle aged (M=62.7 yrs) BC survivors were recruited. Participants were, on average, 11.4 yrs from diagnosis and most (78.2%) reported Stage I or II BC. Participants reported an average of 9.2 symptoms, most commonly fatigue (67%), joint pain (66%), weight gain (60%), decreased sexual drive (55%), and insomnia (52%). Participants reported an average of 2.8 unmet needs for assistance with symptoms, most commonly joint pain (29%), fatigue (25%), weight gain (23%), and difficulty with memory (21%). Overall levels of depressive (M=2.45) and anxiety (M=4.89) symptoms were low, and elevated depressive and anxiety symptoms were reported by 3% and 18% of the sample, respectively. Number of symptoms and anxiety were unrelated to any demographic, disease or treatment variables. Depressive symptoms and unmet needs were related younger age (p < .05) and depressive symptoms were further related to not having received radiotherapy (p < .05). Number of symptoms experienced and unmet needs were moderately related to both depressive (all r > 0.49, p < .001) and anxiety symptoms (all r > 0.31, p < .01).

Conclusion:
Among long term BC survivors symptoms are common, while unmet need and symptoms of anxiety and depression are more modest. However, both symptoms and unmet need are associated with symptoms of depression and anxiety and represent a potentially missed opportunity for improving outcomes among BC survivors.
Title: Enhancing compliance with national nutrition recommendations in breast cancer survivors. Experience in an underprivileged community

Zelek L, Festa A, Bodere C and Morello S. Ac'Santé93, Bobigny, France and Avicenne Hospital, AP-HP, Bobigny, France.

Body: BACKGROUND: To enhance compliance with national nutrition recommendations in breast cancer survivors (BCS), a 3-year program granted by the Regional Health Authority began in 2013 in an area (Seine-Saint-Denis, SSD) which is among the poorest in France.

PATIENTS AND METHODS: Ac'Santé 93 is a non-profit organization whose aim is to provide supportive care, health education and individualized assistance to patients and families, and to facilitate timely access to quality medical and psychosocial care. Vulnerability was evaluated using an 11-item standardized score (EPICES) previously investigated by French Health Examination Centers. This score is more strongly related to health status than the administrative classification of poverty (Sass, Sante Publique 2006). Vulnerability was defined by a score >30 and considered as severe when >40. Given the high level of poverty in the area and the incidence of financial difficulties in cancer survivors, a particular attention was paid to comparing the costs of different foods in order to promote affordable dietary changes. Between March 2013 and December 2015, 109 BCS were enrolled in a 3-month education program including 3 sessions of a professionally led support group (with dieticians and social workers).

RESULTS: Ten BCS were lost for follow-up before the end of the program; 54 BCS attended all the sessions. Mean age was 52. Median vulnerability score was 51.8 (0-93.48) and 59% of patients had a score >30. Dietary intakes were assessed at baseline, and 1 and 6 mos. after the last session. At 1 mo. 65% BCS had knowledge of healthy dietary choices and 63% were ready to translate it into practice. Of note, 47% BCS decided to enroll in a tailored 1-year physical activity program or planned to do it, although it was not the aim of the study. At 6 mos. 52% of BCS still had knowledge of healthy diet and 49% of turned it into practice. However, only 12% were still practicing physical activity. Barriers were reported in 67% BCS and included asthenia or other treatment side effects (40%), anxiety or depression (27%), reluctance of relatives (20%), social isolation (20%) or cost (18%). Semi-directive interviews revealed unexpected benefits from this program such as empowerment, socialization or improvement of body image.

CONCLUSION: A short-term dietary intervention is feasible in vulnerable BCS living in an underserved area and improves adherence to higher quality diet in a meaningful number of patients. In spite of the attention paid to the affordability of dietary modifications, numerous barriers still exist in this population, the main one being treatment related side effects, including fatigue. Furthermore, compliance to a tailored physical activity program spontaneously decreases over time.

**Title:** Factors associated with multidisciplinary care in the management of early stage breast cancer

Quyyumi F, Accordion MK K, Buono DL L, Neugut AI I, Hillyer GC C, Wright JD D and Hershman DL L. Columbia University Medical Center, New York, NY.

**Body:**

**Introduction:** In patients with early stage breast cancer (BC) treated with curative intent, multidisciplinary teams (MDT) have emerged as a way to involve a wide range of specialists and encourage effective communication to formulate an optimal treatment strategy for patients. We sought to evaluate the frequency and predictors of MDT evaluation in patients with BC.

**Methods:** We used the Surveillance, Epidemiology, and End Results (SEER)-Medicare linked dataset to evaluate patients diagnosed with stages I and II breast cancer who underwent primary surgery from 2002-2007 and were followed through 2012. We evaluated claims for outpatient visits and characterized the treating physician as a surgeon, radiation oncologist (RO) or medical oncologist (MO). We defined MDT as having seen a physician in each of the three specialties within 12 months of diagnosis. We used multivariable logistic regression to evaluate factors associated with MDT.

**Results:** A total of 35,484 stage I and II breast cancer patients were included in the analysis. Within the first year, 77.5% visited a medical oncologist, 57.8% visited a radiation oncologist, and 47% of women were seen by all 3 specialists. Prior to surgery, 4.9% of patients were seen by all 3 physicians, with 14.8% seen by a MO and 16.4% seen by a RO in addition to the surgeon. Evaluation by a MDT was more frequent in women who had a lumpectomy vs mastectomy (57.1% vs 28.4%, p<0.0001), Caucasian race as opposed to black and Hispanic (47.4% vs 42.1% vs 37.4%, p<0.0001), those that lived in an urban setting versus rural (48.1% vs 36.25%, p<0.0001), and those that were married versus unmarried (50.8% vs 43.1%, p<0.0001). As age increased, the number of patients who saw all three physicians decreased. As socioeconomic status improved, more patients saw all three physicians. In a multivariate model, evaluation by a MDT was higher in patients with Stage II disease (OR [95% CI] = 1.10 [1.04-1.18]), diagnosed in 2006-2007 (as compared to 2002-2005) (OR = 1.73 [1.63-1.85]), and those who received chemotherapy (OR = 1.51 [1.39-1.64]) and was less likely for older women (OR = 0.77 [0.71-0.84]), those who underwent mastectomy (OR = 0.73 [0.68-0.78]), and those in the lowest socioeconomic quintile (OR = 0.88 [0.80-0.97]). Of those seen by all 3 physicians in the first year, 20.4%, 10.1%, 6.1%, and 3.9% were seen by all 3 specialists in years 2, 3, 4 and 5 respectively. Only 2.2% of patients saw all three specialists all five years.

**Conclusions:** Early stage breast cancer patients are evaluated by a medical oncologist, surgeon and radiation oncologist less than 50% of the time in the first year after diagnosis. Prior to surgery, where decision making may be most important, only 5% of patients were evaluated by all three specialties. Further research is needed to determine if MDT improves quality of care delivered, treatment adherence, patient satisfaction or breast cancer survival.
**Title:** Longitudinal patterns of postdiagnosis weight changes according to adjuvant systemic treatments in Korean breast cancer survivors

Lee JW, Min Y, Chung IY, Son BH and Ahn SH. Asan Medical Center, Seoul, Republic of Korea and Gachon University, Incheon, Republic of Korea.

**Body:** The aims of this study were to investigate patterns of postdiagnosis weight changes from diagnosis to within 5 years since diagnosis and determine the association of adjuvant systemic treatments with weight gain or loss in Korean breast cancer survivors.

According to the types of adjuvant systemic therapy, 14540 patients whose body weight data could be retrieved from electronic medical record (EMR) system from January 2004 to December 2013 were divided into (1) no adjuvant therapy group (Gr 1, n = 1209), (2) endocrine therapy alone group (Gr 2, n = 5469), (3) chemotherapy alone group (Gr 3, n = 3122), (4) chemotherapy followed by endocrine therapy group (n = 4505), and (5) no available data group (n = 235). In this study, 9800 patients (Gr 1, 2, and 3) were included and their 5 years of follow up BMI data were analyzed. The numbers of follow up patients whose BMI data were available at 12th, 24th, 36th, 48th, or 60th month since diagnosis were 4908 (4908/9800, 50%), 4765 (4765/9800, 49%), 4745 (4745/9800, 48%), 4191 (4191/9800, 43%), and 4109 (4109/9800, 42%), respectively.

Paired comparisons among mean values of follow up body weights within each adjuvant group showed different longitudinal changing patterns: no statistically significant weight gains or losses in the Gr 1; significant weight loss only at 12 month in the Gr 2 (weight at 12th month - weight at diagnosis, mean ± SD = -0.15 ± 2.9 kg, paired t-test, p=0.01); and significant weight losses consistently at all follow up months with the maximal weight loss at 24th month in the Gr 3 (weight at 24th month - weight at diagnosis, mean ± SD = -0.78 ± 3.5 kg, paired t-test, p < 0.01). Comparisons of estimated body weights at each follow up month between the adjuvant groups (Gr 2 vs. Gr 1 and Gr 3 vs. Gr 1), which were calculated after adjusting two covariates such as initial weight and age at diagnosis, endocrine therapy was not associated with weight gain or loss throughout 5 years since diagnosis (ANCOVA, p > 0.05 at all follow up months), but chemotherapy was related to weight loss significantly emerged from 24th to 48th month since diagnosis (ANCOVA; p >0.05, < 0.001, 0.016, 0.001 and >0.05 at 12th 24th, 36th, 48th, and 60th month, respectively).

Endocrine therapy showed no association with postdiagnosis weight changes, whereas chemotherapy was temporarily associated with postdiagnosis weight loss in Korean breast cancer survivors.

Title: Arthralgia-associated aging perceptions predict adherence to aromatase inhibitors among women with breast cancer

Body: Background: Aromatase inhibitors (AIs) are associated with reduced risk of breast cancer recurrence, yet many women discontinue their treatment prematurely, often due to arthralgia. Empirically, breast cancer survivors who experience AI-associated arthralgia often report that they have aged quickly over a short period of time. Objective: We aimed to determine whether survivors with a heightened sense of aging due to arthralgia were more likely to non-adhere to their AI regimen. Methods: We conducted a prospective cohort study in an urban academic cancer center among post-menopausal women with hormone receptor positive breast cancer who were within the first two years of their aromatase inhibitor therapy. Perceptions of aging due to arthralgia were measured by the previously validated Penn Arthralgia Aging Scale. Non-adherence was defined as interrupting treatment or discontinuing the AI before the prescribed treatment length was over. Trained raters abstracted adherence data from medical charts. We performed Cox proportional hazards regression to evaluate the relationship between perceptions of aging due to arthralgia and time to non-adherence while adjusting for potential confounders. Results: Among 509 participants, most were White (81.2%) and had at least some college education (77.9%). The majority had been prescribed anastrozole (88.0%), followed by letrozole (9.0%), and exemestane (3.0%). During the follow up period, 144 (28.3%) did not adhere to the AIs as originally prescribed. In univariate analysis, women with a heightened sense of aging due to arthralgia were at more than twice the risk of non-adherence compared to women with low levels of aging perceptions (Hazard Ratio [HR], 2.20; 95% CI, 1.50 – 3.21; p < 0.001). After adjusting for arthralgia pain severity, depression, and AI type, aging perceptions remained a statistically significant predictor of adherence (HR, 1.71; 95% CI, 1.10-2.67; p = 0.02). Depression status also uniquely predicted non-adherence risk (HR, 1.63; 95% CI, 1.03 – 2.59; p = 0.04). Arthralgia pain severity, which predicted adherence in univariate analysis, was not a significant predictor in the final model (HR, 1.21; 95% CI, 0.84 – 1.75; p = .30). Conclusions: Breast cancer survivors on AIs who have a heightened sense of aging due to arthralgia are at greater risk of non-adhering to their AI regimen. Interventions are needed to help survivors reduce arthralgia and develop adaptive appraisals of their AI experience to achieve optimal adherence.

**Title:** Simplifying survivorship surveillance

Pories SE E, Myers LE E and Dusenbery KL L. Hoffman Breast Center Mount Auburn Hospital, Cambridge, MA.

**Body:** Breast cancer survivors represent 4 of 10 female cancer survivors in the United States, comprising an estimated 3.1 million women living with breast cancer in the US. Addressing survivors' unique post-treatment needs is critical to providing quality health care. In fact, Survivorship Care Plans are now required for all breast cancer patients by the National Accreditation Program for Breast Centers. To ensure that we meet recommended guidelines and provide comprehensive survivorship care, we have created a computerized treatment summary and developed a unique simple assessment tool to be incorporated at the patient's survivorship visit. The goal is to increase awareness of short and long term side effects post treatment and develop a plan to address the patient's needs. The visits are carried out by the nurse practitioners and average 60 minutes.

Data from the first 20 patients in our new program show that most are age 40-49 (30%), 25% are age 60-69, 20% age 50-59, 20% age 70-79 and 5% age 30-39. The majority of patients (65%) were treated with breast conserving surgery and sentinel node biopsy. Most women who had a mastectomy also had reconstruction (83%). The majority (95%) had lymph nodes removed as part of their cancer surgery and 30% report a sensation of tightness or swelling on the side where lymph nodes were resected. The majority (90%) are receiving hormonal therapy and 40% also had chemotherapy. A majority (75%) reported side effects from hormonal therapy such as hot flashes, joint pain, or vaginal dryness. 15% of patients reported concerns with sexual function or sexual activity. Over a third of patients (35%) felt anxious, nervous, or on edge, 25% of patients reported that they had little interest or pleasure in doing things, 15% felt down, depressed or hopeless. Memory problems were reported by 30% of patients, 25% complained of difficulties multitasking or paying attention and 10% reported their thinking seemed slow. Over half of the patients (55%) reported problems with insomnia, 30% complained that fatigue interfered with their usual activities, 15% had persistent fatigue, and 15% reported excessive sleepiness. 25% complained of ongoing discomfort related to their cancer treatment but only 5% felt the pain interfered with their usual activities. There were no reports of difficulties with activities of daily living. However, 25% had concerns about their body image and appearance since cancer treatment. Most patients (90%) report eating a well-balanced diet and 65% engage in regular physical activity yet 45% of patients are concerned about their weight. Only 5% are smokers, 40% have up to 3 alcoholic beverages a week, 20% have 4-7 drinks a week, 10% drink more than 7 alcoholic beverages a week, and 25% do not drink alcohol at all. Only 50 percent had a recent pap smear, 45% had a recent colonoscopy, 60% had a recent bone density, and 80% see an ophthalmologist regularly. Most patients (60%) did not need referrals for other services, but 5% were sent for mental health services, 10% for consultation with the plastic surgeon, 10% for consultation regarding sexual functioning, 5% for physical therapy, and 5% for social work intervention.

We have had an overwhelmingly positive response from patients to the survivorship visits and will continue to expand this useful and effective program.
Title: The feasibility of nurse intervention to improve and maintain the BMI of breast cancer survivors over 25 to appropriate levels

Arakaki M, Tamaki K, Kamada Y, Uehara K and Gushikawa H. Nahanishi Clinic, Naha, Okinawa, Japan; Nahanishi Clinic, Naha, Okinawa, Japan; Nahanishi Clinic, Naha, Okinawa, Japan; Nahanishi Clinic, Naha, Okinawa, Japan and Nahanishi Clinic, Naha, Okinawa, Japan.

Body: Background: Some studies have shown that women with breast cancer who have a BMI value gain of more than 2.0 kg/m2 after diagnosis have an elevated risk of dying of breast cancer, and likewise breast cancer patients who gained 5 or more kilograms had a higher mortality rate than those who maintained their weight. Therefore it can be said that weight control is important for women with breast cancer.

In addition to the survival benefit, preliminary research suggests that exercise intervention for weight control may also be effective for enhancing the QOL of cancer survivors.

Purpose: We designed an exercise intervention study to assess the feasibility of the intervention in maintaining standard weight and also the effect of the exercise in breast cancer patients.

Patients and methods: Breast cancer patients aged 20 to 75 years, stage I to IIIA, with no metastases, who had completed chemotherapy, with BMI values greater than 25 kg/m2 are eligible for participation. The intervention will be to have the patients do aerobic exercise 150 minutes per week, and assess the BMI and health-related QOL using the care note questionnaire, at baseline, 6 months, and 12 months later for each participant. We are also planning dietary interventions for the patients. We will calculate the actual calorie consumption of each patient and give dietary advice for optimal calorie intake. Patients will be required to record their exercise in a formatted note so we can check the exercise adherence.
Title: Abstract Withdrawn
Title: Triple negative breast cancer - Adjuvant chemotherapy use and survival outcomes in Stage IA disease

Patel AN N, Shi R, Peddi P and Burton GV V. Feist Weiller Cancer Center, Louisiana State University Health Sciences Center, Shreveport, LA.

**Body: Background:** The potential benefit of adjuvant chemotherapy in patients with Stage IA triple negative breast cancer (TNBC) has not been defined. In general, patients with T1a and T1b lesions have not been included in adjuvant chemotherapy trials and the inclusion of T1c tumors has been limited. In this study using National Cancer Data Base (NCDB) we investigated the actual use of adjuvant chemotherapy in Stage IA TNBC patients relative to tumor size (T1a, T1b, T1c) and report their survival outcomes.

**Patients and Methods:** Using NCDB we evaluated a cohort of 13,065 women with TNBC diagnosed between 2010-2012 who had American Joint Committee on Cancer Stage IA (node-negative with pathological T1a, T1b or T1c) tumors. Overall survival (OS) was the primary outcome variable. Based on the tumor size, patients were stratified on receipt of adjuvant chemotherapy or not. Patients were also stratified according to receipt of adjuvant radiation, radiation with boost, or none. Other adjusted variables included: age, race, Charlson comorbidity index, payer status, income, education, distance traveled, treating facility, and treatment delays. Multivariate Cox regression was employed to analyze the effect of adjuvant chemotherapy on overall survival.

**Results:** The mean patient age for the entire cohort was 59.2 years (range 22-90 years), 55.8 years for the chemotherapy group, and 67.8 years for the non-chemotherapy group. There were 1275 T1a, 3197 T1b, and 7729 T1c patients. Tumor size was a very strong predictor of survival. Compared to T1a tumors, HR for death was 1.43 (95% CI: 0.86 – 2.37) for T1b tumors and 3.00 (95% CI: 1.86 – 4.83) for T1c tumors. Out of all T1a, T1b, and T1c tumors in this cohort, 48.1% , 72.6%, and 89.3% of patients received adjuvant chemotherapy respectively. A hazard ratio (HR) of death was 0.42 (95% CI: 0.31 – 0.57) for all patients who received chemotherapy compared to non-chemotherapy group. 4-year OS by tumor size and chemotherapy usage is listed in the table indicating an absolute increase of OS with adjuvant chemotherapy employment. HR for death was 0.90 (CI: 0.62 – 1.31) with use of radiation only and 0.67 (95% CI: 0.53 – 0.85) with use of radiation with boost when compared to no radiation therapy.

</tbody>
</table>

**Conclusion:** NCDB indicated that the majority of patients with Stage IA TNBC received adjuvant chemotherapy, including 48% of patients with T1a lesions. Our data analysis demonstrated a statistically significant 4-year OS benefit in patients with T1b and T1c tumors who received adjuvant chemotherapy compared to those who did not. The survival benefit of adjuvant chemotherapy in patients with T1a tumors, however, did not reach statistical significance. Prospective randomized trials could define the potential benefits of adjuvant chemotherapy in patients with Stage IA TNBC, particularly for those with T1a and T1b tumors.
van Rossum AGH GJ, Oosterkamp HM M, van Werkhoven E, Opdam M, Mandjes IAM AM, van Leeuwen-Stok E, van Tinteren H, Kok M, Imholz ALT LT, Portielje JEA EA, Bos MMEM MEM, van Bochove A, Wesseling J, Rutgers EJ J, Rodenhuis S and Linn SC C. Netherlands Cancer Institute, Amsterdam, Netherlands; Medical Center Haaglanden-Bronovo, The Hague, Netherlands; BOOG Study Center, Amsterdam, Netherlands; Deventer Ziekenhuis, Deventer, Netherlands; HagaZiekenhuis, The Hague, Netherlands; Reinier de Graaf Gasthuis, Delft, Netherlands; Zaans Medical Center, Zaandam, Netherlands and University Medical Center, Utrecht, Netherlands.

Body: Background: Anthracycline-based adjuvant chemotherapy has substantially improved breast cancer survival. Both the addition of taxanes as well as using a dose dense treatment schedule can further ameliorate outcome, but inter-individual differences exist. Here we present the efficacy and toxicity of dose dense scheduled doxorubicin/cyclophosphamide (ddAC) versus docetaxel/doxorubicin/cyclophosphamide (TAC), which is, to our knowledge, the first direct comparison of these treatment regimens.

Methods: In this Dutch, multicenter phase III trial (ISRCTN61893718), patients with pT1-3, pN0-3, M0 breast cancer were randomized between six cycles of either A_{60}C_{600} every 2 weeks or T_{75}A_{50}C_{500} every 3 weeks. All patients received pegfilgrastim. Patients were evaluated for recurrence-free survival (RFS) and overall survival (OS). Survival was compared in a Cox regression analysis and adjusted for known prognostic factors. These factors include age, type of surgery, tumor size, histological grade, ER/PR status, HER2 status, and lymph node status. Adverse events were reported according to the common toxicity criteria (CTCAE version 3.0).

Results: Between 2004 and 2012, 664 patients were enrolled of whom 531 (80%) had node positive disease. At a median follow up of 5 years, OS was 92% in the ddAC treated subgroup and 93% in the TAC treated subgroup (adjusted hazard ratio [HR] 0.75, 95% confidence interval [CI] 0.42-1.34, intention to treat population). Forty-two breast-cancer specific deaths were equally divided over both treatment arms. Similarly, no significant difference in RFS was observed between both treatment groups (adjusted HR 0.85, 95% CI 0.55-1.32). Molecular subtypes were defined by St. Gallen criteria: 548 patients (83%) had estrogen receptor positive disease and 102 patients (15%) triple negative disease. No heterogeneity regarding treatment efficacy was observed in these subtypes. In particular, there was no survival benefit for ddAC or TAC in the triple negative subtype. Both treatment regimens were well tolerated. Whereas anemia was more frequent in ddAC treated patients (19% vs 4.7%; p<0.001), peripheral neuropathy occurred more frequently in TAC treated patients (4.6% vs 14.4%; p<0.001). The frequency of febrile neutropenia was not significantly different between the treatment arms (11% vs 12.5%; n.s.). Six patients developed congestive heart failure: 2 ddAC treated patients, 4 TAC treated patients. One ddAC treated patient and one TAC treated patient were diagnosed with acute myeloid leukemia after study treatment; another patient in the ddAC treatment group developed myelodysplastic syndrome.

Conclusions: At a median follow up of 5 years no significant survival differences were observed between adjuvant ddAC and TAC, in all patients and in molecular subgroups, including triple negative. Our findings are in line with the Oxford overview, which reported no significant differences between taxane-based chemotherapy and more, non-taxane based chemotherapy given in a dose dense schedule. ddAC could be a reasonable alternative for patients with a contra-indication for TAC.

Title: Abstract Withdrawn
Title: Capecitabine in early breast cancer: A meta-analysis of randomized controlled trials

Natori A, Ethier J-L, Amir E and Cescon DW W. Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada and University of Toronto, Toronto, ON, Canada.

Body: Background
Capecitabine is an effective therapy for metastatic breast cancer. Its role in early breast cancer is uncertain due to conflicting data from randomized controlled trials (RCTs).

Methods
PubMed and major conference proceedings were searched to identify RCTs comparing standard chemotherapy (defined as cyclophosphamide/methotrexate/5-fluorouracil, anthracycline-based regimens or anthracycline/taxane combinations) with or without capecitabine in the neo-adjuvant or adjuvant setting. Hazard ratios (HR) for disease-free (DFS) and overall survival (OS), as well as odds ratios (ORs) for safety and tolerability were extracted or calculated and pooled in a meta-analysis. Subgroup analysis compared triple negative breast cancer (TNBC) to non-TNBC and whether capecitabine was given in addition to or in place of standard chemotherapy. Meta-regression was used to explore the influence of TNBC on OS.

Results
Eight studies comprising 9302 patients were included. In unselected patients, capecitabine did not influence DFS (HR 0.99, p=0.93) or OS (HR 0.90, p=0.36). There was a significant difference in DFS when capecitabine was given in addition to, compared to in place of standard treatment (HR 0.92 vs. 1.62, interaction p=0.002). Addition of capecitabine to standard chemotherapy was associated with significantly improved DFS in TNBC vs non-TNBC (HR 0.72 vs. 1.01, interaction p=0.02). Meta-regression confirmed this association with OS (R=-0.967, p=0.007). Capecitabine increased Grade 3/4 diarrhea (OR 2.33, p<0.001) and hand foot syndrome (OR 8.08, p<0.001), and resulted in more frequent treatment discontinuation (OR 3.80, p<0.001).

Conclusion
Adding capecitabine to standard chemotherapy appears to improve DFS and OS in TNBC, but increases adverse events in keeping with its known toxicity profile. Consideration of this treatment is warranted, especially in high-risk patients.
**Title:** The effect of adjuvant chemotherapy in a large consecutive series of ER-pos HER-2 negative early breast cancers

**Body:**

**Background:** The last EBCTCG-overview reported, in general, a significant better breast cancer outcome if adjuvant chemotherapy was added to surgery and endocrine therapy in ER-pos breast cancers, but the precise indication for adjuvant chemotherapy in this population remains controversial. We study the effect of adjuvant chemotherapy on breast cancer outcome in consecutive patients with an ER-pos HER-2 negative breast cancer treated with adjuvant antihormonal therapy.

**Methods:** Data were collected prospectively from consecutive patients with non-metastatic breast cancer that were primary operated between 2000 and 2012 at the University Hospitals Leuven (Belgium). A Propensity Score (PS) weighted analysis was performed to estimate the average treatment effect (ATE). The primary endpoint was recurrence free interval (RFI). Secondary endpoints were distant recurrence free interval (D-RFI) and breast cancer specific survival (BCSS). Covariates used to generate the propensity score and to include in the PS weighted analysis were age at diagnosis, body mass index, tumor size, grade, pN, lymph vessel invasion, PR, and radiotherapy. Cause-specific hazard models were fitted, using death not from breast cancer as competing risk. Treatment heterogeneity was examined by evaluating interactions of each covariate with adjuvant chemotherapy, using the Bonferroni-Holm method to correct for multiple testing.

**Results:** In the total cohort of 5609 patients, 4282 had a hormone sensitive HER-2 neg breast cancer and 4121 (96.2%) of these received adjuvant antihormonal therapy. Adjuvant chemotherapy was given in 1179/4121 patients (29%). Median follow-up was 8.5 years. Due to very strong differences between patients with and without adjuvant chemotherapy, a restricted PS weighted analysis was used according to a recent recommendation in the statistical literature. This analysis is based on 1750 patients with a PS between 0.1 and 0.9. In this group, 807 (46%) received adjuvant chemotherapy, 211 (12%) observed an event for RFI, 167 (10%) for D-RFI, and 108 (6%) for BCSS. Adjuvant chemotherapy was associated with better prognosis: the adjusted cumulative incidence of recurrence within 5 years was 9.7% without and 5.3% with adjuvant chemotherapy. The adjusted hazard ratio for RFI was 0.50 (95% CI 0.33-0.74). There were no strong interactions with adjuvant chemotherapy. Results for D-RFI and BCSS were similar.

**Conclusion:** Based on PS analysis to reduce confounding and chemotherapy indication bias, we observed clear benefit from adjuvant chemotherapy in ER-pos HER-2 negative breast cancers.
Title: Abstract Withdrawn
Title: Adjuvant and neoadjuvant chemotherapy for elderly patients (≥70 years) with early high-risk breast cancer: A retrospective analysis of 116 patients

Servent V, Tresch E, Vuagnat P and Bonneterre J. Centre Oscar Lambret, Lille, France.

Body: Background: adjuvant or neoadjuvant chemotherapy in elderly patients (pts) is currently considered as a toxic treatment and reserved for fit women and high-risk breast cancer; few guidelines are available in this age group. The aim of this study was to evaluate the tolerability of chemotherapy in this patient population. Patients and Methods: We performed a retrospective analysis of the use of adjuvant and neo adjuvant chemotherapy in our Cancer Center in two groups of patients (≥70y-75y and >75y) with early high-risk breast cancer. Between 2009 and 2014, 116 consecutive breast cancer patients (90pts:70-75y and 26pts:75>y: range70-84) received adjuvant or neoadjuvant chemotherapy; all patients had optimal surgery. The chemotherapy regimens were 3 FEC100 (epirubicine 100mg/m2 + 5-fluorouracil and cyclophosphamide 500mg/m2) + 3 docetaxel100mg/m2 or 4 TC( docetaxel 75mg/m2 + cyclophosphamide 600mg/m2). In case of HER2 positive breast cancer (IHC3+ or Sish+), the patients received trastuzumab for one year. The treatment is considered non optimal when there was a decrease in the number of courses or a dose reduction. However Docetaxel75mg/m² after 3 FEC100 was considered acceptable as well as weekly administration. A yearly follow-up was performed after the end of the chemotherapy. The association between clinical data and age group (70-75) or (>75) was analyzed with Khi-2 test or Fisher test. Results Pts > 75y had more ≥ 3 co-morbidities: (38.5% vs 18.9% (p= 0.04), had more frequently triple negative breast (TN) breast cancer (53.8% vs 20% (p=0.001), inflammatory breast cancer (19.2% vs 3.3%) (p=0.014). Pts>75y had less frequently RH+ breast cancer (23.1% vs 61.1% (p=0.001); there was no significant differences for N+ between the two groups. The >75y pts received more frequently growth factors: 57.7% vs 35.6% (p=0.043); they had more often comprehensive geriatric assessment: 42.3% vs 11.1% (p<0.001) and were more often hospitalized (38.5% vs12.2% (p=0.002). There was no differences between the two age groups for Her2 status, SBR histoprognostic grading, grade ≥3 toxicity, 1year and persistent toxicity. One patient died in the group 70y-75y because of sepsis. There was no differences between the age groups in the rate of decrease of chemotherapy dosing. There was a statistical association between co-morbidities and grade ≥3 toxicity (p=0.004), grade≥3 toxicity and hospitalization rate (p<0.001), grade ≥3 toxicity and chemotherapy dosing (p<0.001). Conversely no association was found between chemotherapy dosing and 1 year health status. One year Trastuzumab was well tolerated in both groups. Conclusions: Adjuvant or neo adjuvant chemotherapy for elderly high-risk breast cancer patients is feasible. The >75 years old patients, those with ≥3 co morbidities are especially frail, at risk of toxicity, hospitalization, inadequate chemotherapy. These results questioned about the best tools for survey and the value of geriatric intervention along the treatment.

Title: Luminal A breast cancer: Is it really a “good prognosis” disease? Preliminary results of the GIM-13 - AMBRA study

Body: BACKGROUND

Luminal breast cancer is a highly heterogeneous disease comprising different histologies, gene-expression profiles and mutational patterns, with different clinical behavior and responses rate to systemic treatments. It has been shown that IHC determined ER, PgR, and HER2/neu status largely describe the subgroups when genetic profiling data is unavailable. There is strong evidence from some studies that chemotherapy does not add benefit when compared with endocrine therapy alone in defined subgroups resembling and including luminal A disease. Despite adjuvant endocrine therapy and chemotherapy treatment for patients at high risk of relapse, both early and late relapses still occur, a fact that highlights the unmet medical needs of these patients.

PATIENTS AND METHODS

The AMBRA Study is a longitudinal cohort study, aiming at describing the choice of first and subsequent lines of treatment in HER2-ve ABC pts. Data of 30 consecutive pts per centre at first disease relapse in the years 2012-2015 and treated with chemotherapy (CHT) for the metastatic disease are collected. For the purpose of this analysis, we identified, basing on IHC expression of ER and PgR, all the Luminal A cases in the whole study population registered in the AMBRA Study, with the aim of describing the type of adjuvant therapy, the sites of relapse and the treatment offered as 1\textsuperscript{st}-line therapy.

RESULTS

At the moment of the present preliminary analysis, 747 out of the planned 1200 pts have been enrolled in the main study. 234 cases of Luminal A tumours (31.3%) have been identified. Median age at diagnosis of the primary tumour was 50 years (42-76). Ductal carcinoma was the most frequent histology (68.3%). 148 pts (63.2%) have received CHT as part of their adjuvant treatment. The most used regimens were anthracycline-based therapies (77, 52%), and anthracyclines+taxanes (41, 27.7%). Median Disease Free Interval was 133 months (1-390). At the moment of 1\textsuperscript{st} relapse, a biopsy was done in 134 cases (57.3%) to obtain new biology information: a concordance between primary biology and metastatic one was defined in 84 cases (66.7%), 40 cases lost PgR expression, becoming Luminal B tumors, and 10 cases lost both receptors (TNBC). Main sites of relapse were bone (58.9%), viscera in 50.4% and soft tissue (12.8%). As 1\textsuperscript{st}-line treatment, 162 (69.2%) pts received CHT; the most frequently used CHT were the combination of Paclitaxel+Bevacizumab (36, 22.2%), Single agent CHT was chosen in 66 cases (40.7%), mainly Paclitaxel (33, 20.3%). Among pts treated with CHT as 1\textsuperscript{st}-line, 81 pts (74.3%) received a 2\textsuperscript{nd}-line CHT, as single agent (52, 64.2%; Capecitabine 15, 18.5% Nab-paclitaxel 10, 12.3%).

CONCLUSION

These preliminary results of the GIM 13 - AMBRA Study show that Luminal A tumours have a quite long DFI, but relapse at visceral sites in half of the cases, often requiring the use of a CHT regimen. Despite guide lines recommend the use of single agent sequential CHT, a vast majority of the pts are still treated with a combination regimen.
Title: Weekly doxorubicin and daily oral cyclophosphamide followed by nab-paclitaxel for adjuvant therapy of high-risk localized breast cancer

Cho E, Wu Q, Rubinstein L, Linden H, Gralow J, Specht J, Gadi V and Ellis G. Palo Alto Medical Foundation, Sunnyvale, CA; Seattle Cancer Care Alliance, Seattle, WA; University of Washington, Seattle, WA and Fred Hutchinson Cancer Research Center, Seattle, WA.

Body: BACKGROUND: The addition of taxanes to anthracycline-based adjuvant chemotherapy has improved disease free survival (DFS) in women with high-risk early-stage breast cancer. Many studies have sought to optimize the dose intensity and density of these agents to produce improvements in outcome and tolerability. The purpose of this study was to assess the use of metronomic doxorubicin plus daily oral cyclophosphamide (AC) for 12 weeks followed by nab-paclitaxel (nP) for 12 weeks in this population. Those patients with Her2 positive disease were also given adjuvant trastuzumab.

METHODS: A non-randomized phase II clinical trial was designed to (1) test the DFS at 2 years compared to historical controls, (2) assess dose intensity delivered, (3) assess use of nP in the adjuvant setting, and (4) evaluate toxicities associated with the regimen. Overall survival (OS) was a secondary outcome. The dosing of A was 24mg/m2 IV qweek and C was 60mg/m2 oral daily; nP, 100mg/m2 IV qweek.

RESULTS: Sixty patients were enrolled on the study with a median follow-up of 6 years and a median age of 50 (range 30-69). 58% of patients had node positive disease. Receptor categories included hormone receptor positive (ER positive or PR positive) and HER2 negative (n=24; 40%); ER negative, PR negative, and HER2 negative (triple negative; n=19; 32%); or HER2 positive (n=17; 28%). DFS at 2 years was 93% (1 death, 3 recurrence) and at 6 years was 82%, comparable to historical controls. OS at 2 years and 6 years was 98% and 88%, respectively.

Mean dose intensity was greater than 90% for AC and 88% for nP. Treatment was well-tolerated with the most common grade ≥3 toxicity being neutropenia and a 2% incidence of febrile neutropenia.

CONCLUSIONS: Patients achieved similar DFS to that seen in historical controls with similar rates of adverse events. Since nP dosing was 100 mg/m2, even with 88% dose intensity, the delivered taxane dose is greater than standard weekly paclitaxel. Notably disease control was particularly impressive in the triple negative subtype, which has been shown to benefit from nP over standard paclitaxel in the neoadjuvant setting in the GeparSepto (GBG 69) trial. Metronomic AC followed by nP is a safe, effective option for delivery of adjuvant chemotherapy for high-risk patients.
Title: An estimation of the population survival benefit of first-line chemotherapy and immunotherapy for breast cancer

Delaney GP P, Do V, Ng W and Barton MB B. Collaboration for Cancer Outcomes Research and Evaluation (CCORE), Ingham Institute for Applied Medical Research, Sydney, NSW, Australia; Crown Princess Mary Cancer Centre Westmead, Sydney University, Sydney, NSW, Australia and University of NSW, Sydney, NSW, Australia.

Body: Purpose: Randomized clinical trials describe the benefit of chemo-and immunotherapy for specific breast cancer patients with selected patient and disease characteristics. However, variability in practice occurs despite evidence-based guidelines [1]. The overall survival benefit for the whole population of breast cancer patients in Australia, if evidence-based guidelines for chemo-and immunotherapy were implemented, is unknown. Our study's purpose was to estimate the overall population survival benefit of routinely using evidence-based practice.

Methods and Materials: Decision trees with evidence-based indications for chemotherapy have been previously defined [2]. Each branch corresponds to a specific cohort who have, or do not have, defined indications for chemotherapy and/or immunotherapy. Chemo-and immunotherapy benefit was defined as the absolute incremental benefit of either chemotherapy and/or immunotherapy over no chemo- and/or immunotherapy for radical and palliative indications. Multiple electronic citation databases were systematically queried, including Medline and the Cochrane Library. In cases where there were multiple sources of the same level of evidence, hierarchical meta-analysis was performed. The benefits of chemo- and immunotherapy were estimated for 1, 5, 10-year survival. To assess the robustness of our estimates, sensitivity analyses were performed.

Results: The estimated 1-year, 5-year and 10-year absolute population-based overall survival benefits of optimally utilized chemo- and immunotherapy for breast cancer in Australia are 1.0% (95% CI, 0.9%-1.2%), 4.4% (95% CI, 4.3%-4.6%) and 5.2% (___-___), respectively. They are summarized in the Table 1.

Estimation of Population Survival Benefit for First Line Chemo- and Immuno Therapy

Conclusion: Chemo- and immunotherapy agents improves overall survival in breast cancer at 1-, 5- and 10-years. Chemo-and immunotherapy provides a modest survival benefit to this patient population in Australia when it is used in accordance with guideline recommendations. These outcomes may allow comparison of treatment outcomes in a jurisdiction against what would be considered optimal based on evidence.

2. Ng, W., Estimating the optimal chemotherapy utilisation rate as an evidence-based benchmark in cancers of the breast, upper gastrointestinal tract, gynaecological tract, head and neck, kidney, bladder, thyroid and unknown primary., in University of NSW, Faculty of Medicine. 2010, UNSW: Sydney.
Title: Long-term outcome of HER2-normal early stage breast cancer (ESBC) patients (Pts) treated with docetaxel-cyclophosphamide (TC) chemotherapy (CTx): Mature results of a single-institution experience

Losurdo A, Gullo G, Buckley C, Lowry C, Ballot J, Silva N, Hammond L and Crown J. St Vincent's University Hospital, Dublin, Ireland; Clinical Cancer Research Trust, Dublin, Ireland; Oncology Pharmacy Unit, St Vincent's Private Hospital, Dublin, Ireland and Oncology Pharmacy Unit, St Vincent's University Hospital, Dublin, Ireland.

Body: BACKGROUND
Anthracycline(A)-containing regimens (AReg) became an established standard (neo)adj CTx for ESBC following fairly consistent demonstration of a modest superiority over older anti-metabolite/alkylating CTx. However, substantial translational data and a recently presented pooled analysis [Blum, 2016] suggest that this superiority could be largely driven by greater benefits in specific ESBC subgroups, i.e. HER2-altered BrCa (due to co-amplification of topoisomerase 2 and HER2), and triple-negative BrCa (TNBC). A are cardiotoxic (including late onset of cardiomyopathic congestive heart failure) and potentially leukaemogenic. In late 2006, following the results of the first USONC randomized clinical trial that showed superior outcomes of the non-AReg TC (docetaxel/cyclo−phosphamide) over AC, we established a routine, uniform policy of TC for all Pts receiving (neo)adj CTx for HER2-normal ESBC. We report the mature follow up of this single-institution unselected experience.

METHODS
We performed a retrospective outcome analysis of all Pts who received at least 1 cycle of (neo)adj TC (docetaxel 75 mg/m² + cyclophosphamide 600 mg/m² IV every 3 weeks) at our Department for HER2-normal ESBC and with at least 5 years of follow up (FU). Pts were identified by systematic analysis of the dataset of the Oncology Pharmacy Unit. Information on tumour characteristics [e.g. axillary lymph nodes (N) metastases, hormonal receptors (HR) and HER2 status] and Pts FU were retrieved and collected into an ad hoc designed database. Pts with node-positive (N+) ESBC received TC×6 cycles, and Pts with high-risk node-negative (N−) [e.g. primary tumour (T) >2 cm, or HRneg, or T >3 cm] ESBC received TC×4 cycles. Pts received adjuvant hormone therapy and radiotherapy as per standard of care. From 2008 on, many lower risk HR+/N− Pts were not given CTx due to OncotypeDx availability.

RESULTS
Between September 2006 and December 2015, 810 female HER2-normal ESBC Pts were treated with (neo)adj TC. In the final outcome analysis we included 464 Pts treated before June 2011 thus having a minimum FU of 5 years. Pts characteristics are: median age 53 yrs (range 30-77), N− 246 (53%), N+ 218 (47%), hormone receptors positive (HR+) 391 (84%), TNBC 73 (16%). The database was locked as of June 1st 2016. Median FU from first cycle of TC is 7.5 yrs (range 5.3-10). 63 BrCa-specific relapse events (defined as time to local, regional or distant recurrence, invasive contralateral breast cancer, excluding non-breast second primaries) have been observed, accounting for an overall Relapse-Free Survival (RFS) rate of 86.4%. 42 deaths have occurred, 36 (86%) due to BrCa, accounting for an Overall Survival (OS) rate of 91%. RFS and OS rates for the different Pts subgroups are reported in Table 1

CONCLUSIONS
These mature data with long FU suggest that the outcome for a large cohort of unselected Pts with HER2-normal HR+ ESBC (regardless of nodal status) and for TN/N− ESBrCa treated with nonAReg TC is excellent. However, N+TN ESBrCa in this setting remains a significant clinical challenge.
Title: Phase 1b/2 study to evaluate eribulin mesylate in combination with pembrolizumab in patients with metastatic triple-negative breast cancer

Tolaney S, Savulsky C, Aktan G, Xing D, Almonte A, Karantza V and Diab S. Dana-Farber Cancer Institute, Boston, MA; Eisai Ltd, Hatfield, England, United Kingdom; Merck & Co., Inc., Kenilworth, NJ; Eisai Inc, Woodcliff Lake, NJ and Rocky Mountain Cancer Centers-Aurora, Aurora, CO.

Body: Background: Eribulin, a non-taxane microtubule inhibitor, is approved for the treatment of (1) patients (pts) with advanced or metastatic breast cancer (MBC) who have received ≥1 [European Union] or ≥2 [United States] prior chemotherapy regimens for metastatic disease, including an anthracycline and taxane in either the adjuvant or metastatic setting and (2) pts with unresectable or metastatic liposarcoma who have received a prior anthracycline regimen. Pembrolizumab is a human programmed death receptor-1 (PD-1)-blocking antibody approved for the treatment of (1) pts with unresectable or metastatic melanoma and disease progression following ipilimumab and, if BRAFV600-mutation positive, a BRAF inhibitor and (2) pts with advanced non-small cell lung cancer with tumors expressing PD-L1. Pembrolizumab is also being evaluated for the treatment of metastatic triple-negative breast cancer (mTNBC) and other tumor types. Here, we report an interim analysis from an open-label, single-arm, multicenter, phase 1b/2 study to evaluate the safety and efficacy of the eribulin and pembrolizumab combination in pts with mTNBC previously treated in the metastatic setting.

Methods: A total of 95 pts (aged ≥18 yrs, ECOG PS 0 or 1) with mTNBC previously treated with ≤2 prior lines of chemotherapy for metastatic disease will be enrolled. Phase 1b included a safety run-in cohort in which ≥6 pts received intravenous (IV) eribulin mesylate 1.4 mg/m² on day (d) 1 and d8 and IV pembrolizumab 200 mg on d1 of a 21-d cycle. Dose-limiting toxicity (DLT) of the combination regimen were assessed in the first cycle to determine the recommended phase 2 dose (RP2D). In phase 2, patients were enrolled in 2 cohorts according to receipt of prior chemotherapy in the metastatic setting (0 vs 1–2 prior lines). Primary endpoints were determination of safety and tolerability (phase 1b) and evaluation of objective response rate (phase 2); secondary endpoints included evaluation of progression-free survival, overall survival, and duration of response.

Results: We report an interim analysis of the first 39 enrolled pts (n=7, phase 1b; n=32, phase 2). No DLTs were observed in phase 1b. The RP2D was defined as eribulin 1.4 mg/m² on d1 and d8 and pembrolizumab 200 mg on d1 of a 21-d cycle. As of data cut-off (May 16, 2016), the most frequent adverse events (AEs; all grades) were fatigue (69%), nausea (51%), alopecia (36%), neutropenia (36%), and peripheral neuropathy (28%). The most frequent AEs of grade 3 or 4 were neutropenia (31%) and fatigue (8%). Serious AEs (all nonfatal) occurred in 36% of pts and AEs leading to dose adjustment were observed in 56% of pts. Objective responses, including a complete response, by investigator assessment were observed during this interim analysis, and will be presented at the meeting.

Conclusions: The combination of eribulin with pembrolizumab represents a novel treatment regimen in pts with mTNBC. AEs observed with the combination were comparable to those observed with either treatment as monotherapy.

Title: *nab*-paclitaxel + carboplatin or gemcitabine vs gemcitabine/carboplatin as first-line treatment for patients with triple-negative metastatic breast cancer: Results from the randomized phase 2 portion of the tnAcity trial

Yardley D, Coleman R, Conte P, Cortes J, Brufsky A, Shtivelband M, Young R, Bengala C, Ali H, Eakel J, Schneeweiss A, de la Cruz Merino L, Wilks S, O'Shaugnessy J, Glück S, Li H, Beck R, Barton D and Harbeck N. Sarah Cannon Research Institute, Nashville, TN; Weston Park Hospital, University of Sheffield, Sheffield, United Kingdom; University of Padova, Padova, Italy; Vall d’Hebron University Hospital, Barcelona, Spain; University of Pittsburgh School of Medicine, Pittsburgh, PA; Ironwood Physicians, P.C., Chandler, AZ; The Center for Cancer and Blood Disorders, Fort Worth, TX; Misericordia General Hospital, Grosseto, Italy; Henry Ford Health System, Detroit, MI; Florida Cancer Specialists, Sarasota, FL; Heidelberg University Hospital, Heidelberg, Germany; Hospital Universitario Virgen Macarena, Reus, Tarragona, Spain; Cancer Care Centers of South Texas, San Antonio, TX; Baylor Sammons Cancer Center, Texas Oncology, US Oncology, Dallas, TX; Celgene Corporation, Summit, NJ and Breast Center of the University of Munich, Munich, Germany.

**Body**:

**Background**: *nab*-Paclitaxel (*nab*-P)–containing regimens have demonstrated efficacy and safety in triple-negative breast cancer (TNBC). In the absence of a standard of care for metastatic (m) TNBC, tnAcity evaluated the efficacy and safety of 3 common chemotherapy combination regimens: *nab*-P + carboplatin (*nab*-P/C) or gemcitabine (*nab*-P/G) vs G/C as first-line treatment (Tx) for patients (pts) with mTNBC based on a ranking algorithm of efficacy and safety. Results of the phase 2 portion are reported here.

**Methods**: Pts with pathologically confirmed mTNBC, no prior cytotoxic chemotherapy for metastatic disease, and no brain metastases were enrolled. Pts received (1:1:1) *nab*-P 125 mg/m² + C AUC 2, *nab*-P 125 mg/m² + G 1000 mg/m², or G 1000 mg/m² + C AUC 2, all given on d 1 and 8 every 3 weeks. The phase 2 primary endpoint was investigator-assessed progression-free survival (PFS); secondary endpoints included overall response rate (ORR), overall survival (OS), percentage of pts initiating cycle 6 receiving doublet therapy, and safety.

**Results**: 191 pts were included in the phase 2 portion. Median age was 55, 53, and 59 years in the *nab*-P/C, *nab*-P/G, and G/C groups, respectively. Overall, 98% of pts had an ECOG PS of 0 - 1, 83% were white, and 48% were treated in North America. Most pts (81%) had relapsed disease. Median Tx duration was 25, 18, and 20 weeks, and 47%, 33%, and 52% of pts had ≥ 1 dose reduction for both agents in the *nab*-P/C, *nab*-P/G, and G/C groups, respectively. Key efficacy and safety results are summarized in the table.

\[a \text{ } P = 0.03 \text{ vs nab-P/G; } P = 0.02 \text{ vs G/C; } b \text{ } P = 0.85 \text{ vs G/C; } c \text{ Including grade } \geq 3 \text{ neutropenia, thrombocytopenia, anemia, bleeding, febrile neutropenia, or red blood cell/platelet transfusion.} \]

PFS was significantly longer with nab-P/C vs either nab-P/G or G/C (median, 7.4 vs 5.4 mo, \( P = 0.03 \) and 7.4 vs 6.0 mo, \( P = 0.02 \)). Overall, 179 pts discontinued Tx; of these, 55% discontinued due to progression and 16% due to adverse events (AEs). Grade \( \geq 3 \) AEs in \( \geq 10\% \) of pts were mainly hematologic. The rank sum of the algorithm for 5 key weighted efficacy and safety endpoints favored nab-P/C.

**Conclusions:** In this phase 2 study, nab-P/C demonstrated a statistically significant longer PFS and a better risk/benefit profile vs nab-P/G or G/C as first-line Tx in pts with mTNBC. These data demonstrate nab-P/C efficacy in mTNBC and address a relevant question around a nab-P/C chemotherapy backbone for this difficult-to-treat tumor type. Further studies are warranted in the context of immunotherapies and targeted agents. NCT01881230.
Body: Purpose
We investigated whether the combination of irinotecan plus capecitabine improved progression free survival (PFS) compared with capecitabine alone in patients with HER2 negative MBC previously exposed to anthracyclines and taxanes.

Patients and methods
A total of 211 patients were randomly assigned to irinotecan (80mg/m2 on D1 and D8) and capecitabine (1,000mg/m2 bid on D1 to D14) or capecitabine alone (1,250mg/m2 bid on D1 to D14) every 3 weeks. The primary objective was PFS; secondary objectives included overall response rate, overall survival and safety.

Results
Both arms were well balanced in terms of age, hormone receptor status, visceral involvement, and number of previous treatment

IX, irinotecan plus capecitabine; X, capecitabine.

There was no significant difference in PFS between the combination and capecitabine monotherapy arm (median, 6.6 vs. 5.3 months; HR=0.87; 95% CI, 0.65 to 1.16; P=0.33). In patients with triple negative breast cancer (N=87), the combination treatment significantly improved PFS (median, 4.8 vs. 2.8 months; HR=0.59; 95% CI, 0.37 to 0.94; P=0.03). Overall response rate was higher in the combination arm though it did not reach statistical significance (42.7% vs. 29.6%, P=0.06). Overall survival did not differ between two groups (median, 2.2 vs. 1.7 years; P=0.47). Grade 3 or 4 neutropenia occurred in 39.6% in the combination arm and 10% in the monotherapy arm. Hand-foot syndrome (≥ grade 2) was more common in the monotherapy arm (23.0% vs. 12.6%).

**Conclusions**

Irinotecan plus capecitabine did not demonstrate superior clinical activity in heavily treated HER2 negative MBC patients. The role of adding irinotecan to capecitabine in triple negative breast cancer remains to be elucidated.

**Title:** Randomized phase II study evaluating different schedules of nab-paclitaxel in metastatic breast cancer (MBC): Results of the SNAP study

**Body:**

**Background**

Longer chemotherapy (CT) duration is associated with a significant improvement in progression-free survival (PFS) and a moderate, but significant improvement in overall survival (OS) in MBC patients (pts). Prolonged CT administration, however, must be weighed against the side effects of continuous CT delivery. The SNAP trial was designed to improve the tolerability of prolonged CT by studying alternative treatment schedules.

**Methods**

The SNAP trial enrolled 258 women from April 2013 to Aug 2015. Eligibility criteria included HER2- MBC, no prior CT for advanced disease, measurable and/or non-measurable disease. All eligible pts were randomized to one of three arms. Pts received the same induction chemotherapy consisting of 3 cycles of nab-Paclitaxel given days 1,8,15 Q28, followed by one of the three maintenance therapy schedules. Originally, the dose of the induction chemotherapy was 150 mg/m$^2$, but this was reduced to 125 mg/m$^2$ following the first safety review of 48 treated pts. The three schedules of nab-Paclitaxel used as maintenance therapy were (Arm A) nab-Paclitaxel 150 mg/m$^2$ d 1,15 Q28; (Arm B) nab-Paclitaxel 100 mg/m$^2$ d 1,8,15 Q28; (Arm C) nab-Paclitaxel 75 mg/m$^2$ d 1,8,15,22 Q28.

The primary objective is to evaluate the efficacy of three nab-Paclitaxel regimens as measured by progression-free survival (PFS), using the historical reference of PFS (based on AVADO study) of docetaxel for first-line treatment of metastatic breast cancer. Each of the three regimens is compared to the historic 7-month median PFS to determine whether any of the three regimens are worthy of further investigation. Secondary endpoints include tolerability, feasibility, response rate, OS and QoL.

**Results**

Two-hundred-fifty-eight pts have been randomised and 255 are available for primary endpoint evaluation. At 18.2 months' median follow-up, 182 PFS events and 85 deaths have been observed. Median PFS was 7.9 months (90%CI 6.8-8.4) in Arm A, 9.0 months (90%CI 8.1-10.9) in Arm B and 8.5 (90%CI 6.7-9.5) in Arm C. PFS in Arm B was significantly longer than the historic PFS of first-line docetaxel (one-sided log-rank p=0.03).

As expected, neurotoxicity was the most frequent adverse event. In the induction phase, grade≥2 sensory neuropathy was reported in 14.8% of pts at the starting dose of 150 mg/m$^2$ and 7.5% at the starting dose of 125 mg/m$^2$; grade≥3 sensory neuropathy occurred in 2.5% and 0% of the pts, respectively. In the maintenance phase, grade≥2 sensory neuropathy was reported in 37.9% of pts in Arm A, 36.1% in Arm B and 31.2% in Arm C; grade≥3 sensory neuropathy occurred in 9.1%, 5.6% and 6.6% of the pts, respectively.

199 pts started the maintenance phase. The median number of maintenance cycles was 3, 4, and 5, respectively. Stopping maintenance for reasons other than objective progression occurred in 41%, 58%, and 53%, respectively.

**Conclusion**

The SNAP trial indicates that alternative maintenance chemotherapy schedules with reduced doses after a short term induction phase at conventional doses are feasible and significantly more active than the historical PFS of docetaxel in the first line treatment of advanced breast cancer.

**Title:** Impact of post-progression therapy on overall survival (OS) in the IMELDA randomized phase III trial evaluating the addition of capecitabine (CAP) to maintenance bevacizumab (BEV) for HER2-negative metastatic breast cancer (mBC)

Mustacchi G, Bines J, Alba E, Cortes P, Doval D, de Ducla S, Button P and Gligorov J. University of Trieste, Trieste, Italy; Instituto Nacional de Cancer, Rio de Janeiro, Brazil; Hospital University Clinic Virgen de la Victoria, Malaga, Spain; University Hospital of Santa Maria, Lisbon, Portugal; Rajiv Gandhi Cancer Institute & Research Center, Delhi, India; F Hoffmann-La Roche Ltd, Basel, Switzerland; Roche Products Limited, Dee Why, Australia and APHP Tenon, IC-UPMC, Paris, France.

**Body:** BACKGROUND The open-label randomized phase III IMELDA trial demonstrated that adding CAP to maintenance BEV until disease progression after initial BEV + docetaxel (DOC) provides statistically significant and clinically meaningful improvements in both progression-free survival (PFS [primary endpoint]; hazard ratio [HR] 0.38, 95% CI 0.27–0.55; log-rank p<0.001; median 4.3 vs 11.9 months with BEV vs BEV + CAP, respectively) and OS (HR 0.43, 95% CI 0.26–0.69; median 23.7 vs 39.0 months, respectively) [Gligorov, Lancet Oncol 2014]. The type and extent of post-progression therapy were not collected prospectively; to address questions from the oncology community and provide further insight into the observed OS benefit with CAP, we collected these data retrospectively in the post-IMELDA study.

**METHODS** In IMELDA, patients (pts) with HER2-negative measurable mBC and no prior chemotherapy for mBC received 3-6 cycles of BEV + DOC. Pts with a response or stable disease were randomized to BEV alone or BEV + CAP (BEV 15 mg/kg d1 q3w; CAP 1000 mg/m\(^2\) bid d1-14 q3w) until disease progression, unacceptable toxicity, or consent withdrawal. OS from randomization was a secondary endpoint. In post-IMELDA, data until study closure were collected retrospectively from available records of pts randomized in IMELDA. Ethics, consent, and feasibility reasons prevented some sites participating in post-IMELDA.

**RESULTS** Post-IMELDA data were available from 118 (64%) of the 185 randomized pts. Of these, all but 8 had received further systemic anticancer therapy and 92 of 118 (78%) had received chemotherapy. Post-progression treatment exposure and efficacy are shown below. In Cox regression models stratified by further anticancer therapy after stopping study therapy, HRs were 0.30 (95% CI 0.19–0.48) for PFS and 0.50 (95% CI 0.30–0.82) for OS. Sensitivity analyses using two extremes of imputation (assuming all pts with missing follow-up data did vs did not receive further anticancer therapy) supported OS findings.

NE=not estimable
CONCLUSIONS Post-IMELDA is limited by retrospective collection of data from only two-thirds of randomized pts and only until the date of study closure (thus potentially underestimating crossover to CAP). Nevertheless, these analyses suggest that the OS benefit from adding CAP to maintenance BEV in the IMELDA trial was robust despite extensive post-progression therapy in both treatment arms and crossover to CAP in more than half of pts randomized to maintenance BEV alone. Ongoing and future mBC trials should include prospective collection of information on subsequent therapy.
Title: First and further line choices of treatment for HER2-VE metastatic breast cancer (MBC) according to adjuvant treatment and biological subtype. Preliminary results of the observational “GIM-13 – AMBRA” Italian study

**Irrespectively of biological subtype, nab-paclitaxel was used in 3.6%, 15.3% and 16.4% of cases in 1st, 2nd and 3rd line, respectively**

BACKGROUND
Breast Cancer prognosis improved in the last years due both to early diagnosis and Adj treatments. The choice of CHT regimens...
should consider previous Adj treatments, pattern of relapse and biological subtype. There are few information on the treatment of MBC in the clinical practice outside controlled trials, last study has been published 15 yrs ago in Italy.

PATIENTS AND METHODS
The GIM13-AMBRA Study is a multicenter longitudinal cohort study, describing the choice of first and subsequent lines of treatment for MBC in HER2-ve pts. We are collecting data of 30 consecutive pts from 42 Italian Centres who developed the first relapse in the years 2012-2015 and were treated with CHT, (+/- previous endocrine treatments (HT)) for MBC. One of the secondary aims is to evaluate the Time to Treatment Change (TTC) (time between treatment start and its change for any reason) as surrogate endpoint for Time To Progression outside clinical trials. The present report is focused on the choice of treatments in any line and TTC, according to biological subtypes.

RESULTS
For the present analysis, 683 pts are evaluable. Pts with Luminal A and B tumours received CHT and HT in 65.3% (Adjuvant), 21.7% (1st line), 7.1% (2nd line) and 7% (3rd line) of the cases. The most used regimens according to tumour subtype and line of treatment are shown in Table 1.
Median TTC from 1st to 2nd line was 8.1 and 17.9 months in TNBC and Luminal tumours, respectively, whereas TTC from 2nd to 3rd line was 3.1 and 12.9 months, respectively.

CONCLUSION
Preliminary results of the AMBRA-GIM13 Italian observational study confirm that in most cases treatment for MBC is strongly related to the type of the Adj regimen, being the use of anthracyclines marginal in MBC, whereas taxanes are widely used in any line. In 1st line the most used regimens are Taxane and Bevacizumab or Capecitabine/Vinorelbine combinations. The last one remains the most used CHT in 2nd and 3rd lines. No difference have been observed according to biological subtype, except for Platinum-based regimens in TNBC. HT alone remains the preferred choice in 1st and 2nd line in Luminal cases. TTC seems to be a reliable surrogate for PFS in the “real world” practice. CHT still plays a crucial role in the treatment of MBC HER2-ve pts.
Title: A phase 2 study of eribulin as early-line treatment for HER2- MBC: Evaluation of efficacy, toxicity, and patient-reported outcomes

Metzger O, Lin NU U, Schneider B, Faggen M, Come S, Openshaw T, Constantine M, Walsh J, Giobbie-Hurder A, Burstein HJ J and Mayer EL L. Dana-Farber Cancer Institute, Boston, MA; Indiana University Simon Cancer Center, Indianapolis, IN; Beth Israel Deaconess Medical Center, Brewer, MA and Eastern Maine Medical Center, Brewer, ME.

Body: Background:
Patient-reported outcomes (PROs) independently and directly describe patient (pt) treatment experiences, complement clinician reports, and are increasingly included in drug development. Eribulin (E) has activity in metastatic breast cancer (MBC) previously treated with ≥ 2 regimens. Limited data are available on the activity of E in earlier lines. This phase II single arm study evaluated the activity, safety, and PROs of E in an earlier line setting for HER2- MBC.

Methods: Eligible pts had HER2- MBC, 0-1 prior lines of chemotherapy, and enrolled into one of two parallel cohorts: HR+, TNBC. E was dosed 1.4 mg/m² weekly, 2 wk on/1 wk off; 1 cycle = 3 wks. The primary objective was overall response rate (ORR); additional objectives included progression-free survival (PFS) and safety. Correlative PRO endpoints included description and comparison of toxicity evaluation by PROs vs provider-report for degree of concordance or divergence for each class of toxicity, and description of QOL over time. Neuropathy was evaluated by the FACT-Neurotoxicity subscale, as well as exploration of predictive host polymorphisms. PRO instruments (PRO-CTCAE, FACT-B and FACT-NTX) were administered electronically at baseline, cycles 1-3, then every other cycle.

Results: 83 pts enrolled: 45 HR+ and 38 TNBC. Median age was 56 (range: 34-87). 55.4% were first line, and 66% had received previous taxane in the adjuvant or metastatic setting. ORR for all pts was 25.3% (90% CI: 18%-34%); 35.6% in HR+ (90% CI: 24%-49%) and 13.2% in TNBC (90% CI: 5%-26%). mPFS estimate was 5.8 months (mo) for all pts, HR+ 6.2 mo (90% CI: 5.9-8.7) and TNBC 4.0 mo (90% CI: 3.5-4.8). Related toxicities occurring in ≥ 20% of pts were: fatigue (61.4% overall, 32.5% G1, 27.7% G2, 1.2% G3), alopecia (51.8% overall, 16.9% G1, 32.5% G2), nausea (39.8% overall; 26.5% G1, 12.0% G2, 1.2% G3), peripheral sensory neuropathy (36.1% overall; 18.1% G1, 13.3% G2, 4.8% G3), decreased neutrophil count (32.5% overall; 3.6% G1; 4.8% G2, 13.3% G3, 10.8% G4), peripheral motor neuropathy (22.9% overall, 13.3% G1, 6.0% G2, 3.6% G3), and mucositis (20.5% overall, 16.9% G1, 2.4% G2, 1.2% G3). FACT-B Breast Cancer Concern (BCC) and Trial Outcome Index (TOI) scores were stable during therapy. The greatest mean improvement in summed BCC (mean change 3.3) and TOI (mean change 7.9) compared to baseline occurred at cycle 9 in pts with stable disease. Changes from baseline in the NTX and TOI of FACT-NTX worsened during the first 7 cycles of therapy (mean changes NTX 5.3, TOI 4.8). Pharmacogenomic analysis exploring host polymorphisms and development of neuropathy is ongoing.

Conclusions: PROs are indispensable in the evaluation of anti-cancer agents in clinical trials. In this phase II trial, E demonstrated activity and safety in early lines of therapy for HER2- MBC. Additionally, improved QOL metrics were observed among pts experiencing stable disease. CTCAE rates of severe neuropathy were low, however PRO testing by FACT-NTX highlights progressive worsening of neurotoxicity. In contrast to classic CTCAE criteria producing aggregate estimates of toxicity, this phase II trial shows longitudinal collection of PROs provides meaningful, complementary, and dynamic clinical information.
Evaluation of growth modulation index as a marker of benefit for consecutive lines of treatment for metastatic breast cancer

Background: Sequencing of single-agent chemotherapy (CT) is the current standard of treatment for endocrine-resistant metastatic breast cancer (MBC). However, shrinking benefit for consecutive lines of CT and lack of data from randomized trials may question the real value of advanced lines of treatment. Growth modulation index (GMI), the ratio of progression free survival (PFS) with PFS of previous line, has been reported as a marker of treatment benefit when equal to or above 1.3. This value is similar to the clinical benefit threshold proposed by ESMO and ASCO for non-curative CT. The aim of this work was to determine GMI change across the successive lines of CT for MBC.

Methods: We retrospectively analyzed all MBC patients currently on treatment at our center. GMI was determined for each CT line and for each patient and a cut-off value of 1.3 was chosen as a marker of treatment benefit. Chi-squared test and Spearman's Rho were used for proportion comparison and correlations. Kaplan-Meier curves and log-rank test were performed for survival analysis.

Results: 128 ABC patients were included; median age: 57; ECOG 0-1: 92.2%; visceral disease: 46%; bone-only disease: 46.9%; TNBC: 5.5%, HER2+: 23.5%, ER+HER2-: 71.1%; 50% more than 2 lines of CT. GMI and PFS values are shown in Table 1. GMI values were significantly associated with PFS values in all lines (p<0.001 for 2nd, 4th and 5th lines; p<0.01 for 3rd and 6th). GMI was neither significantly different between CT lines nor significantly correlated with GMI of previous line. No consistent association of GMI values with age, performance status, tumor subtype or visceral disease were found.

Conclusions: GMI does not significantly change along successive CT lines for MBC. Our results, showing a constant rate of 20-40% of patients with GMI≥1.3 up to the sixth line of CT, suggest a benefit within the range of magnitude established by ASCO and ESMO framework for cancer care value. Although potential biases of this work warrant further evaluation with a cohort design, GMI, together with toxicity data and absolute gains of PFS, may be used as an additional tool to establish the real value of late lines of CT for MBC.
Eribulin mesylate (eribulin) showed inhibitory effects on epithelial-mesenchymal transition (EMT) in tumors of metastatic breast cancer patients. -First preliminary report of a prospective study-

Utsumi T, Hayashi T, Kobayashi N, Hikichi M, Ushimado K, Ri Y, Nakano S, Fujii K and Ando T. Fujita Health University, Toyoake, Aichi, Japan; Fujita Health University, Toyoake, Aichi, Japan and Aichi Medical University, Aichi, Japan.

**Body:** **Background:** EMT is thought to contribute to metastasis in patients with breast cancer, leading to their poor prognosis. Pivotal phase III trials have demonstrated that eribulin improved overall survival in patients with triple negative metastatic breast cancer (MBC). Preclinical studies have shown that eribulin suppressed EMT and this phenomenon could be one of reason for an improved prognosis of MBC patients treated with eribulin. However, there is no direct clinical data on the effect of eribulin treatment on EMT in tumors of MBC patients. We designed a prospective study to clarify if eribulin treatment suppresses EMT in tumors of MBC patients.

**Patients and methods:** Patients with recurrent or MBC were treated with eribulin (1.4 mg/m² intravenously on days 1 and 8 of a 21-day cycle). Dose reductions were allowed according to eribulin's prescribing information. Treatment continued until disease progress, unacceptable toxic effects, or discontinuation requests from patients or physicians. Breast cancer tissue samples were obtained from all patients before and on day 15±4 of 1st cycle of eribulin treatment. The quantitative analysis of mRNA levels of EMT markers (E-cadherin, cytokelatin18, cytokelatin19, N-cadherin, vimentin, ZEB1, Slug, Snail, and Twist) were carried out by qPCR. Primary outcome measure was to assess the change from baseline to day 15±4 in mRNA levels of EMT related markers in tumor tissue. This study was approved by the Ethic Committee of Fujita Health University.

**Results:** Eleven patients were enrolled. Median age of the patients was 63 years old (44-72). Of the 11 tumors, 6 were luminal B and 5 were triple negative (TN). Median number of prior chemotherapy regimen for recurrent or metastatic disease was 0 (0-3). Four patients were treated with dose reduced eribulin (1.1 mg/m²) and administration of eribulin on day 8 during 1st cycle of the treatment were skipped in 2 patients. To identify meaningful EMT markers, differences in expression levels of each EMT marker were investigated between TN and luminal B tumors. At baseline mRNA levels of N-cadherin and vimentin were higher in TN tumors than in luminal B tumors, 8.12±10.78 vs 1.02±0.68, 5.13±4.50 vs 0.88±0.47, respectively. After the treatment, a decrease of expression of N-cadherin and vimentin was more frequent in TN tumors (100% and 80%, respectively) than in luminal B tumors (33.3% and 16.7%, respectively). Frequency of a decrease of expression of ZEB1, Slug, Snail, and Twist in TN tumors and luminal B tumors were 80% (TN) vs 83.3% (luminal B), 80% vs 16.7%, 40% vs 66.7%, and 100% vs 50%, respectively.

**Conclusions:** This is the first prospective study to investigate the effect of eribulin treatment on expression of EMT markers in tumors of MBC patients. We demonstrated that eribulin treatment suppressed EMT in tumors. Our results suggested that eribulin showed antitumor effect by improving the tumor microenvironment. In our study, eribulin seems to have different effects on EMT pathway in individual cases. Our findings may provide a light to a scientific basis for solving underlying mechanisms for improvement of overall survival of patients with MBC treated with eribulin.
Title: Eribulin should be a candidate strategy in combination with pertuzumab plus trastuzumab for taxane pretreated HER2 positive advanced breast cancer

Authors: Araki K, Fukada I, Kobayashi K, Takahashi S and Ito Y. Breast Medical Oncology, The Cancer Institute Hospital Ariake, the Japanese Foundation for Cancer Research, Koto, Tokyo, Japan.

Body: Background: Pertuzumab (P) improves clinical outcome when combined with docetaxel and trastuzumab (T). The efficacy of continuing multiple anti-HER2 therapy including P and/or T after initial progression is unclear. Eribulin mesylate (ERI) is able to overcome taxane (TAX) resistance advanced breast cancer (ABC). The objective of this study is to investigate the efficacy and safety of ERI plus P and T for both TAX and T pretreated HER2-positive ABC. Methods: This is a single institute, open-label, single-arm, Phase II study with pharmacokinetics (PK) of ERI (UMIN000012375). The initial dose of P is 840 mg, followed by 420 mg q3w; the initial dose of T 8 mg/kg, followed by 6 mg/kg q3w; ERI is administered at 1.4 mg on Days 1 and 8 of each cycle, q3w. Dose reductions of ERI (to 1.1 and 0.7 mg/m²) were permitted to manage any toxicity (more than grade 3). Patients (Pts) must have previous treatment with both TAX and T. The primary endpoint is assessed overall response rate (ORR). Secondary endpoints include progression-free survival (PFS), overall survival (OS), safety, and PK of ERI. Left ventricular ejection function (LVEF) was evaluated before and end of this study. Results: Thirty Pts were enrolled. Median age at baseline was 57 years. Half of Pts had endocrine positive. All Pts were treated with TAX and T. Twenty-one Pts were treated with anthracycline-based treatment (70%). Median number of previous chemotherapy was 4 (2-5). Pts had multiple metastases, 40% with bone, 36.7% with lung, 20% with liver, and 10% with brain. Pts received a median number of 8 cycles of ERI (mean dose ± 0.19 mg/sqm), 8 cycles of both P and T. Total number of 27 Pts needed to reduce dose of ERI because of adverse events (AEs) especially grade 3 neutropenia. The ORR (CR+PR) was 34.8% (95% CI 16.4-57.3, n=23) with median PFS of 42.6 weeks (95% CI 20.3-51.9, n=30). Clinical benefit rate (CR+PR+≥6 month SD) was 60.9% (95% CI 16.4-57.3%). T-DM1 pretreated affected poor outcome than the other factors (p=0.0011). The most common grade 3/4 AEs were neutropenia in 20 Pts (66.7%) without febrile neutropenia. Grade 1/2 AEs were fatigue in 24 Pts (80%), anorexia in 23 Pts (76.7%), anemia in 22 Pts (73.3%), diarrhea in 20 Pts (66.7%), peripheral neuropathy in 16 Pts (53.3%), and hand-foot syndrome in 12 Pts (43.3%). Baseline LVEF was 67%. One Pt had asymptomatic LVEF decrease (below an absolute value of 55%). Otherwise, there was no overall decrease in mean LVEF from baseline. Nine points (pre-dose, end of infusion, 0.5, 1, 2, 4, 24, 72, and 168 h after ERI) of PK analyses were evaluated in 6 Pts, and 3 point (pre-dose, end of infusion, and 168 h after ERI) in 10 Pts. PK parameters of ERI were as follows; Maximum plasma concentration (Cmax) was 375.96 (257.6-531.8) ng/ml, terminal half-life was 36.807 (31.90-40.80) h, total clearance was 1.945 (1.15-3.15) L/h/m². Cmax of ERI was not correlated with neutrophil count (R²=0.2338, n=16). Conclusions: The combination of ERI plus P and T was well tolerated; no new safety signals were observed. PK parameter of ERI were as same as previous reports when combined with both P and T. ERI might be a one of strategy in combination with P plus T for TAX pretreated HER2 positive ABC.
**Title:** Real-life activity of oral vinorelbine in metastatic breast cancer patients in the Unicancer ESME database

Pierre H, Mahasti S, Damien P, Nicolas M, Chritelle L, Florence D, Mony U, Lionel U, William J, Paule A, Audrey M, Claudia L, Mario C, Marie-Paule S, Marie-Ange M-R, Marianne L, Jean-Christophe E, Thierry P, Jean-Marc F, Bruno C, Anthony G, Christian C, Gaëtane S and David P. Centre Léon Bérard, Lyon, France; Institut Gustave Roussy, Villejuif, France; Institut Jean Godinot, Reims, France; Institut Bergonié, Bordeaux, France; Centre François Baclesse, Caen, France; Institut Claudius Regaud, Toulouse, France; Institut Curie, Paris & Saint-Cloud, France; Institut de Cancérologie de Lorraine, Vandoeuvre-lès-Nancy, France; Institut du Cancer de Montpellier, Montpellier, France; Institut de Cancérologie de l'Ouest, Nantes & Angers, France; Centre Oscar Lambret, Lille, France; Centre Eugène Marquis, Rennes, France; Centre Jean Perrin, Clermont-Ferrand, France; Centre Henri Becquerel, Rouen, France; Centre Paul Strauss, Strasbourg, France; Centre Antoine Lacassagne, Nice, France; Centre Georges-François Leclerc, Dijon, France; Institut Paoli-Calmettes, Marseille, France and R&D Unicancer, Paris, France.

**Background:** In 2014, UNICANCER, composed of 18 French Comprehensive Cancer Centers, launched the Epidemiological Strategy and Medical Economics (ESME) program to investigate real-world data in oncology. Real-world data give the opportunity to assess the activity of specific products outside the framework of clinical trials. Oral vinorelbine (OV) is one of the therapeutic options available for metastatic breast cancer (mBC). Few data are available regarding its real clinical efficiency in current practice. We aimed at evaluating such activity within the ESME population.

**Methods:** The ESME-mBC database was built from information systems, treatment databases and patients’ electronic files, with homogenous on-site collected information and high-level quality-control (Delaloge et al, Ann. Oncol 2016 (in press)). All patients having started a systemic treatment for mBC in a cancer center participating in the ESME program between 01-Jan-2008 and 31-Dec-2013 have been selected into the database.

For the purpose of the current analyses, data cut-off was July, 2015 and all patients who received OV at any time during the course of their disease were selected and analyzed. Primary end point was progression-free survival (PFS) from initiation of OV. Secondary end points were descriptive and prognostic analyses, and overall survival (OS).

**Results:** Among 13,853 patients recorded in the ESME-mBC database, 1402 received OV as a monotherapy or in combination (809 and 593 patients / 57.7% and 42.3% respectively). Most frequent combinations were with capecitabine (368 patients) and anti-HER2 therapy (165 patients). De-novo mBC was observed in 282 patients (20.1%) and 569 patients (40.6%) had only non-visceral metastases. At metastatic diagnosis, 221 patients (16.9%) had HER2-positive and 298 patients (22.9%) triple-negative tumors respectively. At OV initiation, median age was 59.0 [IC95%: 50-67] years. Endocrine therapy was given prior OV in 769 patients (54.9%). For PFS analysis, 1345 patients were evaluable. The following table summarizes PFS results according to the treatment patterns and the OV-line.

Following diagnosis of mBC, median OS was 38.2 months [IC95%: 36.1-40.0] in the cohort of patients who received OV at any time.

Conclusions: This study allows large scale assessment of real life benefit of OV over subsequent lines and shows that OV yields clinical benefit even in heavily pre-treated mBC patients.
Title: Capecitabine in combination with bendamustine in pretreated women with HER2-negative metastatic breast cancer: Final PFS results of a phase II trial (AGMT MBC-6)

Rinnerthaler G, Gampenrieder SP P, Voskova D, Petzer A, Hubalek M, Petru E, Hartmann B, Andel J, Balic M, Melchardt T, Ulmer H, Mlineritsch B and Greil R. Salzburg Cancer Research Institute with Laboratory of Immunological and Molecular Cancer Research and Center for Clinical Cancer and Immunology Trials, Cancer Cluster Salzburg, Paracelsus Medical University Salzburg, Salzburg, Austria; Kepler University Linz, Linz, Austria; Barmherzige Schwestern Hospital Linz, Linz, Austria; Innsbruck Medical University, Innsbruck, Austria; Medical University Graz, Graz, Austria; General Hospital Feldkirch, Feldkirch, Austria; County Hospital Steyr, Steyr, Austria; Medical University Graz, Graz, Austria and Medical University Innsbruck, Innsbruck, Austria.

Body: Background: Capecitabine is a well-established treatment option in HER2-negative advanced breast cancer (ABC) patients. Bendamustine is a generally well tolerated cytotoxic drug. Since bendamustine has already shown anticancer activity in ABC we evaluated the efficacy and tolerability of bendamustine in combination with capecitabine in pretreated patients with ABC. Here we present the final PFS results of this phase II trial.

Patients and methods: MBC-6 is a non-randomized, multicenter, open-label, single-arm phase II study in patients with HER2-negative ABC (ClinicalTrials.gov: NCT01891227). All patients were pretreated with anthracyclines and/or taxans and had measurable disease according to RECIST 1.1. Patients received 1000 mg/m² capecitabine twice daily on days 1 to 14 in combination with 80 mg/m² bendamustine on day 1 and 8 of a 3-week cycle for a maximum of 6 cycles. Afterwards capecitabine was continued as monotherapy. The primary endpoint was overall response rate (ORR). Secondary endpoints were progression-free survival (PFS), clinical benefit rate (CBR), safety and quality of life.

Results: From September 2013 to May 2015, 40 patients were recruited in eight Austrian centers. Median age was 60 years (range 29-77). Twenty-five percent of patients had triple-negative disease (TNBC) and 93% showed visceral involvement. Sixty-five percent had received prior chemotherapy in the (neo)adjuvant setting and 63% for ABC (43% one line, 15% two lines, 5% three lines). All patients with ER-positive disease had received prior endocrine therapy. At data cut-off on 06/08/16 overall 39 of 40 patients had discontinued treatment with a median PFS of 7.0 months (95% CI 4.6-9.5), 7.4 months in ER-positive and 4.0 months in triple negative disease (TNBC), respectively. Twelve patients (30%) experienced at least one drug related non-hematological AE ≥ grade 3 during combination treatment and further 6 patients (15%) during capecitabine maintenance. Three grade 4 hematological AEs (neutropenia) were observed. One patient died as a result of restrictive cardiomyopathy, where a relationship to capecitabine cannot be excluded, but seems unlikely.

Conclusion: The combination of capecitabine and bendamustine shows promising efficacy and a moderate toxicity profile. Further evaluation of this drug combination is warranted.
Title: Metronomic capecitabine in heavily pretreated metastatic triple negative breast cancer

El-Sadda WM M. Mansoura University, School of Medicine, Mansoura, Egypt.

Body: Background:
Triple negative breast cancer (TNBC) is defined histologically as an invasive carcinoma of the breast that lacks staining of ER, PgR and HER2/neu. Metastatic TNBC is an aggressive subtype of breast cancer marked by higher rate of visceral and CNS metastatic as well as poor survival. Metronomic chemotherapy regimens have shown efficacy in patients with metastatic breast cancer by enhancing the antiangiogenic mechanism. Capecitabine monotherapy is active against metastatic breast cancer and when used metronomically, the toxicity profile is low. The purpose of this study is to evaluate the metronomic capecitabine in patients with MTNBC in terms of response rate, toxicity profile, progression free survival and overall survival.

Patients and methods:
Forty patients with measurable metastatic/recurrent TNBC during the period from Jan 2012 to Jan 2014, patients had WHO PS <2, adequate renal, liver and bone marrow functions. Capecitabine administered orally in a low dose of 500 mg/m² twice daily and continued until progression or death. Response was assessed every two months, with any evidence of disease progression; patients were withdrawn from the study.

Results:
All patients were evaluated for response rate and toxicity. The median age was 50 years (range 36-59), median WHO PS was 1. Main metastatic sites were liver 40%, lung 30%, bone 40%, skin 10% and local recurrence 20%. Fifty percent of patients had one metastatic site, 40% had two metastatic sites and 10% had more than two metastatic sites. Partial response (PR) was observed in 12 patients (30%), stable disease (SD) in 20 patients (50%), and progressive disease in 8 patients (20%). Median time to progression was 5 months and median survival 9 months. Grade 2, 3 and 4 hematological toxicities and clinical side effects were uncommon. Hand and foot syndrome (G1) was experienced by 8 patients (20%).

Conclusion:
Metronomic capecitabine was effective and minimally toxic in heavily pretreated patients with metastatic TNBC.

Title: Phase II study of navelbine plus carboplatin followed by oral navelbine in patients with metastatic/recurrent triple negative breast cancer previously treated with anthracycline and taxane

El-Sadda W, Abdel Halim I and El-Ibrashi M. Mansoura University, School of Medicine, Mansoura, Egypt.

Body: Background:
Navelbine (N) and carboplatin (C) are both active drugs in the treatment of breast cancer, N is a semisynthetic drug belongs to the vinca alkaloids, its oral form has proved to be effective as the iv form. Metastatic triple negative breast cancer (TNBC) is an aggressive subtype of breast cancer marked by higher rate of visceral and CNS metastases as well as poor survival. We investigated the efficacy and safety of IV navelbine plus carboplatin followed by oral navelbine in patients with metastatic TNBC in terms of response rate, toxicity profile, progression free survival (PFS) and overall survival (OS).

Patients and methods:
Between Dec 2011 and Dec 2013, forty patients with histologically proven measurable metastatic/recurrent TNBC were enrolled in the study. Patients had history of previous treatment with anthracyclines and taxanes. WHO PS <2, adequate renal, liver and bone marrow functions. Treatment consisted of navelbine 25mg/m² D1 & D8 (IV infusion over 6-10 min) and carboplatin AUC 5 D1 (IV infusion over 30 min), repeated every three weeks. Response was assessed every two cycles, patients showed an objective response (CR, PR or SD) had continued to 8 cycles followed by oral navelbine 60 mg/m² D1 & D8 for the first cycle then escalated to 80 mg/m² D1 & D8 every three weeks for six months.

Results:
All patients were evaluated for response, toxicities and survival. Median age was 43 years (range 36-56) and median WHO PS 0. Main metastatic sites were liver 40%, lung 30%, bone 60%, skin 10%, and local recurrence 20%. Fifty percent of patients had one metastatic site, 30% had two metastatic sites and 20% had more than two metastatic sites. The ORR after navelbine/carboplatin was 65% (CR 15%, PR 50%), SD in 25% and PD in 10%, while after oral navelbine, the ORR was 75% (CR 25%, PR 50%), SD 16.6 and PD 8.4%. The median PFS & OS were 12.3 & 19.8 months respectively. No G 3 & 4 toxicities were noted. G2 neutropenia and G2 anemia were observed in 10% and 5, respectively.

Conclusion:
Navelbine & carboplatin followed by oral navelbine is an effective, safe and tolerable regimen in patients with metastatic/recurrent TNBC previously treated with adjuvant anthracycline and taxane with ORR 75%.
Title: Utilization and outcomes of eribulin in triple negative metastatic breast cancer: Real-world findings

Kish JK K, Mougalian SS S, Copher R, McAllister L, Zhixiao W and Broschis M. Cardinal Health Specialty Solutions, Dallas, TX; Yale Cancer Center, Yale School of Medicine, New Haven, CT and Eisai Inc., Woodcliff Lake, NJ.

Body: Background
Triple-negative breast cancer (TNBC) accounts for 10-20% of all breast cancers (BCs) and a significant proportion of all BC deaths. Eribulin is approved for the treatment of metastatic BC (MBC) after treatment with two prior regimens. A pooled analysis of two phase III studies of eribulin in women with TNBC patients found a 26% reduction in the risk of death vs. controls. Treatment patterns of eribulin and clinical outcomes associated with early vs. late use among TNBC patients treated in community oncology practices have not been evaluated.

Methods
Physicians from the Cardinal Health Oncology Research Network completed an electronic case report form (CRF) on up to 7 TNBC patients treated with eribulin between 01/01/11 and 12/31/13. Adult female patients with pathologically confirmed metastatic disease and not participating in any interventional clinical trial were included. Providers indicated the usage of chemotherapy, either alone or in combination, by line of therapy (LOT) up to the LOT of eribulin initiation. Reported data points include: clinical parameters (e.g., site of metastases, ECOG performance status, and comorbidities), treatment events (e.g., LOT start/end date and rationale for discontinuation), and outcomes (e.g., clinical response and date of death). Dosing, adverse events, use of supportive care medications, and hospitalization were also captured during eribulin treatment. Use of eribulin in LOT 1/LOT 2 was considered early; LOT 3+ was considered late. All comparisons are univariate.

Results
An interim analysis was performed on 123 TNBC patients (planned sample size of 250) collected from 26 providers. Patient mean age at eribulin treatment initiation was 55.0 years. Mean follow-up duration was 27 mo (SD = 11.9) from initiation of first line metastatic treatment until date of last visit, death, or loss to follow-up. Overall, 74.0% were deceased, 85.4% had received at least 3 LOTs in the metastatic setting, and 45.4% were stage IV at diagnosis. Most women were prescribed eribulin in a later LOT (61.8%), 3 (2.4%) patients received eribulin in LOT1 and 44 in LOT2 (36.7%). Among patients with known treatment start and end dates (87.0%), mean duration of treatment (DOT) was 6.2 mo (SD = 3.3), median 5.8 mo among early recipients and 5.5 mo (SD = 5.7), median 4.1 mo, among later recipients (p = 0.39). Early users were more likely (p = 0.05) to have a complete/partial response (71.1% vs. 47.7%) and less likely to have progressive disease (7.1% vs. 12.3%). In comparing eribulin users to all other therapies, eribulin users had a significantly longer DOT in LOT2 (5.9 vs. 4.7 mo, p = 0.01) and LOT3 (5.8 vs. 3.6 mo, p = 0.03). In LOT3, eribulin users were significantly more likely to have complete/partial response (54.2% vs. 18.8%) and less likely to have to have progressive disease (4.2% vs. 37.5%) compared to all other observed LOT3 therapies.

Conclusions
This interim analysis indicates longer DOT for patients treated with eribulin for TNBC in LOT2 and LOT3 and a more favorable response rate compared to all other agents used in each LOT, respectively, among patients treated in community oncology practices. Full results will be available at the conference.

Title: Platinum salts in advanced breast cancer: A systematic review and meta-analysis of randomized clinical trials

Petrelli F, Barni S, Bregni G, de Braud F and Di Cosimo S. Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy; ASST Bergamo Ovest, Treviglio, Italy and IRCCS A.O.U. S. Martino-IST, Genova, Italy.

Body: Background The interest in platinum salts for breast cancer (BC) treatment has been recently renewed as inhibition of DNA damage response may enhance the effects of DNA-damaging agents in tumors with high genomic instability. The present systematic review and meta-analysis of randomized trials was performed to assess the efficacy and safety of platinum salts in patients with advanced BC. Methods We searched Pubmed, EMBASE, SCOPUS, Web of Science, the Cochrane Library and CINAHL for phase II/III clinical trials that assessed efficacy of platinum-based therapy in patients with advanced BC. Pooled estimates of overall response rate (RR), median progression-free survival (PFS) and overall survival (OS) and major toxicities were computed by using random or fixed effects models. Results A total of 4,625 patients from 23 phase II/III trials (11 with cisplatin, 11 with carboplatin and 1 with either agents) were analyzed. Estimates for RR, PFS and OS were obtained from 23, 13 and 15 studies, respectively. Though at the price of increased hematological, gastrointestinal toxicity and fatigue, compared with non platinum-salts schemas, cisplatin and carboplatin prolonged OS (HR 0.91; 95% CI 0.83 to 1.00, p= 0.04), PFS (HR 0.84; 95% CI 0.73 to 0.97, p= 0.01), and RR (HR 1.27; 95% CI 1.03 to 1.57, p=0.03). Conclusions Despite some limitations of the studies examined, including the lack of information on hormonal receptor and HER2 status, the use of platinum salts significantly improved RR, PFS and OS of patients with advanced BC with no unexpected toxicity.
Title: Abstract Withdrawn
Title: A randomised phase III trial comparing two dose-dense, dose-intensified approaches (ETC and PM(Cb)) for neoadjuvant treatment of patients with high-risk early breast cancer (GeparOcto)

Body: Background: The sequential use of dose-dense, dose-intensified epirubicin, paclitaxel, and cyclophosphamide (EPC) (Möbus et al. J Clin Oncol 2010) as well as weekly treatment with paclitaxel/liposomal doxorubicin (plus carboplatin in triple negative disease, TNBC) (PM(Cb)) (von Minckwitz et al. Lancet Oncol 2014), both with dual HER2 blockade in HER2+ breast cancer (BC), are considered highly efficient regimens for high-risk early stage BC patients and will be compared in the GeparOcto study.

Methods: GeparOcto (NCT02125344) patients received either 18 weeks EPC (E 150mg/m² q2w for 3 cycles, P 225mg/m² q2w for 3 cycles, C 2000mg/m² q2w for 3 cycles) or PM(Cb) (P 80mg/m² q1w concomitantly with M 20mg/m² q1w and, in case of TNBC, Cb AUC 1.5 q1w). Patients with HER2+ BC received trastuzumab 6 (8) mg/kg q3w and pertuzumab 420 (840) mg q3w concomitantly with all P, C, and PM(Cb) cycles. Due to a high risk of chemotherapy induced anaemia in both regimens, patients developing iron deficiency anaemia during the study were also randomized to parenteral ferric carboxymaltose or physician's choice for treatment.

Patients with untreated, histologically confirmed, cT1c - cT4a-d BC and central receptor assessment were included. Patients with HER2+ or TNBC were eligible irrespective of nodal status, luminal B-like tumours only if pN+. Primary objective is to compare pCR rates (ypT0/is ypN0). Sample size calculations assumed a pCR rate of 50% for EPC and 60% for PM(Cb), requiring 950 patients to show superiority of PM(Cb). Secondary objectives are to compare pCR rates between treatment arms within the stratified subpopulations (BC subtype [HER2+ vs HER2- HR+ vs HER2- HR-], Ki-67 [≤20 vs >20%], lymphocyte-predominant BC [≥60% tumor infiltrating lymphocytes (TILs), no vs yes]), amongst others.

Results: 961 patients were recruited between 12/2014 and 05/2016, 946 started treatment. Median age was 48/48 years (EPC/PM(Cb)), 2/2% had bilateral, 13/16% multifocal, 7/7% multicentric, 4/4% T3, 4/4% T4, 46/47% N+, 81/83% ductal invasive, 65/68% G3 tumors; 41/40% were HER2+, 43/43% TNBC. 286 patients reported SAEs (147 EPC/139 PM(Cb)) and 1 died (1 PMCb: multiorgan failure due to sepsis). Final analysis on primary endpoint will be presented.

Conclusions: GeparOcto investigates the efficacy of dose-dense dose-intensified EPC compared to weekly PM(Cb), both with dual HER2-blockade in HER2+ BC, in high-risk early stage breast cancer patients. The trial is financially supported by Roche, Amgen, Teva and Vifor.
Body: Introduction: Pathological complete response (pCR) in unselected triple negative breast cancer (TNBC) is associated with excellent long-term survival. However, controversy remains as to whether pCR in BRCA mutation associated (BRCA[+]) TNBC is predictive of improved long-term outcome. A recent study suggests that pCR was not a surrogate for outcomes in BRCA1 associated TNBC. All of the patients in this study harbored an Ashkenazi Jewish founder BRCA1 mutation and the majority of mutation carriers underwent lumpectomy. Impact of pCR as it relates to BRCA status in a larger, heterogeneous TNBC cohort treated in a contemporary time frame is not known.

Aim: Evaluate and compare the prognostic impact of pCR as it relates to the BRCA mutation status in patients enrolled in a prospective multisite TNBC registry.

Methods: 453 patients with stage I-III TNBC were enrolled within a multisite registry between 2011-2015, out of which 173 received neoadjuvant chemotherapy (NAC) and also underwent germline BRCA testing. pCR in the breast and axilla was evaluated and patients were followed for reoccurrence and survival. Recurrence free survival (RFS) was estimated according to the Kaplan-Meier method and compared among groups with log-rank statistic.

Results: For the 173 eligible patients the median age was 49 years; African-American:14%; median tumor size:3 cm; 42%.Lymph node positive; and 18% (32/173) demonstrated BRCA mutation (BRCA1=28, BRCA2=4). All patients received anthracycline and/or taxane based NAC. pCR rates for BRCA[+] and wild type (BRCA[-]) patients was 72% and 46% respectively (p=0.01). 97% of BRCA[+] and 42% of BRCA[-] patients underwent bilateral mastectomy (p=0.001). The three year RFS was 92% and 81% in BRCA[+] and BRCA[-] patients, respectively (p=0.18). Attainment of pCR was associated with excellent 3 year RFS of 95% and 97% in BRCA[+] and BRCA[-] patients, respectively (p=0.85). Among BRCA[-] patients lack of pCR was associated with significantly worse 3 year RFS (70% RFS in patients without pCR, compared to 97% in patients with pCR; p=0.001). Among BRCA[+] patients lack of pCR was associated with numerically lower but not statistically significant worse 3 year RFS (83% RFS in patients without pCR, compared to 95% in patients with pCR; p=0.41). On multivariable Cox regression analysis, only stage III disease was associated with higher risk of relapse (p<0.001).

Conclusions: Our observation of higher pCR in BRCA-carriers compared to wild-type TNBC patients is consistent with previously published literature. In this contemporary cohort of TNBC patients for whom the majority of BRCA[+] patients underwent bilateral mastectomy, attainment of pCR carried an excellent prognosis in both BRCA[+] and BRCA[-] patients. On the other hand, BRCA[+] patients who do not attain pCR may have better outcomes compared to BRCA[-] patients without pCR. Further research to explore the underlying biological mechanisms involved in tumor response and relapse in BRCA[+] and BRCA[-] TNBC patients is needed. Furthermore, given these observations, germline BRCA mutation status should be used as a stratification variable in studies evaluating pCR and long term outcomes with investigational therapies in TNBC.
**Title:** Peripheral sensory neuropathy occurrence and resolution: Results from the neoadjuvant randomized GeparSepto study (GBG 69)

**Body:** Background: The GeparSepto (NCT01583426) study showed that nab-paclitaxel (nP) increases the pathological complete response (ypT0 ypN0) rate when it replaces paclitaxel (P) as part of a sequential taxane followed by epirubicin/cyclophosphamide (EC) neoadjuvant chemotherapy for pts with early breast cancer (BC) (Untch Lancet Oncol 2016). After a safety analysis showed a higher rate of dose reductions, treatment discontinuations as well as peripheral sensory neuropathy (PSN) with nP 150 mg/m² w (nP150) compared to P 80mg/m² w, dose of nP was reduced to 125 mg/m² w (nP125). The risk-benefit ratio of nP125 was improved over nP150 (von Minckwitz SABCS 2015). We reported follow-up (FU) data on PSN occurrence and resolution.

Methods: Pts with untreated BC received P 80mg/m² w or nP 150/125mg/m² w followed by four cycles of E 90 mg/m² plus C 600 mg/m² q3w, with trastuzumab 6 mg/kg (loading (LD) dose 8 mg/kg) and pertuzumab 420 mg (LD 840 mg) q3w if HER2+. After the end of the study the protocol was amended in order to collect long-term data on PSN outcome as well as on treatment modalities. PSN will be reported according treatment and dose received on day 1.

Results: Overall 601 pts received P80; 220 pts nP150 and 385 pts nP125 on day 1. PSN grade 2-4 was observed in 18.8% (n=113/601) of pts treated with P80 and in 41.8% (n=92/220) vs 39.2% (n=151/385) with nP150 and nP125 respectively (p=0.547). Grade 3-4 PSN was reported for 2.7% (n=16/601) of pts in the P80 group and 14.5% (n=32/220) vs 8.1% (n=31/385) in the nP150 vs nP125 group respectively (p=0.018). In 31.8% (36/113), 35.9% (33/92) and 27.2% (41/151), PSN was not resolved at the end of the treatment (EOT); PSN grade 3-4 was not resolved in 37.5% (6/16), 56.3% (18/32) and 58.1% (18/31).

After a median FU of 110 weeks after EOT, data on PSN status for pts with unresolved PSN grade 2-4 were available from 30, 22 and 32 pts; 26 pts did not provide update information (n=7 died, n=5 data not yet available, n=14 status unknown). For 63.3% (n=19), 40.9% (n=9) and 56.2% (n=18) of pts, PSN grade 2-4 was resolved to grade 1. Time to resolve (TTR) of PSN grade 2-4 was significantly different between nP150 and nP125 (p<0.001); no significant difference was seen between P and nP (p=0.405) [Tab.1]. After a median FU of 103 weeks after EOT, data on PSN status of pts with unresolved PSN grade 2-4 were available for 6, 14 and 14 pts. For 66.6% (n=4), 42.8% (n=6) and 50.0% (n=7) of pts PSN grade 3-4 was resolved to grade 1. TTR of PSN grade 3-4 was not significantly different neither for nP150 vs nP125 (p=0.103) nor for P vs nP (p=0.120) [Tab.1].

Conclusions: nP125 is associated with a lower occurrence of PSN compared to nP150 but higher PSN than P80. If PSN occurred nP125 is associated with a more rapid resolution compared to nP150. Nearly 10.7% had no resolution of PSN so far. Further FU and markers for selecting pts at risk are needed.

The trial is supported by Celgene.

Title: A randomized phase II neoadjuvant study comparing docetaxel and cyclophosphamide (TC) with 5-fluorouracil, epirubicin, and cyclophosphamide followed by docetaxel (FEC-D) for hormone receptor-negative breast cancer: The Kanagawa breast oncology group (KBOG) 1101 study

Narui K, Ishikawa T, Shimizu D, Tanabe M, Sasaki T, Oba MS Saito, Morita S, Nawata S, Kida K, Mogaki M, Doi T, Tsugawa K, Ogata H, Ota T, Kosaka Y, Sengoku N, Kuranami M, Saito Y, Suzuki Y, Suto A, Arioka H, Chishima T, Ichikawa Y, Endo I and Tokuda Y. Yokohama City University Medical Center, Yokohama, Japan; Tokyo Medical University, Tokyo, Japan; Yokosuka Kyosai Hospital, Yokosuka, Japan; Shonan Kinen Hospital, Kamakura, Japan; St. Marianna University School of Medicine, Kawasaki, Japan; Kitasato University, Sagamihara, Japan; Tokai University, Isehara, Japan; Yokohama Rosai Hospital, Yokohama, Japan and Yokohama City University, Yokohama, Japan.

Body: Purpose: This study aimed to evaluate response to neoadjuvant chemotherapy (NAC) for patients with hormone receptor-negative (HR-negative) breast cancer (BC) to identify subtypes that require anthracycline treatment.

Methods: In total, 103 patients with operable HR-negative BC were registered. They were randomly assigned to administration of 6 cycles of docetaxel (75mg/m$^2$) and cyclophosphamide (600 mg/m$^2$) (TC6) or 3 cycles of 5-fluorouracil (500 mg/m$^2$), epirubicin (100mg/m$^2$), and cyclophosphamide (500mg/m$^2$) followed by 3 cycles of docetaxel (100mg/m$^2$) (FEC-D). Cytokeratin (CK) 5/6 and EGFR expression were used to identify basal and non-basal triple-negative (TN) BC. The primary endpoint was pathological complete response (pCR); secondary endpoints were safety, breast-conserving surgery, disease-free survival, and overall survival. Predictive factors of pCR for each regimen were also evaluated.

Results: The pCR rate was 36% for FEC-D and 25.5% for TC6, which did not differ significantly ($P=0.265$). When TN BC was subdivided into basal and non-basal subtypes, the pCR rate in the basal subtype was significantly lower for TC6 (13.6%) than for FEC-D (42.9%) ($P=0.033$), but did not significantly differ in the non-basal (TC6, 36.4%; FEC-D, 25.0%) and HER2-positive (TC6, 41.7%; FEC-D, 35.7%) cases.

The relative dose intensities of epirubicin and docetaxel in FEC-D and docetaxel in TC6 were 96.3±13.0%, 93.5±14.6%, and 93.9±16.3% (mean±SD), respectively. Occurrence of grade $\geq$2 adverse events was significant in FEC-D-treated patients. Poor appetite ($P<0.001$), nausea ($P<0.001$), vomiting ($P<0.001$), dysgeusia ($P=0.03$), and fatigue ($P=0.05$) were significantly more common for FEC-D than TC6. Patients treated with FEC-D experienced significantly more febrile neutropenia and anemia ($P=0.016$ and 0.017, respectively).

The rates of breast-conserving surgery were 68.0 and 72.3% for FEC-D and TC6, respectively ($P=0.641$). Patients achieved pCR had better DFS (log rank test, $P = 0.287$) and OS (log rank test, $P = 0.069$), though not significant. Patients treated with FEC-D had better DFS (log rank test, $P = 0.107$) and OS (log rank test, $P = 0.159$), though not significant.

Among patients with TN BC, those treated with FEC-D had significantly better DFS (log rank test, $P = 0.016$) and OS (log rank test, $P = 0.034$) than treated with TC6.

Low ALDH1 expression and high topo II$\alpha$ protein expression were strongly correlated with pCR in FEC-D, with odds ratios (ORs) of 4.33 [95% CI, 1.02–18.38] and 4.08 [0.97–17.2], respectively. ALDH1 was also associated with pCR in TC, OR=3.50 [0.84–14.6]. Other factors, including age, tumor size, nodal status, tumor grade, Ki67, p53, and TOP 2A status were not associated with pCR in either regimen.

Conclusions: We found that TC6 was less effective than FEC-D for treating HR-negative BC because it was insufficient for TNBC, particularly for basal BC. This suggests that anthracycline is more important than taxane for basal BC. Additionally, ALDH1 could be a marker for resistance to conventional chemotherapy.
Title: MINT trial yields MammaPrint High1/High2 risk classes associated with significant differences in pCR and receptor subtype

Body: Background: Previous clinical trials have validated that the 70-gene signature MammaPrint™ provides prognostic and predictive information for early stage breast cancer patients and can identify low risk patients who may safely avoid adjuvant chemotherapy. Additionally, the neo-adjuvant I-SPY 1&2 TRIALs demonstrated that further stratification of patients into MammaPrint High 1 (MP1) and MammaPrint High 2 (MP2) risk groups may help predict chemo-sensitivity. There were significant differences in pathological complete response (pCR) rates for early stage, locally advanced breast cancer patients who were not HR+HER2- MammaPrint Low Risk. Specifically, the PARP inhibitor veliparib in combination with carboplatin recently graduated the I-SPY 2 phase 2 screening trial, having met the 85% predictive probability criterion with a triple-negative breast cancer signature, which was the subset recommended for this regimen’s subsequent development. Given these data, we wanted to determine whether the Multi Institutional Neo Adjuvant Therapy MammaPrint Project (MINT) patient population confirmed the MP1/MP2 risk stratification, clarify if there is an associated receptor subtype for MP1/MP2 risk classes, and conclude if the stratification correlates to a significant difference in pCR.

Methods: Array data from pre-treatment samples were obtained from 180 patients classified as MammaPrint High Risk, subtyped by IHC and treated with neo-adjuvant chemotherapy according to protocol. Response was measured by centrally assessed residual cancer burden pursuant to guidelines. Patients were then further stratified based on the MammaPrint Index per their classification threshold between MP1/MP2. Fisher’s exact test was used to assess significance of association with pCR overall and within hormone receptor (HR) and HER2 subtypes.

Results: MP1 vs MP2 risk classes yielded subsets with significant (p=0.007) differences in pCR. 44% (40/92) of MP2 patients achieved a pCR, compared to 24% (21/88) of MP1 patients. Next, we investigated whether the MP1 and MP2 risk classes were associated with receptor subtype. MP1 demonstrated a significant association and MP2 near significance. 32% (21/66) of triple-negative patients were classified as MP2 vs only 3% (2/66) MP1. Similarly, in the overall population, 28% (51/180) HR+HER2- are classified as MP1 vs 4% (8/180) MP2. Results in the pCR population were reflective of these subtype trends. 63% (58/92) of MP2 patients were classified triple-negative, of which nearly one quarter (21/92) had a measured pCR, whereas 58% (51/88) of MP1 patients were HR+HER2- with 3% (3/88) achieving pCR (Table 1).

Conclusion: This analysis in the MINT patient population supports previously published data and suggests that the MammaPrint High 1/2 risk classification may help predict chemo-sensitivity. Given the statistical significance of these data, we are currently investigating the biological mechanisms distinguishing the MP1/MP2 subgroups that may account for its use as a specific biomarker of response to chemotherapy treatment in future trials.

Row#1= pCR, #2= RD, #3= Total
Body: Introduction: Triple negative breast cancer (TNBC) remains a challenging disease with dismal prognosis. Platinum analogs have not yet shown to improve long term outcome in this setting, but are associated with increased pathological complete response rate (pCR) at the cost of higher toxicity.

Aim: To further increase or maintain the high pCR rate with platinum containing schedules while decreasing toxicity by administering low dose weekly carboplatin instead of high-dose 3 weekly carboplatin as in CALGB 40603.(1)

Patients and methods: We evaluated the tolerability and the impact of the addition of weekly carboplatin (CP) to paclitaxel (P) and dose dense epirubicin-cyclofosfamide (EC) on pCR in an open-label multicenter phase II study in stage II/III TNBC patients (pts). Sixty three pts received dose dense paclitaxel (P:80mg/m²/wk) concurrent with carboplatin (CP: AUC=2) for 12 wks, followed by two-weekly epirubicin (E:90mg/m²) and cyclophosphamide (C:600mg/m²) for 4 cycles. The primary endpoint is pCR in the breast and axilla. Additionally treatment delivery and adverse events are recorded. A correlative assessment of germline mutations in homologous recombination (HR) genes is planned. Pts are monitored for response by magnetic resonance and mammography and also for relapse free survival and time to treatment failure. The study size sample has been calculated according to the optimal Simon's two-stage design method. The target sample size was 63 patients with 80% power to detect a pCR rate of $\geq 47\%$ ($\alpha=0.05$).

Results: Accrual to the study is completed with 63 eligible pts with operable, noninflammatory stage II and III TNBC included. Most patients were between 40 and 60 yrs old and were clinical stage T2 tumors. Half of the pts were clinically node + and 70% were G3. Sixty six percent had breast conserving surgery. Sixteen out of 26 (61.5%) of the currently evaluable pts achieved a pCR rate in the breast and axilla. The other ongoing patients have not yet reached this endpoint. Four out of 21 evaluable pts that completed the chemotherapy missed two or more doses of CP due to neutropenia (NP) G3/4(2), general deterioration G3(1) and polyneuropathy (PNP) G3(1) and seven pts needed one dose reduction of P and/or CP due to NP G3-4 (3-2) and PNP G2(1) and one abdominal infection.

Conclusion: These preliminary data suggest that the addition of weekly carboplatinum to neoadjuvant paclitaxel and EC is feasible and has a promising pCR rate in the breast and axilla as high as 61.5% in early TNBC pts. More mature toxicity and outcome data and correlation with genome analysis will be presented.

Title: Non-anthracycline-containing docetaxel plus cyclophosphamide was inferior to docetaxel, anthracycline and cyclophosphamide in neoadjuvant treatment of triple negative or HER2 positive breast cancer: Long term follow-up result from NATT study

Chen X, Ye G, Zhang C, Li X and Shen K. Comprehensive Breast Health Center, Ruijin Hospital Shanghai Jiaotong University School of Medicine, Shanghai, China; The First People's Hospital of Foshan, Foshan, Guangdong, China; Guangzhou General Hospital of Guangzhou Military Area, Guangzhou, Guangdong, China and Shanxi Provincal Cancer Hospital, Taiyuan, Shanxi, China.

Body: Objective: Previous study demonstrated that non-anthracycline-containing docetaxel plus cyclophosphamide (TC) regimen was associated with lower response rate and worse disease outcome compared with docetaxel, anthracycline and cyclophosphamide (TAC) regimen in neoadjuvant treatment of triple negative or HER2 positive breast cancer in terms of short term survival outcome. In this study, we evaluate the long-term survival outcome between TC and TAC.

Methods: Clinical stage IIB or III TNBC or HER2+ breast cancer patients were treated with six cycles of TC or TAC. The primary end point was pathological complete remission (pCR). Secondary end points included clinical response rate, event free survival (EFS), disease free survival (DFS), and overall survival (OS).

Results: 102 patients were randomized and 96 patients were available for this data analysis (TC: n=45; TAC: n=51). TAC regimen had a trend of higher pCR rate than TC regimen: 17.6% vs. 6.8%, P = 0.113. With a median follow-up of 53 (8-76) months, patients achieved pCR after neoadjuvant chemotherapy had a superior EFS, DFS and OS compared with patients without pCR (P < 0.05). TAC treatment resulted in a significantly superior outcome than TC treatment: the estimated 5-year EFS was 68.1% vs 29.8%, P = 0.001; the estimated 5-year DFS was 69.7% vs 34.0%, P = 0.001; and the estimated 5-year OS was 88.4% vs 51.6%, P < 0.001. Multi-variable survival analysis demonstrated that treatment regimen was the independent prognostic factor for these patients. Patients treated with TAC had a superior EFS, HR = 0.40 (95% CI 0.21-0.75), P = 0.004; a better DFS, HR = 0.40 (95% CI 0.21-0.78), P = 0.007; and a better OS, HR = 0.19 (95% CI 0.07-0.57), P = 0.002.

Conclusions: Long term follow-up data demonstrated that adding anthracycline to TC could significantly improve disease outcome, indicating anathracycline should be considered as a necessary and effective drug in this trial setting.

**Title:** Risk factors of locoregional relapse in locally advanced breast cancer treated with neoadjuvant chemotherapy following mastectomy and radiotherapy

Chen S, Huang L and Shao Z-M. Shanghai Cancer Center, Shanghai, China; Shanghai Cancer Center, Shanghai, China and Shanghai Cancer Center, Shanghai, China.

**Body:**

**Purpose:** We seek to investigate the prognostic factors that could possibly affect the local-regional recurrence (LRR) of breast cancer patients who do not achieve pathological complete response (pCR) after neoadjuvant chemotherapy (NCT), and to build a prognostic nomogram to predict patients' outcome.

**Methods:** The retrospective analysis included 510 patients who had received NCT followed by surgery and radiotherapy. The NCT regimens included anthracycline-containing, vinorelbine-containing, and taxane-containing regimens for a median of 3 cycles. The clinical responses to neoadjuvant chemotherapy were evaluated based on MRI and ultrasound examinations and in accordance with the Response Evaluation Criteria in Solid Tumors (RECIST) 1.1. The Miller-Payne (MP) grading system was employed to evaluate the decrease in cancer cellularity. Multivariate analyses were used to identify independent predictors of LRR.

**Results:** The median follow-up for the entire study population was 61 months (range 5-128 months). There were 40 isolated local recurrences, 17 regional-only recurrences and 5 patients with local and regional recurrences. Sixteen patients (25.8%) occurred synchronously with distant metastasis, and no LRR was detected after distant failure. Fifteen patients had recurrences in the supraclavicular field. The 5-year cumulative LRR-free survival rate was 88.0% (95% CI: 85.2%-90.1%). The 5-year overall survival and disease-free survival rates were 79.0% (75.5%-82.6%) and 63.1% (58.9%-67.3%), respectively. Multivariate analysis revealed that positivity for $\geq$ 4 lymph nodes and Ki-67 index $\geq$ 14% were independent factors for LRR-free recurrence. The prognostic model was established based on the sum of both independent prognostic factors, with positivity for $\geq$ 4 lymph nodes and Ki-67 index $\geq$ 14% individually contributing 1 point to the risk score. The patients in the validation set were assigned to a low-risk group (0 point), median-risk group (1 point) and high-risk group (2 points). The 5-year LRR-free survival rates in the low, intermediate, and high-risk groups were 95.5%, 89.1%, and 67.1%, respectively ($p < 0.001$). We also show the annual LRR rate among these 3 groups using our single-institution data, as well as to review relevant literature-based data to compare with our observations. Four publications that reported ARR (annual recurrence rate) after surgery for primary breast cancer were identified as eligible. In the relevant literature, the annual risk of local-regional recurrence peaked between two and three years after the initial diagnosis. In contrast, the ARR curve of the high risk subgroup for neoadjuvant patients exhibited one peak near 1 year (17% per annum). The median and low-risk subgroups did not have an obvious recurrence peak.

**Conclusion:** This prognostic model has considerable clinical value in predicting local-regional recurrence, which could help clinicians to design appropriate local-regional treatment specifically and to perform surveillance individually.
**Title:** Overall survival of patients with non-metastatic triple negative breast cancer who received neoadjuvant vs adjuvant chemotherapy: Cohort analysis of National cancer data base (NCDB) 2010 - 2011

Cheng YC, Smith E and Yen T. Medical College of Wisconsin, Milwaukee, WI.

**Body:**

**Background:** One of the benefits of neoadjuvant approach to the treatment of breast cancer is early microscopic disease control, which should translate to improved survival. However, clinical trials have not yet shown a survival benefit for neoadjuvant approach in even high risk patients, such as triple negative cases. Few studies have been performed outside of clinical trials.

**Purpose:** The objective of our study was to compare the overall survival of Stage I-III triple negative breast cancer patients who received neoadjuvant vs adjuvant chemotherapy within the NCDB, a prospectively collected, large, nationwide, hospital-based cancer outcomes database which contains information for more than 1,500 Commission on Cancer-accredited cancer programs in the U.S.

**Patient and Method:** We identified a cohort of women, aged > 18 year-old at diagnosis, with clinical stage I-III triple negative breast cancer diagnosed in 2010-2011, who received either neoadjuvant chemotherapy only or adjuvant chemotherapy only. Patients with incomplete or missing vital status, receptors status and treatment information were excluded. Demographic (age at diagnosis, race, ethnicity, comorbidities, insurance, median income, urbanicity), tumor (clinical stage, histology, grade) and treatment (breast surgery, surgical margin, radiation) factors were examined. Stabilized inverse proportion weights were developed and assigned to balance the neoadjuvant and adjuvant groups on all demographic, tumor and treatment covariates. Unadjusted and adjusted overall survival was calculated using the Kaplan-Meier method and compared using the log-rank test.

**Results:** Among the 15,483 women with triple negative breast cancer, 4,335 (28%) received neoadjuvant chemotherapy and 11,148 (72%) received adjuvant chemotherapy. Most of the demographic, tumor and treatment factors were similarly distributed among neoadjuvant and adjuvant groups except age at diagnosis and clinical stage. Compared to patients received adjuvant chemotherapy, patients received neoadjuvant chemotherapy were more likely to be younger (45% vs. 31% < 50 year-old, \( p < 0.0001 \)) and have a higher clinical stage (35% vs. 6% stage III, \( p < 0.0001 \)). The unadjusted 4-year overall survival of patients received neoadjuvant vs adjuvant approach was 75.8% (95% CI 74.4%-77.4%) and 87.5% (95% CI 87.1%-87.9%), respectively. After adjusting for demographic, tumor and treatment factors, the 4-year overall survival of patients received neoadjuvant vs adjuvant approach was 81.9% (95% CI 79.5%-84.3%) and 85.3% (95% CI 85.2%-85.4%), respectively.

**Conclusion:** In this NCDB study, the overall survival of triple negative breast cancer patients received neoadjuvant chemotherapy was inferior to those received adjuvant chemotherapy, even after adjusting for demographic, tumor and treatment factors. However, information regarding the chemotherapy regimen used and whether a full course of chemotherapy was delivered (2 factors that affect disease response and outcome) was not available. Patient and tumor factors at the time of disease presentation that are important in determining which triple negative patients will benefit from neoadjuvant approach remain to be defined.

Title: Zoledronic acid combined with neoadjuvant chemotherapy for HER2-negative early breast cancer (JONIE 1 trial): Survival outcomes of a randomized multicenter phase 2 trial

Ishikawa T, Akazawa K, Hasegawa Y, Tanino H, Horiguchi J, Miura D, Hayashi M, Takao S, Kim SJ, Yamagami K, Miyashita M, Konishi M, Shigeoka Y, Suzuki M, Taguchi T, Kubota T and Kohno N. Tokyo Medical University, Tokyo, Japan; Niigata University Medical and Dental Hospital, Niigata, Japan; Hirosaki Municipal Hospital, Hirosaki, Japan; Kitasato University Hospital, Sagamihara; Gunma University Hospital, Maebashi, Japan; Toranomon Hospital, Tokyo, Japan; Tokyo Medical University Hachioji Medical Center, Tokyo, Japan; Hyogo Cancer Center, Kobe, Japan; Osaka University, Osaka, Japan; Shinko Hospital, Kobe, Japan; Konan Hospital, Kobe, Japan; Hyogo Prefectural Nishinomiya Hospital, Kobe, Japan; Yodogawa Christian Hospital, Osaka, Japan; National Hospital Organization, Chiba Medical Center, Chiba, Japan; Kyoto Prefectural University of Medicine, Kyoto, Japan; Kamiiida Daiichi General Hospital, Nagoya, Japan and Kobe Kaisei Hospital, Kobe, Japan.

Body: BACKGROUND and AIM:
Findings from a randomized phase 2 JONIE1 trial in women with HER2-negative early breast cancer have shown that the addition of zoledronic acid (ZOL) to neoadjuvant chemotherapy (CT) has potential anticancer benefits in postmenopausal and triple-negative breast cancer patients. We report the data for the prespecified secondary endpoint of disease-free survival (DFS).

METHODS:
We enrolled women with HER2-negative early breast cancer and randomly assigned them to receive CT or CT+ZOL (CTZ). All patients received 4 cycles of FEC100 (fluorouracil 500 mg/m², epirubicin 100 mg/m², and cyclophosphamide 500 mg/m²), followed by 12 cycles of paclitxel at 80 mg/m² weekly. ZOL (4 mg) was administered 3-4 times weekly for 7 weeks to the CTZ group patients. Definitive surgery was performed 3-4 weeks after the last paclitaxel dose. The primary endpoint was pathological complete response (pCR). The secondary endpoints were the clinical response rates, rate of breast-conserving surgery, safety, and DFS (defined as the time from randomization to disease occurrence or death). The trial is registered as UMIN000003261 (www.umin.ac.jp/english/) with ongoing follow-up.

FINDINGS:
Of the 188 patients enrolled, 95 were assigned to the CT group and 93 to the CTZ group. The mean (95% CI) DFS time of the CT group was 5.15 years (4.83-5.47) and that of the CTZ group was 5.38 years (5.11-5.66). The 3-year DFS rate was 84.6% (95% CI 77.2-92.0) in the CT group and 90.7% (84.6-96.8) in the CTZ group with no significant difference (p = 0.120). The particular benefit from ZOL for the neoadjuvant CT seen as improvement of the pCR rate was indicated in the 3-year DFS period for triple-negative cancer cases (CT vs CTZ: 70.6% vs 94.1%), but not for postmenopausal cases.

CONCLUSIONS:
ZOL slightly improved DFS when combined with CT. Although a significant difference was not found in this study, plans are underway for conducting a combined analysis of 3 neoadjuvant CT trials together with ZOL. The improvement of the pCR rate may be associated with DFS in triple-negative cases. Previous studies have shown that ZOL was more efficacious in an estrogen-suppressed condition. However, the short-term application of ZOL in this study may not be sufficient to improve the outcome in postmenopausal patients.
Title: Residual cancer burden (RCB) as a strong prognosis factor in breast cancer (BC) patients treated with neoadjuvant chemotherapy (NACT) based on carboplatin, doxorubicin and taxanes

de Juan Ferré A, Mayorga Fernández M, Alonso Bartolomé P, Azcarretazabal González-Ontaneda T, Muñoz Cacho P, Múgica Estébanez M, Anchuelo Latorre J, Mata Velasco E, Saiz Isa L and López Vega JM. Marqués Valdecilla University Hospital, Santander, Cantabria, Spain; Sierrallana Hospital, Torrelavega, Cantabria, Spain; Teaching Unit of Family and Community Medicine, Santander, Cantabria, Spain and Navarra Hospital, Pamplona, Navarra, Spain.

Body: Purpose: Many pathologic response systems have been used since the arrival of NACT. The RCB is a standardized method, but not universally implemented (Symanns WF, et al. J Clin Oncol 2007). The main objective is to apply the RCB and check its prognostic value in patients treated with platinum-based NACT with a long follow up.

Methods: Patients diagnosed and treated with platinum based NACT are analyzed. They receive 4 cycles of carboplatin AUC 6 and doxorubicin 50 mg/m², followed by either docetaxel 75 mg/m² (4 cycles) or weekly paclitaxel 80 mg/m² (8 doses), preoperatively. Pathological complete response (PCR) is defined as the absence of invasive tumor in the breast and axillary nodes, allowing the presence of DCIS. RCB system is applied and correlated with disease free survival (DFS) and overall survival (OS) according to Kaplan-Meier method; differences between curves with log rank test.

Results: 109 patients (110 tumors) are included from Mar-2004 Mar-2009. Characteristics of patients and tumors: Mean age: 50.9 years (range 28-78 years); Premenopausal: 69 (62.7%). Median tumor diameter: 35 mm (0-90 mm); histology: ductal 85 (77.3%). Stage: IIa 46 (41.4%); IIIb 40 (36%); IIIa-11 (10%); IIIc 12 (10.9%); IIIc 1 (0.9%). Phenotypes: luminal A 18 (16.4%); luminal B 36 (32.7%); HER2 luminal B 22 (20%); HER2 13 (11.8%); triple negative 21 (19.1%). Responses: pCR: 17.3%; pCR and RCB-I: 37.3%. Responses according to phenotypes:

Surgery: lumpectomy 66 (60%). Follow up: DFS (median follow up 8.2 years (0.5-11.8)): 78.9%; OS (median follow up 8.6 years (0.8-11.41)). OS according to RCB: pCR: 94.7%; RCB-I: 86.4%; RCB-II: 76.6%; RCB-III: 58.8% (p 0.03).

Conclusion: RCB is a strong prognostic factor, here validated for a platinum based CT with a long follow up. Additional data on OS according RCB in different phenotypes will be presented at the meeting.
Title: Pertuzumab and trastuzumab in combination with weekly paclitaxel delivers high pCR rates with favourable toxicity profile in neo-adjuvant treatment of Her-2 positive breast cancer

**Body: Background:** A combination of Pertuzumab (P) and trastuzumab (H) with chemotherapy is the standard of care for the neo-adjuvant treatment of locally advanced/inflammatory Her-2 +ve breast cancer. Neutropenia and diarrhea are the two common significant side-effects observed with the commonly used chemotherapy regimens. We evaluated the efficacy and safety of a combination of P and H with weekly paclitaxel (T) given in a neo-adjuvant fashion in Her-2 +ve patients.

**Methods:** Women with a tumor size >2 cm or LN positive or inflammatory breast Ca with Her-2 positivity by IHC or FISH were treated. The treatment regimen studied was; Pertuzumab on D-1 at a loading dose of 840 mg, followed by 420 mg every 3 weeks, Trastuzumab on D-1 at a dose of 8 mg/kg loading dose, followed by 6 mg/kg every 3 weeks, and Paclitaxel on D-1/8 at a dose of 80 mg/m2. Six cycles were given at 3 week intervals. Herceptin was continued for a total of one year. Adjuvant radiation and hormonal treatments were given per the NCCN guidelines. Data on the pCR rate and safety profile were collected. LVEF was measured at baseline and every 6 weeks during neoadjuvant treatments.

**Results:** A total of 31 women were treated from Mar 2014 - Jan 2016. Median age was 43 years (31-80). Two pts had T-1 disease, 23 had T-2, 5 had T-3 and, 1 pt. had inflammatory breast ca. 16 pts had LN involvement. Receptor profile was: ER/PR +ve: 22 pts., ER+/PR-ve: 2 pts., ER/PR - ve: 7 pts.. All patients were able to complete the planned six cycles. Thirteen pts. achieved a pCR (41.9%). Five out of 7 ER/PR-ve patients (71.4%) had a pCR. Grade-3/4 neutropenia was seen in 3 patients (9.6%), febrile neutropenia was not observed in any pt. (0%). Grade-3/4 diarrhea was seen in 1 pt. (3.2%).Grade-3/4 neuropathy was seen in 2 pts. (6.4%). LVEF drop of more than 10% from baseline to less than 50% was seen in 1 patient (3.2%).

**Conclusion:** A combination of Pertuzumab, Trastuzumab and Paclitaxel (PHT) yields impressive pCR rates with minimal side-effects compared to the commonly used chemotherapy regimens. This combination could be explored further in larger trials.
Title: Predictive and prognostic value of Ki-67 expression in triple-negative breast cancer before and after neoadjuvant chemotherapy with weekly paclitaxel plus carboplatin

Wang R-X, Chen S, Jin X and Shao Z-M. Shanghai Cancer Center, Shanghai, China.

Body: Background: Neoadjuvant chemotherapy (NCT) is one of the main treatment strategies for patients with locally advanced breast cancer. This study was designed to demonstrate the utility of a platinum-containing treatment regimen in the neoadjuvant setting and to identify the predictive or prognostic value of Ki-67 among patients with triple-negative breast cancer (TNBC).

Methods: Data from 280 patients with stage II–III TNBC were collected. All patients underwent four cycles of NCT with paclitaxel (80 mg/m2) and carboplatin (AUC 2 mg*min/ml) on days 1, 8, and 15 of a 28-day cycle. Ki-67 values were evaluated in both biopsy and excision specimens. The clinical responses to NCT were evaluated based on MRI and ultrasound examinations in accordance with the response evaluation criteria in solid tumors (RECIST) version 1.1. The pathological evaluation of surgical specimens was conducted at by the Miller-Payne (MP) grading system. Logistic regression analysis was performed to identify independent predictors of pathological complete response (pCR). Survival analysis was performed to evaluate the prognostic value of various clinical and pathological variables.

Results: The overall pCR rate was 33.9%. Both the categorical and linear Ki-67 were independently correlated with pCR (P<0.001). There were also statistically significant differences among Ki-67 categories with respect to clinical response (P<0.001), Miller-Payne (MP) grades (P<0.001), and node status (P<0.001). A significant reduction of Ki-67 after NCT was most likely observed in patients with a relatively better response. Among 185 patients with a residual tumor after NCT, the tumor cell proliferation significantly decreased from a median Ki-67 value of 20.0% before chemotherapy to 15% after chemotherapy. The mean absolute reductions in Ki-67 were 29.4%, 8.5%, and -10.2% in patients with an ideal response (MP 5/4), a partial response (MP 3) and a poor response (MP2/1), respectively. In the multivariate model for non-pCR patients, Ki-67 reduction presented an independent prognostic value for relapse of disease (HR=0.986, 95% CI: 0.978-0.994; P=0.001). Residual node involvement was also an independent predictor of patient outcome (HR=0.895, 95% CI: 0.355-2.259 for 1-3 nodes and HR=2.424, 95% CI: 1.048-5.608 for more than 4 nodes, using 0 nodes as a reference; P=0.002). Better survival was more frequently observed in patients with a greater reduction in the Ki-67 value and fewer involved nodes.

Conclusions: The primary Ki-67 might help in further classifying TNBCs into subtypes with different responses to chemotherapy. The significant reduction of Ki-67 after treatment could indicate a favorable prognosis in non-pCR patients.
Title: NOSTRA PRELIM: A non randomised pilot study designed to assess the ability of image guided core biopsies to detect residual disease in patients with early breast cancer who have received neoadjuvant chemotherapy to inform the design of a planned trial

Francis A, Herring K, Molyneux R, Jafri M, Trivedi S, Shaaban A and Rea DW W. University Hospital Birmingham, Birmingham, West Midlands, United Kingdom and University of Birmingham, Birmingham, West Midlands, United Kingdom.

Body: BACKGROUND
Patients receiving neoadjuvant chemotherapy for breast cancer go on to have surgery regardless of their response. Women with HER-2 positive ER negative tumours (7.5% of all operable breast cancers in the UK) respond so well to neoadjuvant treatment with dual anti-HER2 therapy in combination with chemotherapy that pathological complete response rates of 80% can be achieved. This means that for patients receiving this treatment surgery is being performed to remove a cancer that isn’t there in the large majority. A study is planned in the UK (NOSTRA) to assess if it is feasible to treat patients with HER-2 positive ER negative breast cancer who achieve a pCR after neoadjuvant chemotherapy with trastuzumab and pertuzumab with radiotherapy alone. The first phase of the trial will be a feasibility study commencing in 2017 where all patients will have image guided tumour bed biopsies post treatment and all patients will have surgery. If the group of patients where a pCR is achieved can be accurately identified then a phase III trial randomising to surgery and radiotherapy or radiotherapy alone is planned.

The NOSTRA PRELIM study reported here assessed the ability of post neoadjuvant chemotherapy tumour bed biopsies to detect residual disease to provide experience to inform the much larger NOSTRA feasibility trial biopsy protocol.

METHODS
23 consecutive patients with operable primary breast cancer scheduled for neoadjuvant chemotherapy were approached to take part in the study and 20 gave consent.

All 20 patients had a clip inserted into the tumour bed under ultrasound (USS) guidance at diagnosis as is standard procedure. The number of cores taken ranged from 2-6. The median number of biopsies was 4

Tumour size range at diagnosis was 15-61mm with USS. All received neo-adjuvant chemotherapy and those who were Her2 positive received neoadjuvant trastuzumab. At completion all patients had USS guided tumour bed biopsy. They then went on to have surgery, after which pathology was assessed and an RCB score calculated for each patient.

For this study patients all tumour types were included as non pCR outcomes were required to determine accuracy and inform changes to the biopsy protocol for future use.

RESULTS
Only 2 patients in this study achieved a pCR
Residual disease was correctly identified in 16/20 patients.
Four patients had no tumour in their post treatment biopsies but had small residual invasive tumour at surgery. The size of residual disease in these patients ranged from 0.5 -9mm and all these patients had 3 core biopsies.

One patient had negative post treatment biopsies and a PCR of their invasive tumour. This patient had a diagnostic biopsy that confirmed separate area of DCIS several centimetres from the invasive component. This area did not undergo post treatment tumour bed biopsies (although both areas were clipped at diagnosis).

CONCLUSION
A protocol for biopsy in the upcoming NOSTRA feasibility study has been designed to both take more biopsies and sample a larger area of the tumour bed in order minimise the false negative rate.

Title: Lymph-vascular invasion in the absence of stomal invasion after neoadjuvant therapy: A rare pattern of residual carcinoma that lacks an AJCC/UICC T category

Guilbert M-C and Lester SC Carole. Brigham and Women's Hospital, Boston, MA.

Body: **Background:** Response to neoadjuvant chemotherapy in breast cancer serves as an important prognostic indicator, as patients whose estrogen receptor (ER) negative and/or HER2 positive cancers undergo a pathologic complete response (pCR) have an excellent outcome. Guidelines on classification of treatment response are available, but data is lacking for the rare event where lymph-vascular invasion (LVI) is the only residual disease in the breast. Only one study (Rabban JT et al, Am J Surg Pathol, 2009) has investigated the significance of this pattern of residual disease. These authors reported 6 patients with residual LVI in the breast in the absence of stromal invasion. Five of the patients also had residual disease in lymph nodes. Prognosis was poor with four of the patients dying in less than 4 years and an additional patient dying at 10 years. The aim of our study was to gather more data on this rare pattern of residual disease, with a focus on node negative cases. **Design:** We retrospectively identified from our pathology database all cases in which LVI was the only residual disease in the breast after neoadjuvant therapy. **Results:** A total of 16 cases were identified, yielding an incidence of 1.6% of all cancers undergoing neoadjuvant chemotherapy over a 10 year period. All patients were females with a mean age of 54 years (range 40-69 years). Eight cancers initially presented as a palpable breast mass, 4 as vague breast symptoms, 2 as inflammatory carcinoma and 1 was detected on screening mammogram. In twelve cases the axillary lymph nodes were either suspicious by imaging or proven positive by needle biopsy. The mean pre-neoadjuvant tumor size was 2.7cm (range 0.5-8.0cm). Six cancers were negative for hormone receptors and HER2, eight cancers were positive for HER2 and 4 cancers were positive for ER. After neoadjuvant chemotherapy, nine patients had no residual disease in lymph nodes. The remaining seven patients had residual disease in lymph nodes, although minimal in the majority. The mean follow-up was 65 months for the node negative group (range 9-125 months) and 44 months for the node positive group (range 7-102 months). One death occurred in each group (at 12 months and 67 months respectively), two patients are alive with metastatic disease in the node negative group and the remaining 12 patients are alive without disease. **Conclusions:** Pure residual LVI after neoadjuvant chemotherapy is a rare event. Our findings show that the outcome associated with residual LVI, with or without residual cancer in nodes, might not be as dismal as previously reported, although longer follow-up will be required. The more favorable outcome observed is in contrast to the single study previously published. Although the difference may be due to details in the type of chemotherapy or stage at presentation, it is difficult to compare the 2 groups of patients due to limited information about the earlier cases. More data is needed to draw conclusions on the prognostic significance of this type of residual disease. The lack of a current AJCC/UICC T category for this finding will make identification of these patients difficult in large databases.

Title: Role of tumor microenvironment, as assessed by breast MRI background parenchymal enhancement (BPE), in modulating response to neoadjuvant chemotherapy in young women with localized breast cancer

Spring L, Rutledge G, Yala A, Haddad S, Specht M, Moy B, Barzilay R, Lehman C and Bardia A. Massachusetts General Hospital, Boston, MA and Massachusetts Institute of Technology, Cambridge, MA.

Body: Background:
Neoadjuvant chemotherapy (NACT) is generally established as a therapeutic option for selected high-risk patients with localized breast cancer, including triple negative breast cancer (TNBC). On a patient level, achievement of pathologic complete response (pCR) at the time of surgery is associated with improved long-term outcomes and is considered to be a surrogate marker. Response to NACT is a complex phenomenon dependent on both host and tumor characteristics. While tumor characteristics, such as receptors and tumor grade, have been well studied as predictors of pCR, host characteristics to predict pCR have been less well studied. Background parenchymal enhancement (BPE) is an imaging characteristic that reflects the normal enhancement of the fibroglandular tissue on breast MRI, and could potentially modulate response to NACT by influencing the tumor microenvironment and vasculature. The aim of this study was to explore the ability of baseline BPE to predict pCR in a cohort of young women with localized breast cancer.

Methods:
A retrospective chart review was conducted of women ages 40 and under with stage II-III breast cancer treated with NACT at our institution from 2004 – 2014. Demographic, clinical, and pathological variables were extracted from the medical records. The primary outcome was achievement of pCR, defined as ypT0/is ypN0, after NACT. BPE pattern in the contralateral breast was obtained from pre-treatment breast MRI reports if available and otherwise was retrospectively determined by a breast radiologist blinded to patient outcomes. BPE was dichotomized as low (minimum and mild) vs. high (moderate and marked). Logistic regression was used for statistical analysis.

Results:
A total of 69 patients ages 40 and under received NACT for localized breast cancer during the study period and had available pre-treatment breast MRI images. Median age at diagnosis was 36 (range 27-40). The majority of patients had grade 3 (65.2%), ER+/HER2- (60.9%) tumors while 24.6% had TNBC. Among pre-treatment breast MRIs, 42 (60.9%) patients had minimum or mild BPE and 27 (39.1%) patients had moderate or marked BPE. The overall pCR rate was 39%. After controlling for tumor grade, ER status, HER2 status, clinical stage, and type of NACT, high baseline BPE was associated with a trend towards higher odds of achieving pCR compared to low BPE (OR = 1.49, 95% CI 0.47–4.71), though statistical significance was not reached (p = 0.50). When stratified by ER status, the relationship was stronger among the ER+ subset (OR 1.8, p = 0.49) compared to the ER- subset (OR 1.3, p = 0.78).

Conclusions:
A statistically significant association between high baseline BPE and achievement of pCR was not found in this limited sample size, but a trend towards higher pCR rates, particularly with ER+ tumors, was seen. While tumor factors have traditionally been used to predict pCR, BPE is a readily available MRI imaging characteristic that reflects the tumor microenvironment and may be useful in building a model that incorporates tumor factors along with host factors to develop personalized NACT regimens for young women with breast cancer.
Title: Population based long term outcomes of pathologic complete response after neoadjuvant chemotherapy in stage I-III breast cancer: The British Columbia experience

Body: Background:
Neoadjuvant chemotherapy is a treatment option for breast cancer patients (pts) with locally advanced disease and for pts with operable breast cancer who desire breast conservation. Neoadjuvant therapy also allows for early evaluation of the effectiveness of systemic therapy. Pathologic complete response (pCR) has been shown in clinical trials to be associated with improved survival. The objective of this study was to determine if the outcomes demonstrated in clinical trials can be applied in the population based setting by comparing the outcomes of breast cancer pts who achieved pCR (no invasive disease in breast and nodes) vs. those that did not achieve a pCR.

Methods:
This is a retrospective cohort study of stage I-III invasive breast cancer pts treated with neoadjuvant chemotherapy from 2005 to 2010 in British Columbia. Cases were identified from the Breast Cancer Outcomes Unit database. Data was collected on demographics, tumor pathology, and type of treatment (chemotherapy, endocrine therapy, trastuzumab) and linked to standard clinical outcomes.

Results:
267 pts who met inclusion criteria were identified, of whom 5% had stage I, 33% Stage II and 59% Stage III breast cancer. Median follow up was 7.4 years. Overall 74 pts (28%) demonstrated a pCR and 193 pts did not. pCR pts had better 5-yr overall survival (OS) vs. non-pCR pts: 88% vs. 73% (HR 0.43, 95% CI 0.23-0.82, p=0.01). 5-yr disease free survival (DFS) was 84% in pCR pts vs. 70% in non-pCR pts (HR 0.45, 95% CI 0.24-0.83, p=0.01). Similarly, 5-yr breast cancer specific survival (BCSS) and distant disease free survival (DDFS) were significantly better in favor of the pCR cohort: HR 0.39 (95% CI 0.18-0.82, p=0.01) and HR 0.45 (95% CI 0.24-0.83, p=0.02) respectively. pCR pts were more likely to be HER2-positive and/or ER negative.

Conclusions:
Our population based results showed that early stage breast cancer pts who achieved pCR after neoadjuvant chemotherapy had better outcomes on all survival parameters compared to pts who did not achieve a pCR. This finding is consistent with results from neoadjuvant clinical trials and the FDA meta-analysis. These ‘real world’ results demonstrate that pCR can be used as a surrogate endpoint for survival outcomes even among non-trial pts.
Pathological complete response (pCR) has been shown to demonstrate improved outcomes in breast cancer. Often novel treatments, such as taxanes or HER2 based therapies, trastuzumab or pertuzumab, have shown an increase of pCR with possible impact on the prognosis of breast cancer patients. These therapies are usually introduced into the patient population through clinical trials. Therefore, it can be hypothesized participation in neoadjuvant clinical trials might improve the pCR rate in early breast cancer patients. The aim of this study was to explore this association.

Methods: This is a retrospective study of consecutive breast cancer patients who were treated with a neoadjuvant chemotherapy at a single institution. Trial participation status was known for all patients. From 1995 to 2012 the institution participated in 10 different neoadjuvant chemotherapy trials. Outside those clinical trials, patients were treated according to national neoadjuvant therapy guidelines. Patients who took part in clinical trials were compared with patients who did not take part in clinical trials with appropriate univariate tests. Additionally, logistic regression was performed with pCR as the dependent variable and commonly known predictors of pCR (tumor size and molecular subtype) as independent variables. The model was adjusted for age at diagnosis, year of treatment and trial participation status. Furthermore, exploratory survival analyses were performed.

Results: A total of 281 patients were treated within a neoadjuvant clinical trial and 822 patients outside a clinical trial. There are significant differences in the patient populations with regards to age (p=0.0009) and tumor size (<0.0001). pCR rate in patients with trial participation was 21.4% and 19.0% in patients who did not take part in clinical trials. Multivariate logistic regression showed an OR of 1.393 (95%CI 0.937-2.071, p=0.1012). Exploratory survival analyses showed a better prognosis in patients taking part in clinical trials.

Conclusions: This study shows an increased chance of pCR in patients taking part in clinical trials; however the statistical test could not show statistical significance. Most likely the effect can be explained by trial participants having access to drugs which improved pCR rates, such as HER2 based therapies or taxanes.
Evaluation of weekly paclitaxel plus carboplatin followed by anthracycline chemotherapy on the neoadjuvant treatment of patients with triple-negative breast cancer

Castrellon AB B, Velez M, Blaya M, Barnick S, Dumais K and LeCroy N. Memorial Cancer Institute, Hollywood, FL.

Background
Triple negative breast cancer (TNBC) accounts for 15 to 20 % of the invasive breast cancers. Pathological complete response (pCR) in this subgroup of breast cancer is associated with improved long term event free survival. Results from previous studies indicate that the addition of carboplatinum (Cb) to standard neoadjuvant anthracycline-taxane chemotherapy results in an increase in pCR. One of the investigational arms of the CALGB 40603 tested paclitaxel 80 mg/m2 once a week (wP) for 12 weeks with concurrent Cb (area under curve 6) once every 3 weeks for four cycles, followed by doxorubicin plus cyclophosphamide once every 2 weeks (ddAC) for four cycles. Although effective this regimen has been difficult to reproduce in the daily practice. The purpose of this study was to evaluate the effectiveness and tolerability of wP in combination with weekly Cb (wP+wCb) area under curve 2 (AUC=2) followed by anthracycline chemotherapy.

Methodology
The electronic medical record system was used to identify female patients 18 years of age or older with clinical stage I-III (TNBC) who received neoadjuvant chemotherapy of wP+wCb (AUC=2) before or after anthracycline chemotherapy between January 1, 2014 and March 1, 2016. The primary outcome was to evaluate the tolerability of fractionating carboplatin to weekly infusions in combination with weekly paclitaxel. The secondary outcomes included the pCR (no evidence of invasive tumor in the breast and axilla), Residual Cancer Burden (RCB), the number of cycles received in each chemotherapy regimen and frequency of chemotherapy related toxicities.

Results:
For the 32 eligible patients, median age: 51 years, Stage I: 6%, Stage II: 68%, Stage: III 26%, germline BRCA mutation: 10%, Ki 67 > 75% : 72%. 93% of the patients received 11-12 cycles of wP+wCb and 83% received all 4 planned cycles of anthracycline chemotherapy. 83% of patients completed all planned therapy. pCR and RCB 0/1 rates were 60% (19/32) and 75% (24/32) respectively. RCB 2: 22% (7/32), RCB 3: 3% (1/32). 93% of the patients experienced grade 3 neutropenia during wP+wCb requiring GCSF, Grade 3 anemia was seen in 15 % (5/32) and Grade 3 thrombocytopenia was seen in 18 % (6/32).

Conclusion:
The combination of neoadjuvant chemotherapy with wP+wCb before or after anthracycline chemotherapy was well tolerated among patients with TNBC as demonstrated by the fact that most participants were able to receive all planned 12 cycles of wP+wCb and all 4 cycles of anthracycline chemotherapy. Complete pathologic response rates were comparable to historically seen. The findings support the continued use of this treatment modality in the general practice.
Impact of “immunohistochemistry-based molecular subtype” on chemo-sensitivity and survival in Hispanic breast cancer patients following neoadjuvant chemotherapy (NAC)

Gomez-Wolff R, Garcia H and Ossa C. Instituto de Cancerología SA, Medellín, Antioquia, Colombia and Universidad de Antioquia, Medellín, Antioquia, Colombia.

Body: NAC it’s the standard procedure when handling non-surgical tumors and inflammatory breast carcinomas, increases the possibility of conservative surgery and must be considered an evaluative tool in designing a therapeutic strategy. NAC improves Disease-Free Survival (DFS) and Overall Survival (OS) in patients achieving pathological complete response (pCR). “Immunohistochemistry-Based Molecular Subtyping” (IMS) with ER, PR,HER2 and Ki67 has shown good correlation with gene expression assays to identify Intrinsic Molecular Subtypes. The relationship between IMS, chemo sensitivity and survival is currently a matter of interest. Achieving pCR at the time of Surgery has been associated with a favorable prognosis.

Objectives: to investigate the pathological response to NAC and its correlation with IMS, as well as its correlation with DFS and OS in patients who have undergone NAC.

Methods: Women > 18 years old. treated with NAC and surgery at IDC (January 2009 to December 2013). Demographic, clinical en follow-up variables were obtained from de IDC patient’s registry. Patient’s vital status was traced through phone calls. pCR was defined as ypT0 ypN0 (the absence of invasive cancer AND in situ cancer in the breast and axillary nodes). IDC’s IRB approved the research project.

Results: A total of 592 patients fulfilled the study’s inclusion criteria. The distribution by subtypes were: “Luminal A”: 150 (25.3%), “Luminal B/HER2 -”: 189 (31.9%), “Luminal B/HER2+”: 114 (19.3%), “HER2-enriched”: 45 (7.6%) and “Triple negative”: 94 (15.9%). The median follow-up was 51 months (interquartile range: 37-68). Pathological response to NAC was: complete pathological response (pCR) in 59 (10%) patients, partial pathological response in 426 (72.0%); stable disease in 82 (13.8%), and progression in 25 (4.2%) patients. In Multivariable Cox Regression Models, pCR is associated with a significant improvement in the DFS (HR 6.89; 95% CI: 2.53 to 18.75. p=0.01) and OS (HR 6.82; 95% CI 2.13 to 21.78. p=0.01). By “Immunohistochemistry-based molecular subtype” the pCR is associated with a significantly better DFS for “Luminal B”, “Triple Negative” and “HER2-enriched”. For OS we found significantly association with pCR for “Triple negative” and “Luminal B”. “Immunohistochemistry-based molecular subtype”. The “HER2-enriched” shown a trend to better OS if obtain pCR (p=0.05).

Conclusions: pCR is associated with an improved overall survival and disease-free survival rates in this group of Hispanics patients. In advanced stages, histological grade 3, Luminal B, Triple Negative and HER2+ enriched tumors the pCR is associated with a significantly better DFS.
Title: The association of higher tumor HER2 load with treatment response to neoadjuvant therapy in HER2 positive breast cancer patients

Body: Background: Neoadjuvant therapy for HER2 positive invasive breast cancer is used to downstage tumor prior to surgery, objectively measure response, and evaluate novel therapies in clinical trials. Residual Cancer Burden (RCB) established by pathologic evaluation of post-treatment surgical specimens is a marker of tumor response to chemotherapy as well as predictor of recurrence-free survival in HER2 positive breast cancer. The relationship between the HER2 tumor load and the response to chemotherapy in not known.

Specific Aims: To evaluate RCB after neoadjuvant chemotherapy and HER2-targeted treatment for HER2-positive breast cancer, and to determine clinicopathologic factors associated with treatment response as represented by RCB.

Methods: This retrospective chart review included all HER2-positive breast cancer patients, stage I – III, receiving neoadjuvant chemotherapy and HER2-targeted therapy with post-treatment surgical resection at an Allina Health hospital from 2013-2016. Review of clinicopathologic variables included HER2/CEP17 ratio, HER2 absolute copies, ER/PgR status (using the H score calculation), patient age, baseline tumor size, and gross and microscopic pathology review of breast tissue specimens with RCB evaluation completed by breast pathologists. To compare factors related to response, chi-square with Monte-Carlo simulation was used to analyze dichotomous variables, and Mann Whitney U-tests were used for continuous variables.

Findings: The study included 97 patients. Upon surgical resection, complete pathologic response (RCB-0) was found in 47% (46/97 patients), and partial pathologic response (RCB-I) in 15% (15/97 patients). As compared to non-responders (RCB-2 and RCB-3) the complete and partial responders (RCB-0 and RCB-1) were associated with greater HER2/CEP17 ratios (10.2 vs. 6.5; p=0.003), and greater HER2 absolute copies (25 vs. 15.8; p <0.001). Complete responders were associated with lower ER expression (H scores of 89.2 vs. 171.8; p=0.005) than non-responders, with RCB-1 responders associated with ER H-scores between RCB-0 and non-responders (H score=145.9). No significant differences were noted between responders and non-responders on age at diagnosis, pre-treatment tumor size, PgR expression, or the percentage of tumor infiltrating lymphocytes.

Conclusions: The majority of patients with HER2 positive tumors show considerable benefit with neoadjuvant chemotherapy and HER2-targeted treatment (63% in our study) based on RCB assessment. Predictors of response as measured by RCB include high HER2/CEP17 ratios, high absolute copies of HER2 signals by FISH, and lower ER expression.
Title: Survival after adjuvant and neoadjuvant chemotherapy in elderly patients with triple negative breast cancer: A Cleveland Clinic experience

Mohapatra S, Seepana J, Haddad A, Spiro T and Daw H. Fairview Hospital/ Cleveland Clinic, Cleveland, OH and Moll Cancer Center, Fairview Hospital/ Cleveland Clinic, Cleveland, OH.

Body: Background:
Triple negative breast cancer (TNBC) comprises of approximately 15% of the total breast cancers. There is limited data on treatment outcome of these patients in elderly population. We report our experience with elderly patients with TNBC treated at our tertiary care centers.

Objectives and rationale:
1. Percentage of TNBC patients who received neoadjuvant chemotherapy (NACT) vs. Adjuvant chemotherapy (ACT).
2. Chemotherapeutic agents used for NACT and ACT.
3. Progression free survival (PFS) and overall survival (OS) after neoadjuvant CT and adjuvant CT.
4. Outcomes between elderly patients 65-74 years vs. 75 years and above.

Methods:
With IRB approval, the Cleveland Clinic's database was used to identify TNBC patients treated between 2000 to 2013. OFS from the diagnosis of TNBC was the primary end point. Cox proportional hazard models with stepwise variable selections were used for data analysis.

Results:
A total of 223 patients, divided in to two groups, were prospectively followed. The age group from 65-74 years consisted of “Group A” (N=140, median 69) and 75 or older formed “Group B” (N= 83, median 80, maximum 92). Eighty eight percent had ductal carcinoma. Clinically majority had stage I (50%) and stage II (33%) disease; 17% had stage III disease and most tumors were poorly differentiated (74%, grade 3). Slightly more than half the patients had lumpectomies (55%); and in only 13% of cases (25/190) were margins positive. Patients who received neoadjuvant (NACT), aduvant chemotherapy (ACT) and radiation therapy (RT) were 65%, 53% and 38% respectively. For NACT primarily doxorubicin, cyclophosphamide and paclitaxel were used whereas for ACT it was docetaxel with cyclophosphamide. Group B had somewhat poorer performance status than younger patients (p=.05), received chemotherapy especially neoadjuvant therapy much less frequently (p<.0001). OS and PFS were significantly lower in Group B (p=0.001 and 0.007 respectively). This holds true even if one adjusts for performance status and use of chemotherapy (p=0.04 and 0.03 respectively).

Conclusion:
Among elderly patients with triple negative breast cancer, those above 75 years and older have poorer outcomes compared to those with age 65-74 years. However, this is a retrospective study and has limitations; prospective randomized studies are needed to confirm these findings.
Title: Rapid germline *BRCA* screening for locally advanced breast cancer changes surgical procedure after neoadjuvant chemotherapy

Body:

Introduction

Neoadjuvant chemotherapy (NAC) is proposed in case of locally advanced breast cancer (LABC) to improve breast conservative treatment (BCT). In the case of germline BRCA mutated (gBRCAm) patients, risk-reducing prophylactic surgical strategies in France are mastectomy for pre-symptomatic. On the other hand, BCT is proposed to all patients after NAC according to clinical response, regardless their gBRCAm status. Moreover, in the case of BRCA mutation, local recurrence risk at 15 years is higher in the BCT group (23%) vs mastectomy (5%) (Pierce 2010). The aim of this retrospective one-institution analysis is to evaluate if the knowledge of gBRCAm status impact surgical decision.

Patients and methods

All patients who underwent BRCA genetic testing during NAC for ≥ 3cm breast cancer between 2012 and 2015 were included. BRCA testing was decided with each patient based on age, familial history of breast or ovarian cancer and histological characteristics of the tumor. Rapid germline BRCA mutation screening was performed through targeted next generation sequencing with a 25-genes panel including full coding sequence of BRCA1 & 2. Deleterious mutations were detected using MiSeq reporter and confirmed by Sanger sequencing before giving the results to the clinical geneticist, and finally used for the choice of surgical strategy. At the end of NAC (6 three-weeks cycles in our center), a shared-decision making for surgical procedure was performed, based on pre and post-NAC clinical and radiological features, and results of the genetic testing.

Results

A total of 25 patients (including three with bilateral cancer) were tested during NAC: mean age 38 years (26-64); mean clinical size 46 mm (20-130mm); histological types: triple negative (n=14), HER-2 positive (n=7), luminal (n=7). A germline BRCA mutation was detected in 10 patients (40%): 8 BRCA1 and 2 BRCA2, including 8 patients among the 14 patients with a Manchester score > 20 (6 BRCA1 & 2 BRCA2). Two patients were secondarily excluded (one being metastatic and one died during NAC), one of them having a gBRCAm status. All the 23 patients evaluable for the surgical procedure after NAC could be eligible for a BCT. All the 9 patients with gBRCAm status choose mastectomy in the shared-decision making procedure while a BCT was performed in 12 of the 14 remaining patients without BRCA mutation.

Discussion

In this highly selected subgroup of patients, gBRCAm rate is higher (40%) than the usual rate for BRCA testing (17% in our center). Regarding the rationale for BCT or mastectomy procedure in LABC or pre-symptomatic gBRCAm patients, the duration of NAC allows rapid germline BRCA screening that looks very useful considering the high incidence of mutation we observed and the impact on surgical final decision. Furthermore, in the group of high Manchester score (>20), patients without BRCA mutation harbored incidental mutation, currently under analysis, especially on other genes involved in hereditary breast cancer, that could also be used as a compelling argument for mastectomy.

Title: Prognostic factors after neoadjuvant chemotherapy in breast cancer: Surgery type as a new prognostic factor

Fujihara M, Kin T, Yoshimura Y, Kajiwara Y, Ito M and Ohtani S. Hiroshima City Hiroshima Citizens Hospital, Hiroshima, Japan.

Body: Background: Pathological complete response (pCR) after neoadjuvant chemotherapy (NAC) is not necessarily linked to long-term survival. Response to chemotherapy and outcomes after NAC differ among breast cancer subtypes, so we analyzed prognostic factors by subtype.

Methods: We retrospectively analyzed 451 patients treated with anthracycline and taxane-based NAC between 2007 and 2015. Trastuzumab was added for human epidermal growth factor receptor (HER)-2-positive breast cancer. pCR was defined as no residual invasive breast carcinoma; noninvasive residuals and infiltrated lymph nodes were allowed. In our institute, mastectomy was performed in patients in whom the breast could not be preserved, such as patients with large residual tumors and diffusely spread tumors throughout the breast after NAC. Kaplan–Meier and univariate and multivariate cox regression analyses were used to evaluate disease-free interval (DFI) and DFI prognostic values, respectively.

Results: Median follow-up was 43 months; median age was 56 (range, 23–88) years. The 3-year DFI and OS were 82.1% and 94.4%, respectively. In total, 85 patients had recurrence (18.8%) and 31 patients died (6.9%). Response rate (RR) was 93.4% (421/457). pCR rate was 26.2% (118/451) in all cases: 0% (0/82), luminal A; 10.9% (14/128), luminal B HER2(−); 43.1% (31/71), luminal B HER2(+) ; 59.4% (38/64), HER2; and 34% (36/106), triple negative (TN). For all subtypes, patients who achieved pCR had a non-significantly higher DFI.

Multivariate cox regression showed these associations with DFI: surgery type and Ki-67 > 30% for all cases and luminal B HER2(−); ypN (lymph node status after NAC), luminal B HER2(+) ; ypN and menopausal status, HER2; and age, surgery type, and clinical lymph node status (cN), TN.

Kaplan–Meier analysis showed that surgery type was strongly associated with DFI after NAC. Mastectomy patients had significantly poorer prognoses than partial mastectomy patients for all subtypes except HER2. For all cases, the median DFI in mastectomy patients was 73 months, but DFI was not reached in partial mastectomy patients (p < 0.0001). Compared with partial mastectomy patients, mastectomy patients had more advanced disease in terms of tumor size, lymph node status, and stage and showed lesser clinical and pathological responses to NAC and effects on ypN. Furthermore, first recurrences in mastectomy patients were often distant metastases, leading to poor prognosis.

Moreover, we analyzed the prognostic factors in 118 patients who achieved pCR. Univariate Cox regression analysis showed the association of the following with DFI: age (≤40, >40), cN, stage, surgery type, and ypN for all cases; decreasing Ki-67 values after NAC, luminal B HER2(−); clinical tumor size (cT), cN, surgery type, and luminal B HER2(+) ; ypN and HER2; age (≤40, >40), cN, stage, surgery type, and TN. In multivariate cox regression analysis, age (≤40, >40), surgery type, and ypN were independent predicting factors for all cases.

Conclusions: Prognostic factors after NAC differ among subtypes. Surgery type was strongly associated with outcomes after NAC, so it could be an independent prognostic factor.
Title: Serum 25-hydroxyvitamin D levels and oncologic outcomes of breast cancer patients receiving neoadjuvant chemotherapy

Body: Background: According to prior studies, the role of serum vitamin D3 has been inconsistent and clinical implications of 25-hydroxyvitamin D (25-OHD) have been little studied in breast cancer patients receiving neoadjuvant chemotherapy (NCT).

Objectives: The aims of study were to investigate changes in 25-OHD levels before and after NCT and to determine the association of 25-OHD and oncologic outcomes including pathological complete response (pCR) in breast cancer patients.

Patients and Materials: From January 2010 to December 2013, serum 25-OHD levels at pre- and post-NCT were measured in 377 breast cancer patients. The association of serum 25-OHD levels with clinicopathological data including breast cancer subtypes, pCR and survival were retrospectively analysed. Delta 25-OHD was calculated as serum 25-OHD levels before minus after NCT.

Results: Mean age of study population was 48.7 years and mean follow-up periods were 35.9 months. Mean baseline serum 25-OHD concentration was 14.60 ng/mL (standard deviation, 7.44) and more than 80% of patients showed insufficient 25-OHD levels. The mean 25-OHD at post-NCT was 12.16 ng/mL (standard deviation, 6.87). There was a significant decrease in serum 25-OHD after NACT (p<0.001). The pCR rates were 25.7% among study cohort. However, 25-OHD levels at baseline and post-NCT were not related to pCR and survival outcomes. No associations were found between pCR and delta 25-OHD. According to stratification by breast cancer subtypes, however, patients with ≥ -2.67 (median value) of delta 25-OHD revealed a trend of higher achievement of pCR and better survival in luminal A subtype. No associations were found among the other subtypes.

Conclusions: Many Korean breast cancer patients showed insufficient serum 25-OHD levels at diagnosis of malignancy and a significant decrease in serum vitamin D3 after NACT was observed. No significant association of 25-OHD with pCR and survival was found. Therefore, correction or maintenance of appropriate serum 25-OHD levels should be focused for bone health as comprehensive management of breast cancer during NCT. In addition, possible oncological aspects of 25-OHD should further researched individually considering breast subtypes.
Title: National trends in neoadjuvant therapy for breast cancer

Body: Purpose: Neoadjuvant therapy has been widely integrated in the treatment of locally advanced breast cancer. Over time, this strategy has been extended to include patients with earlier stage disease to allow for assessment of in vivo response to treatment. The aim of this study was to describe the national trends in neoadjuvant therapy for all invasive breast cancers with a particular focus on triple negative disease and HER2 status.

Methods: The National Cancer Database (NCDB), an oncology outcomes database that collects data from more than 1500 Commission on Cancer (CoC) accredited cancer programs, was queried for all women diagnosed with invasive breast cancer from 2006-2013. Patients with unknown systemic therapy sequence were excluded. Women were classified by whether or not they received neoadjuvant systemic, chemo and/or endocrine, therapy.

Results: We identified 1,221,976 cases that were eligible for this analysis. Of these, 29.7% were HER2 negative, 18.4% were classified as triple negative, and 8.9% received neoadjuvant systemic therapy. The percentage of patients receiving neoadjuvant therapy increased from 7.5% in 2006 to 9.8% in 2012 with a slight decrease to 9.5% in 2013. This increase in the use of neoadjuvant therapy over the time period was statistically significant (p<0.0001).

There was a small increase in the percent of patients with HER2 positive status who received neoadjuvant therapy, from 5.7% in 2006 to 6.5% in 2013. During this time period, there was a 9% increase in the percent of triple negative patients who received neoadjuvant therapy (13.1% in 2016 to 22.1% in 2013).

Conclusions: Over the time period from 2006-2013, there has been an apparent increase in the percentage of patients who received neoadjuvant therapy. This trend is accompanied by increases in the percentage of TNBC patients and in Her2 positive patients who received neoadjuvant therapy. Other factors and the joint effects of these factors on the observed increase in the use of neoadjuvant therapy are under evaluation to elucidate the basis for this observation in the NCDB data.
Body: Introduction
Neoadjuvant chemotherapy (NAC) is an important initial strategy in the management of stage III locally advanced breast cancer (LABC) as being advised in our national guidelines. Furthermore, NAC is increasingly being used in stage II BC for downsizing the tumour in order to enable breast conservation therapy (BST). The aim of this study was to examine which patient-, tumour- and hospital related factors influence its use in clinical daily practice. In addition, we investigated the preferences of the surgical- and medical- oncologist as well as the patients’.

Methods
(1) All operated women [aged 18-70] from January 2011 to September 2015 were selected from the multidisciplinary NABON Breast Cancer Audit (NBCA). Multivariable logistic regression was used to assess significant independent predictors of NAC use.
(2) Both specialists and ex-patients were provided with a survey about decision-making.

Results
Overall, 21% of stage II (N=18011) and 70% of stage III patients (N=1715) received NAC. Factors associated with NAC utilization included young age, a diagnostic MRI, histology, large tumour size, more advanced nodal disease, hormone-receptor negative tumours and participation in neoadjuvant trials. After case mix correction variation between hospitals remained (range 10% – 90%). Evidenced by additional survey research, reasons for indication of NAC vary widely among specialists (response rate of 24%; N=100). From the patient survey (response rate of 52%; N=390) it appears that in patients where chemotherapy is recommended, 50% was not informed about the option of NAC.

Conclusion
There is considerable variation in the use of NAC for BC in the Netherlands. Although various patient, tumor and institutional factors are associated with the use of NAC, these can only explain part of the observed variation in treatment patterns between hospitals. Survey research shows a need for uniformity of selection criteria in the use of NAC between specialists. Also, the information necessary for patients to decide on which treatment option they prefer seems far from complete in clinical practice.
Title: A single-institution clinical experience with neoadjuvant docetaxel/carboplatin/trastuzumab/pertuzumab (TCHP): A safety and efficacy analysis

Tariq R, Ajaz B, Shah N, Mamounas E and Moroose R. UF Health Cancer Center- Orlando Health, Orlando, FL.

Body: Background: Pertuzumab, a monoclonal antibody targeting subdomain II of HER2 and blocking dimerization, was approved by the FDA in 2013 for use in combination with trastuzumab and docetaxel as neoadjuvant therapy for pts with HER2+, locally advanced, inflammatory or early-stage breast cancer (>2cm and/or node-positive). This accelerated approval was based on results from the NeoSphere and the TRYPHAENA trials. In NeoSphere, pathologic complete response in the breast and nodes [pCR] was 39.3% after 4 cycles of neoadjuvant pertuzumab/trastuzumab/docetaxel. In TRYPHAENA, pCR was 63.6% among 76 patients treated with 6 cycles of neoadjuvant TCHP (47.5% in pts with ER+ and/or PR+/HER2+ tumors and 81.1% in those with ER-/PR-/HER2+ tumors). Aside from TRYPHAENA, we have limited information on clinical outcomes, with neoadjuvant TCHP. Here we report our institutional experience at UF Health Cancer Center, Orlando (UFHCC) with Neoadjuvant TCHP in patients with operable or locally advanced breast cancer.

Patients and Methods: After IRB approval, electronic medical record search was performed in order to identify HER2+ patients with tumors T2-T4/N0-3 or Tany/N1-3, treated with neoadjuvant TCHP between 10/13 and 5/16. Information from chart review included patient and tumor characteristics at the time of diagnosis, details of neoadjuvant chemotherapy plus anti-HER2 therapy, clinical, radiologic and pathologic assessment of tumor response to neoadjuvant TCHP, type of breast and axillary nodal surgery, surgical outcomes as well as disease outcomes.

Results: 76 patients (75 female, 1 male) met the inclusion criteria; median age: 52 yrs; 83% of pts presented with clinical stage II and 17% with clinical stage III; 62% were ER+ and/or PR+ and 38% were ER-/PR-negative. 49 patients received all planned 6 cycles without dose reduction. The remaining 27 patients required dose reduction due to rash, diarrhea, nausea, vomiting, neuropathy or neutropenia; 5 patients requested dose reduction due to poor quality of life and fatigue; 2 patients required dose delay due to asymptomatic cardio-toxicity with ≥10% drop in EF. None had symptomatic CHF; 37% of patients underwent breast conserving surgery, 7% unilateral mastectomy and 55% bilateral mastectomy. Surgical lymph node assessment was performed after neoadjuvant chemotherapy and included sentinel lymph node biopsy (SLNB) in 74%, axillary dissection (ALND) in 8% or both in 18% of pts. Overall pCR rate (ypT0/is, ypN0) was 63.2%. pCR rate was 53.1% in pts with ER+ and/or PR+ tumors and 79.3% in those with ER-/PR- tumors. pCR by stage was 61% for Stage IIA, 65% for Stage IIB, 67% for Stage IIIA and 71% for Stage IIIC. Toxicity profile was consistent with what has been observed in the TRYPHAENA trial with fatigue, nausea, vomiting and neuropathy being the more commonly noted grade 3/4 toxicities. With median follow up of 18 months, all patients are disease-free with no documented recurrences observed.

Conclusion: Our clinical experience with neoadjuvant TCHP confirms the efficacy and safety data from the TRYPHAENA trial in a single-institution, tertiary care center setting.
Nanoparticle albumin-bound paclitaxel as neoadjuvant chemotherapy of breast cancer: A meta-analysis

Zong Y, Wu J and Shen K. Comprehensive Breast Health Center, Shanghai Ruijin Hospital Affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China.

Background: Nanoparticle albumin-bound paclitaxel (nab-Paclitaxel), a novel solvent-free taxane-based regimen, was hypothesized to have enhanced drug transport to tumors, shorter infusion schedules and no need for premedication. The value of nab-Paclitaxel in neoadjuvant systemic therapy (NST) for breast cancer remains uncertain. We performed a meta-analysis to assess efficacy and toxicity of nab-Paclitaxel compared to conventional taxane regimens (paclitaxel, docetaxel) within randomized clinical trials.

Methods: A systematic search was performed using the medical subject heading (MeSH) terms "breast neoplasms", as well as (1) breast cancer; AND (2) nab-Paclitaxel OR nanoparticle paclitaxel; AND (3) neoadjuvant OR preoperative OR primary systemic in both Pubmed databases and proceedings of oncologic meetings including ASCO, ESMO and SABCS. Pooled rates of pathological complete response (pCR), odds ratios (ORs) and 95% confidence intervals (CIs) were calculated using fixed-effect or random-effect model to determine the effect of neoadjuvant nab-paclitaxel.

Results: Twenty-one studies with 2357 patients were included, 3 of which (GeparSepto\(^{[1]}\), ETNA\(^{[2]}\), Showa trial\(^{[3]}\)) were randomized clinical trials. The aggregate pCR rate (ypT0/is ypN0) was 32% (95% CI 25-38%) in unselected breast cancer patients and was 14%(95% CI 11-17%), 41% (95% CI 38-45%), 54% (95% CI 43-66%) in hormone receptor-positive/human epidermal growth factor receptor 2-negative (HR+/HER2-), triple negative breast cancer(TNBC), HER2+ patients, respectively. Within the HER2+ population, pCR rate was 61%(95% CI 47-74%) for HR- and 40%(95% CI 28-52%) for HR+ tumors. Regarding randomized clinical trials, the probability of achieving pCR was significantly higher in the nab-paclitaxel group than in the conventional taxanes group (OR=1.383, 95%CI 1.141-1.676, p=0.001). A funnel plot of the effect size for each randomized trial against the precision showed no asymmetry, which indicating no potential publication bias. In the safety analysis (GeparSepto\(^{[1]}\), ETNA\(^{[2]}\)), hematological toxic effects were generally equivalent in nab-paclitaxel and paclitaxel group. For non-hematological toxic effects, all grades and grade $\geq 3$ peripheral sensory neuropathy occurred more frequently with nab-paclitaxel compared to paclitaxel (all grades, OR=2.090, 95%CI 1.016-4.302, p=0.045; grade $\geq 3$, OR=3.766, 95%CI 2.324-6.100, p<0.001). Hypersensitivity was more common with paclitaxel than nab-paclitaxel at any grade and grade $\geq 3$. Other non-hematological toxic effects did not significantly differ between two groups.

Conclusion: nab-Paclitaxel is an effective antitumor drug in NST of breast cancer, especially for TNBC and HER2+ tumors, in terms of pCR. Exchange of nab-Paclitaxel for conventional taxanes could significantly improve pCR rate with reasonable toxicities.

Feasibility trial for identification of patients for eliminating breast cancer surgery following neoadjuvant systemic therapy

Background: Contemporary improved neoadjuvant systemic therapy (NST) for breast cancer may result in a pathologic complete response (pCR) in up to 60% of patients (pts) yet imaging alone has a poor negative predictive value to determine which pts might be spared surgery. This study was designed to evaluate the hypothesis that percutaneous image guided biopsy after NST can accurately identify patients who may forgo surgery.

Methods: Prospective single-center IRB approved study of 34 pts with clinical T1-3 N0-3 triple-negative (TN, n=23) or HER2-positive (n=11) invasive ductal cancer who received standard NST and consented for ultrasound/mammography guided vacuum-assisted core biopsy (VACB) and fine-needle aspiration (FNA) biopsy prior to standard surgery. Main outcome measures included accuracy, false-negative rate (FNR), and negative predictive value of image guided biopsy in predicting residual disease after NST. Breast pCR was defined as no residual DCIS or invasive disease. Final biopsy showing atypia and/or suspicion of residual disease was recorded as positive.

Results: Median initial maximum tumor size based on imaging and physical exam was 3 cm (1.2-7 cm) and 47.1% had FNA/core biopsy proved nodal metastases. Final median maximum residual tumor size after NST was 0.9 cm (0-4.2 cm) with 94.1% having no palpable abnormality. Median number of VACB (9G) removed following NST was 10 (4-14) and was performed by stereotactic (67.6%) or ultrasound (32.4%) guidance. Overall, a breast pCR occurred in 18 (52.9%) of pts and breast pathologic response was concordant with nodal pathologic response in 33 (97%) of pts (1 pt with a breast pCR had 1/15 nodes with metastases). Overall, VACB combined with FNA following NST had a 100% (95% CI 89.7-100) accuracy, 0% FNR (95% CI 0-20.6), and 100% (95% CI 81.5-100) negative predictive value for determination of residual breast disease. Grade 1 adverse events which resolved from biopsy (bleeding, hematoma, bruising) occurred in 6 pts (17.6%).

Conclusions: High rates of pCR among pts with TN/HER2-positive breast cancer receiving NST occur in a significant proportion of pts. The use of image guided VACB/FNA can identify pts after NST where significant residual disease is unlikely. Based on these results, an IRB approved clinical trial will shortly commence for pts with T1-2 TN/HER2-positive breast cancer with documented image guided biopsy proved pCR after NST to be followed by standard definitive whole-breast radiotherapy without surgery.
Title: The SIRT2 deacetylase stabilizes Slug to control malignancy of basal-like breast cancer

Zhou W and Kuperwasser C. Tufts University School of Medicine, Boston, MA and Raymond and Beverly Sackler Convergence Laboratory, Boston, MA.

Body: Overabundance of Slug protein is common in human cancer and represents an important determinant underlying the aggressiveness and poor survival of basal-like breast cancer (BLBC). Despite its importance, this transcription factor is rarely mutated in BLBC, and the mechanism by which it becomes deregulated in cancer remains unknown. Here we report that Slug undergoes acetylation-dependent protein degradation and identify the deacetylase SIRT2 as a key mediator of this post-translational mechanism. SIRT2 inhibition rapidly destabilizes Slug, whereas SIRT2 overexpression extends Slug stability. We show that SIRT2 deacetylates Slug protein at lysine residue K116 to prevent Slug degradation. Interestingly, SIRT2 is frequently amplified and highly expressed in BLBC. Genetic depletion and pharmacological inactivation of SIRT2 in BLBC cells reverses Slug stability, causes the loss of clinically relevant pathological features of BLBC, and inhibits tumor growth. Collectively, these findings unravel a novel molecular interplay between SIRT2 amplification, Slug perdurance and the BLBC phenotype. As such, targeting SIRT2 may be a rational strategy for diminishing Slug abundance and its associated malignant traits in BLBC.
Title: Integration of whole-genome sequencing and functional screening to identify breast cancer lung metastatic drivers

Yang H-Y, Jiang Y-Z, Chen L, Zuo W-J, Di G-H, Hu X, Chen H-Q and Shao Z-M. Key Laboratory of Breast Cancer in Shanghai, Fudan University Shanghai Cancer Center, Shanghai, China and Fudan University Shanghai Cancer Center, Shanghai, China.

Body: Purpose: Changes in phenotype and genotype of breast cancers during the metastatic process remain to be elucidated. Here, we aim to characterize genetic alterations and potential drivers underlying breast cancer lung metastases using whole-genome sequencing. To discern driver from passenger genes, we developed an in vivo gain-of-function screening for metastases-related copy number variation (mCNV) genes using Gene-barcoding library.

Methods: We retrospectively enrolled 7 metastatic breast cancer (MBC) patients receiving surgical removal of lung metastases. Matched primary and metastasis tumors were collected. In total, whole-genome sequencing was performed on either frozen or formalin-fixed paraffin-embedded samples with 50-and 30-fold coverage for tumoral and normal tissues. A gain-of-function screening was performed in lung metastasis model using MDA-MB-231 cells (multiplicity of infection= 0.2) with a retrovirus-based human open reading frames (ORF) pooled library. Each gene was labeled with 3 unique barcodes. The lung metastases enriched genes were identified using polymerase chain reaction and next-generation sequencing(NGS).

Results: For 7 patients enrolled in this study, MBC1 was triple-negative breast cancer (TNBC), MBC2~5 were hormone receptor(HR) positive and human epidermal growth factor receptor 2 (HER2) negative, and MBC6~7 was HR-/HER2+. Median age at primary diagnosis was 50 years (range, 28-70 years). Median disease-free interval was 36.4 months (range, 19.7 -62.3 months). Most patients received anthracycline/taxane based adjuvant chemotherapy, expect for two HR+ patients. All HR+/HER2- patients received adjuvant endocrine therapy, and all HER2+ patients received adjuvant trastuzumb therapy. Patient MBC1 had an a high frequency of novel mutations in the lung metastases, including TP53, CYP19A1, PCDH9, NCAM2, MAP2K7 and MAPK4. In contract, the somatic mutation profiles of MBC2~7 show high concordance between primary tumor and metastases. CNV discordances were common in TNBC and HR+/HER2- cases. Meanwhile, changes in CNV were rarely observed in HR-/HER2+. In TNBC and HR+ patients, we identified a series of copy number gain/amplification regions involving chromosome 3q25~26, 3q28~29, 8p11, 8q13, and 8q21~24 in lung metastasis compared with primary tumor. Recurrent copy number gain encoding genes (frequency≥ 3/5) were selected as metastases-related copy number variation (mCNV) genes, including PLSCR1, PTX3, ARL14, WHSC1L1, FGFR1, ADAM9, OXR1, EBAG9, TNFRSF11B etc. We therefore established a gene-barcoding ORF library for 65 mCNV encoding genes for the pooled screening in lung metastasis model. The readout of gain-of-function screening shows that PTX3, FGF12 and WDR49 are enriched in lung metastases.

Conclusion: Whole-genome copy number analysis suggested CNVs discordance between primary breast cancer and lung metastasis, especially in TNBC and HR+/HER2- disease. PTX3, FGF12 and WDR49 may play pivotal roles in driving lung metastasis of breast cancer. An in vivo gene-barcoding library screening enabled identify copy number gain/amplification genes likely contribute to cancer metastasis, providing a robust method to explore the phenotype-genotype correlation in cancer evolution.
Title: N-terminus Slit2 suppresses breast cancer metastasis by inhibiting tumor associated macrophages

Ahirwar DK K, Shehab RS S, Mishra S, Shilo K and Ganju RK K. The Ohio State University, Columbus, OH.

Body: Distant metastasis is a major cause of breast cancer related death. Recent insights suggest that stromal cells including macrophages present in tumor microenvironment plays crucial role to enhance the metastatic potential of breast cancer cells. Primarily discovered as neuronal guidance cue, Slit2 has recently been emerged as an important tumor suppressor gene. Slit2 is reported to be genetically mutated and highly methylated in various cancers including breast cancer. Slit2 possess a proteolytic site and generates N-terminus and C-terminus fragments. We have previously shown that the N-terminus Slit2 (N-Sli2)contains biological activity and suppresses tumor growth. However, its effect on lung specific metastasis and tumor microenvironment is not studied yet. To analyze the effect of Slit2 on breast cancer growth and metastasis, we used MVT-1 cells derived orthotopic syngenic mammary tumor model. We observed that the Intra-tumoral injection of Adeno-virus particles overexpressing NSlit2 (Adeno-Slit2) significantly inhibited MVT-1 implanted tumor growth and lung metastasis compared to Adeno-virus particles expressing control vector (Adeno-Null). We further validated anti-metastatic activity of Slit2 using human breast cancer cell line MDA-MB-231 overexpressing N-Slit2 (231-Slit2) or control vector (231-Null) implanted in Nude/SCID/Gamma (NSG). The 231-Slit2 derived xenografts grow slower than 231-Null. Interestingly, the metastasis of 231-Slit2 to lung significantly reduced compared to 231-Null. To analyze the cellular events involved, we analyzed tumors for immune cell recruitment and observed less number of CD11b/F4/80/CD206 positive tumor associated macrophages (TAMs) in 231-Slit2 tumors compared to 231-Null. To further explore the underlying molecular mechanism, we analyzed the genes modulated by slit2 overexpression in MDA-MB-231 cells and observed decreased IL6 expression, which was further validated by protein array. In vitro assays depicted that the IL6 up-regulates various TAM markers and helps macrophage to convert to TAMs. We also analyzed Slit2 expression in human breast cancer TMA and an inverse correlation of Slit2 expression was observed with the incidence of breast cancer and distant metastasis. This study highlights the ability of Slit2 to prevent macrophage alternative activation to TAMs, thereby restrict tumor growth and lung metastasis.
Title: Abstract Withdrawn
Title: Novel cytotoxic RNA aptamers that distinguish between metastasis-prone and indolent breast and prostate cancers

Bishopric NH H, Speransky S, Serafini P, De la Fuente AC C, Bicciato S, El-Ashry D and Lippman ME E. University of Miami Miller School of Medicine, Miami, FL and University of Modena and Reggio Emilia, Modena, Italy.

Body: Background: Prostate and breast cancers are, respectively, the most common malignancies diagnosed in men and women worldwide. These cancers develop in different organs but have significant biological similarities: both are typically hormone-dependent, and both require early detection and treatment, as metastatic disease is incurable. At the same time, early stage tumors are often over-treated. Better markers for tumor aggressiveness would help to optimize treatment strategies in both breast and prostate cancer.

Objective: Develop high affinity nucleic acid oligomers (aptamers) that can distinguish between indolent tumors that will remain organ-confined and those with heightened potential to metastasize.

Methods: We performed subtractive RNA Cell-SELEX to select for surface ligands specific to aggressive tumors, using as a positive selector the highly metastasis-competent LN3 subclone of prostate cancer cell line LNCaP, and as negative selectors parental LNCaP and a non-metastasizing subclone, Pro5. The RNA aptamer pool was PCR amplified from a 40-mer random nucleotide cDNA library with appropriate flanking sequences, and transcribed in vitro. After 11 SELEX cycles, aptamer pools from cycles 0, 4, 9, and 11 were subjected to high-throughput sequencing. Eight aptamers, representing 4 sequence families, were chosen for further study. Representative relevant and irrelevant aptamers were labeled with Cy3 and used to stain LNCaP-LN3 and LNCaP-Pro5 in culture and as xenografts in NOD-SCID-gamma mice. Additional cell and tumor lines from both breast and prostate cancer were used for validation.

Results: Two aptamers bound avidly to the surface of the aggressive LNCaP-LN3 subclone, both in culture and in fixed xenograft tumors, but not to the indolent Pro5 subclone. Aptamer binding led to rapid and specific cytotoxicity in vitro but had no effect on other cell lines to which the aptamer did not bind. The same aptamers showed similar high specificity for multiple other metastasis-competent cancer cells, including the prostate adenocarcinoma PC-3 and PC-3ML subclones, breast cancer cell lines MDA-MB436 and MDA-MB231, and the primary dissociated breast tumor DT28, while exhibiting no detectable binding to the non-metastasizing MCF-7 breast cancer cell line and DT22 primary dissociated breast tumor cells, and the non-tumorigenic prostate epithelial cell line RPWE-1.

Conclusion: We identified RNA aptamers that specifically bind to metastasis-prone prostate cancer and breast cancer cell surface targets, and exert cell-specific toxicity dependent upon aptamer binding. While the target(s) remain to be identified, we propose that these aptamers may discriminate between progressive and indolent breast and prostate cancers, and may have substantial promise as anticancer agents either alone or suitably liganded to toxic moieties.
Title: Glutamine metabolism drives breast cancer invasion by providing a source of extracellular glutamate to activate the GRM3 metabotropic glutamate receptor

Body: Glutamine metabolism is well-established to contribute to cancer cell growth and proliferation by providing a source of nitrogen for nucleotide and amino acid biosynthesis as well as TCA cycle intermediates. There is also accumulating evidence that glutamine metabolism may contribute to metastasis although mechanistic links to tumour cell migration and invasion remain unclear. We have generated a number of highly invasive primary cell lines from the polyoma middle-T genetically engineered mouse model of breast cancer (MMTV-PyMT) and found that withdrawal of glutamine from these cells reduces not only their proliferation, but also their invasive migration into 'stroma-like' preparations of fibroblast-derived extracellular matrix. Our metabolomic analyses indicate that invasive MMTV-PyMT cells actively secrete glutamate, a product of glutamine metabolism, into the extracellular milieu. Moreover, addition of glutamate is sufficient to restore invasiveness (but not cell growth or proliferation) to glutamine-starved MMTV-PyMT cells. We have pursued these findings by investigating the role played by plasma membrane receptors for glutamate in cell migration and invasion in PyMT cells and in MDA-MB-231 triple negative breast cancer cells. We provide evidence that glutamate generated within the cell by deamidation of glutamine leaves the cell via the xCT antiporter to activate the GRM3 metabotropic glutamate receptor at the cell surface. This, in turn, suppresses adenylate cyclase activity to prevent protein kinase A activation and to drive an invasive programme. Indeed, knocking out GRM3 with CRISPR technology or inhibition using a selective GRM3 antagonist (LY341495) is sufficient to oppose invasiveness without compromising proliferation. Conversely, a specific GRM3 agonist (LY354740) drives invasiveness without increasing proliferation. Consistently, treatment with LY341495 was sufficient to abrogate lung colonisation following tail vein injection whilst tumour growth after orthotopic injection was unaffected. Our results provide a mechanistic link between glutamine metabolism and invasion and identify GRM3 as a potential therapeutic target in breast cancer.
Title: Mitochondria-nuclear communication regulates epithelial-mesenchymal transition and metastasis in triple negative breast cancer

Park JH, Jung KH, Sirupangi T, Vithayathil S, Jin F, Putluri V, Piyarathna DWB, Yotnda P, Bhat VB, Sreekumar A, Lewis MT T, Coarfa C, Putluri N, Creighton CJ J, Wong L-JC C and Kaiparettu BA Abraham. Baylor College of Medicine, Houston, TX; Baylor College of Medicine, Houston, TX; Dan L. Duncan Cancer Center-Biostatistics, Baylor College of Medicine, Houston, TX; Center for Cell and Gene Therapy, Baylor College of Medicine, Houston, TX and Agilent Technologies, Wilmington, DE.

Body: For triple negative breast cancer (TNBC), the driver pathways are still poorly understood. Advances in cancer metabolism research over the last decade have enhanced and modified our understanding on Warburg effect. It is now known that mitochondria in tumors are not always defective in their ability to carry out oxidative phosphorylation. Instead, in proliferating cells, mitochondrial energy pathways are reprogrammed to meet the challenges of macromolecular synthesis and to escape from apoptosis. Tumor initiating cells (TICs) maintain cancer stem cell properties and are known to play significant role in TNBC metastasis. Mitochondrial retrograde regulation (MRR) is a bidirectional communication between mitochondria and nucleus. MRR is triggered by mitochondrial functional demands and it responds in a continuous manner to change metabolic needs of the cell. Using transmitochondrial cybrid (cybrid) technology, we generated different cybrid models under common nuclear backgrounds of benign breast epithelium or TNBC. Mitochondria from cells with different cancer potential such as benign breast epithelium, moderately metastatic and highly metastatic breast cancer cell lines were studied under the common nuclear background to understand MRR-regulated TIC properties and cancer pathways. Using genomic, metabolomic, and proteomic approaches, we confirmed the significance of mitochondrial character in the regulation of epithelial mesenchymal transition (EMT), TIC and metastatic properties. Altogether, our results suggest that MRR is critical in TNBC TIC character and stemness.
**Title:** Identifying metastatic drivers in patient derived xenograft models of triple negative breast cancer

**Body:** Metastases are responsible for the vast majority of deaths due to breast cancer. Triple negative breast cancer (TNBC) is an aggressive subtype of breast cancer characterized by high rates of metastasis and poor response to chemotherapy. We are using patient derived xenograft (PDX) models of TNBC to identify drivers of TNBC metastasis. Using these models, we demonstrated that human breast tumors are capable of completing all stages of the metastatic cascade in mice, and metastatic lesions are observed in organs normally found in patients with metastatic breast cancer including lung, liver, bone, brain and lymph nodes. Lentiviral transduction was employed to express both bioluminescent and fluorescent proteins in three distinct PDX models of TNBC. In this way, metastatic lesions can be isolated using bioluminescent imaging and circulating tumor cells (CTCs) are isolated by flow cytometry. A lung metastasis gene expression signature was generated and comprehensive gain-of-function screens are being conducted in vivo to validate this signature and identify functional drivers of TNBC metastasis.
MiRNA-200b suppresses triple negative breast cancer metastasis by targeting ARHGAP18 and causing sustained Rho A activation.

Wang Z, Humphries B, Li Y and Yang C. Michigan State University, East Lansing, MI.

Body: Triple negative breast cancer (TNBC) refers to a group of highly heterogeneous malignant tumors that lack estrogen receptor and progesterone receptor expression, and human epidermal growth factor receptor 2 amplification, accounting for 10-20% of newly diagnosed breast cancer cases. Compared to other subtypes of breast cancer, TNBCs usually show worse clinical features such as rapid tumor growth, earlier recurrence, and more aggressive metastasis. Unfortunately, the mechanism of TNBC metastatic behavior has not been well understood. Moreover, no efficient targeted therapies for TNBCs are currently available, representing a real unmet need for effective new therapies. MicroRNAs (miRNAs) are a large family of small non-coding RNAs that negatively regulate protein-coding gene expression post-transcriptionally by interacting with messenger RNAs (mRNAs), causing mRNA degradation or translation inhibition. MiR-200 family members are among the first miRNAs reported to function as potent inhibitors of epithelial to mesenchymal transition (EMT), an important event in cancer metastasis. However, the effect of miR-200 family on TNBC metastasis has not been well understood. In this study, we investigated the effect of miR-200b, one member of the miR-200 family, on TNBC metastasis using cell culture and mouse orthotopic mammary xenograft tumor models. We found that the expression level of miR-200b is significantly lower in TNBC cells and tissues than that in other types of breast cancer. Stably expressing miR-200b significantly reduced TNBC cell migration and invasion and suppressed TNBC metastasis in a mouse orthotopic mammary xenograft tumor model. Mechanistic studies revealed that miR-200b overexpression in TNBC cells caused drastic changes in cellular actin cytoskeleton organization patterns as evidenced by reduced lamellipodia formation but increased stress fiber formation. In consistent with these findings, Rho GTPase pulldown assays demonstrated that stably expressing miR-200b significantly increased the Rho GTPase Rho A activation, but reduced the Rho GTPase Rac1 activation. Moreover, inhibition of Rho A signaling impaired the inhibitory effect of miR-200b on TNBC cell migration. Bioinformatics analysis indicated that ARHGAP18, a specific Rho A GTPase activating protein (GAP), is a predicate target of miR-200b. Knocking down ARHGAP18 in TNBC cells using siRNAs significantly increased Rho A activation but reduced Rac1 activation. To further determine the role of ARHGAP18 in TNBC, ARHGAP knockout TNBC cells were generated using the CRISPR technology. It was found that knockout ARHGAP18 phenocopied the effect of miR-200b overexpression. Moreover, overexpressing ARHGAP18 in miR-200b stable expression cells overcome the inhibitory effect of miR-200b on TNBC metastasis. Together, these findings suggest that miR-200b suppresses triple negative breast cancer metastasis by targeting ARHGAP18 and causing sustained Rho A activation.
Title: Estrogen receptor β2 and β5 increase expression of ABCG2 and drug resistance of the triple-negative breast cancer cell line SUM159

Faria M, Gustafsson J-A and Strom A. University of Houston, Houston, TX and Karolinska Institutet, Huddinge, Sweden.

Body: Recent clinical studies indicate that estrogen receptor β2 (ERβ2) and β5 (ERβ5) expression in TNBC correlates to worse prognosis. We have expressed ERβ2 and ERβ5 in the triple negative cell line SUM159. Estrogen receptors β2 and β5 are highly similar to estrogen receptor β1, except for a truncated C-terminus making the remaining ligand-binding domain incapable of binding to estrogen. In addition, at the C-terminus, ER β2 and β5 have a unique peptide each of 27 and 4 amino acids in length respectively. Stably expressing ERβ2 and ERβ5 using a transposon integrated, tetracycline-regulated expression system increases expression of the drug resistance gene, ABCG2 in the triple negative SUM159 cells. Furthermore, we also find that the cells become more resistant to treatments with paclitaxel. We find that ERβ2 and ERβ5 interact with HIF-1α and HIF-2α and are recruited to HIF response elements (HRE's) in chromatin. In agreement with this, we find that ERβ2 and ERβ5 are recruited to the ABCG2 promoter, which contains HRE's and is known to be a target of HIF signaling. We propose that ERβ2 and ERβ5 play a role in chemo-resistance of TNBC and that targeting these factors may reduce chemo resistance thus preventing tumor-relapses and their associated mortalities.
Title: Distinct recruitment of tumor-associated immune cells correlates with increased pro-malignant chemokines in tumors expressing epithelial atypical chemokine receptor 1 (ACKR1/DARC), indicating a unique tumor microenvironment

Jenkins BD D, Martini RN N, Hire R, Monteil MA A and Davis MB B. University of Georgia, Athens, GA and AU/UGA Medical Partnership, Athens, GA.

Body: The breast tumor microenvironment is a complex assortment of cancer and host immune cells that interact to produce a myriad of clinical outcomes for breast cancer (BrCa) patients. Chemokine receptors, such as the Atypical Chemokine Receptor 1 (ACKR1), play an important role in maintaining the homeostasis of pro-inflammatory chemokines, as well as influencing the migration of host immune cells. ACKR1 has the ability to modify the breast tumor microenvironment in multiple ways, including sequestering chemokine activity and affecting leukocyte migration. The purpose of this study is to characterize the variation in immune cell signaling between ACKR1 positive and negative tumors, and determine any correlation between ACKR1 and CCL2 (MCP-1) and CXCL8 (IL-8) in various BrCa cell types.

Primary breast tumor samples were stained using immunohistochemistry for ACKR1, in addition to various immune cells including, T-cells, B-cells, dendritic cells, and macrophages. We determined levels of circulating chemokines using a Luminex assay kit on whole blood lysate. We also tested the localization of ACKR1-associated chemokines and the abundance of ACKR1 using immunofluorescence techniques. Pilot data collected from primary breast tumor tissue suggested that differential expression of ACKR1 from various tumor subtypes leads to the recruitment of a specific subset of host immune cells to the tumor microenvironment. In our cohort, ACKR1 positive tumors tended to recruit B cells and dendritic cells to the site of the tumor, whereas ACKR1 negative cells did not. We also detected a positive correlation between ACKR1 levels in tumor tissue with CCL2 and CXCL8 levels in the circulating blood of our study group. Finally, co-localization of ACKR1 with CCL2 and CXCL8 was observed in cultured mammalian breast cancer cells. Overall, our pilot data suggests that there is differential recruitment of immune cells within the ACKR1 positive and negative BrCa tumor microenvironments, and that circulating CCL2 and CXCL8 concentrations are positively correlated with ACKR1 levels in BrCa cells.
Title: Inhibiting ADP-ribosylation factor 1 activation to suppress breast cancer metastasis

Teng Y, Chavanieu A and Xie X. Augusta University; Georgia Cancer Center, Augusta University; Institut des Biomolécules Max Mousseron (IBMM) and Emory Children's Center, Emory University.

Body: ADP-ribosylation factor 1 (ARF1) is a crucial regulator in vesicle-mediated membrane trafficking and involved in the activation of signaling molecules. However, virtually nothing is known about its function in cancer metastasis. We show for the first time that ARF1 is the most amplified gene in ARF gene family in breast cancer. Amplification of ARF1 is associated with increased mRNA expression, and knockdown of ARF1 leads to suppression of migration and invasion in breast cancer cells. The orthotopic xenograft model in NSG mice shows knockdown of ARF1 in breast cancer cells inhibits pulmonary metastasis. The zebrafish-metastasis model confirms that the loss of ARF1 expression suppresses breast cancer cells to metastatic disseminate throughout fish body. ARF1 function largely dependents on it activation and there are no drugs that directly target ARF1 gene expression. LM11, a cell-active inhibitor that specifically inhibits ARF1 activation through targeting the ARF1-GDP/ARNO complex at the Golgi, significantly impairs metastatic capability of breast cancer cell in zebrafish. These observations indicate that LM11 has potent anti-cancer activities. Here, we demonstrate that ARF1 is a very compelling target to limit metastasis, and inactivation of it could be a potential therapeutic approach to inhibit the late stage of breast cancer progression. Therefore, our study has significant impact on the design and execution of effective therapy of patients with high risk or metastatic breast cancer.
Title: BCAP31 promotes EMT and metastasis upon nutrient deprivation through autophagy in breast cancer

Fu W, Sun H, Gao S, Li L and Jin W. Key Laboratory of Breast Cancer in Shanghai, Collaborative Innovation Center of Cancer Medicine, Fudan University Shanghai Cancer Center, Shanghai, China and Shanghai Medical College, Fudan University, Shanghai, China.

Body: Reprogramming of cellular metabolism has regained substantial research interest over recent years. To survive, metastasizing cancer cells exhibit metabolic flexibility to acquire necessary nutrients from a frequently nutrient-poor environment and utilize these nutrients to both maintain viability and build new biomass. In present study, we found that B-cell receptor-associated protein 31 (BCAP31) was induced by the unfolded protein response pathway under energy stress. Despite its cleavage product, p20Bap31, has been reported to contribute to apoptosis, function of the entire protomer of BCAP31 was still unclear in cancer. Here, we demonstrated that up-regulation of BCAP31 under stress promoted tumorigenesis and increased the expression of epithelial-mesenchymal transition markers in breast cancer cell lines. Furthermore, overexpression of BCAP31 promoted the metastatic and invasive ability of breast cancer cells both in vitro and in vivo. These effects were associated with the unique role of BCAP31 in autophagy initiation. Depletion of BCAP31 or blockage of the autophagy process eradicated these tumorigenic effects. Mechanically, up-regulation of BCAP31, as a putative chaperone/quality control factor, triggered autophagy by aggregating JNK1 and the Bcl-2/Beclin 1 complex in endoplasmic reticulum (ER), therefore in turn increased the phosphorylation of Bcl-2, leading to its dissociation from Beclin 1. Taken together, the results uncovered a novel adaptive mechanism coupling ER cargo genes with the potential of malignant cells to expand their metabolic repertoire, and provided a broad framework to understand further the prevention of tumor progression.
**Title:** Dissection of the Abl interactor 1 signaling in metastatic breast cancer cells

Jiang P, Tang H, Hogan H, Tate S, Ryan W, Paul L, Liu X and Zonghan D. Texas Tech University Health Sciences Center, Amarillo, TX; West Virginia University Health Sciences Center, Morgantown, WV and Texas Tech University Health Sciences Center, Amarillo, TX.

**Body:** Abl interactor 1 (Abi1) is a key component of WAVE regulatory complex (WRC) that regulates actin cytoskeleton reorganization, membrane receptor signaling, and intracellular trafficking. Recent in vitro and in vivo studies as well as the studies of human patient samples suggest that Abi1 may play an important role in breast cancer (BC) metastasis. To determine if Abi1 is deregulated in metastatic breast cancer cells, we compared the expression of Abi1 in a panel of human breast cancer cell lines exhibiting distinct metastatic properties. In comparison with low-metastatic ER+/PR+ BC lines MCF-7 and T47D and a non-transforming mammary epithelial cell line MCF-10A, two ER-BC lines CN34 and MDA 231 and their sublines selected by high metastatic potential to bone (231Bo), brain (231Br and CN34Br), and lung (231LM2) show significantly reduced Abi1 protein levels, with greater reduction found in highly metastatic sublines. It is unlikely that the down-regulation of Abi1 expression in these metastatic BC cells occurs at mRNA level, because RT-PCR analysis shows no significant difference in Abi1 mRNA levels among the cells analyzed. Interestingly, despite a reduction in protein level, the tyrosine phosphorylation of Abi1 was increased in CN34, MDA231, and their metastatic sublines compared to low-metastatic BC cells. The tyrosine phosphorylation of Abi1 is stimulated by epidermal growth factor (EGF) in these cells and Abi1 is recruited to EGF receptor (EGFR) upon EGF stimulation. The deregulation of Abi1 in metastatic BC cells is mediated by Abl tyrosine kinases, as the inhibition of Abl family kinases by imatinib not only attenuates EGF-stimulated Abi1 tyrosine phosphorylation but also rescue the down-regulation of Abi1 protein in metastatic BC cells.

These findings are consistent with a role of the EGFR-Abl-Abi1 signaling in BC metastasis. The studies suggest that this pathway may serve as a biomarker for diagnosis and/or prognosis of metastatic breast cancer. We have identified the tyrosine 213 in Abi1 as a major phosphorylation site stimulated by Abl kinases and have generated a unique conditional Abi1 depletion/re-expression system to dissect how the deregulation of the Abi1 signaling contributes to BC metastasis.

Title: Novel regulation of breast cancer cell aggressiveness by cancer testis antigen

Kannan A, Wells RM M, Ikebe M and Dasgupta S. The University of Texas Health Science Center; The University of Texas Health Science Center and The University of Texas Health Science Center.

Body: We recently demonstrated that a vesicular endocytosis associated protein SH3GL2, attenuates spontaneous metastases of breast cancer cells by inducing a mesenchymal to epithelial differentiation and the onset of the intrinsic apoptotic pathway. The present study aims to understand the molecular mechanism behind the SH3GL2 mediated reduction of spontaneous metastasis of the breast cancer cells.

We employed a cDNA microarray analysis of the SH3GL2-overexpressing breast cancer cells exhibiting reduced pulmonary metastasis and identified a 12.1 fold downregulation of SPANXB1, a cancer-testis antigen that regulates sperm motility. A limited number of studies reported an association between increased SPANXB1 expression and progression of melanoma and hepatocellular carcinoma. Augmented SPANXB1 mRNA and protein expression was evident in primary breast tumors and its upregulation was associated with pulmonary metastasis of breast cancer cells. However, the expression pattern of SPANXB1 and its role in BCa development and progression is unknown. By immunohistochemical analysis, we detected high expression (p=0.002) of SPANXB1 in 78% (18/23) of the primary breast cancer tissues and corresponding lymph node metastases compared to the matched normal breast tissues. A couple of non-tumorigenic human breast epithelial cell lines were stably transformed with SPANXB1 to understand its effect on cellular growth and progression. The SPANXB1-transformed cells exhibited increased invasion (p=0.0001) and epithelial to mesenchymal transition accompanied by an augmented expression ratio of Vimentin/E-Cadherin, molecules regulating differentiation and metastasis. The SPANXB1-transformed cells also exhibited a markedly reduced expression of SH3GL2, implicating a SPANXB1:SH3GL2 crosstalk accompanied by an enhanced production of lactate (p=0.004). Our investigation identifies new breast cancer promoting role of a cancer testis antigen, which bears potential for biomarker and targeted therapeutic development.
Title: The phosphorylation-specific association of STMN1 with GRP78 promotes breast cancer metastasis

Kuang X, Jiang H, Hu X, Shao Z and Lin Y. The First Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China and Key Laboratory of Breast Cancer in Shanghai, Fudan University Shanghai Cancer Center, Shanghai, China.

Body: Background
Stathmin 1 (STMN1) is a phosphoprotein associated with cancer metastasis. The activity of STMN1 can be modulated by its phosphorylation of multiple Serine residues (Ser16, Ser25, Ser38, and Ser63). In this study, we examined STMN1 expression and the phosphorylation status and explored the related signaling mechanism in breast cancer metastasis.

Methods
A phospho-specific protein microarray containing 1318 phosphoprotein antibodies was used between MDA-MB-231 and highly metastatic variant MDA-MB-231-HM cells. STMN1 and phospho-STMN1 signatures were assessed by immunohistochemistry of 310 patients and cell migration tests of different alanine-substituted STMN1 mutants. Tandem affinity purification followed by mass spectroscopy and kinase inhibitors treatment were used to explore the related signaling mechanism and finally confirmed in mouse models.

Results
High expression of STMN1 and phosphorylation of STMN1 at Ser25 and Ser38 are necessary to maintain cell migration capabilities and is associated with shorter disease-free survival (DFS) in breast cancer, while Ser16 and Ser63 phosphorylation showed the opposite effects (P<0.01). Mass spectroscopy showed that glucose-regulated protein of molecular mass 78 (GRP78) bind to wild type and mutant S16A/S63A but not S25A/S38A STMN1. Conversely, mutations at Ser25 and Ser38 significantly reduced STMN1 binding to GRP78. Then we selected mitogen-activated protein kinase (MEK) kinase inhibitor PD0325901 significantly reduce both Ser25 and Ser38 phosphorylation and GRP78-STMN1 binding. Suppression of GRP78 expression reduced the migration of MDA-MB-231 cells expressing wild type but not S25A or S38A mutant STMN1 (P<0.01). These findings suggested that MEK kinase phosphorylation at Ser25 and Ser38 is required for GRP78 binding to STMN1 and that GRP78 binding to phosphorylated STMN1 is necessary for cell migration. In vivo mouse models showed that 20% of the hosts in the S25A/S38A group developed metastasis compared to the wild type control and the S25A/S38A mutant group had lower GRP78 expression levels. A prognostic p-STMN1/GRP78 signature was also established by a Cox proportional hazards model: risk score = -0.680*Ser16+0.722*Ser38-0.636*Ser63+0.899*GRP78. The prognostic accuracy of the risk score was assessed by using a time-dependent ROC analysis and found that it has a higher prognostic accuracy compared to the TNM staging system (area under the ROC curve (AUC) for the p-STMN1/GRP78 model: 0.792; AUC for TNM staging: 0.674; P=0.023)

Conclusion
In this study, we investigated the metastasis-specific phosphorylation states of STMN1 and their correlation with clinical outcomes. GRP78 was identified as a novel phospho-STMN1 binding protein upon STMN1 Ser25/Ser38 phosphorylation and this phosphorylation-dependent interaction is regulated by MEK kinase. We also propose a prognostic model based on phospho-STMN1 and GRP78 to assess metastatic risk which could enable oncologists to target breast cancer patients for appropriate treatment.
**Title:** Epithelial paradox; clinical significance of co-expression of E-cadherin and vimentin in the invasion and the metastasis of breast cancer

Yamashita N, Tokunaga E, Inoue Y, Tanaka K, Saeki H, Oki E and Maehara Y. Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; National Hospital Organization Kyushu Cancer Center, Fukuoka, Japan and Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.

**Body:** Background: E-cadherin and vimentin are now regarded as major and conventional canonical markers of epithelial-mesenchymal transition (EMT). It is commonly assumed E-cadherin is uniformly lost during the process of EMT. We previously reported that the elevated expression of vimentin contributes to the aggressive phenotype in invasive breast cancer. On the other hand, the role of E-cadherin in breast cancer biology might be unclear and more complex. Although, cell cohesion during breast cancer invasion is often overlooked, accumulating evidences indicate breast tumor cells are typically cohesive and often display membrane-localized E-cadherin in both the primary tumor and distant metastases, termed collective invasion. Multiple mechanisms have emerged to address how epithelial breast tumors invade.

**Aims:** The aim of this study is to reveal the clinical importance of the expression pattern of E-cadherin and vimentin in breast cancer.

**Methods:** The E-cadherin and vimentin protein expression were evaluated by immunohistochemistry (IHC) in 177 invasive breast cancer samples. Among these, E-cadherin and vimentin expression were evaluated in the set of primary breast cancer and metastatic lymph nodes in 65 cases. In addition, E-cadherin and vimentin expression were analyzed by immunofluorescent staining and evaluated using confocal laser scanning microscopy to see E-cadherin and vimentin localization in the breast cancer cells.

**Results:** The positive vimentin expression was highly correlated with poor disease-free survival (DFS) and overall survival (OS) (p=0.019 and p=0.0044), however, the E-cadherin expression alone did not correlate with prognosis. Interestingly, both E-cadherin and vimentin positive tumors had the worst DFS and OS among all breast cancer (p=0.03 and p=0.0089). Vimentin expression was highly correlated between primary tumors and metastatic lymph nodes. However, E-cadherin expression levels were significantly elevated in metastatic lymph nodes (p=0.0017). Co-expression of E-cadherin and vimentin in the metastatic lymph nodes also showed worst DFS and OS (p=0.12 and p=0.027). Immunofluorescent analysis revealed that E-cadherin and vimentin were co-localized within the same tumor cells in many of the E-cadherin high/vimentin positive tumors.

**Conclusions:** Co-expression of E-cadherin and vimentin seems to be associated with the most aggressive phenotype and poorest prognosis in breast cancer. Moreover, co-localization of E-cadherin and vimentin within the same breast cancer cells suggests the significance of the expressions of both proteins in breast cancer invasion and metastasis.
Title: Early detection of development of a pre-metastatic niche in lungs in response to primary breast tumor using Raman spectroscopy

Zheng C, Rizwan A, Paidi SK Kumar, Yu Z, Barman I and Glunde K. The Second Hospital of Shandong University, Jinan, Shandong, China; The Johns Hopkins University In Vivo Cellular and Molecular Imaging Center, The Johns Hopkins University School of Medicine, Baltimore, MD and Johns Hopkins University, Baltimore, MD.

Body: Background: An alarmingly large proportion of cancer-related deaths result from metastatic cancers. Development of quick, reliable and non-invasive or minimally invasive approaches to objectively assess the secondary tissues (potentially in vivo) will be instrumental in substantially reducing the cancer burden due to metastasis, which accounts for majority of cancer related mortality. In our study we report the utilization of Raman spectroscopy and chemometric techniques in identifying formation of pre-metastatic niche in lungs prior to observing morphological changes.

Methods: Six-week-old female athymic nu/nu mice (NCI, MD) were implanted with $2 \times 10^6$ cells of human breast cancer cell lines - MDA-MB-231 (n=3), and MCF-7 (n=3) in their fourth right mammary fat pad orthotopically. And control mice (n=3) without tumor cell implantation were also employed. The primary tumor size was monitored and the mice were sacrificed within 8-12 weeks of cell implantation when the primary tumors volume grew to 500-600 mm$^3$. Control mice were also sacrificed in this timeframe. The freshly excised lungs of the mice were cleaned in PBS and utilized for obtaining Raman spectra (830 nm, thermoelectrically cooled CCD). Each tissue was collected from multiple points. Principal component analysis (PCA) and Partial least squares discriminant analysis (PLS-DA) were employed as discriminating algorithm. Following spectral acquisition, the tissues were fixed in 10% formalin, embedded in paraffin, and then HE staining, and Masson's trichrome staining for collagen. Collagen quantification of Masson's trichrome stained slides was achieved using MATLAB (Mathworks, MA). The Institutional Animal Care and Use Committee at Johns Hopkins University School of Medicine approved the protocol of the study.

Results: 900 Raman spectra each acquired from the lungs of the control mice and mice bearing MCF-7 and MDA-MB-231 tumor xenografts were assigned class labels - 'Control', 'MCL' and 'MDL' respectively for further analysis. Select principal components from those obtained by subjecting all the chosen 900 spectra to PCA clearly evident that the differences in the Raman spectra belonging to tissues being primed by derivatives of different primary cells are quite pronounced. The average correct rates of PLS-DA prediction of 90.1%, 97.7% and 78.4% were obtained for the spectra belonging to the classes - Control, MCL and MDL respectively. The HE images are negative for any signs of cancerous lesions. Masson's trichrome staining results show that the metastatic potential of the cell lines responsible for the primary tumor is positively correlated with the collagen density in the pre-metastatic niche, the MDL shows the highest collagen density (P<0.001). These differences clearly indicate the remodeling of extracellular matrix anticipating incoming tumor cells in response to primary tumor derived factors occurs very early in the metastatic cascade.

Conclusion: The current study introduces Raman spectroscopy in conjunction with chemometric techniques as are liable and minimally invasive tool for diagnosis of metastatic cancers significantly early in the metastatic cascade, and also opens a new route for early targeting of cancer metastasis and its associated burden.
Title: Decoding the genetic basis of mammary mineralization and their putative role in promotion of distant metastases

Zheng C, Rizwan A, Paidi SK Kumar, Yu Z, Barman I and Glunde K. The Second Hospital of Shandong University, Jinan, Shandong, China; The Johns Hopkins University In Vivo Cellular and Molecular Imaging Center, The Johns Hopkins University School of Medicine, Baltimore, MD and Johns Hopkins University, Baltimore, MD.

Body: Background: Breast microcalcifications are the sole early stage diagnostic markers of breast cancer. The association of mineralization (especially type II microcalcifications) with both benign and malignant lesions often leads to unnecessary biopsies. The processes by which these ectopic microcalcifications form are unknown. In the current work, we attempted to explore the possibility of obtaining genes responsible for the formation of microcalcifications in breast cancer cell lines at cellular level and understand their potential involvement in disease progression and distant metastases.

Methods: The GEO dataset GSE16795 used in this study contains gene expression profiles of 28 human breast cancer cell lines that were divided into two groups - metastatic and non-metastatic. Gene expression levels of OPN were found to be significantly \( p=0.0002 \) elevated for the metastatic group compared to the non-metastatic group. Hence, the human breast cancer cell lines - metastatic (MDA-MB-231 and SUM 149) and non-metastatic (BT-474 and T47D) from the American Type Culture Collection were cultured and their OPN expression at mRNA and protein levels determined by qRT-PCR and Western blotting were compared. Additionally, the same cell lines were cultured in media enriched with an osteogenic cocktail containing 10mM \( \beta \)-glycerophosphate (Sigma, USA) and 50 mg/ml\(^{-1}\) ascorbic acid (Sigma, USA) for induction of microcalcifications. Next, several clones were generated using shRNA knockdown of OPN gene in MDA-MB-231 cells for further study. In vitro studies were conducted to assess the effects of OPN knockdown on the migration and invasion potential of MDA-MB-231 cells using transwell migration assays.

Results: The expression of OPN at both mRNA and protein levels are significantly higher for the metastatic cell lines when compared to non-metastatic cell lines. It can also be observed that OPN expression in the cells increases substantially with addition of exogenous phosphates in the form of osteogenic cocktail and thereby indicating that OPN possibly plays a crucial role in mediating formation of microcalcifications in these cells(\( P<0.001 \)). Metastatic cell line MDA-MB-231 was employed as a model system for further investigation in this study. There is a consistent inhibition of formation of cellular microcalcifications due to the knockdown of gene responsible for OPN, suggesting that OPN gene is directly associated with the formation and regulation of hydroxyapatite formation in MDA-MB-231 breast cancer. Further, the above observation is strengthened by the similarity of the trend of variation in level of mRNA expression of OPN and cellular calcification content across the knockdown clones. OPN knockdown cell lines show reduced cell migration and invasion in the assays compared to the control MDA-MB-231 cells.

Conclusion: The knockdown of OPN gene not only reduced the formation of microcalcifications in the cells in response to osteogenic cocktail but also affected their migration and invasion characteristics. The observed dual roles of the OPN gene encourage us to probe further into the possible existence of a direct relationship between microcalcifications and ability to metastasize to distant organs mediated by common genetic factors in the future.
**Title:** Effects of local and radiation enhanced TGFβ on the invasive nature of inflammatory breast cancer cells

Barkataki S and van Golen K. University of Delaware, Newark, DE and University of Delaware, Newark, DE.

**Body:** Inflammatory Breast Cancer (IBC) is the deadliest form of epithelial breast cancer, accounting for ~10% of breast cancer deaths in the United States. A hallmark of IBC is the formation intralymphatic emboli that are known to be chemotherapy and radiation resistant and contribute to rapid metastasis. This form of breast cancer progresses very quickly, expressing aggressive behavior. IBC and melanoma share a number of similarities in disease presentation and progression. Both spread via dermal lymphatics, form intralymphatic emboli and have a propensity to form cutaneous metastases. Melanoma can also present as “inflammatory melanoma”, which resembles IBC phenotypically. Thus, new leads for studying cutaneous metastasis can be gathered from the melanoma literature. Studies demonstrate a role for transforming growth factor beta (TGFβ) in the etiology of melanoma cutaneous metastasis. TGFβ promotes tumor cell invasion and its expression can be induced in the stroma by radiation treatment. Recently, our lab has demonstrated low expression of TGFβ in IBC patients, which we believe promotes cohesive invasion of IBC cells. Stimulation of IBC cells with 2ng/ml of TGFβ causes altered tumor cell behavior such as stimulating single cell invasion. The invasion of KPL4, SUM149 and MDA-MB231 cell lines were significantly higher in TGFβ stimulated cells compared to non-stimulated cells. As in melanoma cells we hypothesize that radiation enhanced local TGFβ production in the stroma. We radiated normal human epidermal fibroblasts cells with 0gy, 0.5gy, 1.0gy, 2.5gy and 5.0gy intensity and observed that the invasion was significantly higher in 1.0gy, 2.5gy and 5.0gy. We have also looked at the levels of TGFβ-1 in different conditioned medium. ELISA results don't show significant level of increase in TGFβ-1. Since there are two more TGFβ receptors in the TGFβ pathway (TGFβ -2 TGFβ -3), next I will look at the level of TGFβ-2 and 3 on the different intensity of radiation-conditioned medium. Our prediction is that the increase in the invasion of IBC cells is because of TGFβ, which alters the cohesive nature of IBC cells, and enhance single cell invasion. Moreover, radiation increases TGFβ levels in the stroma, which is responsible for rapid metastasis of IBC cells to the skin.
Title: Novel CD146-downstream signaling pathway involved in breast tumor suppression

Ouhtit A, Fernando A, Abd Elmageed Z, Rahman M and Zayed H. College of Arts and Sciences, Qatar University, Doha, Qatar and College of Health Sciences, Qatar University, Doha, Qatar.

Body: While CD146 is a promoter of various tumor types, its true function in breast cancer (BC) is still controversial. However, evidence from our work and others indicate that CD146 acts as a tumor suppressor in BC. To test this hypothesis, we developed both in vitro and in vivo tetracycline (tet On)-inducible system of CD146 using MDA-MB-231 founder BC cell line. Our results demonstrated that induction of CD146 suppressed BC cell migration and invasion in vitro as well as tumor growth and progression in mouse breast xenograft model. Microarray gene expression profiling revealed latexin (LXN: a variant of Tissue Inhibitor of Metalloproteinases) as a novel potential CD146-downstream signaling transcriptional target, which was validated using various in vitro approaches. To further validate our finding, immunohistochemical analysis of breast tumor tissues from both human and mouse (tet-inducible system) breast tissues showed that, while the expression of both CD146 and LXN were highly expressed in the early stages of BC (normal and benign tissues), it was lost in advanced stages (malignant and metastatic tissues). Pharmacological approach combined with luciferase assay revealed that NFκB activation via Akt pathway couples CD146 to the transcription of LXN in BC CD146-inducible cells. The present study discovers the main molecular players of a novel signaling pathway that underpin CD146-suppressed BC progression.
Title: Metabolic stress induces GD2 expression and cancer stem cell phenotype in triple negative breast cancer

Battula VL, Piyaranthna B, Nguyen K, Sun JC C, Jin F, Coarfa C, Nagireddy P and Andreeff M. The University of Texas MD Anderson Cancer Center, Houston, TX and Baylor College of Medicine, Houston, TX.

Body: Breast cancer stem cells (BCSCs) have been characterized as a fraction of cells in primary tumors that are drug resistant and have metastatic potential. Ganglioside GD2 has been shown by us and others as a marker for BCSCs. Furthermore, nutrient deprivation associated metabolic stress seen during tumor progression is reportedly associated with the cancer stem cell phenotype. We hypothesized that metabolic stress could induce spontaneous generation of GD2+ BCSCs during tumor progression. To test our hypothesis, we cultured breast cancer cell lines MDA-MB-231 and SUM159 at low seeding density and measured percentage and absolute number of GD2+ cells daily. Flow cytometry analysis revealed that the percentage of GD2+ cells increased from 4.5 ± 2.5 on day 2 to 15 ± 3.8% on day 5 in MDA MB-231 cells and from 8.5 ± 2.8% on day2 to 28 ± 6.2% on day 5 in SUM159 cells (both designated as triple-negative breast cancer, TNBC). To investigate this phenomenon in-vivo, we injected GFP+ MDA-MB-231 cells in NSG mice mammary fat pads and examined GD2 expression in the implanted tumors weekly. Interestingly, we noticed that the percentage of GD2+ also increased from 12 ± 1.5% on week 1 to 30 ± 2.5% on week 6. Next, SUM159 cells were cultured in either nutrient rich (NR, i.e., 10% serum) or nutrient deprived (ND, 1% serum) for 4 days. We found that the percentage of GD2+ cells in NR medium at the end of 4 day culture was ~20% of the total cell population, whereas in ND medium was almost 50%. We then tested the effects of nutrient rich environment on GD2 expression by refreshing the media daily. Interestingly, cells that received fresh media had lower number of GD2+ cells (15 ± 1.5%) compared to cells cultured in the same medium for 4 days (33 ± 2.5%). Our data suggests that nutrient deprivation induces a stem cell phenotype in TNBC cells.

Next, we performed global metabolic profiling (i.e., for a total of 300 biochemical metabolites) using a mass spectroscopy-based approach. We profiled SUM159 cells cultured with NR vs. ND medium (set-1); GD2+ vs GD2- SUM159 cells (set -2); GD2+ vs GD2- MDA-MB-231 cell (set-3). Metabolites associated with amino acid metabolism, in particular glutathione metabolism, including glutamyl-alanine, 5-oxy-proline, proline, glutamine, and glutathione itself were found to be most highly up-regulated in GD2+ compared to GD2- cells and also in cells cultured in serum starved compared to serum rich conditions. Further analysis of these metabolites and their association with GD2+ cell signature ravelled that gamma-glutamyl transferase (GGT5), was one of the most highly up-regulated (>150-fold) gene across all the groups. GGT is expressed on cell surface and transfers glutamyl group to amino acids, which then get transported across the membrane. In cancer, cells expressing GGT has been shown to be resistant to chemotherapeutic agents including cisplatin. Targeting glutathione metabolism could be future therapeutic strategy to inhibit BCSC growth in TNBC.
Title: Uridine diphosphate glucose dehydrogenase is required for hyaluronic acid production and breast cancer invasion

Arnold JM M, Rasaily U, Ramirez-Peña E, Pathak R, San Martin R, Purwaha P, Rao A, Putluri N, Rowley D, Sikora A, Mani S and Sreekumar A. Baylor College of Medicine, Houston, TX; MD Anderson Cancer Center, Houston, TX and BSW Memorial Hospital, Temple, TX.

Body: Breast cancer is a significant public health concern and there remain unmet challenges in the diagnosis and treatment of triple negative breast cancer (TNBC). Gene expression profiling has revealed that TNBC is composed of a diverse set of disease states and thus there is a need for a more integrated approach to describe phenotypic subtypes within TNBC. Metabolism, as the integrated product of upstream signaling events, environmental conditions and energetic demands, is deeply linked to cellular phenotype. In recent years it has been unequivocally demonstrated that cancers exhibit altered metabolism compared to normal tissues, and furthermore many of these alterations are potentially actionable therapeutic targets. In a recent publication we described several metabolic alterations which occur during the epithelial-mesenchymal transition (EMT) and demonstrated these alterations could be used to define a prognostic metabolic signature in breast cancer patients. Following up on that work, I identified a set of metabolic enzymes which are specifically upregulated during EMT and are significantly upregulated in a subset of TNBC patients with mesenchymal-like disease. Using genetic and biochemical approaches, I have identified one of these enzymes, uridine diphosphate glucose dehydrogenase (UGDH), to be necessary for EMT and cellular invasion. UGDH facilitates the rate-limiting step in the production of cellular uridine diphosphate glucuronic acid (UDP-GlcUA), a precursor for hyaluronic acid (HA) and other glycosylaminoglycans. HA production has previously been identified as an important process for EMT and cancer progression. Here we demonstrate that RNAi-mediated depletion of UGDH significantly decreases HA production and inhibits breast cancer invasion in both in vitro and in vivo models. Additionally, we demonstrate the compound 4-methylumbelliferone (4-MU), which inhibits HA production via depletion of intracellular UDP-GlcUA, significantly inhibits cellular invasion, colony formation, and partially reverses EMT. Taken together, this research indicates that UGDH and intracellular UDP-GlcUA may represent novel, pharmacologically actionable therapeutic targets for the inhibition of breast cancer invasion.

Title: Leptin receptor (OB-R) in breast carcinoma tissue: Ubiquitous expression and correlation with leptin-mediated signaling, but not with systemic markers of obesity

Chang MC C, Ennis M, Dowling RJO J O, Stambolic V and Goodwin PJ J. Mount Sinai Hospital/Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada; Applied Statistician, Markham, ON, Canada; Princess Margaret Hospital, Toronto, ON, Canada and University of Toronto, Toronto, ON, Canada.

Body: Background/Aims: Obesity is associated with a 30-50% increased risk of breast-cancer (BC) mortality, most consistently in estrogen receptor (ER) positive disease, through unclear mechanisms. Leptin is a multi-functional protein with key actions on adipose tissue. In pre-clinical studies, leptin stimulates the growth, survival, and progression of BC cells through both estrogen dependent and other (e.g. JAK/STAT, PI3K/Akt, MAPK) pathways. Leptin has also been associated with increased BC risk and poor prognosis. Our aim was to correlate tumor leptin-receptor (OB-R) expression with tissue markers of cell signaling and systemic markers of obesity, inflammation, and metabolism in a cohort of ER+/HER2- BC patients.

Methods: From our biorepository, we identified ER+/HER2- BC patients having both blood and tissue samples available. Data included BMI, menopausal status, and family/cancer/medical history, tumor histology, grade, stage, and ER/PgR/HER2 status. We performed blood assays for factors related to inflammation, tumor growth, hormonal regulation, and metabolism (see below). Immunohistochemistry for OB-R, pAkt (S473), pERK (T202/Y204), and insulin-receptor (IR) was performed on archived tissue, and scored for % positive cells and intensity of staining. Allred and H-scores were calculated. Associations with OB-R scores were calculated using Pearson, Spearman, and \( \chi^2 \) methods.

Results: 129 patients were eligible; 69.8% were post-menopausal and mean BMI was 27.8 ± 6.5 kg/m\(^2\). Most tumors were no-special-type (79%), PgR+ (90%), and node-neg (78%). The tissue expression of OB-R and other markers was scorable in 118 (91%) cases.

OB-R was expressed in all 118/118 cancers (Allred score range: 3 to 8; median 7, mean 6.61). High blood leptin did not downregulate OB-R (Spearman R=0), even though leptin was strongly correlated with BMI (Pearson r=0.78, p<0.00001). Increasing OB-R correlated with phosphorylation of Akt (R=0.19) but not ERK (R=0.08). By contrast, high BMI was associated with lower Akt (R=-0.18) and ERK (R=-0.11) phosphorylation.

OB-R correlated with ER (Spearman R = 0.27), PgR (R=0.29), and insulin receptor (R = 0.24), weakly correlated with estradiol (Spearman, R=0.11) and fasting glucose (R=0.18), and negatively correlated with systemic IL-2 (R=-0.11) and IL-6 (R=-0.21). OB-R was not correlated with other blood markers (insulin, HOMA, PAI-1, IL-1β, IL-8, VEGF, EGF, TNF-α, hsCRP, SHBG, or estrogens) or tumor grade.

Conclusions: OB-R is highly expressed in breast tumor tissue even in non-obese patients. Although leptin and BMI did not modulate OB-R expression, downstream signaling (e.g. Akt, ERK) did show a BMI-dependent effect, albeit of limited magnitude. This suggests that leptin acts on breast cancer cells through OB-R activation and downstream Akt/ERK signaling, without a coupled change in total OB-R expression. Further work is needed to elucidate the roles of inflammation, estrogens, and regulatory mechanisms within the PI3K-PTEN and Ras-MAPK cell-signaling networks.

Title: Atorvastatin insensitivity is associated with increased lipid droplets accumulation and fatty acid metabolism in breast cancer cells

Lettiero B, Kimbung S and Borgquist S. Lund University, Lund, Sweden and Skåne University Hospital, Lund, Sweden.

Body: Lipophilic statins, including atorvastatin, may exert significant antiproliferative and proapoptotic effects in breast cancer as demonstrated in both clinical trials and cell models. However, heterogeneity in treatment response still remains a noteworthy challenge to be addressed. In this regard, we previously proposed a multigene signature including genes involved in cholesterol biosynthesis, which were dysregulated upon atorvastatin treatment and was shown to predict statin responsiveness in breast cancer (BC) cell lines and primary tumors. To further delineate the molecular mechanisms underlying this variability, we sought to characterize the differential statin-induced effects on intracellular lipid regulation observed in BC cell lines based on their sensitivity to atorvastatin treatment. BC cells were classified as insensitive (MCF-7 and T47D) or sensitive (MDA-MB-231) to atorvastatin by virtue of growth inhibition rate consequent to treatment with doses ranging up to 10 \( \mu \text{M.} \) Under complete culture conditions, atorvastatin-induced decrease in cell proliferation was inversely correlated to a progressive accumulation of neutral lipids in lipid droplets (LDs) in the insensitive cells following 72 hours treatment. Interestingly, in the sensitive MDA-MB-231 cells no significant change in LDs formation was observed despite the very potent antiproliferative effects (60% impairment of growth). However, in correspondence of severe inhibition of growth rate of at least 80% by atorvastatin treatment, MDA-MB-231 cells displayed a consistent reduction in LDs accumulation despite the severe atorvastatin treatment. Transcriptional profiling of genes involved in lipid metabolism using microarrays and validated by qRT-PCR ruled out the possibility that atorvastatin treatment altered lipid uptake and export mechanisms in sensitive cells in the presence of exogenous lipid supply. Nevertheless, gene ontology analysis indicated that an induction of cell stress responses was likely associated to atorvastatin sensitivity. Significant deregulation of genes involved in the fatty acid metabolic process, including biosynthesis of monounsaturated fatty acids (MUFAs), and cholesterol biosynthesis were instead linked to atorvastatin insensitivity. Accordingly, we found that the magnitude of the induction of the mRNAs of stearoyl-CoA desaturase (SCD), the key effector in MUFAs metabolism, and 3-hydroxy-3-methylglutaryl-CoA reductase (HMGCR), the established target of statins, were consistently lower in sensitive cells compared to the insensitive counterpart in response to atorvastatin treatment. Therefore, we suggest that the ability to significantly increase the number of stored neutral lipids in response to statin treatment may likely confer a proliferative advantage to BC cells. Our results also identified MUFAs metabolism as an attractive pathway to be further investigated in view of finding promising biomarkers for unraveling the molecular basis of statin sensitivity in breast cancer.
Title: Modulation of FASN under obese conditions

Pham T, Lee G, Quach D, Galvan G, Jolly C, Cavazos D, Brenner A and deGraffenried L. The University of Texas at Austin, Austin, TX and The UT Health Science Center at San Antonio, San Antonio, TX.

Body: Introduction: Obesity is known to be associated with a worse breast cancer prognosis, in part through altering metabolism in cells of the tumor microenvironment. In particular, changes in metabolism associated with fatty acid utilization have been noted in not only breast cancer, but also several other cancer types. This includes changes to both expression and activity of the Fatty Acid Synthase enzyme (FASN), which is responsible for production of long chain fatty acids, including palmitate. These changes in long chain fatty acid production can modulate tumor behavior through modulation of energy utilization such as beta-oxidation, as well as plasma membrane modulation with phospholipids. Our previous studies have demonstrated that exposure to obese conditions induces significant changes in breast cancer cell proliferation. Additionally, obesity modulates activity of other cells within the tumor microenvironment, including adipocytes, which might influence the cancer cell itself. We hypothesize one particular mechanism that supports these changes is obesity-induced upregulation of FASN and that FASN may be a viable target to limit obesity-induced progression.

Methods and Results: FASN has been shown to promote cancer cell proliferation through generating fatty acid precursors required for cell proliferation, altering membrane fluidity, and activating oncogenic signaling pathways. To determine if modulation of FASN is an important mechanism by which obesity promotes disease progression, MCF-7 breast cancer cells and human pre-adipocyte cells (ASC) were exposed to 2% sera from obese postmenopausal women and 2% sera from non-obese (control) women. Preliminary quantitative PCR results demonstrated that exposure to the obese sera resulted in increased expression of FASN in both the cancer cells as well as the ASC. Current studies are on-going to determine if 1) FASN up-regulation results in increased long-chain and free fatty acid production in both the cancer and adipocyte cells, 2) whether changes in long chain and free fatty acid production results in altered metabolism and plasma membrane status and 3) whether targeting FASN with a new generation of FASN inhibitors currently being investigated in the clinic can modulate obesity-induced disease progression.

Conclusions: Our findings indicate that obesity promotes upregulation of FASN in several cells within the tumor microenvironment, including adipocytes and the cancer cell itself. Our on-going studies will confirm if this is an important mechanism by which obesity promotes disease progression. Since FASN inhibitors are currently being investigated in the clinic, the results of these studies will provide a better understanding of how obesity alters the biology of the disease, and may identify a novel target for improving patient outcomes.
Body: Breast cancer (BC) is the most common cause of death among women worldwide. Nowadays, research directed toward the discovery of cancer molecular characteristics has extended into various biological aspects, from early investigations of cancer genomics and proteomics to recent efforts in cancer metabolomics. We consider that breast cancer cells display significantly altered cellular processes, and thus metabolites, compared to normal cells. In this regard, the application of metabolomics towards cancer research can lead to the discovery of metabolite cancer biomarkers and the identification of target therapeutics.

Methods: Metabolomics signature was extracted from primary BC and adjacent tissue samples from a cohort of 182 breast cancer patients from the Institut Gustave-Roussy and Institute Curie – Paris, University of Debrecen – Hungary, and University of Tartu – Estonia. The Biocrates Life Science® company, performed the metabolomics analysis using the Absolute IDQ p180 kit. Statistical analysis was performed by MetaboAnalyst 3.0 software (p <0.05). Results: We observed 99 differential metabolites between breast tumor and adjacent tissues (p<0.05). In the tumor tissue we observed an increase of glycolysis, glutamine uptake and synthesis, glutamate production, intermediates for redox homeostasis, as well reduction in tricarboxylic acid cycle and β–oxidation impairment. Together, these pathways, favor lipogenesis with a consequent increase in saturated fatty acids and cholesterol synthesis for the formation of membranes and lipid rafts in tumors. The increase in rafts in tumors maintains proliferation signaling via membrane receptors, making them important biomarkers. Conclusion: Metabolomics analysis is useful in identifying differential metabolites between breast cancer and adjacent tissue. In this scenario, cancer cells may be dependent on some metabolites for its development, making them therapeutically valuable biomarkers.
Title: Metabolomic analysis by nuclear magnetic resonance spectroscopy discriminates hormone receptor positive/HER2 negative breast cancer cell lines resistant to palbociclib

Bonechi M, Guarducci C, Meoni G, Tenori L, Biagioni C, Schiff R, Osborne CK Kent, Luchinat C, Di Leo A, Malorni L and Migliaccio I. Hospital of Prato, Azienda USL Toscana Centro, Prato, Italy; CIRMPP, University of Florence, Italy; Hospital of Prato, Azienda USL Toscana Centro, Prato, Italy; Lester and Sue Smith Breast Center, Baylor College of Medicine, Houston, TX and University of Florence, Italy.

Body: Introduction: Clinical trials of palbociclib in combination with endocrine therapy have recently shown unprecedented activity for the treatment of hormone receptor positive/HER2 negative (HR+/HER2neg) advanced breast cancer. However, de novo and acquired resistance to palbociclib limit its clinical utility. Moreover, combining palbociclib with endocrine therapy increases toxicity and costs of the treatment. Identifying patients more likely to benefit from this compound and understanding the mechanisms of resistance to palbociclib is critical. In this study we investigated whether metabolomic profiles of breast cancer cell lines with acquired resistance to palbociclib (PDR) differ from their sensitive counterpart (PDS). In addition we sought to identify metabolic biomarkers of sensitivity to palbociclib by analyzing a breast cancer cell line unable to acquire resistance to palbociclib.

Material and methods: We have established in our lab three PDR HR+/HER2neg breast cancer models (MCF7L, T47D and ZR75-1) by chronically exposing cells to escalating doses of palbociclib. PDR derivatives show IC50 values 6 to 30 times higher than their PDS counterparts. One additional model, CAMA-1, was unable to develop resistance. Whole-cell lysates and conditioned cell culture media from five replicates of each of the PDS and PDR models and from CAMA-1 were analyzed by nuclear magnetic resonance (NMR). Principal component analysis (PCA) was used as first exploratory analysis and as dimension reduction technique. Canonical Analysis (CA) was used to discriminate different groups. Differentially expressed metabolites between PDR and PDS models and between CAMA-1 and PDS cells were analyzed.

Results: Unsupervised PCA analyses of H NMR spectra, in which no information about PDS and PDR was inserted in the statistical model, correctly identified individual cell lines on both whole-cell lysates and conditioned media. However this analysis did not discriminate PDS from PDR within each model. Using a supervised approach, in which the statistical model was trained to discriminate between PDS and PDR, these groups were categorized with accuracy of 80% using whole-cell lysates and of 65% using conditioned media, using a cross-validation analysis by repeatedly testing the model on blind samples. CAMA-1 was correctly identified as a PDS model; however it showed a distinct metabolic profile compared to other PDS models. Over 30 metabolites were identified as differentially expressed between PDS and PDR models in lysates and conditioned media, but only glycerophosphocholine levels in conditioned media remained significantly higher in PDR compared to PDS models after correction for multiple testing.

Conclusions: In this study we show that analysis of metabolic profile of cells lysates discriminates PDR from PDS cell lines with a high accuracy. Analysis of metabolic pathways implicated in resistance/sensitivity to palbociclib is ongoing and might help identifying new targets to overcome resistance. Additionally, metabolites associated with palbociclib resistance may be potentially tested in clinical samples as biomarkers for patients stratification. Further studies are warranted.
Title: Modulation of indoleamine 2, 3-dioxygenase (IDO1) expression in breast cancer cells by activated CD8+ T cells is controlled by DNA promoter methylation

Gu F, Noonepalle SK K, Lee E-J, Choi J-H, Shull AY Y, Pei L, Sreekumar A, Ambj S and Shi H. Baylor College of Medicine, Houston, TX; Georgia Regents University Cancer Center, Augusta, GA; Georgia Regents University, Augusta, GA and Georgia Regents University, Augusta, GA.

Body: Tumor infiltrating lymphocytes (TILs) play a critical role in regulating the immunomodulatory properties of triple negative breast cancer (TNBC). However, the specific adaptations that TNBC tumors undergo when challenged by lymphocyte infiltration remain unclear. In order to address this gap in knowledge, we conducted an immuno-phenotype comparison using mRNA sequencing between the TNBC cell line MDA-MB-231 and the luminal breast cancer cell line MCF7 after both were co-cultured with activated human T-cells. Although the cytokine-induced immune signature of the two cell lines were similar, MDA-MD-231 cells were able to transcribe the tryptophan catabolizing enzyme IDO1 at a significantly higher level than MCF7 cells. Stimulation with IFNg was able to differentially induce IDO protein expression and enzymatic activity in ER- cell lines compared to ER+ cell lines, though no differences were observed in upstream JAK/STAT1 signaling or IDO1 mRNA stability between the two cell lines. Further experiments showed that treatment with the demethylating agent 5-aza-deoxycytidine was able to reverse suppression of IDO1 expression in MCF7 cells, suggesting that DNA methylation serves as a potential determinant in IDO1 induction. Analysis of TCGA and other previously published breast cancer datasets revealed subtype-specific mRNA and promoter methylation differences in IDO1, with TNBC/basal-like subtypes exhibiting lower promoter methylation and higher mRNA expression than ER+/luminal subtypes. Bisulfite pyrosequencing validated the subtype-specific association of decreased promoter methylation with increased IDO1 expression in breast cancer cell lines and an independent cohort of primary breast tumors. In addition, decreased IDO1 promoter methylation and elevated IDO1 expression in basal-like breast tumors was found to be associated with increased levels of kynurenine, the metabolic product of IDO1, as well as higher numbers of CD8+ TILs. Furthermore, high kynurenine levels in breast tumors were associated with worse patient survival. Taken together, these findings suggest that subtype-specific IDO1 promoter methylation regulates the ability of breast tumors to escape from antitumor immune responses driven by CD8+ TILs and could be used as a predictive biomarker for IDO inhibitor-based immunotherapy.
Title: Abstract Withdrawn
A combination of dual inhibition in HER2-network by T-DM1 and GDC-0980 provides maximal antitumor efficacy in preclinical model of HER2+ breast cancer

De PK K, Carlson JH H, Sun Y, Lin X, Friedman L, Dey N and Leyland-Jones B. Avera Center for Precision Oncology, Sioux Falls, SD and Genentech Inc., SF, CA.

Body: Background: PIK3CA mutation is associated with a lower pCR rate in primary HER2+ breast cancer (BC) treated with trastuzumab and lapatinib in addition to chemotherapy (from five clinical trials, PMID: 27177864). The BOLERO-1 study showed that the efficacy of a combination of mTOR inhibitor (everolimus) plus trastuzumab (T) and paclitaxel was not very efficacious with HER2+ advanced BC patients except for HER2+/ER- BC patients (PMID: 26092818). In the same line, BOLERO 3 trial data showed the same combination (T + everolimus + vinorelbine) is also not efficacious in T-resistant, HER2+ advanced breast cancer women (median PFS 7 months with everolimus and 5.78 months with placebo, HR: 0.78) (PMID: 24742739). T-DM1 does not have typical adverse events of chemotherapy. Therefore, there has been interest in combining it with other targeted agent. Here we tested the efficacy of a combination of T-DM1 plus GDC-0980 (a dual PI3K/mTOR inhibitor) in HER2+/T-resistant BC cell lines in vitro and in vivo. Methodology: Here we have studied the in vitro and in vivo effects of GDC-0980 along with T-DM1 in HER2+/T-sensitive (BT474), HER2+/T-resistant (BT474HerR), and HER2+/PIK3CA (HCC1954, MDA-MB453) mutated models. We assessed in vitro anti-proliferative, pro-apoptotic and activation status of the PI3K-AKT-mTOR signaling pathway following the combination of GDC-0980 plus T-DM1 in HER2+ BC cell lines. We next evaluated the impact of GDC-0980 plus T-DM1 on tumor growth and angiogenesis using xenograft models. Results: 1) GDC-0980 inhibited downstream activation of the PI3K-mTOR signaling pathway effectors, p-AKT (Ser473, The308), p-P70S6K, p-S6RP and p-4EBP1, and this inhibition was more pronounced when GDC-0980 was combined with T-DM1, 2) similarly the anti-proliferative activity of a combination of GDC-0980 plus T-DM1 was significantly higher by 3D-ON-TOP clonogenic assay following hergulin stimulation, 3) consistent with anti-proliferative effects of GDC-0980, the proportion of cells in the G1 phase of the cell cycle increased in HER2+ cell lines with a concomitant decrease in the S phase of their treatment with GDC-0980, 4) the initiation of apoptotic activity (annexin V) of GDC-0980 was significantly superior to that of an allosteric inhibitor of mTOR, RAD001. GDC-0980 also induced apoptotic markers like cleaved CASPASE3, cleaved PARP1, BIM in HER2+ BC cells and 5) a combination of GDC-0980 plus T-DM1 significantly blocked tumor growth to tumor regression in the HER2+/T-sensitive, HER2+/T-resistant and HER2+/PIK3CA mutated BC xenograft models. Along with its anti-tumor effect, this combination effectively decreased tumor angiogenesis (tumor micro-vessel density via CD31 staining). Conclusions: A combination of GDC-0980 plus T-DM1 significantly blocked in vitro and in vivo HER2+ breast tumor cells growth irrespective of PIK3CA mutation status. This strategy warrants further clinical investigation.
Title: Chronic CXCL12 exposure induces a metastatic phenotype in ER-positive breast cancer cells through transcriptional reprogramming

Sun J, Slingerland JM M and Lippman ME E. University of Miami, Miami, FL.

Body: The chemokine CXCL12 is transcriptionally activated by estrogen in estrogen receptor (ER)-positive breast cancer cells. We have found that CXCL12 signaling is essential to maintain the long-term growth of ER-positive breast cancer cells and promotes cancer cell growth in the absence of estrogen. Chronic blockade of CXCL12 signaling with AMD3100, an inhibitor of CXCL12 receptor CXCR4, causes cell death in these cells. Chronic exposure to CXCL12 reprograms ER-positive breast cancer cells through genome-wide transcriptional changes and activates numerous signaling pathways including EMT and the inflammatory response. Many ER target genes are activated in CXCL12-reprogrammed cells even in the absence of estrogen which leads to the diminished estrogen modulated transcription in these cells. These cells also show enhanced signaling via TGFβ, EGFR and Rac1 pathways, rendering these cells more sensitive to the CDK7 inhibitor, THZ1, and to drug combinations of THZ1 with the EGFR inhibitor Gefitinib or the RAC1 inhibitor EHT 1864. Furthermore, CXCL12-reprogrammed ER-positive breast cancer cells become more motile in vitro and display a metastatic phenotype in a mouse model. The lung-tropic phenotype of CXCL12-reprogrammed MCF-7 cells could be explained by increased expression of integrins and pro-inflammatory signaling molecules. Our novel finding of chronic CXCL12 action on ER-positive breast cancer cells suggests a mechanism by which the interaction between stromal and tumor cells leads to increased breast tumor metastatic potential.
Tropomyosin-related kinase A is overexpressed in HER2-positive breast cancers

Faulkner S, Roselli S, Oldmeadow C, Attia J, Forbes JF F, Walker MM M and Hondermarck H. School of Biomedical Sciences & Pharmacy, The University of Newcastle, Callaghan, NSW, Australia; Hunter Medical Research Institute; School of Mathematical and Physical Sciences, The University of Newcastle, Callaghan, NSW, Australia and School of Public Health & Medicine, The University of Newcastle, Callaghan, NSW, Australia.

The neurotrophin tyrosine kinase receptor TrkA (NTRK1) contributes to breast cancer cell invasion and metastasis, but its clinicopathological significance in breast tumours is unclear. In this study, TrkA immunohistochemistry was performed in a cohort of 366 breast tumours including ductal carcinomas in situ (DCIS), invasive ductal carcinomas (IDC), and invasive lobular carcinomas (ILC). TrkA protein was detected in both cancer and myoepithelial cells and was preferentially associated with IDC (39% of cases) as compared to DCIS (24% of cases) (p<0.0001) and ILC (20% of cases) (p<0.0001). There was a linear association between TrkA expression and lymph node invasion (p=0.0052), confirming the involvement of TrkA in the metastatic potential of breast cancer cells. Interestingly, TrkA expression was significantly increased in tumours positive for the human epidermal growth factor receptor-2 (HER2). TrkA was detected in 48% of HER2-positive tumours compared to only 25% of HER2-negative tumours (p<0.0001). When considering molecular subtypes of breast cancer, HER2+ and luminal B tumours were associated with higher TrkA levels (p=0.006). In Western-blotting, TrkA immunoreactivity was observed at 140 kDa and 180 kDa, with higher levels of TrkA in HER2-positive as compared to HER2-negative breast cancer cell lines. TrkA tyrosine kinase activity in breast cancer cell lines was inhibited by various pharmacological inhibitors and the impact on cell growth was investigated. Together, these data reveal the association between TrkA and HER2 protein expression in breast cancer.
Title: Engineering mesenchymal stem cells (MSCs) to secrete tumour-suppressing exosomes for breast cancer therapy

O’Brien KP P, Khan S, Thompson K, Joyce D, Lalor P, Dockery P, Ingoldsby H, Kerin MJ J and Dwyer RM M. Discipline of Surgery, Lambe Institute for Translational Research, National University of Ireland, Galway, Ireland; Discipline of Anatomy, School of Medicine, NUI Galway, Galway, Ireland and Discipline of Pathology, School of Medicine, NUI Galway, Galway, Ireland.

Body: Introduction: Mesenchymal Stem Cells (MSCs) are multipotent stromal cells that are known to engraft into tumours, raising their potential as tumour-targeted delivery vehicles. MSCs secrete tiny vesicles known as exosomes, which contain genetic material including microRNAs, and are effectively taken up by recipient cells. This study aimed to characterise a tumour-suppressing microRNA, miR-379, and engineer MSCs to secrete exosomes enriched with the microRNA.

Methods: The mechanism of action of miR-379 In Vivo was determined through lentivirus-mediated upregulation of miR-379 in breast tumours, and analysis of changes in tumour angiogenesis, proliferation and progression. Subsequently, MSCs were engineered with lenti-379 and any impact on MSC migration, proliferation and morphology was assessed. MSC-secreted exosomes were isolated and characterised using Transmission Electron Microscopy (TEM) and Western Blot. The exosomal microRNA content was analysed by RQ-PCR, and transfer between cell populations visualised using confocal microscopy.

Results: While elevated miR-379 expression did not impact tumour size In Vivo, an increase in tumour necrosis and decrease in invasion was observed. MSCs were successfully transduced with miR-379, resulting in a distinct change in cell morphology. Despite this, MSC-379 cells maintained inherent tumour-targeted migratory capacity, with no impact on proliferation observed. MSC-379 derived exosomes were 30-120nm in size and expressed the exosome-associated protein CD63. A 5-fold increase in miR-379 was observed in engineered exosomes. Successful transfer of RFP-labelled MSC-derived exosomes to breast cancer cells was visualised using confocal microscopy.

Conclusion: Engineering tumour-targeted MSCs to secrete exosomes enriched with miR-379 holds exciting potential as a novel therapy for breast cancer.
Title: Low BRCA2 levels cause epigenetic activation of growth adaptive pathways without inducing recurrent genomic mutations

Gruber JJ J and Snyder M. Stanford University, Palo Alto, CA.

Body: The development of therapeutics to prevent cancer onset is hindered by a lack of robust cell systems to study the earliest steps of malignant transformation. Significant barriers to studying cancer-initiating events include intrinsic cellular pathways to prevent cell proliferation in the setting of activating oncogenes or genomic instability. To circumvent this limitation, we studied *in vitro* transient depletion of breast cancer tumor suppressor genes followed by selective growth conditions to enrich for *de novo* mutations or stable epigenetic alterations that can confer a growth advantage to non-transformed breast epithelial cells. We report that transient BRCA2 depletion, but not depletion of other breast cancer genes, leads to a selective growth advantage in EGF-free media. This is due to a failure of BRCA2 inactivated cells to enact a mesenchymal-to-epithelial transition upon withdrawal of EGF. Genomic profiling and biochemical approaches indicate that transient loss of BRCA2 induces chromatin remodeling in concert with NF-κB signaling and histone H2B deacetylation to repress genes associated with the epithelial state. Notably, this process did not appear to require recurrent driver mutations, nor DNA methylation changes, but was dependent on ATR signaling. Overall, our work suggests that transiently low BRCA2 levels are sufficient to induce aberrant cell proliferation under certain conditions and that targeting epigenetic modifiers may be an approach to prevent BRCA2-induced malignancy.

Title: Breast cancer increased risk on women using combined oral contraceptive

Fenile R, Nazario ACP Celso Pinto and Simoes CM Mittidieri. EPM- UNIFESP, São Paulo, SP, Brazil; EPM- UNIFESP, São Paulo, SP, Brazil and EPM- UNIFESP, São Paulo, SP, Brazil.

Body: The most controversial aspect in relation to oral hormonal contraception is the risk of developing breast cancer. Knowledge of the factors that influence the proliferation of normal breast epithelium is essential to understanding carcinogenesis and proliferative activity can be assessed by various techniques, including the immunohistochemical analysis of Ki 67. In this work, we aim to compare the overall proliferative activity of breast after 3 cycles of combined oral contraceptive with a natural cycle and with that presented after only one cycle. Were selected 65 women attended in the period July 2006 to February 2007. These underwent excision of breast lump and breast tissue macroscopically regular adjacent to the node, lying this at least 1 cm. The patients were divided into two groups: group A, consisting of 20 women using three cycles of combined oral contraceptive consisting of 150 ug levonorgestrel and 30 ug of ethinyl estradiol, and the group B consisting of 35 women with natural cycles eumenorrheic, ie not used any hormonal medication. In the fourth month after initiation of use of the ACO, the group A patients were divided into four groups according to the use of the contraceptive. The A1 group (5 patients) in the first week; A2 (5 patients) in the second week; A3 (5 patients) in the third week and the A4 (5 patients), the break of the week.

Results: The highest levels of Ki67 count occurred in the third (16.65%) and fourth week (16.56 %) similar to one another. Additionally, it is noted that the average pause week count was greater than the first week (10.25%) and of the second week (8.52%), which in turn were not distinct. When comparing the use of 3 cycles with 1 cycle, we found that there was no difference in Ki67 levels by the time the first two weeks. However, note that the Ki67 levels were higher in women who used contraceptives for longer both in the third week as the week's break.

In conclusion, the proliferative activity of artificial cycle was significantly higher than the natural cycle.

, and after three cycles, showed higher rates of proliferation in the third and fourth weeks of the menstrual cycle, representing increased carcinogenesis and possible increased breast cancer risk. More studies including compensatory apoptosis must be considerer to confirm this hypothesis.
Title: Investigating the effects of low-dose mixtures of environmental contaminants on breast cancer initiation

Body: The alarming increase in the incidence of breast cancer worldwide cannot be explained solely by hereditary factors and strong evidence suggests that a substantial risk can be attributed to extrinsic exposures. In fact, estimates show that 26.8% of all new breast cancers are related to lifestyle and environmental factors. While several lifestyle factors, such as alcohol and a high-fat diet, have been identified as risk factors for breast cancer, still little is known about the contribution of environmental factors, such as environmental contaminants, to breast cancer risk. Research has shown that chemicals, such as plasticisers, pesticides and cosmetic additives cause effects in animal and cell-based models that promote breast cancer. However, many of these effects are only seen at levels of the chemicals that are much higher than those found in human tissues. Also, most studies examining links between exposure to individual chemicals and breast cancer in humans have produced unconvincing results. These observations often lead to the assumption that the concerns associated with the role of chemicals in breast cancer are unfounded, as their levels in tissues are not high enough to increase breast cancer risk. The problem with this assumption is that humans are exposed to low levels of large numbers of chemicals that could act together to increase breast cancer risk. We, and others, have demonstrated the importance of mixture effects in vitro and in vivo, however, this possibility has not been investigated in breast cancer.

Our work aims to address this question by studying the way chemicals act together at low levels to potentially cause breast cancer. We analysed a mixture of four ubiquitous chemicals, all combined at levels found in human tissues: the plasticiser Bisphenol A, the pesticide o,p'-DDT (although banned, it is still present in tissues), the cosmetic preservative propylparaben and the UV filter benzophenone-3. The effect of this mixture on the structure and behaviour of the breast epithelium was investigated in a three-dimensional culture system that resembles the mammary tissue. Here, we observed that all chemicals induced a dose-dependent increase in the disruption of acinar structures, characterised by the formation of aberrant, highly proliferative and disorganised acini with filled lumen, resembling the events that occur during breast carcinogenesis. Interestingly, these effects were also observed when chemicals were combined at very low levels that, individually, produced no measurable effects. Finally, we observed that similar low-dose mixtures elicited changes in the epigenetic and genetic profile of acini, suggesting an epigenetic link between chemical exposure and cancer development.

The outcome of this work paves the way to better estimations of the realistic breast cancer risk in women and provides an essential framework to inform the development of practical solutions, guidance and advice to help reduce exposure of women.
The title of the research paper is "Relationship between obesity and breast tumor pathology in a contemporary set of patients." The authors include Ellsworth RE E, Lovejoy L, Costantino N and Sheiver CD D. The research was conducted at Murtha Cancer Center, Washington, DC and Chan Soon-Shiong Institute of Molecular Medicine at Windber, Windber, PA.

The background of the research highlights that obesity is a risk factor for breast cancer in postmenopausal women, and it is associated with decreased survival regardless of menopausal status. The outcome disparity is attributed to factors such as delayed diagnosis, inadequate dosing with chemotherapeutic agents, and co-morbid conditions. The study evaluates the association between pathological characteristics and BMI in a cohort of patients enrolled in the Clinical Breast Care Project (CBCP) 2001-2013.

Methods: All female patients with invasive breast cancer who had height and weight recorded at the time of diagnosis were identified from the CBCP database. BMI was calculated and patients were categorized as normal/lean (<24.9 kg/m²), overweight (25-29.9 kg/m²), or obese (>30.0 kg/m²). Chi-square univariate analysis was performed to determine statistical significance followed by multivariate logistic regression. Statistical significance was defined as p <0.05. Survival analysis was done using Cox proportional hazard regression models.

Results: Of the 1,705 patients, 32.4% were normal/lean, 31.6% were overweight and 36.0% were obese. Univariate analysis revealed that obese women were significantly more likely to be older at age at diagnosis, African American, menopausal and treated at Joyce Murtha Breast Care Center, a rural civilian hospital in western-central PA. These factors were thus included in multivariate analysis which showed that obese patients were at an increased risk relative to normal/lean patients of having a higher tumor stage (OR = 1.32, 95% CI [1.043-1.681], p = 0.021), size (OR = 1.42, 95% CI [1.091-1.857], p = 0.009), and grade (OR = 1.37, 95% CI [1.085-1.718], p = 0.008) but at decreased risk of PR- tumors (OR=0.57, 95% CI [0.394-0.837], p = 0.004). Overweight patients did not differ significantly from either normal weight or obese patients. Neither breast cancer-specific nor overall survival differed significantly between groups.

Discussion: Higher tumor stage and size may reflect delayed detection in obese women. In contrast, tumor grade and PR status likely reflect underlying biological differences driven by increased adiposity in the breasts of obese women. Despite these differences in pathology, survival did not differ by BMI status, suggesting that factors such as suboptimal dosing may not be relevant in current patient care.
Title: The expression of lysyl oxidase and fibrotic focus is related to inflammation in breast cancer

Park SH Hwan, Jeong YJ Ju, Bong JG Gu and Oh HK Kyu. Daegu Catholic University Medical Center, Daegu, Republic of Korea.

Body: Background: Lysyl oxidase (LOX) is an extracellular matrix enzyme that catalyzes the cross-linking of collagens or elastin. Our hypothesis is that LOX contributes to the formation of a fibrotic focus (FF), which is related to inflammation in breast carcinogenesis. In this study, we analyzed the association between the expression LOXs and FF, and investigated prognostic significance in breast cancer.

Methods: Tissue microarrays were constructed from the specimens of 444 patients with primary invasive breast cancer. Immunohistochemical staining for LOX, LOXlike (LOXL)-1, LOXL-2 and LOXL-3 was performed. The status of FF within the tumor was assessed. The number of CD4+ T cells, CD8+ T cells, CD68+ macrophages was counted, and intratumoral and peritumoral lymphocyte infiltration were evaluated. The clinicopathologic characteristics of the patients were analyzed.

Result: The percentage of positive FF was 39.2% and positive rate of LOX expression was 50% in primary breast cancer tissues. FF was found to be significantly associated with intratumoral and peritumoral inflammation, lymph node metastasis, high histologic grade, larger tumor size. LOX was associated with intratumoral and peritumoral inflammation, CD8+ T cells and menopausal status. LOXL-3 was significantly associated with positive expression of ER and PR, and molecular subtype.

Conclusions: FF and the expression of LOX were associated with inflammation in breast cancer in this study. Our results suggest that LOXs may contribute to the formation of a FF indirectly in relation with inflammation in breast cancer. Further studies are needed to clarify the role of LOXs, FF and inflammation in tumorigenesis and prognostic value of them in breast cancer.
Title: High-grade human cytomegalovirus IEA is associated with expression of COX-2 and 5-LO in human breast cancer samples

Body: Background: The role of cyclooxygenase-2 (COX-2) in breast cancer development and progression has been supported by an increasing number of studies that show the overexpression of COX-2 in all the stages of the disease but in particular, in the metastatic phase. Besides COX-2 and its derived metabolites, 5-lipoxygenase (5-LO) and leukotrienes have also been associated with cancer progression. Human Cytomegalovirus (HCMV) detection in samples from primary BC, sentinel lymph nodes and brain metastases obtained from breast cancer patients' suggests that viral infection may also have a critical role in the development of breast cancer metastasis. Interestingly, in vitro studies showed that HCMV infections induce COX-2 in human fibroblasts, which augments viral replication through a prostaglandin dependent pathway. Thus, our main objective was to investigate whether there is a correlation between HCMV infection and overexpression of COX-2 and 5-LO in breast cancer. If so, HCMV could be an important additional target for breast cancer treatment.

Material and Methods: Paraffin embedded breast cancer biopsies (n=48), ductal carcinoma in-situ (DCIS, n=14) and adjacent, benign breast tissue samples (n=29) were retrospectively examined for HCMV-immediate early (IE), HCMV-Late (LA) proteins, COX2 and 5LO by using immunohistochemical techniques established in our laboratory. Clinical data were available from the patients’ hospital files provided from the departments of oncology and pathology at Akershus University Hospital, Norway. All patients underwent direct surgery in 2011. All patients received standard adjuvant treatment according to the Norwegian guidelines. For in vitro studies, breast cancer cell lines (MCF-7, MB-MDA-231 and SKBR3) were infected with HCMV VR1814 strain and levels of COX-2 and 5-LO were determined by qPCR and western blot and immunofluorescence.

Results: High levels of COX-2, 5-LO and HCMV-IE were detected mainly in breast cancer samples. High grade HCMV-IE (defined as >50% positive cells in the tumor tissues) was detected in 72% of infiltrating BC and in 28% of DCIS, but it was detected only in 7% of benign, adjacent breast tissue samples. Similarly, high grade COX-2 and 5-LO were detected in 58% and 53% of BC, in 21% and 8% of DCIS, and in 4% and 7% of benign, adjacent breast tissue samples, respectively. We found a statistically significant positive correlation for the levels of HCMV-IE and COX-2 (p=0.001) as well as for HCMV-IE and 5-LO (p=0.0002) in infiltrating breast cancer. Furthermore, induction of COX-2 and 5-LO was confirmed in breast cancer cell lines following infection with HCMV was shown at both mRNA and protein level.

Conclusion: Our findings confirm a positive correlation of HCMV-IE protein synthesis and overexpression of COX-2 and 5-LO in infiltrating breast cancer, DCIS and benign, adjacent breast tissue samples, which is consistent with the up-regulation of these enzymes in breast cancer cells infected with HCMV. These results suggest that the inflammation driven by COX-2 and 5-LO in human breast cancer might be induced by HCMV infections and lead to tumor progression. Thus, anti-viral therapy should be considered as an additional experimental treatment in selected breast cancer patients.

Publication Number: P6-06-02

Title: Low expression levels of hormone receptors (ER-α and PGR) in human breast cancer samples is significantly associated with high-grade human cytomegalovirus-IEA

Body: Background: Breast cancer (BC) is the most common type of malignancy and second leading cause of cancer deaths in women worldwide. While contemporary breast cancer therapy allows many patients with localized breast cancer to be cured for their disease, subgroups experience non-curable distant metastasis. In addition, majority of BC cases are considered to be "sporadic", with unknown underlying mechanisms. Thus, it is of major importance to investigate alternative factors that may initiate or promote human breast cancer. Recently, human cytomegalovirus (HCMV) has been detected in samples from primary BC, sentinel lymph nodes and brain metastases obtained from breast cancer patients. However, the oncomodulatory role of HCMV in BC is unknown. Accordingly, the purpose of this study was to elucidate possible correlations between expression of HCMV proteins and established histopathological markers (ER-α, PgR, HER2 etc.) in human breast cancer tissues.

Material and Methods: Paraffin embedded breast cancer biopsies (n=62), ductal carcinoma in-situ (DCIS, n=18) and adjacent, benign breast tissue samples (n=42) were retrospectively examined for HCMV-immediate early (IE) and late (LA) proteins by using immunohistochemical techniques. Clinical data were available from the patients’ hospital files provided from the departments of oncology and pathology at Akershus University Hospital, Norway. All patients underwent direct surgery in 2011. The median age at time of surgery was 55 years. All patients received standard adjuvant treatment according to the Norwegian guidelines.

Results: HCMV-IE was detected at different levels in all BC cases, DCIS and benign breast tissue samples. Interestingly, high grade HCMV-IE (defined as >50% positive cells in the tumor tissues) was detected in 77% of infiltrating BC and in 39% of DCIS and merely in 7% benign breast tissue samples. High grade HCMV-IE was detected in 40%, 76% and 83% of BC patients with >50-90%, >10-50% and <10% tumor cells expressing PgR in their tumors, respectively (p=0.003). All BC samples with negative or low (0-10%) positive staining for estrogen receptors (ER-α) showed high-grade HCMV-IE staining. In subgroups of patients with increasingly positive staining for ER-α between 10-50% and >50-90% of tumor cells, high HCMV-IE was found in 86% and 74%, respectively (p=0.02). A trend but no significant correlation was found between high-grade HCMV-IE and HER2 negativity (p=0.09). In contrast, High grade HCMV-LA proteins were detected in 5%, 11% and 3% of adjacent benign breast samples, DCIS and infiltrating BC, only. Conclusion: Our findings demonstrate that HCMV-IE but not HCMV-LA proteins are frequently detected in samples obtained from infiltrating BC and DCIS. Although the role of HCMV in carcinogenesis of BC is not defined, our findings suggest a negative correlation between high grade HCMV-IE and hormone receptors in general. All in all, our findings may indicate a possible oncomodulatory role of HCMV-IE in human BC, hampering the expression of hormone receptors and forcing the BC cells to a more aggressive phenotype. The effects of HCMV-induced proteins in human breast cancer cells should be investigated further.
Development of a Prosigna® (PAM50)-based classifier for the selection of advanced triple negative breast cancer (TNBC) patients for treatment with enzalutamide

Body: Background: Enzalutamide is an orally administered androgen receptor (AR) inhibitor approved by the FDA for use in men with metastatic castrate-resistant prostate cancer. A recent phase II study of enzalutamide in patients with advanced, AR positive, TNBC (NCT01889238) demonstrated significant improvements in both PFS and OS for patients whose tumors exhibited a gene expression (Gx) profile enriched in AR signaling and luminal biology. A PAM50-based signature was developed from the phase 2 study which used next generation RNA sequencing (NGS) to identify patients likely to respond to enzalutamide. We transitioned the test to the NanoString (NS) nCounter® Analysis System using Prosigna reagents to support clinical validation in a phase 3 trial. Here we describe the development and analytical performance of the NanoString Androgen Gene Expression Profiling Assay-1 (NS-AR-01). Methods: The NS-AR-01 algorithm coefficients were calibrated from the Predict AR algorithm by testing FFPE tumor tissue from patients who were pre-screened but not enrolled in the phase II study with both platforms (NGS and NS). Three unique algorithms were developed and subsequently challenged with an independent sample set with NGS data to provide an unbiased evaluation of the concordance of the platforms. A pre-specified clinical accuracy verification study was performed through prediction of NS-AR-01 scores from the NGS Gx data from the patients included in the phase 2 study efficacy analysis. The final NS-AR-01 algorithm was selected based on performance in the clinical accuracy verification. The final NS-AR-01 algorithm was evaluated in the 118 patients included in the ITT analysis, as well as those treated with 0-1 lines of prior therapy. The analytical performance of the assay was characterized by testing precision from RNA, reproducibility from FFPE tissue, sensitivity to RNA input amounts, and the impact of common interferents. Results: All three algorithm translations met the pre-specified clinical accuracy verification acceptance criteria. The final NS-AR-01 algorithm generated a hazard ratio most similar to that observed from the NGS algorithm. The total standard deviation when testing multiple FFPE sections from the same block was < 1.5% of the score range with an empirical concordance rate of 100% for biomarker status. The range of RNA input specified for Prosigna was successfully verified for NS-AR-01 (125ng–500ng total RNA). The assay was demonstrated to be robust to common interferents including non-tumor tissue. Conclusions: Based on these results, NS-AR-01 is an accurate, precise, and robust assay for the identification of advanced TNBC patients who may respond to treatment with enzalutamide. The assay is well suited to clinical applications, and its ability to identify responders to enzalutamide will be evaluated in future investigational studies.
Title: CDK4 phosphorylation status and corresponding gene expression profile predict sensitivity to Palbociclib

Body: Although the specific CDK4/6 inhibitor PD0332991 (Palbociclib) was recently approved by the FDA to treat advanced ER+ breast tumors, there is yet no reliable sensitivity prediction tool. Cyclin D-CDK4/6 are the first CDK complexes to be activated in G1 phase in response to oncogenic pathways. They phosphorylate and inactivate the central cell cycle/tumor suppressor pRb. CDK4 activity requires its binding to a cyclin D (CCND1-3 genes) with which INK4 CDK4 inhibitors such as p16 (CDKN2A-D genes) compete. Although the assembly of the CDK4-cyclin D complexes was considered to be the main level of CDK4 activity control, we have shown that the activating T172-phosphorylation of CDK4 is actually the central rate-limiting event that initiates the cell cycle decision and signals the presence of active CDK4.

Here, using 2D-gel electrophoresis to separate the modified forms of CDK4, we found in breast cancer cell lines that only the CDK4 T172-phosphorylation correlates with the sensitivity to PD0332991. The only exception was in the rare case of combined CCNE1 amplification and CDKN2A loss wherein combination of PD0332991 with a CDK2 inhibitor is required to block entry in the cell cycle. Additionally, three types of CDK4 modification profile were identified by 2D-gel electrophoresis in 56 breast tumors. In the first profile, the phosphorylated CDK4 was undetectable as in normal breast samples despite a high KI67 index. In the second and third profiles, the CDK4 phosphorylation was detectable and its intensity was either above or below 90% of the intensity of a second yet unidentified form of CDK4, respectively. The proportions of these profiles differ among breast tumors according to their clinic-pathological characteristics, molecular subtypes and risk. Finally, we identified a 11-gene expression signature that faithfully predicted the CDK4 modification profiles of breast tumors and cell lines (concordance rates of 84% and 100% in the 56 analyzed breast tumor samples or cell lines respectively). All three CDK4 modification profiles were evaluated in a merged independent dataset of 4034 published gene expression profiles. In these 4034 patients, 70% of triple-negative tumors, 18% of HER2-positive tumors and 5% of ER-positive tumors were predicted to have the first CDK4 profile wherein CDK4 phosphorylation is undetectable and to be completely unresponsive to CDK4 inhibitors. The phosphorylated CDK4 was predicted to be the major modified form in 26% of triple-negative tumors, 48% of HER2- positive tumors and 56% of ER-positive tumors. These patients should benefit the most from treatment with CDK4 inhibitors. Therefore, prediction of the CDK4 modification profile may allow extending treatment with Palbociclib to presently ineligible patients. As tumors with the third CDK4 modification profile generally present low grade and low OncotypeDX risks, the added value of including CDK4 inhibitors in their treatment compared to surgery and hormone therapy alone is questionable.

In conclusion, we identified CDK4 phosphorylation as the most direct biomarker of CDK4 inhibitor sensitivity in breast cancer and developed a promising 11-gene based surrogate marker to guide their use in the clinic.
Body: Background: Circulating tumor DNA in plasma may present a minimally invasive approach to identify tumor-derived mutations that could be used to inform the selection of targeted therapies for individual patients, particularly in cases of metastatic disease where biopsy is often difficult. We hypothesized that plasma DNA will genetically reflect DNA derived from multiple tumors in patients with metastatic breast cancer. To test this hypothesis and assess the utility of plasma DNA obtained as a “liquid biopsy” for precision medicine, we sought to determine whether massively parallel sequencing of plasma DNA is a reliable surrogate for sequencing of DNA from tissue biopsies in patients with metastatic breast cancer.

Methods: Blood samples were obtained from 7 patients with multiple advanced breast cancer lesions (recurrent breast and metastatic tumors), and tumor specimens were obtained thereafter by biopsy or surgical excision. DNA extracted from plasma, buffy coat of blood, and tumor tissues was used for probe-directed capture of all exons in 196 genes followed by massively parallel sequencing with an average coverage of 3000x for plasma DNA. Tumor and plasma DNA sequences were bioinformatically compared to buffy coat controls, and high-confidence somatic mutations were called. One patient with extensive metastatic disease was evaluated in further detail to study the contribution of different tumors to the overall plasma DNA pool. In this patient, 9 metastatic tumors were sampled in an axillary lymph node, heart, kidney (2), liver, omentum (3), and ovary by biopsy or at autopsy.

Results: Mutations were found in plasma that were represented in one or more tumors in each patient. Three classes of mutations were discovered: 1) mutations overlapping between both plasma and tumors (e.g., TP53 p.R273C and SRC p.E527K); 2) mutations found in plasma but not tumors (e.g., AKT p.E17K and multiple known and novel ESR1 mutations); 3) mutations found in tumors but not plasma (e.g., PIK3CA p.H1047R, p.D350G, and p.N345K). The presence of mutations in each of these classes was validated in plasma and/or tumors using mutation-specific droplet digital PCR (ddPCR). In the patient with extensive metastatic disease, DNA sequencing revealed heterogeneity of tumor contribution to plasma DNA, with some tumors better represented than others. No correlation was found between tumor size (measured by CT scan) and mutational burden in plasma. Interestingly, a significant correlation was found between blood perfusion to the organ where the tumor resides and mutational burden in plasma, with the greatest tumor contribution coming from the heart metastasis (Pearson's r = 0.835, p=0.039).

Conclusions: Plasma DNA sequencing adds a layer of depth to sequencing analysis of tumor biopsy samples, and serves to both confirm tumor-derived mutations as well as detect new mutations. However, plasma DNA profiling does not comprehensively reflect the mutational profiles of tumors in patients with metastatic breast cancer, and thus is unlikely to serve as a surrogate for tumor biopsy as a source of DNA for genetic profiling. Furthermore, plasma DNA contains many mutations not found in tumors, which will confound treatment decision-making and precision medicine.

Title: Comprehensive genomic profiling to assess tumor mutation burden in >8,000 breast cancer cases: Implications for immunotherapy

Frampton GM M, Connelly C, Fabrizio D, Miller VA A and Stephens PJ J. Foundation Medicine, Cambridge, MA.

Body: Background

Breast cancer presents a management challenge, particularly when cytotoxic, hormone and anti-HER2 (ERBB2) therapies are not indicated or have failed. Tumor mutational burden (TMB) is linked to predicted benefit from immune checkpoint inhibitors in several types of advanced cancers, but its effectiveness in breast cancer has not yet been accurately assessed. Using comprehensive genomic profiling (CGP) we assessed the relationship between TMB, histologic sub-type, and clinically relevant genomic alterations in breast cancer samples in the course of routine clinical care.

Methods

DNA was extracted from 40 microns of FFPE sections from patients with breast cancer. CGP was performed on hybridization-captured, adapter ligation based libraries to a mean coverage depth of greater than 500x for up to 405 cancer-related genes. TMB was characterized as the number of somatic coding base substitution and indel mutations per megabase of genome assessed. Cases were stratified by patient age, histologic sub-type, and presence or absence of therapeutically relevant genomic alterations. The vast majority of samples were from patients with advanced disease.

Results

The genomic profiles from a total of 8302 breast cancer samples from unique patients were assessed. Median patient age was 54 years. 10th, 25th, median, 75th, and 90th percentiles of TMB were 1.3, 2.5, 4.5, 6.3, and 10.1 mutations per megabase of coding genome. 210 cases (2.6%) had high TMB of ≥20 mutations per megabase. High TMB was found more frequently in breast invasive lobular carcinoma (24/437, 5.5%) than in breast invasive ductal carcinoma (56/3694, 1.5%) or breast carcinoma, sub-type not otherwise specified (124/3754, 3.3%). Of the 25 most frequently altered genes in this series (Table 1) CDH1, ARID1A and RB1 were >3x more likely to be mutated in the high TMB cohort. Cases with high TMB had higher median age (62 years) than the cohort overall.

**Conclusions**

CGP in the course of clinical care can be used to assess TMB in breast cancer. Cases with high TMB were relatively rate in breast cancer, as compared to other tumor types in which immunotherapies have been most effective. Nevertheless, a meaningful subset of breast cancer patients have high TMB and may be more likely to respond to immunotherapy treatments. Incorporation of CGP into ongoing prospective immunotherapy trials and clinical practice is needed to refine these relationships. Further correlation to clinical outcomes will be investigated to assess the correlation between tumor mutation burden and response to immunotherapy.
Title: PD-L1 expression and decreased tumor-infiltrating lymphocytes are associated with poor prognosis in patients with triple negative breast cancer

Mori H, Kubo M, Yamaguti R, Nishimura R, Osako T, Arima N, Okumura Y, Okido M, Yamada M, Kai M, Kishimoto J, Oda Y and Nakamura M. Graduate School of Medical Sciences, Kyushu University, Fukuoka City, Japan; Kurume Medical Center, Kurume City, Japan; Breast Center, Kumamoto Shinto General Hospital, Kumamoto City, Japan; Kumamoto Shinto General Hospital, Kumamoto City, Japan; Kumamoto City Hospital, Kumamoto City, Japan; Hamanomachi Hospital, Fukuoka City, Japan; Faculty of Medical Sciences, Kyushu University, Fukuoka City, Japan and Graduate School of Medical Sciences, Kyushu University, Fukuoka City, Japan.

Body: Background: Tumor microenvironment has been considered to have an active role in determining the aggressiveness of tumor cells. Recently, programmed cell death ligand-1 (PD-L1) expression or tumor-infiltrating lymphocytes (TILs) are known to be an important prognostic factor of breast cancer. However, the correlation of expression of PD-L1 and TILs still remains unclear. Triple-negative breast cancer (TNBC) is a heterogeneous tumor that encompasses many different subclasses. Further identification of these subclasses is necessary in order to predict prognosis and choose appropriate treatments. Our goal was to correlate PD-L1 expression with clinicopathological features including TILs by using a large cohort of TNBCs.

Patients and Methods: This study included 248 patients with primary TNBC who underwent resection without neoadjuvant chemotherapy at our three hospitals between January 2004 and December 2014. The tumor subtypes were routinely determined immunohistochemically by using resected specimens. IHC scoring for PD-L1 expression was defined in reference to that for HER2 expression. PD-L1 positivity was defined as both IHC 2+ and IHC 3+. Cases were defined as high if stromal TILs ≥50% according to recommendations by the International TILs Working Group.

Results: Of the 248 TNBCs, PD-L1 were expressed as positive in 103 (41.5%) tumors, and TILs were highly present in 118 (47.6%) tumors. PD-L1 expression was significantly correlated with higher levels of TILs (P < 0.0001). There was no significant difference when the prognosis of the patients who had PD-L1-positive tumors was compared with that of the patients who had PD-L1-negative tumors (P = 0.56 in recurrence free survival [RFS] and P = 0.13 in overall survival [OS]). Meanwhile, the patients with high-TILs tumors had longer OS, compared to the patients with low-TILs tumors (P = 0.55 in RFS and P = 0.016 in OS). The analysis in the cross effect between PD-L1 expression and TILs using cox proportional hazards model demonstrated that the PD-L1 expression and TILs are not independent factors (P = 0.0018 in RFS and P = 0.015 in OS). The PD-L1-positive group with low-TILs had significantly shorter survival than the PD-L1-positive group with high-TILs (hazard ratio [HR] = 4.7, 95% confidence interval [CI] 1.6–12.7, P = 0.0067 in RFS; HR = 8.4, 95%CI 2.3–30.3, P = 0.0019 in OS).

Conclusions: Our data indicated that PD-L1 expression was related to higher levels of TILs, and PD-L1-positive tumors with low-TILs were associated with poor prognosis in patients with TNBCs. It is proposed that these biomarkers may be of use for predicting their prognosis and essential in the subclassification of TNBCs.
Title: Effect of serum biomarkers (activin A, CAIX, HER2, TIMP-1, and uPA) on outcome in HER2+ metastatic breast cancer patients treated in first line with lapatinib or trastuzumab combined with taxane: CCTG MA.31

Body: Background: In MA.31, the lapatinib-taxane combination led to shorter PFS than trastuzumab-taxane in HER2+ metastatic breast cancer. We investigated the prognostic and predictive effects of pretreatment serum biomarkers.

Methods: MA.31 accrued 652 patients; 537 (82%) were centrally-confirmed HER2+. Biomarkers were categorized for univariate and multivariate predictive investigations with a median cut-point, ULN cut-points (15 ng/ml- HER2; 506 pg/ml- CAIX; 454 pg/ml- TIMP-1; 1940 pg/ml– uPA; 600 pg/ml- activin A), and custom cut-points (30 and 100 ng/ml for HER2). Stratified step-wise forward Cox multivariate analysis used continuous and categorical biomarkers for PFS in the ITT and central HER2+ populations; central HER2+ biomarker results are shown.

Results: Serum was banked for 472 (72%) of 652 patients. Higher serum activin A (>median; >ULN; p<0.0001); higher CAIX (>median; ≥ULN; p=0.02; p=0.001); higher HER2 (>median; ≥15; ≥30; or ≥100 ng/ml; p=0.05-0.002) and higher TIMP-1 (>median; ≥ULN; p=0.001; p=0.02) had shorter univariate PFS. In multivariate analysis for PFS: higher continuous activin A (HR=6.75 with Box-Cox transformation, P<0.0001) was associated with significantly shorter PFS, along with treatment arm, prior adjuvant anthracyclines, and higher central EGFR status. In multivariate analysis for OS: higher continuous activin A (HR=85.9, with Box-Cox transformation, P<0.0001) was associated with significantly shorter OS, along with treatment arm and higher central EGFR status. The interaction terms of serum biomarkers with treatment were not significant. Elevated serum activin A was also significant at the median cutpoint for PFS (HR 1.79, p=0.0002) and OS (HR 2.39, p=0.006) in multivariate analysis.

Conclusions: Higher serum activin A was a significant independent prognostic biomarker of shorter progression-free and overall survival. No serum biomarker was predictive of differential response to lapatinib vs. trastuzumab. Evaluation of activin A and CAIX-targeted therapy in addition to HER2-targeted therapy may be warranted in patients with elevated serum levels of these biomarkers.

Title: ESR1 amplification and 5’-3’ exon imbalance in metastatic breast cancer

Oesterreich S, Basudan A, Preideig N, Hartmaier RJ J, Bahreini A, Gyanchandani R, Leone JP P, Lucas PC C, Hamilton RL L, Brufsky AM M and Lee AV V. University Of Pittsburgh Cancer Institute, Pittsburgh, PA; Foundation Medicine, Cambridge, MA and University of Iowa Carver College of Medicine, Iowa City, IA.

Body: BACKGROUND: Growing evidence indicates that base pair mutations in ESR1 are relatively uncommon in newly diagnosed, treatment-naive breast cancer, but frequently acquired in hormone-resistant metastatic breast cancer (MBC). We and others have recently identified ESR1 gene fusion and amplification in MBC, with the ESR1 fusions generally encompassing AF1 and the DNA binding domain. The genomic break required for gene fusions often results in an imbalance in the DNA copy number of exons around the break. We examined ESR1 amplification and 5’ and 3’ exon copy number imbalance in MBC.

MATERIALS and METHODS: We designed NanoString DNA hybridization probes against coding and non-coding exons (n=9) in ESR1 and 15 reference probes. We analyzed 128 samples consisting of 61 ER-positive and 44 ER-negative metastases, and 23 primary breast cancers. DNA copy number (CN) was determined using nSolver, with >2.7CN as copy number gain, and >10 as CN amplification. ESR1 CN was calculated by averaging the DNA copy number obtained from all coding exons. The 5’-3’ copy number ratio was the average copy number of the 5’ exons (3-6) divided by the 3’ exons (7-10).

RESULTS: 8 (13%) ER positive metastatic breast cancers showed ESR1 amplification with 5 (8%) having >2.7CN, and 3 (5%) with >10CN. In contrast, in ER-negative metastases, we did not detect any samples with amplification >10CN, and a gain (>2.7 CN) in one case. Similarly, in ER+ primary cancers we did not detect any samples with >10 CN amplifications and 2 samples with CN gain (>2.7 CN). ESR1 showed 5’-3’ CN imbalance in 1 primary (5%) and in 5 metastatic (5%) breast cancers. We are currently confirming and expanding these data in a larger dataset.

CONCLUSIONS: In addition to ESR1 mutations, ESR1 CN amplifications and 5’-3’ imbalance are represent frequent occurrences in endocrine resistant breast cancer. Future studies are aimed at understanding whether the observed exon imbalances are associated with generation of fusion proteins, and whether and how ESR1 amplifications cause changes in endocrine treatment response.
Title: The complete spectrum of ESR1 mutations from 7590 breast cancer tumor samples

Body: Background: Approximately 70% of newly diagnosed breast cancers express estrogen receptor alpha (ERα), and are treated with agents that block ER signaling. Acquired mutations in ESR1, the gene that encodes ERα, have been associated with resistance to aromatase inhibitor therapy in patients with ER positive metastatic breast cancer (ER+ mBC). The most frequently occurring ESR1 mutations are clustered between amino acids 536 to 538 within the ligand binding domain (LBD), although limited data exists characterizing the full mutation profile in a large number of breast cancer samples.

Methods: We surveyed the Foundation Medicine dataset of 7590 primary and metastatic breast cancer tumor samples for ESR1 short variants and copy number alterations. Hormone receptor status was unavailable, therefore two assumptions were made to provide an estimate of prevalence in the ER+ HER2- population: 70% of the tumor samples are from ER+ HER2- patients, and all ESR1 mutations from non-HER2 amplified metastatic sites are from ER+ HER2- patients. In a separate cohort of 48 ER+ mBC patients, circulating tumor DNA (ctDNA) was analyzed for ESR1 mutations using the BEAMing method by Sysmex and with Foundation Medicine's sequencing assay, FoundationACT (Assay for Circulating Tumor DNA).

Results: The prevalence of mutations in ER+ HER2- breast cancer was estimated to be 22% in samples from metastatic sites but less than 3% in samples from primary sites. ESR1 amplification was rare in samples from both primary and metastatic disease sites at 1.3% and 2.0% respectively. A total of 153 unique short variants of known and unknown status were identified. In addition to hotspot mutations at 537 and 538, previously undescribed rare mutations were identified throughout the entire length of the LBD, although 10 alterations at amino acids 380, 463, 536, 537, and 538 account for 86% of all ESR1 mutations in the ER+ HER2- metastatic sites. We also characterized the overlap of ESR1 alterations with commonly altered and clinically relevant genes in breast cancer, including PIK3CA mutations and HER2 amplification, and we report here a landscape of co-occurring alterations. In the cohort of patient samples where ctDNA was analyzed, BEAMing and FoundationAct assays both detected ESR1 mutations in 19 out of 48 samples, and overall concordance of mutation status (wild-type vs mutant) was 100%. A total of 51 individual mutations were detected with the BEAMing assay, 42 of which were detected with the FoundationACT assay. Seven mutations that were undetected by FoundationACT had mutant allele frequencies less than 0.1%. Ten ESR1 mutations were detected only by FoundationACT, 9 of which are not covered with the BEAMing assay. Alterations in PIK3CA, CDH1, TP53, ERBB2, and other breast cancer relevant genes were also detected with FoundationACT.

Conclusions: Understanding the mutational landscape of ESR1 and co-occurring alterations is important for diagnostic development in conjunction with the clinical development of novel anti-endocrine therapies. Our data demonstrate a large spectrum of mutations in the LBD in addition to known hotspot mutations. In addition, the FoundationACT assay offers a robust NGS-based method to screen for mutations in ctDNA that is highly concordant with digital PCR methods.
Body: Introduction KRISTINE (NCT02131064) is an open-label, phase 3 study of neoadjuvant trastuzumab emtansine + pertuzumab (T-DM1+P) vs docetaxel + carboplatin + trastuzumab + pertuzumab (TCH+P) in pts with HER2+ EBC (all pts, Table). In exploratory analyses we assessed whether HER2 expression and gene amplification levels and PIK3CA mutation were associated with pathologic complete response (pCR) in KRISTINE.

Methods Treatment-naive pts with stage II–IIIC HER2+ EBC were randomized to receive 6 cycles of T-DM1+P or TCH+P and assessed for the primary endpoint, pCR (ypT0/is, ypN0). HER2 status was confirmed centrally as immunohistochemistry (IHC) status of IHC3+ and/or HER2/CEP17 gene ratio ≥2 by in situ hybridization (ISH) before study entry. Baseline HER2 mRNA, PIK3CA mutation, and hormone receptor (HR) status were evaluated. Rates of pCR were compared across biomarker subgroups, including: HER2 mRNA, HER2 IHC staining percentage, HER2 gene ratio, and PIK3CA mutation. Incidence of overlap between biomarkers was assessed. All analyses were descriptive.

Results KRISTINE randomized 444 pts (data cutoff, Dec 3, 2015; TCH+P=221; T-DM1+P=223). The biomarker population was representative of the ITT population. Biomarker values and distribution were balanced across treatment arms. Lower pCR rates were seen in both treatment arms across biomarker subgroups with lower vs higher HER2 expression levels (Table). PIK3CA mutation was associated with numerically lower pCR with T-DM1+P but not TCH+P. Evaluation of 15 pts who progressed during T-DM1+P neoadjuvant therapy suggests that nonresponse to therapy in this arm may be associated with low HER2 levels (mRNA, IHC, and ISH).

PIK3CA mutation rate was higher in tumors with ≤median HER2 mRNA (38%) vs >median (16%), and in focal (53%) and variable (41%) HER2 expression vs homogeneous (24%). A numerically higher proportion of HR positivity was seen in the HER2 IHC2+ (81%) subgroup vs IHC3+ (55%), and in the focal (83%) and variable (62%) HER2 subgroups vs homogeneous (53%).

*Categorization based on sum of IHC2+ and IHC3+ staining percentage.

**Conclusions** None of the evaluated biomarker subgroups showed superior pCR rates for T-DM1+P vs TCH+P. Lower HER2 levels based on mRNA and protein expression and gene amplification were associated with numerically lower pCR in both treatment arms. PIK3CA mutation results differ from prior observations. Unfavorable biomarkers for pCR, like low HER2, PIK3CA mutation, and HR positivity, showed a tendency for co-expression, which should be considered when planning future trials in HER2+ BC.
Title: DNA methylation signature predicting bevacizumab efficacy in metastatic breast cancer

Gampenrieder SP P, Rinnerthaler G, Pulverer W, Weinhäusel A, Hufnagl C, Hackl H, Hauser-Kronberger C, Miineritsch B and Greil R. Salzburg Cancer Research Institute with Laboratory of Immunological and Molecular Cancer Research and Center for Clinical Cancer and Immunology Trials, Cancer Cluster Salzburg, Paracelsus Medical University Salzburg, Salzburg, Austria; Business Unit for Molecular Diagnostics, AIT – Austrian Institute of Technology GmbH, Vienna, Austria; Medical University of Innsbruck, Innsbruck, Austria and Paracelsus Medical University Salzburg, Salzburg, Austria.

Background: Biomarkers predicting response to bevacizumab containing therapy in breast cancer are still missing. Since epigenetic modifications can contribute to an aberrant regulation of angiogenesis and to treatment resistance, we investigated the influence of DNA methylation on bevacizumab efficacy.

Patients and methods: A genome-wide methylation profiling using the Illumina Infinium HumanMethylation450 BeadChip was performed in archival FFPE specimen of 36 patients with HER2-negative metastatic breast cancer treated with chemotherapy in combination with bevacizumab as first-line therapy (learning set). Based on objective response and progression-free survival (PFS) and considering ER expression, patients were divided in responders (R) and non-responders (NR). Differentially methylated gene loci (methylation variable position = MVP) and differentially methylated regions (DMR) between R and NR were identified. Only significant sites with a strong change in methylation levels ($\Delta\beta>0.15$ or $\Delta\beta<-0.15$), an area under the curve of at least 0.85 by logistic regression analysis, and/or sites in proximity to genes functionally involved in angiogenesis and carcinogenesis were selected and further validated. Validation was performed in 81 bevacizumab treated breast cancer patients (validation set) and in 15 patients treated with chemotherapy only (control set) using targeted bisulfite sequencing. Methylated gene loci were considered predictive if there was a significant association with outcome (PFS) in the validation set but not in the control set using Spearman rank correlation, Cox regression, and logrank test.

Results: In the learning set 435 MVPs ($p<0.001$) and 144 DMRs (adjusted combined $p<0.0001$ with at least 3 significant MVPs $p<0.05$ in the same region) showed significantly different methylation between R and NR. In R 152 sites were hypermethylated with a median change of methylation ($\Delta\beta$) of 0.13; 283 sites were hypomethylated with a median $\Delta\beta$ of -0.09. A methylation signature of 48 genes was specified allowing a good separation between responders and non-responders (odds ratio=101, $p<0.0001$; data presented at the 38th SABCS 2015, P3-07-43). At least one methylated cytosine in close proximity to 24 of these genes showed a significant association with PFS in the validation set but was not (or in the other direction) in the control set. Based on these data the methylation signature predicting long lasting response to bevacizumab could be reduced to 24 genes including several genes involved in angiogenesis and carcinogenesis, respectively (FLT1 also known as VEGFR-1, MLH1, GNAS, APC, DKK3, WNT2B and COL4A1).

Conclusion: A 24-gene methylation signature can reproducible discriminate between responders and non-responders to a bevacizumab-based therapy in breast cancer and could help to identify patients deriving greater benefit from anti-VEGF agents.
Title: Serum levels of RANKL are increased in primary breast cancer patients in the presence of disseminated tumor cells in the bone marrow

Kasimir-Bauer S, Bittner A-K, Goebel A, Hoffmann O, Browne AJ, Rauner M, Hofbauer LC C, Wimberger P, Kimmig R and Rachner TD D. University Hospital Essen, Essen, Germany; University Hospital Dresden, Dresden, Germany and University Hospital Dresden, Dresden, Germany.

Body: Background: Receptor activator of nuclear factor kappa-B ligand (RANKL) is an essential protein for osteoclast regulation that is associated with benign and malignant bone disease. The activity of RANKL is controlled by its soluble decoy receptor osteoprotegerin (OPG). There is increasing evidence that RANKL may also directly affect breast cancer progression and metastasis to the bone. This study was aimed to assess the levels of RANKL and OPG in 509 newly diagnosed breast cancer patients with regard to the presence of disseminated tumor cells (DTCs) in the bone marrow (BM), circulating tumor cells (CTCs) in blood and clinical parameters.

Patients and Methods: 509 patients with first diagnosis of breast cancer between Aug 2006 and Dec 2009 were included in our study. Blood and BM sampling was performed before surgery in an adjuvant setting. Blood was collected from each patient and sRANKL as well as OPG in the serum were measured by ELISA (Immunodiagnostic, Vienna, Austria). Two BM aspirates were analyzed for DTCs by immunocytochemistry using the pan-cytokeratin antibody A45-B/B3. In a subgroup of 364 patients, 2 x 5 ml blood was studied for CTCs using the AdnaTest BreastCancer (QIAGEN, Hannover GmbH, Germany) for the detection of EpCAM, MUC-1, HER-2, and beta-Actin transcripts.

Results: Mean serum values for RANKL and OPG were 0.23 ± 0.20 pmol/l and 4.24 ± 1.70 pmol/l, respectively. RANKL levels were significantly lower in women above 60 years of age (0.19 pmol/l vs 0.26 pmol/l; p < 0.0001). This finding was reflected by higher RANKL serum levels and RANKL/OPG ratios in premenopausal patients compared to peri- (p<0.05) and postmenopausal patients (p<0.001), respectively. RANKL/OPG ratios were also higher in patients with lymph node involvement (N1-N3, p=0.03). All other clinical parameters did not influence RANKL or OPG levels. DTCs were detected in 213/509 (42%) patients and CTCs in 81/364 (22%) patients, respectively. However, while RANKL levels were unchanged in patients with detectable CTCs, they significantly increased by 33% (p<0.0001) in patients with DTCs. There was no difference in OPG levels, resulting in an increased RANKL to OPG ratio in patients with DTCs in the BM (0.087 vs. 0.060; p < 0.0001).

Conclusion: In conclusion, we show that RANKL serum levels and RANKL/OPG ratios are increased in patients with detectable DTCs in the BM, prior to the establishment of detectable bone metastases. This finding warrants further investigation as it may provide a rational for novel diagnostic or therapeutic approaches.
A physical activity and dietary counseling intervention in breast cancer survivors and changes in known and novel prognostic biomarkers

Peterson LL L, Ford ME E, Gregoski MJ J, Knight KD D, Hilton EJ J, Magwood G and Turner DP P. Washington University, St. Louis, MO and Medical University of South Carolina, Charleston, SC.

Body: High rates of overweight/obesity are commonly seen in breast cancer (BC) survivors. Observational data show an association between post-treatment increased weight and lack of physical activity (PA) and risk of BC recurrence and death. Increases in prognostic inflammatory associated biomarkers (BM) such as interleukin-6 (IL6) and C-reactive protein (CRP), and their downstream effects, are linked to overweight/obesity and provide a potential mechanistic explanation for this increase in recurrence risk, but studies are mixed regarding the effect of lifestyle interventions on these BM. In addition, better BM may exist. The Getting on Board with an Active Lifestyle (GOAL) study tested the feasibility of a PA and dietary counseling (DC) intervention in BC survivors and included known BM (IL6, CRP) as well as a novel BM (advanced glycation end-products [AGEs]). AGEs are reactive metabolites produced by an uncontrolled reaction between sugars and proteins and were selected because they are seen in chronic diseases including: diabetes, neuro-degenerative disorders, stroke, heart disease and more recently, BC. Further, dietary AGEs are consumed in high fat and highly processed foods that contribute to overweight/obesity.

Methods: Ten overweight/obese women (BMI≥25) within 36 months of BC diagnosis (stage I-III) participated in a 12-week supervised PA and DC intervention consisting of two supervised PA sessions per week and weekly DC sessions. Body mass index (BMI), resting heart rate (HR) and blood pressure (BP) and blood samples were collected at baseline, week 4, 8, 12, 24, 36, 52. IL-6, CRP and AGEs were assessed in serum using commercially available 96-well format ELISAs. Data through week 12 is presented here.

Results: Ten participants (four African American) completed the 12-week intervention. The age range of participants was 50-68 years (mean 56 years). The average number of daily active minutes increased significantly between baseline (45) and week 11 (71). There was a drop off at week 12 due to right-censoring of the data. Dietary AGE intake decreased in 8 of 10 participants from baseline to week 12 (average reduction 53%). Significant reductions in mean serum AGEs were seen (baseline=53 ug/ml, week 12=38ug/ml, p<0.001). No correlating reductions in CRP or IL6 were found. Correlations were seen between AGE levels and AGE intake (r=0.24 at week 12). There were no significant correlations between AGE levels and IL6 or CRP. Decreases in BMI (average change -.54 kg/m²), resting HR and BP corroborated with AGE reductions.

Conclusions: The GOAL intervention has the potential to improve PA and dietary AGE intake among overweight/obese BC patients. Participants improved weight, resting HR, BP, and number of daily active minutes; which are important metrics for overall health. There were no changes in IL6 and CRP, but reductions in AGEs correlated with reductions in dietary AGE levels, indicating that serum AGEs may be reduced through diet and PA. Serum AGEs may represent a better BM than IL6 and CRP in BC survivors. Further investigation of AGEs in BC survivors is warranted.
Title: Association of pre-chemotherapy peripheral blood pro-inflammatory (IL-6, CRP) and coagulation (D-dimer) markers with chemotherapy toxicity in women with breast cancer

Body: Background: Pro-inflammatory and coagulation factors serve as biomarkers of aging and functional reserve. Chemotherapy (chemo) decreases the risk of relapse and mortality from breast cancer (BC); however, it comes with the risk of toxicity. The utility of these markers as biological risk factors for chemotherapy toxicity in patients with BC is unknown. This study was performed to determine if pre-chemo IL-6, CRP and D-dimer were associated with chemotherapy toxicity in women with breast cancer receiving adjuvant or neoadjuvant chemo.

Methods: This study enrolled women across the aging spectrum with Stage I-III BC. Prior to (neo)adjuvant chemo initiation, peripheral blood was collected for IL-6, CRP, and D-dimer. (Neo)adjuvant chemo regimens were prescribed at the MD’s discretion. Grade 3 or above toxicities defined by National Cancer Institute Common Terminology Criteria for Adverse Events (NCI CTCAE), version 4.0, were captured. Univariate and multivariate analyses were performed to describe the association of these biomarkers with chemo toxicity controlling for relevant tumor and host factors (stage, receptor status, age and co-morbidities).

Results: 159 patients (mean age of 58.4, range 30-81) with stage I-III BC (Stage I [n=34; 21.3%], Stage II [n=88; 55.3%], and Stage III [n=37; 23.3%]) were enrolled. 89% and 11% received adjuvant and neoadjuvant chemotherapy respectively. Chemo regimens include: doxorubicin+cyclophosphamide/paclitaxel (37%), docetaxel/cyclophosphamide (35%), doxorubicin+cyclophosphamide/paclitaxel/trastuzumab (7%), docetaxel/carboplatin/trastuzumab (7%), sequential doxorubicin/paclitaxel/cyclophosphamide (5) and other regimens (9%). At least one grade 3 to 5 toxicity occurred in 70 (44%) patients (93% grade 3, 6% grade 4, and 1% grade 5). Grade 3 to 5 hematological (heme) and non-heme toxicity occurred in 23% and 39%, respectively. The most common grade 3 to 4 heme toxicities were anemia (38%), leucopenia (29%), and neutropenia (24%). One patient developed grade 5 toxicity (pneumonitis). The most common grade 3-4 non-heme toxicities were electrolyte abnormalities (12%), neuropathy (10%), mucositis (8%), infection (8%) and fatigue (8%). Univariate analysis revealed an association of increased pre-chemo D-dimer and grade ≥3 toxicity (p=0.02) (Table 1). Among the clinical factors, increased age and number of co-morbidities was associated with grade ≥3 toxicities (p<0.01 respectively). After controlling for age and number of comorbidities the association between elevated D-dimer and chemo toxicities remain significant (OR 2.1 [95%CI1.1-3.9]).

Conclusions: Grade 3-5 toxicities are common in women with breast cancer undergoing (neo)adjuvant chemo. A biomarker of aging, D-dimer, is associated with increased risk of chemo toxicity.

New method to measure functional HER2-driven signaling activity in primary tumor cells identifies HER2-negative breast cancers with abnormal HER2 signaling activity: New group of patients may benefit from anti-HER2 therapy

Body: Background: Clinical trials have indicated a weak correlation between HER2 expression levels and HER2 targeted therapy benefit. Other biological factors, such as HER2 signaling activity, may be important to measure, in addition to expression and amplification of HER2, when identifying patients eligible for HER2 therapies. To measure the HER2-driven signaling activity of a patient's tumor cells, a new assay using an impedance biosensor, the CELx HER2 Signaling Profile (CELx HSP) Test, was developed. This study set out to provide an initial assessment of the CELx HSP Test, specifically to: 1) quantify HER2-driven signaling activity (HER2 S) in cell lines and primary epithelial cells; 2) assess the correlation between HER2 expression levels and HER2 signaling activity; 3) define a preliminary cut-point between normal and abnormal HER2 signaling; and 4) estimate the proportion of HER2- primary breast cancer tumors with abnormal HER2 signaling.

Methods: A training set of de-identified fresh breast tissue specimens was obtained from 50 patients, 34 with HER2- breast cancer (IHC 0 or 1+) and 16 healthy patients. Cell samples were comprised of epithelial cells extracted and cultured from each specimen. Reference human breast cancer cell lines (9 HER2+, 10 HER2-) were also tested, including two cell lines used as controls in IHC HER2 tests. Real time live cell response to specific HER2 agonists (NRG1b or EGF) and with or without an antagonist (pertuzumab, an FDA-approved HER2 dimerization inhibitor) was measured and quantified using an xCELLigence RTCA impedance biosensor (ACEA Biosciences, San Diego, CA). From these responses, the net amount of HER2 participation in HER2 signaling initiated by the HER2 agonists ("HER2 S") was determined. Fluorescence cytometry was used to measure HER2 expression levels of each cell sample.

Results: Of the HER2- breast tumor cell samples tested, 7 of 34 patients (20.5%; 95% CI=10%-37%) had net HER2 signaling activity that was greater than the median HER2 S of the HER2+ cell lines. There was no categorical correlation between HER2 IHC status (+ or -) and HER2 signaling activity (abnormal or normal) (Pearson's Chi-Square = 3.68; Phi Max = -0.78, Contingency Coefficient 0.28). The median HER2 S, or net HER2 signaling activity, was comparable for the HER2- tumor, HER2- cell line, and the healthy patient samples (Md = 100, 117, 77, respectively). The median HER2 S in HER2+ cell lines (Md = 248) is approximately 2.5-3.0 fold greater than the median of the other groups. A HER2 S above 250 was considered abnormal or test positive, and was defined as the cut-point. The HER2 S for the two IHC HER2 test control cell lines, SKBR3 for HER2+ and MDA-MB231 for HER2-, was 544 and 0.

Conclusions: These findings provide strong evidence that measurement of HER2 signaling activity may provide clinically relevant information, particularly for HER2- breast cancer patients. These results suggest a new group of HER2- breast cancer patients with abnormal HER2-driven signaling may benefit from anti-HER2 therapy. Additional studies are underway to confirm these findings and to analytically validate the CELx HSP test.

Title: Quantitative proteomic analysis of FGFR by mass spectrometry may improve identification of FGFR amplified tumors sensitive to inhibitor therapy

Body: Background: The fibroblast growth factor receptors 1 and 2 (FGFR1 and FGFR2) have been reported as amplified in multiple solid tumors, including lung, breast and gastric cancers. The FGFR family of proteins is an attractive target for therapy due to the importance of FGFR signaling in the pathogenesis of diverse tumor types. However, pan-FGFR inhibitor have shown only modest efficacy in patients with FGFR1 or FGFR2 gene amplification as determined by fluorescence in situ hybridization (FISH). Gene copy number alterations may not be the optimal predictive biomarker since the targets of these drugs are FGFR proteins; recent findings suggest that direct measurement of the protein targets of FGFR inhibitor therapies may be necessary to assess their treatment efficacy. We therefore developed quantitative FGFR protein assays using selected reaction monitoring mass spectrometry (SRM-MS). We sought to correlate levels of FGFR1, FGFR2 and pan-FGFR (FGFR1-4) proteins as measured by SRM-MS with FGFR gene amplification status as determined by FISH.

Methods: Formalin-fixed, paraffin-embedded (FFPE) tissue sections from breast (n=18), esophageal (n=1), gastric (n=1), lung (n=2), and endometrial (n=1) tumors were obtained. A board-certified pathologist marked the tumor area for laser microdissection. Tumor cell proteins were extracted using the Liquid Tissue® process and subjected to SRM-MS for analysis of protein expression levels of FGFR1, FGFR2 and FGFR1-4, as well as other targetable proteins including MET, EGFR, and PD-L1. We compared FGFR protein levels with FGFR amplification defined as FGFR to CEP FISH ratio >2.2.

Results: Of 23 tumor samples analyzed, the pan-FGFR1-4 proteomic assay detected FGFR protein in 11 cases (protein expression range: 217.8-3199.5 amol/ug). Ten of these 11 samples (91%) showed FGFR gene amplification. Only a single non-amplified case showed protein expression (235.6 amol/ug). FGFR protein (of 1, 2, and 1-4) was undetectable in 12 samples, of which 5 (42%) harbored FGFR1 amplification. Two of 2 (100%) of FGFR2-amplified cases (average copy number=38) showed high FGFR2 protein expression (3063.0 and 3199.5 amol/ug). Sensitivity of the pan-FGFR1-4 assay was superior to single FGFR assays.

Conclusion: A subset of FGFR-amplified tumors does not express FGFR protein when assessed by highly-sensitive SRM-MS. Patients whose tumors do not express FGFR protein are not likely to respond to FGFR inhibitor therapy, as supported by previous findings in squamous cell lung tumors, in which FGFR1 mRNA and/or protein expression levels greatly outperformed FGFR1 gene copy number in predicting sensitivity to a pan-FGFR inhibitors. An approach combining quantitative proteomics and FISH analyses may accurately identify patients most likely to respond to anti-FGFR protein agents.

Title: A novel fluorescence in situ hybridization assay to detect 9p24.1 amplification in triple negative breast cancer

Chen M, Andreozzi M, Pockaj B, Barrett MT T, Ocal IT Tolgay, McCullough AE E and Anderson KS S.  Center for Personalized Diagnostics, Biodesign Institute, Arizona State University, Tempe, AZ;  Public Laboratory, Tianjin Medical University Cancer Institute and Hospital; Tianjin Medical University, Tianjin, China;  Mayo Clinic, Phoenix, AZ;  Mayo Clinic, Phoenix, AZ and Mayo Clinic, Phoenix, AZ.

Body: Introduction: Previously, we detected amplification of chromosome 9p24.1 encoding PDL1, PDL2, and JAK2 (the PDJ amplicon) in up to 25% of triple negative breast cancers (TNBC) using oligonucleotide CGH arrays (aCGH). Amplification was associated with poor outcome and activation of the JAK/STAT pathway. Here, we have developed a novel fluorescence in situ hybridization (FISH) for detection of the JAK2/PDL1 amplification.

Methods: We selected five 9p24.1-amplified and five non-amplified paraffin embedded TNBC tumor samples, defined by aCGH log_2 ratio>2.0 as amplified for FISH validation. 5’ JAK2 DNA labeled with SpectrumGreen dUTP, 3’ JAK2 DNA labeled in SpectrumOrange dUTP and a commercially available chromosome 9 centromeric probe (Spectrum Aqua) were combined as one probe set. The break-apart (BAP) probe set was applied to individual slides, hybridized, and washed, 50 events/sample were counted. We defined 9p24.1 amplification by FISH as the ratio of average JAK2 score/ average centromere 9 (CEN 9) score >1.1. Nonparametric student’s t-test was used for statistical analysis.

Results: In the amplified subgroup (n=5), JAK2 amplification was detected by FISH with the range from 1.89 to 21.0 (mean, 6.76). To adjust for aneuploidy, the ratio of JAK2 to CEN 9 was measured with the range from 1.02 to 9.21 (mean ratio, 2.9). The sample with highest level of amplification (aCGH log_2 ratio =4) detected by aCGH also scored highest by FISH (FISH ratio=9.21). One case with JAK2 amplification (aCGH log_2 ratio =3) was not detected by FISH (ratio, 1.02), but had low tumor cell content. In the non-amplification subgroup (n=5), JAK2 amplification was detected by FISH with the range from 0.98 to 3.54 (mean, 1.8), the ratio of JAK2 to CEN 9 was measured with the range from 0.48 to 1.05 (mean, 0.73). Of note, two tumors with copy number loss by aCGH were confirmed by FISH (ratio 0.48, 0.56). In total, the 9p24.1 amplification was detected in 4 out 5 (80%) amplified samples defined by aCGH and 5 out 5 not amplified. A significant difference in JAK2: CEN 9 ratio (p=0.03) was observed between the amplified and non-amplified subgroups but not in JAK2 absolute scores (p=0.095).

Conclusion: In this study, we have developed a novel FISH assay for detection of the 9p24.1 amplification in TNBC, encoding JAK2, PD-L1, and PD-L2. The FISH assay correlates with detection of the amplification by aCGH, but is less sensitive, in particular in tissue with lower tumor cell content. We predict that 9p24.1 amplification will be a clinically relevant biomarker in TNBC.
Title: A pilot study of the impact of a single dose of zolendronic acid on biomarkers in breast cancer

Body: Backgrounds: In randomized trials for early stage breast cancer, patients who received adjuvant zolendronic acid (ZA) had superior disease-free survival and greater tumor shrinkage. Preclinical data suggest that ZA has anti-cancer properties by modulating angiogenesis and tumor immune environment. This is the pilot study to assess changes in tumor biomarkers and immunological function in response to a single dose of ZA in paired tumor specimens (from core biopsy and definitive surgery).

Methods: Postmenopausal women with early stage invasive ductal breast carcinoma who have estrogen receptor and/or progesterone receptor positive tumor for which a lumpectomy or mastectomy was planned prior to systemic therapy were enrolled. A single dose of ZA 4mg IV was given 10-14 days prior to their planned definitive surgery. 14 biomarkers in tumor tissue was assayed; 10 by gene microarray (VEGF, IL1β, IL-6, MMP-1, MMP-2, MMP-9, TGF, Interferon α and STAT3)) and 4 by RT-PCR(P13K, PTEN, IGF-1-R, EGFR. Patient blood samples were drawn at baseline, at 48-72hrs after the single dose of ZA and at the time of surgery and assayed for cytokines and chemokines by using 30-plex Luminex panels.

Results: Eight patients were enrolled in the study (median age 65 and range (57-75); 4 caucatians, 2 hispanic and 1 asian; 6 stage I, 1 stage II and 1 stage III). 30-plex luminex assays showed MIG, IP-10 and IL-12 were found to increase in Day 1-3 of ZA therapy from baseline and normalized by Day 10-24. MCP-1, IL2R, MIP-1b and Eotaxin were found to have changes in Day 1-3 from baseline and mix outcome by Day 10-24. EGF, G-CSF, HGF, IFN-alpha and IFN-gamma and RANTES showed no clear pattern among eight patients. Tumor markers and proteomics from pair tumor samples will be presented.

Conclusions: Changes in multiple tumor biomarkers and immunological markers, MIG, IP-10, IL-12, MCP-1, IL2R, MIP-1b, Eotaxin, IFN-alpha and IFN-gamma are seen within 2 weeks of a single dose of ZA.
Title: An alteration of hormonal receptor status throughout tumor progression related to prognosis in breast cancer patients

Body: Purpose
We aimed to identify whether hormonal receptors change throughout tumor progression, because this may influence management and influence prognosis in breast cancer patients.

Patients and Methods
From the institution’s database, we collected data of 963 patients who developed relapse during their follow-ups. To determine estrogen receptor (ER) and progesterone receptor (PR), we retrospectively reviewed immunohistochemical (IHC) results in both primary and relapsed tumors.

Results
Among a total of 963 patients, 280 and 683 patients experienced locoregional relapse only and distant metastasis irrespective of locoregional relapse, respectively. ER in 650 patients and PR in 590 patients from both primary tumor and relapse were identified, revealing a change in 157 (24.2%) and 154 (26.1%) patients, respectively. In patients with distant metastasis, assessment of ER and PR showed an alteration in 86 and 56 patients, respectively. The overall survival related to the change of ER and PR status in primary tumor and relapse was significantly different (log rank, \(P<0.001\) in both ER and PR status). In addition, women with hormone receptors negative primary tumors that changed to hormone receptors positive tumors who received anti-hormonal therapy after relapse showed a statistically significant good overall survival (\(p<0.001\)) compared with women who had constant ER-negative tumors. (cox regression, hazard ratio 2.32 ; 95% CI, 1.91 to 3.01)

Conclusion
The breast cancer showed alterations of hormone receptor status throughout tumor progression, hat were related to the strategy of treatment and significantly influences survival. Therefore, investigations of hormone receptor at relapse are essential and helpful in breast cancer patient management.
Title: Allele-specific PCR assay for estrogen receptor (ESR1) mutation detection

Litterst CM M, Tran HB, Chien S, Chen X, Wen W and Begovich A. Genomics and Oncology, Roche RMS, Pleasanton, CA; Assay Development, Roche RMS, Pleasanton, CA and Bioinformatics, Roche RMS, Pleasanton, CA.

Body: Seventy percent of breast cancers are estrogen receptor (ER) positive and, while the majority of these patients initially respond to hormone therapy, approximately 20-30% will become therapy refractory. Recent data suggest activating-mutations in the estrogen receptor gene (ESR1) ligand binding domain (LBD), which are acquired during anti-estrogen treatment and rarely found in primary untreated ER+ breast cancer, are associated with resistance. Some researchers propose that ESR1 mutations are a prognostic and predictive marker, but more studies are needed to assess the clinical utility of the ESR1 mutations. However, current ESR1 mutation detection methods, that is, next generation sequencing and digital PCR, are very labor-intensive, lengthy, and expensive and require special training.

To aid research on the diagnostic potential of ESR1 mutations, we developed a prototype allele-specific qPCR assay for the detection of 18 recurrent mutations in the ESR1 LBD. The test is suitable for DNA obtained from FFPE tissue as well cfDNA from plasma. It is sensitive, yet simple, robust and results can be obtained in less than 8 hours. Herein, we demonstrate the analytical performance of our ESR1 mutation detection assay using contrived samples. We are also planning to test clinical FFPE and plasma samples in the future.
Body: Background Circulating tumour cells (CTC) may be a good biomarker to guide the management of patients with LAMBC (Cristofanilli, NEJM 2004). Detection of CTCs in peripheral blood is a simple procedure. Eribulin monotherapy has shown improved survival in patients with LAMBC that has progressed after 2 or 3 chemotherapy regimens (EMBRACE study). The aims of this study were to evaluate the kinetics of CTCs before and after eribulin treatment, and its correlation with clinical outcomes.

Methods Patients received eribulin (1.23 mg/m² on days 1 and 8 of every 21-day cycle) as third-line therapy until progression, unacceptable toxicity or withdrawal. CTCs were measured in 7.5ml of blood at baseline and after the second cycle of treatment. Cell counting was performed using the CellSearch System, Veridex. Cox proportional hazards regression modeling was used to identify independent prognostic factors for survival endpoints.

Results Out of 59 eligible women (mean age 57.7 years), 58 (98.3%) had received previous taxanes and/or anthracyclines. Nearly all (98.3%) had HER2-negative tumors, 72% were positive for estrogens, 21% were triple-negative; 64.4% had liver metastasis and 57.6% bone metastasis. The mean number of administered cycles was 6.9 ± 5.4. Follow-up was performed in 54 patients, with 18.5% (n=10) partial response, 42.6% (n=23) stable disease, and 38.9% (n=21) progressive disease. Clinical benefit was achieved in 33 patients (61.1%). Median progression-free survival (PFS) was 5.13 months (95% CI 3.23, 8.90) and median overall survival (OS) was 13.6 months (95% CI 11.8, not reached). CTC levels were measured in 50 patients. The mean number of CTCs at baseline was 16.8 (IQR 0-21) and on cycle 2, 5.4 (IQR 0-8.5), p<0.001. In patients with CTC ≥ 5 at baseline, 52.4% reduced their levels to CTC < 5 on cycle 2 (p=0.043). No significant differences (p=0.066) were found in PFS when baseline CTC levels were < 5 or ≥ 5 cells/ml. Statistical differences were, however, found in OS (p= 0.0083). On cycle 2, significant differences were observed for both PFS (p=0.045) and OS (p=0.0129) with CTC levels <5 or ≥ 5 cells/ml. No correlation could be found between CTC levels and the objective response at baseline or on cycle 2.

Conclusions Our study suggests there is a significant correlation between levels of CTCs and disease prognosis. Eribulin monotherapy was related to a significant reduction in CTCs.

Keywords eribulin, metastatic, breast cancer, circulating tumour cells.
Body: Introduction
Hedgehog pathway dysregulation is observed in different types of cancers including breast. In the present study, expression profiles of hedgehog pathway molecules in breast cancer cohort of Pakistan and their probable association with molecular sub-types were explored.

Methods
The study was preceded with ethical approval and informed consent from respective institutions and participants. During 2013-2015, a total of 150 cancer biopsies along with adjacent normal tissues were prospectively collected immediately after surgery and processed for RNA isolation. Transcriptional profiles of salient members including SHH, DHH, IHH, PTCH-1, SMO and GLI-1 were quantified using qRT-PCR. Cohort was categorized into molecular sub-types following St. Gallen International Expert Consensus System. Association of expression levels of these aforementioned molecules with various clinico-pathological parameters was explored.

Result
Both SHH (p=0.01) and DHH (p<0.001) showed elevated expression among tumors in comparison to their controls. Similarly, PTCH-1 (p<0.001) and GLI-1 (p=0.002) were also significantly up regulated in the cohort. Interestingly, strong positive correlations were observed among the pathway molecules (r-value ranging from 0.45 to 0.81) which highlight their interdependence towards tumor progression. A significant correlation of SHH, DHH, PTCH-1 and GLI-1 was observed with advanced tumor sizes, stages, grades and nodal involvement (p<0.05). Association of IHH, SMO and GLI-1 over expression with cancer metastasis was also established in the cohort. SHH, PTCH-1 and GLI-1 were significantly linked with laterality, age and menopausal status. Expression of SHH (p=0.002) was more related to younger age group (mean age < 45 yrs) patients in comparison to elderly women.
Moreover all hedgehog molecules were strongly related to hormonal receptors (ER and PR) (r-value ranging from 0.51 to 0.86) while over-expression of HER-2 was not associated with any pathway component. Briefly, 53% (79) of the cohort was categorized as Luminal-B, 18% (27) triple negative, 15% (23) Luminal-A and 14% (21) HER-2 for sub-typing of breast cancer patients in the cohort. Expression of SHH was significantly associated with the molecular sub-types (p=0.02) and age (p=0.005) using Pearson Chi-Square test. Elevated expression of SHH was observed in 60% of the patients in Luminal B sub-type.

Conclusion
Hedgehog pathway plays a crucial role in breast cancer progression and is found to be activated in Luminal B sub-type in this cohort. As Luminal B is a more aggressive type of breast cancer having poor prognosis and early-onset, association of SHH with Luminal-B and younger age patients signify it importance as a biomarker for early diagnosis of young patient's. Hence therapeutic interventions for hedgehog pathway can improve the prognosis of patients categorized as Luminal B subtype of breast carcinogenesis.
Title: The ELK3 expression is positively associated with interferon signaling molecules in triple-negative breast cancer

Song IH, Heo S-H, Kim Y-A, Park IA, Park HS, Choi SK, Park SY, Bang WS, Gong G and Lee HJ. University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea and Asan Center for Cancer Genome Discovery, Asan Institute for Life Sciences, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea.

Body: Background
ELK3 is one of the ETS transcription factor family members and functions as either a transcriptional activator or repressor with or without RAS signaling. ELK3 mainly locates in nucleus but can be exported to cytoplasm in the response to stress activated kinases. Previous studies reported that ELK3 show suppressive effect on the VEGF-induced angiogenesis through inhibiting ETS-1, and ELK3 expression is associated with cell migration and invasion in MDA-MB-231 breast cancer cells. However, the mechanism of ELK3 action associated with immune microenvironment is not defined. In this study, we evaluated the nuclear and cytoplasmic expression of ELK in breast cancer cells and investigated its relationship to subtypes of breast cancer and expression of immune-associated molecules.

Methods
We evaluated the nuclear and cytoplasmic expression of ELK3 by immunohistochemistry and the level of stromal tumor infiltrating lymphocytes (TILs) in hematoxyline and eosin sections of the 224 consecutive breast cancer cohort and the 581 primary triple negative breast cancer (TNBC) cohort. The expression of ELK3 was analyzed in each breast cancer subtype in the consecutive breast cancer cohort. The expressions of immune-associated molecules, including human leukocyte antigen (HLA)-ABC, MxA and protein kinase RNA-activated (PKR), were also evaluated by immunohistochemistry in TNBC cohort. The relationships between expression of ELK3 and immune-associated molecules were analyzed.

Results
The high nuclear expression of ELK3 was more frequently observed in hormone receptor (HR)+/human epidermal growth factor receptor (HER2)- and TNBC subtypes than HR-/HER2+ subtype in consecutive breast cancer cohort (p = 0.010 and 0.002, respectively); 38.4% (48/125) of HR+/HER2- breast cancer, 29.4% (5/17) of HR+/HER2+ breast cancer, 9.5% (2/21) of HR-/HER2+ breast cancer, and 47.5% (29/61) of TNBC (p = 0.017). In contrast, the cytoplasmic positivity for ELK3 was less frequently observed in TNBC subtype than HR+/HER2+ subtype (p = 0.008); 13.6% (17/125) of HR+/HER2- breast cancer, 35.3% (6/17) of HR+/HER2+ breast cancer, 28.6% (6/21) of HR-/HER2+ breast cancer, and 6.6% (4/61) in TNBC.

In TNBC cohort, nuclear and cytoplasmic positivity rate of ELK3 were 9.3% (54/581) and 6.0% (35/546), respectively. High nuclear expression of ELK3 was significantly correlated with higher histologic grade of tumor (p = 0.025) and higher expression of HLA-ABC (p = 0.001), MxA (p < 0.001), and PKR (p = 0.001). In contrast, the cytoplasmic positivity for ELK3 was significantly associated with lower expression of HLA-ABC (p = 0.031) and MX1 (p = 0.040), and lower level of TILs (p = 0.004).

Conclusion
The nuclear and cytoplasmic expression of ELK3 is various in each subtype of breast cancer and associated with immune-associated molecules and lymphoid infiltration in TNBC.
miR-19b-3p and miR-4687-5p as novel circulating miRNAs as potential prognostic biomarkers in breast cancer

Tiryakioglu NO Ozan, Cabioglu N, Coskunpinar E, Tukenmez M, Ozturk D, Ozkurt E, Igci A, Pence S and Muslumanoglu M. Institute of Experimental Medicine, Istanbul, Turkey; Istanbul University Istanbul Faculty of Medicine, Istanbul, Turkey and Faculty of Medicine, Istanbul University, Istanbul, Turkey.

Body: Background
Circulating microRNAs (miRNAs) as regulators of gene expression have recently been promising suitable potential biomarkers due to their stability and ease of detection in blood. In this study, we aimed to determine the plasma expression levels of 372 different miRNAs in patients with invasive ductal breast cancer (IDC).

Methods
The expression levels of 372 circulating miRNAs in plasma samples of 20 patients with operable stage I-III IDC and 10 healthy controls were determined using RT-PCR arrays. Mean ages of patients and healthy controls were 45.9+/-8.8 and 45.4+/- 5 respectively. Of 20 breast tumors, 12 were luminal breast cancer, whereas 8 were non-luminal as pure HER2-neu or triple negative breast cancer. RNA was isolated using miRNeasy Serum/Plasma Kit (Qiagen, Hilden, Germany, Cat. No: 217004). cDNA synthesis was performed according to manufacturer’s instructions with miScript II RT Kit (Qiagen, Hilden, Germany, Cat. No: 218161). Serum/Plasma 384 HC PCR arrays with miScript SYBR Green PCR Kit (Qiagen, Hilden, Germany, Cat. No: 218076) were used RT-PCR analysis. These assays included 372 miRNAs in addition to housekeeping genes and reaction controls. All reactions were performed in triplicates. Ct values were analyzed via an online software developed by Sabiosciences. P values were calculated using Student’s t-test and p values lower than 0.05 were considered significant.

Results
Among 372 miRNAs, 19 were found to be deregulated in plasma samples of patients with IDC. 8 miRNAs were upregulated, and the other 11 were downregulated.

Table 1

miR-19b-3p was the most upregulated miRNA with a fold change of 3.759 (95%CI:1.83- 5.68, p=.048) while miR-4687-5p was the most downregulated with a fold change of 0.216 (95%CI:0.00001-0.43, p=.005).

Conclusion
Our findings indicate that these 19 deregulated circulating miRNAs might be promising biomarker candidates for detection of IDC. The two most deregulated miRNAs were miR-19b-3p and miR-4687-5p. miR19b-3p belongs to a cluster of miRNAs which has been shown to function as oncogenes resulting in the downregulation of tissue factor expression in breast cancer cells. Further
validation studies are ongoing in order to determine their clinicopathological prognostic value in breast cancer.
Title: Prostate-specific membrane antigen (PSMA) expression in breast cancer and its metastases

von Heesen A, Kasoha M, Solomayer E-F, Unger C, Bohle R, Zaharia C, Ezziddin S and Juhasz I. University of Saarland, Homburg, Saarland, Germany; Institute for General and Special Pathology, University of Saarland, Homburg, Saarland, Germany and University of Saarland, Homburg, Saarland, Germany.

Body: Background:
Prostate-specific membrane antigen (PSMA) is a type II transmembrane glycoprotein with folate hydrolase and neurocarboxypeptidase activity. PSMA has been shown to be consistently expressed in prostatic carcinoma as well as benign prostatic tissue. In addition, PSMA is selectively expressed in the neovascularization of multiple non-prostatic solid tumours including breast cancers. Inducible PSMA specific expression on angiogenic vasculator suggests that PSMA participates in neovessel growth in developing tumours. Treatment of solid tumours with anti-angiogenic agents has become an established paradigm in cancer therapy. Our study aims at detecting protein expression level of PSMA in breast cancer patients with or without metastases both in the primary tumour and metastases tissues.

Materials and methods:
79 patients with histologically proven breast cancer at the department of Gynecology and Obstetrics at the University of Saarland (Germany) were included. 37 patients showed no sign of lymph node or distant metastases (N0M0). 18 patients showed lymph node metastases (N1M0) and 24 patients were diagnosed with distant metastases occurring on different sites (n=5 liver, n=3 lung, n=5 bone, n=7 brain) (M1). Representative formalin-fixed paraffin-embedded tumour blocks from these specimen were obtained from the department of pathology of University of Saarland. Immunohistochemical staining for PSMA and CD31 was performed on parallel representative tumour sections in each case.

Results:
An immunohistochemical PSMA expression could be detected in tumour cells and in the neovascularization of breast cancer in 36 patients, 16% (n=25) of these patients with primary breast cancer and 45% (n=11) with metastatic disease. The expression is higher in patients with lymph node metastases (40%) and even higher in patients with distant metastases (45%). The distant metastases themselves showed the highest expression of PSMA (67%) compared to the PSMA expression of lymph nodes (30%) or the primary tumor (45%) in patients with metastatic disease. Besides these results we could show that the PSMA expression significantly depends on the tumor stage of the primary tumor. Patients suffering of early stage breast cancer (T1=12%) showed significantly less PSMA expression than patients with T2 primary tumor (29%) (p=0,008). The PSMA expression in T3 and T4 staged primary breast cancer was elevated up to 75%.

Conclusion:
This data suggests that PSMA might be involved in the pathogenicity of breast cancer and its metastasis. In addition, PSMA may be an ideal target for diagnostic purposes as well as targeted therapies against metastatic breast cancer.
Title: ST8SIA1 is over-expressed in triple negative breast cancer and associated with p53 mutations

Yan Y, Nguyen K, Do K-A, Ueno N, Andreeff M and Battula VL. The University of Texas MD Anderson Cancer Center, Houston, TX.

Body: Cancer stem cells constitute a small fraction of cells present in primary tumors, are highly tumorigenic, drug resistant and cause metastases. We discovered Ganglioside GD2 as a breast cancer stem cell (BCSCs) marker in triple negative breast cancer (TNBC). GD2 biosynthesis is tightly regulated by the enzyme ST8SIA1 (GD3 synthase). However, expression of ST8SIA and its association with different breast cancer sub-types is not known. Here we hypothesize that ST8SIA1 is up-regulated in TNBC or basal-type breast tumors and associated with stemness in primary breast tumors. First, we examined ST8SIA1 protein expression in breast cancer cell lines (n=12) and found up-regulation of ST8SIA1 in basal compared to luminal-type breast cancer cells. To investigate ST8SIA1’s expression in primary tumors, we analyzed RNAseq data from the cancer genome atlas (TCGA) data base which has expression data from 1105 primary and metastatic breast tumors as well as adjacent normal tissues. We found that ST8SIA1 expression varies widely among different breast tumors and that 'basal' type tumors express highest levels of ST8SIA1 compared to all other types of breast cancers including luminal-A or luminal-B or HER2 enriched (p<0.01) tumors. In addition, triple negative breast cancer (TNBC, n=115) express 4.63fold higher ST8SIA1 levels compared to hormone receptors positive tumors including ER+ or PR+ or HER2+ tumors (n=852, p<0.001). Survival analysis by log-rank test indicates that patients with ST8SIA1high tumors survive shorter (median survival 2.6 years) compared to patients with ST8SIA1low tumors (median survival 4.3 years). These data suggests that ST8SIA1 expression is associated with basal-like TNBC tumor types and high ST8SIA1 levels in tumors may shorten survival in TNBC patients.

To investigate the association between ST8SIA1 expression and the most commonly mutated genes in breast cancer, we chose the top 20 most frequently mutated genes in TCGA dataset and examined their correlation with ST8SIA1 mRNA expression. We found that, among the top 20 mutations, p53 has a very strong positive correlation with ST8SIA1 expression (p<0.00001). The expression of ST8SIA1 is >2 fold higher in p53 mutated tumors compared to p53 wild type tumors. The other positively correlated mutation was a nuclear envelop protein called Spectrin Repeat Containing, Nuclear Envelope 1 (SYNE1; p<0.05). Mutations in GATA3 are the most negatively correlated (p<0.001) with ST8SIA1 expression. Interestingly, GATA3 plays a role in epithelial cell differentiation in the mammary gland, supporting the notion that ST8SIA1 is a stem cell-associated gene. In addition, correlation of ST8SIA1 mRNA expression with other genes revealed that FOXA1, the protein which is co-expressed with GATA3 and serves as negative predictor of basal type of breast cancer, is down regulated in ST8SIA1high tumors. In conclusion, ST8SIA1 is associated with basal-type TNBC tumors and has a strong positive correlation with p53 mutations and negative correlation with GATA3 mutations. Knowing that TP53 mutations have a major role in tumorigenesis and drug resistance, these data suggest ST8SIA1 as a potential therapeutic target in TNBC patients with p53 mutations.
Title: Characterization of neuroendocrine breast carcinomas for biomarkers of therapeutic options

Gatalica Z, Feldman R, Ghazalpour A and Vranic S. Caris Life Sciences, Phoenix, AZ; University of Sarajevo Clinical Center, Sarajevo, Bosnia and Herzegowina and University of Sarajevo School of Medicine, Sarajevo, Bosnia and Herzegowina.

Body: Introduction: Neuroendocrine breast carcinoma (NBC) is an extremely rare type of cancer, constituting less than 0.1% of all breast tumors, without specific treatment options. We investigated a biomarker database for frequency of molecular markers that may guide personalized treatment choices for these patients.

Materials and Methods: Molecular profiles of 40 breast carcinomas with neuroendocrine features [ER/PR+ (n=20), HER2+ (n=1) and TNBC (n=14)] were assessed (all female patients, mean age: 60.3 years, range: 39-83 years). Gene expression (Illumina DASL microarray platform), protein expression (IHC), gene amplification (ISH) and next-generation sequencing (NGS; TruSeq Illumina platform) were performed.

Results: 57% of NBCs were positive for hormone receptors (ER/PR), 40% were triple negative TNBC and 3% HER2+ subtypes. Therapeutic biomarkers (IHC) that may guide chemotherapies (and used in other primary sites neuroendocrine tumors) included: high TOP2A (85%) for etoposide or doxorubicin, low TS (57%) for 5-fluorouracil and low ERCC1 (45%) for cisplatin. Additional biomarkers for chemotherapy included: high TOPO1 (60%) for irinotecan, low RRM1 (48%) for gemcitabine and low MGMT (57%) for temozolomide. Biomarkers associated with available targeted therapies included: PTEN loss (39%), positive ALK (33%), cKit (30%), EGFR (29%), AR (26%) and PDGFRA (17%). No gene amplifications were detected in cMET, EGFR, or TOP2A. Targeted sequencing analysis of 47 genes detected variants in TP53, PIK3CA, ERBB4 and APC genes. Gene expression data (included somatostatin receptor gene family- SSTR1/2/3/4/5) was available for 5 patients, for which 3/5 patients exhibited overexpression of at least one SSTR gene.

Conclusions: Molecular profiling by a multiplatform approach reveals potential personalized therapy options for this very rare breast cancer subtype. With recent success of somatostatin analogs for other neuroendocrine tumors, the overexpression of SSTR gene family in NBC is worthy of further investigation.
Title: The 21-gene assay in the decision impact assessment of ER+, HER2- Breast cancer: A French real life prospective study

Gligorov J, Dohollou N, Mouysset JL, Laplaige P, Fignon A, Lafuma A and Michaud P. AP-HP Hôpital Tenon, Paris, France; Clinique de Bordeaux Nord, Bordeaux, France; Clinique Rambot-Provençale, Aix en Provence, France; Polyclinique de Blois, La Chaussée St Victor, France; Clinique de l'Alliance, Sant Cyr sur Loire, France; Cemka-Eval, Bourg la Reine, France and Clinique de l'Archette, Olivet, France.

Body: BACKGROUND: Tumour gene expression analysis is useful in predicting adjuvant chemotherapy benefit in breast cancer (BC). The 21-gene assay test is used to estimate the risk of recurrence and to predict the benefit of adjuvant chemotherapy (ACT) at an early stage of hormone-receptor-positive (ER+) BC. This study aims to examine the implications of RecurrenceScore (RS) testing within the routine clinical practices in France.

METHODS: We conducted a prospective multicenter study, with voluntary participation, involving women with ER+, HER2-, BC. Performing the assay was left at the discretion of the physicians. The final treatment decision was discussed pre and post assay among tumor board (TB). The therapeutic changes after knowledge of RS were collected. RS and classical BC prognostic markers were investigated in parallel including an estimate of the budget impact of the assay.

RESULTS: 603 patients were included in this analysis (tumor size ≤ 20 mm: 70.6%; node-negative patients: 61.2%; SBR 2: 74.9%). After the first TB, ACT was recommended for 529 patients (88.0%) and hormonotherapy (HT) alone for 74 patients (12.0%). The RS was low for 59.7% of the cases, intermediate for 34.0% and high for 6.3%. Based on RS results, second TB changed treatment decision for 70.48% of patients, avoiding CT in 64% of cases. Only 24% received ACT while 76% received HT alone. The calculated budget impact as a minimal estimate according to the French healthcare payer perspective is estimated at a savings of € 570 per patient, corresponding to a global cost-saving of € 221,730.

CONCLUSION: The results of this “real life” study confirm that the 21-gene assay had a significant impact on therapeutic decision. These findings warrant further consideration for the use of this genomic assay in patients with early stage BC in France.
Title: Heterogeneity of PD-L1 expression in primary tumors and paired lymph node metastases of triple negative breast cancer

Li M, Li A, Zhou S, Xu Y, Xiao Y, Bi R and Yang W.  Fudan University Shanghai Cancer Centre, Shanghai, China and Fudan University, Shanghai, China.

Body: **Background:** Programmed cell death ligand 1 (PD-L1) is a potential predictive biomarker of the response to anti-PD-L1/anti-PD-1 therapy in multiple cancers, including triple negative breast cancer. The purpose of this study was to investigate whether PD-L1 expression is homogenous in primary tumors and synchronous axillary lymph node metastases of triple negative breast cancer.

**Patients and Methods:** PD-L1 expression was immunohistochemically evaluated in 61 triple negative breast cancer patients' primary tumors and paired lymph node metastases. PD-L1 expression in tumor cells and infiltrating immune cells in the primary tumors and associated lymph node metastases was scored separately and was correlated with patients' clinical parameters and prognoses.

**Results:** PD-L1 expression exhibited spatial heterogeneity in both the infiltrating lymphocytes and tumor cells of primary tumors and lymph node metastases. The PD-L1 expression levels were significantly higher in the infiltrating lymphocytes and tumor cells of the lymph node metastases than in those of the primary tumors. In addition, its expression was more frequent among the lymph node metastases ($p=0.045$). Furthermore, the disease-free survival and overall survival were similar between the primary tumor negative/lymph node metastasis positive and primary tumor positive/lymph node metastasis positive patients, both of which exhibited worse disease-free survival than primary tumor negative/lymph node metastasis negative patients.

**Conclusions:** The different expression of PD-L1 between the primary tumors and lymph node metastases suggest that the lymph node metastasis PD-L1 status may be used to indicate whether a node-positive triple negative breast cancer patient is suitable for PD-1/PD-L1-targeted therapy in the future.
Breast cancer characterized by human epidermal growth factor receptor 2 (HER2) overexpression represents approximately 25-30% of all breast cancer cases. Many patients acquire resistance to current chemotherapies, leading to a more aggressive disease state with severe clinical outcomes. Lapatinib, a first generation tyrosine kinase inhibitor of HER2 and EGFR (epidermal growth factor receptor), is commonly used to treat HER2+ breast cancer. Resistance to lapatinib is steadily increasing among HER2+ patients, highlighting the need for therapy development. Identifying markers that predict treatment response or potential drug targets could enhance treatment efficacy and patient survival. To investigate this, we have used MALDI mass spectrometry to identify N-linked glycans specific to human breast cancer cell lines with known resistance and sensitivity to lapatinib treatment, JIMT-1 (resistant) HER2+ and BT474 (sensitive) HER2+. After different lapatinib dose and time course experiments, N-linked glycans were isolated and comparatively profiled by high resolution MALDI mass spectrometry. Differences in the levels of fucosylation and sialylation of glycans from sensitive and resistant cell lines, before and after treatment, were evaluated. In addition, mouse xenograft tumor tissues derived from the same cell lines treated with and without lapatinib were processed for on-tissue imaging of N-glycans using a MALDI imaging mass spectrometry approach. Tissues from HER2+ human breast tumors were also imaged with the same MALDI imaging approach. Cumulatively, these preliminary studies have identified novel glycosylation patterns associated with lapatinib treatment sensitivity and resistance.
Title: Molecular mechanism of alcohol-associated breast cancer

Zhong S, Zhang Y, Lei J, Li W, Wu Z and Shi G. Zhongshan School of Medicine, Sun Yat-sen University, Guangzhou, Guangdong, China; University Shantou University Medical College, Shantou, Guangdong, China and Keck School of Medicine, University of Southern California, Alhambra, CA.

Body: Epidemiological studies have indicated that alcohol consumption is an established risk factor for breast cancer. The association of alcohol consumption and breast cancer is more pronounced in ER+ cases than in ER- cases. However, this molecular mechanism remains to be determined. Deregulation of RNA polymerase III (Pol III) transcription enhances cellular tRNAs and 5S rRNA production, increasing translational capacity to promote cell transformation and tumor formation. Our results reveal that alcohol increases Pol III gene transcription in both normal and cancer breast cell lines. The induction of Pol III genes by alcohol in ER+ breast cancer cells is significantly higher than in ER- normal breast cells and ER- breast cancer cells. E2 causes slight increase in Pol III gene transcription. The addition of ethanol to this system produces a marked increase. Alcohol increases ERα expression to enhance the cellular levels of Brf1 protein and mRNA. In addition, ethanol markedly stimulates phosphorylation of JNK1. Inhibition of JNK1 decreases ERE-Luc reporter activity and represses expression of ERα, Brf1 and Pol III genes. Reduction of ERα by its siRNA represses Brf1 and Pol III gene transcription. Ethanol with E2 produces larger and more numerous colonies. Repression of ERα or Brf1 inhibits alcohol-induced cell transformation. More interestingly, human biopsies studies show that Brf1 expression is significantly increased in nuclei of breast cancer cells, compared to tissue adjacent to the carcinoma. Together, these results support the idea that alcohol increases ERα expression through JNK1 pathway to elevate Brf1 expression and Pol III gene transcription, leading to greater phenotypic changes. ERα mediates Pol III gene transcription through Brf1, suggesting that ERα play a critical role in alcohol-induced deregulation of Pol III genes in ER+ breast cancer development.

*: The project is supported by NIAAA/NIH grants: AA017288, AA021114 and AA02324 to S Zhong.
**Title:** Vitamin D as a potential biomarker of aggressiveness in non-metastatic breast cancer

**Body:**

**Background:** Vitamin D (VD) is known to play a proapoptotic and antiproliferative role in cancer cells. Recent studies have shown that low serum VD may be associated with worse prognosis in cancer patients (pts). However, levels of VD are not routinely measured in daily clinical practice.

**Methods:** We retrospectively evaluated pts diagnosed with non-metastatic breast cancer between January 2010 and November 2015. Serum 25(OH)-VD and bone density were measured any time after surgery, during either adjuvant treatment or the follow-up. VD insufficiency (VDi) and deficiency (VDd) were defined as serum VD levels of 20-30 ng/ml and <20 ng/ml, respectively. Possible association between VD levels and baseline characteristics as AJCC stage, immunohistochemistry (IHC) subtype, ki67 and differentiation grade were studied. Correlation between synchronous densitometry and VD levels was also evaluated.

**Results:** 98 pts that met the above described criteria were included in the analysis. Median (M) VD was 20.68 (range, 3 – 65.60). 72.4 % of pts had VD under 30 ng/ml (23.4% had VD insufficiency and 49% had deficiency). AJCC stages II-III were more frequent in patients with low VD levels (Normal: 48%; VDi: 52%; VDd: 65%). VD levels were similar across IHC subtypes (Normal VD levels: Luminal A: 51%; Luminal B: 30%; Triple Negative: 14%; VDi: LA: 52%; LB: 35%; TN: 13%; VDd: LA: 39%; LB: 48%; TN: 13%). Undifferentiated tumors were more frequent among pts with VD levels <30ng/ml (Normal: 27%; VDi: 45%; VDd: 45%). Elevated Ki67 was more commonly found in pts with lower VD (Normal: 40%; VDi: 40%; VDd: 61%). Our results did not show correlation between densitometry and VD levels.

**Conclusions:** Lower levels of 25(OH)-Vitamin D may be associated with more advanced and aggressive non-metastatic breast cancer. 25(OH)-VD should be evaluated at diagnosis. Although it may be a promising biomarker, further research in this field is required.
Title: Metrics of drug sensitivity based on growth rate inhibition correct for the confounding effects of variable division rates

Hafner M, Niepel M and Sorger PK K. Harvard Medical School, Boston, MA.

Body: Drug sensitivity and resistance are conventionally quantified by $IC_{50}$ or $E_{\text{max}}$ values, but these metrics suffer from a fundamental flaw when applied to growing cells: they are highly sensitive to the number of divisions that take place over the course of a response assay. Division rate varies with cell line, experimental conditions, and genetic alterations. The dependency of $IC_{50}$ and $E_{\text{max}}$ on division rate creates artefactual correlations between genotype and drug sensitivity while obscuring important biological insights and interfering with biomarker discovery. In this work, we derive alternative drug response metrics that are insensitive to number of divisions occurring during the assay. These are based on estimating growth rate inhibition (GR) in the presence of a drug using endpoint or time-course assays. The latter provides a direct measure of phenomena such as adaptive drug resistance.

Using a simple model of drug response, we first show how $GR_{50}$ and $GR_{\text{max}}$ are superior to $IC_{50}$ and $E_{\text{max}}$ for assessing the effects of drugs in dividing cells. By expressing an oncogene in a transformed cell line, we illustrate how conventional metrics can lead to artefactual connections between mutations and drug sensitivity. We further validate the superiority of $GR_{50}$ over $IC_{50}$ values by reanalyzing a recently published large dataset of drug sensitivity and showing cases where difference in division rates is the only reason why $IC_{50}$ values correlate with tissue type or genetic alterations. Using $GR_{50}$ values prevents these artificial correlations and restores known connections between drug resistance and genomic markers. Finally, we show how $GR_{\text{max}}$ values, which reflect efficacy, quantify differences in the phenotypic response and thus can be used to identify new biomarkers of sensitivity.

Adopting GR metrics requires only modest changes in experimental protocols. GR values and metrics can be evaluated using scripts are available on github (www.github.com/sorgerlab/gr50_tools) or using an interactive website: www.grcalculator.org. We expect GR metrics to improve the use of drugs to identify response biomarkers, study mechanisms of cell signaling and growth, and identify drugs effective on specific patient-derived tumor cells.
Title: The prognostic impact of inositol polyphosphate 5-phosphatase PIPP (INPP5J) expression in breast cancer tissue

Body: Background: Inositol polyphosphate 5-phosphatase PIPP (INPP5J) has been identified as a suppressor of oncogenic PI3K/Akt signaling in breast cancer. INPP5J depletion increases transformation and accelerates oncogene-driven tumor growth in vivo, while paradoxically reducing cell migration, invasion, and metastasis. Therefore, we hypothesized that INPP5J gene expression in human breast cancer tissues would be prognostic in early breast cancer patients over long-term follow-up.

Methods: A total of 478 breast cancer tissue samples collected between 2003 and 2008 was available for analysis. We measured INPP5J mRNA using a TaqMan gene expression assay. PIK3CA mutation status was evaluated using a TaqMan mutation detection assay. We then investigated the correlations of clinicopathological factors and prognosis with levels of INPP5J mRNA and the PIK3CA mutation status.

Results: INPP5J mRNA was expressed at a low level in 30.1% (144/478) and at a medium to high level in the remaining breast cancer samples. Low INPP5J mRNA correlated with larger tumor (p=0.015), high grade (p<0.0001) and, ER-negativity (p<0.0001). PIK3CA mutations were detected in 46% (63/138) of patients analyzed. We found that disease-free survival (DFS) was significantly worse in patients with low levels of INPP5J (p=0.008). Although DFS and INPP5J levels tended to be associated in estrogen receptor (ER)-positive patients (p=0.052), DFS was significantly worse in patients with wild-type PIK3CA and low INPP5J mRNA expression (p=0.008).

Conclusion: We shows that the level of INPP5J mRNA expression is prognostics in breast cancer patients and that its prognostic impact is affected by PIK3CA mutation status.
A directed siRNA screen identifies INHBA as a major regulator of tumor aggressiveness in basal HER2 breast cancer

Korkola JE E, Liu M, Smith R, Liby T, Heiser L and Gray JW W.  Oregon Health & Science University, Portland, OR.

HER2+ breast cancers can be treated with several HER2-targeted inhibitors, but tumors often acquire or have de novo resistance to the therapies, limiting the long term efficacy of these treatments. To identify genes associated with resistance, we performed drug screens on a panel of HER2 positive breast cancer cell lines using lapatinib, then performed statistical analyses to identify differentially expressed genes. We procured siRNA against the top 20 targets expressed in the resistant subset for subsequent viability screening, both in the presence and absence of lapatinib. This screen identified INHBA, a member of the TGF-B superfamily, as a strong mediator of cell growth and lapatinib response in two resistant HER2+ cell lines. Both these lines were of the basal subtype, which tend to be more resistant in our cell line panel. We tested 8 different HER2+ breast cancer cell lines (4 basal and 4 luminal subtype) with siRNA against INHBA. We observed significant inhibition of growth in 3 out of 4 basal lines, with growth rates of 40-55% of scramble control lines. In contrast, none of the luminal lines showed significant growth inhibition when treated with the INHBA siRNA. Furthermore, treatment with INHBA siRNA sensitized cells to lapatinib, with GI50 (dose required to inhibit growth by 50%) dropping from 10uM to less than 2 uM in JIMT1 and 21-MT1 basal lines. We also tested the effects of knockdown in 3-d matrigel cultures, which recapitulated the 2-d findings with decreased growth and increased sensitivity. For the cell line 21-MT1, growth following INHBA siRNA treatment was 12.6% of scramble control, and lapatinib treatment further reduced this to 7.8%, in contrast to scramble control/lapatinib treated cells, which grew at 97.7% of control rate. We performed RNAseq on 21-MT1 and JIMT1 cells treated with siRNA and looked at both relative changes in expression as well as absolute magnitude changes in expression. There were a large number of mitochondrial genes induced in the INHBA siRNA knockdown cells and loss of glycolytic genes such as LDHA compared to scramble control cells, suggesting a change in metabolic activity. We tested this by treating cells with the oxidative phosphorylation inhibitor oligomycin or the glycolysis inhibitor 2-deoxyglucose (2-DG). We found that JIMT1 cells treated with INHBA siRNA were more sensitive to oligomycin but less sensitive to 2-DG compared to scramble treated controls, suggesting a shift from glycolytic to oxidative phosphorylation metabolism. Since this type of metabolic shift has also been associated with reduced invasive capacity, we performed invasion assays on cells treated with INHBA or scramble-control siRNA. We found that knockdown of INHBA reduced invasion of both 21-MT1 and JIMT1 cells, with invasion rates less than 10% of control cells. Finally, we mined expression data sets to determine associations between INHBA levels and outcome, and found that high levels of expression of INHBA were associated with poor outcome in both HER2+ and the basal subtype of breast tumors, but not in luminal tumors. In conclusion, we identified INHBA as a major regulator of metabolism and aggressiveness in HER2+ basal breast cancer cells that is associated with poor outcome in patients.
Title: Disruption of the estradiol-regulated NTN1-UNC5A dependence receptor signaling axis causes a hybrid basal/luminal molecular phenotype in estrogen receptor-positive breast cancer cells

Padua MB B, Bhat-Nakshatri P, Anjanappa M, Hao Y, Liu Y, McElyea K, Sandusky G, Althouse S, Perkins S and Nakshatri H. School of Medicine, Indiana University, Indianapolis, IN; School of Medicine, Indiana University, Indianapolis, IN; School of Medicine, Indiana University, Indianapolis, IN and School of Medicine, Indiana University, Indianapolis, IN.

Body: Luminal subtype of breast cancers that express the estrogen receptor alpha (ERα) represents approximately two-thirds of all breast cancer cases. ER+ tumors tend to have the most favorable prognoses when treated with endocrine therapy. However, a relapse or endocrine therapy resistance is often seen in ER+ breast tumors. UNC5A belongs to the dependence receptor family which can mediate two different intracellular signals: cell survival, differentiation or migration when engaged with its ligand (such as Netrin-1; NTN1) or cell death/apoptosis in the absence of the ligand. Here we demonstrate that, depending upon the cell type, UNC5A and NTN1 are estradiol (E2)-inducible genes. Using shRNA or CRISPR knockdown strategies, we show that the disruption of the NTN1-UNC5A signaling axis in ER+ (MCF7 and T-47D) cells generates a mixed basal-like/luminal phenotype with stem cell-like characteristics. RNA-seq of UNC5A knockdown cells showed deregulated expression of several E2-target genes in both cell lines. Moreover, knockdown of UNC5A resulted in increased cell proliferation, and elevated expression of the E2-inducible anti-apoptotic, BCL2. Furthermore, the expression of ΔNp63 was enhanced in UNC5A knockdown cells. ΔNp63 is a TP53 family transcription factor that promotes breast epithelial stem cell maintenance and basal-like breast cancer. Accordingly, UNC5A knockdown cells displayed cancer stem cell phenotype as evident from ~3-fold increase in the number of CD44+/CD24−, CD44+/EPCAM+ and ITGA6+/EPCAM+ subpopulation compared with control cells. In addition, the expression of NTN4, a pro-angiogenic and lymphangiogenic factor, was increased upon UNC5A knockdown. In vivo, UNC5A knockdown cells implanted in nude mice were able to form tumors in the mammary fat pad independent of E2 supplementation and were able to colonize and develop into overt metastasis in multiple organs such as lungs, ovaries and adrenal glands. Consequently, analysis of mammary fat pad tumors from animals that received UNC5A knockdown cells revealed an increased expression of PECAM1 (CD31), a marker for endothelial cells used to evaluate tumor angiogenesis. In contrast to UNC5A, knocking down NTN1, decreased the expression of BCL2 and TP63 in both cell lines. Thus, knockdown of UNC5A resulted in deregulated expression of E2-regulated genes, E2-independent and anti-estrogen-resistant growth in vitro, and E2-independent tumor formation in xenograft models. Consistent with results of in vitro studies, analysis of tissue samples from breast cancer patients (n=196) revealed that lower expression of UNC5A is associated with lower overall survival (P < 0.05). Thus, loss or mutational inactivation of UNC5A could lead to unrestricted E2:ERα signaling and anti-estrogen resistant growth while simultaneously enabling ERα-positive luminal breast cancer cells to acquire basal-like and cancer stem cell-like features.
Title: Dynamics of cancer stem cell surface marker, CD44 and CD44v6 in the antitumor efficacy of PARP inhibitor in combination with PI3K pathway inhibitor in TNBC xenograft model

Body: Introduction: Triple Negative (TN) BC has a limited benefit from conventional therapy and a few options for targeted therapy like PARP inhibitor. We reported that doubling down on the PI3K-mTOR pathway enhances the antitumor efficacy of PARP inhibitor in TNBC (Neoplasia, 2014). Tumor cells with distinctive stem cell (CSC) like properties exist in carcinomas including breast and CD44+CSC marker expression correlates with decreased survival (Fillmore and Kuperwasser, 2008). In TNBC the intratumoral presence of stem cell population is associated with increased aggressiveness. Among many CSC markers, CD44 is best known to have a prognostic role (Collina et al., 2015) and the PI3K/E2F1 pathway has been identified as a potential signaling link to HA/CD44 activation. Hypothesis: We hypothesized that xenografts of TNBC cell lines bearing stem cell property will respond in a characteristic way to GDC0980 in combination with ABT888 plus carboplatin. Methods: Athymic mice bearing BRCA-competent TNBC xenograft tumors were used to test the combination of GDC-0980 with ABT888 plus carboplatin. Mechanism-based in vitro studies were conducted to understand the mode of action of the drugs. IHC for CD44 and CD44v6 was standardized in positive tumor-controls and identified in (1) BC TMAs, (2) TNBC cell lines and (3) patients from our Avera cohort. Finally, the CD44-expression in tumors of different arms of the xenograft study (MDA-MB231 and MDA-MB468) was evaluated independently by a pathologist who was unaware of the study design. Results: CD44 was identified primarily in the membrane and to a lesser extent in the cytosol of tumor cells of BC patients (TMA and Avera cohort), TNBC cell lines and xenograft-tumors. GDC-0980 in combination with ABT888 plus carboplatin blocked the growth of established xenograft tumors by 80-90% with a concomitant decrease in Ki67 IHC-levels. Membrane expression of CD44 inversely correlated to tumor sizes which significantly reduced in response to drug combinations. Mechanistically, GDC-0980 treatment led to DNA damage (increased pgH2AX), gain in PAR and a subsequent sensitization of BRCA-competent TNBC cells to ABT888 plus carboplatin with a time-dependent (1) decrease in proliferation signals (pAKT), PAR/PARP ratios, PAR/pgH2AX ratios, live/dead cell ratios, and clonogenic 3D growth & (2) increase in apoptosis markers (cleaved-caspase3, cleaved-PARP and annexinV positivity). The relationship between expression of CD44 and CD44v6 in the xenograft tumors the following treatment is being worked out which will be presented at the meeting. Significance: Our findings demonstrated that PARP inhibitor plus carboplatin in combination with dual PI3K-mTOR inhibition effectively reduced the CD44+CSC population in TNBC xenograft tumors. In a BRCA-competent model, PI3K-pathway inhibition not only enhanced the antitumor activity of ABT888 plus carboplatin by inhibiting proliferation and tumor-induced angiogenesis but also by decreasing CD44+CSC. We present the first mechanism-based study to demonstrate the integral role of PI3K-mTOR pathway and DDR pathway in the control of CSC surface marker in orchestrating antitumor actions of PARP inhibitor in TNBC.
Title: Preclinical efficacy of dasatinib in combination with PARP inhibitor plus standard cytotoxic agent in triple-negative breast cancer xenograft model

Sun Y, Lin X, Carlson JH H, De P, Dey N, Jepperson T, R & D NCI, Williams C and Leyland-Jones B. Avera Center for Precision Oncology, Sioux Falls, SD and R & D Agreements Regulatory Affairs Branch, CTEP, NCI, Bethesda, MD.

Body: Background: Dasatinib is an orally-active ATP-competitive small molecule kinase inhibitor that potently inhibits Abl kinase, Src family kinases and other kinases (Lombardo et al., 2004). Src, one of the key targets of dasatinib is involved in the regulation of cell proliferation, survival and apoptotic ability of cancer cells (Tryfonopoulos et al., 2011; Pusztai et al., 2014). Dasatinib has shown its anti-proliferative and anti-metastatic effectiveness against triple-negative breast cancer (TNBC) in both preclinical and clinical studies (Finn et al., 2011). Several molecular targets including poly ADP ribose polymerase (PARP) are under clinical investigation for the treatment of TNBC. Recently, PARP inhibitors in combination with chemotherapy have shown promising results in this disease in clinical and preclinical studies (Tutt et al., 2010; Kim et al., 2013; De et al., 2014). Here, we hypothesize that dasatinib in combination with PARP inhibitor (ABT888) plus standard cytotoxic agent (carboplatin) will attenuate the growth of both TNBC cell lines and xenograft tumors.

Methodology: We have used BT-20 (PIK3CA mutated, H1047R), HCC70 (PTEN null), HCC1937 (BRCA1 mutated, PTEN null), MDA-MB-231 (KRAS/BRAF mutated), MDA-MB-468 (PTEN null) and SUM149PT (BRCA1 mutated, PTEN null) cells for in vitro study. Survival/proliferation, colony formation and apoptosis were examined by using 2D proliferative/growth assay, 3D-ON-TOP assays, and annexinV staining respectively. We next studied the activation status of Src and its downstream signaling. We also have evaluated the effects on tumor growth inhibition of dasatinib/ABT888/carboplatin as a single agent or in combination by using mouse xenograft model.

Results: We observed that 1) Dasatinib inhibited Src activation in all tested lines, induced dephosphorylation of ERK1/2 and S6 RP; 2) level of Cyclin D1 was decreased by dasatinib treatment; 3) high anti-proliferative activities were observed following the treatment of dasatinib along with ABT888 plus carboplatin in both 2D proliferation assay and 3D-ON TOP colony formation assay; 4) dasatinib in combination with ABT888 plus carboplatin inducing early stage apoptosis was seen by Annexin V staining in all tested cell lines; 5) dasatinib alone or combined with ABT888 or carboplatin or in triple combination inhibited tumor growth in TNBC xenograft models, the best tumor inhibition result was induced by triple combination (comparing to no treatment control, the mean tumor volume was decreased ~ 87% ).

Conclusion: Our in vitro and in vivo studies suggest that dasatinib may enhance the antitumor activity of PARP inhibitor plus standard cytotoxic agent in TNBC. Mechanistic studies of xenograft tumor samples are ongoing, the results of which will be presented in the meeting.
Title: Genome-wide identification of transcripts regulated by estrogen in MCF-7 cells using BrU-seq

Sun J, Capobianco E, Tsinoremas N and Lippman M. University of Miami, Miami, FL and Institute of Clinical Physiology, Pisa, Italy.

Body: Estrogen promotes estrogen receptor (ER)-positive breast cancer cell growth by modulating transcription through ligand activated ER. The spectrum of early ER target genes has been identified through gene expression microarray and more recently with RNA-seq analyses. These methods, although comprehensive, fall short in identifying many ER-regulated transcripts which are either not present in microarray; too abundant to determine estrogen regulated changes among steady-state pools of RNAs; or have very short half-lives and low abundance such as some non-coding RNAs, including RNAs generated by enhancers bound by ER (eRNAs). Global run-on sequencing (GRO-seq) has been used to identify ER target genes and eRNAs in breast cancer cells. It is technically cumbersome and is performed under non-physiological condition.

We have applied BrU-seq technique to identify global transcripts regulated by estrogen in MCF-7 breast cancer cells. The newly synthesized RNAs in MCF-7 cells treated with or without estrogen for various time points, were labeled with 5'-bromo-uridine (BrU). The labeled RNAs were purified by immunoprecipitation using an anti-BrdU antibody and then subjected to RNA sequencing analysis, which provides greater sensitivity than regular RNA-seq analysis from steady-state total RNA samples. Robust estrogen-regulated transcripts can be detected within 30 min of treatment. Significantly more transcripts (both coding and non-coding RNAs) were identified as estrogen targets using BrU-seq analysis than RNA-seq analysis from total RNA pools. Many of these estrogen-regulated transcripts are located close to ER binding sites identified from ER ChIP-seq analysis, indicating a functional role for these ER binding sites in regulating RNA transcription. For estrogen targets identified through both analyses, the magnitude of expression changes (both up- and down-regulation) is usually greater from BrU-seq than from the regular RNA-seq analysis. The dynamics of RNA synthesis and degradation for some unstable RNAs (such as eRNAs) can be interrogated through our data set. Also, RNA pol II elongation rate can be deduced from some long ER target genes (>100 kb) such as GREB1. In addition to identifying estrogen targets, BrU-seq should be a very useful technique in assessing transcriptional changes triggered by various signal transduction pathways.
**Title:** A positive feedback loop couples CD44s and HAS2 for sustained Akt activation and tumor cell survival

Liu S and Cheng C.  Lester & Sue Smith Breast Center, Baylor College of Medicine, Houston, TX and  Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL.

**Body:** Breast cancer is the second leading cause of cancer death in women worldwide. Despite recent advances in breast cancer treatment, tumor metastasis and recurrence remain the most significant clinical obstacles, largely due to the resistance of residual breast tumor cells to existing therapies. RNA alternative splicing is a fundamental mechanism for gene regulation and protein diversity. Despite the fact that nearly all human genes are regulated by alternative splicing, very limited studies have addressed the role of alternative splicing in tumorigenesis. Our lab uses the cell adhesion molecule CD44 as a model to investigate the role of alternative splicing in breast cancer metastasis. CD44 undergoes extensive alternative splicing, giving rise to the standard (CD44s) and variant (CD44v) isoforms. Previous work from our lab demonstrated that the CD44s isoform is required for Epithelial to Mesenchymal transition (EMT) and breast tumor metastasis. Mechanistically, we have shown that CD44s, but not CD44v, potentiates Akt signaling, promoting cell survival and chemoresistance in breast cancer cells.

To better understand CD44s-mediated downstream pathways critical for breast tumor metastasis, we analyzed CD44s-dependent gene signature and identified Hyaluronan Synthase 2 (HAS2), an enzyme that produces hyaluronan (HA), as one of the most significantly upregulated genes in response to CD44s expression. Interestingly, HA is the major ligand for CD44, and HA/CD44 interaction promotes Akt activation. These results led us to test a hypothesis that a positive feedback loop, involving CD44s and HAS2, sustains Akt signaling and promotes tumor cell survival. Indeed, our results show that CD44s-mediated Akt activation stimulates HAS2 transcription. This increase in HAS2 transcription is mediated by Akt phosphorylation of FOXO1, a transcription repressor inactivated by phosphorylation. We further show that HAS2 and HA activate Akt signaling in a CD44s-dependent manner. Importantly, disruption of this feed-forward loop inhibits EMT and triggers cell death.

PI3K/Akt signaling is hyperactive in more than 70% of breast tumors. Hence, the proteins involved in this positive feedback loop represent very attractive and promising drug targets for breast cancer therapy. Our work has demonstrated how aberrant expression of alternative spliced isoform in breast cancer, through a positive feedback loop, leads to sustained Akt signaling, enhanced cell survival, and a metastatic phenotype. Disrupting this positive feedback loop may provide a foundation for an innovative approach to treat metastatic breast cancer patients.
**Title**: Gain and amplification of RAC1 GTP-ase in BC: Explaining alterations in patients by experiments using TNBC model

Dey N, Carlson JH H, Jepperson T, Willis S, De P and Leyland-Jones B. Avera Center for Precision Oncology, Sioux Falls, SD.

**Body:**

**INTRODUCTION:** RAC1-GTPase which transduces signals from cell surface integrins, have been implicated in metastasis. We reported that Wnt-beta-catenin pathway (WP) that signals metastasis (BMC Cancer, 2013), is one of the salient genetic features of Triple-Negative Breast Cancer (TNBC) (PlosOne, 2013). **AIM:** We demonstrated that TNBC cells acquire integrin-directed metastasis-associated (ID-MA) phenotypes following an upregulation of the WP (Oncotarget, In Press). Here we examined how WP signals are transduced in the context of ID-MA phenotypes in TNBC. **METHOD:** We documented gain and amplification of RAC1 gene in Breast Invasive Carcinoma subtypes from cBioPortal. The outcome for RFS was studied in the Hungarian ER-ve BC cohort. Mechanistically, we studied fibronectin-directed (1) migration, (2) matrigel- invasion, (3) RAC1 activation, (4) actin dynamics (confocal microscopy) and (5) podia-parameters using pharmacological agents (sulindac sulfide), genetic tools (beta-catenin siRNA), WP modulators (Wnt-C59, XAV939), RAC1 inhibitors (NSC23766, W56) and WP stimulations (LWnt3ACM, Wnt3A recombinant) in a panel of 6-7 TNBC cell lines. **RESULTS:** The collective percentage of gain and amplification of RAC1 were (1) 31% of total 1105 breast invasive carcinoma samples, (2) 29% of total 594 ER+ve samples, (3) 39% of total 174 ER-ve samples, (4) 38% of total 120 HER2+ve samples and (5) 35% of total 82 TNBC samples (brca/tcga/pub2015; Cell 2015). In invasive ductal BC subtypes, gain and amplification of RAC1 were (1) 32% of total 201 Luminal A samples, (2) 37% of total 122 PAM50 Luminal B samples, (3) 47% of total 51 PAM50 Her2-enriched samples and (4) 33% of total 107 PAM50 Basal-like samples. In invasive lobular cancers, gain and amplification of RAC1 were 24% of total 127 samples. Involvement of WP in different TNBC cells was tested following stimulation by LWnt3ACM and Wnt3Arecombinant protein and different inhibitors of WP by both qRT-PCR and WB for beta-catenin, active beta-catenin, cMYC, cyclin D1 and WP specific several stem cell markers. The WP attenuation, which (a) decreased cellular levels of beta-catenin, as well as its nuclear active-form, (b) decreased fibronectin-induced migration & invasion, (c) altered actin dynamics and (d) decreased podia-parameters was successful in blocking fibronectin-mediated RAC1/Cdc42 activity. Both Wnt-antagonists and RAC1 inhibitors blocked fibronectin-induced RAC1 activation and inhibited fibronectin-induced ID-MA phenotypes following WP stimulation by LWnt3ACM and Wnt3Arecombinant protein. High expression of RAC1 was associated with poor outcome for RFS with HR=1.48 [CI: 1.15-1.9] p=0.0019 in the Hungarian ER-veBC cohort. **CONCLUSION:** In TNBC model, the activation of RAC1 signals downstream of WP mediated ID-MA phenotypes. The identification of the functional relationship between RAC1 signaling and the WP activation in the control of ID-MA mechanistically explains how the activation of WP in TNBC is associated with the high metastatic incidences and a dismal outcome.
Title: GATA3 inhibits breast basal-like tumorigenesis

Body: BACKGROUND: Breast cancer can be broadly categorized into two groups depending on the cell type affected. Luminal-type tumors are typically estrogen receptor (ER) positive that are associated with better survival and respond to hormone therapies whereas basal-like tumors are ER negative, more aggressive, and associated with a poor prognosis. GATA3 is a transcription factor well studied for its role as a master regulator of cellular differentiation and stem cell self renewal. Loss of Gata3 in mouse mammary glands blocks luminal cell differentiation and induces growth defects, and low levels of GATA3 are associated with basal-like and metastatic human breast cancers with epithelial-to-mesenchymal transition (EMT). Importantly, luminal cells have been shown to be the origin of some basal-like breast cancers. Due to the proliferation defects caused by GATA3 deficiency, it remains elusive how loss of function of GATA3 contributes to breast cancers development and progression.

METHODS: We previously demonstrated that p18\textsuperscript{Ink4c} (p18), a cell cycle inhibitor, is a downstream target of GATA3 in regulating mammary luminal cell proliferation and loss of p18 leads to luminal type tumorigenesis. To test the role of Gata3 deficiency in tumorigenesis, we generated p18\textsuperscript{-/-};Gata3\textsuperscript{+/-} mice. Mammary gland development and tumorigenesis were characterized in vivo using a panel of cellular and molecular assays. Results were further confirmed in vitro with well established cell lines.

RESULTS: Loss of p18 rescued mammary growth defects caused by Gata3 heterozygosity. Gata3 heterozygosity impaired luminal, but promoted basal gene expression in mammary epithelial cells. Gata3 heterozygosity in p18 null mice accelerated spontaneous mammary tumorigenesis, reducing the average latency of tumor onset. More importantly, Gata3 heterozygosity transformed the luminal type tumors of p18 null mice into heterogeneous basal-like breast cancers with activated EMT. Conversely, reintroduction of GATA3 inhibited tumor growth and reduced expression of EMT markers in basal-like tumor xenografts. We discovered that expression of GATA3 and Vimentin, an EMT marker, is inversely related in human breast cancers.

CONCLUSION: Our data indicates that GATA3 promotes luminal but suppresses basal cell differentiation in the mammary gland and in tumor development. Mechanisms underlying the role of GATA3 in suppressing basal-like tumor development are under investigation.
Title: Cancer stem cells define 3D clonogenic growth response to rational combinations of PI3K-isoform specific inhibitors in TNBC

Carlson JH H, De P, Williams C, Dey N and Leyland-Jones B. Avera McKennan Center for Precision Oncology, Sioux Falls, SD.

Body: Introduction: 3D cell cultures have been recognized as the method of choice for physiologically relevant modeling of malignant behavior of tumor cells ex vivo. Morphologies of BC cell lines in 3D assays correlated with their gene/protein expression profiles reflecting underlying distinct morphologies associated with tumor cell invasiveness and metastases-associated phenotypes. Studies correlating patient outcome to CD44/CD24/CD44v6 expression highlight a need to understand the molecular characteristics of these cell populations to develop relevant therapies. Recently we have established a method to study cancer stem cell (CSC) populations following 3D clonogenic growth and demonstrated a characteristic pattern of CD44/CD24 expression based on mutational context (PTEN-null MDA-MB468, HCC70; RAS/RAF mutated MDA-MB231; BRCA mutated/PTEN-null SUM149 & HCC1937; PIK3CA mutated BT20) of TNBC cells (AACR, 2016)

Hypothesis: Using 3D clonogenic growth of epithelial tumor cells to model CSC behavior in vitro, we hypothesized that there is a functional association between 3D clonogenic growth and CSC proportion following drug treatment.

Methods: To study the role of CSCs in 3D clonogenic growth, tumor cells were treated with a PARP inhibitor and iso-form specific PI3K inhibitors for 7 days in 3D ON-TOP matrigel assay. Live cells were recovered following de-gelling using PBS-EDTA based buffer. Relative distribution of CD24/CD44/CD44v6 expression was determined by flow cytometry and compared to cells growing in 2D format.

Results: CD44/CD24/CD44v6 expression levels characteristically changed between 2D and 3D growth in individual cell lines. Combinations of AZD6482 and BMN673 was most effective in MDA-MB468 cells as it blocked proliferative signals and enhanced apoptosis as demonstrated by WB, flow cytometry, proliferation assay, cell viability, and live/dead cell assays. Combining GDC-0941 with BMN673 blocked proliferative signals and enhanced apoptosis in PTEN-null as well as PTEN-positive and RAS/RAF mutated TNBC cells. GDC0032 had limited effects in PTEN-null cells. In MDA-MB468 cells, control 3D-growth cells expressed a distinct CSC population as compared to their 2D counterpart. While BMN673 treatment increased CD44L/CD24H population cells as did GDC-0032 treatment, there were no alterations in this population following GDC-0941 or AZD6482. Combining AZD6482 plus BMN673 increased CD44L/CD24H population (67% from 22%) as compared to 3D-control and well as BMN673 single agent treatment (67% from 45%). Similar results were obtained with GDC0032 and BMN673 combination. In SUM149 cells 3D growth increased CD44L/CD24H population (from 23% to 83%) as compared to 2D growth, but drug treatment did not alter CSC distribution. No alterations were observed in MDA-MB231 cells. The mechanistic details of the effect of this combination on the CD44L/CD44v6 stem cell populations are being worked out and will be presented at the meeting.

Significance: Standardizing a method to determine CD24L/CD44H/CD44v6 CSC fraction from live cells following 3D clonogenic transformation, we determined functional correlation between CSCs and 3D clonogenic growth following a combination of PI3K isoform-specific inhibitor(s) and PARP inhibition.
Title: Osteoprotegerin mediates tumor-promoting effects of Interleukin-1beta in breast cancer cells

Tsang Mui Chung S, Geerts D, Roseman K, Renaud A and Connelly L. University of Hawaii at Hilo, College of Pharmacy, Hilo, HI and Erasmus University Medical Center, Netherlands.

Body: It is widely recognized that inflammation promotes breast cancer invasion and metastasis. Given the complex nature of the breast tumor inflammatory microenvironment, much remains to be understood of the molecular mechanisms that govern these effects. We have previously shown that osteoprotegerin (OPG) knockdown in breast cancer cells resulted in reduced invasion and metastasis. Here we present novel insight into the role of OPG in inflammation-driven tumor progression in breast cancer cells by investigating the link between OPG and the potent pro-inflammatory cytokine IL1B (IL1B).

We used human breast cancer cell lines to investigate the effects of IL1B treatment on OPG expression. We analyzed public datasets containing human breast cancer genome-wide mRNA expression data to reveal a significant and positive correlation between OPG mRNA expression and the mRNA expression of IL1B as well as CCL2 (a monocyte chemoattractant protein). We determined the effect of macrophages (which produce IL1B) on OPG expression by co-culturing breast cancer cells and differentiated THP-1 macrophages. In order to demonstrate that OPG mediated functional effects of IL1B we performed cell invasion studies with control and OPG siRNA knockdown breast cancer cells treated with IL1B.

We report that OPG expression is induced by IL1B, independent of breast cancer subtype and basal OPG levels. Co-culture of breast cancer cells with IL1B-secreting macrophages resulted in a similar increase in OPG expression in breast cancer cells as IL1B treatment. We show that OPG expression is regulated by IL1B in a p38-dependent manner. We also demonstrate that OPG knockdown represses IL1B expression, IL1B-mediated breast cancer cell invasion and MMP3 expression.
Title: Histone acetyltransferase 1 interacts with estrogen receptor alpha (ERα) and affects the transcriptional activity of ERα in breast cancer cells

Body: Transcriptional regulation of estrogen receptor alpha (ERα) is a complex and multistep process. In order to identify novel proteins that are involved in ERα-mediated transcription, we used a quantitative proteomic method to identify cellular proteins that interact with ERα. Histone acetyltransferase 1 (HAT1) is one of the identified proteins. We have verified ERα-HAT1 interaction by performing coimmunoprecipitation and in-vitro binding assay. In addition, we found that the interaction occurred mainly in the nucleus. Domain mapping assay shows that ERα binds HAT1 primarily through the ligand binding E domain. In a luciferase assay, we found that knockdown of HAT1 by shRNA resulted in a ~5-fold increase in ERα-mediated transcription in breast cancer MCF7 cells, suggesting that HAT1 is functionally linked to ERα. An enzyme-dead mutant HAT1 showed similar effect on ERα transcriptional activity as the wild-type HAT1, suggesting that the enzyme activity of HAT1 is not involved in its effect on ERα transcriptional activity. Interestingly, Knockdown of HAT1 resulted in increased acetylation of histone H4 at lysine 8. Lastly, we demonstrate that the effect of HAT1 on ERα transcriptional activity is gene specific. Our data suggest that HAT1 regulates ERα-mediated transcription through affecting the interactions of ERα with histone proteins around the promoter region of ERα target genes in breast cancer cells.
Title: DSCAM-AS1, a breast cancer specific and Estrogen receptor α-dependent long noncoding RNA, is a key component of the pathway controlling cell growth and migration

De Bortoli M, Miano V, Ferrero G, Annaratone L, Coscujuela L, Castellano I, Cordero F and Sapino A. University of Turin, Orbassano, Turin, Italy; University of Turin, Orbassano, Turin, Italy; University of Turin, Turin, Italy; University of Turin, Turin, Italy and Candiolo Cancer Institute - FPO, IRCCS, Candiolo, Torino, Italy.

Body: We previously reported that the long noncoding RNA (lncRNA) DSCAM-AS1 is one of the most interesting functional molecules in the Estrogen Receptor alpha (ERα) pathway in breast cancer cells, among a set of lncRNAs showing dependency on ERα in MCF7 cells (Miano et al., Oncotarget Jan 19, 2016. DOI: 10.18632/oncotarget.6420). Importantly, these lncRNAs were identified as dependent on ERα expression in absence of hormones, and DSCAM-AS1 was the most representative of them, presenting a clear ERα ChIP-Seq signal on the DSCAM-AS1 promoter and responding sharply to ERα silencing, but not to estradiol treatment. This behavior was shared with some other, but not all, ERα-dependent lncRNAs. We showed also that DSCAM-AS1 expression was strongly related to the luminal B > A tumor subtype and strongly related to ER+, in all datasets examined. Together with other lncRNAs we identified, they constituted a sharp luminal-specific gene signature. All this was confirmed more recently by another group (Niknafs et al., Nat. Comm. Sept 26, 2016. DOI: 10.1038/ncomms12791), also showing that DSCAM-AS1 may be related to endocrine resistance in breast cancer.

We report here that DSCAM-AS1 silencing in MCF7 cells evokes a response very similar to what we observed by knocking down ERα (Caizzi et al., PNAS 2009. DOI: 10.1073/pnas.1315445111), i.e. growth arrest, morphological changes and cell death. Noteworthy, ERα expression was not altered by DSCAM-AS1 silencing, thus indicating that DSCAM-AS1 is downstream ERα. Thus, we were interested in evaluating the overall transcriptional response to DSCAM-AS1 silencing. LNA-mediated DSCAM-AS1 down-regulation led to changes in the expression level of 436 protein-coding genes, as determined by RNA-seq and the following sample validation by qRT-PCR. Data analysis by means of IPA and EnrichR indicated that DSCAM-AS1 silencing regulated genes of cell growth and proliferation, cell signaling, cell death and survival and cellular movement. On the other side, there was also a clear stress response with involvement of the interferon signaling pathway. As in the case of ERα silencing, the overall picture is that DSCAM-AS1 may have a function in the maintenance of the luminal epithelial phenotype in breast cancer cells. Interestingly, genes related to cell movement were actually activated by DSCAM-AS1 knock-down and, in this respect, our result may be somehow contrasting with those shown by Niknafs et al. (above) who reported that stable DCAM-AS1 silencing by shRNA led to decreased migration and invasiveness. Differences in RNA-mediated long-term downregulation versus shorter term, LNA-mediated downregulation may account for discrepancies, but the matter clearly deserves more investigation.

Finally, we present further data on the association of DSCAM-AS1 with ERα in breast tumors and clinical data. We suggest that its high level of expression, tissue-of-origin specificity and breast tumor phenotype specificity make DSCAM-AS1 an extremely interesting novel biomarker of luminal breast cancer.
Body: Background:
Locoregional recurrence (LRR) is a concern after neoadjuvant chemotherapy. Absolute risk of LRR and risk factors associated with LRR among women with node positive breast cancer treated with neoadjuvant chemotherapy on ACOSOG Z1071 were examined.

Methods:
ACOSOG Z1071 (Alliance for Clinical Trials in Oncology) enrolled cT1-3, N1-2 breast cancer patients treated with neoadjuvant chemotherapy from 2009-2011. All patients underwent axillary dissection. Data was analyzed for locoregional recurrence-free survival (LR-RFS) and multivariable analysis performed to identify factors impacting locoregional recurrence.

Results:
Of 756 women enrolled, 701 patients were eligible. Median follow-up was 4.0 years (range 0.03–6.2). 39 pts (5.6%) experienced LRR (32 LRR alone and 7 LRR concurrent with metastatic disease) and 96 patients (13.7%) died. LR-RFS was lowest in patients with triple negative tumors (TNBC) (87.6% at 3 years), followed by HER2-positive tumors (94.1%) compared with Hormone Receptor (HR) positive/HER2-negative tumors (96.9%).

Residual in-breast disease was present in 57% of patients undergoing BCT and 73% of patients undergoing mastectomy (p<0.0001). LRR was higher in BCT compared to mastectomy (p=0.018), however when evaluated by subtype there was no significant difference in LRR by BCT vs mastectomy. There was no difference in LRR by clinical T stage at presentation or pathologic N stage, however LRR increased with higher pathologic T stage (p=0.006).

Overall LRR was lower in patients who achieved a pathologic complete response (pCR) across all tumor subtypes (0% in HR positive/HER2-negative, 2.1% in TNBC, 4% in HER2-positive at 3 years) than in non-pCR patients (HR=0.37, p=0.04). By tumor subtype, pCR was associated with a lower LRR in patients with TNBC (HR=0.17, p=0.019), but was not significantly different by pCR in HER2-positive (HR=0.50, p=0.31) or HR-positive/HER2-negative tumors (HR=estimable).

In the multivariable model, factors associated with increased LRR risk were tumor subtype (TNBC and HER2-positive tumors, p<0.0001), lack of pCR in the breast (p=0.013), breast conservation surgery (p=0.018) and omission of adjuvant radiation therapy (p=0.010)

**Conclusion:**

In patients with node-positive breast cancer treated with neoadjuvant chemotherapy, early LRR is higher in TNBC and HER2-positive tumors. In TNBC patients pCR is associated with lower LRR than residual disease. In this contemporary cohort of node-positive, HER2-positive tumors treated with anti-HER2 therapy, patients achieving a pCR had low LRR rate. Adjuvant radiation appears to be important for locoregional control regardless of pCR.
**Title:** Impact of 70-gene signature use on adjuvant chemotherapy decisions in early breast cancer patients: Results of the prospective symphony triple A study

Kuijer A, Straver M, Elias S, Smorenburg C, Wesseling J, Linn S, Rutgers E, Siesling S and van Dalen T. Diakonessenhuis, Utrecht, Netherlands; University Medical Center Utrecht, Utrecht, Netherlands; Netherlands Cancer Institute, Amsterdam, Netherlands and Netherlands Comprehensive Cancer Organisation, Utrecht, Netherlands.

**Body:**

**PURPOSE:** gene-expression profiles, such as the 70-gene signature (70-GS), are increasingly used as adjunct to conventional clinicopathological prognostic factors to guide adjuvant chemotherapy (CT) decisions. The Dutch guideline suggests use of validated gene-expression profiles in estrogen-receptor (ER) positive (+) early stage breast cancer patients without overt lymph node metastases. We aimed to assess the impact of the 70-GS on CT decisions in ER+ early stage breast cancer patients.

**PATIENTS AND METHODS:** In this prospective observational multicenter study physicians were asked for their opinion whether to administer or omit adjuvant CT before deployment and after obtaining the test result of the 70-GS in this guideline delineated group of patients.

**RESULTS:** Between January 1 2013 And December 31 2015 660 patients, treated in 31 hospitals, were enrolled. Based on the clinicopathological postoperative findings physicians would administer CT in 41%, withhold CT in 16% of patients and refrained from formulating an advice in the remaining 43% of patients letting their recommendation depend on the result of the 70-GS.

Table 1. Concordance between pre-test CT recommendation of the oncologist and the 70-gene signature (GS) test result.

Note. Agreement between pre-test oncologist CT recommendation and the 70-GS test result: Pearsons r = -0.031 95%CI (-0.11 – 0.045).

Estimated 5-year survival benefit of CT administration was 0.8%, 0.6% and 0.7% respectively (p 0.585). The 70-GS result hardly varied in relation to the initial advice of the physician: 56% and 59% had a low-risk profile in patients in whom CT was recommended or discommended respectively (r = 0.021, Table 1). In 51% of patients in whom a pre-test recommendation was formulated incorporation of the 70-GS test result changed the initial advice. Adherence to the test result was high for the three groups (range 94-97%)

*Percentage of patients in whom the post-test recommendation/actual administered CT was in line with the 70-GS test result (i.e. no CT in case of a low-risk profile and CT in case of a high-risk profile. Note. Change in CT recommendation in patients with a CT or no CT pre-test recommendation McNemar’s chi-square test p < 0.001 and p < 0.001 for actual administered CT.
CONCLUSION: guideline-directed use of the 70-GS in Dutch ER+ early breast cancer patients influenced CT treatment decision in the majority of patients. The physician’s tentative CT advice was not associated with the 70-GS test-result.
Title: Nuclear grade has a limited role in predicting recurrence in DCIS following breast conserving surgery: A population-based study

Nofech-Mozes S, Hanna W, Baehner FL, Saskin R, Tuck A, Sengupta S, Elavathil L, Jani PA, Bonin M, Chang MC, Slodkowska E, Paszat L and Rakovitch E. Sunnybrook Health Sciences Centre, Toronto, ON, Canada; University of Toronto, Toronto, ON, Canada; University of California, San Francisco, San Francisco, CA; Genomic Health, Inc., Redwood City, CA; Institute for Clinical Evaluative Sciences, Toronto, CA; London Health Sciences Centre, London, ON, Canada; Kingston General Hospital, Kingston, ON, Canada; Henderson General Hospital, Hamilton, ON, Canada; Thunder Bay Regional Health Sciences Centre, Thunder Bay, ON, Canada; Northern Ontario School of Medicine, Thunder Bay, ON, Canada; Health Sciences North Sudbury, Sudbury, ON, Canada and Mount Sinai Hospital, Toronto, ON, Canada.

**Body: Aims:** Clinical and pathologic characteristics including histologic grade are used in DCIS patients to assess biologic aggressiveness and the risk of ipsilateral breast recurrence (IBR) in order to align appropriate treatment. The landmark randomized DCIS trials that used an integrated assessment of grade that included nuclear grade, comedo necrosis and histologic subtype (Page 1987). Based on recent recommendations from the College of American Pathologists (CAP), histologic grade for DCIS is assessed by nuclear grade, separate from comedo necrosis and histologic subtype, (Lester, Arch Pathol Lab Med. 2009). ECOG E5194, a prospective cohort study of selected patients with low risk DCIS treated by wide excision and no radiotherapy, stratified patients using the former integrated DCIS grading system and found statistically significant differences in 7 year IBR rates between those with low/intermediate grade and high grade (Hughes, JCO 2009; Page 1987). When CAP nuclear grading was applied to 665 DCIS patients from the E5194 study, it was not associated with IBR (Solin, JCO, 2013 & 2015). The objective of this analysis is to evaluate whether CAP nuclear grade is an independent predictor of IBR in a population of patients with pure DCIS treated w/ breast conservative surgery (BCS).

**Methods:** Study cohort includes the Ontario population-based cohort of pure DCIS study of 3320 women with DCIS from 1994 to 2003 (Rakovitch, BCRT, 2015) REMARK guidelines were followed. Breast pathologists centrally reviewed all H&E slides for: focality (multifocality=at least 2 foci of DCIS 5mm apart), size, CAP nuclear grade (Lester, Arch Pathol Lab Med. 2009), histologic subtype, comedo necrosis & clear margins, (CM=no ink on tumor). Cox modeling was used to determine the relationship between independent covariates & IBR.

**Results:** Tumor blocks were collected for 1751 patients (53% of parent cohort); 718 treated with BCS alone (N=571 with CM). Median follow-up was 9.6 years. Among the 571 pts with CM, 541 were ER+ and 100 patients had an IBR (DCIS, N=44; invasive, N=57). Distribution of nuclear grade was: 55 (9.6%) low nuclear grade, 332 (58.1%) intermediate nuclear grade, and 184 (32.2%) high nuclear grade. The 10-year rates of developing an IBR were: low grade 15.2% (7.9-28.1); intermediate 16.5% (12.7-21.3%), high 25.6% (19.3-33.6), respectively (log rank P=0.1006). In multivariable analyses for IBR in CM cases including nuclear grade (H vs. L/I), comedo necrosis, histologic subtype, tumor size, age and focality only multifocality (P=0.0002), histologic subtype P=0.016), size (P=0.028) and age ≥50 (P=0.018) were significant.

**Conclusions:** CAP nuclear grade as assessed by central pathology review was not significantly associated with the risk of IBR in DCIS patients treated with BCS alone from the Ontario population based DCIS study. These findings confirm those observed in E5194. CAP nuclear grade results in grade migration and is not informative in prediction of IBR. Further studies to determine whether appropriate assessment of grade should return to the integrated grading that was used and was informative in the landmark randomized radiotherapy trials are required.
**Title:** Prognostic and predictive values of high endothelial venules (HEV) and tumor infiltrating CD8+ lymphocytes (CD8) in tumors of patients included in the adjuvant PACS04 trial: HEV is predictive of outcome for HER2+ tumors exposed to trastuzumab

**Body:** Background: HEV are specialized blood vessels that function as portals of entry for lymphocytes into lymphoid organs and tumor tissues (Moussion and Girard, Nature 2011, 479:542-546; Girard et al, Nature Rev Immuniol 2012, 12:762-773). We retrospectively considered HEV and CD8 as potential prognostic and/or predictive factors in a large randomized adjuvant trial of node positive breast cancer patients (PACS04). This trial included 3010 node positive patients randomized between anthracyclins alone or anthracyclins and docetaxel chemotherapy. Patients with HER2+ expressing tumors had a second randomization with or without trastuzumab given sequentially for one year. With 59.5 median follow-up, metastatic free interval (MFI), the first end-point, was 84.5% at 5 years for the whole population.

Methods: 1660 tumor samples (9.7% triple negative, 67.5% HR+/HER2- and 22.8% HER2+) were collected and analyzed by immunostaining on full sections for HEV (MECA-79 mAb, BD Biosciences) and CD8 (C8/144B mAb, Dako). HEV densities were determined as previously described (Martinet et al., Cancer Res 2011, 71:5678-5687). CD8+ cells and tumor-infiltrating lymphocytes (TIL) were scored according to recently published guidelines. Univariate analyses were performed using cox proportional hazard model for continuous variable. Independent analyses for the predictive evaluation of trastuzumab outcome were performed in the HER2+ subgroup.

Results: MFI and overall survival at 5 years for this series are respectively of 84.9% (TN: 77.4%, HR+/HER2-: 89%, HER2+:75.8%) and 91% not different with the total group. The table shows expression of the different markers according to the subgroup of tumors.

</tbody>
</table>

Table 1

No difference in univariate analysis was observed in TN and HR+/HER2- subgroups in terms of relationship between marker expression and outcomes. For the HER2+ group, HEV and CD8 were correlated to better outcome (HEV: HR=0.73, p =0.011; CD8: HR=0.64; p=0.006). For HER2+ patients not receiving trastuzumab (222 pts, 55 events), CD8 was predictive of metastasis risk (HR: 0.65, p=0.032), but not HEV (HR:0.82, p=0.09). Conversely, in the trastuzumab treated group (156 pts, 35 events), HEV was significantly correlated with a lower risk of relapse (HR: 0.45, p=0.02), but CD8 was not (HR:0.63, p=0.07). TIL counts are still ongoing and will be reported at time of presentation.

Conclusions: HEV and CD8 are associated with better prognosis in the HER2+ tumor group. Interestingly, HEV presence in the tumor seems to be a significant predictive factor of trastuzumab efficacy.
Title: Mutation characteristics and tumor infiltrating lymphocytes in early and metastatic HER2-positive breast cancer

Body: Background-aim: HER2-positive breast cancer (BC) features high rates of tumor infiltrating lymphocytes (TILs) and mutations (mut) in various genes, more frequently in TP53. We investigated associations between TILs and mutations in HER2-positive BC and their impact on patient outcome in early and metastatic BC (EBC and MBC, respectively), which remain largely unexplored.

Methods: In 352 primary paraffin tumors from patients with HER2-positive disease, we examined amino acid changing mutations (<0.1% minor allele frequency) in 58 genes for type and possible clonality (>20% variant frequency). Study groups were: (A) 218 EBC, including 117 patients treated with adjuvant chemotherapy only (CT) and 101 patients treated with CT and trastuzumab (CTT); (B) 134 MBC, including 95 patients who relapsed upon adjuvant CT without trastuzumab (R-MBC) and 39 patients who were first diagnosed with metastatic disease (de novo MBC). TILs were assessed as percentage of stromal tumor area. Clinical endpoints were disease-free survival in 5 years (5yr DFS) for EBC, and time-to-progression (TTP) from 1st line CTT treatment start for MBC.

Results: 243/352 tumors (69%) carried at least one mut; 27/352 (8%) of tumors >10 up to 150 mut (hypermut); 192/352 (54%) at least one possibly clonal mut. Mean mut number and TP53 mut in particular were highest in R-MBC and lowest in EBC; mean TILs density followed the opposite pattern (all p<0.001). TILs density was lower in all settings in hypermut tumors and in tumors with multiple clonal mut (p values 0.043 – 0.050). Upon multivariate analysis in EBC, higher risk for relapse in 5yrs was noticed for CT patients compared to CTT (odds ratio [OR] 2.39, 95%CI [CI] 1.13-5.04, p=0.023) and for >3 compared to 0-3 positive nodes (OR 3.83, CI 1.76-8.34, p=0.001); lower risk for relapse was observed for higher TILs irrespectively of treatment (OR 0.93, CI 0.90-0.97, p=0.001), for TP53 mut (OR 0.39, CI 0.18-0.87, p=0.022) and for clonal TP53 mut in CTT-treated patients (OR 0.10, CI 0.02-0.58) but not in CT-treated patients (interaction p=0.084). The presence of any clonal mut (hazard ratio [HR] 2.77, CI 1.42-5.38) and of clonal TP53 mut (HR 2.24, CI 1.20-4.17) conferred worse TTP in de novo but not in R-MBC; these interactions remained significant upon multivariate analysis (interaction p=0.007 and p=0.061, respectively). Higher TILs in the absence of clonal mut conferred longer TTP (HR 0.75, CI 0.56-0.99) but no such effect was observed for tumors with clonal mut (multivariate interaction p=0.052). Classic independent predictors of unfavorable TTP in MBC were younger age (p=0.002), absence of hormone receptors (p=0.001) and poor performance status (p=0.044). PIK3CA mut did not remain significant in any of the examined settings.

Conclusions: The expected pattern of higher TILs associated with mutation number and clonality was not observed in HER2-positive BC; the favorable effect of TILs only in the absence of clonal mut in MBC may imply exhausted immune response. Clonal TP53 mut may serve as a predictor for trastuzumab benefit in EBC but as an adverse prognosticator in trastuzumab-treated de novo MBC, which, if further validated, is of potential clinical relevance.
Title: Real-world clinical experience and outcomes in patients with early-stage breast cancer (EBC) treated according to the 21-gene recurrence score® (RS) result

Body: Evaluating the merits of a genomic assay includes measuring analytic and clinical validity, and establishing clinical utility—a property that is not consistently defined. One definition of clinical utility that has gained traction is “the balance of benefits and harms associated with the use of the test in practice” [Genet Med. 2015; doi:10.1038/gim.2015.173].

The 21-gene RS assay is the only assay clinically validated for both prognosis and prediction of chemotherapy (CT) benefit in patients with node-negative (N0) or node-positive (N+), ER+, HER2− EBC. The original clinical validation studies were prospectively designed using archived tissue from legacy trials that had long-term outcomes (NSABP B-14 and B-20, TransATAC, and SWOG 8814). With 10+ years of the RS assay in clinical use, we now have real-world, prospective outcomes for patients with N0 or N+ disease that meet the aforementioned definition of clinical utility.

Here we summarize the growing body of clinical evidence including the original validation studies, prospective outcomes-based trials, and analyses from two large, real-world registries in which patients were treated based on RS results: the US SEER and Clalit Health Services registries.

The US SEER registry is a population-based cancer surveillance program that covers 30% of the US population and includes 40,134 N0 and 4,691 N+ patients with RS results. The Clalit Health Services registry, from the largest HMO in Israel, has 2,028 N0 and micrometastatic (Nmi) patients who were uniformly tested and had complete treatment information. In the SEER and Clalit cohorts, the distribution of RS results were similar for N0/Nmi and N+ patients: 54% and 57% low (<18), 38% and 36% intermediate (18-30), and 8% and 7% high (≥31), respectively. 5-year outcomes by RS group show that patients with low RS results of any nodal status (N0/Nmi/N1-3) had similar outcomes (Table). Outcomes by RS group and age or grade were also similar for patients with low RS results of any nodal status.

</tbody>
</table>

a. Includes patients 40-84 years of age only (HR+, HER2−, nonmetastatic EBC). b. Includes Nmi and up to three positive nodes [N+(mi,1-3)]. c. Includes 1,815 (89%) N0 and 213 (11%) Nmi.

In summary, after 10+ years of clinical use, the 21-gene RS assay has now amassed a body of clinical evidence from >50,000 patients that confirms the original clinical validation results and supports its clinical utility. The assay identifies patients with low RS results who can be safely and effectively treated with hormonal therapy alone and spared the toxicity of CT exposure. In aggregate, these data support the clinical utility of the 21-gene RS assay and its value to physicians and patients by providing information based on individual tumor biology that they can use to tailor treatment.
Title: Evaluation of tumor infiltrating lymphocytes (TILs) and their association with homologous recombination deficiency and BRCA1/2 mutation status in triple-negative breast cancer (TNBC): A pooled analysis

Telli ML L, Badve S, Vinayak S, Silver DP P, Isakoff SJ J, Kaklamani VG G, Gradishar WJ J, Stearns V, Connolly RM M, Ford JM M, Adams S, Garber JE E, Evans B, Timms K, Wenstrup R and Richardson AL L.  Stanford University School of Medicine, Stanford, CA;  Indiana University, Indianapolis, IN;  Case Western Reserve University School of Medicine, Cleveland, OH;  Dana Farber Cancer Institute, Boston, MA;  Massachusetts General Hospital, Boston, MA;  Harvard Medical School, Boston, MA;  UT Medicine Cancer Therapy and Research Center, San Antonio, TX;  Northwestern University, Chicago, IL;  Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins School of Medicine, Baltimore, MD;  New York University Cancer Insitute, NYU School of Medicine, New York, NY and  Myriad Genetics, Inc., Salt Lake City, UT.

Body: Background: TNBC patients with homologous recombination (HR) deficient tumors have significantly higher pathologic complete response (pCR, ypT0/is ypN0) rates when treated with platinum-based chemotherapy. TILs are prognostic and predictive of chemotherapy benefit in TNBC. Interestingly, recent data suggests that HR deficient TNBCs and BRCA1/2 mutant ovarian cancers may be enriched for immune cell infiltration. Thus, we performed a pooled analysis of 5 phase II studies that included patients with TNBC treated with neoadjuvant platinum-based chemotherapy to evaluate the association of TILs with HR deficiency status and tumor BRCA1/2 mutation status.

Methods: 166 patients with TNBC and known HR deficiency status from the following clinical trials were available for analysis: PReCOG 0105 (N=72), NCT00580333 (N=32), NCT01372579 (N=26), TBCRC 008 (N=18) and NCT00148694 (N=18). Neoadjuvant chemotherapy regimens included 1) carboplatin, gemcitabine, iniparib, 2) cisplatin with or without bevacizumab 3) carboplatin, eribulin, 4) carboplatin, nab-paclitaxel, with or without vorinostat. HR deficiency status was defined as a high HRD score (42 or higher) and/or presence of a BRCA1/2 tumor mutation (tBRCA). Digitized pre-treatment core biopsy H&E sections were reviewed and scored by two blinded expert breast cancer pathologists using the international TIL working group guidelines. The density (%) of both intratumoral TILs (iTILs) and stromal TILs (sTILs) was recorded by deciles (n=122 thus far, additional cases to be included in final analysis).

Results: Among 122 patients, pCR was achieved in 36 patients (29.5%) and 71 tumors (58.2%) were HR deficient. In total, 24 patients (19.7%) patients had a deleterious BRCA1/2 mutation. Among all tumors, iTIL and sTIL median densities were 0% (range 0-20) and 10% (range 0-80), respectively, and were not statistically different in HR deficient versus non-deficient tumors (iTIL p=0.746; sTIL p=0.159). The same absent association was observed for tBRCA mutation status (iTIL p=0.607; sTIL p=0.315) and binary HRD score (iTIL p=0.879; sTIL p=0.364). Updated results with additional cases scored for TILs will be reported at time of presentation. Additional analyses assessing the relationship between TILs and pCR/residual cancer burden adjusting for HRD status and other clinical variables will also be included at the time of presentation.

Conclusion: Several previous studies have reported that TILs are significantly associated with response to standard chemotherapy regimens when given in the neoadjuvant setting. Measures of genomic instability and DNA repair deficiency, including HRD, have been shown to be robust predictors of response to chemotherapy, including platinum containing regimens. It is unclear if TILs will be predictive in a similarly robust way for response to platinum-containing regimens. Results of this study suggest TIL density and HR deficiency status may be independent and non-overlapping. Final analysis including additional cases will be included in the final presentation.
Title: Results of multigene assay (MammaPrint®) and molecular subtyping (BluePrint®) substantially impact treatment decision making in early breast cancer: Final analysis of the WSG PRIME decision impact study

Body: Background: In luminal early breast cancer (EBC) with limited nodal involvement, current guidelines recommend to use multigene assays in addition to conventional clinicopathological factors for decision making regarding adjuvant chemotherapy (CT). The WSG PRIME Study prospectively evaluated the impact of the 70-gene signature (MammaPrint®) and the corresponding molecular subtype (BluePrint®) on clinical therapy decisions in EBC.

Methods: WSG PRIME recruited 452 consecutive patients (pts) in 34 centers with ER+ and/or PR+ HER- pN0-1 EBC (04/15-03/16). Of the 430 evaluable pts, 309 had pN0 and 121 pN1 disease; median age was 58 years (68% post-menopausal). MammaPrint®, TargetPrint®, and BluePrint® results were provided prospectively, after therapy decisions based on clinicopathological factors and/or local IHC (ER/PR/Ki67) had been ascertained.

Results: The WSG PRIME study observed a switch in CT decisions based on the multigene test results of 28.4 % (95% CI 23.3-33.4%). In 57 pts (13.3%), the decision switched from CT to no-CT, in 65 (15.1%) from no-CT to CT; in 107 (24.9%) pts a CT decision and in 201 (46.7%) a no-CT decision was maintained. Physicians strongly adhered to test results, most notably when initial CT recommendation was discordant with the test: 62/72 (86.1%) switched from no-CT to CT following MammaPrint® high risk, with 84.7% in N0 and 92.3% in N1. For MammaPrint® low risk, 56/80 (70%) switched from CT to no-CT; this percentage was similar in pN0 and pN1. Overall adherence (all pts) was 92.9% (CT) for high risk and 90.1% (no-CT) for low risk. Regarding subtype, 1/430 tumors was classified as HER2-enriched by BluePrint®; of the 6 basal-like tumors by IHC, 2 were molecularly re-classified as luminal A and 4 as luminal B. Of the 424 luminal-A/-B-like tumors by IHC, only 283 (66.7%) were subtyped concordantly by BluePrint®; 40% (61/152) of the luminal-B-like tumors were re-classified as luminal A and 29% (79/272) of the luminal-A-like tumors were re-classified as luminal B. Switches in CT decisions were strongly impacted by molecular subtype, with 142/152 (93.4%) of molecular luminal B pts eventually scheduled for CT and 247/272 (90.8%) of molecular luminal A pts for no-CT. After the test results, physicians' confidence in their therapy decision increased in 141 (32.9%) of the cases.

Conclusions: In a decision impact study, the true percentage of CT saved by a prognostic test depends on cohort characteristics. Yet, the WSG PRIME study showed that the70-gene signature (MammaPrint®) and the corresponding molecular subtype (BluePrint®) strongly impacted clinical therapy decisions in EBC with up to 3 involved lymph nodes. There was a substantial discordance between clinical and molecular luminal subtypes. After receiving the test results, physicians focused their indications for adjuvant CT on MammaPrint high-risk luminal-B-like tumors. Where test results were discordant with clinical assessment, physicians mostly omitted CT in MammaPrint low risk patients. Recently, the prospective MINDACT trial had shown that this did not compromise outcome.
Title: Genetic variation in CYP3A affects steady-state exemestane concentrations but does not explain inter-race difference

Hertz DL L, Kidwell KM M, Gersch CL L, Desta Z, Storniolo AM, Stearns V, Skaar TC C, Hayes DF F, Henry NL and Rae JM M. University of Michigan, Ann Arbor, MI; Indiana University and Johns Hopkins University.

Body: Background: Exemestane is a third generation steroidal aromatase inhibitor (AI) used for the treatment of estrogen receptor (ER) positive breast cancer in postmenopausal women. Differences in AI treatment efficacy and side effects may be due, in part, to variability in drug exposure. We previously reported that patients who self-report as white and those who carry the low-activity CYP3A4*22 single nucleotide polymorphism (SNP) have increased exemestane steady-state concentrations. Additional SNPs in CYP3A may contribute to pharmacokinetic variability and explain this inter-race difference. CYP3A5*3 (rs776746) is a non-expresser genotype that is far more common in European (minor allele frequency (MAF)∼0.94) than African (MAF∼0.18) individuals. CYP3A7*1C (rs45446698) is believed to tag adult expression of the fetal CYP3A7 enzyme and is relatively uncommon in tested cohorts (European MAF=0.04, African MAF<0.01). The objective of this secondary analysis was to determine whether these additional CYP3A SNPs contribute to variability in steady state exemestane concentrations and explain the inter-race difference.

Methods: 500 patients were randomly assigned to either drug on the Exemestane and Letrozole Pharmacogenetics (ELPh) Study. Clinical data and DNA were collected at baseline and blood samples were collected after 1 or 3 months of treatment to measure steady-state exemestane concentration via HPLC/MS. Genotyping for CYP3A5*3 and CYP3A7*1C was performed via Taqman Allelic Discrimination. Pharmacogenetic association with log-transformed concentrations were tested for each variant by inclusion in a multivariable model with CYP3A4*22 and self-reported race, assuming additive genetic effect, using Tobit regression to censor concentrations below the lower limit of quantification. SNPs with suggestive p-values <0.10 were included in a multivariable model with relevant covariates (AST or ALT>40, body mass index (BMI), and prior chemotherapy) to assess their independent contribution.

Results: In 231 evaluable patients there was a suggestive trend toward lower steady-state exemestane concentrations for CYP3A7*1C carriers (6.3 vs. 8.0 ng/mL) in the model including CYP3A4*22 and race (p=0.083). In the final multivariable model each CYP3A7*1C allele decreased exemestane concentration 31.5% (p=0.035, Table 1). CYP3A5*3 was not associated with exemestane concentration (p>0.2).

Conclusions: Patients with breast cancer who carry CYP3A7*1C have lower steady-state exemestane concentrations but this association does not explain the greater concentrations in self-reported white patients. Ongoing analyses will determine whether exemestane concentration predicts treatment efficacy or toxicity, and if so, whether genetic and clinical factors can be useful for individualizing dosing to optimize outcomes. CYP3A7*1C should be prioritized for analyses of pharmacokinetic variability of other CYP3A substrates.
Title: A consecutive series of early breast cancers with a low estrogen receptor expression

Body: Background: Estrogen receptor (ER) positivity is not a dichotomous biological phenomenon and within the ER positive cohort, major differences in amount and percentage of ER expression are observed. Women with tumors expressing low ER levels have worse outcome as quantitative ER (qER) expression is predictive for benefit from hormone therapy. The aim of our study was to further characterize these patients, tumors and the distant relapse free survival (D-RFS) based upon qER expression.

Patients and Methods: In this retrospective study we included women with primary operable human epidermal growth factor receptor 2 (HER2) negative breast cancers, diagnosed between January 1st 2000 and September 30th 2015 in the Multidisciplinary Breast Center of University Hospital of Leuven. ER-low tumors ((1-33% immunohistochemical (IHC)staining, Allred proportion score (2-3/5), or H-score (<100/300 + <33% staining)) were compared with ER-high tumors((> 33% IHC staining, Allred proportion score (4-5/5), or H-score ≥ 100/300)) and triple negative (TN) tumors (Allred proportion score (0-1/5) or H-score 0% staining). PR and HER2 were scored according to ASCO/CAP guidelines. Local and adjuvant therapies were given according to the in house guidelines. The Fisher exact text was used for comparing groups on categorical variables and the Kruskal Wallis test or Mann-Whitney test were used for continuous variables. The Kaplan-Meier method was used for estimating the interval to relapse. The log rank test was used for the comparison between groups (2-sided test with 5% significance, SAS software version 9.4).

Results: A total of 5390 women were included, 115 (2 %) were ER-low, 4658 (86.5%) were ER-high and 617 (11.5%) were TN. Average follow-up was 6 years. Patients with ER-low and TN breast tumors were younger at diagnosis compared to patients with ER-high tumors (respectively 55.5y and 56.7y vs 59.3 y; p<0.001). Tumor size and nodal status did not differ between the three subgroups. ER low and TN were more often grade 3 (61% and 89% vs 24%, p<0.001) which led to a higher mean NPI. Adjuvant chemotherapy was more likely to be given in ER-low and TN cases (57% and 75% vs 26%, p<0.001). Women with an ER-low and TN breast cancer were more often referred for BRCA1/2/CHEK-2 testing as compared to those with an ER-high tumor (respectively 21%, 22% vs 10% p<0.001); a mutation was found 5 to 7 times more in the ER-low and TN group (5%-7% vs 1% p<0.001). Metastatic relapse was 18% in ER low (21/114 patients), 15% in TN (90/617 patients) and 6% in ER high (283/4658 patients). Using a Kaplan Meier curve, the 5 year D-RFS was 84%, 85% and 96% in ER-low, TN and ER-high cases. The 10 year D-RFS was respectively 76%, 84% and 91% (p<0.001).

Conclusion: ER-low breast cancers are rare and correlate better with TN than ER-high tumors regarding demographics, tumor grade, BRCA1/2/CHEK-2 mutation risk and breast cancer outcome.
The association between pCR status after neoadjuvant chemotherapy and sites of first distant relapse after surgery: A substudy of the EORTC 10094/BIG-1-00 trial

Touati N, Aalders K, Slaets L, Tryfonidis K, Cameron DA A and Bonnefoi H. European Organization for Research and Treatment of Cancer, Brussels, Belgium; European Organization for Research and Treatment of Cancer, Brussels, Belgium; Western General Hospital & Edinburgh University, Edinburgh, United Kingdom and Institut Bergonié, University de Bordeaux, Bordeaux, France.

Body: Background
Chemotherapy in eligible patients is increasingly applied in the neoadjuvant setting, as it offers the possibility for 'in vivo' monitoring of the activity to the administered treatment, prevention of early micrometastatic spread and often allows less invasive surgery in patients that would otherwise have needed a mastectomy. The achievement of a pathologic complete response (pCR) after neoadjuvant chemotherapy is a prognosticator for better outcome. However, less is known about the patterns of distant relapse between patients that did and did not achieve pCR. We assessed the differences in sites of first distant relapse after pCR versus non-pCR after neoadjuvant chemotherapy in patients enrolled in the EORTC 10094/BIG-1-00 "p53" trial.

Methods
The analyzed population consisted of patients enrolled in the "p53" trial that received ≥1 cycle of chemotherapy before surgery and who have been diagnosed with a distant relapse. pCR was defined as no evidence of residual invasive cancer (or very few scattered tumor cells) in the primary tumor and axillary lymph nodes with or without residual ductal carcinoma in situ (DCIS). Intrinsic subtype classification was performed using the 2011 St Gallen consensus. The first site of distant relapse was collected for all patients and was classified as soft tissue, visceral, skeletal or CNS. As primary analysis, the associations between achievement of pCR and sites of distant relapse were investigated in 4 multivariate logistic regression models, one for each site, adjusting for intrinsic subtype and preceding local recurrence (yes/no). Adjusted P-values are reported (Benjamini-Hochberg correction). Secondary analyses include: associations between site of first distant relapse and pCR by subtype, description of concomitant sites of relapse.

Results
The study included 383 (21%) eligible patients out of the 1856 randomized for the 'p53' trial, of whom 28 (7%) had achieved pCR and 355 (93%) did not. Median follow-up was 5.4 years. Achievement of pCR was associated with a trend towards a decreased presentation with skeletal metastases (21% (pCR) vs 50% (non-pCR), OR=0.32, adj-p=0.071, see Table) and we observed an increase in the proportion of patients with CNS tissue as first site of distant relapse (21% vs 9%, OR=2.39, adj-p=0.183). The trend for skeletal metastases was seen in all subtypes except for Luminal A. Patients with pCR were more likely to present with only one relapse location category when compared to non-pCR (86% vs 69%).

Conclusion
In this group of patients treated with neoadjuvant chemotherapy, patients that achieved a pCR were less likely to present with skeletal metastases as first site of distant relapse, even after adjustment for intrinsic subtype.
Body: Background: Patients achieving pathologic complete response to neoadjuvant chemotherapy have excellent disease free and overall survival. For patients with residual disease, the residual disease in breast and lymph node (RDBN) method provides useful prognostic information. RDBN is calculated as follows: 0.2 * tumor size (in cm) + lymph node status (0-3) + tumor grade (1-3). pCR, low, intermediate and high risk of recurrence categories correspond to RDBN index of 0, 0.1 to 2.9, 3 to <4.4, and ≥ 4.4, respectively. We hypothesized that the prognostic accuracy of RDBN may be improved by also taking into account the residual tumor cellularity.

Methods: Retrospective review of 614 consecutive patients who underwent neoadjuvant therapy for breast cancer was performed. At our institution, tumor size/volume reduction in the breast is determined using the equation:

\[
\text{Estimated } \% \text{ tumor size reduction} = \frac{\text{pre-therapy clinical size} - \text{"revised" pathology tumor size}}{\text{pre-therapy clinical size}} \times 100.
\]

“Revised” pathology tumor size is calculated by multiplying the largest dimension of the gross tumor bed by the invasive tumor cellularity of the tumor bed (in comparison to the pre-therapy core biopsy sample). For example, if a 3 cm tumor bed has only 50% cellularity for invasive cancer (in comparison to pre-therapy core biopsy), the revised tumor size is 1.5 cm. Hence, we were able to use the “revised tumor size” for calculating the modified RDBN index (mRDBN). We also used gross tumor bed size for gross RDBN (gRDBN) to compare with mRDBN. mRDBN and gRDBN could be calculated on 459 of the 514 cases. Chi-Square statistical analysis was performed.

Results: Mean follow up was 33.1 months (median 31, range 4-70).

The results are shown in Table 1 & 2.

Conclusions: Both mRDBN and gRDBN provide prognostic information; however, separation of categories is improved with mRDBN (Table 1). mRDBN reclassified 30% of the high risk-gRDBN patients into intermediate risk category with a recurrence rate of 20%, leaving the 'true' high risk subgroup with a revised recurrence rate of 50% (Table 2). RDBN index also identified a group of low risk patients who have prognosis similar to patients with pCR.
Body: Background: Breast cancer is heterogeneous at different levels: biologic subtypes, intratumoral areas, and sites of metastases. In clinical studies, metastatic sites are usually classified as visceral or non-visceral, but this has little influence in treatment decisions particularly in the absence of clinical urgency. Indeed, it is unclear if response to new treatments differs among sites of metastatic lesions.

Methods: Randomized controlled trials (RCTs) investigating 3 different anticancer strategies in metastatic breast cancer were identified:

(1) Comparison of two endocrine strategies
(2) Endocrine therapy and targeted therapy compared with endocrine therapy alone
(3) New HER-2 targeted therapy compared with existing HER-2 targeted therapy

RCTs reporting hazard ratios (HR) for Progression Free Survival (PFS) and Overall Survival (OS) for sub-groups based on sites of metastases were weighted using generic inverse variance approach, and pooled in meta-analyses using Revman 5.3. Subgroup difference was tested with Chi² and heterogeneity with I² statistics.

Results: A total of 11 RCTs (6,701 pts) qualified.

</table>

There was a significant difference in PFS between women with visceral Vs non-visceral metastases when two endocrine strategies were compared, with benefits limited to women with visceral metastases [Pooled HR 0.85; 95% CI, 0.77-0.95 Vs 1.02(0.88-1.18) for non-visceral; p(difference) 0.05]. However, combination of an endocrine therapy and a targeted therapy was associated with better PFS compared to endocrine therapy alone for both groups [HR 0.51(0.43-0.60) for visceral Vs 0.45(0.36-0.56) for non-visceral; p(difference) 0. 36]. Newer HER-2 targeted therapies were associated with significantly better PFS only in visceral but not in non-visceral metastases [HR 0.59 (0.52-0.66) Vs 0.71(0.44-1.13), p(difference) 0.45]. OS benefit with new HER-2 therapies was observed only for women with visceral metastases [HR 0.64 (0.56, 0.73) Vs 0.82 (0.57, 1.19), p(difference):0.20].

Conclusion: Targeted + endocrine therapy combination results in concordant, superior PFS suggesting similar mechanisms of
targetable endocrine resistance between metastatic sites. Discordant responses with endocrine strategy alone support use of targeted therapy, rather than change in endocrine agent at disease progression. New HER2 therapies display continued challenge of drug penetration to areas of limited vascularization (e.g., soft tissue, bone) with no PFS or OS benefit in that group despite impressive benefits in overall population.
**Title:** Identification of proliferation related derivers and their roles in precision medicine for breast cancers: A retrospective multidimensional comparative, integrated genomic, transcriptomic, and protein analysis

Abdel-Fatah TMA MA, Agarwal D, Zafeiris D, Pongor L, Györffy B, Rueda OM M, Moseley PM M, Green AR R, Liu D-X, Pockley AG G, Rees RC C, Caldas C, Ellis IO O, Ball GR R and Chan SY T T. University of Nottingham Hospital NHS Trust, Nottingham, United Kingdom; John van Geest Cancer Research Centre, School of Science and Technology, Nottingham Trent University, Nottingham, United Kingdom; MTA TTK Lendület Cancer Biomarker Research Group, Budapest, Hungary; Cancer Research UK, Cambridge Research Institute, LiKa Shing Centre, Cambridge, United Kingdom; School of Medicine, University of Nottingham and Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom and Liggins Institute, University of Auckland, New Zealand.

**Body:** Background and Aim: The best test to guide the choice of systemic therapy for breast cancer (BC) has not yet been identified. We did this study to identify factors that drive proliferation features in BC and assess their association with clinical outcomes after systemic therapy.

Methods: We applied an artificial neural network-based integrative data mining approach to three cohorts of patients with untreated lymph node (LN)-negative BC (Wang et al; n=286, Desmedt et al; n=198 and Schmidt et al; n=200). The results were validated in four cohorts of BC patients (the Nottingham discovery cohort (n=171), Uppsala cohort (n=249), The Cancer Genome Atlas-Breast Cancer project [TCGA-BRCA; n= 970] and Molecular Taxonomy of Breast Cancer International Consortium [METABRIC cohort; n=1980]. Genes that featured prominently in our interactome map of proliferation have been chosen to take them forward to investigate their clinicopathological relevance of their gene copy number aberrations (CNAs), mRNA transcript expression, and protein expression and their associations with breast cancer-specific survival (BCSS), distant relapse-free survival (DRFS) and pathological complete response (pCR) in ten international cohorts of BC (n>12000 patients).

Findings: ESR1, SPAG5, EGFR, BCL2, and FOXA1 were among the 39 common gene probes that were predictive across most proliferation features and datasets. In TCGA-BRCA cohort, SPAG5 gene mutation, gain/amplification and loss at the Ch17q11.2 locus were detected in 43 (4.4%), 177 (18.2%) and 180 (18.8%) of 970 patients, respectively and 65 (31%) of 479 ER-positive/HER-positive patients showed gain/amplification of SPAG5 gene. In multivariable analysis, high SPAG5 transcript and SPAG5 protein expression were associated with reduced BCSS compared with lower expression (METABRIC: HR 1·27, 95% CI 1·02–1·58, p=0·034; untreated LN-negative cohort: 2·34, 1·24–4·42, p=0·0090; and Nottingham-cohort: 1·73, 1·23–2·46, p=0·0020). In patients with ER-negative/HER2-negative or ER-positive/HER2-negative BC, high SPAG5 transcript expression was associated with an increased pCR compared with low SPAG5 transcript expression after receiving anthracycline neoadjuvant chemotherapy (AC-NeoACT) [(Multicentre phase 2 clinical trial cohort; n=136; OR 2·47, 95% CI 1·17–5·21, p=0.016) and (MD Anderson- taxane+AC-NeoACT cohort; n=287; OR 3·16, 95% CI 1·46–6·84, p=0.003; respectively]. In patients with ER-positive/HER2-negative BC who received taxane+AC-NeoACT followed by adjuvant tamoxifen (Adj-Tam) for 5 years (MD Anderson- taxane+AC-NeoACT cohort; n=287), high and low SPAG5 transcript expression had similar DRFS (HR 1·40, 95% CI 1·46–6·84, p=0.003). Whereas in ER-positive/HER2-negative BC patients who received only Adj-Tam (n=298), high SPAG5 transcript expression was associated with reduced DRF at 5 years compared with lower expression (HR 1.98, 95% CI 1.19–3.27, p=0.008).

Interpretation: The transcript and protein products of SPAG5 are independent prognostic and predictive biomarkers that might have clinical utility as biomarkers for combination cytotoxic chemotherapy sensitivity in ER-positive/HER-negative BC.
Title: Evaluation of a risk score based on biologic factors to enhance prognostic stratification by the American Joint Committee on Cancer (AJCC) Staging System

Mittendorf EA A, Vila J, Yi M, Chavez-MacGregor M, Chen RL L, Giordano SH H and Hunt KK K. University of Texas MD Anderson Cancer Center, Houston, TX.

Background: The 7th edition AJCC staging system provides prognostic information based on the anatomic extent of disease determined by the tumor size (T), lymph node status (N), and presence or absence of metastatic disease (M). Tumor biology, including grade, estrogen receptor (ER) status and HER2 status, which are known to have prognostic and predictive value, are not incorporated. This study was undertaken to evaluate a risk score that takes into account the tumor grade and other biomarkers that can be added to the current anatomic TNM staging system to improve stratification of patients with respect to disease specific survival (DSS) and overall survival (OS).

Methods: A prospectively maintained database was used to identify 3,327 patients with non-metastatic invasive breast cancer who underwent surgery as a first intervention from January 2007 through December 2013. Clinicopathologic data were recorded including: age, grade, ER status, HER2 status, and pathologic stage. Pathologic stage was determined according to the 7th edition of the AJCC staging guidelines. ER status was recorded as the percentage of cells staining positive by immunohistochemistry (IHC). Prior to 2010, tumors were classified as ER positive if there was >10% staining. A cut-off of 1% was used for patients treated after 2010, consistent with the change in American Society of Clinical Oncology (ASCO) guidelines. HER2 status was defined as positive if 3+ on immunohistochemistry or gene amplification was shown on fluorescence in situ hybridization. A risk score was calculated by assigning one point for each of the following tumor characteristics: ER-negative status, HER2 negative status and grade 3. Univariate survival analyses according to AJCC stage (I, IIA, IIB, IIIA and IIIC) and risk score (0-3) were performed for DSS and OS using the Kaplan Meier method.

Results: Median follow-up time was 5.0 years (range, 0.1 to 8.8). Five year DSS for the entire cohort was 97.9% (95% CI: 97.3%-98.4%). The distribution in risk score in the entire cohort was: risk score 0=81 (2.4%), 1=2289 (68.8%), 2=683 (20.5%), and 3= (8.3%). As shown in the table, for all AJCC stages, the 5-yr DSS and 5-yr OS varied according to risk score (p<.01).

</table>
Conclusion: The current study demonstrates that incorporating the risk score with current AJCC staging significantly improves the ability to stratify breast cancer patients with respect to DSS and OS. We recommend that the risk score be incorporated into the forthcoming revision of the AJCC staging system.

**2016 San Antonio Breast Cancer Symposium**

**Publication Number:** P6-09-18

**Title:** Predictive factors of pathologic complete response to neoadjuvant chemotherapy in patients with Luminal HER2(-) local advanced breast cancer using the DMET microarray

Ruvalcaba-Limon E, Rodriguez-Cuevas S, Hidalgo-Miranda A, Villa-Romero A, Bautista-Piña V, Rebollar-Vega R, Fernandez-Lopez JC and Morales-Vasquez F. Breast Diseases Institute and Breast Cancer Fundation (IEM-FUCAM), Coyoacan, Mexico City, Mexico; Cancer Genomics Laboratory, National Genomics Institution, Tlalpan, Mexico City, Mexico and Faculty of Medicine, Autonomous National University of Mexico (UNAM), Mexico City, Mexico.

**Body: Introduction**

Patients with similar local advanced breast cancer (LABC) could respond different to neoadjuvant chemotherapy (NC). Luminal HER2(-) tumors have pathologic complete response (pCR) by 5-7%. Ki67, tumor grade and hormonal receptors, could be helpful but not enough to choose between NC vs. initial surgery. Response to drugs depends on enzymes involved in absorption, distribution, metabolism and elimination (ADME); the drug-metabolizing enzyme and transporter platform (DMET), could identify 1936 single nucleotide polymorphism (SNP) from 225 genes involved in ADME process.

**Objective**

To identify predictive factors to pCR in patients with Luminal HER2(-) LABC underwent NC, to distinguish wish patients could have a real benefit from NC.

**Material and Methods**

This is a prospective nested case control study (1:4) with LABC patients, pure invasive ductal carcinoma Luminal HER2(-) subtypes, and sequential NC (anthracyclines and taxanes). Cases were defined as patients with pCR (Residual Cancer Burden=0), and controls those without pCR. SNPs were evaluated from DNA of leucocytes using DMET microarrays by Affymetrix. Bivariate analyses were used as appropriate. Microarrays were processed by the DMET analyzer console. OR and 95%CI were used to test association between pCR and variables with a non-conditional logistic regression analysis; p value ≤0.05 was considered statistically significant (two-sided).

**Results**

From 2005 to 2014, of 3762 treated patients, 287 women met inclusion criteria. We included 117 patients, 21 cases and 96 controls. Patients with pCR were 5 years younger than controls (45.4 vs 49.4), have more grade-3 tumors, (66.7 vs 22.3%), more Luminal B subtypes (90.5 vs 64.6%), lower expression of estrogen receptor (60 vs 80%) and higher Ki67 expression (65 vs 12%), all with p≤0.05. No differences in toxicity existed between groups.

In an initial screening procedure, 13 SNPs were identified, but only 4 SNPs (4 genes) are known to participate in ADME of antineoplastic agents. All pCR cases did not have the C/C allelic variant in the rs2072671 SNP (CDA gene); while in rs1883322 SNP (PPARD gene) all had T/T variant

pCR= pathologic complete response

After logistic regression analysis, pCR predictive factors were the presence of grade-3 tumors OR=6.66 (95%CI=1.67-26.56), Ki67 ≥14% OR=15.45 (95%CI=1.71–138.86), premenopausal status OR=6.540 (95%CI=1.50–28.38) and A/A or A/G allele in rs7483 SNP (GSTM3 gene) OR=19.16 (95%CI=1.97–185.93).

Conclusions
Genetic variability encoded in the DMET-chip, could be helpful as a predictive factor of pCR in patients with Luminal HER2(-) LABC, but only in combination with other factors such as grade-3 tumors, elevated Ki67, and premenopausal status.
**Title:** Breast density change at 6 months is associated with change at 12 months as measured by fat-water decomposition MRI in women on tamoxifen

Ding J, Thompson PA A, Wertheim BC C, Roe DJ J, Marron MT T, Altbach MI I, Galons J-P, Wang F, Thomson CA A, Huang C and Stopeck A. Stony Brook University, Stony Brook, NY; Stony Brook Medicine, Stony Brook, NY and University of Arizona, Tucson, AZ.

**Body:** Objective: Tamoxifen (TAM) lowers breast cancer recurrence by 40-50% with evidence of individual variability in responsiveness. A ≥10% decrease in mammography-determined breast density (BD) after 12–18 months of TAM use has been associated with clinical benefit. Early determination of changes in BD may offer a strategy to tailor hormone therapy in non-responders; for responders, it may encourage adherence. Fat-water decomposition MRI (FWD-MRI) is an accurate and fast (< 5 minutes) method for measuring BD without ionizing radiation or contrast agent. Here, we examined whether change in FWD-MRI-derived BD predicts decrease in BD at earlier time points than observable with a 12-month measure of BD.

Methods: The study population included a subset of 44 pre- and post-menopausal women receiving TAM for treatment of early-stage breast cancer or prevention who were enrolled in a randomized, placebo-controlled trial of diindolylmethane. Eligibility for this analysis included participants with FWD-MRI scans at baseline, 6 and 12 months. Median time on TAM at baseline was 13 months (IQR, 5–26 months). All MRI images were acquired on a 1.5T GE Signa NV-CV/i scanner. Automated breast segmentation was performed using MATLAB software and validated against manual ROI drawings. MRI-based BD was calculated as the ratio of breast voxels with <80% apparent fat fraction (Fra80) over the entire breast, a measure previously shown by our group to be highly correlated with mammography-derived BD. For 40 participants, the unaffected, contralateral breast was analyzed. For 4 patients with two unaffected breasts, BD data from the left breast were analyzed. Change in BD was conservatively defined as > 2 times the test-retest variability of Fra80 (0.032). McNemar's test was used to test the association between change from baseline to 6 months and change from baseline to 12 months.

Results and Discussion: At 12 months, 15 (34%) participants had a decrease in BD, whereas 29 (66%) remained unchanged or increased. Of these 29, 28 also had no decrease at 6 months (specificity = 97%), and 9 of the 15 women who showed a decrease at 12 months had a decrease at 6 months (sensitivity = 60%; McNemar's test, P = 0.06). Conversely, for those women with a measured decrease in BD from baseline to 6 months, 9 of 10 had a measured decrease at 12 months. A study limitation is inclusion of participants on TAM for varying duration as the greatest change in BD likely would have occurred earlier. Ongoing efforts will focus on FWD-MRI for measures of change in BD in patients initiating TAM.

Conclusion: Use of the specified cut point would fail to detect a decrease in BD at 12 months in 40% of women. However, a decrease in BD from baseline to 6 months was highly associated with decrease from baseline to 12 months and in some women may be useful as an early biomarker of effect. Ongoing effort is needed to determine the impact of factors such as baseline BD, menopausal status, and time on TAM in misclassification of BD change using the 6-month measure.

Title: Clinical utility of PgR with various cutpoints using 3 commercial assays relative to 15yr survival

Kornaga EN N, Paterson AHG HG, Feng X, Morris DG G, Magliocco AM M and Klimowicz AC C. Translational Laboratories, Tom Baker Cancer Centre, Alberta Health Services, Calgary, AB, Canada; University of Calgaey, Calgary, AB, Canada; BC Cancer Agency, Vancouver Island Cancer Centre, University of British Columbia, Victoria, BC, Canada; Anatomic Pathology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL and Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT.

Body:

Introduction: Hormone receptors ER and PgR are routinely assessed by pathologists using immunohistochemical (IHC) assays to guide treatment decisions. Patients who are hormone receptor positive are offered hormonal therapy, such as tamoxifen, which improves survival. Although both ER and PgR are evaluated, ER is primarily utilized for patient management as the clinical utility of PgR has not been clearly established according to CAP/ASCO guidelines. Notably, a meta-analysis by the Early Breast Cancer Trialists' Collaborative Group reported that PgR status was not significantly predictive of response to adjuvant tamoxifen, suggesting that PgR may not have a role in breast cancer management. More recently, the level of PgR expression has been hypothesized to be important in predicting response to endocrine therapy, where high PgR levels are more indicative of estrogen-dependent tumors, and thus more sensitive to hormonal treatment.

In this study, we evaluate PgR expression using the current cut-point (Allred>2), as well as an optimized cut-point (Allred>5 to identify PgR high tumors), with regards to 15yr disease-free survival (DFS) and disease-specific overall survival (DSOS) using three commercially available ready-to-use (RTU) IHC assays from Dako, Leica and Ventana in an ER+ cohort.

Methods:
The Calgary tamoxifen breast cancer cohort (Calgary cohort) is a TMA series that includes 532 patients diagnosed with primary breast cancer (1985-2000) who received tamoxifen treatment regardless of hormone receptor status. All RTU assays followed vendor recommended protocols. Specific details regarding the cohort and IHC assays have been previously described (Kornaga et al. Mod Path 2016). All analyses were performed using Stata 12, and multivariate models were adjusted for age, grade, size, lymph node and HER2 status. ER status was defined by the corresponding vendor specific IHC assay.

Results:
Multivariate models looking at DFS are presented in Table 1. None of the assays were significant when the clinical cut-point was used; however, when the optimized cut-point was investigated, all assays found high expression of PgR was significantly associated with improved DFS. Table 2 presents the multivariate models looking at DSOS. Similarly, PgR was not found to be associated with improved DSOS using the current cut-point. When the optimized cut-point was examined, Dako and Leica assays were significantly associated with improved DSOS: The Ventana assay did not reach significance.

Conclusions:
High PgR expression (Allred>5) is associated with improved 15yr DFS and DSOS in a tamoxifen-treated cohort, where PgR positivity defined using current guidelines is not associated with improved DFS or DSOS. Additionally, differences were noted between the vendor RTU assays with regards to DSOS.
Title: Prognostic impact of metastatic pattern in stage IV breast cancer at initial diagnosis

Leone BA A, Vallejo CT T, Romero AO O, Machiavelli MR R, Perez JE E, Leone J and Leone JP P. Grupo Oncológico Cooperativo del Sur (GOCS), Neuquén, Neuquén, Argentina; Grupo Oncológico Cooperativo del Sur (GOCS), Bahía Blanca, Buenos Aires, Argentina and University of Iowa Holden Comprehensive Cancer Center, Iowa City, IA.

Background: Stage IV breast cancer at initial diagnosis (BCID) can be recognized in approximately 5% of all breast neoplasms. Clinical outcomes of these patients (pts) are highly variable and depend on tumor biology and pt characteristics. The prognostic influence of metastatic pattern (MP) at initial presentation and factors associated with specific organ involvement have been understudied. The primary aim of this study was to analyze the influence of MP compared with other biologic and clinical factors in the survival of pts with stage IV BCID. The secondary aim was to evaluate factors associated with specific sites of metastatic spread.

Methods: We evaluated women with microscopically confirmed stage IV BCID with known metastatic sites, reported to the Surveillance, Epidemiology and End Results (SEER) 18 registries program from 2010 to 2013. Pts with other primary tumor either before or after breast cancer were excluded. MP was categorized as bone only, visceral (lung, liver or brain), bone and visceral and other. Pt characteristics were compared between MP. Univariate and multivariate analyses determined the effects of each variable on overall survival (OS). Logistic regression examined factors associated with specific sites of metastases.

Results: We included 9143 pts. Median age was 61 years (range 19-102). Median OS for the entire cohort was 28 months (95% CI 27-29 months). At diagnosis, bone only metastases represented 37.5% of pts, visceral 21.9%, bone and visceral 28.8% and other 11.9%. Median OS by MP was: bone only 38 months, visceral 21 months, bone and visceral 19 months and other 33 months (p<0.0001). Bone was the most common site of metastases (66.2%), followed by lung (30.5%), liver (26.2%) and brain (7.4%). Pts with visceral metastases were more often black race, had higher grade, less likely to be lobular histology and more likely to be triple negative (TN) (all p<0.0001). Univariate analysis showed that older age, black race, grade 3/4 tumors, TN pts, bone and visceral MP, higher number of metastatic sites and unmarried pts had worse prognosis (all p<0.0001). In multivariate analysis, older age (HR 1.9; p<0.001), black race (HR 1.17; p=0.002), grade 3/4 tumors (HR 1.6; p<0.001), TN subtype (HR 2.24; p<0.001), bone and visceral MP (HR 2.07, p<0.001) and unmarried pts (HR 1.25; p<0.001) had significantly shorter OS. In adjusted logistic regression, as compared with ER/PR+/HER2- tumors, TN and ER/PR-/HER2+ had higher odds of brain, liver, lung and other metastases (all p<0.05). ER/PR+/HER2+ had higher odds of liver metastases (p<0.001). All three subtypes had lower odds of bone metastases (p<0.001).

Conclusions: To our knowledge, this is the largest study of MP in stage IV BCID. There were substantial differences in prognosis according to MP, bone only was the most common MP and had the best OS, whereas bone and visceral MP had the worst prognosis. We observed significant differences in pt characteristics according to MP. Independent predictors of OS included age at diagnosis, race, marital status, tumor grade, tumor subtype and MP. There was a clear influence of tumor subtype among other factors on specific sites of metastases. Our study identified several prognostic factors that could guide therapy selection in treatment naïve pts.
Title: Detecting high mutational load ER+ breast cancer patients through Foundation One cancer gene panel mutations

Raska P, Abraham J and Budd T. Taussig Cancer Institute, Cleveland Clinic Foundation, Cleveland, OH.

Body: Background:
Cancer gene panels such as Foundation One are widely used clinically for aiding with cancer treatment decision-making since single point mutations in important genes and gene pathways in the tumor can point to tumor susceptibility that can be targeted with specific drugs. Tumor mutational load has more recently been proposed as a useful prognostic factor and indicator of clinical benefit in treatment with PD-1 and CTLA-4 blockade therapy. Breast cancer estrogen receptor positive patients (ER+) in particular appear to have a subset of high mutational load patients that could benefit if identified. However whole exome sequencing needed to directly measure mutational load is not yet widely available as a clinical tool. In this study we evaluate the predictive value of Foundation One cancer gene panel mutations for estimating tumor genome-wide mutational load and its use in identifying a clinically meaningful subset of breast cancer patients.

Methods:
The Cancer Genome Atlas breast cancer sequencing data on 569 ER+ patients was used to establish mutational load distribution. ER+ patients were divided into low mutational load and high mutational load groups according to 3 criteria: mean mutational load, the point of inflection in the mutational load distribution and the mutational load that optimally separates groups in terms of survival. Foundation One (FO) mutational load was then calculated as the number of mutations present within the 314 genes queried by the panel. FO mutational load was used to predict whether patients fell into the low or high mutational load groups found through analysis of the full exome data. Receiver Operating Characteristic (ROC) curves were constructed and optimal values for specificity and sensitivity of the FO mutational load classification were found.

Results:
Mean mutational load for ER+ patients was found to be 57 mutations, the point of inflection of the mutational load distribution was established at 100 mutations, and the number of mutations that best separated groups in terms of survival was 160, (HR = 6.6, p-value=0.004). FO mutational load was found to be a good predictor for the low and high classifications established by all three criteria, with areas under the curve of 0.74, 0.91 and 0.945 respectively. The optimal predictive value of the FO mutational load classification was found at 5 mutations as the cut-off, with 94.2% specificity and 88% sensitivity for predicting groups defined by survival and 95% specificity and 71% sensitivity for those defined by the mean.

Conclusion:
The Foundation One cancer gene panel can be used to effectively identify a clinically meaningful subgroup of ER+ patients with high mutational load. These patients may benefit from targeted treatments such as PD-1 inhibitors being offered through clinical trials. The compromise in sensitivity that results from the reduction in number of genes queried by a panel means an important proportion of patients with high mutational load will be missed but this still translates to a large improvement in the identification of these patients given the wide availability of gene panels in the clinic. Basic and clinical follow-up studies need to take place to clinically validate the high mutational load ER+ patient subgroup.
Title: \( \text{SET}_{\text{ER/PR}} \) - A robust 18-gene predictor of sensitivity to endocrine therapy in metastatic breast cancer

Body: Rationale: A robust index for gene expression related to activity of estrogen (ESR1) and progesterone (PGR) receptors could predict sensitivity to endocrine therapy in metastatic breast cancer.

Methods: Transcripts correlated with ESR1 and PGR expression in 389 hormone receptor-positive breast cancer samples (Affymetrix U133A microarrays) were ranked for reliability according to their pre-analytical (intratumoral heterogeneity, biopsy type) and analytical reproducibility. Eighteen target and ten reference genes were selected and summarized as the \( \text{SET}_{\text{ER/PR}} \) index. The \( \text{SET}_{\text{ER/PR}} \) index was evaluated in a different set of 140 biopsies from distant metastases of hormone receptor-positive and HER2-negative (HR+/HER2-) breast cancer, and in additional pre-analytical and analytical sample cohorts. Thereafter, \( \text{SET}_{\text{ER/PR}} \) was translated to a customized format for application to formalin-fixed and paraffin-embedded (FFPE) sections.

Results: Higher \( \text{SET}_{\text{ER/PR}} \) in a metastasis was associated with longer progression-free survival (PFS, 9 vs. 2 months) and overall survival (OS, 50 vs. 19 months) following endocrine therapy in the cohort with metastatic breast cancer (MBC) and relapsed disease (n=79), so a cut point was defined in that cohort. \( \text{SET}_{\text{ER/PR}} \) was also significantly associated with PFS after adjusting for PR status of the metastasis, presence of visceral metastases, number of previous relapse events, and clinical history of previous sensitivity to endocrine therapy (HR 0.485, 95%CI 0.265 – 0.889, p = 0.019). Technically, \( \text{SET}_{\text{ER/PR}} \) was highly reproducible under different pre-analytical and analytical conditions, including host organ contamination. The translated \( \text{SET}_{\text{ER/PR}} \) assay used a single 10 µM FFPE tissue section, did not require RNA purification, and represented the microarray results from matched fresh samples with excellent agreement (correlation = 0.980, n = 31).

Conclusion: The \( \text{SET}_{\text{ER/PR}} \) index is a new biomarker to predict PFS and OS for patients with HR+/HER2- MBC who receive endocrine therapy. The assay is applicable to FFPE tissue sections from small biopsies of metastases. Additional independent (blinded) validation studies will be necessary to confirm these results.
**Title:** Vitamin D level impacts odds of pathologic complete response following neoadjuvant therapy in operable breast cancer

**Body:**

**Introduction:**
Pathologic complete response (pCR) following neoadjuvant systemic chemotherapy (NAC) serves as a measure of tumor responsiveness and is a recognized surrogate for improved long-term outcomes. Some, but not all, studies have found a positive association between vitamin D (VD) and disease-free survival. We investigated if VD at diagnosis or during chemotherapy impacts pCR following neoadjuvant chemotherapy for operable breast cancer.

**Methods:**
Patients from Iowa were eligible if they were enrolled in one of two Iowa registries and had serum from before or during NAC tested for VD. French patients enrolled in a previous study of the impact of NAC on vitamin D and bone metabolism were considered for this study. VD deficiency was defined as <20 ng/ml. pCR was defined as no residual invasive disease in breast and lymph nodes. Firth-penalized logistic regression multivariable model was used.

**Results:**
The final cohort included 144 women. 84.7% of VD levels were obtained before initiation of chemotherapy. There was no difference between the French and Iowa cohorts with regard to age ($p=0.20$), clinical stage ($p=0.22$), disease receptor status (HER2+ [Hormone receptor (HR)+ or HR-], HR+/HER2-, and Triple Negative) ($p=0.32$) and rate of pCR ($p=0.34$). French women had lower body mass index (mean 24.8 vs 28.8, $p<0.01$), lower VD levels (mean 21.5 vs 27.5, $p<0.01$) and underwent lumpectomy instead of mastectomy more frequently (75.3% vs 47.8%, $p<0.01$) than Iowa women. Only pCR differed between the VD sufficient and deficient groups (Table 1). In multivariate analysis, after adjusting for the effects of cohort, clinical stage, and disease type by receptor status, VD deficiency put a woman at 2.68 times increased odds of not attaining a pCR (95%CI: 1.12-6.41, $p=0.03$) (Table 2). This variable remained significant with VD deficiency defined as <30 ng/ml and when considering this variable continuously.

**Conclusion:**
In this retrospective cohort, VD level before or during NAC was associated with pCR. Prospective trials could elucidate if maintaining VD levels during NAC, a highly modifiable variable, can be utilized to improve cancer outcomes in addition to benefiting other established health outcomes.

Title: Circulating tumor cell clusters-associated gene plakoglobin is a novel prognostic predictor in patients with breast cancer

Goto W, Kashiwagi S, Asano Y, Takada K, Takashima T, Morisaki T, Noda S, Onoda N, Ohsawa M, Hirakawa K and Ohira M. Osaka City University Graduate School of Medicine, Osaka, Japan

Body: Background: Accumulating evidence shows that circulating tumor cells (CTC) are linked to metastatic relapse and are regarded as a prognostic marker for human cancer. It was reported that CTC clusters (CTCc) have more metastatic potential than single CTC. Lately, studies also show that the high expression of plakoglobin, a cell adhesion protein, within the primary tumor are positively associated with CTCc in breast cancer patients. In addition, it is thought that insufficient expression of plakoglobin could promote epithelial-mesenchymal transition (EMT). In this study, we investigated the correlation between plakoglobin expression and survival of breast cancer.

Materials and Methods: A total of 126 patients with resectable early-stage breast cancer were treated with neoadjuvant chemotherapy (NAC). All patients received a standardized protocol of NAC consisting of four courses of FEC100 (500 mg/m² fluorouracil, 100 mg/m² epirubicin, and 500 mg/m² cyclophosphamide) every 3 weeks, followed by 12 courses of 80 mg/m² paclitaxel administered weekly. The expression of plakoglobin were identified by immunohistochemical staining properties in cell membrane. Staining with plakoglobin (clone 4C12) was scored according to the percentage of cells that stained positively: low, 0-25%; medium, 26-75%; high, >75%. We investigated the correlation between the plakoglobin expression in primary tumor specimen and clinical outcomes including overall-survival (OS), disease-free-survival (DFS), distant-metastasis-free-survival (DMFS), the efficacy of NAC. And we examined the relation between the expression of plakoglobin and E-cadherin, EMT marker.

Results: The patient with high plakoglobin expression had significantly worse OS (p=0.021, log-rank) and DFS (p=0.015, log-rank), DMFS (p=0.040, log-rank). And the plakoglobin expression had no correlation with pathological complete response (pCR) rate (p=0.596). Also, there was not a statistically significant relationship between the plakoglobin expression and other clinicopathological parameters including tumor size (p=0.708), lymph node status (p=0.479), subtype (p=0.413), nuclear grade (p=0.642), Ki67 (p=0.202), tumor infiltrating lymphocytes (p=0.828). On univariate analysis with respect to distal metastasis, high plakoglobin expression showed worse prognosis than low plakoglobin expression (p=0.013, hazard ratio=4.221). And multivariate analysis found the same result (p=0.015, hazard ratio=4.070). In addition, there was a significant relationship between the expression of plakoglobin and E-cadherin (p=0.023).

Conclusions: Plakoglobin expression is an independent prognostic factor in the patients with breast cancer; particularly for DMFS, and this mechanism related to EMT.
Title: Effect of race on triple negative breast cancer outcomes

Mosquera C, Amin R and Wong JH H. East Carolina University, Brody School of Medicine, Greenville, NC.

Body: Background: African American (AA) women and patients with Triple Negative Breast Cancer (TNBC) have poor outcomes. It is unclear whether these worse outcomes in AA women are due to a higher frequency of TNBC in AA women. The purpose of our study was to determine difference in outcomes between AA and Caucasian (CA) female with TNBC.

Methods: A retrospective study of women diagnosed with ER, PR and HER2 (1+) negative breast cancer between January 1/2001 and December 31/2013 at Vidant Medical Center (East Carolina University) in Greenville, North Carolina was undertaken. Patient demographics and tumor characteristics were analyzed to determine impact on overall survival.

Results: In our institution, 4,434 women were diagnosed with breast cancer in this study period, of which 378 had TNBC. Our TNBC population was predominantly AA (53%). AA patients were younger (54.1 years vs 58.7 years, p=0.005), less often postmenopausal (62.6% vs 74.5%, p=0.013), more likely to have Medicaid (24.3% vs 7.9%, p <0.001), and to have received chemotherapy (80% vs 69%, p=0.017) compared to CA women. There was no difference in stage at diagnosis between AA and CA patients (p=0.12). By univariate analysis, improved survival in TNBC was associated with non-Medicaid status (p=0.01), early stage at diagnosis (p=0.001), N stage (<0.001), and tumor grade (p<0.001). A Cox regression analysis demonstrated that only insurance status (p=0.007) and N Stage (p=0.01) predicted outcomes in TNBC. Survival in TNBC was not affected by race (p=0.7).

Conclusions: Poorer outcomes in AA women cannot be attributed to the higher frequency of TNBC. Improved access to healthcare, with broader insurance coverage, may help minimize disparities in outcome by diagnosing TNBC at an earlier stage.
The EA2clin test significantly predicts response and survival in both pre and post-menopausal women with ER-positive breast cancers

**Body:** Background

Identifying breast cancer (BC) patients likely to recur on endocrine therapy (ET) is a challenge. Several methods and tests based on clinical parameters and multi-gene or protein classifiers have been shown to predict those likely to recur. Tests that incorporate baseline and on-treatment markers are likely to be more accurate than tests based on baseline characteristics alone. 4 genes were identified by microarray that predicted for to ET: 2 at diagnosis and 2 at 14 days. The EndoAdjuvant2 (EA2) test uses 2 of these genes: IL6ST at diagnosis and on-treatment MCM4 at transcript level or by graded immunohistochemistry (IHC). The aim of this study was to compare EA2 with currently used clinical parameters in 4 different cohorts of pre and postmenopausal women.

**Patients**

The cohorts are (1) 73 post-menopausal women (PMW) with ER+ BC treated with neoadjuvant letrozole (L) then surgery, (2) 39 PMW with ER+ BC treated with neoadjuvant anastrozole (A) then surgery, (3) 108 PMW who received 2-weeks of A or L prior to surgery (4) 25 preMW with ER+ BC who received one 750mg dose of fulvestrant prior to surgery. All had adjuvant ET and 5-10 years follow up. Neoadjuvant response was assessed by periodic 3D ultrasound.

**Results**

The 4 gene assay had 96% (training; cohort 1) and 93% (validation; cohort 2) accuracy of response prediction to neoadjuvant L or A. In cohort 1, clinical parameters were available. On univariate regression analysis intrinsic subtype (luminal A/B; defined using PAM50) (P=0.002), histological grade (P=0.033) and HER2 status (P=0.001) significantly predicted clinical response. EA2 out-performed all these in both univariate (P<0.0001) and multivariate regression analysis (P<0.0001). The final model only retained EA2 as significant. Node status, tumour size and PR expression were not associated with response to endocrine therapy.

EA2 predicted recurrence free in cohorts 1 and 3 combined: RFS (P=0.0004, HR=17.63 95%CI: 4.95-17.6), BCSS (P=0.0007, HR=16.60: 3.36-45.7). The Nottingham Prognostic Index (NPI) also predicted RFS (P=0.0002) and BCSS (P=0.0017) in univariate analysis but in the Cox analysis NPI was not found to be significant, although in the low risk group there were only 1/46 events compared to 19/62 in the moderate/high risk group. Histological grade (P<0.0001), Ki67 (%) (P=0.02) and tumour size (P=0.007) were significant on univariate analysis. In the Cox regression analysis, only EA2 (P=0.012) and histological grade (P=0.016) were significant predictors of RFS and BCSS. Using EA2 and NPI together a high and low risk subgroup could be identified. In the Cox regression analysis, combined EA2 plus NPI (EA2clin) outperformed both NPI and EA2 alone. EA2clin was validated in cohort 4 and predicted RFS (P=0.002, HR=8.43 95%CI: 2.18-32.53) and BCSS (P=0.008, HR=10.95 95%CI: 1.48-64.9).

**Conclusions**

- EA2 predicts clinical response, RFS and BCSS
- EA2clin combines NPI and EA2, outperforms either alone and predicts outcome in a new validation cohort of preMW treated with Fulvestrant
- EA2clin works in preM and PM women regardless of ET.
Title: Prognostic impact of the inclusion of uPA/PAI-1 in ER+/Her2- pN0 early breast cancer adjuvant treatments decision-making

Body: Purpose: Intermediate-risk early breast cancer (EBC) is a heterogeneous group in which adjuvant chemotherapy decision prove to be difficult. Clinical and pathological criteria might be insufficient to determine the best therapeutic options for patients, and validated biomarkers are urgently needed to help decision making, such as the LOE-I uPA/PAI-1 biomarker. The aim of this study is to evaluate the clinical outcome of a large, unselected, ER+/HER2- pN0 EBC cohort of patients in whom the routine clinical decision process included a prospective uPA/PAI-1 determination.

Methods: This monocentric retrospective study included 520 ER+/HER2- pN0/M0 EBC patients who had curative surgery in our center between 2006 and 2011. Adjuvant therapeutic strategy was decided based on clinico-pathological data, altogether with a routine prospective determination of uPA/PAI-1 tumor levels. We evaluated the correlation between uPA/PAI-1 levels, classical clinico-pathological variables and the patient's outcome (relapse free survival, RFS; overall survival, OS).

Results: Median age was 54 years (range 27-85). 75% of tumors were classified T1, 25% T2 and above. We found 80.8% of ductal carcinomas, 12.3% of lobular carcinomas and 6.9% of other histological types. SBR grade 1-2 represented 82.5% of our cohort versus 17.5% of grade 3. Mitotic count was <10 in 63.5% of cases, and ≥10 in 36.5%. Peri-tumoral invasion (PVI) was seen in 17% of tumors. Progesterone receptors (PR) were positive in 79.6% of cases. Median follow-up was 5.4 years. 5 and 10 years RFS were respectively 95% and 89% (n=33 local or metastatic relapse). 5 year OS was 96.3%. We found 40% of low uPA/PAI-1 levels, and 60% of high uPA and/or PAI-1 levels. By using uPA/PAI-1 levels in our adjuvant treatment decision-making, 75% of patients with low uPA/PAI-1 levels did not received chemotherapy and 60% of patients with high uPA and/or PAI-1 levels received chemotherapy. 98.3% of our patients received endocrine therapy as adjuvant treatment for at least 5 years. No statistical significant correlation was found between uPA/PAI-1 levels and RFS (p=0.3) or OS (p=0.28). In univariate analysis, tumor size (p=0.048; p=0.0694), histological grade (p=0.007; p=0.0142), PR status (p=0.001; p=0.0002) and mitotic count (p=0.0001; p=0.0001) were statistically correlated with RFS and OS, respectively. Using cox regression model, PR status (p<0.003) and mitotic count (p<0.001) appeared to be strongly correlated with RFS. No changes in significant variables were seen when the analyses were restricted to the grade 2 subgroup (n=339).

Conclusion: The individualization of patients' treatment using uPA/PAI-1 tumor levels allows the reversion of the well-known poor prognostic impact of high uPA/PAI-1 levels and strongly support the use of this LOE-I biomarker in clinical practice. PR status and mitotic activity remains independent major prognostic factors in optimally treated patients. The evaluation of the additional impact of multigene signature in this setting needs to be performed. Longer 10-years follow-up needs to be done in this ER+/HER2- subgroup, particularly to evaluate the risk of late relapse after endocrine therapy.

Title: Clinicopathological characteristics and survival outcomes in invasive papillary carcinoma of the breast: A population-based study

Zheng Y-Z, Hu X and Shao Z-M. Key Laboratory of Breast Cancer in Shanghai, Fudan University Shanghai Cancer Center, Shanghai, China; Shanghai Medical College, Fudan University, Shanghai, China and Institute of Biomedical Science, Fudan University, Shanghai, China.

Body: Background
Invasive papillary carcinoma (IPC) is defined as having papillary architecture in >90% of the invasive component. The overall incidence of IPC is low, accounting for less than 1-2% of all newly diagnosed cases of invasive breast cancer. Limited data are available that contribute to a comprehensive summarization of the clinicopathological characteristics and prognostic factors that are associated with IPC. We aimed to determine the clinicopathological characteristics and prognostic factors of IPC in a large population and help physicians to acquire a better understanding of the disease and make better informed therapeutic decisions.

Methods
We identified 233,171 female patients in the Surveillance, Epidemiology, and End Results (SEER) database who had IPC (n = 524) or infiltrating ductal carcinoma (IDC) (n = 232,647). The demographics and tumour and treatment characteristics of IPC were compared to those of IDC. A Cox proportional hazards model was used to investigate the effects of baseline characteristics on disease-specific survival (DSS). We performed a 1:1 (IPC: IDC) matched case-control analysis using the propensity score-matching method. A forest plot of hazard ratios (HRs) that was used to illustrate the exploratory subgroup analyses.

Results
Generally, IPCs occurred in older women (≥50 years old) and presented with smaller sizes, lower grades, higher rates of oestrogen receptor (ER) and progesterone receptor (PR) positivity, and reduced lymph node (LN) involvement and were less likely to be treated with mastectomy than patients with IDC. The five-year DSS rates were significantly better in IPC than in IDC (97.5% vs. 93%, respectively; P < 0.001). In the multivariate analysis, patients with IPC showed a DSS that was similar to that of IDC (HR = 0.556, 95% confidence interval 0.289–1.070, P = 0.079). No significant difference was observed in DSS between matched IPC and IDC groups (P = 0.085). Subgroup analyses suggested that differences in outcomes may be partially explained by differences in tumour grade, LN status, and ER and PR status between the 2 groups. Most IPCs are ER-positive tumours. When the analysis was limited to 178,755 ER-positive IPC and IDC patients (457 IPCs and 178,298 IDCs), similar results were observed.

Conclusions
This study is currently the largest analysis of IPC. We investigated a large cohort of patients with IPC and found that this rare tumour type presents unique clinicopathological characteristics and is associated with a higher rate of breast-conserving surgery and favourable prognoses than are observed in the overall IDC population. However, this advantage was diminished after we adjusted for demographic and clinicopathological factors. Therefore, patients diagnosed with this rare variant should be made aware that its biological features are not as favourable as once thought. Therapeutic decisions should not be made based solely on this rare entity and evidence-based treatment guidelines should be strictly followed. Improving our understanding of the clinical and biological features of IPC may lead to more individualized and tailored therapies for breast cancer patients.
Title: Factors influencing survival among patients with HER2-positive metastatic breast cancer treated with Trastuzumab

Blanchette PS S, Desautels DN N, Pond G, Bartlett JMS MS, Nofech-Mozes S, Yaffe M and Pritchard KI I. Sunnybrook Odette Cancer Centre, Toronto, ON, Canada; Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada; McMaster University, Hamilton, ON, Canada; Ontario Institute for Cancer Research, Toronto, ON, Canada; Sunnybrook Health Sciences Centre, Toronto, ON, Canada and Sunnybrook Research Institute, Toronto, ON, Canada.

Body: Background: We have limited capability to predict survival among patients treated for metastatic HER2+ breast cancer. Individual patient survival varies and further research is warranted to identify significant prognostic and predictive factors influencing overall survival (OS).

Methods: We identified HER2+ metastatic breast cancer patients receiving trastuzumab (T) at the Sunnybrook Odette Cancer Centre (SOC) from 1999-2013 through a Cancer Care Ontario Registry (n=256) and selected patients with pathology also available at SOC (n=154). A retrospective chart review was completed documenting clinical, pathologic, laboratory and survival outcomes. OS was defined as date of 1st T therapy to death. The Kaplan-Meier method was used to estimate time-to-event outcomes. Cox proportional hazards regression models and log-rank tests were used to identify prognostic factors for overall survival (OS). Logarithmic transformations were performed for statistical purposes. Multivariable models were constructed including known prognostic factors: 1) number of visceral metastatic sites and 2) CNS metastasis. After adjusting for these two factors, stepwise selection was used to create an optimal model for additional factors. Analyses were two-sided and statistical significance was defined at the p=0.05 level.

Results: Cohort characteristics: mean age was 55 (SD: 13 years), ≥2 sites of visceral metastasis: 45%, CNS metastasis: 7%, ER positive: 53%. Median OS for the cohort was 24 months (95% CI: 21-33). Clinical factors recorded at metastatic presentation such as the presence of a visceral metastasis, having multiple sites of visceral metastasis and CNS metastasis were prognostic for overall survival in univariate models (p<0.05). ER/PR status was not of significance (p>0.05). Laboratory measures such as the neutrophil to lymphocyte ratio (NLR), platelet to lymphocyte ratio (PLR) and alkaline phosphatase (ALP) were of significance in univariate models (p=<0.05). The multivariable model identified older age (HR=1.18 / decade, 95% CI=1.02-1.37, p=0.030), higher PLR (HR=1.75 / log-unit, 95% CI=1.25-2.46, p=0.001), increased ALP (HR=1.87 / log-unit, 95% CI=1.41-2.49, p<0.001) and ER positivity (HR=0.63, 95% CI=0.42-0.96, p=0.032), as significant prognostic factors in addition to the presence of CNS metastasis (HR=3.19, 95% CI=1.59-6.38, p=0.001) and two or more metastatic sites (HR=2.10, 95% CI=1.19-3.70, p=0.010).

Conclusion: Our results have identified a number of prognostic factors influencing survival among patient with HER2+ breast cancer treated with T. Age, ALP, PLR and ER status were identified as significant prognostic factors after adjusting for presence of CNS metastasis and number of metastatic sites. Further study of PLR as a prognostic and predictive factor is warranted.
2016 San Antonio Breast Cancer Symposium

Title: Study of oncotype DX® recurrent score in bilateral synchronous primary invasive breast cancer

Body: Background: The 21-gene Oncotype Dx® Recurrence Score (RS) is routinely used to assess the risk of distant recurrence and benefit for adding chemotherapy in the treatment of ER positive HER2 negative early stage breast cancer. Among patients diagnosed with bilateral primary breast cancer there is limited information on the utilization of RS for each primary cancer. In this study, we evaluate the concordance of RS in bilateral breast cancer, and the value of testing both primary cancers in patients diagnosed with synchronous bilateral breast cancer

Materials & Methods: This is an IRB approved retrospective study. From 2007 to present, we identified 158 patients with synchronous (within 6 months) bilateral primary breast cancer in our Institutional databases. In this dataset, there were 36 patients who had early stage ER positive, and Her-2 negative bilateral invasive cancer, and for whom the 21-gene Oncotype Dx® RS test was ordered. We excluded patients with bilateral invasive cancer who did not have Oncotype Dx® RS test performed (n=20), patients with bilateral in-situ cancers (n=15), patients with unilateral invasive with contralateral in-situ cancer (n= 64), and patients with locally advanced stage of one or both primary invasive cancers (n=23). In this study, RS score was scored low risk <18, intermediate 18-30, and high risk >31. The RS for bilateral primary cancers was noted as concordant if the 2 values were in the same risk category and discordant when 2 values represented different risk category.

Results: Among the 36 patients, 19 patients had Oncotype Dx® RS tested for one primary cancer, and 17 patients had testing from bilateral primary cancers. Patients median age is 55 years (range: 44 years to 75 years), and invasive duct cell was the most common histology. The RS distribution of low risk, intermediate risk and high risk was 60 %, 30% and 10%, respectively. Further, evaluation of the 17 patients in whom the RS score from bilateral invasive breast cancers was obtained, we noted that the RS was concordant in 11 patients (64.7%), and discordant in 6 patients (35.3%). In 4/6 patients the discordance was between low and intermediate risk, and in 2/6 patients it was between low and high risk. Clinical variables including age, histology, receptor positivity, and grade were not predictive of the rate of RS concordance between the 2 primary cancers.

Conclusion: The significant rate of discordance observed in our study suggests that the 21-gene RS for each invasive primary breast cancer should be routinely obtained in patients presenting with bilateral breast cancers. Albeit synchronous events, the individual risk assessment of each primary cancer would help guide risk-tailored personalized cancer treatment.
Title: The association of breast cancer subtype and breast cancer survival with parity and time since last birth

Body: Background: Pregnancy affects breast cancer risk but its influence on breast cancer subtype and prognosis remains controversial. We studied the effect of parity and time since last birth on breast cancer subtype and outcome in women aged ≤50 years at diagnosis.

Patients and Methods: A retrospective multivariate cohort study including all premenopausal women aged ≤50 years (N=1306) at diagnosis and primarily treated with surgery (N=1176) or neo-adjuvant chemotherapy (N=130) at University Hospitals Leuven (Jan. 2000 – Dec. 2009); local and systemic therapies were consistent with guidelines when treated. Tumor subtypes were defined by tumor grade and receptor expression for estrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor receptor 2 (HER-2) amplification; ER+PR+/-HER-2- cases were Luminal A- like if grade 1-2 and Luminal B like if grade 3; HER-2+ cases were Luminal HER-2 if ER+ and HER-2 like if ER-; triple negative breast cancer (TNBC) were ER-PR-HER-2-. Outcome endpoints were breast cancer subtype, disease free (DFS) and distant disease free survival (DDFS) by parity and in parous women comparing short (<5 years) versus long (≥5 years) time since last birth. Statistics used were Cox proportional hazard model. Results were corrected for age at diagnosis, tumor size, lymph node status and tumor subtype.

Results: Breast cancer subtypes didn't differ between nulliparous and parous women but subtypes differed significantly in parous women by time interval since last birth (p<0.001). Breast cancers within 5 years of last birth were proportionally more likely TNBC and HER-2 like compared to Luminal A (p=0.026 and p=0.003 respectively) than breast cancers ≥5 years after last birth even when corrected for age at diagnosis. After a mean follow-up period of 10 years, parous women had a better DFS compared to nulliparous women (DFS: HR 0.754; CI 0.593-0.959; p=0.021) but after correction for known prognostic factors, only a trend remained (HR 0.783; CI 0.611-1.004; p=0.054). In parous women, those with a longer time interval since last birth had a better DFS than women with a recent pregnancy (HR 0.965; CI 0.948-0.982; p<0.001). However, after correction for known prognostic factors, this association was completely attenuated (HR 0.997; CI 0.972-1.023; p=0.828). Comparable results were seen for DDFS.

Conclusion: After correction for age at diagnosis, parity does not but recent birth does affect breast cancer subtype. Such tumors are proportionally more likely ER-negative namely TNBC and HER-2 like. We observed a trend for better DFS for parous women. The prognostic value of time since last birth is mostly due to tumor characteristics and age at time of diagnosis.
**Title:** CASCADE study: Rapid survival decline per treatment line in metastatic breast cancer

García J, De La Haba J, Servitja S, Santaballa A, De Paz L, Plata Y, Garau I, Florián J, Chacón JI, García P, Zamora P, Orcajo L, Rodríguez-Villanueva J, San José B, Martínez E and Seguí MA. Complejo Hospitalario, Orense, Spain; Hospital Reina Sofia, Córdoba, Spain; Hospital del Mar, Barcelona, Spain; Hospital La Fe, Valencia, Spain; Hospital Arquitecto Marcide, Ferrol, A Coruña, Spain; Hospital Médico Quirúrgico, Jaén, Spain; Hospital Son Llàtzer, Son Ferriol, Palma de Mallorca, Spain; Hospital de Barbastro, Barbastro, Huesca, Spain; Hospital Virgen de la Salud, Toledo, Spain; Hospital San Agustín, Avilés, Asturias, Spain; Hospital La Paz, Madrid, Spain; EISAI Pharmaceuticals, Madrid, Spain; OXON Epidemiology, Madrid, Spain; Hospital Provincial, Castellón de la Plana, Castellón, Spain and Hospital Parc Taulí, Sabadell, Barcelona, Spain.

**Body:**

**BACKGROUND:** Appraisal of the impact that current therapeutic strategies of advanced breast cancer (ABC) have on the survival expectancy, is vital to understand the prognosis of this disease. This entails assessing simultaneously the tumour phenotype and the therapeutic approach used per line of treatment. CASCADE is an epidemiological, retrospective, multicenter study aimed to retrieve demographic and clinical information from a representative cohort of ABC patients treated within the Spanish National Healthcare System.

**MATERIAL AND METHODS:** 13 Spanish public hospitals serving nearly 5M inhabitants (~10% of the national population) identified 422 ABC patients between 01/2007 and 12/2008 who received active treatment for their disease and were followed until death, lost to follow-up, or until December 2013. Overall Survival (OS) was analysed per tumour immunotype and treatment line from the diagnosis until a minimum of 10 patients were still evaluable. OS resulting from the different therapeutic approaches per line was also revised. Data collected included demographical, pathological, diagnostic, and therapeutic information for the entire follow-up. Descriptive statistics were applied (Methods previously described in SABCS 2015 Poster P3-07-39).

**RESULTS:**Remarkably, by the 2nd line of treatment, on average, one third of the OS is already gone. Tumour type imposes clear differences in this decline rate. As expected, triple-negative patients have the shortest survival expectancy at diagnosis, but their OS attrition rate is the slowest compared to the other subgroups (Table 1).

OS time derived from the five major therapeutic approaches used at any given line, could only be registered for chemotherapy, hormone therapy and chemo + anti-HER2 therapy. Regardless of their treatment history, patients treated exclusively with hormone therapy portray a less aggressive behaviour than those treated with chemotherapy only, resembling the natural history of HER2-/HR+ and triple-negative phenotypes (Table 2).

**CONCLUSION**: Chances to benefit from effective treatments may be jeopardized if their start is postponed to late lines. Only the most widely used therapies and, ultimately chemotherapy, hold until very late in the treatment of the advanced disease.
Clinical and pathological characteristics of a representative cohort of long-term metastatic breast cancer (MBC) survivors

Giesler DL L, Rosenzweig MQ Q, Diergaarde B and Puhalla SL L. University of Pittsburgh Medical Center, Pittsburgh, PA; University of Pittsburgh Medical Center, Magee Womens Cancer Program, Pittsburgh, PA and University of Pittsburgh Cancer Epidemiology and Prevention Program, Pittsburgh, PA.

Body: Background: Approximately 5-10% of women with MBC survive 5 years or more. Long-term MBC survival has been attributed to hormone receptor positivity, non-visceral metastases, and oligometastatic disease. The exact characteristics that predict long-term survival have still yet to be clearly elucidated. Here we describe the clinical and pathological characteristics of a representative cohort of long-term MBC survivors.

Methods: All patients diagnosed with MBC who were entered into the MBC database at the Magee Womens Cancer Program of UPMC between January 1999 and March 2016 were evaluated (N=1,232); follow-up information was collected through May 2016 and those who survived ≥5 years were included in the analysis.

Results: In total, 238 (19.3%) patients met our inclusion criteria. Median follow-up time was 7.1 years (range: 5.0-17.3), and 81 patients were still alive (34%; median follow-up: 8.5 years) while 157 were deceased (66%; median follow-up: 6.7 years). The majority were Caucasian (N=220; 92.4%) with mean age at diagnosis of MBC of 54.5 years (±12.6; range: 28.2-87.6). Ductal carcinoma was the most common primary cancer (N=177; 74.4%) and 65 (27.3%) women were diagnosed with de novo metastatic disease. Among the primary tumors, 179 (75.2%) were ER- or PR-positive, 76 (31.9%) HER2-positive, and 12 (5.0%) triple negative. Disease burden at metastatic disease presentation was classified according to 2 schemes: a traditional classification of non-visceral involving no vital organ (N=142; 59.7%) vs. visceral (N=96; 40.3%) as well as a more modern classification of limited stage being one site only (N=171; 71.8%) vs. extensive disease being in multiple sites (N=67; 28.2%). Of the patients classified with extensive disease, there were 22 (32.8%) who had disease at 3 or more sites. Lines of systemic chemotherapy received in the metastatic setting were as follows: 0 (N=51; 21.4%), 1 (N=44; 18.5%), 2 (N=35; 14.7%), 3 (N=21; 8.8%), 4 (N=23; 9.7%), and more than 5 (N=64; 26.9%). Additional treatments given included HER2 targeted therapy (N=94; 39.5%) and hormonal therapy (N=205; 86.1%). See Table 1 for additional characteristics by tumor status.

Conclusions: In this cohort, the majority of patients had hormone receptor positive tumors and received hormonal therapy. There was a small subset of long-term survivors who had triple negative disease. Disease burden at metastatic presentation was more commonly non-visceral or limited. Interestingly, there was a large percentage of patients who were classified as having visceral or extensive disease at 3 or more sites. Additionally, there were a number of patients receiving multiple lines of therapy suggesting a benefit to therapy. Many of the patients in our cohort had a long-term survival despite having risk factors that have been previously associated with a poor outcome.
Title: Proposal for a new breast cancer staging classification: Incorporating clinical and biologic factors

Murthy RK K, Song J, Raghavendra AS S, Li Y, Hsu L, Barcenas CH H, Tripathy D, Berry D and Hortobagyi GN. The University of Texas MD Anderson Cancer Center, Houston, TX and The University of Texas MD Anderson Cancer Center, Houston, TX.

Body: Background: The current breast cancer staging system, based on anatomy, does not always reflect the variable clinical course outcomes seen in the clinic. Other important and known determinants of prognosis and survival in breast cancer are age, grade, and receptor subtypes. In this analysis, we sought to demonstrate that these additional factors were important determinants of breast cancer specific and overall survival with an intention to propose a new staging classification.

Methods: Through a prospectively maintained electronic database at the University of Texas MD Anderson Cancer Center, we identified patients with newly diagnosed invasive breast cancer, stage I-IV, who received surgery as an initial treatment from 1997 to 2014. Data points for the earliest invasive breast cancer event were recorded: age, pathologic stage (7th edition AJCC), grade, ER status, PR status, HER2-neu status, adjuvant treatment history, and outcomes (breast cancer-specific survival [BCSS] and overall survival [OS]). Cox proportional hazards model was used for the statistical analysis.

Results: Of 22,131 patients, 99% were women in the following age groups (median age at surgery, 53 years [range, 16-98 years]): age < 40 (13%), 40-69 (76%), ≥70 (11%). Pathologic stages were: I: 50%, II: 39%, III: 9% and IV: 2%; 768 (3.5%) patients had bilateral breast cancer. Biological subtypes were as follows: Triple-negative (TN): 6%, Hormone receptor-positive/HER2-negative (HR+/HER2-): 70%, HER2-positive (HER2+): 24% (HR+, 9%; HR- 15%). Median follow-up was 7.9 years (95% CI, 7.8-8.0). In multivariate Cox regression modeling, age, grade, and clinical biomarker-based subtypes were significantly associated with breast cancer specific survival (BCSS).

*All patients were treated with trastuzumab in the adjuvant setting **Considering TN as the reference (HR (95% CI): HR+/HER2- (0.50 (0.45-0.55)), HR+/HER2+ (0.29 (0.23-0.37)), HR-/HER2+ (0.55(0.45-0.68). Abbreviations - BCSS: HR: hazard ratio, CI: confidence interval, HR+: hormone receptor positive, HR-: hormone receptor negative, HER2+: Her2-neu positive, HER2-: HER2-neu negative, TN: triple negative, Reference: 1.00

**Conclusion:** More individualized prediction of outcomes for breast cancer is possible by considering clinical and biologic characteristics in addition to anatomic stage. We intend to integrate pathologic stage, age, and biologic factors into a novel prognostic model to propose a new staging classification for breast cancer.
Title: Tamoxifen resistance: EGFR expression in hormone receptor-positive and HER2 negative breast cancer

Bae SY, Nam SJ, Lee SK, Kim SW, Lee JE and Yu JH. Samsung Medical Center.

Body: Purpose: Crosstalk between growth factor receptor tyrosine kinases (RTKs) and the estrogen receptor (ER) represents one of the most important mechanisms of endocrine resistance. EGFR and HER2 have been recognized as prominent factors associated with endocrine resistance. Most previous studies did not identify subgroups by HER2 overexpression and/or included breast cancer with HER2 overexpression. Accordingly, we analyzed HR positive (HR+) tumors without HER2 overexpression (HER2-).

Methods: We analyzed the clinical data of 2,166 patients with HR+HER2- breast tumors, between January 2007 and July 2013. We included only patients who had endocrine therapy with tamoxifen. Immunostaining for EGFR was interpreted as positive when at least 10% of the tumor cells showed moderate to strong membrane staining.

Results: EGFR expression (EGFR+) was present in 109 patients (5%). EGFR expression was significantly associated with more advanced stage and higher grades. In the univariate analyses, EGFR+ tumors were associated with poorer prognosis than EGFR- tumors (5-year DFS, EGFR+ vs. EGFR-, 91.2% vs. 96.6%, P < 0.001; 5-year OS, EGFR+ vs EGFR-, 93.1 % vs. 99.4%, P < 0.001). In the multivariate analysis, EGFR+ tumors had a hazard ratio of 2.63 (95% CI 1.14 -6.05) for DFS. EGFR+ tumors had a hazard ratio of 8.8 (95% CI 2.68-132.25) for OS.

Conclusion: EGFR expression could be prognostic factor in hormone receptor-positive and HER2 negative breast cancer, for tamoxifen resistance.
Body: Background
Local recurrence is a major concern in patients (pts) diagnosed with ductal carcinoma in situ (DCIS). Therefore, the need to identify pts at risk for DCIS recurrence is a significant priority. In invasive breast cancers, ER+/PR- subtype is considered a more aggressive tumor phenotype with poorer prognosis as compared to ER+/PR+ tumors. It is unclear whether this molecular subtype holds the same significance in pts with DCIS.

Methods
We designed an analysis to determine if a significant difference exists in the recurrence rates in pts with ER+/PR- DCIS when compared to ER+/PR+ tumors. Six hundred and ninety three pts diagnosed and treated for DCIS at Froedtert & MCW Clinical Cancer Center from Feb 2002-March 2015 were included in our study. Recurrence was defined as either non-invasive or invasive ipsilateral, contralateral or distant disease. Probabilities of recurrences were calculated using Kaplan-Meier estimator. Cox proportional hazards model was used to evaluate the effect of prognostic factors on DCIS recurrence.

Results
Median follow up was 5.2 years. Five year recurrence free survival (RFS) was 91% (95% CI 88.2-93.3) while estimated 7 year RFS was 86% (95% CI 81.9-89.2). Patient characteristics are shown in table below.

| Treatment                |           |

Patient characteristics are shown in table below.
Seventy five pts were found to have a recurrence during their follow-up. Most of the grade 1 tumors were ER+/PR+ whereas almost all of the ER-/PR- subtype were high grade tumors. ER+/PR- tumors were mainly intermediate and high grade (p<0.0001). Pts with ER-/PR- tumors had a significantly higher risk of recurrence (HR 3.7, 95% CI 1.9-7.2, p=0.0001) and those with ER+/PR- tumor subtype did not have a statistically significant difference in risk of recurrence when compared to ER+/PR+ tumors (HR 1.75, 95% CI 0.92-3.32, p=0.085). Pts who did not receive endocrine therapy for their ER+ DCIS had a significantly higher risk of recurrence as compared to those who received endocrine therapy (HR 2.2, 95% CI 1.23-3.92, p=0.0073). When compared to pts undergoing lumpectomy and radiation, pts undergoing lumpectomy alone had a significantly higher risk of recurrence (HR 2.5, 95% CI 1.32-4.93, p=0.005) whereas those who underwent mastectomy had a significantly lower risk of recurrence (HR 0.34, 95% CI 0.15-0.8, p=0.014).

**Conclusion**

ER+/PR- subtype was not a significant predictor of recurrence in DCIS patients. This finding is in contrast to the risk of recurrence and tumor aggressiveness seen in invasive breast cancers. Mastectomy and post lumpectomy radiation were associated with improved outcomes as was adjuvant endocrine therapy.
Title: Interaction between body mass index and hormone receptor status as a prognostic factor in node-positive breast cancer

Body: Purpose: The aim of this study was to investigate the interaction between BMI at breast cancer diagnosis and the various factors including hormone-receptor, menopausal and nodal status, and to find a specific subgroup where BMI has an effect on breast cancer prognosis.

Methods: We retrospectively analyzed the data of 8,763 non-metastatic invasive breast cancer patients from the Asan Medical Center's research database. Overall survival (OS) and breast cancer-specific survival (BCSS) among BMI groups were compared using the Kaplan-Meier method and Cox proportional hazard model with interaction term.

Results: Only in node-positive breast cancer, there was a significant interaction between obesity (BMI $\geq 30.0 \text{ kg/m}^2$) at diagnosis and positive hormone receptor which showed worse overall survival (OS) and breast cancer specific survival (BCSS) than normal weight patients (adjusted hazard ratio [HR] = 1.65, 95% confidence interval [CI] = 1.01 to 2.69 and HR = 1.90, 95% CI = 1.15 to 3.15, respectively). Underweight (BMI $<18.50 \text{ kg/m}^2$) which interacted with negative hormone receptor status in node-positive breast cancer was associated with decreased OS (HR = 2.01, 95% CI = 1.02 to 3.98) and BCSS (HR = 2.15, 95% CI = 1.08 to 4.26). There was no significant interaction between BMI and hormone receptor status in node-negative setting and BMI did not interact with menopausal status in any population.

Conclusions: BMI interacts with hormone receptor status in node positive setting, thereby playing a role in the breast cancer prognosis.
Title: The role of quantitative estrogen receptor status in predicting breast tumor response to neoadjuvant chemotherapy

Raphael J, Trudeau M, Paramsothy T, Lee N and Gandhi S. Sunnybrook Odette Cancer Centre, Toronto, ON, Canada; University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, ON, Canada and Sunnybrook Research Institute, Toronto, ON, Canada.

Body: Introduction:
Patients with Estrogen Receptor negative breast cancer (BC) are known to have higher tumor response rates than ER positive patients when treated with neoadjuvant chemotherapy (NCT). Few studies have assessed ER status as a quantitative continuous measure in predicting tumor response in this setting.

We aimed to study the association between quantitative ER status and tumor response at surgery in BC patients treated with NCT at our institution, and identify potential predictors of better survival outcomes.

Methods:
A retrospective review using a neoadjuvant BC database (The "Sunnybrook Biomatrix") identified 304 eligible patients that were included in the analyses. A univariate followed by a multivariable logistic regression analyses were conducted to assess the association between quantitative ER (expressed in percentage) and tumor response (good vs. poor response defined as < vs. ≥ 50% reduction in tumor size) while controlling for potential confounders.

For the secondary outcome, the Kaplan Meier method was used to estimate the recurrence free survival (RFS) in this cohort. Predictors of RFS were identified using a cox proportional hazards model (CPH) to adjust for clinically relevant variables. A log-rank test was used to compare RFS between groups for any significant binary predictor.

Results:
The median follow up of all patients was 43.3 months (Q1-Q3: 28.7-61.1). Quantitative ER was inversely associated with tumor response in a multivariable logistic regression model (Odds Ratio 0.99 95%CI: 0.99-1.00, p=0.027). A cut-off of 60% seemed to best predict the association based on the c-statistic (c=0.67) and the receiver operating characteristic curve.

However, quantitative ER was not associated with RFS; pathologic complete response (pCR) was shown to be an independent predictor of RFS in a CPH model (Hazard Ratio: 0.17, 95% CI: 0.07, 0.43, p=0.0002) in all patients, after controlling for potential confounders. At 5 years, 93% of patients with pCR and 72% of patients with residual tumor (no pCR) were recurrent-free respectively (log-rank test p=0.0012).

Conclusion:
This study suggests that BC patients with ER status < 60% are more likely to respond to NCT. Although ER status itself did not predict for relapse-free survival, patients with a pCR had better RFS, and this association was seen amongst all tumor phenotypes.

The role of quantitative ER in predicting and maximizing tumour response to NCT (including optimizing pCR rate) needs to be better defined in prospective studies.

Key words: Estrogen receptors, breast cancer, quantitative, tumor response, pathologic complete response.
**Title:** Her2 and hormonal receptor analysis in breast cancer synchronic node metastases could add therapeutic information

**Body: Introduction:** Breast cancer is the tumor with highest incidence and mortality in women in Argentina. Hormonal receptors (HR) and HER2 are the most important prognostic and predictive factors. It is suggested that estrogen receptors (ER), progesterone receptors (PR) and HER2 expression can vary during tumor progression and metastases development. Published evidence has reported discordance between primary tumors and its metastases ranging from 15-54% for HR and HER2 overexpression. A similar discordance situation may exist among primary tumor (PT) and its axillary nodal metastases (NM)

**Objective:** To describe the expression and discordance of ER, PR and HER2 in PT and its synchronic NM

**Material and methods:** Prospective analysis of surgical breast cancer patients (pts) at Instituto Alexander Fleming (Sept 2013 to Feb 2016). HR were analyzed by immunohistochemistry (IHC) according to CAP protocols; values ≥ 10% were considered positive. HER2 overexpression was defined by 3+ IHC or positive FISH. Paired t test was used to compare mean using Prims 5 software.

**Results:** In 587 breast cancer surgeries, 190 pts presented NM. HR and HER2 analysis was performed in 101 paired samples. Median age was 51 years (r 25-83). Mean tumor size was 3.3 ± 0.2 cm. 0.99% (1) were stage I, 68.3% (69) stage II and 30.7% (31) stage III. Most frequent histologic subtype was ductal carcinoma (66.3%). 78.2% presented lymphovascular invasion. Median positive nodes were 2 (r 1-21). Paired samples allowed ER analysis in 99 cases, PR in 98 and HER2 in 96; 8 NM were Her2++; FISH analysis was inconclusive in 4 of them due to insufficient tissue. No differences were observed on ER between PT and NM (72% vs 71.1%, OR: 0.91, IC95 -3.2-5.1; p>0.05), nor PR expression (52.1% vs 54.5%, OR: -2.1, IC95 -7.1-3.01; p>0.05). PT were ER+ in 86.1% of the cases; NM were ER+ in 82.2%. Regarding PR, PT were 74.3% PR+ and NM were 76.2% PR+. 28 of the 101 pts (27.7%) were discordant. 5 pts with ER+ PT had ER- NM, and 3 pts had PT ER- but ER+ NM, representing a 7.9% of discordance. 4 of 75 pts with PR+ in PT were PR- in NM, while 8 of 26 pts were PR- in PT but PR+ in NM. Of the 13 HER2+ pts, 2 (15%) did not present overexpression in NM. On the other hand, 6 (7%) of the 83 HER2- PT were HER2+ in NM. 4 of 9 pts had PT RH and Her2- (TN), but NM RH and/or Her2+.

**Discussion:** Tumor heterogeneity is an important issue that may affect clinical decisions. Axillary nodes are the first metastatic site for breast cancer and different studies have shown discrepancy between PT and NM. We described a discordant expression in ER, PR and HER2 of 8%, 12% and 9% respectively. These differences could be due to technical reasons, intratumor heterogeneity and/or a different cellular phenotype. Although the clinical importance of these changes are not completely understood, NM status could bring important prognostic and therapeutic information defining a particular group of patients in which a specific therapeutic strategy could influence long term results. In fact, in our series 44% of TN tumors presented NM with a therapeutic target, either HR or HER2. We therefore confirm that pathological analysis of NM may bring up additional information that could be useful in a prognostic or therapeutic point of view.
Factors predicting treatment outcomes of angiosarcoma of breast: A 25 year single institution experience

Ammannagari N, Attwood K, Cheney R, Young JS S, Kane JM M, Salerno KE E and Opyrchal M. Roswell Park Cancer Institute, Buffalo, NY.

Background: Primary (PAS) and secondary angiosarcoma (SAS) of breast account for < 1% of all breast neoplasms. SAS develops following radiation therapy (RT) to the breast or chest wall for treatment of breast cancer. The rarity of this tumor type makes it challenging to determine prognostic factors and develop optimal treatment strategies. Historically, large NCI cancer centers have reported a median overall survival ranging from 28 – 100 months with recurrence rate of 55%. Methods: We reviewed demographic, tumor, and treatment characteristics of breast AS patients diagnosed and treated at our institution between 1990 and 2015. Overall (OS) and recurrence free (RFS) survival were compared using standard statistical methods at a significance level of 0.05. Results: Of 12155 breast cancers, 22 patients (0.008%) with AS (PAS in 34%, SAS in 66%) were identified. Median age of PAS patients was significantly lower than SAS – 45 vs 71 years (p < 0.001). Median tumor size was 6.9 cm (7.3 cm vs 6.9 cm, p = 0.93) with multifocal disease seen in 22.7%. Tumor was high grade in 14 (50% vs 83.3%, p = 0.34). Median time from RT to SAS diagnosis was 7.8 years. Treatment included: mastectomy in 17 (77.3%), wide excision in 4 (18.2%), adjuvant RT in 4 (18.2%), taxane based chemotherapy in 11 (50%) and chemo-RT in 1 (4.5%). No significant differences were noted in tumor (p = 0.9) or treatment characteristics (p = 0.4) between PAS and SAS. Recurrence rate (mainly distant) was 36% (8 pts). The 5-year OS and RFS rates were 51% (95% CI 27–72%) and 36% (95% CI 14–58%) with estimated medians of 64.2 and 55.5 months, respectively with no significant difference between the two groups. Black ethnicity (11.6 vs 64.2 months, p = 0.015), multifocal disease (15.5 vs 64.2 months, p = 0.004) and tumor size of > 6.9 cm (8.3 vs 64.2 months, p = 0.03) were associated with poorer outcomes. Tumor grade was not related to OS. Adjuvant treatment (RT p = 0.49, chemotherapy p = 0.36) conferred no RFS or OS benefit. Conclusions: Patients with PAS were younger than SAS. Black race, multifocal presentation and larger tumor size predict worse clinical outcomes. Our institutional experience confirms the poor prognosis of angiosarcoma, and highlights the need for further research.
Title: The role of serum neutrophil-to-lymphocyte ratio (NLR) in triple-negative breast cancer

Lee J, Song BJ, Chae BJ, Lee A, Kim SH and Kang BJ. Division of Medical Oncology, Seoul, Republic of Korea; Surgery; Hospital Pathology; Radiology and Breast Cancer Multidisciplinary Team, Seoul St. Mary's Hospital; The Catholic University of Korea.

Body: Purpose
Neutrophil-to-lymphocyte ratio (NLR) is known as a predictor of mortality in solid cancers including gastrointestinal cancer, lung cancer, pancreas cancer and hepatocellular carcinoma. In breast cancer, NLR is associated with predicting mortality in patient population. However, there are no reports about clinical usefulness of NLR in triple negative breast cancer (TNBC) patients. In our analysis, we analyzed the clinical association of NLR in TNBC patients.

Methods
Between Jan. 2010 to Dec 2014, 260 patients diagnosed as TNBC by pathologic review were analyzed. Initial complete blood count (CBC) during the first diagnosis of TNBC was collected in total patient population. Among patients receiving neoadjuvant chemotherapy, initial CBC records before administration of systemic chemotherapy and CBC records achieved after the maximal response of systemic chemotherapy were retrieved. In metastatic TNBC patients, initial CBC and follow up CBC during each line of systemic chemotherapy was collected. The clinicopathologic characteristics and survival outcomes [overall survival (OS), relapse free survival (RFS), stage IV OS] were analyzed.

Results
The median age was 51 years (range 14~84). Initial NLR was associated to clinical TNM stage and Ki-67 index, with statistical significance (P=0.011 and P=0.021, respectively). Patients with lower NLR (NLR < 2.8) showed longer OS compared to patients with higher NLR (NLR > 2.8) (median OS 34.3 months vs. 32.83 months, P = 0.02). In 38 recurrent or metastatic TNBC patients, lower NLR (NLR < 2.8) group were associated to longer stage IV OS compared to higher NLR (NLR > 2.8) group (median stage IV OS 17.38 months vs. 12.87 months, P = 0.016). In 36 patients who received neoadjuvant chemotherapy, lower NLR group showed trends for superior RFS, but without statistical significance. Furthermore, patients with decreased NLR after neoadjuvant chemotherapy also showed trends for superior RFS, but without statistical significance.

Conclusion
In TNBC patients, lower initial NLR was associated with superior survival irrespective of clinical stage. During neoadjuvant chemotherapy, decreased NLR might be associated with superior RFS, but further analysis is warranted. Further studies with sufficient follow-up duration is warranted for validation of the role of serum NLR in TNBC.
Title: Bcl2 as a long-term prognostic factor in invasive lobular carcinoma of the breast

Body: Background: B-cell lymphoma 2 (Bcl2) is an anti-apoptotic protein with known tumor suppressor effect in breast cancer. Multiple studies have shown that high Bcl2-expression is associated with a better prognosis in breast cancer, but its clinical usefulness as a prognostic factor is still not fully elucidated. Invasive lobular carcinoma (ILC) of the breast is the second most common histologic subtype and comprises 5 to 15 % of all breast cancers. ILC has distinct clinico-pathological features and a specific pattern of recurrence, but treatment strategies are often similar as for the whole group of breast cancers. ILC’s are typically estrogen receptor positive (ER+), progesterone receptor positive (PgR+), HER2 negative, low proliferative and histological grade 2. According to the St Gallen surrogate definitions of the intrinsic subtypes of breast cancer most ILC’s are classified as ‘luminal disease’ and predominantly as low-risk ‘luminal A-like’. Patients with ‘luminal disease’ in general and ‘luminal A-like’ in particular falls into prognostic categories where uncertainty about optimal treatment strategy often arises, as clinicians seek to avoid both over- and under-treatment. Additional prognostic factors are needed in order to further improve risk stratification. The use of multigene assays to better predict recurrence is increasing, but the availability is still limited and the cost is high. Measurement of apoptosis-related factors, such as Bcl2 gene expression is included as a prognosticator in a majority of these tests. The aim of this retrospective study was to evaluate the long-term prognostic effect of Bcl2 in a subset of patients with ILC.

Patients and methods: One hundred and ninety-two well-characterized patients with primary ILC were included in the present study. Bcl2 was evaluated together with ER, PgR, HER2, Ki67, histological grade, tumor size, nodal status and age at diagnosis. Ninety-two percent of the patients were ER and/or PgR positive and 41% were node positive. Forty-one percent of the patients received adjuvant endocrine treatment and 3% received adjuvant chemotherapy. The median follow-up of the 52 patients still alive was 26 years. Bcl2 was analyzed immunohistochemically on whole sections of tumor tissue and Bcl2-positivity (Bcl2+) was defined as more than 10% cells with stained cytoplasm. Eighty-six percent of the patients (165/192) were Bcl2+. The primary endpoint was breast cancer mortality (BCM).

Results: Overall, 32% (61/192) of the patients have died from breast cancer. Bcl2 (positive vs negative) was a significant prognostic factor for BCM in univariable Cox regression analysis (HR 0.44, 95% CI: 0.23-0.85). Essentially the same Bcl2 effect was seen after multivariable adjustment for ER, Ki67, histological grade, tumor size, nodal status, age at diagnosis and adjuvant therapy (HR 0.33, 95% CI: 0.15-0.74).

Conclusions: Bcl2 is an independent long-term prognostic factor in this subset of patients with ILC. Bcl2 might add new prognostic information based on apoptotic tumor features that could be useful in the clinical treatment decision-making.
Title: Tumor-infiltrating lymphocytes (TILs) is associated with improved overall survival in triple-negative breast cancer (TNBC) patients treated with neoadjuvant chemotherapy (NAC)

Sampaio CdDAT de Deus Anjos Tavares, de Lima VCC Cláudio Cordeiro, de Andrade VP Pianna, Neotti T, Tavares MC Celeste, Sessa VA Altoé, Calsavara VF Fernando, Zenun GR Rocha, Giongo AA Alencar and da Costa AABA Balieiro Anastacio. AC Camargo Cancer Center, São Paulo, Brazil.

Body: Background: Recent studies suggest that the percentage of TILs is a predictive factor for response to NAC and a prognostic factor associated with long-term disease control in hormone receptor-negative breast cancer. The TILs working group's current recommendation is to evaluate stromal TILs as the principal parameter in future studies. The term lymphocyte-predominant breast cancer (LPBC) can be used as a descriptive term for tumors that contain more lymphocytes than carcinoma cells. Typically, the threshold of stromal lymphocytes for LPBC is around 50% of the stromal surface area. It is unclear if this cutoff will be used in the future as such an intense TIL infiltration in tumors has been reported to be infrequent (~10%). Studies with TNBC have demonstrated increasingly better overall survival (OS) and disease-free survival (DFS) associated with continuous scores of TIL in patients treated with adjuvant chemotherapy. In patients treated with NAC, TILs predicted pathological complete response (pCR). Our goal was to evaluate the impact of TIL on OS in TNBC patients treated with NAC.

Methods: Data from patients with histologically confirmed TNBC treated with NAC from a single institution (A. C. Camargo Cancer Center - ACCCC), between July 2002 and November 2013, were retrospectively collected using electronic medical records. Patients with metastatic disease or in situ carcinoma at diagnosis were excluded. The density of TILs was evaluated in full-face hematoxylin and eosin-stained (HE) slides. Three blinded pathologists made the assessment of each slide, and a consensus on the TIL percentage was achieved. A cut-off of 10% for TIL percentage was employed for OS and DFS calculations, based on technical statistical maximizing log-rank test. We use this cut-off to test the association with pathological pCR rate as well. For pCR rate, we also used a cut-off of 50% (LPBC). We used Chi-square test to evaluate the association with pCR. A p-value<0.05 was considered statistically significant for all tests.

Results: We identified 78 patients that fulfilled all inclusion and exclusion criteria. The median age was 42 years (range 17-70), and the clinical stage distribution was IIA (14%), IIB (22%), IIIA (19%), IIIB (33%) and IIIC (11%). 58 patients had archival FFPE blocks available and suitable for pathological analysis. Median follow-up was 4.1 years. Overall survival in 5 years in this subgroup was 62% (median not reached). 23 (39.7%) tumors had TIL> 10%, however only 10 had TIL > 50%. TIL >10% was associated with improved OS (HR 0.33, 95% CI, 1.0 to 0.11; p = 0.04). The same cut-off was associated with better DFS, although not statistically significant (HR 0.46, 95% CI, 1.1 to 0.18; p = 0.1). The overall pCR rate was 39.6% (48% for patients with TIL > 10% and 34% for patients with TIL <or = 10%; p = 0.3). LPBC had similar pCR rate (40% for LPBC vs. 39% for non-LPBC), probably due to the small number of samples analyzed. pCR was associated with a decreased risk of death (HR 0.06, 95% CI, 0.008 to 0.47; p<0.01).

Conclusion: We observed improved OS associated with TIL>10% in TNBC patients treated with NAC. pCR was also associated with better OS.
Title: Long-term follow-up of early stage breast cancer patients with results of MammaPrint®, Oncotype DX® and MammoStrat® risk classification assays

Shivers SC C, Russell S, Blumencrancz L, Mehindru A, Acs G, Ellis D, Vrcelj V, Zanchi A, Blumencrancz PW W, Carter E, King J and Cox CE E. Morsani College of Medicine at the University of South Florida (USF), Tampa, FL; Agendia, Inc., Irvine, CA; Florida Hospital Tampa, Tampa, FL and Morton Plant Hospital, Clearwater, FL.

Body: Introduction: The use of genomic tests for the prediction of breast cancer recurrence is becoming more common. MammaPrint® (MP, Agendia Inc.) is a 70-gene microarray assay designed to assess the 10-year risk of recurrence in an untreated population that was not selected for ER/HER2 results. The Oncotype DX® Recurrence Score® (RS, Genomic Health, Inc.) is a 21-gene RT-PCR assay that is clinically validated to predict the 10-year risk of distant recurrence in ER+ patients treated with Tamoxifen. MammoStrat® (MS, Clarient, Inc.) is an IHC assay that uses 5 antibodies and has been validated in a similar population as RS. Several recent reports show that these assays classify patients differently with significant discordances for all risk groups (Shivers, et al., SABCS 2013; Denduluri, et al., ASCO Breast 2011; Poulet, et al., SABCS 2012; Schneider, et al., ASCO 2013). The present study is an analysis of long-term follow-up in a cohort of patients who have results for all three of these risk-stratifying assays side by side in the same samples.

Methods: Patients with ER+ N0-N1 early-stage breast cancer with an MP result obtained as part of their routine clinical care were identified at the University of South Florida (USF, N=65) and Morton Plant Hospital (N=83). After local IRB approval, slides and/or blocks were cut and de-identified at USF and sent to Genomic Health and Clarient for blinded testing. Clinicopathological features were also reviewed by 3 breast pathologists.

Results: 148 patients with an MP result had tissue available to send for RS and MS assays. These patients had a median age of 62 years; median tumor size 1.8 cm; 9% low grade, 59% intermediate grade and 32% high grade. In our previous analysis of this study, of 148 patients with MP results, 53% were low risk and 47% were high risk. Of 135 samples that yielded enough RNA to produce an RS result, 53% were low risk, 26% were intermediate risk and 21% were high risk. Of 129 samples that yielded an MS result, 44% were low risk, 28% were moderate risk and 28% were high risk. Of 121 patients with results for all 3 assays, only 22% were concordant for low risk and 9% were concordant for high risk across all 3 assays. Overall, 30% of cases showed a major discordance such as low risk for one assay and high risk for another. After median follow-up of 54 months, 9 patients have had a distant metastasis and/or 8 patients have died (11 patients total). One patient who had bone metastasis and died had been classified as low risk by all 3 assays. Three patients with distant metastases had a major discordance between assays, with two high risk and one low risk result. Seven patients were classified as high or intermediate/moderate risk by all 3 assays.

Conclusions: This direct comparison demonstrates that although the assays classify a large proportion of patients differently, the patients who ended up with a distant metastasis and/or died of breast cancer had been classified as high risk by at least two of the three assays. This study has important clinical implications since these assays are used to help make treatment decisions regarding which patients might benefit from chemotherapy.
Title: A comprehensive analysis of GNAS DNA copy number, levels of mRNA and protein expression in primary breast cancer

Tomiguchi M, Yamamoto Y, Yamamoto-Ibusuki M, Goto-Yamaguchi L, Fujiki Y, Sueta A, Takeshita T and Iwase H. Graduate School of Medical Sciences, Kumamoto University, Kumamoto, Chuo-ku/Kumamoto, Japan and Kumamoto University Hospital, Kumamoto, Chuo-ku/Kumamoto, Japan.

Body: Background: Result of recent advances in genetics, guanine nucleotide binding protein, alpha stimulating (GNAS), transducer of signals from G-protein coupled receptors, has been noted that this factor is related with the onset and progression of tumor in various cancers. We aimed to analyze gene amplification, mRNA and protein expression of GNAS and their potential association with clinicopathological factors and prognosis in primary breast cancer.

Methods: The cohort of this study included 432 primary invasive breast cancer patients treated with standard care at Kumamoto University Hospital between June 2000 and January 2011. We performed a comprehensive analysis of GNAS at the levels of gene copy number, mRNA and GNAS protein expression analyzed by qPCR, qRT-PCR and immunohistochemistry (IHC), respectively. In the IHC assessment of GNAS protein expression, an H-score<150 was observed in 191 patients (44.2%), who were defined as having a low protein expression level, and an H-score≥150 was observed in 241 patients (55.8%) who were defined as having a high protein expression level.

Results: The median age at diagnosis was 60 (range 27-93). Three hundred fifteen (72.9%) of these were postmenopausal women. One hundred forty two patients (32.9%) had axillary lymph node metastasis. The median Ki67 labeling index was 23.6 (range 0.5-97.0). The subtypes were 321 ER+/HER2-, 24 ER+/HER2+, 34 ER-/HER2+ and 53 ER-/HER2-. Three hundred twenty one patients (75.9%) were treated with endocrine therapy and 146 patients (34.6%) chemotherapy. Most notably, a low levels of GNAS protein expression was observed in 191(44.2%) patients, and was positivity associated with Ki67 (P=0.028). Furthermore, univariate and multivariate analysis revealed that low GNAS protein expression was significantly related with poor relapse-free survival rate (Log-rank test; P=0.0013, OR:0.40, 95%CI:0.22-0.70) and breast cancer specific survival rate (Log-rank-test; P=0.041, OR:0.43, 95%CI:0.19-0.97). GNAS amplification and mRNA expression were not correlated with prognoses.

Conclusion: Contrary to expectations, GNAS expression was positively related with favorable tumor characteristics. Expression levels of GNAS protein may be an independent prognostic factor for primary breast cancer.
Title: The development of personalized diagnostic tests and therapeutic strategies in breast cancer

Kutasovic JR R, Rozali E, Miranda M, Lakhani SR R and Al-Ejeh F. QIMR Berghofer Medical Research Institute, Brisbane, Queensland, Australia and University of Queensland, Brisbane, Queensland, Australia.

Body: Despite some improvement in the overall survival rates of breast cancer, it remains as a leading cause of cancer-related deaths in women. Currently, we are unable to accurately predict patients' response to therapies and their long-term outcome. We developed and patented a 275-gene signature based on in silico meta-analysis of global transcriptome profiles (approximately 10,000 cases) that can predict which patients suffer from aggressive disease and succumb to their disease within 5 years of diagnosis. This test, the integrated Breast Cancer Recurrence (iBCR) score outperformed every clinicopathological indicator available in three independent, large cohorts of breast cancer. The iBCR can also predict the likelihood of response to standard treatments and which emerging targeted therapies should be added to an individual's treatment regime to improve outcomes. In addition, 21 of the genes in this signature are novel potential drug targets that have not previously been described in aggressive breast tumours. We performed a pilot study using the NanoString nCounter Dx platform to measure the expression of the top 125 genes within the signature in a cohort of 48 patients. We have validated with 100% accuracy the prognostic power of the iBCR in the Queensland Follow Up (QFU) cohort with 25 years of follow up (p<0.0001), irrespective of clinicopathological features. Our pilot study using the Nanostring platform successfully counted mRNA molecules from samples that averaged 26.8 years of age (range 24 – 29 years), with an average RNA Integrity (RIN) score of 2.4. Future work will expand this test to the full 275-gene set across 500 patients from the QFU cohort. In vitro siRNA screening of the 21 novel genes revealed that at least 10 of these genes are required for breast cancer cell survival. We have started validation of the top 4 hits and these studies confirm the requirement of these genes in breast cancer progression. These data will pave the way towards the study of these genes as new drug targets. Collectively, our test addresses the significant issue of heterogeneous responses to breast cancer treatment. The iBCR platform aims to improve both patients' clinical outcome and quality of life by directing more appropriate treatment with greater likelihood of success, and preventing overtreatment for those with a less aggressive tumor type.
Development of a predictive model by gene expression profiles for pathological CR after neoadjuvant chemotherapy in ER-positive/HER2-negative breast cancer

Fujiki Y, Yamamoto Y, Yamamoto-Ibusuki M, Goto R, Tomiguchi M, Sueta A, Takeshita T and Iwase H. Graduate School of Medical Sciences, Kumamoto University, Kumamoto, Chuo-ku/Kumamoto, Japan and Kumamoto University Hospital, Kumamoto, Chuo-ku/Kumamoto, Japan.

Body: 

Background: Benefits of neoadjuvant chemotherapy (NAC) are tumor shrinkage, improvement of surgical outcome and monitoring of response to systemic therapy. Pathological complete response (pCR) is one of the indicators of the sensitivity to NAC and is associated with improved long-term outcomes. However, response to NAC is different by tumor subtype. It may be difficult to decide the indication to NAC in ER-positive/HER2-negative subtype because pCR rate and its prognostic value is lower than other subtype. In this study, we aimed to develop a predictive model by gene expression profiles for pCR after NAC in ER-positive/HER2-negative subtype.

Patients and Methods: From the previously published 10 microarray data base in Gene Expression Omnibus, we selected the 858 ER-positive/HER2-negative breast cancer patients who had received NAC. Each 10 data sets were analyzed by logistic regression analysis in terms of pCR. Each analyzed data were combined and the 5686 genes were selected as pCR-related genes in ER-positive/HER2-negative breast cancer. Furthermore, we selected top 20 genes related to chemo-sensitivity and top 20 genes related to chemo-resistance. Furthermore, expression levels of each 40 genes were examined by qRT-PCR using archival materials. Finally, predictive model were developed using most predictive genes chosen from these 40 genes. We used 85 formalin-fixed paraffin-embedded tissues from patients with ER-positive/HER2-negative breast cancer before NAC. Chemotherapy included anthracycline and/or taxane. These patients received subsequent surgery at Kumamoto University Hospital between 2004 and 2014. The overall pCR rate was 12.9% (9 patients).

Result: To develop a pCR prediction model, we selected top 8 pCR-related genes based on the expression levels of each genes by qRT-PCR from the 40 genes which were chosen previously published data base. We developed pCR prediction index (pPI) used by univariate and multivariate logistic regression analysis for the expression profile of the 8 genes by qRT-PCR and calculated based on odd's ration with multivariate analysis. pPI was distributed between 7.4 from 1.5E+11. The patients were divided into 2 groups (Low pPI group ; pPI < 32 and High pPI group; pPI ≥ 32) according to pPI value. Each pCR rate were 0% (Low; 0/17) and 16.7% (High; 9/54), respectively (p=0.021). pPI was not associated with clinicopathological factors such as age, tumor size, nodal status, nuclear grade, ki67 labeling index. pPI (p=0.0198) was significantly related with pCR by multivariate analysis as well as tumor size (p=0.0136).

Conclusions: We developed pCR prediction model (pPI) based on gene expression levels of 8 genes for ER-positive/HER2-negative breast cancer. pPI may be useful tool for selecting NAC in ER-positive/HER2-negative breast cancer. We need to be validate the pCR predictive value of pPI with another data set.

Title: Three-gene signature predictive of high residual risk of recurrence after adjuvant chemotherapy in ER-positive HER2-negative breast cancer

Győrfy B, Ocana A, Herman P, Hatzis C, Pandiella A and Pusztai L. MTA TTK, Budapest, Hungary; Servicio de Salud de Castilla-La Mancha, Albacete, Spain and Yale University, New Haven.

Body: Background: A proportion of ER-positive, HER2-negative patients treated with both adjuvant endocrine and chemotherapy continue to remain high risk for recurrence. These individuals are the ideal patient population for future adjuvant trials.

Methods: We used gene expression data from ER+/HER2- patients who received adjuvant endocrine and chemotherapy. We utilized a training cohort of multiple gene expression datasets (N=131; GSE16391, GSE21653, GSE17907, GSE19615, GSE16716, GSE45255) and a validation cohort (N=277; GSE25066) from similarly treated ER+ patients. All data sets were generated with Affymetrix HGU133 arrays. Cox proportional hazards regression was performed across all genes using all possible cutoff values between the lower and upper quartile. Genes were ranked according to the estimated hazard rates for relapse. The top three genes were combined into a final signature that used the mean expression of these genes as the predictive score. Statistical analyses were performed in the R environment.

Results: The final signature capable to predict survival consisted of three genes, MX1, MBD4, and ZWINT. Each of these genes achieved high significance in a univariate analysis: MX1 HR=5.7 (p=1.8E-04) and HR=4.7 (p=1.3E-03), MBD4 HR=3.4 (p=2.8E-04) and HR=4.3 (p=4.4E-04), and ZWINT HR=4.4 (p=1E-03) and HR=3.7 (p=8.5E-03) in the training and validation cohorts, respectively. Using the mean expression of the three genes, the estimated hazard rates for survival were 20.5 (p=2.5E-05) and 17.5 (p=1E-04) in the two cohorts, respectively. Only one patient relapsed in each cohort. In a multivariate analysis including grade and lymph node status as covariates (size was not available), the three-gene signature retained significance (HR=13.2, p=0.011; and HR=13.9, p=0.01 in the two cohorts, respectively), while only lymph node status (HR=3.6, p=0.007) was significant in the validation cohort and no clinical variable was significant in the training cohort.

Conclusions: High expression of a 3-gene signature can identify ER+ patients who remain at very high risk for recurrence despite current adjuvant endocrine and chemotherapy.
Body: Introduction: Substantial efforts have been made to find factors associated with breast cancer (BC) recurrence and mortality after BC treatment. So far TNM stage, ER, PR, and HER2 status are considered as the major predictive markers of BC recurrence and used for treatment decision. However, most of these factors were evaluated independent from other important confounders such as age, stage, and various anti-cancer treatments because they were mostly derived from clinical trials. In Korea, up to 50% of BC patients are premenopausal women, it is not clear how age at diagnosis affect the progression and outcomes of the disease considering all known prognostic factors including TNM stage, ER, PR, and HER2 status. We aim to evaluate the impact of young age on recurrence and mortality after surgery among Korean women with BC.

Methods: This is a retrospective cohort study conducted using the data from BC registry from 2000 to 2016 at Samsung Medical Cancer, Seoul, Korea. Patients who received curative BC surgery and who had histologically-confirmed invasive BC between 2000 to 2011 were included in the study. Patients who second primary cancer or double primary cancer were excluded. Information local, regional, or distant recurrence and death until May 2016 was collected using electronic medical records and National Health Statistics. Cumulative incidence rates of distant recurrence and mortality at 3-years, 5-years and 10-years were calculated using a competing-risk model. Cox proportional hazards analysis were conducted with 3 different models to take into account for potential confounding factors including age, body mass index (BMI), stage and subtype at breast cancer diagnosis, chemotherapy, radiotherapy and hormone therapy.

Results: There were 7360 BC patients with curative BC surgery between 2000 and 2011, and the average follow up duration was 75.4 months. The mean age at diagnosis was 48.4 years old (Standard deviation (SD)=±10), and 6.2% (n=459) was diagnosed younger than 35. Of total, 13.3% were stage III BC and 73.4% of patients had hormone receptor positive BC. The cumulative incidence (95%CI) of recurrence at 3, 5, and 10 years was 4.4% (3.9-4.9), 7.5% (6.8-8.2), and 14.8% (12.9-16.7) respectively. The incidence of mortality at 3, 5, and 10 years was 1.8% (1.5-2.1), 3.8% (3.3-4.3), and 10.2% (9.1-11.5) respectively. Patients who were diagnosed BC under 35 years of age had 2.14 (95% confidence interval (CI):1.74-3.10) and 1.62 (95% CI:1.02-2.56) times higher risk of distant recurrence and mortality compared to patients whose age at diagnosis were between 50 to 60 after adjusting all well-known prognostic factors including age, body mass index (BMI), stage and subtype at breast cancer diagnosis, chemotherapy, radiotherapy and hormone therapy.

Conclusions: Young age at diagnosis (<35) was the most significant predictor on BC recurrence and mortality independently from BC stage and subtype. Further study is warranted to explain biologic background for the differences in outcomes in young women with BC.

Title: The REQUITE-AB study: Validating predictive models and biomarkers of radiotherapy toxicity to reduce side-effects and improve quality of life in breast cancer patients

Rattay T, Johnson K, Azria D, Chang-Claude J, Davidson S, Dunning A, de Ruyscher D, Gutierrez-Enriquez S, Lambin P, Rancati T, Rosenstein B, Seibold P, Symonds RP, Thierens H, Valdagni R, Vega A, Webb A, Wenz F, West C and Talbot C. University of Leicester, United Kingdom; University of Montpellier, France; German Cancer Research Centre (DKFZ), Heidelberg, Germany; The Christie Hospital Foundation NHS Trust, Manchester, United Kingdom; University of Cambridge, United Kingdom; University Hospitals Leuven/KU Leuven, Belgium; Vall d'Hebron Institute of Oncology, Barcelona, Spain; MAASTRO Clinic, Maastricht, Netherlands; Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy; Icahn School of Medicine at Mount Sinai, New York, NY; Universiteit Ghent, Belgium; Fundacion Publica Galega Medicina Xenomica, Santiago de Compostela, Spain; University Medical Centre Mannheim, Germany and University of Manchester, United Kingdom.

Body: Clinically significant side-effects from radiotherapy affect around a quarter of breast cancer patients and may impact considerably on outcomes from treatment. An increasing number of replicated genetic associations for radiotherapy toxicity are being reported[1][2]. The international REQUITE consortium aims to validate genetic markers and clinical factors implicated in radiotoxicity. The purpose of the REQUITE-AB project is to develop an integrated set of predictors for acute radiotherapy side-effects in breast cancer patients to be used as a clinical decision-making tool.

As part of the REQUITE prospective cohort study, 2,000 patients eligible for adjuvant breast radiotherapy will be recruited in nine centres across Europe and North America between April 2014 and August 2016, with centralised data management, biobanking and two years' follow-up using a standardised data collection protocol. Patient characteristics and treatment details being captured also include dose-volume histograms and DICOM files. Genotyping will take place in fall 2016. Primary endpoints are acute skin toxicity (CTC-AE v4.0) and quality-of-life (QoL) on completion of radiotherapy and at 3 months from start of radiotherapy. Secondary endpoints are late side-effects including change in breast appearance.

1,766 breast cancer patients have been recruited to date with standardized documentation of toxicity and QoL. Among patients who completed radiotherapy so far, 21.6% of patients developed grade 2 skin toxicity (brisk erythema) and 1.3% grade 3 (moist desquamation). The ability of patient, treatment and genetic variables to predict clinical outcomes and QoL will be examined. The REQUITE study includes the largest radiogenomics cohort of breast cancer patients to date recruited under a single standardised protocol. Findings of the REQUITE-AB project are likely to inform the development of interventional biomarker trials and personalise breast cancer care in the future.

Body: BACKGROUND: BC is the 2nd commonest cause of BM. These are associated with considerably poorer prognosis. This study aims to define prognostic factors of brain dissemination in patients with limited BC.

METHODS: We retrospectively analyzed 726 pts with non-metastatic BC, treated between 2008 and 2013 in a single-center. Tumour and patient characteristics were reviewed and correlated to the development of BM, other systemic progression, locoregional failure and survival data available. Univariate (UV) and multivariate (MV) Cox regression analyses were performed.

RESULTS: Median follow-up was 40 months. The majority (66%) of tumours were luminal (RE or RP+ / Her2 -), 9% luminal/Her2+ (RE or RP+ / Her2 +), 3% Her2+ (RE and RP- / Her2 +), 12% triple negative (RE and RP- / Her2 -) and 10% not specified. Median patient's age was 60 years.

DFS at 5 and 10 years was 86% (95%- confidence interval [CI]: 82-90%) and 48% (CI: 34-62%), respectively. OS was 92% (CI: 89-95%) and 62% (CI: 50-74 %), respectively. CSS was 94% (CI: 91-97%) and 64% (CI: 51-77%), respectively. LRC was 97% (CI: 95-98%) and 91% (CI: 84-98%), respectively. BM- free survival was 97% (CI: 96-98%) and 73% (CI: 60-86%), respectively. Other distant metastasis control rates were 90% (CI: 87-93%) and 42% (CI: 25-59%), respectively.

Out of 726 patients, 28 developed BM. Their median OS was 41 months. Median time from initial diagnosis to BM was 59 months. Median time from other metastasis to BM was 13 months. In MV, prognostic factors of BM development were primary tumor >T1, lymphovascular invasion (LVI) and Her2+ or triple-negative (p<0.05) breast subtype (BS). These prognostic factors were also significant for DFS, along with >N1. Percentage increase in progesterone and oestrogen receptor positivity was significantly associated with less BM occurrence (p<0.0001). DFS and OS were also significantly influenced by primary tumor >T1, LVI and Her2+ or triple-negative BS and hormonal receptor percentage expression.

CONCLUSIONS: The risk of BM in early-stage BC remains low, but our study found a substantial variation in risk by BS, tumour size and hormonal receptor positivity. These factors might represent prognostic factors to be considered for early detection and/or prevention of BM.
Title: Targeting RB loss for the precision treatment of triple negative breast cancer

Knudsen E, Essf J, Balaji U and Witkiewicz A. University of Arizona and UT Southwestern.

Body: A precision approach to the treatment of TNBC has been woefully lacking, and the vast majority of cases are still treated based on cytotoxic chemotherapy. In the genetic (n=215) and histological (n=220) analysis of TNBC approximately 30% of cases exhibit loss of function of the RB tumor suppressor. This event deregulates cell cycle regulatory processes and is associated with the aberrant expression of a number of genes that are known drug targets. Through the screening of >1,000 compounds with multiple cancer cell lines including naturally occurring and CRISP/CAS9 deletions we observed that RB loss results in a specific profile of sensitivities related to select chemotherapies and drugs targeting DNA-damage checkpoints (e.g. CHK1) and chromosome segregation (e.g. PLK1). These data agree with the known functions of RB in controlling cell cycle regulatory processes and are consistent with analysis of clinical specimens indicating a role for RB in the response to neoadjuvant chemotherapy. Taking advantage of these findings with single agents, we delineated unique combination treatments that were particularly active in RB-deficient TNBC models and could serve as the basis for a precision-guided approach to treatment based on loss of this critical tumor suppressor.
Title: Long-term recurrence risk and risk-based follow-up after breast cancer treatment

Siesling S, Witteveen A, de Munck L, Groothuis-Oudshoorn K, Sonke G, Klaase J, Boersma L, Poortmans P and Jijzerman M. MIRA Institute for Biomedical Technology and Technical Medicine, University of Twente, Enschede, Netherlands; Comprehensive Cancer Organisation the Netherlands (IKNL), Utrecht, Netherlands; Netherlands Cancer Institute, Amsterdam, Netherlands; Medisch Spectrum Twente, Enschede, Netherlands; Maastro Clinics, Maastricht, Netherlands and Radboud university medical center, Nijmegen, Netherlands.

Body: Background and aim: The Dutch guideline prescribes an age-based policy following the first five years of annual follow-up after curative treatment for breast cancer: women aged <60 years should still be seen annually, 60-75 years biannually and >75 years follow-up could be stopped. In this nationwide population based study we analysed long-term breast cancer recurrence patterns and modelled the age-based hazard of recurrence to support an adapted follow-up frequency.

Patients & Methods: Women diagnosed with primary invasive first breast cancer (M0) in 2003/2005 treated with curative intent, were selected from the Netherlands Cancer Registry (N=18,570). Missing data were multiple imputed. Extended Cox regression was performed to identify prognostic factors for locoregional recurrence and determine the hazards for the current age groups. Using the Logrank test, alternative cut-offs for age were determined by testing for equality of the survivor functions (events predicted vs observed) per five-year age intervals. Based on the hazards of the new age groups, thresholds were chosen and applied on two risk profiles as an illustration of the effect of the new thresholds.

Results: During ten years of follow-up, 658 (3.5%) patients developed a locoregional recurrence as a first event. Multivariable analysis showed that young age, greater tumour size, higher grade, positive lymph nodes, multifocality and no treatment with chemotherapy were prognostic factors for recurrence. The hazard after five years of follow-up for women aged <60 years was 0.70%, for 60-75 years 0.76% and for >75 years 0.58%

</tbody>
</table>

* Used as thresholds

This means that the group of women advised to continue annual follow-up after five years (<60 years) actually have lower risks than women with an advice to visit once every two years (60-75 years).

Testing resulted in alternative cut-offs for age; <50; 50-80, >80 years resulting in distinguishing hazard levels (table). As an illustration, the effect of using these new hazard levels as stopping-thresholds was investigated on two risk profiles based on age and endocrine therapy (ET). Based on the new hazard levels, a redistribution of the visits is suggested over the subsequent five-year follow-up period. The lower risk group (>50 years, with ET) was below the ‘consider stopping’ threshold and the higher-risk group (<50 years, without ET) was advised to receive six yearly follow-up visits.

Conclusion: The current follow-up policy uses suboptimal age cut-offs, as especially young patients (<50 years after five years of follow-up) have higher risks for locoregional recurrences and 50-60 year old patients have comparable risks as 60-80 year old patients. The proposed alternative cut-offs support a more risk-based follow-up frequency and more efficient allocation of resources. However, to get towards truly personalised follow-up, more variables should be taken into account to provide individualised risk estimates and follow-up schedules, also taking into account the risk on second primary tumours.
Title: “Quality, not quantity”: 10X hot-spot (HS) analysis of lymphocyte markers (CD3, CD8, CD4, CD20) in tumor-infiltrating lymphocytes (TILs) is superior to whole tumor (WT) analysis in triple-negative breast cancer (TNBC)

Cui X, McIntire PJ J, Ginter PS S, Irshaid L, Chen Z and Shin SJ J.  Weill Cornell Medicine, New York, NY.

Body: Background TILs have emerged as a prognostic indicator of disease-free survival (DFS) and overall survival (OS) in TNBC. Defined as all mononuclear cells within the tumor, TILs are mostly composed of CD3+ cells with the majority co-expressing CD8+ and less CD4+. Many studies have shown a positive effect of CD8+ TILs, however, the data regarding CD4+ TILs are conflicting. Few studies have assessed CD20+ TILs. Surprisingly, the majority of these published studies were performed on tissue microarrays, a method which is least likely to be representative of TILs. In this study, we aimed to evaluate an alternative approach to assessing lymphocyte markers in TILs compared to the gold standard of whole tumor (WT) analysis using imaging analysis software. Design Immunohistochemistry (IHC) for CD3, CD4, CD8, and CD20 was performed, each on one representative whole tissue section from 76 cases of primary TNBC. Imaging and quantification of WT and 2.2 mm diameter (equivalent to one 10X field) of highest immunoreactivity (HS) for stromal and intratumoral CD3+, CD4+, CD8+, and CD20+ TILs were performed using HALO™ imaging analysis software (Indica Labs; Corrales, NM). Statistical analyses were performed using DFS and OS (range: 16 to 196 months, mean: 110 months) as primary endpoints and results from the HS versus WT (gold standard).

Results CD3+ and CD8+ TILs were significantly correlated with DFS using either WT (CD3: \(P=.0221\), CD8: \(P=.0114\)) or a 10X HS field (CD3: \(P=.0063\), CD8: \(P=.0058\)). In addition, CD4+ TILs was significantly correlated with DFS using a 10x HS field \(P=.0231\) For OS, evaluating a 10X HS field for CD3+ and CD8+ TILs was found to be statistically significant (CD3: \(P=.0400\), CD8: \(P=.0381\)) while none was found in any of the markers studied when using WT. CD4+TILs were only observed to be significantly associated with DFS using a 10X HS field \(P=.0231\). CD20 did not correlate with outcome using either method.

Conclusion In theory, enumeration of immunoreactive cells by image analysis on WT should represent the gold standard in assessing TILs, however, we found that analyzing a single, smaller (10X) field found to have the highest concentration of immunoreactive cells (HS) to be a better predictor of long-term clinical outcome of TNBC. Our findings support the use of HS evaluation in the assessment of immunoreactivity of TILs.
2016 San Antonio Breast Cancer Symposium  

Title: Tissue microarray (TMA) based immunohistochemical studies of lymphocyte-specific markers yield inaccurate results

McIntire PJ J, Ginter PS S, Irshaid L, Cui X, Chen Z and Shin SJ J. Weill Cornell Medicine, New York, NY.

Body: Background Tumor-infiltrating lymphocytes (TILs), in particular cytotoxic (CD8+) T-cells, have been associated with increased survival in patients with triple-negative breast cancers (TNBC). A surprising majority of immunohistochemical studies of TILs have been performed using a TMA, typically consisting of 0.6 to 1.5 mm diameter tissue cores. While not explicitly stated, it is unlikely that these TMAs were made for the purposes of studying lymphocyte specific markers and, thus, inaccurately capturing the extent of TILs given their heterogenous distribution near tumor cells. The purpose of this study was to identify the smallest area of analysis necessary to accurately assess a lymphocyte specific immunohistochemical marker while maintaining a prognostic value based on the hypothesis that a TMA core is too small for accurate analysis of this kind. Design IHC for CD8 was performed on a TMA slide containing 76 cases of primary TNBC and the corresponding whole tissue slides. Imaging and quantification of combined stromal and intratumoral CD8+ T-cells was performed using HALO™ imaging analysis software (Indica Labs; Corrales, NM) on the following sized areas of analysis: 0.6 mm diameter TMA core, 1.1 mm diameter (equivalent to 20X field), 2.2 mm diameter (equivalent to 10X field), 6 mm diameter field and whole tumor. Evaluation of the 1.1 mm diameter, 2.2 mm diameter, and 6 mm diameter areas was performed in the same region which was visually determined to have the highest proportion of CD8+ TILs (“hot-spot”). Statistical analyses were performed using disease-free survival (DFS) (range: 16 to 196 months, mean: 110 months) as a primary endpoint of 76 TNBC cases. Results In all sized areas of analysis performed on the whole tissue section (1.1 mm, 2.2 mm, 6 mm and whole tumor), increased CD8+ TILs were significantly correlated with DFS ($P = .0033, .0058, .0111,$ and $.0114$, respectively), and additionally, the 2.2 mm (10X) “hot-spot” field was significantly correlated with OS ($P = .0381$). CD8+ TILs analyzed on the TMA core were not found to be significantly correlated with DFS ($P < .05$). Conclusion Using HALO™ Image analysis software, we have objectively quantified CD8+ TILs, a marker shown to have predictive and prognostic significance in TNBC, in graduated areas of tumor. We conclude that immunohistochemical analysis of lymphocyte specific markers in TMA yields inaccurate (underestimated) results which raises concern of the validity of published results using this platform in this investigative setting.
**Title:** Stromal density of tumor-infiltrating lymphocytes (TILs): Challenging the 50% threshold that defines lymphocyte predominant breast cancer (LPBC)

McIntire PJ J, Cui X, Ginter PS S, Irshaid L, Chen Z and Shin SJ J. Weill Cornell Medicine, New York, NY.

**Body:**

**Background**

Assessment of TILs as a clinically relevant immunologic marker in breast cancer is becoming more established, particularly in triple-negative breast cancer (TNBC). Typically, thresholds of \( \geq 50 \) or 60% have been used to define LPBC; however, there is no published evidence to indicate that these cutoffs correlate with long-term clinical outcome in TNBC. We sought to determine a clinically relevant threshold for TILs in a cohort of patients with TNBC with long-term outcome. **Design**

Histopathologic assessment was performed on a representative H&E slide of 76 primary invasive TNBC cases. Stromal density of TILs defined as a percentage of intratumoral stroma occupied by mononuclear inflammatory cells over the total intratumoral stromal area was recorded in each case at 5% increments. Statistical analyses using disease-free survival (DFS) and overall survival (OS) (range: 16 to 196 months, mean: 110 months) as primary endpoints were performed to determine clinically relevant thresholds of stromal density to define LPBC from non-LPBC. **Results**

Using DFS as the primary endpoint in our cohort of TNBC, the ideal threshold of stromal density of TILs for LPBC based on the lowest P value (0.0006) was \( \geq 32.5\% \). In addition, a stromal density threshold of \( \geq 50\% \) to define LPBC was significantly associated with DFS (\( P=0.0149 \)). When using OS as the primary endpoint in our cohort of TNBC, the ideal threshold of stromal density of TILs for LPBC based on the lowest \( P \) value (0.0308) was \( \geq 57.5\% \). However, using a stromal density threshold of \( \geq 50\% \) to define LBPC was not found to be significantly associated with OS (\( P=0.0599 \)). Additionally, each 5% increase in stromal density of TILs was significantly associated with improved DFS and OS in TNBC [0.04; 95% confidence interval (CI) 0.01–0.33, \( P=0.0025 \) and 0.09; 95% CI 0.01–0.69, \( P=0.0206 \), respectively].

**Conclusion**

We found that stromal density of TILs correlates significantly with long-term clinical outcome in a dose-response manner in TNBC. Our findings help validate using a higher threshold of a \( \geq 60\% \) for stromal TIL density (instead of 50%) to morphologically classify LPBC in TNBC for survival prognostication. Additionally, our results suggest that using a threshold of \( >30\% \) for may be useful in predicting recurrence.
Body: Background: Immune-based therapeutic strategies represent a promising approach in early and advanced breast cancer treatment. MUC1 glycoprotein is overexpressed and aberrantly glycosylated in over 90% of malignant breast cancer. It is involved in oncogenesis and confers resistance to anti-cancer therapies, thus representing a particularly promising target. Tecemotide is a MUC1-based therapeutic cancer vaccine. The aim of this trial was to investigate the efficacy and safety of preoperative tecemotide in primary breast cancer patients receiving neoadjuvant Standard-of-Care (SoC) treatment.

Patients and Methods: 400 patients with HER2-negative early breast cancer were recruited into this prospective, multicentre randomized 2-arm academic phase-II trial. Patients received preoperative SoC treatment with or without tecemotide therapy. Postmenopausal women with E++, or E++ and Ki67 <14%, and G1,2,X tumors received 6 months of letrozole as SoC. Postmenopausal patients with triple-negative, E- or E+, or E++ and Ki67 ≥14%, and with G3 tumors, and all premenopausal patients received 4 cycles of epirubicin/cyclophosphamide plus 4 cycles of docetaxel as SoC. Patients were additionally randomized to receive reverse or conventional sequence of epirubicin/cyclophosphamide and docetaxel. Primary endpoint was histopathological response measured by Residual Cancer Burden (RCB0/I vs RCBII/III) at the time of surgery. Secondary endpoints included pCR, efficacy of reverse versus conventional sequence chemotherapy, and safety.

Results: We did not observe a significant difference in RCB0/I rates between patients with (36.4%) and without (31.9%) tecemotide in the overall study population (p = 0.40), and in endocrine and chemotherapy treated subgroups (25.0% vs 13.3%, p = 0.17; 39.6% vs 37.8%, p = 0.75). Similarly, addition of tecemotide did not affect overall pCR rates (22.5% vs 17.4%, p = 0.23). RCB0/I rates were comparable regardless of docetaxel being given before or after epirubicin/cyclophosphamide (37.2% vs 40.1%, p = 0.61). Tecemotide addition was not associated with a worse toxicity profile (178 AEs, 57 SAEs vs 180 AEs, 48 SAEs based on patient incidence).

Conclusion: Immune-based targeting of MUC1 by tecemotide is safe but does not improve RCB and pCR rates in early SoC-treated breast cancer.
Title: MHC-II positive breast tumors are more immunogenic and may preferentially select for LAG-3-positive tumor immune infiltrates

Balko JM M, Loi S, Giltane JM M, Combs S, Estrada MV V, Sanchez V, Rimm D, Sanders ME E, Salgado R, Gomez H and Johnson DB B. Vanderbilt University Medical Center; Peter MacCallum Cancer Center; Genentech; Yale University and Institut Jules Bordet.

Body: Background: Lymphocyte-activation gene 3 (LAG-3) is a T-cell checkpoint regulator and a current target in immunotherapy trials. LAG-3’s main ligand is MHC class II (MHC-II), to which it binds with higher affinity than CD4. Binding of LAG3 to MHC-II antigen-presenting cells negatively regulates cellular proliferation, activation, and homeostasis of T cells, similarly to CTLA-4 and PD-1, suggesting that antibodies targeting LAG-3 may demonstrate similar anti-tumor immune effects.

Hypothesis: We recently reported an association of MHC-II on tumor cells and its involvement in mediating sensitivity to PD-1/PD-L1 monoclonal antibodies. MHC-II demonstrates a strong bimodal expression pattern on tumor cells from a variety of tissues, including those of the breast. In breast cancer patients, tumor-specific MHC-II expression on TNBCs is correlated with a 'hot' immune environment. We hypothesized that 1) MHC-II expression may drive potent anti-tumor immune responses and 2) MHC-II-positive tumors that generate immunotolerance may develop a specific immune checkpoint dependency on LAG-3, since LAG-3 is the inhibitory receptor for MHC-II-mediated antigen presentation.

Methods: To determine the functionality of MHC-II in driving anti-tumor immune responses, we constitutively expressed the MHC-II master regulator CIITA in MMTV-neu mouse tumor cells and determined their ability to form tumors in immunocompetent syngeneic hosts. To evaluate the association of MHC-II+ tumors with LAG-3 expression, we evaluated LAG-3-positivity by immunohistochemistry (IHC) in lymphocytic infiltrates in a series of 111 post-NAC TNBC specimens from patients with residual disease remaining after presurgical chemotherapy. Tumor-infiltrating lymphocytes (TILs) were scored by H&E, PD-L1 and MHC-II (HLA-DR) were scored in the stroma and tumor compartments using automated quantitative immunofluorescence (AQUA).

Results: Enforced expression of MHC-II via constitutive expression of CIITA caused rejection in 60% of mice, while only 11% of mice rejected MMTV-neu tumors expressing the vector control (Fisher's exact p=0.04). All rejecting mice were immune to rechallenge with parental (non-CIITA-expressing) MMTV-neu cells, suggesting a memory effector response. Clinically, 11/102 patients (10.8%) had LAG-3+ immune cells in their tumor. LAG-3+ tumors were strongly correlated with MHC-II positivity in tumor cells (p<0.0001). Presence of LAG-3+ cells also correlated strongly with overall TILs (p<0.0001), and PD-L1 expression on TILs (p<0.02). Since the likelihood of identifying LAG3+ lymphocytes is confounded by the inclusion of poorly-infiltrated tumors, we performed a subset analysis on only those tumors with substantial TILs (>20%). When this subset was analyzed, LAG-3 positivity retained its association with tumor MHC-II expression (p=0.0001), while the association of LAG-3 with stromal PD-L1 was reduced below the level of significance (p=0.052).

Conclusions: MHC-II expression causes increased immune activation in breast cancers, consistent with our previous findings. MHC-II positivity in breast tumors may identify a population with preferential dependence on the LAG-3 checkpoint, which may be important for future immunotherapy trials.
Body: Background: In the multicenter, nonrandomized phase Ib KEYNOTE-012 trial (NCT01848834), the anti–PD-1 antibody pembrolizumab demonstrated promising antitumor activity (18.5% ORR in patients [pts] with measurable disease at baseline as assessed by RECIST v1.1 and central radiology review; 6-mo PFS rate, 24%; 12-mo OS rate, 43.1%; data cutoff date, March 23, 2015) and a manageable toxicity profile as later-line of therapy for previously treated, PD-L1+ mTNBC. Here we present updated data for the mTNBC cohort of KEYNOTE-012.

Methods: Key enrollment criteria were: age $\geq 18$ yr; ER-negative, PR-negative, HER2-negative, recurrent or metastatic breast cancer; measurable disease based on RECIST v1.1; ECOG PS 0-1; any number of prior systemic treatments in the metastatic setting; and PD-L1+ tumors (expression in stroma or $\geq 1\%$ of tumor cells by IHC using the 22C3 antibody). Pts received pembrolizumab 10 mg/kg Q2W for 24 mo or until disease progression or unacceptable toxicity. Clinically stable pts with initial evidence of radiographic progression could remain on pembrolizumab until progression was confirmed. Response was assessed every 8 wk by central radiology review based on RECIST v1.1. After pembrolizumab discontinuation, pts were followed every 3 mo until death or withdrawal of consent. OS was estimated using the Kaplan-Meier method.

Results: Thirty two female pts were enrolled. Median age was 50.5 yr (range, 29-72); 46.9% had received $\geq 3$ lines of therapy and 25.0% had received $\geq 5$ lines of therapy for metastatic disease. As of the data cutoff date of April 26, 2016, median follow-up duration was 10.7 mo (range, 0.4-32.7). Median OS was 10.2 mo (95% CI, 5.3-17.5) and 12-mo OS rate was 41.1%; 25 (78.1%) pts had died. Median PFS was 1.9 mo (95% CI, 1.3-4.3) and 12-mo PFS rate was 15.0%. Of the 5 responders (including 1 complete response [CR] and 4 partial responses [PR]), 3 have had long-lasting benefit from pembrolizumab. The pt with CR discontinued study medication 11 mo after achieving CR and has remained in CR for approximately 15 mo without receiving any additional anticancer treatment. Two pts with PR discontinued pembrolizumab after completing 2 yr of treatment. The first pt has maintained response for 22.7 mo; the second pt had disease progression after 7.7 mo of response and recently restarted pembrolizumab as allowed by protocol. Median duration of response has not been reached (range, 15-58+ wk). Thirty (93.8%) pts discontinued pembrolizumab (27 [84.4%] with progressive disease and 3 [9.4%] for AEs) before reaching 2 yr of treatment. Six (18.8%) pts experienced grade 3-5 treatment-related AEs; there was 1 treatment-related death (disseminated intravascular coagulation with decreased blood fibrinogen).

Conclusions: Pembrolizumab provides long-lasting responses in heavily pretreated pts with mTNBC. Further development of pembrolizumab for treatment of this poor-prognosis pt population is warranted, and a phase II study evaluating efficacy and safety of single-agent pembrolizumab as later line of treatment for mTNBC is ongoing (KEYNOTE-086, NCT02447003).
**2016 San Antonio Breast Cancer Symposium**

**Title:** Determining the optimal vaccination strategy using a combination of the folate binding protein (FBP) peptide vaccine (E39+GM-CSF) and an attenuated version (E39') to maximize the immunologic response in breast cancer patients

Jackson DO O, Qiao N, Peace KM M, Hale DF F, Vreeland TJ J, Greene JM M, Berry JS S, Trappey AF F, Clifton GT, Ibrhim N, Toms A, Peoples GE E and Mittendorf EA A. San Antonio Military Medical Center, San Antonio, TX; University of Texas MD Anderson Cancer Center, Houston, TX; Womack Army Medical Center, Fayetteville, NC and Cancer Vaccine Development Program, San Antonio, TX.

**Body:**

**BACKGROUND**

FBP is overexpressed in 20-50% of breast (B) cancers (Ca) and roughly 90% of endometrial (E) and ovarian (Ov) Ca. E39 (FBP191-199, EIWTSHSYKV)+GM-CSF is an HLA-A2 restricted FBP peptide vaccine, which has been shown to generate significant *in vivo* immunologic response (IR) in a phase I/Ila trial in E Ca and Ov Ca patients (pts). There is a risk of inducing immunologic tolerance after multiple inoculations with a highly immunogenic vaccine. Thus, we are investigating a novel vaccination series using combinations of E39 and E39' (EIWTFSTKV, an attenuated version of E39) in a phase Ib, randomized, single-center trial. We are assessing short and long-term IR. Here, we present the initial IR analysis to the primary vaccination series (PVS) within B Ca pts.

**METHODS**

HLA-A2 positive B or Ov Ca pts were enrolled after completion of standard of care therapy and randomized into three arms: EE (6 inoculations of E39); EE'(3 inoculations of E39, then 3 of E39'); or E'E'(3 of E39', then 3 of E39). Theoretically, due to lower FBP expression and less aggressive chemotherapy regimens, B Ca pts are more antigen naïve and have a less suppressed immune system. Thus, only B Ca pts were included in this analysis. The PVS includes 6 inoculations total (R1-R6), one every 3-4 weeks, and containing 250mcg GM-CSF+500mcg peptide in the first 5 pts per arm and 1000mcg of peptide in second 5 pts. To assess the *in vivo* IR, local reaction (LR) was measured 48 hours after each inoculation (R1-R6), and delayed type hypersensitivity (DTH) was measured pre-PVS (R0), 1, and 6-months post-PVS (RC1, RC6). *Ex vivo* IR was measured via dextramer assay for E39-specific CD8+ T-cells at R0, RC1, and RC6. Statistical analyses were completed using appropriate tests.

**RESULTS**

Thirty-five B Ca pts were enrolled, with 27 completing the PVS (EE n=10, EE' n=8, E'E n=9). No clinicopathologic differences between groups or significant toxicities > grade 2 were appreciated. LR increased from R1 to R6 in all groups (ΔEE=24.80mm, p=0.14; ΔEE'=38.13mm, p=0.07; ΔE'E=8.05mm, p=0.38), the greatest increase approaching statistical significance in the EE' arm. The only arm with a statistically significant increase for *in vivo* DTH from R0-RC1-RC6 was in the EE' arm (ΔEE=-6.17mm, p=0.27; ΔEE'=-4.48mm, p<0.05; ΔE'E=-1.42, p=0.37). *Ex vivo* analysis of IR revealed no significant difference between groups at R0 (p=0.45) or RC6 (p=0.72), nor within groups over time (EE p=0.32, EE' p=0.47, E'E p=0.30).

**CONCLUSION**

In this phase Ib trial analyzing the IR of B Ca pts receiving a different vaccination strategy, both peptides were noted to be safe and immunogenic. While no difference was seen in E39-specific CD8+ T-cells between groups, the *in vivo* response was enhanced with the use of E39' after E39; this may indicate expansion of more effective clonal populations of CD8+ T cells with this strategy. These results may be specific to B Ca pts who are relatively antigen naïve with relatively intact immune systems. Further analysis of these pts as this trial continues will determine the optimal vaccination strategy capable of stimulating and maintaining an IR to prevent B Ca recurrence.
Title: A pilot study of radiation (RT) and CTLA4-mediated checkpoint blockade with tremelimumab for the treatment of breast cancer brain metastases (BCBM)

Memorial Sloan Kettering Cancer Center, New York, NY.

Body: Background: BCBM is a common and morbid complication of breast cancer. Conventional systemic therapies have demonstrated limited effectiveness in preventing and treating BCBM. Whole brain RT (WBRT) and stereotactic radiosurgery (SRS) remain the cornerstone of BCBM management but offer modest benefits. Preclinical and clinical data indicate that the local effects of RT may be augmented by immunotherapy. Furthermore, abscopal, or distant benefits outside of the RT field have been reported when combined with CTLA4-blockade. Thus, a pilot study of standard-of-care brain RT with tremelimumab, a CTLA4-directed monoclonal antibody, was undertaken to evaluate the impact on distant (non-CNS) disease control in women with HER2-normal (HER2-) disease and to confirm safety when administered with HER2-directed therapy (H) in women with HER2-positive (HER2+) disease.

Methods: Eligible women were age ≥18y, ECOG 0-2, with radiologically confirmed BCBM of any histology for which WBRT or SRS was planned, and non-CNS disease progression (PD) or stable disease (SD) for which a change in systemic therapy was planned. Women with HER2- disease were enrolled in an efficacy cohort with a primary endpoint of 12 week non-CNS disease control by RECIST. Women with HER2+ disease were enrolled in a safety cohort and continued H. Tremelimumab (10mg/kg) was administered within 5 days prior or 3 days after the first fraction of RT, then monthly for 6 months, and then every 3 months. Planned exploratory studies included comparison of non-CNS responses by RECIST to immune related Response Criteria (irRC). The study is closed to accrual and intention-to-treat analyses are reported.

Results: Of the 6 women with HER2+ disease: 6 (100%) had WBRT; 1 had a non-CNS partial response (PR) at 12 weeks (56% by RECIST and 86% by irRC) that was durable at 6 months (after PD on 5th line chemotherapy with H prior to enrollment); 1 had PD at 12 weeks; 1 died at 5 weeks; and 3 have not yet reached 12 weeks. Of the 20 women enrolled in the efficacy cohort: 17 (85%) had WBRT; 12 (60%) had estrogen receptor positive (ER+) disease; 1 with ER+ disease had non-CNS SD at 12 weeks and remains on study; 5 had non-CNS PD at 12 weeks; 3 had PD-related death within 12 weeks of enrollment (median survival 6.4 weeks, range 4.7 - 9.6 weeks); and 7 have not yet reached 12 weeks. Among all 26 study subjects, 20 grade 2 and 3 grade 3 potentially attributable toxicity events were reported.

Conclusions: BCBM RT with tremelimumab was associated with acceptable tolerance and few attributable toxicity events. This is a poor prognosis population with 3/13 (23%) PD-related deaths reported within 12 weeks of enrollment in the evaluable HER2-cohort. Only modest activity (SD in 1/13, 8%) has been observed in the HER2- cohort to date. However, 1 woman with HER2+ disease had a non-CNS PR by RECIST at 12 weeks that was durable at 6 months. This is the first report of a durable response with HER2-directed treatment and checkpoint blockade in breast cancer. The contribution of RT to this patient's response is not discernible but because of the potential importance of this potential interaction, studies of immune therapy with HER2-directed therapy +/- RT are planned.

Title: Inducing immune responses to tumor associated carbohydrate antigens by a carbohydrate mimetic peptide vaccine: Clinical experience in phase I and phase II trials

Kieber-Emmons T, Hutchins LF F, Emanuel PD D, Pennisi A, Siegel E, Jousheghany F, Karbassi BM M and Makhoul I. Winthrop P. Rockefeller Cancer Institute, University of Arkansas for Medical Sciences, Little Rock, AR.

Body: Active immunization of cancer patients to induce de novo functional anti-tumor immune responses is an alternative/complementary approach to chemotherapy. Tumor vaccines hold the potential to deliver durable, specific and systemic anti-tumor responses in patients. We have been developing active vaccination strategies targeting tumor associated carbohydrate antigens (TACAs) using carbohydrate mimetic peptides. TACAs play roles in initiation and metastasis of cancer and considered as common targets shared by many tumor types. TACA support cell survival that can be interrupted by anti-carbohydrate antibodies. An early-phase 3+3 clinical trial was conducted to evaluate the feasibility, safety and immune functionality of a carbohydrate mimetic-peptide (CMP) vaccine referred to as P10s, which can induce TACA reactive, proapoptotic antibodies. In this trial a dose-escalation trial of vaccine plus adjuvant was conducted in two cohorts of 3 subjects each. Patients were restricted to females of all races with histologically or cytologically confirmed stage IV breast cancer who had stable disease and a positive recall-antigen response. P10s was synthesized with the Pan-T-cell epitope PADRE and formulated at 300 and 500 µg/injection with MONTANIDE™ ISA 51 VG for the 1st and 2nd cohorts, respectively. Doses of the appropriate formulation of the vaccine were administered to research participants subcutaneously on weeks 1, 2, 3, 7 and 19. Blood samples were collected at various time points and tested for presence and functionality of antibodies. Antibody response to P10s and in particular against the ganglioside GD2 was measured by ELISA. Binding of pre-immune and post-immune sera was assessed against breast cancer cell lines. Vaccination generates IgG response with serum antibodies capable of inhibiting tumor growth in spheroid culture of breast cancer cell lines. The vaccine induced antibodies in all 6 subjects, displaying significant cytotoxic activity against several representative human breast-cancer cell lines. Caspase 3 was involved in the postimmune serum-mediated apoptosis. No cytotoxicity toward a normal breast epithelial cell line was detected. Apoptosis and caspase 3 activation seems to be involved in anti-tumor cell activity. Immunization with the P10s vaccine was found to be safe and tolerable, and induces functional antibodies that potentially have a cell-death-mediated therapeutic benefit. Incubation of spheroids with post-immune serum further sensitized cells to drugs, improving the efficacy of drug treatment at lower doses. The data suggest that the vaccine-induced anti-tumor immune response in combination with standard of care chemotherapy may further improve clinical outcome. Consequently, we are testing the vaccine in a Phase II study in the neoadjuvant setting. 5 Cohorts of 5 patients each administered with the vaccine at different schedules of chemotherapy are being assessed for immune response to the vaccine as in the Phase I study and if the combination approach contributes to a difference in pathological complete response (PCR) from chemotherapy alone.

**Title:** Long survival of patients with locally advanced breast cancer on combined neoadjuvant chemotherapy and immune potentiation: Modern lessons from an old study

Pohlmann PR R, van Cruijsen H, Stam AGM GM, van den Eertwegh AJM JM, Hoekman K, Scheper R, Buter J, van der Hoeven J JM, van der Wall E, Pinedo HM M and de Grujil TD D. MedStar Georgetown University Hospital/Lombardi Comprehensive Cancer Center, Washington, DC; Vrije Universiteit Medical Center, Amsterdam, Netherlands; Medical Center Alkmaar, Alkmaar, Netherlands and University Medical Center Utrecht, Utrecht, Netherlands.

**Body:**

**Background:** Effective neoadjuvant chemotherapy in combination with hematopoietic growth factors may act as an *in vivo* immunization regimen, leading to effective anti-tumor immunity. In addition to a direct anti-tumor effect, the balance between immunostimulatory Dendritic Cells (DC) subsets on the one hand and regulatory T cells (Tregs) and Myeloid Derived Suppressor cells (MDSC) on the other, may be decisive in clinical outcome.

**Methods:** We studied the effects of neoadjuvant treatment with doxorubicin and cyclophosphamide on these immune effector subsets in peripheral blood of a subgroup of patients (n=16) with Locally Advanced Breast Cancer (LABC) who were enrolled in the Spinoza trial at the VU University Medical Center in Amsterdam, The Netherlands, from Feb/1999 to Dec/2002. Patients were randomized for systemic administration of either GM-CSF (n=10) or G-CSF (n=6). Small sample size precluded multivariate analysis. Age-matched healthy donors were selected from the VUmc tissue bank. All study procedures were approved by the VUmc IRB.

**Results:** Average tumor size diameter of patients at VUmc site was 8.0cm (median 6.8cm). Pre-treatment frequencies of conventional CD1c/BDCA1+ Dendritic Cell (cDC-1) and CD16+M-DC8+ non-classical monocytes subsets were significantly lower than in 13 age-matched healthy women. Frequencies of the cDC-1 and -3 subsets, as well as of monocytes, MDSC and Tregs increased over treatment with either GM-CSF or G-CSF administration, whereas plasmacytoid DC (pDC) and BDCA3+ cDC-2 rates only increased in G-CSF-administered patients. High pre-treatment frequencies of cDC-1, and (non-)classical monocytes, and low (below median) pre-treatment frequencies of Tregs were associated with prolonged overall survival, although patient numbers and events were too small for these associations to reach significance. Despite the observed similarity in systemic effects on immune effector subsets, prolonged disease free (P=.05) and overall survival (P=.15) was observed for the GM-CSF-administered patients as compared to patients receiving G-CSF. Additional analyses revealed increased numbers of mature migratory cDC in the tumor-draining lymph nodes of GM-CSF- rather than of G-CSF-administered patients (P=.03).

**Conclusions:** Enhanced systemic DC differentiation occurred with effective neoadjuvant chemotherapy supported either by GM- or G-CSF. GM-CSF has additional maturational effects on regional cDC. In this subgroup analysis, treatment with GM-CSF instead of G-CSF in combination with neoadjuvant chemotherapy containing doxorubicin and cyclophosphamide was associated with prolonged disease free survival. Our data supports additional studies with GM-CSF as potential immunotherapeutic strategy for patients with breast cancer.

Title: Efficacy of Hsp90 inhibitor ganetespib plus standard neoadjuvant therapy in high-risk breast cancer: Results from the I-SPY 2 trial

Forero A, Yee D, Buxton MB B, Symmans WF Fraser, Chien AJ Jo, Boughey JC C, Elias AD D, DeMichele A, Moulder S, Minton S, Kaplan HG G, Albain KS S, Wallace AM M, Haley BB B, Isaacs C, Korde LA A, Nanda R, Lang JE E, Kemmer KA A, Hylton NM M, van't Veer L, Lyandres J, Perlmutter J, Hogarth M, Yau C, Sanil A, Berry DA A and Esserman LJ J. University of Alabama at Birmingham, Birmingham, AL; University of Minnesota, Minneapolis, MN; University of California, San Francisco, San Francisco, CA; MD Anderson Cancer Center, Houston, TX; Mayo Clinic, Rochester, MN; University of Denver, Denver, CO; University of Pennsylvania, Philadelphia, PA; MD Anderson Cancer Center, Houston, TX; Moffitt Cancer Center, Tampa, FL; Swedish Medical Center, Seattle, WA; Loyola University, Chicago, IL; University of California, San Diego, San Diego, CA; UT Southwestern Medical Center, Dallas, TX; Georgetown Lombardi Comprehensive Cancer Center, Washington, DC; University of Washington, Seattle, WA; University of Chicago, Chicago, IL; University of Arizona, AZ; Oregon Health and Science University, Portland, OR; QuantumLeap Healthcare Collaborative, San Francisco, CA; Gemini Group, Ann Arbor, MI; University of California, Davis, Davis, CA and Berry Consultants, Austin, TX.

Body: Background: Pathologic complete response (pCR) after neoadjuvant therapy is an established prognostic biomarker for high-risk breast cancer (BC). Improving pCR rates may identify new therapies that improve survival. I-SPY 2 uses response-adaptive randomization within biomarker subtypes to evaluate novel agents when added to standard neoadjuvant therapy for women with high-risk stage II/III breast cancer; the goal is to identify regimens that have ≥85% Bayesian predictive probability of success (statistical significance) in a 300-patient phase 3 neoadjuvant trial defined by hormone-receptor (HR), HER2 status and MammaPrint (MP). We report the results for Ganetespib, a selective inhibitor of Hsp90 that induces the degradation/deactivation of key drivers of tumor initiation, progression, angiogenesis, and metastasis. Ganetespib + taxanes previously have resulted in a superior therapeutic response compared to monotherapy in multiple solid tumor models including BC.

Methods: Women with tumors ≥2.5cm were eligible for screening and participation. MP low/HR+ tumors were ineligible for randomization. QTcF >470msec and HbA1C >8.0% were ineligible. MRI scans (baseline, +3 cycles, following weekly paclitaxel, T, and pre-surgery) were used in a longitudinal statistical model to improve the efficiency of adaptive randomization. Ganetespib was given with weekly T at 150 mg/m² IV weekly (3 weeks on, 1 off). Patients were premedicated (dexamethasone 10mg and diphenhydramine HCl 25-50 mg, or therapeutic equivalents). Analysis was intention to treat with patients who switched to non-protocol therapy counted as non-pCRs. The Ganetespib regimen was open only to HER2- patients, and eligible for graduation in 3 of 10 pre-defined signatures: HER2-, HR+/HER2- and HR-/HER2-.

Results: Ganetespib did not meet the criteria for graduation in the 3 signatures tested. When the maximum sample size was reached, accrual stopped. Ganetespib was assigned to 93 patients; there were 140 controls. We report probabilities of superiority for Ganetespib over control and Bayesian predictive probabilities of success in a neoadjuvant phase 3 trial equally randomized between Ganetespib and control, for the 3 biomarker signatures, using the final pCR data from all patients. Safety data will be presented.

Conclusion: The I-SPY 2 adaptive randomization model efficiently evaluates investigational agents in the setting of neoadjuvant BC. The value of I-SPY 2 is that it provides insight as to the regimen's likelihood of success in a phase 3 neoadjuvant study. Although no signature reached the efficacy threshold of 85% likelihood of success in phase 3, we observed the most impact in HR-/HER2- patients, with a 16% improvement in pCR rate. While our data do not support the continued development of Ganetespib alone for neoadjuvant BC, combinations with Ganetespib, which could potentiate its effect, may be worth pursuing in I-SPY 2 or similar trials.
Title: A phase 2 open-label study of lucitanib in patients (pts) with FGF aberrant metastatic breast cancer (MBC)

Mayer IA A, Arteaga CL L, Nanda R, Miller KD D, Jhaveri K, Brufsky AM M, Rugo H, Yardley DA A, Vahdat LT T, Sadeghi S, Audeh MW William, Rolfe L, Litten J, Knox A, Raponi M, Tankersley C, Isaacson J, Wride K, Morganstern DE E, Vogel C, Connolly RM M, Gradishar WJ J, Patel R, Pusztai L and Abu-Khalaf M. Vanderbilt-Ingram Cancer Center, Nashville, TN; University of Chicago Medical Center, Chicago, IL; Indiana University Simon Cancer Center, Indianapolis, IN; Memorial Sloan Kettering Cancer Center, New York, NY; University of Pittsburgh Cancer Institute, Pittsburgh, PA; University of California, San Francisco, San Francisco, CA; Sarah Cannon Research Institute, Nashville and Tennessee Oncology, PLLC, Nashville, TN; Weill Cornell Medicine, Iris Center Breast Center, New York, NY; University of California, Los Angeles, Los Angeles, CA; Cedars Sinai Medical Center, Los Angeles, CA; Clovis Oncology, San Francisco, San Francisco, CA; Clovis Oncology, Boulder, Boulder, CO; Dana Farber Cancer Institute, Boston, MA; University of Miami, Deerfield Beach, FL; John Hopkins Kimmel Cancer Center, Baltimore, MD; Northwestern University, Chicago, IL; Comprehensive Blood and Cancer Center, Bakersfield, CA and Yale University, New Haven, CT.

Body: BACKGROUND: Lucitanib is a potent, oral antiangiogenic tyrosine kinase inhibitor of Vascular Endothelial Growth Factor Receptors 1-3 (VEGFR1-3), Platelet-Derived Growth Factor Receptors alpha and beta (PDGFRα/β), and Fibroblast Growth Factor Receptors 1-3 (FGFR1-3). FGF aberrancies (amplification of FGFR1, or 11q[amplicon containing FGF ligands 3, 4, and 19]), are genomic alterations observed in over 20% of breast cancer pts and promote cancer proliferation and survival.

METHODS: MBC pts who had received at least 1 metastatic line of therapy were randomized 1:1 to 10 or 15 mg QD of lucitanib. Stratification was based on local assessment of FGF aberrancy; pts with both FGFR1 and 11q-amplified tumors were stratified as FGFR1 amplified. Central confirmation of FGFR1 or 11q amplification was done using Abbott FISH probes (FGFR1 or 11q copy number ≥ 6 and a ratio of FGFR1 or 11q to centromere ≥ 2). Investigator-assessed progression-free survival (PFS) was the primary endpoint. Secondary endpoints included objective response rate (ORR) per RECIST 1.1, disease control rate (DCR), duration of response (DR), and incidence of treatment-emergent adverse events (TEAE).

RESULTS: Enrollment completed in 3/2016; 178 pts that received at least 1 dose of lucitanib are included in this analysis (baseline characteristics in Table 1).

Due to grade 3 hypertension in the 15 mg group (46% vs 37% in 10 mg group), enrollment to the 15 mg group was halted. Overall, most pts (97%) experienced at least 1 TEAE, with the most frequently (≥ 30%) occurring events being hypertension (73%), fatigue (48%), nausea (43%), hypothyroidism (40%), and headache (33%). Grade ≥ 3 TEAEs occurred in 66% of pts, with hypertension as the most frequent event (40%) followed by proteinuria and hyponatremia (both 6%). AEs were manageable with dose interruption or reduction, with approximately 8% of pts ending treatment due to an AE. Current median PFS is 3.5 mos (95% CI 2.8-4.6; range 0.62-12.95) and 2.6 mos (95% CI 1.8-2.9; range 0.82-18.87) respectively for the 10 mg and 15 mg treatment groups. No differences in clinical activity were observed by treatment group, FGF aberrancy, hormone receptor or HER2 status. Of the 168 evaluable pts, confirmed ORR was 3%; overall DCR was 27% (32% for pts in the 10 mg group compared to 20% for the 15 mg group); overall mean (standard deviation) DR of 3.3 (1.8) mos.

CONCLUSION: At 10 mg QD, lucitanib has modest activity with manageable toxicity in this heavily pretreated pt population. Future clinical development for lucitanib may focus on alternative biomarkers to identify sensitive tumors and rational combinations with other anti-cancer drugs.
Title: The evaluation of ganitumab/metformin plus standard neoadjuvant therapy in high-risk breast cancer: Results from the I-SPY 2 trial

University of Minnesota, Minneapolis, MN; QuantumLeap Healthcare Collaborative, San Francisco, CA; University of California, San Francisco, San Francisco, CA; Berry Consultants, Austin, TX; University of Alabama at Birmingham, Birmingham, AL; University of California, San Diego, San Diego, CA; MD Anderson Cancer Center, Houston, TX; Loyola University, Chicago, IL; Swedish Medical Center, Seattle, WA; University of Denver, Denver, CO; UT Southwestern Medical Center, Dallas, TX; Mayo Clinic, Rochester, MN; Oregon Health & Sciences University, Portland, OR; University of Washington, Seattle, WA; Georgetown Lombardi Comprehensive Cancer Center, Washington, DC; Moffitt Cancer Center, Tampa, FL; University of Chicago, Chicago, IL; University of Pennsylvania, Philadelphia, PA; University of Arizona, AZ; University of California, Davis, Davis, CA and Gemini Group, Ann Arbor, MI.

Body: Background: I-SPY 2 is a multicenter, phase 2 trial using response-adaptive randomization within biomarker subtypes to evaluate novel agents when added to standard neoadjuvant therapy for women with high-risk stage II/III breast cancer - investigational agent(I) + paclitaxel(T) qwk, doxorubicin & cyclophosphamide(AC) q2-3 wk x 4 vs. T/AC (control arm). The primary endpoint is pathologic complete response (pCR) at surgery. The goal is to identify/graduate regimens that have ≥85% Bayesian predictive probability of success (statistical significance) in a 300-patient phase 3 neoadjuvant trial defined by hormone-receptor (HR) & HER2 status & MammaPrint (MP). Regimens may also leave the trial for futility (< 10% probability of success) or following accrual of maximum sample size (10% < probability of success < 85%). We report the results for experimental arm Ganitumab, a type I insulin-like growth factor receptor (IGF1R) inhibitor. IGF1R inhibitors are known to induce insulin resistance and all patients assigned to Ganitumab received metformin.

Methods: Women with tumors ≥2.5cm were eligible for screening. MP low/HR+ and HER2+ tumors were ineligible for randomization. Hemoglobin A1C ≥ 8.0% were ineligible. MRI scans (baseline, 3 cycles after start of therapy, at completion of weekly T and prior to surgery) were used in a longitudinal statistical model to improve the efficiency of adaptive randomization. Ganitumab was given at 12mg/kg q2 weeks and metformin at 850mg PO BID, while receiving ganitumab. Analysis was intention to treat with patients who switched to non-protocol therapy counted as non-pCRs. Ganitumab/metformin was open only to HER2- patients, and eligible for graduation in 3 of 10 pre-defined signatures: HER2-, HR+/HER2- and HR-/HER2-.

Results: Ganitumab/metformin did not meet the criteria for graduation in the 3 signatures tested. When the maximum sample size was reached, accrual to this arm stopped. Ganitumab/metformin was assigned to 106 patients; there were 128 controls. We report probabilities of superiority for Ganitumab/metformin over control and Bayesian predictive probabilities of success in a neoadjuvant phase 3 trial equally randomized between Ganitumab/metformin and control, for each of the 3 biomarker signatures, using the final pathological response data from all patients. Safety data will be presented.

Conclusion: The I-SPY 2 adaptive randomization study estimates the probability that investigational regimens will be successful in a phase 3 neoadjuvant trial. The value of I-SPY 2 is to give insight about the performance of an investigational agent's likelihood of achieving pCR. For Ganitumab/metformin, no subtype came close to the efficacy threshold of 85% likelihood of success in phase 3, and this regimen does not appear to impact upfront reduction of tumor burden. Our data do not support its continued development for the neoadjuvant treatment of breast cancer.
Title: Phase 1 study of CB-839, a small molecule inhibitor of glutaminase (GLS), in combination with paclitaxel (Pac) in patients (its) with triple negative breast cancer (TNBC)

DeMichele AM, Harding JJ, Telli ML, Münster P, McKay RR, Iliopoulos O, Whiting S, Orford KW, Bennett MK, Mier JW, Owonikoko TK, Patel MR, Kalinsky K, Carvajal RD, Infante JR and Merit-Bernstam F. University of Pennsylvania, Philadelphia, PA; Memorial Sloan Kettering Cancer Center, New York, NY; Stanford University, Stanford, CA; University of California, San Francisco, San Francisco, CA; Harvard University, Cambridge, MA; Emory University, Atlanta, GA; Florida Cancer Specialists, Sarasota, FL; Columbia University, New York, NY; Tennessee Oncology, Nashville, TN; University of Texas, Houston, TX and Calithera Biosciences, San Francisco, CA.

Body: Background: CB-839 is a first-in-class highly selective inhibitor of GLS, a key enzyme in the utilization of glutamine by cancer cells. TNBC has high GLS expression and is very dependent upon GLS-mediated conversion of glutamine to glutamate for tumor cell growth. CB-839 has antitumor activity in vitro and in vivo in preclinical models of TNBC. Recent studies demonstrate that glutamine utilization can contribute to resistance to paclitaxel, a therapy frequently used to treat TNBC patients. Paclitaxel sensitivity is dependent on down-regulation of the glutamine transporter, SLC1A5, and over-expression of SLC1A5 causes paclitaxel resistance. Consistent with these observations, inhibition of glutamine metabolism with CB-839 has demonstrated strong antitumor activity in combination with paclitaxel.

CX-839-001 is an ongoing Phase 1 trial of CB-839 as monotherapy and in combination with approved agents. We previously reported pharmacodynamic studies demonstrating robust inhibition of GLS in pt blood and tumors and excellent tolerability of CB-839 monotherapy in a variety of tumor types including TNBC. In light of the preclinical rationale and monotherapy tolerability a combination arm was opened testing CB-839 with paclitaxel (Pac-CB) in patients with advanced TNBC. We report here updated results on the Pac-CB dose escalation and expansion cohorts.

Methods: Patients with refractory advanced/metastatic TNBC (prior taxane therapy allowed) received escalating doses of CB-839 (400-800 mg BID) in combination with a fixed weekly Pac dose of 80 mg/m2 Days 1, 8, 15 of a 28 day cycle. Upon demonstration of safety and tolerability, an expansion cohort of TNBC pts was opened.

Results: To date, 15 pts have received Pac-CB at three dose levels of CB-839: 7 pts at 400 mg BID, 5 at 600 mg BID and 3 at 800 mg BID with the latter dose level not completed. 40% of enrolled patients have received >5 prior lines of systemic therapy for adv/met disease, and 10 pts have received prior taxane therapy including 5 in the adv/met setting. The Pac-CB combination has been well tolerated with one DLT during dose escalation (G4 neutropenia at 400 mg BID) and a low rate of dose reductions (2 for Pac and 1 for CB-839). Of 15 pts, the best overall response rate (BORR, see Table) has been PR in 20% (3 pts), SD in 47% (7 pts) and PD in 33% (5 pts) with 5 patients remaining on study. At doses ≥600 mg BID (n=8) the BORR is 38% (3 pts), and disease control rate (CR + PR + SD) is 88% (7 pts). All 3 pts with PRs have received prior Pac, including 2 pts with disease that was refractory to Pac in the advanced/metastatic setting.

Conclusions: The Pac-CB combination has been well tolerated and has demonstrated clinical activity in heavily pre-treated pts with TNBC. At doses ≥600 mg BID, BORR has been 38% and DCR 88%. Notably, PRs have occurred in pts with prior Pac therapy, including 2 pts with Pac-refractory disease in the adv/met setting. Updated data on the escalation and expansion cohorts will be presented.

Title: Bromodomain inhibitors represent a rational therapeutic option for the treatment of invasive lobular carcinoma

O'Connor DP P, Walsh L, Tarrant F, Chin S-F, Schouten P, Linn S, Bernards R, Caldas C, Gallagher WM M and ni Chonghaile T. Royal College of Surgeons in Ireland, Dublin, Ireland; University College Dublin, Dublin, Ireland; Cambridge University, Cambridge, United Kingdom and Netherlands Cancer Institute, Amsterdam, Netherlands.

Body: Invasive lobular carcinoma (ILC) is the second most common type of breast cancer after invasive ductal carcinoma (IDC), accounting for approximately 10-15% of all breast tumors. ILC is characterized by inactivation of E-Cadherin and neoplastic cells that invade the stroma in a “single-file” pattern. Women with ILC are usually older, have used hormone replacement therapy and are more likely to have hormone receptor–positive disease. ILCs have similar survival to IDCs at both five and 10 years, but despite this, the clinical course is distinct: ILCs are three times more likely to metastasize to the peritoneum, gastrointestinal tract, and ovaries and are more frequently bilateral. Therefore, tailored therapeutic options for this distinct, hard-to-treat subtype of breast cancer are required.

As part of the RATHER FP7 HEALTH consortium (www.ratherproject.com), we carried out RNA-Seq analysis of 61 primary ILC samples and identified that high expression of the BET family protein Brd3 was associated with poor recurrence free survival (p=0.03, HR 8.63, CI 1.22-60.85). This observation was further validated in the independent METABRIC cohort (n=99), where again, high Brd3 expression was associated with poor recurrence-free survival (p<0.01, HR=3.16, CI 1.24-8.03). Using a two ILC cell lines (SUM44PE and MDA-MB134VI) we found that ILC cells were relatively resistant to the anti-estrogen therapies tamoxifen and fulvestrant compared to those derived from IDC. Next, we tested whether the ILC cell lines were sensitive to BET protein inhibition using the pan-BET family inhibitor JQ1. Interestingly, while JQ1 inhibited cell growth in both ILC cell lines tested, apoptosis was only induced in SUM44PE cells, while MDA-MB134VI cells exhibited G1 arrest. Dynamic BH3 profiling was used to dissect the underlying anti-apoptotic dependencies in each ILC cell type and showed that in the JQ1-resistant MDA-MB134VI cells, survival was predominantly Bcl2-dependent. Combination of JQ1 and the Bcl2-inhibitor venetoclax (ABT-199) synergistically killed MDA-MB134V1 cells compared to treatment with JQ1 alone, while combination with the Bcl2/Bcl-Xl/Bcl-W inhibitor navitoclax (ABT-263) added further synergy.

With a number of BET inhibitors now entering clinical trials, the data described here suggest that BET inhibition is a rational therapeutic option for some ILC cases, and for those that do not respond, combination with venetoclax may be a suitable therapeutic strategy. In our cell line models, baseline Bcl-2 expression was sufficient to predict induction of apoptosis in response to JQ1 and could be used to guide therapeutic choice. These results should now be investigated in vivo before a prospective clinical trial.

Title: Methylation of BRCA1 and response to the PARP inhibitor veliparib

Body: Background: The BRCA1 promoter has been demonstrated to be methylated in up to 14% of sporadic breast and up to 30% of sporadic ovarian cancers, resulting in decreased mRNA expression. Drugs targeting tumors that are deficient in DNA repair, such as the PARP inhibitor veliparib, show great promise in BRCA-deficient cancers.

Hypothesis: BRCA1 promoter methylation is an alternative mechanism to mutation resulting in “BRCAness”-associated vulnerabilities that can be clinically targeted.

Methods: BRCA1 methylation was analyzed in samples (n=58 pre-tx samples) from two multi-institutional clinical trials in patients with advanced primary breast and ovarian tumors evaluating veliparib as a single agent (NCT00892736) or in combination with chemotherapy (NCT01281150). Eligibility included advanced malignancy with BRCA germline mutation, or sporadic, BRCA wild type (BRCA-wt) triple negative breast cancer or ovarian cancer. Of the 58 tumors, 35 were BRCA mutation positive (+), and 23 were BRCA-wt/unknown (21 breast/2 ovary). DNA was isolated from FFPE sections using the Allprep kit (Qiagen), bisulfite converted and used for pyrosequencing, covering region -56 to +7 bp covering the TSS of the BRCA1 promoter, and containing 5 CpG sites that were previously shown to be associated with BRCA1 mRNA expression. MCF-7 and HCC38 served as negative and positive controls, respectively. BRCA1 methylation was calculated by averaging the % methylation of the 5 CpG sites, with CpG average % methylation >34.68 (75%ile) considered methylated.

Results: Methylation of the 5 CpG sites tested was concordant amongst sites. The methylation ranged from 6.3% to 47.7%. The mean in the BRCA+ group was 27.96 and 32.29 in the BRCA-wt group, with a trend to more unmethylated tumors in the BRCA+ group. In the BRCA-wt group treated with single agent veliparib or in combination with carboplatinum/paclitaxel, those with higher BRCA methylation were numerically more likely to have response. There was a larger % of BRCA+ or BRCA methylated subjects who had objective response (complete response+ partial response + stable disease) than those who were BRCA-wt and not methylated (59.5% vs 46.2%). This was not statistically significant though likely due to small sample size. In addition, there were 2 patients with pre and post treatment biopsy samples with decrease in methylation after treatment, both of whom had a partial response. The remaining 6 patients with pre- and post-treatment samples had no change in methylation after treatment with veliparib + chemo with some responders and non-responders in this group. One BRCA-wt patient with high BRCA methylation in the tumor had exceptional response > 5 years to chemo + veliparib, followed by maintenance veliparib.

Conclusion: There was evidence of detectable BRCA methylation in patients who were BRCA-wt and some of these patients had response to veliparib. There were clinical objective responses seen in both BRCA methylated and non-methylated patients suggesting that there are additional explanations for BRCAness in this population. Assessment of BRCA methylation status deserves additional evaluation in larger data sets.
Body: Introduction

Mutations/deregulations in the phosphatidylinositol-3-kinase (PI3K) pathway are common in breast cancer. Inhibition of the PI3K pathway is recognized as a promising target for the treatment of breast cancer. Although taxanes are effective early on in advanced stage breast cancer, resistance often develops. It has been demonstrated that activation of the PI3K/AKT pathway confers resistance to paclitaxel, and in preclinical models, concomitant inhibition of the PI3K pathway enhances the efficacy of taxanes. BYL719 is a potent oral, class I PI3K inhibitor which strongly inhibits the PI3K alpha isoforms and is significantly less active against the other class I isoforms. Targeting the alpha isoform of PI3K is expected to improve the therapeutic window over inhibitors with less isoform specificity. Nab-Paclitaxel is a solvent-free, nanoparticle, albumin-based paclitaxel which takes advantage of the antitumor activity of paclitaxel while decreasing the toxicities typically associated with the solvent (Cremophor) used to administer the most common formulation of paclitaxel.

Methods

A 3+3 dose-escalation design evaluated three dose levels of BYL719 (250mg, 300mg, and 350mg) administered PO once daily (D1-28) with nab-Paclitaxel (100 mg/m² intravenously D 1, 8, 15) every 28 days in patients with metastatic HER 2 negative breast cancer. The aims of the study were to 1) determine the recommended phase II dose (RPTD) of BYL719 + nab-Paclitaxel, 2) assess pharmacokinetics of BYL and nab-paclitaxel, and 3) assess preliminary efficacy.

Results

10 patients were enrolled at 3 dose levels of BYL719 and 3 patients were enrolled in expansion cohort at the RPTD of BYL719 of 350 mg PO daily plus nab-paclitaxel 100mg/m2 (D 1, 8, 15). Median age was 61 years; 54% (7/13) of patients were hormone receptor positive and 46% (6/13) triple negative. 85% (11/13) had visceral disease, 69% (9/13) had received prior chemotherapy for metastatic disease and 85% (11/13) had received prior taxane in adjuvant/metastatic setting. There were no DLTs in the three cohorts and the MTD of BYL was not reached. Hyperglycemia (G3:31%, G4:0%) and neutropenia (G3:15%, G4:8%), were the most common grade 3/4 adverse events. There were no Grade 3/4 diarrhea or rash. Best overall response for 12 patients was 58% (7/12) (complete response=1, partial response=6), and an additional 33% (4/12) demonstrated stable disease. Objective responses were noted in both hormone positive and triple negative disease. Median duration of response is 6.5 months (range 2-14 months). No pharmacokinetic interactions were detected when BYL and nab-paclitaxel were co-administered.

Discussion:

This phase I study demonstrates that combination of BYL719 and nab-paclitaxel was well tolerated and shows encouraging efficacy in metastatic HER2 negative breast cancer. Enrollment in the phase II portion of the trial at the RPTD (BYL719 350mg PO daily plus nab-paclitaxel 100mg/m2 D1,8,15 every 28 days) continues. Ongoing analysis of PI3K pathway alterations in tumor and cfDNA will be correlated with clinical response.
Heavily pre-treated breast cancer patients show promising responses in the first in human study of the first-In-class fatty acid synthase (FASN) inhibitor, TVB-2640 in combination with paclitaxel

Brenner AJ, Falchook G, Patel M, Infante JR, Arkenau HT, Dean EM, Borazanci E, Lopez JS, Moore K, Schmid P, Frankel AE, Jones S, McCulloch W, Kemmer G, Grimmer K and Burris H. Cancer Therapy and Research Center, San Antonio, TX; Sarah Cannon Research Institute at HealthONE, Denver, CO; Sarah Cannon Research Institute, Florida Cancer Specialists, Sarasota, FL; Sarah Cannon Research Institute, Tennessee Oncology, Nashville, TN; Sarah Cannon Research Institute UK, London, England; United Kingdom; The Christie NHS Foundation Trust, Manchester, England, United Kingdom; HonorHealth Research Institute, Phoenix, AZ; The Royal Marsden, Institute of Cancer Research, Sutton, Surrey, United Kingdom; University of Oklahoma Health Sciences Center, Oklahoma City, OK; Barts Cancer Institute, London, England, United Kingdom; Univ. of Texas Southwestern Medical Center, Dallas, TX and 3-V Biosciences, Inc., Menlo Park, CA.

Body: Introduction
FASN inhibition is a novel approach to cancer treatment involving selective disruption of palmitate biosynthesis that, in tumor cells, leads to apoptosis. TVB-2640 is an oral, first-in-class, small molecule reversible inhibitor of FASN that demonstrates in vivo antitumor effects. We previously reported the results of dose escalation and now present evidence of preliminary activity in breast cancer patients treated in the dose expansion cohort.

Methods
This ongoing international, multicenter Phase I trial enrolls patients (pts) with advanced solid tumors with adequate organ function. TVB-2640 is given orally once daily at the MTD (100 mg/m^2) as monotherapy (mono) or in combination (combo) with weekly IV paclitaxel (80 mg/m^2).

Results
The most common AE's observed [mono, N=53; combo, N=47] were: alopecia (57%), palmar-plantar erythrodysesthesia (PPE) (36%), dry eye (13%) and increased lacrimation (11%). Gr. 3 toxicities include corneal edema (3%) and PPE (10%). Other toxicities were ≤ Gr. 2 and only minor GI symptoms occurred. All toxicities were reversible on dose interruption and no enhancement of common paclitaxel toxicity was observed when given with TVB-2640. Rare cases of pneumonitis in combination have been observed but the contribution of TVB-2640 to this effect is uncertain.

14 breast cancer patients were enrolled and treated in combination with weekly paclitaxel while 3 breast patients were given monotherapy (during the dose escalation phase). Among patients treated in combination, three (3) confirmed RECIST partial responses (cPR) were seen and multiple cases of prolonged stable disease (SD) (≥16 wks) despite heavy pre-treatment and taxane resistance in all but 2 cases. One ER+, PR+, Her2+ patient achieved a cPR and was on study for 26 weeks. One ER-/PR-/Her2+ patient whose previous best response to paclitaxel treatment was SD for 24 weeks, reached a cPR at week 12, discontinued paclitaxel at week 21 and remains on monotherapy TVB-2640 with a sustained cPR at week 29. The third responder with cPR is an ER+, PR+, HER2- patient whose previous taxane treatment lasted 15 weeks (response unknown) and she remains on study at week 24. Of the remaining 11 patients, 10 achieved SD > 12 weeks and 8 of the 10 maintained that response for 16-45 weeks. The ongoing SD patient at week 45, discontinued paclitaxel at week 35 and remains on monotherapy TVB-2640.

Summary
TVB-2640 demonstrated multiple cPRs and prolonged SD when combined with weekly paclitaxel in 93% of patients treated. Further exploration of response in patients recently progressed on a taxane (progression within the prior 6 months) and safety with TVB-2640 in combination with docetaxel is being explored.
Preclinical efficacy of the novel PIM2 kinase inhibitor, JP11646 in triple negative breast cancer models

Mehta R, Kothai Guruswamy Sangameswaran D, Bezbatchesko K, Moore J, Gil M, Khoury T, Baldino C, Caserta J, Fetterly Jr. G, Lee K, Adjei A and Opyrchal M. Roswell Park Cancer Institute, Buffalo, NY; Univ of Texas Medical School at Houston, Houston, TX; Physician Assistant Practice Program, College of Health and Sciences and Professions, Ohio University, Dublin, OH; Roswell Park Cancer Institute, Buffalo, NY; Jasco Pharmaceuticals, Woburn, MA; Roswell Park Cancer Institute, Buffalo, NY; Roswell Park Cancer Institute, Buffalo, NY and Mayo Clinic, Rochester, MN.

**Body: Background:** Triple negative breast cancer (TNBC) patients have poorer prognosis and there remains a lack of novel targeted therapies for their treatment. PIM2 (Proviral Integrations of Moloney virus 2) belongs to a family of three kinases that have been implicated in the survival and progression of hematologic malignancies and solid tumors. PIM2 has been linked to epithelial to mesenchymal transition in TNBC, which can lead to metastasis and chemotherapeutic resistance. We hypothesized that PIM2 may present as a therapeutic target in TNBC.

**Materials and Methods:** The study involved both *in vitro* and *in vivo* studies involving a novel PIM2 inhibitor JP11646 (obtained from Jasco Pharmaceuticals). TNBC cell lines MDA-MB-231 and BT-549 were obtained for our *in vitro* studies. Cell viability was evaluated using MTT assay. Western Blot assay was used to evaluate relative protein expression. For *in vivo* studies, female SCID mice were inoculated in the mammary fat pads with $1 \times 10^6$ MDA-MB-231 cells. When tumor volumes reached 100 mm$^3$, the mice were treated with JP11646 at the dosage 15mg/kg intraperitoneally for 2 consecutive days weekly for total of 4 weeks as determined from previous experiments. Control animals received vehicle only. The mice were euthanized once tumors reached $\sim 1,700$ mm$^3$.

**Results:** BT-549 cells treated *in vitro* with 3 different available PIM kinase inhibitors AZD 1208, LGB321 and JP12641 showed only modest reduction in cell viability. However, treatment of both MDA-MB-231 and BT-549 with JP 11646 demonstrated significant reduction in cell viability with IC50 ranging from 40 to 71.6 nM. Treatment with JP11646 demonstrated a novel mechanism of action resulting in downregulation of PIM2 in both cell lines. Treatment with JP11646, but not other PIM kinase inhibitors, resulted in activation of apoptosis as measured by cleaved PARP (cPARP) levels. Anti-PIM2 siRNA treatment but not treatment with non-specific PIM kinase inhibitor AZD1208 resulted in cPARP induction. Inhibition of proteolysis by bortezomib resulted in preservation of PIM2 and inhibition of apoptosis as demonstrated by decreased cPARP levels after treatment with JP11646. PIM2 over-expressing clone of MDA-MB-231 cells showed enhanced proliferation and migration properties both *in vitro* and *in vivo*. Treatment of mice with orthotopically implanted MDA-MB-231 tumors with JP 11646 resulted in significant reduction in the tumor growth (p=0.0019) and increased overall survival (p=0.018) as compared to control mice.

**Conclusions:** PIM2 upregulation in TNBC cell line resulted in more aggressive phenotype. JP11646, through novel mechanism of action resulting in degradation of PIM2, showed robust activity in TNBC cell lines both *in vitro* and *in vivo*. Further correlative studies in tumors harvested from *in vivo* experiments are ongoing. These results encourage further exploration of use of JP11646 as a targeted agent in treatment of TNBC.
Title: Abemaciclib exposure-response relationship in patients with metastatic breast cancer in MONARCH 1

O’Shaughnessy J, Chigutsa E, Kambhampati SRP, Sykes A, Frenzel M, Nanda S, Koustenis A, Smith I and Turner PK Kellie. Baylor-Sammons Cancer Center, Dallas, TX and Eli Lilly and Company, Indianapolis, IN.

Body: Objective: Abemaciclib is an oral, selective inhibitor of CDK4 & 6 that exhibited single agent activity in the MONARCH 1 clinical trial. The relationship between abemaciclib exposure as monotherapy and response for efficacy and adverse events was evaluated in patients with metastatic breast cancer.

Methods: Abemaciclib (200 mg) was administered orally on a continuous schedule every 12 hours in 28 day cycles until disease progression. Sparse pharmacokinetic samples (PK) were collected, cycle (C) 1 day (D) 1 pre dose, C1D15 4 and 7 hours post dose, C2D1 pre and 3 hours post dose, and pre dose on C3D1. Exposure metrics were predicted from a population PK model and included the minimum concentration after a single dose on D1(Cmin,d1), maximum concentration at steady state (Cmax,ss), and minimum concentration at steady state (Cmin,ss ). Exposure to abemaciclib, active metabolites LSN2839567 (M2) and LSN3106726 (M20), and total active species (abemaciclib + M2 + M20) were tested.

Response endpoints including efficacy and adverse events were evaluated 12 months after the last patient entered treatment. The relationship between exposure and objective response rate (ORR) was evaluated by quartile analysis and logistic regression. The relationship between exposure and progression free survival (PFS) was evaluated by Kaplan Meier analysis of exposure quartiles and a Cox Proportional Hazard model with PFS as the response and exposure as a covariate. The relationship between exposure and neutropenia, diarrhea, fatigue, nausea, vomiting, and any treatment emergent adverse event (TEAE) was evaluated by logistic regression on the incidence of any grade, grade ≥ 2, and grade ≥ 3 events. No adjustments for multiplicity were performed.

Results: Analyses included 132 patients. A summary of the exposures in MONARCH 1 are presented in Table 1. The confirmed ORR was 19.7%, and median PFS was 5.95 months (95%CI: 4.2, 7.5). There was no statistically significant relationship between Cmin,d1, Cmin,ss, Cmax,ss for abemaciclib, M2, M20, or total analyte and ORR or PFS. There were no statistically significant and clinically relevant relationships between abemaciclib exposure and TEAEs.

Conclusion: The results of the exposure-response analysis support the abemaciclib single agent starting dose of 200 mg twice daily and dose reductions in 50 mg decrements as needed for adverse events. Further studies to refine the PK model and evaluate relationships between exposure and response are warranted.

Title: Subgroup Analysis by prior treatment and disease burden in MONARCH 1: A phase 2 study of monotherapy abemaciclib, a CDK4 & 6 inhibitor, in patients with HR+/HER2 metastatic breast cancer (MBC) following chemotherapy

Rugo H, Nanda S and Koustenis A. University of California San Francisco Comprehensive Cancer Center, San Francisco, CA and Eli Lilly and Company, Indianapolis, IN.

Body: Background: The MONARCH 1 (NCT0210249) study demonstrated durable single agent activity of abemaciclib in patients (pts) with HR+/HER2- breast cancer, with an objective response rate of 19.7% and median duration of response of 8.6 months. The MONARCH 1 study population was heavily pretreated and had a high disease burden: all pts had previously received endocrine therapy and chemotherapy, had median of 3 prior systemic therapies for metastatic disease 90.2% had visceral disease and 85.6% had ≥ 2 metastatic sites.

Methods: MONARCH 1 was a phase 2 single-arm study designed to evaluate safety and efficacy of abemaciclib monotherapy in women with HR+/HER2- MBC whose disease progressed on/after endocrine therapy and chemotherapy. Abemaciclib (200 mg) was administered orally on a continuous schedule every 12 hours until disease progression. The primary objective planned to evaluate investigator-assessed objective response rate (ORR= complete response [CR] + partial response [PR]) in a sample size of approximately 128 pts) using RECIST v1.1. Subgroup analyses evaluating ORR by prior treatment and disease burden were performed.

Results: A total of 132 pts were treated with abemaciclib monotherapy. Analyses of subgroups based on prior treatment and disease burden are summarized in Table 1.

Conclusions: Abemaciclib monotherapy administered on a continuous schedule has consistent single agent activity across the subgroups analyzed.

Title: Phase Ib study evaluating the safety and clinical activity of lumretuzumab combined with pertuzumab and paclitaxel in HER2-low metastatic breast cancer

Schneeweiss A, Park-Simon T-W, Albanell J, Lassen U, Cortes J, Dieras V, May M, Schindler C, Marmé F, Cejalvo JM Miguel, Martinez-Garcia M, Gonzalez I, Lopez-Martin J, Welt A, Joly F, Michielin F, Jacob W, Adessi C, Moisan A, Meneses-Lorente G, James I, Ceppi M, Hasmann M, Weisser M and Cervantes A. National Center for Tumor Diseases, University Hospital, Heidelberg, Germany; 2Clinics of Obstetrics and Gynecology, Hannover Medical School, Hannover, Germany; Hospital del Mar, Barcelona, Spain; Rigshospitalet, Copenhagen, Denmark; Vall d'Hebron Institute of Oncology, Barcelona, Spain; Institut Curie, Paris, France; Biomedical Research Institute INCLIVA, University of Valencia, Valencia, Spain; Hospital Universitario 12 de Octubre, Madrid, Spain; West German Cancer Centre, University Hospital Essen, Essen, Germany; Center François Baclesse, Caen, France; Roche Pharmaceutical Research and Early Development, Roche Innovation Center Basel, Basel, Switzerland; Roche Pharmaceutical Research and Early Development, Roche Innovation Center Munich, Penzberg, Germany; Pharma Research and Early Development, Clinical Pharmacology, Roche Innovation Center Welwyn, Welwyn Garden City, United Kingdom and A4P Consulting Ltd, Sandwich, United Kingdom.

Body: Background: Inhibition of HER2 and HER3 heterodimerisation is a novel treatment concept in HER2-“low” expressing breast cancer (BC). Lumretuzumab, a glycoengineered monoclonal anti-HER3 antibody, in combination with pertuzumab has demonstrated synergistic anti-tumor activity in preclinical HER2–low expressing preclinical BC models.

Methods: This open-label, multicenter phase I study selectively enrolled metastatic BC patients (pts) expressing HER3 protein and low levels of HER2 (defined as IHC 1+ and 2+ and ISH-negative) in a formalin-fixed paraffin-embedded pretreatment tumor biopsy sample. Eligible pts were treated with a combination of paclitaxel (PA) qw plus lumretuzumab (L) and pertuzumab (P) q3w in three dose cohorts. The safety, antitumor activity and tumor biomarkers including protein expression (IHC, MS) and mutational data (NGS) in association with clinical activity were evaluated.

Results: Overall, 35 pts were included in this study. The median age was 60 (range: 33 to 77) years. The median number of prior treatments for metastatic disease ranged from 0 to 5 with 23 pts (65.7%) without prior chemotherapy for metastatic disease. Cohort 1 was treated with PA at 80 mg/m², L at 1000 mg and P at 840 mg for Cycle 1 followed by 420 mg for the following cycles. This cohort was stopped after two pts both experienced grade 3 diarrhea within the first treatment cycle which was considered a dose-limiting toxicity (DLT). For Cohort 2 the dose of L was reduced to 500 mg based on PK modelling and simulation data. No DLTs were seen for the first 6 pts. A total of 20 pts were recruited with an objective response rate (ORR) and disease control rate (DCR) of 30% and 75%, respectively, for 1st-line pts (n=9) in this cohort. Diarrhea (≥G3) and hypokalemia (≥G3) occurred in 50% and 55% of pts, respectively, and all pts experienced chronic diarrhea throughout the course of treatment. For Cohort 3 the dose of L was maintained at 500 mg, PA at 80 mg/m², and P was administered at 420 mg at all cycles. In addition, a prophylactic loperamide regimen was introduced. Altogether, 13 pts - all 1st-line for metastatic disease - were treated. No DLTs were seen for the first 6 pts. Diarrhea (≥G3) and hypokalemia (≥G3) were reduced to 31% and 15%, respectively, but chronic diarrhea was still observed throughout the treatment in all pts. The ORR and DCR were 31% and 77%, respectively. Preliminary mechanistic safety experiments revealed HER2/HER3-dependent chloride channels in the intestine as likely cause of diarrhea. Biomarker data will be presented along with updated clinical and safety data.

Conclusions: The combination of L, P and PA was associated with high rates of persistent diarrhea. Dose modifications and prophylactic anti-diarrheal medication led to significantly reduced diarrhea intensity but did not change the incidence and persistence of diarrhea overall. Despite encouraging clinical activity especially in 1st line pts, the therapeutic window of this combination is too low to warrant further clinical development.
Title: Src homology 2 domain containing transforming protein 1 and steroid receptor coactivator-3 as novel targets for triple-negative breast cancer

Chang Y-F, Wang Y and Greene GL L. The University of Chicago, Chicago, IL.

Body: Triple-negative breast cancer (TNBC) accounts for 15-20% of breast cancer cases and is more prevalent among young women and African American women. Metastasis and chemoresistance remain significant challenges in TNBC. The development of targeted therapies for TNBC may dramatically improve the survival of patients and the quality of life. An adaptor protein, Src Homology 2 Domain Containing Transforming Protein 1 (SHC1) and steroid receptor coactivator-3 (NCOA3) are found to be overexpressed in breast cancers and important in the regulation of tumor progression and metastasis and drug resistance in ER+ breast cancer. The elevated SHC1 or NCOA3 correlates with poor prognosis in breast cancer patients. However, the biological significance of SHC1 and NCOA3 in TNBC is not well known. In this study, we performed siRNA-mediated knockdown to determine the importance of SHC1 and NCOA3 in the cell proliferation and death of TNBC. The effect of siSHC1 or siNCOA3 on the invasion and chemoresistance was also assayed in vitro. We found that although SHC1 and NCOA3 knockdown slightly inhibited the tumor growth of TNBC cells (MDA-MB-231, BT549, and HS578T), siSHC1 + paclitaxel and siNCOA3 + paclitaxel significantly decreased cell proliferation and increased caspase-3/7 activity in vitro, compared to drug alone. In vivo studies using MDA-MB-231 xenografts and a TNBC PDX model also showed that siSHC1 and siNCOA3 significantly augmented paclitaxel-induced tumor shrinkage. In invasion assays, SHC1 and NCOA3 knockdown significantly decreased the invasion of TNBC cells. These results suggest that targeting SHC1 and NCOA3 is worth investigating for the treatment of TNBC.
Pre-clinical investigation of estrogen receptor β agonists for the treatment of breast cancer

Samayoa C, Krishnegowda NK K, Vadlamudi RK K and Tekmal RR R. University of Texas Health Science Center at San Antonio, San Antonio, TX.

Breast Cancer is the primary cause of cancer-associated mortality worldwide, and in United States alone, more than 250,000 women are diagnosed every year. Current breast cancer treatment strategies focus on Estrogen Receptor α signaling, given that the majority of cases diagnosed are ERα positive. These treatment strategies include endocrine therapies; such as anti-estrogens or aromatase inhibitors. Although, endocrine therapy has been demonstrated to be successful and effective, therapy resistance commonly arises and results in relapse. While current endocrine therapies focus on ERα signaling, emerging studies highlight the importance of Estrogen Receptor β. Unlike ERα, ERβ has been shown to have tumor-suppressive function in various cancers, including breast cancer. Recent studies have identified, synthesized, and tested the clinical safety of ERβ-selective agonists. The objective of this study was to investigate the utility of using ERβ agonists in the treatment of breast cancer.

To investigate the utility of ERβ agonists in the treatment of breast cancer, we used in-vitro and in-vivo pre-clinical models systems. Our results demonstrated that treatment with ERβ agonists, S-Equol and LY500307, was able to inhibit the short-term and long-term growth of both endocrine therapy sensitive and resistant breast cancer cells. Progression through the cell cycle, cell migration and cell invasion was also abrogated upon treatment. In-vivo, our syngeneic tumor mouse model demonstrates a decline in tumor growth rate after treating with a combination of letrozole and ERβ agonist. Gene expression array analysis reveal that treatment with ERβ agonist elicits changes in key signaling molecules involved in cell death and cell cycle pathways. In Letrozole resistant cells, Letrozole treatment had not effect on gene expression, while LY500307 treatment resulted in the modulation of 780 genes. Interestingly, combining Letrozole with LY500307 resulted in the modulation of 966 genes, of which 417 were unique to the combination treatment. Our studies suggest that activation of ERβ signaling is a valuable strategy in the treatment of breast cancer, even in cases which have developed resistance to current endocrine therapies.
Title: PYTHIA: A phase II study of palbociclib plus fulvestrant versus placebo plus fulvestrant for pretreated patients with ER+/HER2- metastatic breast cancer

Zardavas D, Regan M, Maibach R, Ruepp B, Hiltbrunner A, Blacher L, Goulioti T, Gelber R, Flamen P, Piccart M and Malorni L. Breast International Group, Brussels, Belgium; International Breast Cancer Study Group, Bern, Switzerland; Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA; Frontier Science and Technology Research Foundation, Amherst, NY; Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium and Hospital of Prato, Azienda USL Toscana Centro, Prato, Italy.

Body: Background: Palbociclib (PD 0332991) is an orally bioavailable, potent, and selective inhibitor of CDK4/6, blocking cell cycle progression from G1 into S phase. Preclinical data indicate that palbociclib has enhanced activity against luminal ER+ human breast cancer (BC) cell lines in vitro, showing synergy with endocrine treatment. Recently, randomized clinical trials showed significant PFS prolongation in patients with newly diagnosed and pretreated metastatic luminal BC, when palbociclib was combined with letrozole and fulvestrant respectively (PALOMA-1/2 and -3 trials). However, predictive biomarkers for patient selection to receive palbociclib plus endocrine treatment are still missing.

Study design: PYTHIA is a phase II, two-arm, randomized (3:1), double-blind, multicenter, study of fulvestrant and palbociclib versus fulvestrant and placebo in postmenopausal women with ER+/HER2-, advanced BC, progressed after prior endocrine therapy (1st or 2nd line). Of note, only patients successfully enrolled in the AURORA program (NCT02102165), a longitudinal cohort study incorporating extensive molecular characterization of matched primary and metastatic BC samples are eligible. The primary endpoint is PFS, based on local assessment of response using RECIST 1.1. Secondary endpoints are safety and tolerability, as well as disease control rate. PYTHIA incorporates several correlative objectives, with the exploration of the potential predictive value of: i) mutations and copy number aberrations in a panel of cancer-related genes in both primary and metastatic tumor lesions, ii) gene signatures inferred by RNA sequencing, iii) early FDG-PET/CT assessment performed by two blinded, independent experts, for a subset of 30 patients, at baseline and Day 28, and iv) a serum thymidine kinase-1 (TK1) assay, performed at baseline and after Cycle 1.

Statistical methods: The sample size was determined in consideration of the primary and correlative objectives. The median PFS of patients treated with fulvestrant alone is assumed to be 6 months. When 92 events are observed, there is 75% power to detect an improvement in median PFS from 6 to 10.5 months (43% reduction in hazard, HR=0.57; one-sided $\alpha=0.05$) with palbociclib plus fulvestrant, and 52% power to detect a 50% improvement in median PFS to 9 months (33% reduction in hazard, HR=0.67).

Target accrual: Enrollment opened in May 2016, with the target-recruitment being 120 patients at 21 sites in Belgium, Italy and the UK.

Title: Mutations in PIK3R1 activate multiple pathways in breast cancer

Abukhdeir AM, Turturro SB, Major MS, Brar SS and Cobleigh MA. Rush University Medical Center, Chicago, IL.

Body: It has been estimated that by the end of this year, 270,000 American women will be newly diagnosed with breast cancer, while 40,000 women who already have breast cancer will succumb to the disease. Considerable attention has been given to the PI3K signaling cascade following the discovery that PIK3CA is the most frequently mutated oncogene in breast cancer. However, few studies have explored the function of PIK3R1, which is the regulatory domain of the PI3K complex, despite being mutated in ~3% of all breast cancers. Several studies have demonstrated that expression of PIK3R1 is downregulated in human cancers. Decreased expression of the PIK3R1 protein leads to tumor formation, suggesting its role as a tumor suppressor gene and a potential prognostic marker in breast cancer. However, PIK3R1 is a gene with little pre-clinical evidence to recommend experimental therapies. Despite this lack of evidence, commercial services that perform molecular analyses of tumors suggest the use of an mTOR inhibitor for patients whose breast cancers carry mutant PIK3R1.

In order to determine if mTOR inhibitors were indeed effective in mutant PIK3R1 tumors, we created and characterized a model for mutant PIK3R1 in the non-tumorigenic, human breast epithelial cell line, MCF-10A. Surprisingly, we observed that mTOR inhibitors were ineffective in these cells. However, in searching for other classes of small molecule inhibitors that were effective, we observed that mutations in PIK3R1 sensitized cells to MAPK inhibitors. Herein, we present the first evidence for the use of targeted therapies in breast cancers carrying mutant PIK3R1. We provide evidence against the use of mTOR inhibitors and provide a rationale for the use of MAPK inhibitors.
Title: A novel subgroup of estrogen receptor positive breast cancer may benefit from super-enhancer guided patient selection for retinoic acid receptor α agonist treatment

Body: Endocrine-resistance remains a major challenge for treatment of breast cancer. Multiple mechanisms for endocrine resistance have been proposed, including altered expression of ER co-regulators such as Retinoic Acid Receptor Alpha (RARα). Furthermore, crosstalk between estradiol and RA signaling is known and upregulation of RARα has been observed in tamoxifen resistance. We propose a novel treatment paradigm for a newly-defined subset of HR+ patients based on our discovery of a super-enhancer (SE) associated with the RARA locus. SEs are large, highly active chromatin regions that pinpoint cancer vulnerabilities. The RARA SE-identified vulnerability can be targeted using the potent, selective, and metabolically stable RARα agonist SY-1425 (tamibarotene). SY-1425 is approved in Japan to treat Acute Promyelocytic Leukemia, has a well-established efficacy and safety profile, and may enhance response to hormonal therapy (HT) in this newly-defined subset of HR+ patients potentially delaying the need for alternate treatment.

Tumor samples from 42 breast cancer patients were analyzed across a range of molecular subtypes. We identified an SE linked to the RARA gene in 54.5% of the hormone positive patient samples. RARA SEs predicted sensitivity to SY-1425 in 12 breast cancer cell lines confirming their functional role, and showed a correlation with RARA gene expression. A panel of 37 breast cancer cell lines was tested for SY-1425 anti-proliferative activity and gene expression levels, and identified RARA as the single best predictor of response. Proliferation of RARA-high cells was inhibited by SY-1425 with low nanomolar EC50s. Transcriptional profiling was performed on 4 HR+ and 3 HER2+/HR- breast cancer cell lines and analyzed by GSEA to examine the molecular response to SY-1425. Signatures for growth including E2F, MYC, DNA replication, and cell cycle were significantly downregulated while retinol metabolism and luminal signaling were upregulated. Estrogen signaling was also significantly altered by SY-1425, supporting known crosstalk between RARα and ER. Consistent with differentiation, CYP26A1 and VE-Cadherin were induced and Actin and Ki67 were diminished at relevant concentrations of SY-1425 and could serve as pharmacodynamic markers of response.

To test responses to SY-1425 in vivo, two cell line-derived models and two patient-derived breast cancer models (one RARA-high, and one RARA-low each) were treated with SY-1425. SY-1425 inhibited tumor growth in the RARA-high models, but not the RARA-low models (43% versus 0% TGI). Consistent with the observed changes in transcription, SY-1425 in combination with tamoxifen synergistically inhibited proliferation of RARA-high breast cancer cell lines.

Although a few clinical studies have investigated the use of ATRA in HR+ breast cancer without success, our results suggest that patient selection based on the RARA SE may predict which HR+ breast cancer patients could derive benefit by adding an RARα agonist to HT. The potential to prolong or increase the clinical effect of anti-estrogen therapy with SY-1425, which has improved potency, selectivity, and PK stability versus ATRA, would be an attractive strategy to explore.
**Title:** Phase II study of taselisib (GDC-0032) plus fulvestrant in HER2-negative, hormone receptor-positive advanced breast cancer: Analysis by PIK3CA and ESR1 mutation status from circulating tumor DNA

**Methods:**
In this phase II, open-label, single-arm study (PMT4979g; NCT01296555), pts were postmenopausal with HER2-negative, HR-positive locally advanced or metastatic BC and progression or non-response to \( \geq \)1 prior endocrine therapy in the adjuvant or metastatic setting. Pts received taselisib (6 mg capsule orally, daily) plus fulvestrant (500 mg intramuscular on Days 1 and 15 of Cycle 1, then Day 1 of each 28-day cycle) until disease progression or unacceptable toxicity. PIK3CA-mutation testing on archival tumor tissue used the cobas® PIK3CA Mutation Test. The Sysmex Inostics' BEAMing Digital PCR platform was used for ctDNA analysis of ESR1 and PIK3CA mutations (pre-dose on Cycle 1, Day 1). Primary endpoints were objective response rate (ORR) and clinical benefit rate (CBR) in all pts and those with PIK3CA mutations. ORR was confirmed complete response (cCR) and confirmed partial response (cPR). CBR was cCR, cPR, or stable disease for \( \geq \)6 months. Secondary endpoints included safety, efficacy, pharmacokinetics, and exploratory biomarker analysis.

**Results:**
60 pts were enrolled. Median age was 61.5 years (range 31–82). In the metastatic setting, pts had received prior chemotherapy (21.7%) and prior hormonal therapy (50.0%). 86.7% of pts had received prior treatment with an AI. 45 pts had PIK3CA mutation status from archival tumor tissue and ctDNA testing; concordance was 86.7% (39/45). ctDNA analysis, vs archival tumor tissue testing, identified 4 pts and 9 pts with PIK3CA mutations from pts with WT and unknown PIK3CA mutation status, respectively. Based on ctDNA analysis (N=60), 13 pts (21.7%) had mutations in both ESR1 and PIK3CA, 21 pts (35.0%) were 'mutation not detected' (MND) for both genes, 8 (13.3%) had ESR1 mutations and PIK3CA MND, and 18 (30.0%) had ESR1 MND and PIK3CA mutations.

In pts with measurable disease at baseline, confirmed responses (all partial) were: PIK3CA mutation, 38.1% (8/21); PIK3CA MND, 8.7% (2/23); all pts, 22.7% (10/44). CBRs were: PIK3CA mutation, 42.9%; PIK3CA MND, 17.4%; all pts, 29.5%. ORR and CBR from ctDNA analyses were similar to archival tumor tissue data.

**Conclusions:**
ctDNA analysis identified PIK3CA mutations in pts with previously unknown or WT mutation status from archival tumor tissue; ORR and CBR were similar to those from archival tumor tissue suggesting that PIK3CA mutation testing from ctDNA may be used as a surrogate when tissue is unavailable. 21.7% of pts had mutations in both ESR1 and PIK3CA.
Title: SYD985, a novel anti-HER2 ADC, shows promising activity in patients with HER2-positive and HER2-negative metastatic breast cancer

Aftimos PG G, van Herpen CM M, Mommers EC C, Koper NP P, Goedings P, Oesterholt M, Awada A, Desar IM M, Lim J, Dean E, Rolfo C, Macpherson I and Banerji U. Institut Jules Bordet - Université Libre de Bruxelles, Brussels, Belgium; Radboud University Medical Center, Nijmegen, Netherlands; Synthon Biopharmaceuticals BV, Nijmegen, Netherlands; The Institute of Cancer Research and The Royal Marsden, London, United Kingdom; The Christie NHS Foundation Trust, Manchester, United Kingdom; University Hospital Antwerp, Edegem, Belgium and Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom.

Body: Background:
SYD985 is a HER2-targeting antibody-drug conjugate (ADC) based on trastuzumab and a cleavable linker-duocarmycin (vc-seco-DUBA) payload. Following proteolytic cleavage the synthetic duocarmycin prodrug is activated, binds to the minor groove of DNA, and subsequently causes irreversible DNA-alkylation. SYD985 has demonstrated unprecedented anti-tumor activity in preclinical breast cancer models with high (HER2 3+) or moderate/low expression of HER2 (HER2 2+ and HER2 1+). Clinical data of patients with HER2-positive and HER2-negative breast cancer treated with SYD985 in an ongoing first-in-human phase I trial (NCT02277717) in patients with locally advanced or metastatic solid tumors are presented.

Trial design:
Main inclusion criteria are ECOG performance status 0-1, left ventricular ejection fraction ≥ 55%, and adequate organ function. Patients are treated with SYD985 every three weeks until tumor progression or unacceptable toxicity. Thirty nine patients, including 26 breast cancer patients, were enrolled in the dose-escalation part and treated with doses varying from 0.3 mg/kg to 2.4 mg/kg SYD985. Patients enrolling in the first expanded cohort will be treated with 1.2 mg/kg SYD985. In this cohort a total of 48 patients with HER2-positive breast cancer (IHC 3+ or ISH positive) will be enrolled from May 2016 onwards. HER2 status was determined locally in the dose-escalation part but will be done centrally in the expanded cohort part of the trial. Tumor evaluation (RECIST 1.1) is performed every 6 weeks.

Results:
Enrolled breast cancer patients were heavily pretreated with a median of 7 systemic therapies. All patients with HER2-positive breast cancer were previously treated with trastuzumab and ado-trastuzumab emtansine (T-DM1). As of 16 May 2016, tumor evaluation data were available for 19 of the 26 enrolled breast cancer patients. In total, 8 partial responses were observed of which 6 were confirmed by a second CT-scan. The number of cycles administered ranged from 1 to 11. Ten of the 26 patients are still on treatment.

One dose-limiting toxicity occurred at 2.4 mg/kg SYD985, i.e. pneumonitis (grade 5). Overall, SYD985 is well tolerated up to doses of 1.8 mg/kg every 3 weeks. The most frequently reported drug-related AEs were conjunctivitis, stomatitis, fatigue, and decreased appetite. The majority of drug-related AEs were of mild or moderate intensity.

Conclusion:
SYD985 shows promising efficacy in both HER2-positive and HER2-negative metastatic breast cancer patients with an acceptable safety profile. SYD985 may offer a new targeted treatment option for patients who have become refractory to the available HER2-targeting therapies, and potentially for breast cancer patients who are not indicated for HER2-targeting therapies. Updated data, including additional results of up to 48 HER2-positive breast cancer patients, will be presented during the meeting.
**Title:** A phase I study of AZD9496, a novel oral, selective estrogen receptor degrader (SERD) in women with estrogen receptor positive, HER-2 negative advanced breast cancer (ABC)

Hamilton E, Patel M, Armstrong A, Baird R, Jhaveri K, Hoch M, Morgan S, Dowdall T, Schiavon G, Klinowska T, Weir H, Bujac S, Nash T and Im S-A. Sarah Cannon Research Institute/Tennessee Oncology; Sarah Cannon Research Institute/Florida Cancer Specialists; The Christie NHS Foundation Trust and the University of Manchester, United Kingdom; Cambridge Cancer Centre, United Kingdom; Memorial Sloan Kettering Cancer Center, New York; AstraZeneca, Cambridge, United Kingdom and Seoul National University Hospital, Korea.

**Body:**

**Background** AZD9496 is a potent orally bioavailable ER antagonist and degrader that has shown antitumor efficacy in a range of preclinical xenograft models including ESR1 wild-type tamoxifen-resistant and long term estrogen deprived models and an ESR1 mutant model.

**Methods** This is a phase I, open label global multicenter study in women with ER+ HER2–ve BC either metastatic or locoregionally recurrent, not amenable to treatment with curative intent. Patients are post-menopausal, or pre-menopausal women receiving LHRH agonist therapy, with disease progression after ≥6 months endocrine therapy for ER+ BC (no limit on number of prior endocrine therapies; ≤2 prior chemotherapies in advanced setting). The primary objective is to determine the safety and tolerability of AZD9496. Cohorts of 3-6 patients received daily oral therapy and dose limiting toxicities (DLTs) occurring in cycle 1 (28 days) were assessed. Patients are dosed until MTD (defined as ≤1/6 patients with a DLT) or maximum feasible dose (MFD) is reached. Key secondary objectives include determination of single and multiple dose pharmacokinetics (PK), and preliminary antitumor efficacy. ER target modulation by protein and gene expression is evaluated in circulating tumor cells and paired tumor biopsies.

In addition to the dose escalation phase, expansion cohort(s) in patients with or without ESR1 mutations can be enrolled to examine the safety, tolerability, PK and biological activity of AZD9496 further.

**Results** Preliminary data as of 30th April 2016: 45 patients (median age 62 (range 41-83); 38 post-menopausal, 7 pre/perimenopausal; visceral metastases 76%, prior fulvestrant 25/45) received AZD9496 in 7 dose escalation cohorts: 20mg QD n=4, 40mg BID n=6, 80mg BID n=5, 150mg BID n=6, 250mg BID n=6, 400mg BID n=6, 600mg BID n=6 and also a 250mg BID expansion cohort n=6. The majority of adverse events (AEs) were grade 1 or 2; the most common treatment-related AEs (≥10%) have been diarrhoea (33%), fatigue (27%), nausea (22%), upper abdominal pain (13%) and increased liver function tests (13%). Six patients had treatment-related grade 3 AEs, 5 of which were manageable with dose interruption +/- dose reduction. Specifically, three had DLTs: grade 3 increased AST/ALT/GGT-150mg BID, serious adverse reaction (SAR) leading to withdrawal; grade 3 diarrhoea and grade 3 increased AST/ALT/GGT-400mg BID, SAR, manageable with dose reductions; grade 3 diarrhoea 600mg BID, manageable with dose reduction. The MTD/MFD has not been reached. Following the first dose up to 400mg the AZD9496 exposure increased in reasonable proportion to increasing dose. At 600mg a more than dose-proportional increase in exposure was observed. Evidence of reduced ER and Ki67 has been observed in on-study biopsies at 150mg BID and above. 10 subjects received treatment for >3-<6 months (5 ongoing, 5 discontinued), 4 subjects >6-<12 months (3 ongoing, 1 discontinued), 3 subjects ≥1 year (2 ongoing, 1 discontinued).

**Conclusions** AZD9496 has a tolerable safety profile, evidence of PD biomarker modulation and prolonged stabilisation of disease in women with heavily pre-treated ER+ve ABC.
Title: Phase 1 study of the antibody-drug conjugate (ADC) SGN-LIV1A in patients with heavily pretreated metastatic breast cancer

Forero-Torres A, Modi S, Specht J, Miller K, Weise A, Burris III H, Liu M, Krop I, Pusztai L, Kostic A, Li M and Mita M. University of Alabama at Birmingham, Birmingham, AL; Memorial Sloan Kettering Cancer Center, New York, NY; Seattle Cancer Care Alliance, University of Washington, Seattle, WA; Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN; Karmanos Cancer Institute, Detroit, MI; Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN; Mayo Clinic, Rochester, MN; Dana-Farber Cancer Institute, Boston, MA; Yale University School of Medicine, New Haven, CT; Seattle Genetics, Inc., Bothell, WA and Cedars-Sinai Medical Center, Los Angeles, CA.

Body: Background

LIV-1, a transmembrane protein and downstream target of STAT3, is highly expressed in breast cancer cells. It is associated with lymph node involvement and metastatic progression. SGN-LIV1A is an anti-LIV-1 antibody conjugated via a protease-cleavable linker to monomethyl auristatin E (MMAE). Upon binding to cell-surface LIV-1, SGN-LIV1A is internalized and releases MMAE, which binds to tubulin and induces G2/M arrest and apoptosis.

Methods

This is an ongoing, phase 1 dose-escalation study evaluating safety, tolerability, pharmacokinetics, and antitumor activity of SGN-LIV1A (q3 wks IV) in women with LIV-1-positive, unresectable, locally advanced or metastatic breast cancer (LA/MBC) (NCT01969643). Patients (pts) with measurable disease and ≥2 prior cytotoxic regimens for LA/MBC were eligible. Pts with ≥Grade 2 neuropathy were excluded. Response was assessed per RECIST v1.1; pts with stable disease (SD) or better could continue treatment until disease progression or intolerable toxicity. At completion of dose escalation in hormone receptor-positive/HER2-negative (HR+/HER2–) and triple-negative (TN) pts, expansion cohorts were opened to further evaluate safety and antitumor activity of monotherapy in TN pts and combination therapy with trastuzumab (Tz) in HER2-positive (HER2+) pts. Pre- and post-treatment tumor biopsies were done to evaluate LIV-1 expression and other correlative endpoints.

Results

To date, 39 pts (18 HR+/HER2–, 21 TN) have received a median of 3 cycles (range, 1–10) of SGN-LIV1A monotherapy at doses of 0.5–2.8 mg/kg. Median age was 57 yrs (range, 33–79). At baseline, pts had a median of 4 prior cytotoxic regimens for LA/MBC (range, 2–8); 36 had visceral disease and 25 had bone involvement. No dose-limiting toxicities (DLT) occurred in 19 DLT-evaluable pts; maximum tolerated dose was not exceeded at 2.8 mg/kg. Treatment-emergent adverse events (AEs) reported in ≥30% of pts were: fatigue (64%), nausea (54%), alopecia (46%), decreased appetite (41%), constipation (39%), neutropenia (33%), and vomiting (31%). Peripheral neuropathy was reported in 9 pts (23%). Most AEs were Grade 1/2, except neutropenia (all ≥Grade 3). Four pts discontinued treatment due to AEs (acute respiratory distress syndrome, nausea, pneumonia, tachycardia). In dose escalation, modest activity was observed in 17 efficacy evaluable (EE) HR+/HER2- pts, with a disease control rate (DCR) of 59% (10 SD), including 1 pt with SD≥24 wks. Among the 17 EE TN pts (dose escalation plus cohort expansion), the overall response rate (ORR) was 41% (7 PR), DCR was 82% (7 PR, 7 SD) and clinical benefit rate (CBR=OR+SD≥24 wks) was 53% (9 pts). For TN pts, median PFS was 17.1 wks (95% CI: 6.0, 18.4); 6 pts remain on treatment. Of 281 MBC tumor samples evaluated for LIV-1, 93% were positive; 81% had moderate-to-high expression (H-score ≥100).

Conclusions

LIV-1 is expressed in almost all MBC tumors. SGN-LIV1A monotherapy has been generally well tolerated and shown encouraging antitumor activity in heavily pretreated TN MBC, with a PR rate of 41% and a CBR at ≥24 wks of 53%. Response duration data continue to evolve. Enrollment continues in the TN monotherapy expansion cohort and the HER2+ combination cohort with Tz.
Title: Targeting estrogen receptor mutations for treatment of endocrine therapy resistance in breast cancer

Body: Objectives:
Breast cancer is the most commonly diagnosed non-cutaneous cancer and the second leading cause of cancer-related deaths (>40,000 estimated deaths in 2015) among women in the United States. Approximately 70% of all breast cancers express the Estrogen Receptor (ER) and inhibition of the ER signaling remains the mainstay of systemic therapy in such cancers. However, acquired endocrine therapy resistance is a major obstacle to effective treatment of a significant proportion of ER-positive breast cancers. Our group and others have recently reported mutations in the gene encoding the Estrogen Receptor (ESR1) in metastatic breast cancer patients. Preliminary studies have suggested that ESR1 mutations confer endocrine therapy resistance in ER-positive breast cancers. Recent studies have shown that bromodomain and extraterminal (BET) family of proteins act downstream of ER activation and regulate the transcriptional function of ER. We hypothesized that BET inhibition serves as a novel strategy for targeting ESR1 mutations and represents an attractive approach for treatment of endocrine therapy resistance.

Methods: In vitro models of endocrine therapy resistance in breast cancer were developed by ectopic expression of two of the most commonly found ESR1 mutations (Y537S and D538G) in ER-positive cell lines, MCF-7 and T47D. Cell growth assays in estradiol-free conditions were used to assess growth of these cells in the presence of tamoxifen and BET inhibitor, OTX015.

Results: MCF-7 and T47D cells expressing mutant ESR1s show significant growth advantage when compared to the isogenic cells expressing the wild type ESR1 in estradiol-free conditions (which mimic the estradiol-free state of post-menopausal women treated with aromatase inhibitors). Cells expressing the ESR1 mutations showed remarkable resistance to growth inhibition by tamoxifen while cells expressing the wild type ESR1 were highly sensitive. BET inhibitor, OTX015, was highly effective in inhibiting the growth of breast cancer cells expressing ESR1 mutations. OTX015 was also highly effective in down-regulating canonical ER-responsive genes such as Gene Regulated by Estrogen in Breast Cancer 1 (GREB1) in cells harboring ESR1 mutations while tamoxifen only showed marginal effectiveness.

Conclusion: ESR1 mutations confer endocrine therapy resistance in breast cancer. BET inhibitor OTX015 targets the transcriptional function of mutant ER proteins and is effective in reversing endocrine therapy resistance due to ESR1 mutations in in vitro models of breast cancer. Further validation of our findings in in vivo models may provide impetus for clinical evaluation for BET inhibitors for treatment of endocrine therapy resistance due to ESR1 mutations.

Title: Nonsteroidal, tissue selective androgen receptor modulator (SARM), enobosarm, reduces growth of androgen receptor-positive breast cancer in patient-derived preclinical models

Body: Introduction: In breast cancer the androgen receptor (AR) is the most abundantly expressed steroid receptor with 75-95% of estrogen receptor (ER)-positive and 40-70% of ER-negative breast cancers expressing the AR. Historically, advanced breast cancer has been treated with androgens, resulting in significant clinical response. However, the use of steroidal androgens fell from favor as a result of their virilizing side effects. Nonsteroidal, tissue selective androgen receptor modulators (SARMs) will provide a novel targeted approach to exploit the therapeutic benefits of androgens in breast cancer.

Aims: To test the effects of enobosarm (a first-in-class SARM) and enzalutamide (AR antagonist) on the growth of patient-derived breast cancer xenografts (PDX) and to discern the mechanism of action of AR-targeted therapies in AR-positive breast cancer.

Materials and Methods: AR-positive PDXs with varying receptor expression (ER, progesterone receptor (PR), and HER2) were implanted in immunecompromised mice. Mice carrying PDXs were treated with vehicle, 10 mg/kg/day (mpk) enobosarm (GTx, Inc., Memphis, TN), or 20 mpk enzalutamide (Medivation Inc.), orally. Tumor volume was measured twice or thrice weekly. Tumors that received enobosarm were further analyzed to determine the mechanism of action.

Results: Enobosarm significantly (p<0.01) inhibited the growth of ER-, PR-, and HER2- positive HCI-7 and ER- and PR- negative and HER2-positive HCI-12 PDX. While enobosarm inhibited the growth of HCI-12 by ~80% and HCI-7 by ~60%, enzalutamide failed to inhibit the growth of the HCI-7 PDX. In contrast, neither enobosarm nor enzalutamide inhibited the growth of ER- and PR-negative and HER2-positive HCI-9 PDX, consistent with the heterogeneity of AR-positive breast cancers. Growth of two triple-negative breast cancer (TNBC) PDXs were inhibited by 30-40% by enobosarm, but not by enzalutamide. These results were reproduced in xenografts developed with breast cancer cell lines, MCF-7 and MDA-MB-231 expressing the AR. Gene expression studies conducted with the HCI-12 tumors indicated that enobosarm inhibited the expression of various proliferative genes (MUC2, IL10RA, IGSF1, SLC6A4, and others) and increased the expression of growth inhibitory genes (CYP4F8, MYBPC1, and others). Ingenuity pathway analysis demonstrated that enobosarm inhibited genes that are downstream of HER2 signaling. Interestingly, miR-21-3p, which has been implicated in chemo-resistance, was consistently expressed at approximately 10-50-fold higher than miR-21-5p in PDXs. This imbalance was partially reversed by enobosarm.

Conclusion: These results indicate that AR-positive breast cancers are highly heterogeneous and that enobosarm has promise as novel targeted therapy to treat AR-positive breast cancer. Enobosarm is currently in phase II clinical trial in both ER-positive breast cancer and in TNBC patients.
Title: Neutralization of BCL2/XL enhances the cytotoxicity of T-DM1 in vivo

Zoeller JJ J, Dillon DA A, Bronson RT T, Sampath D, Leverson J and Brugge JS S. Harvard Medical School, Boston, MA; Brigham & Women's Hospital, Boston, MA; Genentech, San Francisco, CA and AbbVie, Chicago, IL.

Body: One of the most recent advances in the treatment of HER2+ breast cancer is the development of the antibody-drug conjugate, T-DM1. T-DM1 has proven clinical benefits for patients with advanced and/or metastatic breast cancer who have progressed on prior HER2-targeted therapies. However, T-DM1 resistance ultimately occurs and represents a major obstacle in the effective treatment of this disease. We previously identified BCL2 upregulation as a critical component of the adaptive response to inhibition of PI3K/mTOR or HER2, and thus examined whether BCL2/XL combinatorial strategies could improve the initial efficacy of T-DM1.

We have found that combined inhibition of BCL2/XL plus T-DM1 significantly enhances the cytotoxicity of T-DM1 in vivo. The effectiveness of T-DM1 plus BCL2/XL inhibition was evaluated in two patient-derived xenograft (PDX) models, both established from advanced and treatment resistant HER2+ patient pleural effusions (PDX8;12). Animals were randomized into one of four groups: T-DM1, ABT-263, T-DM1 + ABT-263 or vehicles. To minimize thrombocytopenia induced by ABT-263, we included a fifth group that received pulsed treatment of ABT-263 + T-DM1. Notably, unlike continuous treatment, pulsed administration of ABT-263 reduced weight loss to vehicle levels and allowed recovery of platelets. Our results after a 14d treatment period indicate that combined treatment with T-DM1 + ABT-263, the dual BCL2/XL inhibitor, confers an exceptional tumor cell cytotoxic advantage characterized by widespread elimination of the tumor cells.

To quantitate pathological responses in vivo and to incorporate a tumor size measurement, we adapted and applied a Residual Tumor Burden (RTB) score system. We estimate the residual tumor area and viable tumor cell content and calculate an RTB score to summarize these two measurements. Supportive of our H&E observations, the RTB scores highlight the dramatic effectiveness of combination treatment in PDX8 & 12. We have subsequently developed a modified treatment plan that maximizes treatment effectiveness and minimizes side effects. We have also tested this drug combination in two additional PDX models of HER2+ breast cancer.

We also characterized the residual tumor cells that escape combination treatment. Some of the residual tumor nests in the PDX8 tumor model were encapsulated within p63+ intraductal-like structures. These observations recapitulate complete pathological responses with residual DCIS as observed in patient tumors. In addition, we found that T-DM1 either alone or in combination with ABT-263 down regulates HER2 protein levels in PDX8 & 12 tumors. The loss of target expression could, in part, account for a sub-population of the residual cells. Despite initial classification as HER2+ and significant responses to combination treatment, clinical assessment of HER2 status indicated that the PDX8 & 12 xenografts used in our study were FISH- and IHC 0-1+. These results provide strong motivation to extend pre-clinical investigations of this drug combination beyond HER2/FISH+ disease. The dramatic improvement in tumor regression observed in these preclinical studies, together with the safety benefits of ABT-263 modified dosing, provides substantial rationale for the clinical investigation of this drug combination.
Title: Phase I study of low dose oral cyclophosphamide (C) plus the poly-ADP-ribose- polymerase (PARP) inhibitor veliparib (V) in women with HER2/neu-negative inoperable locally advanced/metastatic breast cancer (MBC): NCI P8853

Anampa JD D, Patel M, Pellegrino C, Fehn K, Makower D, Oh S-y, Noah K, Chen A, Sparano JA A and Andreopoulou E. Montefiore Medical Center/ Albert Einstein College of Medicine, Bronx, NY; CTEP/NIH, Bethesda, MD and Weill Cornell Breast Center/ New York Presbyterian Hospital- Weill Cornell Medicine, NYC, NY.

Body: BACKGROUND: PARP, an essential nuclear enzyme, is involved in the recognition of DNA damage and facilitation of DNA base-excision repair (BER). PARP inhibition sensitizes tumor cells to cytotoxic agents which induce DNA damage, including C. Metronomic dosing of C may optimize potential for synergy with PARP inhibitors, and also inhibits angiogenesis (Kerbel et al, Nat Rev Cancer, 4:423-36, 2004) and may enhance anti-tumor immunity (Ghiringhelli et al. Cancer Immunol Immunother 56:641–648, 2007) V is an oral small molecule inhibitor of PARP which potentiates the antineoplastic activity of DNA damaging agents such as C in MX-1 breast xenograft model (Donawho et al Clin Cancer Res 13:2728-37, 2007). We performed a phase I trial of metronomic dose oral C plus V in patients with MBC.

METHODS: The primary objective was to determine the safety and identify the recommended phase II dose (RPTD) of the combination of low-dose oral C once daily in combination with V (100, 200, 300 mg) administered BID for 21 days using a standard 3+3 design. Eligibility included HER2/neu negative MBC, ECOG PS 0-1, and at least 1 prior chemotherapy regimen for MBC. Dose limiting toxicity (DLT) was defined as any Grade 3 non-hematological toxicity or Grade 4 thrombocytopenia/neutropenia occurring during cycle 1. After the RPTD of V was shown to be 200 mg BID with C 50 mg daily, the trial was amended to increase the C dose to 75, 100 and then 125 mg daily until hematologic toxicity was dose-limiting.

RESULTS: 31 patients were enrolled, 19 treated with 50 mg of C and 12 treated at higher doses (75-125 mg), with V doses ranging from 50 mg-300 mg BID (see table); 5 patients with not evaluable due to rapid disease progression (N=2), non-compliance (N=2), or tumor pain that was not a DLT (N=1). Median age was 52 years (28-72 years), 14 (45 %) had triple negative disease, all had at least 1 prior chemotherapy regimen for metastasis (median 2, range 1-8), and, 7 had germline BRCA mutations, (3 BRCA1 and 4 BRCA2). When combined with 50 mg C daily, RPTD of V was 200 mg PO BID, with nausea being DLT at 300 mg BID. DLT was not observed in any of the 9 additional patients. The median number of cycles given was 3 (range 1-14). Clinical benefit (response or stable disease for at least 24 weeks) occurred in 3/7 (43%), 1/3 (33%) and 1/16(6%) for BRCA mutated, BRCA negative and BRCA unknown, respectively. Median progression-free survival was 4.3 months (1.2-10.9 months) for BRCA mutated patients and 2 months (0.7-10 months) for non-mutated.

CONCLUSIONS: The combination of oral continuous dosing of V (200 mg PO BID) with metronomic C (50, 75, 100 and 125 mg daily) is well tolerated and shows antitumor activity in patients with BRCA mutation associated MBC. The RPTD is C 125 mg daily plus V 200 mg BID, although further escalation of the C dose may be feasible since DLT was not seen at this dose level.

Title: Pan-HER, an antibody mixture with antitumor activity against drug-resistant HER2-overexpressing breast cancers with high ERBB ligand expression

Body: Background: Amplification/overexpression of ERBB receptors and/or ligands has been associated with resistance to anti-HER2 therapies. Pan-HER is a mixture of six antibodies targeting each of the ERBB receptors, EGFR, HER2 and HER3, with synergistic pairs of antibodies. Each pair of antibodies simultaneously blocks ligand binding and/or induces target degradation, thus preventing compensatory mechanisms to anti-ERBB therapies. We examined the antitumor activity of Pan-HER against drug-sensitive and -resistant HER2+ breast cancer cells and xenografts.

Results: Pan-HER exhibited potent growth inhibitory activity against a panel of HER2+ breast cancer cells (BT474, MDA-453, MDA-361, SUM190, HCC1954, UACC893 and SKBR3). Growth inhibition was associated with internalization and degradation of EGFR, HER2 and HER3. Pan-HER was superior to the combination of trastuzumab/pertuzumab (TP) against HER2+/PIK3CA mutant MDA-361, HCC1954, UACC893 and MDA-453 cells. We next compared the effect of Pan-HER against BT474, HCC1954 and MDA-361 xenografts established in nude mice to that of trastuzumab/lapatinib (TL), TP and T-DM1. All treatments were effective across the panel of xenografts. In mice with MDA-361 tumors, Pan-HER and TP were superior to TL. Immunoblot analysis showed significant downregulation of EGFR, HER2 and HER3 only in tumors treated with Pan-HER. After a complete response, treatment was discontinued. Among mice with BT474 xenografts treated with TP, TL and T-DM1, 25-50% of mice exhibited a tumor recurrence within 50 weeks of follow-up, while no recurrences were registered in mice treated with Pan-HER. Tumors recurring after TP and T-DM1 expressed significantly higher HER3 and P-HER3 protein levels and NRG1 mRNA levels. HCC1954 xenografts recurring after T-DM1 also overexpressed NRG1 mRNA compared to tumors before therapy.

We next examined the effect of Pan-HER against trastuzumab-resistant HR6 (BT474) cells (Ritter et al. CCR 2007) and HCC1954 and UACC893 cells with acquired resistance to T-DM1 (TDR; IC_{50} >5-, >6- and 600-fold in HR6, UACC893-TDR and HCC1954-TDR cells, respectively, vs. parental cells). All T-DM1-resistant cells expressed significantly higher HER3 and P-HER3 protein levels and NRG1 mRNA and protein levels. Treatment with the HER3 neutralizing antibody LJM716 resensitized HR6 and HCC1954-TDR cells to T-DM1, suggesting a causal association between the NRG1-HER3 axis and drug resistance. Mice with HR6 tumors were treated with Pan-HER, TL, TP and T-DM1. Only Pan-HER arrested HR6 tumor growth and downregulated EGFR, HER2, HER3, P-HER3 and P-AKT. Finally, HCC1954-TDR tumors rapidly grew in vivo despite treatment with T-DM1. Administration of Pan-HER to mice bearing HCC1954-TDR xenografts growing in the presence of T-DM1, induced rapid tumor regressions.

Conclusions: These data suggest that multitarget therapeutic interventions, such as Pan-HER, which simultaneously remove and/or block all ERBB receptors and ligands, are a feasible and effective approach against HER2-overexpressing cancers both sensitive and resistant to anti-HER2 therapies.
**Title:** Bone seeking matrix metalloproteinase-2 inhibitors prevent bone metastatic breast cancer growth

Tauro M, Laghezza A, Tortorella P and Lynch CC. H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL and University of Bari “A. Moro”, Bari, Italy.

**Body:** Bone metastasis is a common event during breast cancer progression. The resultant lesions are painful and currently, despite medical advances, are incurable. The progression of bone metastatic breast cancer is critically dependent on interactions with the surrounding microenvironment. Therefore, identifying the underpinning molecular mechanisms is vital for the development of new therapies.

Rationale: Gene expression analysis and validation in human and murine specimens of bone metastases revealed that matrix metalloproteinases, such as MMP-2, are highly expressed in the bone metastatic microenvironment and significantly associated with aggressive breast cancer and poorer overall survival. In bone, tumor or host derived MMP-2 contributes to breast cancer growth and does so by processing substrates including type I collagen and transforming growth factor beta (TGFβ) latency proteins. These data provide strong rationale for the application of MMP-2 inhibitors to treat the disease. However, in vivo, MMP-2 is systemically expressed. Therefore, to overcome potential toxicities noted with previous broad-spectrum MMP inhibitors (MMPIs), we used highly selective bisphosphonic based MMP-2 inhibitors (BMMPIs) that allowed for specific bone targeting.

Methods: We utilized a novel chemical approach to synthesize bone seeking MMP inhibitors (BMMPIs) on a bisphosphonic backbone, with specificity for MMP-2 in the nanomolar range (IC$_{50}$=140 nM).

Results: In vitro, we tested the effect of BMMPIs at varying doses (1nM-100µM) on the viability of the major cellular components of the cancer-bone microenvironment, namely breast cancer cells, (PyMT, 4T1, MDA-MB-231, MCF-7), osteoblasts (MC3T3) and osteoclasts (primary monocytes and RAW 264.7). In vivo, we demonstrated using two bone metastatic models (PyMT-R221A-Luc and 4T1-Luc) that BMMPI treatment significantly reduced tumor growth and tumor associated bone destruction. Additionally, BMMPIs are superior in promoting tumor apoptosis compared to the standard of care bisphosphonate, zoledronate. MMP activity was also lower in the BMMPI treated groups (using tumor burden to normalize values). µCT/Xray/Histomorphometry analysis also illustrated the significant beneficial effects of the BMMPIs in reducing the size of osteolytic lesions (up to 80% by µCT; p<0.05).

We demonstrated MMP-2 selective inhibition in the bone microenvironment using specific and broad spectrum MMP probes. Further, compared to zoledronate, BMMPI treated mice had significantly lower levels of TGFβ signaling and MMP generated type I collagen carboxy-terminal (ICTP) fragments. Taken together, our data show the feasibility of selective inhibition of MMPs in the bone metastatic breast cancer microenvironment.

Conclusions. MMP-2 specific inhibition was achieved in the bone microenvironment. BMMPIs significantly inhibit breast cancer growth in bone, they are able to induce breast cancer cell apoptosis and prevent cancer induced bone destruction. Given that bisphosphonates are well tolerated in the clinical setting, we predict that BMMPIs could be translated to the clinical setting for the treatment and eradication of bone metastatic breast cancer.

Title: A randomized, double-blind, placebo-controlled window of opportunity trial evaluating clinical effects of high dose vitamin D in patients with breast cancer

Arnaout A, Robertson S, Addison C, Chang N, Pond G and Clemons M. Ottawa Hospital Cancer Center, Ottawa, ON, Canada; Ottawa Hospital Research Institute, Ottawa, ON, Canada and Ontario Clinical Oncology Group Research Centre at Juravinski Hospital, Hamilton, ON, Canada.

Body: Background: Considerable epidemiologic and preclinical laboratory data suggest that there is a role for vitamin D in breast cancer therapy through its tumor suppressive effects. Window of opportunity trials in breast cancer are a feasible way of assessing the biologic efficacy of therapies in the pre-surgical setting. It takes advantage of the current wait times (2-6 weeks) for breast cancer surgery as a “window of opportunity” to rapidly assess biological changes in vivo with short term administration of novel potentially therapeutic agents. The objective of this study was to assess the biologic effects of short term high dose vitamin D intake on breast tumor biology as demonstrated by changes in biomarkers of proliferation and apoptosis.

Methods: This is a prospective, randomized, double blind, placebo-controlled phase 2 trial assessing the effect of high dose (40,000 IU) of oral vitamin D3 on breast cancer biology in patients awaiting surgical management of their primary breast cancer. Eligible patients took the study drug for at least 2 weeks leading up to the day of surgery. Pre- and post- 25-OH vitamin D blood levels were obtained. In addition, tumor biomarkers including the Ki67 index (marker of proliferation) and caspase 3 (marker of apoptosis) analyzed on the original diagnostic core biopsy sample and then compared to a repeated analysis on the tissue obtained at the time of the definitive surgical procedure.

Results: 80 patients completed the study; 38 in the control group and 42 in the vitamin D group. The mean duration on the study was 19 days. Within the study cohort, 16/80 (64%) were ER positive, 55/80 (55%) were PR positive, 65/80 (61%) were Her2 negative. Mean overall baseline blood 25-OH Vitamin D levels in the study cohort was 76.4 nmol/L, which increased to 241.9 nmol/L in the vitamin D treated group (p=0.0001). Mean Ki67 level at baseline was 35.4% overall and there was no statistically significant difference in the ki67 obtained from the surgical specimen between the treatment group (mean = 39.3%) and the control group (41.0%). Baseline caspase 3 level was 31.2% overall and there was no statistically significant difference in the caspase 3 obtained from the surgical specimen between the treatment group (mean = 13.1%) and the control group (15.6%). However, the overall caspase 3 level (14%) obtained from the surgical specimen from both study groups was significantly lower than that at obtained from the core biopsy at baseline (31.2%) (p=0.04).

Conclusion: This is the first prospective randomized trial evaluating the effect of short term, high dose vitamin D on the in vivo markers of proliferation and apoptosis. No significant difference was seen in these markers as a result of vitamin D intake, despite significantly higher circulating levels of 25-OH vitamin D in the blood. A significant reduction in caspase 3 was noted in both study arms when comparing the biopsy sample to the surgical specimen, which could be due to a reduction in apoptosis activity or technical factors affecting the measurement of caspase 3.
Title: Phase I study of the JAK 1/2 inhibitor ruxolitinib with weekly paclitaxel for the treatment of HER2 negative metastatic breast cancer (MBC)

Body: Introduction: Inflammatory breast cancer (IBC) contains a predominance of CD44+/CD24- cells which are reported to be associated with disease proliferation and metastasis. The IL6/JAK2/STAT3 pathway is active and necessary for the survival of CD44+/CD24- cells. Pre-clinical data have shown that >80% of all IBC overexpress activated STAT3 (pSTAT3) and >95% of triple negative (TN) IBC specimens overexpress pSTAT3 (SABCS 2012 P4-06-01). Ruxolitinib is an approved JAK1/JAK2 inhibitor and has been studied in combination with paclitaxel in IBC PDX models resulting in a synergistic reduction in tumor weight. In anticipation of initiating a phase II study of ruxolitinib and paclitaxel for the treatment of TN IBC, conducted by the Translational Breast Cancer Research Consortium (TBCRC), we completed a phase I study of the combination in patients (pts) with MBC treated at Dana Farber/Harvard Cancer Center.

Methods: Pts with HER2 negative MBC, having acceptable hepatic, renal and hematologic status, were eligible if they had received ≤3 chemotherapy regimens for advanced disease. Objectives included: determination of maximum tolerated dose (MTD) and recommended phase II dose (RP2D), dose-limiting toxicity (DLT), adverse events (AE), clinical activity and association of IL6 and CRP levels with response. Pts were treated with escalating doses of ruxolitinib (10mg bid-25mg bid) in a 3+3 dose escalation design. Weekly (wk) paclitaxel (80 mg/m2/wk) was administrered concurrently with ruxolitinib on a 3-wk cycle. DLT was assessed during the first 2 cycles. Pts with stable disease (SD) or disease response could discontinue paclitaxel after 4 cycles and continue on single-agent ruxolitinib until disease progression (PD). IL6 and CRP values were obtained initially and at the time of PD.

Results: 19 pts were enrolled, with a mean age of 45 years. BC was TN in 8 (42%), 11 (58%) were hormone receptor positive; 12 (63%) had visceral disease. 10 (53%) were enrolled as 1st-line therapy. Pts received a median number of 5 (range 1-12) cycles of combined therapy. 5 pts continued to receive ruxolitinib alone for 1,1,3,4 and 29 cycles. One pt with TN IBC remained on single agent ruxolitinib for 40 cycles. The MTD of ruxolitinib was 25 mg bid. 1 DLT of grade (gd) 3 osteonecrosis of the jaw occurred at 20mg bid, due to bisphosphonate use. 13 (68%) pts required dose reductions or doses held, with toxicities of neutropenia (50%), anemia (33%), fatigue (17%), edema (10%) and dyspnea (1%). 5 of the 6 pts in the 20 mg bid cohort required a dose reduction of paclitaxel prior to completing 4 cycles. The RP2D was determined to be 15 mg bid. 4 (21%) pts had partial response (PR), 12 (63%) pts had SD and 3 (16%) had PD as best response. Pts with PR received a median of 11 cycles and pts with SD received a median of 4 cycles of combination therapy.

Conclusions: The combination of ruxolitinib and weekly paclitaxel was well tolerated with evidence of clinical activity. The R2PD of 15 mg bid ruxolitinib will be used with paclitaxel 80 mg/m2 wk dosing in the upcoming phase II preoperative study for TN IBC conducted by the TBCRC. Clinical trial information: NCT02041429.
Title: Single domain antibody (SBT-100) inhibits growth of human HER2+ and triple negative breast cancers (TNBC) in xenografts by binding STAT3 and P-STAT3

SBT-100 is a single domain antibody (sdAb), developed by Singh Biotechnology, that binds unphosphorylated signal transducer and activator of transcription 3 (STAT3) and phosphorylated STAT3 (P-STAT3). SBT-100 is approximately 13 kD or less than 1/10th the size of a human IgG molecule, and is able to cross the cell membrane to bind intracellular STAT3 and P-STAT3. This in turn inhibits its effects on genes that promote malignant behavior of cancer cells. SBT-100 has a short serum half-life but a long biological half-life. Since certain types of human breast cancers express P-STAT3, we wanted to determine if SBT-100 could inhibit the growth of human breast cancers in vitro and in vivo by studying its effects on MCF-7 (ER+/PR+), BT474 (HER2+), and MDA-MB-231 (TNBC) cells.

BACKGROUND: Many different types of human cancers (solid tumors, leukemias, and lymphomas) are dependent on constitutive expression of (P-STAT3) for their malignant phenotype. Growth factors, tyrosine kinase receptors, cytokines (IL-6, IL-11, IL-12, IL-23), BCR-ABL, and Src are some ways that STAT3 can be activated. In turn P-STAT3 turns on genes such as Cyclin D1 & D3, MMPs, Bcl-xL, Mcl-1, survivin, VEGF, and HIF-1 alpha. Constitutive expression of P-STAT3 has been shown to promote cancer cell proliferation, survival, angiogenesis, immune suppression, and metastasis. Additionally there is increasing evidence suggesting that unphosphorylated STAT3 contributes to malignant phenotype of cancers. STAT3 is also important for the survival of cancer stem cells as well as for some human breast cancers.

METHODS: Immunoprecipitation and Western blot analyses were carried out to test whether SBT-100 binds cytoplasmic STAT3 and P-STAT3 in various malignant cell lines (e.g., MDA-MB-231, PANC-1, DU145, and HeLa). MTT assays were done to determine if SBT-100 could suppress the growth of different types of human breast cancers in vitro. Xenograft cancer models using ER+/PR+ (MCF-7), HER2+ (BT474), and TNBC (MDA-MB-231) cancer cells were used to evaluate treatment with SBT-100 (1mg/kg/BID) for 28 days.

RESULTS: Immunoprecipitation and Western blot studies demonstrated that SBT-100 binds to both STAT3 and P-STAT3 in human cancers cells (MDA-MB-231, PANC-1, DU145, and HeLa). In a three day MTT assay, at least 90% growth suppression was achieved for all three subtypes of human breast cancer, which is highly significant. In the xenograft cancer models, SBT-100 (1mg/kg/BID) treatment for 28 days, yield growth suppression as follows: MDA-MB-231 44.8% (p<0.05) versus its control group and BT474 52% (p<0.07). While the MCF-7 xenograft cancer model showed no suppression.

CONCLUSION: Singh Biotechnology’s novel sdAb, SBT-100 suppresses growth of TNBC and HER2+ human breast cancers in vivo and suppresses growth of ER+/PR+, HER2+, and TNBC cells in vitro. The most significant anti-cancer effects of SBT-100 is observed against human TNBC.
Title: Proteasome inhibitors prevent bi-directional HER2/estrogen-receptor cross-talk leading to cell death in endocrine and lapatinib-resistant HER2+/ER+ breast cancer cells

Thaler S, Schmidt M, Thiede G, Schad A and Sleeman JP P. Centre for Biomedicine and Medical Technology Mannheim (CBTM), Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany; University Medical Center, Johannes Gutenberg University, Mainz, Germany; Institute of Pathology, University Medical Center, Johannes Gutenberg University, Mainz, Germany and Karlsruhe Institute of Technology Campus Nord, Institute for Toxicology and Genetics, Karlsruhe, Germany.

Body: Background: Aberrant signaling through HER2 and other members of the HER family has been identified as mediator of endocrine resistance in estrogen receptor alpha (ERα) positive breast cancer. On the other hand, ERα co-expression has been shown to attenuate the efficiency of anti-HER2 targeted therapies. These findings indicate that HER2 and ERα synergize to allow breast cancer cells to escape from both anti-ERα and anti-HER2-targeted therapies. Rationally designed clinical trials that combine endocrine therapy with anti-HER2 agents to interfere with HER2/ERα cross-talk have been conducted. However, the outcome of these trials suggests that novel therapeutic approaches are needed to further improve inhibition of HER2 and other HER family members in conjunction with a more efficient ERα blockade. We examined the ability of proteasome inhibitors (PIs) to disrupt HER2/ERα cross-talk in HER2+/ER+ breast cancer (BC) cells. Furthermore we investigated the potential of PIs to suppress the activity of a constitutively active HER2 variant resistant to trastuzumab and lapatinib.

Method: HER2+/ER+ BC cells and fulvestrant resistant ER+ BC cells that overexpress a constitutively active HER2 variant resistant to trastuzumab and lapatinib have been treated with the PIs carfilzomib and bortezomib. The potential of these PIs to suppress ERα expression, to block HER2 activation and to inhibit the HER2 downstream pathways PI3K/Akt and Ras/MAPK was monitored by western blotting. Induction of cell death upon PI treatment was measured by quantification of SubG1 cells using propidium iodide staining or the use of colony formation assays.

Results: Carfilzomib and bortezomib markedly inhibit bi-directional HER2/ERα signaling pathways in HER2/ER+ BC cells. Both PIs suppress ERα expression, inhibit HER2 activity and subsequently suppress the HER2 downstream pathways PI3K/Akt and Ras/MAPK that are major executors for endocrine resistance. Furthermore we observed that both PIs stabilize the HER2 specific tyrosine phosphatase BDP1 (PTPN18), thereby suppressing the activity of even a constitutive active HER2 variant that cause resistance to trastuzumab and lapatinib. Based on these findings we hypothesize that PIs inhibits ERα and HER2 activity through different mechanisms as currently used therapeutic regiments.

Conclusion: These findings demonstrate that PIs disrupt the cross-talk between HER2 and ERα signaling pathways and therefore might have the potential to expand treatment opportunities for HER2+/ER+ and possibly also for other groups of BC patients.

**Title:** Efficacy results of a phase 1/2 study of glucocorticoid receptor (GR) antagonist mifepristone (MIFE) in combination with eribulin in GR-positive triple-negative breast cancer (TNBC)

Han HS S, Wilks S, Paplomata E, Modiano MR R, Becerra C, Braiteh FS S, Spira AI I, Pluard TJ J, Richards DA A, Conzen SD D, Baker G, Fishman RS S, Marcantonio A, O'Shaughnessy J and Nanda R. Texas Oncology San Antonio; ACRC/Arizona Clinical Research Center and Arizona Oncology; Virginia Cancer Specialists Research Institute; Texas Oncology - Baylor Charles A Sammons Cancer Center; Moffitt Cancer Center; The US Oncology Network/Mckesson Specialty Health; Emory University Winship Cancer Institute Midtown; Saint Luke's Cancer Institute; Tyler Cancer Center, US Oncology Research; Baylor University Medical Center Texas Oncology US Oncology, Dallas, TX; Corcept Therapeutics, Inc; University of Chicago Medical Center and Beth Israel Deaconess Medical Center.

**Body:**

**Background:** GR is variably expressed in TNBC and high expression is associated with poor prognosis in estrogen receptor-negative (ER-) early stage breast cancer. Treatment with mifepristone (MIFE) potentiates the effectiveness of chemotherapy in GR+ TNBC xenografts. Enrollment is complete in this study of patients with GR+ TNBC treated at the recommended Phase 2 dose (RP2D) of MIFE in combination with eribulin. **Objectives:** To determine the safety, tolerability, pharmacokinetics (PK) and clinical activity of the MIFE plus eribulin combination in pts with GR+ TNBC at the RP2D. **Methods:** Eligibility: In Part 1 (dose finding), pts with solid tumors; in Part 2 (expansion phase), pts with TNBC (GR result required at time of screening in Part 1, but could be pending at time of screening in Part 2). Up to 5 prior chemotherapy regimens for advanced disease; ECOG PS 0-1; adequate end-organ function. Design: 3 + 3 dose escalation scheme. After a 7-day lead-in of oral daily MIFE alone, MIFE was continued daily and eribulin was given on days 1 and 8 of a 21-day cycle. GR+ was defined as >10% of tumor cells with any intensity of GR staining. **Results:** 16 pts with metastatic breast cancer were treated in Part 1, and 21 pts with TNBC were treated in Part 2. Median age was 54 (range 30-81). MTD/RP2D was MIFE 300 mg/day + eribulin 1.1 mg/m². Safety: DLT in Part 1 was neutropenia. Neutropenia occurred in 23/36 total patients (2 Grade [G] 1, 10 G3, 11 G4); 2 instances included neutropenic fever. Recovery of WBC was brisk with growth factor support. Neuropathy was observed in 8 pts (5 G1, 1 G2, 2 G3). Other most common AEs (fatigue, hypokalemia, nausea, alopecia) were mainly G1 or G2; among these, G3/G4 events were limited to fatigue (4 G3), hypokalemia (3 G3 and 1 G4) and nausea (1 G3). There were 2 instances of G1 vaginal bleeding. There was no impact of MIFE on eribulin PK. Efficacy: There were 23 evaluable pts with TNBC across Parts 1 and 2 treated at the RP2D: 21 GR+, 2 GR status unknown; median of 3 prior chemotherapy regimens; 1 patient had received prior eribulin. Responses were: 3 PR, 8 SD, 11 PD and one too early to assess. Median PFS was 9 weeks. **Conclusions:** MIFE plus eribulin was well tolerated and appears to be an active treatment regimen. Five TNBC patients had a PFS longer than the upper 95% CI for PFS (i.e., >15 wks) reported by Aogi et al. for TNBC treated with eribulin (Annals of Oncology 2012;23:144148). Clinical trial information: NCT02014337.
**Title:** Delivery and anti-tumor activity of nanoliposomal irinotecan (Nal-IRI, MM-398) in metastatic xenograft models of triple negative breast cancer

Lee H, Ventura M, Bernards N, Mohammad AS S, Foltz W, Fitzgerald J, Jaffray DA A, Lockman PR R, Zheng J and Hendriks BS S. Merrimack Pharmaceuticals, Inc., Cambridge, MA; TECHNA Institute for the Advancement of Technology for Health, Toronto, ON, Canada; West Virginia University HSC, School of Pharmacy, Morgantown, WV; University of Toronto, Toronto, ON, Canada and Institute of Biomaterial and Biomedical Engineering, University of Toronto, Toronto, ON, Canada.

**Body:**

**Introduction:** Nal-IRI (MM-398, nanoliposomal irinotecan), is designed for extended circulation relative to nonliposomal irinotecan and to exploit leaky tumor vasculature for enhanced drug delivery to tumors. Nal-IRI (ONIVYDE®), in combination with 5-fluorouracil and leucovorin, was recently approved for the treatment of patients with advanced pancreatic cancer who have been previously treated with gemcitabine. A pilot clinical study established ferumoxytol (FMX) measured by magnetic resonance imaging (MRI) as a potential surrogate for assessing nanoparticle delivery to tumors. Lesions with FMX uptake above the median were associated with greater reductions in tumor size following treatment with nal-IRI. Nal-IRI with FMX MRI is currently being evaluated in patients with metastatic breast cancer (NCT01770353). Here we present preclinical data demonstrating the activity of nal-IRI monotherapy in multiple models of triple negative breast cancer (TNBC).

**Methods:** Imaging and treatment efficacy studies were carried out in the MDA-MB-231 derived mouse models of TNBC, including the LM2-4 variant with spontaneous metastases. Delivery of nal-IRI to brain metastases was assessed in MDA-MB-231-Br-Luc model (intracardiac implantation) using fluorescently labeled nal-IRI. Kinetics of FMX tumor uptake were evaluated with 7T MRI. Total tumor irinotecan and the active metabolite SN-38 were quantified by high performance liquid chromatography.

**Results:** Nal-IRI treatment was well-tolerated based on body weight monitoring. In the LM2-4 model, nal-IRI (10 mg/kg salt) was more effective in suppressing primary tumor regrowth (median tumor volume of 155 mm$^3$ vs. 946 mm$^3$ at day 14), reducing metastatic burden (median bioluminescence flux of $0.4 \times 10^9$ vs. $2.1 \times 10^9$ at day 12), and prolonging overall survival (median survival of 66 days vs. 14 days), compared to nonliposomal irinotecan (50 mg/kg salt). Similarly, nal-IRI demonstrated benefits in reducing brain metastatic burden and extended survival compared to untreated control in the MDA-MB-231 brain metastasis model. Fluorescence microscopy revealed that nal-IRI primarily localized in the metastatic lesions, with undetectable signal in normal brain tissue. At 24 h post FMX-injection, FMX uptake correlated positively with tumor SN-38 levels at 24 h following treatment with nal-IRI ($p = 0.0222$, Spearman correlation), supporting that nanoparticle imaging may be useful as a surrogate measure of nal-IRI tumor delivery. Furthermore, higher tumor FMX deposition was associated with increased tumor growth inhibition with nal-IRI, corroborating observations from the pilot Phase 1 clinical study.

**Conclusions:** These studies support the evaluation of nal-IRI in patients with TNBC, as well as further evaluation of nanoparticle imaging as a potential biomarker for identifying lesions likely to respond.
**Title:** H-ferritin allows nanometronomic treatment of breast cancer with doxorubicin preventing drug resistance and circumventing cardiotoxicity

Mazzucchelli S, Fiandra L, Bellini M, Truffi M, Rizzuto MA A, Sorrentino L, Longhi E, Nebuloni M, Prosperi D and Corsi F. University of Milan, Department of Biomedical and Clinical Sciences "L. Sacco", Milan, Italy; University of Milan-Bicocca, Milan, Italy and IRCCS S. Maugeri Foundation, Pavia, Milan, Italy.

**Body:** Chemotherapeutic treatment of breast cancer is based on maximum tolerated dose (MTD) approach. However, advanced stage tumors are not effectively eradicated by MTD owing to suboptimal drug targeting, onset of therapeutic resistance and neoangiogenesis. In contrast, “metronomic” chemotherapy is based on frequent drug administrations at lower doses, resulting in neovascularization inhibition and induction of tumor dormancy. However, several limiting factors remain for LDM in order to displace MTD treatments in clinical practice, including 1) low drug accumulation at tumor site, 2) controversial effectiveness against chemoresistance in advanced metastatic cancers, and 3) acquired resistance after prolonged treatment. Recent advances in nanotechnology could offer groundbreaking solutions to improve the effectiveness of LDM chemotherapy, by taking advantage of the unique targeting efficiency of engineered nanocarriers.

Here, we propose a new concept of “nanometronomic” chemotherapy, exploiting the H-ferritin (HFn)-mediated targeted delivery of doxorubicin (DOX) in an aggressive and metastatic breast cancer mouse model with DOX-inducible chemoresistance. HFn nanocages naturally target cancer cells owing to its affinity for transferrin receptor 1. HFn-DOX was recently demonstrated to overcome chemoresistance by actively promoting DOX nuclear translocation *in vitro* and was tested as a MTD treatment on a DOX-sensitive tumor model with encouraging results. We find that LDM administration of HFn-DOX strongly improves the antitumor potential of DOX chemotherapy arresting the tumor progression. Indeed, *in vitro* and *in vivo* results demonstrate that HFn nanocages mediate the nuclear delivery of DOX and increase DOX accumulation both in tumor tissue and in cancer cell nuclei, resulting in increased efficacy. Moreover, we find that HFn-DOX antitumor effect is attributable to multiple nanodrug actions beyond cell killing, including inhibition of tumor angiogenesis and avoidance of chemoresistance. Otherwise, although an even better reduction of tumor progression was achieved with liposomal DOX (pl-DOX) a five-fold increase in MDR-1-positive cells has been displayed, suggesting that liposomal DOX is not suitable in view of a protracted metronomic treatment, due to the onset of chemoresistance. Multiparametric assessment of heart tissues, including histology, ultrastructural analysis of tissue morphology, and measurement of markers of reactive oxygen species and hepatic/renal conditions, provided evidence that metronomic HFn-DOX allowed us to overcome cardiotoxicity contrary to what is observed with DOX and pl-DOX. Our results suggest that HFn-DOX has tremendous potential for the development of “nanometronomic” chemotherapy toward safe and tailored oncological treatments.

Haugen MH, Lindgjærde OC, Krohn M, Zhao W, Lindholm EM M, Silwal-Pandit L, Borgen E, Garred Ø, Fangberget A, Holmen MM M, Schlichting E, Skjerven H, Lundgren S, Wist E, Naume B, Mælandsmo GM M, Lu Y, Børresen-Dale A-L, Mills GB B and Engebråten O. Oslo University Hospital, Oslo, Norway; University of Oslo, Oslo, Norway; MD Anderson Cancer Center, Houston, TX; Vestre Viken Hospital Trust, Drammen, Norway and St. Olavs Hospital, Trondheim, Norway.

**Body:** BACKGROUND: Patients with HER2 negative primary tumors of $\geq 25$ mm were treated with neoadjuvant chemotherapy (4 x FEC100 + 12 weeks of taxane-based therapy) and randomized (1:1) to receive bevacizumab or not. Mammography, ultrasound and MR imaging were used for response evaluation, in addition to the final pathology assessment after surgery.

METHODS: Tumor responses were evaluable in 132 patients; of which 66 received bevacizumab. Ratio of the tumor size at final pathology assessment, and at inclusion was calculated to obtain a continuous scale of response reflecting the percentage of tumor shrinkage in response to therapy. Tumor material was obtained at screening, 12 weeks into treatment and at surgical removal of tumors at 25 weeks. Lysates from each sample was analyzed on reverse phase protein arrays (RPPA) for expression levels of 210 proteins of which 54 were phospho-specific.

RESULTS: Several proteins were found for which expression prior to treatment reflected a better response on tumor shrinkage in the combination treatment arm (chemotherapy+bevacizumab). The proteomic response from week 0 to 12 in both treatment arms had an overall similar profile regarding up- and down-regulated proteins; however, the combination treatment (FEC100 + bevacizumab) induced a more pronounced effect on regulation of each protein. This might reflect the capability of bevacizumab therapy to potentiate the effects of the anthracyclin based chemotherapy from week 0 to 12. Conversely, from week 12-25 (taxane-based therapy + bevacizumab) this effect was lost or even reversed, except for certain phosphoproteins where potentiation imposed by bevacizumab was sustained throughout the whole treatment period. We are in the process of analyzing the impact of phosphorylation and thus protein activation states on treatment response. Furthermore, tumors with low hormone receptor pathway score demonstrated a better response in the combination treatment (chemotherapy+bevacizumab).

Additionally, in these good responders the hormone signaling pathway was significantly upregulated during treatment. Further investigations are conducted to determine if this was due to selective ablation of hormone receptor negative tumor cells, or a re-programming of the molecular phenotype of cells present prior to treatment. The above mentioned results have potentially important clinical relevance and will be further investigated with respect to subtypes and the biological pathways affected by antiangiogenic therapy.
Title: Efficacy of first-line bevacizumab (BEV)-containing therapy for poor-prognosis advanced breast cancer (aBC): Subgroup analyses of the German AVANTI observational study

Mueller V, Jakob A, Aktas B, Pott D, Grafe A, Jungberg P, Maerz W, Fett W, Bruch H-R, Klare P, Boller E, Hoefflin S and Schneeweiss A. Universitaetsklinikum Hamburg-Eppendorf, Klinik und Poliklinik für Gynaekologie, Hamburg, Germany; Ortenau-Klinikum, Offenburg, Germany; Universitaetsklinikum Essen, Essen, Germany; Schwerpunktpraxis Haematologie und Onkologie, Bottrop, Germany; MVZ Nordhausen gGmbH, Praxis Dr. Grafe/Brustzentrum der Frauenklinik, Suedharz- Klinikum Nordhausen gGmbH, Nordhausen, Germany; Frauenarztpraxis Dr. Jungberg, Chemnitz, Germany; Onkologie Klinikum Kulmbach, Kulmbach, Germany; Onkologische Praxis, Wuppertal, Germany; Schwerpunktpraxis Bonn, Bonn, Germany; Brustzentrum Berlin, Berlin, Germany; iOMEDICO Clinical Research Organisation, Freiburg, Germany; Roche Pharma AG, Grenzach-Wyhlen, Germany and Universitaets-Klinikum Heidelberg, Nationales Centrum für Tumorerkrankungen, Heidelberg, Germany.

Body: Background: The multicenter AVANTI observational study is evaluating the safety and effectiveness of EU-approved BEV-containing regimens (BEV + paclitaxel [PAC] or BEV + capecitabine [CAP]) as first-line therapy for HER2-negative aBC in German routine oncology practice.

Methods: Eligible patients (pts) had received no prior chemotherapy (CT) for aBC and had no BEV contraindications. CT schedule, diagnostics, and frequency of follow-up visits are at the physician’s discretion. Data are collected for 1 year after starting BEV, with 6-monthly follow-up for 1.5 years thereafter. We explored treatment outcomes in pts with triple-negative aBC (TNBC), pts considered at high risk according to a simple prognostic index for OS in BEV-treated pts [Llombart, 2014], and subgroups defined by timing of BEV+CT initiation.

Results: Between Oct 2009 and Feb 2015, 2168 pts treated at 331 centers received BEV+PAC (n=1774) or BEV+CAP (n=394). Of these, 445 (21%) had TNBC and 306 (14%) met the high-risk criteria. Within the hormone receptor-positive (HR+) subgroup, pts receiving endocrine therapy (ET) before BEV+CT were older than pts starting BEV+CT immediately (median age 65 vs 60 years, respectively) and included a smaller proportion with ECOG performance status 0 (39% vs 47%), visceral metastases (70% vs 77%), or prior (neo)adjuvant CT exposure (46% vs 57%). In all subgroups, median BEV treatment duration was longer than median CT duration. At the data cutoff for this interim analysis (Mar 1, 2015), median duration of observation was 10.8 (range <0.1–47.5) months. The table shows treatment exposure and efficacy overall and in selected subgroups.

Conclusions: Interim results from this large observational study indicate that first-line BEV+CT is an effective therapy in all risk subgroups of a general population of pts with HER2-negative aBC treated in routine oncology practice, including pts with a particularly poor prognosis. Results of these exploratory subgroup analyses suggest that BEV+CT could be considered irrespective of HR status.
2016 San Antonio Breast Cancer Symposium

Title: Enhanced efficacy of redirected T-cell therapy of TNBC with a Trop-2/CD3 bispecific antibody in combination with a checkpoint inhibitor

Body: Bispecific antibodies (bsAbs) for redirecting T cells to cancers have shown promise in both pre-clinical and clinical studies. However, clinical success has been minimal for solid cancers to-date. Previously, we reported highly effective T-cell redirected therapy of pancreatic and gastric tumors in xenograft models using a trivalent bsAb, designated (E1)-3s, which comprises an anti-CD3 scFv covalently conjugated to a stabilized dimer of a Trop-2-targeting humanized Fab. Trop-2 is highly expressed in diverse epithelial cancers, including breast, lung, gastric, colorectal, pancreatic, bladder, ovarian, uterine, and prostate carcinomas, with limited presence on normal human tissues. Compared to first generation bsAbs (e.g., BiTE), which induce high-level cytokine production that can lead to serious side effects, efficient T-cell killing is mediated by (E1)-3s with minimal cytokine release. Herein, we report the potential utility of (E1)-3s for therapy of breast cancers, including TNBC. Additionally, we show that addition of a checkpoint inhibitor can enhance bsAb-redirected T-cell therapy. IMMU-cPD1 is a chimeric mAb that binds with high affinity to human PD-1 and efficiently blocks binding to its ligand, PD-L1. The MDA-MB-231 human TNBC cell line has relatively low levels of surface Trop-2 (36,000/cell) and expresses PD-L1 constitutively. In ex-vivo assays, where MDA-MB-231 cells were mixed with purified human T cells, (E1)-3s mediated potent T-cell redirected killing (IC\textsubscript{50}< 10 pM). Addition of IMMU-cPD1 enhanced (E1)-3s-mediated T-cell killing. The advantage of combining the checkpoint inhibitor with redirected T-cell therapy was supported with in-vivo xenograft studies. NOD-SCID mice were co-injected with purified human T cells (2.5 x 10\textsuperscript{6}) and MDA-MB-231 (5 x 10\textsuperscript{6}). Groups were administered: 1) five daily injections of (E1)-3s; 2) cPD-1 twice weekly for 4 weeks; or 3) a combination of (E1)-3s and cPD1 treatments. An untreated control group comprising T cells and tumor cells reached the endpoint (tumors >1 cm\textsuperscript{3}) with a median survival time (MST) of 35 days. The group treated with (E1)-3s had significantly smaller tumors (P=0.0023, AUC) and improved MST (42 days, P=0.0019). The group treated with the combination of (E1)-3s and IMMU-cPD1 had significantly smaller tumors (P=0.0121, AUC) and longer MST (49 days, P=0.008), compared to those treated with (E1)-3s alone. Treatment with IMMU-cPD1 alone did not retard tumor growth or improve MST, compared to the untreated control group. In conclusion, (E1)-3s is an attractive candidate for T-cell redirected therapy of breast cancer due to its potent activity with potentially reduced side effects and the prevalence of Trop-2 expression associated with this disease. Tumor microarrays representing 117 breast cancer patients showed >85% positivity for Trop-2. Our immunohistochemical analysis of more than 50 individual TNBC patient specimens demonstrated 92% positivity, with 80% having moderate to strong Trop-2-staining. Combining checkpoint inhibitors with redirected T-cell therapy may represent a new paradigm for the management of solid cancers, including breast, and is worthy of further investigation.
Title: An anti-PD1 antibody-based therapy results in dramatic reduction of TNBC PDX tumors in humanized mice models

Rosato RR R, Davila-Gonzalez D, Choi DS Soon, Dave B and Chang JC C. Houston Methodist Cancer Center, Houston, TX.

Body: Recently, the field of cancer immunotherapy has seen a rapid growth based on a better understanding of the complex interplay between the tumor and the immune system. Although for long time breast cancer has been considered non-immunogenic and patients have seen limited options to immunotherapies, new strategies have changed this paradigm. In the present study, we aimed to test the in vivo activity of a human anti-PD1 antibody against the TNBC tumor line MC1. One of the main limitations of performing laboratory-based in vivo studies resides in the availability of the appropriate animal models. To circumvent these obstacles, we used patient-derived breast cancer tumor lines xenografts (PDX) from our existing collection previously established in immuno-compromised SCID/beige mice. Low-passage fresh xenograft tumor fragments of the TNBC tumor lines MC1 and HM#2147 were transplanted into the cleared fat pad of recipient non-humanized (non-hNSG) and humanized NSG (hNSG) mice. Humanized mice were obtained by i.v. injecting 3-4 weeks old NSG mice with CD34+ hematopoietic stem cells (HSC) following whole body radiation. Flow cytometry and immuno-histochemistry analyses of hNSG blood, spleen and bone marrow showed the presence of human CD45+ (15.1% ± 10.3; 61.5% ± 19.1; 71.9% ± 17.9; respectively), CD20+, CD3+, CD8+, CD68+, and CD33+ cells. BC tumor engraftment was then evaluated by comparing the growth of the MC1 tumor line in non- and hNSG mice, showing a slower growth in the corresponding humanized mice. Importantly, the presence of hCD45+ cells was readily detectable in all the hNSG-derived tumors, localizing both toward the periphery of the tumors and inside them. Analysis of hCD45+ subpopulation cells showed also the tumor presence of hCD20+ cells (B cells), hCD8+ T-cells and CD68+ (macrophages) cells. To determine whether BC PDX may have conserved the capability to metastasize to the lung, hNSG mice were engrafted with the tumor line HM#2147. Once the primary tumor reached the maximum volume allowed by humane standards, mice humanization levels, tumor engraftment and lung metastasis were evaluated. Humanized engrafted mice showed same levels of human cells and primary tumor engraftment as those harboring MC1 PDXs. Macroscopically, lungs displayed clear evidence of metastases. IHC assays using Ki67 and CK19 identified the microscopic region corresponding to its localization. Importantly, as described in the primary breast tumor, the presence of hCD45+ was also observed infiltrating the lung metastatic tumor. The efficacy of an anti-PD1 therapy was then evaluated. Levels of tumor PD-L1 were determined by western blot showing high levels of expression. Animals were weekly i.p.-administered either the human anti-PD1 antibody or vehicle. Evaluation of tumor volumes showed a significant reduction in anti-PD1- vs. vehicle-treated animals at day 18 of treatment (i.e. 457.8 mm$^3$ vs. 1074.24 mm$^3$, respectively; P= 0.001). The present study show encouraging results associated with anti-PD1 immunotherapy to treat TNBC tumors. In addition, our results provide evidence supporting the use of humanized mice as key animal model that may allow to overcome some of the technical difficulties associated with the investigation of immune-based therapies.
Title: Analysis of renal function in MONARCH 1: A phase 2 study of abemaciclib, a CDK4 & 6 inhibitor, as monotherapy, in patients with HR+/HER2- breast cancer, after chemotherapy for metastatic breast cancer (MBC)

Tolaney S, Lam AQ Q, Mukundan S, Nanda S, Cox J and Barriga S. Dana-Farber Cancer Institute, Boston, MA; Brigham and Women's Hospital, Boston, MA and Eli Lilly and Company, Indianapolis, IN.

Body: Background: Abemaciclib is an oral, selective inhibitor of CDK4 & 6 that has demonstrated activity in different tumor types. In a phase 1 trial, treatment emergent adverse events (TEAEs) of increased creatinine, grade 1 or 2 severity by Common Terminology Criteria for Adverse Events (CTCAE v4.0) were reported in > 10% of patients (pts) who received abemaciclib monotherapy. In vitro, abemaciclib and its major metabolites inhibit renal transporters OCT2, MATE1, and MATE2-K. Methods: MONARCH 1 is a phase 2 single-arm study designed to evaluate safety and efficacy of abemaciclib monotherapy in women with HR+/HER2- MBC whose disease progressed on/after endocrine- and chemotherapy. Abemaciclib (200 mg) was administered orally on a continuous schedule every 12 hours until disease progression or unacceptable toxicity occurred. We retrospectively analyzed changes in serum creatinine, blood urea nitrogen (BUN), cystatin C, and calculated glomerular filtration rate (GFR) based on cystatin C using central lab values. TEAEs (CTCAE v4.0), dose delays, and treatment discontinuation associated with renal events were examined.

Results: Of the 132 pts treated, 130 pts had central laboratory data available, and 128 pts (98.5%) experienced an increased serum creatinine: 61 pts (46.9%) grade 1, 66 pts (50.8%) grade 2, 1 pt (0.8%) grade 3. Creatinine increases occurred during cycle 1 and remained elevated but stable during treatment. Serum creatinine decreased following treatment discontinuation. No changes in mean BUN, cystatin C or estimated GFR were observed. TEAEs of increased serum creatinine were reported in 17 pts (12.9%); one was grade 3. Due to increased serum creatinine, 2 pts experienced dose reductions, 2 pts dose omissions, and 1 pt treatment discontinuation. Serious AEs (SAEs) of increased creatinine was were experienced by 4 patients; 3 were possibly related to abemaciclib. A non-drug related SAE of acute kidney injury was reported for 1 pt. Review of all reported AEs/SAEs failed to indicate any evidence of renal impairment. The Standardized MedDRA Queries (SMQ) acute renal failure was used to search and identify all reported cases of increased creatinine with or without acute kidney injury. Twenty pts (15.2%) who experienced an AE were included in this category: 4 pts (3.0%) met the narrow term SMQ, and 17 pts (12.9%) the broad term SMQ.

Conclusions: Safety data from the MONARCH 1 study shows a causal association of the reversible increased blood creatinine with abemaciclib therapy, but not as a result of renal injury, renal insufficiency, or impaired renal function. The rise in serum creatinine is consistent with in vitro data indicating that abemaciclib is a competitive inhibitor of renal efflux transporters of creatinine.

Title: Phenotypically distinct HRG positive cancer cells impact standard of care therapies in metastatic breast cancer models

Body: ErbB3 is a member of the human epidermal growth factor receptor (ErbB or HER) family which is comprised of four receptors (ErbB1-4). A defining feature of the ErbB network is that two members of the family, ErbB2 and ErbB3, are non-autonomous. ErbB2 lacks the capacity to interact with a growth-factor ligand, whereas the kinase activity of ErbB3 is defective. Heregulin (HRG), the ErbB3 ligand, has been identified as a potent driver of proliferation and enhanced survival. HRG expression leads to a distinct tumor cell phenotype characterized by an inability to respond to the effects of numerous Standard of Care (SOC) therapies, including chemotherapies, anti-hormonal agents and other targeted therapeutics.

In surveys of HRG expression, we have shown the presence of HRG+ cells in approximately 50% of the cases of most solid tumor types. We hypothesize that these HRG+ cells are protected from the effects of SOC therapy and continue to proliferate even in the presence of SOC, resulting in limited clinical benefit. In this model, if HRG activity is blocked, HRG+ cells become susceptible to SOC, resulting in enhanced clinical benefit. Seribantumab is a fully human anti-ErbB3 monoclonal antibody designed to block HRG activity by inhibiting the binding of HRG to ErbB3. In the presence of seribantumab, HRG+ tumor cells are predicted to be able to respond to co-administered SOC therapy.

For hormone receptor positive (HR+) breast cancer, hormone deprivation strategies have proven clinical benefit in the adjuvant and metastatic settings. Unfortunately, clinical benefit from these therapies can be short-lived in some patients. Optimal clinical management of these patients requires a comprehensive molecular understanding of the drivers of rapid clinical progression. We and others have found that HRG mRNA expression measured in tumor samples defines a subgroup of patients who derive only limited clinical benefit from SOC when compared to patients whose tumors do not express HRG. This was observed in a previously published Phase 2 clinical study with exemestane, and preclinically with multiple classes of anti-hormonal agents, including letrozole and fulvestrant -- treatments that currently represent the mainstay of treatment options for HR+, HER2 negative (HER2-) advanced breast cancer.

Here we will present data supporting the hypothesis that phenotypically distinct HRG+ cells in breast cancer models persist despite treatment with SOC and various novel classes of therapy. We will also show that the addition of the anti-ErbB3 antibody seribantumab to these other therapies promotes sustained treatment responses. Continued expansion of HRG+ cells could be the key to rapid clinical progression in breast cancer patients treated with SOC therapy. These findings support the development of seribantumab in combination with anti-hormonal agents in a planned Phase 3 clinical trial in HR+, HER2- advanced breast cancer.
Title: Dual targeting of mammary tumors and tumor-associated functional limitations through inhibition of NF-κB

Wang R, Nakshatri P, Padua MB B, Anjanappa M, Penthala N, Crook PA A, Liu J, Zimmers T and Nakshatri H. IU School of Medicine, Indianapolis, IN; Richard L Roudebush VA Medical Center, Indianapolis, IN and College of Pharmacy, the University of Arkansas, Little Rock, AR.

Body: Breast cancer progression is associated with systemic effects such as functional limitation, sarcopenia and cachexia. These effects are manifested as muscle weakness, body pain or depletion of skeletal muscle mass. Over a quarter of 2.8 million breast cancer patients in the United States experience a precachexia to cachexia syndrome. It has been reported that cancer-induced cytokines activate NF-κB, which promotes cancer progression, metastasis, and chemoresistance. These cytokines could potentially induce NF-kB in skeletal muscle, impair skeletal muscle function, and cause functional limitations. Therefore, NF-κB inhibitors could serve dual purpose of inhibiting cancer progression and reducing functional limitations. In present study, we used MMTV-PyMT transgenic mammary tumor model to test therapeutic effects of the NF-κB inhibitor, Diaminomethylparthenolide (DMAPT), an orally bioavailable NF-κB inhibitor. We observed deteriorating physical and functional conditions in PyMT+ mice with the progression of mammary tumor. Compared to wildtype mice, PyMT+ mice with mammary tumors showed decreased fat mass and grip strength, both are markers of functional limitations. Treatment with DMAPT (100mg/kg, 5 times/week, orally), starting at 8 week-old prior to mammary tumor occurrence, delayed mammary tumor onset and slowed tumor growth rates compared to vehicle treatment. Consequently, DMAPT-treated mice showed lower systemic effects of mammary tumors on grip strength and alterations of body compositions (i.e. body fat, lean mass). Moreover, systemic treatment with DMAPT significantly increased survival trends in PyMT+ mice. These results suggest that NF-κB is a critical signaling relay engaged by paracrine effects of breast cancer on skeletal muscle function. Mechanistic studies in vitro suggested that cancer-induced cytokines specifically target microRNAs in skeletal muscle. miR486 is a muscle-enriched microRNA that controls differentiation of myoblasts. In particularly, conditioned media from a number of mammary tumor cell lines, including PO1058 (poorly invasive tumor cells from PyMT-WapCre-mGFP+ mice in C57BL6 background) and PO1059 (highly invasive cells from PyMT-WapCre-mGFP+ mice) reduced the levels of miR486 in the myoblast cells C2C12. Literature demonstrated that reduced miR486 in muscle is linked to musculoskeletal defects in muscular dystrophy patients. These data are consistent with previous studies in which lower circulating miR486 occurred in plasma of breast cancer patients with metastasis compared with healthy women, and as well in skeletal muscle of mammary tumor bearing animals. Further studies are essential to establish a cancer-induced cytokine, NF-κB activation in muscle, deregulated expression and release of miR486 from muscle and cancer-associated systemic effects circuitry. In summary, mammary tumors result in changes in body composition with decreased grip strength, which may be associated with altered NF-κB signaling pathways, and NF-κB inhibitor DMAPT can be used as a potential candidate for the treatment of breast cancer and associated functional limitations to improve the quality of life. Additionally, circulating miR486 may serve as a useful clinical indicator of progression and systemic effects of breast cancer.
The importance of loco-regional tumor burden and surgery on survival in patients with de novo stage IV breast cancer; post-hoc analyses of protocol MF07-01

Body: Background: The MF07-01 trial is a multicenter phase III randomized controlled trial of treatment naive stage IV BC patients comparing loco-regional surgery (LRS) followed by appropriate systemic therapy (ST) versus ST alone.

Aims: To evaluate the importance of loco-regional tumor burden and surgery on overall survival rate in patients with de novo stage IV breast cancer.

Methods: At initial diagnosis patients were randomized 1:1 to LRS group or ST group. The surgery was a lumpectomy (L) or mastectomy (M) and sentinel lymph node biopsy (SLNB) ± axillary lymph node dissection (ALND). After surgery all patients received systemic treatment + endocrine treatment (ET) and Trastuzumab based on pathology results. The demographic, pathologic, and clinical characteristics of the patients were recorded.

Results: 274 patients were accrued; 138 in the LRS group and 136 in the ST group. The groups were comparable regarding age, BMI, HER2 neu, tumor type and size, histologic grade, and bone and visceral metastasis (all p>0.05). In the LRS group 36 patients (26%) had L+ALND, 92 patients (67%) had M+ALND and 10 patients (7%) had M+SLNB, respectively.

The patients and tumor characteristics

The axillary positivity rate was 89.1%. There were 76 (55%) deaths in the LRS group and 101 (74%) in the ST group during the median 40 (20-51) month follow-up. Overall survival (OS) was 34% higher in the LRS group compared to the ST group (HR: 0.66, 95%CI 0.49-0.88: p = 0.005).

Overall survival rate was higher in LN (+) (p=0.01), tumor size<5cm (p<0.0001), and high histologic grade (HG III, p<0.008) patients who underwent axillary surgery than ST group; OS rate was with a marginal significant level in patients without axillary involvement (pN0) in the LRS group compared with ST group (p=0.05).

**Conclusion:** In this subgroup analysis, we observed that patients with high grade tumor, without skin or chest wall involvement and positive axilla who underwent surgery for primary breast tumor and axilla had better overall survival than ST in de novo stage IV breast. These results can be considered in clinical research design for stratification.
Title: Beta-adrenergic receptor blockers (BB) and increased progression free survival (PFS) in patients with advanced triple negative breast cancer (TNBC): A retrospective analysis of the ROSE/TRIO012 study

Spera G, Fresco R, Fung H, Dyck JRB RB, Pituskin E, Patterson I, Aspeslet L and Mackey JR R. Translational Research in Oncology (TRIO), Montevideo, Uruguay; Biostatistics, Translational Research in Oncology (TRIO), Edmonton, AB, Canada; University of Alberta, Edmonton, AB, Canada; Faculty of Nursing, University of Alberta, Edmonton, AB, Canada; Mazankowski Alberta Heart Institute, University of Alberta, Edmonton, AB, Canada; Translational Research in Oncology (TRIO), Edmonton, AB, Canada and University of Alberta, Edmonton, AB, Canada.

Body: Introduction: Recent retrospective studies suggest beta-adrenergic blocking drugs are associated with improved survival in patients with a wide range of cancers. Although limited and discordant data suggest that the use of BB may increase overall survival (OS) of patients with localized breast cancer (BC), there is no information on the effects of BB in women with advanced BC, which may be a more appropriate clinical scenario to evaluate anti-cancer effects of new treatment strategies.

We analyzed the relationship between BB use and clinical outcomes in the ROSE/TRIO-012 study, a double-blinded multinational registration phase III trial that randomized 1,144 patients with HER2-negative advanced BC to receive first-line docetaxel in combination with ramucirumab (RAM) or placebo.

Objective: To explore the association between BB use and BC outcomes in patients participating in the ROSE/TRIO-012 trial.

Methodology: We retrospectively compared PFS, OS, Overall Response Rate (ORR) and Clinical Benefit Rate (CBR) using the ITT population, in patients who received BB during the trial with those who did not receive them. PFS and OS were estimated using the Kaplan-Meier method. PFS and OS of both treatment groups were compared using the Log-Rank test. Cox proportional models were fitted to determine the association between BB, PFS and OS. ORR and CBR in both groups were compared using the Fisher's Exact Test.

Results: 153/1,144 (13%) patients received BB during the trial. Median PFS in patients treated with BB was 10.3 months, compared to 8.3 months in patients who did not receive them (HR 0.81; 95% CI 0.66-0.99; p=0.0379). In patients treated with BB only after enrolment (57/153, 37%) median PFS was 15.5 months vs. 8.3 months in patients with no BB (p=0.0005). In the subset of patients with TNBC, median PFS was 13 months if received BB compared to 5.2 months if no BB (HR 0.52; 95% CI 0.34-0.79; p=0.002). No difference in PFS was observed in patients with hormone receptor positive BC. The magnitude of PFS benefit in the RAM arm was similar as the whole ITT population (HR 0.73; 95% CI 0.57-0.94; p=0.014. If BB received only after enrolment HR 0.50; 95% CI 0.35-0.72; p=0.0003). The benefit of BB intake in PFS was independent of development of treatment-emergent hypertension (hypertension occurring within 42 days of first study drug administration; HR 0.92; 95% CI 0.73-1.15; p=0.476) but dependent on treatment arm (HR 0.86; 95% CI 0.74-0.99; p=0.037). The test for interactions between BB and treatment arm was not significant (p =0.276). No differences in OS, ORR or CBR were seen.

Conclusions: In this exploratory post-hoc analysis of the ROSE/TRIO012 study, BB intake was associated with a significant improvement in PFS compared to patients who did not receive them, particularly in patients with TNBC and patients not previously exposed to these drugs. Further evaluation of the BB intake on BC outcomes warrants evaluation in a prospectively-designed clinical trial.

Title: Phase 2 trial of everolimus and/or trastuzumab in hormone refractory, hormone receptor (HR)-positive, HER2-normal metastatic breast cancer (MBC)

Papломата Е, Gogineni K, Meisel J, Santa-Maria C, Yuan L, Kramer J, Bill Li X, Zelnak A, Pakkala S, Kaklamani V and O'Regan R. Winship Cancer Institute of Emory University School of Medicine, Atlanta, GA; Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Chicago, IL; Atlanta Cancer Care, Atlanta, GA; University of Texas Health Science Center San Antonio, San Antonio and University of Wisconsin.

Body: Background: Increased signaling through growth factor pathways including PI3K/Akt/mTOR and HER2 have been implicated in hormone resistance. Everolimus (EVE) improves outcomes when added to endocrine therapy for patients with HR-positive MBC. This study evaluated the efficacy of everolimus (EVE) and trastuzumab (TRAS) in hormone refractory HER2-normal metastatic breast cancer.

Methods: Eligible patients had HR-positive, HER2/neu-negative (IHC +1 or +2, HER2-non-amplified) MBC that had progressed within 6 months of the most recent endocrine therapy. Patients continued on the most recent endocrine therapy they received and were randomized to receive EVE 10 mg oral daily or TRAS IV (8 mg/kg loading dose followed by 6 mg/kg every 3 weeks). At progression, the other agent was added (TRAS in the EVE arm and EVE in the TRAS arm). Patients were followed until disease progression or death.

Results: 54 eligible patients were included in the analysis, and were randomized to EVE (n=30) or TRAS (n=24). 33% of patients were on fulvestrant, 31% exemestane, 22% tamoxifen and 7% letrozole, which were continued. The median PFS was 5.7 months for EVE vs. 2 months for TRAS until first progression or death with hazard ratio of 0.45 (95% CI 0.25-0.81, p=0.008). Among 48 patients who had disease progression, EVE was added to 16 patients who were originally treated by TRAS, and TRAS was added to 12 patients who were originally treated by EVE; the median time to the second progression was 6.3 months for the arm where EVE was added vs. 3.1 months in the arm where TRAS was added. Three patients were taken off study due to decrease in ejection fraction.

Conclusions: This trial demonstrates the efficacy of EVE alone or in combination with TRAS in patients with hormone refractory HR-positive, HER2-negative metastatic breast cancer, who remained on the endocrine therapy they had experienced disease progression on. This suggests that mTOR inhibition has the potential of restoring sensitivity to endocrine therapy and potentially allows the re-use of endocrine agents. Updated results and correlative studies will be presented. Clinical trial information: NCT00912340.
Title: Real World data and patterns of care of metastatic breast cancer (MBC) in Brazil: First results of LACOG 0312 retrospective study

Body: Background
Randomised clinical trials (RCT) are considered a gold standard generating efficacy and safety data supporting drug approval. However, real world data (RWD) reflecting health care delivery is becoming increasingly important. RWD on patient profiles and patterns of care in MBC are scarce in developing countries. As an example, observational studies suggest that despite guideline recommendations clearly indicating ET for hormone receptor positive MBC, a considerable proportion of patients in clinical practice begin chemotherapy in early lines of therapy. This pragmatic information addresses the uptake and applicability of the RCT results and should be able to help informing health care planning complementing RCT generated data. The objective of this study is to describe patient characteristics and evaluate actual physician-reported treatments for MBC in Brazil.

Methods
This analysis addresses the first 362 patients included in LACOG-0312, a retrospective study planning to recruit over 700 patients (cut-off date April 30th 2016) with recurrent locally advanced or MBC diagnosed in 2012 in 18 institutions across Brazil. Patient characteristics, type of health insurance coverage, treatment and survival outcome were analysed.

Results
Median age at BC diagnosis was 53 years and 37% were premenopausal. Regarding the educational level, 63.2% had completed elementary (primary) schooling, 75.7% were covered by the public health system while 24.3% had some form of private coverage. 70% of patients had hormone receptor positive (HR+) and 18% had HER2 positive tumors. Median disease free survival time from surgery was 29 months. Interestingly, 30% of patients underwent a biopsy of a metastatic site. Of the 362 patients, 349 (96.9%) received some form of palliative systemic therapy. Median time from diagnosis of metastatic disease to first-line therapy initiation was 46 days but a significant difference was noted between patients with public versus private health insurance (50 vs. 33 days p=0.012). Half of the patients received at least 3 lines of therapy (chemo or endocrine) to a maximum of 9 lines. In patients with HR+ tumors, endocrine therapy was administered in 47% in first, 65% in second and 61% in third-line, respectively. Median overall survival (OS) from diagnosis of metastatic disease was 34 months (CI 95%: 25.7-44.3) and no differences in OS were observed between patients with public or private coverage (34 months vs. 35 months p=0.808). Causes of death were cancer in 85.2% of patients and treatment toxicity in 3.6%.

Conclusion
Our study included a population with predominantly low educational level and mostly public health insurance. This likely corresponds to the majority of cases and reflects cancer care patterns in Brazil and many developing countries. A considerable proportion of patients were premenopausal at MBC diagnosis. More than half of HR+ patients received at least 3 lines of endocrine therapy although 54% of them had chemotherapy as the first systemic treatment. Patients from the public health system experienced a delay in starting first-line therapy but this didn't seem to jeopardize cancer outcomes in this setting.

Title: Early utilization pattern of palbociclib 1 year post-approval in the United States

Body: Background
Palbociclib was approved in the U.S. in February 2015 for the treatment of advanced/metastatic breast cancer (MBC) in combination with letrozole as initial endocrine based therapy for post-menopausal women with ER+/HER2- disease. We examined the demographic, clinical characteristics and treatment patterns of patients initiating palbociclib (PAL) + letrozole (LET) in real-world, community oncology practices.

Methods
This was a retrospective observational study of female breast cancer patients identified in the Navigating Cancer (NC) EMR database. The NC database collects EMR data, in both structured and unstructured fields (patient/clinical progress notes), from over 975 oncology and hematology providers across more than 50 locations in 25 states. Female patients with record of treatment with PAL after 01/31/2015 were selected. Combination treatment with LET was defined as having a record for LET within 30 days of the PAL prescription. Line of therapy (LOT) was assessed from the date of metastatic diagnosis and assigned by evaluating treatment plans pre-and post PAL initiation. Bi-monthly cohorts were constructed based on the month of initiation of PAL from 02/01/2015-01/31/2016. Interim results are presented; data from an additional three months of follow-up (through 03/31/2016) are pending.

Results
Overall, 931 unique patients were identified as having initiated PAL treatment. Of those, 608 (65.3%) received PAL + LET. Mean follow-up was relatively short at 5.4 mo (SD=3.5). Confirmed ER+/HER2- was observed in 71.6% of patients and 50.3% were age ≥65, mean age was 64.3 yrs. Of patients with available ECOG-PS at treatment initiation (n=424): 0/1=78.5%, 2=17.5% and 3=4.0%. Of patients with a known starting dose (n=418), 69.9% initiated with PAL 125mg, 22.0% at 100mg and 8.1% at 75mg. Compared to women < 65, women ≥ 65 were more often started with 100mg (25.4% vs. 18.9%) and 75mg (10.0% vs 6.5%). Any dose reductions were observed in 20.6% of patients (21.5% of patients receiving 125mg). During the year following approval, 39.8% of patients initiated PAL + LET at LOT1, 15.6% at LOT2, 13.0% at LOT3 and 31.6% at LOT4+, following MBC diagnosis. Over time the proportion of late use (LOT4+) declined from 39.7% in Feb/Mar ‘15 to 23.9% in Dec ’15/Jan ’16 with more patients utilizing in LOT3 from 7.9% in Feb/Mar ’15 to 19.5% in Dec ’15/Jan ’16).

Conclusions
There was a trend toward earlier utilization of PAL + LET from Feb-Jul ‘15, an increase in later use during Aug/Sep ’15, and a return towards earlier use in subsequent cohorts reaching the lowest proportion of LOT 4+ use observed in Dec ’15/Jan ’16. After a mean follow-up of 5.4 mo, 21.5% of patients receiving the 125 mg dose had a dose reduction. Final results, with additional follow-up, will be presented at conference.
Body: Background: Cancer immunotherapy is revolutionizing treatment today. While MBC with estrogen receptor positive (ER+) tumors, responding or stabilizing after first line chemotherapy, may have a benefit from a maintenance endocrine therapy combined with the monoclonal antibody bevacizumab, no option exists for ER- patients. In the past, we have shown, that a combination of 13-cis retinoic acid (RA) and interleukin-2 (IL-2) was able to improve the immune function [enhancing lymphocyte and natural killer cell (NK) counts, and CD4+/CD8+ ratio] of cancer patients who had had a clinical benefit from chemotherapy (Clin Cancer Res 2001;7:1251). With the aim of improving the immune function which eventually would lead to improvement of progression free survival (PFS) and overall survival (OS), patients with ER- LA or MBC, with a clinical benefit from chemotherapy, were treated with a combination of IL-2 and RA. Methods: Eligible patients with ER-, LA or MBC, and no evidence of progression after induction chemotherapy received the following immunotherapy: IL-2, (1.8 M UI), and oral RA (0.5 mg/kg), 5 days/week, 3 weeks/month for 1 year. Therapy was continued, with intermittent schedule until progression. Primary endpoints were the differences in lymphocyte, natural killer cell (NK) counts, and CD4+/CD8+ ratio, secondary end points were progression free survival (PFS), overall survival (OS) and toxicity. Results: From 12/1996 to 04/2009, 74 patients with ER-, LA (49%) or MBC (51%) were entered into the study. Median age was 55 years (range 31-75), 31% of patients were pre-menopausal. Each patient had received a median of 11 courses of first line and salvage chemotherapy regimens (total 850 courses). In addition, 31 patients had received high-dose chemotherapy with peripheral blood progenitor cell transplantation. Disease sites were as follows: soft tissue 54%, viscera 28%, bones 18%. After a median follow-up of 118 months (range 84-232), a total of 374 courses of immunotherapy were delivered. No WHO grade 3 or 4 toxicity was observed; grade 2 cutaneous toxicity and autoimmune reactions occurred in 19% and 16% of patients, respectively. A Statistically significant improvement with respect to baseline values was observed in the number of lymphocytes (p<0.001), NKs (p<0.001), and the CD4+/CD8+ ratio (p<0.01). Median PFS and OS were 44.9 months and 104.8 months, respectively. Conclusions: Maintenance immunotherapy with IL-2 and RA in ER-LA or MBC patients who do not progress after induction chemotherapy is well tolerated, improves lymphocyte, NK, CD4+/CD8+ ratios, and seems to delay disease recurrence.
Title: Analysing the factors affecting survival of breast cancer patients with leptomeningeal metastasis

Niwinska A, Rudnicka H, Kunkiel M, Jagiello-Gruszfeld A and Nowecki Z. The Maria Sklodowska-Curie Memorial Cancer Center, Warszawa, Poland.

Body: **AIM:** To assess those factors which affect survival in three groups of breast cancer patients with leptomeningeal metastasis (LM) treated at the Warsaw Cancer Center in Poland. Subject groups were: 187 patients consecutively referred during 2003-2015 (group A), 69 patients with LM as the first/only site of dissemination of the disease (group B) and 27 patients who survived for more than 1 year (group C).

**Methods:** Univariate and Cox multivariate analysis were performed using the following variables: age, Karnofsky Performance Status (KPS), biological subtype of breast cancer (ER/PR+HER2- vs. HER2+ vs. ER-PR-HER2-), systemic intravenous/oral treatment, intrathecal treatment, radiation therapy and the number of treatment methods.

**Results.** Median survival of patients in group A was 17 weeks, in group B 18 weeks (p=0.72) and in group C 19.2 months. In group A, factors positively affecting survival were: KPS => (p=0.01), older age (p=0.003), biological subtype ER/PR+HER2- (p=0.003), systemic intravenous/oral treatment (p=0.0001), intrathecal treatment (p=0.001) and radiation therapy (p=0.001). In the group B, the most important factors affecting survival were a KPS=> 70 (p=0.001), biological subtype ER/PR+HER2- (p=0.04), systemic therapy (p=0.001) and intrathecal therapy (p=0.001). For group C, older patients (p=0.01) with ER/PR+HER2- breast cancer (p=0.05, HR 0.18) and after systemic intravenous/oral treatment (p=0.02) had higher a probability of survival after 1 year.

**Conclusions:** Those breast cancer LM patients who were older, having high KPS, with luminal breast cancer and treated with systemic intravenous/oral therapy had a higher probability of survival than the rest of the group. Based on the presented data, the role of intrathecal therapy could not be exactly defined.
Title: The impact of genomic mutation on metastatic breast cancer treatment: A retrospective clinical trial

Body: Background: Next-Generation Sequencing (NGS) has made genomic mutation-driven cancer medicine feasible. Recognizing the importance of pathway and biomarker-driven personalized therapy for patients with metastatic breast cancer (MBC), we frequently submit tumor tissue for FoundationOne® genomic sequencing. Here we report the results and clinical impact of this test in 44 patients with MBC.

Patients and Methods: An institution IRB protocol was established for this retrospective clinical trial performed at the City of Hope Comprehensive Cancer Center from January 2014 to May 2016 with available tumor genomic DNA mutation results through FoundationOne® testing. Patients' clinical characteristics including age, race, treatment history, clinical outcome and genomic mutation profiles were reviewed.

Results: We identified 44 patients with MBC submitted for FoundationOne® genomic profiling: 24 triple negative breast cancer (TNBC), 16 estrogen receptor positive (ER+) and 4 human epidermal growth factor receptor 2 positive (HER2+). A total of 23 patients received over 3 lines of chemotherapies prior to FoundationOne® testing. Actionable mutations were identified in 42 of the 44 patients and 23 patients (52%) initiated mutation-driven targeted therapies. Of these 23 patients treated, a total of 17 had accessible responses and 6 patients did not have accessible responses due to short exposure (<2 weeks) and transition to hospice. The remaining 19 patients failed to initiate targeted therapy: 7 transitioned to palliative care/hospice, 5 were placed on other chemotherapies by treating physician, 4 had exhausted all of the targeted therapies recommended, and 3 chose not to start on treatment. Of the 7 responders, 2 received pazopanib and 5 received everolimus containing regimen. Durable response was observed in 3 cases: two patients carried PIK3CA alterations and were treated with everolimus, and the other responder had FGFR1 amplification and was treated with pazopanib. Comparing the genomic mutation profiling with The Cancer Genome Atlas (TCGA) database which contains primary breast cancer, the heavily pretreated TNBC tumors carried higher percentage of PIK3CA mutations (29% vs. 8%, p<0.01).

Conclusion: Targeted genomic sequencing through FoundationOne® can identify effective therapy that has not generally been used based on pathology type. NGS should be performed early in patients with good performance status. This approach should be utilized in a setting where genomic mutation driven therapeutic trials are available.

Title: Adjuvant treatment with zoledronic acid (ZOL) in stage II/III breast cancer. The AZURE trial (BIG 01/04) 10 year follow-up

Coleman R, Collinson M, Bell R, Marshall H, Dodwell D, Keane M, Gil M, Gregory W and Cameron D. University of Sheffield, Sheffield, United Kingdom; University of Leeds, Leeds, United Kingdom and AZURE Investigators.

Body: Background: The AZURE trial is an academic study designed to determine whether treatment with ZOL added to standard adjuvant therapy improves DFS and time to bone metastases in a broad range of patients with stage II/III breast cancer. Previous analyses after 7521 and 9662 events showed that, despite a reduction in the risk of developing bone metastases, there was no effect on overall breast cancer recurrence. However, preplanned subset analyses identified benefit in women who were in established menopause at study entry, an observation which has subsequently been confirmed by the EBCTCG meta-analysis of >18,000 women included in randomized trials of adjuvant bisphosphonates with reductions in risk of bone metastases and breast cancer mortality of around one third and one sixth respectively.3 All patients in AZURE are now >10 years since randomization and we will present the long-term effects of zoledronic acid on disease relapse, site of recurrence and overall survival.

Materials and methods: Between September 2003 and February 2006, 3360 patients from 174 centres were randomized to receive (neo) adjuvant chemotherapy (CT) and/or endocrine therapy (ET) +/- ZOL 4mg iv every 3-4 weeks for 6 doses, then 3 monthly x 8 and 6 monthly x 5 to complete 5 years treatment. Thereafter patients were reviewed annually until 10 years. Follow-up investigations were as clinically indicated with no protocol mandated imaging to identify sub-clinical disease. Dates of recurrence were backdated to the first clinical suspicion of relapse rather than the date actually confirmed.

Results: Baseline patient demographics, disease characteristics and treatment type were well balanced. 3207 patients (95%) received (neo) adjuvant CT (93% anthracyclines, 23% taxanes). 152 patients received ET alone. As of the datalock on June 7th 2016, with a maximum follow up of ~120 months, there have been 1137 DFS, and 910 OS events. The effects of ZOL on these outcomes, sites of recurrence as well as interactions between treatment effects and both menopausal status and age at study entry will be presented. Further follow up has not identified any new safety concerns. 30 confirmed cases of osteonecrosis of the jaw (ONJ) in the ZOL arm have occurred. There have been no reports of atypical femoral fracture.

Discussion: AZURE is one of the largest phase III studies of adjuvant bisphosphonates, and the first to report results with 10 years of follow-up.

Body: Introduction: The BCCA started funding the Oncotype DX genomic test for node negative, hormone receptor positive and HER2 negative early breast cancer patients in April 2014. Individual requests for the test are reviewed and approved based on predefined BCCA specific eligibility criteria which are, any size grade 3 cancer and any grade 2 cancer over 1cm (later amended to any size) in women 80 and younger, and any grade 1 cancer in women 40 and younger. General consensus is the test result, or Recurrence Score (RS), can be used to guide whether patients should receive endocrine therapy alone (low RS\[LRS] \(<18\)) or chemoendocrine therapy (high RS\[HRS] \(>30\)). For patients with intermediate RS (IRS), there is no consensus on whether the benefits of chemotherapy outweigh the risks of potential toxicities.

Objectives: To determine (1) the concordance of RS with treatments given to patients with LRS or HRS, (2) the treatments given to patients with IRS, and (3) the reasons for requesting the genomic test for patients outside the eligibility criteria.

Methods: This was a retrospective, multi-centre analysis of breast cancer patients for whom the genomic test was requested between June 1, 2014 and May 31, 2015. Charts were reviewed to determine the RS and the therapy given following knowledge of the RS. The primary outcome was the concordance rate between LRS and receipt of endocrine therapy only, and HRS and receipt of chemoendocrine therapy. The discordance rate between RS-based recommendations and treatments given, and the type of therapy received by patients with IRS were also explored. Treatments for those with low IRS (18-24) or high IRS (25-30) were examined separately. Finally, we examined the reasons for requesting the genomic test outside eligibility criteria.

Results: 435 requests were received during the study period. 395 requests were approved and test results were not found in 20 cases. Among the 375 RS results, 191 were LRS (51%), 122 were IRS (33%), and 62 were HRS (16%). The concordance rate between RS low and high and given treatments was 96%. Reasons for discordance included: patients with HRS refusing chemotherapy (n=3), patients with LRS receiving chemotherapy (n=3), patients refusing systemic treatment (n=3), and no explanation (n=1). Among the 122 patients with IRS, 81 were low-IRS and 41 were high-IRS. Overall, 27% of patients with IRS received chemotherapy. Chemotherapy was given in 16 patients (19.7%) with low-IRS and 17 patients (41.4%) with high-IRS. The main reasons for requesting the test for patients outside eligibility criteria were: grade 1 tumors in patients older than 40 years old (n=20), node-positive disease (n=9), and grade 2 tumors less than 11 mm (n=3).

Conclusion: Our results showed that the majority of patients with LRS or HRS were treated in accordance to RS-based recommendations. When treatment differed from RS-based consensus, the main reason was treatment refusal by patients. Only a quarter of patients with IRS received chemotherapy. Ongoing prospective trials will determine the utility of IRS in defining optimal therapy. Patients denied for the test were older and with grade 1 tumors, or with node-positive disease.
Title: The importance of the ultimate ratio of Omega-6 to Omega-3 fatty acids in the efficacy of fish oil supplements in suppressing inflammation in obese postmenopausal women

Quach D, Lengfelder L, Winnika L, Harlow B, Galvan G, Jolly C, Brenner A and deGraffenried L. University of Texas at Austin, Austin, TX and The UT Health Science Center at San Antonio, San Antonio, TX.

Body: Over the last decade, a large body of evidence has established that obesity is associated with a worse breast cancer prognosis for both pre- and postmenopausal women. There are several mechanisms which have been proposed for promoting this effect, including stage of diagnosis and co-morbidities, but more recent evidence suggests that the obese state is associated with changes in the biology of the disease, promoting a more aggressive phenotype. Our recently published in vitro and retrospective studies suggest that this is due, at least in part, through cyclooxygenase 2 (COX-2)-derived prostaglandin E2 (PGE2), and that interventions that suppress COX-2 PGE2 production may provide significant benefit for the obese ER+ patient in preventing many of the cancer-promoting effects associated with obesity. Omega-3 fatty acids have demonstrated anti-cancer benefit through multiple mechanisms, including suppression of inflammation-related signaling. DHA and EPA (omega-3 PUFAs found in fish oil) modulate inflammatory responses through COX-2 dependent and independent mechanisms. However, previous studies investigating the potential anti-cancer benefit of omega-3 PUFA and fish oil supplementation have produced mixed results, and none have focused specifically on the obese patient population.

To determine if supplementation with non-steroidal anti-inflammatory drugs (NSAIDs), including omega-3 fatty acids, can effectively suppress PGE2 production in the obese postmenopausal patient, we conducted a double-blind, prospective Phase 0, comparative, 30 day, non-interventional study with correlative biomarker endpoints. One hundred twenty (120) postmenopausal women without breast cancer were randomized to three arms 1. ASA 81mg po daily, 2. 1500mg of docosahexaenoic acid (DHA) and 2500mg eicosapentanoic acid (EPA) given daily and 3. Combined ASA and DHA/EPA at above doses. Serum samples were collected prior to and on day 29 of taking the supplements. PGE2 levels in the pre- and post-supplement serum samples were analyzed in triplicate by ELISA and presented as the percentage of change between post- and pre-supplement levels. Of the women in Arm 2 (DHA + EPA only), only 55% demonstrated a significant suppression of PGE2 levels after 30 day of supplements, compared to those in Arm 1 (ASA), in which 80% demonstrated a significant response.

We anticipate that the omega-3 fatty acid supplements were not as effective in as large a population as the aspirin due to a failure to reach a critical ratio between circulating levels omega-6 and omega-3 fatty acids, which has been shown by our own group and others to be a key determinant of cellular response. Studies are on-going to analyze the PUFA levels in both the pre and post supplement serum samples, and pre-clinical studies are being conducted to determine if the ratio of omega-6 to omega-3 PUFAs modulates PGE2 production in several different cell types, including macrophages, adipocytes and the breast cell itself. These results will be critical for moving clinical studies utilizing these agents forward, both in terms of elucidating the mechanism mediating an effect, and also in identifying an accurate biomarker for monitoring compliance and response.
Title: Mechanisms of drug sensitization by DHA on doxorubicin-resistant human breast adenocarcinoma

Rahman MM M, Veigas JM M, Auhtit A and Chowdhury W. College of Arts and Sciences, Qatar University, Doha, Qatar; University of Texas Health Science Center at San Antonio, San Antonio, TX and University of Texas Health Science Center at San Antonio, San Antonio, TX.

Body: The major reason for therapeutic failure of chemotherapeutic drugs is the development of resistance against anticancer agents used. Marine derived docosahexaenoic acid (DHA), a non toxic natural lipid (approved by FDA as generally recognized as safe (GRAS) category), has been shown to enhance the cytotoxicity of various anticancer drugs to a variety of cancer cell lines or tumors in animal models. Chemotherapeutic drugs in combination with DHA has also shown better outcomes in clinical trials. We have recently demonstrated that DHA enhanced the chemosensitization of doxorubicin-resistant human breast adenocarcinoma MCF-7 cells (MCF-7-Dox) to doxorubicin. However, the mechanisms by which DHA exerts its chemosensitizing effect remains nascent. This promoted us to explore the possible mechanisms of action of DHA in chemosensitization of MCF-7-Dox cell line. MCF-7-Dox cells were treated either with doxorubicin and DHA alone or in combination. Doxorubicin in the presence of DHA enhanced MCF-7-Dox cell death via inhibition of cell proliferation and invasion, accumulation of doxorubicin within the cells, cell cycle arrest at G2/M phase, and by inducing apoptosis. Combined treatment also reduced the levels of P-glycoprotein (P-gp)- a classical multi drug resistance (MDR) transporter, and TG2- a tumor survival factor under stress condition, and increased levels of lipid peroxidation and pro-apoptotic markers Bak1 and caspase 3. These findings are of potential clinical importance, as DHA might be a promising natural adjuvant drug in treating chemotherapy-refractory breast cancer.
Site-specific activation of curcuminoids in the breast cancer bone metastases microenvironment

Kunihiro AG G, Frye JB B, Brickey JA A, Luis PB B, Schneider C and Funk JL L. University of Arizona, Tucson, AZ; University of Arizona, Tucson, AZ; University of Arizona, Tucson, AZ and Vanderbilt University, Nashville, TN.

Body: The majority of women with advanced breast cancer (BCa) develop incurable osteolytic bone metastases. Our laboratory has previously demonstrated that curcuminoids, bioactive compounds isolated from turmeric rhizomes, prevent the development of lytic bone lesions in a murine xenograft model of human BCa bone metastasis and inhibit tumor cell secretion of TGFβ-stimulated parathyroid-related protein (PTHrP), a signaling pathway known to drive bone metastasis progression. In both humans and mice, glucuronidated phase II metabolites of curcumin, which are thought to be biologically inactive, are the primary form detected in circulation after consuming curcuminoid-containing foods or supplements. This has led to an untested postulate that curcuminoids may be deglucuronidated at sites of action to form bioactive, aglycone (free) curcumin. Studies were therefore undertaken to test this hypothesis in the context of the murine BCa bone metastasis model, assessing site-specific deconjugation of curcuminoids in the tumor-bone microenvironment.

Effects of curcumin-glucuronide (G-CURC) vs. curcumin (CURC) on TGFβ-stimulated PTHrP secretion by bone-tropic MDA-MB-231 (MDA) cells was determined by immunoradiometric assay. G-CURC and CURC levels were quantified by LC-MS in plasma and bone marrow specimens isolated from curcuminoid-treated female nude mice. Endogenous β-glucuronidase enzyme expression was localized by immunohistochemical (IHC) staining in paraffin-embedded sections of decalcified, MDA metastases-containing hind limbs of nude mice inoculated, via intracardiac injection 21 days prior, with MDA cells. Glucuronide deconjugation activity of bone marrow lysates was determined by colorimetric assay.

In contrast to the inhibitory effects of a naturally occurring curcuminoid mixture or pure CURC, G-CURC did not alter TGFβ-stimulated PTHrP secretion, confirming its postulated lack of biologic activity. In mice treated with curcuminoids, the majority of circulating curcumin was conjugated (91%). In contrast, the majority of curcumin in the bone marrow (56%) was unconjugated free (aglycone) curcumin (p <0.01). IHC staining of MDA tumor-bearing hind limbs of nude mice demonstrated expression of β-glucuronidase (GUSB), an enzyme that deconjugates compounds in mice and humans, by bone marrow cells, but not by tumor cells. Consistent with IHC, bone marrow from female nude mice displayed significantly higher (30-fold) deconjugation enzyme activity compared to MDA cells (p < 0.01). Female C3H/HeJ mice, which possess a partial loss-of-function mutation in the GUSB gene, had significantly decreased (66% lower) deconjugation enzyme activity compared to normal female C57BL/6 (p < 0.001) or nude (p < 0.01) mice. In addition, treatment with the β-glucuronidase inhibitor, saccharolactone (SL), also decreased deconjugation enzyme activity in marrow lysates from female nude mice.

These results suggest that curcuminoids, in the setting of breast cancer bone metastases, may act as a pro-drug, becoming activated within the tumor-bone microenvironment by glucuronidase-expressing hematopoietic bone marrow cells, to limit the progression of osteolytic lesion formation in a murine model of BCa bone metastasis.
