Title: Increasing the dose density of adjuvant chemotherapy by shortening intervals between courses or by sequential drug administration significantly reduces both disease recurrence and breast cancer mortality: An EBCTCG meta-analysis of 21,000 women in 16 randomised trials

Richard Gray¹, Rosie Bradley¹, Jeremy Braybrooke¹, Christina Davies¹, Hongchao Pan¹, Richard Peto¹, Judith Bliss², David Cameron³, John Mackey⁴, Lucia Del Mastro⁵, Sandra Swain⁶, Michael Untch⁶, Jonas Bergh⁸, Kathleen Pritchard⁹, Larry Norton¹⁰ and For the EBCTCGⁱ. ¹University of Oxford, Oxford, United Kingdom; ²Institute of Cancer Research, Sutton, United Kingdom; ³University of Edinburgh, Edinburgh, United Kingdom; ⁴University of Alberta, Edmonton, AB, Canada; ⁵National Cancer Research Institute, Genoa, Italy; ⁶Georgetown University, Washington, DC; ⁷HELIOS Klinikum Berlin-Buch, Berlin, Germany; ⁸Karolinska Institutet, Stockholm, Sweden; ⁹University of Toronto, Toronto, ON, Canada and ¹⁰Memorial Sloan Kettering Cancer Center, New York City, NY.

Body: Background: Much contemporary adjuvant chemotherapy uses conventional 3-weekly scheduling. Yet, cytokinetic modelling suggests that increasing the dose density of cytotoxic therapy by shortening the intervals between courses, or by using sequential rather than concurrent treatment schedules may enhance efficacy.¹ At least 15 randomised trials have directly tested this hypothesis and this meta-analysis by the Early Breast Cancer Trialists’ Collaborative Group (EBCTCG) brings together the worldwide evidence to clarify the balance of risks and benefits of dose-dense chemotherapy.

Methods: Individual patient data were provided for 98% (21,537/21,944) of women randomised in relevant trials: 7 randomised trials (10,004 women, 2240 breast cancer recurrences, 1481 breast cancer deaths) that compared 2-weekly dose-dense chemotherapy versus the same chemotherapy given 3-weekly, and 9 trials (11,533 women, 2773 breast cancer recurrences, 1711 breast cancer deaths) that compared sequential with concurrent anthracycline and taxane-based chemotherapy. Primary outcomes were time to recurrence and breast cancer mortality.

Results: Highly significant reductions in disease recurrence [rate ratio (RR)=0.83 (95%CI 0.76-0.91), p=0.00004] were seen with 2-weekly compared with 3-weekly chemotherapy, and 10 year breast cancer mortality was 3.0% lower [16.7% vs 19.7%: RR=0.85 (95% CI 0.76-0.95), p=0.003]. Overall survival was also improved [RR=0.86 (95% CI 0.78–0.95), p=0.003]. Similarly, for sequential versus concurrent taxane plus anthracycline chemotherapy the rate ratio for disease recurrence was 0.86 (95% CI 0.79-0.93, p=0.0001), 10-year breast-cancer mortality was 2.3% lower [19.2% vs 21.5%: RR=0.87 (95% CI 0.79-0.96), p=0.005], and overall survival was improved [RR=0.85 (0·78–0·94), p=0.0008]. The proportional reductions in recurrence with dose-dense chemotherapy were similar and highly significant (both p<0.002) in ER-positive and in ER-negative disease, and did not differ significantly by any other patient or tumour characteristics, including age, HER2 status, nodal status, tumour size, or grade. Increasing dose density did not have any material adverse effect on non-breast-cancer mortality, which was similar with 2-weekly and with 3-weekly chemotherapy [RR=0·93 (95% CI 0·74–1·17), p=0.6] and was if anything lower with sequential than with concurrent chemotherapy [RR=0·73 (95% CI 0·55–0·97), p=0.03]. Trial publications also indicate that, with haematopoietic growth factor support, dose-dense chemotherapy does not substantially increase toxicity.

Conclusion: Increasing the dose density of adjuvant chemotherapy is safe and results in fewer disease recurrences and fewer deaths from breast cancer.

Title: NSABP B-47 (NRG oncology): Phase III randomized trial comparing adjuvant chemotherapy with adriamycin (A) and cyclophosphamide (C) → weekly paclitaxel (WP), or docetaxel (T) and C with or without a year of trastuzumab (H) in women with node-positive or high-risk node-negative invasive breast cancer (IBC) expressing HER2 staining intensity of IHC 1+ or 2+ with negative FISH (HER2-Low IBC)

Body: Background: Adjuvant trastuzumab (H) reduces cancer recurrence and improves survival in patients (pts) with HER2-amplified or overexpressing (IHC 3+ staining intensity) IBC. Two of the landmark trials that demonstrated the efficacy of H-based eligibility on HER2 testing performed at local site laboratories were found to contain a cohort of pts without amplification or IHC overexpression on tissue submitted for central testing. These HER2-low cohorts appeared to benefit from the addition of H, and efforts at external HER2 testing validation and laboratory explorations did not negate these findings. NSABP B-47 was performed to determine if these findings would be confirmed in a large prospective randomized trial. The primary aim was to determine whether the addition of H to chemotherapy (CT) regimens of AC→WP or TC (choice per investigator discretion) would improve invasive disease-free survival (IDFS).

Methods: From 2/8/2011 to 2/10/2015, 3270 women were enrolled with 1630 pts randomly assigned to Arm 1 [TC: docetaxel 75mg/m2, cyclophosphamide 600 mg/m2 every 3 weeks x 6 cycles; or AC→WP: doxorubicin 60 mg/m2 and cyclophosphamide 600 mg/m2 every 2 or 3 weeks x 4 cycles followed by paclitaxel 80 mg/m2 every week x 12], and 1640 pts to Arm 2 [same CT regimens + 12 months of H]. Pts were stratified by IHC score (1+ vs 2+), number of positive nodes (0-3, 4-9, ≥10), hormone receptor status (ER or PgR positive vs both negative), and CT (TC vs AC→WP). Overall 58.5% were ≥50 years, 57% had tumors with IHC 1+, 17.3% were ER- and PgR-, 19.9% were node negative, and 27.4% had ≥4 positive nodes. TC was the intended CT regimen for 44.2%.

Results: As of 7/31/2017, the median follow-up time was 46.1 months. We observed 264 IDFS events, which triggered the definitive analysis for the primary endpoint. The addition of H to CT showed a 5-year IDFS of 89.6% compared to 89.2% for CT alone (HR 0.98; 95%CI 0.77-1.26; P=0.90). The findings did not differ by level of HER2 IHC expression, level of lymph node involvement, or hormone receptor status. 5-year point estimates for RFI were 92.0% for CT+H compared to 92.2% for CT alone (HR 0.995; 95%CI 0.75-1.32; P=0.97). 5-year estimates for DRFI were 92.7% for CT+H and 93.5% for CT alone (HR 1.10; 95%CI 0.81-1.49; P=0.55). The addition of H did not change OS significantly with 5-year point estimates of 94.8% in CT+H vs 96.2% in CT alone (HR 1.33; 95%CI 0.91-1.94; P=0.14). 4.3% of women in the CT arm experienced Grade 4 or 5 toxicities compared to 4.3% in the CT+H arm.

Conclusion: The addition of H to CT did not demonstrate a reduction in IDFS, RFI, or DRFI in women with non-overexpressing but IHC measurable HER2 IBC. This prospective study did not confirm the retrospective findings in NSABP B-31 or N9831. The threshold of HER2 expression or genetic amplification for H benefit remains unchanged.

**Title:** Peri-operative aromatase inhibitor treatment in determining or predicting longterm outcome in early breast cancer – The POETIC* Trial (CRUK/07/015)

John FR Robertson¹, Mitchell Dowsett², Judith M Bliss³, James P Morden³, Maggie Wilcox, Abigail Evans⁵, Chris Holcombe⁶, Kieran Horgan⁷, Cliona Kirwan⁸, Elizabeth Mallon⁷, Mark Sibbering⁸, Anthony Skene¹⁰, Raghavan Vidyā¹¹, Maggie Cheang³, Jane Banerji³, Lucy Kilburn³, Andrew Dodson² and Ian Smith⁴. ¹University of Nottingham, Royal Derby Hospital Centre, Derby, United Kingdom; ²Ralph Lauren Centre for Breast Cancer Research, Royal Marsden Hospital, London, United Kingdom; ³The Institute of Cancer Research, Surrey, United Kingdom; ⁴The Royal Marsden NHS Foundation Trust, London, United Kingdom; ⁵Poole Hospital NHS Foundation Trust, Poole, United Kingdom; ⁶Royal Liverpool University Hospital, Liverpool, United Kingdom; ⁷Leeds Teaching Hospital, NHS Trust, Leeds, United Kingdom; ⁸University Hospital of South Manchester, Manchester, United Kingdom; ⁹Derby Teaching Hospital, NHS Trust, Derby, United Kingdom; ¹⁰Bournemouth and Christchurch Hospitals NHS Foundation Trust, Wolverhampton, United Kingdom and ¹¹Birmingham University, Wolverhampton, United Kingdom.

**Body: Background**

Experimental evidence (Fisher et al, 1989) & a small clinical trial (IMPACT) respectively suggested peri-operative endocrine therapy (ET) may improve long-term disease-related outcome in patients undergoing primary surgery for ER positive (ER+) breast cancer (BC) & that tumor Ki67 levels after 2 weeks of peri-operative aromatase inhibitor (POAI) therapy might offer an effective way of predicting outcome & the need for additional adjuvant treatment. POETIC (*Peri-Operative Endocrine Therapy - Individualising Care) is a phase III randomized controlled trial designed to test these hypotheses & provide data to determine whether 2 week Ki67 improves prediction beyond that by baseline Ki67 of the group who have a higher risk of relapse in the first years after diagnosis in spite of best current standard of care.

**Patients & methods**

Postmenopausal patients with ER+ BC were randomised 2:1 to either, POAI (centre choice: letrozole 2.5mg or anastrozole 1mg daily) for 14 days prior to & 14 days following surgery or no POAI (Control). Randomization was stratified by treating center; adjuvant treatment was per UK routine practice. Tissue samples were collected at baseline & surgery (FFPE) for blinded Ki67 testing. Primary endpoint was Time to Recurrence (TTR: time from randomization to loco-regional or distant recurrence or BC death). A secondary endpoint was Ki67 at baseline & after 2 weeks of AI.

**Results**

Between 2008 & 2014, 4480 patients (2976 AI, 1504 Control) were randomized from 130 UK centers. Median age was 67 (IQR 62-75), 18% had grade 3 tumors, 39% were node positive and 61% had tumor size>2cm. For adjuvant ET 314 patients (7.2%) received tamoxifen (Tam), 3695 (84.6%) an AI, 251 (5.7%) Tam changing to AI and 109 (2.5%) changing from AI to Tam. On 8 August 2017, median follow-up was 60.7 months (IQR 49.5 to 72.2).

408/4480 (9.1%) patients have had a TTR event; 263 (8.8%) allocated to POAI compared to 145 (9.6%) controls: HR=0.91 (95%CI: 0.74, 1.12) Log-rank p=0.37. Adjusted HR=0.91 (95%CI: 0.74, 1.11).

The relationship of Ki67 (baseline & after 2 weeks) with TTR in both the POAI & control groups will be presented for the overall ER+ population & HER2 defined sub-groups.

**Discussion**

There was no significant evidence that four weeks of POAI improved TTR compared with no POAI. POETIC will provide definitive evidence on the role of 2 week POAI-treated Ki67 to inform future practice & trials in terms of the potential to identify a group of patients for whom current standard of care appears insufficient in the few years post diagnosis.
Title: Copy number aberration analysis to predict response to neoadjuvant anti-HER2 therapy: Results from the NeoALTTO phase III trial

Body: Background
In the NeoALTTO trial, the combination of trastuzumab and lapatinib for the neoadjuvant treatment of HER2 positive early breast cancer patients (pts) nearly doubled the rate of pathological complete response (pCR) compared with either anti-HER2 treatment alone. In the same trial, pCR was shown to be a surrogate for long-term outcome. Expression of ERBB2, ESR1 and immune signatures were the main drivers of pCR (Fumagalli et al. JAMA Oncol 2016). The main aim of the current study was to investigate the relevance of copy number aberrations (CNAs) for pCR and event-free survival (EFS).

Methods
For 271 out of the 455 pts enrolled in the study with sufficient tumour content, DNA was hybridized on CytoScan HD arrays. The \( \log_{2} \) ratio intensities and B allele frequencies were segmented jointly using the multitrack segmentation algorithm. Integer level estimates of total copy number and major allele were obtained using GAP. Recurrent CNAs were found with GISTIC2. The genome instability index (GII) was defined as the median absolute deviation of the normalized copy number. Tumor infiltrating lymphocytes (TILs) and gene expression were obtained as described previously. The correlations between different parameters were assessed using Spearman correlations (\( \rho \)). The Mann-Whitney test was used to relate binary and numerical features. EFS analysis was performed using the Cox proportional hazard model.

Results
CNAs estimates were obtained for 185 out of 271 pts. CNA distribution was similar to the ones observed in HER2+ pts from the METABRIC and the TCGA datasets. There were 64% of diploid pts, 26% of triploid and 9% of tetraploid or more. Aneuploidy level was not associated with pCR or EFS. Of interest, there were many significant differences in CNA profiles between ER+ and ER- pts. Those differences mirror those observed between ER+ and ER- among HER2- pts in TCGA (\( \rho=56\% \)) and METABRIC (\( p=56\% \)). ERBB2 amplification was predictive of high pCR (\( p=0.0007 \)), albeit less so than ERBB2 expression, and ceased to be significant correcting for ERBB2 expression. The pCR rate increased with the GII (\( p=0.03 \)), independently of ERBB2 amplification. The effect was stronger in ER+ patients (\( p=0.01 \)). GISTIC analysis revealed 159 recurrent CNA regions. Amplification of 2 regions on 6q23-24 was significantly associated with higher pCR (\( p=0.00005 \) and \( p=0.00087 \), FDR=0.006 and 0.05). The most significant segment of 6q23-24 contained 39 genes, some whose expression level also predicted pCR (e.g. MAP3K5, \( p=10^{-4} \)). Gene ontology analysis of the genes correlated with this segment highlighted the category 'response to interferon-alpha' (\( p=4.3x10^{-7} \)). No amplified region or gene was found to be predictive of EFS, after multiple testing correction.

Conclusions
The amplification of ERBB2 was shown to be predictive of pCR, however its expression was more predictive. High genomic instability was associated with higher rate of pCR in ER+ subgroup. Of interest, a novel amplified region, involving chromosome 6 was shown to be predictive of pCR, which may warrant further investigation.
Title: Tandem duplicator phenotypes define 50% of triple negative breast cancers

Edison T Liu¹, Francesca Menghi¹, Floris Barthel¹, Vinod Yadav¹, Ming Tang², Bo Ji¹, Gregory Carter¹, Jos Jonkers³ and Roeland Verhaak¹. ¹The Jackson Laboratory for Genomic Medicine, Farmington, CT; ²MD Anderson Cancer Center, Houston, TX and ³Netherlands Cancer Institute, Amsterdam, Netherlands.

Body: Background. We recently discovered a unique chromotype, the Tandem Duplicator Phenotype (TDP), characterized by hundreds of somatic tandem duplications (TDs) scattered throughout the genome of a large percentage of triple negative breast cancers (TNBCs). Importantly, we observed that the TDP associates with a better response to cisplatin therapy in vitro and in vivo, suggesting that it is a tractable and quantitative biomarker of response to platinum-based therapy. Here, we expand on our initial findings by analyzing Whole-Genome (WG) sequences of over 2,700 tumors.

Methods. TD coordinates from WG sequences relative to 2717 tumors were assembled from over 30 independent studies representing several cancer types, including 254 TNBCs. WG sequencing of mouse breast tumors was carried out using standard Illumina protocols. The number, distribution and span-size of somatic TDs from a training set of 992 tumors were used to develop a TDP classifier that identifies highly recurrent but clearly distinct TDP profiles. The TDP classifier was then applied to the remaining tumor sequences. WG mutation and copy number datasets were investigated to identify the genetic drivers associated with each TDP profile, and the genomic consequences of different TDPs were evaluated through identification of genomic hotspots for gene duplication and transection.

Results. We describe six different TDPs featuring distinct TD span size distributions, with peaks at 10Kb (group 1), 300Kb (group 2) and 3Mb (group 3), or different combinations of these (mix12, mix13 and mix23). More than half of all TNBC display a TDP. Of these, 55% classify as group 1, 14% as group 2 and 15% as group mix12. Whereas all TDP groups show a higher TP53 mutation rate compared to non-TDP tumors, each TDP profile is characterized by specific additional gene perturbations, with loss of BRCA1 occurring in groups 1, mix12 and mix13; CCNE1 amplification in group 2; and CDK12 mutations in group mix23. We show that different TDPs are subject to the perturbation of specific oncogenic networks resulting from the duplication of oncogenes by larger TDs (>300Kb) or the disruption of tumor suppressors via double transections by shorter TDs (10Kb). Indeed, tumor suppressor genes such as PTEN, RB1 and MLL3 are frequently disrupted by TDs in TNBC TDP group 1 tumors, whereas TNBC TDP group 2 tumors commonly feature duplication of oncogenes such as MYC and MALAT1. Finally, through WG analyses of 18 mouse models (GEMMs) of breast cancer, we provide the first mechanistic evidence of the driving role of conjoint loss of TP53 and BRCA1, but not of BRCA2, in inducing the TDP group 1 profile.

Conclusions. Our study shows a definitive genetic induction of one specific form of TDP (group 1) characterized by 10kb TD span. Different TDP profiles are characterized by alternative somatic genetic origins but always couple with disruptive TP53 mutations. The consequences of the massive TD formation in TDP TNBCs suggest a systems strategy to tumor induction involving heterogeneous combinations of oncogenes and tumor suppressors. That these TDP forms, accounting for ~50% of TNBC, are associated with significant sensitivity to cisplatin suggest that this chromotype may identify TNBC patients who would benefit from upfront platinum-based chemotherapy.

Title: Extended adjuvant bisphosphonate treatment over five years in early breast cancer does not improve disease-free and overall survival compared to two years of treatment: Phase III data from the SUCCESS A study

Wolfgang Janni¹, Thomas WP Friedl¹, Tanja Fehm², Volkmann Müller³, Werner Lichtenegger⁴, Jens Blohmer⁵, Ralf Lorenz⁶, Helmut Forstbauer⁷, Emanuel Bauer¹, Visnja Fink¹, Inga Bekes¹, Julia Jückstock⁸, Andreas Schneeweiss⁹, Hans Tesch¹⁰, Sven Mahner⁸, Sara Y Brucker¹¹, Georg Heinrich¹², Matthias W Beckmann¹³, Robert Coleman¹⁴ and Brigitte Rack¹. ¹University Hospital Ulm, Ulm, Germany; ²University Hospital Düsseldorf, Heinrich-Heine University, Düsseldorf, Germany; ³University Hamburg-Eppendorf, Hamburg, Germany; ⁴Charité University Hospital Campus Virchow, Berlin, Berlin, Germany; ⁵Charité University Hospital Campus Virchow, Berlin, Berlin, Germany; ⁶Gynecologic Practice Dres Lorenz, Hecker, Wesche, Braunschweig, Germany; ⁷Hemato-Oncological Practice Dres Forstbauer and Ziske, Troisdorf, Germany; ⁸Ludwig-Maximilians-University Munich, Munich, Germany; ⁹National Center for Tumor Diseases, University Hospital Heidelberg, Heidelberg, Germany; ¹⁰Onkologie Bethanien, Frankfurt, Germany; ¹¹University Hospital Tübingen, Tübingen, Germany; ¹²Schwerpunktpraxis für Onkologische Gynäkologie, Fürstenwalde, Germany; ¹³University Hospital Erlangen, Friedrich-Alexander-University Erlangen-Nuremberg, Nuremberg, Germany and ¹⁴Sheffield Cancer Research Centre, Weston Park Hospital, University of Sheffield, Sheffield, United Kingdom.

Body: Background:
A recent meta-analysis has reported benefits of adjuvant bisphosphonate treatment in early breast cancer patients with improved breast cancer survival and reduced rate of breast cancer recurrences in the bone, especially in postmenopausal patients. However, a comparison between bisphosphonate treatments duration is lacking. Therefore, we examined 2 and 5 years of zoledronate treatment following adjuvant chemotherapy in the SUCCESS A trial.

Methods:
The SUCCESS A trial is a randomized, open-label, 2x2 factorial design Phase III study in high-risk early breast cancer patients that were randomized to adjuvant chemotherapy treatment with 3 cycles of FEC followed by either 3 cycles of docetaxel or 3 cycles of gemcitabine-docetaxel. After chemotherapy, patients were subject to a second randomization of 5 years of zoledronate treatment (4 mg i.v. every 3 months for 2 years, followed by 4 mg i.v. every 6 months for 3 years) vs. 2 years of zoledronate treatment (4 mg i.v. every 3 months for 2 years). Outcome was analyzed using adapted disease-free survival (DFS) and adapted overall survival (OS), with survival times measured as of 2 years after the start of zoledronate treatment. Maximal observation time was set to 4 years. Median observation time was 2.95 years for DFS and 3 years for OS.

Results:
Overall, 3421 of the 3754 patients randomized in the SUCCESS A study received at least one zoledronate dose. 434 patients had a DFS event or were lost to follow up in the first two years after the start of zoledronate treatment; thus, 2987 patients were available for analysis (1540 and 1447 patients in the 5-year and 2-year zoledronate treatment arm, respectively). Both adapted DFS and adapted OS did not differ between the two treatment arms (5 vs. 2 years) as shown by multivariate cox regressions adjusted for patient and tumor characteristics as well as chemotherapy (DFS: hazard ratio [HR] 0.97, 95% confidence interval [CI] 0.75 – 1.25, p = 0.81; OS: HR 0.98, 95% CI 0.67 – 1.42, p = 0.90). In addition, subgroup analyses according to menopausal status revealed no difference in DFS or OS between the two treatment arms in premenopausal women (DFS: HR 1.21, 95% CI 0.81 – 1.81, p = 0.35; OS: HR 0.93, 95% CI 0.57 – 1.53, p = 0.78) or postmenopausal women (DFS: HR 0.85, 95% CI 0.62 – 1.16, p = 0.30; OS: HR 0.96, 95% CI 0.67 – 1.39, p = 0.84).

Conclusions:
Our study showed no difference in DFS or OS between 5-years and 2-years of adjuvant zoledronate treatment in early breast cancer patients, irrespectively of menopausal status. Thus, our results indicate that extended treatment with zoledronate does not improve DFS or OS in high-risk early breast cancer patients.
Title: Sacituzumab govitecan (IMMU-132), an anti-Trop-2-SN-38 antibody-drug conjugate, as ≥3rd-line therapeutic option for patients with relapsed/refractory metastatic triple-negative breast cancer (mTNBC): efficacy results

Aditya Bardia1, Linda T Vahdat2, Jennifer Diamond3, Kevin Kalinsky9, Joyce O'Shaughnessy4, Rebecca L Moroose5, Steven J Isakoff1, Sara M Tolaney6, Alessandro D Santin7, Vandana Abramson8, Nikita C Shah5, Serengulam V Govindan10, Pius Maliakal10, Robert M Sharkey10, William A Wegener10, David M Goldenberg10 and Ingrid A Mayer8. 1Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA; 2Weill Cornell Medicine, New York, NY; 3University of Colorado Cancer Center, Aurora, CO; 4Texas Oncology, Baylor University Medical Center, US Oncology, Dallas, TX; 5UF Health Cancer Center, Orlando, FL; 6Dana Farber Cancer Institute, Harvard Medical School, Boston, MA; 7Yale University School of Medicine, New Haven, CT; 8Vanderbilt-Ingram Cancer Center, Nashville, TN; 9Columbia University-Herbert Irving Comprehensive Cancer Center, New York, NY and 10Immunomedics, Inc., Morris Plains, NJ.

Body: Background: mTNBC has an aggressive course with limited therapeutic options. Sacituzumab govitecan (IMMU-132) is a novel antibody drug conjugate consisting of SN-38, the active metabolite of the topoisomerase I inhibitor, irinotecan, conjugated to a humanized mAb targeting Trop-2, which is highly expressed in most epithelial cancers, including TNBC. A phase I/II basket trial (NCT01631552) was conducted in patients (pts) with multiple, advanced epithelial cancers. We previously reported preliminary results in mTNBC (N=69; objective response rate [ORR] = 30%, Bardia et al., JCO 2017;35:2141-2148). In 2016, sacituzumab govitecan was granted Breakthrough Designation based on this encouraging data, and we resumed enrollment in a more defined patient population (≥3rd-line setting in mTNBC).

Methods: Pts received sacituzumab govitecan on days 1 & 8 of a 21-day cycle until progression or unacceptable toxicity. Eligibility included > 2 prior lines of therapy for metastatic disease, measurable disease by CT or MRI and prior taxane. Efficacy was assessed locally by RECIST 1.1 and confirmed by independent centralized blinded review. ORR, DOR, progression-free survival (PFS) and overall survival (OS) were determined. Adverse events (CTCAE v4.0), immunogenicity, and Trop-2 expression in archived tumor samples, when available, were evaluated.

Results: 110 mTNBC pts (109 female, 1 male; median age 55 yrs, range 31-81), including 53 from the previously reported cohort of 69 pts who had received ≥2 prior regimens for metastatic disease, were accrued between 7/2013 and 2/2017. As of data cutoff on 6/30/2017, 71 are deceased, 23 in long-term follow-up, and 16 still on treatment. All pts were treated at the 10 mg/kg IMMU-132 dose level, receiving 14.5 median doses (range 1-88). Treatment was well tolerated, with no treatment-related deaths, 2 treatment discontinuations for toxicity, and no anti-drug antibodies detected. Grade ≥3 toxicity (≥10%) included neutropenia, 39%; leukopenia, 14%; anemia, 10%; the incidence of febrile neutropenia was low (7%). By local radiologist assessment, the ORR is 34% (37/110), including 3 CRs and 34 PRs, the clinical benefit rate (CBR: CR+PR+SD>6 mo.) is 46%, the KM median DOR and PFS are 7.6 mo. (95% CI: 4.8 to 11.3) and 5.5 mo. (95% CI: 4.8 to 6.6), respectively, including 10% (11 pts) with long-term PFS (12 to 30+ mo.), and the KM median OS is 12.7 mo. (95% CI: 10.8 to 13.6). Results of the independent central blinded review along with sensitivity analyses of prior treatment regimens, including checkpoint inhibitor use, and exploratory biomarker analysis of Trop-2 expression will be presented at the meeting.

Conclusions: Sacituzumab govitecan demonstrated significant clinical activity as a single agent in the ≥3rd-line setting for patients with relapsed/refractory mTNBC. Given the high unmet medical need, data from this trial is being submitted for consideration of accelerated approval, and a global confirmatory randomized Phase III trial (NCT02574455) is underway. Additional studies including rational combinations are currently being evaluated for mTNBC and other breast cancer subsets.
Discovery and characterization of an estrogen bound LncRNA in late-Stage breast cancer

Christopher A Maher\textsuperscript{1,2}, Jessica Silva-Fisher\textsuperscript{1,2}, Abdallah Eteleeb\textsuperscript{1,2}, Cynthia Tang\textsuperscript{1,2}, Charles Perou\textsuperscript{3}, Jorge S Reis-Filho\textsuperscript{4}, Elaine R Mardis\textsuperscript{5} and Matthew J Ellis\textsuperscript{6}. \textsuperscript{1}Washington University School of Medicine in St. Louis; \textsuperscript{2}The McDonnell Genome Institute; \textsuperscript{3}University of North Carolina at Chapel Hill; \textsuperscript{4}Memorial Sloan Kettering Cancer Center; \textsuperscript{5}Nationwide Children's Hospital, Institute for Genomic Medicine and \textsuperscript{6}Baylor College of Medicine in Houston.

Body: Breast cancer is the second most common newly diagnosed cancer and the second leading cause of cancer death among women in the United States. Despite the proven benefits of adjuvant endocrine therapy in women with hormone receptor positive breast cancer, relapses still occur over 5 years after initial treatment with endocrine therapy, referred to as late-stage relapse. Currently, the mechanisms of driving late-stage relapse are poorly characterized. To date, breast cancer research has primarily focused on protein-coding genes thereby missing the emerging class of long intergenic non-coding RNAs (lncRNAs) that may serve as critical regulators of relapse. Furthermore, the current understanding of lncRNA function is still in its infancy representing a critical gap for translating lncRNA discoveries into real-world applications to benefit patient care. Several well-described examples indicate that lncRNAs may be master epigenetic regulators in cancer biology through their interactions with proteins regulating target gene expression. Therefore, we hypothesize that lncRNAs may interact with estrogen receptor alpha 1 (ESR1) to regulate genes promoting late-stage relapse. To address this, we performed a transcriptome analysis of tumors from a unique cohort of 24 patients that had late-stage relapse to discover a novel set of lncRNAs, most of which have not yet been characterized. Next, we used RNA Immunoprecipitation coupled with transcriptome sequencing (RIP-Seq) to identify transcripts bound to ESR1 in T47D cells. We discovered 217 lncRNAs bound to ESR1 of which 50 were up-regulated in late-stage breast cancer. We chose to focus the most up-regulated lncRNA in late-stage relapse. Since it is an unannotated lncRNA we will refer to it as '\textit{LAte\text{-}Stage relapse ESR1\text{-}Bound LncRNA 1}', or LASER-1. To further understand the interplay between LASER-1 and ESR1, cells endogenously expressing LASER-1 were subjected to partial digestion to preserve lncRNA and protein interactions. Protected RNA fragments were subsequently immunoprecipitated with ESR1 and quantified by qPCR to reveal specific ESR1 interaction sites within LASER-1. Next, we observed increased expression of LASER-1 in ER\textsuperscript{+} breast cancer cell lines. Notably, LASER-1 expression was elevated in MCF7 long-term estrogen deprived (MCF7 LTED) cells -- that have amplified ESR1 -- relative to parental MCF7 cells. To demonstrate that LASER-1 promotes oncogenic phenotypes we transiently silenced LASER-1 in two cell lines with high endogenous expression of LASER-1 (including MCF LTED) and observed a decrease in cellular proliferation and invasion. Subsequent gene expression analysis after silencing LASER-1 altered mRNA and protein levels of critical cell cycle genes (i.e., p27). Overall, this is the first study to discover ESR1 bound lncRNAs that may be contributing to late-stage relapse in breast cancer. In the short-term, our ongoing research may lead to significant breakthroughs establishing the importance of LASER-1 as a master regulator in late-stage relapse. In the longer-term, we envision this research may lead to the development of novel therapeutics targeting LASER-1 with the potential for rapid clinical translation.
Body: Inactivating germline mutations in the NF1 gene (encoding neurofibromin) cause neurofibromatosis type 1. In addition to peripheral nervous system tumors, NF1 patients are at higher risk for other cancers, including breast cancer. Tumor exome-sequencing studies demonstrate that approximately 20% of all human cancers have somatic NF1 mutations. NF1 has been best known for its ability to inactivate Ras as a GAP (GTPase Activating Protein). However, this function is served by a small GAP domain in a very large protein. Recurrent missense mutations inactivating the GAP activity are infrequent. In contrast, it is common to detect frameshift (FS) and nonsense (NS) NF1 mutations, which can create an NF1-null state deleting not only GAP, but also, potentially, undefined NF1 functions whose loss could also drive tumorigenesis. As we reported at SABCS previously, in 600+ patients treated by tamoxifen adjuvant monotherapy, we found that FS/NS NF1 mutations independently correlate with relapse risk (HR=2.6, p=0.03). To explore this finding, we silenced NF1 in preclinical models of ER+ breast cancer, which markedly enhanced ER transcriptional activities, causing estradiol (E2) hypersensitivity and converted tamoxifen into an agonist (in vitro and in vivo). Most important, these activities depend on ER, but not on NF1’s GAP activity. These findings readily explain the poor patient outcomes associated with NS/FS NF1 mutations, and reveal a previously unrecognized function for NF1 in ER regulation.

In the presence of an agonist, liganded ER repels co-repressors and recruits co-activators, while the reverse is true with an antagonist such as tamoxifen. Many co-regulators contain leucine/isoleucine rich motifs, which bind directly to the ligand-binding domain (LBD) in ER. NF1 has several of these motifs that are much more highly conserved in species with a functional ER pathway, and some of these are mutated in cancers (e.g., in our patient cohort). Furthermore, we found that NF1 can bind directly to ER, and that this binding is mediated between the ER LBD and the NF1 leucine-rich regions. Like a classic co-repressor, wildtype NF1 (but not mutants lacking GAP activity or the Leu-rich motif) binds to ER, and is recruited by ER to the ERE in the presence of tamoxifen, but not E2. Further preclinical treatment studies indicate that while NF1-deficient ER+ breast cancer should not be treated by tamoxifen or AIs, fulvestrant remains effective. Furthermore, when fulvestrant is combined with dabrafenib and trametinib to inhibit Ras effectors Raf and MEK, apoptosis is induced in vitro, and tumor regression is observed in vivo. In conclusion, we have demonstrated that NF1 is a dual negative regulator at the intersection of two potent oncogenic signaling pathways, Ras and ER, and that NF1-deficient ER+ breast cancer patients may be more effectively treated by co-targeting the Ras and ER signaling. These patients, up to 10% of those with advanced ER+ breast cancer, can be readily identified for treatment by ctDNA analysis. A clinical trial is under development.
Title: Highly recurrent transcriptional remodeling events in advanced endocrine resistant ER-positive breast cancers

Nolan Priedigkeit¹, Damir Vareslija², Ahmed Basudan¹, Rebecca J Watters¹, Peter C Lucas¹, Nancy E Davidson³, Jens-Uwe Blohmer⁴, Carsten Denkert⁴, Anna Machleidt⁴, Barbara I Heppner⁴, Adam M Brufsky¹, Steffi Oesterreich¹, Leonie Young⁵ and Adrian V Lee¹. ¹University of Pittsburgh, Pittsburgh, PA; ²Royal College of Surgeons in Ireland, Dublin, Ireland; ³Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA and ⁴Charité University Hospital, Berlin, Germany.

Background: Although individual cancers are driven by heterogeneous processes, cancer mortality has a near universal cause—therapy resistance, recurrence and metastasis to vital organs. Characterizing more advanced tumors has borne valuable insight into cancer progression, yet studies of longitudinally collected breast cancer specimens are scarce given lengthy periods of cancer dormancy. In this study, we aimed to create the most comprehensive characterization of gene expression alterations to date between patient-matched pairs of primary and advanced ER-positive breast cancers.

Materials/Methods: Hybrid-capture RNA-sequencing was performed on 50 patient-matched pairs of primary and advanced ER-positive tumors from various recurrence sites (9 brain, 11 bone, 3 GI, 10 ovary, 17 local). Time to recurrence was up to 14.1 years with a median of 3.4 years. A shared variant analysis confirmed all paired samples were patient-matched. 1,380 cancer-related genes were analyzed for outlier expression fold-changes in matched recurrences versus primary tumors. Pair-specific, outlier fold-change thresholds were defined as Q1/Q3 +/- [1.5 X IQR]; using each pairs' fold-change values across all genes as the distribution. These discrete, longitudinal transcriptional remodeling events (LTREs) were assessed for recurrence across all sites and analyzed for enrichments within specific cohorts (Fisher's exact tests), such as locoregional vs. distant recurrences. To determine if LTREs represent acquired vulnerabilities, ex vivo and in vivo experiments targeting a recurrent, druggable LTRE gain of RET was performed.

Results: The majority of advanced cancers were transcriptionally similar to patient-matched primaries with 23 of 33 distant metastases retaining PAM50 assignments of the matched primary—shifts to HER2 (n=4, 12%) or Luminal B (n=5, 15%) subtypes accounted for most metastatic discordances. Despite this intrinsic conservation, remarkably recurrent gene-level LTRE gains and losses were observed in advanced disease. Recurrent LTRE gains included NCAM1 [42%], FGFR4 [40%], IBSP [36%], ROBO2 [36%] and SPP1 [30%]. Notable LTRE losses included RELN [42%] and ESR1 [26%]. NCAM1 LTREs showed the most significant enrichments (p < 0.001) in distant disease (20 of 33, 61%) versus locoregional disease (1 of 17, 6%). A prominent LTRE enriched in brain metastasis (BrM) was RET (p-value = 0.003), expression of which showed outlier gains in 56% of ER-positive BrMs. Marked anti-tumor activity was demonstrated with the RET inhibitor cabozantinib in ex vivo explant cultures of patient resected BrMs (n=3) and a BrM patient-derived xenograft.

Conclusions: Taken together, these results demonstrate profound, recurrent and metastatic site-specific LTREs in advanced breast cancers, which may be essential to our understanding of endocrine-therapy resistance and metastasis. Although current emphasis for longitudinal clinical profiling of tumors is on DNA-level alterations, these results suggest LTREs as a compelling, shared mechanism of cancer progression. Given remarkably high recurrence rates of specific LTREs across multiple cohorts, further preclinical and clinical investigations of LTREs are demanded, especially considering some (i.e. FGFR4 and RET) are readily druggable.
**2017 San Antonio Breast Cancer Symposium**

**Title:** First-line ribociclib vs placebo with goserelin and tamoxifen or a non-steroidal aromatase inhibitor in premenopausal women with hormone receptor-positive, HER2-negative advanced breast cancer: Results from the randomized phase III MONALEESA-7 trial

**Body: Background:** Endocrine therapy (ET) with ovarian function suppression is an established first-line treatment for pre- and peri-menopausal women with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2–) advanced breast cancer (ABC). Addition of ribociclib (orally bioavailable, selective cyclin-dependent kinase [CDK] 4/6 inhibitor) to first-line ET prolonged progression-free survival (PFS) in a Phase III trial of postmenopausal women with HR+, HER2– ABC (MONALEESA-2). Here we report results from MONALEESA-7 (NCT02278120), the first double-blind, randomized, Phase III trial evaluating ribociclib + tamoxifen/non-steroidal aromatase inhibitor (NSAI) and goserelin specifically in pre- and peri-menopausal patients.

**Methods:** Pre- or peri-menopausal women with HR+, HER2– ABC who had received ≤1 line of chemotherapy and no prior ET for ABC were randomized (1:1) to ribociclib (600 mg/day, 3-weeks-on/1-week-off) or placebo in combination with either tamoxifen (20 mg/day) or an NSAI (letrozole [2.5 mg/day] or anastrozole [1 mg/day]) + goserelin (3.6 mg every 28 days). The primary endpoint was locally assessed PFS. Secondary endpoints included overall response rate (ORR), clinical benefit rate (CBR), and safety.

**Results:** 672 patients were enrolled. Baseline patient characteristics were balanced between treatment arms. The primary analysis was conducted after 318 events had occurred; median time from randomization to data cut-off date was 19.2 months. The study met its primary objective: PFS was significantly improved in the ribociclib arm (median PFS = 23.8 months; 95% CI: 19.2–not reached) vs the placebo arm (median PFS = 13.0 months; 95% CI: 11.0–16.4), with a hazard ratio of 0.553 (95% CI: 0.441–0.694; p=9.83×10⁻⁶). Subgroup analyses demonstrated consistent PFS benefits for ribociclib vs placebo. In patients with measurable disease at baseline, ORR was 51% vs 36% (ribociclib vs placebo arm; p=3.17×10⁻⁴) and CBR was 80% vs 67% (p=3.40×10⁻⁴). The most frequent all-grade adverse events (Aes) ≥25% of patients; ribociclib vs placebo arm) were neutropenia (76% vs 8%), hot flush (34% vs 34%), nausea (32% vs 20%), leukopenia (31% vs 6%), and arthralgia (30% vs 27%). Of these, neutropenia (61% vs 4%) and leukopenia (14% vs 1%) were the only Grade 3/4 events reported in ≥5% of patients (ribociclib vs placebo arm). Febrile neutropenia (ribociclib vs placebo arm) occurred in 2% vs <1% of patients. Grade 3/4 QT prolongation (ribociclib vs placebo arm) was reported in 1% vs <1% of patients. Aes leading to permanent discontinuation of ribociclib + tamoxifen/NSAI + goserelin vs placebo + tamoxifen/NSAI + goserelin occurred in 4% vs 3% of patients.

**Conclusions:** MONALEESA-7, the first dedicated trial investigating a CDK4/6 inhibitor in pre- and peri-menopausal women with HR+, HER2– ABC, demonstrated that addition of ribociclib to first-line ET (tamoxifen/NSAI + goserelin) significantly prolonged PFS and had a manageable safety profile. The trial validates the clinical utility of ribociclib with multiple endocrine therapies, including tamoxifen, in premenopausal women with HR+, HER2– ABC.
Title: Phase Ib/II study evaluating safety and efficacy of pembrolizumab and trastuzumab in patients with trastuzumab-resistant HER2-positive metastatic breast cancer: Results from the PANACEA (IBCSG 45-13/BIG 4-13/KEYNOTE-014) study

International Breast Cancer Study Group and Breast International Group.

Body: Background Preclinical and clinical data suggest that HER2-positive (HER2\(^+\)) breast cancer (BC) will be amendable to immunotherapeutic approaches. We evaluated pembrolizumab with trastuzumab in patients (pts) with trastuzumab-resistant HER2\(^+\), PD-L1 positive (PD-L1pos), unresectable loco-regional or metastatic BC and a parallel cohort of pts with HER2\(^+\), PD-L1 negative (PD-L1neg) BC during the phase II study.

Methods: Pts with advanced BC and progression on prior trastuzumab-based therapies, ECOG 0-1, and a metastatic tumor biopsy in the last year were eligible. HER2 positivity and quantity of tumor-infiltrating lymphocytes (TILs) on H&E slide were centrally evaluated. PD-L1 score was assessed by Merck central lab. Tumor imaging was performed at weeks 12, 18, 24 and every 12 weeks, thereafter. Primary endpoints were safety of the combination (phase Ib) and objective response rate (ORR) per RECIST 1.1 (phase II). Secondary endpoints were PFS, duration of response, and OS. Phase Ib was a 3+3 dose-escalation of 2 pembrolizumab doses (2mg/kg, 10mg/kg) Q3W. In phase II, pts received pembrolizumab 200mg Q3W for 24 months or until disease progression. Clinically stable pts with progression were allowed to continue pembrolizumab until confirmation on subsequent assessment. Pts with isolated CNS progression were also allowed to continue pembrolizumab after local treatment. Planned total enrollment was 61 pts. For the phase II PD-L1pos cohort, a Simon two-stage design (N=40; proceed if \(\geq\ 2/17\) respond) was used which had 85% power to compare ORR of 7% vs. 22% (1-sided \(\alpha=0.05\)). For the PD-L1neg cohort, a single-stage design with 15 pts had >95% power to compare ORR of 1% vs. 20% (1-sided \(\alpha=0.14\)). Clinicaltrials.gov: NCT02129556.

Results: 6 pts enrolled in phase Ib between April and July 2015; no DLTs were observed. The PD-L1pos cohort enrolled 40 pts between August 2015 and September 2016. The PD-L1neg cohort enrolled May 2016 to April 2017, stopping after 12 pts due to low rate of PD-L1 negativity, maintaining >90% power to detect the target difference in ORR. PD-L1 testing labs changed in April 2016. Prior to this time, QualTek PD-L1 positive was defined as \(\geq 1\)% on tumor or TILs. Using the Dako 22C3 antibody, positive was defined as tumor PD-L1 combined positive score (CPS)\(\geq 1\)%.

146 pts were screened to enroll 58 pts. Of screened pts, median stromal TILs was 1% (mean: 4.8%, SD: 9.1%, range: 0 to 60%; n=127); 52% of pts were PD-L1pos, with higher positivity rates while using the Dako assay compared with Qualtek (65% vs. 43%, p=0.009). Median TILs of pts in the PD-L1pos cohort was 2% (mean: 8.1%, SD: 11.2%, range: 0 to 40%) and 0% (mean: 1.2%, SD: 2.2%, range: 0 to 5%) in the PD-L1neg cohort.

Of enrolled pts, median age was 51yrs (range: 28-72), 69% had visceral metastases. 29% of pts received prior pertuzumab, 72% had prior T-DM1, 40% prior lapatinib. 38% of pts were ER-positive, 62% were ER-negative. Median TILs in enrolled ER pos and ER neg pts were 1.5% and 2.0%, respectively. PD-L1 positivity rates were also not significantly different by ER status (p=0.5). Final safety data and efficacy results will be presented at the meeting.
Title: MANTA - A randomized phase II study of fulvestrant in combination with the dual mTOR inhibitor AZD2014 or everolimus or fulvestrant alone in estrogen receptor-positive advanced or metastatic breast cancer

Body: Background: Resistance to endocrine therapy remains a major clinical challenge with aberrant PI3K/ mTOR pathway activation being one of the main drivers. Randomised clinical trials have demonstrated a substantial benefit of adding everolimus to endocrine therapy. Vistusertib (AZD2014), a dual inhibitor of mTORC1 and mTORC2, has shown a broader range of activity in preclinical ER+ breast cancer models, showing superior activity to everolimus (EVE) both in hormone-sensitive and resistant models. The MANTA trial was designed to evaluate the safety and efficacy of vistusertib (VIS) in combination with fulvestrant (FULV) relative to FULV alone or FULV + EVE. In addition to a continuous (cont) daily schedule of VIS, the study also explored an intermittent (int) schedule to assess the potential of short-term, maximum target inhibition.

Methods: MANTA is an investigator-led, randomised, open-label phase II trial. Postmenopausal women with estrogen-receptor (ER)-positive breast cancer were eligible if they had disease recurrence while on or within 12 months of end of adjuvant treatment with an aromatase inhibitor (AI), or progression while on or within one month of end of AI treatment for locally advanced or metastatic breast cancer. Patients were randomly assigned (2:3:3:2) to receive either FULV (500 mg intramuscular injection on day 1, followed by 500 mg doses on days 15 and 29, and then every 28 days); FULV + daily VIS (50mg BD), FULV + intermittent VIS (2 days on, 5 days off; 125mg BD); or FULV + EVE (10mg OD). Treatment was given until disease progression (RECIST 1.1) or intolerable toxicity. Patients were stratified by disease measurability and response to prior endocrine therapy. The primary endpoint was investigator-assessed progression-free survival (PFS). Secondary objectives included objective response, clinical benefit rate, duration of response and clinical benefit, overall survival and safety.

Results: Between 04/2014 and 10/2016, a total of 333 patients were randomised at 88 sites in 9 countries. 66 patients were assigned to receive FULV; 101 to FULV+VIS (cont), 95 to FULV+VIS (int); and 64 to FULV+EVE. Median PFS was 4.6 months (95% CI 3.4–6.9) in patients assigned to FULV; 7.5 months (95% CI 5.6–9.4) in those assigned to FULV+VIS (cont); 7.6 months (95% CI 5.5–9.6) in those assigned to FULV+VIS (int); and 12.2 months (95% CI 7.5–14.3) in those assigned to FULV+EVE. No significant difference was recorded between the patients assigned to FULV+VIS (cont) and FULV (hazard ratio 0.87, 95% CI 0.62–1.23; log-rank p=0.42); FULV+VIS (int) and FULV (HR 0.78, 95% CI 0.55–1.12; log-rank p=0.16); and FULV+VIS (cont) and FULV+VIS (int) (HR 1.11, 95% CI 0.81–1.52; log-rank p=0.52). PFS was significantly longer in patients assigned to FULV+EVE compared to FULV+VIS (cont) (HR 0.64, 95% CI 0.45–0.91; log-rank p=0.01) and FULV+EVE compared to FULV (HR 0.64, 95% CI 0.43–0.94; log-rank p=0.02).

Conclusion: The trial failed to demonstrate a benefit of adding the TORC1/2 inhibitor vistusertib (AZD2014) to FULV. The combination FULV+EVE demonstrated significantly longer PFS compared to FULV+VIS or FULV.
Title: A prospective randomized multi-center phase-III trial of additional 2 versus additional 5 years of anastrozole after initial 5 years of adjuvant endocrine therapy – results from 3,484 postmenopausal women in the ABCSG-16 trial

Body: Background: While extended adjuvant therapy with aromatase inhibitors (AI) after initial tamoxifen has been demonstrated to improve disease-free-survival (DFS) of postmenopausal patients with hormone-receptor positive breast cancer, the optimal duration of extended AI is unknown. Moreover, it remains unclear whether patients after AI in the first 5 years benefit similarly from extended adjuvant AI therapy as patients after Tamoxifen.

Methods: From February 2004 to June 2010, 3484 women with postmenopausal stage I-III hormone-receptor positive early breast cancer were randomized in 71 centers in Austria to receive either 2 years or 5 years of additional Anastrozole (1 mg daily) as extended adjuvant therapy, after initial 5 years of adjuvant endocrine treatment. Eligible patients had to be recurrence-free at 60 months of initial adjuvant therapy with Tamoxifen (Tam) or AI or Tam→AI, and younger than 80 years of age. Stratification factors were tumor stage, nodal status, initial endocrine therapy, adjuvant chemotherapy, and quantitative hormone receptors. Patients were followed-up at least annually. Primary end point of ABCSG-16 was DFS, secondary end points included overall survival (OS), fractures, contralateral breast cancer, and toxicity.

Results: As of June 30, 2016, the median follow-up of the 3468 patients included in the analysis of ABCSG-16 was 105.9 months (IQR 102.2-110.3 months) after randomization (i.e. approx. 14 years after diagnosis). Median patient age was 64 years, 2507 (72%) patients had tumors smaller than 2 cm, 2301 (66%) patients were node-negative, 674 (19%) patients had high-grade tumors, 2683 (77%) patients had tumors both ER and PR positive. 2764 (80%) patients were treated with breast conserving surgery. Before randomization into ABCSG-16, 1000 (29%) patients had undergone (neo)adjuvant chemotherapy, 1774 (51%) patients had received 5 years of Tamoxifen, whereas 1688 (49%) patients had received other (AI containing) regimens in the first five years.

As of June 30, 2016, 757 DFS events have been recorded, 377 (22%) in the 2-year group, and 380 (22%) in the 5-year group. There was no significant difference in DFS (HR 0.997, 95%CI 0.86-1.15, log rank p=0.982), in OS, time to secondary carcinoma and time to contralateral breast cancer. With respect to drug adherence, 81.2% of patients in the 2-year arm were taking the study drug still at 2 years, and 80.1% at 2 years in the 5-year arm. At 5 years, 65.6% of patients in the 5-year arm were still on the assigned medication. Bone fractures were more frequent in the 5-year arm (i.e. years 3 to 5 after randomization: 6% vs 4 %, HR=1.405, 95%CI 1.03-1.91, p=0.029).

Conclusion: After 5 years of adjuvant endocrine therapy (Tamoxifen or AI or Sequence), 2 additional years of Anastrozole are sufficient for extended adjuvant therapy – a further extension to 5 additional years did not yield additional outcome benefit but added toxicity.

Support: AstraZeneca
**Title:** Invasive disease-free survival and gene expression signatures in CALGB (Alliance) 40601, a randomized phase III neoadjuvant trial of dual HER2-targeting with lapatinib added to chemotherapy plus trastuzumab

Ian E Krop¹, David Hillman², Mei-Yin Polley³, Joel Parker³, Lucas Huebner², N Lynn Henry⁴, Sara M Tolaney¹, Chau Dang⁵, Lyndsay Harris⁶, Donald A Berry⁷, Charles M Perou³, Ann Partridge¹, Eric P Winer¹ and Lisa A Carey³. ¹Dana-Farber Cancer Institute, Boston, MA; ²Alliance Statistics and Data Center, Mayo Clinic, Rochester, MN; ³University of North Carolina, Chapel Hill, NC; ⁴University of Michigan, Ann Arbor, MI; ⁵Memorial Sloan Kettering Cancer Center, New York, NY; ⁶National Cancer Institute, Bethesda, MD and ⁷MD Anderson Cancer Center, Houston, TX.

**Body:**

**Purpose**

Dual HER2 targeting increases pathologic complete response (pCR) rate to neoadjuvant therapy and improves outcomes in both early and metastatic HER2-positive disease. CALGB 40601 is a randomized phase III trial examining the impact of dual HER2 blockade consisting of trastuzumab (H) and lapatinib (L) added to paclitaxel (T) on pCR, considering tumor and microenvironment molecular features. We previously found that pCR was numerically but not significantly increased with dual therapy, and that tumor molecular subtype and evidence of immune activation significantly and independently affected pCR (Carey et al, JCO 2016). In this secondary analysis, we sought to evaluate the effects of treatment arm and gene expression-defined subgroups on invasive disease free survival (IDFS).

**Patients and Methods**

Patients (Pts) with stage II to III HER2-positive breast cancer underwent tumor biopsy followed by random assignment with equal probability paclitaxel plus trastuzumab alone (TH) or with the addition of lapatinib (THL) for 16 weeks before surgery. A paclitaxel plus lapatinib (TL) arm was closed early based on reports of futility from other trials. A secondary endpoint was IDFS, defined as the time from surgery until local or distant recurrence, new primary, or death from any cause, whichever was first. Gene expression signatures were identified by RNA sequencing.

**Results**

Between 12/2008 and 2/2012, 305 pts were enrolled. 261 pts had IDFS and gene expression information available (THL, n = 103; TH, n =101; TL, n = 57); there were no significant differences in clinical characteristics between this subset and the entire population. The median IDFS follow-up was 4.6 years with 40 IDFS events having occurred (THL, n=7; TH, n=19; TL, n=14). IDFS was significantly longer in the THL arm compared to standard TH (HR=0.34; 95% CI: 0.14-0.82; p=0.02). IDFS was also significantly longer among pCR than non-pCR pts (HR=0.40; 95% CI: 0.19-0.81; p=0.01), and did not differ by hormone receptor (HR) status, clinical stage, tumor size, race, menopausal status or age. Among gene expression signatures, only immune activation measured by an IgG signature was associated with longer IDFS (HR=0.71; 95% CI: 0.51-0.98; p=0.04); this signature was previously also associated with pCR. Multivariate analysis showed dual therapy (HR=0.35; p=0.02), pCR (HR=0.36; p=0.01), IgG (HR=0.69; p=0.05), and molecular subtype (LumA vs HER2E, HR=0.24, p=0.005) were associated with longer IDFS. A subgroup analysis by hormone receptor status revealed that among pts with HR+ disease, pts with luminal A experienced longer IDFS (HR=0.23; p=0.02) compared to those with luminal B or HER2-enriched molecular subtypes.

**Conclusion**

Dual HER2-targeting with lapatinib added to 16 weeks of TH produced significantly longer IDFS than TH alone, despite modest effects on pCR. Similar to pts with HER2-negative disease, pts with luminal A had better IDFS than those with other molecular subtypes. Immune activation as measured by RNA-based signature independently predicted both pCR and IDFS.

Body: Background
Inhibition of COX-2 has been shown to attenuate the metastatic process in pre-clinical models of human breast cancer (BC). The primary aim of this study was to assess the effect of 2 years adjuvant therapy with the COX-2 inhibitor celecoxib compared with placebo in HER2-ve primary BC patients.

Patients & Methods
Patients were randomised in a 2:1 ratio to receive celecoxib 400mg once daily or placebo for 2 years. Patients had to have completely resected BC with prior local and systemic adjuvant treatment according to local practice. Concurrent radiotherapy was permitted and hormone receptor +ve patients received endocrine therapy according to local practice. Patients with HER2+ or node negative, T1 and grade 1 disease were excluded. Median age of patients was 55 years (IQR: 49-63). 50% of patients had tumours >2cm; 42% were grade 3; 48% had node +ve disease. According to local assessment 73% were ER/PgR +ve. Primary endpoint was Disease Free Survival (DFS); defined as time from randomisation to date of first event, with events contributing to analysis defined as recurrence (distant/local), new primary BC (ipsilateral/contralateral) and death. Secondary endpoints included Overall Survival (OS), toxicity, cardiovascular mortality and incidence of second primaries. Subgroup analysis by hormone receptor status was pre-planned. Survival endpoints are analysed using Cox-proportional hazards and log-rank tests; restricted mean survival is used where proportional hazards do not hold.

Results
Between January 2007 and November 2012, 2639 patients were randomised (1763 celecoxib; 876 placebo) from 181 centres across the UK and Germany. At 13th April 2017, median follow up was 60 months (IQR: 48-72) with 428 DFS events reported. Unadjusted survival analysis results are presented below, with hazard ratio<1 favouring celecoxib:

</tbody>
</table>

The interaction between ER status and treatment was not significant; p=0.36.

In the celecoxib and placebo groups there were 17 and 8 deaths respectively in patients who had not relapsed. These were due to cardiac (n=3; 2) and other (n=14; 6) in the celecoxib and placebo groups respectively; none were GI related. In total 304 serious adverse events were observed in 265 patients (186/1763 celecoxib; 79/876 placebo). In the celecoxib and placebo groups respectively these were related to cardiac (n=12; 7), GI (n=9; 2) and other (n=193; 81). Work is ongoing to determine whether a subset of ER+ patients whose primary tumours show the characteristics of a COX-2 signature receive greater benefit from celecoxib.

**Conclusions**

There is no benefit of celecoxib in the ITT population. Further exploratory studies focussing on the ER+ subpopulation are ongoing. Celecoxib treatment is not associated with significant toxicity when compared to placebo in this population of BC patients.
Title: A randomized phase III study of adjuvant trastuzumab for a duration of 9 weeks versus 1 year, combined with adjuvant taxane-anthracycline chemotherapy, for early HER2-positive breast cancer (the SOLD study)

1Helsinki University Hospital and University of Helsinki, Helsinki, Finland; 2Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom; 3University Hospitals Leuven, Leuven, Belgium; 4Turku University Central Hospital, Turku, Finland; 5Kuopio University Hospital, Kuopio, Finland; 6Helsinki University Hospital and University of Helsinki, Helsinki, Finland; 7Päijät-Häme Central Hospital, Lahti, Finland; 8Örebro University Hospital, Örebro, Sweden; 9Helsinki University Hospital and University of Helsinki, Helsinki, Finland; 10Västerås Central Hospital, Västerås, Sweden; 11Skåne University Hospital, Lund, Sweden; 12Eskilstuna Hospital, Eskilstuna, Sweden; 13Oulu University Hospital, Oulu, Finland; 14Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom; 154Pharma, Turku, Finland; 16University Hospitals Leuven, Leuven, Belgium; 17Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom; 18Auckland City Hospital, Auckland, New Zealand; 19Tampere University Hospital, Tampere, Finland and 20Uppsala University Hospital, Uppsala, Sweden.

Body: Background: The optimal duration of trastuzumab (T), when given together with chemotherapy and after chemotherapy as adjuvant treatment in patients with HER2+ breast cancer (BC), is unknown. Whilst the international standard is 12 months of T, the benefits and harms of T treatment continued beyond the chemotherapy are unclear.

Methods: Women with histologically confirmed node-negative or node-positive HER2+ BC were eligible for the trial (NCT00593697). The primary tumor diameter was required to be >5 mm in node-negative cancer. Patients with distant metastases, inflammatory cancer, clinically significant cardiac disease, left ventricular ejection fraction (LVEF) <50%, unknown estrogen receptor (ER) status, World Health Organization performance status >1, and those who had received neoadjuvant systemic cancer therapy were excluded. Patients were randomly assigned to 2 groups prior to starting systemic cancer therapy. The initial systemic treatment was identical in the groups consisting of 3 cycles of 3-weekly docetaxel plus T followed by 3 cycles of fluorouracil, epirubicin, and cyclophosphamide (FE75C). Thereafter, no further T or chemotherapy was administered in Arm A, whereas in Arm B single-agent T was administered 3-weekly for 14 cycles to complete 1 year of T treatment. The docetaxel dose was either 80 mg/m2 or 100 mg/m2 (prespecified for each center). Radiation therapy and endocrine therapy (for patients with ER+ cancer) were given according to the institutional practice; the minimum scheduled duration of endocrine therapy was 5 years. The LVEF was measured pretreatment, and on study weeks 18, 31, 43, and 61 and month 36. The primary endpoint was disease-free survival (DFS) compared between the groups using a Cox model and the non-inferiority approach.

Results: A total of 2,176 patients were entered into the study from 63 centers in 7 countries from Jan. 3, 2008 to Dec.16, 2014. The median follow-up time was 5.2 years at data collection closure (Dec. 31, 2016). The efficacy and safety data will be presented at the meeting.
Title: Survival analysis of the prospectively randomized phase III GeparSepto trial comparing neoadjuvant chemotherapy with weekly nab-paclitaxel with solvent-based paclitaxel followed by anthracycline/cyclophosphamide for patients with early breast cancer – GBG69

Body: Introduction
The GeparSepto study showed that the substitution of paclitaxel (P) with nab-paclitaxel (nP) followed by epirubicin/cyclophosphamide (EC) as neoadjuvant chemotherapy increased the rate of pathological complete response (pCR) from 29% to 38% (p<0.001). A pronounced improvement of pCR from 26% to 48% (OR: p<0.001) was achieved in patients with triple-negative BC (TNBC) (Untch et al. Lancet Oncology 2016). It has not yet been shown whether these effects on pCR will be translated into a survival benefit. We here report the survival analysis of the GeparSepto trial.

Patients and Methods
In the GeparSepto trial (NCT01583426) patients were randomized in a 1:1 ratio to receive either nP 125mg/m² or P 80 mg/m² q1w for 12 weeks followed by 4 cycles of conventionally dosed EC (E: 90mg/m²; C: 600 mg/m²) q3w (Furlanetto et al. Annals Oncol 2016). Patients with HER2+ tumors received trastuzumab 6(8)mg/kg q3w and pertuzumab 420(840)mg q3w concomitantly to all chemotherapy cycles (Loibl et al. Annals Oncol 2016). Patients with untreated, histologically confirmed uni- or bilateral, cT2-cT4d breast carcinoma, and no clinically relevant cardiovascular and other co-morbidities were included. Primary objective was pCR rate (ypT0 ypN0). Secondary objectives were invasive disease-free survival (IDFS), and overall survival (OS) overall and according to stratified subpopulations, amongst other time to event endpoints, quality of life focusing on peripheral sensory neuropathy (PNP), treatment of PNP, and cardiac toxicity, detection of circulating tumor (ct) DNA at the time of surgery and during follow up and correlation with pCR and early relapses. The IDFS analysis is planned after 248 events have occurred. The log-rank test will have 80% power to detect an improvement of the 5 year IDFS from 75% to 81.8% (HR=0.70) at a 2-sided significance level of \(\alpha=0.05\).

Results
In 69 German centers, 1229 patients were randomly assigned (07/2012 – 12/2013) to receive either nP (606) or P (600). nP was given for the majority of cycles at a dose of 150mg/m² to 179 patients and at a dose of 125mg/m² to 426 patients. Follow-up is still ongoing. The expected number of events will be awaited for October 2017.

Conclusion
Neoadjuvant GeparSepto study demonstrated a significantly higher pCR rate when patients received nP instead of P as part of an anthracycline/taxane based sequential chemotherapy. The expected long-term results will help to assess the overall benefit of nP in BC and the surrogate value of pCR for survival endpoints.
Title: Long-term follow-up of CALGB 40502/NCCTG N063H (Alliance): A randomized phase III trial of weekly paclitaxel (P) compared to weekly nanoparticle albumin bound nab-Paclitaxel (NP) or ixabepilone (Ix) +/- bevacizumab as first-line therapy for locally recurrent or metastatic breast cancer (MBC)

Body: Background: CALGB 40502/NCCTG N063H (Alliance) compared weekly NP or Ix to P; most patients received bevacizumab. Ix was inferior to P, and NP was not superior with a trend toward inferiority. Toxicity was increased in the experimental arms compared to P (Rugo et al, JCO 2015). We report long-term follow-up (FU) of this trial with an unplanned subset analysis in hormone receptor positive (HR+) and triple negative (TNBC) breast cancer.

Methods: Patients were randomized 1:1:1 to receive P (90 mg/m²), Ix (16 mg/m²) or NP (150 mg/m²) on a 3 week (wk) on, 1 wk off schedule, stratified by prior adjuvant taxane use and hormone receptor status. B was initially given to all patients, but became optional in 3/2011 and was added to stratification. The primary endpoint was progression-free survival (PFS); secondary endpoints included safety and overall survival (OS). With a target N=900 patients, the study was powered to detect a hazard ratio of 1.36 (median PFS 10 vs 13.6 months). Eligibility included no prior chemotherapy for MBC, >12 mo from adjuvant P and measurable disease.

Results: 799 patients were randomized between 11/08 and 11/11 (283 to P, 271 to NP, 245 to Ix); 98% received bevacizumab. 68% (546) had HR+ disease, 25% (201) had TNBC. Median FU is 5 years. Median PFS is unchanged at 10.8, 9.2 and 7.4 mo for P, NP and Ix with hazard ratios (95% CIs) of 1.13 (0.94-1.34) and 1.44 (1.2-1.72) for NP and Ix to P, respectively. Median OS was 27.1, 24.2 and 23.6 months for P, NP and Ix with hazard ratios of 1.28 (0.9-1.82) and 1.35 (1.07-1.71) for NP and Ix to P, respectively. The effects of NP vs P on PFS and OS were significantly modified by subtype (interaction p=0.0018 and 0.0073), whereas Ix vs P was unchanged (interaction p's > 0.9, Table). More patients discontinued treatment due to adverse events in the experimental arms (14 vs 27 vs 23% for P, NP and Ix).

</table>

Interaction tests: 1. p=0.0018; 2. p=0.0073; 3. p=0.96; 4. p=0.92 mo: months; HR: hazard ratio

Conclusion: In patients with chemotherapy-naive MBC, Ix was inferior to P for PFS, and P was better tolerated than either NP or Ix. In this retrospective subset analysis, Ix and NP were inferior to P in HR+ disease, with a suggestion of improved PFS and OS with NP in patients with TNBC. Further investigation is required to explain and validate the subtype specificity seen in this exploratory analysis.

Title: Genome-wide copy number analysis of chemotherapy-resistant metastatic triple-negative breast cancer from cell-free DNA

Daniel G Stover¹, Heather A Parsons², Gavin Ha³, Sam Freeman³, Bill Barry², Hao Guo², Atish Choudhury², Greg Gydush³, Sarah Reed³, Justin Rhoades³, Denisse Rotem³, Melissa E Hughes², Deborah A Dillon², Ann H Partridge², Nikhil Wagle²,³, Ian E Krop², Gad Getz³, Todd A Golub², J Christopher Love³, Eric P Winer², Sara M Tolaney³, Nancy U Lin² and Viktor A Adalsteinsson³. ¹The Ohio State University Comprehensive Cancer Center, Columbus, OH; ²Dana-Farber Cancer Institute, Boston, MA; ³Broad Institute of Harvard and MIT, Cambridge, MA and ⁴Massachusetts Institute of Technology, Cambridge, MA.

Body: Introduction:
Triple-negative breast cancer (TNBC) is a poor prognosis breast cancer subset characterized by relatively few mutations but extensive copy number alterations (CNAs). Cell-free DNA (cfDNA) offers the potential to overcome infrequent tumor biopsies in metastatic TNBC (mTNBC) and interrogate the genomics of chemotherapy resistance.

Methods:
506 archival or fresh plasma samples were identified from 164 patients with mTNBC who had previously received chemotherapy. We performed low coverage whole genome sequencing to determine genome-wide copy number and estimate 'tumor fraction' of cfDNA (TFx) using our recently-developed approach, ichorCNA. In patient samples with TFx >10%, we identified regions that were significantly gained or lost using GISTIC2.0. We compared CNAs of 20 paired primary-metastatic samples and also mTNBCs from cfDNA versus primary TNBCs from TCGA and METABRIC.

Results:
We successfully obtained high quality, low coverage whole genome sequencing data for 478 (94.5%) plasma samples from 158 patients, with 1 to 14 samples per patient. TFx and copy number profiles were highly concordant with paired metastatic biopsy (n=10, range 0-7 days from biopsy to blood draw) with sensitivity of 0.86 and specificity of 0.90 and reproducible in independently-processed blood draws (TFx intraclass correlation coefficient 0.984). Median overall survival from time of first blood draw was 8 months, and TFx was highly correlated independent of primary stage, primary receptor status, age at primary diagnosis, BRCA status, and metastatic line of therapy: adjusted hazard ratio between 4th and 1st quartiles = 2.14 (95% CI 1.40-3.28; p=0.00049). 101/158 patients (63.9%) had at least one sample with TFx >10%, our threshold for high confidence CNA calls. Copy number profiles and percent genome altered were remarkably similar between mTNBCs and primary TNBCs in TCGA and METABRIC (n=433), suggesting that large-scale chromosomal events are infrequent in TNBC metastatic progression. We identified chromosomal gains that demonstrated significant enrichment in mTNBCs relative to paired primary TNBCs (n=20) and also TCGA/METABRIC, including driver genes (NOTCH2, AKT2, AKT3) and putative antibody-drug conjugate targets. Finally, we identify a novel association of gains of 18q11 and/or 19p13 with poor metastatic prognosis, independent of clinicopathologic factors and TFx.

Conclusions:
Here, we present the first large-scale genomic characterization of metastatic TNBC to our knowledge, derived exclusively from cfDNA. 'Tumor fraction' of cfDNA is an independent prognostic marker in mTNBC. Primary and metastatic TNBC have remarkably similar copy number profiles yet we identify alterations enriched and prognostic in mTNBC. Collectively, these data have potential implications in the understanding of metastasis, therapeutic resistance, and novel therapeutic targets.

**Body:** Background: Pathological complete response (pCR) is accepted by FDA as a surrogate endpoint for accelerated approval of targeted agents in combination with chemotherapy based on better long-term outcomes compared to residual disease (Cortazar 2014).

**Methods:** The multi-center, adaptively-randomized I-SPY2 platform trial uses pCR as the primary endpoint to identify investigational agents that will improve outcomes in women with stage 2/3 breast cancer with high risk of early recurrence, across all signatures, based on hormone receptor (HR), HER2, and 70-gene (MammaPrint) status. For patients with HR+ HER2- tumors, only 70-gene (MammaPrint) high-risk patients are enrolled. To date, 1200+ patients have been randomized to one of 14 arms: control (paclitaxel followed by AC); veliparib/carboplatin; neratinib; MK2206; trebananib; trastuzumab/pertuzumab; ado-trastuzumab emtansine/pertuzumab; pembrolizumabx4; ganitumab/metformin; ganetespib; PLX-3397. 7 agents graduated in the first 522 pts (median follow-up:2.5 years). 180 pts achieved pCR (36%) while 338 did not (RCB=1-3). There were 82 EFS and 65 DRFS events. Over the entire group (including all arms), pCR was highly associated with 3-year EFS (p<0.001 for both). Pts achieving pCR had a 3% recurrence risk (RR) at 3 years; those with non-pCR had 24% RR over this time period. For distant recurrence, the 3-year RR with pCR was 2%, compared to 20% in pts with non-pCR. As expected, pCR rates varied by breast cancer subtype (HR+/HER2: 18% (35/196), HR+/HER2+: 40% (33/82), HR-/HER2+:68% (34/50), HR-/HER2-:41% (76/188)). The relationship between pCR and EFS was significant and clinically impactful within each subtype.

**Conclusions:** The first long-term efficacy results from the I-SPY2 TRIAL demonstrate that achieving pCR is a very strong surrogate endpoint for improved EFS and DDFS in a high-risk population, across all treatment arms, regardless of subtype. I-SPY2 shows substantially lower estimated EFS hazards for patients achieving pCR, compared to the 5 yr EFS hazard ratio for pCR vs not in Cortazar (hazard ratio 0.49), demonstrating important differences between a metaanalysis compared to a platform trial with uniform high-risk eligibility, standardized pathology assessment, and multiple targeted therapies. Our data support the use of pCR as a primary endpoint for accelerated approval of new drugs if EFS is evaluated in the same population. Based on these findings, the I-SPY2 TRIAL will test whether therapy can be deescalated or escalated for individual patients with the goal of achieving pCR for all.
Title: Pooled analysis of five randomized trials investigating temporary ovarian suppression with gonadotropin-releasing hormone analogs during chemotherapy as a strategy to preserve ovarian function and fertility in premenopausal early breast cancer patients

1 Institut Jules Bordet, Brussels, Belgium; 2 Cleveland Clinic Foundation, Cleveland, OH; 3 Imperial College, London, United Kingdom; 4 GBG - German Breast Group, Neu-Isenburg, Germany; 5 UCSF - University of California, San Francisco, CA; 6 IRCCS AOU San Martino-IST, Genova, Italy; 7 AOU Careggi and Istituto Toscano Tumori, Florence, Italy; 8 SWOG - Fred Hutchinson Cancer Research Center, Seattle, WA; 9 University of Edinburgh, Edinburgh, United Kingdom; 10 Moffitt Cancer Center, Tampa, FL; 11 Loyola University Medical Center, Cardinal Bernardin Cancer Center, Maywood, IL; 12 Tayside Cancer Centre, Ninewells Hospital, Dundee, United Kingdom; 13 University Hospital Rostock, Rostock, Germany; 14 Nexgen Oncology, Dallas, TX; 15 Singleton Hospital, Swansea, United Kingdom and 16 Dana-Farber Cancer Institute, Boston, MA.

Body: Background

The role of temporary ovarian suppression with gonadotropin-releasing hormone analogs (GnRHa) during chemotherapy as a strategy to preserve ovarian function and fertility in premenopausal early breast cancer patients remains highly controversial. This option is considered experimental by the ASCO and ESMO guidelines on fertility preservation in cancer patients. The present pooled analysis aimed at elucidating the efficacy and safety of temporary ovarian suppression with GnRHa during chemotherapy as a strategy to preserve ovarian function and fertility in premenopausal early breast cancer patients.

Patients and methods

This study included individual patient data from 5 trials (PROMISE-GIM6, POEMS/SWOG S0230, Anglo Celtic Group OPTION, GBG-37 ZORO, Moffitt-led trial) in which premenopausal women with early breast cancer were randomized to receive (neo)adjuvant chemotherapy alone or with concurrent administration of GnRHa. Efficacy endpoints were premature ovarian insufficiency (POI, according to the definition used as primary endpoint in the included trials), 1- and 2-year amenorrhea rates and post-treatment pregnancy rate. Safety endpoints were disease-free survival (DFS) and overall survival (OS). Odds ratio (OR), incidence rate ratio (IRR) and hazard ratio (HR) with 95% confidence intervals (CI) were calculated for the effect of adding GnRHa to chemotherapy alone. As each study represents a cluster, statistical analysis has been performed using a random effects model.

The study is registered with the PROSPERO registration number CRD42014015638.

Results

A total of 873 patients from 5 randomized trials were included. Median age was 38 years (interquartile range: 34-42 years). POI rate was 14.1% in the GnRHa group and 30.9% in the control group (adjusted OR 0.38; 95% CI 0.26-0.57; p < 0.001). The incidence of 1-year amenorrhea was 36.8% in the GnRHa group and 40.4% in the control group (adjusted OR 0.92; 95% CI 0.66-1.28; p = 0.623). The incidence of 2-year amenorrhea was 18.2% in the GnRHa group and 30.0% in the control group (adjusted OR 0.51; 95% CI 0.31-0.85; p = 0.009). A total of 37 patients had at least one post-treatment pregnancy in the GnRHa group and 20 in the control group (IRR 1.83; 95% CI 1.06-3.15; p = 0.030).

There were no significant differences in DFS (adjusted HR 1.01; 95% CI 0.72-1.42; p = 0.999) or OS (adjusted HR 0.67; 95% CI 0.42-1.06; p = 0.083) between the GnRHa and control groups.

Subgroup analyses of both efficacy and safety endpoints according to age of the patients, hormone receptor status, type and duration of chemotherapy will be presented at the conference.

Conclusions

This study provides level 1A of evidence for the efficacy and safety of temporary ovarian suppression with GnRHa during chemotherapy in premenopausal early breast cancer patients. Given the findings of this pooled analysis, temporary ovarian suppression with GnRHa during chemotherapy should be considered as a new standard option to reduce the likelihood of chemotherapy-induced POF and possibly improve future fertility in premenopausal early breast cancer patients.
Title: Randomized comparison of adjuvant aromatase inhibitor exemestane (E) plus ovarian function suppression (OFS) vs tamoxifen (T) plus OFS in premenopausal women with hormone receptor positive (HR+) early breast cancer (BC): Update of the combined TEXT and SOFT trials

Body: Background: The combined results of TEXT and SOFT, after 5.7 years median follow-up, found adjuvant E+OFS significantly improved disease-free survival (DFS) vs T+OFS in premenopausal women with HR+ BC (Pagani et al, NEJM 2014). Follow-up was immature for overall survival (OS). We report a planned update with visit cut-off of 31Dec16 after 9 years median follow-up.

Methods: TEXT and SOFT enrolled premenopausal women with HR+ early BC from Nov 2003 to Apr 2011 (2660 TEXT, 3047 SOFT in the intention-to-treat populations). TEXT randomized women within 12wk of surgery to 5 yrs E+OFS vs T+OFS; chemotherapy (CT) was optional and concurrent with OFS. SOFT randomized women to 5 yrs E+OFS vs T+OFS vs T alone, within 12wk of surgery if no CT planned, or within 8mo of completing (neo)adjuvant CT after premenopausal status was (re-)established. OFS was by choice of 5yr GnRH agonist triptorelin, oophorectomy or ovarian irradiation. Both trials were stratified by CT use. The primary endpoint was DFS: randomization until invasive local, regional, distant recurrence or contralateral breast; invasive second malignancy; death. Secondary endpoints included invasive breast cancer-free interval (BCFI), distant recurrence-free interval (DRFI) and OS. Stratified Cox models estimated hazard ratios; Kaplan-Meier method estimated 8yr endpoint rates. NCT00066703/NCT00066690.

Results: DFS for patients assigned E+OFS (n=2346) continued to be significantly improved over T+OFS (n=2344): 8yr DFS was 86.8% vs. 82.8%. The 8yr BCFI was improved by 4.1% (89.3% vs 85.2%) and 8yr DRFI by 2.1% (91.8% vs 89.7%). There was no difference in OS in patients assigned E+OFS vs T+OFS: 93.4% vs 93.3% OS at 8yrs. For 1996 women without CT there have been 45 deaths, with 98% OS at 8yrs with both treatments.

Overall toxicity was not significantly worse with E+OFS than with T+OFS (32% vs 31% grade 3-4 targeted AEs). Hot flashes, musculoskeletal symptoms and hypertension were the most frequent targeted grade 3-4 AEs. Overall, 15% of patients stopped all protocol-assigned treatment early. Patients assigned E+OFS had increased risk of assigned oral endocrine therapy cessation (25% vs 19% for patients assigned T+OFS by 4yrs) but not of triptorelin cessation (18% vs 19% by 4yrs, respectively).

Conclusions: After 9 yrs median follow-up, adjuvant E+OFS, as compared with T+OFS, shows a sustained reduction of the risk of recurrence but did not improve overall survival. As in postmenopausal women, oncologists need to consider potential absolute benefits and properly select patients at sufficient risk for recurrence for whom E+OFS seems indicated. Follow-up continues, which will further clarify the effect of E+OFS for safety, late recurrence and overall survival.
Title: Randomized comparison of adjuvant tamoxifen (T) plus ovarian function suppression (OFS) versus tamoxifen in premenopausal women with hormone receptor-positive (HR+) early breast cancer (BC): Update of the SOFT trial

Body: Background: The primary results of SOFT at 5.6 years median follow-up found adding OFS to T did not provide a significant benefit in the overall study population of premenopausal women with HR+ BC (Francis et al, NEJM 2015). For those women at sufficient risk for recurrence to warrant adjuvant chemotherapy (CT) and who remained premenopausal, the addition of OFS improved disease outcomes. Follow-up was immature for overall survival (OS). We report a planned update with visit cut-off of 31Dec16 after 8 yrs median follow-up.

Methods: SOFT randomized premenopausal women with HR+ BC from Nov 2003 to Jan 2011 to 5 yrs of T vs T+OFS vs Exemestane(E)+OFS. OFS was by choice of GnRH agonist triptorelin, oophorectomy or ovarian irradiation. SOFT was stratified by the use of prior CT; 47% received no CT and 53% remained premenopausal after prior CT, determined by premenopausal estradiol level within 8 months of CT completion. The primary endpoint was invasive disease-free survival (DFS; randomization until invasive local, regional, distant recurrence or contralateral breast; invasive second malignancy; death). Secondary endpoints included invasive breast cancer-free interval (BCFI), distant recurrence-free interval (DRFI) and OS. NCT00066690.

Results: DFS for patients assigned T+OFS (n=1015) was significantly improved over T (n=1018; HR=0.76 [95%CI 0.62-0.93]) and 8yr DFS was 83.2% vs 78.9%, respectively; BCFI and DRFI results were supportive (see Table). Hazard ratios for these 3 endpoints showed no heterogeneity by use of prior CT. For patients with prior CT, 8yr DFS was 76.7% with T+OFS vs 71.4% with T (Δ=5.3%); in those without CT, 8yr DFS was 90.6% vs 87.4% (Δ=3.2%). E+OFS (n=1014) improved outcomes relative to T (Table); 8yr DFS for E+OFS was 85.9% (80.4% with use of prior CT and 92.5% for those without CT). OS was improved with T+OFS vs T (8yr OS 93.3% vs 91.5%). 8yr OS was 92.1% with E+OFS. 201/225 deaths occurred in women with prior CT. For women without CT there have been 10, 5 and 9 deaths in the T+OFS, T and E+OFS groups (total n=1419), respectively, only half of these deaths after breast cancer event.

Overall toxicity was worse with T+ OFS than with T, including 32% vs 25% grade 3+ targeted AEs. Early cessation of tamoxifen occurred for 19% assigned T+OFS and 22% of women assigned T; the cumulative incidence of early cessation of triptorelin on the T+OFS arm was 23% by 4yrs. Early cessation of exemestane occurred for 28% and of triptorelin for 21% by 4yrs on the E+OFS arm.

Conclusions: With additional follow-up to a median of 8yrs, SOFT further supports the value of OFS for some premenopausal women. Follow-up continues, which will further clarify the safety and the benefit of OFS for late recurrence and overall survival. Oncologists appear to be able to select a low risk group (no chemotherapy) for whom treatment escalation is unlikely to improve survival.
Title: Randomized blinded sham- and waitlist-controlled trial of acupuncture for joint symptoms related to aromatase inhibitors in women with early stage breast cancer (S1200)

Dawn L Hershman¹, Joseph M Unger², Heather Greenlee³, Jillian Capodice³, Danika L Lew², Alice T Kengla⁴, Marianne K Melnik⁵, Carla W Jorgensen⁶, William H Kreisle⁷, Lori M Minasian⁸, Michael J Fisch⁹, Lynn Henry¹⁰ and Katherine D Crew¹. ¹Columbia University Medical Center, New York, NY; ²Fred Hutchinson Cancer Research Center, Seattle, WA; ³Mount Sinai Hospital, New York, NY; ⁴Kaiser Permanente Medical Center, Walnut Creek, CA; ⁵Spectrum Health Medical Group, Grand Rapids, MI; ⁶NCORP of the Carolinas (Greenville Health System), Greenville, SC; ⁷St. Luke’s Mountain States Tumor Institute, Boise, ID; ⁸National Cancer Institute, Bethesda, MD; ⁹AIM Specialty Health, Chicago, IL and ¹⁰University of Utah Huntsman Cancer Institute, Salt Lake City, UT.

Body: Background: Musculoskeletal symptoms are the most common side effect of aromatase inhibitors (AIs) and can result in decreased quality of life and discontinuation of therapy. Pilot data from two prior single institution studies showed that acupuncture decreased AI-induced joint symptoms in breast cancer (BC) patients.

Methods: We conducted a SWOG multicenter randomized controlled trial among postmenopausal women with early stage BC. Patients taking an AI for ≥30 days and having a worst pain score of ≥3 out of 10 using the Brief Pain Inventory (BPI-WP) were eligible. Subjects were randomized at a 2:1:1 ratio to true acupuncture (TA) vs. sham acupuncture (SA) vs. waitlist control (WC).

The TA protocol used a standardized protocol of body and auricular acupoints tailored to joint symptoms. The similarly standardized SA protocol utilized superficial needling of non-acupoints. Both the TA and SA protocols consisted of a 12 week intervention, with 12 sessions administered over 6 weeks, followed by 1 session per week for 6 additional weeks. The primary endpoint was change in the BPI-WP (worst pain) score at 6 weeks. Secondary outcomes included other BPI scores, the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) for the hips and knees, the Modified Score for the Assessment of Chronic Rheumatoid Affections of the Hands (M-SACRAH), and functional testing with grip strength and “Timed Get Up and Go” (TGUG). The design specified alpha=.025 two-sided tests to account for two independent comparisons (TA vs. SA and TA vs. WC).

Results: Among 226 patients registered, 110 were randomized to TA, 59 to SA and 57 to WC. Baseline characteristics were similar between the groups. In a linear regression adjusting for the baseline score and stratification factors, 6-week mean BPI-WP scores were 0.92 points lower (correlating with less pain) in the TA compared to SA arm (95% CI: 0.20-1.65, p=.01), and were 0.96 points lower in the TA compared to WC arm (95% CI: 0.24-1.67, p=.01). The proportion of patients experiencing a clinically meaningful (>2) reduction (i.e. improvement) in BPI-WP was 58% for TA compared to 33% on SA and 31% on WC. Patients randomized to TA had improved symptoms compared to SA at week 6 according to all other BPI pain measures (average pain, p=.04; pain interference, p=.02; pain severity, p=.05; worst stiffness, p=.02). Results were similar compared to WC. Patients randomized to TA compared to SA or WC had statistically significant or marginally statistically significant improvements in BPI pain measures at week 12. Patients randomized to TA had generally improved symptoms compared to SA at week 6 according to all other BPI pain measures (average pain, p=.04; pain interference, p=.02; pain severity, p=.05; worst stiffness, p=.02). Results were similar compared to WC. Patients randomized to TA compared to SA or WC had statistically significant or marginally statistically significant improvements in BPI pain measures at week 12. Patients randomized to TA had generally improved symptoms compared to SA at week 6 and at week 12 according to the M-SACRAH and WOMAC measures (p<0.05). With regard to adverse events, more patients on the TA arm experienced Grade 1 bruising compared to SA (47% vs. 25%, p=.01). No other differences by arm for selected adverse events were observed.

Conclusions: This study was the first large multicenter trial to investigate the effect of acupuncture in treating AI-induced joint symptoms in BC patients. According to multiple measures, TA generated better outcomes than either SA or WC with minimal toxicity.
Cancer risks and response to targeted therapy associated with BRCA2 variants of uncertain significance

Fergus J Couch¹, Hermela Shimelis¹, Steven N Hart¹, Raymond M Moore¹, Abigail Thomas¹, Gary B Lipton² and Edwin Iversen².
¹Mayo Clinic, Rochester, MN and ²Duke University, Durham, NC.

Background: Germline genetic testing of individuals with a diagnosis of triple negative breast cancer, young age at diagnosis, or a family history of breast and/or ovarian cancer has led to the identification of many unique BRCA2 missense variants of uncertain significance (VUS). VUS in BRCA2 are predominantly missense mutations that have unclear relevance to breast, ovarian, and other cancers. Thus, patients found to have a germline BRCA2 VUS do not know if the variant is associated with high risks of these cancers similar to truncating mutations, intermediate risks more similar to CHEK2 mutations, or low risks of no clinical significance. Furthermore, it is unclear if germline BRCA2 VUS, or somatic VUS identified by tumor sequencing, are associated with hypersensitivity to selected DNA damaging and cross-linking agents.

Methods: We have used a homology directed repair (HDR) cell-based assay to characterize missense variants in the DNA binding domain (DBD) of BRCA2. The method has been validated using known pathogenic and known non-pathogenic BRCA2 missense variants and has 100% sensitivity (95% confidence interval (CI): 75.3%–100%) and 100% specificity (95% CI: 81.5%–100%) for pathogenic BRCA2 variants. A classifier of variant pathogenicity based on the mean and variances of the HDR results of the known pathogenic and neutral variants has been established. We have also developed PARP inhibitor and cisplatin drug response assays for BRCA2 missense variants.

Results: Assessment of 207 BRCA2 missense variants, identified in public databases such as BRCA exchange and ClinVar, by the HDR assay identified 71 deleterious variants with >99% probability of pathogenicity, 116 neutral variants with >99% probability of neutrality, and 20 with hypomorphic activity and potentially intermediate risk. A combination of the functional data and sequence-based predictors of protein activity in a Bayesian prediction model resulted in classification of the deleterious variants as pathogenic cancer predisposing variants and the neutral variants as non-pathogenic with low clinical significance. The influence of the deleterious/pathogenic variants on PARPi and cisplatin response was also assessed.

Conclusion: The HDR assay is effective for characterization of BRCA2 VUS. The combination of functional data and in silico prediction models provides a robust tool for clinical annotation of BRCA2 VUS. HDR function of BRCA2 missense variants is strongly correlated with response to targeted therapy.
Title: Results from a randomized placebo-controlled phase 2 trial evaluating exemestane ± enzalutamide in patients with hormone receptor–positive breast cancer

Body: Background: The androgen receptor (AR) is expressed in >75% of hormone receptor (HR)+ tumors. AR signaling has been associated with resistance to endocrine therapy (ET). Aromatase inhibitors (AIs) divert estrogen precursors to androgens; in preclinical models enzalutamide (ENZA) blocked both estrogen- and androgen-mediated growth of HR+ cells. In a phase 1 study of ET+ENZA in breast cancer, doubling the dose of exemestane (EXE) to 50 mg was necessary to restore exposure observed with 25 mg.¹

Methods: This placebo (PBO)–controlled phase 2 trial randomized patients (pts) with HR+/HER2-normal advanced/metastatic breast cancer (MBC) to either 25 mg EXE+PBO or 50 mg EXE+160 mg ENZA daily (NCT02007512). Two parallel cohorts enrolled pts who had no prior ET (C1) or who had received 1 prior ET for MBC (C2). Randomization was stratified on resistance to prior ET and prior exposure to AI. Tissue samples for biomarker development were mandatory. Brain metastases or a history of seizure was exclusionary. One prior chemotherapy regimen for MBC was permitted. Response was assessed every 8 weeks for 48 weeks, then every 12 weeks. Crossover to ENZA+EXE was allowed at disease progression. A gene signature–based biomarker (Bmkr) indicating AR signaling predictive of response to ENZA was developed using a training set of RNAseq data from 2/3 of randomized pts and validated using a test set of data from the remaining 1/3 of pts. Progression-free survival (PFS) according to RECIST v1.1 was the primary endpoint in the intent-to-treat (ITT) population and in the Bmkr+ subgroup of each cohort. Secondary endpoints included clinical benefit rate at 24 weeks (CBR24), best overall response, and safety.

Results: A total of 247 pts were randomized (C1, n=127; C2, n=120). In C1, 50 pts (39.4%) were Bmkr+; in C2, 53 pts (27.8%) were Bmkr+. Statistically significant improvements in median PFS and CBR24 were observed only in the Bmkr+ population with no prior ET (Table). The most common adverse events (AEs) reported in the ENZA+EXE arms were nausea (39%) in C1 and fatigue (37%) in C2. In C1, 9 pts (15%) and 10 pts (16%) discontinued the study due to AEs in the ENZA+EXE and PBO+EXE arms, respectively. In C2, 11 pts (18%) and 5 pts (8%) discontinued due to AEs in the ENZA+EXE and PBO+EXE arms, respectively.

Conclusions: In the first reported randomized trial of ENZA in HR+ MBC, ENZA+EXE was well tolerated with no new safety signals. The study met its primary endpoint in pts with Bmkr+ MBC with no prior ET.

Title: Appropriate margins for breast conserving surgery in patients with early stage breast cancer: A meta-analysis

Chirag Shah¹, Vivek Verma², Harlan Sayles², Abram Recht³ and Frank Vicini⁴. ¹Cleveland Clinic, Cleveland, OH; ²University of Nebraska Medical Center, Omaha, NE; ³Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA and ⁴21st Century Oncology/Michigan Healthcare Professionals, Farmington Hills, MI.

Body: Background: Significant controversy exists regarding the appropriate minimum tumor-free margin width for patients undergoing breast-conserving therapy. The SSO-ASTRO guidelines recommend 'no ink on tumor' based upon a meta-analysis of 33 studies, but this had significant limitations. In order to address these concerns, a meta-analysis of all available data (using 31 of the initial studies) was performed but employing stricter criteria for acceptability and quality of evaluable studies.

Methods: Study eligibility criteria were: (1) minimum follow-up of 50 months; (2) explicit pathologic criteria for defining margins; and (3) consistent endpoints associated with local recurrence. The compiled studies were analyzed using generalized linear mixed models for the outcome of local recurrence, with random effects for study and fixed effects for various patient and study characteristics.

Results: The analysis incorporated 38 studies, which included 55,302 patients treated from 1968-2010. Two of the previous studies were excluded (one because of short follow-up, and the second because it was updated) with seven new studies added from the previous meta-analysis including an update of a previously included analysis. Median follow-up was 7.2 years. The median age of the cohort was 55 years, 74% of patients had T1 tumors, and 72% were node negative. The crude rate of local recurrence for patients with positive margins was 10.3%, compared to 3.8% for those with negative margins defined as no tumor on ink or wider (p<0.001). The crude rates of local recurrence decreased as the margin distance increased: 7.2% for patients with margins >0-<2 mm, 3.6% for margins of 2-5 mm (3.6%), and 3.2% for margins wider than 5 mm (p<0.001 for each). Use of endocrine therapy and increasing median study year were associated with a reduction in local recurrence in univariate models but not in multivariable analyses.

Conclusions: The current meta-analysis indicates that having margin widths 2 mm or greater is associated with a lower risk of ipsilateral breast failure than narrower but uninvolved margins. It therefore fails to confirm that 'no-tumor on ink' is optimal. Further analyses are needed to clarify this issue, particularly to identify the critical minimum tumor-free margin for different patient subgroups.

Title: Axillary dissection vs. no axillary dissection in patients with cT1-T2cN0M0 breast cancer and only micrometastases in the sentinel node(s): Ten-year results of the IBCSG 23-01 trial

Viviana Galimberti1, Bernard F Cole1, Giuseppe Viale1, Paolo Veronesi1, Elisa Vicini1, Mattia Intra1, Giovanni Mazzarol1, Samuele Massarut1, Janez Zgajnar1, Mario Taffurelli1, David Littlejohn1, Tina Egli1, Carlo Tondini1, Angelo Di Leo1, Marco Colleoni1, Meredith M Regan1, Alan S Coates1, Richard D Gelber1 and Aron Goldhirsch1. 1International Breast Cancer Study Group Trial 23-01 Investigators.

Body: BACKGROUND: The phase III IBCSG 23-01 multicenter, randomized, non-inferiority trial compared disease-free survival (DFS) in breast cancer patients with one or more micrometastatic (≤2 mm) sentinel nodes (SNs) randomized to either axillary dissection (AD) or no axillary dissection (no-AD). Results after 5 years showed no difference in DFS between the arms. Here we report results after a median follow-up of 9.8 years.

METHODS: Eligible patients had cancers of pathological diameter ≤5 cm and one or more micrometastatic (≤2 mm) foci, including isolated tumor cells, in the SNs. Patients with axillary macrometastases were excluded. Breast surgery was conservative or mastectomy. Eligible patients were randomized to AD vs. no-AD. The primary endpoint was disease-free survival (DFS); secondary endpoints were overall survival (OS), site of recurrence (particularly axillary recurrence), and surgical complications of AD. DFS and OS were estimated using the product-limit method, and the log-rank test was used to compare the treatment groups. Patients without a DFS or OS event were censored at the date of last follow-up. Non-inferiority margin for no-AD vs. AD was defined as a DFS hazard ratio (HR, no-AD relative to AD) of <1.25, and was assessed using a z-test applied to the log HR. Active follow-up of patients was terminated in February 2017.

RESULTS: From 2001 to 2010, 934 patients were randomized at 27 centers; 931 were evaluable (467 in the no-AD group and 464 in the AD group). Median follow-up was 9.8 (IQR: 7.8–12.7) years. The number and types of first DFS events according to treatment group are shown in the Table.

</table>

10-year DFS was 75% (95% confidence interval [CI]: 72%–81%) in the no-AD group and 75% (95% CI: 71%–79%) in the AD group (HR [no-AD vs. AD]=0.85; 95% CI: 0.65–1.11; log-rank p=0.23; non-inferiority p=0.002). There were 45 deaths in the no-AD group and 58 in the AD group. 10-year OS was 91% (95% CI: 88%–94%) in the no-AD group and 88% (95% CI: 85%–92%) in the AD group (HR [no-AD vs. AD]=0.77; 95% CI: 0.56–1.07; log-rank p=0.19).

CONCLUSION: Findings after a median follow-up of 9.8 years fully support the findings at 5 years in that no-AD is not inferior to AD with respect to DFS, and there is no significant difference between the arms for DFS and OS, thus confirming that AD is not
indicated in patients with micrometastatic SNs.

Title: Risk of arm morbidity after local therapy in young breast cancer survivors

A Kuijer\textsuperscript{1,2,3,4}, L S Dominici\textsuperscript{1,2,3}, S M Rosenberg\textsuperscript{1,3}, J Hu\textsuperscript{1}, S Gelber\textsuperscript{1}, S Di Lascio\textsuperscript{1}, K J Ruddy\textsuperscript{5}, J Wong\textsuperscript{1,2,3}, R M Tamimi\textsuperscript{2,3}, L Schapira\textsuperscript{6}, V F Borges\textsuperscript{7}, S E Come\textsuperscript{3,8}, K Sprunck-Harrild\textsuperscript{1}, A H Partridge\textsuperscript{1,3} and T A King\textsuperscript{1,2,3}.\textsuperscript{1}Dana-Farber Cancer Institute, Boston, MA;\textsuperscript{2}Brigham and Women's Hospital, Boston, MA;\textsuperscript{3}Harvard Medical School, Boston, MA;\textsuperscript{4}Diakonessenhuis Utrecht, Utrecht, Netherlands;\textsuperscript{5}Massachusetts General Hospital, Boston, MA;\textsuperscript{6}Stanford Cancer Institute and/or Stanford University, Stanford, CA;\textsuperscript{7}University of Colorado Cancer Center, Aurora, CO;\textsuperscript{8}Beth Israel Deaconess, Boston, MA and \textsuperscript{9}Mayo Clinic, Rochester, MN.

Body: BACKGROUND: Arm morbidity, the most reported comorbidity following axillary surgery for breast cancer, is of particular importance in young patients given the longer survivorship period and detrimental effects of arm-morbidity on body image and social-, home- and personal care functions. We assessed the incidence of arm-morbidity stratified by local therapy strategies in young women enrolled in the Young Women's Breast Cancer Study (YWS).

PATIENTS AND METHODS: The YWS, a multicenter prospective cohort study, established to explore biological, medical and psychosocial issues in young breast cancer patients, enrolled 1302 women with stage 0-4 breast cancer ≤40 years of age from October 2006 to June 2016. For this analysis, we examined incidence of patient reported arm-swelling or decreased range of motion (ROM) 1-year after diagnosis using relevant items of the CARES-SF. Patients with stage 4 disease (n = 60), those for whom no information on arm-morbidity was available (n=198) and those with bilateral cancer with different local therapy strategies on each side (n=7), were excluded. We performed logistic regression analyses to identify risk factors for arm morbidity.

RESULTS: Among 1037 patients (median age 37 years), 13% and 40% reported arm-swelling or decreased ROM, respectively, in the ipsilateral arm at 1-year. 52% (n=539) of patients underwent SLNB and 39% (n=407) ALND. The incidence of arm-swelling was 4% (11/280) in patients who underwent SLNB without RT, 8% (21/252) in patients who underwent SLNB with RT, 20% (13/66) in patients who underwent ALND without RT and 24% (84/337) in patients who received ALND with RT. The incidence of decreased ROM was 21% (59) in patients who underwent SLNB without RT, 34% (86) in patients who underwent SLNB with RT, 33% (22) in patients who underwent ALND without RT and 44% (148) in patients who received ALND with RT. Being overweight, uncomfortable financial status, T4 tumors, ALND and RT were independently associated with an increased risk of arm-swelling. Overweight, mastectomy and RT were independently associated with an increased risk of a decreased ROM.

Note. In these analysis we also corrected for age, incidence year, employment status, stage of disease, reconstructive surgery, and chemotherapy treatment.

**CONCLUSION:** Patient reported outcomes reveal high rates of arm-swelling and decreased ROM 1 year after breast cancer diagnosis in a large prospective cohort of young breast cancer survivors. These findings suggest an opportunity for pre-operative education and early intervention for arm impairment in this population.

Title: Prediction of occult invasive disease in ductal carcinoma in situ using deep learning features

Joseph Y Lo¹, Lars J Grimm¹, Maciej A Mazurowski¹, Jay A Baker¹, Jeffrey R Marks², Lorraine M King², Carlo C Maley³, Eun-Sil Shelley Hwang² and Bibo Shi¹. ¹Carl E. Ravin Advanced Imaging Laboratories, Duke University School of Medicine, Durham, NC; ²Duke University School of Medicine, Durham, NC and ³Biodesign Center for Personalized Diagnostics and School of Life Sciences, Arizona State University, Tempe, AZ.

Body: Background: Deep learning, especially deep convolutional neural network (CNN), has emerged as a promising approach for many image recognition or classification tasks, demonstrating human or even superhuman performance. Used as feature extractor, some pre-trained CNN models can match or surpass the performance of domain-specific, “handcrafted” features. In this study, we aim to determine whether deep features extracted from digital mammograms using a pre-trained deep CNN are prognostic of occult invasive disease for patients with ductal carcinoma in situ (DCIS) on core needle biopsy.

Materials and Methods: In this retrospective study, we collected digital mammography magnification views for 99 subjects with DCIS at biopsy, 25 of which were subsequently upstaged to invasive cancer. We utilized a deep CNN model that was pre-trained on non-medical images (e.g., animals, plants, instruments) as the feature extractor. Through a statistical pooling strategy, we extracted deep features at different levels of convolutional layers from the lesion areas, without sacrificing the original resolution or distorting the underlying topology. A multivariate classifier was then trained to predict which tumors contain occult invasive disease. This was compared to the performance of traditional “handcrafted” computer vision (CV) features previously developed specifically to assess mammographic calcifications. The generalization performance was assessed using Monte Carlo cross validation and receiver operating characteristic (ROC) curve analysis.

Results: Deep features were able to distinguish DCIS with occult invasion from pure DCIS, with an area under the ROC curve (AUC-ROC) equal to 0.70 (95% CI: 0.68-0.73). This performance was comparable to the “handcrafted” CV features (AUC-ROC = 0.68, 95% CI: 0.66-0.71) that were designed with prior domain knowledge.

Conclusion: In spite of being pre-trained on only non-medical images, the deep features extracted from digital mammograms demonstrated comparable performance to “handcrafted” CV features for the challenging task of predicting DCIS upstaging.

Acknowledgments: This work was supported in part by NIH/NCI R01-CQA185138 and DOD Breast Cancer Research Program W81XWH-14-1-0473.
Title: Primary endocrine therapy for ER-positive ductal carcinoma in situ (DCIS) CALGB 40903 (Alliance)

E Shelley Hwang\textsuperscript{1}, Stephanie Duong\textsuperscript{2}, Isabelle Bedrosian\textsuperscript{3}, Jacob Allred\textsuperscript{2}, Dorota Wisner\textsuperscript{4}, Terry Hyslop\textsuperscript{1}, Abigail Caudle\textsuperscript{3}, Joesph Guenther\textsuperscript{5}, Cliff Hudis\textsuperscript{6}, Eric Winer\textsuperscript{7}, Laura Esserman\textsuperscript{4} and Nola Hylton\textsuperscript{4}. \textsuperscript{1}Duke University, Durham, NC; \textsuperscript{2}Mayo Clinic, Rochester, MN; \textsuperscript{3}MD Anderson, Houston, TX; \textsuperscript{4}UCSF, San Francisco, CA; \textsuperscript{5}St. Elizabeth Medical Center South, Edgewood, KY; \textsuperscript{6}ASCO, Alexandria, VA and \textsuperscript{7}Dana Farber Cancer Institute, Boston, MA.

Body: Background: Standard treatment for ductal carcinoma in situ (DCIS) consists of surgery, often followed by adjuvant radiation therapy or endocrine therapy. This current approach is thought to represent overtreatment for some patients. This study was undertaken to determine whether an alternate approach of primary endocrine therapy alone could result in measurable radiographic changes in unresected estrogen receptor (ER)-positive DCIS.

Methods: A phase II open-label single arm multi-center cooperative group trial (CALGB 40903) was conducted for postmenopausal patients diagnosed with ER-positive DCIS. All eligible patients underwent baseline mammography and MRI, followed by 6 months of preoperative therapy with letrozole. Follow up breast MRI was obtained at 3 and 6 months of treatment. The primary endpoint was change in total MRI volume of DCIS enhancement from baseline to 3 months and from baseline to 6 months. Secondary endpoints were change in MRI maximum diameter over baseline and change in mammographic extent of disease over baseline. Endpoints were analyzed via 2-sided paired t-tests (a=0.05).

Results: From 8/1/12 to 2/1/16 108 patients were enrolled; Of the 77 patients who completed letrozole treatment per protocol, 66 patients were assessable. 2 additional patients who did not complete treatment per protocol were considered assessable and thus included in the analysis for a total of 68 patients. Median age of the cohort was 62.7 years. DCIS nuclear grade was low in 10% of patients, intermediate in 49%, and high in 40%. 82% of patients had ER-positive, PR-positive DCIS. The total mean MRI volume decreased from baseline to 3 months by 1.93 cm\textsuperscript{3} (p<0.001) and from baseline to 6 months by 1.82 cm\textsuperscript{3} (p<0.001). There was no significant difference in tumor volume between 3 and 6 months. Mean total mammographic tumor diameter decreased from baseline to 6 months by 3.31 mm\textsuperscript{2} (p=0.078).

Conclusions: In a cohort of postmenopausal women treated with 6 months of preoperative endocrine therapy for ER-positive DCIS, MRI volume decreased markedly by 3 months, while mammographic extent of disease was not altered significantly. Correlation of imaging changes with pathology and baseline biomarkers will be conducted. These results will help determine whether MRI could be an effective modality for monitoring treatment response in some patients treated with primary endocrine therapy for ER-positive DCIS.
**Title:** A U.S. food and drug administration pooled analysis of outcomes of older women with hormone-receptor positive metastatic breast cancer treated with a CDK4/6 inhibitor as initial endocrine based therapy

Harpreet Singh1, Lynn J Howie1, Erik Bloomquist1, Suparna Wedam1, Laleh Amiri-Kordestani1, Shengui Tang1, Rajeshwari Sridhara1, Amna Ibrahim1, Kirsten Goldberg1, Amy McKee1, Julia A Beaver1 and Richard Pazdur1. 1US Food and Drug Administration, Silver Spring, MD.

**Body:** Background: With recent FDA approvals of inhibitors of Cyclin Dependent Kinases 4 and 6 (CDK 4/6) in combination with endocrine therapy for the treatment of postmenopausal women with hormone-receptor positive metastatic breast cancer (MBC), an increasing number of older adults will be treated with this class of agents. An improved understanding of the safety and efficacy of CDK 4/6 inhibitors in this population is important to inform clinical decision making for the treatment of older patients.

**Methods:** Data from two prospective randomized controlled studies (n=1334) of different CDK 4/6 inhibitors in combination with an aromatase inhibitor for the initial treatment of postmenopausal patients with hormone-receptor positive MBC were pooled and analyzed. The effect of age on progression free survival (PFS) was explored using Kaplan Meier (KM) estimates and a Cox-proportional hazard model. Safety analysis included adverse events up to 30 days after last administration of drug based on standardized adverse event datasets.

**Results:** Age was balanced between the two studies, and between treatment arms within each study. The median age of women was 62 (range 23-91). Of the 1334 total patients, 42% were ≥65, and 24% were ≥70. For patients ≥70 who were treated with a CDK4/6 inhibitor in combination with an aromatase inhibitor, the estimated PFS was not reached (95% CI: 25.1months, NR) vs an estimated 18 months (95% CI: 13.8, 31.3) for those treated only with an aromatase inhibitor. For patients <70 treated with a CDK4/6 inhibitor, the estimated PFS was 23.5 months (95% CI: 21.4, 25.7) vs an estimated 13.8 months (95% CI: 12.9, 16.5) for those treated only with an aromatase inhibitor.

Safety was evaluated in the 778 patients who received at least one dose of CDK4/6 inhibitor.

Conclusions: This exploratory analysis suggests the use of a CDK4/6 inhibitor in combination with an aromatase inhibitor for the first line treatment of HR+ MBC in older women results in similar efficacy benefit as seen in younger women. Although incidence and severity of Grade 1-4 adverse reactions appeared similar between age groups, greater serious adverse events and discontinuations occurred in patients ≥65. The inclusion of greater numbers of patients ≥70, in clinical trials will further inform clinicians about the safety and efficacy of CDK4/6 inhibitors in older adults.
Title: Weight change in postmenopausal women and breast cancer risk in the women's health initiative observational study

Rowan T Chlebowski¹, Juhua Luo², Garnet L Anderson³, Michael Simon⁴, Wendy Barrington⁵, Kerryn Reding⁵, JoAnn E Manson⁶, Thomas Rohan⁷, Jean Wactawski-Wende⁸, Dorothy Lane⁹, Howard Strickler⁷, Yasmin Mossavar-Rahmani⁷, Jo Freudenheim⁸, Abu Taiyab Nazmus Saquib¹⁰ and Marcia Stefanick¹¹.

¹City of Hope National Medical Center, Duarte, CA; ²Indiana University, Bloomington, IN; ³Fred Hutchinson Cancer Research Center, Seattle, WA; ⁴Karmanos Cancer Institute, Detroit, MI; ⁵University of Washington, Seattle, WA; ⁶Brigham and Women's Hospital, Harvard Medical School, Boston, MA; ⁷Albert Einstein College of Medicine, New York, NY; ⁸University at Buffalo, SUNY, Buffalo, NY; ⁹Stony Brook University School of Medicine, Stony Brook, NY; ¹⁰Sulaiman Al Rajhi College, School of Medicine, Al Bukayriyah, Saudi Arabia and ¹¹Stanford University School of Medicine, Stanford, CA.

Body: Purpose
While obesity is an established breast cancer risk factor, information about the influence of weight loss on breast cancer risk in postmenopausal women is mixed precluding generation of a strong public health message regarding potential benefits of weight loss with respect to cancer risk. Therefore, we evaluated associations between weight change and invasive breast cancer risk in postmenopausal women participating in the Women's Health Initiative (WHI) Observational Study.

Patients and Methods
Postmenopausal women (n=61,335) with no prior breast cancer and normal mammogram who were not underweight (body mass index [BMI] ≥ 18.5 kg/m²), ages 50-79 years at WHI enrollment between 1993 and 1998 at 40 US clinical centers, had body weight and height measured and BMI calculated at the clinical centers at baseline and at year 3. Weight change over 3 years was categorized as: stable (no change ≤ 5%), loss (change ≥ 5%), or gain (change ≥ 5%) with weight loss intentionality determined by self-report response to direct query at year 3. Breast cancers were initially ascertained through annual survey and were centrally confirmed by medical record review. Multi-variable Cox proportional hazards regression models incorporating breast cancer risk factors and baseline BMI were used to evaluate relationships between weight change and breast cancer incidence.

Results
During 11.4 years (mean) of follow-up, 3,061 women developed invasive breast cancer. In multi-variable analyses, compared with women with stable weight (n=41,139), women with weight loss (≥ 5%) (n=8,175) had a significantly lower breast cancer risk (hazard ratio [HR] 0.88 95% confidence interval [CI] 0.78-0.98). Adjustment for mammography did not alter findings (HR 0.88 95% CI 0.78-0.99). There was no significant interaction for breast cancer effect by weight loss intentionality determined by self-report response to direct query at year 3. Breast cancers were initially ascertained through annual survey and were centrally confirmed by medical record review. Multi-variable Cox proportional hazards regression models incorporating breast cancer risk factors and baseline BMI were used to evaluate relationships between weight change and breast cancer incidence.

Conclusion
Weight loss in postmenopausal women is associated with lower breast cancer risk. These findings suggest that postmenopausal women who lose weight may reduce their breast cancer risk.
**Title:** A validation of DCIS biological risk profile in a randomised study for radiation therapy with 20 year follow-up (SweDCIS)

Fredrik Wärnberg¹, Hans Garmo⁹, Yasin Folkvaljon¹, Lars Holmberg², Per Karlsson³, Kerstin Sandelin⁴, Steven Linke⁵, Stephen Lyle⁶, Karl Simin⁷, Glen Leesman⁵, Todd Barry⁷, Jess Savala⁹, Pat Whitworth⁹ and Troy Bremer⁵. ¹Uppsala University, Uppsala, Sweden; ²King’s College London, Medical School, Division of Cancer Studies, King’s College London, London, United Kingdom; ³Sahlgrenska University Hospital, Göteborg, Sweden; ⁴Karolinska Institutet, Stockholm, Sweden; ⁵PreludeDx, Laguna Hills, CA; ⁶University of Massachusetts Medical School, Worcester, MA; ⁷Spectrum Pathology, Mission Viejo, CA; ⁸Nashville Breast Center, Nashville, TN and ⁹Regional Cancer Centre, Uppsala University, Uppsala, Sweden.

**Body:**

**Background:** Women diagnosed with ductal carcinoma in situ (DCIS) and their physicians need tools that assess individualized risk and predict treatment benefit. A DCIS biologic signature was previously validated in an observational study at Kaiser Permanente NW. We evaluated the results of the signature for predictive utility in a national randomized clinical trial (SweDCIS) by assessing the 10-year benefit of adjuvant radiotherapy (RT) on ipsilateral breast event (IBE) and invasive breast cancer (IBC) risks.

**Methods:** The signature was validated in a prospective-retrospective study in women from the SweDCIS trial (n=1046) performed by the Swedish Breast Cancer Group. Women were treated with breast conserving surgery (BCS) between 1987-1999 and randomized to RT or no RT. A central pathology review of paraffin embedded tissue blocks (n=873) was performed at Uppsala University (UU). Freshly cut slides were provided to PreludeDx for biomarker testing. Extended follow-up of SweDCIS was published in 2014.

A panel of biomarkers (HER2, PR, Ki67, COX2, p16/INK4A, FOXA1 and SIAH2) were assayed and scored in PreludeDx’s CLIA lab by board-certified pathologists. Continuous Decision Scores (DS) were calculated with the biologic signature using the biomarker and clinical factors (age, size, margin, and palpability) blinded to patient outcome. The DS results were provided to the Uppsala Regional Cancer Center for analysis. A predefined and co-developed statistical analysis plan was executed. Absolute 10-year RT benefit was assessed using Kaplan-Meier survival analysis. Hazard ratios (HR) were determined using Cox proportional hazards analysis and the interaction of the DS and RT benefit was assessed.

**Results:** Complete biomarker and clinical information was available in 584 women. In women with clear margins (n=506), 78 IBEs, including 31 IBCs, were recorded within 10 years of diagnosis. The multivariate analysis of DS (0-10 unit scale) and the RT interaction was significant for risk of IBC (p=0.048) and IBE (p<0.001) at 10 years. The DS defined an elevated risk group (>3) for which there was pronounced 10-year benefit of RT (p=0.01) with an absolute risk reduction of 9% for IBC (Table 1). The corresponding low risk group (≤3), which included 48% of all patients, demonstrated no significant RT benefit (p=0.70) with an absolute risk reduction of 1%. The continuous DS variable was correlated with IBE risk, HR 1.49/per 5 units 95%CI [1.02,2.18] (p=0.038), in addition to the RT benefit for IBE in low (p=0.04) and elevated (p<0.001) risk groups.

**Discussion:** Evaluation of the SweDCIS trial validated prognostic and RT predictive utility of the biologic signature. Women diagnosed with DCIS and treated with BCS ±RT were stratified into clinically relevant low and elevated risk groups (≤3 vs >3). Women in the elevated risk group had twice the treatment benefit for IBC from RT compared to prior randomized trials, while the low risk group had no benefit from RT.

Table 1. 10-year RT benefit in women from the SweDCIS trial.
Body: Background: The prediction of late distant recurrence (DR) is an important clinical goal for managing women with hormone receptor positive disease who have reached the end of 5 years' endocrine treatment without recurrence. Molecular profiles have produced conflicting results for the prediction of late DR. Here, we develop and validate a simple clinicopathological tool (Clinical Treatment Score post-5 years (CTS5)) to estimate the residual risk of DR after 5 years' endocrine treatment, which should help in discussions with patients about the potential benefits or not of continued endocrine therapy.

Patients and Methods: The ATAC dataset (N=4735) of postmenopausal women with oestrogen receptor (ER) positive breast cancer treated with 5 years' tamoxifen or anastrozole was used as a training cohort to establish a prognostic score for post-5-year risk of DR. CTS5 was based on five categories for nodal status, linear and quadratic terms for tumour size (capped at 30mm), three categories for grade, and continuous age. The validity of the CTS5 was tested in the BIG1-98 dataset (N=6711), which included postmenopausal women with ER-positive breast cancer treated with tamoxifen or letrozole (either monotherapy or sequential). Both cohorts included women who were alive and DR-free 5 years after randomization. Time to late DR, defined beginning at 5 years after ATAC or BIG 1-98 randomization, was the primary endpoint. Cox regression models estimated the prognostic performance of the CTS5. Hazard Ratios (HRs) are for a change of one Standard Deviation.

Results: The CTS5 model was a significant predictor for late DR in ATAC (HR=2.47 (95% CI, 2.24-2.73), P<0.001) and performed better than the established 0-10 year CTS model (Cuzick et al., JCO, 2011). CTS5 was confirmed as highly predictive for late DR in the BIG1-98 validation cohort (HR=2.07 (1.88-2.28), P<0.001). Of greatest importance was that CTS5 risk stratification defined in the training cohort as low (<5% risk of DR during years 5-10), intermediate (5-10% risk), high (>10% risk), identified 43% of the validation cohort as low risk, with an observed DR rate of 3.6% (95% CI 2.7-4.9) during years 5-10. Within nodal subgroups, 63% of node-negative were low risk with 3.9% (2.9-5.3) DR rate between years 5-10, and 24% having 1-3 nodes positive were low risk with 1.5% (0.5-3.8) DR rate between years 5-10. Separation of intermediate-risk from high-risk categories was also shown in the training set but improvements in calibration seem necessary for clinical utility for that assessment.

Conclusion: The CTS5 is a simple tool based on information that is readily available to all clinicians. It was more accurate in its prediction of DR risk in years 5-10 than the published CTS model. CTS5 was validated as highly prognostic for late DR in the independent BIG 1-98 study. The algorithm identified a subgroup of women with either node-negative disease or 1-3 positive nodes as having less than 1% per year risk of DR who could be advised of the limited value of extended endocrine therapy.
Title: The benefit of abemaciclib in prognostic subgroups: An exploratory analysis of combined data from the MONARCH 2 and 3 studies

Matthew P Goetz¹, Joyce O'Shaughnessy², George W Sledge Jr.³, Miguel Martin⁴, Yong Lin⁵, Tammy Forrester⁶, Colleen Mockbee⁶, Ian C Smith⁶, Angelo Di Leo⁶ and Stephen Johnston⁷. ¹Mayo Clinic, Rochester, MN; ²Baylor University Medical Center, Texas Oncology, Dallas, TX; ³Stanford University, Stanford, CA; ⁴Instituto De Investigacion Sanitaria Gregorio Marañon, Ciberonc, Geicam; Universidad Complutense, Madrid, Spain; ⁵Eli Lilly and Company, Indianapolis, IN; ⁶Hospital of Prato, Istituto Toscano Tumori, Prato, Italy and ⁷The Royal Marsden NHS Foundation Trust, London, United Kingdom.

Body: Background: Abemaciclib is an orally administered, selective inhibitor of cyclin-dependent kinases 4 & 6 that is dosed on a twice daily continuous schedule. Abemaciclib has demonstrated clinical efficacy with a generally tolerable safety profile in patients with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-) advanced breast cancer in combination with fulvestrant in MONARCH 2 (NCT02107703) and in combination with non-steroidal aromatase inhibitors (NSAI) in MONARCH 3 (NCT02246621). These analyses were conducted to evaluate if patient and disease characteristics may better inform in whom and when abemaciclib should be initiated to define optimal treatment strategies.

Methods: MONARCH 2 and 3 enrolled patients with HR+, HER2- advanced breast cancer. In MONARCH 2, patients whose disease had progressed while receiving endocrine therapy were treated with abemaciclib/placebo plus fulvestrant. In MONARCH 3, patients were treated with abemaciclib/placebo plus NSAI as initial therapy for advanced disease. An exploratory pooled analysis of the two studies was performed to determine significant prognostic factors. Efficacy results (progression-free survival [PFS] and objective response rate [ORR] in patients with measurable disease) were examined for patient subgroups corresponding to each of the identified significant prognostic factors. Subpopulation treatment effect pattern plot (STEPP) methodology was performed to examine the association between treatment-free interval (TFI) following adjuvant endocrine therapy and outcomes of endocrine therapy alone or in combination with abemaciclib in MONARCH 3.

Results: Analyses of clinical factors in over 1000 patients confirmed the following to have prognostic value: bone-only disease, liver metastases, tumor grade, progesterone receptor (PgR) status, and ECOG performance status. Prognosis was poor in patients with liver metastases, PgR-negative tumors, and high-grade tumors. While all subpopulations benefited from the addition of abemaciclib to endocrine therapy regardless of prognosis, substantial benefit of abemaciclib was observed in poor prognosis subgroups, characterized by large increases in PFS (hazard ratios = 0.4 to 0.5) and ORR (over 30%). In addition, STEPP analysis of TFI on a subset of the MONARCH 3 population showed that patients with the shortest TFI appeared to have a poorer prognosis and received more benefit from the addition of abemaciclib compared to patients with longer TFI.

Conclusions: This exploratory analysis has provided data that could help optimize treatment strategies by identifying that patients with poor prognostic factors may receive greater benefit from the addition of abemaciclib to endocrine therapy.

Title: Circulating tumor cells (CTCs) five years after diagnosis are prognostic for late recurrence in operable stage II-III breast cancer

Joseph A Sparano1, Anne O'Neill2, Katherine Alpaugh3, Antonio C Wolff4, Donald W Northfelt5, Chau Dang6, George W Sledge, Jr.7 and Kathy D Miller8. 1Montefiore Medical Center, Albert Einstein College of Medicine; 2Dana Farber Cancer Institute; 3Fox Chase Cancer Center; 4Johns Hopkins Oncology Center; 5Mayo Clinic; 6Memorial Sloan Kettering Cancer Center; 7Stanford Cancer Center and 8Indiana University Cancer Center.

Body: **Background:** Late recurrence 5 or more years after diagnosis accounts for least one-half of all breast cancer recurrences, especially in hormone receptor (HR)+ disease. Biomarkers prognostic for late recurrence offer potential to more accurately identify subjects who might benefit from extended adjuvant endocrine therapy, or novel strategies to reduce late recurrence risk. **Methods:** CTCs were assessed at a single time point using the CELL SEARCH® assay in patients without clinical evidence of recurrence between 4.5-7.5 years after an initial diagnosis of HER2- stage II-III breast cancer and enrolled in trial E5103; all patients received surgery plus adjuvant chemotherapy and endocrine therapy for at least 5 years if HR+ disease. Patients were followed for evidence of clinical recurrence in accordance with standard care, and the association between CTCs and clinical recurrence was evaluated. **Results:** 546 patients without clinical evidence of recurrence enrolled between 2/25/13-7/29/16 and provided a blood sample that yielded a CTC result; 16 (2.9%) subsequently had a recurrence, of whom 15 had HR-positive disease. The median time between enrollment on E5103 and CTC assay was 5.2 years, and median/mean followup after the CTC assay was 1.6 years (range 0-3.9 years). The CTC assay was positive in 27 (4.9%) (median CTC count 1/7.5 ml blood, range 1-15). There were no significant differences in patient characteristics in the CTC+ vs. CTC- cases, including age < 50 years at initial diagnosis (52% vs. 44%), tumor size > 2 cm (63% vs. 59%), >/= 1+ node (81% vs. 72%), ER and/or PR+ (70% vs. 64%) or poor histologic grade (44% vs 55%). The recurrence rate per person-year in the CTC+ vs. CTC- groups was 19.6% vs. 1.1%, respectively (P<0.01). The median/time to recurrence after a positive CTC assay was 2.8 years. In multivariate analysis adjusted for clinical covariates (see table), a positive CTC assay was associated with an 18.3-fold increased risk of recurrence.

**Conclusions:** A single positive CTC assay in patients without clinical evidence of recurrence 5 years after diagnosis of stage II-III HR+, HER2- breast cancer provides independent prognostic information for late recurrence, providing proof of concept for using liquid-based biomarkers for late relapse risk assessment. These findings provide a foundation for further evaluation of this new risk assessment paradigm using CTC and other blood-based assays in this setting, and designing clinical trials to tailor therapeutic risk interventions. Body: Background:
In the neoadjuvant treatment setting of ER+/HER2- breast cancer (BC) the choice between preoperative endocrine - (NET) or preoperative chemotherapy (NCT) is largely based on the expression of hormone receptors (HR), grading and possibly Ki-67. The EndoPredict 12-gene molecular score (EP) is a validated prognostic score based on the expression of genes involved in cellular processes including proliferation and ER signaling/differentiation. The application of the EP molecular score may thus provide additional insight into neoadjuvant response of tumors.

Methods:
This prospective translational study was carried out as an exploratory endpoint within the ABCSG 34 protocol (SABCS 2016, Singer et al.) and included only the HR+ subset of women. ABCSG 34 was a randomized 2-arm academic phase-II trial including 400 patients (250 ER+) with HER2 negative early BC. Patients were selected for either NET or NCT according to the study protocol reflecting standard of care: postmenopausal women with ER+++, or ER++ and Ki67 <14%, and G1,2,X tumors received 6 months of Letrozole. Postmenopausal patients with ER-(and PgR+) or ER low and Ki67 ≥14%, and with G3 tumors, and premenopausal patients, received 8 cycles of anthracycline/taxane based chemotherapy. Primary endpoint was Residual Cancer Burden score (RCB0/I vs RCBII/III) at surgery in women with or without Tecemotide (L-BLP25). EP was assessed from diagnostic cores and the predefined risk groups (EP low-risk vs EP high-risk; cutoff value: 5.0) and the score as a continuous variable (EPc) were applied to all patients with both full molecular - and RCB data (n=217).

Results:
134 patients (EP low-risk:9; EP high-risk:125) with HR+ tumors received NCT. Stage I: 14.9%, II/III: 84%; G3: 56%; mean Ki-67: 40.4%. No patient with EP low-risk score showed RCB0/I (NPV: 100%) whereas 26.4% of EP high-risk showed full response. In logistic regression EP as a continuous score (EPc) was a significant predictor of RCB0/I, showed an AUC (95% CI) of 0.736 (0.63 - 0.84) and revealed close correlation with Ki-67.

83 patients (EP low-risk:44; EP high-risk:39) received NET. Stage I: 38.6%, II/III: 60.2%; G3: 4.8%; mean Ki-67: 14.9%. 27.3% (n=12/44) with EP low-risk and 7.7% (n=3/39) with EP high-risk showed RCB0/I. EPc was a significant predictor of RCB0/I with an AUC (95% CI) of 0.726 (0.60 - 0.85). In all multivariate analyses low anatomic stage was the most powerful predictor of RCB0/I.

Conclusions:
Clinical standard of care separated ABCSG 34 patients into two HR+ cohorts with differing clinical features and treated distinctly with either NET or NCT: In women treated with neoadjuvant Letrozole a high molecular score indicated a very low possibility of endocrine response. In women clinically selected for neoadjuvant chemotherapy, a high EP score was associated with a higher
probability of chemotherapy response and the low EP risk group outlined a group of women with very poor tumor response to NCT (NPV 100%).

In summary, EP low risk is associated with tumor response to endocrine treatment and predicts resistance in the chemotherapy group. NCT, especially to attain breast conservation in ER+/HER2-/EP low risk should be reconsidered.
Title: Gain-of-function kinase library screen identifies FGFR1 amplification as a mechanism of resistance to antiestrogens and CDK4/6 inhibitors in ER+ breast cancer

Luigi Formisano¹, Yao Lu¹, Valerie M Jansen¹, Joshua A Bauer¹, Ariella Hanker¹, Paula Gonzalez Ericsson¹, Kyung-Min Lee¹, Melissa J Nixon¹, Angel L Guerrero-Zotano¹, Luis J Schwarz¹, Melinda Sanders¹, Dhivya Sudhan¹, Teresa C Dugger¹, Marcelo Rocha Cruz², Amir Behdad², Massimo Cristofanilli², Aditya Bardia³, Joyce O'Shaughnessy⁴, Ingrid A Mayer¹ and Carlos L Arteaga¹. ¹Vanderbilt Medical Center; ²Robert H Lurie Comprehensive Cancer Center; ³Massachusetts General Hospital Cancer Center and ⁴Baylor University Medical Center.

Body: Background: CDK4/6 inhibitors have been approved in combination with endocrine therapy for treatment of ER+ metastatic breast cancer. The goal of this study was to discover mechanisms of resistance to ER antagonists alone and in combination with CDK4/6 inhibitors.

Results: To achieve this goal, we used lentiviral vectors to individually express 559 human kinase open reading frames (ORFs) in ER+ MCF7 human breast cancer cells treated with fulvestrant ± the CDK4/6 inhibitor ribociclib. In MCF7 cells treated with fulvestrant alone or with ribociclib, we identified 15 and 17 kinases associated with resistance, respectively. Ten of these kinases overlapped in both groups. In a secondary screen, MCF7 cells were stably transduced with V5-tagged lentiviruses expressing the positive 'hits' for treatment with fulvestrant/ribociclib. Five of 17 kinases (FGFR1, FRK, HCK, FGR, CRKL) were confirmed to induce resistance to fulvestrant/palbociclib and fulvestrant/ribociclib. Survey of TCGA for copy number alterations and/or expression of these 5 genes showed only FGFR1 to be amplified/overexpressed in ~15% of ER+ breast cancers. Experiments in vitro showed that ER+/FGFR1-amplified (amp) MDA-134, CAMA-1 and HCC1500 human breast cancer cells and MCF7 cells stably transduced with FGFR1 were relatively resistant to estrogen deprivation, fulvestrant and fulvestrant/palbociclib compared to non-FGFR1 amp MCF7 cells. This resistance was abrogated by treatment with the FGFR tyrosine kinase inhibitor (TKI) lucitanib. Treatment with fulvestrant or palbociclib alone modestly delayed growth of ER+/FGFR1-amp breast cancer patient-derived xenografts (PDX) established in nude mice. However, addition of the FGFR TKI erdafitinib to fulvestrant/palbociclib resulted in marked PDX regression in all mice without associated toxicity and a complete cell cycle arrest measured by Ki67. Treatment of FGFR-amp cells with FGF-2 strongly induced CCND1 (cyclin D1) expression. Downregulation of CCND1 with CCND1 RNAi oligonucleotides restored sensitivity of FGFR1-amp cells to fulvestrant/palbociclib, thus phenocopying the effect of FGFR TKIs. Conversely, overexpression of CCND1 in MCF7 cells induced resistance to estrogen deprivation and to fulvestrant ± palbociclib. Finally, we examined next gen sequencing of cell free tumor DNA by Guardant360 in 34 patients before and after progression on CDK4/6 inhibitor. In 10/34 (29%) post-progression specimens, we detected alterations in the FGFR pathway: FGFR1 amplification (n=7), FGFR1 N546K (n=1), FGFR2 N549K (n=1), and FGFR2 V395D (n=1) activating mutations.

Conclusions: These data suggest aberrant FGFR signaling is a mechanism of resistance to anti-ER therapies ± CDK4/6 inhibitors. We posit overexpression of cyclin D1 induced by both FGFR signaling and ER transcription plays a role in drug resistance. Based on these findings we propose ER+/FGFR1 amplified breast cancers are endocrine resistant and should be candidates for treatment with combinations of ER and FGFR antagonists. Accordingly, we have initiated a phase Ib trial of fulvestrant, palbociclib and erdafitinib in patients with antiestrogen resistant ER+/HER2-negative breast cancer with FGFR1-4 amplification.
Title: Identifying metastatic drivers in patient-derived xenograft models of triple negative breast cancer

Emily Powell¹, Jiansu Shao¹, Hector M Picon¹, Zhongqi Ge¹, Gloria V Echeverria¹, Michael Peoples¹, Christopher Bristow¹, Shirong Cai¹, Yizheng Tu¹, Aaron M McCoy¹, David Piwnica-Worms¹, Giulio Draetta¹, John R Edwards², Stacy L Moulder¹, William F Symmans¹, Timothy P Heffernan¹, Han Liang¹ and Helen Piwnica-Worms¹. ¹MD Anderson Cancer Center and ²Washington University in St. Louis.

Body: Metastases are responsible for the vast majority of deaths due to breast cancer. Triple negative breast cancer (TNBC) is an aggressive subtype of breast cancer characterized by high rates of metastasis and poor prognosis. We are employing patient derived xenograft (PDX) models of TNBC to identify drivers of metastasis. Tumor samples are obtained from the breast tumors of patients with TNBC and engrafted immediately into the humanized mammary fat pads of immune compromised mice. Lentiviral transduction was employed to express bioluminescent and fluorescent markers in two independent PDX models of TNBC. Using these models, we demonstrated that human breast tumors are capable of completing all stages of the metastatic cascade in mice, and metastatic lesions are observed in organs normally found in patients with metastatic breast cancer including lung, liver, bone, brain, and lymph nodes. Dynamic and reversible epithelial to mesenchymal transition (EMT) was observed as tumors metastasized to lung and were re-passaged to recipient mouse mammary glands. Lung metastases were isolated using bioluminescence imaging and lung metastasis gene expression signatures were generated. Metastasis signatures from two independent PDX models were compared to identify genes that were commonly de-regulated in lung metastases relative to corresponding mammary tumors. Comprehensive gain-of-function screens were then conducted in vivo to identify functional drivers of TNBC metastasis. Carcinoembryonic antigen-related cell adhesion molecule 5 (CEACAM5) was identified as a metastatic driver in this screen. CEACAM5 mRNA and protein levels were elevated in lung metastases relative to corresponding mammary gland tumors in mice. In addition, we demonstrated that CEACAM5 expression was upregulated in the lung metastases of breast cancer patients, and its expression inversely correlated with patient survival. Our data indicate that the metastatic function of CEACAM5 is to promote growth of breast tumors in the lung by inducing MET (mesenchymal to epithelial transition).
EMBRACA: A phase 3 trial comparing talazoparib, an oral PARP inhibitor, to physician’s choice of therapy in patients with advanced breast cancer and a germline BRCA mutation

Jennifer Litton1, Hope S Rugo2, Johannes Ettl3, Sara Hurvitz4, Anthony Gonçalves5, Kyung-Hun Lee6, Louis Fehrenbacher7, Rinat Yerushalmi8, Lida A Mina9, Miguel Martin10, Henri Roché11, Young-Hyuck Im12, Ruben GW Quek13, Iulia Cristina Tudor13, Alison L Hannah13, Wolfgang Eiermann14, and Joanne L Blum15.

Body: Background: Talazoparib (TALA) is a highly potent, dual-mechanism PARP inhibitor that inhibits the PARP enzyme and effectively traps PARP on single-stranded DNA breaks, preventing DNA damage repair and causing cell death in BRCA1/2-mutated cells.

Methods: EMBRACA is an open-label, randomized, 2-arm, phase 3 trial comparing the efficacy and safety of TALA (1 mg/day) with standard single-agent physician’s choice of therapy (PCT) (capecitabine, eribulin, gemcitabine, or vinorelbine) in patients with advanced breast cancer (aBC) and a germline BRCA1/2 mutation (gBRCAmut). The primary objective was PFS assessed by blinded independent central review (BICR). Secondary objectives: OS, ORR, CBR at 24 weeks (CBR24), and safety. Exploratory objectives: patient-reported QoL and DOR. Eligibility criteria: age ≥ 18 years; HER2-negative aBC; deleterious or suspected deleterious gBRCAmut; ≤ 3 prior cytotoxic regimens for aBC; and ECOG PS ≤ 2. Prior platinum was allowed. Patients were randomized 2:1 and stratified by receptor status, extent of prior therapy, and CNS metastases (NCT01945775).

Results: 431 patients were randomized (median age 46 years; 54% hormone-receptor [HR]+ BC; 45% BRCA1+ and 55% BRCA2+; 55% ECOG PS = 0; 38% chemo-naïve for aBC; 18% prior platinum; 15% CNS metastases); 287 were assigned to TALA and 144 to PCT (1 TALA, 18 PCT patients were not treated). Median duration of exposure was 6.1 and 3.9 months, respectively; TALA had a relative dose intensity of 87%. At 62% PFS data maturity:

</tr>
</tbody>
</table>

INV, investigator. *Not a randomized subset.

Improved clinical benefit was seen in all subsets including those with HR+ BC (HR 0.47; 95% CI 0.32-0.71) and CNS metastasis (HR 0.32; 95% CI 0.15-0.88). There was a significant delay in the time to deterioration in global health status (GHS/QoL for TALA vs PCT (HR 0.38; 95% CI 0.26-0.55; P < 0.0001). Grade 3-4 hematologic adverse events (AEs) occurred in 55% TALA (mainly anemia)/39% PCT (mainly neutropenia). Grade 3-4 non-hematologic AEs were seen in 32% TALA/38% PCT; TALA was associated with fewer gastrointestinal disorders (5.6% vs 11.9%) and skin/subcutaneous tissue disorders (0.7% vs 5.6%) than PCT. Grade 3-4 serious AEs were observed in 26% TALA/25% PCT. AEs associated with permanent study drug discontinuation occurred in 8% TALA/10% PCT. AE resulting in death occurred in 2.1% TALA/3.2% PCT. Conclusions: Single-agent TALA significantly prolonged PFS by BICR in HER2-negative aBC patients with a gBRCAmut compared to PCT; all key secondary efficacy endpoints demonstrated benefit with TALA, with a significant delay in time to deterioration in GHS/QoL.

TALA was
generally well tolerated with minimal non-hematologic toxicity and few AEs associated with treatment discontinuations.
Body: Objectives: Brain metastases of breast cancer demonstrate low and heterogeneous levels of permeability to drugs in mouse models and human craniotomies. The Blood-Brain Barrier (BBB), the protective lining of CNS blood vessels, impedes drug entry into the normal brain. When a metastasis forms, the BBB is locally altered to a poorly characterized Blood-Tumor Barrier (BTB). Quantitative experimental models indicate that most brain metastases have increased permeability over the normal BBB, but BTB permeability is both heterogeneous and ~2 logs less than that of systemic metastases. We have interrogated three hematogenous models of brain metastasis of breast cancer to ask (1) whether the BTB is an ordered structure or a random breakdown of the BBB; (2) among brain metastases, whether consistent differences underlie the BTBs of lesions with low- and high permeabilities to fluorescent markers and drugs; (3) if alterations in BTB composition can functionally change its permeability. Our long term goal is to enhance uptake of drugs into brain metastases to effective levels.

Results: When uninvolved brain was compared with any brain metastasis, alterations in endothelial, pericytic, astrocytic, and microglial components of the BBB were observed. Both the pericyte and astrocyte components of the BTB were consistently altered with increased permeability: When metastases with relatively low and high permeability were compared, increased expression of a desmin+ subpopulation of pericytes was associated with higher permeability (231-BR6 P=0.0002; JIMT-1-BR3 P = 0.004; SUM190-BR3 P=0.008). A trend toward reduced CD13+ pericytes was observed in highly permeable metastases (231-BR6 P =0.014; JIMT-1-BR3 P =0.002, SUM190-BR3, NS). For GFAP+ astrocytes in the neuroinflammatory response surrounding metastases, no overall difference in cell number was observed between low and high permeability lesions. However, gene expression profiling of laser capture microdissected low and high permeability lesions demonstrated overexpression of the sphingosine-1 phosphate receptor 3 (S1P3) in the astrocytes of highly permeable lesions, which was confirmed at the protein expression level in all three models (231-BR6 P=0.034; JIMT-1-BR3 P = 0.01; SUM190-BR3 P=0.016). Inhibition of S1P3 via S1PR3 shRNA or a selective antagonist (TY-52156) functionally tightened the BTB in an in vitro model. Administration of TY-52156 to mice harboring 231-BR6 brain metastases had no effect on metastasis number, but decreased uptake of Texas Red Dextran dye into metastases (P=0.016). S1P3 mediated its effects on BTB permeability through astrocytic secretion of IL-6 and CCL2, which altered endothelial expression and localization of adhesive proteins, a potentially translatable pathway. Both desmin+ pericytes and S1P3+ astrocytes are present in human craniotomy specimens.

Conclusions: These experiments demonstrate that the BTB is a structure with consistent properties, and that further consistent changes underlie the transition from a low to high permeability BTB. While proof of principle, S1P3 inhibition studies indicate that the BTB permeability can be functionally modulated in vivo.
Title: Targeting PTK6 to treat mesenchymal triple negative breast cancer

Koichi Ito¹, Sun Hee Park¹, Anupma Nayak¹, Jsccia Byerly¹ and Hanna Y Irie¹. ¹Icahn School of Medicine at Mount Sinai, New York, NY.

Body: Background/Rational: Patients with triple negative breast cancers (TNBC) have limited therapeutic options beyond conventional chemotherapy. Unfortunately, high-risk for metastatic recurrence and chemotherapy resistant diseases cause the worst 5-year survival rate in patients with TNBC, which have been significant clinical challenges. Novel therapeutic targets or strategies to combat metastasis and chemotherapy resistance are necessary to improve quality of life and outcomes for patients with high risk TNBC. Epithelial-to-mesenchymal transition (EMT) and anoikis resistance are processes recognized as contributing to enhanced metastatic potential and treatment resistance. A subset of TNBC exhibits mesenchymal gene signatures and phenotypes that may be associated with high metastatic recurrence, chemotherapy resistance and immunosuppression. In a functional genomic screen, we identified several candidates as novel regulators of EMT and anoikis sensitivity of TNBC cells. We have focused on roles of one highly validated candidate, protein tyrosine kinase 6 (PTK6) on EMT, anoikis resistance and metastatic capacity in TNBC. Methods: We analyzed expression of PTK6 and mesenchymal markers in patient triple negative tumors by immunohistochemistry. In breast epithelial and TNBC cell lines, the levels of PTK6 were genetically modulated, and determined effects on growth, migration and EMT. In vivo mouse models were used to show effects of PTK6 inhibition on metastatic capacity of TNBC cells. We have also validated effects of PTK6 specific small molecule inhibitor on TNBC growth and metastases. In order to dissect specific mechanisms by which PTK6 inhibition regulates TNBC mesenchymal phenotypes, we used a siRNA library screening and identified novel E3 ligases that may be responsible for PTK6 inhibition-induced EMT regulation. Results: Overexpression of PTK6 in MCF10A cells is sufficient to promote an EMT; promotes migration, suppresses epithelial markers (E-cadherin/claudin-1) and increases mesenchymal markers (N-cadherin and fibronectin). In contrast, PTK6 inhibition either PTK6 shRNAs or treatment with a specific kinase inhibitor enhances E-cadherin expression and suppresses migration, anoikis resistance and lung colonization of TNBC cells. PTK6-dependent E-cadherin regulation is specifically dependent on levels of SNAIL, a transcriptional repressor that is associated with poor TNBC patient prognosis. SNAIL down-regulation by PTK6 inhibition is directly responsible for the modulation of anoikis sensitivity, which is in turn causally linked to lung colonization potential. PTK6 inhibition promotes the proteasome-dependent degradation of SNAIL via a novel mechanism independent of GSK3β/β-TRCP pathway or Fbox E3ligases (FBXO5, FBXO11, FBXL14) that are known to regulate SNAIL ubiquitination. Using a siRNA library screening approach, we identified novel E3 ligase candidates that may be responsible for SNAIL ubiquitination and degradation downstream of PTK6 inhibition. Conclusion/Future direction: PTK6 is a representative novel regulator of EMT and anoikis resistance that can be targeted to prevent metastases of TNBC. Modulation of mesenchymal phenotypes of TNBC cells may be able to regulate chemotherapy resistance and/or immunosuppressive microenvironment.
Title: Preclinical evidence that distant metastases occur via the lymphatic route

Patrick L Leslie¹, Subrata K Ghosh¹, Alessandro Porrello¹, Brian C Cooley¹ and Chad V Pecot¹. ¹University of North Carolina, Chapel Hill, NC.

Body: Cancer that metastasizes beyond the lymph nodes is almost invariably terminal. Therefore, understanding how cancer metastasizes is a critical aspect to understanding and eventually preventing cancer spreading from tissue to tissue. A major question that remains controversial is whether cancer cells that metastasize to the LNs are able to physically leave the LNs to colonize distant tissues. Moreover, whether cancer cell metastasis between different tissues involves unique genes is a question that requires further research. Using the metastatic mouse breast carcinoma line 4T1 in an LN microinjection model, we provide evidence suggesting that cancer cells can indeed metastasize and colonize distant tissues after direct implantation into the LNs. Interestingly, direct comparison of distant tissue metastatic capability comparing LN-microinjected cells and tail vein-injected cells suggests that the lymphatic route of cancer cell spreading may be a more efficient mechanism of metastasis than the hematogenous route. Moreover, our comparative transcriptome analysis results suggest that LN metastases show unique gene expression profiles relative to the primary breast tumors and distant metastases. We identified several genes that are up- or down-regulated in an LN-specific manner and thus may play a role in metastasis to the LNs and beyond. Collectively, our results suggest that LN metastases constitute an active “staging site” from which breast cancer cells can further metastasize to distant sites. Furthermore, we identify a unique set of genes that may be involved in the breast cancer metastatic process, several of which are potentially targetable using currently available inhibitors.

**Title:** Mutational profiling of breast cancer brain metastases – matched pair analysis of next generation sequencing between primary breast cancer and later developed brain metastases

Anna Thulin¹, Carola Andersson¹, Elisabeth Werner Rönnerman², Shahin De Lara², Chaido Chamalidou³, Arnd Schoenfeld⁴, Anikó Kovacs², Fredrik Enlund² and Barbro K Linderholm¹. ¹Sahlgrenska Academy and University Hospital, Gothenburg, VGR, Sweden; ²Sahlgrenska Academy and University Hospital, Gothenburg, VGR, Sweden; ³Södra Älvsborgs Hospital, Borås, VGR, Sweden and ⁴Norra Älvsborgs Hospital, Trollhättan, VGR, Sweden.

**Body: Background:** Despite increased survival in patients with advanced breast cancer, breast cancer brain metastases (BCBM), remains a final frontier with a mean survival of 3-12 months. The biology facilitating BCBM is not fully understood.

**Aims:** To compare gene expression profiles in primary BC, and later diagnosed, surgically removed BCBM.

**Material and Methods:** A total of 58 BCBM and 46 breast tumors were analyzed with next generation sequencing (NGS). DNA was isolated from FFPE sections and then the Cancer Hotspot Panel v2 (ThermoFisher Scientific) covering 207-targeted regions in 50 cancer related genes was used. Template preparation and enrichment were performed with the IonChef™ Instrument (ThermoFisher Scientific). Eight barcoded samples were pooled per Ion 318™ v2 BC chip and sequenced on the Ion PGM™ System (ThermoFisher Scientific). Alignment to the hg19 human reference genome and variant calling was performed by the Torrent Suite Software v5.2.0 (ThermoFisher Scientific) also IonReporter™ System (ThermoFisher Scientific) was used.

**Results:** 46 of the BCBM were matched with a primary breast cancer tumor. All but 12 tumors had the same IHC characteristic in the matched pairs. The most common transformation was Luminal A to Luminal B in 8 tumors. The other changes were triple negative subtype (TNBC) to Luminal B, HER2+ to Luminal B, Luminal A to TNBC and Luminal A to HER2+ with one case respectively. The BCBM had the following IHC profile: one tumor was luminal A (1%), 15 tumors were Luminal B (25%), 29 were TNBC (50%) and 14 HER2 overexpressing (24%). The preliminary NGS data shows that the most common mutation in BCBM was found in the tumor suppressor gene p53 (22/58, 38%). Other common mutations were PIK3CA (17/58, 29%); KDR (16/58, 28%), KIT (9/58, 16%) and PTEN (2/58, 3%). The corresponding figures in the primary BC were p53 (15/46, 33%), PIK3CA (16/46, 35%), KDR (17/46, 37%), KIT (7/46, 15%) and no tumors with PTEN. The mutational spectra in the 50 cancer related genes were similar in the primary BC as in the BCBM with 1-5 different driver mutations but additional mutations were registered in 6/46 matched cases (13%). We fail to identify any specific differences in mutations between the different morphological subtypes (LumA/LumB/TNBC/HER2+) in the metastatic sample. In the NGS analysis of the metastases and primary tumors 3 different variations of p53 was detected.

**Conclusions:** In this large matched pairs of primary breast tumors and BCBM we show that the majority of BCBM have a similar gene profile as the primary BC. The most common aberrations were found in TP53, PIK3CA and KDR. Additional post analyses are under investigation and will be added to the results. It appears that brain metastases are not different from other metastases in that they remain fairly stable in their driver mutational profile. When the mutational profile changes there is addition of mutation rather than deletion. A clinical implication of these results could be to treat BCBM according to the mutational profile of the primary tumor which decreases the need for sampling of BCBM; something that if the patient is not eligible for surgery might otherwise prove complex.
Title: Wnt5a induces ROR1 to associate with cortactin, which undergoes tyrosine phosphorylation, and enhances migration of breast cancer cells

Md Kamrul Hasan¹, Victoria Tripple¹, George F Widhopf II¹, Jian Yu¹, Suping Zhang¹, Barbara A Parker¹ and Thomas J Kipps¹.
¹Moores Cancer Center, University of California San Diego, La Jolla, CA.

Body: Background: ROR1 is an evolutionarily conserved, oncoembryonic surface-antigen expressed in breast cancer. Previously, we found that ROR1 can serve as a receptor for Wnt5a, which can induce non-canonical Wnt signaling that enhances cancer-cell migration. Recently we found that Wnt5a could induce ROR1 to complex with a cytoskeletal protein designated HS1, which recruited ARHGEF1, enhanced activation of RhoA, and promoted leukemia-cell migration. These effects of Wnt5a on CLL cells could be inhibited by cirtuzumab, a humanized, high-affinity monoclonal antibody (mAb) specific for ROR1. As expression of HS1 is limited to hematopoietic cells we examined breast cancer cell lines and primary breast cancer cells for expression of cortactin. Cortactin (also called EMS1), is a cytoskeletal protein, which is homologous in structure and function to HS1 and is broadly expressed in human cancers, including breast cancer.

Methods: We performed immunoprecipitation studies using high-affinity mAb to ROR1 or cortactin and immunoblot analysis to examine for the association of ROR1 with cortactin and tyrosine phosphorylation of cortactin at Y421. We also assessed the expression levels of cortactin, ROR1, and ARHGEF1, in the MCF7 breast cancer cell line and in breast-cancer patient-derived xenografts (PDX). We also generated MCF7-ROR1 cells, which were stably transfected to express ROR1 or various mutant forms of ROR1 generated to study the structure-function requirements for effective ROR1-cortactin interactions.

Results: We found that ROR1 associates with cortactin in freshly-isolated breast cancer PDX tumors or in PDX cells cultured with exogenous Wnt5a. We corroborated these results in breast cancer cell line MCF7-ROR1 cells, which were transfected to express ROR1 and found to migrate more effectively than the parental MCF7 lacking expression of ROR1. Wnt5a also induced cortactin tyrosine phosphorylation at Y421, recruitment of ARHGEF1, and activation of RhoA, which we found associated with enhanced breast-cancer cell migration. The capacity of Wnt5a to induce such changes could be blocked by treatment of the cells with cirtuzumab. We generated truncated forms of ROR1 without a proline-rich domain (PRD) and found PRD was necessary for this association or Wnt5a-induced cortactin phosphorylation and enhanced cancer-cell migration. Accordingly, we introduced single amino-acid substitutions of proline (P) to alanine (A) in the ROR1-PRD at positions 784, 808, 826, or 841 in potential SH3-binding motifs. In contrast to wild-type ROR1, or other ROR1P→A mutants, ROR1P(841)A had impaired capacity to recruit cortactin and ARHGEF1 to ROR1 in response to Wnt5a. Moreover, Wnt5a could not induce cells expressing ROR1P(841)A to phosphorylate cortactin or activate ARHGEF1, and was unable to enhance the motility of the MCF7 cells transfected with this mutant form of ROR1.

Conclusions: Collectively, these studies indicate the capacity of cortactin to complex with ROR1 plays an important role in ROR1-dependent Wnt5a-enhanced breast cancer cell migration. These studies also demonstrate that cirtuzumab can inhibit the formation of cortactin-ROR1 complexes, cortactin phosphorylation, and cancer-cell migration, and metastasis.
Title: Targeting the SphK1/S1P/S1PR1 axis that connects obesity, chronic inflammation, and breast cancer metastasis

Masayuki Nagahashi¹,²,³, Akimitsu Yamada²,³, Tomoyoshi Aoyagi²,³, Wei-Ching Huang²,³, Krista P Terracina²,³, Nitai Hait⁴, Jeremy C Allegood⁵, Junko Tsuchida¹, Masato Nakajima¹, Eriko Katsuta²,³,⁴, Sheldon Milstien³, Toshifumi Wakai¹, Sarah Spiegel³ and Kazuaki Takabe²,³,⁴,⁵. ¹Niigata University Graduate School of Medical and Dental Sciences, Niigata City, Japan; ²Virginia Commonwealth University School of Medicine, Richmond, VA; ³Virginia Commonwealth University School of Medicine, Richmond, VA; ⁴Roswell Park Cancer Institute, Buffalo, NY and ⁵University at Buffalo the State University of New York, Buffalo, NY.

Body: Introduction: Obesity with associated inflammation is now recognized as a risk factor for breast cancer and increased incidence of distant metastases. However, the link between obesity and breast cancer progression remains poorly understood. There is growing evidence that sphingosine-1-phosphate (S1P), a pleiotropic bioactive sphingolipid metabolite enriched both in blood and lymphatic fluid is involved in inflammation, obesity, and breast cancer progression. Our hypothesis is that obesity increases levels of S1P in both tumor and its microenvironment, which play a role in obesity-induced inflammation and breast cancer metastasis. The aim of this study is to test this hypothesis in in vitro and in vivo as well as patient settings.

Methods: Levels of sphingolipids including S1P in serum from breast cancer patients were quantified. Orthotopically-implanted E0771 syngeneic breast cancer and MMTV-PyMT transgenic breast cancer mouse models were used. Mice were fed with normal or high-fat diet (HFD). FTY720 was administered orally (1 mg/kg/day). To examine pre-metastatic niche formation, a mouse model utilizing tail vein injection of E0771 cells was used. In this model, mice were treated with conditioned media from E0771 breast cancer cells overexpressing SphK1 (K1-CM) or that from E0771 cells cultured with the vector control (CT-CM), prior to tail vein injections of naive E0771 cells. S1P levels were determined by electrospray ionization-tandem mass spectrometry.

Results: We found that obesity significantly increased S1P levels in serum from breast cancer patients. In animal breast cancer models, HFD upregulated expression of sphingosine kinase 1 (SphK1), the enzyme that produces S1P, and its receptor S1PR1 in syngeneic and spontaneous breast tumors. HFD also significantly increased S1P in breast tumors and in the tumor interstitial fluid, which is a component of the tumor microenvironment and bathes cancer cells in the tumor. Targeting the SphK1/S1P/S1PR1 axis with FTY720/fingolimod attenuated obesity-induced key pro-inflammatory cytokines, macrophage infiltration, and tumor progression. In addition, S1P produced by tumor SphK1 primed lung pre-metastatic niches, increased macrophage recruitment into the lung, and induced IL-6 and signaling pathways important for lung metastatic colonization. FTY720 suppressed HFD-induced lung IL-6 and macrophage infiltration as well as S1P-mediated signaling pathways and dramatically reduced formation of metastatic foci. In tumor bearing mice, FTY720 also suppressed obesity-related inflammation, S1P signaling, pulmonary metastasis, and prolonged survival.

Conclusion: Our results highlight a critical role for circulating S1P produced by tumor and the SphK1/S1P/S1PR1 axis in obesity-related inflammation, metastatic niche formation and breast cancer metastasis and suggest that targeting the SphK1/S1P/S1PR1 axis would be a useful therapeutic for obesity promoted metastatic breast cancer.
Clinical and histological characteristics of peritoneal metastases of invasive lobular breast cancer

Maria M Karsten¹, Barbara Ingold-Heppner², Steffi Oesterreich⁴, Steffen Sander⁴, Anna Machleidt¹, Gabriel von Waldenfels¹, Carsten Denkert² and Jens U Blohmer¹. ¹Charité Klinik für Gynäkologie mit Brustzentrum, Berlin, Germany; ²Charité Institut für Pathologie, Berlin, Germany; ³Charité Comprehensive Cancer Center, Berlin, Germany and ⁴Magee Women`s Research-Institute, Pittsburgh, PA.

Body: Introduction: In previously reported autopsy series, peritoneal metastases have been detected in up to 40% of patients with invasive lobular breast cancer (ILC). Despite modern diagnostic techniques such as high-resolution ultrasound, it remains a challenge to differentiate ovarian cancer from metastatic breast cancer with peritoneal manifestation before or during surgery. The goal of this analysis was to determine typical clinical and immunohistological features of peritoneal metastasis of ILC. Specifically, we asked the question whether there are predictive factors in primary breast cancer associated with subsequent development of peritoneal metastasis. Patients and methods: We identified 58 patients with ovarian metastases in the Charité cancer register (4,792 breast cancer patients from 2003 to 2015). We looked for clinical and pathological differences between breast cancer patients with (N=58) and without (N=4734) peritoneal metastases and between ILC and non-ILC breast cancer subtypes. Imaging and surgical reports of these 58 patients with ILC intraperitoneal metastases were reviewed. Results: The majority (84.7%) of primary breast cancers consisted of subtypes other than ILC and only 15.3% were histologically characterized as ILC. In contrast, 63.6% of patients with peritoneal metastases had histologically proven ILC in the metastatic tissue. Other subtypes where found in the 36.4% of the metastatic tissue (p<0.001). The Odds ratio for peritoneal metastases for ILC was 2.35 (95% CI 1.655-3.332) and for Non-ILC 0.23 (0.185-0.284). There were no significant differences in receptor status between primary and peritoneal metastatic ILC. Comparing ER/PR expressions levels on primary tumor versus metastasis, while statistically not significant (p=0.805), showed a rise in ER expression in 42.95% in the metastatic tissue while PR expression remained stable with no difference in 53.3% and a rise in the metastatic site in only 26.7% (p=0.715). Median age of all patients with primary breast cancer was 60 years (10%-90%: 41-75). There was a significant difference in age at diagnosis of metastasis between patients with (50.5 years) and without peritoneal metastases (59 years) (p= 0.002). Median time to development of peritoneal metastases for all patients was 48.5 months (10%-90%: 0-191.7), for ILC 44 months (0-198.2) and for Non-ILC 56.5 months (6.7-206.4) (p= 0.487). Median survival time for patients with ILC and peritoneal metastases was 56 months, for Non-ILC 53 months (p=0.759). 33 of 58 patients had radiologic evidence of disease, 26 with ILC and 7 with Non-ILC. An ovarian mass was detected by imaging in 15/26 patients with ILC and 4/7 patients with non-ILC. Ascites and diffuse peritoneal metastases were seen in 18/26 patients with detectable ILC and in 4/7 patients with Non-ILC. Conclusion: This is the first comprehensive analysis of clinical and pathological characteristics of peritoneal metastases showing ILC is more frequent than other histologic subtypes. Patients with peritoneal metastasis are significantly younger (median 50.5y.) than patients without. The clinical signs are similar to those of ovarian cancer except and therefore the diagnosis of metastatic ILC must be taken into consideration as a differential diagnosis.
Title: DPYSL3 modulates proliferation and migration in claudin-low breast cancer

Ryoichi Matsunuma¹, Doug W Chan¹, Beom-Jun Kim¹, Purba Singh¹, Airi Han¹, Anna Malovannaya², Charles M Perou³ and Matthew J Ellis¹. ¹Lester and Sue Smith Breast Center, Baylor College of Medicine, Houston, TX; ²Baylor College of Medicine, Houston, TX and ³Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC.

Body: Cancer is often driven by deregulated protein kinases pathways including breast cancer. To profile the kinome at the protein level we are developing a kinase pulldown (KiP) proteomic platform that uses multiple kinase inhibitors conjugated to sepharose beads for protein kinase profiling. Mass spectrometry-base tryptic peptide sequencing is used to identify and quantify the kinome in an unbiased manner. To date, we have profiled and analyzed the kinomes of more than 50 breast cancer PDX model systems that include all five breast cancer subtypes. In these analyses we have begun to explore the kinome interactome because we have observed that KiP also pulls down breast cancer subtype specific kinase interacting proteins that may represent new biological insights. For example we have consistently identified dihydropyrimidinase-like 3 (DPYSL3) in p21-activated kinase (PAK) inhibitor KiP interactome in the claudin-low WHIM12 PDX model.

DPYSL3 is an intracellular phosphoprotein known to play a role in cell migration and metastasis. However it remains to be seen if DPYSL3 functions as a suppressor or a promoter of metastasis. We therefore generated DPYSL3 knock-down cell lines to evaluate function in claudin-low breast cancer. Proliferation levels of DPYSL3 depleted Claudin-low WHIM12 cells (DPYSL3-) were lower than those of control WHIM 12 (DPYSL3+) cells. In contrast, migration levels of DPYSL3- WHIM12 were greater than those of control cells, suggesting a pivotal role for DPYSL3 in several cellular physiologies. Additionally the activity of a PAK inhibitor (FRAX597) on migration appeared to require DPYSL3, as the inhibitory effect of FRAX579 on migration in WHIM12 was lost when DPYSL3 expression was depleted.

Additionally we find that only the long isoform of DPYSL3, not a short isoform, interacts with PAK to regulate migration, suggesting that alternative splicing of DPYSL3 may an important to the control of migration. Furthermore Snail is also negatively regulated DPYSL3 with elevated expression in DYPSL3- cells.

In conclusion, the study of the kinome interactome in breast cancer PDX identified DPYSL3 as regulator of the PAK family of kinases in a claudin low breast cancer. DPYSL3 is necessary for PAK to promote migration and may play a pivotal role in complex cellular transitions from a proliferative state versus an EMT/cell migratory state.

Title: BMP4 suppresses the progression of breast cancer through altered expression of metastasis regulating genes

Andrew D Redfern¹, Bedrich L Eckhardt², Yuan Cao³, Erica K Sloan⁴, Belinda S Parker⁵, Sherene Loi⁶, Naoto T Ueno², Peter K Lau⁶, Bruce Latham⁷ and Robin L Anderson⁸. ¹University of Western Australia, Perth, Western Australia, Australia; ²The University of Texas MD Anderson Cancer Center, Houston, TX; ³the University of Melbourne, Melbourne, Victoria, Australia; ⁴Monash Institute of Pharmaceutical Sciences, Monash University, Melbourne, Victoria, Australia; ⁵La Trobe University, Bundoora, Victoria, Australia; ⁶Peter MacCallum Cancer Centre, Melbourne, Victoria, Australia; ⁷Fiona Stanley Hospital, Perth, Western Australia, Australia and ⁸Olivia Newton-John Cancer Research Institute, Melbourne, Victoria, Australia.

Body: Metastasis is a lethal manifestation of cancer, the development of which is the major cause of death in cancer patients. During a search for metastasis-regulating elements, an inverse correlation was identified between the in vivo tumor expression of bone morphogenetic protein-4 (BMP4) and spontaneous metastasis in a panel of isogenic mammary tumors of varying metastatic capacity. BMP4 is an essential morphogen in development, regulating cellular mechanisms akin to those in metastasis, including cellular differentiation, pluripotency and apoptosis. We therefore initiated an investigation of the impact of BMP4 expression on the metastatic process.

We studied the effect of enforced expression of BMP4 in a highly metastatic mammary tumour model called 4T1.2, comparing in vitro properties and tumour progression in mice. There were no differences in proliferation in vitro or when implanted into the mammary gland of immunocompetent mice. In contrast, mice bearing equivalent-sized 4T1.2-BMP4 tumors revealed dramatically reduced metastasis to lung, lymph node and bone. In a parallel study where the established orthotopic primary tumor was resected, survival was significantly extended in mice bearing 4T1.2-BMP4 tumors. Enforced BMP4 expression in tumor cells introduced intravenously resulted in a 2.5-fold decrease in lung metastatic burden, consistent with the impaired capacity of tumor cells to survive in circulation and colonize the lung. Conversely, silencing BMP4 expression in separate weakly metastatic tumours enhanced their ability to colonize the lung and shortened the survival of the mice. No changes were found in the ability of tumor cells expressing BMP4 or treated with recombinant BMP4 to migrate or invade through Matrigel in chemotactic assays but BMP4 enhanced anoikis in both mouse and human breast cancer cells, indicating that BMP4 sensitizes disseminated cells to anoikic stresses induced by cell-substrate detachment and shear flow during systemic transit. BMP4 activated canonical BMP-SMAD signaling in our mammary tumours, leading to altered expression of known metastasis-regulating genes, including SMAD7. SMAD7 depletion in metastasis-deficient 4T1.2-BMP4 tumors accelerated the onset of metastatic disease.

In a meta-analysis of 3,587 breast cancer patients in publically available datasets, low BMP4 mRNA expression was significantly associated with reduced relapse-free survival (RFS) (HR = 0.85, P = 0.01). In an independent analysis using the BreastMark algorithm, low levels of BMP4 mRNA were associated with reduced RFS (HR = 0.88, P = 0.035), distant metastasis-free survival (HR = 0.83, P = 0.035) and overall survival (HR = 0.78, P = 0.006). At the protein level, in a tissue microarray from 415 treatment naïve patients, improved overall survival was observed in multivariate analysis for both BMP4 (HR = 0.66, P = 0.037) and SMAD7 expression (HR = 0.64, P = 0.035) individually. Expression of both proteins compared to neither further improved OS (HR = 0.55, P = 0.005).

In summary, we found strong evidence that BMP4 is a metastasis suppressor correlating inversely with metastatic potential in preclinical breast cancer models and predicting improved relapse-free and overall survival in breast cancer patients.
Title: Expression of adipocyte fatty acid binding protein promotes obesity-associated mammary tumor growth

Edward R Sauter, Bing Li, Jiaqing Hao and Maijing Kong. 1University of Connecticut School of Medicine, Farmington, CT and 2University of Louisville School of Medicine, Louisville, KY.

Body: Background: Obesity increases the risk of many types of cancer, including breast cancer. The underlying mechanisms that drive obesity-related breast cancer remain unclear. Fatty Acid Binding Proteins (FABPs) are a family of cytosolic proteins which are organ specific and coordinate lipid transportation. Adipocyte FABP (A-FABP) is highly expressed in adipose tissues and may provide a link to obesity-associated breast cancer risk. We previously observed that A-FABP serum levels were associated with obesity, and decreased with surgically induced weight loss. In this report, we evaluate the role of A-FABP in promoting obesity-associated mammary tumor growth.

Hypothesis: Deficiency of A-FABP in mice decreases obesity-associated mammary tumor progression.

Methods: Weaned wild type control and A-FABP-deficient (genetically depleted A-FABP/-) female mice (n=15/group) were randomly grouped and fed either a high fat diet (HFD) (60% fat) or a low fat diet (LFD) (10% fat). After 6 months on the diets, serum was collected from the tail vein and measured for levels of circulating A-FABP by ELISA. E0771 mammary tumor cells (0.5x10^6/mouse) were injected into the mammary fat pad and tumor volume measured at 3-day intervals. The student's t-test was used to compare A-FABP levels and ANOVA to compare tumor sizes in the lean and obese mice.

Results: HFD-fed control mice exhibited a significant increase in body weight (31.5±2.13g) compared to LFD-fed control mice (19.86±0.36) (p<0.01). Serum levels of A-FABP were correspondingly elevated in obese (104.9±8.3 ng/ml) vs. lean controls (31.8±5.4 ng/ml) (p<0.01). Interestingly, although A-FABP deficient mice fed a HFD were more obese than HFD-fed control mice (final body weight 43.4g vs. 31.5g) (p<0.05), tumor growth in the A-FABP deficient mice was significantly less than in controls (p<0.0001), suggesting that A-FABP expression is critical for obesity-associated mammary tumor growth. Long term tumor growth in lean A-FABP deficient vs. control mice was not significantly different. Thus, A-FABP deficiency appears to uncouple obesity and mammary tumor growth in HFD-induced obese mice. Impact: A-FABP is associated with obesity related breast/mammary cancer, and appears to be an important driver of tumor development. Downregulation of this protein may be useful to prevent and/or treat these tumors.

**Title:** The small Rho GTPase Rho A activation mediates the inhibitory effect of microRNA-200b on triple negative breast cancer cell migration and tumor metastasis

Zhishan Wang¹, Brock Humphries², Yunfei Li¹ and Chengfeng Yang¹. ¹University of Kentucky, Lexington, KY and ²Michigan State University, East Lansing, MI.

**Body:** The small Rho GTPases are master regulators of cellular actin cytoskeleton reorganization and focal adhesion dynamic turnover. Many studies including ours have shown that active Rho GTPases promote cancer cell survival, proliferation, migration and tumor metastasis. Therefore, Rho guanine nucleotide exchange factors (Rho-GEFs), positive regulators of Rho GTPases, are generally thought having oncogenic functions; Rho GTPase-activating proteins (Rho-GAPs), negative regulators of Rho GTPases, are usually considered having tumor suppressive functions. Triple negative breast cancer (TNBC) refers to a group of highly heterogeneous malignant tumors that lack estrogen receptor and progesterone receptor expression, and human epidermal growth factor receptor 2 amplification, accounting for 10-20% of newly diagnosed breast cancer cases. Compared to other subtypes of breast cancer, TNBCs usually show worse clinical features such as rapid tumor growth, earlier recurrence, and more aggressive metastasis. Unfortunately, the mechanism of TNBC metastatic behavior has not been well understood. In this study, we investigated the effect of miR-200b, one member of the miR-200 family, on TNBC metastasis using cell culture and mouse orthotopic mammary xenograft tumor models. We found that the expression level of miR-200b is significantly lower in TNBC cells and tissues than that in other types of breast cancer. Stably expressing miR-200b significantly reduced TNBC cell migration and invasion and suppressed TNBC metastasis in a mouse orthotopic mammary xenograft tumor model. Mechanistic studies revealed that miR-200b overexpression in TNBC cells caused drastic changes in cellular actin cytoskeleton organization patterns as evidenced by reduced lamellipodia formation but increased stress fiber formation. In consistent with these findings, Rho GTPase pulldown assays demonstrated that stably expressing miR-200b significantly increased the Rho GTPase Rho A activation, but reduced the Rho GTPase Rac1 activation. Moreover, inhibition of Rho A signaling impaired the inhibitory effect of miR-200b on TNBC cell migration. Bioinformatics analysis indicated that ARHGAP18, a specific Rho-GAP, is a predicated target of miR-200b. Further Q-PCR, Western blot and 3’UTR reporter analysis confirmed that ARHGAP18 is a target of miR-200b. Knocking down ARHGAP18 in TNBC cells using siRNAs significantly increased Rho A activation but reduced Rac1 activation. To further determine the role of ARHGAP18 in TNBC, ARHGAP18 knockout TNBC cells were generated using the CRISPR technology. It was found that knockout ARHGAP18 photocopied the effect of miR-200b overexpression. Moreover, overexpressing ARHGAP18 in miR-200b stable expression cells overcome the inhibitory effect of miR-200b on TNBC metastasis. This study identifies a new mechanism by which miR-200b suppresses TNBC cell migration and tumor metastasis. Moreover, it also demonstrates that ARHGAP18, a Rho-GAP, is essential for TNBC cell growth, migration, tumor growth and metastasis, opposing current dominant view of tumor suppressive roles of Rho-GAPs.
Title: Expression of autophagy related genes impacts clinical outcomes of human breast carcinoma and is associated with estrogen and progestin receptor status

James L Wittliff, Zohair R Hameed, Michael W Daniels and Alan Cheng. 1University of Louisville, Louisville, KY and 2University of Colorado at Aurora, Aurora, CO.

Body: The dual role of autophagy in breast cancer initiation, progression and responsiveness to various therapies is the focus of extensive studies. Our goal is to assess the relationship of expression of certain autophagy related genes in primary breast carcinomas to predict risk of recurrence. Our hypothesis includes the caveat that unique gene expression subsets will be deciphered by utilizing Laser Capture Microdissected breast carcinoma cells from tissue biopsies containing many cell types.

Methods: Comprehensive analyses of de-identified biomarker results, characteristics of 247 breast carcinoma specimens and clinical outcomes were performed by univariable Cox regressions, Kaplan Meier plots and LASSO with R software version 3.2.5. Microarray analyses were performed on RNA isolated from LCM-procured carcinoma cells to identify gene signatures associated with breast cancer behavior.

Results: Expression levels of 22 autophagy related genes analyzed by univariable Cox regression revealed that RB1CC1, KEAP1, ATG7, RUBCN, NOD2, HMOX1, BECN1, PIK3R4 were significant for predicting Progression Free Survival (PFS) at the discovery level of the adjusted p-value < 0.3. Of these, RB1CC1, KEAP1, & ATG7 were significant for Overall Survival (OS) without regard to ER/PR status. Using Kaplan Meier analyses, expression levels of each of 10 candidate genes predicted PFS of which expression of 6 of these genes also predicted OS using a median split cutoff without regard to ER/PR status. Applying LASSO computations without regard to ER/PR status of the primary breast cancer, a clinically relevant gene expression profile consisting of ATG7, BCL2, HMOX1, KEAP1, NOD2, PTEN, RB1CC1, and ULK4 predicted PFS. Collectively, expression of these 8 genes with TP53 and RUBCN predicted OS without regard to ER/PR status. Violin plots of relative gene expression of each of the 22 candidate genes known to be associated with autophagy pathways revealed that ATG7, ATG12, BCL2 and BECN1 were elevated in ER+ lesions while BCL2 and BECN1 were also elevated in PR+ breast carcinomas. Expression levels of 16 of the 22 autophagy related genes examined by univariable Cox regression were related to either ER or PR status of the primary lesion and predicted either PFS or OS. Refinement of clinically relevant gene subsets was accomplished by LASSO calculations in which either the ER or PR protein status of the primary breast carcinoma was considered. Of the genes in the molecular signatures derived, expression levels in breast carcinomas separated by either ER or PR status of the lesion were tested by Kaplan Meier analyses to assess relationships to PFS and OS.

Conclusions: Using gene expression results derived from microarray analyses of LCM-procured breast carcinoma cells of primary lesions, subsets of autophagy related genes were identified that predict a patient's risk of recurrence and overall survival. Expression of a number of candidate genes appears to be related to either/both the ER or PR protein status of the primary lesion. Collectively, results suggest that expression of certain autophagy related genes may serve as biomarkers for assessing prognosis of breast carcinoma thus impacting clinical management of breast cancer.
Title: Mucin-2 (Muc-2) modulates the biology of breast cancer

Anna Astashchanka\textsuperscript{1}, Thomas Shroka\textsuperscript{1} and Britta M Jacobsen\textsuperscript{1}. \textsuperscript{1}University of Colorado School of Medicine, Aurora, CO.

Body: Background: Metastasis and therapeutic resistance are major issues in treating patients with breast cancer. Breast tumors that secrete mucus are generally resistant to chemotherapy. One type of secreted mucin, Mucin-2 (Muc2), is expressed in some breast cancers, but is absent in non-neoplastic breast tissue, suggesting that it plays a role in modulating breast cancer biology. Whether Muc2 expression correlates with breast cancer patient survival is controversial. Thus, the effects of Muc2 on the biology of breast cancer are largely unknown. This study examined the role of Muc2 in modulating breast cancer cell proliferation in vitro and in vivo, response to chemotherapy, and metastasis.

Methods: Two novel cell lines were developed from patient derived tumor xenografts. These two cell lines, BCK4 and PT12, both express high levels of Muc2. In order to modulate Muc2 levels in both cell lines, shRNA targeted to Muc2 (shMuc2) were compared to non-targeting control shRNA (shNT). Decreased expression of Muc2 was confirmed using immunoblotting. Proliferation in vitro was measured using the Incucyte live cell imaging system and crystal violet staining. Response to chemotherapy was measured by examining apoptosis using cleaved-caspase 3 expression. BCK4 and PT12 cells with shNT or shMuc2 were grown as solid tumors in immunocompromised mice and tumor volume measured by caliper. BCK4 cells with high Muc2 (shNT) and low Muc2 (shMuc2) were labeled with luciferase and examined in an experimental metastasis model where total disease was monitored by IVIS imaging.

Results: Decreased Muc2 expression decreased proliferation in BCK4 and PT12 cells versus non-targeting control cells both in vitro and in vivo. Treatment with the chemotherapeutic Docetaxel induced minimal apoptosis in BCK4 control cells with high Muc2 however, apoptosis was significantly increased in BCK4 cells with reduced Muc2. In an experimental metastasis model, mice injected with BCK4 cells containing low Muc2 had decreased disease burden versus those injected with control cells with high Muc2. Endogenous Muc2 expression in wild-type BCK4 cells increased with addition of EGF and this effect was abolished by addition of the EGF-receptor inhibitor, Erlotinib.

Conclusions: Muc2 expression plays an important role in mediating proliferation, apoptosis and metastasis of breast cancer cells. These data suggest that Muc2 is important in controlling the biology of Muc2 positive breast tumors. In addition, Muc2 may be important in guiding treatment and predicting outcomes in breast cancer patients.
The hemidesmosome protein collagen 17A1 is required for collective invasion and growth of mammary tumor organoids

Erin Greenwood¹, Paula Cane Gasull¹, Breanna Moore¹ and Kevin Cheung¹. ¹Fred Hutchinson Cancer Research Center, Seattle, WA.

**Background:** Invasion is a fundamental step in metastasis, the leading cause of breast cancer-related death. We have shown previously that primary breast tumors invade collectively as clusters of cancer cells (Cheung et al. Cell 2013). These clusters are led by a small subpopulation of cancer cells that highly express the basal epithelial protein cytokeratin 14 (K14) and other stem cell genes (Cheung et al. PNAS 2016). K14+ leader cells metastasize as clusters, reverting to a proliferative growth state upon colonization of a secondary site (Cheung and Ewald. Science 2016). The mechanisms regulating their transitions between collective invasion and growth states remains poorly understood. Understanding these mechanisms could produce new insights into tumor cell collectivity and uncover new ways to treat disseminated cell clusters that have already metastasized.

**Results:** RNA-seq analysis of K14+ and K14- tumor cells revealed that K14+ tumor cells have increased expression of genes encoding the hemidesmosome, a major adhesion complex that plays an essential role in anchoring epithelial cells to the basement membrane. The highest upregulated hemidesmosome gene was collagen 17A1 (COL17A1), a transmembrane protein and structural component of the hemidesmosome that is involved in cell migration during wound healing and tissue regeneration. Consistent with these RNA-seq data, we observed by IF staining in vivo that K14 and COL17A1 are typically co-expressed in collective invasive strands at the invasive front of MMTV-PyMT mammary carcinomas.

We next applied ex-vivo 3D culture assays to determine the function of COL17A1 in K14+ cell invasion and proliferation. In mammary tumor organoids we observed that COL17A1 is expressed in basal K14+ tumor cells. However, while the COL17A1 endodomain is uniformly expressed, the ectodomain is expressed in patches, indicating active ectodomain cleavage, a process that reduces cellular motility (Franzke et al. The EMBO Journal 2002). Surprisingly, loss of total COL17A1 expression by shRNA-knockdown significantly impairs tumor organoid growth ~2 fold and prevents invasion in basement membrane rich matrigel. Further studies are underway to investigate the role of COL17A1 during collective invasion in other extracellular matrix environments.

**Conclusions:** Taken together, our data shows that invasive leader cells express COL17A1 in 3D culture and in vivo and that this protein is required for tumor organoid invasion and growth. Therefore, therapeutically targeting COL17A1, a cell surface protein, could prevent both the migratory and proliferative phases of breast cancer metastasis. We are currently investigating how COL17A1 and its shed COL17A1 ectodomain enable leader cells to toggle between invasive and proliferative states.
Title: Investigation of phosphoserine aminotransferase 1 and its role in breast cancer progression

Stephanie Metcalf, Traci Kruer, Carolyn Klinge and Brian Clem. 1University of Louisville School of Medicine, Louisville, KY.

Body: Metastasis and endocrine resistance are two factors that complicate therapeutic intervention in breast cancer patients and lead to poorer overall survival. Metastasis is known to be responsible for 90% of cancer related deaths, and is especially prevalent in triple negative breast cancer (TNBC); while endocrine resistance can affect up to 50% of patients diagnosed with estrogen receptor positive breast cancer (ER+BC). Phosphoserine aminotransferase 1 (PSAT1) catalyzes the second step within de novo serine biosynthesis and increased expression of enzymes in this pathway have been linked to progression of breast cancer and poor clinical outcomes. Within our preliminary retrospective analysis of human breast cancer patients, we identified an inverse association with elevated transcript levels and poorer distant metastasis free survival, which, coupled to a previously reported correlation of PSAT1 with response to endocrine therapy in patients with ER+BC, we postulate that PSAT1 contributes to breast cancer progression through promotion of metastasis and/or endocrine resistance. To initially determine relevance for PSAT1, immunohistochemistry was performed to determine PSAT1 expression in human breast cancer patients. We found that PSAT1 expression is increased through breast cancer progression, with highest levels observed within metastatic conditions. To investigate the metastatic contribution of PSAT1, we silenced PSAT1 expression within the triple negative breast cancer cell line (TNBC), MDA-MB-231. While suppression of PSAT1 had no effect on proliferation, there was a significant decrease in the motility and invasion of these cells. In addition, decreased PSAT1 substantially inhibited lung metastasis following tail-vein injections of MDA-MB-231 cells in vivo. To investigate PSAT1's role in endocrine resistance, we used parental MCF-7 cells and an endocrine-resistant derivative cell line (LY2) and found that LY2-resistant cells exhibited higher PSAT1 expression compared to parental MCF-7 cells. Lastly, suppression of PSAT1 was able to sensitize the LY2 cells to 4-hydroxytamoxifen treatment. Taken together, these data indicate that PSAT1 may contribute to the progression of human breast cancer via either metastasis or endocrine resistance or both and could potentially serve as a viable target for new therapies.
Title: Detection of disseminated tumor cells in DCIS patients impacts local recurrence

Vincent P Walter¹, Florin-Andrei Taran¹, Markus Wallwiener², Sara Y Brucker¹ and Andreas D Hartkopf¹. ¹University of Tuebingen and ²University of Heidelberg.

Body: Background
Recently it was shown that tumor cell dissemination is an early event in breast cancer progression (Hosseini et al., Nature 2016). This has been backed up by an assessment of over 100,000 patients with in situ carcinoma (DCIS), where some patients developed distant metastases and died from breast cancer without presenting with local invasive recurrence (Narod et al., JAMA Oncology 2015). We therefore analyzed the presence and clinical impact of disseminated tumor cells (DTC) in the bone marrow (BM) of DCIS patients.

Methods
BM aspirates were collected from patients undergoing surgery for primary DCIS at Tuebingen University Hospital between 2001 and 2016. Exclusion criteria were presence of invasive breast cancer, bilateral or metastatic disease as well as other malignancies in their history. DTC were identified by immunocytochemistry using the A45-B/B3 anti-pancytokeratin antibody.

Results
627 patients were included. Median follow-up was 49 months. 72 (11%) had detectable DTC. The detection of DTC was not significantly associated with lymph node positivity (3/479, Fisher's exact test: p=0.307) or tumor size (median 30mm, Wilcoxon test: p=0.952).

In 33 (5%) women, a disease recurrence was observed. Of 31 local recurrences 19 were invasive. 7 Patients developed distant metastases, four without an invasive recurrence beforehand. 14 patients died during follow-up.

The detection of at least 2 DTC per 1.5x10⁶ mononuclear BM cells was significantly associated with a lower local recurrence free survival (log-rank: p=0.023) whereas there was no significant difference in distant disease free survival (p=0.315) and overall survival (p=0.083).

Discussion
For the first time, we were able to show that DTC-detection in DCIS patients is associated with local recurrence.

The number of distant metastases in women without invasive local recurrence detected in this cohort was comparable to earlier findings at different centers. This study warrants further investigations concerning evolutionary relationship between primary tumor, minimal residual disease, local recurrence and clinically detectable macrometastases.

Title: Characterization of novel ESR1 (c.749T>C; p.Met250Thr) mutation in enhancing cellular invasiveness of breast cancer

Ning Liao, Guo-Chun Zhang, Yulei Wang, Li Cao, Kai Li, Chong-Yang Ren, Ling-Zhu Wen, Yumei Shi, Wenzhen Zhu and Xiaoqing Chen. 1 Cancer Center, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China.

Body: Emerging evidence has revealed that the mutations in estrogen receptor alpha (ERα) gene (ESR1) is frequently observed in ER+ metastatic breast cancer, and is associated with the aggressively invasive and metastatic phenotype in advanced breast cancer due to the resistance of endocrine therapy. In our previous study, we have identified three novel mutations of ESR1, including ESR1 G74R, D230H and M250T, in the untreated patients with early breast cancer. However, the functional roles for these novel mutations in the cellular biology of breast cancer remain to be elucidated. In this study, we described the molecular mechanism underlying potential roles for the novel mutation ESR1 p.Met250Thr (c.749T>C) in regulating the cellular invasiveness of breast cancer. Firstly, we found, as compared with wild-type (WT) HA-ESR1, forced expression of HA-ESR1 M250T enhanced the invasive capacity of breast cancer MCF-7 cells by using Transwell assay. Moreover, we found that the levels of miR-190 were significantly up-regulated in the MCF-7 (HA-ESR1 M250T) cells, and further verified that miR-190 played an important role in ESR1 M250T-mediated induction of cellular invasiveness by using specific shRNA to knock down miR-190 levels in MCF-7 (HA-ESR1 M250T) cells. Further bioinformatics analysis showed that there were several half Estrogen Response Elements (EREs) in the promoter region of Talin-2, as the host gene of miR-190. Talin-2-driven luciferase reporter assay indicated ESR1 M250T resulted in a higher increase in the luciferase activity than ESR1 WT. Chromatin-immunoprecipitation (ChIP) assay identified a higher binding ability with Talin-2 promoter for ESR1 M250T than ESR1 WT. Collectively, our mechanistic study revealed that the ESR1 M250T mutation, located in the DNA-binding domain, increased the invasive capacity of breast cancer cells via the transcriptional induction of Talin-2 and miR-190. The potential role for ESR1 M250T in affecting the efficacy of endocrine therapy has been under the investigation in our laboratory, and the result from which will help us better elucidate the clinical relevance for novel ESR1 mutations in affecting the sensitivity of endocrine therapy. This study was supported in part by National Natural Science Foundation of China (8160111571) and Guangdong Natural Science Foundation (2016A030313768).
An increasing number of studies have found that other cells in the tumor microenvironment can influence tumor cells. Adipocytes, which were once thought to function only in energy storage, are now considered an active endocrine organ that secretes pro-inflammatory cytokines and proteases. In human breast cancer patients, invading tumor cells are surrounded by mature adipocytes. The breast cancer cells cause the adipocytes to undergo phenotypic changes and overexpress pro-inflammatory cytokines and matrix metalloproteinases (MMPs), such as MMP-3 and MMP-11. The presence of the changed adipocytes then increases the invasion capacity of breast cancer cells. Obesity is an important breast cancer risk factor. It causes changes to adipocytes and the surrounding microenvironment by invasion of macrophage cells. The effects of obesity-induced macrophage invasion have not been well characterized in the sector of breast cancer-adipocyte crosstalk. A novel 3D co-culture system was used to investigate how macrophage-induced inflammation can worsen this crosstalk, and what changes are involved in cytokine expression, adipocyte de-differentiation, breast cancer aggressiveness, and extracellular matrix (ECM) composition. When macrophage conditioned media was added to adipocytes and breast cancer cells in co-culture, the breast cancer cells showed increased cell proliferation and migration abilities. Experimental co-culture (adipocytes, breast cancer cells, macrophage conditioned media) showed almost twice the number of cells than the control co-culture (adipocytes, breast cancer cells, non-conditioned media). Interestingly, breast cancer cells alone in macrophage conditioned media did not show an increase in proliferation. This shows that macrophages may not affect breast cancer proliferation directly, as all three cell types are needed for increased proliferation of breast cancer cells. Introducing macrophages into this crosstalk also resulted in increased migration abilities. After 24 hours, breast cancer cells grown in experimental co-culture migrated further to close a wound than breast cancer cells grown in control co-culture. These results show that macrophages can affect adipocyte-breast cancer cell crosstalk. This may help explain why obese breast cancer patients have worse prognosis than non-obese breast cancer patients. Further investigation into these effects may identify targets to improve prognosis and abate breast cancer aggressiveness in obese breast cancer patients.
Title: The role of S100A7 in microbiota mediated inflammation and breast cancer progression

Tasha Wilkie¹, Helong Zhao², Moh'd Nasser³, Dinesh Ahirwar¹, Sanjay Mishra¹, Abhay Satoskar¹, Vijay Pancholi¹ and Ramesh Ganju¹. ¹The Ohio State University, Columbus, OH; ²The University of Utah, Salt Lake City, UT and ³University of Nebraska Medical Center, Omaha, NE.

Body: Introduction
While it is accepted that inflammation is a key component of cancer development, the intricate mechanism linking the two are not fully defined. Unparalleled progress has been underway to provide better understanding of this mechanism. We investigate the role of bacterial microbiota in promoting an inflammatory environment through the induction of the pro-inflammatory molecule, S100A7, and its activation of STAT-3 signaling pathways to promote tumor growth and metastasis in breast cancer (BC).

Methods
Immune-competent mouse models of orthotopic breast cancer was used to identify and characterize populations of bacterial microbiota in the cancerous breast tissue at tumor onset. Isolated tissues were homogenized and cultured, then processed for DNA extraction. Bacterial species were identified by aligning the sequences on NCBI BLAST. Mouse mammary tissue and tumors were analyzed for S100a7 after intraperitoneal exposure to LPS after cancer cell injections. Isolated tissues were analyzed by IHC, Western Blot analysis and real time RT-PCR.
mRNA and Protein expression using real time PCR, western blot and flow cytometry, and binding assays analyzed expression and affinity of LPS/S100A7/TLR4 in BC cell lines in vitro under varying conditions. Protein expression and in vitro functional assays including matrigel invasion and wound closure assays determined the effect of LPS/S100A7 on TLR4 and STAT-3 expression and signaling pathways in promoting tumor invasiveness.

Results
We observed microbiota in cancerous breast tissue, which is predominantly composed of Gram-negative bacteria at tumor onset. The population of mainly gram negative bacteria at tumor initiation is unique from those populations from feces and skin. This suggests that breast tissue microbiota may be a potential source of LPS in breast tumors. Stimulation with LPS induces secretion/expression of S100A7 in mouse mammary tissue and tumors, as well as BC cell lines. Furthermore, inhibition of LPS by polymixin B decreases S100A7 to basal levels in BC cell lines. LPS/S100A7 combinational treatment has an additive effect on the invasive potential induced by LPS in BC cell lines as shown by invasion assays and wound closure assays. S100A7 over expression increases TLR4 expression as observed by TLR4 mRNA by real time PCR and protein by flow cytometry. Furthermore, secreted S100A7 protein promotes interaction between S100A7 protein and TLR4 receptor in cell lines with endogenous TLR4 expression. In addition, both S100A7 and LPS stimulation of TLR4 can activate STAT3 signaling pathway, and inhibition of either S100A7 and or TLR4 impairs the invasiveness of BC cell lines.

Conclusion
A unique population of gram negative bacteria characterizes breast cancer tissues. LPS of bacterial cells walls, representative of gram negative bacteria induces S100A7, which interacts with TLR4 to activate the STAT-3 pathway in tumors. This LPS-S100A7-TLR4-STAT3 axis in turn increases the invasiveness of tumor cells to promote tumor metastasis. This suggests that microbiota plays an important role in the initiation and progression of breast cancer through regulation of the pro-inflammatory molecule S100A7.
Title: Adjuvant statin therapy efficacy is dictated by tumor dormancy and statin lipophilicity in ex vivo and in vivo models of metastatic breast cancer

Colin H Beckwitt¹, Amanda M Clark¹, Katsuhiko Warita², Zoltan N Oltvai¹ and Alan Wells¹. ¹University of Pittsburgh School of Medicine and ²Tottori University School of Veterinary Medicine.

Body: Metastasis in breast cancer patients heralds mortality, as disseminated disease is generally chemoresistant. After tumor cells reach the ectopic tissue, they undergo an epithelial reversion to enter a period of quiescence, termed dormancy, which may last for decades before outgrowing again as mesenchymal/dedifferentiated masses. Thus, long-term, relatively non-toxic interventions that prevent metastatic outgrowth are needed to treat this mortal stage of tumor progression. Epidemiological analyses have suggested that statin usage, for cardiovascular indications, is correlated with a reduction in clinically-evident metastatic (though not in incidence of primary) breast cancer. The goal of this study is to demonstrate this is due to statins suppressing breast cancer cell proliferation and keeping the micrometastases in the dormant state. We have found that atorvastatin and simvastatin limit the growth of some cancer cell lines, but not others. The sensitive lines were marked by lacking surface E-cadherin, the hallmark of the mesenchymal phenotype. When E-cadherin is downregulated on epithelial tumor cells, the cells become growth inhibited by the statins. Furthermore, this is a direct effect, as we now have shown that hydrophilic statins are relatively ineffective compared to the membrane permeant lipophilic statins as tumor cells generally lack the transporters that enable these drugs to gain access to the cells.

To determine whether the statins target the emergent metastatic tumor cells, we are using an all human microphysiological system (MPS) of the most common site for metastases, the liver. Briefly, a micro-hepatic tissue is established by seeding primary human liver cells in a porous scaffold subject to a physiological flow. RFP-labeled breast cancer cells are seeded into these microtissues and examined weeks later. Liver function and health are monitored by clinical chemistry assays performed on supernatant samples. We have previously shown that this system robustly reproduces tumor dormancy. Initial studies suggest that statins suppress the emergence of dormant tumor cells when challenged by stressors that lead to outgrowth. Additionally, atorvastatin suppresses proliferation of mesenchymal but not epithelial breast cancer cells in intrasplenic and mammary fat pad injection models for breast cancer metastasis to the liver and lung respectively. As 26% of adults currently take a statin for other medical conditions, these studies may suggest the best statin to use in the context of maintaining breast cancer dormancy long-term and delaying or avoiding the morbid emergence.
The levels of sphingosine-1-phosphate and its related gene expressions in breast cancer patients

Junko Tsuchida¹, Masayuki Nagahashi¹, Masato Nakajima¹, Kazuaki Takabe²,³ and Toshifumi Wakai¹. ¹Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; ²Roswell Park Cancer Institute, Buffalo, NY and ³University at Buffalo the State University of New York, Buffalo, NY.

Body: Background: The bioactive lipid mediator sphingosine-1-phosphate (S1P) has emerged as a key regulatory molecule in cancer progression. We previously demonstrated that S1P is a crucial mediator of breast cancer-induced angiogenesis and lymphangiogenesis, and promote metastasis. Although increasing number of in vitro and in vivo experiments have revealed the importance of S1P in cancer progression, the data on the roles of S1P in human patients are very limited. The aim of this study is to reveal the clinical relevance of S1P in the interaction between cancer and the tumor microenvironment by examining the levels of the sphingolipids in patient breast cancer tissue samples.

Material and Method: Breast cancer tissue, peri-tumor tissue, and normal breast tissue were collected from 20 breast cancer patients immediately after surgery that were conducted from November 2015 to February 2016 at Niigata University Medical and Dental Hospital. Sphingolipids were quantified by liquid chromatography–electrospray ionization tandem mass spectrometry. The expression level of each enzyme-encoding gene involved in S1P production was evaluated by retrieving RNA sequencing and gene expression quantification data from breast cancer tissues (n = 112) and paired normal breast tissues (n = 112) using the Genomics Data Commons (GDC) data portal of the The Cancer Genome Atlas (TCGA) cohort. Gene expression levels were derived using normalization methods provided in the DESeq2 package.

Result: The levels of the sphingolipids sphingosine (Sph), dihydro-sphingosine (DHSph), S1P, and dihydro-S1P (DHS1P) were successfully determined in breast cancer, peri-tumor, and normal breast tissues from all of the 20 patients. As expected, a one-way ANOVA revealed that S1P levels were significantly different depending on the location (F(2,57) = 7.029, P = 0.002). The Tukey post hoc test revealed that S1P levels in tumors were significantly higher than those in normal breast tissue and peri-tumor tissue (P < 0.05). Similarly, Sph and DHSph levels in tumors were significantly higher than in normal breast tissue and peri-tumor tissue. Both SPHK1 and SPHK2 gene expression levels in breast cancer tissue were higher than those in normal breast tissue. Interestingly, expression of some of the S1P-related genes; S1PR3, ABCC1, SGPL1, and ORMDL2, were significantly increased in the breast cancer tissue compared to normal breast tissue. On the other hand, there was significantly decreased expression of the S1P-related genes S1PR1, S1PR2, ABCG2, SPNS2, SGPP1 and ORMDL3, in breast cancer tissue compared to normal breast tissue.

Conclusion: We demonstrated that the major source of S1P is the tumor tissue, and not the peri-tumor tissue despite the fact that angiogenesis and lymphangiogenesis are occurring more in the peri-tumor area, which implicate that S1P may have further role inside the tumor. Our results indicated the complexity of S1P signaling in human cancer than expected based on the results in vivo experiments.

**Title:** TGFβ-Smad3-TMEPAI axis drives the tumor progression of triple negative breast cancer

Pothana Saikumar¹, Prajjal K Singha¹, Sreelakshmi Pandeswara¹ and Venakatachalam A Manjeri¹. ¹UT Health at San Antonio, San Antonio, TX.

**Body:** **Background:** In the absence of mutations and/or deletions in the TGF-β signaling molecules, how triple negative breast cancer (TNBC) cells become resistant to growth inhibitory signaling of TGF-β was addressed by screening of several TNBC cell lines for Smad proteins involved in TGF-β signaling. Unexpectedly, altered Smad2 and Smad3 protein levels were detected in breast cancer cells relative to normal mammary epithelial cells, suggesting a novel mechanism to escape from TGF-β mediated growth inhibition. In order to reflect the true functional status of the endogenous molecules, Smad2 or Smad3 were individually knocked down and tested its effect on pro-oncogenic behavior of TGF-β.

**Materials and Methods:** All cell lines were cultured according to the recommended standard procedures. TMEPAI knockdown was achieved by using lentiviral vectors and knockdown of Smad2 and Smad3 was achieved by using retroviral vectors. DNA transfections and luciferase assays were performed according to vendor instructions. Cell proliferation was measured by quantitation of total cellular DNA. Immunoblotting, invasion and immunohistochemical assays were performed using standard methods. **Bioinformatics:** Triple negative breast cancer patient dataset (GSE58812) was used to compare Smad2, Smad3, Smad4 and TMEPAI/PMEPA1 expressions correlated with overall survival using the PROGgene tool by using median gene expression value as a dividing point.

**Results:** While Smad2 deficiency has no effect on breast cancer cell behavior, Smad3 deficiency reduced growth and invasion capacity of breast cancer cells. Interestingly, Smad3 deficiency was associated with reduced gene expressions of transmembrane prostate androgen induced (TMEPAI or PMEPA1) gene and EMT inducing transcription factors and increased expression of cell cycle inhibitors. In contrast, Smad2 deficiency had opposite effect on these regulators. Importantly, the decreased growth and invasion and their associated gene expressions in Smad3 knockdown cells were largely reversed by overexpression of TMEPAI. Meta-analysis of Jezequel dataset of triple negative breast cancer patients suggested higher TMEPAI/PMEPA1 and lower Smad2 expressions are significantly associated with decreased survival. Our results support the idea that development of several triple negative breast cancers may involve expansion of cell populations with altered Smad2 and Smad3 levels resulting in Smad3 dependent expression of TMEPAI, which provides a competitive advantage for cancer cells to grow and metastasize in presence of TGF-β. Moreover, following meta-analysis of published microarray datasets in lung and gastric cancers also revealed that increased TMEPAI and Smad3 expression and decreased Smad2 expressions were significantly associated with poorer patient prognosis in non-small cell lung adenocarcinomas and gastric cancers suggesting universality of this phenomenon.

**Conclusion:** We identified TGF-β-Smad3-TMEPAI signaling axis as a driver of tumor progression in triple negative breast cancer. Our results suggest that novel therapeutics targeting TMEPAI will selectively inhibit oncogenic activity of TGF-β and promote its tumor suppressive activity in treating TNBC.
Title: Hypoxia induced centrosome amplification via HIF-1α/Plk4 signaling axis associates with poorer overall survival in TNBC

Karuna Mittal¹, Da Hoon Choi¹, Nagini Maganti¹, Angela Ogden¹, Brian D Melton¹, Jaspreet Kaur¹, Meenakshi V Gupta², Kristin Jonsdottir³, Emiel AM Janseen³, Mohammad A Aleskandarany⁴, Emad A Rakha⁴, Padmashree CG Rida¹ and Ritu Aneja¹.

¹Georgia State University, Atlanta, GA; ²West Georgia Hospital; ³Stavanger University Hospital, Norway and ⁴University of Nottingham and Nottingham University Hospitals NHS Trust.

Body: Background: Centrosome amplification (CA) which refers to presence of supernumerary or abnormally large centrosomes drives tumor progression by promoting chromosomal instability and the generation of aggressive tumor clones. Although the role of CA in cancer progression is well-defined, no studies have yet discussed how CA is induced in tumor cells. We report here that intra-tumoral hypoxia, which is considered one of the major contributors to intratumor heterogeneity, induces CA via HIF-1α.

Methods: We first immunohistochemically labeled 24 breast carcinoma and uninvolved adjacent normal tissue samples for HIF-1α and calculated weighted indices (WIs) for nuclear HIF-1α. Adjacent serial sections from the same tumors were also immunofluorescently labeled for γ-tubulin and CA was calculated. Using public microarray datasets (Kao dataset, n=327), we investigated whether centrosomal gene expression is enriched in breast tumors characterized by a hypoxia gene expression signature. Finally, to determine the role of hypoxia in CA induction we exposed cultured TNBC cells (MDA-MB-231 and MDA-MB-468) to hypoxia and overexpressed (OE) and knocked out (KO) HIF-1α in TNBC cells and quantitated CA. Additionally, to discern the biological pathway through which HIF-1α induces CA we performed ChIP assay and in silico analyses to identify the possible targets of HIF-1α.

Results: A strong positive correlation between nuclear HIF-1α WI and CA was found in breast tumor samples (Spearman's rho p=0.722, p<0.001). In addition, we found that higher nuclear HIF-1α was associated with worse overall survival (p=0.041; HR=1.03). Our in silico findings suggest that breast tumors with high expression of hypoxia-associated genes exhibited higher expression of centrosomal genes than breast tumors with low expression of hypoxia-associated genes. In addition, cells cultured in hypoxic conditions exhibited ~1.5 fold higher (p<0.05) CA when compared to the cells cultured in normoxic conditions. Interestingly level of CA decreased when HIF-1α KO TNBC cells were exposed to hypoxia and it increased when HIF-1α OE TNBC cells were culture in normoxic conditions. Furthermore, we discovered that HIF-1α induced CA by directly regulating the expression of Plk4 which was confirmed by performing ChIP assay. Our results indicated HIF-1α interaction with the motif in the PLK4 promoter from genomic DNA of MDA-MB 231 cells under hypoxic conditions, was significantly (p=0.04) higher when compared with the cells cultured under normoxic conditions. Plk4 mRNA expression was assessed using the online BC gene expression data sets (n=25). We found significantly higher expression of Plk4 in TNBC (n=374) when compared with non-TNBC (n=4098) and it was associated with poor overall survival (HR=1.76; p=0.054) in TNBC.

Conclusion: Collectively our findings suggest that hypoxia drives CA in TNBC via HIF-1α and contribute to poor outcomes. Thus, determination of CA and HIF-1α can help risk stratification in TNBC patients for more personalized treatments.
Body: Background: Combination of metabolomics and epidemiological approaches opens new perspectives for ground-breaking discoveries. The aim of the present study was to investigate for the first time whether plasma non-targeted metabolomic profiles, established from a simple blood draw from healthy women, could contribute to predict the risk of developing breast cancer within the following decade and to better understand the etiology of this complex disease.

Methods: A prospective nested case-control study was set up in the SU.VI.MAX cohort, including 206 breast cancer cases diagnosed during a 13y follow-up, and 396 matched controls. Non-targeted NMR metabolomic profiles were established from baseline plasma samples. Multivariable conditional logistic regression models were computed for each individual NMR variable and for combinations of variables derived by principal component analysis.

Results: Several metabolomic variables from 1D NMR spectroscopy were associated with breast cancer risk. Women characterized by higher fasting plasma levels of valine, lysine, arginine, glutamine, creatine, creatinine, and glucose and lower plasma levels of lipoproteins, lipids, glycoproteins, acetone, glycerol-derived compounds and unsaturated lipids had a higher risk of developing breast cancer. P-values ranged from 0.00007 (OR_{T3vsT1}=0.37[0.23-0.61] for glycerol-derived compounds) to 0.04 (OR_{T3vsT1}=1.61[1.02-2.55] for glutamine).

Conclusion: This study highlighted associations between baseline NMR plasma metabolomic signatures and long-term breast cancer risk. These results provide interesting insights to better understand complex mechanisms involved in breast carcinogenesis and evoke plasma metabolic disorders favorable for carcinogenesis initiation. This study may contribute to develop screening strategies for the identification of at-risk women for breast cancer well before symptoms appear.
Title: FASN inhibition by TVB-3166 associates with breast cancer subtype

Aleksandra B Gruslova¹, Chun-Liang Chen¹, Chiou-Miin Wang¹, Richard M Elledge¹, Virginia G Kaklamani¹, Kate Lathrop¹, Tim H Huang¹ and Andrew Brenner¹. ¹UT Health, San Antonio, TX.

Body: Fatty acid synthase (FASN) is overexpressed in numerous tumor types, including breast carcinomas, and promotes changes in the genetic program controlling lipid biosynthesis. While inhibiting FASN appears to be an attractive therapeutic approach under development, the success of this approach may depend on the identification of tumor subtypes with specific metabolic requirements. Applying a comprehensive profile of circulating tumor cells (CTC) using canonical pathway gene sets, we identified a correlation of metabolic subtypes with breast tumor subtype. A lipogenic subtype is strongly associated with Luminal A subtype, whereas the glycolytic subtype associated with Luminal B tumors. The triple negative subtype was more heterogeneous and had the expression of both sets of gene. Such a difference in the metabolic profile may dictate differential sensitivity to inhibitors targeting de novo lipid synthesis, including FASN. This was supported by in vitro studies using selective FASN inhibitor, TVB-3166. Exposure to TVB-3166 over 14 days incubation in Advanced MEM with 1% charcoal-stripped FBS selectively inhibited growth and viability of Luminal A breast cancer cells, but had no effect on Luminal B subtype. This was further confirmed in short-term patient derived cultures. Mechanistic studies suggest that TVB-3166 quickly disrupts FA synthesis leading to the disruption of the lipid raft architecture and tumor cell death through an apoptotic mechanism. In conclusion, our findings highlight that success of targeting cancer metabolism directly may depend on identification of tumor subtypes with specific metabolic requirements.
Title: The Y537S ESR1 mutation carries unique metabolomics profiling in breast cancer

Guowei Gu¹, Badrajee Piyaratna¹, Cristian Coarfa¹, Levin Ellis², Sebastiano Ando³ and Suzanne Fuqua¹. ¹Baylor College of Medicine, Houston, TX; ²UC-Irvine and the Tibor Rubin VA Medical Center University of California, Long Beach, CA and ³University of Calabria, Rende, Calabria, Italy.

Body: Background:
Estrogen receptor (ESR1) mutations occur at a high frequency in metastatic breast tumors in patients treated with hormonal therapy in the metastatic setting. We do not know if these mutations changed metabolomics and whether these metabolomics change could affect metastasis.

Experimental design and methods:
We generated ESR1 Y537S homozygous mutations using CRISPR Casp-9 technology. Globe metabolites screening was performed using 6550 Agilent QTOF instrument. Athymic mice were used in tumor xenograft studies. Affymetrix microarrays were performed to compare gene expression changes in Y537S mutant compared with parental cells. Enriched metabolite pathways and gene expression integrated analysis was analyzed by using online analysis tool http://www.metaboanalyst.ca.

Results:
We generated CRISPR ESR1 Y537S mutation homozygous knock-in clones in MCF-7 cells. In vivo experiments revealed that mutant cells are dominant drivers of metastasis. Transcriptome profiling revealed elevated expression of Hallmark pathways, including EMT and estrogen-regulated gene expression. We performed globe metabolites screening using MCF-7 Y537S and MCF-7 parental and identified 134 metabolites. Serum starvation media was used and estrogen was used as control for both cell lines. As we expected estrogen treatment induced metabolites changes in parental cells. However, metabolites in mutant cells were not changed significantly under estrogen treatment. Interestingly, metabolites in the mutant cells at baseline were remarkably upregulated (78 out of 134 identified total metabolites) indicating mutant cells in serum starvation condition had significantly different metabolomics compared with parental cells. Top upregulated pathways include protein biosynthesis, betaine metabolism and ammonia recycling. Integration of microarray gene expression and metabolites reviewed several metabolomics pathways significantly changed in mutant compared with parental cells including for example aminoacyl-tRNA biosynthesis, arginine and proline metabolism and alanine, aspartate and glutamate metabolism.

Conclusion: The Y537S ER mutation is a driver of distant metastasis in ER-positive breast cancer cells. Y537S ER mutant had globe changes of metabolites expression which was confirmed by integrated analysis combining microarray gene expression. The roles of these metabolites need to be studied to correlate with metastasis. Enzymes responsible for converting these metabolites changes could be served as potential therapeutic targets.
Metabolomics shows distinct pattern of one-carbon metabolism in invasive breast cancer

Jéssica Reis¹, Ismael Dale², Angela Logullo², Maria Mitzi Brentanni¹, Tharcisio Tortelli Junior¹, Dan Waitzberg¹ and Graziela Ravacci¹. ¹University of São Paulo Medical School, São Paulo, Brazil and ²Federal University of São Paulo, São Paulo, Brazil.

Body: One-carbon metabolism involving the folate and methionine cycles integrates nutritional status from amino acids, glucose and vitamins, and generates diverse outputs, such as the lipidic nucleotide and proteic biosynthesis and the maintenance of redox status and substrates for methylation process. Long considered as a 'housekeeping' process, this pathway has recently been shown additional complexity. Genetic and functional evidence suggest that one-carbon metabolism hyper activation works as oncogenesis driver and establishes a link to cellular epigenetic status. However, results in breast cancer area remain inconclusive. Methods: In this sense, target metabolomic analysis was performed from primary BC and adjacent tissue samples from a cohort of 182 breast cancer patients treated at the Institut Gustave-Roussy and Institute Curie – Paris, University of Debrecen – Hungary, and University of Tartu – Estonia. The Biocrates Life Science® company performed the metabolomics analysis using the Absolute IDQ p180 kit. Statistical analysis was performed by MetaboAnalyst 3.0 software (p <0.05). We performed the combined analysis of genes from public database (GEO: GSE61725) with genes of interest related to one-carbon metabolism. Differently expressed genes analysis between breast tumor and normal breast tissue were performed by TMev program using test T student (p≤0.05). We selected only differently expressed genes related with one-carbon metabolism.

Results: We observed that metabolites of one-carbon such as glucose, serine and threonine, precursors of glycine, as well as, glutamate, glutamine and production of glutathione increased when compared with adjacent tissue samples. Also, we found a rising of methionine, assymetric dimethylated arginine (ADMA), and arginine used in redox homeostasis, in protein post-translational modification and epigenetic events. Surprisingly, the leucine metabolites indicated a link to cholesterol synthesis. In tumor tissue samples an increase of saturated fatty acid synthesis (SFA) was observed, such as palmitic acid, sphenolipids and phosphatidylycolines SFA enriched when compared to normal tissue, suggesting an increase of lipid rafts and membranes in the breast tumor cells. To validate these data, we found 11 genes differently expressed genes related to one-carbon metabolism from public DataBase: G6PD, GLUT4, GLS, STK11, PRMT1, NOX1, AUH, ABCG1, HMGCS2, DHCR7 and NPC1. Conclusion: Our results indicate that one-carbon metabolism were hiperactivated in primary breast cancer when compared with adjacent tissue. Given the wealth of clinically available agents that target one-carbon metabolism, these new findings could present opportunities for treatment in breast cancer medicine.
The effect of obesity and metabolic factors on genomic assays for risk of recurrence

Hatem Soliman\(^1\), Tina Treece\(^2\), William Audeh\(^2\) and IMPACt Investigators Group\(^2\). \(^1\)Moffitt Cancer Center, Tampa, FL and \(^2\)Agendia, Inc, Irvine, CA.

**Body: Background:** Obesity and other factors contributing to metabolic syndrome (MS) have become increasingly prolific in today's population. They are also known risk factors or comorbidities in many disease states including breast cancer (BC). While obesity and MS are known to increase the risk of developing BC, the effect on the risk of distant recurrence is uncertain. This substudy evaluated the relationship of BMI, blood pressure, cholesterol, triglyceride, diabetic status, and MS on the risk of recurrence in early BC patients. **Methods:** The effect of these metabolic factors on MammaPrint (MP) and Oncotype DX (ODX) risk of recurrence assays was compared. Additionally, gene expression analysis was performed to elucidate the differences between obese patients who were MP high risk (HR) vs. low risk (LR), and MP HR patients who were obese vs. not-obese. This subanalysis included patients from the PROMIS (n=198) and IMPACt (n=382) studies for whom metabolic characteristics were captured with informed consent. From the IMPACt study, 98 patients also reported ODX results (RS range 0-69). **Results:** By BMI, 1% of patients were classified as underweight (BMI <18.5), 22% normal (18.5 ≤ BMI <25), 31% overweight (25 ≤ BMI <30), and 46% as obese (BMI ≥30). To be classified as having MS, the patient had to exhibit any 3 of the 5 metabolic factors. In the full cohort, having MS was significantly associated with ethnicity (p < 0.05) and menopausal status (p < 0.001), but not histopathological tumor type, histological grade, tumor stage, or lymph node status (p > 0.05). 36% (207/580) of patients were considered as having MS in the full cohort, similarly 36% (35/98) had MS in the ODX subset. Of the patients with MS, MP classified 52% (108/207) as HR. For the subset of ER-positive patients with an ODX result, ODX classified the 11% (4/35) as HR whereas MP classified 57% (20/35) of the same patients as HR. **Conclusions:** Patients with obesity as measured by BMI and with MS were more frequently classified as HR by MP, in contrast to ODX which classified nearly all patients as intermediate or LR, confirming previous findings by Robinson, et. al (SABCS 2012 and 2014). Understanding the biological foundation of how obesity and metabolic factors affect risk of recurrence in breast cancer will improve both the treatment and care of patients.
Body: Background
Reprogramming of metabolism is a hallmark in cancer. In previous works we observed differences in glucose metabolism between tumors from different breast cancer subtypes, suggesting the possibility to use drugs against metabolism in this disease. Flux Balance Analysis (FBA) is widely used to study biochemical networks, allowing to predict growth rates and to simulate drug response.

Material and methods
Breast cancer cell lines and different drugs against metabolic targets were evaluated with dose-response curves, and pharmacological parameters for each condition were calculated. Proteomics data from breast cancer cells lines treated with sub-lethal doses and controls were obtained applying a mass spectrometry-based approach. Differences in protein expression between treated vs. control were assessed. An FBA approach using the human metabolic reconstruction Recon2 and including the protein expression values from perturbation experiments was also applied. Model predictions were validated using dynamic FBA and growth rate for each sample was estimated. With the aim to compare the activity of the different pathway fluxes between control and treated cells, flux activity was calculated for each condition and for each pathway and response predictive models were performed.

Results
Drug response was diverse across different breast cancer cells. Mass spectrometry from cell samples allows identifying and quantifying 4,114 proteins. FBA predicted that growth rates decrease in treated cells vs. control, as observed in cell viability assays. Dynamic FBA showed that our model correctly reflects cell growth rates. Finally, using flux activities, it is possible to build models which could predict response against these drugs.

Conclusions
Proteomics provide insights of the mechanisms responsible of cells' response to metabolism drugs. A validated computational model able to predict tumor growth using data from proteomics was developed. Model predicts growth rates and also dysregulation of biological processes triggered by drug treatment. Moreover, these computational approaches could be used to propose new mechanisms of action and effects of metabolic drugs.

**Body:** Background - The metabolic syndrome (MetS) is prevalent among post-menopausal breast cancer patients and is associated with increased breast cancer risk. Mammographic breast density (BD) is also positively associated with increased breast cancer risk. The relationship between MetS and mammographic BD is unclear and requires further investigation.

**Aim** - The aim of this study was to examine the relationship between the MetS and its component features with breast density.

**Methods** - 112 post-menopausal women with breast cancer were recruited. Body composition (Body Mass Index (BMI), waist circumference (WC)) was measured objectively in participants prior to surgery. Metabolic profiles were measured in blood taken from participants prior to surgery. MetS was defined according to the International Diabetes Federation (IDF) criteria. BD was classified according to the Breast Imaging Reporting and Data System (BI-RADS). Participants were categorised into those with 'Dense' (BI-RADS score 3 or 4) or 'Less Dense' (BI-RADS score 1 or 2) breasts. Group means were compared using unpaired t-tests for parametric or Mann Whitney tests for non-parametric data. Categorical data was analysed using Fisher's exact test or Chi squared test as appropriate.

**Results** - An inverse relationship was observed between measures of adiposity and BD. Participants with 'dense' (BI-RADS 3/4) breasts had significantly lower BMI ($p=0.0034$), waist circumference ($p=0.0007$), systolic blood pressure ($p=0.03$), circulating insulin level ($p=0.009$) and glycated haemoglobin ($p=0.008$) than those with 'less dense' (BI-RADS 1/2) breasts. HDL was significantly higher in those with 'dense' versus those with 'less dense' breasts ($p=0.03$). Participants with 'less dense' breasts were significantly more likely to be insulin resistant (HOMA-IR $\geq 2$) than those with 'dense breasts' (50.6% versus 20% respectively); $p=0.01$.

Other components of the MetS (Serum triglycerides, glucose and diastolic blood pressure) did not differ significantly between participants with 'dense' and 'less dense' breasts. No differences in overall survival were observed between participants with 'Dense' versus those with 'Less Dense' breasts ($P=0.93$).

**Conclusion** - Although both MetS and BD are positively associated with breast cancer risk; it is unlikely that the MetS is related to an increase in breast cancer risk through a mechanism involving BD. Further work on this study is currently underway and will involve adjusting for potential confounders including age and BMI as well as examining the relationship between MetS and BD in pre-menopausal breast cancer patients.
Reprogramming glucose metabolism and energy production in breast cancer cells

Hyejin Kim1, Jiabin Dong1, Jimin Xu2, Dengfeng Li1, Zhi Zheng1, Na Ye2, Ziwei Zhang1, Haiying Chen2, Jia Zhou2 and Qiang Shen1.

1The University of Texas M.D. Anderson Cancer Center, Houston, TX and 2University of Texas Medical Branch, Galveston, TX.

Most mammalian cells use glucose as a main fuel source. Glucose is metabolized via glycolysis to pyruvate, which enters the mitochondria and then generates ATP through Krebs cycle in normal condition. However, metabolism is characteristically reprogrammed and cancer cells or highly proliferative cells preferably generate ATP through lactate production by lactate dehydrogenase (LDH/LDHA), referred to as the Warburg effect or metabolic reprogramming toward aerobic glycolysis. Efficient control of energy metabolism is the key to maintaining metabolic homeostasis, and disturbance in energy balance provokes diseases such as obesity, diabetes and cancer. However, the mechanisms underlying efficient energy metabolic homeostasis and breast cancer development are poorly understood. HJC0152, a novel small molecule glucose metabolism modulator, was developed using structure- and fragment-based drug design strategies and molecular modeling techniques. Aggressively growing and metastatic breast cancer cells of triple-negative subtype (MDA-MB-231) treated with HJC0152 showed decreased activity and protein level of LDHA, which resulted in a decrease lactate production. In addition, these cells also exhibited decreased glucose uptake and HK2 protein level. Furthermore, the amount of intracellular ATP in MDA-MB-231 cells was significantly reduced. Our findings suggest that HJC0152 is capable of reprogramming cancer metabolism by modulating glucose metabolism and ATP production. These results may provide a rationale to develop HJC0152 as an effective therapeutic for cancer and other metabolic diseases with aberrant glucose metabolism. In addition, HJC0152 can serve as a molecular probing tool for elucidating the key factors responsible for developing breast cancer and other metabolic diseases. This work was supported by Grants P50 CA097007, and P30DA028821 (JZ) from the NIH, CPRIT (JZ), John Sealy Memorial Endowment Fund (JZ), DFI Grants from MD Anderson Cancer Center (QS), Holden Family Research Grant in BC Prevention (QS), and NCI PREVENT Program HHSN26100002 (QS).
Targeting breast cancer stem cell state equilibrium through modulation of redox signaling

Ming Luo¹, Li Shang¹, Michael Brooks¹, Evelyn Jiagge¹, Yongyou Zhu¹, Sarah Conley¹, Melissa A Fath², Ramdane Harouaka¹, Sofia D Merajver¹, Douglas R Spitz² and Max S Wicha¹. ¹University of Michigan Comprehensive Cancer Center, Ann Arbor, MI and ²University of Iowa, Iowa City, IA.

Body: Breast cancer stem cells (BCSCs) maintain the plasticity to transition between quiescent mesenchymal- (M) and proliferative epithelial-like (E) states, but how this plasticity is regulated under metabolic/oxidative stress is poorly understood. Here, we show that M- and E-BCSCs exhibit markedly different sensitivities to the inhibitors of glycolysis and redox metabolism. Metabolic/Oxidative stress generated by 2DG/H₂O₂ or hypoxia promotes ROS⁻ M-BCSCs transition to their ROS⁺ E-state. This transition is reversed by the antioxidant N-acetyl cysteine and facilitated by the activation of the AMPK-HIF1α axis. Moreover, E-BCSCs exhibit robust expression of NRF2/NFE2L2 and a wide variety of NRF2 downstream antioxidant responsive genes including the family of drug transporters and detoxification enzymes, NADPH production as well as the thioredoxin (TXN) and glutathione (GSH) antioxidant pathways. Suppression of NRF2 activity by a small-molecular inhibitor Trigonelline or shNRF2 mediated knockdown significantly decreased ALDH⁺ E- but not CD24⁻CD44⁺ M-BCSCs. This specific vulnerability of E-BCSCs to the inhibition of NRF2-mediated antioxidant defenses was also observed following inhibition of the downstream TXN and GSH antioxidant pathways, which promotes ROS-mediated differentiation and subsequent apoptosis of E-BCSCs. Co-inhibition of glycolysis and TXN/GSH pathways synergistically suppressed tumor growth and tumor initiating potential in two patient-derived xenograft models of triple negative breast cancer by eliminating both M- and E-BCSCs. Together, our studies reveal novel cellular and molecular mechanisms demonstrating how modulation of redox signaling regulates the equilibrium of two distinct BCSC states. These studies define the metabolic vulnerabilities of M- and E-BCSCs, and also provide a novel therapeutic approach to collectively target these distinct CSC states. As the CSC state equilibrium may be similarly regulated across a spectrum of tumors with diverse oncogenic drivers, this approach may have broad therapeutic applicability.
Title: Preclinical efficacy of a novel and potent inhibitor of the MDM2-p53 axis AMG 232 in ER+ breast cancer model

Pradip K De¹, Jennifer H Carlson¹, Tyler Jepperson¹, Amy Krie¹, Kirstin Williams¹, Jessica Klein¹, Jude Canon², Casey Williams¹, Nandini Dey¹ and Brian Leyland-Jones¹. ¹Avera Center for Precision Oncology, Avera Cancer Institute, Sioux Falls, SD and ²Amgen, Thousand Oaks, CA.

Body: Background: Approximately 70% of breast cancers (BC) express estrogen receptors (ER) and/or progesterone receptors (PR) which define their degrees of estrogen dependence. Although mutations in the tumor suppressor TP53 gene are thought to be the most abundant genetic alterations occurring in cancers, the relative prevalence of TP53 mutations in ER+ BC is low (luminal A 12% and luminal B 29%) compared to HER2+ or TNBC, and total MDM2/4 alterations are about 12% (Cancer Genome Atlas Network Nature. 2012). In our (Avera Cancer Institute, Sioux Falls, SD) ER+ BC cohort TP53 and MDM2/4 alterations are 25% and 14% respectively. Purpose: Blocking the interaction between MDM2 and p53 may generate a novel treatment opportunity in TP53 wild-type ER+ BC patients. Methods: Comprehensive genomic profiles from 160 ER+ BC patients (February 2014 through May 2017) were analyzed. Patients were biopsied after consultation and samples were analyzed for genomic [FoundationOne] and proteomic analyses [Theranostics]). We also evaluated mutation distribution in cell-free DNA via digital NGS using the Guardant360 panel. We tested the anti-tumor efficacy of MDM2 inhibitor (AMG 232) alone or a combination of an aromatase inhibitor, letrozole plus AMG 232 in ER+ BC model (MCF7, Zr-75-1, & MDA-MB415). Results: 1) AMG 232 binds the MDM2 protein, blocks the MDM2-p53 interaction and induces p53 expression and activity, 2) p53 effector molecule p21 is robustly induced following the treatment of AMG 232, 3) the anti-proliferative activity of AMG 232 was observed by 3D-ON-TOP clonogenic assay and real-time monitoring in an IncuCyte Zoom, 4) ER+/TP53 wild-type (WT) cell lines exhibited an increase in annexin V positivity (initiation of apoptotic activity) following AMG 232 treatment. AMG 232 also induced the apoptotic markers cleaved-CASPASE3 and cleaved PARP1 protein expression in ER+/PR+/TP53 WT and PTEN null breast cancer cell lines, 5) AMG 232 treatment induced G1 cells cycle arrest (Flow cytometric analysis of PI staining) dose dependently which may be associated with upregulation of p21. 6) we also assessed mRNA expression (several pro-apoptotic and anti-apoptotic molecules) by RT-qPCR following the treatment of AMG232 in MCF7 (ER+/TP53 WT) and Zr-75-1 (ER+/PR+/TP53 WT and PTEN null) cell lines. Similar to our protein expression data, mRNA data also showed that pro-apoptotic/cell cycle inhibitor transcripts such as p21 and PUMA mRNA expression were significantly increased following the treatment of AMG 232. On the contrary anti-apoptotic/ pro-survival transcripts such as survivin (BIRC5) and stathmin (STMN1) mRNA expression were significantly decreased following the treatment of AMG 232 and 7) importantly, normoxic-proteasomal degradation of HIF1α (responsible for the development of chemotherapy and targeted therapy resistance) was not rescued by prior treatment of this novel MDM2-p53 interacting inhibitor AMG 232 in Zr-75-1 cell line. Conclusion: Taken together, our data suggest that AMG 232 effectively inhibited proliferation and enhanced apoptosis via inhibition of the MDM2-p53 interaction and p53-mediated downstream signaling events in ER+/TP53 wild-type BC model.

Title: Invasive lobular carcinoma and invasive ductal carcinoma differ in immune response, translation efficiency and metabolic rate

Kevin M Levine¹, Tian Du², Li Zhu¹, Nilgun Tasdemir¹, Adrian V Lee¹, Bennett Van Houten¹, George C Tseng¹ and Steffi Oesterreich¹. ¹University of Pittsburgh, Pittsburgh, PA and ²Tsinghua University, Beijing, China.

Body: Background

Invasive lobular carcinoma (ILC) is the second most common histological subtype of breast cancer after invasive ductal carcinoma (IDC). ILC differs from IDC in pathologic, molecular, and clinical features. ILC tumors are most often characterized as luminal A by PAM50 analysis, suggestive of an indolent disease. Yet, when matched for receptor status and tumor grade, patients with ILC tend to have worse long-term outcomes than patients with IDC. The main distinguishing molecular feature of ILC is the loss of functional E-cadherin, and yet, beyond that loss, the mechanisms underlying the differences between ILC and IDC are largely unknown. We examined the RNA expression profiles of ILC and IDC tumors to assess if there may be underlying vulnerabilities of ILC tumors to novel therapeutic strategies.

Methods

Differential expression analysis was performed on 159 luminal A (LumA) ILC tumors versus 311 LumA IDC tumors from The Cancer Genome Atlas (TCGA). The METABRIC cohort (65 LumA ILC and 533 LumA IDC) was used as a validation dataset. Pathway enrichment analysis was performed to identify potential differences in biological processes, and these potential differences were then tested in a series of in vitro experiments, using 3 ER+ ILC (MDA-MB-134VI, SUM44PE, and MDA-MB-330) and 3 ER+ IDC (MCF7, T47D, and ZR75.1) cell lines.

Results

Pathway analysis led to the identification of three main signaling differences between LumA ILC and LumA IDC: immune regulation, translation, and metabolism. A series of immune pathways, including Immunological Synapse, Biocarta IL17 pathway, and Response to Wounding were up-regulated in ILC tumors. We examined specific cell type markers, and found that ILC tumors have a higher activity of nearly all immune cell types, including CD4+ T cells, CD8+ T cells, B cells, NK cells, dendritic cells, M1 macrophages, and M2 macrophages. These results were surprising, since ILC tumors have a lower incidence of stromal inflammation, as defined by H&E staining, suggesting a unique immune regulatory mechanism in ILC.

Next, we examined the translational regulation in ILC vs IDC tumors by comparing RNA expression and protein quantities as determined by RPPA analysis. ILC tumors have a lower protein:RNA ratio, suggesting a lower translation efficiency. This was reflected in the RPPA data by lower protein expression of eIF4G, ribosome protein S6 (S6) and p70-S6K in ILC tumors. Phosphorylation of 4E-BP1 (Ser65), eEF2, S6 (Ser235/236, Ser240/244), and mTOR (Ser2448) were also significantly lower in LumA ILCs. This lower translation efficiency was then validated in cell lines by O-propargyl-puromycin treatment. Finally, the pathway analysis suggested lower rates of metabolism in lobular tumors. Comparative studies of OXPHOS and glycolysis with a Seahorse analyzer confirmed this finding.

Conclusions

ILC tumors have a higher immune activity than IDC tumors, even with lower rates of stromal inflammation, suggesting a potential for differential response to immunotherapy. The lower rates of translation and metabolism, which are general identifiers of tumor dormancy, could enable ILC to escape from cytotoxic therapies, and may play an important role in the late recurrence of ILC.
Title: Role of PTEN and BRCA1 as determinants of synergy for the combination of vistusertib with carboplatin and olaparib in TNBC

Jennifer H Carlson¹, Mark J O’Connor², Pradip De¹, Nandini Dey¹ and Brian Leyland-Jones¹. ¹Avera Center for Precision Oncology, Avera Cancer Institute, Sioux Falls, SD and ²AstraZeneca, Cambridge, United Kingdom.

Body: Introduction: Platinum agents are being used in combination with targeted agents in advanced triple-negative breast cancer (TNBC) (See K. Gelmon et al., 2012). Additionally inhibition of PARP is also being considered as a “targeted” therapy for TNBC (Anders CK et al., 2010). PARP inhibitor (i), Lynparza (olaparib,AstraZeneca)met the primary endpoint of a Phase III trial in which Lynparza was compared to physician's choice of a standard of care chemotherapy in patients with HER2-negative metastatic BC harboring germline BRCA1/2 mutations (BRCAm). Based on cBioportal data analyses and experimental studies we and others have reported that more than 30% PTEN loss in TNBC leads to activation/upregulation of the PI3K pathway (Nature. 2012; Ellis and Perou, 2013; Dey et al., 2012; De et al., 2016; Reed and Shokat 2017;). In line with active kinase profiling, genetic and pharmacological data which defined mTOR as an important target in TNBC (Montero JC et al., 2012), we have demonstrated that mTORi has anti-tumor activity in TNBC (De et al., 2014). Aim: These studies focused on exploring the synergy of biology-based targeted drugs PARPi (olaparib, O), mTOR kinase (vistusertib, V), and platinum (C) in TNBC models. Method: TNBC cells of multiple genetic backgrounds were used to test the combination(s) on proliferation and apoptosis by monitoring growth and using real time Annexin V reagent in a microscopy-based assay (Essen IncuCyte Zoom). Flow cytometric analysis of cell cycle progression by PI staining was also used. Long term clonogenic 3D growth was monitored in matrigel. Results: In BRCAm/PTEN null Sum149 and HCC1937 cells and BRCA wild type (wt)/PTEN null MDA-MB-468 the addition of (V) to (O) and (C) enhanced apoptosis induction and further slowed growth. In Sum149 cells, single agent V treatment induced G1 arrest while O plus C or the triple combination increased S phase accumulation. In MDA-MB-468 cells G1 arrest was seen with V alone and in the triplet. In BRCA wt/PTEN null HCC70 cells V decreased cell proliferation and induced G1 arrest. In the HCC70 model, the addition of O plus C did not synergize with V. In BT20, a BRCA wt/PTEN wt but PI3KCA mutant cell line, no effect on proliferation or apoptosis was seen in the O plus C treated arms. V slowed cell proliferation and increased G1 arrest in a dose-dependent manner. As expected in a BRCA wt/PTEN wt, but RAS active mutant cell line MDA-MB-231 this treatment combination was not effective and was used as an internal negative control. Based on ratios of the normalized slopes of proliferation curves (for triplet), the cells were graded in terms of synergy as SUM149>MDA-MB-468>HCC1937 and HCC70>BT20>MDA-MB231. Treatment with the triplet had the largest effect on reducing 3D colony formation and size as compared to control over single or double treatment. Summary: Here, we present the effect of the combination of vistusertib with olaparib plus carboplatin in several TNBC models. Our data demonstrate that increased effectiveness of the triple combination is seen in cells harboring BRCA1 and PTEN-null mutations. The mechanistic role of these two targets on determining this synergy is being worked out and will be presented at the meeting.
Body: SOX10 is a transcription factor that plays a key role in multiple processes of cellular behaviors in both pathological and physiological processes. In breast cancer biology, the expression of SOX10 is positively correlated with malignancy and prognosis of patients, while the mechanisms under SOX10 mediated malignant phenotypes are not entirely clear. We designed the experimental systems to evaluate SOX10 in promoting progression and metastasis using human triple-negative breast cancer cell line, HCC1806 cells as parental cells. We demonstrated that SOX10 forms a complex with zyxin characterized by co-immunoprecipitation assays and direct binding assays in vitro. Phosphopeptide analyses suggest that $^{45}$S of SOX10 would be modified by phosphorylation. Mutation of $^{45}$S to A in SOX10 ($^{45}$S/A-SOX10) resulted in the failure of the formation of complex with zyxin. In order to characterize SOX10-zyxin complex for regulating gene expressions, we performed microarray studies and demonstrated that the transcription of genes important for breast cancer progression such as TROP2, MSLN, RAB25, CLDN4, CTAG4, MAPK13, PRKCZ, CD74, HPSE, and NEDD9 were significantly upregulated in wt-SOX10 but not $^{45}$S/A-SOX10 transfected HCC1806 cells, suggesting key roles of SOX10-zyxin complex in facilitating cancer metastasis through regulating specific gene expressions. These results were further supported by the results of upregulation of EpCAM, CD44, and ALDH1A1 by wt- SOX10 but not by $^{45}$S/A-SOX10, implicating SOX10 as a regulator of stem cell phenotypes of breast cancer cells. Thus, our results revealed a novel transcriptional regulation by SOX10-zyxin complex and a key residue in SOX10 to mediate the interaction. Given SOX10 is highly expressed in malignant cancer cells, our results suggest that blocking of $^{45}$S of SOX10 is a promising drug target for inhibiting proliferation and metastasis of cancer cells. Furthermore, these results will provide a novel model of the transcription factor-cytoskeletal protein interaction to promote specific gene expressions in microenvironments in the processes of both cancer progression and possibly development.

Title: GNB2 suppresses tumor growth and cancer stem cell load of triple negative breast cancer by controlling STAT3 pathway

Jin Zhang. "Tianjin Medical University Cancer Institute & Hospital, Tianjin, China.

Body: Background: Gametogenetin binding protein 2 (GGNBP2) is encoded in human chromosome 17q12-q23, a region known as a breast and ovarian cancer susceptibility locus. GGNBP2 has a single C2H2 zinc finger and a consensus LxxLL nuclear receptor (NR) binding motif. We have reported that GGNBP2 suppresses ERα-positive breast tumorigenesis by acting as a nuclear receptor co-repressor to restrain ERα activity. However, the detailed molecular mechanisms of GGNBP2 and its role in triple negative breast cancer (TNBC) remain largely unclear.

Methods: A human breast cancer tissue array containing 138 human breast tumor tissues were utilized to examine GGNBP2 expression in breast cancer samples by IHC. To address the potential anti-breast tumor activity of GGNBP2 in vitro, we expressed exogenous GGNBP2 in TNBC cells, including MDA-MB-231 and Cal51 cell lines. Cell proliferation and cell cycle were assessed by cell growth curve/EdU assays and flow cytometry after propidium Iodide staining. Apoptosis was determined by flow cytometry after annexin V staining, by caspase 3/7 and caspase 9 activity assays. Cancer stem cell properties were determined by expression of CD44/CD24/ALDH1 markers. The levels of phosphorylated STAT3 and total STAT3 were determined by western blot. Quantitative PCR and Western blot were carried out to evaluate the effects of GGNBP2 overexpression on STAT3 target genes, CCND1, Mcl-1, survivin, bax and bim expression.

Results: GGNBP2 expression is down-regulated in TNBC cells and patient tumors and it is associated with poor patient survival. Overexpression of GGNBP2 significantly induces cell cycle G0/G1 phase arrest and apoptosis in TNBC cell lines. Expression of cancer stem cell markers also decreased in GGNBP2-overexpressed TNBC cells. GGNBP2 reduces the expression levels of CCND1, Mcl-1 and survivin, promotes the expression levels of bax and bim proteins. Importantly, overexpression of GGNBP2 inhibits STAT3 phosphorylation and STAT3 downstream garget gene expression, including CCND1, Mcl-1 and survivin.

Conclusion: GGNBP2 serves as a critical nuclear negative regulator of STAT3-mediated gene expression and tumorigenesis.
Junctional adhesion molecule-A (JAM-A) is a transmembrane protein with important physiological functions in regulating cell-cell adhesion. Pathophysiologically, its high expression in breast tumour tissue has been shown to correlate with that of Human Epidermal Growth Factor Receptor-2 (HER2), whilst JAM-A knockdown in breast cancer cells has been shown to reduce HER2 expression and signaling. Although HER2 has been successfully targeted in the oncology setting for several years, the problem of clinical drug resistance to HER2-targeted therapies (among other factors) has recently put the spotlight on other HER family members and their upstream regulators as potential drug targets. HER3 is the most potent binding partner of HER2 in activating tumor growth signaling, and accumulating evidence suggests that HER3 plays an important role in resistance to anti-HER2 therapies. Furthermore HER3 is frequently overexpressed in HER2-negative breast cancers, and, along with other HER family members, may drive HER2-independent tumorigenic mechanisms. Since JAM-A levels have been reported to regulate HER2 expression (Brennan et al, Oncogene 2013 32(22):2799-804), we hypothesised that JAM-A also regulates expression of HER3 in breast cancer cells. Results from our study showed that stable overexpression of JAM-A in MCF7 breast cancer cells (MCF7-JAM) increased both mRNA and protein expression of HER3. Correspondingly, transient gene silencing of JAM-A reduced the mRNA and protein expression of HER3 in MCF7 and MCF7-JAM cells. JAM-A silencing also reduced HER3 expression in HER2-positive BT474 breast cancer cells. As the cell lines tested were all Estrogen Receptor-α (ERα)-positive, we examined whether ERα was required to permit JAM-dependent regulation of HER3. However concomitant silencing of ERα in MCF7 cells did not alter the capacity of JAM-A silencing to reduce HER3 protein levels. In MCF7 and MCF7-JAM cells, JAM-A gene silencing phenocopied that of HER3 gene silencing by reducing protein expression of the HER downstream effectors phospho-AKT and phospho-ERK, in parallel with significant reductions in cell viability (measured by Alamar Blue assay). To begin exploring the mechanism whereby JAM-A regulates HER3 expression, we focused on the HER3 transcription factor FOXA1. JAM-A knockdown reduced expression of FOXA1 in MCF7 and MCF7-JAM cells, and knockdown of FOXA1 was sufficient to reduce HER3 expression in the same cells. Taken together, our data provide novel evidence of a direct relationship between levels of JAM-A, FOXA1 and HER3 in breast cancer cells. The relationship appears to be uni-directional, since silencing of HER3 did not alter JAM-A expression in any cell line tested. In conclusion, we suggest that JAM-A merits investigation as a novel target to inhibit HER3-dependent tumorigenic signaling in breast cancer. Our ongoing investigations will determine the pharmacological value of inhibiting JAM-A signaling in breast cancer models, and its potential significance in the setting of resistance to HER2-targeted therapies.
Title: TMEM126A suppresses TGFβ-driven epithelial-to-mesenchymal transition and metastasis in breast cancer by regulating mitochondrial retrograde signaling

Hefen Sun¹, Yang Zhao¹, Mengting Chen¹ and Wei Jin¹. ¹Key Laboratory of Breast Cancer in Shanghai, Collaborative Innovation Center of Cancer Medicine, Fudan University Shanghai Cancer Center, Shanghai, China.

Body: TMEM126A is a one of mitochondrial transmembrane proteins and its functions and mechanisms involved in breast cancer progression remain unclear. Here, by performing SILAC assays in breast cancer primary and metastasis cell models we found that TMEM126A expression was decreased in breast metastasis cell. We further confirmed its expression in breast cancer cells and tissues. Down-regulation of TMEM126A in breast cancer cell lines significantly elevated cell metastasis in vitro and in vivo and overexpression it decreased the metastatic potential. Mechanistic studies by RNA-Seq indicated that TMEM126A may regulate cell metastasis by MAPK, CAMs, Focal adhesion, actin cytoskeleton, TGFβ. Our further study revealed that loss of TMEM126A can activate p-smad3 and promoted cell epithelial-to-mesenchymal transition and actin cytoskeleton rearrangement. What's more, TMEM126A silence induces an increase in production of ROS, depolarization of MMP and cell metabolic disorders, such as increased ATP productin and decreased lactate secretion. Low TMEM126A expression correlated with tumor progression and poor prognosis in patients. Collectively, our study shows that loss of TMEM126A induces mitochondrial dysfunction and subsequently leads to cell metastasis promotion via activating p-smad3 induced epithelial-to-mesenchymal transition and actin cytoskeleton rearrangement. These findings identified TMEM126A as a novel metastasis suppressor and may providing potential new prognostic indicators for breast patients.
Title: Breast tumour kinase and its role in mTOR signalling

Amanda Harvey¹, Helen Foster¹, Maria Thorpe¹ and Emmanouil Karteris¹. ¹Brunel University London, London, United Kingdom.

Body: Background: The development of distal metastases and the acquisition of resistance to chemotherapeutic agents are one of the leading causes of cancer related death in breast cancer patients. There is both a scientific and clinical need to understand the alterations in cellular signalling pathways that could contribute to chemotherapeutic resistance in breast cancer, thereby identifying novel targets for therapy. The intracellular tyrosine kinase Brk/PTK6 enhances coupling of ErbB signalling to PI3K/Akt and we hypothesise that Brk plays a role in chemo-resistance and activation of downstream effectors such as mTOR.

Methods: The protein and activation levels of mTOR pathway components and expression levels of Brk, in both Taxol-sensitive and resistant breast cancer cells, were examined by western blotting and immunofluorescence. Brk transfected cells were treated with BEZ-235 for 72 hours and relative cell numbers determine by MTT assay. Immunoprecipitation studies were carried out on lysates from T47D cells, transfected to express FLAG-tagged Brk, with ANTI-FLAGM2 agarose beads. Sequence alignment was done using the NCBI BLAST Tool.

Results: We found that mTOR signalling was up-regulated in the Taxol-resistant cell line compared to parental Taxol-sensitive cells. This up-regulation was also accompanied by increased Brk levels. Transfection of a Brk-negative breast cancer cell line, MDA-MB-468 with wild-type Brk resulted in increased levels of both mTOR and, to a lesser extent, the downstream signalling component GβL at the protein level compared to cells transfected with vector only. Levels of the mTOR inhibitor DEPTOR were also decreased in response to Brk expression and mTOR co-precipitated in FLAG-Brk pull downs using FLAG M2 beads. The Taxol resistant cells also showed altered responses to the mTOR inhibitor RAD-001/everolimus. Interestingly, sequence alignment revealed that there are common amino acid motifs between Brk and the mTOR regulatory molecule DEPTOR.

Conclusions: These data implicate Brk in up-regulating mTOR expression and indicate that Brk may influence mTOR signalling in the development of Taxol resistance. It is possible that Brk could substitute for DEPTOR in mTOR complexes providing a mechanism for elevated mTOR signalling in many breast cancers.
Title: The ratio of omega-3 to omega-6 PUFAs impact cancer cell phenotype in the tumor microenvironment

Laura Winikka¹, Duan Quach¹, Brittany Harlow¹, Andrew Brenner², Nathalie Munoz¹, Stefano Tiziani¹ and Linda deGraffenried¹.
¹University of Texas, Austin, TX and ²University of Texas Health Science Center, San Antonio, TX.

Body: Background: Studies have shown that obesity is associated with a worse breast cancer prognosis. Besides the effect of different stages of diagnosis and co-morbidities, recent data from our published in vitro and retrospective studies suggests that this phenomenon may occur because the obese state promotes a more aggressive cancer phenotype through the cyclooxygenase (COX-2) pathway and its production of prostaglandin E2 (PGE2). The metabolization of omega-3 fatty acids decreases the production of PGE2, and have been shown to have potential benefit to cancer patients by decreasing inflammation-related signaling. Our previous clinical trial showed mixed results in the effect of omega-3 PUFA supplements on PGE2 production in post-menopausal obese women. This led us to the hypothesis that the ratio of omega-3 to omega-6 PUFAs have differential effects on cell types within the tumor microenvironment, impacting cancer cell phenotype.

Approach: In vitro experiments, including wound-healing assays to determine motility, and clonogenic assays to determine overall survival, were performed to determine if exposure to higher ratios of omega-6 to omega-3 fatty acids lead to a more aggressive cancer phenotype. MCF-7 breast cancer cells were treated with the following fatty acid ratios of omega-6 (arachidonic acid (AA)) to omega-3 (eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA)): 46:1, 20:1, 10:1, and 1.3:1. The wound-healing assays showed greater motility with higher ratios of omega-6 to omega-3 fatty acids conditions and the clonogenic assays showed greater survival with the higher ratios.

Conclusion: These data indicate that lowering ratios of omega-6 to omega-3 fatty acids may lessen the aggressiveness of breast cancer cells and be beneficial to some patients. Studies are on-going to investigate the impact of PUFA ratios on cancer cell phenotype directly, including proliferation and invasion, as well as the indirect effects from modulation of the other cells within the tumor microenvironment, including the macrophages and adipocytes.
Title: A novel oncolytic herpes simplex virus, GD116, has enhanced antitumour efficacy in human breast cancer

Lin Cheng¹, Jiani Wang¹ and Renbin Liu¹. ¹The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong, China.

Body: Background: Oncolytic herpes simplex virus-1 (oHSV-1) vectors are promising new therapeutic agents for cancer. For the neurovirulence of ICP34.5 protein, the encoding gene named γ34.5 is deleted in all oHSV-1 mutants currently in clinical trials. However, the deletion of γ34.5 also promotes the interferon-induced shutoff of viral protein synthesis, and attenuates the virus replication in cancer cells at the same time. Previous studies reported that the carboxyl-terminus of MyD116/GADD34 was homologous to that of γ34.5 gene; hence, it might substitute for γ34.5 gene to enhance the replication and cytotoxicity of the virus.

Objective: To reconstruct a novel oHSV-1 mutant named GD116 by inserting γ34.5-MyD116 chimeric gene into G47Δ genome, and to investigate whether the carboxyl-terminus of murine MyD116 can enhance the antitumour efficacy of GD116 on human breast cancer cell line in vitro and in vivo. Methods: Using G47Δ genome and bacterial artificial chromosome (BAC) as the backbone, the GD116 virus expressing γ34.5-MyD116 was reconstructed via Cre/loxp and FLP/FRT recombinase systems. A GD-empty virus mutant containing only the CMV sequence was also constructed as a control at the same time. Then, the replication and cytotoxicity of these two virus mutants in MDA-MB-231 human breast cancer cell line was evaluated in vitro. Meanwhile, the subcutaneous tumor model was also generated by injecting MDA-MB-231 cells into the right flank of BALB/c mice. Then, the antitumor efficacy of GD116 on breast cancer in vivo was evaluated by intratumoral injection. Results: Compared with GD-empty, GD116 possessed an enhanced replication capability and oncolytic efficacy in MDA-MB-231 cell line. On the fifth day after infection with GD116 at MOIs of 0.1 and 0.3, 35.0% and 50.2% of MDA-MB-231 cells were killed respectively, which were higher than that with GD-empty (24.3% and 37.8%). Additionally, GD116 exhibited enhanced antitumor efficacy on subcutaneous tumor xenografts of human breast cancer cells in vivo compared with GD-empty. On day 21 after treatment, the average tumor volume of mice was 585.5 mm³, 289.0 mm³ and 121.9 mm³ in Control, GD-empty and GD116 group respectively. Conclusion: Our findings indicate that the carboxyl-terminus of the murine MyD116 can substitute for the corresponding domain of the γ34.5 gene in oHSV-1 to promote the replication of the virus in infected cancer cells; and the mutant GD116 armed with γ34.5-MyD116 chimaera has enhanced oncolytic effect on MDA-MB-231 breast cancer cells in vitro and in vivo.
Body: The human body harbors ten times more bacterial cells than human cells – a stunning figure that suggests a likely dynamic between our bodies and the bacteria we carry, both in health and disease. In this study, we characterized and compared the gut, oral, and breast tissue microbiomes from women with invasive breast cancer, women with ductal carcinoma in situ (DCIS), and healthy women. Samples were collected prior to any systemic therapy to avoid therapy-associated effects on the microbiomes studied. Kits containing materials for collecting oral and stool swab samples were distributed to patients for self-collection. DNA was isolated from these samples and bacterial 16S rRNA was PCR amplified and sequenced. Based on the sequencing results, bacterial taxa present in the samples were enumerated. In our analyses, we looked at microbial diversity and differential relative abundance of bacterial taxa across the three cohorts. Oral and gut microbial diversity at various taxa levels were assessed using Shannon and Simpson diversity indices. The oral microbiome did not show any significant difference in microbial diversity across the three cohorts. In the gut microbiome, the invasive cohort showed a significant decrease in microbial diversity when compared to the healthy cohort. Differences in phylogenetic and relative abundance of bacterial taxa across the three cohorts were measured using a T-test analysis with a p value less than 0.05 considered significant. In the oral microbiome, there were no significant differences in the relative abundance of bacteria across the three cohorts. In the gut microbiome, there were significant differences in the relative abundance of bacteria within each cohort on the phylum, family, and genus levels. The genus *Fusicanterbacter* (associated with the *Lachnospiraceae* family and *Firmicutes* phylum) was significantly overabundant in gut microbiomes of healthy women when compared to the gut microbiomes of women with DCIS or invasive breast cancer. Meanwhile, the genus *Bacteroides* (associated with the *Bacteroidaceae* family and *Bacteroidetes* phylum) was significantly overabundant in the gut microbiomes of women with invasive breast cancer when compared to the gut microbiomes of healthy women. Although tissues are often thought of as sterile, there is emerging data indicating that different tissues may harbor their own unique microbiomes. We obtained breast tissue microbiome data from a small subset of our breast cancer and DCIS cohorts, as well as healthy breast tissue from reduction mammaplasty specimens. At the genus level, we observed an enrichment of *Lactococcus, Lactobacillus,* and *Halomonas* in healthy breast tissues compared to breast cancer tissues and an enrichment of *Hyphomicrobiunm* in breast cancer tissues compared to healthy breast tissues. Understanding how gut, oral, and tissue microbiomes relate to breast cancer may open up new opportunities for the development of novel markers for early detection (or markers of susceptibility) as well as new strategies for prevention and/or treatment.
**Title:** CRISPR/Cas9-guided editing of spliceosome factors enhances major histocompatibility complex proteins in triple-negative breast cancer

Matias A Bustos¹, Javier IJ Orozco¹, Matthew P Salomon¹,², Dave SB Hoon¹,² and Diego M Marzese¹. ¹John Wayne Cancer Institute, Santa Monica, CA and ²Sequencing Core Center, John Wayne Cancer Institute, Santa Monica, CA.

**Body:** Triple-negative breast cancer (TNBC) exhibits an extraordinary plasticity allowing adaptation to unfamiliar microenvironments and survival despite hindrances imposed by aggressive therapeutic approaches and the immune system. Alternative mRNA splicing (AS), catalyzed by spliceosome factors (SFs), is a major source of transcriptional diversity and phenotypic plasticity for normal and cancer cells. We ascertained that patients with TNBC present up-regulation of specific subsets of SFs mainly involving the epithelial splicing regulatory proteins 1 and 2 (ESRP1/2) and the polypyrimidine tract binding proteins (PTBP1/2). Methods and Results: Through the integration of in-house and publicly-available gene expression profiles (n=890), we evaluated the correlation between the levels of 290 SFs in patients with TNBC. This analysis identified nine subsets of TNBC based on SFs expression profiles with diverse clinical and pathological characteristics. These findings were further validated using data generated by the TCGA-BRCA (n=1,105) and METABRIC projects (n=2,509). Interestingly, up-regulation of PTBP1 was significantly associated with a shorter relapse-free survival interval for patients with TNBC (n=305; HR=1.58 (1.07 – 2.33); p-value=0.02). To systematically identify PTBP1-regulated AS events, we generated and clonally selected CRISPR/Cas9-guided PTBP1 knock-out (KO) TNBC cell lines. Analysis of our RNA-sequencing data at the gene level revealed a significant enrichment of inflammatory response and antigen presentation pathways. Evaluation of potential upstream transcriptional regulators for the enriched molecular pathways and predicted PTBP1 targets identified SMARCA4, a member of the SWI/SNF chromatin remodeling complex, to be significantly activated after PTBP1KO (q-value<0.01). Integration of ENCODE ChIP-sequencing and JASPAR transcription factor binding profile databases revealed clusters of SMARCA4 binding sites upstream of several members of the major histocompatibility (MHC) class I and MHC class II genes. Mechanistically, we identified that PTBP1 induces SMARCA4 exon 30 retention leading to the full length transcript variant 1, which has lower affinity for HLA gene promoter regions. Significant up-regulation of HLA-A, HLA-B, HLA-DPA1, and HLA-DRA genes in CRISPR-guided PTBP1KO TNBC cells was further demonstrated by either western blot or indirect immunofluorescence. Finally, a negative correlation between PTBP1 and HLA genes expression was also identified in multiple breast cancer gene expression datasets. Conclusions: This study suggests that alterations in the PTBP1-associated splicing programming lead to a reduction of the antigen presentation capability of TNBC cells. Due to the limited therapeutic alternatives for patients with TNBC, beyond chemotherapy, further understanding and modulation of this novel alteration may expand the applications of immunotherapy for patients with TNBC.
Title: JNK signaling regulates tumor cell–tumor-associated macrophage cross-talk in triple-negative breast cancer

Xuemei Xie, Shimpei Otsuka, Khoi Chu, Alexander Y Lu, Debu Tripathy, Kevin N Dalby, Walter N Hittelman, Steven Van Laere, Chandra Bartholomeusz and Naoto T Ueno. ¹The University of Texas MD Anderson Cancer Center, Houston, TX; ²The University of Texas at Austin, Austin, TX and ³University of Antwerp, Antwerpen, Belgium.

Body: Despite advances in our understanding of the molecular mechanisms underlying the aggressiveness of triple-negative breast cancer (TNBC), the contribution of tumor-associated macrophages (TAMs) to TNBC pathogenesis has not been therapeutically exploited. TAMs are the most abundant cell types in the tumor microenvironment (TME) and the key contributor to tumor progression and invasion. We have found that c-Jun NH2-terminal kinase (JNK), a member of the MAPK family and a major regulator of inflammation, contributes to TNBC tumorigenesis by promoting the cancer stem-like cell phenotype. However, whether the JNK pathway regulates TAMs and their cross-talk with tumor cells in TNBC remains unknown. Here, we tested the hypothesis that JNK signaling contributes to TNBC aggressiveness by promoting the tumor cell–TAM cross-talk that facilitates TNBC cell invasiveness.

We found that, among 80 patients with primary inflammatory breast cancer (IBC), TNBC tumors (n=18) had 2-fold more TAMs than non-TNBC tumors (n=62, P=0.05) and that high TAM counts were correlated with shorter disease-free survival of patients with IBC (P=0.05). Both JNK1 and c-Jun were highly activated in TAMs, and JNK-IN-8, a pan-inhibitor of JNK, suppressed c-Jun activation. JNK-IN-8 also increased expression of M1 macrophage markers (CD80 and HLA-DR) but reduced expression of TAM markers (CD163 and CD206), suggesting that JNK suppresses M1 macrophage differentiation but promotes TAM differentiation. Co-culture with TAMs significantly enhanced migration and invasion of HCC70 and MDA-MB-468 human and 4T1 murine TNBC cells. Similarly, an enhancement in TNBC cells migration and invasion was observed following culture with TAM-conditioned medium, suggesting that TAMs enhance TNBC cellular activities through paracrine signaling. In addition, inhibition of JNK signaling in TNBC cells or in TAMs by JNK-IN-8 significantly suppressed TAM-promoted enhancement of TNBC cell migration and invasion. These studies strongly suggest that JNK regulates M1/TAM differentiation and TNBC cell–TAM cross-talk. Furthermore, cytokine/chemokine profiling analysis showed that, of the identified molecules, MCP-1 (secreted by TAMs) and VEGF (secreted by TNBC cells) had the highest expression levels and that their expression was dramatically reduced following JNK-IN-8 treatment. Stimulation with recombinant VEGF increased proliferation of MDA-MB-468 cells, and stimulation with recombinant MCP-1 enhanced migration of the cells. These findings suggest that VEGF and MCP-1 are involved in JNK-mediated TNBC cell–TAM cross-talk.

Together, our results suggest that JNK signaling regulates tumor cell–TAM cross-talk through MCP-1– and/or VEGF-mediated paracrine signaling and that JNK is an important therapeutic target in TNBC. Further animal studies using JNK-knockout TNBC cells co-injected with TAMs are needed to confirm our in vitro findings.
Title: Progestin receptor content of breast cancer associated with expression of gene subsets for peptide/protein hormones and cognate receptors in LCM-procured cells that impact clinical outcomes

Michael W Daniels\textsuperscript{1,2}, Guy N Brock\textsuperscript{2} and Wittliff L James\textsuperscript{1}. 1Institute for Molecular Diversity & Drug Design, Louisville, KY and 2Department of Biostatistics & Bioinformatics, Louisville, KY.

Body: Assessing breast cancer prognosis and treatment selection was first enhanced by discovery that estrogen (ER) and progestin receptor (PR) proteins were clinically relevant biomarkers. Later reports suggested expression of certain protein hormones in breast cancer cells appear to be related to clinical behavior. We deciphered clinically relevant relationships between PR content in tissue biopsies and relative expression levels of genes directing synthesis of peptide/protein hormones and their cognate receptors in LCM-procured breast cancer cells. This global approach revealed unique relationships between both PR+ or PR- carcinomas and small subsets of genes for these peptide/protein hormones and cognate receptors as independent predictors of risk of recurrence.

Methods: Expression of genes for 61 peptide/protein hormones and 81 cognate receptor proteins were measured by microarray analyses of LCM-procured carcinoma cells from de-identified primary breast carcinoma biopsies. Using an IRB-approved biorepository and database, previously total RNA was extracted from carcinoma cells to determine expression levels of ~22,000 genes. Univariable and multivariable Cox regressions with interaction of each hormone receptor gene, individually or paired, and use of LASSO were determined with relative gene expression values of each protein ligand and its cognate receptor. PR content and ligand binding affinity of each carcinoma were quantified by FDA approved assays.

Results: Using de-identified clinical outcomes that extended up to 12 years, univariable Cox regression analyses of 142 candidates revealed AVPR1A, AVPR2, CALCR, CRH, LHB, POMC, SCT, SST, SSTR1 and TMSB10 independently predicted PFS or OS. Violin plots identified candidate genes associated with PR content. Multivariable analyses of relative gene expression of 115 hormone-receptor pairs showed IAPP-CALCR, RLN2-RXFP1, GHRH-GHRHR, CGA-TSHR, EDN1-ENDRA and POMC-MC5R exhibited statistically significant interaction for predicting OS among 145 PR+ cancers. Four gene pairs (HCRT-HCRTR2, CRH-CRHR1, HCRT-HCRTR1 and CORT-SSTR4) were associated with OS among 101 PR- lesions. Using LASSO, PR+ lesions expressing either (CGA & SSTR2) or (CGA) predicted OS and PFS, respectively. Similarly, for PR- cancers, gene subsets (GRP, TMSB15, VIP2) or (AGT, GH1, GRP, TMSB15A) predicted OS and PFS, respectively. Three of four signatures were externally validated with SurvExpress.

Conclusion: Different gene expression profiles for protein hormones and cognate receptors were identified in PR+ or PR- carcinomas at time of diagnosis that predict PFS and OS regardless of treatment. Combining PR content with gene expression of LCM-procured cells is likely to provide insight into alternative treatments whereby standard of care performed poorly or to identify genes that correlate with cancer progression regardless of treatment modality. Collectively, results suggest that many primary breast cancers exhibit considerable endocrine autonomy for controlling disease progression, supporting investigation of protein products of gene candidates in isolated populations of breast carcinoma cells to develop novel biomarker assays.
Title: Hyperthermia regulates transporter expression via ROS production and enhances the cytotoxicity of doxorubicin

Azusa Terasaki, Hiromi Kurokawa, Masahiko Terasaki, Hiromu Ito, Hirofumi Matsui, Emika Ichikawa, Yukiko Tsushima, Akiko Manaka-Iguchi, Hiroko Bando and Hisato Hara. 1University of Tsukuba, 1-1-1, Tennodai, Tsukuba, Ibaraki, Japan; 2University of Tsukuba, 1-1-1, Tennodai, Tsukuba, Ibaraki, Japan and 3Graduate School of Medical and Dental Sciences, Kagoshima University, Kagoshima, Japan.

Body: Introduction: Hyperthermia (HT) is a non-invasive cancer therapy. Treatment temperature between 41°C to 44°C has no cytotoxic damage in normal cells, however shows cytotoxicity in cancer cells because of the underdeveloped vascular system. HT often used with other cancer therapy such as radiation therapy and chemotherapy. However mechanism of synergistic effect using these therapies remains unclear. Compared to 37°C, 42°C is mild heat stress for cells, thus superoxide anion is released from tissue. Superoxide anion is produced by mitochondrial electron transport chain. Reactive oxygen species (ROS), produced by mild heat stress, can be released from mitochondria. We have previously reported that ATP-binding cassette sub-family G member 2 (ABCG2) expression was suppressed by increasing mitochondrial ROS, and induction of the cancer specific porphyrin accumulation. ABCG2 is a transporter of doxorubicin (DOX), therefore we hypothesized that synergistic effect of HT and chemotherapy would be induced by down-regulation of ABCG2 expression via intracellular ROS increase. In this study, we investigated if cytotoxic effect of breast cancer cell using DOX can be enhance by HT via intracellular ROS increase.

Materials and methods: The murine breast cancer cell line, 4T1E was incubated at 37°C or 42°C for 1h. Intracellular ROS generation after HT treatment was detected by electron spin resonance (ESR). Twenty four hours after HT treatment, cells were incubated in medium containing 0, 0.1 and 1 µM DOX for 24 h. Cell viability was measured using the Cell Counting Kit 8, a water-soluble tetrazolium-8 based colorimetric assay. ABCG2 expression in whole cells was analyzed by Western blotting.

Results and discussion: ESR signal peak with HT treatment became high as compared to without HT treatment, indicating intracellular ROS level was increased by HT treatment. Cell viability and ABCG2 expression were decreased by DOX exposure and by HT treatment. The enhancement of HT treatment effect by DOX is considered to be result of down-regulation of ABCG2 expression by ROS. When cells were exposed to DOX with 5-aminolevulinic acid (ALA), cell viability reduced further. Since it is known that porphyrin is introduced by ALA and is transported by ABCG2, we speculate that ALA worked as a competitive inhibitor of DOX excretion transporter to enhance cell death. ESR signal peak in ALA treatment cells was higher than that in non-ALA treatment cells. Significant increase in cellular damage by HT treatment was shown by adding ALA, but not without ALA. Moreover, cell death induced by HT and ALA treatment was suppressed by adding N-acetylcysteine (NAC), which is an antioxidant. These results suggest that cellular damage of HT treatment is due to ROS production induced by ALA.

Conclusion: HT treatment involved intracellular ROS production and down-regulated the expression of ABCG2 protein. HT treatment also enhanced the cell damage by DOX. Cell death by DOX was enhanced by combination with HT and ALA treatment, possibly via intracellular ROS generation, and was suppressed by adding antioxidant.
Title: Putting multigene signatures to the test: Prognostic assessment in population-based contemporary clinical breast cancer

Johan Staaf¹, Johan Vallon-Christersson¹, Jari Häkkinen¹, Lao H Saal¹, Cecilia Hegardt¹, Christer Larsson², Anna Ehinger¹, Lisa Ryden³, Niklas Loman¹, Martin Malmberg⁴ and Åke Borg¹. ¹Lund University, Lund, Sweden; ²Lund University, Lund, Sweden; ³Lund University, Lund, Sweden and ⁴Skåne University Hospital, Lund, Sweden.

Body: Background
Gene expression signatures hold promise for a molecularly driven division of primary breast cancer with clinical implications. A gap still remains in the application/validation of such signatures in actual clinical treatment groups from unselected, population-based, primary breast cancer receiving current standard of care therapy. We analyzed classification proportions and overall survival (OS) of 14 reported gene expression phenotypes (GEPs) and risk predictors (RPs) in seven clinical treatments groups from an 3273-sample breast cancer cohort representative of population-based disease in the South Swedish healthcare region.

Patients and methods
Between 2010-09-01 to 2015-03-31, 5101 (87%) of 5892 patients with invasive primary disease in the healthcare region were included in the SCAN-B study (ClinicalTrials.gov ID: NCT02306096). Inclusion criteria included no generalized/prior contralateral disease and known surgery/treatment status (neo- or adjuvant). 3273 tumors were profiled by RNA sequencing and matched to clinicopathological patient data from the National Breast Cancer Register, with distribution of clinicopathological characteristics reflecting proportions in the catchment region. RNA profiles were classified according to 14 reported gene signatures featuring both GEPs (PAM50, IC10, CIT, TNBCtype) and specific risk predictors (e.g. Oncotype Dx, 70-gene, 76-gene, ROR-variants, genomic grade index). Classifications were investigated for association with patient OS by univariate and multivariate analyses in seven adjuvant clinical treatment groups: TNBC-ACT (adjuvant chemotherapy, n=228), TNBC-untreated (n=83), HER2+/ER- with trastuzumab + ACT treatment (n=101), HER2+/ER+ with trastuzumab + ACT + endocrine treatment (n=210), ER+/HER2- with endocrine treatment (n=1477), ER+/HER2- with endocrine + ACT treatment (n=637), and ER+/HER2- untreated (n=216).

Results
For the majority of signatures, analysis of classification demonstrated prognostic value limited to ER+/HER2- tumors given follow-up time. Several signatures (including Oncotype Dx, 70-gene, ROR-variants) showed strong predictive value in identifying a subset of ER+/HER2- patients receiving a combination of endocrine and ACT therapy with excellent overall survival (>96%), indicating appropriate therapy selection. In addition, for both ER+/HER2- treatment groups signature analysis identified high-risk groups of patients in clear need of additional treatment beyond standard therapeutic regimes, even with less than 5-years of follow-up.

Conclusions
Our results support the prognostic association of gene expression signatures in large unselected population-based primary breast cancer cohorts even with a short follow-up of OS. Importantly, prognostic associations are limited to specific subgroups for different classifiers and in population-based breast cancer some clinically important subgroups constitute a small proportion of cases. In this context, continued population-based inclusion and broad transcriptional profiling of breast cancer patients provides an opportunity for application to broader patient groups (e.g. TNBC and HER2+), and for consensus classification of individual risk assessments that could potentially provide more stable predictions.
Comparative survival analysis of multiparametric tests in the TEAM pathology study: What to do when molecular tests disagree?

Body: Multiparametric assays for risk are increasingly used in the management of node-negative and node-positive hormone receptor-positive invasive breast cancer. Data from multiple sources suggests different tests may provide different risk estimates at the individual patient level¹. Analysis from the TEAM pathology study (Bayani and Yao et al npjBreast Cancer, 2017) allows direct comparison of prognostic information from gene signatures in a clinical trial cohort of postmenopausal patients. Risk classifications using genes comprising the following multi-parametric tests: OncotypeDx® (Genomic Health Inc.)²,³, Prosigna® (NanoString Technologies, Inc.)⁴-⁶, Mammaprint® (Agendia Inc.)⁷,⁸ were performed. For the OncotypeDX-Like Recurrence Score (RS), RNA abundance was processed to fit the measurement range as described²,³, with classification into high, intermediate or low risk groups based the derived RS and modeled for DRFS. For the Prosigna-Like Risk of Recurrence Score (ROR), samples were processed as previously outlined⁹, then modelled against DRFS. For the MammaPrint-Like Risk Score, samples were processed by published methods⁸ and modelled for DRFS. Comparing OncotypeDx-Like with Prosigna-Like showed that 45% of cases were classified identically by both (3.3% low risk, 20.9% intermediate, 20.7% high). Of 3370 cases, 353 (10.5%) had scores differing by more than 1 classification (i.e. hi/low or low/high). Almost all (343) of these were cases classified high risk by OncotypeDX-Like RS/low risk by Prosigna-Like ROR (Table 1). Univariate Cox regression analysis, using low/low cases as a reference (relative risk of distant metastasis =1.0), suggested that cases called low risk by Prosigna-Like ROR/High risk by OncotypeDX-Like RS did not perform differently from cases called low risk by both tests (Table 2). However, all cases called intermediate by one test and high risk by another appeared to be high risk (Table 2). Comparisons between Prosigna-Like ROR and MammaPrint-Like scores showed similar concordance between low/low and high/high (52.5% of cases with concordant results). In Prosigna-Like ROR intermediate risk cases, MammaPrint-Like results divided cases between low and high risk, as predicted. Comparisons between these tests is challenging, and evidence on their discordance in risk stratification presents further dilemmas. Preliminary analysis of TEAM suggests a complex inter-relationship between test results in the same patient cohorts requiring careful evaluation.

Title: Breast cancer-specific survival (BCSS) in SEER patients with 21-gene Recurrence Score® (RS) results <11 classified as prognostic stage IA by new 8th edition AJCC staging manual

Frederick L Baehner1,2, Valentina I Petkov3, Debbie McCullough1 and Steven Shak1. 1Genomic Health, Inc., Redwood City, CA; 2University of California, San Francisco, San Francisco, CA and 3National Cancer Institute, Bethesda, MD.

Body: Introduction: The 8th edition of the AJCC Staging Manual added molecular features for the first time and now includes ER, PR, HER2, and the 21-gene assay for prognostic staging. We obtained real-world evidence of BCSS by age, tumor size, and grade in a population-based SEER analysis of N0, HR+, HER2-negative breast cancer and RS <11 (tumor size up to 5 cm) to obtain more detailed information on clinically “unfavorable” subgroups.

Methods: RS results were provided to SEER registries as mandated by their methods for linkage (Petkov npj Breast Cancer 2016). Patients (pts) with RS <11 and size up to 5 cm were eligible if N0, HR+, HER2-negative, had no prior malignancy, and were diagnosed between Jan 2004 and Dec 2012 (SEER survival updated through 2013). 5-year BCSS was estimated using actuarial methods.

Results: 9,304 pts had RS <11 (19% of those meeting all other eligibility), with median follow-up of 40 months. Median age was 59 y, with 22% <50 y and 16% ≥70 y. Tumor size was >2 cm in 21% of pts. Tumor grade was moderate in 54% and poor in 8% of pts. Overall, 5-year BCSS for pts with RS <11 was 99.6% (95% CI 99.4%, 99.7%), with reported chemotherapy (CT) use in 3.3% of pts. In contrast, BCSS for pts with RS >25 and RS ≥31 was 3.5% and 4.7%, respectively, with frequent CT use. 5-year BCSS for important clinicopathologic subgroups show high 5-year BCSS despite “unfavorable” age, tumor size, and grade (Table).

5-y BCSS for RS <11, by Clinicopathologic Factors

</table>

Conclusions: In this SEER population-based study, pts with RS <11 had a wide range of clinicopathologic features. 5-year BCSS was high (>99%), regardless of age, tumor size, or grade. These results support the new AJCC staging criteria that classify N0, HR+, HER2-negative pts with RS <11 and tumor size up to 5 cm as having Prognostic Stage IA disease.
Title: Simplified histological grading of breast carcinoma – potential for improved concordance and consistency in breast cancer grading?

Body: Histological grade remains an independent predictor of outcome for invasive breast cancer. The internationally accepted standard grading system is the Elston and Ellis grading system based on a local hospital (Nottingham) cohort treated between 1951-1973. Histological grade, with nodal status, tumour size and receptor measurements (ER, PgR, HER2) give important information even in the context of current molecular testing for breast cancer. In 2009 we proposed a simplified approach to the EE system based on evidence from another hospital series (Thomas et al Histopathology 2009 DOI 10.1111/j.1365-2559.2009.03429.x). Here we report a second validation of this approach using a large phase III clinical trial cohort the Tamoxifen Exemestane Adjuvant multicentre Trial.

A single pathologist (EM) regraded over 4200 cases using a single H&E slide from the TEAM pathology study. Individual scores (1-3) were provided for tubule formation, nuclear pleomorphism and mitotic count and summed to provide the EE score (3-9) resulting in a final grade of 1, 2 or 3 for each case. As previously reported the Simplified Binary Scoring system (SBS) reorganizes this data such that each component is given a score of 1 or 2 with a sum ranging from 3-6. In the current analysis we compared the impact of this revised grading system on patient outcome.

Of 4264 centrally regraded tumours in the TEAM pathology cohort, EE scores for tubular formation were 1 in 102 cases (2.4%), 2 in 503 cases (11.8%) and 3 in 3659 (85.8%). For nuclear pleomorphism only 2 cases were EE score 1 (0.05%), 3117 were score 2 (73.1%) and 1146 score 3 (26.9%). For Mitotic count 3423 (80.3%) were scored 1, 707 (16.6%) scored 2 and 134 scored 3 using the EE system. As previously observed, most/all EE categories could be captured using a simple binary system (SBS, see Table 1).

In a comparison between conventional grading and molecular (using a Genomic-Grade signature) we observed the predicted equal split of EE Grade 2 cases into GG high/versus low. For the SBS score the higher scores were enriched for GG High cases. We show a novel grading system can provides a potentially simple and more reproducible approach to immunohistochemical grading. Comparisons with molecular grading approaches may suggest improved concordance between novel grading approaches and molecular systems. Further comparisons with outcome and molecular signatures will be presented.
Clinical practice and mortality in patients with oncotype DX intermediate score: What do we know about the gray zone?

Abiola F Ibraheem¹, David Press¹, Huo Dezheng¹ and Funmi Olopade¹. ¹University of Chicago, Chicago, IL.

**Body:**

**BACKGROUND:** The 21 gene expression signature Oncotype DX (ODX) is a powerful predictor of disease outcome in early stage hormone receptor positive breast cancer. ODX can be used for better risk stratification of patients who may benefit from chemotherapy. ODX testing increases confidence in treatment decisions especially when ODX recurrence score (RS) is low or high. However, for the intermediate RS, decisions on receiving chemotherapy or not is a joint decision made by the physician and patient, in part because results from the TAILORx and RxPONDER randomized clinical trials addressing this very important clinical question has yet to be published.

**OBJECTIVE:** To examine “real world” oncology practice and survival outcome for breast cancer patients with ODX RS score in the intermediate range.

**METHODS:** A retrospective cohort of women diagnosed with early stage, hormone receptor positive breast cancer whose ODX score was in the intermediate range was established using the National Cancer Data Base (NCDB), 2009-2013. We assessed the relationship of overall survival with chemotherapy receipt and RS score using Cox proportional hazards models adjusted for patient characteristics, including age, race/ethnicity, grade, year of diagnosis, Charlson Co-morbidity Index, lymphovascular invasion, nodal involvement, tumor size, and histology. Intermediate RS score was analyzed as both continuous variable and categorical variables (18-20, 21-23, 24-26, and 27-30).

**RESULTS:** Of 24,945 females reported to have intermediate ODX score, 10,179 (41.4%) received chemotherapy. Receipt of chemotherapy depended on ODX score monotonically, ranging from 19.1% in patients with RS = 19 to 76.1% in patients with RS = 30. In total, 426 patients have died from all causes. Overall, chemotherapy receipt was associated with a statistically significant reduction in the risk of death (hazard ratio=0.77; 95% confidence interval [CI]: 0.62-0.96, p=0.02) in multivariable Cox model. RS score was statistically positively associated with increased risk of death, with one unit increment in RS corresponding to 6.2% increased mortality risk (95% CI 3.2%- 9.2%, p<0.0001). Using a categorical scale, we found patients with intermediate ODX scores in RS 27-30 range had 1.64-fold increased risk of death (95% CI: 1.13-2.37) compared to patients with ODX scores in RS 18-20 range.. The association between ODX score and overall survival was more pronounced in women younger than 50 (hazard ratio per 1 unit increment = 1.28, 95% CI: 1.17-1.40) than in women 50 years or older (hazard ratio per 1 unit increment = 1.04, 95% CI: 1.01-1.07).

**CONCLUSION:** Our analysis revealed the ODX score in the intermediate range still has prognostic value for overall survival especially for young-onset breast cancer patients, which is independent of other clinopathologic factors. As we eagerly await results from randomized clinical trials, young women with intermediate RS should be counseled to consider more aggressive treatment including chemotherapy, ovarian function suppression or participation in ongoing clinical trials of CDK inhibitors to improve overall survival outcomes.

Title: No age-related outcome disparities according to 21-gene recurrence score groups in early breast cancer patients treated by adjuvant chemotherapy in the prospective WSG PlanB trial

Nadia Harbeck¹, Oleg Gluz²,³, Rachel Wuerstlein¹, Michael Clemens⁴, Wolfram Malter⁵, Toralf Reimer⁶, Benno Nuding⁷, Andrea Stefek⁸, Anke Pollmanns⁹, Doris Augustin¹⁰, Christoph Uleer¹¹, Fatemeh Lorenz-Salehi¹², Steve Shak¹³, Calvin Chao¹³, Matthias Christgen¹⁴, Ronald Kates¹², Hans Kreipe¹⁴ and Ulrike Nitz²,³. ¹University Hospital LMU, Clinics of Gynecology and Obstetrics, Breast Center and CCCLMU, Munich; ²West German Study Group; ³Breast Center Niederrhein, Evangelical Bethesda Hospital, Moenchengladbach; ⁴Mutterhaus Clinics, Trier; ⁵University Hospital, Clinics of Gynecology and Obstetrics, Cologne; ⁶University Hospital Suedtsadt, Clinics of Gynecology and Obstetrics, Rostock; ⁷Evangelical Hospital, Clinics of Gynecology and Obstetrics, Bergisch Gladbach; ⁸Johanniter Hospital, Breast Center, Stendal; ⁹Evangelical Hospital, Clinics of Gynecology and Obstetrics, Oberhausen; ¹⁰Breast Center Ostbayern, Deggendorf; ¹¹Gynecological-Oncological Practice, Hildesheim; ¹²HSK, Clinics of Gynecology and Obstetrics, Wiesbaden; ¹³Genomic Health, Redwood City and ¹⁴Medical School, Institute of Pathology, Hannover.

Body: Background: Elderly breast cancer (BC) patients (pts) have been reported to have worse BC-related outcome than younger pts, even within clinical trials such as TEAM. Shak et al. recently showed in a large SEER data analysis that in the high 21-gene recurrence score (RS) group, older pts (≥70y) receive less chemotherapy (CT) and have a worse BC-specific mortality than younger pts. Here, we therefore aimed to see whether there are age-related outcome disparities according to RS groups in pts receiving state-of-the-art CT in the prospective WSG PlanB trial.

Material and Methods: PlanB compared 6 cycles of anthracycline-free TC vs. standard anthracycline-taxane based CT (4xECà4xDoc) in patients with high risk pN0 (T2-4, G2-3, <35 years, or high uPA/PAI-1) or pN+ HER2- early BC. 21-gene assay was performed in all HR+ tumors and omission of chemotherapy (CT) recommended in RS≤11 HR+ pN0-1 BC. Final analysis for the CT randomization for RS 12-25 after 60 months median follow-up revealed similar 5-year DFS and OS outcomes for both CT arms (ASCO 2017).

Results: In all pts with luminal cancer and RS results (n=2577), there was an age-related significant difference in RS risk group assignment (p<0.0001): in young pts (<40y), 9.1% had RS≤11, 52.7% RS 12-25, and 38.2% RS>25; in pts 40-69 years, 18.3% had RS≤11, 61% RS 12-25, and 20.7% RS>25; in elderly pts (≥70y), 19.5% had RS≤11, 55.3% RS 12-25, and 25.2% RS>25. Among patients receiving chemotherapy, RS>25 vs. RS≤25 was associated with significantly poorer DFS separately within the elderly subgroup (HR=3.03, 95%-CI [1.15-7.96]) and in those aged 40-69 years (HR=3.14, 95%-CI [2.18-4.52]); there were only nine events among patients <40y. In particular, among pts receiving CT with RS>25, there were no significant differences in DFS between any two of these three age groups.

Conclusion: A substantial percentage of elderly patients (≥ 70y) presents with high-risk luminal disease; these patients are candidates for CT. In PlanB, about 25% of elderly luminal BC patients had high-risk (RS>25) tumors. Nevertheless, after receiving modern adjuvant CT, their DFS was comparable to that of non-elderly pts with high-risk RS tumors. Consequently, older BC pts with high-risk luminal tumors who are fit enough to receive adjuvant CT should be treated according to guidelines in order to overcome age-dependent survival disparities which have been observed in registries for high-RS tumors.
**Title:** Mayo clinic TNBC outcome calculator: A clinical calculator to predict disease relapse and survival in women with triple-negative breast cancer

Mei-Yin C Polley¹, Roberto A Leon-Ferre¹, Heshan Liu¹, Judith Gilbert¹, Victoria Cafourek¹, David W Hillman¹, Vivian Negron¹, Judy C Boughey¹, Minetta C Liu¹, James N Ingle¹, Krishna Kalari¹, Fergus Couch¹, Daniel W Visscher¹ and Matthew P Goetz¹.

¹Mayo Clinic, Rochester, MN.

**Body:** Purpose: Triple negative breast cancer (TNBC) is an aggressive breast cancer subtype with substantial risks of disease recurrence. While cytotoxic chemotherapy is commonly administered and reduces recurrence, disease outcomes vary considerably and few prognostic tools are available for risk stratification for TNBC patients. We constructed and validated clinical calculators for invasive-disease free survival (IDFS) and overall survival (OS) for TNBC and compared their performance against AJCC-based models which include only tumor size and nodal status.

Methods: From a surgical cohort of 9,982 patients who underwent breast cancer surgery at Mayo Clinic between January 1985 and December 2012, 605 centrally reviewed TNBC patients were identified and used to construct Cox models for IDFS and OS. Patients treated with neoadjuvant chemotherapy were excluded. Variables considered included age, menopausal status, tumor size, nodal status, Nottingham grade, type of breast surgery (mastectomy vs. lumpectomy), adjuvant radiation therapy, adjuvant chemotherapy, Ki67, stromal tumor infiltrating lymphocytes (sTILs), and neutrophil-to-lymphocyte ratio (NLR). Missing values were imputed using single imputation with all variables (including outcomes) included in the imputation model. Backward step-down procedure was used for model selections. The final models were internally validated for calibration and discrimination using bootstrapping methods and compared with AJCC-based models.

Results: For both IDFS and OS, higher sTIL's, less extensive nodal involvement, use of adjuvant chemotherapy, and lower NLR were significant predictors of improved clinical outcomes. Premenopausal status and younger age were additionally predictive of improved IDFS and OS, respectively. Models for IDFS and OS have good calibration and are associated with bias-corrected C-indices of 0.68 and 0.71, respectively, as compared with C-indices of 0.59 and 0.62 for AJCC-based models.

Conclusions: Our data indicate that a clinical calculator that includes sTIL's, NLR, menopausal status, age, nodal involvement as well as chemotherapy use can provide significantly greater prediction of clinical risk than tumor size and nodal status alone. These tools may be used to identify TNBC patients at elevated risk of disease relapse and to aid physician's communication with patients regarding their long-term disease outlook and planning treatment strategies. External validation is required to further evaluate broader applicability of this tool, which was developed utilizing a single-institutional experience.
Title: Independent validation of EarlyR gene signature in E2197: A randomized clinical trial comparing doxorubicin plus docetaxel to doxorubicin plus cyclophosphamide as adjuvant chemotherapy in breast cancer

Sunil Badve¹, Victoria Wang², Scooter Willis³, Brian Leyland-Jones³, Yesim Gokmen-Polar¹, Lawernce Shulman⁴, Silvana Martino⁵, Joseph Sparano⁶, Nancy Davidson⁷, Lori Goldstein⁸ and Steven Buechler⁹. ¹Indiana University, Indianapolis, IN; ²ECOG-ACRIN, Boston, MA; ³Avera Health, Sioux Falls; ⁴University of Pennsylvania, Philadelphia, PA; ⁵The Angles Clinic, Los Angeles, CA; ⁶Montefiore Medical Center, Bronx, NY; ⁷Fred Hutchinson Cancer Center, Seattle, WA; ⁸Fox Chase Cancer Center, Philadelphia, PA and ⁹Notre Dame University, South Bend, IN.

Body: Background: EarlyR is a prognostic gene signature score in ER+ breast cancer (BC) computed from the expression values of ESPL1, SPAG5, MKI67, PLK1 and PGR using a nonlinear mathematical formula. EarlyR has been validated in multiple cohorts profiled on Affymetrix and Illumina microarrays and by RNA-seq. This study sought to assess the prognostic features of EarlyR in a cohort of E2197.

Patients and Methods: Illumina DASL assay was used to measure gene expression in FFPE tissue of primary BC from a case-cohort sampling subset of women in E2197 treated with doxorubicin plus docetaxel (AT) or doxorubicin plus cyclophosphamide (AC). ER+ patients received hormone therapy at physician’s discretion. After 79.5 months median follow-up, disease-free survival was 85% in both treatment arms. Among patients centrally reviewed with sufficient RNA material for the DASL assay, 319 with ER+ status and assessed for EarlyR are included in the analytic cohort. EarlyR scores and pre-specified risk strata (≤25=low, 26-75=intermediate, >75=high) were computed, while blinded to clinical data. The analysis endpoint was disease-free survival (DFS), defined as the time from randomization to date of invasive BC recurrence or death from any cause within 8 years. Weighted Cox proportional hazards models were used to associate EarlyR score or risk strata with DFS. Variances of the estimated coefficients were adjusted to account for the case-cohort design.

Results: The distribution of the EarlyR risk groups was 59% low, 11% intermediate and 30% high risk in this ER+ cohort. The continuous EarlyR score was significantly prognostic of DFS up to 8 years after randomization (p = 0.02). Patients with low EarlyR score (≤ 25) had significantly lower risk of BC recurrence within 8 years (p = 0.031, univariate HR=0.562, 95%CI: 0.334-0.948) compared to those with high EarlyR score (> 75). Analysis within the AC arm showed that patients with low EarlyR score had significantly lower risk of 8-year BC recurrence (p = 0.023, univariate HR=0.392, 95%CI: 0.175-0.878) compared to those with high EarlyR score. Within the AT arm there was no significant difference in 8-year DFS prognosis between any of the EarlyR risk groups.

Conclusions: This study confirmed the prognostic significance of EarlyR using FFPE tissue in a cohort of patients treated with AC chemotherapy from E2197. Patients with high EarlyR score who were treated with AC had significantly higher risk of recurrence than low EarlyR score patients treated with AC. On the other hand, prognosis of high EarlyR score AT-treated patients was not significantly lower than the prognosis of low EarlyR score AT-treated patients. Further study in a larger cohort is needed to assess the relative benefits of AC versus AT within the EarlyR high risk group and the EarlyR low risk group.
Title: Correlation of breast cancer index (BCI) results to lymphovascular invasion in early stage HR+ breast cancer

Manasa Vulchi¹, Max Sagalnik², Catherine A Schnabel² and Jame Abraham¹. ¹Cleveland Clinic and ²Biotheranostics, Inc.

Body: Background: Positive lymphovascular invasion (LVI) is a negative prognostic factor for women with early-stage ER+ breast cancer. LVI, along with other clinicopathologic factors such as larger tumor size, higher grade and positive nodal status, increase a patient's risk of late (post-5y) recurrence. Breast Cancer Index (BCI) is a validated gene expression-based assay for patients with early-stage HR+ breast cancer that reports an individualized risk of late distant recurrence based on a combination of the HOXB13/I17BR ratio and the molecular grade index (MGI). The correlation of LVI and individualized risk stratification by genomic analysis is not well characterized. Therefore, this study evaluated risk stratification by BCI based on the presence or absence of LVI.

Methods: A population of 2,613 patients with known LVI status were identified in the Breast Cancer Index Clinical Database for Correlative Studies, an IRB-approved de-identified database which contains clinicopathologic and molecular variables of more than 19,000 clinical cases submitted for BCI testing. LVI was recorded as either positive or negative based on pathology report review. BCI results based on LVI status from LN- (n=2035) and LN+ patients (n=578) were evaluated separately. Chi-squared tests were used to compare BCI results between LVI groups.

Results: In analyses of 2,613 patients with LVI data available (median age 59.1 y; range 28-89y; 74% ≥50y), 18.3% of patients showed evidence of LVI (LVI-pos). In comparison to the LVI-neg tumors submitted for BCI testing, the LVI-pos tumors had a higher proportion of grade 3 tumors (33% vs 16%, p<0.0001), more LVI-pos tumors were 2.0 cm or greater (45% vs 23%, p<0.0001), a higher percentage LVI-pos patients had node-positive disease (51% vs 16%, p<0.0001), and a higher proportion of LVI-pos tumors showed high Ki67 (Ki67 ≥14%; 64% vs 51%, p=0.004). A correlation between LVI positivity and high BCI prognostic risk was observed, with a higher proportion of LVI-pos patients classified as high risk of late distant recurrence in both the LN- (68% vs 49%, p<0.0001) and LN+ subsets (84% vs 70%, p<0.0001) compared to LVI-neg patients. LVI-pos patients had a higher median molecular proliferative status (MGI) compared to LVI-neg patients regardless of nodal status (p<0.0001 for both). In contrast to the categorical LVI prognostic factor, the wide distribution of BCI individual risk scores provides additional resolution that identifies a substantial subset of LVI positive tumors (32%) that that have a low risk of late recurrence by genomic analysis.

Conclusion: While BCI Prognostic stratification correlated with LVI status, BCI identified a subset of patients with LVI positivity as having a low risk of late distant recurrence that otherwise would have an unfavorable prognosis based on LVI and/or LN positivity. These findings help to characterize differential patient stratification based on an individualized assessment of tumor biology versus LVI for patients considering EET.
Title: Correlative analysis of breast cancer index (BCI) restratification of 21-gene recurrence score (RS) in patients with hormone receptor-positive (HR+), node-negative breast cancer

Fengting Yan¹, Aashini K Master², Mason A Israel³, Junmei Liu³, Catherine A Schnabel³, Sara Hurvitz² and Vijayakrishna K Gadi¹. ¹University of Washington/Fred Hutchinson Cancer Research Center; ²University of California Los Angeles and ³Biotheranostics, Inc.

Body: Background: In a cross-stratification analysis performed within the TransATAC cohort, Breast Cancer Index (BCI) and 21-gene Recurrence Score (RS) had a concordance of 58.2% (Sestak et al., Clin Cancer Res, 2016). Restr stratification by BCI of the low and intermediate RS risk groups led to subgroups with significantly different rates (P < 0.001 and P = 0.003, respectively); in contrast, restratified subgroups created by RS of BCI risk groups did not differ significantly. The objective of this study was to analyze the concordance of BCI and RS test results in HR+, node-negative (LN-) patients tested in the real-world setting and to investigate molecular, clinical, and pathologic correlates within discrepant cases.

Methods: This study utilized a subset of cases from the BCI Clinical Database for Correlative Studies, an IRB-approved de-identified database which contains clinicopathologic and molecular variables from clinical cases submitted for BCI testing. Clinicopathologic variables, abstracted from pathology reports, were available for a subset of cases. This analysis evaluated cases from LN- patients with available RS data. Concordance was evaluated between BCI Prognostic risk groups (Low, High) and RS risk groups (Low, Intermediate, High based on TAILOR Rx cutpoints [0-10, 11-25, and 26+]). Fisher's Exact tests were used to compare molecular (HoxB13/IL17BR [H/I] endocrine response biomarker and Molecular Grade Index [MGI] proliferation marker) and clinicopathologic (age, grade, size, HER2, Ki67) data in discrepant risk groups.

Results: There were 456 LN- patients included. Median age was 58.0y (range 27.2-84.0y; 73.9% ≥50y); 33.1%/50.1%/16.8% were grade 1/2/3; and 24.0%/59.5%/15.3% were T1ab/T1c/T2. BCI classified 47.8% (n=218) of patients as Low Risk vs 52.2% (n=238) as High Risk. RS classified 17.1% (n=78), 67.1% (n=306), and 15.8% (n=72) of patients as Low, Intermediate, and High Risk, respectively. BCI restratified RS-Low patients as high risk in 17.1% of cases, restratified RS-Intermediate as Low Risk in 48.4% and High Risk in 51.6%, and restratified RS-High as Low risk in 20.8% of cases. In RS-Low patients, only H/I (P=0.0004) and MGI (P=0.047) were significantly correlated with restratification to BCI-High Risk. In RS-Intermediate patients, H/I (P<0.0001), MGI (P<0.0001), grade (P<0.0001), and Ki67 >20% (P=0.0003) were significantly correlated with restratification by BCI to High or Low Risk. In RS-High patients, H/I (P=0.0008), MGI (P<0.0001), grade (P=0.016) were significantly correlated with restratification to Low Risk.

Conclusion: BCI restratified a substantial proportion of patients in each RS risk group. Based on previous studies demonstrating that BCI has improved prognostic ability for assessment of risk of late distant recurrence (Sgroi et al., Lancet Oncol, 2013), these results highlight the clinical utility of BCI within all RS risk groups. The estrogen signaling pathway biomarker H/I and proliferative biomarkers (MGI, grade, Ki67) were associated with restratification by BCI, while age, HER2 status, and tumor size were not.
**Title:** Prediction of oncotype DX® results based on local gene expression measurements by MammaTyper®

Hans-Anton Lehr¹, Sebastian Aulmann², Mark Laible³, Alfred Etzrodt², Kerstin Hartmann³, Claudia Gürtler³, Ugur Sahin³ and Zsuzsanna Varga⁴. ¹Institute of Pathology, Medizin Campus Bodensee, Friedrichshafen, Germany; ²OptiPath - MVZ für Pathologie, Frankfurt a.M., Germany; ³BioNTech Diagnostics GmbH, Mainz, Germany and ⁴Institute of Surgical Pathology, University Hospital Zurich, Zurich, Switzerland.

**Body:** Background: Oncotype DX® recurrence score (RS) has emerged as a recommended risk classifier for patients with ER+/HER2- early-stage breast cancer. While RS is one of the most rigorously studied risk scores, it is also one of the most expensive tests, thus remaining beyond reach for a many patients.

The necessity for an affordable method for estimating risk of recurrence has motivated investigations on the correlation between RS and traditional parameters such as IHC for ER, PR and Ki67. However, semi-quantitative IHC lacks standardization across different laboratories especially for Ki67.

In this study we therefore investigated whether the standardized assessment of HER2, ER, PR, and Ki67 on mRNA level could better serve for prediction of low risk RS cases.

**Methods:** ERBB2, ESR1, PGR and MKI67 mRNA expression was measured by RT-qPCR in extracts from FFPE breast cancer samples using the MammaTyper® test. Complete data for RS, IHC, grading and mRNA measurement was available for 198 samples. Tumor subtypes according to St Gallen surrogate definition from 2013 were assigned based on binary mRNA marker classification (pos/neg) according to pre-defined cut-offs. Subtype results were compared to RS risk classes based on commercial and TAILORx-trial cut-offs. RS low risk classification (RS ≤25) based on four IHC markers and grading was estimated using the online tool breastrecurrenceestimator.onc.jhmi.edu and compared to observed RS classes.

Finally, the prediction of continuous RS values by mRNA or semi-quantitative IHC measurement was compared by linear regression and subsequent ROC analysis of prediction models.

**Results:** The distribution of RS risk classes in the set of samples with full data was 21% RS 0-10, 39% RS 11-17, 27% RS 18-25, 7% RS 26-30 and 7% RS >30. MammaTyper® called 38% (76) of the samples as Luminal A-like. From these samples 70% and 99% had RS values below 18 and 25 respectively. Only 1 MammaTyper® Luminal A-like sample had an RS >30.

Estimation of RS according to the online tool resulted in classification of 61% (121) of the samples as low risk (RS ≤25). Of these 74% and 98% of samples had observed RS values below 18 and between 18 and 25 respectively. 2 and 1 samples called as low risk by the online tool had an RS of 26-30 and >30 and, respectively.

In linear regression analysis of IHC against RS only PR and Ki67 were significant predictors (p-values <0.0001 and 0.0128) while when using mRNA values ESR1, PGR and MKI67 were found as predictors of RS in the multivariate model (all p-values <0.0001). On a training set (67% of samples) the IHC based prediction model was correlated to the observed RS with an R² of 0.305 whereas the mRNA based model achieved an R² of 0.489. When the models were applied to training and validation dataset (33% of samples) for prediction of an RS >25 result, the IHC based model had AUCs of 0.887 and 0.836, respectively, while the mRNA based model achieved AUCs of 0.909 and 0.899, respectively.

**Conclusion:** mRNA based prediction of RS was considerably better than prediction based on IHC. As Ki67 IHC standardization is reaching its limits, local gene expression measurements with their high degree of standardization could serve as a safer way for prediction of Oncotype low risk results.

**Title:** Optimizing the use of oncotype Dx in early breast cancer

Rossana Ruiz¹², Fernando Namuche¹, Claudio Flores¹, Alfredo Aguilar¹ and Henry L Gomez¹. 'Oncosalud, Lima, Peru and ²Instituto Nacional de Enfermedades Neoplasicas, Lima, Peru.

**Body:**

**Background:** Oncotype Dx (ODX) prognosticates the risk of recurrence and predicts the benefit of adjuvant chemotherapy in estrogen-receptor-positive breast cancer (BC). However, its cost makes it prohibitive for many health care systems. Our objective was to develop a model that uses routine clinical and pathological parameters to identify ODX high risk patients which require adjuvant chemotherapy.

**Methods:** We retrospectively reviewed ODX and pathology reports from 190 early BC patients treated between 2014 and 2016 in a specialized cancer center. Our population was divided into a training (n:133) and validation set (n:57). In the training set, among available clinico-pathological variables (age, T, ER, PR, Ki67, Elston-Ellis grade) a multiple linear regression model was carried out to select those significantly associated with ODX. Coefficients of statistically significant variables were used to build an equation. The equation was applied in the training set. These results were confronted to ODX categories. The best threshold for selecting high risk patients was identified in the training set and tested in the validation set.

**Results:** Among the tested variables, tumor size (pT), progesterone receptor (PR), Ki67 and Ellston-Ellis grade were significantly associated with ODX RS (Table 1). The linear predictor is: 

\[(0.2544 \times pT) – (0.0739 \times PR) + (0.0861 \times Ki67) + (5.4232 \times Elston\ grade)\]

The threshold score for this equation was set on 14 to discriminate high from low-intermediate risk patients. The test was able to correctly classify high risk patients with a sensitivity of 78%, a specificity of 72% and a negative predictive value of 98%.

**Conclusion:** With further refinement ODX could be omitted in patients classified as high risk by our predictor therefore restricting and optimizing the use of ODX to a smaller population of patients. The observed ODX distribution in our patients is similar to previously reported series suggesting that this equation could be informative in similar clinical settings. Additional external testing using new datasets is ongoing.

Title: HLA class I expression is associated with tumor-infiltrating lymphocytes and response and survival after neoadjuvant chemotherapy in hormone receptor-positive, HER2-negative breast cancer

Bruno V Sinn1,2, Karsten Weber3, Carsten Denkert1, Peter A Fasching4, Wolfgang D Schmitt1, Karin Thomas4, Barbara Ingold-Heppner1, Marion van Mackelenbergh6, William F Symmans8, Frederic Marmé8, Eliane Taube1, Volkmar Müller9, Catarina A Kunze1, Christian Schem6, Berit M Pfitzner1, Elmar Stickeler10, Gunter von Minckwitz2 and Sibylle Loibl3. 1Charité – Universitätsmedizin Berlin, Berlin, Germany; 2Berlin Institute of Health, Berlin, Germany; 3German Breast Group Forschungs GmbH, Neu-Isenburg, Germany; 4University Hospital Erlangen, Erlangen, Germany; 5University Hospital Frankfurt, Frankfurt, Germany; 6University Hospital Schleswig-Holstein, Kiel, Germany; 7The University of Texas – MD Anderson Cancer Center, Houston, TX; 8University Hospital Heidelberg, Heidelberg, Germany; 9University Hospital Hamburg-Eppendorf, Hamburg, Germany and 10RWTH Aachen, Aachen, Aachen, Germany.

Body: Background: Interactions between cancer cells and the host immune system influence tumor biology, response to therapy and patient survival and their modulation offers promising new approaches for cancer therapy. The downregulation or loss of HLA class I expression in breast cancer cells might be an effective mechanism to evade the recognition by the immune system facilitating malignant behavior.

Aim: To evaluate the association of tumor-infiltrating lymphocytes (TILs) with HLA class I expression and its theranostic value for therapy response and survival after neoadjuvant chemotherapy.

Methods: HLA class I expression was evaluated by immunohistochemistry in a cohort of 732 pre-therapeutic core biopsies from breast cancer patients treated within the neoadjuvant GeparTrio trial. Patients received anthracycline- and taxane-based neoadjuvant therapy and adjuvant endocrine treatment if hormone receptor-positive (HR+). A publicly available microarray dataset of pre-therapeutic core biopsies from 508 breast cancer patients that received neoadjuvant chemotherapy and endocrine treatment if HR+ was used for validation of the results. The association of HLA class I expression with predefined genomic signatures for immune cell populations was evaluated in publicly available data from the cancer genome atlas.

Results: HLA class I expression was associated with TILs (p < 0.001) and was predictive of better response to neoadjuvant chemotherapy in the subgroup of patients with HR+/HER2- breast cancer (14 % in tumors with high HLA vs. 7 % in tumors with low HLA, p = 0.029). Interestingly, high HLA was also predictive for shorter progression-free survival in univariate analysis (HR 1.590, 95 % CI 1.062—2.380; p = 0.024) and after adjustment to clinical and pathological parameters (HR 1.701, 95 % CI 1.105—2.618; p = 0.016). The results could be validated in the independent microarray-based dataset (HR 1.521, 95% CI 1.088 – 2.129; p = 0.0142). HLA class I was not associated with therapy response or survival in hormone receptor-negative breast cancer. HLA class I was associated with a predefined signature for T-cells and cytotoxic T- cells in the cancer genome atlas dataset (rho = 0.546).

Conclusion: HLA class I expression is associated with better response but shorter progression-free survival in HR+/HER2- breast cancer following neoadjuvant chemotherapy. The underlying mechanisms warrant further investigation.
Title: Evaluation of the prognostic value of CD3, CD8 and FOXP3 mRNA expression in early breast cancer patients treated with anthracycline-based adjuvant chemotherapy

Marinos Tsiatas¹, Konstantine T Kalogeras¹, Kyriaki Manousou¹, Ralph M Wirtz², Helen Gogas¹, Elke Veltrup², Flora Zagouri¹, George Lazaridis¹, Angelos Koutras¹, Christos Christodoulou¹, George Pentheroudakis¹, Constantina Petraki¹, Dimitrios Bafaloukos¹, Dimitrios Pectasides¹, Paris Kosmidis¹, Epaminontas Samantas¹, Charisios Karanikiotis¹, Pavlos Papakostas¹, Meletios-Athanassios Dimopoulos¹ and George Fountzilas¹. ¹Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece and ²STRATYFIER Molecular Pathology GmbH, Cologne, Germany.

Body: Background: Tumor-infiltrating lymphocytes (TILs) have been shown to be of prognostic value in several cancer types. In early breast cancer, TILs have a prognostic utility, as well, especially in HER2-positive and triple-negative breast cancer (TNBC). TILs presence is broadly associated with improved survival, however there is controversy regarding TILs subpopulations. In general, T cell infiltration is higher in non-luminal and more aggressive tumors, like the basal-like subtype. Among TILs subpopulations, CD8-positive T cell infiltration is associated with better outcome, whereas high numbers of FOXP3-positive T regulatory cells are associated with worse outcome in ER-positive tumors and better outcome in HER2-positive and TNBC tumors.

Patients and Methods: Early breast cancer patients, treated with anthracycline-based chemotherapy within two randomized trials (HE10/97 and HE10/00) were included in the study. We evaluated, by qRT-PCR, 826 macrodissected formalin-fixed paraffin-embedded tumor tissue samples for mRNA expression of CD3, CD8 and FOXP3 for potential prognostic significance in terms of disease-free survival (DFS) and overall survival (OS). TILs were evaluated in whole sections as percent of total cells.

Results: Median age was 52.7 years, while 54.2% of the patients were postmenopausal and 79.0% ER/PgR-positive. After a median follow-up of 133.0 months, 255 patients (30.9%) had died and 314 (38.0%) had disease progression. All three mRNA markers were positively correlated with TILs (Spearman's r=0.52 for CD3, 0.41 for CD8 and 0.47 for FOXP3, all p-values <0.001), while Ki67 protein expression was greater in tumors with high mRNA expression (median cut-off) of the markers (Mann-Whitney, all p-values <0.001). Additionally, tumors of higher histological grade and negative ER/PgR status were more frequent in patients with high CD3, CD8 or FOXP3 mRNA expression, as compared to patients with low expression, (chi-square, p-values <0.010). In the univariate analysis, high CD3 and CD8 mRNA expression was found to be of favorable prognostic value for DFS (HR=0.74, 95% CI 0.59-0.92, Wald's p=0.007 and HR=0.76, 95% CI 0.61-0.95, p=0.016, respectively). In multivariate analyses, the association of high CD8 mRNA expression with increased DFS was retained (HR=0.77, 95% CI 0.60-0.99, p=0.048), whereas that of high CD3 mRNA expression was of marginal statistical significance (HR=0.77, 95% CI 0.59-1.01, p=0.059). Moreover, a significant interaction was observed between HER2 status and CD3 mRNA expression with respect to DFS (interaction p=0.032). In the HER2-positive subgroup, the hazard ratio associated with high CD3 mRNA expression was of greater magnitude (HR=0.48, 95% CI 0.30-0.76, p=0.002) compared to the hazard ratio presented above, for the entire cohort. No significant findings were observed for FOXP3 in terms of DFS, while none of the studied markers were of prognostic value for OS.

Conclusions: High CD3 and CD8 mRNA expression in early breast cancer patients is of prognostic value for decreased risk for relapse and, in the future, could potentially be of importance in deciding the most appropriate therapeutic strategy in light of the recent immune-related treatment developments.
Background: Obesity and inactivity are associated with an increased risk of cancer-related and overall mortality in women with early-stage breast cancer, but there are few data in advanced breast cancer.

Methods: C40502 was a Phase III trial of first-line chemotherapy for patients with metastatic breast cancer (MBC). Participants were randomized to weekly paclitaxel, nab-paclitaxel or ixabepilone. Height and weight at the time of study enrollment were abstracted from medical records. After study activation, the protocol was amended to collect physical activity (PA) data. Participants completed the Nurses’ Health Study Exercise Questionnaire, indicating the frequency, type and duration of recreational PA in which they engaged at study enrollment. Metabolic equivalent (MET)-hours of weekly PA (MET-hrs/wk) were calculated using the Ainsworth Compendium. PA was dichotomized to 0-9 or ≥ 9 MET-hrs/wk based on data in early stage breast cancer suggesting that women who engaged in > 9 MET-hrs/wk had lower cancer-specific mortality. Association with clinical endpoints was evaluated using multivariate Cox proportional hazard models adjusting for treatment assignment, age, tumor hormone-receptor status, prior taxane use, disease-free interval and visceral metastases.

Results: 799 patients enrolled in C40502 between 2008 and 2011. Baseline body mass index (BMI) was available for 792 patients and PA data for 500 participants. Median follow up was 60 months. Median age was 56.7 years; 72% of patients had hormone receptor (HR)-positive cancers. Median BMI was 28.6 kg/m² (IQR: 24.7-33.1 kg/m²). Patients engaged in a median of 3.3 MET-hrs/wk (about 1 hour of moderate-intensity PA/wk) (IQR: 0.7-12.7 MET-hrs/wk). Neither BMI nor PA was significantly associated with progression-free (PFS) or overall survival (OS).

There was a trend toward longer PFS and OS in patients who reported PA > 9 MET-hrs/wk vs 0-9 MET-hrs/wk, especially in individuals with HR+ cancers (median PFS 11.7 vs 9.2 months [adj HR = 0.84 (0.66-1.05)] and OS 34.0 vs 26.5 months [adj HR = 0.83 (0.66-1.05)] with PA >9 vs 0- 9 MET-hrs/wk).
Conclusions: In some of the first data looking at the relationship between lifestyle factors and outcomes in MBC, there was no relationship between BMI and PFS or OS in patients receiving first-line chemotherapy for advanced disease. A trend toward improved PFS and OS was seen in multivariate analysis in patients who reported higher levels of PA, but results were not statistically significant and could have been influenced by other patient factors. More information is needed regarding the relationship between PA and cancer outcomes, especially in patients with HR+ cancers.

**Title:** AIB1 is a new putative prognostic biomarker in the luminal A and B-like (HER2-negative) classification of invasive lobular carcinoma

Ulrik Narbe¹, Carina Forsare¹, Pär-Ola Bendahl¹, Kristina Lövgren¹, Sara Alkner¹, Martin Sjöström¹, Lisa Rydén², Fredrik Leeb-Lundberg³, Christian Ingvar² and Mårten Fernö¹. ¹Lund University, Lund, Sweden; ²Lund University, Lund, Sweden and ³Drug Target Discovery, Lund University, Lund, Sweden.

**Body:**

**Background:** Estrogen receptor (ER) positive HER2-negative breast cancer comprises 75–80% of all breast cancer. This fraction is even higher (>90%) in invasive lobular carcinoma (ILC). According to the St Gallen surrogate definitions of the intrinsic subtypes, Ki67 and progesterone receptor (PgR) are used to classify these tumors as luminal A- and luminal B-like (HER2-negative). These guidelines are based on information derived from patient materials with mixed histological types, where the vast majority of the patients have invasive ductal carcinoma. The ‘luminal-like classification’ together with histological grade, tumor size and lymph node status is widely used in the clinic for prognostication. The aim of the present study was to investigate if the same markers are applicable for ILC, and furthermore, if additional biomarkers involved in the endocrine signaling system, e.g. Amplified in breast cancer 1 (AIB1) and the putative G protein-coupled estrogen receptor (GPER), might provide complementary prognostic information.

**Patients:** Two hundred and thirty-three (N = 233) well-characterized patients with primary ILC, diagnosed between 1980 and 1991 were included. Forty-two percent of the patients received adjuvant endocrine treatment and 2% received adjuvant chemotherapy. All biomarkers were analyzed immunohistochemically on tissue microarray, whereas histological grade was evaluated on whole sections according to Elston and Ellis (NHG). The primary endpoint was breast cancer mortality (BCM).

**Results:** In univariable analyses with 10-year follow-up, Ki67 (high vs. low), NHG (3 vs. 1+2) and AIB1 (high vs. low) were significantly associated to BCM (Hazard Ratio: 4.7, 95% CI: 2.1–10.4, p <0.001; HR: 3.1, 95% CI: 1.5–6.4, p = 0.003; HR: 3.2, 95% CI: 1.4–7.2, p = 0.005 respectively), whereas PgR (<1% vs ≥1%) and GPER (linear 0-4) were not (p = 0.25; p = 0.31 respectively). Essentially the same effect was seen after multivariable adjustment for lymph node status (+ vs. -), tumor size (>20 mm vs. ≤20 mm), adjuvant treatment and age (continuous). Subgrouping the tumors into luminal A- and B-like (HER2-negative) according to St Gallen surrogate definitions did not show significant prognostic differences between the two groups (p = 0.12). Patients with ≤20 mm, lymph node negative breast cancer and favorable tumor characteristics (low Ki67, NHG 1+2, and low AIB1) had a 10-year BCM of 4.2% (95% CI: 1.4–12%). This group constituted 34% of the patients included in the present study.

**Conclusions:** In contrast to other previous studies, where breast cancers of mixed histological types were included, PgR was not significantly associated to prognosis in the ER-positive HER2-negative subgroup in the present study, consisting only of ILC. The prognostic role of PgR and the clinical usefulness of the luminal A and B-like (HER2-negative) classification (using only Ki67 and PgR) in ILC is still to be further investigated. The prognostic importance of Ki67 and NHG in this subgroup was, however, confirmed also in ILC, and AIB1 might be a new putative prognostic factor. By combining Ki67, NHG, and AIB1, together with lymph node status and tumor size, a group of patients with an excellent prognosis could be identified.
Title: The relationship between Klintrup-Makinen score and cancer-specific survival in primary operable breast cancer

Elizabeth S Morrow¹, Fadia Gujam¹, Zahra MA Mohammed¹, Donald C McMillan¹ and Joanne Edwards². ¹Academic Unit of Surgery, University of Glasgow, United Kingdom and ²Institute of Cancer Sciences, University of Glasgow, United Kingdom.

Body: Introduction
It is increasingly being recognised that cancer prognosis is dependent on a complex interaction of tumour factors and the host response. The degree of inflammatory response at the invasive tumour edge, as measured by the Klintrup-Makinen score, has been shown to have prognostic relevance in some cancers but its role in breast cancer remains unclear.

Aim
To evaluate the relationship between Klintrup-Makinen score and prognosis in primary operable breast cancer.

Methods
Patients who underwent surgery for primary operable invasive breast cancer between 1995 and 2007 were studied. Full section haematoxylin and eosin slides from surplus tissue from each breast cancer were analysed. Each was visually scored for the level of inflammatory infiltrate at the invasive edge of the tumour, according to Klintrup-Makinen criteria. Kaplan Meier survival analysis was performed using SPSS.

Results
1195 patients were included in the study, of which 298 had a Klintrup-Makinen score (KM) of 0 (no inflammatory cells at the invasive edge), 589 had a score of 1, 238 had a score of 2 and 70 had a Klintrup-Makinen score of 3 (high inflammatory cell infiltrate). 833 (69.7%) patients were ER positive and 172 (14.4%) patients were HER2 positive. Median follow up was 158 months (28-183) and there were 234 cancer deaths. Patients with the highest and lowest KM scores had the best prognosis (10 year breast cancer specific survival (BCSS) 84% for KM score 3 and 82% for KM score 0), while those with KM score 2 had the worst prognosis with 67% 10 year cancer specific survival (p=0.003). When analysed by subtype, in ER negative patients 10 year BCSS was 95% in KM 0 patients, 80% for KM 3, 72% for KM 1 and 67% for KM 2 (p=0.082). Conversely, in HER2 positive patients, the best prognosis was seen in patients with KM 3 with 86% 10 year BCSS but patients with KM 0 had the worst prognosis (BCSS 62%), but this did not reach significance (p=0.544).

Conclusion
The Klintrup-Makinen score appears to have a prognostic role in primary operable invasive breast cancer, however there is a suggestion that it varies between tumour subtypes. Further work is required to further define this role for each molecular subtype.
Purpose: Incidence of LRs in patients (pts) treated for HR+ HER2- localized BC and distribution overtime have not been described in recent years after introduction of new generation of adjuvant therapies and more extensive use of radiotherapy. We evaluated the incidence and distribution overtime of LRs in pts with HR+ HER2- N+ BCs who entered PACS 01 and PACS04 trials.

Patients and Methods: Data were analyzed from 2909 pts with HR+/HER2- BC out of 5008 included in both trials. Pts underwent mastectomy or lumpectomy plus axillary dissection for a localized N+ BC and, according to study design, were randomized to: 6 cycles of FE100C (standard arm) versus FE100C x 3 cycles followed by docetaxel 100 mg/m2 x 3 cycles (FEC-D) (PACS01) or 6 cycles of Epirubicin 75mg/m2 and Docetaxel 75 mg/m2 (ED75)(PACS04). Loco-regional radiotherapy was mandatory after lumpectomy and recommended in other cases. All pts received 5 years of hormone therapy (HT). A competing risk multivariate analysis was conduct using Fine and Gray model to identify risk factors associated to isolated LRs. Competing events were nodal recurrence, contralateral BC, distant metastasis and death. Cumulative incidence associated to each event was estimated by a Kaplan-Meier estimator.

Results: Pts’ median age was 50 (22-65); 67.2% underwent lumpectomy, 32.8% mastectomy; 67.6% had 1 to 3 N+, 32.4% more than 3 N+; 45.7% had lymphovascular invasion; 49.5% received FE100C, 35.8% ET75, 14.7% had FEC-D; while radiotherapy was given to 97.3% and HT to 92.2%, of whom 90.5% received tamoxifen. At a median follow-up of 9.1 years, 60 pts (2.1%) experienced LR as first event. The 5-year and 10-year cumulative incidence of LRs were 1.04% and 2.53%, respectively. The cumulative incidence of LRs increased from the 5th year, and the annual risk tended to remain constant over time. Multivariate analysis of competing risk showed that younger age, conservative surgery and omission of HT (not prescribed or non-adherence) were independently associated with risk of developing LRs.

Table 1. Multivariate analysis on competing risk of predictors of LRs

Conclusion: Our analysis showed that incidence of LRs in pts with HR+ N+ BCs treated within PACS trials were considerably lower as compared to earlier studies. These findings may reflect differences in treatment era, as the more extensive use of radiotherapy and new generation of adjuvant chemotherapy. Despite current adjuvant strategies, young age at diagnosis and omission of HT remain independent risk factors of LRs.
Title: Young age and the risk of disease recurrence as assessed by the 70-gene signature – an analysis from the EORTC 10041/BIG 03-04 MINDACT trial

Kim Aalders¹, Els Genbrugge¹, Coralie Poncet¹, Anne Kuijer², Barbara Pistilli³, Martine Piccart⁴, Konstantinos Tryfonidis¹, Thijs van Dalen², Fatima Cardoso⁵, Laura van ‘t Veer⁶ and Emiel Rutgers⁷. ¹European Organisation for Research and Treatment of Cancer (EORTC) Headquarters; ²Diakonessenhuis Utrecht; ³Institut Gustave Roussy; ⁴Institut Jules Bordet, Universite Libre de Bruxelles; ⁵Champalimaud Cancer Center; ⁶UCSF Helen Diller Family Comprehensive Cancer Center and ⁷Netherlands Cancer Institute/Antoni van Leeuwenhoek.

Body: Purpose: Increased insight in tumor biology has revealed that not all young women are at high risk of disease recurrence. Therefore, in some patients extent of treatment could probably be safely scaled down. We aimed to evaluate the risk of breast cancer (BC) relapse according to the 70-gene signature (70-GS) result in relation to young age, in early-stage BC patients enrolled in the MINDACT trial.

Patients and Methods: The analyzed population consisted of enrolled BC patients in the MINDACT trial with available clinical (C), as per a modified version of Adjuvant!Online, and genomic (G), according to the 70-GS, risk assessments and known age (n=6693). Patients were categorized in three age groups; <45 (young), 45-55 (peri-menopausal) and >55 years (post-menopausal). Clinicopathological and treatment characteristics as well as gene expression were compared for the different age groups further split by corrected risk groups (C-low/G-low, C-low/G-high, C-high/G-low, C-high/G-high). Subsequently, the 5-year distant metastasis-free survival according to risk category was calculated.

Results: The study included 1100 patients <45 (16%), 2272 aged 45-55 (34%) and 3321 patients >55 years of age (50%). Median age of the young group was 41 (25.8-45.0) years. The young age group had a higher frequency of lymph node involvement (25% vs. 22% and 19%), poorly differentiated tumors (42% vs. 26% and 27%), ER-negative tumors (20% vs. 11% and 11%) and triple negative molecular IHC subtype (16% vs. 9% ad 8%). Median tumor size was the same across the 3 age groups (17mm). Of the 1100 young patients, 61% were C-high while the 70-GS assessed 48% as G-high. Overall, 31% were CL/GL (vs. 43% in other age groups), 9% CL/GH, 21% CH/GL and 40% CH/GH (vs. 24% and 25%).

In the discordant risk groups, chemotherapy (CT) allocation when randomized to no chemo occurred in 5% of young women as compared to 3% and 1% in the older age groups. Reason for non-compliance was 50/50 between patient refusal and PI decision. Overall, the 5-year DMFS was 94.1% (95% CI 92.4-95.4) in <45 age group, 95.3% (95% CI 94.2-96.1) in 45-55 and 94.9% (95% CI 94.0-95.6) in >55. For the young patients, 5-year DMFS was 98.3% for the CL/GL (96.0-99.3), 97.4% in CL/GH (90.0-99.4), 95.5% in CH/GL (91.6-97.7) and 89.2% in CH/GH (85.6-92.0). In the older two age groups (45-55 and >55), the 5-year DMFS rates were 97.8% (96.5-98.6) and 97.2% (96.2-98.0) for CL/GL, 93.9% (88.8-96.7) and 94.5% (91.0-96.7) for CL/GH, 94.5% (92.0-96.3) and 95.4% (93.5-96.8) for CH/GL and 92.0% (89.2-94.1) and 90.4% (88.0-92.4) for CH/GH, respectively. With 9 events in the <45 group at a CH/GL risk, numbers were too small to evaluate chemotherapy effect in this population.

Conclusion: The use of the 70-GS reduces the proportion of patients characterized as high risk as compared to traditional clinical risk assessment (48% vs. 61%). Outcome was comparable for the 3 age categories with a very good 5-year DMFS of 95-98% in all GL groups. Performing the 70-GS provides clinically relevant information concerning the prognosis for young early-stage BC patients categorized as CH. These results add important new data to the limited available evidence on genomic expression in young BC patients.

Title: Serum activin A and outcomes in HR+/HER2- metastatic breast cancer patients treated with everolimus: Results from BOLERO-2

Suhail M Ali1,2, David Chen3, Ayesha Ali1, Laura Krecko1, Kim Leitzel1, Monali Vasekar1, Vinod Nagabhaira4, Eric Marks1, Hyma Polimera1, Angelique Richardson1, Maren May5, Wei He3, Parul Patel6, Meredith Lavin1, Scott Hofsess1, Robert Sweetman3, Gabriel Hortobagyi6, Jose Baselga7 and Allan Lipton1. 1Penn State Hershey Medical Center, Hershey, PA; 2Lebanon VA Medical Center, Lebanon, PA; 3Novartis Pharmaceutical Corp, East Hanover, NJ; 4Pinnacle Health System, Harrisburg, PA; 5R & D Systems, Minneapolis, MN; 6MD Anderson Cancer Center, Houston, TX and 7Memorial Sloan Kettering Cancer Center, New York, NY.

Body: Background: Everolimus (EVE) plus exemestane (EXE) doubled progression-free survival (PFS) while maintaining quality of life versus EXE alone in postmenopausal women with hormone receptor positive (HR+), HER2-negative metastatic breast cancer (mBC) (BOLERO-2 phase 3; NCT00863655). Pretreatment serum activin A was previously reported as a prognostic factor in first-line hormone therapy (letrozole vs tamoxifen) (Novartis P025) and anti-HER2 mBC (lapatinib vs trastuzmab) (CCTG MA.31) trials. Here we investigate the prognostic and predictive ability of activin A in BOLERO-2.

Methods: Activin A levels were determined on pretreatment serum samples using ELISA. Cox-proportional hazards model was used to assess the efficacy of EVE in the activin A low and high subgroups (median cut-point), and the prognostic effect of activin A on PFS and overall survival (OS).

Results: Baseline activin A levels were determined in 513 patients (71% of 725 BOLERO-2 patients randomized 2:1 to EVE+EXE or EXE). Predictive and prognostic signals are shown in the table below.

In multivariate analysis (including sensitivity to prior hormone therapy and visceral disease), activin A remained a significant independent prognostic factor for PFS and OS [HR 0.57 (0.46-0.69) and 0.34 (0.27-0.43), respectively].

Conclusions: Higher serum activin A was strongly associated with shorter PFS and OS in HR+/HER2- mBC patients. Everolimus was efficacious regardless of serum activin A level. These results are similar to our previous studies in phase 3 trials of letrozole-tamoxifen (Novartis P025), and HER2-targeted therapy, lapatinib vs trastuzmab (CCTG MA.31): pretreatment serum activin A was prognostic for outcome, but was not a predictive factor for treatment arm selection.
Title: Molecular subtypes of triple negative breast cancer have different sensitivity signature to established chemotherapy agents

Balázs Győrffy1, Ádám Nagy1, Libero Santarpia2 and Christos Hatzis3. 1MTA TTK, Budapest, Hungary; 2Humanitas Clinical and Research Institute, Milan, Italy and 3Yale Comprehensive Cancer Center, New Haven, CT.

Body: Background: Triple negative breast cancer (TNBC, ER/PR/HER2 negative) patients have the worst prognosis among all breast cancer patients. Recently, six molecular subtypes have been proposed to sub-divide TNBC into clinically relevant sub-cohorts. It is unknown whether these molecular subtypes have different sensitivity against known chemotherapy agents. Here, we identified the cross-section of predictive and prognostic genes in a large TNBC dataset.

Methods: An integrated database comprising 2,071 TNBC patients with transcriptome-level gene expression data and clinical follow-up was set up from 52 different GEO and EGA datasets. The database included n=418 basal-like 1, n=170 basal-like 2, n=465 immunomodulatory, n=384 mesenchymal, n=207 mesenchymal stem-like, and n=427 luminal androgen receptor samples. The prognosis was computed for all genes (n=54,675) in each of the six subtypes separately using Cox proportional hazards regression. Another database (n=1,641) was set up for tumors with known therapy response as defined by pathological complete response (PCR) – in this, the correlation to response against a taxanes/anthracycline chemotherapy was computed using Mann-Whitney analysis. The overlap between the two datasets was determined at p<0.0001.

Results: The proportion of responder patients was lowest in basal like 2 subtype. There were more genes significant for response to anthracyclines (n=6,118) than to taxanes (n=3,927). When comparing each subtype separately, most genes were prognostic in basal-like 1 and luminal androgen receptor subtypes (n=73/110 and n=73/111 respectively for taxane/anthracycline response genes). Almost no genes were overlapping to the immunomodulatory and mesenchymal stem-like subtypes (n=8/14 and n=3/7, respectively). When comparing anthracycline and taxane treatment across all six subtypes, there was no significant difference. We have to note that the different sample sizes in the different TNBC cohorts provide different power to detect an association.

Discussion: Based on our results, TNBC tumors in the basal-like 1 and luminal androgen receptors are most likely to benefit from chemotherapy while there is no difference for the selection between the two most common agents.
2017 San Antonio Breast Cancer Symposium

Title: Risk factors for the development of brain metastases (BM) in 506 patients with HER2-positive breast cancer (HER2+ BC): A single institutional retrospective analysis

Christian Maurer¹,², Lorraine Tulip¹, Cristina Dumitrescu¹,², Evandro de Azambuja¹, Michel Moreau⁴, Marianne Paesmans⁴, Jean-Marie Nogaret⁵, Martine Piccart¹ and Ahmad Awada¹. ¹Medical Oncology Clinic, Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium; ²University of Cologne, Cologne, Germany; ³Medical Oncology Clinic, Charleroi University Hospital, Université Libre de Bruxelles, Charleroi, Belgium; ⁴Unité de Gestion de l'Information, Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium and ⁵Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium.

Body: Introduction: BC is the most common malignancy in women. HER2+ BC is the 2nd leading cause of BM after lung cancer. The prognosis of BC patients with BM is poor. Determining risk factors for the development of BM is warranted in order to establish more accurate screening for patients at risk.

Material and Methods: This is a retrospective analysis of patients with HER2+ BC treated at Institut Jules Bordet, Belgium, between 2000 and 2014. Patients’ charts were reviewed for disease characteristics, treatment regimens for primary and metastatic disease as well as clinical outcomes. Statistical analyses were conducted with SAS 9.4 using Cox regression analyses, log-rank test and Kaplan-Meier method.

Results: A total of 506 patients with HER2+ BC were included in the analysis. Median age was 52.7 years (range, 21.5-89.2 years). In total, 138 (27.3%) were diagnosed with metastatic BC and 74 (14.6%) had BM. Among the 138 metastatic patients, 12 (8.7%) had BM as a first site of metastatic disease and 3 (2.2%) developed BM as only site of distant relapse. Median overall survival (OS) for patients with BM was 1.74 years (range, one month-3.2 years). In multivariate analysis, risk factors for the development of BM at time-point of initial BC diagnosis were de-novo metastatic disease (hazard ratio [HR] 4.46; p<0.0001), postmenopausal status (HR 16.65; p<0.0001), and adjuvant breast radiotherapy (HR 1.79; p=0.0198). Identified risk-factors for BM at the time-point of metastatic disease were postmenopausal status (HR 1.90; p=0.0464), the presence of lung metastases (HR 2.61; p=0.0004), an interval of more than one year between initial BC diagnosis and development of metastatic disease (HR 1.91; p=0.0179) and age of <40 years (HR 1.78; p=0.0353). In this cohort, biological factors such as hormone receptor status, degree of HER2 amplification and tumor grade had no impact on the development of BM both in univariate and multivariate analysis. Furthermore, the type of systemic treatment in the adjuvant or metastatic setting (chemotherapy, anti-HER2 treatment) did not modulate the risk for BM. The combination of local treatment (surgery, stereotactic radiosurgery [SRS] or whole brain radiotherapy [WBRT]) and anti-HER2 directed therapy as first-line therapy for BM was associated with an improvement in overall survival (OS) that was more pronounced for tyrosine kinase inhibitors (HR 0.13; 95% confidence interval [CI] 0.05-0.33); p<0.0001) than for trastuzumab and/or pertuzumab (HR 0.53; 95% CI 0.24-1.15; p=0.1085).

Conclusion: The development of BM is a common complication in patients experiencing metastatic HER2+ BC. Until now, no imaging screening for BM is recommended in this patient population. Compared to WBRT, surgery and SRS are associated with an improvement in OS and/or less cognitive impairment. However, these treatment approaches are limited to patients with less extensive BM disease. In this context, randomized trials examining the role of MRI screening for BM in metastatic HER2+ BC with high risk features are warranted.
**Title:** Correlation of breast cancer index (BCI) prognostic and predictive results to clinicopathologic risk groups in early stage HR+ breast cancer

Jose Mayordomo¹, Carla Falkson², Jeffrey Kepes³, Mason A Israel³, Brock E Schroeder³, Catherine A Schnabel³ and Anthony Elias¹. ¹University of Colorado; ²University of Alabama and ³Biotheranostics, Inc..

**Body:**

**Background:** Both clinicopathologic factors and genomic tests have been shown to be prognostic for risk of late distant recurrence (DR); however, few studies have characterized differential patient stratification. Breast Cancer Index (BCI) is a validated gene expression assay for patients with early-stage HR+ breast cancer that provides a prognostic result for high vs low risk of late distant recurrence and a separate predictive result (based on the HoxB13/IL17BR [H/I] ratio) for high vs low likelihood of benefit from extended endocrine therapy. Thus four categories of results are possible based on a patient's tumor biology. To better understand how patient stratification is affected by a combination of clinicopathologic and genomic factors, this study examined BCI assay results within clinicopathologic risk categories based on tumor size and grade.

**Methods:** This study utilized data from the BCI Clinical Database for Correlative Studies, an IRB-approved de-identified database which contains clinicopathologic and molecular variables from 19,126 clinical cases submitted for BCI testing. Clinicopathologic variables, abstracted from pathology reports, were available for a subset of these cases. This analysis evaluated cases from LN- patients with available clinicopathologic data. Chi-squared tests were used to compare BCI results between tumor size and grade subgroups.

**Results:** Analyses included 3843 LN- patients (median age 59.1y; range 26-89y; 74% ≥50y), of which 31%, 52%, 17% were Grade 1, 2, and 3, respectively, and 5%, 22.7%, 48.9%, 21.7%, and 1.6% were T1mi/a, T1b, T1c, T2, and T3, respectively. In analysis based on tumor size, there was a wide distribution of individual BCI Prognostic scores in all tumor size subsets; however, the proportion of patients classified as high risk increased with larger tumor size (T1a/b 39.0%, T1c 50.1%, T2 61.0%; p<.0001). In contrast, BCI Predictive (H/I) was not as strongly correlated with size, with a modestly larger proportion of patients classified as High H/I with larger tumor size (T1a/b 37.2%, T1c 40.5%, and T2 45.3%; p=.005). Within each tumor size category, the proportion of patients classified as BCI High Risk and High H/I increased with tumor grade (p<.0001). However, there was a wide distribution of individual risk assessments by BCI Prognostic and stratification by BCI Predictive (H/I) in all size + grade subsets. In patients with the most favorable clinicopathologic risk profile (T1a/b, G1), BCI classified 20% as high risk, 68% of whom also had High H/I.

**Conclusion:** While BCI results correlated with tumor size and grade, BCI identified substantial proportions of patients with favorable clinicopathologic features as high risk for late DR and apparent high likelihood of benefit from EET; conversely, BCI also identified patients with high risk clinicopathologic features as low risk for late distant recurrence and apparent low likelihood of benefit from EET. These findings help to differentiate between genomic-based and clinicopathologic-based risk/benefit assessment for patients considering EET.
Obesity is associated with poor prognosis of Japanese breast cancer, especially in ER positive/HER2 negative subtype, which tendency is prominent

Masako Sato¹, Sayuri Terai¹, Hanae Tachikawa¹, Hideki Maeda¹, Mitugu Yamamoto¹, Nobumoto Tomioka¹, Kenichi Watanabe¹ and Masato Takahashi¹. ¹NHO Hokkaido Cancer Center, Sapporo, Hokkaido, Japan.

Body: Introduction: Body mass index (BMI) is defined as a poor prognostic factor in breast cancer patients in western countries. Since the percentage of the overweight differs between Asian and western breast cancer patients, we do not know if breast cancer prognosis in Asia is related to obesity, the same as in western countries. Therefore, we have investigated the association between BMI and the prognosis of Japanese breast cancer patients.

Patients and Methods: This study is a retrospective analysis of the 1,924 primary Japanese female breast cancer patients with clinical stage I through III disease to have undergone surgery between January 2004 and December 2013 at the Hokkaido Cancer Center. The data of BMI were at the time of diagnosis, and stratified into 2 groups as non-Obese (BMI < 25 kg/m²), Obese (BMI ≥ 25 kg/m²). The overall survival (OS) and disease-free survival (DFS) were compared between two BMI groups using the Kaplan-Meier method and Cox hazards model.

Results: The number of non-Obese group was 1,353 (70.3%) and Obese group was 571 (29.7%) of the 1,924 patients. Six hundred and thirty two patients were in premenopausal (32.8%), 1,289 were in postmenopausal (67.0%) and 3 were unknown. The median follow-up period was 73 months. Breast cancer recurred in 239 patients (12.2%), and 204 patients died. There were 110 cases of breast cancer-related death, 48 cases of non-breast cancer death, and 46 cases of unknown as the cause of death. Patients in Obese group had shown significantly poorer OS (adjusted hazard ratio (HR) = 1.68, 95% confidence interval (CI) = 0.45 to 0.79) and DFS (HR = 1.46, 95% CI = 1.16 to 1.82). As investigating by subtype analysis, a high BMI in ER positive/HER2 negative patients was associated with a significantly worse OS (HR = 2.04, 95% CI = 1.42 to 2.92) and significantly worse DFS (HR = 1.61, 95% CI = 1.23 to 2.11). On the other hand, there was no significant interaction found between the BMI and OS or DFS in ER negative/HER2 negative patients and HER2 positive patients. Subsequently, when analysis was limited to ER positive HER2 negative, there was a difference in the degree of association between obesity and prognosis due to the difference in menopause status. In premenopausal patients with ER positive/HER2 negative cancer, Obese group had significantly poorer OS (HR = 2.83, 95%CI = 1.32 to 5.88) and significantly poorer DFS (HR = 2.41, 95%CI = 1.41 to 3.99). In postmenopausal patients, Obese group patients had significantly poorer OS (HR = 1.71, 95%CI = 1.11 to 2.58) and poorer DFS (HR = 1.35, 95%CI = 0.98 to 1.86), however. The relevance was not so large compared with that in premenopausal patients.

Conclusion: Among Japanese breast cancer patients, Obese (BMI ≥ 25 kg/m²) was one of poor prognostic factors. Specifically, obesity was associated as an extremely strong prognostic factor in ER positive/HER2 negative premenopausal patients. Since hormone therapy has been practiced in almost all ER positive breast cancers, the relationship between hormonal therapy susceptibility and obesity is noticed not only in western patients but also in Asian patients.
Title: Real-life analysis evaluating >1000 N0/N1mi estrogen receptor (ER)+ breast cancer patients for whom treatment decisions incorporated the 21-gene recurrence score (RS) result: Clinical outcomes with median follow up of > 9 years

Salomon M Stemmer1,2, Shulamith Rizel1, Mariana Steiner3, David B Geffen4, Lior Soussan-Gutman5, Avital Bareket-Samish6, Debbie McCullough7, Christer Svedman7, Bella Nisenbaum8, Larisa Ryvo9, Tamar Peretz10, Georgeta Fried11, Ora Rosengarten12, Nicky Liebermann13 and Noa Ben Baruch14.

Body: Background: The 21-gene Recurrence Score (RS) Assay (Oncotype DX®) is a validated prognosticator and predictive of chemotherapy (CT) benefit in patients with hormone receptor (HR)+ human epidermal growth factor receptor 2 (HER2)-negative breast cancer. In Israel, the RS assay has been reimbursed by Clalit Health Services (CHS, the largest HMO in Israel) since 2006, and the assay is widely used in eligible estrogen receptor (ER)+ patients. Notably, ER+ breast cancer patients have a protracted risk of recurrence with approximately half of all distant recurrences occurring after 5 years from diagnosis. The goal of the current ongoing analysis was to investigate early (≤ 5 years) and late (>5 years) distant recurrence in N0/N1mi ER+ HER2-negative breast cancer patients who were RS-tested through CHS.

Methods: This analysis of the CHS registry included breast cancer patients with ER+ HER2-negative N0/N1mi disease who underwent RS testing from 1/2006 (CHS approval of the assay) through 1/2009. Data sources included CHS claims arms (for patient/tumor characteristics), Teva Pharmaceuticals (for tumor characteristics, RS result), and medical records (for treatment/recurrence/survival). The study was approved by the institutional review boards of the CHS Community Division and was granted a waiver for obtaining patient consent.

Results: The analysis included 1026 patients with median (interquartile range) follow up of 9.3 (8.8-10.2) years. Most patients were females (99%). Median (range) age was 59 (25-84) years; 92% had N0 and 8% had N1mi disease; 14%, 52%, and 16% had grade 1, 2, and 3 tumors, respectively (grade information was not available for 18% of patients); median (range) tumor size was 1.5 (0.3-6.5) cm. The majority of patients (78%) had invasive ductal carcinoma and 12% had invasive lobular carcinoma. Overall, 489 patients (48%) had RS<18, 434 (42%) had RS 18-30, and 103 (10%) had RS≥31. The use of adjuvant CT was consistent with the RS result: 3%, 27%, and 90% of RS<18, RS 18-30, and RS≥31 patients, respectively. Overall, 25 distant recurrences were reported within 5 years of RS testing: 5 (1.0%) in RS<18 patients, 9 (2.1%) in RS 18-30 patients, and 11 (10.6%) in RS≥31 patients. In the first 5 years, breast cancer-specific death was reported in 8 patients including 3 (0.7%) with RS 18-30 and 5 (4.9%) with RS≥31 results. Among N0 patients with RS 11-25 who did not receive adjuvant CT (n = 540), 5 (0.9%) distant recurrences and one (0.2%) breast cancer death were reported within 5 years of RS testing. Analysis of ‘late’ recurrences and breast cancer-specific death (from 5 to 9.3 years of follow-up) is ongoing.

Conclusions: These will be the first late recurrence data from over 1000 patients for whom the RS result was used in real-life clinical decision making. Consistent with previous analyses of the CHS registry, CT use was appropriately based on the RS result, and the recurrence/survival outcomes (for the first 5 years) demonstrated the prognostic performance of the RS. Distant recurrence and breast cancer death beyond 5 years will be presented at the meeting.
Title: Retrospective analysis of oncotype DX recurrence score (RS) and discordance in patients with node-negative, ER+ breast cancer with recurrence

Brittney S Zimmerman¹, Krystal P Cascetta¹, Meng Ru¹, Lauren Eggert³, Madeline C Molot², Anupma Nayak⁴, Ira Bleiweiss⁴ and Amy Tiersten¹. ¹Mount Sinai Hospital and Icahn School of Medicine, New York, NY; ²Barnard College of Columbia University, New York, NY; ³Stanford University Hospital, Stanford, CA and ⁴Hospital of the University of Pennsylvania, Philadelphia, PA.

Body: BACKGROUND: Oncotype RS is a 21-gene assay used to predict the likelihood of distant recurrence and benefit of chemotherapy in patients with node-negative, tamoxifen treated breast cancer. We developed a database to determine tumor recurrence rates and identify cases of discordance between Oncotype RS and tumor grade (TG). Our goal was to recognize patients with discordant tumors who had breast cancer recurrence and to understand the implications for patient management.

METHODS/RESULTS: We analyzed patient and tumor characteristics from 704 breast cancer patients between 2006-2016. Of these patients, there were thirteen recurrences (n=13), or 1.9% recurrence rate at a median follow-up of 4.2 years. When stratified by RS, recurrence rates were 1%, 2.4% and 4.3% in low, intermediate and high-risk groups respectively. Of the 13 patients who recurred, 31% had a low RS (<18), 54% had an intermediate RS (18-30) and 15% had a high RS (>31). The median RS was 23 and median age at time of recurrence was 55 years (62% postmenopausal). Tumor characteristics at time of recurrence were notable for: 77% metastatic, 23% locally recurrent, 85% PR positive, 69% moderately-differentiated (MD) and 31% poorly-differentiated (PD). No well-differentiated (WD) tumors recurred.

We defined Oncotype discordance as either 1-step or 2-step difference between Oncotype risk group (low, intermediate, high) and tumor grade (WD, MD, PD). Prior studies have demonstrated 7-19% “2-step discordance” between TG and RS (i.e. PD tumors with low-risk RS or WD tumors with high-risk RS). Of the 13 recurrences in our database, 46% were at least 1-step discordant, compared with 64.3% in our overall database. Among these recurrences, we compared discordant versus concordant tumors using two-sided T-tests. We found that fewer patients were treated with systemic chemotherapy in the discordant group (p=0.045), which was statistically significant. Among discordant patients, only one received chemotherapy, though all displayed MD or PD tumor grade. Discordant tumors tended to have lower RS (mean 17 vs. 27, p=0.34) and tended to be larger (mean 1.88cm vs. 1.33cm), however this was not statistically significant (p=0.84). Notably, the two largest tumors were both discordant. There were no significant differences in terms of age, Oncotype ER/PR score or mitotic count.

CONCLUSION: Although the sample size of recurrent patients is small, our data may suggest that patients with discordant tumors of low-risk Oncotype RS but higher TG may be receiving inadequate treatment (i.e. no chemotherapy). In addition to RS, other factors such as discordance, TG and tumor size should perhaps be considered when determining treatment plans.

Title: Discordant breast cancer: Genomic verse clinicopathologic

LeAnn M Blankenship¹, Daniel Ezekwudo¹, Ishmael Jaiyesimi¹, Michael Stender¹, Osama Alassi², Cynthia Kresge¹ and Susanna Gaikazian¹. ¹Beaumont Health, Hematology and Oncology, Royal Oak, MI and ²Beaumont Health, Pathology, Royal Oak, MI.

Body: Background: Studies using the 21-gene recurrence score (RS) have shown early-stage, low-risk pathologic and genomic breast cancers do not benefit from systemic chemotherapy (CTx) whereas early stage, high-risk breast cancers have improved outcomes when treated with CTx. Data is lacking for patients with discordant risk factors and which feature, genomic or clinical, plays more of a role in determining outcomes.

Methods: A retrospective analysis was conducted to identify early-stage breast cancer patients with discordant features, defined as low-risk genomic/high-risk pathologic factors (LG/HP) or high-risk genomic/low-risk pathologic factors (HG/LP), from August 2011–December 2016. LG/HP breast cancer was defined as a RS <18 with ≥2 high-risk pathologic factors: tumor size (T) ≥2cm, lymph node (N) positivity, or grade 2-3 disease. HG/LP breast cancer was defined as a RS ≥31 with all three low-risk pathologic factors: T <2cm, N negativity, and grade 1-2 disease.

Results: There were 469 patients with low-risk RS identified of whom 118 (25%) met discordant high-risk pathologic criteria and 62 patients with high-risk RS of whom 14 (23%) met discordant low-risk pathologic criteria. Thirty patients in the LG/HP group received CTx despite a low RS. Of the 118 LG/HP patients, there were 22 (19%) breast cancer recurrences; 21 with locoregional and one with metastatic disease. Of the locoregional recurrences, 10 were contralateral breast whereas 11 were in-breast recurrence despite breast conservation therapy. Of the 14 HG/LP discordant patients, of whom 12 received CTx, 3 (21%) had breast cancer recurrence; one with metastatic disease to the lung and the other two with contralateral breast cancer. Majority of all recurrences occurred >5 years after initial diagnosis. Staging and management depicted below.

**Conclusions:** Using traditional low-risk RS of 18, we observed more than expected recurrences in our LG/HP discordant patients. Thus suggesting, in patients with discordant results, clinicians must consider both pathologic and genomic factors to optimize patient-specific treatment. Further studies are needed to improve the outcomes of this unique patient population.

Title: Clinicopathologic and molecular correlates of breast cancer index (BCI) results in patients with HR+, LN- breast cancer that are high risk of late distant recurrence (DR) / low likelihood of benefit from extended endocrine therapy (EET)

Melanie Royce¹, Graham Poage², Mason A Israel², Catherine A Schnabel² and Frankie A Holmes³. ¹University of New Mexico Comprehensive Cancer Center; ²Biotheranostics, Inc. and ³Texas Oncology.

Body: Background: BCI is a gene expression assay for patients with early stage HR+ breast cancer that provides 2 results: BCI Predictive, based on the HoxB13/IL17BR (H/I) ratio, reports a prediction of high vs low likelihood of benefit from EET; BCI Prognostic, based on the algorithmic combination of H/I and a set of proliferation-based genes, reports the risk of late distant recurrence (DR). Clinical actionability is distinct based on the 4 possible combinations of prognostic and predictive results. To better characterize patients classified by BCI as having a high risk of late DR but a low likelihood of benefit from EET, we assessed clinicopathologic and molecular correlates in this subset.

Methods: The BCI Clinical Database for Correlative Studies is a de-identified database containing >50 clinicopathologic and molecular variables from cases submitted for BCI in clinical practice (N=19,126). Clinicopathologic variables abstracted from pathology reports were available for a subset of these cases. Molecular proliferation status (molecular grade index [MGI]) and clinicopathologic parameters were examined in the 4 possible BCI result categories of BCI Prognostic (High vs Low risk) and BCI Predictive (High vs Low H/I). Chi-squared tests and ANOVA were used to compare BCI results within subsets.

Results: Analyses included 3843 LN- pts with clinicopathologic data: Median age was 59.1y (range 26-89y; 74% ≥50y); 30.9%, 51.7%, and 17.4% were Grade 1, 2, and 3, respectively; 27.8%, 48.9%, 21.7%, and 1.6% were T1a/b, T1c, T2, and T3, respectively. BCI categorized 41.4% of pts as having Low risk/Low likelihood of benefit, 31.3% with High risk/High benefit, 18.0% with High risk/Low benefit, and 9.3% with Low risk/High benefit. Patients with High Risk/Low Benefit had increased median proliferation scores (MGI), and a greater proportion of pts with grade 2/3 tumors and high Ki67 scores compared to pts with Low Risk/Low Benefit (P<.0001 for all). In contrast, there were only modest differences in clinicopathologic parameters between patients with High Risk/ Low Benefit and those with High Risk/High Benefit.

Conclusion: In characterizing the molecular and clinical correlates in BCI cases with a high risk of late DR but low likelihood of benefit from EET, we found that higher proliferative status was associated with classification of high risk of DR. Future studies might investigate whether patients with this molecular pattern might benefit from combinatorial therapy (e.g., CDK 4/6 inhibitors) with EET. This study highlights the importance of predictive biomarkers for individualized EET therapy recommendation.
Title: Protective effect of 27-hydroxycholesterol on disease recurrence in HER2-negative luminal type of early breast cancer

Sim Sung Hoon¹, Park In Hae¹, Jung So-Youn¹, Lee Seeyoun¹, Kong Sun-Young², Kang Han-Sung¹, Lee Eun Sook¹ and Lee Keun Seok¹. ¹Center for Breast Cancer, Research Institute, National Cancer Center, Goyang-si, Gyeonggi-do, Korea and ²Graduate School of Cancer Science and Policy, Center for Diagnostic Oncology, National Cancer Center, Goyang-si, Gyeonggi-do, Korea.

Body: Background: 27-hydroxycholesterol (27-HC) is a metabolite of cholesterol (Chol) and known as endogeneous selective estrogen receptor modulator (SERM). Laboratory researches showed high 27-HC could stimulate cancer cell proliferation and promote metastasis processes in hormone receptor positive breast cancer. However, there is no clinical data about the effect of 27-HC on disease recurrence in early breast cancer.

Methods: A total of 539 early breast cancer patients who underwent surgery at the National Cancer Center Hospital between 2001 and 2010 with the deposition of blood samples at Tumor Bank were accrued. The blood samples were taken with overnight fasting at surgery day. Serum 27-HC was analyzed by liquid chromatography–mass spectrometry (LC-MS). 27-HC and Chol were categorized into two groups (low vs high) by median, respectively.

Results: Hormone receptor was positive in 441 patients and negative in 98 while HER2 was positive in 81, negative in 325 and unknown in 133 patients. The median follow up time was 92 months (range 24-153.7). The 27-HC (median, 115.73 ng/ml with the range of 29.36-234.0) and Chol (median, 170.0 mg/dl with the range of 91-290) showed weak correlation (\( \rho = 0.24, P < 0.001 \)). While 27-HC was not significant in analysis for RFS in all cases, it showed marginal significance for RFS in the subset analysis with HER2-negative luminal breast cancer patients (HR, 0.463; 95% CI, 0.208-1.031; \( P = 0.059 \)). When the patients were grouped according to 27-HC and Chol level (group \( 27\text{HC}/\text{Chol} \)) in luminal subgroup, it showed a trend for increasing RFS in the order of group \( \text{low/high} \), group \( \text{low/low} \), group \( \text{high/low} \) and group \( \text{high/high} \) (\( P_{\text{trend}} = 0.009 \)).

Conclusion: Serum 27-HC was not associated with poor RFS. High serum 27-HC could be related to good prognosis in HER2-negative luminal type of breast cancer, which may be related to the protective effect of 27-HC from disease recurrence. Further study is warranted.

Body: Background: Despite novel, targeted therapies, metastatic breast cancer patients have an extremely unfavourable prognosis. Prognostic and predictive factors for patients with advanced breast cancer are not well understood. Molecular assessment of the patient and the tumor in the metastatic situation is not routinely performed despite advances in molecular precision medicine indicating great benefit to this patient group. Here we present early findings from the first 142 patients of a prospective molecular breast cancer registry with completed transcriptomic profiling.

Methods: The PRAEGNANT study protocol (NCT02338767) is a molecular registry designed to provide an infrastructure for the real-time comprehensive analysis of tumor and patient molecular characteristics under study conditions. Formalin fixed paraffin embedded tumors have been used from this registry to identify molecular, transcriptomic predictors for overall survival (OS). Known clinical correlates for OS (e.g. hormone-receptor status, age at diagnosis, and BMI) were analyzed by Cox proportional hazard ratios, and compared to transcriptomic markers of outcomes. Transcriptomes for all patient tumors were sequenced on the Illumina sequencing platform, and analyzed by RSEM to estimate transcripts per million (TPM) values for each gene isoform. Log-TPM values were used in established (PAM50) and novel (hierarchical clustering) expression-based subtyping of tumor samples. Expression-based subtypes were demonstrated to be strong prognostic indicators by Cox analysis. A Lasso regression machine learning algorithm was used to develop an expression-based predictive model of OS.

Results: Hormone receptor positivity (HR=0.7, p<0.006) and TNBC status (HR=1.4, p<0.01) were significantly associated with outcomes. PAM50 subtypes were also strong indicators of outcomes (e.g. Basal disease compared to Luminal-A subtype has HR=1.4, p<0.017). A novel expression-based high-risk cluster in this cohort was more indicative of poor prognosis than clinical variates or Basal-type, with a HR=2.7 (p<0.009) when compared to Luminal-A subtype. An expression-based survival prediction model achieved a concordance-index of 0.65 in an unseen validation cohort. Patients predicted as having the shortest survival times were in the high-risk cluster.

Conclusions: Here we demonstrate using molecular profiling to develop prognostic signatures that out-perform standard clinical correlates of poor outcomes, even in a small subset of the total cohort. As the PRAEGNANT cohort expands these prognostic tools will continue to improve and supplement physician knowledge to improve patient outcomes.

Title: Relationship between hereditary cancer syndromes and oncotype DX recurrence score

Sarit Toltzis¹, Nicole Casasanta¹, Shawn Lipinski², Amy Marino³, Allison McHenry¹, Neelima Denduluri², Patricia Rodriguez² and Rebecca Kaltman¹. ¹GW Cancer Center, Washington, DC; ²Virginia Cancer Specialists, US Oncology Network, Arlington, VA and ³University of Pittsburgh Medical Center, Pittsburgh, PA.

Body: Background
Oncotype DX Recurrence Score (RS) is used to stratify breast tumors into those likely to respond to cytotoxic chemotherapy. Women and men with hereditary cancers tend to have tumors that are chemosensitive. We hypothesize that a high RS may harbor a signal of potential hereditary risk. This analysis aims to identify whether breast cancer patients with hereditary cancer syndromes have a disproportionate amount of high RS compared to sporadic cases.

Methods
Individuals with a personal history of breast cancer who received treatment at participating research facilities and had hormone receptor positive breast cancer, Oncotype DX testing and hereditary cancer mutation testing were included. Oncotype DX RS was recorded along with the type of genetic testing and the genetic testing results. RS was categorized as low (0-17), intermediate (18-30), and high (31+). Those with deleterious mutations in any known hereditary cancer gene were considered positive. Individuals with a variant of uncertain significance (VUS) or negative genetic testing result were considered negative. Difference in distribution of tumors with low, intermediate, and high Oncotype DX results in those with hereditary breast cancers compared to those with sporadic breast cancers was determined with Chi-square.

Results
419 patients with Oncotype DX testing from two clinical sites were collected from 2013. Of those, 123 underwent genetic risk assessment. Mutations identified included the following genes: BRCA1 (1), BRCA2 (5); CHEK2 (3); BRIP1 (3); NBN (2); MSH6 (1). Of those testing positive for a deleterious mutation, the number of patients with RS results in each category were 5, 4 and 6 for low, intermediate and high, respectively. For those considered negative on hereditary cancer panel testing, the RS results were 76, 52 and 8, respectively. Of those with high RS, 43% had deleterious mutations. Chi square test was statistically significant for a difference between the RS of those with deleterious hereditary mutations versus those with sporadic cancers (p = 0.000086).

Conclusions
High RS may indicate a higher likelihood of harboring a hereditary cancer syndrome. Further investigation with larger numbers and multivariate analysis is needed to validate if a high RS serves as an independent predictor of benefit from genetic counseling and testing.
Title: Androgen receptor positivity is associated with nodal disease in triple negative breast cancer

1The University of Texas MD Anderson Cancer Center, Houston, TX.

Body: Background: Gene expression profiling (GEP) has identified several molecularly distinct subtypes of triple negative breast cancer (TNBC). Currently, GEP-based molecular diagnostics are not routinely used in clinical decision making due to the lack of proven benefit, costs involved and long turnaround time. However, two molecularly distinct subtypes of TNBC, the luminal androgen receptor (AR) and mesenchymal subtypes, have surrogate CLIA-certified immunohistochemical (IHC) markers, AR and vimentin (VM), respectively, which have the potential for application in the clinic. Here we report the rates of AR and VM positivity and their association with clinicopathological characteristics in a cohort of TNBC pts receiving NACT.

Methods: As part of an ongoing molecular triaging protocol, 144 pts with stage I-III TNBC underwent a pretreatment biopsy for molecular characterization (MC) prior to initiating neoadjuvant chemotherapy (NACT). IHC for AR and VM were performed using commercially available antibodies. AR+ and VM+ were defined as ≥10% and ≥50% staining, respectively. Pts were randomized 2:1 to know (intervention arm, n=93) and not know (control arm, n=51) the MC results. The charts of pts randomized to the intervention arm were reviewed. Categorical variables were analyzed using Fisher's exact test. Ordinal and continuous variables were analyzed using the Wilcoxon rank-sum test and Student's t test as appropriate.

Results: 31% (29/93) and 16% (15/93) of pts were AR+ and VM+, respectively. Only 4% (4/93) of pts were both AR+ and VM+. Clinicopathological characteristics are summarized in Table 1. AR+ pts were more likely to have clinically node positive disease as compared to AR- pts (66% vs 34%, p=0.007). There were no significant differences in clinical tumor size or grade between AR+ and AR- pts. VM+ and VM- pts had similar clinicopathological characteristics.

Conclusion: Pts with AR+ TNBC were more likely to have node positive disease. The impact of AR+ on long term outcomes should be investigated in prospective studies.

The quality and quantity of visceral fat tissue are associated with insulin resistance and survival outcome after chemotherapy for patients with early-stage breast cancer

Toshiaki Iwase¹, Takafumi Sangai¹, Takeshi Nagashima¹, Masahiro Sakakibara¹, Hiroshi Fujimoto¹, Yuji Sawabe³, Kengo Nagashima² and Masayuki Otsuka¹. ¹Chiba University Hospital, Chiba, Japan; ²Department of Global Clinical Research/Biostatistics, Chiba, Japan and ³Department of Laboratory Medicine, Chiba, Japan.

Body: Background: Obesity and insulin resistance are associated with inferior levels of chemosensitivity and overall prognosis for breast cancer (BC) treatment. Recent studies suggest that the quality and quantity of visceral adipose tissue (VAT) play a significant role in adipocyte function, and are related to insulin resistance. We therefore tested the hypothesis that high amount and low quality of VAT worsen treatment outcomes via insulin resistance mechanisms.

Patients and Methods: We examined two independent studies: a cross-sectional study (cohort 1) and a retrospective study (cohort 2). Cohort 1 included 106 women with early-stage BC who were undergoing surgery. Patients with normal weight (17.5< body mass index [BMI, kg/m²] ≤25, n = 53) and overweight/obese patients (BMI >25, n = 53) were selected by a pair-matching method. Insulin resistance was evaluated by HOMA-R: fasting insulin (microU/L) × fasting glucose (nmol/L)/22.5. And insulin-like growth factor (IGF) family including IGF-1 and IGF-binding protein 3 (IGFBP3) were measured before beginning treatment. The amounts of visceral fat (aVAT) was measured by 3-dimensional volumetric software using the stocked computed tomography (CT) imaging data. The quality of VAT was assessed based on the mode value of CT Hounsfield Unit of VAT (VAT-HU) at navel level of CT axial view. The association between the former variables and the quality and quantity of VAT was analyzed. Cohort 2 included 271 patients who received chemotherapy in the neo-adjuvant (NAC) or adjuvant setting. Imaging analysis was performed in the same way, and the association between those values and survival outcome after chemotherapy was analyzed by retrospective chart review.

Results: In cohort 1, aVAT was significantly correlated with serum insulin and HOMA-R levels (Pearson's R 0.44 and 0.42, respectively; P<0.05). On comparing the two groups divided by BMI, the levels of IGF-1 and IGFBP3 were not significantly different between the normal weight and the overweight/obese groups (P = 0.31 and 0.77, respectively). However, the overweight/obese group demonstrated significantly higher HOMA-R (P<0.05). In cohort 2, aVAT was significantly correlated with BMI (P<0.05). In a multivariate analysis, pathological complete responses were not associated with aVAT (P = 0.60). After a median follow-up of 112 months, tertile stratification revealed that the third tertile of aVAT had a significantly shorter distant disease free survival (DDFS) in the NAC setting (p<0.05). When adjusted by covariates in the Cox proportional regression model, aVAT and VAT-HU demonstrated significant contribution to a worsened DDFS (p<0.05, hazard ratio (HR) 1.39; 95% confidence interval (CI) 1.11 to 1.75) and (p<0.05, HR 1.20, 95% CI 1.01 to 1.43), respectively.

Conclusions: Our study found that high amounts and low quality of VAT worsen treatment outcomes. Furthermore, we found that insulin resistance was related to those two factors. Although further validation is needed, our present work suggests the importance of evaluating the quality and quantity of visceral fat for estimating insulin resistance and treatment outcomes after chemotherapy for patients with early-stage BC.
Title: Evaluation of the prognostic value of all four HER family receptors in patients with metastatic breast cancer treated with trastuzumab: A hellenic cooperative oncology group (HeCOG) study

Body: Background-aim: Metastatic breast cancer (MBC) is an incurable disease. Trastuzumab, a recombinant humanized monoclonal antibody, was found to significantly prolong survival of patients with metastatic HER2 over-expressing and/or amplified breast cancer. In the current study, we performed a complete analysis, with four different methods, of all four HER family receptors, in a series of patients with metastatic breast cancer treated with trastuzumab-based regimens and evaluated their prognostic value.

Methods: Formalin-fixed paraffin-embedded tumor tissue samples were collected from 227 patients, considered to be HER2-positive when assessed at the local laboratories. We evaluated gene amplification, copy number variations (CNVs), transcriptional profiling and protein expression of all four HER family members. In addition, our analysis included the evaluation of several other factors by immunohistochemistry (IHC), such as pHER2Tyr1221/1222, pHER2Tyr877 and PTEN.

Results: Central review of HER2 status by IHC and fluorescence in situ hybridization revealed that of the 227 patients, only 139 (61.2%) were truly HER2-positive. Regarding the 191 patients treated with trastuzumab as first-line therapy, median time to progression (TTP) was 15.3 months and 10.4 months for HER2-positive and HER2-negative participants, respectively. Median survival was 50.4 months for HER2-positive and 38.1 months for HER2-negative patients. In HER2-positive patients, high HER3 mRNA expression was of favorable prognostic significance for TTP and survival (HR=0.43, 95% CI 0.21-0.88, Wald's p=0.022 and HR=0.43, 95% CI 0.21-0.88, p=0.021, respectively), while EGFR copy gain and EGFR protein expression were associated with higher risk for disease progression in HER2-negative patients (HR=3.53, 95% CI 1.19-10.50, p=0.023 and HR=3.37, 95% CI 1.12-10.17, p=0.031, respectively). Positive HER3 protein expression was a favorable factor for TTP in HER2-negative patients (HR=0.43, 95% CI 0.22-0.84, p=0.014). In the multivariate analysis, only EGFR copy gain retained its prognostic significance for TTP in the HER2-negative population (HR=4.81, 95% CI 1.52-15.82, p=0.008), while none of the examined factors retained their prognostic significance for TTP or survival in the HER2-positive subgroup.

Conclusions: The present study suggests that EGFR copy gain represents a negative prognostic factor for TTP in HER2-negative patients with metastatic breast cancer. In addition, high HER3 mRNA expression appears to be of favorable prognostic significance for TTP and survival in HER2-positive patients. Given the small number of patients included in the current analysis and the retrospective nature of the study, our findings should be validated in larger cohorts.

Title: Differences among young breast cancer patients based on subtype: A study from the Korean Breast Cancer Society – Running head: Do breast cancers in 20s have worse prognosis than 30s?

Jai Min Ryu¹, Jonghan Yu¹, Seok Jin Nam¹, Isaac Kim¹, Jeong Eon Lee¹, Se Kyung Lee¹, Jae Myung Kim¹, Hee Jun Choi¹ and Seok Won Kim¹. ¹Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea.

Body: Purpose Numerous studies demonstrated that breast cancer in young women (BCY) has unfavorable prognostic features and unfavorable subtype. However, there were few studies to evaluate the effect on the prognosis of breast cancer according to the subtype disparities by age especially BCY. We analyzed breast cancer mortality stratified tumor subtype according to age among the patients with less than 50 year-old. Patients and Methods Data obtained from the Korean Breast Cancer Society Registry (KBCSR), patients diagnosed with invasive breast cancer were retrospectively between 2003 and 2010. We excluded patients with male breast cancer, underwent neoadjuvant chemotherapy, distant metastasis or inflammatory breast cancer at presentation, and other histopathology except invasive ductal or invasive lobular carcinoma. We also excluded patients with lack of immunohistochemistry data and short-term follow-up duration (<12 months). Results We identified 37,865 patients, and excluded by study protocol. Among those, 30,793 patients with breast cancer for eligible for analysis, 793 (2.6%) were 20-29 years and 8,926 (28.8%) were 30-39 years of age. Median follow-up duration was 84 months. Mean age was 42.4 years old. Younger patients with breast cancer were more likely to have advanced stage, higher nuclear grade, present lymphovascular invasion, and more likely to be unfavorable subtype such as triple negative breast cancer (TNBC)

Patients with younger age group showed worse prognosis than patients with older age patients. In multivariate analysis for overall survival, as patients were younger group, hazard ratio was increased, and the patients with TNBC showed higher HR than HER-2, Luminal B, and Luminal A subtype ($P < .0001$, $P < .0001$, $P < .0001$, and $P < .0001$, respectively). Stratified by subtype, luminal subtype showed significant worse prognosis as the age group was younger, while as, HER-2 and TNBC subtype showed no significantly different by the age group. **Conclusion** Patients with 20s breast cancer showed unfavorable characteristics and worse prognosis than 30s and older aged group. Stratified by tumor subtype, breast cancer in 20s with luminal subtype showed worse prognosis, while as HER-2 and TNBC showed no significantly different compare to breast cancer in 30s.
Clinicopathological predictors of axillary lymph node metastasis in early breast cancer patients

Mohan Satish¹, Ryan Walters¹ and Peter T Silberstein¹. ¹Creighton University School of Medicine, Omaha, NE.

Axillary lymph node (ALN) status is key in the prognosis of early breast cancer. Sentinel lymph node biopsy (SLNB) is the standard treatment in determining ALN status in clinically node negative patients with early breast cancer, but nearly 70% exhibit no ALN metastasis (a regional lymph node (RLN) metastasis). Likewise, selective use of SLNB has engendered modeling ALN metastasis. Using the National Cancer Database (NCDB), this study aimed to evaluate clinicopathological factors to help predict first and subsequent RLN metastasis in patients with early breast cancer.

Methods: We identified 660,258 women from 2004-2013 with early breast cancer stage (cT1-T3, cN0-N1, and M0). A two-part model was estimated using multivariable logistic regression to evaluate 1) predictors, by odds (OR), of having at least one RLN metastasis, and 2) predictors, by rate difference (RD), of having additional RLN metastasis relative to women with only one RLN metastasis. The same set of predictor variables were included in both parts of the model. All analyses were conducted using SAS v. 9.4 with p <.05 indicating statistical significance.

Results: Adjusted ORs and RDs of RLN metastasis for selected variables from the model are shown in Table 1. Increased likelihood of at least one RLN metastasis was significantly associated with the presence of larger tumor size (p <0.0001), a primary tumor in the nipple region (p <0.0001) of the left breast (p <0.0001), lobular or ductal type histology (p <0.001, and p <0.0001, respectively), positive estrogen (ER) and progesterone (PR) receptor statuses (p <0.0001 for both), younger age (p <0.0001), being white (p <0.0001), and greater comorbidity (Charlson/Deyo - CD) (p < 0.0001). Predictors of at least one RLN metastasis were also significantly associated with higher adjusted rates of further metastasis, except age, tumor size, ductal type histology, ER, and PR. However, a primary tumor in the central region (p =0.037), not the nipple region, was most associated with additional metastasis.

Conclusion: Utilizing a large dataset, several clinicopathological factors emerged from the NCDB as independent predictors of at least one, or additional RLN metastasis, supporting their weighted inclusion in prediction tools for ALN metastasis. Notably, different primary tumor sites of the breast predicted the two events modeled.
**Title:** Prognostic value of programmed death 1/Programmed death ligand 1/ mammalian target of rapamycin/Rictor/Tuberin in human breast cancer

Michal Uhercik¹,³, Andrew J Sanders¹, Sioned Owen¹, Eleri L Davies², Anup K Sharma³, Wen G Jiang¹ and Kefah Mokbel⁴.

¹Cardiff China Medical Research Collaborative at Cardiff University, Cardiff, United Kingdom; ²Cardiff Breast Centre, University Hospital Llandough, Cardiff and Vale University Health Board, Cardiff, United Kingdom; ³St George’s University Hospital, London, United Kingdom and ⁴The London Breast Institute, Princess Grace Hospital, London, United Kingdom.

**Body:**

**Background:** The Mammalian Target of Rapamycin (mTOR) regulates a multitude of cellular processes including metabolism, proliferation and growth. It is known to form two multi-protein complexes - complex 1 (mTORC1) and complex 2 (mTORC2) with Raptor and Rictor being their core proteins vital for their integrity.

Tuberin, the product of the Tuberous Sclerosis Complex gene 2, TSC2, has been characterized as a tumour suppressor and negatively regulates the mTOR pathway.

Programmed Death 1 (PD-1), a transmembrane protein particularly expressed on the surface of tumour cells, acts as an immune checkpoint receptor. Together with its ligand Programmed Death Ligand 1 (PDL-1) they form a pathway which when activated influences anti-tumour immunity and suppresses anti-tumour adaptive responses. The expression of PD1/PDL-1 is lightly regulated by the mTOR pathway.

We investigated the value of expression patterns of all these molecules in breast cancer as potential prognostic factors.

**Materials and Methods:** Quantitative PCR (qPCR) analysis was used to determine the transcript expression profile of the five genes of interest (PD-1, PDL-1, mTOR, Rictor and Tuberin) in 128 breast cancer specimens. The correlation between PD-1 or PDL-1 with mTOR, Rictor and Tuberin was assessed using the Spearman Rank Order Correlation. Subsequently, a combined analysis was performed, where the influence of favourable expression in relation to patient overall (OS) and disease free survival (DFS) using the Kaplan Meier survival curves and multivariate analysis.

**Results:** The mRNA expression of the molecules showed a varying degree of association with the clinicopathological parameters. PD-1 transcript expression showed a significant correlation with mTOR expression (p < 0.001). PDL-1 transcript expression was seen to correlate with mTOR (p < 0.001), Rictor (p < 0.001) and Tuberin (p < 0.01) transcript expression.

However, when the expression profile was analysed using an integrated expression score, the combined predictive value for the clinical outcome of the five genes was highly significant in terms of OS (p < 0.001) and DFS (p = 0.001), and was found to be an independent prognostic factor (p<0.001) for breast cancer related death using a multivariate analysis.

**Conclusions:** Our study identifies a molecular signature of 5 genes as a powerful prognostic predictor of OS and DFS in patients with breast cancer.
Title: Retrospective analysis of clinicopathologic features predictive of oncoType DX discordance in estrogen receptor positive, node negative breast cancer patients

Krystal P Cascetta¹, Brittney S Zimmerman¹, Lauren Eggert², Madeline C Molot³, Meng Ru¹, Anupma Nayak⁴, Ira Bleiweiss⁴ and Amy Tiersten¹. ¹Mount Sinai Hospital and Icahn School of Medicine, New York, NY; ²Stanford School of Medicine, Stanford, CA; ³Barnard College of Columbia University, New York, NY and ⁴Hospital of the University of Pennsylvania, Philadelphia, PA.

Body: BACKGROUND: Oncotype DX (ODX) is a validated recurrence score (RS) used to predict the risk of recurrence and benefit of chemotherapy in ER positive, node negative breast cancer patients. Prior to ODX, treatment recommendations regarding adjuvant chemotherapy and mortality approximation have taken into account clinical and pathologic risk factors. A discordance rate of 7-19% between risk allocating pathologic factors and ODX RS has been previously reported with progesterone receptor (PR) negativity noted as a defining clinical feature in numerous cases. The association between other clinicopathologic features and discordance is less certain.

METHODS: ODX data and clinicopathologic features were retrospectively reviewed for 724 breast cancer tumors belonging to 704 patients between 2006 and 2016. ODX discordance was defined as either 1-step discordance or 2-step discordance between ODX risk group (low, intermediate, high) and tumor grade (TG) (well differentiated, moderately differentiated, poorly differentiated). Tumors with 1-step discordance received a discordance score (DS) of 1 while those with 2-step discordance received a DS of 2. The database was subsequently analyzed using Paik's RS cutoffs as well as those outlined in the TAILORx trial. An odds ratio (OR) of >1 was consistent with discordance.

RESULTS: Among 724 tumor samples, ODX ER score (p=0.000), ODX PR score (p=0.000), ODX HER2 score (p=0.000), TG (p=0.000), mitotic count (MC) (p=0.0012), DCIS grade (p=0.0046), DCIS type (comedo necrosis vs. non-comedo necrosis) (p=0.0335) and micropapillary features (p=0.0044) were significantly associated with RS. Median age of cohort was 59 years and median tumor size was 1.2 cm.

Of 724 tumors, 619 from 604 subjects were eligible for assessment of discordance. Median RS was 16. Using Paik's RS cutoffs, 64.3% discordance was observed: 52.5% 1-step discordance (DS 1) and 11.8% 2-step discordance (DS 2). The TAILORx categorization yielded a discordance rate of 44.3%: 40.1% 1-step discordance and 4.2% 2-step discordance. On univariate analysis and using Paik's RS cutoffs, young age (p= 0.0240), high MC (p=0.0006), large tumor size (>20 mm) (p=0.0209), the presence of DCIS (p=0.0480), high DCIS grade (p= 0.0033), and high ODX PR and ER scores (p= 0.0000) were significant clinicopathologic features predictive of discordance. On multivariate analysis, high MC (p= 0.0000), high ODX PR and ER scores (p=0.0000) remained significant as well as premenopausal status (p=0.026).

CONCLUSION: In this retrospective ODX database, premenopausal status, high MC, high ODX PR and ER scores as per Paik's RS cutoffs were significant predictors for ODX discordance while high ODX PR and ER scores were significant predictors per the RS's outlined in the TAILORx trial. RS cutoffs per the TAILORx trial appear to create less discordance between RS and TG than the original cutoffs outlined by Paik and colleagues.
Clinicopathologic characteristics and prognostic factors of pure mucinous breast cancer

Sung Chan Gwark, Jong Won Lee, Sae Byul Lee, Guiyun Sohn, Jisun Kim, Il Yong Chung, Hee Jeong Kim, Beom Seok Ko, Byung Ho Son, and Sei Hyun Ahn. Asan Medical Center, Seoul, Republic of Korea.

Background: Mucinous carcinoma of the breast is a uncommon particular type of breast cancer and comprises approximately 4% of all invasive breast cancers. It is characterized by abundant extracellular mucin production and present a more favorable prognosis than IDC-NOS. Pathologically, mucinous carcinoma is divided into two subtypes: pure and mixed. In this study, we reviewed the clinicopathologic characteristics and prognostic factors of pure mucinous carcinoma.

Methods: We reviewed the 23 years cumulative data of pure mucinous breast cancer patients from database of the Breast Cancer Center at ASAN medical center, Korea, between 1989-2011, retrospectively. Total 386 pure mucinous carcinoma cases were reviewed to analyze clinicopathologic characteristics and prognosis.

Result: Total of 386 patients with pure mucinous breast cancer were identified. Mean age was 46.7. 149 patients underwent modified radical mastectomy and 236 underwent breast-conserving therapy. The T-stage was T1 in 187 patients, T2 in 178 patients, T3 in 17 patients and T4 in 4 patients. Node negative was 325 and node positive was 61. Estrogen receptor was positive in 342 and negative in 29. Progesterone receptor was positive in 342 and negative in 29. Progesterone receptor was positive in 276 and negative in 95. HER-2 was positive in 47 and negative in 273. 152 patients received adjuvant chemotherapy and 240 patients received adjuvant radiotherapy. 351 patients received hormone therapy and among these patients, 231 patients were treated with Tamoxifen alone, 81 were Tamoxifen with ovarian function suppression, 37 were AI only and one patient was ovarian function suppression only. The 5 year disease free survival rate was 93.3%, 5 year cancer specific survival rate was 98.2% and 5 year overall survival rate was 96.6%. Univariate analysis showed that ER status, nodal status and Her2 status were appear to be prognostic factor of Disease free survival rate. Using Cox regression, result of multivariate analysis revealed that only nodal status is the most significant prognostic factor for survival rate.

Conclusions: Pure mucinous carcinoma of the breast is a rare subtype with a favorable prognosis. Nodal status rather than ER status, Her2 status are considered to be the most significant prognostic factor of pure mucinos breast cancer.
Title: Predictive factors of sentinel lymph node biopsy invasion in extended ductal carcinoma in situ treated by radical mastectomy

Judicaël Hotton, Julia Salleron, Philippe Rauch, Julie Buhler, Léa Leufflen, Shaghayegh Ameloot and Frédéric Marchal. 
1Cancer Institute of Lorraine, Vandoeuvre-lès-Nancy, France.

Body: Introduction: The incidence of ductal carcinoma in situ (DCIS) increased with the practice of organized breast cancer screening to reach 14 % in France in 2010. The incidence of positive sentinel lymph node biopsy (SLNB) ranged from 0 to 16.7 %. The main hypothesis would be the presence of an invasive contingent on the definitive analyze not identified preoperatively. The objective was to identify predictive factors of SLNB positivity in the management of extended DCIS treated by radical mastectomy.

Method: This study was retrospective, longitudinal, descriptive conducted at the Cancer Institute of Lorraine from January 2000 to July 2015. All patients whose management consisted of a radical mastectomy for an extended DCIS, associated with a sentinel lymph node procedure were included.

Results: 161 patients were included. The mean age at diagnosis was 56 years; 15 had a clinical nodule. The diagnosis was made in 63.3 % with macrobiopsies. Preoperatively, 16 patients (9.9 %) had DCIS associated with microinvasion (DCIS-MI) and the others were pure DCIS. An average of 3.9 ± 2.7 SLNB were sampled. Twelve patients (7.4 %) had a SLNB invasion. Eleven of them had axillary lymph node dissection (ALND) of which only 1 was positive. The final histological analysis found 104 pure DCIS (64.6 %), 23 DCIS-MI (14.3 %) and 34 occult invasive ductal carcinomas (IDC) (21.1 %). Mean follow-up was 41.1 months. There were 2 recurrences and 2 deaths.

Predictive factors were size of palpated mass (mean: 46 mm, p = 0.04) and microinvasion on biopsy (p = 0.02). Positivity of the SLNB was an overstaging risk factor on the final histology (p < 0.001). Postoperative histological results were significantly different from preoperative (p = 0.001) with poor concordance (kappa = 0.15).

Discussion: After SLNB, the rate of secondary lymphedema in the literature was 5%. Our study included 7.4 % (12 cases) of axillary lesions, majority of which were unique micrometastases or isolated tumor cells (ITC). All predictive factors were identified in literature. In our study, mean size of palpated mass was 46 mm whereas it was 30 mm in literature. Of the 9.9 % of DCIS-MI, 4 patients had a positive SLNB. In cases of pure DCIS, the percentage of positive SLNB was reduced to 5.5 %. The rate of occult invasive ductal carcinoma was 21,1%, similarly like in literature where rate was in mean 23%.
Conclusion: The low rate of SLNB invasion in pure DCIS suggests that ALND is carried out in the presence of predictive factors. New techniques for identification of SLNB could report axillary staging after obtaining the definitive histologic results.
Body: Backgrounds: MicroRNA (miRNA) play a crucial role in cancer progression, and altered miRNA expression has been demonstrated to be associated with breast cancer. MiRNA is also known to be stably detectable not only in tissue but peripheral circulation; therefore it could be a feasible and potential biomarker of breast cancer in clinical settings. However, few studies have been reported to identify promising miRNA profiles as predictive biomarker using statistically satisfied large cohorts of breast cancer patients. The aim of this study is to identify miRNA signature that can predict patient survival utilizing integrated and unbiased transcriptomics analyses.

Methods: Integrated and unbiased transcriptomics approach was conducted on genomic and clinicopathological information of 2580 breast cancer patients. We utilized The cancer Genome Atlas (TCGA) to identify miRNA signature that could significantly associated with clinical relevance including prognosis and metastatic information, followed by validation analyses with the Molecular Taxonomy of Breast Cancer International Consortium (METABRIC) and Gene Expression Omnibus (GEO)

Results: A novel risk scoring model including three miRNAs signature (miR-19a, miR-93, and miR-106a) was identified using Cox model. This miRNA score was able to extract the patient population with extremely poor prognosis in TCGA (5-yr overall survival rate, 49.2 %, p=0.0005). This result was validated with another three completely independent cohorts with microarray dataset accompanied with sufficient clinical information and miRNA expression (GSE19536, n=96, p=0.0009; GSE22220, n=210, p=0.0003; METABRIC, n=1223, p=0.0023). Interestingly, the subtype stratification with PAM-50 classification using bioinformatics pipeline demonstrated that this miRNA score could predict poor overall or disease-free survival especially in the population with luminal A, B or normal like subtype (p=0.0300 and p=0.0001, respectively). In addition, competing risk analysis for tumor recurrences demonstrated that the risk scoring using three miRNAs signature could be significantly associated with bone metastasis (p=0.0052). Finally, Gene Set Enrichment Analysis (GSEA) identified that high risk score using three miRNAs associated significantly with several critical gene sets related to metastatic formation such as angiogenesis (p <0.0001), epithelial mesenchymal transition (EMT) (p = 0.0155), focal adhesion (p <0.0001), TGF-beta signaling pathway (p = 0.0025), and ECM receptor interaction (p = 0.0068).

Conclusions: We demonstrated a promising miRNAs signature score system for predicting extremely poor prognosis and metastatic potentiality in breast cancer using novel integrated transcriptomics concept.
Title: Validation of the new AJCC eighth edition of the TNM classification for breast cancer with a single center breast cancer cohort

Ji-Yeon Kim¹, Ji Eun Lim², Hae Hyun Jung², Soo Youn Cho¹, Eun Yoon Cho¹, Se Kyung Lee¹, Jong Han Yu¹, Jeong Eon Lee¹, Seok Won Kim¹, Seok Jin Nam¹, Yeon Hee Park¹, Jin Seok Ahn¹ and Young-Hyuck Im¹. ¹Samsung Medical Center, Seoul, Korea and ²Biomedical Research Institute, Seoul, Korea.

Body: Introduction : Our understanding of biology of breast cancer has led to significant changes in diagnostic and therapeutic approaches for breast cancer. The new eighth edition of the TNM classification of the AJCC for breast cancer (BC) determined by a multidisciplinary team of BC experts incorporate biologic factors, such as tumor grade, estrogen and progesterone receptor (ER and PR) expression, human epidermal growth factor 2 (HER2) expression, and gene expression prognostic panels in addition to traditional anatomic factors. In this study, we aimed to evaluate prognostic value of this new staging system compared to previous AJCC 7th staging system using single center, long term followed BC cohort.

Methods : We conducted a retrospective analysis of women with stage I, II, or III BC who underwent curative surgery with/without adjuvant systemic therapy at Samsung Medical Center between July 2004 and December 2008 (n=3,029). We excluded patients who received neoadjuvant therapy (n=183), and patients with missing information about immunohistochemistry (n=7), HER2 status (n=82) or histologic grade (n=74). The final sample size was 2,683.

Results: Of 2,683 BCs, 1,689 (63%) were hormone receptor (HR)-positive(+), 244(9%) were HR+ andHER2+, 289(11%) were HR-negative(-) andHER2+, 461(17%) were triple negative BCs. According to AJCC 7th pathologic staging system, there were 1,135 of stage IA, 4 of IB, 368 of stage IIA, 258 of stage IIIA, 11 of stage IIIB and 104 of stage IIIC. In terms of 10 year overall survival (OS) according to AJCC 7th staging system, 95.8% in stage IA, 100% in stage IB, 93.5% in IIA, 86.0% in stage IIB, 85.6% in stage IIIA, 90.9% in stage IIIB and 63.6% in stage IIIC were observed (p<0.001) (Medial follow up duration : 118 months). According to AJCC 8th clinical staging system, there were 722 of stage IA, 693 of IB, 306 of stage IIA, 201 of stage IIB, 251 of stage IIIA, 137 of stage IIIB and 160 of stage IIIC. In terms of 10 year overall survival (OS) according to new staging system, 96.7% in stage IA, 96.6% in stage IB, 91.4% in IIA, 92.1% in stage IIB, 86.2% in stage IIIA, 80.2% in stage IIIB and 66.8% in stage IIIC were observed (p<0.001). However, 213 BCs(7.9%) could not be staged by AJCC 8th clinical staging system. In depth analysis will be presented.

Conclusions: AJCC 8th clinical staging system provides a good prognostic value and makes up for the weakness of AJCC 7th anatomical pathologic staging. But this system cannot count whole pathologic stages. Modification of AJCC 8th clinical staging system would be warranted.
Impact of family history of breast and/or ovarian cancer in triple negative breast cancer

Zaida Morante1, Gabriel De la Cruz-Ku3, Joseph Pinto3, Daniel Enriquez1, Maria Lujan3, Renato Luque3, Eduardo Eyzaguirre3, Antonella Saavedra3, Hugo Fuentes1, Silvia Neciosup1 and Henry Gomez1. 1Instituto Nacional de Enfermedades Neoplasicas, Lima, Peru; 2Oncosalud, Lima, Peru and 3Universidad Cientifica del Sur, Lima, Peru.

Body: Background: A family history of breast and/or ovarian cancer (FHBOC) is a risk factor for breast cancer. The influence of FHBOC in the prognosis of triple-negative breast cancer (TNBC) is controversial. The aim of this study was to analyze the impact of FHBOC on the prognosis in TNBC patients.

Methods: We retrospectively reviewed a database of patients diagnosed of TNBC (period 2000-2014) and treated at “Instituto Nacional de Enfermedades Neoplasicas”. The patients were divided into two groups: with FHBOC and non-FHBOC. The clinical features and prognosis between groups were compared. Disease-free survival (DFS) and overall survival (OS) differences were calculated by the Kaplan-Meier Method and differences were evaluated by the Log-Rank test. Prognostic factors were identified by the Cox regression analysis.

Results: Overall, 266 out of 2007 TNBC patients, had +FHBOC (13.3%). The median age for the general population was 49 years. Compared with the non-FHBOC group (51.1%), the 43.8% +FHBOC were premenopausal. Prevalence of +FHBOC in a first-, second- and a third-degree relative was 26.8%, 28.5%, and 44.7%, respectively. Regarding histological subtype, invasive ductal carcinoma was the most prevalent (93.5%). Clinical stages (CS) II/III was more frequent in both groups (86.3 vs. 86.1). A total of 59% of FHBOC patients underwent surgery and 52% for non-FHBOC (p=0.029- Conservative 41.1 vs. 30.7 - Mastectomy 58.9 vs. 69.3). The median of follow-up was 9 years. DFS rate was higher in FHBOC patients (53.6% vs. 42.9%, p=0.001). OS was significantly better in the FHBOC group (Table 1). In the multivariate analysis, poor prognosis variables to DFS were an advanced age at diagnosis (≥50 years) (p=0.006) and higher clinical stage (CS I vs. CS III, p<0.001) while chemotherapy (CT) and radiotherapy (RT) were associated with an improved DFS. In regard to the OS, FHBOC was associated with a better prognosis (HR:0.77, 95%CI:0.62- 0.95, p=0.016).

Conclusion: Our results showed a better prognosis in TNBC patients with family history of breast and/or ovarian cancer in terms of DFS and OS.

Title: Clinical outcomes of single versus double hormone receptor positive breast cancer patients treated with neoadjuvant chemotherapy

Jacques Raphael\textsuperscript{1,2}, Sharon Nofech-Mozes\textsuperscript{3} and Maureen E Trudeau\textsuperscript{2}. \textsuperscript{1}Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada; \textsuperscript{2}Sunnybrook Health Sciences Centre, Toronto, ON, Canada and \textsuperscript{3}Sunnybrook Health Sciences Centre, Toronto, ON, Canada.

Body: Purpose
This study aimed to evaluate and compare tumor response rates and survival outcomes between single and double hormone receptor (HR) positive (+) [Estrogen Receptor (ER+)/Progesterone Receptor (PR) negative (-) or ER-/PR+ versus ER+/PR+] breast cancer (BC) patients with any HER2 status treated with neoadjuvant chemotherapy at a single institution.

Methods
A retrospective review was conducted using the Sunnybrook “Biomatrix” database to identify eligible patients. A multivariable logistic regression analysis (MLR) was performed to assess the association between HR status (single or double HR+) and pathologic complete response (pCR) rates at surgery. A Kaplan-Meier method was used to estimate Disease Free Survival (DFS) and a log-rank test was used to compare DFS between 3 subgroups of patients: single or double HR+ and HR negative patients.

Results
Three hundred and four BC patients were identified and included in the analysis with a median follow up of 43.3 months (Q1-Q3: 28.7-61.1) and a mean age of 49.7 years (Standard deviation 10.9). Forty seven percent (47/101), 31% (11/36) and 14% (24/167) of patients with HR negative, single HR+ and double HR+ disease achieved a pCR respectively ($X^2$ test $<$0.0001). In a MLR analysis, HR status and HER2 status were associated with pCR rates. Compared to HR negative patients, patients with double HR+ disease were less likely to achieve pCR (Odd ratio (OR):0.14, 95%CI 0.06-0.31, $p$<0.0001) while single HR+ patients did not differ (OR:0.51, 95%CI 0.19-1.4). The association between HR+ status (single versus double HR+) and pCR rates compared to HR negative patients remained the same in subgroup analyses of HER2+ and HER2 negative patients separately. No difference in survival (DFS) was seen between the 3 subgroups of patients: HR negative, single and double HR+ patients.

Conclusion
BC patients with single HR+ disease behave differently than double HR+ patients in terms of likelihood of achieving pCR after neoadjuvant chemotherapy and do not differ from HR negative patients. This difference does not translate into a difference in DFS. Prospective studies are needed to validate these findings before considering different treatment strategies for these 2 subgroups of HR+ BC patients.
Adipokine receptor CAP1 expression as predictor of survival outcome among breast cancer patients

Ann H Rosendahl¹, Malin Bergqvist¹, Siker Kimbung¹ and Signe Borgquist¹². ¹Lund University, Clinical Sciences Lund, Oncology and Pathology, Lund, Sweden and ²Aarhus University, Aarhus, Denmark.

Background: Obesity is a challenging health concern in breast cancer. Not only are obese women at higher risk of breast cancer, but if diagnosed with the disease, obesity is also impairing the prognosis of a breast cancer. Understanding the underlying biology behind these associations are key to improve survival rates in breast cancer. In obesity, the more abundant, activated adipose tissue may lead to insulin resistance and secretion of soluble mediators that may contribute to impaired breast cancer outcomes observed among obese women. The adipokine resistin is implied to be an important link between obesity and insulin resistance, and to be elevated among breast cancer patients. Yet, the expression of the newly identified resistin receptor CAP1 and its impact on breast cancer prognosis is poorly understood.

Purpose: To evaluate the impact by the adipokine receptor CAP1 tumor expression on breast cancer outcomes.

Experimental Design: CAP1 mRNA expression was explored among 1,881 primary breast tumors. Associations between CAP1 expression, categorized into tertiles, and survival outcomes were estimated using the Kaplan-Meier method and log-rank test, and by multivariable Cox regression models providing adjusted hazard ratios (HRadj) with 95% confidence intervals (CI). Independent biological network interaction analyzes were conducted in a subset of 1,105 invasive breast carcinomas within The Cancer Genome Atlas (TCGA) project.

Results: CAP1 was linked to poor tumor characteristics with higher CAP1 expression found among estrogen receptor (ER)-negative tumors, relative to ER-positive tumors, as well as with increasing tumor grade (P=0.025). High CAP1 tumor expression was further associated with shorter overall survival (HRadj 1.54; 95% CI, 1.11-2.13) and relapse-free survival (HRadj 1.47; 95% CI, 1.10-1.96), compared with low or intermediate CAP1 expression, particularly among ER-positive tumors or lymph node positive tumors. Additionally, CAP1 was identified in complex with genes involved in growth promoting and cell motility processes.

Conclusion: These results highlight the potential role of the resistin receptor CAP1 regarding breast cancer outcomes. Further investigations are needed to elucidate the biological and clinical implication of the resistin-CAP1 link in obesity-associated breast cancer.
Title: Outcomes and failure of primary endocrine therapy for operable breast cancer in the elderly: A regional North-east of England study

Robert Thomas¹, Rachel Rowell², Siobhan Crichton³ and Henry Cain². ¹Gateshead NHS Foundation Trust, United Kingdom; ²Newcastle Upon Tyne Hospitals NHS Foundation Trust, United Kingdom and ³Medical Research Council Trials Unit University College London, United Kingdom.

Body: Introduction
Primary Endocrine therapy (PET) to treat oestrogen receptor (ER) positive operable breast cancer in the elderly is used widely in the UK. A previous Cochrane analysis revealed its inferiority in long-term local control in comparison to surgery. As such, current guidance from the Society of International Geriatric Oncologists (SIOG) suggest that PET should be reserved for patients with a reduced life-expectancy (2-3 years) or for those considered unfit for surgery. Inaccurate assessment of life expectancy could lead to treatment failure which is potentially catastrophic for the patient.

The aim of this study was to evaluate treatment failures in elderly breast cancer patients treated with PET and to determine predictors of failure.

Methods
A retrospective observational study was performed on consecutive patients with ER positive early stage breast cancer treated with PET between 2005 and 2015 in the three breast units in the north east of England. The primary outcome measure was treatment failure and the secondary outcome measure was disease progression.

Results
488 patients were included with mean follow up 31 months (SD 23). 465 (95.2%) patients were started on Letrozole as their initial therapy. Overall, 206 patients were still alive with their disease controlled at the end of follow up, 219 had died with their disease controlled and 63 (12%) experienced treatment failure. Kaplan-Meier survival analysis predicted at 3 years 40% of patients to have died with controlled disease and 10% to have failed, leaving 50% living beyond this point with controlled disease.

Regression analysis identified younger age [SHR 0.96 (95% CI 0.94 to 0.99) p 0.013], larger tumours [SHR 1.03 (1.01 to 1.06) p 0.015], grade 3 cancers [SHR 3.58 (1.93 to 6.63) p<0.001] and axillary lymph node metastases [SHR 1.93 (1.06 to 3.52) p 0.030] were all independent predictors of treatment failure. Disease progression was reported in 86 (17.6%) of patients.

Conclusions
This is the largest retrospective series conducted evaluating PET treatment failure. Our comparably low rate of failure in comparison to that in the literature (12-85%) reflects good clinical acumen. Clear predictors of failure have been identified, which support previous analyses, further validating our results. Patients are able to live longer term (beyond 3 years) and maintain local disease control, which may represent a viable long-term treatment in the absence of risk factors for failure. Further work on our series is underway examining the effect of decision-making on PET outcomes.
2017 San Antonio Breast Cancer Symposium

Publication Number: P1-08-01

Title: Combination checkpoint inhibition and epigenetic modulation promotes tumor suppression and improves survival in Her2+ models of breast cancer

Evanthia T Roussos Torres¹, Hayley Ma¹, Brian Christmas¹, Todd Armstrong¹ and Elizabeth M Jaffee¹. ¹Johns Hopkins University, Baltimore, MD.

Body: Background: Checkpoint inhibition is a very successful treatment strategy in cancers that are naturally immunogenic by attracting T cells into the tumor microenvironment (TME) and promoting cytotoxic signaling pathways. While this strategy has shown some efficacy in metastatic breast cancer, most breast cancers are not highly immunogenic likely due to an immunosuppressive microenvironment and a lack of tumor antigen expression and recognition. One strategy to transform the breast TME is to use epigenetic modulation to affect activation and trafficking of myeloid derived suppressor cells (MDSCs), known to alter the immunogenicity of the TME and sensitize tumors to checkpoint modulation. We hypothesize that combinatorial therapy primes the TME by altering infiltration and function of MDSCs leading to a more robust T cell response. Methods: We are using a HER-2/neu transgenic mouse model with tumor challenge of syngeneic cell lines to test the efficacy of different combinations of an epigenetic agent, the histone deacetylase inhibitor entinostat (ENT), checkpoint inhibitors anti-programmed cell death protein (a-PD-1) and anti-cytotoxic T-lymphocyte-associated protein 4 (a-CTLA-4) antibodies, with and without anti-HER2 antibodies. We will examine treatment effects on tumor growth, and hope to identify co-stimulatory and inhibitory factors regulating T cell and MDSC responses. Characterization of tumor infiltrating lymphocytes and their functional capabilities are being investigated in primary tumors using fluorescence-activated cell sorting, nanostring gene expression profiling, and immunohistochemistry. Results: We found significant improvement in survival and delay in tumor growth in mice treated with ENT in combination with a-PD-1 and/or a-CTLA-4. Addition of anti-HER2 therapy to ENT and a-CTLA4 or a-PD1 also significantly improves survival and delay in tumor growth. We also found addition of ENT to checkpoint inhibition leads to significantly increased infiltration of granulocytic-MDSCs into the TME. We demonstrate an increase in CD8+ T effector cells in mice treated with combination therapy. Flow cytometric evaluation of markers of T cell activation, exhaustion, and MDSC function demonstrate significantly increased T cell activation, exhaustion, and myeloid function however it is unclear how this directly effects the phenotype we have observed in these mice. Gene expression profiling of both MDSCs and lymphocytes infiltrating tumors is underway to help determine significant changes in immune related pathways that lead to our observed outcomes. Conclusions: Addition of ENT to checkpoint inhibition significantly increases infiltration of innate and adaptive immune cells into the highly tolerant neu-N breast tumors and leads to improved survival and decreased tumor burden. Functional assays are underway and future studies will further delineate changes in immune infiltration as well as genetic alterations responsible for these observations. It is our hope that these novel findings will provide further rationale for combination therapy and improve the response rate of these immune therapies in patients with breast cancer.
Title: Breast tumor-specific MHC-II expression drives a unique pattern of adaptive resistance to antitumor immunity through MHC-II receptor checkpoint engagement

Justin M Balko¹, Douglas B Johnson¹, Paula Ericsson-Gonzalez¹, Mellissa J Nixon¹, Roberto Salgado², Violeta Sanchez¹, Daniel M Shreeder³, David L Rimm⁴, Ju Young Kim⁶, Jennifer Bordeaux⁶, Melinda E Sanders¹ and Randall S Davis⁷.
¹Vanderbilt University Medical Center; ²GZA and Jules Bordet Institute; ³University of Pennsylvania; ⁴Yale University; ⁵Peter MacCallum Cancer Center; ⁶Navigate BioPharma Services, Inc., a Novartis Company and ⁷University of Alabama.

Body: Background: We have previously shown that some breast cancers express major histocompatibility complex II (MHC-II), correlating with enhanced immune infiltration. In other tumor types, we have shown that MHC-II expression on tumor cells predicts clinical response to checkpoint inhibition. We sought to determine the direct effects of MHC-II on anti-tumor immunity and characterize mechanisms of immune escape in this breast cancer subset.

Methods: To determine the functional effects of MHC-II on tumor cells, we generated isogenic mouse breast tumor cells with enforced MHC-II expression and determined their ability to generate tumors in syngeneic mice, the impact on immunity, and their response to checkpoint inhibition. In a series of molecularly-characterized HER2+ (n=8) and triple-negative breast cancers (TNBC; n=103), we performed immunohistochemistry (IHC) and quantitative immunofluorescence (QIF) for Lag-3, PD-L1, CD4, CD8, FCRL6, and granzyme B.

Results: Following injection in syngeneic immunocompetent mice, MHC-II+ mouse breast tumors were more frequently rejected (p=0.04) and recruited greater numbers of CD4+ TILs. When MHC-II+ tumors escaped rejection, they expressed higher degrees of PD-1 and Lag-3 in the tumor and in the draining lymph node. Since Lag-3 is a checkpoint that specifically targets MHC-II, we hypothesized that MHC-II+ breast cancers escape anti-tumor immunity through suppressing MHC-II-mediated antigen presentation. Combinations of anti-Lag-3 and anti-Pd-1 antibodies inhibited growth of MHC-II+ tumors. These findings led us to also explore Fc receptor-like 6 (FCRL6), a previously reported MHC-II receptor expressed on NK and cytotoxic T cells. Residual MHC-II+ TNBC post-neoadjuvant chemotherapy (NAC) recruited greater numbers of CD4+ and CD8+ TILs (p=0.0001 and p=0.0002), suggesting enhanced immune recognition. However, MHC-II+ TNBCs also demonstrated a greater frequency of Lag-3+ and FCRL6+ TILs (p<0.001 and p=0.01, respectively) which frequently co-occurred (p=0.003). Thus, our data suggest that MHC-II expression in breast tumors supports recruitment of MHC-II-specific checkpoint-positive TILs. In line with this concept, QIF analysis demonstrated that the presence of Lag3+ and/or FCRL6+ TILs was strongly associated with suppression of T cell cytotoxicity as assessed by granzyme-B+ CD8+ T cells (p=0.0001 and p=0.002, respectively). Functional analyses of FCRL6 on human NK cell lines and peripheral blood mononuclear cells (PBMCs) demonstrated that like Lag3, FCRL6 is a checkpoint which engages MHC-II and suppresses cytotoxic NK and T cell activity.

Conclusions: These data suggest that MHC-II+ breast tumors are immunologically active and circumvent anti-tumor immunity by targeting MHC-II antigen presentation through recruitment of Lag-3+ and FCRL6+ TILs. We describe herein FCRL6 as a novel bona fide immune checkpoint which targets MHC-II, which may impact a variety of cancers. MHC-II expression status may be a useful biomarker for patient stratification on anti-PD-1/anti-Lag-3 combination, and eventually, anti-PD-1/anti-FCRL6 combinations in patients with breast cancer.
Title: Phase I-II trial of pembrolizumab and either doxorubicin (Dox) or an aromatase inhibitor (AI) for triple negative (TN) or hormone receptor positive (HR+) metastatic breast cancer (MBC)

George Somlo, Yuan Yuan, James Waisman, Christina Yeon, Paul Frankel, Wanqiu Hou, Arti Hurria, Niki Tank, Mina Sedrak, Timothy Synold, Joanne Mortimer and Peter Lee. City of Hope Cancer Center, Duarte, CA.

Body: Background: Metastatic TN and HR+ BC are incurable with current therapies. Preliminary data suggest modest activity with the PD-1 inhibitor pembrolizumab (pembro) in MBC. The addition of dox may increase expression of neoantigens enhancing PD-1 activity, while an AI effect may be enhanced by the PD-1 inhibitor in HR+ disease.

Methods: Primary endpoints were response and secondary endpoints included clinical benefit, safety, and progression-free survival. Cohort 1 includes patients (pts) without prior exposure to an anthracycline. Pts received escalating doses of dox at 50 and 60 mg/m2 to define the recommended phase 2 dose (RP2D) for a maximum of 6 cycles as well as pembro at 200 mg/every 3 weeks for up to 2 years. Cohort 2 includes 20 HR+ patients with treatment consisting of pembro 200 mg/every 3 weeks, and any AI to which a pt has not been exposed previously (exemestane preferred). PD-L1 expression was assessed by central laboratory-conducted immunohistochemistry. Peripheral blood samples before, during, and after treatment were collected and analyzed for cytokine production by Luminex multiplex assays and for immune cell markers by using flow cytometry. Biopsies were collected to assess immune profiles by using the Vectra automated quantitative pathology imaging system. CD8 T cells from the peripheral blood and FFPE slides were isolated before, during, and after treatment and T-cell receptor repertoires were compared to identify neoantigen-specific T cell clonotypes.

Results: Cohort 1 (TN MBC) accrued 3 pts without dose-limiting toxicities at 50mg/m2 with no grade 3 AEs, resulting in 1 partial response (PR), 1 unconfirmed PR, and 1 pt without progression for 7 cycles. At 60mg/m2, Cohort 2 is accruing and the RP2D will be reported. Cohort 2 (HR+ MBC) completed accrual of the planned 20 pts. The median age was 54, (range 43-78). There was 1 unconfirmed PR (still on after 3 cycles), 1 SD (progressed after 12 cycles), and 3 other patients are still on after 1-2 cycles. 1 pt came off for grade 3 liver enzyme (LFT) abnormalities in cycle 1, 14 pts progressed within 4 cycles. The median number of cycles is 2.5 (range 1-12). Grade 3 toxicities included 1 LFT abnormality, 1 grade 3 rash, and 1 grade 3 lymphocytopenia. Grade 2 toxicities were fatigue (N=5), rash (N=3), and 1 each of cough, headache, hot flashes, hypertension, insomnia, arthralgia and ankle edema. Plasma cytokines, blood and tumor immune profiles, and T cell clonotypes are under analysis.

Conclusions: The combination of dox or an AI with pembro is feasible. In the cohort of HR+ pts limited activity was observed and correlative analysis is underway to explore opportunities for patient selection. Responses were seen with the dox combination, and the RP2D will be reported on, along with additional follow-up. Early proliferation of peripheral blood T cell subsets may be a potential on-treatment biomarker to identify the MBC subset that will benefit from the additional of pembrolizumab and a full analysis of correlative studies is underway in the TN cohort to better guide effective and efficient cancer immunotherapy.
Title: A phase I trial of chemotherapy followed by infusions of activated T cells armed with anti-CD3 and anti-HER2 bispecific antibody for stage III, Her2+ or Her2− breast cancer

Patrick Dillon¹, Ritesh Rathore², Archana Thakur¹, Gerald Colvin², Nicola Kouttab² and Lawrence Lum¹. ¹University of Virginia, Charlottesville, VA and ²Roger Williams Medical Center, Providence, RI.

Body: Background: The balance in the immune system between immune surveillance and tolerance is known to be associated with the prognosis of breast cancer patients. The aim of this phase I study was to assess the safety of anti-CD3 x anti-HER2Bi bispecific antibody targeted (BAT) activated T cells (TC) in high risk breast cancer patients. The BAT T-cells exhibit anti-HER2 cytotoxicity, proliferate, and secrete immunokines upon tumor engagement.

Methods: High risk adjuvant breast cancer patients were recruited and completed standard adjuvant chemotherapy. BATs were produced by stimulating peripheral blood mononuclear cells (PBMC) obtained by leukapheresis; collected TC were then activated with anti-CD3 monoclonal antibody and expanded in IL-2 for 12-14 days. TC were armed with bispecific antibody and cryopreserved until used. Groups of 3 patients received 20, 40, 80 or 160 x 10⁹ BATs per infusion twice a week for four weeks. All patients were treated at Roger Williams Medical Center.

Results: Nine patients were accrued and all had N3 disease. Eight of 9 patients were ER positive; 2 of 9 were HER2 overexpressing. The median OS has not reached as five of nine patients are still alive. OS range from 14.3 to 154.7 months (as December 11, 2016). Five out of the five patients who are alive have no evidence of disease and 1 patient had a secondary primary that has been successfully treated and she has no evidence of disease. It was feasible to grow up to 160 x 10⁹ BATs and this dose level was tolerable without any cell-based dose limiting toxicities. BATs persisted in the blood for at least a week. BAT infusions induce cellular anti-tumor responses and cytokine responses.

Conclusion: Targeting HER2 positive and negative tumors induced cytotoxic anti-tumor responses, increases in Th1, cytokines and IL-12 serum levels. The prolonged survival in a high risk population suggests that BAT infusions provided a clinical benefit. These results are being confirmed in a phase II trial for metastatic breast cancer.
Title: Evaluating the anti-tumour efficacy of HAGE-derived vaccines in pre-clinical models

Divya Nagarajan¹, Lindy Durrant², Dennis Christensen³, A Graham Pockley¹ and Stephanie McArdle¹. ¹Nottingham Trent University, Clifton, Nottingham, Nottinghamshire, United Kingdom; ²Nottingham City Hospital, Nottingham, United Kingdom and ³Statens Serum Institut, Copenhagen, Denmark.

Body: Background: The management of patients with TNBC continues to present a significant clinical challenge and the prognosis of patients remains poor due to the lack of targeting structures for existing therapies. We have found that the cancer testis antigen HAGE (DDX43, CT13) is expressed in 43% of patients with TNBC and that it is an independent predictor of a patient's response to chemotherapy. Moreover, patients with HAGE-positive residual disease after neoadjuvant therapy have an increased risk of recurrence and death (Abdel-Fatah et al., 2016). Therefore, patients with HAGE positive tumours might benefit from a HAGE-specific vaccine.

Aim: To determine the anti-tumour efficacy of peptide and DNA-based HAGE-derived vaccines.

Methods: HHDII/DR1 transgenic mice were vaccinated with a 30mer HAGE sequence either in the form of a peptide + adjuvants (CpG vs CAF09) or as a DNA vaccine, Immunobody®. Seven days after the last injection, splenocytes were harvested and peptide-specific immune response towards individual vaccine-derived shorter peptides were determined using an IFNγ ELISpot assay. The ability of splenocytes derived from immunised mice to recognise HAGE+ tumour cells after one week in vitro stimulation with HAGE-derived peptides was also determined. The anti-tumour efficacy of the vaccines was also tested against established HAGE+/HHDII+ tumours in pre-clinical models.

Results: Both peptide with adjuvants and the Immunobody® generated strong anti-HAGE immune responses, as demonstrated by the significant increase in the number of IFNγ secreting splenocytes. Moreover, splenocytes from vaccinated mice stimulated in vitro could recognise and specifically respond to HAGE+ tumour cells. This response was both HAGE and CD8+ T cell-specific. Vaccination with HAGE 30mer vaccine significantly slowed the growth of HAGE+/HHDII+ tumours.

Conclusion: Cancer testis antigens such as HAGE / DDX43 are ideal candidates for anti-cancer therapies due to their restricted expression in normal tissue and over-expression in cancer tissues. However, many of these antigens suffer from poor immunogenicity, and therefore require strong adjuvants and/or appropriate delivery systems. The adjuvants/delivery system tested in this study show promising results. Future work will investigate combination approaches using checkpoint inhibitors. Overall, demonstrating potential value of HAGE-derived vaccines for the treatment HAGE positive cancers will underpin the development of a platform for a phase I clinical trial in the relevant patient group(s) upon demonstrating potential value of HAGE-derived vaccines for the treatment HAGE positive cancers.
Title: A phase 1b study of abemaciclib plus pembrolizumab for patients with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-) metastatic breast cancer (MBC)

Hope S Rugo¹, Peter Kabos², Maura N Dickler³, William J John⁴, Ian Smith⁴, Yi Lu⁴, Suzanne Young⁴ and Sara M Tolaney⁵.
¹University of California San Francisco Comprehensive Cancer Center, San Francisco, CA; ²University of Colorado, CO; ³Memorial Sloan Kettering Cancer Center, New York, NY; ⁴Eli Lilly and Company, Indianapolis, IN and ⁵Dana-Farber Cancer Institute, Boston, MA.

Body: Background: Abemaciclib is a selective and potent small molecule inhibitor of CDK4 and 6, with evidence of single-agent antitumor activity, and a safety profile that enables dosing on a continuous schedule. Abemaciclib demonstrated anti-tumor activity as a single agent with a 19.7% objective response rate for women with previously treated HR+, HER2- MBC ¹. In the phase 1b study JPBH, abemaciclib demonstrated a tolerable safety profile when combined with endocrine or HER2 targeted agents for MBC ². Abemaciclib given BID in combination with pembrolizumab also demonstrated a tolerable safety profile in phase 1b study of stage IV NSCLC ³.

Methods: JPCE is a multicenter, nonrandomized, open-label, phase 1b study of abemaciclib plus pembrolizumab for patients with HR+, HER2- MBC or NSCLC (ClinicalTrials.gov NCT02779751). The study has 3 disease-specific cohorts, each with approximately 25 patients (N=75); the HR+, HER2- MBC cohort (part C) will be presented here. The primary objective was to characterize safety of the abemaciclib and pembrolizumab combination. Secondary objectives included efficacy endpoints (objective response rate, disease control rate, duration of response, progression-free survival, and overall survival), pharmacokinetics of abemaciclib plus pembrolizumab, and changes in patient-reported pain and disease-related symptoms. Patients received 150 mg of abemaciclib orally Q12H plus pembrolizumab 200 mg as a 30-minute IV infusion on Day 1 every 21 days. Eligible patients included women with confirmed HR+, HER2- MBC who have previously received at least 1 but no more than 2 prior chemotherapy regimens for MBC; are able to provide tumor tissue at baseline and at cycle 3, day 1; have measurable disease (RECIST v.1.1), adequate organ function, ECOG PS ≤1, are able to swallow oral medications; and have not received treatment with CDK4 & 6 or PD-1/ PD-L1 inhibitors.

Results: At the time of abstract submission, study JPCE part C cohort (HR+, HER2- MBC) was fully enrolled at 25 patients. Data to be presented include patient demographics, baseline disease characteristics, adverse events by frequency and by grade, and preliminary efficacy of the abemaciclib plus pembrolizumab combination in HR+, HER2- MBC.

Title: Bromodomain inhibitors for the treatment of invasive lobular carcinoma

Darran P O'Connor¹, Louise Walsh¹, Yue Fan², Finbarr Tarrant², Suet-Feung Chin³, Philip Schouten⁴, Carlos Caldas³, Rene Bernards⁴, Triona Ni Chonghaile¹ and William M Gallagher². ¹Royal College of Surgeons in Ireland, Dublin, Ireland; ²University College Dublin, Dublin, Ireland; ³University of Cambridge, Cambridge, United Kingdom and ⁴Netherlands Cancer Institute, Amsterdam, Netherlands.

Body: Invasive lobular carcinoma (ILC) is the second most common type of breast cancer after invasive ductal carcinoma (IDC), accounting for approximately 10-15% of all breast tumors. ILC is characterized by inactivation of E-Cadherin and neoplastic cells that invade the stroma in a "single-file" pattern. Women with ILC are usually older, have used hormone replacement therapy and are more likely to have hormone receptor–positive disease. ILCs have similar survival to IDCs at both five and 10 years, but despite this, the clinical course is distinct: ILCs are three times more likely to metastasize to the peritoneum, gastrointestinal tract, and ovaries and are more frequently bilateral. Therefore, tailored therapeutic options for this distinct, hard-to-treat subtype of breast cancer are required.

As part of the RATHER FP7 HEALTH consortium (www.ratherproject.com), we carried out RNA-Seq analysis of 61 primary ILC samples and identified that high expression of the BET family protein Brd3 (uniquely among BRD family members) was associated with poor recurrence free survival (p=0.03, HR 8.63, CI 1.22-60.85). This observation was further validated in the independent METABRIC cohort (n=99), where again, high Brd3 expression (and not other BRD members) was associated with poor recurrence-free survival (p<0.01, HR=3.16, CI 1.24-8.03). Using a two ILC cell lines (SUM44PE and MDA-MB134VI) we found that ILC cells were relatively resistant to the anti-estrogen therapies tamoxifen and fulvestrant compared to those derived from IDC. Next, we tested whether the ILC cell lines were sensitive to BET protein inhibition using the pan-BET family inhibitor JQ1. Interestingly, while JQ1 inhibited cell growth in both ILC cell lines tested, apoptosis was only induced in SUM44PE cells, while MDA-MB134VI cells exhibited G1 arrest. Dynamic BH3 profiling was used to dissect the underlying anti-apoptotic dependencies in each ILC cell type and showed that in the JQ1-resistant MDA-MB134VI cells, survival was predominantly Bcl2-dependent. Combination of JQ1 and the Bcl2-inhibitor venetoclax (ABT-199) synergistically killed MDA-MB134VI cells compared to treatment with JQ1 alone, while combination with the Bcl2/Bcl-Xl/Bcl-W inhibitor navitoclax (ABT-263) added further synergy.

With a number of BET inhibitors now entering clinical trials, the data described here suggest that BET inhibition is a rational therapeutic option for some ILC cases, and for those that do not respond, combination with venetoclax may be a suitable therapeutic strategy. In our cell line models, baseline Bcl-2 expression was sufficient to predict induction of apoptosis in response to JQ1 and could be used to guide therapeutic choice. These results should now be investigated in vivo before a prospective clinical trial.

Global knockdown of cellular kinases identifies MPS1 as a novel modulator of endocrine and palbociclib resistance highlighting a new role for MPS1 inhibitors

Joanna Nikitorowicz-Buniak¹, Sunil Pancholi¹, Nikiana Simigdala¹, Ricardo Ribas¹, Spiros Linardopoulos¹, Mitch Dowsett², Stephen R Johnston³ and Lesley-Ann Martin¹. ¹Breast Cancer Now, Toby Robins Research Centre, Institute of Cancer Research, London, United Kingdom; ²Ralph Lauren Centre for Breast Cancer Research, Royal Marsden Hospital, London, United Kingdom and ³Royal Marsden Hospital, London, United Kingdom.

Body: Background Estrogen-receptor positive (ER+) breast cancer (BC) accounts for over 75% of diagnosed cases. Despite treatment, a large proportion relapse with de novo or acquired endocrine resistant disease, making it one of the greatest challenges for BC research. Using a kinome siRNA library screen, we identified MPS1 that is required for recruitment of the spindle assembly checkpoint complex, as strongly associated with resistance to endocrine therapy and palbociclib. Until now, the target population for MPS1 inhibitors has focused on triple negative BC. Our unexpected finding shows, potential efficacy of MPS1 inhibitors in ER+ BC resistant to endocrine therapies and palbociclib, a prominent contemporary first-line combination for advanced disease.

Methods ER+ BC cell lines (MCF7, SUM44, ZR75.1, HCC1428 and T47D) adapted to estrogen independent growth (LTED) and sequential resistance to palbociclib (991R) were subjected to a siRNA screen targeting 709 kinases. Z-scores were used to identify the most robust candidates. Cell viability upon MPS1 inhibition with CCT289346 (MPS1i) was assessed 2D and 3D. The class effect was confirmed with other compounds targeting MPS1. Impact of MPS1i on ER co-localisation and ER-transactivation was assessed using confocal microscopy and reporter assays, respectively. Effect of MPS1i on chromosomal alignment and time spent in mitosis was established by time lapse and confocal microscopy. BrdU incorporation and cell cycle were assessed by FACS. PARP cleavage was used to measure apoptosis. Global gene expression analysis of MPS1 was carried out in two independent neoadjuvant studies of aromatase inhibitor (AI) treated patients.

Results Kinome knockdown identified targets associated with the G2/M checkpoint as strongly implicated in the LTED phenotype. In particular, MPS1 was the top common hit in LTED and 991R cell lines. Increase in MPS1 was evident in MCF7-LTED at both the transcript and protein level. Notably, the MPS1 inhibitor CCT289346 caused a significant reduction in viability of the majority of LTED and 991R cell lines tested.

Upon inhibition of MPS1, cells demonstrated shorter time in mitosis, aberration of cell cycle and amplified mitotic errors, resulting in increased apoptosis.
To evaluate the clinical relevance of \textit{MPS1} in ER+ BC treated with endocrine therapy, we interrogated publicly available datasets from patients treated with neoadjuvant AI therapy. In the anastrozole cohort, on-treatment gene expression of \textit{MPS1} (p<0.0001) was significantly associated with poor response to anastrozole based on a 2-week residual Ki67 score <10%. In the letrozole cohort, increased on-treatment expression of \textit{MPS1} (p=0.0118) was associated with poor response based of tumor shrinkage ≥50%.

\textbf{Conclusion} This novel finding shows MPS1 inhibitors are capable of inducing mitotic aberrations and apoptosis in ER+ BC models resistant to endocrine therapy and palbociclib providing a new therapeutic strategy.
Activity of CT7001 an orally bio-available cyclin-dependent kinase 7 selective inhibitor in models of triple negative breast cancer

Ashwani K Bahl¹, Edward Einscow¹, Andrew Leishman¹, Elaine Sullivan¹, Simak Ali², Raoul C Coombes², Anthony GM Barrett⁵, Bo Li³, William M Gallagher³, Neil O Carragher⁴ and Tesh Patel⁴. ¹Carrick Therapeutics, Dublin, Ireland; ²Imperial College, London, United Kingdom; ³UCD School of Biomolecular and Biomedical Science, UCD Conway Institute University College Dublin, Dublin, Ireland; ⁴Cancer Research UK, Edinburgh Centre, Institute of Genetics and Molecular Medicine, Edinburgh, United Kingdom and ⁵Imperial College, London, United Kingdom.

Body: Triple-negative breast cancer (TNBC) is a highly aggressive and heterogeneous subtype of breast cancer that commonly exhibit poor prognosis and high relapse rates at early stages after conventional neoadjuvant chemotherapy. CDK7 inhibition has emerged as an ‘Achilles heel’ in TNBC via blocking transcriptional addiction to a defined cluster of genes (Wang et al 2015). CDK7 acts as a CDK-activating kinase controlling proliferation and as a transcriptional kinase phosphorylating RNA Polymerase II. Eukaryotic RNA polymerase II (Pol II) is a 12-subunit DNA-dependent RNA polymerase that is responsible for transcribing nuclear genes encoding messenger RNAs and several small nuclear RNAs (R Young 1991)

We have demonstrated that established cell-lines and patient derived tumour tissue (PDTT, explants established as models at low passage numbers that have not been grown in plastic or propagated as cell cultures) of TNBC are sensitive to a potent, selective and orally bioavailable CDK7 inhibitor CT7001 (ICEC0942). CT7001 produces a concentration-dependent inhibition of growth with GI50s <1 micromolar across all TNBC cells tested to-date. The inhibition of proliferation was associated with an inhibition of c-MYC, Mcl-1 and phospho-Pol II as determined by Western Blot analysis. This demonstrates that CT7001 effectively controls transcriptional regulation and anti-apoptotic mechanisms in a diverse group of TNBC cellular models.

CT7001 was also evaluated in an in vivo orthotopic-PDX model of TNBC in nu/nu mice. Establishing PDX-xenograft tumour models from PDTT at low passage is believed to conserve original tumour characteristics such as heterogeneous histology, clinical biomolecular signature, malignant phenotypes and genotypes. Therefore, patient-derived tumour grafts are believed to offer relevant predictive insights into clinical outcomes when evaluating the efficacy of novel cancer therapies. Orally administered CT7001 monotherapy produced strong and sustained regression of the tumour that persisted during the dosing schedule and strong suppression was still maintained upon cessation of treatment. At doses that produced regression CT7001 was well tolerated with little effect on body weight loss (<10%)

CT7001 is a potent, selective and orally bioavailable inhibitor of CDK7 that shows promise as a potential new treatment for TNBC.

Radiosensitization of androgen receptor (AR)-positive triple-negative breast cancer (TNBC) cells using seviteronel (INO-464), a selective CYP17 lyase and AR inhibitor

Corey W Speers, Benjamin Chandler, Eric Olsen, Kari Wilder-Romans, Leah Moubadder, Shyam Nyati, James Rae, Daniel F Hayes, Daniel E Spratt, Daniel R Wahl, Joel Eisner, Felix Y Feng and Lori J Pierce. 1University of Michigan, Ann Arbor, MI; 2Innocrin Pharmaceuticals, Inc., Durham, NC and 3University of California San Francisco, San Francisco, CA.

Body: Background: Increased rates of locoregional recurrence (LR) have been observed in TNBC despite chemotherapy and radiation (RT). A novel radiosensitizer screen nominated the AR as a promising target for treatment of radioresistant breast cancer, including TNBC. We assessed the activity of seviteronel (Sevi), a selective CYP17 lyase and AR inhibitor in Phase 2 clinical development for advanced breast and prostate cancer, as a potential radiosensitizer in AR+ TNBC model.

Methods: Clonogenic survival assays were used to determine the intrinsic RT sensitivity of 21 breast cancer cell (BCC) lines. IC50 values were determined for 130 clinically available compounds and correlation coefficients were calculated using IC50 values and SF-2Gy. Gene expression was measured using RNA Seq or qRT-PCR and protein expression was measured using RPPA arrays. AR function was assessed using functional inhibition with Sevi in MDA-MB-453, ACC-422, ACC-460, SUM-185 (all four AR+ TNBC), MDA-MB-231 (AR- TNBC), and T47D (AR- ER+) BCC lines. Double-stranded DNA (dsDNA) break repair was assessed with γH2AX foci counting. In vivo tumor growth was measured with varying control and treatment groups (16-20 tumors/group). Kaplan-Meier analysis was performed to estimate local control. A Cox proportional hazards model and multi-variate analysis (MVA) were used to determine variables associated with LRF survival.

Results: Our novel radiosensitizer screen identified the activity of anti-androgen therapy as a potentially effective strategy for radiosensitization in RT-resistant BCC lines (R² =0.46, p-value < 0.01) (Speers et al, J Clin Oncol 35, 2017 (suppl; abstr e12102). Heterogeneity in AR expression was identified in human BCC lines and TNBC samples from patients (N=2098). There was a strong correlation between AR RNA expression and protein expression across all BC intrinsic subtypes. AR inhibition using Sevi induced radiation sensitivity in vitro with an enhancement ratio (ER) of 1.24-1.69 in four different AR+ TNBC lines. No such radiosensitization was seen in AR(-) TNBC or ER+, AR(-) BCC lines. Radiosensitization was at least partially dependent on impaired dsDNA break repair with significant delays in dsDNA break repair at 16 and 24 hours in all AR+ TNBC lines examined (p-value < 0.01). AR inhibition with Sevi significantly radiosensitized AR+ TNBC xenografts in mouse models and markedly delayed tumor-volume tripling time (TTT) and tumor growth (MDA-MB-453: median TTT 16.1 days for RT alone vs. not reached after 45 days for Sevi+RT, p-value <0.001). Similar delays were seen in tumor growth, weight, and tumor doubling. Clinically, TNBC patients whose tumors had higher than median expression of AR had higher rates of LR after RT (HR for LR ~3, p-value <0.01, 2 independent datasets). In MVA, high AR expression was the variable most significantly associated with worse LR survival after RT in TNBC patients, outperforming all other variables (HR of 3.42; p-value < 0.01).

Conclusions: Our results implicate the AR as a mediator of radioresistance in breast cancer and support the rationale for developing Sevi as a novel radiosensitizing agent in AR+ TNBC.
Blocking ER coregulator signaling enhances CDK4/6 inhibitor palbociclib therapy in ER-positive advanced breast cancer

Body: BACKGROUND: Recently, CDK4/6 inhibitors in combination with endocrine therapy (AE/AI/SERDs) is approved for the treatment of ER+ advanced breast cancer (BCa). However, not all patients benefit from CDK4/6 inhibitors therapy. Emerging studies indicate many therapy-resistant tumors retain ER signaling, via interaction with critical oncogenic coregulator proteins. Considering complex signaling interplay of ER and CDK4/6 axis, combination therapy of CDK inhibitor with other potent ER-targeted agents that block ER coregulatory signaling may extend the efficacy and may prevent the development of resistance to the CDK4/6 inhibitors. We recently developed a small organic molecule, ER coregulator binding modulator ERX-11 (EtiraRx-11). The objective of this study is to test the utility of novel combination therapy of ERX-11 with CDK4/6 inhibitor palbociclib in treating therapy resistant advanced BCa.

METHODS: We have utilized multiple therapy sensitive and therapy-resistant BCa models with various genetic backgrounds. We tested efficacy using both acquired resistance and engineered models that express ER mutations or oncogenes. Efficacy of combination therapy was tested using established in vitro assays including, MTT, colony formation, apoptosis, and cell cycle progression. Mechanistic studies were conducted using reporter gene assays, gene expression, RNA-seq analysis and signaling alterations. Patient-derived BCa explant and Xenograft studies were used to determine the in vivo efficacy of the combination therapy.

RESULTS: ERX-11 effectively blocked ER-mediated and ER-coregulator mediated oncogenic signaling and has potent anti-proliferative activity against both endocrine therapy-sensitive and therapy-resistant BCa cells. Mechanistic studies using IP-Mass spectrometry showed that ERX-11 blocks the interaction between a subset of coregulators with ER in resistant BCa models. ERX-11 exhibited potent anti-proliferative activity against therapy-sensitive and therapy-resistant ER-driven BCa cells in vitro, in xenograft models in vivo and in patient-derived breast tumor explants ex vivo. Co-treatment of ERX-11 with palbociclib synergistically reduced cell viability and induced apoptosis of therapy sensitive and resistant BCa model cells. Importantly, combination therapy of ERX-11 and the palbociclib synergistically reduced the growth and induced apoptosis of tamoxifen and letrozole resistant xenograft tumors compared to either drug alone. RNA-seq studies revealed that combinational treatment with ERX-11 and palbociclib uniquely activated p53 and unfolded response mediated apoptotic pathways and suppressed E2F and Myc target genes. Biochemical studies confirmed combination therapy significantly altered E2F1 and ER signaling pathways and promoted apoptosis.

CONCLUSIONS: Our data support a critical role of blocking ER coregulator signaling in treating therapy resistance in advanced ER+ BCa. Combinational treatment with ERX-11 and palbociclib may overcome/delay endocrine therapy resistance.
Title: Breast cancer initiating cells express functional ROR1, which can be targeted by cirmtuzumab to potentially mitigate the risk of relapse after therapy

Suping Zhang1,2, Han Zhang1, Emanuela M Ghia1, Grace Liu1, Victoria Tripple1, Shuangyue Xu1, Bing Cui1, George Widhopf1, Jian Yu1, Richard Schwab1, Karen Messer1,3, Barbara A Parker1 and Thomas J Kipps1. 1Moores UCSD Cancer Center, University of California, San Diego, La Jolla, CA; 2Medical Cancer Research Center, School of Medicine, Shenzhen University, Shenzen, Guangdong, China and 3University of California, San Diego, La Jolla, CA.

Body: Although initially responsive to chemotherapy, patients with advanced breast cancer often relapse, generally with incurable metastatic disease. This may be due to a subpopulation of tumor cells, called cancer-initiating cells, or cancer stem cells (CSCs), which are relatively resistant to chemotherapy and have self-renewing and tumor-initiating capacities. Prior studies in our laboratory found that CSCs may express ROR1, an onco-embryonic, tyrosine-kinase-like orphan receptor, which we found could bind Wnt5a to activate non-canonical Wnt-signaling (Proc Nat Acad Sci USA 111:17266, 2014). Interrogation of the transcriptomes of breast-cancer cells obtained from patients before and after paclitaxel therapy revealed that chemotherapy treatment enhanced cancer-cell expression of ROR1, along with genes induced by activation of Rho-GTPases (e.g. RhoA, cdc42, and Rac1). We found that primary breast-cancer patient-derived xenografts with high-level expression of ROR1 were enriched for cells that had activated Rho-GTPases and stem-cell-like gene-expression signatures. Furthermore, we found that treatment of breast cancer cell lines with Wnt5a induced ROR1-dependent activation of Rho-GTPases and AKT and induced high-level protein expression of BMI1, also known as polycomb group RING finger protein 4 (PCGF4) or RING finger protein 51 (RNF51); Wnt5a also enhanced the capacity of breast cancer cell lines to form spheroids. All these effects could be inhibited by cirmtuzumab, a humanized high-affinity anti-ROR1 mAb, which can block Wnt5a signaling. We find that ROR1-positive breast cancer cells have a greater capacity to form spheroids or engraft immune-deficient mice than did ROR1-negative cancer cells isolated from the same PDX tumor. Treatment of immune-deficient mice bearing breast-cancer PDX with paclitaxel reduced tumor volumes but enhanced expression of ROR1 and other CSC markers, such as aldehyde dehydrogenase 1 (ALDH1). Moreover, the breast cancer cells surviving such paclitaxel treatment had increased activation of Rho-GTPases and AKT, and increased expression of BMI1, relative to that of breast cancer cells obtained from the same primary tumor prior to therapy. On the other hand, treatment of such mice with cirmtuzumab also reduced breast cancer PDX tumor volumes, but the remaining cells had reduced expression of ROR1 and CSC markers and had impaired capacity to re-engage immune-deficient mice. Finally, therapy with cirmtuzumab and paclitaxel was more effective in eradicating breast-cancer PDX than treatment with either agent alone. Collectively, these findings support use of cirmtuzumab in combination with conventional anti-cancer drugs to improve the outcome of patients with advanced breast cancer.
Title: *BCL2L1* (BCL-XL) expression and MYC super-enhancer positivity predict sensitivity to the covalent CDK7 inhibitor SY-1365 in triple negative breast cancer (TNBC) cell lines

Nisha Rajagopal¹, Graeme Hodgson¹, Shanhu Hu¹, Michael McKeown¹, Alex Bush¹, Christian Fritz¹, David Orlando¹, Eric Olson¹ and Emmanuelle di Tomaso¹. ¹Syros Pharmaceuticals, Cambridge, MA.

Body: Effective therapies for TNBC remain elusive. As such, TNBCs are associated with a high risk of relapse and short progression free- and overall-survival. Recent studies showed that TNBC cells are highly dependent on the transcriptional regulator CDK7, and suggest that the mitochondrial apoptosis pathway is important in mediating cell survival in CDK7-dependent cells. Further, TNBC has been shown to have a distinct epigenetic and transcriptional program, with super-enhancers (SE) mediating the expression of key oncogenic drivers such as *MYC*. SY-1365, a covalent and selective inhibitor of CDK7, was developed to exploit dysregulated programs thought to drive SE-mediated transcriptional-dependencies in TNBC and other cancers. To identify potential biomarkers predictive of sensitivity to SY-1365, we evaluated SY-1365 inhibitory activity in a large panel of human tumor cell lines, including TNBC lines, and correlated sensitivity with RNA expression and epigenetic profiles.

SY-1365 dose-response curves were measured using the ATP-lite assay in a panel of 406 human tumor cell lines, including 19 TNBC cell lines. Clustering of growth-rate adjusted dose response curves of cell-lines treated with SY-1365 allowed the classification of cell-lines into low and high response groups. An unbiased genome wide approach was used to compare response classification to RNA expression data across all cell lines to identify gene expression markers predictive of sensitivity to SY-1365. Furthermore, a hypothesis driven approach was followed to interrogate whether the *MYC* SE predicted sensitivity to SY-1365.

Twenty-five genes were differentially expressed between SY-1365-sensitive and -insensitive tumor lines (FDR<0.05). Lower expression of *BCL2L1*, which encodes the mitochondrial apoptosis regulator BCL-XL, was identified as the most predictive expression biomarker of sensitivity across all profiled cell lines, strongly separating the two classes of sensitivity (Accuracy=70%, FDR<0.005). Further, this predictive power of lower *BCL2L1* expression was maintained in an analysis restricted to the subset of TNBC cell-lines (Accuracy=73%).

Expanding beyond expression analysis, we also found that the strength of the *MYC* SE (as defined by H3K27Ac) was predictive of response to SY-1365 in TNBC (Accuracy=86%, FDR<0.05).

In this study, we show for the first time that SY-1365 induced differential responses across a large panel of human tumor cell lines derived from multiple indications. We also show that in this panel of cell lines the response could be predicted in an “indication agnostic” manner by the level of expression of *BCL2L1*. Finally, in line with prior reports, in TNBC cell lines, MYC SE was significantly associated with sensitivity to SY-1365. These observations have generated strong hypotheses for selection strategies aimed at identifying patients with tumors particularly sensitive to CDK7 inhibition with SY-1365, and warrant further investigation with respect to predictive biomarkers of response in patients. SY-1365 is currently being assessed in a phase 1 trial in adult patients with advanced solid tumors, including a planned expansion cohort enriching for patients with TNBC (NCT03134638).
Title: Efficacy of estrogen receptor β agonists in the prevention of breast cancer progression to therapy resistance

Kumaraguruparan Ramasamy¹, Cathy Samayoa¹, Naveen K Krishnegowda¹, Ratna K Vadlamudi¹ and Rajeshwar R Tekmal¹. ¹UT Health San Antonio, San Antonio, TX.

Body: Estrogen plays an important role in the initiation and progression of breast cancer (BCa). Approximately, 70% of breast tumors are estrogen receptor (ER) positive at the time of presentation. Endocrine therapy using aromatase inhibitors (AI), or anti-estrogen (AE) molecules are widely used for treating ER+ve BCa. However, their efficacy is limited by intrinsic and acquired therapy resistance and most patients develop resistance to these drugs. The transcriptional effects of estrogen are mediated by two ERs (ERα and ERβ) and both are expressed in normal breast tissue. Unlike ERα, ERβ functions as tumor suppressor. However, role of ERβ specific agonists in the prevention of BCa progression remains elusive. In this study, we investigated the effectiveness of two ERβ agonists (S-Equol and LY500307) in the prevention of BCa progression using endocrine therapy sensitive (MCF7-aro) and letrozole resistant (MCF7-aro-LTLT) cells. Our results demonstrated that treatment with ERβ agonists inhibit short-and long-term growth of both endocrine therapy sensitive and resistant BCa cells. In addition, ERβ agonists treatment inhibited invasion and migration of both MCF7-aro and MCF7-aro-LTLT cells. Importantly, cell cycle analysis revealed that ERβ agonists induced cell cycle arrest. Our gene microarray analysis demonstrated that both ERβ agonists significantly modulated genes involved in the cell cycle progression, DNA replication and cell death pathways. Further, gene enrichment analysis of differentially expressed genes revealed that genes involved in the cell cycle checkpoints emerged as significant pathway modulated by ERβ agonists treatment in MCF7-aro cells. Interestingly, in letrozole-resistant MCF7-aro cells, DNA replication was significantly affected by ERβ agonists treatment. Pathway analysis also identified enrichment for chemokine signaling pathways. We confirmed pathway analysis by qRT-PCR and western blot analysis. Accordingly, treatment of in vivo syngeneic xenografts with ERβ agonists significantly inhibited BCa progression. Collectively, these results from this study suggest that ERβ agonists have potential to prevent the progression of BCa progression.
Title: ICOSL anti-HER2 V-mAbs: Localizing engineered ICOSL costimulatory agonists to HER2+ tumors through trastuzumab

Erika Rickel1, Lawrence Evans1, Ryan Swanson1, Steve S Levin1, Mark Rixon1, Martin Wolfson1, Janhavi Bhandari1, Sean MacNeil1, Joe Hoover1, Michael Kornacker1, Irene Capuano1 and Stanford L Peng1. 1Alpine Immune Sciences, Seattle, WA.

Body: Background: The presence of tumor infiltrating lymphocytes (TILs) has been associated with improved prognosis in HER2+ breast cancer patients. Antigen specific TCR and costimulatory receptor signaling drive increases in TIL number, effector function, and tumor cytotoxicity. Improving the number and effector phenotype of tumor localized TILs has curative potential by enhancing the adaptive and memory immune response. Targeting HER2 with the monoclonal anti-HER2 antibody trastuzumab has improved survival in HER2+ breast cancer patients and is known to increase peripheral type I immunity, which may be reflected by increased TILs.

The Immunoglobulin Superfamily (IgSF) includes a large, diverse family of immunotherapy targets expressed on immune cells and tumors. Transmembrane IgSF receptors, CD28 and inducible T cell co-stimulator (ICOS), related costimulatory molecules expressed on T cells, interact with CD80/CD86 and ICOS ligand (ICOSL), respectively, and play critical roles in T cell activation and adaptive immunity. The Alpine Immune Science's vIgD™ platform uses directed evolution to derive novel, therapeutically-applicable IgSF extracellular domains with tailored specificity and affinity. The vIgD platform has generated human ICOSL vIgDs capable of binding both ICOS and CD28, activating both pathways. To promote anti-tumor activity of TILs in HER2+ tumors, we developed trastuzumab-ICOSL “V-mAbs” consisting of trastuzumab fused to activating ICOSL vIgDs. These V-mAbs are designed to localize to HER2+ tumors and activate antigen-specific, resident T-cells through costimulatory receptor agonism.

Methods: V-mAbs were generated by fusing ICOSL vIgDs to either the N- or C-termini of the heavy and/or light chains of trastuzumab. V-mAb binding to CD28, ICOS or HER2 was measured by flow cytometric analysis of transfected cells or ForteBio analysis. V-mAb costimulatory activity was confirmed by immobilization in the presence of anti-CD3 in a primary human T cell assay. Finally, V-mAbs were co-cultured with HER2+ target cells and human T cells; T-cell activity was measured by proliferation, cytokine production, and target lysis.

Results: V-mAbs were successfully produced and bound to CD28, ICOS and HER2. In a plate bound costimulation assay, the V-mAbs increased the amount of IFN-gamma produced by T-cells stimulated with anti-CD3. When incubated with HER2+ target cells, V-mAbs promoted T-cell proliferation, cytokine secretion, and target cell lysis. Data from in vivo studies, to determine the impact of trastuzumab V-mAbs on HER2+ cancers, will be presented when available.

Conclusions: Trastuzumab-ICOSL V-mAbs are novel ICOS- and CD28-activating immunotherapies for HER2-positive tumors, promoting T-cell proliferation, cytokine secretion, and target cell lysis in a HER2 dependent fashion. The V-mAb platform has broad potential to enable tumor-localized immune modulation via the diverse array of IgSF members. Preclinical development of trastuzumab-ICOSL clinical therapeutics is in progress.
Title: A phase Ib study of oral administration of lucitanib in combination with fulvestrant in patients with HR+ metastatic breast cancer (mBC)

Mario Campone¹, Thomas Bachelot², Frederique Renault-Llorca³, Athanasios Pallis⁴, Valerie Agrapart⁴, Marie-Jeanne Pierrat⁴, Camille Poirot⁴, Gauthier Paux⁴, Frederic Dubois⁴, Laura Xuereb⁴, Renata Robert⁵ and Fabrice Andre⁵. ¹Institut de Cancérologie de l'Ouest – Centre René Gauducheau, Saint-Herblain, France; ²Centre Léon Bérard Centre de Lutte Contre le Cancer (CLCC) de Lyon, Lyon, France; ³Centre Jean Perrin, Clermont-Ferrand, France; ⁴Institut de Recherches Internationales Servier, Suresnes, France and ⁵Institut Gustave Roussy, Villejuif, France.

Body: FGFR1 amplification could mediate resistance to endocrine therapy and FGFR1 inhibition reverses this resistance. This phase Ib seeks to evaluate whether the combination of lucitanib, a potent FGFR/VEGFR/PDFGR inhibitor, in combination with fulvestrant, an endocrine agent, reverses resistance to fulvestrant.

Eligible patients for this study were postmenopausal with ER+/HER2- mBC and have relapsed during or after treatment with fulvestrant. There were 2 parts in the study: a dose allocation to assess the tolerability of the combination in terms of DLTs and MTD using a modified Continual Reassessment Method (mCRM) [part I] and a dose expansion, with patients assigned to 2 different cohorts based on FGFR amplification, to further evaluate the tolerability of the combination and to identify the recommended phase II dose (RP2D) [part II]. Surrogate target hitting biomarkers were also dosed at baseline and on-treatment. The sponsor decided to halt the clinical development in mBC indication and the study was prematurely terminated after 18 patients (15 in part I and 3 in part II). The presentation will focus on these 18 patients.

Patients had ECOG PS 0 or 1 and median number of previous treatments in metastatic setting was 3. Two doses of lucitanib (10mg daily n=9 and 12.5mg daily n=6) in combination with 500 mg/month of fulvestrant were tested in part I. At the 10mg dose level, one patient experienced a DLT (grade 3 hypertension). Based on global lucitanib development program data, it was decided to start Part II with lucitanib 10mg daily. The most common related grade ≥3 toxicities occurring in more than 10% of patients were hypertension (78%) and asthenia (22%). All patients required at least one dose interruption mainly for toxicities, while 13 patients (72%) required at least a dose reduction for toxicities. Thirteen patients (72%) withdrew from the study for disease progression, 3 (17%) withdrew from the study for adverse events (at 10mg) and 2 (11%) for non-medical reasons. Three patients achieved a confirmed partial response (as per RECIST v1.1), one at 10mg and two at 12.5mg. About 55% of the patients experienced clinical benefit with a median duration of the benefit of 39.6 weeks and a maximum duration of the benefit of 79.1 weeks for 1 patient (PR at Cycle 4). Biomarker modulations were consistent with lucitanib mode of action; targeting VEGFRs (significant increase of VEGFA, IL8, PIGF) and FGFR1 (significant increase of FGF23).

The combination is feasible but requires close patient monitoring and intensive management of adverse events. Those are in line with the anti-angiogenic activity of lucitanib.

Title: mTORC1 is responsible for metastasis of ER+ breast cancer downstream of RON tyrosine kinase

Najme Faham1 and Alana welm1. 1Huntsman Cancer Institute, Salt Lake City, UT.

Body: Metastatic breast cancer is one of the major challenges of tumor biology, remaining the underlying cause of death in the vast majority of breast cancer patients. Despite advances in treatment strategies, metastatic breast cancer is still considered incurable and mostly resistant to the current treatment options. There is, therefore, a clear need for development of novel targeted therapeutic agents, which must be built on a foundation of a deeper understanding of the molecular mechanisms responsible for development of metastasis. It is well accepted that aberrant expression of the RON receptor tyrosine kinase in breast cancer contributes to development of metastasis, and is associated with poor patient prognosis. Elevated expression of RON has been reported in about 50% of primary breast cancer samples. However, in later metastatic stage, RON is overexpressed in 100% of breast cancer samples, pointing toward its important role in inducing metastasis.

RON is known to activate multiple signaling pathways, including MAPK, PI3K, Src, phospholipase C-γ and β-catenin. Although some of these pathways have been linked to specific biological outcomes in vitro, contributions of each signal transduction pathway to cancer progression and metastasis are still poorly defined. To address this critical question, we used a combination of inhibitory and mutational strategies. We engineered T47D cells to conditionally overexpress RON upon addition of doxycycline, enabling us to achieve titratable levels of RON. For inhibition of RON signaling, we used a highly selective RON inhibitor, ASLAN002. To obtain a broader knowledge about signaling networks downstream of RON, we used a high-throughput functional proteomics assay, Reverse Phase Protein Array (RPPA). RPPA analysis showed robust phosphorylation of ribosomal protein S6 (rpS6) upon RON activation, which could be reversed by RON inhibitor. We were then able to dissect the components of the pathway responsible for phosphorylation of rpS6 using inhibitors against different potential kinases. These analyses revealed that mTORC1 is the main kinase responsible for profound phosphorylation of rpS6 downstream of RON, which itself is fed dominantly by PI3K rather than MAPK. To validate the PI3K/mTORC1/p70S6K axis as the main feeder of rpS6, we took advantage of a mutational approach to modulate RON signaling to specific pathways. Biochemical analysis of various mutants in T47D cells showed that they signal differentially, with mutant A strongly signaling through PI3K/mTORC1. To assess the importance of PI3K/mTORC1 in RON-mediated metastasis, we conducted in vivo studies. Our results indicated that mutant A is the highest metastatic mutant, inducing metastasis in 100% of the mice studied. To examine whether mTORC1 is critical for induction of metastasis downstream of RON, we treated mice with mTORC1 inhibitor, everolimus, and monitored metastasis. Our data revealed that mTORC1 inhibition could dramatically shrink metastatic lesions, before resistance occurs.

We report a dissected analysis of the RON signaling pathway responsible for induction of metastasis in ER+ breast cancer. Our data strongly indicate that RON dominantly signals through PI3K/mTORC1/p70S6K/rpS6, and that this pathway is important in inducing metastasis.
**Title:** Safety and efficacy of neoadjuvant metformin with trastuzumab and chemotherapy in women with HER2-positive early breast cancer: A randomized, open-label, multicenter, phase 2 trial

Sonia Pernas¹, Joan Dorca², Isabel Álvarez-López², Susana Martínez³, Cristina Saura⁴, Norberto Batista López⁵, César A Rodríguez-Sánchez⁶, Kepa Amillano⁷, Severina Domínguez-Fernández⁸, María Luque Cabal⁹, Idoia Morilla¹, Gemma Viñas¹, Javier Cortés⁴, Elisabet Cuyàs¹⁰, Sara Verdura¹⁰, Salvador Fernández-Arroyo¹¹, Jorge Joven¹¹, Elsa Pérez¹², Margarita García¹, Neus Bosch¹, Eugeni López-Bonet¹², Samia Saidani¹, María Buxó¹¹, Javier A Menendez¹ and Begoña Martin-Castillo¹. ¹Catalan Institute of Oncology, Barcelona, Spain; ²Hospital Donostia, Donostia-San Sebastián, Spain; ³Hospital de Mataró, Barcelona, Spain; ⁴Vall d’Hebron Institute of Oncology (VHIO), Barcelona, Catalonia, Spain; ⁵Hospital Universitario de Canarias, La Laguna, Tenerife, Spain; ⁶Hospital Universitario de Salamanca, Salamanca, Spain; ⁷Sant Joan de Reus University Hospital, Reus, Spain; ⁸Hospital de Txagorritxu, Vitoria-Gasteiz, Araba, Spain; ⁹Hospital Universitario Central de Asturias, Oviedo, Spain; ¹⁰Girona Biomedical Research Institute, Girona, Spain; ¹¹Institut d’Investigació Sanitària Pere Virgili, Reus, Spain and ¹²Dr. Josep Trueta Hospital of Girona, Girona, Spain.

**Body: Background:** Epidemiological, pre-clinical, and window-of-opportunity trials have suggested that the anti-diabetic drug metformin (MET) may have beneficial effects on breast cancer (BC). The clinical relevance of combining MET with current standards of care for first-line treatment of BC is unknown. We investigated the safety and efficacy of adding MET to neoadjuvant chemotherapy plus trastuzumab (TTZ) in patients with HER2-positive early BC.

**Methods:** In a randomized, multicenter, open-label phase 2 study, women with operable, locally advanced, or inflammatory HER2+ BC were randomly assigned in a 1:1 ratio to receive daily MET (1,700 mg) for 24 weeks concurrently with 12 cycles of weekly paclitaxel plus TTZ followed by four cycles of fluorouracil, epirubicin, cyclophosphamide/3w plus TTZ (arm A) or equivalent sequential chemotherapy plus TTZ without MET (arm B), followed by surgery. Patients were stratified by age, extent of disease (cT2 cN0-1 vs ≥T3 or ≥N2), and hormone receptor (HR)-status. The intention-to-treat (ITT) safety population comprised all women who underwent randomization and received at least one treatment dose. Primary endpoint was the rate of pathological complete response (pCR) analyzed in the per-protocol (PP) efficacy population. pCR was defined as absence of invasive cancer in the breast and axillary nodes, irrespective of carcinoma in situ (ypT0/is ypN0). **Results:** From June 1, 2012 to March 17, 2016, 98 patients were assessed for eligibility at 10 centers in Spain. Of 84 (85.7%) patients who were randomized, 41 patients were allocated to arm A and 43 to arm B. The most common adverse effects (AEs) in the 79 ITT patients were fatigue, diarrhea, nausea, alopecia, sensory neuropathy, mucositis, neutropenia, and elevated AST/ALT. Most AEs were grades 1–2 (>90% in both arms). The most common AEs grade ≥3 were neutropenia (7/38 women in arm A and 5/41 women in arm B) and diarrhea (5 and 0, respectively). The number of serious AEs was 3 in arm A (none of them was deemed to be MET-related) and 2 in arm B. Patients were stratified by age, extent of disease (cT2 cN0-1 vs ≥T3 or ≥N2), and hormone receptor (HR)-status. The intention-to-treat (ITT) safety population comprised all women who underwent randomization and received at least one treatment dose. Primary endpoint was the rate of pathological complete response (pCR) analyzed in the per-protocol (PP) efficacy population. pCR was defined as absence of invasive cancer in the breast and axillary nodes, irrespective of carcinoma in situ (ypT0/is ypN0). **Results:** From June 1, 2012 to March 17, 2016, 98 patients were assessed for eligibility at 10 centers in Spain. Of 84 (85.7%) patients who were randomized, 41 patients were allocated to arm A and 43 to arm B. The most common adverse effects (AEs) in the 79 ITT patients were fatigue, diarrhea, nausea, alopecia, sensory neuropathy, mucositis, neutropenia, and elevated AST/ALT. Most AEs were grades 1–2 (>90% in both arms). The most common AEs grade ≥3 were neutropenia (7/38 women in arm A and 5/41 women in arm B) and diarrhea (5 and 0, respectively). The number of serious AEs was 3 in arm A (none of them was deemed to be MET-related) and 2 in arm B. At week 12, one (2.9%) patient in arm A and 6 (15%) in arm B exhibited asymptomatic decreases in the left ventricular ejection fraction (LVEF). At week 24, none (0%) of the patients in arm A and 3 (7.9%) patients in arm B presented decreases of LVEF below 50% and >10% from baseline. Only one patient (2.7%) in arm B experienced symptomatic heart failure. The rates of breast-conserving surgery were 79.3% and 58.6% in PP arms A and B, respectively. Also, 19/29 PP patients in arm A (65.5%, 95% CI 47–80) had a pCR versus 17/29 PP patients (58.6%, 95% CI 41–74) in arm B (OR 1.34 [95% CI 0.46–3.89], p=0.589). The combined rates of pCR and near-pCR (ypT1aN0) were 79.3% in arm A and 72.4% in arm B. Significantly fewer pCR were noted for tumors that were HR-positive regardless of which arm the patients were randomized. **Conclusion:** The higher pCR rate in HER2+ BC patients receiving MET-containing neoadjuvant therapy and TTZ did not reach statistical significance. Evaluation of long-term outcome data such as 5-year disease-free survival and correlative biological studies are needed to evaluate the clinico-molecular relevance of these findings.
A phase II study of copper-depletion using tetrathiomolybdate in patients with breast cancer at high risk for recurrence: Updated results

Background: Metals have emerged as a viable therapeutic target for a new generation of anti-cancer and anti-metastatic agents. Copper, an essential trace element, serves as an important catalytic cofactor in several biological functions and has emerged as an essential factor in carcinogenesis. Among other elements, bone marrow derived VEGFR2+ endothelial progenitor cells (EPCs) and copper-dependent lysyl oxidase (LOX) are key elements in tumor progression. We hypothesized tetrathiomolybdate (TM)-associated copper depletion (CD) inhibits tumor metastases by reducing the number of EPCs and other copper dependent processes in the pre-metastatic niche. These results are an update of our previously reported study (Chan N, Willis A, Kornhauser N et al. Influencing the Tumor Microenvironment: Phase 2 Study of Copper Depletion with Tetrathiomolybdate in High Risk Breast Cancer and Preclinical Models of Lung Metastases. Clin Cancer Res. October 21, 2016) with longer follow-up.

Methods: A single arm phase II study of breast cancer (BC) patients (pts) at high risk for recurrence, defined as node+ triple negative (TNBC), stage 3 and 4 with no evidence of disease (NED) were enrolled on a trial of CD with TM. TM was given to maintain ceruloplasmin (Cp) levels between 8-16 mg/dl for two years with an extension phase or until relapse. The primary endpoint was a change in EPCs measured by flow cytometry before and during treatment. Secondary endpoints included tolerability, safety, PFS and LOXL-2 levels.

Results: Seventy-five pts received 2778 cycles of TM on the primary and extension study. The primary study treatment duration was 24 cycles (each cycle is 28 days) plus an extension phase. The median age is 51 years (range 29-66). Forty-five pts have stage 2/3 BC and 30 with stage 4 NED. Forty-eight percent of pts are TNBC and 40% of pts are stage 4 NED. Median Cp levels were monitored with each cycle. A decrease from 28 to 16 (p<0.0001) was seen after one cycle. Interestingly, TNBC pts seemed to have a greater decrease from 23.5 to 13 after one cycle. TM was well tolerated with grade 3/4 toxicities including: reversible neutropenia (2.3%), febrile neutropenia (0.04%), fatigue (0.2%). Five-year analysis showed a decrease in EPC's (p=0.004) and LOXL-2 (p<0.001). At a median follow-up of 7.1 years, the EFS for 75 pts is 71.4%. The EFS for 36 pts with TNBC is 71.7%. EFS for stage 2/3 TNBC is 83% and for stage IV TNBC is 59.3%.

Conclusions: TM is safe, well tolerated and appears to affect multiple components of the tumor microenvironment that have been identified in pre-clinical models as important for progression. Ongoing studies in banked specimens are underway to further delineate its effect on copper dependent processes necessary for metastases. Randomized trials are warranted, especially in patients who are at high risk for relapse such as those with TNBC.
Title: Precision therapeutic combinations are synergistic against triple negative breast cancer using compensatory pathways

Jeffrey Solzak¹, Brad Hancock¹, Robin Paul¹ and Milan Radovich¹. ¹Indiana University School of Medicine, Indianapolis, IN.

Body: Introduction: Triple negative breast cancer (TNBC) accounts for 15% of all breast cancer cases in the United States, and despite its lower incidence, contributes to a disproportionately higher rate of morbidity and mortality compared to other breast cancer subtypes. In an effort to treat TNBC, a cancer that has no targeted therapies, many have chosen to experiment with combinations of drugs that are chosen for their genomic expression or “hard targets”. It has been previously noted however, that single agent therapeutics can change the genomic landscape of both mice and human cells and may be responsible for resistance. Here we show that targeting a compensatory pathway after treatment with a single therapy, results in synergistic combinations and can outperform the choice of hard target therapies.

Methods: Eight TNBC cell lines were chosen based on their abundance of clinically actionable targets. The primary hard target combinations were chosen using data from TCGA and a board consisting of oncologists and researchers at Indiana University School of Medicine. Compensatory therapies were found using RNA sequencing data from untreated versus single therapeutic treated TNBC cell lines. The merged transcript RPKMs were transformed and analyzed for differential expression. Statistically significant genes were imported into Ingenuity Pathway Analysis (IPA) to identify either therapeutics or genomic targets using the Causal network analysis and Upstream regulator functions. All drug combinations were tested in their respective cell lines and cell viability was assessed via Celltiter-Fluor. Synergy of the combinations was calculated using the Chou-Talalay method.

Results: Using genomically chosen hard targets for drug combinations, all eight cell lines displayed additive or antagonistic results except low nanomolar doses for the MDA-MB-231 cell line. Dosing of MDA-MB-231s with Debrafinib and Pazopanib however, turned highly antagonistic as dosing increased. Using next-generation RNA sequencing data of TNBCs, IPA analysis identified several compensatory targets for each cell line when treated with one of the primary genomically driven drug at its IC50. Using dose escalation of the new drugs with a single hard target drug, we found that each compensatory combination displayed a striking increase in synergy across all TNBC cell lines treated when compared to their original hard target combination.

Conclusion: RNA sequencing of TNBC cells lines treated with single therapies chosen by actionable genomic landscape has revealed compensatory pathways, indicating further druggable targets. These compensatory pathways have been observed to more efficacious in treating TNBC cell lines. Using therapeutics that are either FDA approved or in clinical trials we have found that each compensatory combination shows a higher level of synergy across all cell lines. These data show that choosing a secondary therapy based on compensatory pathways may outperform hard target combinations in the clinic.
Title: Elacestrant, a novel oral selective estrogen receptor degrader (SERD), decreases tumoral \(^{18}\text{F}\)-FES uptake in a phase 1 study of ER+, HER2-, advanced breast cancer patients

Elisabeth GE de Vries, Clasina M Venema, Andor WJM Glaudemans, Agnes Jager, C Willemien Menke-van der Houven van Oordt, Patrick Neven, Hai Jiang, Dannie Wang, Alison O'Neill, Abhay Patki and Philippe Aftimos. 1University Medical Center Groningen, Groningen, Netherlands; 2Erasmus MC Cancer Institute, Rotterdam, Netherlands; 3VUMC Medical Center & Cancer Center Amsterdam, Amsterdam, Netherlands; 4UZ KU-Leuven, Belgium; 5Radius Health, Inc., Waltham, MA and 6Institut Jules Bordet – Universite Libre de Bruxelles, Brussels, Belgium.

Body: Background: The estrogen receptor (ER) expressed in approximately 70% of breast cancers, can be mapped using \(^{18}\text{F}\)-\(\alpha\)-\[^{18}\text{F}\]Fluoro-17\(\beta\)-estradiol (FES)-PET, a non-invasive molecular whole body imaging tool capable of assessing ER target engagement by endocrine therapy. Elacestrant (RAD1901) is a novel, non-steroidal oral SERD that has demonstrated single-agent activity in heavily pre-treated patients with ER+ advanced breast cancer (Bardia et al., J Clin Oncol 35, 2017: suppl; abstr 1014).

The primary objective of this study was the visualization and quantification of residual ER-binding with FES-PET after treatment with elacestrant.

Methods: In the RAD1901-106 phase 1 study (NCT02650817), patients with advanced ER+/HER2 - breast cancer were treated with elacestrant at two dose levels (200 mg or 400 mg qd orally) for the first 14 days. Tumoral FES uptake was measured at baseline and day 14. After FES-PET scan at day 14, all patients received elacestrant 400 mg qd until disease progression or discontinuation due to another cause. Key inclusion criteria included postmenopausal women with advanced ER+/HER2- breast cancer, who have progressed after \(\geq\) 6 months of at least 1 line of endocrine treatment in the metastatic setting, with measurable disease according to RECIST criteria v1.1 or clinically evaluable disease. The PET scan was performed 60 min after intravenous injection of 200 MBq FES. Maximum standardized uptake values (SUVmax) were calculated and corrected for background activity. FES positive lesions had a SUVmax >1.5. FES response was defined as a \(\geq\) 75% median decrease of SUVmax between the two scans. ESR1 mutation status was determined from circulating tumor DNA collected at multiple time points.

Results: Twenty-four patients were screened and 16 patients were enrolled (8 at each dose level). Median lines of prior therapy were 3, with 6 (38%) patients having previously received fulvestrant and 8 (50%) patients harboring at least 1 ESR1 mutation at baseline. Elacestrant demonstrated a median of 88% (range 59-97.1%) reduction in tumorFES uptake following 14 days of treatment. Eleven out of 16 patients had >75% reduction in FES uptake at day 14. At the data cutoff date of 2 May 2017, median treatment duration was 8.1 weeks and 8 (50%) patients remained on study. Elacestrant was generally well-tolerated, with the most common treatment-related adverse events (CTCAE v4.03) being low grade nausea (gr1 = 50%; gr2 =19%; gr3/4 = 0%), dyspepsia (gr1 = 25%; gr2 = 19%; gr3/4 = 0%) and dysphagia (gr1 = 19%; gr2 =12%; gr3/4 = 0%). Updated analyzes with mature data on correlation of FES uptake reduction and tumor response, treatment duration, safety and ESR1 mutation will be presented.

Conclusions: Elacestrant significantly reduced FES uptake at both 200 mg and 400 mg doses after 14 days of treatment in heavily pre-treated patients with advanced ER+/HER2- breast cancer, including those harboring ESR1 mutations.
Title: ICEC0942, a new oral selective inhibitor of the cell cycle and transcriptional regulator CDK7 for the treatment of estrogen receptor positive and negative breast cancer

Body: CDK7 is remarkable as a key regulator of both cell cycle progression and gene expression. CDK7 promotes cell cycle progression by phosphorylating cell cycle CDKs in the T-loop, thus stimulating their activities. Additionally, phosphorylation of RNA polymerase II (PolII) by CDK7 is required for transcription initiation. Deregulation of cell cycle and transcription processes is common to most cancer types, so CDK7 inhibitors offer considerable promise as cancer therapeutics.

We previously reported the identification of the first selective CDK7 inhibitor, BS-181, and demonstrated its ability to inhibit breast cancer cell growth in vitro and in vivo (Ali et al 2009 Cancer Res). Screening of more than one thousand analogues has allowed development of a clinical candidate CDK7 inhibitor, named ICEC0942. ICEC0942 selectively inhibits CDK7 with an IC$_{50}$ of 40nM. In vitro analyses reveal that ICEC0942 inhibits hormone receptor positive and triple-negative breast cancer cell lines, with GI$_{50}$ values ranging between 0.2-0.3 µM. Growth inhibition is accompanied by inhibition of CDK7 targets, including CDK1, CDK2 and PolII phosphorylation. In xenograft studies using several cancer cell lines, the drug shows substantial anti-tumor effects, with a notable lack of toxicity at efficacious doses. In the combination setting with tamoxifen, ICEC0942 completely blocks growth of ER-positive tumor xenografts, indicative of potential for co-treatment with hormonal agents.

Extensive ADMET and PK/PD studies confirm the suitability of ICEC0942 as a cancer drug and have shown that ICEC0942 is orally bioavailable. Moreover, xenograft tumor studies have allowed definition of surrogate biomarkers of tumor response. Taken together, our findings confirm CDK7 as an important drug target for ER-positive and -negative breast cancer and identify ICEC0942 as a prototype drug with utility as a single agent or in the combination setting. Our findings also point to the potential value of CDK7 inhibition by ICEC0942 in other cancer types that have characteristics of transcription factor addiction and/or cell cycle deregulation.

Development of ICEC0942 was made possible through funding by EPSRC, Cancer Research UK and Cancer Research Technologies.
Title: A randomized phase II trial evaluating the endocrine activity and efficacy of neoadjuvant degarelix versus triptorelin in premenopausal patients receiving letrozole for primary endocrine responsive breast cancer (TREND; IBCSG 41-13)

Marco Colleoni1, Kathryn Gray1, Elisabetta Munzone1, Silvia Dellapasqua1, Claudio Zamagni1, Lorenzo Gianni1, Harriet Johansson1, Giuseppe Viale1, Roswitha Kammler1, Rudolf Maibach1, Manuela Rabaglio-Poretti1, Angelo Di Leo1, Alan S Coates1, Richard D Gelber1, Meredith M Regan1 and Aron Goldhirsch1. 1International Breast Cancer Study Group.

Body: Background: Neoadjuvant endocrine therapy (NET) with gonadotropin-releasing hormone (GnRH) agonist and aromatase inhibitors is effective in selected premenopausal patients (pts). Degarelix, an antagonist of GnRH, has immediate onset of action through binding to GnRH receptors in the pituitary gland and thereby suppressing the production of LH and FSH. Its suppressing activity in premenopausal women might be faster and free of estrodial breakthrough on continued treatment compared with a GnRH angonist, and thereby provide significant clinical value for pts who are candidates for short-term NET.

Methods: Eligible pts were premenopausal women with cT2-4b, any nodal stage, ER and PgR >50%, HER2-negative (by IHC and/or ISH) breast cancer who were not candidates for breast conserving surgery. Premenopausal status was determined locally with estradiol (E2) levels >54 pg/mL (or >198 pmol/L), measured within 14 days prior to randomization. Pts were randomized 1:1 to Triptorelin (T) 3.75 mg i.m. on day 1 of every cycle or Degarelix (D) 240 mg s.c. given as two injections of 120 mg on day 1 of cycle 1, then 80 mg s.c. on day 1 of cycles 2-6 with letrozole (L) 2.5 mg/day for 6 cycles. Each cycle was 28 days. Definitive surgery was performed within 2-3 weeks after the last administration of T or D. Serum was collected prior to the first injection (baseline), 24 and 72 hours, 7 and 14 days, then prior to injection on day 1 of cycles 2-6. The primary endpoint was time to optimal ovarian function suppression (OFS) calculated as time from the first injection of D or T to the first assessment of centrally assessed 17-β-estradiol (E2) level in the range of optimal OFS (≤2.72 pg/mL or ≤10 pmol/L) during the 6 cycles of NET. The trial had 90% power to detect a difference using a logrank test, 2-sided α=0.05. Secondary endpoints included tolerability, Ki67 changes, PEPI score, best overall response. NCT02005887

Results: TREND completed accrual of 51 pts in January 2017. A preliminary analysis based on the first 45 pts is reported here. 89% of patients were ≥40 yrs, 76% had T1-2 and 22% T3 tumors, and 51% were node-positive. Dominant histology type was ductal (93%). The table summarizes centrally-assessed E2 according to treatment at baseline and for the first 5 assessment time points indicating immediate suppression for the D+L arm. E2 levels on day 1 of cycles 2-6 were all below the limit of quantification (0.625 pg/mL) for the D+L arm. For the T+L arm continued OFS was not maintained in 4 pts.

Title: Efficacy and safety results from a randomized, phase II study of CC-486 in combination with fulvestrant in postmenopausal women with estrogen receptor–positive (ER+), human epidermal growth factor receptor 2–negative (HER2−) metastatic breast cancer (MBC)

Mario Campone¹, Jasgit Sachdev², Giulia V Bianchi³, Joseph T Beck⁴, Noelia Martínez-Jáñez⁵, Javier Cortes⁶, Marcus Schmidt⁷, Claudio Zamagni⁸, Peng Chen⁹, JulieAnn Miller⁹, Abderrahim Fandi⁹ and Luca Gianni¹⁰. ¹Institut de Cancérologie de l'Ouest, Site René Gauducheau, Saint-Herblain Cedex, France; ²HonorHealth Research Institute/ TGEN, Scottsdale, AZ; ³Fondazione IRCCS Istituto Nazionale Tumori, Milano, Italy; ⁴Highlands Oncology Group, Fayetteville, AR; ⁵Hospital Universitario Ramon y Cajal, Madrid, Spain; ⁶Vall d’Hebron Institute of Oncology, Madrid, Spain; ⁷University Medical Center Mainz, Mainz, Germany; ⁸Policlinico Saint'Orsola-Malpighi, Bologna, Italy; ⁹Celgene Corporation, Summit, NJ and ¹⁰Ospedale San Raffaele, Milano, Italy.

Body: Background: Most patients diagnosed with breast cancer have ER+ tumors. Treatment of ER+ MBC typically involves endocrine therapy, including aromatase inhibitors and selective ER modulators such as tamoxifen; however, many patients develop resistance. Fulvestrant, an ER antagonist, is a commonly prescribed second- or third-line therapy for postmenopausal patients who have progressed on endocrine therapy; although, most patients will eventually develop resistance to this drug as well. It was hypothesized that CC-486, an oral formulation of azacitidine, may resensitize patients to endocrine therapy and possibly delay resistance to fulvestrant through the epigenetic regulation of certain genes.

Methods: 97 postmenopausal female patients aged ≥ 18 years with ER+, HER2− MBC refractory to an aromatase inhibitor were randomized 1:1 to receive CC-486 300 mg on days 1 through 21 and fulvestrant 500 mg on days 1 and 15 of cycle 1 and day 1 of subsequent 28-day cycles or the same fulvestrant regimen alone. The primary endpoint was progression-free survival (PFS) based on investigator’s assessment using RECIST version 1.1 and summarized by the Kaplan-Meier method. A Cox proportional hazards model was used to estimate the hazard ratio (HR; including a 2-sided 95% CI), and a log-rank test was used to calculate P values for comparisons between treatment arms. Key secondary endpoints included objective response rate (ORR), overall survival (OS), and safety.

Results: 48 patients were included in the CC-486 + fulvestrant arm and 49 in the fulvestrant-alone arm. Median age was 63 years. Baseline characteristics were generally balanced between treatment groups, with some exceptions. The CC-486 + fulvestrant treatment cohort had fewer patients aged ≥ 65 years (40% vs 49%), with an ECOG PS of 1 (25% vs 57%), or with liver metastases (29% vs 43%) than did the fulvestrant-alone cohort. At the time of this analysis, 36 patients (75%) in the CC-486 + fulvestrant arm and 40 patients (82%) in the fulvestrant-alone arm had discontinued treatment, mostly due to progressive disease (81% and 90%, respectively). Median PFS was 5.5 months in both treatment groups (HR 0.87; 95% CI, 0.54 - 1.42; P = 0.599). ORR was 8.3% vs 2.0% in patients receiving CC-486 + fulvestrant vs fulvestrant alone, respectively. Median OS has not been reached. In patients who received CC-486 + fulvestrant, the most common any-grade nonhematologic treatment-emergent adverse events (TEAEs) were nausea (78%), vomiting (78%), diarrhea (44%), and constipation (41%), and the most frequent any-grade hematologic TEAE was neutropenia (26%). Of patients who discontinued due to AEs, most patients receiving CC-486 + fulvestrant treatment discontinued due to gastrointestinal (GI) TEAEs.

Conclusion: The addition of CC-486 to fulvestrant did not improve PFS in patients with ER+, HER2− MBC compared with fulvestrant alone, and GI TEAEs were reported in a majority of patients. These results do not support further evaluation of this combination in this setting.
Title: Development of a first-in-class oral selective ERα covalent antagonist (SERCA) for the treatment of ERα<sup>WT</sup> and ERα<sup>MUT</sup> breast cancer

Body: Mutations in estrogen receptor alpha (ERα) are detected in up to 30% of breast cancer patients who have relapsed during endocrine therapy. ERα mutations functionally confer resistance to existing classes of endocrine therapies, likely through gaining constitutive activity. The fact that current ER-directed therapies are only partially effective in the ERα mutant setting, and that a significant proportion of resistant breast cancer metastases continue to remain dependent on ERα signaling for growth/survival, highlights the critical need to develop the next generation of ERα antagonists that can overcome aberrant ERα activity. Using structure-based drug design approaches we have identified a novel class of ERα antagonist referred to as Selective ERα Covalent Antagonist (SERCA) that inactivate both wild-type and mutant ERα by targeting a unique cysteine residue that is not conserved among other steroid hormone receptors. Biophysical, biochemical and cellular analyses confirm the covalent mechanism of action, specific binding to ER and selective inhibition of ERα-dependent transcription of SERCAs. H3B-6545 is a highly selective SERCA that potently antagonizes wild-type and mutant ERα in biochemical and cell based assays demonstrating increased potency over standard of care and other experimental agents. In vivo, H3B-6545 shows superior efficacy to fulvestrant in the MCF-7 xenograft model with once daily oral dosing, achieving maximal antitumor activity at doses >10x below the maximum tolerated dose in mice. In addition, H3B-6545 shows superior antitumor activity to both tamoxifen and fulvestrant in patient derived xenograft models of breast cancer carrying estrogen receptor mutations. In summary, H3B-6545 is a first-in-class, orally available and selective ER covalent antagonist with a compelling pre-clinical profile that is being developed for the treatment of ERα positive breast cancer.
Title: EPHA2-targeting enhances eicosapentaenoic acid cytotoxicity against triple-negative inflammatory breast cancer via ABCA1 inhibition–mediated membrane rigidity

Background: Effective treatment options for triple-negative inflammatory breast cancer (TN-IBC), the most aggressive form of breast cancer, are currently lacking. We previously reported that mediators of inflammation promote the growth of TN-IBC xenografts. Eicosapentaenoic acid (EPA), an omega-3 fatty acid (fish oil) with anti-inflammatory properties, is an emerging FDA-approved therapeutic with a favorable toxicology profile. Here we aimed to develop a novel approach to enhance EPA efficacy against TN-IBC by identifying a kinase inhibitor that synergizes with EPA's antitumor activity.

Methods and Results: Using a high-throughput siRNA screen in the TN-IBC cell line SUM149PT, we identified inhibition of ephrin type-A receptor 2 (EPHA2), an oncogenic receptor tyrosine kinase, as a target that sensitizes TN-IBC cells to EPA therapy. To determine the clinical relevance of EPHA2, we investigated a meta-analysis of breast cancer mRNA expression data sets and found that high EPHA2 tumor expression, compared with low expressing, correlated significantly with poor overall survival in TN-IBC patients (P = 0.01), while not with other subtypes. Similar findings were observed in vitro, were EPHA2 protein and mRNA overexpression occurred predominantly in the TN subtypes among 49 and 51 breast cancer cell lines (63% and 47%, respectively), highlighting EPHA2 translational potential. Functional expression studies using proliferation and apoptosis assays in vitro, and xenografts in vivo, were performed in two EPHA2-expressing TN-IBC cell lines, SUM149PT and BCX010, to validate EPHA2 as a synergistic combinational target with EPA. EPHA2 gene silencing in combination with EPA significantly reduced cell growth, and enhanced apoptosis, compared with untreated and monotherapy in vitro (P < 0.05), and in vivo (P < 0.001). To translate our findings to the clinic, we validated dasatinib, an FDA-approved small molecule inhibitor of EPHA2, in combination to EPA to significantly enhance apoptosis of TN-IBC cells in vitro (P < 0.05) and in vivo (P < 0.05), compared with untreated and monotherapies. Using membrane fluidity assessment and cholesterol quantification we determined that apoptosis induction after combination therapy was due to increased membrane rigidity and cholesterol concentrations in the plasma membrane of TN-IBC cells (P < 0.05, compared with monotherapies). Finally, we discovered by western blot and gain/loss-of-expression studies that combination therapy inhibited the cholesterol efflux protein ATP-binding cassette sub-family A member 1 (ABCA1), which plays a significant role mediating increased cellular cholesterol (P < 0.05), cell membrane rigidity (P < 0.05), and induction of apoptosis (P < 0.05) in TN-IBC after EPA and EPHA2-targeting combination therapy.

Conclusions: This is the first study demonstrating that EPA can enhance conventional targeted therapy against breast cancer. Our study provides molecular and preclinical evidence to support the development of an EPA/EPHA2-inhibition–based phase I clinical trial for patients with EPHA2-positive TN-IBC; our study further suggests the use of EPHA2 and ABCA1 protein expression as biomarkers for patient selection and therapeutic response.
Title: Tumor infiltrating lymphocytes (TILs) among high risk for recurrence breast cancer patients treated with tetrathimolybdate (TM)

Marissa D Rybstein¹, Eleni Nackos¹, Naomi Kornhauser¹, Tessa Cigler¹, Eleni Andreopoulou¹, Anne Moore¹, Marta Cobham¹, Veronica Fitzpatrick¹, Sandra Demaria¹ and Linda T Vahdat¹. ¹New York Presbybyterian - Weill Cornell Medical Center, New York, NY.

Body: Background: Tumor infiltrating lymphocytes (TILs) evaluated in the primary tumor biopsy or surgical resection have been well established as having prognostic significance in patients with triple negative breast cancer (TNBC) and HER2+ breast cancer treated with adjuvant chemotherapy (Savas et al, Nat Rev Clin Oncol 2016). In TNBC, stromal TILs behave as a continuous variable with every 10% increase in TIL resulting in a decrease in risk of recurrence and death. The definition of lymphocyte-predominant breast cancer (LPBC) has been used for tumors that contain 50%–60% TILs and usually have a particularly good outcome (Salgado et al, Ann Oncol 2015). Our group recently demonstrated in a phase II single arm study that tetrathimolybdate (TM), a copper-depleting agent, resulted in improved event free survival (EFS) for TNBC patients compared to historical controls. The 2-year event-free survival (EFS) for stage 2-3 and stage 4 NED was 91% and 67%, respectively. In this analysis, our goal was to explore whether the encouraging results we observed were influenced by enrolling TNBC patients with better prognostic factors at initial diagnosis, namely higher stromal TIL score, in our copper depletion trial.

Methods: Archived primary breast tissue was available from 67 of the 75 patients enrolled in the phase II TM trial. The phase II study included patients with stage II TNBC or stage III or IV NED breast cancer patients, who were treated with TM for 2 years or until relapse. Here we focused on the 30 patients with TNBC. The demographic data for the patients is included in the following table.

The number of TILs in each sample was calculated by an experienced pathologist using published criteria (Salgado et al, Ann Oncol 2015). We used TILs >50% to define LPBC.

Results: Overall, we found that only 3/30 (10%) of TNBC patients had TILs >50%. In addition, 14/30 (46.7%) of TNBC patients had tumors with <10% TILs. The 2-year EFS for the patients with TILs >10% v. <10% was 76.9% v. 69.8%, respectively. (P=0.65)

Conclusions: Only 10% of TNBC patients enrolled in the study had LPBC at diagnosis thus indicating that this cohort was not enriched for patients with immunogenic tumors. When stratified by TILs >10% or <10%, there was no statistically significant difference in EFS. Although the analysis is limited due to the small sample size, it does suggest that the amount of TILs present at initial diagnosis did not influence the overall outcome for patients treated with TM.
Title: Multivalent exposure of trastuzumab on iron oxide nanoparticles enhances antitumor activity and weakens drug resistance in HER2+ breast cancer cells

Marta Truffi¹, Matteo Monieri¹, Luca Sorrentino¹, Serena Mazzucchelli¹, Miriam Colombo², Laura Pandolfi², Davide Prosperi² and Fabio Corsi¹,³. ¹University of Milan, “L. Sacco”, Milan, Italy; ²University of Milan-Bicocca, Milan, Italy and ³ICS Maugeri S.p.A., Pavia, Italy.

Body: **Background:** The identification of new strategies aimed to optimize the treatment of breast cancer and its metastases represents a great technical and medical challenge. Target-specific therapies, such as Trastuzumab (TZ), have revolutionized the clinical scenario in certain subsets of cancer. However, the huge variability in response to therapy and the frequent onset of drug resistance in patients still hamper the therapeutic success. Antibody-conjugated nanoparticles may combine specific recognition of tumor cells with the capability to act as innovative reservoir of active drugs. Here, multivalent TZ-conjugated colloidal nanoparticles were developed as target-specific and biologically active nanosystem to enhance the therapeutic potential toward HER2+ breast cancer.

**Methods:** Iron oxide nanoparticles conjugated with multiple half chains of TZ have been developed and tested in different HER2+ breast cancer cell lines, in comparison to free TZ or untargeted nanoparticles. Active targeting and specificity toward HER2 receptor was assessed by flow cytometry and confocal microscopy. Cellular uptake of nanoparticles and HER2 endocytosis were followed by electron or confocal microscopy. Direct anticancer efficacy was assessed by incubation of free or nanoformulated TZ on sensitive breast cancer cells, and analysis of cell viability, cell cycle, and expression of p27kip1. Finally, nanoparticles were tested on TZ-resistant breast cancer cell lines for capability of re-sensitization.

**Results:** TZ-conjugated nanoparticles showed specific targeting of HER2, with induction of site-specific phosphorylation in the catalytic domain of the receptor and cellular uptake by endocytosis. Treatment with TZ-conjugated nanoparticles dramatically decreased cancer cell viability, by significantly improving the antitumor activity of TZ. This effect was independent from the ADCC mechanism, and associated with marked induction of p27kip1 expression and cell cycle arrest in G1 phase in TZ-sensitive SKBR-3 cells. TZ-conjugated nanoparticles also affected viability of breast cancer cells insensitive to TZ, further confirming enhanced potential of the nanoformulation and suggesting interference with some mechanisms of resistance.

**Conclusions:** Our results provide evidence that multivalent exposure of TZ half chain on iron oxide nanoparticles affords enhanced antitumor potential and target-specific activity in HER2+ breast cancer cells. Powerful inhibition of HER2 signaling by TZ-conjugated nanoparticles could favor responsiveness of drug resistant cells, thus suggesting novel therapeutic strategies to overcome resistance.
Differential benefit of intra-operative administration of ketorolac on breast cancer disease recurrence according to baseline body mass index

Christine Desmedt\textsuperscript{1}, Romano Demicheli\textsuperscript{2}, Marco Fornili\textsuperscript{2}, Imane Bachir\textsuperscript{1}, Mariana Duca\textsuperscript{1}, Giulia Viglietti\textsuperscript{1}, Martine Piccart\textsuperscript{1}, Christos Sotiriou\textsuperscript{1}, Maurice Sosnowski\textsuperscript{1}, Patrice Forget\textsuperscript{3} and Elia Biganzoli\textsuperscript{2}.\textsuperscript{1}Institut Jules Bordet, Université Libre de Bruxelles (ULB); \textsuperscript{2}University of Milan and \textsuperscript{3}Universitair Ziekenhuis Brussel (UZ Brussel).

Body: Background:
According to the last estimates, 63% of the women in the US are either overweight or obese. Increased body mass index (BMI) has been recognized as a risk factor for developing breast cancer (BC) and associated with adverse survival. So far, few treatment modalities focusing on the biological features of BC patients with increased adiposity have been evaluated. In cancer patients, elevated leptin levels have been found, among others, to stimulate the Rho GTPase pathway, involved in cell adhesion and motility. Here, using a unique retrospective institutional cohort including a total of 847 BC patients, we aimed at assessing whether the intra-operative administration of ketorolac, a Non-Steroidal Anti-Inflammatory Drug (NSAID), with a recently documented Rho GTPase inhibitory activity, would be associated with an improvement in distant disease recurrence according to BMI. We further assessed in an independent series of 1,009 patients, the effect of intra-operative diclofenac, another NSAID without Rho GTPase inhibitory activity.

Patients and methods:
In the institutional retrospective and consecutive 'ketorolac' series of patients with primary BC surgery, 538 were treated with and 309 without a single-dose (typically 20 mg in patients under 60 kg and 30 mg in patients ≥60 kg) of intra-operative ketorolac. In the 'diclofenac' series, 789 patients were treated with intra-operative diclofenac (75 mg) and 220 without. Competing risk analysis of distant recurrences was done by crude cumulative incidence curves to be interpreted as the cumulative probability of distant metastases as first event and consistently by Fine & Gray semi-parametric models on sub-distribution hazards. Subgroup analyses were conducted according to the Dixon&Simon approach. These analyses were adjusted for standard clinico-pathological variables: NSAID use, tumor size, age, nodal status, grade, ER status, and BMI. The median follow-up time of the ketorolac and diclofenac cohort was 5.7 and 8.0 years, respectively.

Results:
In both cohorts, the administration of the NSAID was associated with younger age at diagnosis, consistent with previous reports. The administration of ketorolac was associated with decreased incidence of distant recurrences both in the unadjusted and adjusted analysis (HRadj= 0.55, 95%CI: 0.35-0.86, p=0.01). Subgroup analyses in patients with BMI<25 and ≥25 (overweight and obese) revealed that the effect was limited to the high BMI group of patients both in the unadjusted and adjusted analysis (HRadj= 0.58, 95%CI: 0.33-0.98). The administration of diclofenac was not associated with decreased incidence of distant recurrences, nor in the global population, neither in the BMI subgroups.

Conclusion:
The fact that only ketorolac but not diclofenac was associated with a significant reduction of distant recurrences in BC patients with elevated BMI could be explained by the specific Rho GTPase inhibitory effect of the R-enantiomer of ketorolac, absent in diclofenac. While this study is limited by its retrospective nature, it suggests a potentially important repositioning of ketorolac in the intra-operative treatment of BC patients with elevated BMI. A prospective study is on its way.
Title: Olaparib nanoformulation in H-ferritin as a promising option for both BRCA-mutated and sporadic triple negative breast cancer: An in vitro study

Serena Mazzucchelli¹, Marta Truffi¹, Luca Sorrentino¹, Michela Bellini², Maria A Rizzuto², Roberta Ottria¹, Pierangela Ciuffreda¹, Davide Prosperi³ and Fabio Corsi¹,³. ¹University of Milan, Milan, Italy; ²University of Milan-Bicocca, Milan, Italy and ³Istituti Clinici Scientifici ICS Maugeri Pavia Spa SB, Pavia, Italy.

Body: Background: PolyADP-ribose polymerase (PARP) inhibitors are a novel promising strategy toward triple-negative breast cancer (TNBC), which often shows genomic instability or BRCA mutations. However, clinical results are controversial, and no benefits were demonstrated in case of wild type BRCA, possibly due to poor bioavailability, and inadequate nuclear delivery. Nanotechnology could overcome these major limitations. The aim of this study was to assess the anticancer efficacy of H-Ferritin nanoformulated Olaparib (HOla) vs. free Olaparib (Ola) on BRCA-mutated and non mutated TNBC cells.

Methods: BRCA-mutated HCC1937 cells and BRCA-wild type MDA MB-231 and MDA MB-468 cells were treated with HOla or free Ola in vitro. Active targeting and binding capability of HOla toward transferrin receptor 1 (TfR-1), over-expressed on TNBC cells, was assessed by flow cytometry. Internalization and intracellular localization of Ola and HOla was assessed by confocal microscopy. Anticancer efficacy was assessed by administration of increasing doses of HOla or Ola, comparing cell viability, cell cycle, cell death, PARP-1 cleavage and DNA damage. Finally, anti-PARP efficacy and proportion of drug in the nuclear compartment were compared between treatments.

Results: All TNBC cell lines over-expressed TIR-1 and were successfully recognized by HOla. Confocal microscopy showed a fast internalization of nanoparticles into cells, with intracellular persistence up to 48h. A marked increase in nuclear concentration of drug was observed with HOla compared to Ola, due to a strongly improved nuclear delivery by H-Ferritin mediated by a self-triggered mechanism. No significant antiproliferative effect was demonstrated with Ola at 10 nM, 50 nM or 100 nM. Conversely, HOla at 50 nM and 100 nM showed a 1000-fold higher anticancer activity in all TNBC cell lines. A possible contribution in cytotoxicity by H-Ferritin nanovector itself was excluded treating cells with void nanoparticles. Proportions of cell cycle arrest in G2/M, cell death, cleaved PARP-1 and DNA damage in terms of phosphorylated histone H2A.X were higher in HOla treated samples than in ones treated with free Ola.

Conclusions: Our findings suggest that nanoformulation of Ola strongly enhances cytotoxic efficacy of PARP inhibition as a stand-alone therapy, on both BRCA-mutated and wild type TNBCs allowing a targeted delivery into TNBC cells and a prompt homing into the nuclear compartment.
Title: Abemaciclib tablet formulation is bioequivalent to capsules

P Kellie Turner1, Jill C Chappell1, Aktham Aburub1, Wee Teck Ng1, Wei Zhang1, Jane Royalty2 and Palaniappan Kulanthaivel1. 1Eli Lilly and Company, Indianapolis, IN and 2Covance Early Clinical Development, Madison, WI.

Body: Introduction: Abemaciclib is being developed for the treatment of cancer, including advanced and metastatic breast cancer. Tablet formulations, which are smaller than the capsules used in the pivotal MONARCH 1, 2 and 3 breast cancer studies, have recently been developed. This study evaluated the bioequivalence of abemaciclib capsule and tablet formulations following single 150-mg doses, and the effect of food on the pharmacokinetics (PK) of abemaciclib following dosing with a 150-mg tablet.

Methods: This was an open-label, randomized, 3-part study conducted in 127 healthy male (13%) and female (87%) subjects. Plasma concentrations of abemaciclib and its major metabolites were assessed up to 192 hours postdose using validated LC-MS/MS methods.

Part A was a 2-period, crossover pilot study to compare abemaciclib capsules (3 x 50-mg) and tablets (1 x 150-mg) formulations in the fasted state. Results from Part A were used to ensure adequate PK sampling and estimate intra-individual variability to confirm the sample size required for Part B of the study.

Part B was a 3-period, crossover, bioequivalence study of a 50-mg capsule (3 x 50-mg) compared to a 150-mg tablet (1 x 150-mg) and a 50mg tablet (3 x 50-mg) in the fasted state.

Part C was a 2-period crossover food effect study to determine the effect of a high-fat, high-calorie meal on the PK of abemaciclib when administered as a single 150-mg tablet compared to the fasted state.

Abemaciclib $C_{\text{max}}$ and AUC determined using noncompartmental methods were log-transformed and analyzed using a linear mixed-effects model. Geometric least squares (LS) mean for each treatment, the ratio of the geometric LS means, and their 90% CIs were calculated.

Results: In Part A, the abemaciclib intra-subject variability for $C_{\text{max}}$ was 26.7%, requiring a sample size of 76 subjects for Part B to ensure approximately 90% probability that the 90% CIs of the geometric means would be contained within the 0.80 to 1.25 limits, assuming that the true ratio was 1.09.

In Part B, both the 3 x 50-mg and 1 x 150-mg tablets were bioequivalent to the 3 x 50-mg capsules; the 90% CIs of the ratios of geometric LS means for $C_{\text{max}}$ and AUC were contained within the bioequivalence interval of 0.80 to 1.25.

</tr>
<tr>
<td>AUC(0-∞)</td>
</tr>
<tr>
<td>$C_{\text{max}}$</td>
</tr>
</tbody>
</table>

In Part C, consumption of a high-fat, high-calorie meal before abemaciclib dosing resulted in an increase of 13% (90% CI 1.05,1.22) in AUC(0-∞) and 30% (90% CI 1.20,1.40) in $C_{\text{max}}$, which was not considered clinically relevant given the magnitude of the effect relative to the inter-subject variability for $C_{\text{max}}$ (36.5%). Also, the magnitude of the change was within the therapeutic window for abemaciclib. There was no difference in median $t_{\text{max}}$ in the fed state compared to the fasted state for abemaciclib. Single 150-mg doses of abemaciclib were generally well tolerated when administered with or without food. The majority of the AEs reported during the study were gastrointestinal and mild in severity.

Conclusions: Abemaciclib 150-mg and 50-mg tablets are bioequivalent to the 50-mg capsule formulation, based on a single dose in the fasted state, and could be administered with or without food.
Title: Development of humanized anti-CD47 monoclonal antibodies with differentiated functional profiles

Robert W Karr, Katherine Liu, Ronald Hiebsch, Benjamin Capoccia, Michael Donio, Kathleen Crowley, Robyn Puro, Sanjay Chanda and Pamela Manning. Tioma Therapeutics, Inc., St. Louis, MO.

Body: CD47 is a cell surface transmembrane protein that binds to signal regulatory protein alpha (SIRPα) on macrophages and results in a “don't eat me” signal that inhibits phagocytosis. Breast cancer cells, both primary and metastatic, frequently overexpress CD47 and exploit this pathway to evade macrophage-mediated destruction. Anti-CD47 monoclonal antibodies (mAbs) block the CD47/SIRPα interaction and promote tumor cell destruction via phagocytosis. Anti-CD47 mAbs also contribute to an anti-tumor T-cell response in immune-competent mice. Therefore, anti-CD47 antibodies represent a new class of immune checkpoint inhibitors that modulate both the innate and adaptive immune systems.

CD47 is expressed on multiple cell types, including tumor cells and normal cells. Many anti-CD47 mAbs block the CD47/SIRPα interaction and cause phagocytosis of tumor cells, but do not directly induce the death of human tumor cells. Tioma has created new humanized anti-CD47 mAbs with novel and differentiated functional profiles to enhance functional heterogeneity. Ti-104, Ti-176 and Ti-108 block the binding of SIRPα to CD47 and increase phagocytosis of human tumor cells. They also induce cell death of human hematological and solid tumor cell lines (including breast cancer lines) in a cell autonomous manner. Cell death was determined by an increase in phosphatidylserine-positive/7AAD-positive tumor cells assessed by flow cytometry following incubation in media containing anti-CD47 mAb or a negative control immunoglobulin. In vitro, these mAbs bind to human tumor cell lines with apparent binding affinities ranging from low pM to low nM, depending on the cell line and method of analysis (solid-phase or cell-based ELISA, flow cytometry or surface plasmon resonance). In vitro, Ti-104 and Ti-108 bind to human RBCs, whereas Ti-176 has markedly reduced binding to human and cynomolgus monkey RBCs.

In a four-week (once-weekly dosing) exploratory safety study in cynomolgus monkeys with Ti-176 and Ti-108, no dose-limiting toxicity or gross pathological or microscopic findings were identified after an initial dose of 5 mg/kg (Week 1) followed by doses of 50 mg/kg (Weeks 2, 3, and 4). Ti-176 treatment resulted in minimal decrease in red cell mass, hemoglobin and hematocrit, which corresponded in vitro to markedly reduced binding to cynomolgus monkey RBCs. Ti-108 caused transient reduction of RBC parameters comparable to some previously reported anti-CD47 mAbs.

Ti-104, Ti-176 and Ti-108 showed potent, dose-dependent efficacy in multiple mouse tumor models, including in the MDA-MB-231 triple-negative breast cancer orthotopic model.

These data provide the preclinical rationale for further evaluation of Ti-104, Ti-176 and Ti-108 as breast cancer treatments.
**Title:** *In vitro* delivery of model fluorescent dyes through the mammary papilla

Samantha L Kurtz¹ and Louise B Lawson¹. ¹Tulane University, New Orleans, LA.

**Body:** In the United States, 100,000 women each year are diagnosed with atypical hyperplasia (AH), significantly increasing their risk of developing breast cancer. However, only 40% of patients accept breast cancer preventive treatment, in part, due to systemic side effects. The localization of pre-cancerous cells within the ducts or lobules of the breast permits a local treatment strategy employing the innate mammary ducts. This expansive tree-like structure extends throughout the entire breast and may serve as a conduit for local delivery of therapeutics, thereby minimizing side effects associated with current preventive treatment strategies. This study examines how lipophilicity influences diffusion through porcine tissue using a model hydrophilic dye, Sulforhodamine B (SRB), and a model lipophilic dye, Nile Red (NR). Porcine nipple or skin tissue was positioned in a Franz diffusion cell and the formulations were applied topically. With equivalent dye concentrations applied to the donor surface, we noted no significant difference in total dye permeation when comparing diffusion through skin versus nipple tissue or when comparing SRB versus NR after 48 hours. However, the diffusion coefficient for both NR and SRB through the nipple was almost 700-fold greater compared to through the skin indicating improved drug delivery via the nipple. Additionally, after 48 hours there was significantly higher retention of SRB in the nipple and skin compared to NR. When we further looked at the distribution of each dye within the nipple using fluorescence microscopy, we saw a distinction in the localization of each dye. Fluorescence micrographs show that lipophilic NR is retained within the ducts while the hydrophilic SRB diffuses throughout the entire tissue section, suggesting that hydrophobicity impacts the ability of molecules to diffuse from the duct into the surrounding tissue. This suggests that lipophilic carriers may be effective for delivery of cancer therapeutics or preventative agents targeting the mammary ducts, where AH is localized.
Title: Effectiveness, safety and quality of life (QoL) results from the German multicenter AVANTI study of 1st-line bevacizumab (BEV)-containing therapy in >2000 patients (pts) with advanced breast cancer (aBC)

Body: Background: In Europe, BEV is approved with either paclitaxel (PAC) or capecitabine (CAP) as 1st-line therapy for HER2-negative aBC. These regimens are being evaluated in routine oncology practice in the German AVANTI (ML22452) observational study.

Methods: Eligible pts had received no prior chemotherapy (CT) for aBC and had no BEV contraindications. CT schedule, diagnostics and frequency of follow-up are at the physician's discretion. Data are collected for 1 y after starting BEV, with 6-monthly follow-up for 1.5 y thereafter. QoL is assessed using EORTC QLQ-C30. Data cutoff for the 3rd interim analysis was Dec 1, 2016.

Results: Between Oct 2009 and Feb 2015, 2056 eligible pts at >300 centers began treatment with BEV+PAC (n=1658) or BEV+CAP (n=398). Median follow-up was 12.7 (range <0.1–50.9) mo. Median treatment duration was 4.4 (95% CI 4.2–4.6) mo for CT and 6.0 (95% CI 5.8–6.5) mo for BEV. Table 1 summarizes PFS. In the overall population, grade 3/4 AEs were reported in 20% of pts (20% BEV+PAC; 22% BEV+CAP) and led to treatment discontinuation in 5% (5% and 5%, respectively). Mean QLQ-C30 scores were relatively stable over time both overall and in subgroups aged <65 vs ≥65 y, indicating maintained QoL during therapy; no relevant QoL differences between age groups were seen (Table 2). To characterize 'long responders', we identified 459 pts with PFS ≥15 mo (410 BEV+PAC; 49 BEV+CAP). Of these, 33% were aged ≥65 y, 15% had triple-negative aBC (TNBC) and 25% had ≥3 metastatic sites. Median treatment duration was 5.1 mo for CT and 10.8 mo for BEV.

BL=baseline.  aHigher score=better QoL/functioning.  bHigher score=greater symptom burden.

Conclusions: More mature results from AVANTI show median PFS of 14.2 mo, favorable tolerability and maintained QoL, supporting 1st-line use of BEV for aBC. The subgroup with prolonged disease control (PFS >15 mo) was heterogeneous; further analyses of these pts are ongoing.
Title: Clinical efficacy of a humanized monoclonal antibody against the Lewis-Y antigen (Le\(^y\)): Results of a phase II clinical trial

Laura Testa\(^1,2\), Sergio V Serrano\(^3\), Roberto J Arai\(^1\), Marina C Zorzetto\(^3\), Ruffo Freitas-Junior\(^4\), Oren Maletz\(^5\), Max S Mano\(^1\) and Paulo M Hoff\(^1,2\). \(^1\)Instituto do Cancer do Estado de Sao Paulo, Sao Paulo, SP, Brazil; \(^2\)Hospital Sirio Libanes, Sao Paulo, SP, Brazil; \(^3\)Hospital de Câncer de Barretos - Fundação Pio XII, Barretos, SP, Brazil; \(^4\)Universidade Federal de Goiás, Goiania, GO, Brazil and \(^5\)Recepta Biopharma.

Body: Background. The Lewis-Y (Le\(^y\)) antigen is a blood group-related antigen expressed in over 70% of epithelial cancers. It is expressed in 44% of breast cancers.

Objectives. The primary endpoint was to evaluate the clinical efficacy of hu3S193, a humanized monoclonal antibody against the Lewis-Y antigen, in advanced hormone positive breast cancer after failure of at least one line of endocrine therapy.

Methods. This multicenter, single arm, phase II trial enrolled eligible patients to receive hu3S193 weekly at a dose of 20 mg/m\(^2\) intravenously. Efficacy was measured as clinical benefit rate (objective response or stable disease for at least 24 weeks).

Results. Of 49 patients screened, 27 (55%) were Le\(^y\) positive. Of these 27, only 20 were eligible for efficacy analysis. No complete or partial responses were observed. Five patients had stable disease for 24+ weeks (clinical benefit rate 25%). One patient remains on study drug maintaining stable disease for over 2 years. This patient had high expression of Le\(^y\). The most common treatment-related adverse events were headache (50%), cough (45.5%) and nausea/vomiting (31.8%).

Conclusions. Hu3S193 lacked sufficient activity in is trial and the investigators stopped accrual at the first interim analysis. High expression of Le\(^y\) might play a role in selecting patients to this strategy.
Title: Duration of adjuvant trastuzumab in HER-2 positive breast cancer: Pooled results of overall, and disease-free survivals from meta-analyses of randomized controlled trials

Saroj Niraula¹ and Bishal Gyawali². ¹University of Manitoba and CancerCare Manitoba, Winnipeg, MB, Canada and ²Institute of Cancer Policy, London, United Kingdom.

Body: Background: The duration of one year of trastuzumab for treatment of HER-2 positive breast cancer was chosen arbitrarily. Randomized controlled trials (RCTs) have since explored efficacy of shorter durations of trastuzumab compared to 1 year, but the results from such RCTs are inconsistent, and are subject to different interpretations due mainly to varying definitions of non-inferiority.

Methods: Systematic search of pubmed, embase, and major conference proceedings was performed to identify RCTs comparing outcomes of one year versus shorter trastuzumab in the adjuvant treatment of breast cancer. Efficacy outcomes [Hazard Ratios (HR) for Overall Survival (OS) and Disease Free Survival (DFS) with respective 95% Confidence Intervals (CI)] and toxicity outcome [Odds Ratios (OR) and 95% CI for cardiac events] from each study were weighted using generic inverse variance approach and pooled in a meta-analysis using RevMan 5.3 software. Heterogeneity among studies was assessed using tau² and i² statistics. Interactions on overall results by hormone receptor status, and nodal status were assessed using chi² statistics.

Results: Three RCTs involving 5,114 patients reported outcomes on both OS and DFS. Two studies evaluated 6 months and 1 study evaluated 9 weeks of adjuvant trastuzumab, compared to 1 year. Individual RCTs had failed to demonstrate non-inferiority of shorter duration compared to 1 year based on various pre-specified upper limits of CI (of <1.15, <1.29 and <1.59, respectively). Pooled analyses demonstrated statistically significant improvements in both OS (HR 0.78, 95% CI: 0.62-0.98), and DFS (HR 0.80, 95% CI 0.73-0.93) with the use of 1 year of trastuzumab compared to shorter durations suggesting superiority favoring 1 year of treatment, despite non-inferiority designs of individual trials. Sensitivity analyses based on duration of the experimental arm (9 weeks or 6 months) did not influence the direction, or size of overall effects. Pooled sub-group analyses demonstrated no interaction by hormone receptor status, or nodal status on overall results (p for sub-group difference = 0.73, and 0.52, respectively). Odds of cardiac events increased significantly with 1 year of treatment. (table 1)

Conclusion: Pooled analyses of RCTs demonstrated a significant improvement in overall, and disease-free survivals with 1 year of adjuvant trastuzumab compared to shorter durations for adjuvant treatment of HER-2 positive breast cancer. One year of trastuzumab should remain as the standard of care. Cardiotoxicity increased significantly with the longer treatment.

**Title:** Effects of neratinib after trastuzumab-based adjuvant therapy in hormone receptor-positive HER2+ early-stage breast cancer: Exploratory analyses from the phase III ExteNET trial

Stephen KL Chia¹, Miguel Martin², Hiroji Iwata³, Beverly Moy⁴, Alshad S Lalani⁵, Frankie Ann Holmes⁶, Janine Mansi⁷, Gunter von Minckwitz⁸, Marc Buyse⁹, Suzette Delaloge¹⁰, Bent Ejertsen¹¹, Bin Yao⁵, Adolfo Murias Rosales¹², Beth Hellerstedt¹³, Søren Cold¹⁴, Kenichi Inoue¹⁵, Zhen-Zhou Shen¹⁶, Teresa Galeano¹⁷, Carlos H Barrios¹⁸ and Arlene Chan¹⁹.¹ British Columbia Cancer Agency, Vancouver, BC, Canada; ²Hospital General Universitario Gregorio Marañón; ³Aichi Cancer Center Hospital; ⁴Massachusetts General Hospital Cancer Center; ⁵Puma Biotechnology Inc.; ⁶Texas Oncology; ⁷Guy’s and St Thomas’ NHS Foundation Trust and Biomedical Research Centre, King’s College London; ⁸German Breast Group; ⁹International Drug Development Institute; ¹⁰Institut Gustave Roussy; ¹¹Rigshospitalet; ¹²Compejo Hospitalario Materno Insular de Las Palmas; ¹³Texas Oncology, P.A; ¹⁴Odense University Hospital; ¹⁵Saitama Cancer Center; ¹⁶Shanghai Cancer Center; ¹⁷Magna Graecia University; ¹⁸Pontifical Catholic University of Rio Grande do Sul School of Medicine and ¹⁹Breast Cancer Research Centre-Western Australia and Curtin University.

**Body:** Background: The international, randomized, placebo-controlled phase III ExteNET trial showed that a 1-year course of neratinib after trastuzumab-based adjuvant therapy significantly improved 2-year invasive disease-free survival (iDFS) in patients with early-stage HER2+ breast cancer (BC) (hazard ratio 0.67; 95% CI 0.50–0.91; p=0.009) [Chan et al. Lancet Oncol 2016]. The significant iDFS benefit with neratinib was maintained after a median 5 years' follow-up (hazard ratio 0.73; 95% CI 0.57-0.92; p=0.008) [Martin et al. ESMO 2017]. At both time-points, marked benefit with neratinib was evident in patients with hormone receptor (HR)+ tumors, whereas in patients with HR– disease, initial improvements with neratinib diminished after completing treatment. We report exploratory analyses from the ExteNET trial done to better characterize the effects of neratinib in the HR+ subgroup.

**Methods:** Patients with early-stage HER2+ BC were randomly assigned to oral neratinib 240 mg/day or placebo for 1 year after standard primary therapy and trastuzumab-based adjuvant therapy. Randomization was stratified by HR status (locally assessed), nodal status, and trastuzumab regimen. Adjuvant endocrine therapy was recommended for patients with HR+ disease. Data concerning disease recurrences were collected prospectively during year 1-2 post-randomization, and from medical records during year 3–5 post-randomization. Primary endpoint: iDFS. Secondary endpoints: DFS including ductal carcinoma in situ (DFS-DCIS); time to distant recurrence (TTDR); distant DFS (DDFS); cumulative incidence of central nervous system (CNS) recurrences; overall survival (OS). Hazard ratios (95% CI) were estimated using Cox proportional-hazards models. Data cut-off: March 2017. Clinicaltrials.gov: NCT00878709.

**Results:** 2840 patients were randomized (neratinib, n=1420; placebo, n=1420); 1631 (57%) patients had HR+ tumors (neratinib, n=816; placebo, n=815). 93% and 94% of HR+ patients in the neratinib and placebo groups, respectively, were receiving adjuvant endocrine therapy at baseline. Efficacy outcomes in the HR+ cohort after a median follow-up of 5.2 years are shown in the table. In subgroup analyses of the HR+ cohort, hazard ratios for iDFS were 0.49 in centrally confirmed HER2+ patients (n=951), and 0.58 in patients who had completed prior trastuzumab ≤12 months before randomization (n=1334). CNS recurrence and OS data are not yet mature.

Conclusions: Neratinib was associated with an absolute iDFS benefit of 4.4% in patients with HR+/HER2+ BC after 5 years’ follow-up. HR/HER2 receptor cross-talk may underpin the notable effect of neratinib in patients with HR+ tumors when given in combination with endocrine therapy.
Impact of hormone receptor status in HER2-Positive early breast cancer in the trastuzumab era: Results of a National multi-institutional study

Alexandre de Nonneville, Anthony Gonçalves, Monique Cohen, Fabien Reyal, Jean Marc Classe, Sylvia Giard, Pierre Emmanuel Colombo, Xavier Muracciole, Nicolas Chopin, Eric Lambaudie and Gilles Houvenaeghel. 1Aix-Marseille Univ, CNRS, INSERM, Institut Paoli-Calmettes, CRCM, Marseille, France; 2Aix-Marseille Univ, CNRS, INSERM, Institut Paoli-Calmettes, CRCM, Marseille, France; 3Institut Curie, Paris, France; 4Institut René Gauducheau, St Herblain, France; 5Centre Oscar Lambret, Lille, France; 6CRLC Val-d’Aurelle, Montpellier, France; 7Hôpital de la Timone, Marseille, France and 8Centre Léon Bérard, Lyon, France.

Body: Background: Recent updated analysis of the HERA (HERceptin Adjuvant) trial indicate that tumor hormone receptor status (HR) remains a major determinant of outcome in HER2-positive (HER2+) early breast cancer (BC) patients, with higher rates of recurrence and death in women with HR-negative (HR-) disease, even after 11 years’ median follow-up. Furthermore, data reported from the HERA trial suggest that the timing of recurrences is different, with an initial higher frequency of disease-free survival (DFS) events in patients with HR- disease than those with HR-positive disease (HR+). No evidence of a different trastuzumab efficacy according to the HR of the primary tumor was found. In this study, we examined the impact of HR on outcome in a large, multicenter, “real-world”, retrospective cohort of HER2+ early breast cancer patients.

Methods: HER2+ BC were retrospectively identified from a large cohort of 23,375 consecutive patients who underwent primary surgery at 17 French centers between Dec 1987 and Jan 2014. A multivariate Cox model was built including age, tumor size, SBR grade, lymphovascular invasion, lymph node involvement, hormonal receptors status, adjuvant chemotherapy, adjuvant hormone therapy, trastuzumab, radiotherapy and type of surgery.

Results: A total of 1308 cases were identified, including 829 (63%) HR+ and 479 (47%) HR- patients. Median follow-up was 52 months (range 0 to 201). Compared with HR+, HR- patients had significantly smaller tumors (37 vs. 31% ≤ 10mm, p=0.027; information for multifocal tumors was not available), with higher SBR grade (58 vs. 40% grade 3, p<0.001) and had more lymph nodes involvement (41 vs. 32% pN+, p=0.001). HR- patients were more frequently treated by mastectomy (41 vs. 31%, p<0.001), received more trastuzumab (63 vs. 53%, p<0.001) and less radiotherapy (85 vs. 89%, p=0.020). Endocrine therapy was administered in 90% (744) of HR+ patients. No other significant difference in patient, tumor or treatment characteristics was found. HR status impacted DFS, metastasis free-survival (MFS) and BC-Specific survival (BC-SS) (hazard ratios: 0.46 [0.32-0.66]; p<0.001, 0.52 [0.33-0.82]; p=0.004 and 0.56 [0.34-0.90]; p=0.017, respectively, log-rank test) in overall population with higher rates of recurrence and death in women with HR- disease. In multivariate analysis, lymph node involvement and use of trastuzumab but not HR status impacted significantly DFS, MFS and BC-SS. Considering patients by treatment groups (with or without trastuzumab), HR status was not predictive of survival outcomes in the trastuzumab group, as opposed to the group without trastuzumab. Regarding the timing of recurrences, we observed an increased tendency for later relapse in patients with HR+ disease compared with HR- disease, for both DFS and MFS events.

Conclusions: Our results suggest that HR status remains a major determinant of outcome in HER2+ BC, including the timing of recurrence. Yet, this prognostic impact appears to be mitigated by trastuzumab-based adjuvant treatment.

Title: Timing of initiation of neratinib after completion of trastuzumab-based adjuvant therapy in early-stage HER2+ breast cancer: Exploratory analyses from the phase III ExteNET trial

1Rigshospitalet, Copenhagen, Denmark; 2Breast Cancer Research Centre-Western Australia and Curtin University; 3Comprehensive Cancer Centre, Medical University of Vienna; 4German Breast Group; 5Institut Gustave Roussy; 6International Drug Development Institute; 7Texas Oncology-Baylor Charles A. Sammons Cancer Center; 8Guy's and St Thomas' NHS Foundation Trust and Biomedical Research Centre, King's College London; 9Massachusetts General Hospital Cancer Center; 10Aichi Cancer Center Hospital; 11Puma Biotechnology Inc; 12Vanderbilt-Ingram Cancer Center; 13Westmead Hospital and the University of Sydney, Sydney, NSW, Australia; 14Hospital Universitario Virgen del Rocio; 15Instituto Valenciano de Oncología; 16Shanghai Cancer Center; 17Texas Oncology; 18Szpital Morski im. PCK Oddzial Onkologii Klinicznej, Gdyńskie Centrum Onkologii and 19Hospital General Universitario Gregorio Marañón.

Body: Background: The international, randomized, placebo-controlled phase III ExteNET trial showed that 1 year of neratinib after trastuzumab-based adjuvant therapy significantly improved 2-year invasive disease-free survival (iDFS) in early-stage HER2+ breast cancer (HR 0.67; 95% CI 0.50–0.91; p=0.009) [Chan et al. Lancet Oncol 2016]. The significant iDFS benefit with neratinib was maintained after a median of 5 years' follow-up (HR 0.73; 95% CI 0.57-0.92; p=0.008) [Martin et al. ESMO 2017]. We present exploratory analyses from the ExteNET trial examining the effects of the interval between completion of trastuzumab and randomization to commence neratinib on iDFS.

Methods: Women with early-stage HER2+ breast cancer were randomly assigned to oral neratinib 240 mg/day or placebo for 1 year after standard primary therapy and trastuzumab-based adjuvant therapy. Under the original study protocol, (neo)adjuvant trastuzumab was to be completed ≤24 months before randomization; this was revised to ≤12 months before randomization after the NCCTG-N9831/NSABP B-31 4-year analysis showed that the risk of relapse is greatest during the first 12 months after completing trastuzumab. Disease recurrences were collected prospectively during 1 and 2 years post-randomization, and from medical records during 3–5 years post-randomization. Patients randomized ≤12 months after completion of adjuvant trastuzumab were further separated to look at those who initiated neratinib ≤6 months of completing adjuvant trastuzumab. Primary endpoint: iDFS. HR (95% CI) estimated using Cox proportional-hazards models. Data cut-off: March 1, 2017. Clinicaltrials.gov: NCT00878709.

Results: The intention-to-treat population comprised 2840 patients (neratinib, n=1420; placebo, n=1420). Median time from last trastuzumab dose to randomization was 4.4 and 4.6 months in the neratinib and placebo groups, respectively. 81% of patients were randomized ≤12 months of completing trastuzumab. The effects of the interval between the last dose of trastuzumab and randomization/initiation of neratinib on iDFS after a median follow-up of 5.2 years are shown in the table.

a. Neratinib vs placebo; b. Protocol-defined subgroups

Conclusions: In ExteNET, patients who initiated neratinib within 12 months of completing trastuzumab-based adjuvant therapy...
appeared to derive greater benefit from treatment than those who started neratinib later. Further, exploratory analyses suggest that the magnitude of benefit with neratinib is greater if initiated sooner (i.e. within 6 months of completing trastuzumab). Given the benefits of neratinib overall in those initiating treatment ≤12 months from the end of adjuvant trastuzumab, extended adjuvant treatment with neratinib should be initiated early following completion of trastuzumab.
Title: Safety of trastuzumab in the subcutaneous formulation for the treatment of HER2 positive early breast cancer (eBC) patients: Primary results of SCHEARLY trial

Milvia Zambetti¹, Filippo Montemurro², Paolo Morandi³, Claudio Zamagni⁴, Alessia Stell⁵, Antonella Rozzi⁶ and Luca Gianni¹.
¹Ospedale San Raffaele, Milano, Italy; ²Istituto di Candiolo IRCCS, Candiolo, Italy; ³Ospedale dell'Angelo, Venezia, Italy; ⁴Policlinico S.Orsola-Malpighi, Bologna, Italy and ⁵Roche SpA, Monza, Italy.

Body:
Background: This study in Italian breast cancer patients is part of a phase IIIB, open-label, multinational umbrella study (UmbHER1), assessing the safety and tolerability of the subcutaneous (SC) formulation of Trastuzumab as primary end point. Present analysis is relative to the safety during the treatment period, with a major focus to side effects associated with the Trastuzumab SC administration.

Methods: Patients with HER2-positive eBC and LABC were eligible and included in two sequential cohorts: 120 patients treated with Trastuzumab SC by handheld syringe (Cohort A), and 120 with Trastuzumab SC by single-use injection device (SID, Cohort B). All the patients received adjuvant or neo-adjuvant treatment (clinician choice) with Anthracycline-containing regimens (FEC/EC/AC) followed by Trastuzumab SC in combination with taxanes (weekly Paclitaxel or Docetaxel) and then in monotherapy for a total of 18 cycles. Safety clinical and instrumental evaluations were planned at definite time points.

Results: 240 patients were enrolled and 202 patients (82.6% in cohort A and 84.9% in cohort B) completed the treatment. Reasons for discontinuation were the following: 7.9% AE/intercurrent illness, 3.3% withdrew consent, 1.7% recurrence of disease, 1.7% refused treatment, 0.9% violation of inclusion criteria, 0.9% other reasons. In the safety population, 98.2% of patients experienced at least one adverse event from the start of the Anthracycline treatment until the Safety Follow-up visit. Patients experiencing a Treatment Emergent (from Trastuzumab start date) AEs defined as Grade ≥3 were 26.8%; of these, 3.9% were considered related to study drug; Treatment Emergent Serious Adverse Events appeared in 7.5% of the safety population, of which 0.9% were considered related to study drug: one pleuropericarditis and one anaphylactic shock, both resolved. The frequency of systemic administration-related reactions, ARRs (pyrexia 25%, erythema 20.2%, rash 7.0%, chest pain 7.0%, pruritus 6.6%, chills 1.3%, anaphylactic shock 0.9%) and local injection site reactions, ISRs (pain 6.6%, injection site reactions 3.9%, subcutaneous abscess 0.9%, administration site oedema 0.4%) potentially related to the subcutaneous formulation is cumulatively reported below.

The mean reduction of Left Ventricular Ejection Fraction (LVEF) at the end of 1 year treatment from screening was 2.9%. 8.8% of patients experienced a decrease in LVEF, in most cases defined related to study drug (18 patients out of 20); no cases of CHF were reported.

Conclusion: Local and systemic tolerability of subcutaneous Trastuzumab administration is good in both groups and there is no evidence of increased incidence and severity of IMP-related systemic side effects in comparison with the standard intravenous route.
**Title:** Incidence and management of diarrhea with adjuvant pertuzumab and trastuzumab in HER2-Positive breast cancer

**Body: Background**
Diarrhea is the most commonly reported adverse event (AE) on pertuzumab (Ptz) in both early and metastatic breast cancer (BC) settings. We report safety analyses of diarrhea from the large adjuvant APHINTITY study in HER2 positive early breast cancer (EBC).

**Patients and methods**
In this exploratory analysis, the safety population included 2364 patients in the Ptz arm and 2405 in the placebo (Pla) arm. No specific prophylaxis was mandated by the protocol, however early intervention with loperamide as well as fluid and electrolyte replacement was recommended. Diarrhea incidence, severity (NCI-CTCAE v4.0), onset and management were analyzed.

**Results**
Diarrhea was the most common AE in the Ptz arm (71.3% vs. 45.2% in the Pla arm) and the events were mostly G1. Diarrhea ≥G3 was observed in 9.8% and 3.7% in Ptz and Pla arms, respectively. The highest incidence was reported during administration of HER2 targeted therapy and taxane (61.4% vs. 33.8% with Ptz and Pla, respectively) with a marked decrease observed upon chemotherapy cessation (18.1% vs. 9.2% with Ptz and Pla, respectively). The median time from first targeted treatment to onset of diarrhea during the chemotherapy phase was 7 and 10 days (Ptz/Pla). On average, diarrhea events lasted longer in the Ptz than in the Pla arm (median 8 vs. 6 days). Diarrhea events were more frequent with the administration of docetaxel + carboplatin and targeted agents, irrespective of the severity. Detailed results are reported in Table 1.

**Conclusions**
In the curative setting, diarrhea due to Ptz was mild, generally manageable with common antidiarrheals and did not affect patients’ ability to receive treatment. The APHINTITY findings are consistent with the well-characterized pattern of pertuzumab-related diarrhea across the HER2 BC spectrum.

Title: Extended adjuvant neratinib/fulvestrant blocks ER/HER2 crosstalk and maintains complete responses of ER+/HER2+ tumors following treatment with chemotherapy and anti-HER2 therapy

Dhivya R Sudhan¹, Luis J Schwarz¹, Angel L Guerrero-Zotano¹, Mellissa Nixon¹, Luigi Formisano¹, Sarah Croessmann¹, Paula I Gonzalez Ericsson¹, Melinda E Sanders¹, Justin M Balko¹, Francesca Avogadri-Connors², Richard E Cutler², Alshad S Lalani², Richard Bryce², Alan Auerbach² and Carlos L Arteaga¹. ¹Vanderbilt-Ingram Cancer Center, Vanderbilt University Medical Center, Nashville, TN and ²Puma Biotechnology Inc., Los Angeles, CA.

Body: Background: Neratinib is a potent, irreversible pan-HER tyrosine kinase inhibitor. The phase III trial ExteNET showed improved disease-free survival in patients (pts) with HER2+ breast cancer treated with neratinib vs placebo after trastuzumab-based adjuvant therapy. The benefit from neratinib appeared to be greater in pts with ER+ tumors. Thus, we sought to elucidate mechanisms that may explain the benefit from extended adjuvant therapy with neratinib in pts with ER+/HER2+ breast cancer using a human-in-mouse model that simulates the clinical outcomes seen in ExteNET.

Results: Mice with established ER+/HER2 amplified MDA-361 tumors were treated with trastuzumab (tz) + paclitaxel (pac) for 4 weeks, and then randomized to fulvestrant (fulv) ± neratinib for 4 weeks. All MDA-361 tumors exhibited a prompt and marked reduction in volume after tz/pac treatment; 10 mice achieved a complete response (CR) before receiving 'extended adjuvant' therapy with fulv (n=5) or neratinib/fulv (n=5). A CR was maintained with neratinib/fulv following tz/pac. However, mice treated with fulv alone, relapsed rapidly (p<0.05 at week 8) despite of a complete downregulation of tumor ER levels. In a second experiment, nude mice with established MDA-361 xenografts were treated with pertuzumab/tz/pac for 4 weeks. Following a CR, mice were randomized to neratinib/fulv vs. fulv. Again, mice treated with neratinib/fulv maintained a CR, while mice in the fulv alone arm exhibited tumor progressions within a week. In three ER+/HER2+ cell lines (MDA-361, BT474 and UACC893) but not in ER+/HER– MCF7 cells, treatment with neratinib induced ER reporter transcriptional activity whereas treatment with fulv resulted in an increase in HER2 phosphorylation, suggesting compensatory crosstalk between the ER and HER2 pathways. To further understand the molecular basis of this crosstalk, MDA-361 tumor-bearing mice were treated with either fulv, neratinib or the combination for 7 days, after which tumors were harvested and analyzed using a Nanostring breast cancer ER panel consisting of 196 ER-regulated genes. Compared to vehicle or fulv-treated tumors, tumors treated with neratinib alone and neratinib/fulv showed marked downregulation of cyclin D1 mRNA expression. Similarly, in MDA-361, BT474 and UACC893 cells but not in MCF7 cells, only neratinib/fulv downregulated cyclin D1, P-AKT and P-ERK. Finally, treatment with neratinib/fulv but not fulv alone reduced cyclin D1 transcriptional reporter activity and cyclin D1 protein levels, and induced cell cycle arrest, suggesting double blockade is required to overcome compensatory crosstalk between ER and amplified HER2.

Conclusions: Neratinib/fulv but not fulv alone maintained complete responses of ER+/HER+ tumors following treatment with tz/pac or pertuzumab/tz/pac, reminiscent of the results in ExteNET. Neratinib treatment promoted ER transcriptional activity whereas ER downregulation with fulv was associated with increased HER2 signaling. In ER+/HER2+ breast cancer cells and tumors, neratinib/fulv synergistically inhibited growth, cyclin D1 expression, and AKT and MAPK activation, thus providing a plausible mechanism to explain the results in the ExteNET trial.
Title: Adjuvant treatment of HER2+ breast cancer: Should trastuzumab be given sequentially or concurrently with chemotherapy?

Gwen MHE Dackus, Katarzyna Jóźwiak, Elsken Van der Wall, Paul J Van Diest, Michael Hauptmann, Sabine Siesling, Gabe S Sonke, and Sabine C Linn.

1. Netherlands Cancer Institute, Amsterdam, Noord-Holland, Netherlands; 2. University Medical Center Utrecht, Utrecht, Netherlands; 3. Netherlands Cancer Institute, Amsterdam, Noord-Holland, Netherlands; 4. University Medical Center Utrecht, Utrecht, Netherlands; 5. Netherlands Comprehensive Cancer Organisation, Utrecht, Netherlands; 6. MIRA Institute for Biomedical Technology and Technical Medicine, University of Twente, Enschede, Overijssel, Netherlands and 7. Netherlands Cancer Institute, Amsterdam, Noord-Holland, Netherlands.

Body: Background

Human Epidermal growth factor Receptor 2 positive (HER2+) breast cancers have a high risk of recurrence in the absence of systemic treatment. The monoclonal antibody trastuzumab in combination with chemotherapy has significantly improved survival. Randomized trials have given trastuzumab both concurrently and sequentially with chemotherapy. To date, only one study reported a comparison between concurrent and sequential trastuzumab, with a numerically but not statistically significant benefit for concurrent use.

Our aim is to evaluate whether there is a difference in survival between patients who received trastuzumab sequentially to chemotherapy compared to concurrently with chemotherapy using data from the population-based, Netherlands Cancer Registry (NCR).

Methods

All women diagnosed in the Netherlands with a HER2+, T_{any}N_{any}M_0 breast tumor between 2005 and 2007 who received both chemotherapy and trastuzumab were identified from the NCR. Kaplan Meier survival estimates and Cox regression were used to compare recurrence free survival (RFS) and overall survival (OS) by trastuzumab sequence. Hazard ratios (HR) were adjusted for grade, pathological T-stage, pathological N-stage, estrogen receptor (ER), progesterone receptor, radiotherapy, hormonal therapy and ovarian ablation.

Results

A total of 1,849 patients were identified, with a mean follow-up of 7.8 years. Of these, 1,260 received concurrent trastuzumab and 589 sequential trastuzumab. Most tumors were grade 3, node positive and ER+. During follow-up 358 RFS events occurred, 231 in the concurrently treated patients compared to 127 in sequentially treated patients. Regarding OS, 290 deaths were observed, 188 deaths in concurrently treated patients compared to 102 deaths in sequentially treated patients, respectively. OS and RFS were similar among sequentially versus concurrently treated patients (adjusted HR 1.11; 95% CI 0.87-1.42; P=0.420 and adjusted HR 1.15; 95% CI 0.92-1.44; P=0.209, respectively).

Conclusion

We observed no significant difference in OS and RFS between patients who received sequential trastuzumab compared to patients treated concurrently. Based on our results no recommendation can be made favoring either of the two treatment sequences for the adjuvant treatment of HER2+ breast cancer patients.
**Title:** Neratinib in the extended adjuvant treatment of patients from Asia with early-stage HER2+ breast cancer after trastuzumab-based therapy: Exploratory analyses from the phase III ExteNET trial

**Body:**

**Background:** Current breast cancer knowledge is based largely on studies conducted in western populations. Their findings may not be generalizable to Asian women because of ethnic, genetic and lifestyle differences. Neratinib (N) is an irreversible tyrosine kinase inhibitor of HER1, 2 and 4. The international, randomized, placebo (P)-controlled phase III ExteNET trial showed that 1 year (yr) of N after trastuzumab (T)-based adjuvant therapy significantly improved 2-yr invasive disease-free survival (iDFS) in patients (pts) with early-stage HER2+ breast cancer (HR 0.67; 95% CI 0.50–0.91; p=0.009) [Chan et al. Lancet Oncol 2016]. The significant iDFS benefit with N was shown to be durable after 5 yrs’ follow-up (HR 0.73; 95% CI 0.57-0.92; p=0.008) [Martin et al. ESMO 2017]. We report efficacy and safety findings from pts enrolled from Asian centers (China, Hong Kong, Japan, Korea, Malaysia, Singapore, and Taiwan) on the ExteNET trial to better characterize the effects of N in Asian women.

**Methods:** Pts with early-stage HER2+ breast cancer were randomly assigned to oral N 240 mg/day or P for 1 yr after standard primary therapy and T-based adjuvant therapy. Antidiarrheal prophylaxis was not required by protocol. Data concerning disease recurrences were collected prospectively during yr 1-2 post-randomization, and from medical records during yr 3–5 post-randomization. Primary endpoint: iDFS. HR (95% CI) estimated using Cox proportional-hazards models stratified by nodal status, hormone-receptor status and prior T regimen. Data cut-off: 2-yr analysis, July 2014; 5-yr analysis, March 2017. Clinicaltrials.gov:NCT00878709.

**Results:** Of 2840 randomized pts (N, n=1420; P, n=1420), 341 (12%) were enrolled from Asian centers (N, n=165; P, n=176). Baseline characteristics: median age 53 yr; hormone receptor-positive 48%. Median treatment duration was similar in both groups (N, 351 days; P, 352 days). iDFS events in Asian vs ITT populations are shown in the Table.

a. Primary study endpoint; b. Neratinib vs placebo
The incidence of grade 3/4 diarrhea with N was slightly higher in Asian pts (46.1% vs ITT, 39.8%). All other grade 3/4 adverse events with N were rare among Asian pts (elevated ALT, mucosal inflammation, 2 pts each; other events, 1 pt each). Compliance with N in Asian pts was also improved (71% vs ITT, 61%).

**Conclusions:** In Asian pts enrolled into ExteNET, compliance with N was better and the magnitude of N effect was similar or greater that that observed in the ITT population. Although N-related grade 3/4 diarrhea was more common in Asian pts than in the ITT population, all other grade 3/4 events were rare. Despite small pt numbers, our analyses suggest that the findings from ExteNET are applicable to Asian pts, and support the conclusion that N reduces disease recurrences in Asian pts with early-stage HER2+ breast cancer after T-based adjuvant therapy.

Body: Background: Improvement to and maintenance of the highest possible health-related quality of life (QoL), in addition to disease control, are key goals of treatment in patients with advanced breast cancer (ABC). Endocrine therapy is preferred as first-line therapy in ABC because of its preferable safety profile compared with chemotherapy. In the MONALEESA-2 study, the cyclin-dependent kinases 4 and 6 inhibitor ribociclib, in combination with letrozole, significantly extended progression-free survival (PFS) compared with placebo + letrozole in patients with hormone receptor–positive (HR+) human epidermal growth factor receptor 2–negative (HER2−) ABC. Patient-reported outcomes demonstrated similar QoL among patients in both treatment groups. Here, we present data from US patients enrolled in the MONALEESA-2 study on overall QoL as well as individual domains.

Methods: Postmenopausal women (N=668) with HR+, HER2− ABC who did not receive prior systemic treatment for ABC and had an Eastern Cooperative Oncology Group performance status score of ≤1, adequate bone marrow and organ function, and no history of active cardiac dysfunction were randomized 1:1 to receive either ribociclib (600 mg/d, 3 weeks on/1 week off) + letrozole (2.5 mg/d, continuous) or placebo + letrozole. The primary end point was locally assessed PFS. Quality of life was reported using the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire-Core 30 (EORTC QLQ-C30), the EuroQol 5-domain 5 level (EQ-5D-5L) visual analog scale (VAS) of overall health, and the breast symptom score of the EORTC QLQ-Breast Cancer 23 (EORTC QLQ-BR23) module. Data cutoff in this analysis was January 29, 2016.

Results: Patient characteristics and QoL survey reports were well balanced across treatment groups in US patients (n=213). The global health status/QoL scores of the EORTC QLQ-C30 were maintained between groups, and improved over time in the ribociclib group (mean ± standard deviation [SD] score at baseline, 69.1 ± 19.0; at 8 months, 71.3 ± 18.2; and at 16 months, 73.0 ± 16.0) and the placebo group (mean ± SD score at baseline, 69.9 ± 20.0; at 8 months, 75.9 ± 19.2; and at 16 months, 77.0 ± 15.0), which was consistent with scores in the overall population. At 16 months, the proportion of patients who did not experience ≥10% deterioration of all QoL scores was similar among treatment groups.

Quality of Life Outcomes of US Patients in the MONALEESA-2 Study at 16 Months

Conclusions: Addition of ribociclib to letrozole in US patients enrolled in MONALEESA-2 led to significant prolongation of PFS while maintaining QoL.
The treatment patterns and clinical outcomes of trastuzumab in early human epidermal growth factor receptor 2 (HER2) positive breast cancer in the real-world setting in China

Jihong Guo1,2, Binghe Xu1, Qing Li1, Pin Zhang1, Peng Yuan1, Jiayu Wang1, Fei Ma1, Ying Fan1, Ruigang Cai1, Yang Luo1 and Qiao Li1. 1Cancer Hospital, Chinese Academy of Medical Sciences, Panjiayuan, Chaoyang District, Beijing, China and 2Beijing Chaoyang Hospital, Capital Medical University, Chaoyang District, Beijing, China.

Body: Background: Several prospective interventional studies have proved the efficacy and safety of trastuzumab in adjuvant treatment in HER2 positive breast cancer, while limited data existed to address the treatment patterns and real-world performance of trastuzumab in early HER2 positive breast cancer in China.

Methods: We retrospectively analyzed all the pts who were diagnosed with HER2-positive breast cancer, underwent surgery and received adjuvant treatment in National Cancer Center from 2000 to 2012. The treatment patterns and disease free survival (DFS), overall survival (OS) were analyzed respectively.

Results: A total of 1398 HER2 positive breast cancer pts were identified. The median follow-up time was 79.1 months. 68.5% pts received chemotherapy alone, 3.4% pts only received mono trastuzumab, 28.2% pts received trastuzumab plus chemotherapy. Among 433 trastuzumab treated pts, 64.7% received concurrent trastuzumab with chemotherapy, and 35.3% pts received sequential trastuzumab with chemotherapy.

Baseline characteristics by Chemotherapy alone and Chemotherapy + Trastuzumab.

Trastuzumab plus chemo had significantly longer DFS compared with chemo alone (85.03% vs 72.15%, hazard ratios, HR=0.531, 95% confidence interval, 95% CI: 0.406-0.696, p<0.001). In addition, the concurrent trastuzumab showed the trend...
with longer DFS compared to the sequential regimen (86.07% vs 82.35%, HR=0.843, 95% CI: 0.515-1.378, p=0.495). Age, tumor size, lymph node status, clinical stage were associated with DFS.

OS was also prolonged in trastuzumab plus chemotherapy compared with chemotherapy alone (93.20% vs 85.45%, HR=0.561, 95% CI: 0.377-0.835, p=0.004).

Conclusions: Our study revealed that, there were still more than half of HER2-positive breast cancer pts couldn't reach anti-HER2 therapy in China, the early stage HER2-positive breast cancer pts could significantly benefit from trastuzumab adjuvant therapy in real-world setting.
Introduction: Triple positive breast cancer is one of intrinsic subtype in breast cancer that is defined namely, ER/PR/Her2 positive tumors. It has multiple strategies for systemic therapy according to the characteristics of hormonal and anti-HER2 responsiveness. Each targeted therapy plays cross-talks between HER-2 and estrogen receptor signaling pathway resulting in endocrine resistance and anti Her2 resistance.

Results: Median follow up duration of 76 months in KBCS cohort (2006-2010) showed the overall survival graph of triple positive breast cancer located in the middle in between Luminal A intrinsic subtype and HER2 enriched subtype \( P<.001 \). Also HER2 directed trastuzumab therapy did not improve the overall survival in triple positive breast cancer patients \( P= .899 \) in contrast to the improved overall survival using trastuzumab therapy in HER2 enriched subtype \( P=.018 \). Like the preceding results, CMC breast cancer data showed the similar results in recurrence free survival \( P<.001 \) and no recurrence free survival improvement using trastuzumab therapy in triple positive breast cancer patient during the median follow up of 33 months \( P=0.800 \).

Conclusion:
1) Anti-HER2 therapy seems less beneficial in Triple positive breast cancer subtype regardless of breast cancer stage.
2) Triple positive breast cancer may require different therapeutic approaches
3) Other targeted agents (mTOR inhibitor, CDK4/6 inhibitor, PIK3CA inhibitor) can be a substitute option for the Trastuzumab therapy in triple positive breast cancer.
**Title:** Final analysis of overall survival (OS) for the epoetin alfa (EPO) phase 3 study, EPO-ANE-3010, of EPO plus standard supportive care (SOC) versus SOC in anemic patients with metastatic breast cancer (MBC) receiving standard chemotherapy

Abeloff Laboratory Cancer Research Center, Tbilisi, Ukraine; 7Chemotherapy and Immunotherapy Clinic MEDULLA, Tbilisi, Georgia; 8Tbilisi Cancer Center, Tbilisi, Georgia; 9St. Luke's Medical Center, Quezon City, Philippines; 10Kidwai Memorial Institute of Oncology, Bangalore, India; 11Research Institute of Clinical Medicine, Tbilisi, Georgia; 12Institute of Medical Radiology, Kharkiv, Ukraine; 13Lviv State Oncology Regional Treatment and Diagnostic Centre, Lviv, Ukraine; 14Chernigov Regional Oncology Center, Chernigov, Ukraine; 15Pyatigorsk Oncology Dispensary, Pyatigorsk, Russian Federation; 16Janssen R&D, Titusville and 17Janssen R&D, Neuss, Germany.

**Body:** Background: In the interim analysis of study EPO-ANE-3010, for the primary endpoint of progression-free survival (PFS), the non-inferiority objective in ruling out a 15% increased risk in progressive death (PD) or death per investigator-determined PD was not achieved (JCO 34:1197-1207, 2016). PFS, based on independent review committee (IRC)-determined PD, however, met the non-inferiority criteria. At the interim analysis, OS with 1,337 deaths was reported; we now report the final analysis at 1,653 deaths and the updated PFS.

Methods: This multinational (19 countries and 132 participating sites), phase 3, randomized, open-label noninferiority study included anemic (≤11.0 g/dL hemoglobin) women receiving first- or second-line standard chemotherapy for MBC (Eastern Cooperative Oncology Group performance status of 0 or 1). Subjects were randomized (1:1) to receive either standard SOC for treatment of anemia plus EPO (40,000 IU subcutaneous) weekly up to 4 weeks after the last dose of cytotoxic chemotherapy, or SOC alone. The primary endpoint was PFS (using Cox's regression model). Secondary endpoints included OS, time to tumor progression (TPP), overall response rate (ORR) and safety assessments.

Results: A total of 2,098 subjects were enrolled (EPO plus SOC: n=1,050; SOC alone: n=1048). Demographic and baseline characteristics were well-balanced across the groups; median age was 52 years, most were white (67.5%) or Asian (30.5%) and median BMI was 26.0 kg/m². Primary efficacy analysis (based on investigator-determined PD) showed a median PFS of 7.4 months for both groups (hazard ratio [HR], 1.094; 95% CI: 0.996, 1.201); upper bound exceeded prespecified noninferiority margin of 1.15. A 9% increased risk for PD/death in the EPO plus SOC group was observed and did not statistically rule out a 15% increased risk. Median PFS per IRC-determined PD was 7.6 months in both groups (HR, 1.028; 95% CI: 0.922, 1.146), this met pre-defined non-inferiority margin of 1.15 with a 3% risk increase in PD/death in EPO plus SOC group. At the final analysis for OS, median OS was 17.8 months in the EPO plus SOC group and 18.0 months in the SOC group; HR: 1.073 (95% CI: 0.974, 1.182); median TPP was 7.5 months in both groups (HR, 1.099; 95% CI, 0.998 to 1.210), and ORR was 50% in the EPO plus SOC group and 51% in the SOC group (odds ratio, 0.939; 95% CI, 0.789, 1.117). Red blood cell (RBC) transfusions were 5.8% versus 11.5% (P<0.001), and thrombotic vascular events were 2.8% versus 1.4% (P=0.038), respectively, in EPO plus SOC group and SOC group. The incidence of death due to PD were similar in both groups (EPO plus SOC: 93%; SOC: 91%).

Conclusion: The primary endpoint, PFS based on investigator-determined PD, did not meet noninferiority criteria but for PFS based on IRC-determined PD, noninferiority criteria was met. Overall, this study did not statistically rule-out a 15% increased risk in PD/death. The final analysis did not show statistically different OS in the EPO plus SOC group versus the SOC group. No new safety signals were noted with EPO treatment and the results are consistent with the known safety profile of EPO.
2017 San Antonio Breast Cancer Symposium

Publication Number: P1-14-02

Title: Impact of loco-regional treatment (LRT) on overall-survival (OS) in patients with de novo metastatic breast cancer (MBC): Results of the French ESME multicenter national observational programme

Institut Claudius Regaud IUCT Oncopole, Toulouse, France; Institut Curie Saint-Cloud, Paris, France; Institut Cancérologie de l'Ouest, Nantes, France; Institut François Baclesse, Caen, France; Institut Gustave Roussy, Paris, France; Centre Oscar Lambret, Lille, France; Institut Bergonié, Bordeaux, France; Institut du Cancer de Montpellier, Montpellier, France; Centre Henry Becquerel, Rouen, France; Institut Paoli Calmette, Marseille, France; Centre Georges-François Leclerc, Dijon, France; Centre Eugène Marquis, Rennes, France; Centre Léon Bérard, Lyon, France; Centre Antoine Lacassagne, Nice, France; Institut Cancérologie de Lorraine, Nancy, France; Institut Jean Godinot, Reims, France; Centre Jean Perrin, Clermont-ferrand, France; Centre Paul Strauss, Strasbourg, France and R & D UNICANCER, France.

Body: Background

Previous retrospective studies and meta-analysis suggest an improved overall survival (OS) brought by loco-regional treatment (LRT) of primary tumor in de novo metastatic breast cancer (MBC) patients (pts), while prospective trials have mixed results. Most of the previous studies recruited pts before 2005 and consequently did not include recent medical therapies and advances used in MBC.

Patients and methods

The ESME database include individual data from MBC pts diagnosed between 2008 and 2014, who initiated their treatment in 1 of the 18 participating French comprehensive cancer centers. Our first aim was to study the impact of LRT, defined as surgery, radiotherapy or both, on OS in de novo MBC pts, defined as pts diagnosed with synchronous metastasis or within 90 days from diagnosis of primary tumor. OS was calculated from the date of diagnosis of metastatic stage and was estimated by the Kaplan Meier method. Univariate and multivariate analyses were performed using Logrank-test and Cox-model, respectively.

Results

Of the total ESME cohort (16703 pts), 4507 (26.9%) were diagnosed with de novo MBC and 4276 fulfilled inclusion criteria for the present study. Median age was 60 years. 66.3% pts had T3-T4. 13.1% (n=495) had triple-negative (TN) BC, 24.4% (n=918) HER2+ BC and 62.5% (n=2536) HR+/HER2- BC. Sites of metastases were bone (69%), liver (30.9%), nodes (29.5%) and lung (25.7%). 77.4% had less than 3 sites involved by metastatic disease.

Of 4276 pts, 1706 (39.9%) received a LRT. Among them, 444 (26%) and 535 (31.4%) had surgery or radiotherapy alone respectively, 727 (42.6%) had a combination of both. 99% of pts received a systemic treatment: hormone therapy for 60.3% and chemotherapy +/- targeted therapy for 72.8% of them. Compared with pts with no LRT, pts in the LRT group were younger (median age: 57 vs 61 years, p<0.0001), had smaller tumor (40.4% ≤ T2 vs 28.2%, p<0.0001) with more N0 status (26.5% vs 19.3%, p<0.0001), and different phenotypes: TN 12.1% vs 13.8%; HER2+ 26.4% vs 23.1%; HR+/HER2- 61.5% vs 63.1% (p=0.0447). Metastatic disease in the LRT group was more likely to be limited to 1 or 2 sites (86.4% vs 71.4%), with more non-visceral sites (52.3% vs 36.5%).

With a median follow-up of 45.3 m, median OS and initial PFS for the whole population were 45.2 m [95%CI: 43.3-47.1] and 13.8 m [95%CI: 13.2-14.4], respectively. Median OS for TN, HR+/HER2- and HER2+ pts were 19 m [95%CI:17-21], 47.4 m [95%CI: 45.2-50.4] and 53.3 m [95%CI: 48.9-60.2], respectively. By multivariate analysis, LRT was an independent prognostic factor for OS (HR=0.76; 95%CI: 0.64-0.89; p=0.001), together with age, histological subtype, number and patterns of metastatic sites. More advanced analyses will be presented in December. </del>

Conclusion

As in older series, this work finds that de novo MBC pts treated after 2008 may derive a prolonged OS, extending up to 4 years for HR+ and HER2+ subgroups. Given the classical prescription biases in such retrospective works, this should be carefully interpreted but might help in better selecting those pts for whom such strategy would be beneficial.
**Title:** ABRAZO: Exposure-efficacy and -safety analyses of breast cancer patients with germline *BRCA1/2* mutations receiving talazoparib in a phase 2 open-label trial

Melinda L Telli¹, Nicholas C Turner², Audrey Mailliez³, Johannes Ettl⁴, Eva-Maria Grischke⁵, Lida A Mina⁶, Judith Balmana⁷, Sara A Hurvitz⁸, Andrew M Wardley⁹, Peter A Fasching¹⁰, Cristina Tudor¹¹, Linh Nguyen¹¹, Alison L Hannah¹¹, Mark E Robson¹² and Hope S Rugo¹³. ¹Stanford University School of Medicine, Stanford, CA; ²Royal Marsden Hospital, The Institute of Cancer Research, London, United Kingdom; ³Centre Oscar Lambret, Lille, France; ⁴Klinikum Rechts der Isar, Technische Universität München, Munich, Germany; ⁵Universitäts-Frauenklinik Tubingen, Eberhard Karls University, Tubingen, Germany; ⁶Banner Health, Phoenix, AZ; ⁷Hospital Vall d'Hebron, Barcelona, Spain; ⁸University of California Los Angeles Health, Santa Monica, CA; ⁹The NIHR Cancer Research UK Christie Clinical Research Facility, Manchester, United Kingdom; ¹⁰University of Erlangen, Erlangen, Germany; ¹¹Medivation, Inc. (Medivation was Acquired by Pfizer Inc., in September 2016), San Francisco, CA; ¹²Memorial Sloan-Kettering Cancer Center, New York, NY and ¹³University of California San Francisco Comprehensive Cancer Center, San Francisco, CA.

**Body:**

**Background:** Talazoparib (TALA) is a dual-mechanism poly (ADP-ribose) polymerase (PARP) inhibitor that traps PARP on DNA. Efficacy results of this phase 2 trial were previously presented (Turner et al, ASCO 2017, abstract 1007). This study included sparse pharmacokinetic (PK) sampling for patients through cycle 4 of therapy. Exploratory analyses included assessment of exposure versus parameters of efficacy and safety.

**Methods:** ABRAZO (NCT02034916) was a parallel-cohort, open-label phase 2 study of TALA (1 mg/d) following (i) platinum-based therapy (cohort 1) or (ii) ≥3 platinum-free cytotoxic-based regimens (cohort 2) in patients with locally advanced or metastatic breast cancer and germline *BRCA1/2* mutation. Sparse PK sampling was performed on day 1 of cycles 1-4, consisting of a predose sample collected ≤60 minutes prior to dosing and 2 postdose samples collected ≥30 minutes after dosing (time of food ingestion prior to the dose was collected). The collection times of the 2 postdose samples were separated by ≥2 hours. Efficacy parameters included radiographic progression-free survival (rPFS) by central review and objective response rate (ORR). Safety parameters included incidence of overall adverse events (AEs) and grade ≥3 AEs. Individual AUCs (area under concentration-time curves) for exposure-response analyses were predicted by population PK analyses.

**Results:** Patients were divided into AUC tertiles: low (median, 109.0 ng·hr/mL; n=27), intermediate (median, 170.8 ng·hr/mL; n=27), and high (median, 219.2 ng·hr/mL; n=27). Median rPFS was 5.3 months (95% confidence interval [CI], 3.1, 8.3) in the lowest AUC tertile, 5.6 months (95% CI, 3.7, 8.4) in the intermediate AUC tertile, and 5.3 months (95% CI, 3.9, 5.6) in the highest AUC tertile. The ORR was 22.2% (95% CI, 8.6, 42.3) in the lowest AUC tertile, 25.9% (95% CI, 11.1, 46.3) in the intermediate AUC tertile, and 37.0% (95% CI, 19.4, 57.6) in the highest AUC tertile. AEs of any grade were reported in 11 patients (40.7%) in the lowest AUC tertile, 21 patients (77.8%) in the intermediate AUC tertile, and 22 patients (81.5%) in the highest AUC tertile. Grade ≥3 AEs were reported in 8 patients (29.6%) in the lowest AUC tertile and in 18 patients (66.7%) in the intermediate and highest AUC tertiles. The most common AEs in all 3 exposure tertiles were anemia, thrombocytopenia, and neutropenia.

**Conclusions:** Median rPFS did not change with increasing systemic exposure. There may be a trend to higher ORR in patients with highest systemic exposure. A larger percentage of patients experienced AEs with elevated systemic exposure. Increased response rates with greater exposure does not translate to improved rPFS. These results should be interpreted with caution due to the low patient numbers in each cohort.
**Body:** BACKGROUND - Metastatic breast cancer (MBC) is a life-threatening disease. It is important to provide data about real-life MBC patients (pts) to understand the current prognostic factors. The aim of the present observational study, named COSMO (Checking Overall Survival in a MBC Observational study) is to describe the overall survival (OS) in a large cohort of MBC pts, assessing its correlation with specific prognostic factors (demographic, clinic, pathologic and biological).

**PATIENTS AND METHODS** - The COSMO study is a multicenter, retrospective, cohort study, developed throughout the collaboration of 31 Italian oncological centers. Data about pts diagnosed as metastatic from 01/01/2000 to 31/12/2008, were collected. The association between molecular subtypes, metastatic sites, disease free interval (DFI) and OS were assessed. Pts were classified in three subgroups, based on the biological characteristics of their tumor: luminal, HER2-positive (regardless of hormone receptor) and triple negative (TN). Metastatic sites were categorized as visceral versus non-visceral disease, only bone and central nervous system (CNS) metastases. DFI was calculated from diagnosis to first relapse only for M0 pts.

**RESULTS** - Of 3931 MBC pts enrolled in the study, 3720 were evaluable, with a median age of 61 years (interquartile range, IQR, 51-71). 1804 (62,1%) pts had a luminal disease, 691 (23,8%) HER2-positive, 410 (14.1%) TN. Median DFI was 3.2 years (IQR 1.7- 6.0). Regarding metastatic sites, pts with visceral disease were 2332 (63%); 826 (22,2%) pts had bone isolated metastases; in 306 (8,3%) pts, CNS metastases were reported. With a median follow up of 9 years (IQR 5.7-11.0) and 3098 (83.3%) recorded events, we founded a median OS of 2.8 years (95%CI: 2.7-2.9) years. OS was strictly depending from molecular subtypes with a better prognosis for HER2-positive versus luminal and TN MBC pts, median OS of 3.1 (95%CI 2.8-3.4), 3.0 (95%CI: 2.9-3.1) and 1.5 (95%CI: 1.3-1.7) years respectively (p-value<0.001). 525 (14,1%) pts received trastuzumab. Metastatic sites affect prognosis, with a better OS for bone disease (3.4 years, 95%CI: 3.1-3.6) versus visceral disease (2.2 years 95%CI: 2.0- 2.3). Brain metastasis correlate with the worst prognosis: OS of 1.5 years (95% CI: 0.8 – 1.7). Even DFI shows a correlation with prognosis: pts with DFI>2 years show a median OS of 3 years (95% CI: 2.9 – 3.2), while those with DFI<2 years have a median OS of 2.4 years (95% Cl: 2.3-2.6); HR was 0.69 (95%CI: 0,62-0,76) for every five years of increase in DFI (p-value<0.001).

**CONCLUSIONS** - Molecular subtype is crucial for prognosis: HER2-positive subtype has the best prognosis, while TN subtype has the shorter OS. Having a longer DFI from diagnosis (>2 years) correlate with a better prognosis. Our study confirm that sites of metastasis affects outcome: visceral involvement correlates with poor prognosis and, particularly, pts with brain metastasis represent the worst subgroup, while pts with solely bone disease have the best prognosis. The COSMO study provides a view on the Italian landscape of MBC between 2000 and 2008, adding new insights about pts prognosis.
### Title: Ribociclib dose recommendations for potential pharmacokinetic drug interaction and in special patient populations with organ impairment

Ahmed M Abdelhady¹, Tanay S Samant¹, Abhijit Chakraborty¹, Caroline Germa¹, Xiaochun Liu¹, Ken-Ichi Umehara², Felix Huth², Yasong Lu¹, Shu Yang¹, Michelle Quinlan¹, Marc Laisney², Martin Mueller-Zsigmondy¹ and Mohamed Elmeliegy¹. ¹Novartis Pharmaceuticals Corporation, East Hanover, NJ and ²Novartis Pharma AG, Basel, Switzerland.

### Body: Background:
Ribociclib (Kisqali®) is a CDK4/6 inhibitor, recently approved in the U.S. as a first line therapy for HR+/HER2- advanced breast cancer (ABC) in combination with an aromatase inhibitor. The recommended starting dose is 600 mg/day orally (3 wks-on/1 wk-off). Ribociclib inhibits CYP3A4 and its metabolism is mostly CYP3A4-mediated. Here we evaluate the effect of food, conmeds and special patient populations on ribociclib pharmacokinetics (PK) and dose recommendations.

### Methods: In vitro and clinical data (food effect, drug–drug interactions, organ impairment and Phase I/III trials) were analyzed using physiologically-based PK (PBPK), population PK (PopPK) models and non-compartmental analysis (NCA). Dose recommendations were made considering ribociclib PK, safety and efficacy data.

**Conclusions:** Ribociclib 600 mg daily (3 wks-on/1 wk-off) has shown clinical benefit in treatment of HR+/HER2- ABC with a manageable safety profile. Ribociclib can be conveniently administered without regard to food intake or gastric pH-elevating agents. Appropriate ribociclib dose recommendations with concomitant medications or organ function impairment were made considering ribociclib PK, safety and efficacy.
Title: Selective internal radiation therapy (SIRT) with Yttrium-90 resin microspheres and FOLFOX/5FU chemotherapy in pre-treated breast cancer patients with liver metastases: A retrospective analysis of response rates, times to progression and survival of patients treated in Manchester UK between 2010 and 2016

Gregory Wilson¹, Saifee Mullamitha¹, Debra Bentley¹, Jon Bell¹, Damian Mullan¹, Louise Carter¹, Abbas Chittalia¹, Sacha Howell¹, Hans-Ulrich Laasch¹, Thomas Westwood¹, Steve Jeans¹, Jill Tipping¹, David Ryder¹, Finn Farquharson², Parthiban Arumugam², Aali Sheen², Bala Rajashanker², Anne Armstrong¹, Vivek Misra¹, Prakash Manoharan¹ and Jeremy Lawrance¹. ¹The Christie NHS Foundation Trust, Manchester, Lancashire, United Kingdom and ²Central Manchester University Hospitals NHS Foundation Trust, Manchester, Lancashire, United Kingdom.

Body: Background:
SIRT is a globally licensed technique of Radio-Embolization (RE) of hepatic tumors via intra-arterial infusion of β-particle emitting Yttrium-90 (Y-90) radio-labelled microspheres. It increases response rates and hepatic time to progression in metastatic colorectal cancer when used in combination with 5FU/Oxaliplatin (FOLFOX) chemotherapy with acceptable toxicity profile. FOLFOX gives a radio-sensitizing effect and also controls disease outside the liver. Breast cancer liver metastases (BCLM) patients often have extra-hepatic disease and respond to multiple lines of systemic therapy and SIRT is infrequently used.

Methods and patients
Between 2010 and 2016 we treated 25 BCLM patients with Y-90 SIRT. Receptor status: 20 ER+ve/HER-2 -ve, 3 ER-ve/HER-2 +ve, 2 triple -ve. Eleven patients had liver only disease with 14 also having known extra-hepatic disease. Average number of previous lines of therapy in metastatic setting: chemotherapy = 2.4; endocrine = 1. Sixty-four % patients had prior Capecitabine (n=16); 12% platinum (n=3, all Carboplatin). Twenty patients received chemotherapy with SIRT: 17 had modified FOLFOX6 (Oxaliplatin/bolus 5FU day1, infusional 5FU day 1-3 (46 hrs); 3 patients had Modified de Gramont style 5FU alone. Five patients had no chemotherapy.

Sir-spheres were inserted on day 2 of FOLFOX with the 5FU infusion pump continuing to day 3. Further 2-weekly FOLFOX chemo cycles were at clinician's discretion: average number delivered 3.8. Four patients had the liver treated in two halves, approximately 6 weeks apart. One patient received SIRT only to half the liver. Patients were imaged with PET-CT/CT before and 2-3 months after SIRT. Retrospective case note review was performed and data correlated to evaluate tumor response (RR); hepatic and extra hepatic progression free survival (HPFS and EHPFS) and overall survival (OS). Accurate toxicity data was not recorded.

Results
Hepatic CT response rates: PR 56% (n=14), SD 28% (n=7) and PD 16% (n=4). Hepatic PET response rates: CR 32% (n=8), PR 40% (n=10), SD 12% (n=3), PD 16%(n=4). (Overall PET liver disease control rate = 84%).

Eight patients (32%) had extra-hepatic PD at first assessment. Of them, 4 had PR, 2 SD and 2 PD in the liver at that assessment. Two HER-2 +ve patients had brain metastases as first sign of PD within 75 days, an area not previously screened. Of 16 pre-treated with Capecitabine, liver CT response rates: 62.5% PR, 18.75% SD (n=10,3). Post SIRT/FOLFOX, average number of therapy lines: 2 for chemo and 0.75 for endocrine, with 8 patients still alive at time of censoring.

Median OS: 766 HPFS: 210 days (CI 140-286). Median EHPFS in patients with extra-hepatic disease: 152 days (CI 96-636).

Conclusions
SIRT with FOLFOX in previously treated BCLM patients produces high response rates, excellent tumor control and time to progression in the liver with good overall survival. It does not seem to decrease the ability to give further lines of chemotherapy and can be considered as an option for breast cancer patients with liver metastases.

Body: BACKGROUND: The SWOG S0230/POEMS study demonstrated a 70% reduction in ovarian failure (OF) with goserelin coadministration during chemotherapy (CT) for ER-negative early breast cancer (BC; Moore H et al, NEJM 2015). Goserelin use was also associated with more pregnancies as well as favorable disease free survival (DFS) and overall survival (OS). Here we report the final analysis after 5 years of follow-up.

METHODS: Premenopausal women age <50 with stage I-IIIA ER/PR-negative BC to be treated with cyclophosphamide-containing CT were randomized to receive standard CT with or without monthly goserelin 3.6 mg SQ starting at least 1 week prior to the first CT dose. The primary endpoint was OF at 2-years, defined as amenorrhea for the prior 6 months and post-menopausal FSH. Secondary endpoints included pregnancies, disease free survival (DFS) and overall survival (OS). An unplanned analysis of rate of menses recovery at 2 years (presence of menses within 6 months of the 2 year time-point or pregnancy within the first 2 years) was also conducted. OF and pregnancy endpoints were analyzed using multivariable logistic regression adjusting for stratification factors (age and CT regimen); DFS and OS were examined using multivariable Cox regression, adjusting for stratification factors and stage. Two-sided p-values are reported unless otherwise specified in accordance with protocol design.

RESULTS: Among 257 randomized participants, 218 were eligible and evaluable. One hundred thirty-six eligible and evaluable patients had OF data and 186 had menstrual data. Median age was 37.7 years. Among the 136 patients with OF data, the odds ratio (OR) for OF at 2 years was 0.30 (95% CI 0.1-0.98; one-sided p=0.023) comparing CT with goserelin to standard CT alone. Among 186 patients with menstrual data, 80% recovered menses by 2 years in the goserelin arm compared with 70% in the standard arm (OR=1.74, 95% CI: 0.83-3.66, p=0.15). Pregnancies, DFS and OS are reported for all 218 eligible and evaluable patients. With a median follow-up of 5.1 years, 22% of patients in the goserelin group had at least one pregnancy compared with 12% in the standard group (OR 2.38, 95% CI 1.08-5.26, p=0.03). Cumulative incidence of pregnancy at 5 years is 23% in the goserelin arm compared with 12% in the standard group. Five-year Kaplan-Meier DFS estimates are 88% in the goserelin arm compared with 79% in the standard arm (HR=0.50, p=0.05). Five-year OS is 92% with goserelin versus 83% in the standard arm (HR=0.47, p=0.06). Including all 257 randomized patients, HR for DFS and OS are 0.67 and 0.48 (p=0.18 and p=0.05).

CONCLUSION: Ovarian suppression with goserelin during chemotherapy for hormone receptor-negative breast cancer reduces OF risk and, after 5 years of follow-up, continues to be associated with more pregnancies and improved survival compared with chemotherapy without goserelin.

**Title:** Benefit of adjuvant chemotherapy in disease-free survival for T1N0 triple negative breast cancer

Zaida Morante\textsuperscript{a}, Gabriel De la Cruz-Ku\textsuperscript{b}, Joseph Pinto\textsuperscript{c}, Jhajaira Araujo\textsuperscript{c}, Hugo Fuentes\textsuperscript{d}, Daniel Enriquez\textsuperscript{d}, Renato Luque\textsuperscript{a}, Eduardo Eyzaguirre\textsuperscript{a}, Antonella Saavedra\textsuperscript{a}, Maria Luján\textsuperscript{a}, Silvia Neciosup\textsuperscript{d} and Henry Gomez\textsuperscript{d}. \textsuperscript{a}Universidad Cientifica del Sur, Lima, Peru; \textsuperscript{b}Instituto Nacional de Enfermedades Neoplasicas, Lima, Peru and \textsuperscript{c}Oncosalud - AUNA, Lima, Peru.

**Body:**

**Background:** Although chemotherapy is not recommended in low-risk early breast cancer, triple-negative breast cancers (TNBC) have twice risk of recurrence despite an aggressive treatment. In this study we evaluated the role of chemotherapy in the outcome of T1N0 TNBC patients in terms of disease-free survival (DFS) and overall survival (OS).

**Methods:** We evaluated a retrospective cohort T1N0 TNBC patients diagnosed between 2000 to 2014 at the Instituto Nacional de Enfermedades Neoplasicas (Lima-Peru). Survival rates differences were assessed by Log-rank test and prognostic factors were identified using the Cox proportional hazards model.

**Results:** We identified 123 T1N0 TNBC patients. The median age was 51 years (range: 28-85), where 38.5% were premenopausal. Thirty-six (29.3%) were pT1a/b and 87 were pT1c (70.7%). ACT was administered more frequently in pT1c patients (74.7% vs 55.6%; P=0.036). Locoregional relapse and distant metastases rates were 8.3% vs 19.5% and 5.6% vs 16.1% for tumors pT1a/b and pT1c, respectively. The median of follow-up was 8.8 years. Independent prognostic factors were pT stage and treatment with ACT. In relation to pT stage, DFS rates were 97% vs 78% (at 5-years) and 97% vs 70% (at 8-years) for pT1a/b vs pT1c patients, respectively (HR=4.8; 95%CI:1.46-17.0; P=0.015). In the other hand, patients treated with ACT had a better outcome with DFS rates to 5-years of 86% vs 74% and 8-years of 81% vs 65% (HR: 0.41, 95%CI: 0.17-0.97, p=0.043). Our study had not statistical power to evaluate benefit of ACT in pT1a/b patients. In cases with pT1c tumors, treatment with ACT was the only factor associated with a better DFS (HR=0.29, 95%CI: 0.11-0.77, p=0.012). Because the low mortality in our cohort, OS was not evaluable.

**Conclusions:** Treatment with adjuvant chemotherapy reduces the recurrence risk in 71% among pT1cN0 TNBC.
Management and outcomes of metaplastic breast cancer

Horatio Thomas¹, Nora Horick², Laura M Spring², Elena F Brachtel² and Rachel B Jimenez². ¹Harvard Medical School, Boston, MA and ²Massachusetts General Hospital, Boston, MA.

Body: Purpose/Objectives: Metaplastic breast cancer (MBC) is a rare malignancy composed of both epithelial and mesenchymal components that accounts for less than 1% of primary breast carcinomas. Knowledge of effective management of the disease remains limited. We retrospectively evaluated the treatment and outcomes of patients with MBC from three academic hospitals.

Materials/Methods: Patients diagnosed with MBC between June 2, 1993 and May 6, 2016 were identified. Demographic and clinical variables were extracted via primary chart review. Descriptive statistics were utilized to summarize the patient cohort's clinical course. The Kaplan-Meier method was used to obtain estimates of local control (LC) and survival.

Results: Seventy-six patients were identified with a median follow-up of 7.6 years (range: 0.18-19.9 years). The median age at diagnosis was 54 (range 28-81). About two-thirds of patients (67%, n=51) presented with a palpable mass while the remaining patients were screen-detected via mammogram (32%, n=24). The majority of patients were AJCC-7 stage I (38%, n=29) or stage II (49%, n=37), while 10% (n=8) were stage III and 3% (n=2) stage IV. About half of tumors (46%, n=35) were subtyped using WHO histologic classification of MBC. Over half of subtyped cases were spindle cell carcinoma (51%, n=18), 17% were matrix-producing carcinoma (n=6), 23% were adenocarcinoma with squamous differentiation (n=8), 6% were carcinosarcoma (n=2), and 3% were mixed (n=1). The majority of patients had triple negative disease (82%, n=62), while 13% (n=10) had HR+/HER2- disease, and 5% (n=4) had HER2+ disease. Most patients had high grade tumors (84%, n=64) and received breast conserving surgery (61%, n=46) while 39% (n=29) had mastectomies. Seventy-six percent (n=58) of patients received chemotherapy and 61% (n=46) received radiation therapy. All HR+ patients received adjuvant endocrine therapy, and 1 patient received immunotherapy. Of patients who received chemotherapy, 78% (n=45) received adjuvant therapy alone, 17% (n=10) neoadjuvant therapy alone, and 5% (n=3) both. Seventy percent (n=41) of chemotherapy regimens included a taxane. Among 74 patients without metastatic disease at presentation, recurrences were observed in 18% (n=13). Most patients recurred distantly (69%, n=9), while the remainder had isolated local recurrences (n=4). Of 9 distant failures, 3 had MBC subtype information and all 3 were spindle cell carcinoma. Of 4 local recurrences, 3 of 4 were adenocarcinoma with squamous cell differentiation and 1 was spindle cell carcinoma. At a median follow-up of 7.6 years, the local recurrence-free survival was 88%, disease-free survival was 80%, and overall survival was 80%. Kaplan-Meier point estimates for remaining free of local recurrence versus distant recurrence were 99% (95% C.I., 90-100) versus 96% (95% C.I., 87-99) at 2 years and 88% (95% C.I., 76-94) versus 87% (95% C.I., 75-93) at 5 years.

Conclusions: MBC is a rare histologic subtype that commonly presents with high-grade disease and triple-negative receptor status. In contrast to other smaller series, local and distant failure rates in this cohort were consistent with non-MBC triple negative cohorts. Additional molecular based research is warranted to further characterize features associated with local and distant failure.
**Title:** Outcome of small (≤1 cm), node-negative breast cancer

Mahvish Muzaffar\(^1\), Praveen Namireddy\(^1\), Rafaeh Naqash\(^1\), Jan Wong\(^1\) and Nasreen Vohra\(^1\). \(^1\)Brody School of Medicine/East Carolina University, Greenville, NC.

**Background:** Screening mammogram has resulted in increased diagnosis of very small breast cancers, especially less than 1 cm node negative. These small tumors have excellent prognosis with cancer-specific survival rates as high as 90% to 95%. This study evaluates outcome in different subtypes of very early breast cancer in a national population database.

**Method:** Patients with stage I breast cancer, tumor ≤1 cm with negative nodes (T1aN0 (<0.5cm), T1bN0 (≥0.5cm to ≤1 cm)) diagnosed between 2006 and 2011 were identified in the SEER database. We excluded patients with missing biomarker information. Treatment outcome and prognostic factors for disease-specific survival (DSS) and overall survival (OS) were evaluated.

**Results:** We identified 70,543 cases and included 54,796 patients with stage T1aN0M0 and T1bN0M0 in the final analysis. The mean age was 62.09 yrs. (CI 95% 62.2-61.99), 84% are white, 7% black and 7% others. 89% had ER positive tumor, 11% ER negative and 3% had Her 2 positive tumors. 71% of patients had T1b (≤1 cm). The 5-year disease specific survival (DSS) and overall survival (OS) for patients with stage T1aN0, T1bN0 was 98.7% and 93.7%, respectively. Estrogen receptor (ER) positive tumors were associated with improved 5-yr DSS 99% vs. 96% in ER negative (p<0.0001) and OS in ER positive 94% vs. 92% (p<0.0001). Among white patients 5-yr DSS was 98.8% and OS was 93.7% while 5yr-DSS was 94%, OS 91.5% among black vs. 5-yr DSS 99% and OS 96.3% in others (Asian or Pacific Islanders, AI), (p<0.0001). Tumor subtype was not associated with significant difference in outcome but T1a tumor was associated with OS 94.5% vs. 93.4% with T1b tumors (p<0.0001) On cox model analysis factors which correlated with prolonged DSS and OS are race (p<0.0001), older age (p<0.0001), ER positivity (p<0.0001) and tumor less than 5mm (p=0.0006).

**Conclusions:** Very early breast cancer is associated with excellent outcome but has some heterogeneity. Nonwhite/Non Black race was associated with better survival compared to white and black patients. ER positive tumors, and older age were also associated with better outcome. This data while reassuring also brings into question the overtreatment of this disease subset. One of the limitations of this dataset is lack of details of systemic therapy administered. Conventional prognostic factors are not sufficient to risk stratify very early breast cancer and molecular profiling may help identify patients who will need adjuvant treatment.

Title: Oncologists’ perception of anti-estrogen therapy benefit

Reema A Patel1, Stevie Maxwell1, Donglin Yan1, Emily Dressler1 and Aju Mathew1. 1University of Kentucky, Lexington, KY.

Body: Background
Recent publication of Suppression of Ovarian Function (SOFT) and Tamoxifen and Exemestane (TEXT) trials provides additional options for premenopausal women with hormone receptor (HR)-positive breast cancer in improving estrogen blockade - tamoxifen (T) plus ovarian function suppression (OFS) and aromatase inhibitors (AI) plus OFS. Analysis of these trials conclude that, for a premenopausal woman with HR-positive breast cancer with high risk features for recurrence have an absolute benefit for five-year breast cancer free interval (BCFI) would be 5% with the use of T + OFS and 10 - 15% with Al + OFS compared to the use of T-alone. However, therapeutic option decision-making is dependent on the oncologists’ perception of the benefit and risk for adjuvant anti-estrogen therapy. We aimed to evaluate an oncologist's perception of the absolute benefit for anti-estrogen therapy options in HR–positive breast cancer and identify predictors for variations in perceptions of benefit.

Methods
We designed a survey using a clinical vignette of a young, premenopausal woman with stage IIIA HR-positive breast cancer with high risk of recurrence. After obtaining Institutional Review Board (IRB) approval from the University of Kentucky, we sent online and paper survey forms to a convenience sample of 510 oncologists in the United States. Using a scale between 0 and 100, the oncologists were asked to estimate the five-year BCFI (first occurrence of invasive locoregional, distant or contralateral breast cancer) for a woman with similar characteristics if treated with the following: 1) lumpectomy (L) + Radiation (RT); 2) L + RT + chemotherapy (C); 3) L + RT + C + T x five years; 4) L + RT + C + T + OFS; and 5) L + RT + C + AI + OFS. Baseline demographics such as gender, practice setting (academic vs community), years in practice and proportion of breast cancer patients in practice were also collected.

Results
The highest estimated mean five-year BCFI for the study patient was 76.5% with the addition of AI + OFS to L + RT + C. The estimated absolute benefit for anti-estrogen therapy options: T + OFS vs T-alone was 3.4% (95% CI: 2.7 – 4.0) and for AI + OFS vs T-alone was 5.9% (95% CI: 5.1 – 6.7).

Oncologists' Perception of Absolute Benefit Therapy in Premenopausal Women with Breast Cancer

There was no difference in perception of benefit with these anti-estrogen therapy options by gender, practice setting, years in practice or proportion of breast cancer patients seen in practice.

Discussion
Regardless of their gender, practice setting, clinical experience or volume of breast cancer patients, oncologists significantly underestimate the absolute benefit for various estrogen blockade therapies when compared to the estimated benefit of data from randomized, controlled SOFT and TEXT clinical trial data. We highlight an area for improvement in quality of care that offers an immediate impact on positive outcomes for large numbers of premenopausal women with breast cancer.
Localized triple negative breast cancer in extremes of life

Zaida Morante\textsuperscript{2}, Gabriel De la Cruz-Ku\textsuperscript{1}, Joseph Pinto\textsuperscript{3}, Daniel Enriquez\textsuperscript{2}, Antonella Saavedra\textsuperscript{1}, Maria Luj\text{\~n}\textsuperscript{1}, Renato Luque\textsuperscript{1}, Eduardo Eyzaguirre\textsuperscript{1}, Hugo Fuentes\textsuperscript{2}, Silvia Neciosup\textsuperscript{2} and Henry Gomez\textsuperscript{2}. \textsuperscript{1}Universidad Cientifica del Sur, Lima, Peru; \textsuperscript{2}Instituto Nacional de Enfermedades Neoplasicas, Lima, Peru and \textsuperscript{3}Oncosalud - AUNA, Lima, Peru.

Body: Background: Triple-negative breast cancer (TNBC) in young and older patients has specific features and outcomes. While in younger patients, it is characterized by being aggressive with worse survival, in advanced ages it may have a better outcome which reasons have not yet fully elucidated. Our objective was to compare clinicopathological characteristics, treatment and survival rates between very young with elderly population diagnosed of TNBC.

Methods: We conducted a retrospective study analysis of patients with TNBC at clinical stages I-III between 2000 to 2014 at "Instituto Nacional de Enfermedades Neoplasicas". A total of 273 medical records were reviewed, our patients were divided in very young (≤35 years) and older (≥65 years) population. The Kaplan-Meier method was conducted to compare Disease-free survival (DFS) and Overall Survival (OS) by age and chemotherapy, while Cox regression analysis assessed hazard ratios.

Results: From 273 patients with TNBC, 132 were ≤35 years, and 141 were ≥65 years. Elderly population had more obesity (13.1% vs 23.6%, \textit{p}=0.03) and comorbidities (15.9% vs 46.1%, \textit{p}<0.001); 42 (15.4%) had antecedent of breast and/or ovarian cancer (≤35y vs. ≥65y - 18.2% vs. 12.8% - \textit{p}=0.22). Younger patients were diagnosed at a higher T stage (T3:27.9% vs 11.3%, \textit{p}< 0.001) and N (N0 vs N1-2, 47.6% vs 34.9%, \textit{p}=0.04), hence CS was higher among this group of age (IIIA: 24.2% vs 12.8%, \textit{p}=0.005). Pathological features, 80.3% presented high histological grade, positive margins (\textit{p}=0.008) and vascular permeation (\textit{p}=0.048) were identified in a younger population. Neoadjuvant chemotherapy (NAC) (24.2% vs 12.8%, \textit{p}=0.01), adjuvant chemotherapy (AC) (72.7% vs 46%, \textit{p}<0.001) and radiotherapy (RT) (56.8% vs 44%, \textit{p}=0.03) were less received in elderly patients, while mastectomy (51.7% vs 65.1%, \textit{p}=0.03) was mostly surgical technique used. There were no differences between locoregional (22.7% vs 32.6%, \textit{p}=0.07) and distant (31.1% vs 39%, \textit{p}=0.17) relapse rates. With a median follow-up of 8.8 years, at 5-year DFS, was better in younger patients (76% vs 60%, \textit{p}=0.02), but no difference was obtained in OS (80% vs 70%, \textit{p}=0.05). Chemotherapy showed to have an impact in a better DFS (HR:0.47, 95\%CI: 0.27-0.83) and OS (HR: 0.53, 95\%CI: 0.31-0.91, \textit{p}=0.02). Indeed, at 5-year OS was 89% for young patients with CT, 78% for elderly population with CT, 64% for ≥65y without CT and 54% for young without CT.

Conclusions: Despite the differences between characteristics of young and old patients, chemotherapy plays a critical role in DFS and OS in both populations. In elderly patients, chemotherapy should be considered in order to offer better outcomes.
Evaluation of menopausal status among breast cancer patients with chemotherapy-induced amenorrhea: A prospective study in China

Bailin Zhang¹, Rongshou Zheng¹, Qain Zhang¹ and Xiang Wang¹. ¹National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union of Medical College, Beijing, China.

Body: Background

Many pre-menopausal patients faced an unclear status of menstruation after chemotherapy, which makes it difficult for oncologists to determine the endocrinotherapy plan. This study aimed to establish a model that predicts and classifies the menstruation status of patients with CIA (chemotherapy-induced amenorrhea).

Methods

This is a hospital-based prospective study of female breast cancer patients. Inclusion criteria included patients diagnosed with breast cancer with a complete medical record of menses. Multivariate models were adjusted for established and potential confounding factors including age, serum concentration of estradiol (E2) and follicle-stimulating hormone (FSH), feeding, pregnancy, parity, abortions, and body mass index (BMI). The hazard ratios and 95% confidence intervals of different risk factors were estimated.

Results

From 2013 to 2016, 1,796 breast cancer patients were included in this study. Among them, 1,175 (65.42%) were pre-menopausal and 621 (34.58%) were post-menopause. The average age of natural menopause was 49.99 ± 3.24.

550 patients were included in CIA analysis, and 449 patients (81.64%) had CIA. As patients older than 60 years were defined as post-menopausal and low proportion of post-menopausal patients among people under 45 years old (4.83%), the target population of menopausal status estimation of patients focused on 1,142 patients aged 45 to 60 years old in this study. Age was found to be associated with menopausal status (OR: 1.856, 95% CI: 1.732-1.990). Other factors included, serum concentrations of E2 (OR: 0.976, 95% CI: 0.972-0.980) and FSH (OR: 1.060, 95% CI: 1.053-1.066), menarche age (OR: 1.074, 95% CI: 1.009-1.144) and number of abortions (OR: 0.829, 95% CI: 0.736-0.933). According to multivariate analysis, menopausal status was correlated with age, serum concentration of E2 and FSH. The model is: Logit (p) = -28.396+0.536Age-0.014E2+0.032FSH.

When $P$ is greater than 0.5, then the patient's menstrual state will be classified as post-menopausal. The areas under the ROC curve (AUC) were 0.9220, 0.8561 and 0.8769, respectively for the single factors of age, E2 and FSH, but the comprehensive model's AUC reached 0.9678. To examine the performance of this model, sensitivity analyses and model validation were conducted using external validation cohort (n=3,073), Leave-One-Out Cross Validation test, 10%, 20%, 30%- fold cross validation check, and Back substitution check. The results show that the sensitivities for different methods were about 85%, and the specificities were higher than 89%.

According to the estimation of National Center Cancer Registry of China and the result of a national-wide Chinese retrospective study, about 137.7 thousands newly diagnosed female breast cancer aged 45-60 each year. Among them, 30.72% was hormone receptor positive, and 41.4 thousands (14.85%) patients annually probably be influenced by chemotherapy and decisions regarding endocrine therapy must be concerned.

Conclusions

The discriminative model obtained from this study for predicting menstrual state is important for pre-menopausal breast cancer patients with CIA. This model has high levels of specificity and sensitivity. A large numbers of patients probably be benefited from this study.
Title: Tumor subtype concordance between breast and bone biopsies in bone only metastasis patients

Amanda M Parkes¹, Katherine K Clifton¹, Aydah Al Awadhi¹, Oluchi C Oke¹, Carla L Warneke¹, Jennifer K Litton¹ and Gabriel N Hortobagyi¹. ¹The University of Texas MD Anderson Cancer Center, Houston, TX.

Body: Background:
Bone is the most common site of metastasis in metastatic breast cancer patients. Notably, bone biopsy is considered technically challenging with concerns regarding yield and reproducibility of immunohistochemistry technique. Our goal was to assess tumor subtype concordance between breast and bone biopsies done in patients with bone only metastases.

Methods:
We identified patients followed at MD Anderson Cancer Center for at least 6 months from 01/01/1997 to 12/31/2015 with bone as first site of metastasis. Breast and bone biopsy immunohistochemistry was used to categorize tumor subtype with hormone receptor positive (HR+) defined as ER or PR >1%. The following four tumor subtypes were identified: luminal A-like (HR+, HER2-), luminal B-like (HR+, HER2+), triple negative (HR-, HER2-), and HER positive (HR-, HER2+).

Results:
We identified 805 bone only metastasis patients with positive bone biopsies, 395 (49%) of which had hormone receptor and HER2 characterization available. Of these 395 patients, 293 (74%) were luminal A-like, 44 (11%) were luminal B-like, 51 (13%) were triple negative, and 7 (2%) were HER2 positive. Of these patients, we identified 281 patients with tumor subtype data available for both primary breast biopsy and bone metastasis biopsy, of which 237 (84%) were concordant, while 44 (16%) were discordant (Table 1).

Table 1. Concordance between breast and bone biopsies based on initial breast biopsy tumor subtype

Conclusions:
When available, bone biopsy tumor subtype had significant concordance with breast biopsy tumor subtype in this large study of bone only metastasis patients. Discordant tumor subtype results were more common in patients with luminal B-like tumor subtype on initial breast biopsy.
Title: Phase II study of the feasibility and safety of radium-223 dichloride in combination with hormonal therapy and denosumab for the treatment of patients with hormone receptor-positive breast cancer with bone-dominant metastasis

Rie K Tahara¹, Takeo Fujii¹, Babita Saigal¹, Nuhad K Ibrahim¹, Senthil Damodaran¹, Carlos H Barcenas¹, James L Murray¹, Beth A Chasen¹, Yu Shen¹, Diane D Liu¹, Gabriel N Hortobagyi¹, Debasish Tripathy¹ and Naoto T Ueno¹. ¹The University of Texas MD Anderson Cancer Center, Houston, TX.

Body: Background
Radium-223 dichloride (Ra-223) is a therapeutic alpha particle-emitting radiopharmaceutical compound which have antitumor effect targeted on bone metastases. Alpha particles induces double strand DNA breaks and localized cytotoxic effect to cancer cells with limiting harm on normal tissues. We are conducting a phase II clinical trial of combination of Ra-223, hormonal therapy, and denosumab treatment in patients with hormone receptor (HR)-positive bone-dominant metastatic breast cancer (NCT02366130). In this preliminary analysis of the study, we aimed to evaluate the feasibility and safety of this combination therapy.

Methods
This single-center phase II study seeks to determine the efficacy and safety of Ra-223 in combination with hormonal therapy and denosumab. Major eligibility criteria include HR-positive breast cancer with bone and/or marrow predominant metastases. Patients with two or more visceral metastases were not eligible. There was no limit in the number of prior hormonal therapies in the metastatic setting. Patients received Ra-223 injection (55 kBq/kg intravenously) on day 1 of the study and then every 4 weeks thereafter for 6 cycles. Patients were also administered a single hormonal agent (i.e., tamoxifen, aromatase inhibitor, or fulvestrant at standard doses) daily and denosumab (120 mg subcutaneously) every 4 weeks. For this analysis, adverse events (AEs) were summarized using descriptive statistics.

Results
A total of 25 patients were enrolled and 22 were evaluable between March 2015 and December 2016. Median age was 58.5 years (range 31-79), and 59% of patients were postmenopausal. ECOG performance status was 0 in 16 patients (73%), and 1 in six patients (27%). HER2/neu was positive in only one patient. Four patients (18%) were de novo metastasis, no patients had visceral metastasis, and multiple bone metastases in 20 patients (91%) vs. focal metastasis in 2 (9%). Median time from diagnosis of bone metastasis was 4.8 months (range 0.5-96.6). Prior therapy for metastatic disease consisted of hormonal therapy in 50% of the patients (eight patients with one line and three patients with two lines), chemotherapy (9%), palbociclib (14%), radiation to bone metastasis (50%), and bone-supportive therapy (27% with zoledronic acid, 27% with denosumab). The median number of cycles of Ra-223 administered was 6 (range 4-6).

The median follow-up time was 4 months (range 2-8). There were no grade 3 or 4 AEs. Major non-hematological grade 1 and 2 AEs were bone pain (77%), fatigue (45%), nausea (36%), diarrhea (32%), AST/ALT elevation (23%), hot flashes (23%), and headache (18%). The most common hematological AEs were grade 1 or 2 neutropenia (23%), anemia (14%), and thrombocytopenia (18%). There was no treatment delay or discontinuation due to AEs.

Conclusion
Our results suggest that the addition of Ra-223 to hormonal therapy and denosumab is a feasible and safe combination therapy in patients with HR-positive breast cancer with bone-dominant metastasis. We continue to enroll patients in the phase II trial to evaluate the efficacy of the treatment.
Title: An open-label, multicenter phase 1b trial of radium-223 + paclitaxel in cancer patients with bone metastases: Safety results from the breast cancer patient subgroup

Sarah J Danson¹, Ruth Perets², Juanita Lopez³, Heikki Joensuu⁴, Avivit Peer², Samuel J Harris³, Fabricio Souza⁵, Bart Ploeger⁶, Kaline MC Pereira⁷ and Ravit Geva⁸. ¹Sheffield Experimental Cancer Medicine Centre, Weston Park Hospital, Sheffield, United Kingdom; ²Rambam Health Care Campus, Haifa, Israel; ³The Royal Marsden Hospital and The Institute of Cancer Research, Sutton, United Kingdom; ⁴Helsinki University Hospital, Helsinki, Finland; ⁵Bayer HealthCare Pharmaceuticals, Whippany, NJ; ⁶Bayer Pharma AG, Berlin, Germany; ⁷Bayer Pharma AG, São Paulo, Brazil and ⁸Tel Aviv Sourasky Medical Center, Tel Aviv, Israel.

Body: Background: Taxanes have an established role in treating breast cancer (BC), and combination with radium-223 (Ra-223) may be an option in patients (pts) with bone metastases. Both therapies impact hematologic parameters, but myelosuppression risk in combination is unknown. A phase 1b trial (NCT02442063) in cancer pts with bone metastases studied Ra-223+paclitaxel (PTX) safety and mode of interaction regarding myelosuppression; BC subgroup safety results are presented.

Methods: Eligible pts had a malignant solid tumor with ≥2 bone metastases and were PTX candidates. Treatment (tx) was 7 PTX cycles (90 mg/m²/wk IV per local standard of care, 3 wk on/1wk off) + 6 Ra-223 cycles (55 kBq/kg IV; 1 injection q4wk, starting at PTX cycle 2). Primary endpoint was % pts with neutropenia and thrombocytopenia during Ra-223+PTX (cycles 2, 3) vs PTX alone (cycle 1). A dose-exposure-response model describing time course of Ra-223+PTX–induced suppression of absolute neutrophil counts was used to evaluate Ra-223+PTX mode of interaction (additive or synergistic) in the total population.

Results: 15/22 enrolled pts were treated (total population); 7 had BC (BC subgroup). Baseline characteristics of the 2 groups were similar; ECOG PS was better in BC pts (Table). Fewer BC pts had prior taxane therapy (29% vs 53%), but rates of ≥3 prior chemotherapy regimens were similar (43% vs 47%). BC pts, vs total population, had slightly longer median tx duration for Ra-223 (6 vs 5.5 cycles) and PTX (7 vs 6 cycles), and more pts who completed 6 Ra-223 doses (57% vs 47%). Tx discontinuation related to disease progression in 29% of BC pts vs 33% in total population. Table shows TEAEs. In the BC subgroup, all 7 pts completed cycle 3 and Gr 3 neutropenia rates were 43% in cycle 2 and 14% in cycle 3, vs 29% in cycle 1; there was no Gr 4 neutropenia or Gr 3/4 thrombocytopenia. In the total population, 13 pts completing cycle 3 were in the pharmacodynamics analysis. Their Gr 3 neutropenia rates were 31% in cycle 2 and 8% in cycle 3, vs 23% in cycle 1; there was no Gr 4 neutropenia or Gr 3/4 thrombocytopenia. Myelosuppression model for the total population showed an additive effect of Ra-223 to PTX-induced neutropenia, with an additional 10% average decrease in absolute neutrophil count vs PTX alone. BC subgroup modeling was not feasible due to small sample size.

TEAE = treatment-emergent adverse event.

*In >15% of patients.

**Conclusions:** Ra-223 was well tolerated when combined with PTX in pts with solid tumors and bone metastases. The BC subgroup vs total population had slightly higher hematologic AE rates, but fewer Gr 3/4 and serious TEAEs; more BC pts also completed study tx. The combination should be explored further in pts with bone metastases.
Somatic mutations, clinicopathologic characteristics, and survival in patients with untreated breast cancer with bone-only and non-bone sites of first metastasis

Miho Kono, Takeo Fujii, Naoko Matsuda, Kenichi Harano, Huiqin Chen, Chetna Wathoo, Joon Y Aron, Debu Tripathy, Funda Meric-Bernstam and Naoto T Ueno. 1Section of Translational Breast Cancer Research, The University of Texas MD Anderson Cancer Center, Houston, TX; 2The University of Texas MD Anderson Cancer Center, Houston, TX; 3Department of Biostatistics, Houston, TX; 4Sheikh Khalifa Bin Zayed Al Nahyan Institute for Personalized Cancer Therapy, The University of Texas MD Anderson Cancer Center, Houston, TX and 5Department of Investigational Cancer Therapeutics (Phase I Clinical Trials Program), Houston, TX.

Body: Background: Bone is the most common site of metastasis of breast cancer, and bone metastasis is associated with a high rate of skeletal-related events, all of which contribute to decreased quality of life and poor outcomes. Biological mechanisms of metastasis to bone may be unique, and identification of distinct signaling pathways and somatic mutations may provide biological insight into or rational targets for treatment of and prevention of bone metastasis. The aims of this study were to compare and contrast somatic mutations, clinicopathologic characteristics, and survival in breast cancer patients with bone only versus non-bone as first metastatic site.

Methods: Tumor samples were collected from 389 patients who had metastasis and untreated primary breast cancer. In each sample, 46 or 50 cancer-related genes were selectively amplified and analyzed for mutations by AmpliSeq Ion Torrent next-generation sequencing. We used Fisher’s exact test to identify somatic mutations associated with bone-only first metastasis and logistic regression models to identify differences in clinicopathologic characteristics, survival, and somatic mutations between patients with bone-only first metastasis and patients with first metastasis in non-bone sites only (“other-only first metastasis”).

Results: Among the 389 patients, the first metastasis was located in bone only in 72 patients (18.5%), non-bone sites only in 223 patients (57.3%), and both in 94 patients (24.2%). Of the cancer-related genes analyzed, the most commonly mutated were TP53 (N=103), PIK3CA (N=79), AKT (N=13), and PTEN (N=2). Compared to patients with other-only first metastasis, patients with bone-only first metastasis had higher rates of hormone-receptor-positive disease, non-triple-negative subtype, and low nuclear grade (grade 1 or 2) (all 3 comparisons, p<0.001); had a lower ratio of cases of invasive ductal carcinoma to cases of invasive lobular carcinoma (p=0.002); and tended to have a higher 5-year overall survival (OS) rate (78.2% [95% confidence interval (CI), 68.6%-89.0%] vs 55.0% [95% CI, 48.1%-62.9%]; p=0.051). However, in the subgroup of patients with TP53 mutation and in the subgroup of patients with PIK3CA mutation, OS did not differ between patients with bone-only and other-only first metastasis (p=0.49 and p=0.68; respectively). In univariate analysis, the rate of TP53 mutation tended to be lower in patients with bone-only first metastasis than in those with other-only first metastasis (15.3% vs 29.1%; p=0.051). In multivariate analysis, TP53 mutation was not significantly associated with site of first metastasis (p=0.54) but was significantly associated with hormone-receptor-negative disease (p<0.001).

Conclusions: We did not find associations between somatic mutations and bone-only first metastasis in patients with untreated breast cancer. Patients with bone-only first metastasis have longer OS than patients with other-only first metastasis. More comprehensive molecular analysis may be needed to further understand the factors associated with bone-only metastatic disease in breast cancer.
Incidence of skeletal-related events in patients suffering of bone metastasis from breast cancer treated with bisphosphonates or denosumab

Anika von Heesen¹, Katja Nilges¹, Julia Radosa¹, Lena Gabriel¹, Erich-Franz Solomayer¹ and Ingolf Juhasz-Böss¹. ¹University of Saarland, Homburg, Saarland, Germany.

Body: Background
Bone is a frequent site of metastases and typically indicates a short-term prognosis in breast cancer patients. Bone metastasis can rarely be cured, but often it can still be treated to slow down its growth and to improve quality of life. The relative incidence of bone metastases in patients with advanced metastatic breast cancer is 65-75%. Bisphosphonates and the human monoclonal RANKL-antibody Denosumab are the most common medical treatment of bone metastasis. Therefore we investigated their effect on skeletal-related events (SRE) in our patient collective.

Materials and methods:
A retrospective analysis of 143 patients with histologically proven breast cancer and bone metastasis at the department of Gynaecology and Obstetrics at the University of Saarland (Germany) between October 2009 and October 2013. SREs were defined as a pathological fracture, a bone surgery, a spinal cord compression and a radiation of bone metastasis. Patients were distributed into 5 different groups according to the treatment received. Group 1: bisphosphonate (n=63), Group 2: denosumab (n=55), Group 3: bisphosphonate switch to denosumab (n=16), Group 4: denosumab switch to bisphosphonate (n=4), Group 5: no anti-resorptive therapy (n=5). Progression of the bone metastasis without skeletal-related event (SRE) was defined as progressive disease.

Results:
At the time of diagnosis of the breast cancer the average age was of 55,2±13,1 years. At the time of data collection n=53 patients were alive, n= 83 had died during follow up, and n= 7 were lost-of follow up. The median follow up from the first diagnosis of the primary breast cancer and the end of data collection was of 88,6 ± 78,5 month. In 103 (72%) patients bone metastases were detected secondarily. 83 patients recieved an anti-resorptive therapy with bisphosphonates (q4w), 75 patients were treated with denosumab (q4w).

In the overall collective, an SRE occured in 95 patients. 65.1% of Group 1(bisphosphonate) and 65.5% of Group 2 (densosumab) patients suffer from an SRE. In the non-treatment Group 2, 5 patients were diagnosed with SRE. The Switch groups showed the most frequent SREs (Group 3: 81,3%), (Group 4: 75,0%) the median duration of treatment prior to the first SRE was 12,33 month in Group 1, 1,5 month in group 2, 38,2 month in Group 3 and 4 month in group 4.

63 of 95 patients received a treatment modification after the first SRE. The time period between the first and second SRE was 31,8 month in Group 1, 10,38 month in group 2, 38,71 month in group 3, 10 month in group 4 and 3 month in group 5.

3,5% of all patients in the overall collective were diagnosed with an osteonecrosis of the Jaw.

Conclusion
This data suggests that the anti-resorptive therapy with densoumab is equal to the bisphosphonate therapy to prevent the first skeletal-related event in patients with bone metastasis of breast cancer. After the first SRE patients benefit significantly of an anti-resorptive therapy compared to no treatment. In our population the prevention of a second SRE in group 3 (bisphosphonate switch to denosumab)showed the best results.
Body: Background: The incidence of brain metastases (BM) in breast cancer patients is rising and has become a major clinical challenge. So far, the incidence of BM after modern neoadjuvant treatment is not clear.

Materials and Methods: In Geparquinto, patients with untreated HER2-positive breast cancer (n=615) received either lapatinib or trastuzumab, patients with HER2 negative breast cancer (n=1925) received bevacizumab in addition to an anthracycline and taxane-containing regimen and those not responding paclitaxel and everolimus (n=32). In Geparsixto, patients with HER2-positive tumors (n=273) received trastuzumab and lapatinib and patients with triple-negative tumors (n=315) received bevacizumab in addition to chemotherapy. We analyzed clinical factors associated with the occurrence of BM as first site of metastatic relapse after neoadjuvant treatment in both trials (n=3160).

Results: After a median follow-up of 61 months, 108 (3%) of a total of 3160 patients developed BM as first site of recurrence and 411 (13%) patients had distant metastases outside the brain. Brain metastases as first site of recurrence occurred later than other metastases (3-year-relapse free-rate 96.7% for patients who developed BM and 89.5% for patients who developed metastases outside the brain). Regarding subtypes of the primary tumor, 1% of luminal A (11/954), 2% of luminal B (7/381), 4% of HER2 positive (34/809) and 6% of triple-negative patients (56/1008) developed BM as first site of recurrence. In multivariate analysis, risk factors for the development of BM were larger tumor size (cT3-4; HR 1.9, 95%-CI 1.3-2.8, p=0.0022), node positive disease (HR 2.8, 95% CI 1.8-4.4, p<0.0001), no pCR after neoadjuvant chemotherapy (HR 2.7, 95% CI 1.6-4.7, p=0.0003) and HER2 positive (HR 3.8, 95% CI 1.9-7.8, p=0.0002) or triple-negative subtype (HR 8.1, 95% CI 4.2 – 15.8, p< 0.0001). Breast cancer subtype remained the most relevant risk factor for BM. Patients who developed BM were more often HER2 positive or triple-negative tumors compared with patients who developed metastases outside the brain (HER2 positive subtype 32 vs. 19%, triple-negative subtype 52 vs. 40%, p< 0.001).

Conclusion: Especially patients with HER2-positive and triple negative tumors are at risk of developing BM despite active systemic treatment. A better understanding of the underlying mechanisms is required in order to develop potential preventive strategies.
Title: Ado-trastuzumab emtansine (TDM-1) treatment and brain metastases in HER2 positive metastatic breast cancer patients: Final analysis of an Italian multicenter study

Alessandra Fabi¹, Daniele Alesini², Enrichetta Valle³, Luisa Carbognin⁴, Graziella Arpino⁵, Filippo Montemurro⁶, Mariangela Ciccarese⁷, Katia Cannita⁸, Ida Paris⁹, Maria Concetta Cursano¹⁰, Luca Moscetti¹¹, Gianluigi Ferretti¹², Michelino De Laurentiis¹³, Alberto Zambelli¹⁴, Nicla La Verde¹⁵, Cecilia Nisticò¹⁶, Simona Gasparro¹⁷, Diana Giannarelli¹⁸ and Francesco Cognetti¹⁹.

Body: Background: Ado-trastuzumab emtansine (T-DM1) is a drug-antibody conjugate whose activity has been confirmed in HER2+ advanced breast cancer (BC) patients by the phase 3 EMILIA trial (Verma et al, NEJM 2012). Within the 991 patients enrolled in this trial, about 10% were affected with brain metastases (BM); in this subgroup, safety and efficacy of T-DM1 were confirmed although without any PFS improvement.

Patients and methods: In an Italian, multicenter, retrospective analysis involving 303 patients with advanced BC treated with T-DM1 (Fabi et al, Oncotarget 2017), we analyzed 87 patients with BM (BM-group). The study wanted to evaluate the efficacy of T-DM1 on BM; furthermore we compared BM-group with the remaining 216 patients without BM (nBM-group) in order to study outcome of disease. MRI was used as assessment imaging.

The number of extracranial metastatic sites in the BM-group and in the nBM-group was 1 for 10 (11.5%) and for 74 patients (34.3%), 2 for 23 (26.4%) and 93 (43%) patients, 3 for 25 (28.7%) and 38 (17.6%) and 4 or more for 29 (33%) and 11 (5%), respectively.

In the BM-group, 5 patients (5.7%) had received surgery alone as local treatment for brain metastases, 13 (14.9%) surgery plus stereotactic radio-surgery (SRS), 4 (4.7%) surgery plus whole-brain radiotherapy (WBRT), 23 (26.5%) SRS alone, 40 (45.9%) WBRT alone and 2 (2.3%) WBRT followed by SRS. Twenty-eight patients (32.9%) and 89 (42.4%) in the BM-group and nBM-group, respectively, received T-DM1 as second line, 24 (28.2%) and 49 (23.3%) as third line and 33 (38.8%) and 72 (34.3%) as fourth line. Mean number of cycles was 6 in both groups.

Results: Among BM-group, 53 patients (60.9%) were evaluable for response. Two (3.8%) obtained brain complete response, 14 (26.4%) partial response and 13 (24.5%) stable disease [brain disease control rate: 54.7%); 24 (45.3%) progressed during T-DM1.

Regarding extracranial metastases, overall response rate was 35.1% in the BM-group and 38.3% in the nBM-group; 6 months-clinical benefit was 50.6% and 52.3%, respectively. Median PFS was 7 months in the BM-group and 8 months in the nBM-group; when T-DM1 was given as second line, median PFS was 5 months in the BM-group and 11 months in nBM-group (p=0.01) while as third, line in which 76% of patients received lapatinib/capacitabine before TDM1, median PFS was 12 and 13 months (p=NS), respectively.

Conclusions: T-DM1 showed a good activity on BM in BC patients. A better outcome was shown in patients previously treated with lapatinib. The identification of clinical and biological prognostic factors could be needed to better select more responder patients with BM to T-DM1.
Title: Abemaciclib for the treatment of brain metastases secondary to hormone receptor positive breast cancer

Thomas Bachelot¹, Peter Kabos², Denise Yardley³, Véronique Dieras⁴, Timothy Costigan⁵, Suzanne Klise⁵ and Ahmad Awada⁶.
¹Centre Léon Bérard, Lyon, Cedex, France; ²University of Colorado Denver School of Medicine, Aurora, CO; ³Tennessee Oncology, Nashville, TN; ⁴Institut Curie Paris and Centre Eugene Marquis Renne, Paris, Cedex 05, France; ⁵Eli Lilly and Company, Indianapolis, IN and ⁶Institut Jules Bordet, Brussels, Belgium.

Body: Background: Although a lower percentage of patients with hormone receptor-positive (HR+) metastatic breast cancer (MBC) develop brain metastases when compared with triple negative and HER2+ MBC patients, there are no regulatory approved systemic agents for the treatment of HR+ breast cancer brain metastases, and this remains an unmet medical need. Standard local treatment options include surgery, stereotactic radiosurgery (SRS), and/or whole brain radiation therapy (WBRT). Abemaciclib, an oral selective CDK4 and 6 inhibitor administered on a continuous dosing schedule, has demonstrated clinical activity and an acceptable safety profile in heavily pre-treated HR+ MBC patients. Preclinically, abemaciclib crosses the blood-brain barrier, which is further supported clinically by detectable levels of abemaciclib similar to plasma levels in resected brain metastases in a subset of patients with HR+, HER2- MBC as previously reported for the current study. Together these data provide further rationale for evaluating abemaciclib in patients with brain metastases.

Methods: Study I3Y-MC-JPBO (NCT02308020) is an open-label, Phase 2, Simon 2-Stage trial evaluating the safety and efficacy of abemaciclib up to 200 mg BID in 4 cohorts of patients with brain metastases secondary to HR+ MBC, NSCLC, or melanoma. With regard to HR+ MBC, one cohort included HR+, HER2- patients, another one included HR+/HER2+ patients. All HR+ MBC patients enrolled to 1 of these 2 cohorts were required to have at least 1 measurable brain lesion. The primary objective was objective intracranial response rate as defined by Response Assessment in Neuro-Oncology brain metastases response criteria. Stage 1 was to enroll 23 evaluable patients per study part; if ≥2 respond to abemaciclib, 33 additional evaluable patients were to be enrolled to Stage 2. Secondary CNS objectives include best overall response, duration of response, and clinical benefit rate.

Results: For Stage 1 efficacy, in patients with HR+, HER2+ MBC futility was met. However, for HR+, HER2- patients, 2 confirmed, durable partial responses were observed and enrollment to Stage 2 is ongoing.

Conclusions: Previously, this study provided evidence that abemaciclib penetrates brain metastases in patients with HR+, HER2- MBC. The current results provide sufficient evidence of anti-tumor activity on brain metastases in patients with HR+, HER2- MBC to merit further exploration, but not for patients with HR+, HER2+ disease. Safety and tolerability results are similar to those previously reported for abemaciclib, with the majority of adverse events being gastrointestinal.
Clinical presentation and outcome of leptomeningeal metastasis in patients with breast cancer in relation to histology and tumor subtypes

Gaia Griguolo\textsuperscript{1,2}, Stephane Pouderoux\textsuperscript{3}, Maria Vittoria Dieci\textsuperscript{1,2}, William Jacot\textsuperscript{3}, Céline Bourgier\textsuperscript{4,5}, Federica Miglietta\textsuperscript{1,2}, Nelly Firmin\textsuperscript{3}, PierFranco Conte\textsuperscript{1,2}, Marie Viala\textsuperscript{3}, Valentina Guarnieri\textsuperscript{1,2} and Amélie Darlix\textsuperscript{3}.

\textsuperscript{1}Istituto Oncologico Veneto IRCCS, Padova, Italy; \textsuperscript{2}University of Padova, Padova, Italy; \textsuperscript{3}Institut Régional du Cancer de Montpellier (ICM), Montpellier, France; \textsuperscript{4}Institut Régional du Cancer de Montpellier (ICM), Montpellier, France and \textsuperscript{5}Institut de Recherche en Cancérologie de Montpellier (IRCM), INSERM U1194, Université de Montpellier, Institut Régional du Cancer de Montpellier (ICM), Montpellier, France.

Body: Background: Among solid tumors, breast cancer (BC) is one of the most common cause of leptomeningeal metastases. Leptomeningeal disease (LMD) typically carries a devastating prognosis; however, disease presentation and prognostic factors are still uncertain. The aim of this study was to characterize clinical features of LMD in relation to BC histology and subtypes.

Patients and Methods: 104 patients (pts) with LMD from BC diagnosed between 2002 and 2017 at two European institutions were included. LMD diagnosis was based on the presence of neoplastic cells on cerebrospinal fluid examination and/or radiological evidence of LMD. Patients’ characteristics and their associations with time from LMD to death or last follow up were evaluated by the Kaplan-Meier method, log-rank tests, and Cox proportional hazard models.

Results: Median age at LMD diagnosis was 56 yrs (range 26-75). Tumor histology (n=102) was ductal in 72 pts (70.6%), lobular in 22 (21.6%) and other histology in 8 (7.8%, including mixed ductal and lobular tumors). Tumor phenotype distribution was as follows: hormone receptor (HR)+/HER2- 54.8%, triple-negative (TN) 14.4%, HR+/HER2+ 12.5%, HR-/HER2+ 6.7% and unknown 11.5%. LMD diagnosis was cytologically proven (n=64, 62.7%) and/or radiologically proven (n=88, 85.4%). At time of LMD diagnosis, 63 pts (58.9%) had an ECOG performance status (PS) ≤ 2. 91 pts (87.5%) had extra-CNS disease localizations and 20 (18.7%) had a history of known BC brain metastasis (BM) (predating LMD diagnosis of more than 30 days). In lobular BC, LMD diagnosis was more frequently made in the absence of a known history of BM compared with ductal BC (95.5% vs 73.3%, Fisher test \( p = 0.036 \)). A majority of pts was treated with intrathecal (n=59, 55.1%) or systemic treatment (n=73, 68.2%) after LMD diagnosis, while only a minority underwent radiotherapy (n=28, 26.2%) or surgical derivation procedures (n=14, 13%). Median overall survival (OS) from LMD diagnosis was 3.2 months (95% CI, 1.9-4.4 months). No significant difference was observed across tumor phenotypes, with HER2+ subgroups experiencing better outcomes (median OS: 2.9, 1.6, 6.6 and 12.9 months in HR+/HER2-, TN, HR+/HER2+ and HR-/HER2+ subgroups; \( p = 0.54 \)). In univariate analysis, ECOG PS ≤ 2 at LMD diagnosis, intrathecal treatment and systemic treatment after LDM diagnosis were significantly associated with an improved OS (see table). Multivariate analysis showed that only ECOG PS ≤ 2 and systemic treatment after LMD diagnosis were independent factors associated with OS (see table). Updated results on an extended cohort of about 150 patients total will be presented at the meeting.

Conclusions: LMD carries a dismal prognosis. The results of this series highlight that patient-related features and treatments (in particular the use of systemic treatment) contribute to modulate the prognosis of BC pts with LMD.
**Title:** Prognostic impact of initial treatment modality for brain metastasis in metastatic breast cancer

*1*Yonsei University College of Medicine, Seoul, Korea and *2*Yonsei University College of Medicine, Seoul, Korea.

**Body:** Background: The routine screening of brain metastasis (BM) is not recommended in patients with metastatic breast cancer (MBC) by guidelines. Due to survival improvement and increased use of magnetic resonance imaging (MRI) contribute the increasing of MBC BM incidence. The incidence of BM and survival from BM were various by molecular subtypes. The prognostic role of early detection of oligo BM and subsequent local treatment by subtypes is not clear. We aimed to compare BM free survival (BMFS) and BM overall survival (BMOS) by both treatment modalities and subtypes.

Methods: In the Yonsei Breast Cancer MBC Database, we identified 1252 MBC patients who were diagnosed from 2006 to 2016. Data of 358 MBC patients (127 HR+/HER2-, 80 HR+/HER2+, 64 HR-/HER2+, 87 HR-/HER2-) with BM were available for the analysis. BMFS was defined as the time from the diagnosis of MBC to the diagnosis of BM. MBC patients with initial BM were excluded from analysis of BMFS. BMOS was defined as the time from the diagnosis of BM to any cause of death. Treatment modalities were analyzed as three categories; whole brain radiotherapy (WBRT), stereotactic radiosurgery (SRS), and neurosurgery.

Results: Among the 1252 MBC patients, 47.7%, 14.7%, 13.1%, 17.6%, and 6.9% had HR+/HER2-, HR+/HER2+, HR-/HER2+, HR-/HER2-, and unknown subtypes, respectively. The incidence of initial BM were highest among patients with HR-/HER2- (14.5%) and were lowest with HR+/HER2- (5.2%)

</table>

The median BMFS was 17.3 months (95% confidence interval (CI); 14.32-20.28) among the all patients with BM. The median BMFS was significantly shorter in the ER-/HER- subtypes (12 months, 95% CI; 20.73-31.67), and followed by ER-/HER2+ (14.8 months, 95% CI; 11.50-18.10), ER+/HER2+ (20.9 months, 95% CI; 16.88-24.92), and ER+/HER2- (26.2 months, 95% CI; 20.73-31.67). The median BMOS was significantly better in the SRS (16.8 months; 95% CI; 13.53-20.07) and surgery group (13.4 months, 95% CI; 7.19-19.61) compared with WBRT (6.9 months, 95% CI; 5.04-8.76) and no treatment (1.2 months, 95% CI; 0.32-2.08).

Conclusions: Incidence of initial BM and BMFS were significantly different by subtypes. Patients who were treated with SRS or neurosurgery showed better survival compared to WBRT. This findings support to consideration of screening of BM in HER2+ or triple negative subtypes for the early detection of oligo BM.
Title: Outcomes of central nervous system radiotherapy for metastatic breast cancer: The Royal Marsden experience 2000 - 2016

Gargi Kothari¹, Paolo B De Ieso², Kabir Mohammed¹ and Gillian M Ross¹. ¹The Royal Marsden NHS Foundation Trust, Sutton and London, United Kingdom and ²Alan Walker Cancer Centre, Darwin, Northern Territory, Australia.

Body: Background: Breast cancer (BC) is one of the most common malignancies affecting women. Brain metastases (BM) are frequently seen in BC, and can have devastating consequences with significant associated morbidity and mortality. Whole brain radiotherapy (WBRT) is commonly used to treat BM, with variable use of stereotactic radiotherapy (SRT). This study reports on the outcomes of BC patients with BM who received central nervous system (CNS) radiotherapy over a 17-year period at the Royal Marsden Hospital (RMH).

Methods: We included all BC patients who had WBRT with or without SRT for intra-parenchymal BM secondary to BC at RMH between 2000 and 2016 inclusive. Instances of meningeal involvement were excluded from analysis. Data collected included age, histological subtype, tumor grade, stage at original BC presentation, receptor status, date of BM diagnosis, number of metastases, size of largest BM, Eastern Cooperative Oncology Group (ECOG) score, presence of extra-cranial metastases (ECM), neurosurgery (NS) and stereotactic radiotherapy (SRT) details, and date of last follow up or death. Univariate and multivariate analyses were performed to analyze the effect of each variable on overall survival (OS) from date of BM.

Results: A total of 426 patients were included with a median age of 54 years at BM diagnosis and a median time to BM from BC diagnosis of 43 months. At diagnosis, 94% had invasive ductal carcinoma (IDC) and 70% had Grade 3 disease. Stage IV disease at original BC presentation was seen in 18% of patients. Estrogen receptor (ER+) was positive in 57% (n = 236), progesterone receptor (PR+) in 44% (n = 147), and HER2 (HER2+) in 44% (n = 166). Twenty-two percent (n = 89) were triple negative (TN). Median number of BM was 4 (range 1 – 205) and 20% (n = 72) of patients had only 1 BM. Average size of the largest lesion was 26 mm (range 1 – 75). The ECOG score was 0 – 1 in 61% of patients. Ten percent of patients (n = 44) underwent SRT and 10% (n = 43) underwent NS. Three hundred and eighty patients had died at the time of analysis. Median OS from date of BM was 6.4 months. On univariate analysis, age < 60 years at BC diagnosis (8.1 vs. 4.0 months, p = 0.0007) and BM diagnosis (8.0 vs. 5.6 months, p = 0.03), ECOG status 0-1 (9.6 vs. 4.0 months, p = <0.0001), ER+ (8.0 vs. 6.0 months, p = 0.0007), PR+ (7.6 vs. 6.9 months, p = 0.04), HER2+ (10.5 vs. 5.6 months, p < 0.0001), SRT (20.3 vs. 5.9 months, p < 0.0001) and NS (20.3 vs. 6.2 months, p < 0.0001) significantly predicted for improved OS. Triple negative status predicted for worse survival (5.6 months vs. 8.1 months, p < 0.0001). On multivariate analysis, ECOG status, ER+, HER2+, treatment with SRT and NS were independent predictors for OS.

Conclusions: This study confirms substantial heterogeneity of prognosis in patients with BM from BC, with significantly improved survival in patients selected for SRT or surgery. Further studies are required to optimize the role of CNS radiotherapy techniques such as SRT and hippocampal sparing WBRT in patients with a favorable prognosis.
**Title:** Preclinical characterization of neratinib in a blood-brain barrier co-culture model: Therapeutic implications for breast cancers with brain metastases

Tracey A Martin, Alshad S Lalani, Francesca Avogadri Connors, Richard P Bryce and Wen G Jiang. 1Cardiff University School of Medicine, Cardiff, United Kingdom and 2Puma Biotechnology, Inc, Los Angeles.

**Body:**

**Background:** Breast cancer patients who develop brain metastases have poor prognosis/short overall survival. Human epidermal growth factor receptor 2 (HER2) +ive breast cancer have an increased propensity for brain metastases. Currently, these metastases have limited therapeutic options. The endothelial cells forming the blood-brain barrier (BBB) are highly specialized to allow precise control over substances that enter/leave the brain via the tight junction. Targeted agents that are efficacious/able to penetrate the BBB are urgently needed. Neratinib is an orally available tyrosine kinase inhibitor that irreversibly binds and inhibits EGFR, HER2/HER4 receptor tyrosine kinases and has previously been shown to reduce the onset/delay symptomatic progression of CNS metastases in patients with advanced HER2-positive breast cancers with brain metastases (Awada 2016 JAMA Oncol; Freedman ASCO 2017 Ab 1005). Using a BBB model, this study aimed to determine if neratinib is able to pass through an endothelial barrier and demonstrate activity against human breast cancer cells lines. We also compared brain and vascular endothelial cells.

**Methods:** The BBB was represented by an in vitro transwell model using TY09 brain endothelial and HECV venous human cell lines in co-culture with a range of HER2+ive (MDA-MB-361;BT-474) or HER2-ive (MDA-MB-231;BT-549) human breast cancer cell lines. Effects on barrier function (trans-endothelial resistance/paracellular permeability) were assessed. Dose response effects on two brain endothelial cell lines (TY09/CMECD3) by neratinib were determined using ECIS (electric cell impedance sensing).

**Results:** Initially, we compared the effects of neratinib on a single brain endothelial cell line (TY09) in comparison to a venous endothelial cell line (HECV) in the presence/absence of EGF (20pg). We used temozolomide (TMZ) (40pmol) as a control treatment. Barrier function, assessed using trans-endothelial resistance and paracellular permeability revealed that neratinib had little effect on resistance over 1-72 hrs. When co-cultured with HER2+ive breast cancer cells, resistance was decreased at 1 hr which then returned to control levels (p<0.05). There was little change following treatment to the HER2-negative cells. A similar effect was also observed with TMZ. There was also a marked effect in HECV cells, but this was mostly observed in those treated with TMZ, regardless of HER2 status of the breast cancer cells in co-culture (p<0.04). Paracellular permeability was increased by 0.5 hr when using 10kDa (p<0.05) but not 40kDa dextran. Neratinib reduced the resistance of both TY09 and CMECD3 cells in a dose-dependent manner, with the same effect observed in cell attachment (p<0.01) and motility (0.05).

**Conclusions:** In our BBB co-culture model, neratinib was able to pass through the barrier created by both brain and venous endothelial cells and reduce the growth of HER2+ive breast cancer cells over 72 hrs. In addition, neratinib caused marked changes in barrier function of the brain endothelial cells with concurrent effects on cell behaviour. These data demonstrate that neratinib may be an attractive therapeutic for HER2-positive breast cancers with brain metastases.
Title: Efficacy of lapatinib and capecitabine combination therapy in brain metastases from HER-2 positive metastatic breast cancer: A systematic review and meta-analysis

Kyaw Z Thein¹, Myo H Zaw², Rachana Yendala¹, Henry P Igid¹, Chatree Chai-Adisaksopha³, Fred Hardwicke¹, Sanjay Awasthi¹ and Saba Radhi¹. ¹Texas Tech University Health Sciences Center, Lubbock, TX; ²The Brooklyn Hospital Center, New York, NY and ³McMaster University, Hamilton, ON, Canada.

Body: Background:
Brain metastases contribute to significant morbidity and mortality in breast cancer. Approximately one fourth of breast tumors overexpress the human epidermal growth factor receptor 2 (HER2) protein and are twice as likely to develop brain metastases. There are currently no systemic therapies approved. We undertook a systematic review and pooled analysis of trials to determine the efficacy of lapatinib and capecitabine combination therapy in brain metastases from HER-2 positive metastatic breast cancer (MBC).

Methods:
We performed a comprehensive literature search using MEDLINE, EMBASE databases, and meeting abstracts through December 31, 2016. Trials that utilized lapatinib and capecitabine combination therapy in brain metastases from HER-2 positive MBC were incorporated in the analysis. The pooled estimated rates were calculated using random effects model. Heterogeneity was assessed using $I^2$ statistic.

Results:
A total of 513 patients with brain metastases from HER-2 positive MBC from 6 trials and a subgroup of another 4 trials were included in our analysis. Lapatinib and capecitabine therapy was used as second-line treatment in 9 studies (n= 468) and as first-line treatment in the LANDSCAPE study (n= 45). Three studies were retrospective evaluations of randomized trials and the rest were phase 2 trials. CNS objective response rate (ORR) was 26% (95% CI: 19 – 33, $I^2$: 65.9%). Complete response (CR) rate was 1% (95% CI: 0 - 2, $I^2$: 0.0%) and partial response (PR) rate was noted at 24% (95% CI: 17 - 31, $I^2$: 66.1%). Stable disease (SD) occurred in 37% (95% CI: 29- 45, $I^2$: 66.6%) and progressive disease (PD) in 19% (95% CI: 12- 25, $I^2$: 66.5%). The first line LANDSCAPE study had the highest PR (49%) and ORR (53%) without a significant impact on CR rate; PD was 7%.

Conclusion:
Brain metastases in breast cancer is an area of urgent unmet need. Our meta-analysis showed that lapatinib/capecitabine therapy had some first line or second line activity in brain metastases from HER-2 positive MBC. Nevertheless, further randomized controlled trials are required in this patient population.
Leptomeningeal disease in ER+HER2- metastatic breast cancer patients: A review of the cases in a single institute over a 14-year period

Junichiro Watanabe¹, Koichi Mitsuya², Nakamasa Hayashi² and Yoko Nakasu². ¹Shizuoka Cancer Center, Shizuoka, Japan and ²Shizuoka Cancer Center.

Body: Background: Leptomeningeal disease (LMD) is a pattern of central nervous system (CNS) metastasis that occurs in metastatic breast cancer (MBC) patients (pts). Some reports have revealed that it occurs more frequently in pts with estrogen receptor-positive (ER+), HER2-MBC than in pts with other subtypes. However, in such ER+HER2-MBC pts, LMD mainly occurs in the terminal stage of the disease; thus, the details of LMD have not been well described.

Methods: We reviewed the medical records of ER+HER2-MBC pts who were treated from 2002 to present, with the aim of assessing the incidence, background and outcomes of LMD. Statistical analyses were performed using the chi-squared test, Kaplan-Meyer method, log-rank test and a multivariate COX regression analysis.

Results: We identified a total of 369 ER+HER2-MBC pts, and 102 (27.6%) developed CNS metastasis. LMD developed in 32 (8.7%) pts, with the median time to LMD of 778 days (95% confidence interval [CI] 335-1221; range 0-3757 days) from the diagnosis of MBC. In most cases (28, 87.5%), LMD was accompanied by bone metastasis, and 24 pts (75.0%) showed metastasis to the skull. Thirteen pts (40.6%) had accompanying brain metastasis (BM) at the diagnosis of LMD. The majority of the pts had symptoms (25, 78.1%), and their accompanying extra-CNS lesions showed progression (23, 71.9%). Palliative radiotherapy (RT) was introduced in 27 pts (84.4%), with 4 pts (12.5%) receiving whole CNS RT. The intrathecal injection of methotrexate was introduced to one patient. The median overall survival (OS) from the diagnosis of LMD was 104 days (95% CI 38-170); however, when limited to pts without BM (N = 19), the median OS was 146 days (95% CI 79-213). All of the pts died, and the causes of death were as follows: CNS lesion progression, n=10 (31.3%); cachexia, n=9 (28.1%); respiratory failure, n=8 (25.0%); hepatic failure, n=4 (12.5%) and infection, n=1 (3.1%). There was no significant relationship between the time to LMD and OS after the diagnosis of LMD (Spearman’s ρ=0.55, not significant). The multivariate analysis did not reveal any specific factors—such as the patient age, the presence of any symptom(s) at the diagnosis of LMD, the distribution of extra-CNS lesion(s) or the control of extra-CNS lesion(s)—that affected OS after the diagnosis of LMD.

As a control, 70 ER+HER2-MBC pts who developed BM without LMD (BM-only group) within the same observation period were analyzed. The median time to BM was 611 days (95% CI 404-818), and it did not differ from that of pts with LMD (LMD-group) to a statistically significant extent (P >0.1). The BM-only group showed superior OS after the diagnosis of their CNS lesions in comparison to LMD-group (median, 295 days and 104 days, respectively, P <0.001). At the diagnosis of the CNS lesion, the LMD-group showed a higher rate of CNS symptoms (P <0.01), a lower rate of liver metastasis (P <0.05), a higher rate of bone metastasis (P <0.05) and a higher rate of skull metastasis (P < 0.01).

Conclusion: Our retrospective analysis at a single institute revealed that the prognosis of LMD in pts with ER+HER2-MBC was still extremely poor. The data suggest that LMD is distinct from BM in terms of its pathology and response to therapy.
Body: Background
The incidence of brain metastases among women with metastatic breast cancer (MBC) ranges from 10 to 30% depending of breast cancer (BC) subtype. Inequities in the access to optimal treatment and shorter survival of BC by type of health care coverage were previously reported in an observational study in Brazil. The present analysis aims to analyze the impact of the type of health care coverage on survival outcomes of patients with MBC and brain involvement.

Methods
LACOG-0312 is a retrospective cohort study that enrolled patients with metastatic or locally advanced/recurrent unresectable BC diagnosed during 2012 in Brazil. Overall survival (OS) was defined as the time from the diagnosis of brain metastases and death from any cause. Comparisons were made using the Kaplan-Meier method based on the type of health care coverage (public vs. private) among patients who developed brain metastases. Cox regression analysis was performed for identification of independent prognostic factors associated with survival after brain metastases diagnosis.

Results
Among the 690 MBC patients included in the LACOG-0312 study, 145 (21%) were diagnosed with brain metastases. Of them, 94 (71.75%) were covered by the Brazilian public health care and 37 (28.25%) had private coverage. Baseline characteristics such as age at MBC diagnosis, stage IV at diagnosis and tumor subtypes were similar between both groups. Median time to develop brain metastases after diagnosis of MBC was 14 months in the whole population with no differences between public and private patients (13 vs. 17 months p=0.172). Median OS from the date of brain metastases diagnosis was similar for both groups: 10.0 months in private and 9.0 months in public health insured patients (HR 0.92 – 95%CI 0.55-1.51; p=0.729). In a multivariable analysis including type of health care coverage, only the triple negative BC subtype was associated with a worse survival post brain metastases diagnosis.

Conclusion
Our study indicates that health care coverage is not associated with survival outcomes in patients with MBC and brain metastases. Potential differences in the access to optimal care such as radiotherapy, surgery and systemic treatments may not play a significant role in the survival of theses patients possibly due to small clinical benefit of the current treatment options for brain metastases in breast cancer.

Title: Trajectory patterns of circulating tumor cells (CTC) in chemotherapy-treated metastatic breast cancer (MBC) patients predict poor clinical outcomes: CALGB 40502 (Alliance)/NCCTG N063H study

Mark J Magbanua¹, Laura Hendrix², Terry Hyslop², William T Barry⁴, Eric P Winer⁴, Clifford Hudis³, Deborah Toppmeyer⁵, Harold Burnstein⁴, Misbah Qadir⁶, Cynthia Ma⁷, Janet H Scott¹, John W Park¹ and Hope S Rugo¹. ¹University of California San Francisco; ²Alliance Statistics and Data Center, Duke University School of Medicine; ³Memorial Sloan Kettering Cancer Center; ⁴Dana-Farber/Partners CancerCare; ⁵Rutgers Cancer Institute of New Jersey; ⁶UNC Lineberger Comprehensive Cancer Center and ⁷Washington University School of Medicine.

Body: Little is known about the dynamics of CTCs during treatment and its clinical significance. We examined the predictive utility of serial CTC analysis in ER+HER2- MBC patients (pts) treated with chemotherapy in the CALGB 40502/NCCTG N063H study, a randomized phase III trial of weekly paclitaxel compared to weekly nanoparticle albumin bound nab-paclitaxel or ixabepilone +/- bevacizumab as first-line therapy (ClinicalTrials.gov Identifier: NCT00785291, Support: U10CA180821, U10CA180882).

Methods: Of the 783 pts treated, 469 had ≥3 serial blood samples (including baseline) successfully analyzed for CTCs by CellSearch® and were included in this analysis (n=2,202). Samples with ≥5 CTCs per 7.5 mLs of blood were considered CTC+.

The prognostic and predictive performance of baseline CTCs (bCTC) and CTC status from baseline to cycle 2 (b2CTC) were compared to a novel latent mixture model classification based on trajectory of CTCs (tCTC). Akaike Information Criterion (AIC) was used to select the model (bCTC vs b2CTC vs tCTC) that best predicts overall survival (OS), progression-free survival (PFS), and time-to-treatment failure (TTF).

Results: 53% of the pts were CTC+ at baseline. b2CTC status changed in 36% of the pts, most of whom were CTC+CTC- (35%), and very few CTC-CTC+ (1%); the rest of the pts did not experience a change in b2CTC status (46% CTC-CTC- and 19% CTC+CTC+). Mixture model analysis revealed 4 groups of pts that show distinct tCTC patterns over the course of treatment: consistently very low/undetectable CTCs (tCTCneg, 56%), low (tCTClo, 24%), intermediate (tCTCmid, 15%), or high (tCTChi, 5%). bCTC, b2CTC, and tCTC were significantly correlated with tumor subtype (all p <0.0022) and presence of bone metastasis (all p <0.0001). Multivariate analysis showed that pts who were CTC+ at baseline, and those whose b2CTC status remained positive (CTC+CTC+) had significantly reduced OS, PFS and TTF.

CTC- (<5 CTCs per 7.5 mLs); CTC+ (≥5 CTCs per 7.5 mLs)

Pts with tCTClo, tCTCmid and tCTChi had significantly shorter OS, PFS and TTF compared to those with tCTCneg. After adjustment for potential confounders, AIC analysis revealed that the tCTC model best predicts OS and PFS, while b2CTC best predicts TTF.

Body: Background: It has been reported in women with advanced estrogen-receptor (ER)-positive/(HER2)-negative breast cancer the acquisition of a HER2-positive CTC subpopulation during therapy (Jordan NV Nature 2016). The clinical significance of acquired HER2 heterogeneity during the evolution of metastatic breast cancer is unknown. We report here the analysis of HER2 status of CTC before and after one cycle of treatment in HER2 negative metastatic breast cancer patients treated with first line weekly paclitaxel and bevacizumab.

Patients & methods: The French cohort COMET is a prospective study including first line HER2 negative patients (pts) receiving weekly paclitaxel and bevacizumab according to EMA approved combination. The aim of this cohort is to evaluate clinical, biological and radiological parameters associated with pts outcome. We confirmed previously the outcome of patients with high CTC count at base line and after one cycle of treatment (Bidard et al, Lancet Oncol 2014). We present here the analysis on 203 pts evaluated for the expression of HER2 on CTC using the FDA cleared CellSearch method. The HER2 expression of CTCs (CB11 clone) was categorized (class 0–3) as described by Riethdorf et al.CCR2010.

Results: At base line, 144 out of 203 pts had at least one detectable CTC (71%), (median 4, and range 1-30,000). Among them, 104 (72%) had one or more HER2 positive CTC (1-21,484). In 25 patients with HER2 2+ primary tumor with FISH or CISH non amplified, the incidence of CTC HER2+ cases (13/25, 52%) was similar than in pts with HER2 0 or HER2 1+ (51%) primary tumor. In each case, 3 to 100% of detectable CTC could be HER2+ stained (median 50% of CTC). Only 12 cases (8% of all CTC cases) had 2+ HER2 staining score on CTC and none 3+. After one cycle of treatment, the number of pts with detectable CTC dropped to 64, including 42 with HER2+ CTC (65%). Out of these cases, 14 were 3+ or 2+ HER2 score (22% of CTC+ cases). This was a significant increase compared to baseline (8%) (p<0.001), including 6 cases with 100% of HER2+ CTC. To note, 7 patients without HER2+ CTC at baseline, had detectable HER2+ CTC after one cycle of treatment. With a median follow-up of 2 years, correlation of CTC variations with pts outcome is planned.

Conclusion: HER2 staining on CTC was heterogeneous with HER2 positive and negative subpopulations in the same patient with primary HER2 negative breast cancer. We observe a variability of HER2 CTC status with an increased intensity or appearance of immunostaining in few cases during treatment. We hypothesize that these phenotypes changes within patient-derived circulating tumor cells could contribute to progression of breast cancer and acquisition of drug resistance.
Improved prognostic information by serial monitoring of CTC enumeration and CTC-clusters from baseline to six months in patients with metastatic breast cancer scheduled for 1\textsuperscript{st} line systemic therapy

Anna-Maria Larsson\textsuperscript{1}, Sara Jansson\textsuperscript{1}, Pär-Ola Bendahl\textsuperscript{1}, Sara Baker\textsuperscript{1}, Cecilia Graffman\textsuperscript{1}, Charlotte Lundgren\textsuperscript{1}, Niklas Loman\textsuperscript{1}, Kristina E Aaltonen\textsuperscript{1} and Lisa Rydén\textsuperscript{2}. \textsuperscript{1}Clinical Sciences Lund, Lund University, Lund, Sweden and \textsuperscript{2}Clinical Sciences Lund, Lund University, Lund, Sweden.

**Body:** Background: Detection and enumeration of circulating tumor cells (CTCs) allows real time monitoring of disease evolution. In women with metastatic breast cancer (MBC), a CTC count of $\geq$5 CTCs is associated with decreased progression-free survival (PFS) and overall survival (OS). Serial sampling after therapy initiation has indicated that longitudinal CTC enumeration adds prognostic information, but data from long time sampling is sparse. The aim of this study was to evaluate if prospective longitudinal detection of CTC count and CTC clusters in women with newly diagnosed MBC can improve prognostication and monitoring of patients in the clinical setting.

**Methods:** Longitudinal blood samples were collected at baseline (BL) and after 1, 3 and 6 months in 156 women with MBC scheduled for 1\textsuperscript{st} line systemic therapy. CTC enumeration and cluster detection were performed by the CellSearch\textsuperscript{®} system in a prospective monitoring trial (NCT01322893). 115 patients had evaluable samples at all time-points. Primary endpoint was PFS and secondary endpoint was OS at BL in relation to CTC count and as landmark analyses during treatment. In addition, change in CTC count during therapy was compared to progressive disease (PD) versus non-PD. Structured clinical and radiological evaluation for PD was performed every 3\textsuperscript{rd} month.

**Results:** Seventy-nine (52\%) of 152 evaluable patients had $\geq$5 CTC and 14/79 patients had CTC-clusters ($\geq$3 clustered CTC) at BL. Median follow-up time was 25 (7-69) months. Patients with $\geq$5 CTCs had inferior PFS and OS in uni-(data not shown) and multivariable analysis (HR\textsubscript{PFS} 1.91 (1.26-2.91), $P=0.003$) (HR\textsubscript{OS} 3.57 (2.02-6.31), $P<0.001$) at BL. Presence of clusters at BL was prognostic for OS (HR\textsubscript{OS} 2.37 (1.25-4.51), $P=0.008$). Longitudinal landmark analysis of number of CTCs and presence of CTC clusters showed a time-dependent increase in HR during treatment for CTCs and CTC-clusters and predicted worse PFS and OS at all time-points. Stratifying patients based on CTC count and presence of clusters revealed four risk groups (0, 1-4, $\geq$5 CTC, $\geq$5 CTC + clusters) where patients with clusters had inferior PFS and OS at all time points. Change in CTC count from BL to 1 and 3 months, and from 3 to 6 months was significantly related to evaluation at 3 and 6 months (PD vs non-PD, $P=0.013$ (3 months), $P=0.016$ (6 months)) and change in CTC count from BL to 1, 3 and 6 months was also significantly predictive of both PFS and OS. Notably, survival was significantly inferior for patients with persistent CTC $\geq$5 during treatment.

**Discussion:** CTC is an independent prognostic factor for MBC patients scheduled for 1\textsuperscript{st} line systemic therapy. By longitudinal monitoring during treatment, the prognostic information by presence of $\geq$5 CTC and clusters increases over time and supports long time monitoring of patients. Importantly, detection of CTC-clusters identifies a subgroup of patients with dismal prognosis at all time-points indicating that CTC-clusters renders important clinical information. Change in CTC count during systemic therapy is related to outcome of evaluation and prognosis at all time-points.
Title: The whole transcriptional landscape of circulating tumor cells compared to metastases in stage IV breast cancer

Alexander Ring¹, Tania Porras¹, Daniel Campo², Pushpinder Kaur¹, Victoria A Forte³, Debu Tripathy⁴, Janice Lu¹, Gabriel Zada¹, Naveed Wagle¹, Julie S Wescsler¹ and Julie E Lang¹. ¹University of Southern California (USC) Norris Cancer Center; ²USC University Park Campus Genomics Core; ³Maimonades Medical Center and ⁴MD Anderson Cancer Center.

Body: Background: Metastatic breast cancer (MBC) and the circulating cells (CTCs) leading to macrometastasis are inherently different than primary breast cancer, evolving under the selection pressure of systemic therapy. A better understanding of the tumor biology of CTCs compared to metastasis may shed light on treatment opportunities.

Methods: We performed whole transcriptome sequencing (RNA Seq) on fresh metastatic tumor biopsies (mets), CTCs, and peripheral blood (PB) from 21 newly diagnosed MBC patients. CTCs were harvested using the ANGLE Parsortix to isolate cells based on size and deformability. Data were analyzed for differential expression, pathways, single nucleotide variants (SNV), fusions, intrinsic subtype, and a CTC-mets shared gene signature was validated using data from The Cancer Genome Atlas (TCGA). Detailed clinical-pathological and treatment data was evaluated.

Results: CTCs as a group showed much stronger gene expression of oncogenes, stem cell genes, keratins and mesenchymal markers than did mets from the same patients. Matched patient comparisons for 66 potentially clinically actionable genes for 8/9 pathways showed no significant difference in gene expression targets between CTCs and mets on ANOVA, although fold-change did vary. Eight SNVs in the ESR1 gene (n=5 patients) and 5 SNVs in the HER2 gene (n=2 patients) were shared between CTCs and distant metastases.

Differential gene expression analysis identified a signature of 8870 genes that were statistically significantly correlated between CTCs and mets (FDR adjusted p<0.05). Ingenuity pathway analysis was applied to the list of genes shared between CTCs and mets, with analysis of canonical pathways and upstream regulators revealing numerous oncogenes and breast cancer related genes. The top 50 genes of this CTC-mets shared signature were prognostic of worse overall survival in the TCGA breast cancer dataset (p<0.001), which included 817 patients with a median follow-up of 59.5 months. Second time-point data for n=5 patients with subsequent PB draws 6 months after baseline is currently pending. Intrinsic subtyping of mets by either NanoString assays or RNA Seq were not concordant with intrinsic subtyping of CTCs by RNA Seq.

Four of 21 CTC samples showed strong whole transcriptome RPKM correlation with PB (R²)>0.9, however, 3/21 CTC samples showed strong whole transcriptome RPKM correlation with mets (R²)>0.8. The remainder showed low correlation with both. Coverage was 91.4X for CTCs, 140.2X for mets and 138.5X for PB.

Conclusions: We present the transcriptomic landscape of CTCs with comparison to metastases and peripheral blood all acquired prior to treatment of newly diagnosed Stage IV breast cancer. Multiple genes, including oncogenes and stem cell genes, were found with higher expression in CTCs versus metastases. When focusing on 66 known potentially clinically actionable genes in breast cancer, CTCs did not show significantly different patterns of expression than mets in terms of up-regulation versus down-regulation compared to PB. RNA Seq of CTCs may be utilized to identify molecular alterations that are potentially clinically actionable.

**Body:** **Background:** CTCs play a major role in tumor dissemination and progression, and represent one of the key components of the metastatic cascade. The aim of this study was to identify signaling pathways associated with presence of CTCs in primary breast cancer (PBC) patients using a comprehensive genomics approach.

**Methods:** This translational study included 78 patients with PBC. CTCs were detected before surgery by quantitative RT-PCR assay for expression of epithelial (EP; CK19) or epithelial-mesenchymal transition (EMT) genes (TWIST1, SNAIL1, SLUG, ZEB1). Total DNA and RNA were extracted, in parallel, from fresh frozen primary tumor and the microRNA and mRNA expression profiles were obtained using Human microRNA Microarray v21.0 and SurePrint G3 Human Gene Expression v3 (Agilent Technologies). Next generation sequencing (NGS) was performed by Illumina Multiplex Sequencing using MiSeq Sequencing Reagent Kit V3.

**Results:** Mutations in \textit{BRCA1/2} genes in tumor tissue were more common in patients with epithelial CTCs (CTC_EP) compared to patients without epithelial CTCs in peripheral blood (23.5\% vs. 0\%, \(p = 0.02\)), while there were no mutations in specific genes associated with CTC with EMT phenotype (CTC_EMT). Further, we identified 90 genes and 7 miRs that were expressed at significantly different levels in tumors with presence of CTC_EP and 199 genes and 13 miRs specifically associated with CTC_EMT, compared to tumors with non-detectable CTCs. We also identified 39 overlapping genes and 7 miRs, that were expressed at significantly different levels in tumors with CTC_EP and/or CTC_EMT compared to tumors with non-detectable CTCs. Overlapping genes and miRs with highest different levels in expression were ATAD3A, TMEM201, DCPS, DOCK9-AS2, TRAF2 and miR-5195-3p, miR-188-5p, miR-6780a-5p, miR-6757-5p. Signalling pathways associated with these genomic alterations belong to several critically functional groups, such as immune response, signal transduction, cell proliferation, cell cycle progression, or apoptosis were significantly differentially based on CTCs status.

**Conclusions:** We identified for the first time various genomic alterations in primary tumor tissue of PBC associated with different CTCs subpopulations in peripheral blood. We hypothesize that these genomic alterations could play a role in tumor dissemination and progression and might lead to identification of new therapeutic targets.
Title: Similarities and differences in RNA profiles of circulating tumor cells in breast cancer subtypes: Do we have therapeutic options?

Ann-Kathrin Bittner\textsuperscript{1}, Oliver Hoffmann\textsuperscript{1}, Corinna Keup\textsuperscript{1}, Siegfried Hauch\textsuperscript{2}, Rainer Kimmig\textsuperscript{1} and Sabine Kasimir-Bauer\textsuperscript{1}. \textsuperscript{1}University Hospital Essen, Essen, Germany and \textsuperscript{2}QIAGEN GmbH, Hilden, Germany.

Body: Background: The success or failure of anti-cancer therapies in breast cancer (BC) is only assessed retrospectively by the absence or presence of overt metastases during the post-operative follow-up period. Circulating Tumor Cells (CTCs), the precursor of metastatic disease, would be an ideal surrogate tissue to identify prognostic and predictive factors directly at primary diagnosis guiding to optimal individual therapeutic strategies for metastasis prevention. Since the prognosis in BC has been shown to be different in various BC subtypes, CTCs present in each subtype may, therefore, also represent distinct metabolic profiles for survival, metastatic spread and therapy resistance Using a multi-marker gene panel for the characterization of the heterogeneous CTC population, we here compared the genetic profiles of CTCs in triple negative BC (TNBC) patients (pts) with CTC characteristics in non-TNBC pts.

Methods: 2x5 ml blood of 43 TNBC pts and 51 non TNBC pts (11= HER2+/HR-, 40=HER2-/HR+) before and/or after neoadjuvant therapy were analyzed for CTCs applying positive immunomagnetic selection targeting EpCAM, EGFR and HER2 using the AdnaTest EMT-2/Stem Cell Select (QIAGEN Hannover GmbH, Germany). Subsequently, cDNA was gene specifically pre-amplified using TaqMan PreAmp Master Mix according to in house designed assays. Establishment of a 19 gene qPCR panel was performed for the markers PI3K, AKT2, ERCC1, Aurka, HER2, HER3, EGFR, ALK, AR (androgene receptor), BRCA1, c-KIT, c-MET, KRT5, mTOR, NOTCH1, PARP1, SRC1, CD45 (leucocyte control) and GAPDH (housekeeping gene) as well as an internal reference. The cutoff was calculated, taken the false positive rate in healthy donors into account and defined as Ct(cutoff)-Ct(sample)-[Ct(CD45cutoff)-Ct(CD45sample)].

Results: PI3K and mTOR as well as the resistance markers ERCC1 and AURKA were predominantly expressed in all BC subtypes, the latter especially after therapy. EGFR could not be detected in any BC subtype. In TNBC pts, all the different genes were expressed, probably representing the most heterogeneous CTC population. Interestingly, HER2/HER3+ CTCs were found before and after therapy in more than 20% of these pts and mTOR/PI3K expression were not reduced after therapy. In HER2+/HR- pts, ALK, AR, c-KIT, HER3, KRT5 were never detected whereas NOTCH, PARP1 and SRC1 seemed to be induced by therapy in about 30% of the pts. Notably, HER2+CTCs, initially detected in 50% of the pts, completely disappeared after therapy, most likely due to anti- HER2 targeted treatment which seemed to also markedly reduce initial PI3K/AKT/mTOR expression whereas resistant, AURKA+ CTCs were found in 40% of cases before and after therapy. The expression pattern in CTCs of HR+/HER2- pts was, although to a lower extend, similar to the profile detected in HER2+/HR- pts but compared better to ERCC1 based resistance induction in TNBC pts.

Conclusion: Although CTCs in TNBC pts and non-TNBC pts show different genetic profiles, the PI3K/AKT/mTOR pathway as well as resistance markers seem to be commonly expressed in CTCs of all BC subtypes. This knowledge about the individual target gene expression profile might efficiently help to predict a personalized targeted therapy for these pts in the future.
Isolation of viable CTCs from leukapheresis product with parsortix system enables subsequent culture

Hans Neubauer¹, André Franken¹, Christiane Driemel², Rita Lampignano¹, Bianca Behrens³, Florian Reinhardt¹, Dieter Niederacher¹, Nikolaus H Stoecklein², Johannes C Fischer³ and Tanja Fehm¹. ¹University Hospital and Medical Faculty of the Heinrich-Heine University Duesseldorf, Germany; ²General, Visceral and Pediatric Surgery, University Hospital and Medical Faculty of the Heinrich-Heine University Duesseldorf, Germany and ³Institute for Transplantation Diagnostics and Cell Therapeutics, University Hospital and Medical Faculty of the Heinrich-Heine University Duesseldorf, Germany.

**Body:** Background: Solid tumors are constantly releasing circulating tumor cells (CTCs) into the circulatory system. They are genotypically and phenotypically different from the primary tumor. Especially viable CTCs can be of high interest to obtain further therapeutically relevant information. Their extremely low frequency is one of the main limiting factors to use them for further characterization.

To overcome this challenge we tested to isolate viable CTCs from diagnostic leukapheresis (DLA) products obtained from breast cancer patients.

**Material/methods:** 16 DLA samples and matched peripheral blood (PB) samples of metastasized breast cancer patients were collected and CTC numbers were determined by CellSearch® analysis. Viable cells were enriched from DLA product with Parsortix system. Genomic DNA of single cultured CTCs was isolated and amplified by whole genome amplification. Array-based comparative genomic hybridization of single cells was performed to analyze for genomic aberrations. Resulting profiles were compared to genomic aberration profiles of CTCs isolated before in vitro culture.

**Results:** CTCs were detected in ten PB and matched DLA samples and in three more DLA samples whose corresponding blood samples were CTC-negative. CTC number per ml was increased by an average of 22.5 fold. Parsortix was optimized to enrich tumor cells from DLA product while keeping them best viable. An enrichment rate of 67.7% ± 11.3% and a harvesting rate of 65.3% ± 9.7% were determined with spiked MCF7 cells. We could grow viable CTCs from three out of eight CTC positive DLA samples from metastasized patients as determined by immune fluorescence analysis. The growing cells harbor genomic anomalies confirming their malignant origin. Most aberrations are widely identical to the aberrations detected in uncultured CTCs.

**Conclusions:** DLA provides greater numbers of viable CTCs which can be enriched with Parsortix system in order to enable their in vitro cultivation. This workflow will allow functional studies.
Title: Enumeration of heterogeneous circulating tumor cells (CTCs) using size-based method in early, and metastatic, breast cancer patients

Katsunori Tozuka¹, Shigenori E Nagai¹, Kazuyuki Kubo¹, Kei Komatsu¹, Ken Takai¹, Kenichi Inoue¹, Hiroshi Matsumoto¹, Yuji Hayashi¹, Miki Tsuboi¹, Yoko Yamada¹, Xiaofei Wang¹ and Masami Suganuma¹,². ¹Saitama Cancer Center, Ina, Kita-adachi-gun, Saitama-ken, Japan and ²Graduate School of Science and Engineering, Saitama University, Saitama, Saitama-ken, Japan.

Body: Background
The detection of circulating tumor cells (CTCs) in peripheral blood is an independent predictor of the efficacy of systemic therapy, and also a prognostic marker for patients with metastatic breast cancer. One of the main methods to detect CTCs is CellSearch system, which uses immune-magnetic separation followed by immunocytochemistry. A microdevice (CTChip from ClearCell system) can capture and enumerate CTCs based on distinctive physiological differences (size and deformability) between cancer cells and blood cells. CTChip thus obtains a larger CTC yield than affinity-based separation, which enriches a particular subgroup of cells expressing EpCAM. In this study, we enumerate CTCs in peripheral blood from early and metastatic breast cancer patients using a size-based method.

Patients and methods
We examined blood samples from a total of 18 early and metastatic breast cancer patients, after obtaining written informed consent. Blood samples were taken in sodium EDTA tubes after discarding the first 1ml of blood from the syringe. Two ml blood samples were applied to CTChip (ClearCell system), and CTCs were eventually trapped in the microwells of the CTChip. Trapped cells were analyzed by immunocytochemistry with monoclonal antibodies specific for leukocytes (CD45) and epithelial cells (CK8/18), along with 4',6-diamidino-2-phenylindole (DAPI) for nuclei: CK8/18-positive, DAPI-positive and CD45-negative cells more than 10 µm in diameter were defined as CTCs. Eight patients were examined using both the CTChip and CellSearch system to compare the yield of CTCs.

Results
Of 18 patients, 6 were de novo stage IV, 6 were recurrent and 6 were early stage breast cancer patients. Of primary tumors, 8 were HER2- and ER and/or PR +, 6 were HER2-and ER- and PR-, 3 were HER2+ and ER and/or PR +, and one was HER2+ and ER- and PR-. Using CTChip, detected CTCs ranged from 3 - 107 cells/2 ml in all cases: 3 - 83 for early stage, 19 - 156 for stage IV and 21 - 146 for recurrent. The number of CTCs found in recurrent patients tended to be higher than in early stage patients. Size-based method using CTChip clearly showed high sensitivity compared with the CellSearch system, which detected CTCs in only 2 cases out of 8. In analysis by immunochemistry, we found CK-negative, CD45-negative and DAPI positive cells with larger diameter (>16 µm) than CK-positive CTCs in most patients, and the numbers were higher in stage IV (8.5 cells of median value) and recurrent (13 cells) patients than in early stage patients (1.5 cells). Our study suggested that CK-negative large cells might be CTCs with epithelial–mesenchymal transition (EMT).

Conclusion
This size-based technology enables us to capture CTCs regardless of EpCAM expression. Enumerated CTCs varied in size and positivity of CK8/18, suggesting the heterogeneity of CTCs. Further research, especially focusing on EMT will be crucial to understand the key mechanism of metastasis and drug resistance.
Title: Circulating tumor cells (CTCs) in the venous drainage of the breast in patients with primary breast cancer

Masaya Hattori1, Hayao Nakaiishi2, Akiyo Yoshimura1, Yayoi Adachi1, Madoka Iwase1, Naomi Gondo1, Haruru Kotani1, Masataka Sawaki1, Yasushi Yatabe3 and Hiroji Iwata1. 1Aichi Cancer Center, Nagoya, Aichi, Japan; 2Aichi Cancer Center Aichi Hospital, Okazaki, Aichi, Japan and 3Aichi Cancer Center, Nagoya, Aichi, Japan.

Body: Background:
CTCs are shed from tumors and circulate in the peripheral blood after passing through the drainage vein. Axillary lymph node dissection (ALND) provides access to the lateral thoracic vein which flows directly into the axillary vein. In this preliminary study, we evaluated the feasibility of detecting CTCs in the peripheral blood and in the lateral thoracic venous blood for breast cancer patients who underwent ALND.

Methods:
From June 2016 to March 2017, breast cancer patients who underwent ALND in our institute were eligible for this study. A peripheral blood sample, 10ml, was drawn just before the surgery or one day before the surgery. A lateral thoracic venous blood sample was taken from the resected breast just after resection. A blood sample of 0.2ml or more was necessary for CTC isolation. The CTCs in the peripheral blood before surgery (periCTC) and in the blood from the lateral thoracic vein of the resected breast (ltvCTC) were quantitatively examined by using a size-selective CTC isolation platform.

Results:
A total of 21 patients with median age 51 years (37-75) were enrolled to the study. Of the 21 patients, 38% were premenopausal, 52% had neoadjuvant chemotherapy. Fifty-seven percent were ER and/or PgR positive, 24% were HER2 positive. Fifty-seven percent were stage II disease and 43% were stage III. In 3 patients, we couldn't obtain sufficient blood samples from the lateral thoracic vein. Of the remaining 18 patients, we were able to obtain the median 0.5ml (0.2-2.0) blood samples from the lateral thoracic vein. CTCs were detected in peripheral blood in 15 patients (71%) and median periCTC count was 1 CTC/10ml (0-39). In lateral thoracic venous blood, CTCs were detected in all patients who had sufficient blood samples and the median ltv CTC count was 35.5 CTC/ml (2.5-370). In 5 of 6 patients whom CTCs in peripheral blood samples were not detected, CTCs could be detected in the blood samples from lateral thoracic vein.

Conclusion:
CTCs can be detected in the peripheral blood and in the blood from lateral thoracic vein in patients with localized breast cancer, and can be detected at a higher rate and at a higher concentration in the blood from lateral thoracic vein than in peripheral blood.
Title: Circulating CAF/CTC complexes and breast cancer metastasis

Body: Background: Metastatic disease in breast cancer (BC) is the leading cause of cancer-related mortality among women worldwide. Synergy between cancer cells and non-cancer cells of the tumor microenvironment (TME) are vital for disease progression. Cancer associated fibroblasts (CAFs) are the major cell type in the stroma of BC and are critical mediators of tumor progression and metastasis. Transport of circulating tumor cells (CTCs) and CTC clusters through the vasculature seeds metastasis and clinical and preclinical studies demonstrate that CTC clusters have a higher metastatic potential than individual CTCs. More recently, circulating cancer stem cells (cCSCs) have been implicated as more metastatic than non-CSC CTCs. In our lab, we have demonstrated that CAFs also circulate (cCAFs). We have observed cCAFs in peripheral blood from breast cancer patients and in murine models of breast cancer. Furthermore, we have observed that cCAFs are present in circulation as both individual cells and as well as in complexes with CTCs. Given the integral role of CAFs in BC metastasis, we hypothesize that cCAFs complex with CTCs/cCSCs to bolster BC metastasis.

Methods: cCAF/CTC clusters were identified and enumerated from peripheral blood of patients with BC, and associations with clinical features and disease outcomes were evaluated. Blood was collected by cardiac puncture from PyMT mice from 4 weeks through to the presence of metastases (10 weeks) and cCAF/CTC clusters enumerated. We co-injected CAFs with MCF-7 cells into NSG mice, blood collected by cardiac puncture, and cCAF/CTC clusters were enumerated. At time of final sacrifice, tumors were removed and assessed for presence of CSCs. Using our established model of cCAF/CTC clustering in vitro we interrogated cCAF/CTC complexing with both metastatic and poorly metastatic BC cells.

Results: Circulating cCAFs/CTCs clusters are significantly increased in the blood of patients with advanced stage BC and associate not only with severity of disease but also with poorer clinical outcomes. In the spontaneous PyMT mouse model, the appearance of circulating cCAF/CTC clusters increased significantly as tumors grew but prior to metastasis. We demonstrate that metastatic BC cells form clusters with CAFs in vitro while non-metastatic BC cells do not form complexes with CAFs in vitro. Enriching for stem cells from MCF7 mammospheres, resulted in CAF/CSC clusters in vitro. In mice that were co-injected with non-metastatic MCF7 cells and CAFs from a TNBC/Basal-like BC (CAF23) we observed disease metastasis, an enrichment for cancer stem cell (CSC)-like CTCs, and the presence of circulating cCAF/MCF7-CSC clusters.

Conclusions: Circulating clusters of CTCs and cCAFs are characteristic, and potentially causative, of BC metastasis. Observations of cCAF/CTC clusters from preclinical and clinical samples are corroborated by our determination that the ability of BC cells to form complexes with CAFs in vitro is related to the intrinsic metastatic ability of the breast cancer cells. Both in vitro and in circulation, the BC cells in cCAF/cBC clusters are CSCs, so cCAF/cCSC clusters. Disrupting the formation of cCAF/CTC complexes may be a potential strategy to reduce treat or prevent breast cancer metastasis.
Title: Dynamics of ctDNA changes during neoadjuvant chemotherapy in triple-negative breast cancer patients

Luca Cavallone¹, Aguilar-Mahecha Adriana¹, Mohammed Aldamry², Josianne Lafleur¹, Lan Cathy¹, Najmeh Alirezaie³, Eric Bareke³, Jacek Majewski⁴, Cristiano Ferrario⁵, Catalin Mihalciou⁶, Josee-Anne Roy⁴, Elisabeth Markus⁷, Andre Robidoux⁸, Manuela Pelmus², Olga Aleynikova², Federico Discepola² and Mark Basik¹. ¹Lady Davis Institute for Medical Research, Montreal, QC, Canada; ²Jewish General Hospital, Montreal, QC, Canada; ³McGill University, Montreal, QC, Canada; ⁴Hopital Sacre Coeur, Montreal, QC, Canada; ⁵John H. Stroger Jr. Hospital, Chicago, IL and ⁶Centre Hospitalier de l'Université de Montreal, Montreal, QC, Canada.

Body: Background:
Liquid biopsies to monitor response to treatment are a minimally invasive and highly attractive method for clinical application. Detection of ctDNA in plasma is now highly sensitive thanks to the use of novel highly sensitive and specific techniques such as ddPCR. In the present study we set out to analyze the utility of using ctDNA to monitor response to treatment in patients receiving standard neoadjuvant chemotherapy in triple negative breast cancer.

Methods:
Serial blood was collected from triple negative breast cancer patients participating in the Q-CROC-03 clinical trial (NCT01276899). The trial recruited triple negative breast cancer patients undergoing standard neoadjuvant chemotherapy. Paired biopsies were collected prior and at the end of treatment and serial biopsies collected throughout the study. Whole exome sequencing was performed on tissues collected and we identified mutated genes of interest. Cell free DNA (cfDNA) was extracted from 3 ml of plasma and 4-10 variants per patient were analyzed by ddPCR in serial plasma samples collected before and during treatment. Response was measured by evaluating residual cancer burden (RCB), and non-responders were RCBII-III, responders RCB0-I.

Results:
For the present analysis, we identified 60 variants in tumors from 12 patients (9 RCBII-III and 3 RCB0-I). Except for TP53, none of the genes were shared among the tumors. 20% of the variants were not detected in ctDNA at any time point and we did not find any correlation between cfDNA levels and tumor size or response to treatment. The average variant allele frequency (VAF) of all detected variants at baseline was higher in RCBII-III patients than in RCB0-I patients (7.0 vs 0.7 respectively). Interestingly, variants that were detected either only in the pre-chemo tumor or in the post-chemo tumor were frequently detected throughout neoadjuvant therapy, highlighting the ability of ctDNA to capture tumor heterogeneity. In almost all cases, we observed a dramatic decrease in ctDNA VAF after one cycle of chemotherapy, including 30% to non-detectable levels. By the 5th cycle of chemotherapy 97% of detected variants had decreased (average 95% decrease). This decrease in ctDNA VAF was independent of RCB score. In some RCBII-III cases, ctDNA VAF increased prior to surgery, reflecting residual tumor presence.

Conclusion:
ctDNA could be detected in plasma of all early TNBC patients undergoing neoadjuvant chemotherapy with the majority of variants detected in plasma collected at baseline prior to chemotherapy. Once treatment started, the abundance of ctDNA markedly decreased in plasma independently of tumor response. The effect of chemotherapy on levels of ctDNA needs further investigation.
Title: Assessment of an immune response panel of serum protein biomarkers for the non-invasive detection of breast cancer

Philip R McQuary1, Karen A F Copeland2, Nadia M Sheibani1, Lyssa A Friedman1, Ronald L Korn3, James V Fiorica4, Ana P Lourenco5, Sara E Struthers6 and Lyndal K Hesterberg1. 1OncoCyte Corporation, Loveland, CO; 2Boulder Statistics, Boulder, CO; 3Scottsdale Medical Imaging, Scottsdale, AZ; 4Sarasota Memorial Hospital, Sarasota, FL; 5Rhode Island Hospital, Providence, RI and 6Mercy Clinic, Oklahoma City, OK.

Body: Background: Breast cancer screening guidelines (ACS) recommend annual mammography for asymptomatic women ages 45 to 54 and once every two years for women age 55 and older. Women with suspicious screening mammograms are recommended for a diagnostic mammogram and may also undergo MRI or ultrasound. Ultimately, unresolved suspicious findings frequently result in the recommendation of a breast biopsy. Approximately 10% of suspicious diagnostic mammograms are recommended for breast biopsies and a large majority of these biopsies yield benign results. We conducted a screen for serum protein biomarkers and identified a novel panel for the non-invasive detection of breast cancer with the goal of developing a diagnostic test that can reduce the number of patients with benign pathology undergoing invasive biopsies.

Methods: Serum samples were collected at 4 US sites from women with suspicious diagnostic mammogram findings (primarily BI-RADS category 4 and breast composition b/c) undergoing biopsy for evaluation of a potential malignancy. Serum samples from 136 patients (87 benign pathology and 49 malignant pathology) were evaluated on the olink® Proteomics Immune Response Panel (92 analytes). Statistical screening methodologies, such as individual t-tests with control for false discovery, were used to identify markers with the potential to distinguish benign from malignant pathology. The candidate markers were further studied and combined using generalized linear modeling to develop potential diagnostic models.

Results: A 19-marker model resulted in an AUC of 0.94 with a sensitivity of 90% and a specificity of 80%. A 12-marker model resulted in an AUC of 0.93, yielding a sensitivity of 90% with a specificity of 77%.

Conclusions: This study reveals a novel panel of serum protein biomarkers that may allow for the non-invasive and sensitive detection of breast cancer in patients presenting with suspicious findings on mammography, thus reducing the need for invasive biopsies.

Publication Number: P2-02-04

Title: Circulating protein biomarker profile for inflammatory breast cancer using a multiplexed proximity extension assay

Evan N Cohen¹, Gitanjali Jayachandran¹, Hui Gao¹, Sandra Tin¹, Ricardo H Alvarez², Vicente Valero¹, Bora Lim¹, Wendy A Woodward¹, Naoto T Ueno¹ and James M Reuben¹. ¹The University of Texas MD Anderson Cancer Center, Houston, TX and ²Cancer Treatment Centers of America at Southeastern Regional Medical Center, Newnan, GA.

Body: Background: Expression of cancer related genes and proteins in clinical specimens are the mainstay of personalized targeted therapy; however, a diagnostic signature for inflammatory breast cancer (IBC) remains elusive. In this study, we employed a blood-based, non-invasive, sensitive technology to map biomarkers in patients with IBC at the protein level. Proximity Extension Assay consists of a harmonious blending of immunoassay and PCR to amplify protein expression signal, thereby enabling multiplexing with small sample input (1 µl). Other multi-platform assays require a large amount of clinical material, multi-step sample processing and complicated data analysis.

Materials and methods: Serum samples (n=159) from patients with primary IBC (IBC, n=30), metastatic IBC (MIBC, n=54), locally advanced breast cancer (LABC, n=24) and metastatic breast cancer (MBC, n=27) were prospectively collected from subjects prior to starting a new therapy (treatment naive) or a new line of therapy between 2009 and 2012. Sera from 24 healthy normal donors (HD) were included in the analysis for comparison. The samples were analyzed using two panels: Proseek Multiplex Oncology II and Proseek Multiplex Inflammation I (Olink Proteomics, Uppsala, Sweden) for simultaneous detection of 92 human protein biomarkers in each panel. In the assay, each protein biomarker is detected by a matched pair of antibodies coupled to unique DNA-tags. Upon binding to the proteins, the correctly hybridized DNA-tags form an amplicon that can be measured by PCR. For initial analysis, sample populations were compared using the Mann-Whitney-U test.

Results: In comparison with HD sera, sera of breast cancer patients had 41 proteins from the oncology panel and 28 from the inflammation panel that were significantly higher, whereas 5 from the inflammation panel were significantly lower. From the inflammation panel, 11 proteins (PD-L1, IL-2, IL-7, IL-18, uPA, CCL4, CCL23, CXCL9, CXCL10, CXCL11 and TNF-alpha) showed significant differential expression between IBC and non-IBC derived samples (irrespective of metastatic status); for each marker, levels were higher in IBC than in non-IBC. In contrast, 9 proteins from the oncology panel (CRNN, CTSV, ERBB4, FR-gamma, ITGAV, MIA, PODXL, SCF and SEZ6L) were differentially expressed; however, each of these proteins was higher in non-IBC than in IBC. Among the aforementioned proteins, CCL4, IL-2, IL-7, PD-L1, TNF-alpha, uPA, CRNN, CTSV, FR-gamma, ITGAV, MIA, SCF and SEZ6L did not differentiate cancer and HD, but were uniquely characteristic of the IBC vs non-IBC comparison.

Conclusion: These preliminary data suggest that it is possible to distinguish between cancer patients and healthy normal donors, and also to delineate between IBC and non-IBC patients based on expression of serum proteins. Validation of this serum protein signature is planned in a larger patient cohort.
Title: Persistence of PIK3CA mutations detection in cell free tumor DNA as surrogate markers for hormonosensibility in patients with hormone receptor-positive breast cancer. The miRho clinical study

William Jacot¹, Florence Dalenc², Evelyne Lopez-Crapez¹, Leonor Chaltiel², Anna Durigova¹, Nathalie Gros¹, Jean-Louis Lacaze², Stéphane Pouderoux¹, Laurence Gladieff², Gilles Romieu¹, Henri Roché², Thomas Filleron² and Pierre-Jean Lamy¹. ¹Institut du Cancer de Montpellier (ICM) Val d’Aurelle, Montpellier, France and ²Institut Claudius Regaud, IUCT-O, Toulouse, France.

Body: Background: HT resistance occurs in nearly all patients with mBC. The identification of early predictive biomarkers of HT failure could help tailoring monitoring or an early change in HT. Circulating biomarkers would allow, a global evaluation of all the metastatic sites without the need of invasive biopsies. Mutation in the phosphatidylinositol 3 phosphate kinase gene (PIK3CA) is one of the most frequent events in ER+ BC and has been involved in HT resistance. We evaluated the early predictive value of cell free DNA (cfDNA) PIK3CA detection in a population of first line HT BC patients.

Material and methods: 39 patients treated for an ER+/HER2- metastatic BC by first line HT in 2 French Comprehensive Cancer Centers were prospectively included in a dedicated clinical trial (NCT01612871) between June 2012 and January 2014. Serial blood sampling was performed before the initiation of HT (T0), 4 weeks (T1), 3 months (T3), 6 months (T6) and at tumor progression. Patients were followed until progression or end of the study (2 years follow-up). cfDNA was isolated from plasma using the QiaAmp circulating nucleic acid isolation kit (Qiagen). Mutation detection was performed using droplet digital PCR on a QX100™ system (Bio-Rad). The assay targeted wild type PIK3CA and mutations p.E542K, p.E545K in exon 9 and p.H1047R in exon 20. Target concentration was calculated as copies/reaction and cfDNA concentrations were reported as number of copies/mL of plasma. To assess the limit of detection of the three assays, isogenic reference DNA with known mutant allele frequency was used (Horizon Diagnostics). Based on confidence interval for Poisson parameter, a sample was considered positive if the average mutant copies detected was 4 copies and above per reaction.

Results: Median age of the population was 63 (range 40-86). HT was as follow: letrozole 32, tamoxifen 5, anastrozole 1 and exemestane 1 patients, respectively. Most patients (28, 71.8%) presented with non-measurable disease, precluding a relevant evaluation of predictive factors for response. Progression-free survival (PFS) was used instead as primary endpoint. Serum samples results were available for 37 and 35 patients at T0 and T1 respectively. PIK3CA mutations were present in 10 (27.8%) and 5 (14.3%) cases at T0 and T1 respectively. While presence of a cfDNA PIK3CA mutation in the T0 sample was not associated with PFS, the persistence of a detectable circulating mutation at T1 was highly significant of a worse PFS (40% vs. 76.7% at 1 year; p=0.0053).

Conclusions: In this dedicated clinical trial, 4-weeks persistence of cfDNA PIK3CA mutation appears highly correlated with PFS. Early identification of this mutated population could allow the evaluation of therapies targeting the PI3K/AKT/mTOR pathway in a selected population affected with an unfavorable prognosis. Dedicated studies and ancillary studies of such targeted therapies are warranted.
Title: Biomarker analysis by next generation circulating tumor DNA (ctDNA) sequencing in patients with advanced breast cancer

Huiping Li1, Jing Wang2, Hope S Rugo3, Yan Zhang4, Ling Yang5, Xiaoran Liu6, Bin Shao7, Yaping Xu8, Liang Yang9, Ruyan Zhang10, Ran Ran11 and Lianpeng Chang12. 1Peking University Cancer Hospital & Institute, Beijing, China; 2Peking University Cancer Hospital & Institute, Beijing, China; 3University of California San Francisco Helen Diller Family Cancer Center, San Francisco, CA; 4Branch of Medical Statistics, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Beijing, China; 5Geneplus-Beijing, Beijing, China; 6Peking University Cancer Hospital & Institute, Beijing, China; 7Peking University Cancer Hospital & Institute, Beijing, China; 8Geneplus-Beijing, Beijing, China; 9Geneplus-Beijing, Beijing, China; 10Peking University Cancer Hospital & Institute, Beijing, China; 11Peking University Cancer Hospital & Institute, Beijing, China and 12Geneplus-Beijing, Beijing, China.

Body: Background: Next-generation sequencing is of increasing interest to identify specific targets for both drug development and treatment. The study of metastatic cancer is complicated by lack of tissue and the potential for change in biology over treatment. We evaluated ctDNA in patients with advanced breast cancer to explore the relationship between specific DNA mutations and prognosis as well as therapeutic decision making.

Methods: Peripheral blood was collected in EDTA at the time of diagnosis of advanced disease. Samples were sent to Geneplus-Beijing for sequencing. Indexed Illumina libraries were prepared from germline and circulating DNA using the KAPA Library Preparation Kit; the capture probe was designed based on genomic regions selected with 1021 genes, covering the most frequently mutated genes and exons in solid tumors. Clinical characteristics, treatment and outcome data were collected. We analyzed progression free survival (PFS) from first-line therapy and overall survival (OS), endpoints were correlated with observed gene mutations.

Results: 54 patients were enrolled; 27 (50%) HER2+, 22 (41%) hormone receptor + (HR+)/HER2-, and 5 (9%) triple negative (TNBC). Median age was 48 (range 26-74). The median follow-up was 8 years (range 12-180 months). First-line therapy included chemotherapy with trastuzumab for HER2+ disease, chemotherapy with endocrine maintenance (17) or endocrine therapy alone (5) for HR+/HER2- disease, and chemotherapy for TNBC. Mutations were found in TP53, PIK3CA, PIK3CA 3140 A>G (p.H1047R), and ERBB (including ERBB1-4), at 40.7%, 35.2%, 20.4% and 25.9%, respectively. In univariate analysis, patients with tumor mutations in TP53 had a shorter OS (median 64 vs 121 months, p=0.006). The PIK3CA 3140 A>G mutation was more frequent in HER2+ (7/27, 25.9%) than HR+/HER2- (4/22 (18.2%) or TNBC (0/5), and was associated with shorter median PFS in HER2+ disease (mutant vs. wild type: 4 (range 2-9) vs. 8 (range 2-22) months, p=0.006). The frequency of ERBB mutation was similar in HER2- 7/27(25.9%) (p=0.707) or HER2+ 7/27(25.9%) disease (p=0.066); there was no significant impact on PFS in any subset. Multivariate analysis for HER2+ disease including age, ER, Ki67, TP53, PIK3CA, PIK3CA 3140 A>G and ERBB, demonstrated that the PIK3CA 3140 A>G mutation was the only factor associated with shorter PFS (p=0.025); further analysis by receiver operating characteristic (ROC) curve showed that the PIK3CA 3140 A>G mutation and the mutation in PIK3CA 3140 A>G and ERBB combination pathway had a large area under the curve (AUC), with AUC of 0.789, and 0.734 respectively.

Conclusions: Using NGS in ctDNA, we found that the PIK3CA 3140A>G mutation was more frequent in HER2+ disease, and was the only mutation associated with shorter PFS on multivariate analysis. The presence of a TP53 mutation was associated with worse OS. Evaluation of ctDNA is feasible in a general breast cancer population and has prognostic impact; further correlation of these findings with tumor samples is ongoing.
Title: Exosomal Del-1 as potent diagnostic marker for breast cancer: Prospective cohort study

Soo Jung Lee¹, Jiyeon Lee¹, Jin Hyang Jung¹, Ho Yong Park¹, Pyong-Gon Moon¹, Moon-Chang Baek¹ and Yee Soo Chae¹.
¹Kyungpook National University Medical Center, Daegu, Korea.

Body: Background: The authors recently reported exosomal Del-1 as a diagnostic marker for breast cancer Therefore, the current study aimed to confirm the diagnostic role of exosomal Del-1 in a prospective cohort by comparing the plasma exosomal Del-1 levels before and after curative surgery.

Patients and methods: To identify the optimal sampling time for the postoperative analysis, blood was serially collected at day 1, 3, 5, and 7 after surgery from 22 patients with breast cancer. Thereafter, 111 breast cancer patients who underwent curative surgery were prospectively enrolled to compare their exosomal Del-1 levels before and after surgery using an ELISA with both anti-Del-1 and anti-CD63 antibodies.

Results: Based on the population of 22 patients, the optimal sampling time was determined as post-operative day (POD) 3, at which point the exosomal Del-1 levels were all normalized and stabilized to 0.5 or less of the optical density (OD) value, as defined in a previous study of 21 patients with a high Del-1 level at diagnosis. Therefore, POD 3 or later was identified as the sampling time for the subsequent prospective cohort study (n=111). At diagnosis, 107 patients (96.4%) showed a high exosomal Del-1 level (OD value > 0.5), while 101 patients (94.6%) showed a normalized Del-1 level (≤0.5) after surgery, representing a significant difference (Mean OD value = 1.232 vs. 0.196; P < 0.00001). In the survival analysis, the clinical outcomes were compared with the Del-1 levels after surgery. During a mean follow-up of 35.9 (range, 11.9 – 70.6) months, 13 (11.7%) patients experienced relapses (5 loco-regional, 1 contralateral, and 7 distant): 4 out of 6 in the high group (>0.5), 3 out of 4 in the borderline group, and 6 out of 95 in the normalized group (≤0.4). The survival analysis also identified that a high postoperative Del-1 level was significantly associated with a worse progression-free survival adjusted to the clinicopathological characteristics, such as age, stage, histological grade, and subtype (hazard ratio [HR] = 24.0; 95% confidence interval [CI] = 3.5 – 163.9; P = 0.0011). Moreover, the HR was significantly higher when OD 0.4 was selected as the cut-off value.

Conclusion: The current prospective cohort study confirmed the normalization of exosomal Del-1 after curative surgery, indicating exosomal Del-1 as a potential potent diagnostic biomarker for breast cancer. Plus, since a high Del-1 level after surgery was also possibly linked with early relapse, this suggests exosomal Del-1 as a potential prognostic marker by identifying the existence of residual cancer, regardless of the risk factors.
Title: Validation of an autoantibody blood test for the detection of early breast cancer (BC), particularly hormone receptor positive BC

Ola H Negm¹, Omar Ahmed¹, Grazziela Patrocinio Figueredo¹, Mohamed R Hamed¹, Lucas Pollard¹, Jonathan Garibaldi¹, Herb Sewell¹ and John F Robertson¹. ¹University of Nottingham.

Body: Background: Breast cancer (BC) remains the most common type of cancer in women, with an incidence of 1.6 million cases per year worldwide. Early detection through mammographic screening reduces BC mortality by ~20%, which while highly significant still leaves 80% of BC deaths unchanged. Furthermore, mammographic screening is only applicable to women between 50-70 years, in which only about one third of BCs occurs. There is an urgent need to identify a test, preferably a blood test showing high sensitivity and specificity for early BC across all ages of patients and all tumour types. Advances in understanding of the human autoantibody (AAB) response to early cancers has allowed us to harness this biological phenomenon for early cancer detection.

Aim: To identify a panel of tumor associated antigens (TAAs) which would detect AABs in the blood with high sensitivity and specificity for early BC: enabling cancer/normal discrimination.

Methods: Serum samples from 120 BC patients and matched controls were tested against a panel of 60 multiple TAAs using an optimised new multiplex microarray platform. A sub-group of 60 samples were also tested for AABs to estrogen receptor (ER). The selected TAAs were spotted onto a glass slide surface in an automated, highly reproducible system platform. If serum autoantibodies are present they bind to one or more of the TAA spots. Bound antibodies are detected with a fluorescent reporter and signal intensity measured using GenePix pro-6.

Data analysis: A Monte Carlo Simulation method was employed to define the best panel of the antigens with optimised cutoff points in each assay that would yield the highest sensitivity and specificity to discriminate BC patients from controls. AAB positivity in the BC group was analysed by tumor size (≤20mm versus >20mm), histological grade, lymph node status (positive or negative) and ER status (positive or negative).

Results: Using a panel of 12 TAAs, AABs were detected in pre-op blood of 34/60 (57%) primary BC patients compared to 9/59 controls (15%) (p=0.000003); one control sample data was unavailable. This gave a sensitivity of 57% and specificity of 85%. Median age of BC patients was 59yrs (20-81) versus 59yrs (28-81) in controls. There was no significant difference for AAB detection when compared to tumour size, grade, lymph node status or ER status. In the sub-group of 60 patients where ER antigen was measured using a panel of 8 TAAs AABs were detected in 20/29 BC patients compared to 2/30 controls (p=3.5e-7). This represents a sensitivity of 69% with a specificity of 93%.

Conclusions: These results confirmed our hypothesis that AABs can be detected in women of all ages with early BC. AABs were not related to tumour size, grade, lymph node status or ER status. If a panel of AAB assays can be validated it opens the possibility of a blood test for detection of early BC. Future direction of this research will be i) validation studies of a panel of AABs for detection of early BC, ii) detection of AABs at the earliest stages of carcinogenesis and iii) a panel of AABs which detect ER positive BC thereby enabling stratified chemoprevention in a high risk group combined with mammographic screening.

Title: Breast cancer subtype distribution and circulating tumor DNA in response to neoadjuvant chemotherapy: Experiences from a preoperative cohort within SCAN-B

Niklas Loman1,2,3, Yilun Chen2,3, Kristina Aaltonen2,3, Christian Brueffer2,3, Anthony M George2,3, Lina Zander1, Johan Vallon-Christersson2,3, Jari Häkkinen2,3, Daniel Förnvik1, Robert Rigo2,3, Anna Ehinger2,3,4, Martin Malmberg1, Christer Larsson2,5, Cecilia Hegardt2,3, Åke Borg2,3, Lisa Rydén2,3,6 and Lao H Saal2,3. 1Department of Oncology, Skåne University Hospital, Lund, Sweden; 2Lund University Cancer Center, Medicon Village, Lund, Sweden; 3Lund University, Lund, Sweden; 4Skåne University Hospital, Lund, Sweden; 5Division of Molecular Pathology, Department of Laboratory Medicine, Lund, Sweden and 6Skåne University Hospital, Lund, Sweden.

Body: Introduction: Preoperative chemotherapy in early breast cancer increases the rate of breast preservation and provides prognostic information. In the case of residual disease, a change in subtypes may be observed. Sensitive and reproducible biomarkers predicting treatment response early during the treatment course are needed in order to better exploit the potential benefit of an individualized preoperative treatment.

Material and Methods: In an ongoing prospective study within the population-based SCAN-B project (NCT02306096), patients undergoing preoperative chemotherapy for early or locally recurrent breast cancer have been treated with iv Epirubicin and Cyclophosphamide q3w x 3 in sequence with either Docetaxel q3w x 3 or Paclitaxel q1w x 9 with a preoperative intent. HER2-positive cases also received HER2-directed treatment. At baseline, patients were staged using sentinel node biopsy for clinically node-negative patients and CT scan for cytologically confirmed node-positive cases. A clinical core needle biopsy as well as tissue from the surgical specimen was collected for determination of conventional biomarkers including ER, PgR, HER2 and Ki67. Tumor biopsies for biomolecule-extraction and RNA-sequencing were taken using ultrasound guidance and collected fresh in RNAlater at baseline, after 2 treatment cycles, as well as at surgery. Blood plasma samples were collected at baseline, after one-, three-, and six- 3w treatment cycles, and post-surgery. Using RNA-sequencing data, somatic mutations were identified in the tumor biopsies and personalized analyses for circulating tumor DNA (ctDNA) were performed. A pathological complete remission (pCR) was defined as the complete disappearance of invasive breast cancer in the breast and axilla at time of definitive surgery. Subtyping was performed using modified St Gallen criteria (2013).

Results: Thus far, 45 patients aged 24-74 years have been included, of which 34 (76 %) were clinical stage 2 and 11 (24%) were stage 3. The subtype distribution at baseline was five Luminal A-like (11 %), 21 Luminal B-like (HER2 negative) (47 %), 8 HER2-positive (18 %) and 11 Triple-negative (ductal) (24 %). The rates of pCR in 38 operated cases to date were 0/3 Luminal A-like, 3/19 Luminal B-like (HER2 negative), 2/8 HER2-positive, and 4/7 Triple-negative (overall 24 % pCR rate). One patient did not undergo surgery due to clinically progressive disease. In 25 cases with evaluable residual disease at surgery, there was a shift in the subtype in 13 (52 %), the majority of which represented a transition from Luminal B to Luminal A. No Triple-negative cases underwent a change in subtype during treatment. Results of the ctDNA analyses will be presented at the meeting.

Discussion: We have established an infrastructure allowing for an extensive evaluation of preoperative chemotherapy in early breast cancer. The goal is to develop methods to refine response-guided treatment in early breast cancer using molecular responses in the tumor as well as in the blood circulation. The patients continue to be prospectively monitored with iterative ctDNA analyses during follow-up.
Title: Circulating level of GP88/Progranulin is associated with clinical outcome and overall survival in stage 4 breast cancer patients

Ginette Serrero¹, Douglas Hawkins², David Hicks¹, Paula Rosenblatt³, Nancy Tait³, Binbin Yue¹ and Katherine Tkaczuk³. ¹A&G Pharmaceutical Inc., Columbia, MD;²University of Minnesota, Minneapolis, MN and ³University of Maryland Greenebaum Comprehensive Cancer Center, Baltimore, MD.

Body: Monitoring of disease status in metastatic breast cancer (MBC) patients is a necessary step for an optimal management of patients during and post-therapy. Imaging technologies are the methods of choice in the standard of care to monitor therapy response and disease status in MBC patients. These methods are expensive, time-consuming and have limited sensitivity for real time monitoring. Measurements of circulating tumor markers CA15-3, CA125 and CEA have contributed, albeit with limitation, minimally invasive methods for MBC disease management. It is our hypothesis that measuring biomarkers involved in tumor biological processes may provide better evaluation of the disease state and thus aid real-time clinical management of MBC patients. Thus, addition of such new circulating disease biomarkers may improve the management of MBC patients. The 88kDa glycoprotein Progranulin (GP88/PGRN) fit these criteria. GP88/PGRN is expressed in tumor tissue and not in normal mammary tissue counterpart and secreted in the circulation of BC patients. Biological studies have established GP88/PGRN as a critical driver of BC cell proliferation, survival, invasiveness and drug resistance. Clinical studies have demonstrated that high tumor GP88/PGRN expression was prognostic for recurrence and that breast cancer patients had a statistically elevated GP88/PGRN serum level compared to healthy individuals. In the present study, we examined whether GP88/PGRN serum levels were elevated in MBC patients and whether GP88/PGRN circulating levels were correlated with patient clinical outcome and overall survival.

Under an IRB approved protocol at the University of Maryland Greenebaum Comprehensive Cancer Center, 101 stage 4 BC patients undergoing standard of care therapy and meeting the inclusion criteria were consented and enrolled. MBC patients’ demographics, clinical and disease characteristics and therapies were collected as part of the study. Blood samples were collected from each patient at specific times at follow-up visits during and post-therapy. The prepared serum was stored at -80C until tested for GP88 using a GP88 enzyme linked immunoassay developed in our laboratory. Statistical analysis using Kaplan-Meier functions established whether there was a correlation between GP88/PGRN serum level and overall survival in MBC patients. MBC patients with distinct survival characteristics (P=0.0002) could be stratified based on their circulating GP88/PGRN levels. Analysis of this association was carried out in MBC patients based on their age, race, tumor characteristics, receptor status and metastatic burden (number and sites of metastasis) and will be reported. We conclude that circulating levels of GP88/PGRN in MBC patients are correlated with overall survival and that monitoring circulating GP88/PGRN levels would provide additional information and valuable insight into real-time MBC disease status.

Title: Circulating HER2 extracellular domain (ECD) predicts a poor prognosis for metastatic breast cancer

Xiying Shao1, Xiaojia Wang1, Ping Huang1, Guangliang Li1, Weibin Zou1, Zhanhong Chen1 and Yabing Zheng1. 1Zhejiang Cancer Hospital, Hangzhou, Zhejiang, China.

Body: Background: Amplification or overexpression of HER2 has been shown to play an important role in approximately 30% of breast cancers and is strongly associated with increased recurrence and a worse prognosis. The HER2 extracellular domain (ECD) may be cleaved and shed from the surface of breast cancer cells and serum ECD can be detected by enzyme-linked ELISA.

Methods: Two hundred and seven metastatic breast cancer patients from March 2009 to July 2011 were involved in this prospective study at Zhejiang Cancer Hospital. In this study, we explored the relationship between circulating HER2 ECD and clinical pathological characteristics, included HER2 status. Then we can predict the outcome of metastatic breast cancer patients and determine the predictive value as a valuable prognostic factors. Serum HER2 ECD levels were measured by ELISA. Tissue HER2 was determined by IHC and FISH in tumor samples, respectively.

Results: For the metastatic breast cancer patients, the percentage of cases with high concentrations (≥15 ng/ml) of serum HER2 ECD is 39.1% (43/110) in HER2-positive cases and 23.4% (22/94) in HER2-negative cases (P=0.017). High serum HER2 ECD levels (≥15 ng/ml) were significantly associated with elevated serum CEA (52.1% v 21.5%, OR 3.978, 95%CI 2.138-7.401, P=0.000), CA125 (48.5% v 23.5%, OR 3.064, 95%CI 1.650-5.691, P=0.000), CA153 (53.2% v 17.1%, OR 5.48, 95%CI 2.897-10.366, P=0.000), LDH (53.3% v 23.1%, OR 3.798, 95%CI 2.011-7.173, P=0.000) and AKP (51.2% v 26.5%, OR 2.911, 95%CI 1.442-5.879, P=0.002) in metastatic breast cancer patients. There were still statistically significant correlation between increased serum HER2 ECD levels and the site of relapse, visceral involved (37.9% v 14.8%, OR 3.511, 95%CI 1.548-7.961, P=0.002), liver(42.7% v 24.0%, OR 2.358, 95%CI 1.294-4.297, P=0.005), brain (50.0% v 26.7%, OR 2.744, 95%CI 1.397-5.391, P=0.003), respectively.

Conclusions: Monitoring the circulating levels of the HER2 ECD in patients with metastatic breast cancer provides a real-time assessment of tumor burden and indicates poor prognosis, and may provide important information for reassessment of HER2 in HER2-negative metastatic breast cancer.
Title: Cell free DNA analysis identifies actionable ERBB2 amplifications in patients with HER2 negative breast cancer

Victoria M Raymond1, Joseph Diaz1, Kimberly C Banks1, Eugene Ahn2, Adam Brufsky3, Matthew Ellis4, Marc Lippman5, Christine Lee1, Timothy Pluard6, Marshall Schreeder7, Richard Schwab6 and Richard B Lanman1. 1Guardant Health, Redwood City, CA; 2Cancer Treatment Centers of America, Zion, IL; 3University of Pittsburgh Medical Center, Pittsburgh, PA; 4Baylor College of Medicine, Houston, TX; 5Sylvester Comprehensive Cancer Center; University of Miami Miller School of Medicine, Miami, FL; 6St. Luke’s Health System, Kansas City, MO; 7Clear View Cancer Center, Huntsville, AL and 8University of California, San Diego, San Diego, CA.

Body: Identification of ERBB2 (HER2) overexpression in metastatic breast cancer informs utilization of HER2 targeted therapy. The NCCN recommends HER2 expression re-evaluation at the first disease recurrence in patients with negative or equivocal tissue status given results discrepancies due to inadequate tissue biopsy, tumoral heterogeneity, biopsy technique or fixation as well as discordance in ERBB2 (HER2) expression between primary and metastatic lesions. We examined the incidence of ERBB2 (HER2) negative to positive “flips” (e.g. to ERBB2-amplified in plasma) in a cohort of patients who underwent a blood-based cell-free DNA (cfDNA) assay at a CLIA-certified/CAP-accredited/NYSDOH-approved molecular diagnostic laboratory. Laboratory database was queried for samples from patients with a breast cancer diagnosis. The query was filtered to ensure patients with multiple cfDNA timepoints were counted only once. Patients without a pathology report submitted at any cfDNA collection timepoint or the pathology report did not include ERBB2 (HER2) status, results were inconclusive or quantity not sufficient were excluded. Between March 2014 and April 2017, 1,853 unique patients were identified with reported ERBB2 (HER2) status. For patients with more than one cfDNA timepoint collected (N=349; 18.8%), the earliest pathology report was referenced. 1,386 patient tumor samples were negative for HER2 overexpression (74.8%), 325 (17.5%) were positive, and 142 (7.7%) were equivocal. Twenty-nine of the 1,386 patients with reported tumor negative HER2 status had amplification on subsequent cfDNA analysis (2.1%).

All 29 patients were female. Most patients (N=21) had a single cfDNA timepoint collected. Median age at cfDNA blood draw was 58 years (range 28–68). Median length of time between reported tissue negative status and cfDNA blood draw was 405 days (range 21–4,060). Median plasma ERBB2 copy number was 2.44 (greater than 50th-centile per laboratory data) (range 2.15–16.5).

Clinical follow-up was obtained for 19 patients (65%). Nine patients were lost to follow-up or succumbed to disease prior to initiation of a new therapeutic regimen. One patient was known HER2 positive prior to receipt of the cfDNA results. In the remaining nine patients, six initiated targeted HER2 therapy following receipt of the cfDNA results, with five of six (83%) demonstrating a clinical response. In one patient with known ER/PR positive, HER2 negative disease, progressing through multiple lines of therapy, addition of trastuzumab and pertuzumab to her paclitaxel regimen following identification of the cfDNA ERBB2 amplification resulted in a significant reduction in CEA levels (238 to 37.9 ng/mL) by week five. In a second patient, following identification of the cfDNA ERBB2 amplification, she was treated with trastuzumab and pertuzumab along with docetaxel and had a dramatic response. She continues on trastuzumab and pertuzumab alone. Although a modest sample size, this is the second cfDNA series demonstrating that ERBB2 (HER2) status may flip from negative to positive upon recurrence or metastasis, and that targeting plasma-detected ERBB2 amplification with anti-HER2 has clinical benefit. cfDNA is a viable alternative to tissue rebiopsy in this patient population.
**Title:** Utilization of cell-free circulating tumor DNA for management of breast cancer: Practices in academic and community oncology

Roby A Thomas¹, Natalie Klar¹, Lesli Kiedrowski², Rebecca J Nagy², Adrian V Lee¹ and Adam Brufsky¹. ¹University of Pittsburgh Medical Center, Pittsburgh, PA and ²Guardant Health, Redwood City, CA.

**Body:** Background: Next-generation sequencing (NGS) of cell-free DNA (cfDNA) is increasingly being utilized to assess somatic genomic alterations in patients with breast cancer. We investigated the clinical use of such testing in breast cancer care in a major healthcare system with both academic and community-based practices. We also explored the observed genomic landscape in the analyzed patient cohort and whether treatment plans were modified based on the results.

Methods: A retrospective review of cfDNA NGS results (Guardant360) ordered at the University of Pittsburgh Medical Center for patients with breast cancer from 7/2015-3/2017 was performed. Test ordering patterns, the landscape of genomic alterations identified, and clinical use of select results were assessed.

Results: During this period 95 samples were submitted, 73 (77%) ordered by academic center providers and 22 (25%) from community providers. Alterations were detected in 88 samples (93%) with a median of 3 alterations per test. Five patients had serial samples ordered assessing dynamic cfDNA across clinical treatment and progressions, leaving 84 unique patients in the dataset. The average patient age was 57, and 95% of patients were female. Patients were most often observed to have alterations in TP53 (51%), PIK3CA (44%), and ESR1 (26%). Additional clinical data were collected for 48 patients with mutations or amplifications in PIK3CA, ESR1, and/or ERBB2 (HER2) to assess for clinical use of genomic information. Results were used to change clinical care in 13 (27%) of these cases. Community providers were more likely to use genomic results to guide clinical management in these cases (9/16, 56%) than academic providers (4/32, 12.5%), p=0.001. Of this patient subset, those with tests ordered by an academic provider had more lines of prior therapy at the time of testing vs. those in the community (average 5.9 vs 3.4 respectively, p=0.019).

Conclusions: CfDNA NGS analysis for somatic genomic alterations in breast cancer is being ordered clinically by both academic and community practices within this healthcare system. Results for a subset of clinically annotated patients were acted on more frequently by community-based ordering providers, which may be related to patients tested at academic sites having had more lines of prior treatment.
Circulating tumor DNA predicts clinical outcome in early stage triple negative breast cancer

Foluso Ademuyiwa¹, Yan-Yang Feng¹, Zachary Skidmore¹, Jason Kunisaki¹, Jason Walker¹, Robert Fulton¹, Kilannin Krysiak¹, Tracy Skinner¹, Katherine Weilbaecher¹, Cynthia Ma¹, Obi Griffith¹ and Malachi Griffith¹. ¹Washington University, St Louis, MO.

Background- Triple negative breast cancer (TNBC) is the most aggressive subtype of breast cancer as these patients have the highest risk of recurrence and death. Only 35% of TNBC patients achieve a pathologic complete response (pCR) following neoadjuvant chemotherapy. Patients who do not achieve pCR have a 27% risk of distant recurrence and ultimate death at 3 years compared to 9% for pCR. Unidentified micrometastases are responsible for ultimate overt progression and death. Developing strategies to identify patients with minimal residual disease following curative treatment is an unmet need. Circulating tumor DNA (ctDNA) can characterize and monitor advanced cancers. In this study, we sought to assess if ctDNA can predict clinical outcome in TNBC.

Methods- Biospecimens were obtained from patients with stages II and III TNBC enrolled on a neoadjuvant trial (NCT02124902). Patients have a research biopsy and plasma for ctDNA collected at baseline, cycle 1 day 3, definitive surgery for those with residual disease, and at recurrence for those who relapse. Plasma for ctDNA is also collected every 6 months for 5 years after treatment. Patients receive docetaxel and carboplatin every 3 weeks X 6 cycles. Surgery is 3-5 weeks after chemotherapy. Six patients' serial tumor samples and germline DNA were studied by whole exome sequencing. The median sequencing depth was 90.13x. Sequencing was performed on samples with high cellularity (≥50%). All 6 patients also had serial ctDNA analyzed using Swift Biosciences Accel-Amplicon™ 56G Oncology Panel v2. After identifying somatic mutations in each breast tumor series, we determined the subset of mutations that intersected with the regions targeted by the Swift 56 gene panel. We then evaluated whether corresponding mutations could be detected in ctDNA, and if ctDNA predicted clinical outcome.

Results- Four of the 6 patients were non-pCR with residual disease following chemotherapy. We identified 627 somatic variants by exome analysis that were called by at least two somatic variant callers and passed additional quality filtering steps. Of these, 10 variants overlapped with the Swift panel. TP53 variants were identified in all 6 patients' tumor tissue samples. At least one TP53 variant was identified in 4 patients' baseline pre-chemotherapy ctDNA samples. Both pCR patients had either no detectable ctDNA TP53 mutations (NTN007-ref. in baseline tumor tissue was 19.58% variant allele frequency [VAF]); or clearance of ctDNA following chemotherapy from 4.45% VAF at baseline to 0.06% following chemotherapy (NTN004-ref. in baseline tumor tissue 37.34% VAF). Three non-pCR patients had persistent TP53 mutations in ctDNA during the treatment course. One non-pCR patient did not have detectable mutations in ctDNA. The only patient with recurrent disease whose ctDNA TP53 mutation persisted during the treatment course (baseline VAF-1.65%, cycle 1 day 3-0.78%, definitive surgery-0.09%), was found to have a higher ctDNA VAF at recurrence (29.55%).

Conclusion- In this pilot study, mutation tracking by ctDNA is sensitive and distinguishes pCR from non-pCR in TNBC patients receiving neoadjuvant chemotherapy. ctDNA also identifies recurrence following curative therapy. Evaluating ctDNA as a biomarker of outcome in TNBC is warranted.
Title: Elevated serum RAS p21 is an independent prognostic factor in metastatic breast cancer

Malgorzata Banys-Paluchowski¹, Tanja Fehm², Wolfgang Janni³, Bahriye Aktas⁴, Peter A Fasching⁵, Sabine Kasimir-Bauer⁶, Karin Milde-Langosch⁶, Klaus Pantel⁷, Brigitte Rack³, Sabine Riethdorf⁷, Erich-Franz Solomayer⁸, Isabell Witzel⁶ and Volkmar Müller⁶.

Body: Background
An important component of the RAS signalling pathway, the RAS p21 oncogene, is frequently hyperactivated in breast cancer. Its expression in tumor tissue has been linked to poor clinical outcome. This study was designed to evaluate the clinical relevance of RAS p21 levels in peripheral blood in a large cohort of metastatic breast cancer patients.

Methods
251 patients with metastatic breast cancer were enrolled in this prospective, multicentre, non-randomized study conducted on behalf of the DETECT Study Group (Current Controlled Trials ISRCTN59722891). Blood samples were collected before start of first-line or later-line treatment. RAS p21 was determined using a sandwich-type ELISA immunoassay. For the determination of the cutoff, blood samples from age-matched healthy controls were analyzed. A value above 452 pg/ml was regarded as elevated (mean + 2 x SD). In the univariate survival analysis, two other cutoffs were considered as well (50th and 75th percentile of patients, i.e. 229 pg/ml and 320 pg/ml). Circulating tumor cells (CTCs) were detected using the CellSearch system.

Results
29 of 251 (12%) patients had RAS p21 levels above the cut-off level of 452 pg/ml. Clinical-pathological parameters, such as hormone receptor and HER2 status, line of therapy and CTC status, did not correlate with RAS p21 levels.

Patients' characteristics.

Elevated RAS p21 was significantly associated with shorter progression-free and overall survival in the univariate analysis (median PFS: 3.9 months [95%-CI: 1.8-6.0] for patients with elevated RAS p21 levels versus 8.5 months [95%-CI: 7.4-9.5] with non-elevated levels [p = 0.01]; median OS: 7.1 months [95%-CI: 0.3-14.2] versus not reached [p = 0.002], respectively). When RAS p21 cutoffs other than 452 pg/ml were considered, elevated RAS p21 was significantly associated with OS (p = 0.019 in case of 229 pg/ml; p = 0.003 in case of 320 pg/ml), but not with PFS. Classical clinical-pathological factors were included into a multivariate Cox regression analysis. In addition, factors previously shown to influence survival in a univariate analysis, such as serum HER2, CAIX and TIMP1, were included as well. In the multivariate analysis, RAS p21, presence of ≥ 5 CTCs per 7.5 ml blood, higher grading and higher line of therapy remained independent predictors of shorter OS.

**Conclusions**

This is the first study to address the clinical relevance of circulating RAS p21 in a large group of metastatic breast cancer patients. Patients with elevated levels of circulating RAS p21 had significantly worse clinical outcome. Hypothetically, these patients might benefit from therapeutic strategies targeting RAS pathway.
**Title:** Use of cell-free circulating RNA and expression of PD-L1 and HER2 in plasma to monitor and predict clinical response in metastatic breast cancer patients

Aurelio B Castrellon\(^1\), Michel Velez\(^1\), Luis E Raez\(^1\), Kathleen Danenberg\(^2\), Shahrooz Rabizadeh\(^3\), Joshua Usher\(^2\), Yolanda Jaimes\(^3\), Brian Hunis\(^1\), Ana C Bittencourt\(^1\), Adriana Milillo\(^1\), Marcelo Blaya\(^1\), Cheryl Habaue\(^1\) and Peter V Danenberg\(^4\). \(^1\)Memorial Cancer Institute, Hollywood, FL; \(^2\)Liquid Genomics, Inc., Culver City, CA; \(^3\)NantOmics, Culver City, CA and \(^4\)Keck School of Medicine of University of Southern California, Los Angeles, CA.

**Body:** Background: In addition to traditional radiology tests, cell-free circulating tumor RNA (cfRNA) extracted from plasma of cancer patients (pts) provides a means of evaluating tumor response, but based on molecular changes in the tumor. Measuring dynamic changes in gene expression and levels of total cfRNA (per ml of plasma) in metastatic patients has shown great potential for evaluating disease status and predicting outcome to anti-tumoral therapy in advance of imaging. Though checkpoint inhibitors have not been assessed widely in breast cancer, TNBC has shown mild responses to pembrolizumab and atezolizumab, with significantly better responses in pts with detectable PD-L1 expression.

**Methods:** Blood was drawn from pts at approximately 6-week intervals under various therapies and CT scans were performed at approximately 3-month intervals. CfRNA was extracted from the resulting plasma and reverse transcribed with random hexamers to cDNA. Levels of cfRNA were quantitated by RT-qPCR and correlated with pt response (PR/SD/PD), as determined by CT scans. Levels of gene expression in cfRNA (including PD-L1 and HER2) were monitored in pts across blood draws.

**Results:** A total of 28 breast cancer pts were enrolled in a 1-year clinical study. Of pts, 39% (11/28) were Caucasian and 36% (10/28) Hispanic. 19 pts completed the first two cycles of therapy: 2 pts had PR and showed no change (NC) or decrease (DEC) in levels of cfRNA, 11 pts achieved SD with 8 showing DEC or NC in cfRNA levels, and 6 pts had PD and all underwent increases (INC) in cfRNA levels (median increase: 788 ng/mL plasma) which correlated with progressive disease status. Of pts with SD/PR, 4 showed either an emergence or significant increase in PD-L1 expression across blood draws (3.7-98 ct); of PD pts, 1 showed a significant emergence of PD-L1 expression (12.5 ct) across blood draws. 3/5 of these PD-L1 expressing pts were being treated with an everolimus combination; the emergence or increase of PD-L1 in response to this therapy suggests use of checkpoint inhibitors as an option for these pts. In response to therapy, 3 of 5 pts had PD-L1 cfRNA levels above levels predictive of response to nivolumab in lung cancer pts. In the only pt with hyperexpressed HER2, the disappearance of HER2 cfRNA matched positive response (PR) to treatment with trastuzumab. PD-L1 decreased concomitantly for this pt.

**Conclusion:** We found a strong correlation between clinical responses and changes in plasma levels of ctRNA in breast cancer (84%). Most of these were documented several weeks before imaging was done. Levels of PD-L1 and HER2 expression in plasma can also be used to monitor pt response to specific therapies. The emergence of PD-L1 expression in response to various therapies in breast cancer may confer sensitivity to checkpoint inhibitor therapy.

Title: Circulating tumor DNA analysis with ultra-high sensitivity sequencing in metastatic breast cancer

Isaac Garcia-Murillas¹, Paula Proszek², Charlotte Fribbens¹,³, Lina Yuan², Hannah Bye², Mike Hubank², John Jiang⁴, Stephanie Yuan⁴, John Palma⁴, Stephen Johnston³, Alistair Ring³ and Nicholas Turner¹,³. ¹Breast Cancer Now Research Centre, The Institute of Cancer Research, London, United Kingdom; ²Centre for Molecular Pathology, The Royal Marsden Hospital, London, United Kingdom; ³The Royal Marsden Hospital, London, United Kingdom and ⁴Roche Sequencing Solutions, Pleasanton, CA.

Body: Introduction.
Circulating tumor DNA analysis has the potential to transform the clinical management of patients with breast cancer. We assessed the accuracy of ultra-high sensitivity ctDNA testing in patients with advanced breast cancer.

Methods.
From a prospective tissue collection study, we identified 25 patients with a contemporaneous metastatic tissue biopsy and plasma for ctDNA testing. Tumour DNA from the metastatic tissue biopsy was sequenced with a validated clinical hybrid capture panel, while plasma cell free DNA was sequenced with AVENIO ctDNA technology – a molecular barcoded duplex sequencing based on CAPPseq technology. Sample collection is on-going and results from the full concordance series will be presented at the conference.

Results.
Circulating tumour DNA was detectable in 87% (20/23) of patients, with at least one variant from tissue sequencing identified in plasma. There was overall high agreement between tissue and plasma sequencing. The sensitivity of plasma testing for variants identified in tumour, positive percent agreement, was 75% (24/32). Plasma testing revealed a diversity of sub-clonal mutations including polyclonal ESR1, polyclonal FGFR2 and FGFR3 mutations, rare KRAS mutations, and TSC1 and MSH2 inactivating mutations.

Conclusions.
Circulating tumour DNA testing with molecular barcoded duplex sequencing offers high sensitivity for tumour variant detection. The extent of sub-clonal resistance mutations identified emphasises the genetic diversity of advanced breast cancer.
Title: Higher mutation burden and mutant allele fraction of circulating tumor DNA corresponds to worse progression free survival in metastatic breast cancer patients

Tanya Keenan1,2, Dejan Juric1,2, Andrzej Niemierko1,2, Laura Spring1,2, Hannah Park1, Giuliana Malvarosa1, Maureen Beeler1, Beverly Moy1,2, Leif Ellisen1,2, Steven Isakoff1,2 and Aditya Bardia1,2. 1Massachusetts General Hospital Cancer Center, Boston, MA and 2Harvard Medical School, Boston, MA.

Body: Introduction: Genomic profiling of circulating tumor DNA (ctDNA) allows non-invasive monitoring of tumor genetic changes and molecular heterogeneity. In addition to actionable mutations, mutational landscape derived from ctDNA could provide a better representation of overall tumor burden and tumor heterogeneity, as well as potentially impact clinical outcomes. To evaluate this hypothesis, this study assessed the association of mutation burden and average mutant allele fraction (MAF) with tumor subtype, therapeutic response, and survival in patients with metastatic breast cancer.

Methods: Whole blood samples from patients with metastatic breast cancer were collected during clinic visits before start of a new therapy. Plasma-derived cell-free DNA underwent complete next-generation sequencing of 73 cancer-related genes with the Guardant360 test. Mutation burden was defined as the number of genes with mutations, and average MAF was calculated as the sum of the highest MAF for each mutated gene divided by the number of genes with mutations. Time to progression was measured from the date of new treatment initiation after circulating tumor DNA collection to the date of progression. Multivariate cox proportional hazard models assessed the association of mutation burden and average MAF with progression free survival (PFS), adjusted for age, receptor subtype (hormone receptor positive, HR+; human epidermal growth factor 2 positive, HER2+; triple negative breast cancer, TNBC), treatment subtype (chemotherapy vs. targeted therapy), and number of prior metastatic breast cancer therapies. A p value of 0.05 was considered statistically significant.

Results: The study population consisted of 158 women with metastatic breast cancer (108 HR+, 14 HER2+, 19 TNBC) with a median age of 59 years and a median of 2 prior metastatic breast cancer therapies. Median follow up time was 4.0 months, and median PFS was 15.7 months. Mutation burden was greater in triple negative compared to hormone receptor positive breast cancer (7.5 vs. 4.8, p = 0.02) but no different in patients with > 2 prior metastatic therapies vs. not (5.1 vs. 4.7, p = 0.60) and age >45 vs. not (5.0 vs. 3.9; p = 0.26). In univariate models, high mutation burden (> median of 2) and high MAF (> median of 1.4) were significantly associated with worse PFS (Table). These results were similar in effect size and significance when adjusted for age, receptor subtype, treatment subtype, and number of prior metastatic breast cancer therapies. Impact of mutation burden on response to specific therapies will be presented at the meeting.

Conclusions: Higher ctDNA mutation burden and average MAF is associated with worse progression free survival and possibly reflects a more treatment refractory phenotype. Whether immunotherapy, alone or in combination, could influence the clinical outcomes in metastatic breast cancer patients with high ctDNA mutation burden is unclear and warrants additional research.
Title: Circulating tumor DNA detection anticipates disease recurrence in early stage breast cancer: A pilot study generating an observational confirmatory trial

Maria Grazia Daidone¹, Serena Di Cosimo¹, Silvia Veneroni¹, Filippo Cascone¹, Loris De Cecco¹, Matteo Dugo¹, Secondo Folli¹, Giulia V Bianchi¹, Elena Tamborini¹, Adele Busico¹ and Valentina Appierto¹. ¹Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy.

Body: Sensitive tumor biomarkers able to monitor disease progression would contribute to post-surgical treatment decision making in early breast cancer. We investigated the feasibility of using circulating tumor DNA (ctDNA) to early detect new disease manifestations in serial plasma samples collected during post-surgery follow-up from patients operated for stage I breast cancer from 1992 to 1993 at Istituto Nazionale Tumori in Milan. Forty patients that underwent radical or conservative surgery for T1/T2-N0-M0 breast cancer and that were followed for at least 15 years were included in a pilot study for the retrospective analysis of ctDNA on at least 3 plasma samples obtained during follow-up. To assess the feasibility of ctDNA analysis in archival plasma samples collected in heparin and stored from 10 to 25 years, preliminary experiments demonstrated that ctDNA was not affected by: 1) heparinase I digestion of extracted DNA and 2) DNA pre-amplification step to overcome limitations due to small plasma aliquots. Mutational analysis of breast cancer tissues was performed by Ion Torrent-targeted next generation sequencing and the identified Single Nucleotide Variations (SNV) were first validated and then tracked in plasma samples by using ad hoc digital polymerase chain reaction assays. One or more SNVs were identified in tumor tissue specimens and validated in 27/40 cases. Among those 27 breast cancers, 6 cases relapsed locally, 4 in distant sites, and 17 remained disease-free for the entire follow-up. ctDNA was undetectable during the post-surgical follow-up in 16/17 disease-free women up to 160 months of surgery, while it was detectable in 9/10 patients developing unfavorable events and anticipated the clinical diagnosis of relapse in 7/10 patients with a median lead time of 20 months. Our results are the first to associate mutation tracking to local recurrence and indicate that in patients with early breast cancer ctDNA monitoring during post-operative follow-up can anticipate the diagnosis of new disease manifestations, thus potentially allowing prompt treatments. These findings establish the rational to plan prospective studies to evaluate in the early breast cancer context the potential of ctDNA as a non-invasive and sensitive biomarker for monitoring tumor progression. Based on these results, we activated in 2016 a prospective observational study to confirm the predictive value of ctDNA on local and distant relapse in patients with early and localized triple negative breast cancer. As for May 2017, 145 patients with triple negative tumors were potentially enrolled for a ctDNA-based post-surgical follow-up: 111 cases at first diagnosis and 34 cases at surgery after neo-adjuvant treatment. One hundred-ten women accepted to participate in the study and signed a specific informed consent, whereas 22 patients refused to participate and 13 were lost to follow-up. For 94 patients (66 at initial diagnosis and 28 after neoadjuvant chemotherapy) plasma samples have been already longitudinally collected and DNA sequencing is currently in progress.
Title: The utility and correlation of circulating tumor cells (CTCs) and cell-free circulating tumor DNA (ctDNA) based on HER2 positivity

Body: Background:
CTCs are well-established prognostic and predictive biomarkers for metastatic breast cancer (MBC) and other solid tumors. ctDNA is emerging as a quantitative blood-based biomarker for monitoring genomic alterations and disease progression. We evaluated the clinical utility and correlation of these liquid biopsy molecular tools in a cohort of MBC patients.

Methods:
CTC samples were obtained from an ongoing, prospective study of blood based prognostic biomarkers for breast cancer patients. At this time, 71 patients and 98 total samples have been collected. CTC enumeration was performed using the CellSearch™ platform (Menarini, IT). Within this cohort, MBC patients who had ctDNA testing were identified. ctDNA testing was performed using Guardant360™ (Guardant Health, CA), a digital next-generation sequencing technology. Two groups were analyzed: (1) HER2-negative patients with CTC ≥ 5 in 7.5 ml of blood (2) HER2-positive patients who had been treated with HER2 targeted therapy.

Results:
22 samples (N=16 patients) were found with CTC ≥ 5 (range 8-904) and concurrent ctDNA testing (median timeframe between collection 0 days, range 0-42 days). There was a significant association between number of CTCs and the total number of genomic alterations detected in ctDNA (paired two sample t-test, p=0.012). In addition, CTC enumeration was significantly correlated with somatic alteration burden of the dominant clone (paired two sample t-test, p=0.023). The most common alterations detected in the blood were TP53 (55% of patients, 18 total mutations), PIK3CA (41% of patients, 15 total mutations), and ESR1 (32% of patients, 14 total mutations). For patients with HER2 positivity receiving HER2-targeted therapies (N=16 samples from 11 patients), only 18.8% of samples had detectable CTCs (all less than 5) as compared to 75.0% of samples with detectable ctDNA alterations. In N=12 samples with detectable ctDNA mutations, mean number of genomic alterations was 4.4 with mean somatic mutation burden of 2.95%.

+excludes ctDNA samples without detected genomic alterations

Conclusions:
In HER2-negative MBC patients, CTC enumeration was significantly correlated with the number of ctDNA genomic alterations and somatic alteration burden, indicating the potential for ctDNA as a prognostic, quantitative biomarker of tumor burden. In patients with HER2 positivity, ctDNA may be a more sensitive liquid biopsy tool given the rarity of detecting CTCs detection in this population using the CellSearch™ system. In HER2-positive patients, consideration of size-dependent selection of CTCs using filtration of cells that have undergone epithelial-mesenchymal transition may improve detection in this subgroup.

Body: Aims: (i) Determine whether between-observer reproducibility for Ki67 when assessed on whole sections according to a standardized scoring protocol is adequate for clinical application. (ii) Compare between-observer reproducibility of Ki67 scores assessed on hot-spots to scores using a global method that averages across a tissue section.

Background: The nuclear proliferation biomarker Ki67 has multiple potential roles in breast cancer, including aiding decisions based on prognosis, but unacceptable levels of between-laboratory variability have been observed. The International Ki67 in Breast Cancer Working Group has undertaken a systematic program to determine whether Ki67 measurement can be analytically validated and standardized across labs. In phase 1, variability in visual interpretation was identified as an important source of variability. Phases 2 and 3a showed that adherence to defined scoring methods substantially improved reproducibility in scoring tissue microarrays and core-cut biopsies. We now assess whether acceptable reproducibility can be achieved on whole sections.

Methods: Adjacent sections from 30 primary ER+ breast cancers were centrally stained for Ki67 to assemble 4 sets of 30 stained tumor sections, circulated among 23 labs in 12 countries. Ki67 was scored by 2 methods by all labs: (a) global: 4 fields of 100 tumor cells each were selected to reflect observed heterogeneity in nuclear staining (b) hot-spot: the field with highest Ki67 percentage of tumor cells with nuclear staining was selected and up to 500 cells scored. Ki67 scores were log2-transformed for statistical analyses and back-transformed for presentation. The primary objective was to assess whether either method could achieve an intraclass correlation coefficient (ICC) significantly greater than 0.8, considered substantial to almost-perfect reproducibility. Secondary objectives were to assess which method had highest observed ICC and to assess whether observers identified the same “hot-spots”.

Results: ICC for the global method was 0.87 (95%CI: 0.799-0.93), marginally meeting the prespecified success criterion. The ICC for the hot-spot method was 0.83 (95%CI: 0.74-0.90) and had a CI extending below the success criterion. Across the 23 labs, geometric mean value of the 30 scores ranged from 8.5 to 19.6 for the global method and from 12.8 to 30.3 for the hot-spot method. The overall mean (95% CI) of these values was 12.9 (11.9-14.0) and 20.9 (19.1-22.8), respectively. Visually, between-laboratory agreement in location of selected hot-spot varies between cases. The median times for scoring were 9 and 6 minutes for global and hot-spot methods respectively.
Conclusions: The global method marginally met the prespecified criterion of success; it should now be evaluated for clinical validity in appropriate cohorts of cases. The hot-spot method was observed to have slightly less reproducibility between labs. The time taken for scoring by either method is practical using counting software we are making publicly available. Establishment of external quality assessment schemes is likely to improve the reproducibility between labs further.

Title: Macrodissection prior to closed system RT-qPCR is not necessary for estrogen receptor and HER2 concordance with IHC/FISH in breast cancer

Swati Gupta¹, Daniel E Carvajal-Hausdorf¹, Brad E Wasserman¹, Kenneth Ho², Jodi Weidler², Wendy Wong², Brian Rhees², Michael Bates² and David L Rimm¹. ¹Yale University School of Medicine, New Haven, CT and ²Division of Oncology Research and Development, and Medical and Scientific Affairs and Strategy, Oncology, Cepheid, Sunnyvale, CA.

Body: Background: An on-demand, closed system RT-qPCR (the GeneXpert system, Cepheid, Sunnyvale, CA) has the potential to provide biomarker information in low resourced settings. The system consists of an inexpensive, single-use, disposable, macrofluidic cartridge and an instrument that automates RT-qPCR. Here we use it with a research use only cartridge (STRAT4) that measures the mRNA expression levels of ESR1, PGR, ERBB2, and MKi67 using a single 5uM thick FFPE tissue section from an excisional or core biopsy specimen containing invasive carcinoma of the breast. The assay, results are expressed as a delta cycle threshold (dCt) value, defined as the Ct of a control gene (CYFIP1) minus the Ct of the target gene (ESR1, PGR, ERBB2, or MKi67). We determine whether the dCt result for each marker is equivalent using the entire non-macrodissected section (non m-d) to the dCt results obtained following tumor macro-dissection (m-d) to eliminate non-tumor elements from the assay.

Methods: We evaluated the impact of m-d versus non m-d using STRAT4 on a cohort of 62 formalin-fixed paraffin-embedded (FFPE) tumor core needle biopsy specimens with a range of HER2 expression determined by clinical immunohistochemistry and fluorescence in situ hybridization (IHC/FISH). Concordance (sensitivity and specificity) of the STRAT4 ESR1 and HER2 mRNA versus ER and HER2 IHC/FISH measurements were also assessed.

Results: We observed excellent agreement of the resulting dCt between the paired samples, m-d versus non m-d, for ESR1 (R²=0.92), PGR (R²=0.90), ERBB2 (R²=0.94) and MKi67 (R²=0.90). No significant difference (P value > 0.99) was observed when we compared the dCt between the paired samples m-d versus non m-d. In addition, using the predefined STRAT4 dCt cutoff for ESR and ERBB2 positivity, we found a significant concordance between RT-qPCR and IHC/FISH for ESR-positivity for the paired samples, m-d (P value < 0.001; sensitivity = 0.98; specificity = 1; PPV = 1; NPV = 0.95) versus non m-d (P value < 0.001; sensitivity = 0.98; specificity = 1; PPV = 1; NPV = 0.95) and HER2-positivity for the paired samples, m-d (P value < 0.001; sensitivity = 0.85; specificity = 0.98; PPV = 0.92; NPV = 0.96) versus non m-d (P value < 0.001; sensitivity = 0.71; specificity = 0.98; PPV = 0.90; NPV = 0.92), respectively.

Conclusion: These data suggest that mRNA for ESR and ERBB2 is sufficiently low in surrounding tissues that m-d of whole sections is not required for accurate assessment of key breast cancer mRNA markers in a closed system RT-qPCR assay. The simplicity of the assay workflow may be particularly valuable in low resourced settings where routine access to pathology expertise and to high quality IHC/FISH is challenging.
Title: A multicenter clinical study of Xpert® breast cancer STRAT4 demonstrates high concordance with central lab ER, PgR, HER2, and Ki67 IHC and HER2 FISH tests in FFPE breast tumor tissues

Natalie C Wu¹, Edith Wong¹, Barbara Acca¹, Jill Birkmeier¹, Lisa Tran¹, Suling Zhao¹, Wendy Wong¹, Victor C Chu¹, Ken Ho¹, Monisha Malek¹, Cici Lu¹, Grace Ge¹, Kerstin David³, Neil B Quigley⁴, Safedin Sajo Beqaj⁵, Simon Davenport², Jodi Weidler¹, Michael Bates¹ and Michael Press². ¹Cepheid, Sunnyvale, CA; ²University of Southern California, Los Angeles, CA; ³Indivumed GmbH, Hamburg, Germany; ⁴Molecular Pathology Laboratory Network, Maryville, TN and ⁵Molecular Testing Lab, Vancouver, WA.

Body: The Xpert® Breast Cancer STRAT4 (STRAT4) is a CE-IVD marked, semi-quantitative, cartridge-based RT-qPCR assay for the detection of ESR1, PGR, ERBB2 (HER2), and MKi67 mRNAs from formalin fixed, paraffin embedded (FFPE) breast tumors. The assay is fast (< 2 hrs), reproducible, robust, and easy to perform. The aim of this multicenter clinical study was to assess the performance characteristics of the STRAT4 assay relative to central lab immunohistochemistry (IHC) for ER, PgR, HER2, and Ki67 and to fluorescence in situ hybridization (FISH) for HER2 gene amplification.

Methods: A total of 200 archived primary invasive breast cancer FFPE blocks were sourced from Indivumed for this study. From each block, twelve (12) adjacent tissue sections (4-µm thickness) on slides were prepared for pathological H&E confirmation to define tumor area, and for testing by STRAT4, IHC (ER, PgR, HER2, Ki67), and HER2 FISH. Standard STRAT4 lysate preparation using a single unstained slide per specimen and testing on N=84, N=68, and N=48 samples was performed at 3 independent sites, respectively (2 US and 1 EU). A single slide from each specimen was also processed using the recommended concentrated lysate procedure for STRAT4 testing at Cepheid. All IHC and FISH testing was performed by a central academic reference laboratory in the US. For a given sample, STRAT4 data generated using the standard lysate procedure was included for concordance analysis when all target gene test results were valid. In cases where the standard lysate preparation yielded indeterminate test results for any target, data from the concentrated lysate preparation was used for the data analysis. Receiver Operating Characteristic (ROC) analysis, overall percent agreement (OPA), positive percent agreement (PPA), and negative percent agreement (NPA) between STRAT4 and IHC (IHC/FISH for HER2) were determined for ESR1, PGR, ERBB2, and MKi67.

Results: Of the 200 samples tested by STRAT4, all samples generated valid results for ESR1 and ERBB2, 199 of 200 samples were valid for PGR, and 198 of 200 samples were valid for MKi67 using the standard or concentrated lysate preparation protocol. One sample failed to generate results for both ER and PgR IHC. Twelve samples failed to yield HER2 FISH results. The STRAT4 success rate and results concordance with IHC were comparable across study sites. OPA between STRAT4 and IHC was 97% for ESR1, 88.9% for PGR, 93.3% for HER2 (92.4% for IHC and FISH), and 90.7% for MKi67 (excluding 10-20% staining). Areas under the ROC curves were 0.9922 for ESR1, 0.9509 for PGR, 0.9958 for ERBB2, and 0.9395 for MKi67.

Conclusion: STRAT4 measurements for ESR1, PGR, ERBB2 and MKi67 mRNA expression are robust and highly concordant with IHC (IHC/FISH for HER2). The technical portion of the assay is easily performed in < 2 hrs including hands-on time using standard FFPE tissue sections. Xpert STRAT4 offers local pathology labs an alternative to centralized, subjective IHC/FISH tests that require a higher level of expertise. Further investigations correlating STRAT4 markers directly with clinical outcomes in independent cohorts are in progress.
Title: Lymphovascular invasion in breast carcinoma following neoadjuvant chemotherapy is a strong prognosis factor

Anne-Sophie Hamy-Petit, Giang-Thanh Lam, Enora Laas, Lauren Darrigues, Thomas Balezeau, Julien Guerin, Alain Livartowski, Benjamin Sadacca, Jean-Yves Pierga, Anne Vincent-Salomon, François-Clement Bidard, Florence Lerebours, Etienne Brain, Veronique Becette, Roman Rouzier, Marick Lae and Fabien Reyal. 1Institut Curie, Paris, France and 2Geneva University Hospitals, Geneva, Switzerland.

Body: Purpose: Lymphovascular invasion (LVI) is a poor prognosis factor in breast cancer (BC), but data on its value in the neoadjuvant setting is scarce. This study evaluates the relationships between post-NAC LVI and prognosis in BC.

Methods: We identified 1197 patients with primary BC receiving NAC +/- trastuzumab between 2002 and 2011. Information on LVI in post-NAC surgical specimen was retrieved from review of medical charts. Univariate and multivariate analyses were performed to assess the association of clinical, pathological factors with disease free survival (DFS) and overall survival (OS) was assessed using a cox proportional hazard model.

Results: On 1197 tumors, 528 were luminal (44.1%), 375 were triple negative breast cancer (TNBC) (31.3%) and 294 were HER2-positive (24.6%). On post-NAC surgical specimens, LVI was present in 302 (25.2%), absent in 531 (44.4%), and was not mentioned in 364 cases (30.4%). The presence of post-NAC LVI was associated with an impaired DFS (HR=2.17, 95 CI [1.65 - 2.86], p<0.001) and the magnitude of this impact varied by BC subtype (p-value for interaction=0.02), (luminal BC: HR=1.75, p=0.006; TNBC : HR=2.77, p<0.001 ; HER2-positive BC : HR=5.12, p<0.001).

ER: oestrogen receptor PR: progesteron receptor RCB: residual cancer burden

Post-NAC LVI was an independent predictor of poor DFS, that overwhelmed the prognostic impact of pathological complete response in all 3 BC subtypes. Post-NAC LVI was also an independent predictor of poor OS in the whole cohort and in all BC subtypes.

Table 1 resumes univariate and multivariate analysis on DFS in whole population.

**Conclusion:** Post-NAC LVI is a strong independent prognostic factor associated with poor DFS and OS, that (i) should be systematically mentioned in pathological reports following NAC and (ii) could be used to select high risk patients candidates to second line trials in the post-neoadjuvant window.
**Title:** AJCC prognostic stage including oncotype DX®RS: Impact on breast cancer staging compared with traditional anatomic TNM stage

Roisin M O’Cearbhaill¹, John M Gannon¹, Liam A Devane¹, Ruth S Prichard¹, Janice Walshe¹, Enda W McDermott¹ and Cecily M Quinn¹. ¹St Vincent's University Hospital, Dublin, Ireland.

**Body:**

**INTRODUCTION**

The recently published AJCC Cancer Staging Manual 8th edition, scheduled to be adopted into clinical practice in January 2018, proposes a new breast cancer (BC) Prognostic stage that includes histological grade, estrogen receptor (ER), progesterone receptor (PR), and HER2 status in addition to the traditional Anatomic TNM stage. In a further modification, patients with ER positive, HER2 negative, lymph node negative BC and an Oncotype DX® recurrence score (RS) of less than 11 will be assigned to Prognostic stage 1A irrespective of histological grade and size (up to 5cm). The changes have been proposed in recognition of the prognostic influence of these parameters and in attempt to improve personalised patient care. The aim of this study is to profile the impact on staging by comparing Prognostic stage, with and without RS, to traditional Anatomic stage, in a series of patients with early BC and an RS of less than 11.

**METHODS**

The study population comprised 127 patients with primary BC and an RS of less than 11, derived from a consecutive series of 729 patients with ER positive, Her2 negative, lymph node negative, primary BC whose tumors were tested using the Oncotype DX® multigene assay between November 2011 and December 2016. The median patient age was 57 years (35-78). Pathological tumour size was T1a (n=2), T1b (n=19), T1c (n=79) and T2 (n= 27). Median tumor size was 15mm. Histological tumour grade was grade 1 (n=14), 2 (n=98) and 3 (n=15).

Each patient was assigned an Anatomic and Prognostic stage, with and without RS modification, according to the AJCC Classification of Cancer Staging, 8th edition. The three staging categories were compared and the impact on stage profiled.

**RESULTS**

Applying the traditional Anatomic Stage (TNM), 100 patients were assigned to stage IA (T1N0) and 27 patients to stage IIA (T2N0). Applying the Prognostic stage (without RS) 89 patients were assigned to stage IA, 33 to stage IB, four to stage IIA, and one to stage IIB. All patients were assigned to stage IA according to the Prognostic stage that includes a RS of < 11.

Comparing Prognostic stage without RS to traditional Anatomic stage, 26.7% of patients (n=34) underwent a change in stage, 9.4% (n=12) to a higher stage and 17.3% (n=22) to a lower stage. 21.3% (n=27) of patients were down staged when comparing Prognostic stage including RS to traditional Anatomic stage. Comparing Prognostic stage including RS to Prognostic stage without RS, 29.9% (n=38) of patients were down staged.

**CONCLUSION**

Breast cancer staging is an important tool in guiding patient management. This study demonstrates that the introduction of the Prognostic stage and the modified Prognostic stage to include RS will alter the assigned stage in approximately 25% of patients with early BC.

Title: Draft recommendations for human epidermal growth factor receptor 2 (HER2) testing in breast cancer will decrease HER2 positivity rates

Eric Johnson1 and Evin Gulbahce1. 1University of Utah, Salt Lake City, UT.

Body: Introduction: A focused update of American Society of Clinical Oncology (ASCO) and College of American Pathologist’s (CAP) guideline recommendations for HER2 testing in breast cancer (BrCa) was published in May, 2017 for public comment (http://www.cap.org/ShowProperty?nodePath=/UCMCon/Contribution Folders/WebContent/pdf/her2-breast-summary-draft-recommendations-2017.pdf). The focused update for in situ hybridization (ISH) addresses following uncommon scenarios: 1) HER2/CEP17 ratio ≥ 2.0, and HER2 /cell <4.0; 2) HER2/CEP17 ratio <2.0 and HER2 /cell ≥6.0; 3) HER2/CEP17 <2.0 and HER2 /cell ≥4.0 and <6.0. The first two groups are currently reported as positive, the third as equivocal. It is recommended that immunohistochemistry (IHC) performed by the same lab for all these groups. If the IHC testing is 3+ or 0/1+ the final diagnosis will be reported as positive or negative respectively. If the reflex IHC is 2+, a recount of the original ISH area of carcinoma with IHC 2+ staining is recommended. The purpose of this study is to review the results of targeted FISH testing following IHC to predict the effects of proposed guidelines in a high volume national reference lab.

Materials and methods: HER2 FISH tests performed on BrCa between 4/2015-5/2017 are included. Our lab offers HER2 testing by IHC (HercepTest™ Dako) and dual probe FISH (Dako IQ). Equivocal (2+) cases showing ≥10% weak or moderate circumferential membrane staining or intense but <10% circumferential staining are circled by a pathologist and reflexed to HER2 FISH with preferential counting performed in the circled areas. Equivocal FISH cases are re-tested with the alternate RAI1 probe (Agilent Technologies). FISH scoring is done manually by 2 people following 2013 ASCO/CAP guidelines with at least 20 cells counted in amplified and non-amplified cases and 40 cells counted in equivocal cases.

Results: 2460 HER2 FISH test requests were received during the study period. 7 cases failed at initial testing and 13 cases failed at repeat testing of equivocal cases with reflex probe. 389 (16.2%) cases were amplified, 1686 (68.7%) non amplified, and 369 (15.0%) were equivocal with FDA approved probe set. 116 (32.6%) of equivocal cases re-tested with alternate probe were amplified increasing overall amplification rate to 21%. The table below shows cases that fall under 3 uncommon categories that are proposed for changes in draft guidelines.

Conclusions: In our lab where all FISH tests with prior IHC are counted on targeted areas, all of the cases within the first two groups will be reclassified as negative. The use of reflex probe in equivocal cases is not recommended in the draft recommendations further decreasing positivity rates. Approximately 5% decrease is expected in HER2 FISH positivity rates.
following proposed recommendations in reference laboratory setting.
Body: INTRODUCTION

Proliferative activity is one of the most important prognostic parameters in cancer. During the pathological examination of breast tumors, it is routinely evaluated by a count of the number of mitoses. Adding immunohistochemical stains of the nuclear protein Ki67 provides extra prognostic and predictive information. However, the currently used methods for both of these evaluations battle imperfections, primarily in reproducibility. In this study, we make an equally broad and detailed evaluation of mitoses, Ki67 and the more recently described Phosphohistone H3 (PHH3) in primary breast cancer using digital image analysis (DIA). Furthermore, we aim to investigate the prognostic and predictive value of proliferation-associated biomarkers in breast cancer stromal cells in relation to patient outcome.

MATERIALS AND METHODS

Two cohorts of primary breast cancer specimens (total n=297) with clinicopathological data including >10 years survival data, were sectioned and stained for Ki67, PHH3 and pancytokeratin (CKMNF116) and all glass slides were digitally scanned at x20. The DIA software used was the Visiopharm Integrator System (VIS) by Visiopharm A/S, Hoersholm, Denmark. VIS operates by a 'digital fusion' method that automatically excludes non-epithelial tissue restricting the analysis of the biomarkers (Ki67 and PHH3) to CKMNF116 positive cells. Both manual and DIA scores were compared for sensitivity and specificity for the gene expression based Luminal B versus A subtype, for high versus low transcriptomic grade as well as for their prognostic value in terms of Cox regression hazard ratios and breast cancer specific and overall survival. Further, we investigated whether the expression of Ki67 in the tumors’ hot spots, invasive edges or as an average across all regions should be assessed for maximum power in relation to these outcomes. In addition, by inverting the DIA algorithm run by the VIS on the same cohorts, the expression of Ki67 and PHH3 was evaluated in the tumor stromal compartment.

RESULTS

Regardless of tumor region, DIA of Ki67 outperformed the other markers in sensitivity and specificity for gene expression subtypes and transcriptomic grade. In contrast to mitotic counts, tumors with high expression of Ki67 as defined by DIA, had significantly increased hazard ratio for all-cause mortality within 10 years from diagnosis. DIA of Ki67 was superior to manual Ki67 and PHH3 evaluations as well as to mitotic counts in terms of separation of patients with poor versus relatively good survival. Finally, we replaced the manual mitotic counts with DIA of Ki67 in hot spots as the marker for proliferation when determining histological grade. This increased the differences in estimated mean overall survival between the highest and lowest grades and added significantly more prognostic information to the classic Nottingham histological grade.

CONCLUSIONS

We conclude that digital image analysis of Ki67 in hot spots should be suggested as the marker of choice for proliferative activity in breast cancer.
Adithya Balasubramanian¹, Kerryn Ireland-Jenkin¹,³, Abi McDonald¹, Richard Khor¹, Belinda Yeo¹,² and Trishe Leong¹. ¹Austin Health, Melbourne, Victoria, Australia; ²Olivia Newton-John Cancer Research Institute, Melbourne, Victoria, Australia and ³University of Melbourne, Faculty of Medicine, Dentistry and Health Sciences.

Body: Background
HER2 targeted therapies have substantially improved survival outcomes for patients with breast cancer and HER2 amplification of their tumour. The recently updated American Society of Clinical Oncology/College of American Pathologists (ASCO CAP) guidelines recommend that HER2 testing to be performed on all invasive breast cancers and that positive HER2 status is defined by either evidence of HER2 protein over-expression measured by immunohistochemistry status (IHC 3+) or by in-situ hybridisation (ISH) amplification. Equivocal results require further testing with the alternative assay.
In Australia, Medicare-funded access to HER2 targeted therapies requires demonstration of HER2 positivity by ISH, regardless of IHC status. Thus, currently most breast units perform IHC and ISH on all breast cancers. Given this discrepancy in practice and significant additional cost of performing ISH, this study evaluated the frequency of discordance and the cost burden in using both assays in a historical series of patients with breast cancer.

Methods
A retrospective audit of HER2 histopathology reports was performed for all breast cancers diagnosed between 2007 and 2016 at a single tertiary hospital in Melbourne, Australia (The Austin Hospital). HER2 IHC results were classified as negative (0 or 1+), equivocal (2+) or positive (3+). An analysis was performed to assess the proportion of concordant (defined as samples with IHC 0/1+ and negative ISH, samples with IHC3+ and positive ISH, and samples with IHC2+ regardless of ISH) and discordant results (defined as IHC 3+ and ISH non-amplified or IHC 0/1+ and ISH amplified). Tumour blocks and slides from discordant cases were reviewed by a breast cancer histopathologist. The cost of additional testing in concordant cases was performed based on the Australian Medicare Benefits Schedule (MBS).

Results
Eight hundred and forty-six histopathology reports were reviewed from 786 patients, all of whom had both IHC and ISH assays. There were 832 (98.8%) concordant cases. There were 10 discordant cases (1.2%) in total, including three cases (0.4%) with a negative IHC (1+) result but positive ISH, and 7 cases (0.8%) with a positive IHC but negative ISH result. A detailed analysis of 10 discordant cases will be presented. HER2 status and subsequent treatment remain unchanged with the addition of ISH testing in 665 (79.0%) cases, which amounted to an additional $209,741 (AUD) being spent on unnecessary ISH testing. Given an estimated incidence of 17,730 new cases of breast cancer per year in Australia, the population cost of performing additional HER2 ISH testing ($315.40 per case) in concordant cases would equate to $4.4 million (AUD) per year.

Conclusion
These results describe an extremely low rate of HER2 IHC/ISH discordance suggesting that routine use of both assays is unnecessary in cases with an unequivocal IHC result. The fiscal burden and potential delays to deciding treatment provide a strong rationale for access to HER2 targeted therapies to be based IHC or ISH, as advised by the ASCO CAP guidelines. Our results will be used to support a national review of IHC and ISH discordance using Australian national registry data.
Title: An institutional look back: Maximizing the utility of MammaPrint® in invasive breast cancer diagnostics without breaking the bank

Ashley W Cross¹ and John R McEvoy². ¹Medical University of South Carolina, Charleston, SC and ²Roper St Francis Healthcare, Charleston, SC.

Body: Subtyping of invasive breast cancer utilizing immunohistochemical stains for estrogen receptor, progesterone receptor, and HER2, with or without the proliferation marker Ki-67, is the current standard of care employed by pathologists. The development of the BluePrint® molecular subtyping assay by Agendia, a microarray-based gene expression test used in conjunction with MammaPrint, to molecularly subtype and assess recurrence risk in early-stage breast cancer, has breast surgeons and oncologists challenging the status quo.

Study Objectives: With increasing emphasis placed of proper use of declining resources, the current study aimed to determine parameters in which such testing has the greatest added value.

Materials and Methods: All invasive breast cancer biopsies and resection specimens with formalin fixed paraffin embedded tissue sent for testing at Agendia Genomics Laboratory from April 2015 to May 2017 were reviewed in an institutional look back. 87 cases were reviewed and conventional immunohistochemical cancer profiling, tumor size, and grade were compared with MammaPrint prognostic reports.

Results and Discussion: Of the 87 cases compared, 67 (77%) showed concordance between immunohistochemical and molecular subtyping. Of the 20 discordant cases, 13 (65%) were subtyped as low risk luminal A by Mammaprint/BluePrint despite demonstrating high risk clinicopathologic features including larger size (average 2 cm vs overall average 1.4 cm), higher grade (1 low grade, 11 intermediate grade, and 1 high grade vs totals of 36 low grade, 42 intermediate grade, and 20 high grade), and increased proliferation indices. 3 (15%) of discordant cases revealed HER2 amplification by fluorescence in situ hybridization. Near complete agreement was found among basal subtype and Luminal A tumors with Ki-67 less than 12%, indicating the lack of added value among these cases.

Conclusion: Study results validate the limited role of MammaPrint/BluePrint in cases of invasive breast cancer. Specifically, the greatest value of MammaPrint/BluePrint was recognized in luminal subtypes with intermediate grade and proliferation indices ranging from 12 – 29%.
Title: Risk factors for upgrading and upstaging of pre-operative biopsies in ductal carcinoma in situ

Gurdeep S Mannu¹, Emilie Groen², Zhe Wang¹, Michael Schaapveld², Esther Lips², Monica Chung², Ires Joore², Flora van Leeuwen², Jelle Teerstra², Gonneke AO Winter-Warnars², Sarah C Darby¹ and Jelle Wesseling¹. ¹University of Oxford, Oxford, Oxfordshire, United Kingdom and ²The Netherlands Cancer Institute Antoni van Leeuwenhoek, Plesmanlaan 121, 1066 CX Amsterdam, Netherlands.

Body: Background: Ductal carcinoma in situ (DCIS), accounts for one fifth of all screen-detected neoplastic breast lesions. Contemporary research in DCIS focuses on separating lesions that need active treatment from those that can be safely left under surveillance. This, in turn, relies on accurate determination of invasive status and DCIS grade at time of initial biopsy. Most previous studies have examined factors associated with upstaging the diagnosis from DCIS to invasive breast cancer (IBC) following surgery, and few have evaluated factors associated with upgrading the diagnosis to a higher grade of DCIS. This is because upgrading has not traditionally influenced clinical management in the way that upstaging has done. However, recent interest in non-operative treatment for low-risk DCIS has meant that accurate determination of grade at time of initial biopsy has become more important. We aimed to compare risk factors for upgrading and upstaging of biopsies in DCIS.

Method: We undertook a cohort study of all women diagnosed with DCIS at a large specialist cancer centre between 2000–2014. Information from the clinical records was abstracted, including the pre-operative mammography (MMG) and pathology information from the initial biopsy. We also abstracted pathology information regarding the excised specimen in order to identify women whose diagnosis was subsequently upgraded or upstaged. We looked for factors that were predictive for upgrading or upstaging.

Result: A total of 641 women were diagnosed with DCIS at initial biopsy. Of these, 72 (11%) were upgraded: 26 (4%) from grade 1 to grade 2, 2 (0.3%) from grade 1 to grade 3 and 44 (7%) from grade 2 to grade 3. A further 115 (18%) were upstaged to IBC: 20 of these (3%) had grade 1 DCIS on initial biopsy, 47 (7%) had grade 2, 43 (7%) grade 3, and for 5 (1%) biopsy grade was not available. Necrosis on biopsy increased the risk of upgrading (with necrosis: 14% upgraded, without: 10% upgraded, p for difference 0.02) and also of upstaging (with necrosis: 23% upstaged, without: 15% upstaged, p for difference <0.01). Lesions measuring ≥50 mm on MMG were more likely to be upgraded than smaller lesions (0-19 mm: 9% upgraded, 20-50 mm: 9% upgraded, ≥50 mm: 19% upgraded, p for heterogeneity <0.01), while lesions measuring 20-50 mm and ≥50 mm were both more likely to be upstaged than lesions measuring 0-19 mm (0-19 mm: 9% upstaged, 20-50 mm: 23% upstaged and ≥50 mm: 21% upstaged, p for heterogeneity <0.01). Fewer 9G vacuum-assisted biopsies than 14G core biopsies were upgraded (9G vacuum-assisted: 7% upgraded, 14G core: 15% upgraded, p for difference 0.01), while the effect of biopsy method on upstaging was not significant (9G vacuum-assisted: 12% upstaged, 14G core: 16% upstaged, p for difference 0.15). Presence of a palpable lump was not significantly associated with upgrading (palpable lump: 13% upgraded, no palpable lump: 10% upgraded, p for difference 0.19) but increased the risk of upstaging (palpable lump: 23% upstaged, no palpable lump: 16% upstaged, p for difference 0.02).

Conclusion: Our findings suggest that consideration of MMG lesion size and necrosis on biopsy may be helpful in selecting low-risk women for non-operative management of DCIS, as may use of the 9G vacuum-assisted method of biopsy.
The immune microenvironment of HER2-positive ductal carcinoma in situ of the breast

Julianne M Ubago1, Luis Z Blanco, Jr.1 and Kalliopi P Siziopikou1. 1Northwestern University, Chicago, IL.

Body: Background: Ductal carcinoma in situ (DCIS) consists of a heterogeneous group of tumors that can be subclassified based on their molecular profile similar to invasive breast carcinomas. DCIS ducts are often surrounded by an inflammatory infiltrate, yet few studies have focused on this inflammatory response in the different subtypes of DCIS. The role of the immune microenvironment in tumor progression and response to therapy has led to a number of effective immune-based therapies, particularly targeting the PD-1/PD-L1 axis, and these approaches may extend to breast cancer subtypes and their precursor DCIS. In this study we evaluated the inflammatory response and PD-1/PD-L1 expression in both tumor-infiltrating lymphocytes (TILs) and tumor cells in HER2-positive (HER2+) and HER2-negative (HER2-) DCIS.

Design: Our population consisted of 85 cases of pure DCIS treated with surgical excision or mastectomy at our institution from 2008 to 2012. The molecular subtypes of DCIS were determined based on ER and HER2 expression. Tissue microarrays (TMAs) were constructed with 3 cores from each case to account for tumor heterogeneity. The presence of tumor-associated inflammation (TAI) was graded as absent, mild (<10%), moderate (10-50%) or severe (>50%) and the extent and intensity of PD1 and PD-L1 in the TILs and in the tumor cells were also assessed. A composite score was calculated by multiplying extent and intensity (range 0-12 with 9-12=strong).

Results: Of the 85 cases, 51 were classified as Luminal A (ER+/HER2-), 15 as Luminal B (ER+/HER2+), 13 as HER2+ (ER-/HER2+) and 6 as basal-like (ER-/HER2-). Moderate/severe inflammation around DCIS correlated with HER2 expression (20/28 HER2-expressing cases (71.4 %) compared to 21/36 HER2-non-expressing cases (58.3%), p=0.005). Of interest, severe inflammation was seen almost exclusively around HER2-expressing cases (7/28, 25% vs 1/57, 1.7 %, p=0.002). Furthermore, over half of the TILs around HER2+ cases expressed PD-L1 (7/13, 54%), while only 6% of Luminal A (3/47) and none of Luminal B (0/15) or basal-like (0/6) cases did (p=0.00001). In addition, about 1/3 of the TILs around HER2+ cases expressed PD-1 (4/13, 31%), while only 8% of Luminal A (4/49) and none of Luminal B (0/15) or basal-like (0/6) cases did (p=0.004). None of the DCIS tumor cells expressed PD-1. Of interest, 15% of HER2+ cases (2/13) and 7% of Luminal B cases (1/15) expressed PD-L1 in the DCIS tumor cells.

Conclusions: 1. Moderate/severe inflammation around DCIS foci correlates with HER2 expression. 2. PD-L1 expression in TILs is seen almost exclusively in HER2+ DCIS cases. 3. About 1/3 of the TILs around HER2+ DCIS cases also express PD-1. 4. None of the DCIS tumor cells express PD-1. 5. Small subgroups of HER2+ and Luminal B DCIS cases show PD-L1 expression in the tumor cells themselves. The results of our study add to the understanding of the role of the immune microenvironment in DCIS, especially in the HER2+ subtype. The complex interactions between DCIS tumor cells and the local immune system may play a role in breast cancer progression and may be further exploited for immune-based therapeutic strategies.

**Title:** Incidence and implications for hormone receptor status change pre- and post- neoadjuvant chemotherapy for locally advanced breast cancer: A retrospective single-center cohort study

Olexiy Aseyev¹², Lisa Simmonds¹, Maddie Gertler¹ and Shailendra Verma¹. ¹The Ottawa Hospital Cancer Centre / The University of Ottawa, Ottawa, ON, Canada and ²The Thunder Bay Regional Health Science Centre/ The Northern Ontario School of Medicine, Thunder Bay, ON, Canada.

**Body:**

**Background:** Hormone receptors (HR) and Human Epidermal Growth Factor Receptor 2 (HER2) status are variables that significantly influence the treatment regimens chosen for each patient (pt). The main objective of this study present was to determine the incidence of HR status change pre- and post- neoadjuvant chemotherapy (NAC) in patients with locally advanced breast cancer (LABC).

**Methods:** A single-centre study was retrospectively conducted at The Ottawa Hospital Cancer Centre looking at a group of 546 pts diagnosed with LABC from 2006-2015. A number of variables were observed including HR and HER2 status, tumor size and grade, regional lymph nodes involvement, presence of DCIS, treatment regimens. 'Positive to Negative' considered pts who were HR and/or HER2 positive pre-NAC and negative post-NAC, 'No Change' represented the pts whose pathology did not change before and after NAC, and 'Negative to Positive' characterized those pts whose HR and/or HER2 pathology was initially negative and became positive post-NAC. Wilcoxon signed-rank test for paired dichotomous variables has been performed in order to estimate statistical significance of changes in status of HR and HER2. To explore possible relationship between HR and HER2 status change and other factors we used Logistic regression method.

**Results:** Of the 386 pts who were examined for Estrogen Receptor (ER) twice, 285 had positive status before surgery, after surgery there were 12 pts (3.11%) with a 'Positive to Negative' change, 362 pts (93.78%) with no change, and 12 pts who represented a 'Negative to Positive' change. 254 of 378 pts, who had two tests for Progesterone Receptor (PR), had positive results at first time, and 29 (7.67%) of those represented a 'Positive to Negative' change, there were 337 (89.15%) with no change, and 12 (3.17%) with a 'Negative to Positive' change. From 387 pts who were tested for HER2 before and after surgery, 105 had initially positive status. Of those, 12 (3.10%) represented a 'Positive to Negative' change, there were 364 (94.06%) with 'No Change' and 11 (2.84%) with a 'Negative to Positive' change. Logistic regression analysis did not reveal any significant factors that can predict changes in receptors’ status. *-Statistically significant changes (p<0.001). The results are comparable with previously published works, which demonstrated changes in IHC status during treatment in metastatic disease (E.Amir, 2011) and a in patients with LABC (Y.Yang, 2013; R.Gahlaut, 2016). Results of comparative meta-analysis will be presented also.

**Conclusions:** Our study shows that a change in HR and HER2 status is common in this population, indicating that close monitoring of biopsy results should be closely compared to surgical pathology specimens to determine a change in biomarkers, and therefore, a potential change in treatment regimen. None of analyzed factors can predict change in status of ER, PR, and HER2 after neoadjuvant treatment. Even though the incidence of change in status is small, the implications for accurate and personalized treatment are important and HR and HER2 testing should be performed as a routine practice on the biopsy and at the time of definitive surgery.

Title: Pathology differentiation during breast conservation surgery using high-frequency ultrasound and peak frequency distribution

Christine E Dalton¹, Garrett M Wagner¹, Huda A Al-Ghaib¹ and Timothy E Doyle¹. ¹Utah Valley University, Orem, UT.

Body: Determining breast tissue pathology in surgical margins is a crucial step in breast conservation surgery (BCS) as this diagnosis decides the need for re-excision. Currently, it can take several days for a pathology laboratory to examine BCS tissue specimens, differentiate between different types of neoplasms (e.g., ALH, LCIS, and ILC), and identify positive margins. Re-excisions cause additional emotional strain, pain, and discomfort for patients, as well as increase medical treatment costs. High-frequency (HF) ultrasound (20-80 MHz) provides a potential new method to discriminate between breast tissue pathologies during BCS. HF ultrasound could also be used to analyze either the surgical cavity in vivo or margin specimens ex vivo. In a 17-patient pilot study that included 14 different pathologies, the HF ultrasonic parameter known as peak density—the number of peaks and valleys in the ultrasonic spectra—displayed a strong correlation to tissue pathology. The objective of this study was to conduct a retrospective analysis of the pilot study data to determine if correlations also existed between the distribution of frequencies of the spectral peaks and valleys with pathology.

The pilot study data were collected from 55 measurements on 34 specimens at the Huntsman Cancer Institute (Salt Lake City, Utah) immediately following BCS and prior to standard pathology preparation and analysis. Through-transmission measurements were acquired with the use of two 50-MHz transducers (Olympus NDT, V358-SU, 6.35-mm active element diameter), a HF square-wave pulser/receiver (UTEX, UT340), and a 500-MHz digital oscilloscope (Hewlett-Packard, HP-54522A). The transmitting transducer was pulsed with a 100-V half-period square wave with a 10-ns width. Waveforms were averaged in the signal acquisition and downloaded onto a computer. Because of the small wavelength of the transmitted ultrasound (30 µm for 50 MHz) in comparison to the size of the active element, the transmitting transducer produced plane-wave pulses which propagated through the tissue to the receiving transducer. Because of the small wavelength and coherent nature of the measurements, the resulting ultrasonic spectra displayed extinction features (peaks and valleys) resulting directly from acoustic wave scattering from cells and nuclei. In this study, the frequencies of the peaks and valleys were plotted as a function of pathology for analysis. The results showed a strong correlation between peak frequency distribution and pathology, particularly in differentiating between malignant and non-malignant pathologies. The peak frequencies for malignant pathologies displayed greater clustering at higher frequencies, whereas the peak frequencies for the non-malignant pathologies displayed greater clustering at lower frequencies. The analyses also verified that the physical mechanism behind the HF ultrasound method is based on acoustic scattering from cells and nuclei, and on the trends arising from the differences between the sizes and morphologies of normal, pre-cancerous, and cancerous cells and nuclei. These results support the use of HF ultrasound as a prospective new method for rapidly distinguishing between different pathologies in breast tissues during BCS.
Body: BACKGROUND: Increasing evidence suggests that epigenetic mechanisms play critical roles in the development of breast cancer. However, precise DNA methylation signatures associated with breast cancer susceptibility remain unknown. We sought to compare DNA methylation changes in the normal breast tissue of women with and without breast cancer to identify patterns of aberrant DNA methylation in women with breast cancer.

METHODS: Samples of normal breast tissue were collected from four cohorts of women: age < 50 years with and without breast cancer, and age ≥ 50 years with and without breast cancer. Normal breast tissue from healthy women was obtained from the Komen Tissue Bank at IU Simon Cancer Center and from women presenting for reduction mammoplasty at Yale New Haven Hospital. Normal breast tissue from women with breast cancer was obtained from patients undergoing adjuvant total mastectomy at Yale Breast Center. DNA was extracted using Qiagen AllPrep Universal kit. Raw data files in idat format were imported to Partek Genomics Suite 6.6 for normalization and differential methylation analysis. Raw intensities were normalized using With Array Normalization (SWAN) method. Principal component analysis (PCA) were performed as quality control. Differentially methylated loci (DML) between control and breast cancer groups were detected when False discovery rate (FDR) < 0.05 and fold change > 1.5. Functional enrichment analysis of genes with DML in the gene body were conducted using METACORE™. Pathways with FDR < 0.05 were selected.

RESULTS: Ninety-three normal breast tissue samples from 89 subjects were analyzed (breast cancer = 40, unaffected = 53). Comparison of DNA methylation patterns between women with and without breast cancer revealed 200 DMLs. The majority of DMLs (186) were hyper-methylated in breast cancer patients, and 48 DMLs locate in enhancers of genes. 170 DMLs locate in 134 genes, enriched in two pathways: (1) Cell adhesion_Endothelial cell contacts by junctional mechanisms, and (2) Neurophysiological process_Constitutive and regulated NMDA receptor trafficking. Genes associated with cell adhesion and cell contacts included: ACTN2, GJA4, GJA7 and MAGI1. Two hyper-methylated loci were found in enhancers of ACTN2. In addition, one hyper-methylated locus in GJA4, one hyper-methylated and one hypo-methylated loci in GJA7, and two hyper-methylated loci in MAGI1 were detected in breast cancer patients. Genes associated with NMDA receptor trafficking include: TPK1, ADCY4 and LIN7C. One and two loci were found in TPK1 and ADCY4, respectively, that were hyper-methylated in normal breast tissue from cancer patients in the gene body, while a hypo-methylated locus in breast cancer patients was identified in LIN7C.

CONCLUSIONS: Comparison of DNA methylation patterns of normal breast tissue from women with and without breast cancer reveal specific mechanistic pathways and genes that are differentially methylated in women with breast cancer. DNA methylation of normal breast tissue deserves further study as a potential biomarker for breast cancer risk stratification and may lend new insight into mechanisms of breast cancer development.
Title: Epigenomic analysis of cancer stem cell (CSC)-enriched triple-negative breast cancer (TNBC) populations reveals gene regulatory circuitry and novel tumor cell vulnerabilities

Matthew G Guenther¹, Arthur W Lambert², Mei Wei Chen¹, Christopher Fiore¹, Matthew Eaton¹, David Orlando¹, Brian Bierie², Robert A Weinberg², Christian C Fritz¹ and Eric R Olson¹. ¹Syros Pharmaceuticals, Cambridge, MA and ²Whitehead Institute for Biomedical Research, Cambridge, MA.

Body: Tumor-initiating cells (TICs), also termed cancer stem cells (CSCs) are involved in breast cancer chemoresistance, metastasis and disease progression. To pinpoint tumor cell vulnerabilities and transcriptional drivers of therapeutic relevance, we have characterized the triple negative breast cancer (TNBC) CSC transcriptional landscape using epigenome mapping and nucleosome occupancy determination. We identify a set of transcriptional regulators and signaling mediators that enforce the cancer stem cell state and instruct potential therapeutic strategies.

The basal epithelial marker, integrin-β4 (ITGB4), can be used to stratify mesenchymal-like triple-negative breast cancer (TNBC) cells into populations of low and high tumor-initiating ability in vivo. We used ChIP-seq to measure H3K27ac occupancy and map the transcriptional enhancers in SUM159 cells segregated into ITGB4⇔ (High tumor initiating ability) and ITGB4⇔ (Low tumor initiating ability) populations. Gene-enhancer linking and comparative analysis of enhancer usage revealed an epigenomically defined set of genes that are candidate drivers of the CSC cell state, including GSK3β, DNA-binding transcription factors and cellular adhesion proteins. To further define the chromatin architecture and transcriptional regulatory circuitry that underlies CSC state, we deployed ATAC-seq (Assay for Transposase-Accessible Chromatin with high throughput sequencing) within ITGB4⇔ and ITGB4⇔ populations. By pairing nucleosome occupancy and transcription factor kinetics, we created enhancer-linked transcriptional regulatory circuitry of these tumor-initiating cells.

Together, the isolation of partially mesenchymal ITGB4⇔ CSCs, coupled with enhancer mapping and distillation of transcriptional regulatory circuitry from these cells enable the identification of cancer vulnerabilities and therapeutic opportunities for high-risk patients with TNBC.
Body: Background: In recent years, there has been great interest in developing drugs that modify epigenetic changes as new therapies for breast cancer (BC). There is evidence that aberrant epigenetic inactivation of genes, essential for normal cell growth, is involved in cancer. These modifications are potentially reversible therefore re-activation of genes in response to epigenetic drugs can result in inhibition of tumour growth or sensitisation to other anti-cancer therapies. Epigenetic drugs are in clinical trials for BC but have some drawbacks: while some can be highly effective \textit{in vitro}, their poor stability could compromise their clinical use. Also, high doses required to induce an effect in patients could increase off-site toxicity. As a result there is an urgent need to develop novel systems for the delivery and release of these drugs.

Objectives: Our aim is to develop targeted microbubbles (MBs) to enhance therapeutic effects \textit{in vitro} and \textit{in vivo}. Ultrasound (US)-mediated drug delivery using MBs is proposed as a non-invasive approach for localised drug administration.

Methods: We developed assays using low doses of a DNA methyltransferase inhibitor, called decitabine (DAC), for determining its delivery and effect \textit{in vitro} and \textit{in vivo}. VEGFR2 was assessed as a targeting molecule for therapeutic delivery to tumour vasculature \textit{in vitro} and in a human BC xenograft model. We have generated therapeutic MBs with DAC using a flow-focussing microfluidic platform and conducted \textit{in vitro} studies to observe tumour and tissue responses.

Results: Treatment of triple-negative BC (TNBC) cells with low DAC doses revealed restoration of epigenetically dysregulated tumour suppressor genes. These genes were used as biomarkers for the assessment of DAC effects in a human TNBC mouse model. To evaluate the use of a targeting molecule for drug delivery, specific binding of VEGFR2-targeted MBs on VEGFR2+ve mouse endothelial cells was verified by a flow assay. VEGFR2 expression was assessed longitudinally in xenograft tissue and demonstrated significantly higher VEGFR2 expression in the vasculature of smaller size tumours, indicating the time that delivery of targeted MBs would be most effective. DAC-loaded liposomes or co-administration of DAC and MBs in combination with US using a specifically designed US transducer, were tested \textit{in vitro}. Currently, investigation of the potential of US-triggered drug delivery enhancing efficacy of DAC \textit{in vivo} is being carried out. In addition, combination treatments have been performed \textit{in vitro}, showing increased sensitisation of cells to anthracycline treatment after priming with DAC.

Conclusions: It may be feasible to combine US, MBs and epigenetic therapy in a pre-clinical setting to improve drug efficacy, particularly for drugs that are rapidly degraded within the body. MB delivery may have the potential to reduce the dosage required, thus reducing off-site side effects in patients.
Body: In spite of its high incidence worldwide, only 10-15% of breast cancers can be attributed to hereditary factors, leaving a substantial proportion with unknown causes. Evidence suggests that 26.8% of new breast cancer cases relate to extrinsic factors, such as lifestyle and environmental exposures. Whilst we have increased our knowledge surrounding factors like alcohol, and obesity, little is known in regards to chemicals in the environment (e.g. pesticides) and consumer goods (e.g. plasticisers and preservatives). Previous research has proved inconclusive, with effects only observed at concentrations considerably higher than what has been identified in human tissues. Furthermore, we have not identified a mechanistic link for many compounds. It has been suggested that epigenetics could provide insight, being defined as 'the link between the environment and our genome'. To date, research has identified links between environmental chemicals and breast cancer through the epigenome, however, this has mainly been undertaken using unrepresentative chemical concentrations that are not comparable to observations from human tissues.

The presented research aims to investigate the relationship between low-dose chemical exposures (similar to concentrations found in human tissues) and breast carcinogenesis. To represent the human breast as closely as possible, mammary epithelial cells (MCF-12A) are grown in three-dimensional collagen co-cultures with endothelial (HMMEC) and fibroblast (HMF) cells and exposed to environmentally relevant concentrations of Bisphenol A (BPA) and propylparaben. Utilising Illumina EPIC beadchip arrays, we observe significant alterations to the epigenetic profile of cells in response to low-levels of chemical exposure. In turn, we show that these changes result in modifications to the gene expression of various genes involved in breast cancer initiation and progression. Finally, confocal microscopy confirms abnormalities to acini formation and development indicative of early breast carcinogenesis in response to exposures.

In addition to these results in the MCF-12A cell line, we present preliminary findings from primary patient derived mammary cells obtained from the Breast Cancer Now cell bank (epithelial, fibroblast and myo-epithelial co-cultures). We demonstrate individuals with and without BRCA1 mutations show altered genetic and epigenetic profiles in response to BPA and propylparaben exposures at low levels.

From these findings, we suggest an involvement of BPA and propylparaben exposure in breast cancer risk. Increasing our understanding of chemical contributions to cancer development not only provides opportunities for cancer prevention, but also allows for more effective risk model development. Furthermore, our results improve our understanding of the multifactorial processes that lead to carcinogenesis, aiding in identifying individuals at high risk for screening programmes. Data presented demonstrates a need additional for research in this area and acts as a model for further studies to be undertaken.
Changes of DNA methylation in the development of breast cancer

Chunyan He¹, Nan Lin¹, Aditi Shendre¹, Guanglong Jiang², Hai Lin², Jun Wan² and Yunlong Liu². ¹Kentucky University Markey Cancer Center and ²Indiana University School of Medicine.

Aberrant DNA methylation plays an important role in breast cancer initiation and progression via inactivation of tumor suppressor genes and activation of oncogenes. To better understand the changes of DNA methylation in the development of breast cancer, we analyzed genome-wide DNA methylation DNA data in breast tumor, adjacent normal tissue, and normal breast tissue from healthy women. Using the Illumina MethylationEPIC array, we investigated approximately 850,000 CpG sites. After quality control, 747,803 probes were retained and included the further analysis. To identify DNA methylation markers associated with breast cancer, we performed differential methylation analysis using ChAMP package implemented in Bioconductor. We identified 590 CpG sites that were differentially methylated (P<1X10^-4) between tumor and normal, and 637 between tumor and adjacent normal tissue samples. Further pathway analyses revealed that changes in DNA methylation between tumor and normal breast tissue were mainly involved in neurogenesis and neuro differentiation, oxidative stress, insulin secretion and epithelial morphogenesis; while changes in DNA methylation between tumor and adjacent normal tissue were mainly involved in angiogenesis, cell morphogenesis, and cell component movement. We further validated our findings using RNA-seq data. Our results suggested distinct DNA methylation changes involved in different biological pathways, reflecting potential causal and reactive biological mechanisms in the initiation and the progression of breast cancer.
**Title:** Triple negative breast cancer-specific chromatin conformation links Notch signal to tumor-specific transcriptional program

Jelena Petrovic\(^1\), Yeqiao Zhou\(^1\), George Georgakilas\(^1\), Golnaz Vahedi\(^1\), Warren S Pear\(^1\) and Robert B Faryabi\(^1\). \(^1\)University of Pennsylvania, Philadelphia, PA.

**Body:** Triple-negative breast cancer (TNBC) is an aggressive subtype of breast cancer that is currently incurable with conventional chemotherapy. Some TNBC patients harbor either recurrent somatic gain-of-function mutations or focal amplification in genes coding for Notch receptors. Recent findings suggest that Notch signals, in the absence of Notch mutations are also important to maintain chemotherapy-resistant circulating tumor cells. Importantly, elevated Notch signaling is specifically enriched in the TNBC and is associated with worse survival in this subtype. These findings underscore the importance of Notch signaling in pathogenesis of TNBC and suggest potential new avenue for therapeutic approaches. Despite this, the target genes and oncogenic mechanisms downstream of aberrant Notch signaling are poorly understood. To create a high confidence map of the oncogenic Notch-driven regulome in TNBC, we performed an integrative, comprehensive and functional genome-wide analysis of Notch-driven targets in Notch-mutated TNBC cell lines by combining high-resolution genome-wide chromatin topology data (HiChIP), dynamic mapping of Notch transcriptional complex members and active and repressive chromatin marks (ChIP-seq), as well as evaluation of dynamic transcription (RNAseq) in presence and absence of Notch signals. One important oncogene and critical Notch target in TNBC is MYC. Our integrative analysis identified detailed map of Notch-dependent MYC regulatory network. The TNBC-specific MYC regulatory region, located 5' of MYC, is much more complex compared to other known Notch-driven malignancies and constitutes of a broad domain of active enhancers marked by H3K27ac that are not present in Notch-driven lymphoma and leukemia. Integrative analysis of ChIP-seq and HiChIP revealed multiple enhancers within this broad domain of regulatory elements that are directly bound by the members of Notch transcriptional complex, sensitive to acute changes in Notch activation and that contact MYC promoter via tumor specific chromatin loops. We showed that genetic perturbation of MYC by CRISPR/Cas9 approach was sufficient to kill TNBC cells. Since, MYC is difficult to target pharmacologically an alternative strategy is to use drugs that inhibit factors regulating MYC expression. To this end, elucidating the Notch regulatory landscape, and in particular, the mechanism by which Notch regulates MYC expression in TNBC may reveal new therapeutic strategies to precisely target MYC in Notch-dependent breast cancer.
Whole genome sequencing reveals enrichment of mutations in mucin gene family in breast cancer diagnosed during pregnancy

Bastien Nguyen¹, David Venet¹, Christine Desmedt¹, Giancarlo Pruneri², Fedro Peccatori², Elaine R Mardis³, Hatem A Azim¹, Françoise Rothé¹ and Christos Sotiriou¹. ¹Breast Cancer Translational Research Laboratory, Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium; ²European Institute of Oncology, Milan, Italy and ³McDonnell Genome Institute, Washington University School of Medicine, St. Louis, MO.

Body: Background

Pregnancy is known to modulate breast cancer (BC) risk. Different reproductive behaviors have been shown to impact not only the risk of developing BC but also the phenotypes of these tumors. Breast cancer diagnosed during pregnancy (BCP) is a rare disease but could serve as a good model to understand how pregnancy modulates BC biology. In this project, we aim to interrogate the effect of pregnancy on the biology of BC by performing whole genome sequencing (WGS) using a unique series of BC patients diagnosed during pregnancy (BCP).

Method

Whole genome sequencing was performed for 35 BCP and 20 non-pregnant controls matched for age and stage with available clinic-pathological data. DNA extracted from primary tumor and matched adjacent normal FFPE tissues was assessed using WGS on Illumina HiSeqXTen platform targeting 60x and 30x coverage for tumor and normal DNA respectively. Briefly, 2x150bp paired end sequence data were generated, cleaned, trimmed and aligned to the reference genome (hg19) using bwa-mem. Somatic mutations were detected using Strelka and annotated using SnpEff. Mutational signatures were extracted using deconstructSigs. Differences on mutational profiles between BCP and case controls were assessed using Wilcoxon test for continuous variables and Fisher exact test for categorical variables.

Result

No difference in clinic-pathological features was observed between BCP and control patients. A median of 10084 and 13829 SNVs and of 26 and 21 indels were identified in the BCP and controls respectively, no significant difference between the two groups being observed ($p = 0.703$ and $p = 0.851$). Of interest, a significantly higher number of mutations was found in the BCP as compared to the control group when considering only mutations associated with a deleterious effect (median: 20 vs. 12, $p = 0.027$). As expected, $TP53$ and $PIK3CA$ were the most frequently mutated genes both in BCP and control cases without any significant difference between the groups (34.3% vs. 22.2%, $p = 0.53$ and 20.0% vs. 16.7%, $p = 1$, respectively). Interestingly, there was a significant enrichment of non-silent mutations in the mucin genes family ($MUC2$, $MUC4$, $MUC12$, $MUC16$, $MUC17$, $MUC20$) in the BCP group: 45.7% of BCP vs. 11.1% of control cases had at least one such mutation ($p = 0.015$). A similar significant result (45.7% vs. 23.1%, $p = 0.034$) was found when comparing BCP with BC control cases from the TCGA dataset (selected to have similar age, ER and PR distribution, N = 56). When comparing the distribution of the twelve BC mutational signatures, a borderline significant enrichment with a signature depicting mismatch-repair deficiency (signature 20) was observed in the BCP patients ($p = 0.059$).

Conclusion

This is the first study reporting the mutational landscape of breast cancer diagnosed during pregnancy using WGS. We found that BCP are associated with a higher number of putative driver mutations including mutations in mucin genes, shown to be implicated in tumorigenesis. Furthermore, BCP were enriched with a mismatch-repair deficiency signature. These results could open new avenues for the development of targeted therapeutic approaches for patients diagnosed with breast cancer during pregnancy.
Title: Functional genomic screening identifies ubiquitin-specific protease 11 (USP11) as a novel regulator of ER-alpha transcription in breast cancer

Lisa Dwane¹, Sudipto Das¹, Bruce Moran², Aisling E O'Connor², Laoighse Mulrane², Annette M Dirac³, Karin Jirstrom⁴, John P Crown⁵, Rene Bernards³, William M Gallagher², Triona Ní Chonghaile¹ and Darran P O'Connor¹. ¹Royal College of Surgeons in Ireland, Dublin, Ireland; ²University College Dublin, Dublin, Ireland; ³Netherlands Cancer Institute, Amsterdam, Netherlands; ⁴Malmö University Hospital, Malmö, Sweden and ⁵St. Vincent's University Hospital, Dublin, Ireland.

Body: Approximately 70% of breast cancers overexpress the estrogen receptor α (ERα) and depend on this key transcriptional regulator for growth and differentiation. The discovery of novel mechanisms controlling ERα function represent major advances in our understanding of breast cancer progression and potentially offer attractive new therapeutic opportunities. Here, we investigated the role of deubiquitinating enzymes (DUBs), which act to remove ubiquitin moieties from proteins, in regulating transcriptional activity of ERα in breast cancer.

To identify DUBs involved in the regulation of ERα transcriptional activity, we performed an RNAi loss-of-function screen using a library of shRNA vectors targeting all human DUB genes. The DUB library consisted of pools of four non-overlapping shRNAs targeting all 108 known or putative DUBs (432 shRNAs in total). We found that suppression of a number of DUBs markedly repressed or enhanced the activity of an estrogen-response-element (ERE) luciferase reporter following estradiol (E2) stimulation. Of particular interest, suppression of the BRCA2-associated DUB, USP11, was found to down-regulate ERα transcriptional activity.

Subsequent validation using two individual siRNAs targeted to USP11 revealed a notable reduction in expression of endogenous ERα target genes in the ZR-75-1 cell line, as quantified using qRT-PCR. Further validation was carried out in a HEK293T USP11 knockout cell line, where reduced activity of an ERE-luciferase reporter was detected when compared to wild-type cells. This phenotype was rescued with a USP11 overexpression vector, both in the presence and absence of E2. Furthermore, USP11 expression was found to be upregulated in the estrogen-independent cell line LCC1 when compared to their parental MCF7 cells. Knockdown of USP11 in LCC1 cells resulted in decreased mRNA expression of a panel of ERα target genes, while RNA-seq revealed a downregulation of several putative ERα target genes and a downregulation of many cell cycle-associated proteins. To support the prognostic relevance of USP11, immunohistochemical staining of a breast cancer tissue microarray (103 ER+ patients available for final analysis) was performed. Kaplan-Meier analysis of this cohort revealed a highly significant association between high USP11 expression and poor overall (p=0.030) and breast cancer-specific survival (p=0.041). In silico analysis of publically available breast cancer gene expression datasets further supported an association between high USP11 mRNA levels and poor prognosis. We observed a significant correlation between high expression of USP11 mRNA in ER-positive patients and poor distant metastasis-free survival (HR 2, CI 1.37-2.91, p=0.00023). This correlation was also significant in ER-positive patients who had received tamoxifen only (HR 2.9, CI 1.63-5.15, p=0.00015).

These results suggest a role for USP11 in driving cellular growth and identify USP11 as novel therapeutic target in breast cancer.
Title: Novel driver genetic alterations in MYB-NFIB-negative breast adenoid cystic carcinomas

Body: Introduction: Breast adenoid cystic carcinoma (AdCC) is a rare type of triple-negative breast cancer associated with an indolent clinical behavior. AdCCs provide a clear example of genotypic-phenotypic correlation with the majority harboring the MYB-NFIB fusion gene. In this study, we sought to identify alternative driver genetic alterations in breast AdCCs lacking the MYB-NFIB fusion gene.

Methods: Nucleic acids obtained from four breast AdCCs lacking the MYB-NFIB fusion gene as defined by reverse transcription (RT)-PCR and/or fluorescence in situ hybridization (FISH) were subjected to RNA-sequencing (n=3), whole-genome (n=2) and/or targeted (n=1) massively parallel sequencing. Sequencing data were analyzed using state-of-the-art bioinformatics algorithms, and potential alternative driver genetic alterations were validated using orthogonal sequencing and molecular pathology methods.

Results: RNA-sequencing revealed the presence of MYBL1-ACTN1 or MYBL1-NFIB fusion genes in two breast AdCCs, which were validated by whole-genome sequencing and/or MYBL1 FISH analysis. Both MYBL1 fusion gene-positive cases were found to overexpress MYBL1 as defined by quantitative RT-PCR analysis. In the third MYB-NFIB-negative breast AdCC studied, a high-level MYB gene amplification coupled with overexpression of MYB at the mRNA and protein levels was identified. In the fourth breast AdCC, which expressed high levels of MYB, whole-genome and RNA-sequencing revealed no definite alternative driver alteration, however, a MYBL2 intronic mutation was found in this case, which was associated with high levels of MYBL2 mRNA expression. In this case, single sample gene set enrichment analysis revealed activation of pathways similar to those activated in AdCCs harboring the MYB-NFIB or MYBL1 fusions genes.

Conclusion: We demonstrate that in breast AdCCs lacking the MYB-NFIB fusion gene MYBL1 rearrangements and MYB amplification are likely alternative driver genetic events. Given that activation of MYB/MYBL1 and their downstream targets can be driven by the MYB-NFIB fusion gene, MYBL1 rearrangements, MYB amplification or other yet to be validated mechanisms (e.g. MYBL2 non-coding mutations), our findings further suggest that breast AdCCs constitute a convergent phenotype.
Title: Deregulation of A-to-I RNA editing is associated with poor prognosis in HER2+ breast cancers in the neoALTTO trial

David Venet1, Françoise Rothé1, Florianie Dupont1, Marion Maetens1, Debora Fumagalli2, Roberto Salgado1, Ian Bradbury3, Lajos Pusztaí1, Nadia Harbeck4, Miguel Izquierdo6, Lorena de la Pena7, Michail Ignatiadis8, Evandro de Azambuja9, Jens Huober10, Paolo Nuciforo11, Jose Baselga12, Martine Piccart13,12, Sherene Loi14 and Christos Sotiriou1,13. 1Breast Cancer Translational Research Laboratory, Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium; 2Breast International Group - BIG aisbl, Belgium; 3Breast Medical Oncology Section, Yale Cancer Center, Yale School of Medicine, New Haven; 4University of Munich, Germany; 5Novartis Pharmaceuticals Corporation; 6SOLTI-Breast Cancer Research Group, Barcelona, Spain; 7Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium; 8Breast European Adjuvant Study Team, Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium; 9University of Ulm, Germany; 10Molecular Oncology Laboratory, Vall d’Hebron Institute of Oncology, Barcelona, Spain; 11Memorial Sloan Kettering Cancer Center, New York; 12Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium and 14Peter MacCallum Cancer Center, Melbourne, Australia.

Body: Background
A-to-I RNA editing, a post-transcriptional modification of the RNA catalyzed by the ADAR family of enzymes, is emerging as a widespread phenomenon in breast cancer (BC). A-to-I RNA editing is more frequent in the highly repetitive Alu regions but can affect both coding and non-coding regions. It has been shown to greatly impact cell functionality. In a recent report, we have shown that A-to-I RNA editing is regulated both by ADAR copy number and type I interferon response (Fumagalli et al. Cell Rep 2015). The main aim of the current study was to investigate the extent and profile of A-to-I RNA editing in HER2+ BC patients (pts) treated in the NeoALTTO trial, and to explore its impact on pathologic complete response (pCR) and survival.

Methods
Aligned RNAseq reads of sufficient quality and quantity were obtained for 252 of the 455 pts enrolled in the study, as described previously (Fumagalli et al. JAMA Oncol 2016). Editing sites from the rediPortal database were assessed. The editing level at a given site was computed by counting the number of Gs and As. Sites with coverage more than 10 were considered for further analyses. Editing in normal tissues was obtained from the GTEx project of the rediPortal database. Tumor infiltrating lymphocytes (TILs) and copy number aberrations were previously reported. Correlations between different parameters were assessed using Spearman correlations (ρ). The Mann-Whitney test was used to relate binary and numerical features. Event-free survival (EFS) analysis was performed using the Cox proportional hazard model.

Results
There was a median of 71470 edited sites per sample. As expected, mean editing per sample correlated with ADAR expression (ρ=59%, p<10^-16) and ADAR copy number (ρ=54%, p<10^-16). It was also correlated with the IFN-gamma driven signature (ρ=22%, p=0.0005), as well as with ESR1 gene expression (ρ=24%, p=0.0002). Neither ADAR expression nor mean editing was correlated with TILs (ρ=-0.5% and p=3%). No relationship between mean editing and pCR or EFS was found. The correlations between editing in NeoALTTO tumor samples and GTEx normal tissues were computed, and the median editing per sample was taken. These median correlations, ranging from 32% to 56%, were not associated with ADAR expression (ρ=-25%, p=6x10^-5) nor mean editing (ρ=8%, p=0.19). Of interest, patients whose tumors showed low correlation with editing in normal tissues were associated with poor EFS (ρ=0.028, HR=0.56 to 0.96) suggesting that deregulation of RNA editing may impact disease progression and outcome. Similar results were obtained when the correlations were assessed between tumor samples instead of between tumor and normal samples (ρ between the two median editing: 76%; p-value survival: 0.013). The median correlations were not predictive for pCR (ρ=0.44). There was no interaction between editing and treatment arm.

Conclusions
Our study shows for the first time that deregulated RNA editing, as compared to editing in normal tissues, is a widespread phenomenon in HER2+ BC patients treated in the NeoALTTO trial and is associated with poor outcome. These results may provide new perspectives for the treatment of HER2+ disease by developing therapies targeting RNA editing.
Title: Genetic heterogeneity as a risk assessment parameter in breast cancer

Body: Cancer is a disease of clonal evolution, and intra-tumor heterogeneity provides the fuel for that evolution. Unfortunately, that heterogeneity poses a challenge for sampling and prognosis, as different biopsies may sample different clones, which may not be relevant to the future behavior of the tumor. However, because heterogeneity helps to drive clonal evolution, measurements of heterogeneity itself may be prognostic. We hypothesized that ductal carcinoma in situ (DCIS) with more clonal heterogeneity would be more likely to progress to invasion and metastasis.

In order to investigate cancer heterogeneity, we have developed new bioinformatics methods that allow us to analyze small amounts of degraded DNA (20ng) extracted from FFPE samples, at multiple regions. Using our method, we investigated the exomes of pairs of DCIS samples taken at 10 mm distances in the same neoplasm. We identified the mutations present in each sample and we evaluated the heterogeneity level between the pairs of samples. Finally, we compared the heterogeneity levels of patients with pure DCIS versus DCIS patients with invasive features.

We found a statistically significant different level of genetic heterogeneity between pure DCIS and invasive DCIS patients. Notably, the DCIS that has adjacent invasive components have a larger number of private mutations than the patients with DCIS alone (mean 31 vs 16 mutations, Mann-Whitney p=0.023), suggesting that heterogeneity may have a relevant role on cancer progression.

This finding supports our ongoing work to further elucidate the relationship between clonal heterogeneity and invasive progression in breast cancer.
Title: Mitochondrial gene fusions and their putative roles in breast cancer

Vartika Agrawal¹, Yee Him Cheung¹, Payal Keswarpu², George Somlo³, Maysa Abu-Khalaf⁴, William Sikov⁵, Vinay Varadan⁶, Lyndsay Harris⁷ and Nevenka Dimitrova². ¹Philips Research North America, Cambridge, MA; ²Philips Genomics, Valhalla, NY; ³City of Hope National Medical Center, Duarte, CA; ⁴Yale Comprehensive Cancer Center, New Haven, CT; ⁵Women and Infants Hospital, Providence, RI; ⁶Case Western Reserve University, Cleveland, OH and ⁷National Institute of Health, Bethesda, MD.

Body: Background: Several mitochondrial DNA (mtDNA) mutations have been identified in human cancer, and suppression of mitochondrial respiratory gene expression has been reported. mtDNA has limited protective mechanisms due to lack of histones and is more susceptible to genomic aberration. While nuclear gene fusions are known to play an important role in tumorigenesis, the role of mitochondrial gene fusions in tumorigenesis and human disease has not been defined. Given the importance of nuclear gene fusions in human cancer, we sought to define the role of mtDNA gene fusions in the clinical behavior of breast tumors and their response to therapy.

Methods: RNA sequencing was performed on pre and post treatment breast cancer samples obtained from neoadjuvant clinical trials BrUOG 211A/211B. There were 73 baseline and 61 post-treatment samples, with 54 samples at both time points. Patients were given a run-in dose of bevacizumab (B), nab-paclitaxel (N) or trastuzumab (T), followed by combination biologic/chemotherapy (HER2- with B/carboplatin/N; HER2+ with T/carboplatin/N). We detected gene fusions using TopHat-Fusion and defuse based on RNA derived from biopsy pairs obtained pre/post 10-day exposure to run-in monotherapy. Results: In this cohort, 385 mtDNA gene fusions were detected in baseline and 344 in post-treatment samples, with an average of 4.6 and 4 mtDNA gene fusions, respectively, per patient, with the following observations:

(1) A number of fusions had recurrent increase from baseline to post-treatment, e.g. MT-ATP6:MT-ND2 (N = 9), MT-ND6:MT-CO1 (N = 6), MT-ND6:MT-CO1 (N = 10), and MT-ND4:MT-ATP6 (N = 9)

(2) Gene fusions MT-ND6:MT-ATP8, MT-CYB:MT-ND2 and MT-ND6:MT-ND1 were observed respectively in 9, 5 and 4 baseline samples but not in their post treatment equivalent.

(3) MT-ND6 had seven gene fusion partners that appeared in fusions that were most abundant among baseline and post-treatment samples (MT-ND4 (N = 39), MT-ND2 (N = 37) and MT-ATP6 (N = 36)).

Of note, MT-CO1 and MT-CO2 both encode the enzyme cyclooxygenase, with MT-CO2 being the inducible isoform that activates inflammatory response and promotes mammary carcinogenesis. MT-ATP6 and MT-ATP8 encode the ATP synthase subunits 6 and 8, and novel mutations have been identified in these genes in breast cancer patients. MT-ND1/2/4/6 encode the subunits of NADH dehydrogenase (Complex I) which is the largest of the respiratory complexes. Polymorphisms in these genes are associated with breast cancer risk and progression.

Conclusions: While several studies have examined the presence of mtDNA mutations in breast cancer, the role of mitochondrial gene fusions is unknown. Many of the mtDNA genes involved in fusions have been shown to play a role in breast tumorigenesis and the clinical behavior of breast tumors. We observed mitochondrial fusions in our cohort of breast tumors treated with preoperative therapy, some of which were seen in pre and post treatment samples suggesting a potential role in resistance to therapy. Further study of mtDNA fusions in breast cancer is needed as this may have important implications for treatment of this disease.
Title: Whole exome sequencing of extreme responders reveals low mutation burden in metastatic breast cancer

Joohyuk Sohn¹, Sun Min Lim², Eunyoung Kim¹, Sora Kim¹, Ja Seung Koo¹, Seung Il Kim¹, Seho Park¹, Hyung Seok Park¹, Nak-Jung Kwon³, Gun Min Kim¹ and Sangwoo Kim³. ¹Yonsei University College of Medicine; ²CHA Bundang Medical Center and ³Macrogen.

Body: Background: Extreme responders toanticancer therapy are rarely encountered in the treatment of advanced breast cancer patients, but their treatment response have not been investigated on the whole exome level. We performed whole exome analysis to characterize genomic landscape of extreme responders in metastatic breast cancer patients.

Methods: Clinical samples were obtained from patients who showed exceptional response to anti-HER2 therapy or hormonal therapy. Non-responders were selected among those who did not respond. Matched breast tumor tissue (somatic DNA) and blood samples (germline DNA) were collected from a total of 18 responders (12 ER+, 6 HER2+) and 8 non-responders (6 ER+, 1 HER2+, 1 TNBC). Whole exome sequencing using Illumina HiSeq2500 was performed on the 26 patients (52 samples). Somatic single nucleotide variants (SNVs), indels and copy number variants (CNVs) were identified for each patient genome. Group specific somatic variants and mutation burden were statistically analyzed.

Findings: Cancer exomes were characterized by 1,455 somatic single-nucleotide variants (1,327 missense, 80 nonsense, 36 splice-site, 12 start/stop-lost), 149 insertions/deletions (108 frameshift, 41 inframe), with a median of 1 mutations per Mb (0.2 to 2.7 mutations per Mb) in all patients. Responders harbored a significantly lower non-synonymous mutation burden than non-responders (median, 27 vs. 90.5, \( P = 0.01 \)), and copy number variation burden was also lower (median 23 vs. 31, \( P = 0.14 \)). Multivariate analyses of factors influencing progression-free survival showed that high mutation burden and visceral metastases were significantly related with progression.

Interpretation: Extreme responders of metastatic breast cancer are characterized by low nonsynonymous mutational burden.

Title: Mucinous breast carcinomas: A genomically distinct subtype of estrogen receptor-positive invasive breast cancers

Fresia Pareja1, Felipe C Geyer1, Salvatore Piscuoglio1, Pier Selenica1, Rahul Kumar1, Raymond S Lim1, Elena Guerini-Rocco1, Caterina Marchio2, Odette Mariani3, Charlotte K Y Ng1, Edi Brogi1, Larry Norton4, Anne Vincent-Salomon3, Britta Weigelt1 and Jorge S Reis-Filho1. 1Memorial Sloan Kettering Cancer Center, New York, NY; 2University of Turin, Turin, Italy; 3Institut Curie, Paris, France and 4Memorial Sloan Kettering Cancer Center, New York, NY.

Body: Introduction: Mucinous carcinoma of the breast (MCB) is a rare histologic form of estrogen receptor (ER)-positive invasive carcinoma, accounting for up to 2% of breast cancers. MCBs are characterized by clusters of tumor cells floating in lakes of extracellular mucin, and are classified into mucinous A (paucicellular) and mucinous B (hypercellular) subtypes. Some MCBs are found admixed with invasive ductal carcinoma components, and then classified as mixed MCBs. The aims of this study were to determine the repertoire of somatic mutations of MCBs and to ascertain whether these genetic alterations are distinct from those identified in common forms of ER+/HER2- invasive breast cancers (IBCs). We also sought to determine whether the mucinous and ductal components of mixed MCBs would be clonally related.

Materials and methods: Thirty MCBs including 25 pure MCBs (n=13 mucinous A, n=12 mucinous B) and five mixed MCBs were microdissected and subjected to whole exome sequencing. Each tumor component of mixed cases was microdissected and analyzed separately. Somatic mutations, copy number alterations and mutational signatures were defined using state-of-the-art bioinformatics methods. The mutational repertoire of MCBs was compared with that of ER+/HER2- IBCs (n=240) from The Cancer Genome Atlas (TCGA) breast cancer study.

Results: The genes most frequently mutated in MCBs were GATA3 (27%, 8/30, all frameshift mutations), KMT2C (13%, 4/30) and MAP3K1 (10%, 3/30). No significant differences were identified in single gene comparisons between mucinous A and mucinous B MCBs or between pure MCBs and the mucinous component of mixed MCBs (Fisher’s exact tests, p>0.05). As compared to common forms of ER+/HER2- IBC, MCBs had a lower frequency of PIK3CA mutations (7% vs 42%, p<0.001) and a higher frequency of GATA3 mutations (27% vs 12%, p=0.04). Mucinous B MCBs had a higher frequency of KMT2C mutations than ER+/HER2- IBCs (25% vs 6%, p=0.04). Most MCBs displayed the mutational signature 1 (aging-related; 20/30, 67%), and no differences in the frequency of specific mutational signatures according to the type of MCBs were observed. Concurrent 1q gains and 16q losses, which are the hallmark genetic alterations of low-grade ER+/HER2- breast cancers, were not observed in pure MCBs, but were found in three of the five mixed MCBs analyzed. The mucinous and ductal components of all five mixed MCBs shared a median of 58% of somatic mutations (range 42%-64%), including clonal GATA3 frameshift mutations in two of them, as well as a similar pattern of copy number alterations, supporting their clonal relatedness. Additional somatic mutations found to be restricted to the ductal or mucinous components of all mixed MCBs analyzed were identified, including clonal missense mutations in PIK3C2B and PIK3R2 in the ductal component of one case, and a PIK3R5 missense mutation in the mucinous component of another case.

Conclusions: The repertoire of somatic mutations in MCBs is distinct from that of common forms of ER+/HER2- IBCs. These differences include the lack of concurrent 1q gains/16q losses, a lower frequency of PIK3CA mutations and a higher frequency of GATA3 mutations in pure MCBs.
Title: Genomic differences and impact on clinical outcomes in patients with pre- and post-menopausal metastatic breast cancer

Samir Zaidi1, Laura M Spring1, Giuliana Malvarosa1, Karleen R Habin1, Long P Le1, Leif W Ellisen1, Anthony J Iafrate1, Daniel A Haber1 and Aditya Bardia1. 1Massachusetts General Hospital Cancer Center and Harvard Medical School, Boston, MA.

Body: Background
Breast cancer accounts for 15% of all new cancers and 7% of all cancer-related deaths. Women diagnosed before the age of 40 years have considerably worse survival rates making this variable an independent risk factor for adverse prognosis. Furthermore, the management of ER+ breast cancer is particularly different between pre- and post-menopausal women. However, there is a paucity of data comparing the genomic landscape of pre- and post-menopausal ER+ breast cancer, particularly differences in actionable alterations. Here, we compare the incidence of mutations in 91 actionable genes in pre-menopausal and post-menopausal metastatic ER+/HER2- breast cancer patients.

Methods
We identified patients with metastatic ER+/HER2- breast cancer who had tumor genotyping testing by Snapshot-NGS assay via multiplex polymerase chain reaction (PCR) technology called Anchored Multiplex PCR, utilizing the ArcherDx platform and Illumina NextSeq next generation sequencing (NGS), for single nucleotide variant (SNV) and insertion/deletion (indel) detection in genomic DNA from formalin-fixed, paraffin-embedded (FFPE) tissue. An ensemble variant calling approach was utilized incorporating MuTect1, LoFreq, GATK, and a laboratory developed hotspot caller. All sequencing and variant calling was performed at the Massachusetts General Hospital Center for Integrated Diagnostics. Demographic data including menopausal status at the time of metastatic diagnosis was determined based on retrospective chart review.

Results
We analyzed the tumor genotyping results from 34 pre- and 98 post-menopausal patients with ER+/HER2- metastatic breast cancer. Pre- and post-menopausal groups were determined to have a median age of 47 and 64, and premenopausal women were more likely to have ER+/PR- disease. While there was no statistically significant difference in the rate of mutation in any gene after multiple testing correction, PIK3CA (0.35 vs. 0.24, OR=1.8, P=0.2), PTEN (0.12 vs. 0.06, OR=2.23, P=0.5), and ESR1 (0.09 vs 0.03, OR=3.4, P=0.45) mutations were skewed towards the post-menopausal group. Conversely, NOTCH1 (0.06 vs 0.02, OR=2.9, P=0.27) and MSH6 (0.03 vs 0, OR=inf, P=0.26) mutations were skewed towards the pre-menopausal group. The impact of these molecular alterations on clinical outcomes will be presented at the symposium.

Conclusions
Our findings highlight key differences in the genomic landscape of actionable genes between pre- and post-menopausal metastatic breast cancer, which may serve as markers for understanding and predicting disease prognosis. Furthermore, our data aim to clarify the utility of routine clinical sequencing panels in pre-menopausal metastatic breast cancer.
Title: ASCO 2013 HER2-equivocal breast cancers CGH array analysis

Carine Ngo1, Edith Borcoman1, Fatoumata Simaga1, Odette Mariani1, Laetitia Fuhrmann1, Emmanuelle Jeannot1, Delphine Loirat1, Marick Lae1, Jean-Yves Pierga1, Gaelle Pierron1 and Anne Vincent-Salomon1. 1Institut Curie, Paris, France.

Body: Background
The status of human epidermal growth factor receptor 2 (HER2, ERBB2) determines breast cancer patients HER2-targeted therapy eligibility. New international guidelines on HER2 determination in breast cancers have been proposed by ASCO/CAP in 2013. HER2 level of amplification is associated to the quality of the anti-HER2 therapy response. The answer to anti-HER2 therapy for equivocal cases remains debated.

Objectives
We first evaluated the impact of the 2013 ASCO/CAP updated guidelines on HER2 fluorescence in situ hybridization (FISH) classification in breast cancers with an equivocal (Score 2+) immunohistochemistry (IHC) result from 2008 to 2014 in our institution. We then investigated genome-wide copy number alterations in breast cancer patients with HER2-equivocal result by both IHC and FISH.

Methods
We reviewed all breast cancers cases analysed by FISH for HER2 status determination between 2008 and 2014 following 2007 ASCO guidelines and reassessed them according to 2013 guidelines. Breast cancers with equivocal HER2 status by both IHC and FISH (49 cases) according to 2013 guidelines were subsequently analysed by Agilent 60-mer oligonucleotide microarrays for array-based comparative genomic hybridization (aCGH).

Results
When applying the 2013 ASCO guidelines, 141 cases (7.2%) out of 1970 cases analysed by FISH had a modified HER2 status. Only five (3.5%) in the HER2-negative category defined with the 2007 ASCO guidelines changed into a positive status. The equivocal category increased from 16 (0.8%) to 119 (6.1%) cases. Out of the 49 HER2-equivocal cases identified by both IHC and FISH (ASCO 2013 guidelines), aCGH showed that 20 cases (40.8%) presented a large copy number gain of chromosome 17, 12 cases (24.5%) had a segmental copy number gains including HER2 and five cases only (10.2%) showed HER2 amplification.

Conclusion
The 2013 ASCO/CAP guidelines increased the number of equivocal results and raised an uncertainty about the most appropriate clinical management of these patients. At the genomic level, HER2-equivocal cases corresponded mostly to chromosome 17 polysomy and / or segmental copy number gains. Genomic copy number analysis may be useful in reclassifying equivocal cases which enabled proper patient selection for HER2-targeted therapy.
Title: CYP19A1 gene Rs1008805 polymorphism is related to the prognosis of early breast cancer

Xiying Shao¹, Yabing Zheng¹, Weibin Zou¹, Guangliang Li¹, Ping Huang¹ and Xiaojia Wang¹. ¹Zhejiang Cancer Hospital, Hangzhou, Zhejiang, China.

Body: Background: Aromatase, encoded by CYP19A1 gene, is a rate-limiting enzyme in the conversion of androgens into estrogens. Given the critical role of CYP19A1 gene in estrogen synthesis, the potential impact of genetic polymorphisms in CYP19A1 gene on the survival of breast cancer deserves further study.

Methods: Rs1008805 polymorphism in CYP19A1 gene were genotyped on 406 Chinese Han women with stage I-II and operable stage III breast cancer. Associations were explored between rs1008805 genotypes and disease-free survival (DFS).

Results: Totally, there were 200 (49.3%) patients with AA genotype, 169 (41.6%) with AG variant, and 37 (9.1%) carrying GG variant. No significant differences were found in DFS or 5-year survival rate among the whole population with these three genotypes. However, in postmenopausal women, rs1008805 genotypes were significantly related to DFS and 5-years DFS rate (AA versus AG versus GG: 63.1 months versus 54.3 months versus 13.7 months; 48.6% versus 46.0% versus 14.3%; \( P = 0.015 \)). In addition, women with GG variant had a poorer DFS, 5-years DFS rate when compared with those carrying AG or AA genotype (GG versus AG or AA: 13.7 months versus 56.3 months; 0% versus 52.1%; HR, 2.462; 95% CI, 1.310-4.628; \( P = 0.004 \)). Being adjusted by patients features in multivariate analyses, GG genotype remained an independent prognostic factor for DFS (HR, 2.706; 95% CI, 1.393-5.257; \( P = 0.003 \)). Whereas, premenopausal women with the homozygous minor allele had a marginally improved DFS, 5-years DFS rate when compared with those carrying the common allele (GG versus AG or AA: 87.0 months versus 48.7 months; 60.3% versus 42.7%; HR, 0.544; 95% CI, 0.295-1.003; \( P = 0.051 \)). However, there was no relationship between GG genotype and DFS or 5-year DFS when adjusted by patients features in multivariate analyses.

Conclusions: The present study demonstrated that homozygous minor allele of rs1008805 SNP in CYP19A1 gene was significantly related to a worse DFS or 5-year DFS in postmenopausal women with early breast cancer. This founding is novel, if confirmed, CYP19A1 rs1008805 genotypes may turned to be a prognostic biomarker for early breast cancer.
Title: Detection of splice variants related to endocrine resistant hormone receptor-positive breast cancer

Han-Byoel Lee¹, Min-Su Kim², Jiyoung Rhu¹, Jung Hyun Park¹, Kyung Eun Kim¹, Young Wook Ju¹, Eun-Shin Lee¹, Hyeong-Gon Moon¹,², Dong-Young Noh¹,³, Sun Kim⁴ and Wonshik Han¹,³. ¹Seoul National University College of Medicine, Seoul, Korea; ²Interdisciplinary Program in Bioinformatics, Seoul National University, Seoul, Korea; ³Cancer Research Institute, Seoul National University, Seoul, Korea and ⁴Interdisciplinary Program in Bioinformatics, and Bioinformatics Institute, Seoul National University, Seoul, Korea.

Body: Introduction: Estrogen receptor is expressed in 75% of breast cancers and is related to a relatively indolent phenotype. Yet, up to 25% of these tumors develop resistance to endocrine therapy. Alternative splicing events are observed in almost every hallmarks of cancer, implying that dysregulation of splicing and cancer progression are closely related. The purpose of this study was to detect splice variants related to endocrine resistance in hormone receptor(HR)-positive breast cancer.

Methods: RNA sequencing data of 455 HR-positive patients with documented endocrine treatment from The Cancer Genome Atlas (TCGA) database was used for analysis. Splice variants of 96 ESR1 pathway-related genes were detected using a data-mining algorithm recognizing spliceomic heterogeneity. A differential analysis of splice variants between 48 endocrine therapy-resistant and 407 endocrine therapy-responsive patients was performed to discover isoforms frequently detected in endocrine-resistant tumors. Isoforms related to endocrine resistance was further analyzed using whole transcriptome sequencing data from 59 HR-positive invasive breast cancer patients (24 endocrine therapy-resistant, 35 endocrine therapy-responsive who underwent operation at Seoul National University Hospital.

Results: Of 96 ESR1 pathway-related genes, 17 genes showed statistically different splice variant isoforms frequencies (AKT1, ATF2, ATF4, CALM2, CALM3, CREB1, EGFR, ESR1, ESR2, GRM1, HRAS, HSP90AA1, OPRM1, PIK3R3, PRKACB, SHC1, and SHC4). A differential analysis of these isoforms using SNUH data confirmed a predominant isoform of HRAS (64.47% vs 57.14%, p-value 0.0037) and a minor isoform of SHC1 (25.53% vs 32.33%, p-value 0.0456) in endocrine therapy-resistant HR-positive patients. In the same analysis using HR-negative patients, the mean isoform percentage was similar between patients with distant recurrence and no recurrence.

Conclusions: Phenotype-specific splice variants can be detected using transcriptome sequencing data. Splice variants in HRAS and SHC1 are potential spliceomic signatures that may be used to predict endocrine therapy-resistant breast cancer. Further investigation is warranted to explore the biological role of these isoforms and identify the role of splice variants as a biomarker for endocrine resistance.
Young breast cancer patients (<40 yo) have unfavorable subtypes, higher stage and worse survival

Jessica S Young¹, Tsutomu Kawaguchi¹, Li Yan¹, Qianya Qi¹, Song Liu¹ and Kazuaki Takabe¹. ¹Roswell Park Cancer Institute, Buffalo, NY.

BACKGROUND:
Over the last 40 years, the incidence of breast cancer in young women in the U.S. has been relatively low and stable, but the absolute number of young women with breast cancer is increasing because of the growing population. Some epidemiological studies have shown that breast cancer diagnosed before age 40 have significantly worse overall 5-year survival. Disease free survival is also inferior in young women, and they have more aggressive cancers in general. This study aims to validate these findings using genomic analysis of large databases.

MATERIALS AND METHODS:
The Cancer Genome Atlas (TCGA; n= 1095) and the Molecular Taxonomy of Breast Cancer International Consortium (METABRIC; n=1894) were used for analysis. We divided the database into the Young (<40 yo) and Non-Young (>40 yo) cohorts, based on age at diagnosis. The following analysis will give the TCGA and METABRIC results in each category, respectively.

RESULTS:
There were 8.9% (98) and 6% (116) patients who were found to be Young. In the Young cohort, 69.5% (64) and 37.9% (44) were ER(+), whereas 77.9% (742) and 79.5% (1415) in the Non-Young cohort were ER(+). Further, 60.8% (56) and 31.9% (37) were PR(+) in the Young cohort, compared to 68.4% (641) and 54.4% (972) in the Non-Young cohort. Her2(+) cancers were noted in 22.2% (12) and 25% (29) in the Young cohort, whereas 22.6% (152) and 11.6% (207) in the Non-Young cohort. Our group developed a pipeline to calculate PAM50 from the RNA-Seq dataset. Utilizing this calculated PAM50 in TCGA, we found that there were less Luminal A and B patients in the Young cohort, 41.6% (42) and 17.8% (18) compared to 49.7% (377) and 22.9% (174) in the Non-Young cohort. This was also the case in METABRIC where 17.2% (20) and 9.5% (11) were Luminal A and B, compared to 36.9% (659) and 25.2% (450) in the Non-Young group. In contrast, there were more basal-like subtypes in the Young group, 17.8% (18) and 28.4% (33), as compared to the Non-Young group, 16.1% (122) and 9.3% (166). These results agree with previous epidemiological studies that showed that hormone receptor positive tumors increase and basal-like subtypes decrease with age. The number of Stage I patients was lower in Young patients 13.5% (13) and 25.3% (22), than in Non-Young patients 17.3% (169) and 34.4% (453). Similarly, there were less Stage II patients in the Young 54.2% (52) and 58.6% (51) compared to 58.3% (569) and 56.9% (749) in the Non-Young. This reverses in Stage III where the incidence is increased in the Young at 31.2% (30) and 16.1% (14) compared to 22.4% (219) and 7.7% (101) in the Non-Young. Young patients had a lower median disease-free survival than Non-Young patients (NA vs 214.7 mo, p=0.027); however, there was no statistical significance in median survival. Young patients had a lower median disease-specific survival than non-young patients of 221.1 months vs 282.6 months (p=0.00123) in METABRIC.

CONCLUSION: We used large datasets to examine survival in very young breast cancer patients (<40 yo) vs older patients and found that young patients are likely to have unfavorable subtypes, higher stage, and a lower overall survival and DFS as compared to their older counterparts. Further analysis with genomics is needed.
2017 San Antonio Breast Cancer Symposium

Publication Number: P2-05-15

Title: Oncotype DX Breast Recurrence Score®: Real-life utilization among node positive patients in Ontario

Roy Richardson¹, Amanda Macchiusi¹, Ashwini Bhasin¹ and Claire Takizawa². ¹Genomic Health Canada, Canada and ²Genomic Health International SARL, Switzerland.

Body: Aims: The 21-gene Oncotype DX (ODX) Recurrence Score (RS) has been extensively validated to predict the risk of distant recurrence and the magnitude of response to hormone and chemotherapy in patients with ER+ N0 and N+ (up to 3 positive nodes) HER2- early stage breast cancer. Outcomes data from multiple large studies further confirm the assays clinical validity and utility. The test is currently reimbursed in Ontario for N0 but not for N1 patients. In 2016, a market access program has been initiated to address lack of data in current clinical practice in Ontario among N1 patients. It collects data assessing the real-life use of the test in Ontario and its impact on treatment decision. This analysis presents the interim analysis until end of May 2017.

Methods: The program allows for prospective data collection in key breast cancer centers in Ontario. Through an online dedicated platform patient data are collected including classical pathological and clinical parameters (e.g. histology, tumor grade and size, ER, PR, and HER2 status), patients age, ODX Recurrence Score results and recommended treatment both before and after the test results have been reported.

Results: A total of 7 qualified breast cancer centers or network of centers participated in the program and collected 90 cases so far. Study results demonstrated that ODX is used among a wide variety of patients profiles: 28% G1, 58% G2 and 14% of G3, 18% pre-, 12% peri- & 69% are post-menopausal, 20% are aged 40-49, 24% are 50-59, 29% are 60-69 and 26% are 70 and older, 3% tumor are <1cm, 38% are 1-<2cm, 52% are 2-<5cm and 7% tumor size are >5cm. RS distribution is the following: <18 (67%), 18-30 (30%) and >30 (3%).

In addition, pre-ODX 90% of patients had a treatment recommendation for chemo-hormonotherapy (CT-HT). Post-testing, the number of patients recommended CT-HT decreased to 36%, highlighting that the test reduces unnecessary use of CT. In fact, the ODX led to an overall 54% net reduction in chemotherapy.

Conclusions: This real-life survey confirms that ODX provides critical information beyond clinical and pathological criteria. The assay changes treatment decisions among N+ patients in Ontario, sparing CT which could result in potential savings to the healthcare system.
Title: Molecular characterization of human malignant phyllodes tumors reveals potential targeted approaches

Hyeong-Gon Moon¹, Jihui Yun¹, Bok Sil Hong¹, Eunshin Lee¹, Han-Byoel Lee¹, Wonshik Han¹, Jong-Il Kim¹, Dong-Young Noh¹, Woohang Heo¹, Saem Hur¹, Wonyoung Kang² and Charles Lee². ¹Seoul National University College of Medicine, Seoul, Korea and ²Jackson Laboratory, Farmington, CT.

Body: Malignant phyllodes tumor (MPT) which belong to the fibroepithelial neoplasm spectrum is a rare type of breast malignancy, and currently there is no effective targeted approach available for MPT. In this study, we tried to identify key genomic alterations and biologic pathways in MPT by whole exome and RNA sequencing of nine MPT tissues. Whole exome sequencing revealed somatic alterations in EGFR, MED12, PIK3CA, PIK3R1, PDGFRA, PDGFRB, PTEN, and TP53. Transcriptome sequencing showed dysregulation of ECM-receptor interaction, focal adhesion, and PI3K-Akt signaling in MPTs when compared to normal breast or invasive breast cancer tissues. Based on the transcriptome profiles, the MPTs were classified into two subtypes; fibrous subtype with upregulation of stromal genes such as collagens and epithelial subtype with upregulation of E-cadherin and Claudins. The molecular classification of fibrous and epithelial subtypes was validated in 28 paraffin-embedded MPT tissues. The fibrous subtype showed higher mitotic index and increased risk for recurrence when compared to the epithelial subtype. We established a patient-derived xenograft model from one fibrous subtype MPT which harbored somatic mutation in PIK3R1 and PDGFRB. In that model, targeted treatment against PIK3CA/mTOR and PDGFR pathways effectively suppressed the tumor growth in vivo. Our data provide insights on the biologic understanding of MPT and suggest a clinically relevant molecular classification. Furthermore, we show that developing effective targeted approaches in MPT can be possible with genomic profiles and patient-derived xenograft models. The clinical efficacy of targeting PDGFR and PIK3CA/mTOR pathways in MPT should be tested in future clinical trials.
Title: Breast cancer HER2 epigenetic intratumoral heterogeneity results from lack of HER2 protein translation

Body: Research objective
Previously, we reported the negative correlation between pathological complete response (pCR) and HER2 positive breast cancer exhibiting amplified HER2 gene tumor cells without HER2 protein overexpression (HER2 epigenetic intratumoral heterogeneity) among trastuzumab-based neoadjuvant chemotherapy treated patients. Our objective in this study was to elucidate if tumor cells with HER2 epigenetic intratumoral heterogeneity express HER2 RNA using a HER2 RNA in situ hybridization (ISH) method.

Materials and methods
Formalin-fixed, paraffin-embedded (FFPE) sections of breast cancer biopsy samples were investigated for HER2 RNA expression at the individual cell level using a HER2 RNA ISH assay. RNA preservation in tissue sections was examined using a peptidylprolyl isomerase B (PPIB) RNA ISH assay.

Three groups of cases were examined:
1) HER2 negative breast cancer cases (HER2 RNA ISH negative control group).
2) HER2 positive breast cancer cases with homogeneous HER2 positive tumor cells (HER2 RNA ISH positive control; pCR group)
3) HER2 positive breast cancer cases with HER2 epigenetic intratumoral heterogeneity (a mixture of HER2 gene and protein positive tumor cells and HER2 gene positive tumor cells without HER2 protein expression; incomplete response group)

Consecutive sections of HER2 RNA ISH slides were stained for HER2 gene and protein concurrently on the same tissue section using HER2 gene-protein assay (GPA) which is a combination of FDA-approved HER2 immunohistochemical (HER2 protein) and HER2 dual ISH (HER2 gene and chromosome 17 centromere) assays. Analyses of HER2 RNA expression in individual cells was microscopically evaluated and matched to HER2 GPA slides.

Results
RNA preservation was confirmed in tissue sections of all three groups by a PPIB RNA ISH assay. Tumor cells of HER2 negative breast cancer cases (negative control group) lacked HER2 RNA ISH signal while HER2 gene and protein positive tumor cells of homogeneous breast cancer cases (positive control group) demonstrated high HER2 RNA expression levels. HER2 gene and protein positive tumor cells of HER2 positive intratumoral heterogeneity cases showed high HER2 RNA expression. However, amplified HER2 gene breast cancer cells without HER2 protein overexpression of HER2 positive intratumoral heterogeneity cases also showed high levels of HER2 RNA expression. Thus, revealing in cases with intratumoral heterogeneity, transcription of HER2 RNA occurs, but translation of HER2 protein is altered by some mechanism(s) in tumor cells.

Conclusions
Transcription of HER2 RNA was observed in breast tumor cells with amplified HER2 gene but absence of HER2 protein overexpression (HER2 epigenetic intratumoral heterogeneity) of patients who showed incomplete response to neoadjuvant trastuzumab therapy. Our study suggests that inconsistent HER2 protein translation in breast cancer with HER2 epigenetic heterogeneity might be the primary resistance mechanism to trastuzumab-based neoadjuvant chemotherapy.
Title: Clinicopathologic characteristics and genomic essence analyses revealed estrogen receptor positive, progesterone receptor negative and human epidermal growth factor receptor 2 negative breast cancer to be more basal-like and endocrine resistant

Xiyu Liu¹,²,³, Ding Ma¹,²,³, Yi-Zhou Jiang¹,²,³, Yi-Rong Liu¹,²,³, Ke-Da Yu¹,²,³ and Zhi-Ming Shao¹,²,³. ¹Fudan University Shanghai Cancer Center, Shanghai, China; ²Cancer Institute, Fudan University Shanghai Cancer Center, Shanghai, China and ³Shanghai Medical College, Fudan University, Shanghai, China.

Body: Background: Estrogen receptor positive/ progesterone receptor negative/ human epidermal growth factor receptor 2 negative (ER+/PR-/HER2-) tumors define a distinct subtype of ER+ breast cancer, characterized by poor response to endocrine therapy and poor prognosis. The genomic landscape of ER+/PR-/HER2- tumor has yet to be systematically studied, and driver events for tumor progression and endocrine resistance with loss of PR expression are yet to be identified. Methods: We assessed 13,410 ER+/PR-/HER2- patients from Surveillance, Epidemiology, and End Results (SEER), the Cancer Genome Atlas (TCGA) and Molecular Taxonomy of Breast Cancer International Consortium (METABRIC) for clinicopathologic characteristics, survival and genomic analyses. Patients were divided into endocrine-resistant and endocrine-sensitive groups using an endocrine therapy sensitivity score \((0.8*\text{ER}+1.2*\text{PGR}+\text{BCL2}+\text{SCUBE2})/4\), and we further explored genomic events enriched in the endocrine-resistant group. Results: Clinicopathologic features and survival outcomes of ER+/PR-/HER2- patients were worse than ER+/PR+/HER2- in SEER and METABRIC cohort. The genomic landscape of ER+/PR-/HER2- tumors revealed them to have more aggressive properties, like a higher percentage of luminal B (29-35%) and basal-like (4-16%) subtypes; more intClust subtypes with high genomic instability (intClust1, 6); more TP53 mutation and less PIK3CA mutation; and more copy number variation events. ER+/PR-/HER2- tumors have more focal amplification events, including 8p11.23 (ZNF703) and 17q23.1 (RPS6KB1) and more focal deletion events, such as 17q21.31 (BRCA1) and 14q24.3 (MLH3). Pathifier pathway analyses showed that up-regulated pathways in ER+/PR-/HER2-tumors included those associated with biosynthesis, metabolism, drug resistance and DNA replications (FDR<0.1). Endocrine sensitivity score for ER+/PR-/HER2- group was significantly lower than ER+/PR+/HER2- group. When split by 1st quartile of endocrine sensitivity score, up to 72.7% of ER+/PR-/HER2- tumors were grouped into the endocrine-resistant group. Mutant-allele tumor heterogeneity (MATH) score is significantly lower in the endocrine-resistant group. Several focal SCNA events were more common in the endocrine-resistant group (P<0.05), including 8q24.21 amplification with only the MYC gene in the “peak” region. Pathways unregulated in the endocrine-resistant group of ER+/PR-/HER2- tumor included MYC pathway and mTORC1 signaling (FDR<0.25). Conclusion: ER+/PR-/HER2- breast cancer was a heterogeneous tumor group and featured more basal-like and luminal B characteristics. The ER+/PR-/HER2- tumors are relatively resistant to endocrine therapy, and MYC pathway enrichment and corresponding 8q24.21 amplification might be one of the drug-resistance mechanisms. Our study provides an overall understanding of the distinct genomic landscape of ER+/PR-/HER2- breast cancer. Further investigations into the pathways activated with the loss of PR expression may provide clues for novel changes in the therapeutic regimens of ER+/PR-/HER2- breast cancer.
Title: Use of principal component analyses to select ER-balanced subset for gene centering in PAM50 subtyping

Praveen-Kumar Raj-Kumar1, Jianfang Liu1, Albert J Kovatich2, Leonid Kvecher1, Craig D Shriver3 and Hai Hu1, 1Chan Soon-Shiong Institute of Molecular Medicine at Windber, Windber, PA; 2Clinical Breast Care Project, Murtha Cancer Center, Uniformed Services University / Walter Reed National Military Medical Center, Bethesda, MD and 3Murtha Cancer Center, Uniformed Services University / Walter Reed National Military Medical Center, Bethesda, MD.

Body: Background: PAM (Prediction Analysis of Microarray) 50 is an established gene expression-based algorithm to classify breast tumors into basal-like, HER2-enriched, luminal A (LA), and luminal B (LB) subtypes. Clinical subtyping is mainly based on immunohistochemistry (IHC) assays of estrogen receptor (ER), progesterone receptor (PR), human epidermal growth factor receptor 2 (Her2) and Ki67 classifying tumors into triple-negative (ER-/PR-/Her2-), Her2+ (ER-/PR-/Her2+), LA (ER+/Her2-/Ki67-), LB1 (ER+/Her2-/Ki67+) and LB2 (ER+/Her2+). These two subtyping methods do not completely match even on comparable subtypes. Nevertheless, the ER-balanced subset for gene-centering in PAM50 subtyping was selected based on clinical status. Here we explored the possibility of using principal component analyses and iterative PAM50 call to refine the selection of an ER balance subset to improve consistency between these methods focusing on LB calls which is more aggressive than LA tumors.

Methods: Normalized gene expression data was obtained from TCGA research network for 712 primary tumors which had IHC status available for ER, PR and Her2. Since Ki67 status was not available LA and LB was discriminated for ER+ cases with Her2- and Her2+ respectively. In house RNA-Seq dataset had 118 primary tumors and were drawn from the Clinical Breast Care Project where breast cancer patients were consented using an IRB-approved protocol. Tumors were selected and processed by laser microdissection. RNA was extracted from tissues using the Illustra triplePrep kit (GE Healthcare). Paired-end mRNA sequencing was performed using the Illumina HiSeq platform. Sequenced reads were processed using PERL based pipeline utilizing PRINSEQ, GSNAP and HTSeq. Principal component analysis (PCA) was done using R. Wilcoxon rank sum test was used for statistical significance (p<0.05).

Results: In both datasets, the PCA map grouping of cases does not perfectly reflect the clinical subtypes. This motivated us to select ER balance subset based on the PC1 separation and IHC subtype. The resulting PAM50 subtypes on PCA map distinguished Basal and LA as two well separated components. Using all of Basal and equal number of LA cases for ER balance subset for PAM50 resulted in increased LB call and a better consistency with IHC LB calls. Among 712 cases in TCGA LB numbers increased from 142 in initial PAM50 call to 203 in ER balanced refined PAM50 call. We noticed that there was significantly higher (p-value = 4.414e-11) MKI67 expression for the 39 cases switch from LA to LB between PAM50 calls. Similar trend was observed in our in-house dataset where majority of the IHC-LB1 cases was called as LB in PAM50. The new method increased LB call from 22 to 27 which in-turn increased consistency between molecular and clinical subtypes from 73 to 79 out of the total of 118 cases.

Conclusion: We show that an iterative PAM50 call coupled with PCA for selection of ER balance set potentially enhanced the consistency of the LB calls with clinical subtyping and that the tumors switched from LA to LB have high MKI67 expression. The views expressed in this article are those of the author and do not reflect the official policy of the Department of Army/Navy/Air Force, the Department of Defense, or U.S. Government.

Title: Integrative analyses of immunophenotypes and multi-omics profiles in breast cancers

Zhengyan Kan, Eric Powell, Sripad Ram, Keith Ching, Ying Ding, Pamela Vizcarra, Tim Nichols, James Hardwick, Soo-Hyeon Lee, Soo Youn Cho, Yoon-La Choi, Jong-Han Yu and Yeon Hee Park. 1Pfizer Oncology Research, San Diego, CA; 2Pfizer Korea, Seoul, Korea and 3Samsung Medical Center, Seoul, Korea.

Body: The advent of immuno-oncology (IO) therapies has made it an imperative to characterize intratumoral immune microenvironment in addition to oncogenic alterations through molecular profiling of the tumor. To elucidate the baseline profiles of tumor infiltrating leukocytes (TILs) in breast cancer (BC) in the context of molecular subtypes and oncogenic alterations, we performed whole-exome sequencing (WES) and RNA-Seq of an Asian BC cohort (SMC) consisting of 178 treatment naïve primary tumors. A subset of 120 tumors was further analyzed by H&E and IHC using a panel of 8 TIL markers (CD45, CD4, CD8, CD163, PD1, PD-L1, IDO1 and FOXP3). Using expression signatures representing distinct immune cell types, we classified an expression compendium of 2,781 tumor samples, including SMC and multiple cancers from TCGA, into three immune subtypes with high, medium and low levels of TILs. Basal and HER2 subtypes show higher levels of TILs than Luminal subtypes, consistent with observed clinical responses to checkpoint blockade in clinical trials. Moreover, Asian BCs were significantly enriched in TIL-high subtype (35.3%) compared to the primarily Caucasian TCGA BC cohort (20.2%) while 50.6% of the highly immunogenic Lung adenocarcinoma was TIL-high. We then applied machine learning methods to detect and quantify TILs from H&E images of 120 SMC and 349 TCGA BC tumors. The expression signature analysis results were concordant with independently derived histology based TIL data. Taken together, our findings suggest that IO therapies may be more effective in HR negative BC subtypes and Asian BCs.

Leukocyte exclusion (LE), an immunophenotype where TILs concentrate at the tumor periphery, has been linked to worse prognosis and resistance to IO therapies. Visual assessment of whole tumor IHC images identified LE patterns in 25% of SMC cases. We observed differential distribution of LE by molecular subtype and evidence for selective exclusion of immune cell subsets. Covariate analyses with clinical and molecular data while controlling for subtype as a confounder identified significant associations with tumor proliferation index, percent tumor purity and TP53 mutations. LE is also significantly associated with expression signatures of chemokine signaling, macrophages, angiogenesis and hypoxia, indicating that marked distinctions exist in both tumor intrinsic and microenvironment characteristics between TIL excluded and TIL infiltrated tumors. To validate these findings, we independently identified LE for 200 cases of TCGA BCs based on patterns of TILs extracted from H&E images and saw significant concordance of covariate relationships identified between TCGA and SMC. Our study provided a rare comprehensive resource for studying tumor associated immunity in breast cancers by generating the integrated multi-omics and IO profiles for a large cohort of primary tumors. Comparative analyses revealed that TIL activities are highly variable across different intrinsic subtypes and geographic origins of BC, with potential implications for IO therapeutic application. Correlative analyses of immunophenotypes with molecular data further yielded insights into LE’s role in immune escape and identified hallmark signatures for LE indicative of causal molecular mechanisms.
Title: Uncovering TNBC molecular heterogeneity by applying integrative “omics” analyses with potential clinical implications

Yacine Bareche¹, David Venet¹, Françoise Rothe¹ and Christos Sotiriou¹. ¹Breast Cancer Translational Research Laboratory, Jules Bordet Institute, Université Libre de Bruxelles, Brussels, Belgium.

Body: Introduction: Triple-negative breast cancer (TNBC), representing about 10-20% of all breast cancers (BC), is a heterogeneous disease characterized by a clinically aggressive course, higher relapse rates and worse overall survival as compared to other BC subtypes. Recent efforts of genome-wide gene expression profiling have improved our understanding of the biological diversity of TNBCs reporting at least 6 different molecular subtypes namely Basal-like 1 (BL1), basal-like 2 (BL2), immunomodulatory (IM), mesenchymal (M), mesenchymal stem-like (MSL) and luminal androgen receptor (LAR). Little is known regarding the potential driving molecular events characterizing each subtype, their difference in survival and response to therapy. Moreover, limited progress has been made so far in the development of effective therapeutic strategies in TNBC partly due to the lack of obvious genetic targets. Further insight into the underlying genomic alterations is therefore needed.

Aims: Here, we aimed to study the genomic aberrations that drive each of the TNBC molecular subtypes as defined by Lehmann et al. by applying an integrative analysis combining somatic mutation, copy number aberrations and gene expression profiles of 272 TNBC derived from METABRIC consortium.

Methods: In silico analyses were performed using microarray, copy number aberrations profiles (CNA) and mutation profiles data retrieved from 272 TNBC patients from the METABRIC consortium. Somatic mutation profiles were derived from targeted sequencing of 173 cancer genes. CNAs at the gene level were computed using GISTIC 2.0.22. The relationship between TNBC molecular subtypes and genomic aberrations were analysed using Fisher test. Survival analyses were performed using Cox proportional hazard models adjust for standard clinical and pathologic variables.

Results: Using a multivariate model, IM and M subtypes were significantly associated with good (HR=0.53; FDR=0.01) and poor (HR=1.8; FDR=0.01) prognosis respectively. BL1 subtype was found to be the most genomically instable subtype with high frequency of TP53 mutations (93%) and copy-number deletions in genes involved in DNA repair mechanisms (BRCA2, MDM2, RB1 and TP53) and MYC overexpression. BL2 subtype was enriched with TP53 (95%) and PIK3CA mutations (52%), whereas LAR subtype was characterized by high frequency of PI3KCA mutations (44%). Of interest, for these two subtypes, mutations in genes in the PI3K signalling pathway were mutually exclusive. IM subtype was enriched in NCOR2 mutations (13%), a co-repressor of the Notch pathway, associated with lower gene expression (p=0.035). M and MSL subtypes were significantly associated with higher signature scores for angiogenesis. In addition, M subtype was associated with higher frequency of NOTCH1 mutations (M p=2.4E-2).

Conclusions: This integrative analysis combining somatic mutation, copy number and gene expression profiles shed new light on TNBC molecular heterogeneity, highlighting TNBC subtype-specific genomic aberrations which could potentially open new avenues for the development of effective targeted therapies in each TNBC molecular subtype such as DNA repair, Notch and angiogenesis.
Title: Systematic characterization of kinase inhibitors reveals heterogeneity in responses by class and cell line

Caitlin E Mills¹, Kartik Subramanian¹, Marc Hafner¹, Mirra Chung¹, Sarah A Boswell¹, Robert A Everley¹, Dejan Juric¹,² and Peter K Sorger¹. ¹Harvard Medical School, Boston, MA and ²Massachusetts General Hospital, Boston, MA.

Body: Several publications have addressed concerns surrounding drug response screens by pointing out sources of variability and by presenting recommendations for better experimental methods and more robust analytical approaches. In the presented profiling effort, we integrated the latest advances in drug response measurement and focused on data diversity and quality rather than on breadth. We selected 32 breast cancer cell lines with a strong bias towards triple negative lines as well as 4 cell lines established from relevant patient-derived xenografts. We evaluated a panel of clinically relevant kinase inhibitors using a microscopy-based dose response assay to measure drug potency, and to quantify drug efficacy in terms of growth inhibition (GR metrics) and cell death. The use of the GR metrics to quantify drug sensitivity enabled us to identify and study differences between cytostatic and cytotoxic responses. This systematic dose response dataset is complemented by measurements of baseline transcript expression levels by mRNAseq, quantification of absolute abundance of ~12,000 proteins, and relative phosphoprotein levels by shotgun mass spectrometry across all cell lines. Additionally, the baseline activity of transcription factors and kinases were inferred from the mRNA (using VIPER) and phosphoprotein (using kinase enrichment analysis) data, respectively. The complementarity of these multi-omics data has allowed us to address questions about the landscape of breast cancer cell lines such as: Where do the patient-derived lines lay relative to the conventional cell lines? How consistent are the landscapes defined by each dataset? How does integration across datasets provide mechanistic insight into signaling pathways that are active in each cancer subtypes? The measured and inferred baseline data were used to build predictors of the observed drug responses with the goal of identifying the biological processes responsible for the differences in sensitivity across drugs and cell lines. Overall the dataset that has been collected is a valuable resource for understanding drug response in triple negative breast cancer, and the molecular mechanisms that influence it.
Title: Molecular regulators of resistance and relapse in chemorefractory triple-negative breast cancers

Bradley A Hancock¹, Yu-Hsiang Chen¹, Jeffrey P Solzak¹, Mufti N Ahmad¹, David C Wedge², Dumitru Brinza³, Charles Scafe³, James Veitch³, Rajesh Gottimukkala³, Walt Short³, Rutuja V Atale¹, Mircea Ivan¹, Sunil S Badve¹, Bryan P Schneider¹, Kathy D Miller¹ and Milan Radovich¹. ¹Indiana University School of Medicine, Indianapolis, IN; ²Oxford University, Oxford, United Kingdom and ³ThermoFisher Scientific, Carlsbad, CA.

Body: Triple-Negative Breast Cancer (TNBC) accounts for approximately one-fifth of breast cancer incidence but disproportionately high mortality. Two-thirds of early-stage TNBCs are resistant to pre-surgical chemotherapy and highly prone to relapse within 3 years. Moreover, no advanced therapies are indicated for patients with these cancers. We have embarked on a comprehensive genomic analysis of chemoresistant TNBC to gain an in-depth understanding of molecular entities driving chemoresistance and relapse. By collecting somatic mutation and copy number, RNA-sequencing, and outcome data in the context of a phase II post-neoadjuvant clinical trial, we have uncovered several molecular mechanisms behind these aggressive cancers. Through the analysis of matched pairs sampled before and after chemotherapy, we have discovered multiple means by which tumors are able to overcome the effects of chemotherapy including clonal evolution of high-level oncogene amplification, repression of the in situ immune system, and upregulation of the stem cell-related MEK-ERK and JAK-STAT pathways. Investigation into factors related to prognosis revealed important correlations between relapse and immune and JAK-STAT signaling. Finally, using a novel method of demarcating loss-of-function of p53, which we have termed graduated inactivation, we discovered additional associations between p53 loss and relapse, mortality, and MYC signalling.
Title: Genomic lesions and PD-1/PD-L1 expression in resected triple negative breast cancers

Body: Introduction: Striking clinical responses to immunotherapies in subsets of patients with a variety of solid tumors have prompted the search for predictive biomarkers. Recent studies have proposed that gene specific and genome wide mutation and copy number signatures in tumor cells may be predictive of responses to immune checkpoint blockade. Notably high levels of PD-L1 on tumor cells, a context associated with an adaptive immune response, has been linked to specific oncogenic driver lesions including loss of PTEN, activating KRAS mutation, and MYC amplification, and to the total burden of copy number variants (CNVs) in aneuploid tumors. Triple negative breast cancers (TNBCs) typically have multiple driver mutations and high levels of CNVs in their genomes. Thus there is significant interest in exploiting genomic data for the development of prognostic immunotherapy biomarkers for patients with TNBC.

Study Design: We interrogated 62 well annotated surgical resections from patients with TNBC and assessed the associations of genomic lesions with expression of PD-1 and PD-L1 in tumor and non-tumor cells in each sample. We applied a systematic approach to rigorously interrogate the genomes of each TNBC sample. Tumor ploidy was initially measured with DNA content flow cytometry followed by sorting the nuclei of distinct diploid, tetraploid, and aneuploid cell populations from each TNBC. The next level of analysis measured genome wide copy number variants (CNV) with oligonucleotide arrays designed for CNV detection using purified (>95%) tumor populations. This enabled the discrimination and mapping of CNVs including single copy losses and gains, focal amplifications, and homozygous deletions across each TNBC genome. Finally we generated whole exome data in a subset of samples to increase the resolution within loci of interest and to incorporate mutations of individual genes into our genomic signatures. This combined approach provides high resolution measures of TNBC genomes from ploidy, whole chromosome and chromosome arm level CNVs, focal amplicons, breakpoints and homozygous deletions across each TNBC genome. Finally we generated whole exome data in a subset of samples to increase the resolution within loci of interest and to incorporate mutations of individual genes into our genomic signatures. This combined approach provides high resolution measures of TNBC genomes from ploidy, whole chromosome and chromosome arm level CNVs, focal amplicons, breakpoints and homozygous deletions, to the level of gene specific indels and mutations. In parallel whole tissue samples were screened by IHC for PD-1 and PD-L1 using validated antibodies and established scoring methods for staining of tumor and non-tumor cells.

Results and Conclusions: High levels of PD-1 and PD-L1 were detected in 5/60 (8.3%) and 16/60 (26.7%) evaluable cases with staining of PD-1 exclusively on non tumor cells, while PD-L1 was primarily on tumor cells; 15/16 (93.8%) cases. These data were then used to test the associations of individual recurring genomic lesions, and the extent and nature of chromosome aberrations on the expression patterns of PD-1 and PD-L1. Homozygous deletion of PTEN or activating mutation in PIK3CA did not correlate with increased expression of either immune checkpoint regulator in TNBC cells. Furthermore tumors with highly aberrant aneuploid genomes and distinct oncogenic drivers frequently express relatively low levels of both proteins suggesting an intrinsic escape from immunosurveillance.
Title: Multi-omics characterization of claudin-low breast tumors

Roxane M Pommier¹², Anne-Pierre Morel¹², Agnès Tissier¹², Emilie Thomas³, Janice Kielbassa³, Laurie Tonon³, Emilie Sohier³, Alain Viari³⁴, Pierre Saintigny¹² and Alain Puisieux¹². ¹Univ Lyon, Université Claude Bernard Lyon 1, INSERM 1052, CNRS 5286, Centre Léon Bérard, Cancer Research Center of Lyon, Equipe Labellisée Ligue Contre le Cancer, Lyon, France; ²LabEx DEVweCAN, Université de Lyon, Lyon, France; ³Fondation Synergie Lyon Cancer, Plateforme de Bioinformatique Gilles Thomas, Centre Léon Bérard, Lyon, France and ⁴Equipe Erable, INRIA Grenoble-Rhône-Alpes, 655, Avenue de l'Europe, Montbonnot-Saint Martin, France.

Body: Breast tumors display highly heterogeneous characteristics both at transcriptional level and in term of genomic landscape. We recently reported that the differentiation status of the cell-of-origin influences the genetic route toward tumorigenesis¹. Indeed, mammary stem cells exhibit the intrinsic property to tolerate the oxidative stress inherent to the oncogenic transformation through the expression of a preemptive program driven by ZEB1, an epithelial-to-mesenchymal transition (EMT)-related transcription factor, and MSRB3, a methionine sulfoxide reductase. Thereby, ZEB1-expressing tumors exhibit low level of DNA damage associated with few genomic alterations and low level of TP53 mutations. Importantly, these tumors share several transcriptional characteristics and features with normal stem cells, and with Claudin-Low (CL) molecular subtype of breast cancers. In the present work, we attempt to decipher molecular traits of CL breast tumors through multi-omics analyses of publicly available databases. This global approach allows us to highlight various CL breast tumors features as clinical attributes, gene expression, copy number alterations (CNA), somatic mutations or drug responses by differential analyses of breast tumors and cancer cell lines. Preliminary results indicate that, independently of tumor purity, CL breast tumors are mostly diploids, present a paucity of genomic rearrangements and a lower mutation rate compared to other breast tumors. They mainly, but not exclusively, show basal features and belong to the integrative cluster 4 (CNA-devoid) described by Christina Curtis and colleagues². Concerning gene expression, CL breast tumors exhibit a frequent activation of RAS signaling pathway, an observation consistent with their sensitivity to MAPK inhibitors. Other analyses are currently ongoing and aim to better understand the biology of CL breast tumors in order to improve both the diagnosis and the therapeutic strategy used.

Title: Exploring novel therapeutic target molecules for metaplastic breast carcinoma using comprehensive genome-wide gene expression analyses

Michiko Yamashita\textsuperscript{1,2}, Yoshiaki Kamei\textsuperscript{1}, Erina Kusakabe\textsuperscript{1}, Haruna Yamasawa\textsuperscript{1}, Reina Aoki\textsuperscript{1}, Kana Taguchi\textsuperscript{1}, Kanako Nishiyama\textsuperscript{1,2}, Akari Murakami\textsuperscript{2}, Yuichiro Sawada\textsuperscript{1,3}, Yasutsugu Takada\textsuperscript{2} and Yuuki Imai\textsuperscript{2}. \textsuperscript{1}Graduate School of Medicine, Ehime University; \textsuperscript{2}Proteo-Science Center, Graduate School of Medicine, Ehime University and \textsuperscript{3}Graduate School of Medicine, Ehime University.

Body: Breast cancer subtypes have been classified based on the gene expression profiles, and the specifically effective treatments for each subtype have been developed and applied in clinical situations. However, there is no effective treatment for metaplastic breast carcinomas, which are pathological tissue types with poor prognosis. Metaplastic breast carcinomas are almost resistant to existing chemotherapy because it has not been identified the specific therapeutic target molecules. Recently, Lehmann et al. reported that breast cancers with chondroid metaplasia are categorized in Mesenchymal (M) type, which is one subtype out of six triple negative breast cancer (TNBC) subtypes based on drug susceptibility. From the knowledge on this report, we hypothesized that integrative analyses using the gene expression profile data sets obtained from various types of breast cancers with or without cartilage formation may enable us to identify the therapeutic target genes for metaplastic breast carcinomas, especially for breast cancers with chondroid metaplasia.

Bioinformatics analyses were performed using the gene expression profile data sets of TNBC, which are registered in Gene Expression Omnibus (GEO). When compared with metaplastic breast carcinomas (28 data sets), 200 genes were specifically fluctuated over 2-fold in breast cancer with chondroid metaplasia (8 data sets). On the other hand, M type (11 data sets) specific 578 genes were identified over 56 TNBC data sets. In addition, 57 genes were overlapped between chondoroid metaplastic 200 genes and M type 578 genes. Therefore, these 57 overlapped genes might be considered as possible poor prognostic factors in breast cancer with chondroid metaplasia. As a result of Gene Ontology analysis on these 57 genes, skeletal system development and extracellular matrix structural constituent were significantly enriched in Biological process and Molecular function, respectively. Also, \textit{SCRG1}, \textit{SOX8} and \textit{SOX10}, which are genes related to cartilage differentiation, were included.

Next, we focused 14 genes because these genes could serve as therapeutic targets. Then, we validated the expression levels of these 14 genes using tissues obtained from surgically resected human breast cancer with chondroid metaplasia dividing into three parts, the invasive ductal carcinoma, the chondroid metaplasia and normal mammary gland. As a result, \textit{SCRG1}, \textit{CD86}, \textit{HCLS1}, \textit{EPSTI1}, \textit{LYZ}, and \textit{SLA} were significantly increased in chondroid metaplasia part, suggesting that these validated genes were identified as possible therapeutic targets for breast cancer with chondroid metaplasia. Further study will help us to investigate a novel and effective therapeutic strategy for metaplastic breast carcinomas.

Title: Prognostic relevance of claudins 4 and 7 in invasive breast carcinoma (NOS) subtypes: A large tissue microarray study

Angela F Logullo¹³, Rafael M Rocha¹², Monica Stiepcich⁴, Fernando A Soares⁵, Fátima S Pasini⁵, Sueli Nonogaki² and Maria M Brentani⁵. ¹Escola Paulista de Medicina UNIFESP- EPM, Sao Paulo, Brazil; ²A.C.Camargo Cancer Center, Sao Paulo, Brazil; ³PhD Patologia Cirúrgica e Molecular, Sao Paulo, Brazil; ⁴Laboratório Fleury, Sao Paulo, Brazil and ⁵2Departamento de Radiologia e Oncologia (LIM24)FMUSP, Sao Paulo, Brazil.

Body: Molecular phenotyping has improved the understanding of a wide range of breast cancer disease. Recently, a new molecular subtype denominated “claudin-low” (CL) was described in breast cancer and correlated to worse prognosis and to CD44+/24- stem cell profile. Among 19 known claudin proteins, isotypes 4 (CL4) and 7 (CL7) are the most common in the breast biology. 

Objective: To verify differences in CL4 and CL7 immunoexpression between Luminal A, HER-2, and triple negative breast cancer phenotypes; and their association to CD44/24 status and tumor prognosis. 

Design: Estrogen and progesterone receptor status (ER/PR), HER-2, CL4 and CL7 expression and CD44/24 profiles were evaluated in 803 invasive ductal breast carcinomas arranged into four tissue microarrays (TMA) and results were correlated with prognosis and important clinical data.

Results: 503 (62.6%) cases were positive for CL4 and 369 (46.0%) cases for CL7. The majority (199/283, 70.3%) of CL4 negative cases were clustered in the luminal A subtype whereas 63 (22.3%) showed triple negative profile and the remaining 21 cases (7.4%) exhibited positive HER-2 expression (p<0.001). Claudin 7 negative samples (44.2%) tended to follow the same pattern. CL4 positive expression was significantly associated to HER-2 expression, presence of lymph nodes and increased tumor grades and inversely correlated to ER and PR expression. However, there was no association between CL7 expression and any of these features. Both CL4 and CL7 did not show correlation to the stem cell markers (CD44+/CD24+) or worse prognosis (survival and disease-free interval).

Conclusion: Claudins 4 and 7 immunoexpression did not provide additional prognostic information within breast cancer subtypes.
Title: Integrative analysis of miRNA and mRNA expression in metastatic versus non-metastatic triple negative breast cancer

Body: Background: Triple Negative Breast Cancer (TNBC) is a subset of breast cancer that is difficult to treat clinically and is characterized by being estrogen receptor (ER) negative, progesterone receptor (PR) negative, and does not overexpress human epidermal growth factor receptor 2 (HER2). Patients with TNBC tend to have a worse prognosis than other breast cancer subtypes.

Methods: We obtained fifteen TNBC sample FFPE tissue blocks with corresponding plasma samples. All samples were from primary tumors; seven samples having metastasized, four samples that had not metastasized and four samples with unknown metastatic status. The total RNA was isolated from FFPE blocks using the RecoverAll Total Nucleic Acid Isolation Protocol. miRNA from plasma was isolated using Ambion's mirVANA kit. The plasma and tissue miRNAs were evaluated using the QuantStudio qPCR platform, capturing ~750 miRNAs. The mRNA was processed using the TruSeq RNA Access kit and sequenced on the Illumina NextSeq platform. Analysis of the miRNA and mRNA individually was performed using limma and DESeq2 packages, respectively. Gene enrichment analysis of the mRNA expression was done using the GAGE package on KEGG pathways while the integrative analysis was done with sparse Canonical Correlation Analysis (sCCA) using the PMA package.

Results: Analysis of plasma miRNA had four miRNAs with a significant difference in raw p-value (p < 0.05) between metastatic and non-metastatic TNBC; miRNA 708, 483-3p, 518f, and 766; in the tissue there were fifteen miRNA with p < 0.05, with one miR-872 still having significance after adjusting for multiple testing. mRNA had 33 genes being significant after multiple testing correction with several immune KEGG pathways being downregulated in metastatic samples (adjusted p < 0.05). The integrative analysis revealed five microRNA (miR-216, miR-127, miR-370, miR-382, and miR-487b) and 312 gene modules enriched in integrin (Fisher p < 10^-5) and extracellular matrix (Fisher p < 10^-6) signaling.

Conclusions: One of the circulating plasma miRNAs, miR483-3p, has been found to promote tumorigenesis, while miR581f and miR766 have not been reported in cancer to date. Further investigation into these miRNA could provide a feasible biomarker. The downregulation of immune pathways observed within the metastatic TNBC subjects implies immune evasion is of particular importance for metastasis and a targeted immunotherapy may be a viable treatment option. The integrative analysis of the miRNA and mRNA showed an enrichment in pathways previously linked to increased proliferation and chemoresistance, with an increased signal compared to either miRNA or mRNA alone.

Title: Loss of function of Brca1 or Gata3 induces basal-like breast cancer

Xin-Hai Pei1,4, Ho Lam Chan1, Lihan Zhang1,2, Chuying Wang1,3, David J Robbins1,4, Tony Capobianco1,4 and Feng Bai1. 1Dewitt Daughtry Family, University of Miami, Miami, FL; 2Lanzhou University, Lanzhou, China; 3Xi’an Jiaotong University Health Science Center, Xian, China and 4Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Miami, FL.

Body: BACKGROUND:
Breast cancer is mainly divided into estrogen receptor (ER)-positive luminal and ER-negative basal-like tumors. Luminal-type tumors are associated with better survival and respond to hormone therapies whereas basal-like tumors are more aggressive and associated with a poor prognosis. Mammary epithelia are mainly composed of luminal and basal cells that are maintained by luminal and basal progenitors, respectively. The maintenance of luminal cell fate is orchestrated by networks of transcription factors, including BRCA1 and GATA3. Functional loss of BRCA1 by germline or somatic mutation or by promoter methylation is associated with more than one third of basal-like breast cancers. GATA3 expression is reduced in basal-like breast cancers and cancers that metastasize. Overexpression of GATA3 in cancer cells inhibits tumor formation. Deletion of Brca1 or Gata3 in mice results in early lethality or growth defects. How BRCA1 and GATA3 suppress breast cancer remains elusive.

METHODS:
We generated mice lacking Brca1 or Gata3 in mammary epithelia. Due to the proliferative defects and induction of p18Ink4c (p18), an inhibitor of CDK4/6, in mammary epithelial cells of these mice, we then generated mice lacking Brca1 or Gata3 in p18 deficient mammary epithelia. We determined spontaneous mammary tumor development in mutant mice and the mechanisms underlying the role of Brca1 and Gata3 in suppressing tumorigenesis and progression.

RESULTS:
Depletion of Brca1 or Gata3 led to growth defects of mammary epithelial cells, which was rescued by loss of p18. Depletion of Brca1 or Gata3 in a p18 null background induced heterogeneous mammary tumors with less luminal and more basal-like features and accelerated metastasis. Deletion of Brca1 eliminated Gata3 expression in human and mouse mammary tissues and cells. How Brca1 interacts with Gata3 to control mammary tumor development and progression is currently under investigation.

CONCLUSION: Our results suggest that loss of function of either Brca1 or Gata3 induces basal-like mammary tumors in p18 deficient background.
Title: Novel tumor suppressor regulating the PI3K/AKT pathway in breast cancer

Stefanie Chan¹, M Dafne Cardamone¹ and Valentina Perissi¹. ¹Boston University School of Medicine, Boston, MA.

Body: Breast cancer affects approximately 1 in 8 women over the course of their lifetime. Of the many genes and pathways deregulated by this heterogeneous disease, alterations of members in the PI3K/AKT pathway are present in approximately 20% of all cases, making it one of the more frequently mutated pathways in breast cancer. The PI3K/AKT pathway is well known to be involved in essential cellular processes necessary for cancer development and progression, including altered proliferation, metabolism, and cell survival. Previous studies have made it well known that the activation of AKT is regulated through its phosphorylation, but recent studies have also shown that AKT can also be regulated via ubiquitination, leading to AKT hyperactivation. However, the mechanism and players involved in this process are not well understood. Better understanding of these pathways could inform on better potential therapeutics to target this disease.

Recent work in our lab has identified GPS2, a member of the NCoR/SMRT complex, as a regulator of the insulin-signaling pathway through the inhibition of AKT ubiquitination by Ubc13. As many human cancers frequently have an increase in activated AKT, here we explore the potential of GPS2 as a tumor suppressor in the context of breast cancer and hope to elucidate the mechanism by which AKT ubiquitination regulates its activation.
An essential role of GRB7 in promoting the growth of therapy resistant HER-2 positive human breast cancer cells in culture and animal models

Shiuh-Wen Luoh\textsuperscript{1,2}, Wendy Wagoner\textsuperscript{1,2}, Xinhe Lai\textsuperscript{1,2}, Zhi Hu\textsuperscript{1}, Koei Chin\textsuperscript{1} and Betsy Ramsey\textsuperscript{1,2}. \textsuperscript{1}Oregon Health Sciences University, Portland, OR and \textsuperscript{2}VA Portland Health Care System, Portland, OR.

**Body:** Background - GRB7 gene encodes a multi-domain signal transduction molecule and is part of the core of the HER-2 amplicon. GRB7 is commonly co-amplified and over-expressed with HER-2 in human breast cancer. Earlier studies found a functional role of GRB7 in breast cancer. The role of GRB7 in HER-2 positive human breast cancer resistant to HER-2 targeted therapy remains unexplored however.

**Materials and Methods** - HCC-1954, 21MT1 and JimT1 are human HER-2 positive breast cancer cell lines that are resistant to trastuzumab and lapatinib treatment. Transient knock down of GRB7 protein expression was achieved with siRNA transfection and stable knock down with lentiviral vector mediated shRNA over-expression. Cell lines transfected with non-targeting siRNA or shRNA serve as negative controls. Knock down of GRB7 protein expression is verified by Western blotting. The growth of human breast cancer cell lines after GRB7 knock down in vitro is measured with the CellTiter Glo assay as well as the Incucyte live cell imaging. Activation status of specific signaling pathways was examined with phospho-specific antibody by immune-blotting and immune-precipitation. To assess the growth promoting function of GRB7 in human breast cancer cell lines in vivo, polyclonal HCC-1954, 21MT1 and JimT1 cells, with GRB7 knock down or their corresponding negative control, were orthotopically injected into the mammary fat pads of female immune-deficient NSG mice. The growth rates of these tumors, measured serially with caliper, and final tumor weights were compared between GRB7 knock down and the negative control. The proliferation rate and apoptosis of these tumors were studied with ki-67 staining and Tunel assay. The effects of GRB7 knock down on signaling were investigated with a proteome profiler receptor tyrosine kinase kit (R&D). The role of signaling molecules differentially activated in the growth of breast cancer cells by GRB7 knock down was examined utilizing siRNA mediated knock down, and antibody and small molecule inhibitors.

**Results** - GRB7 knock down decreased the growth of HCC-1954, 21MT1 and JimT1 cells in vitro and the growth of tumor xenograft these cells formed in animal models. When assayed by ki67 staining and Tunel assay, the mechanism of reduced tumor xenograft growth appeared to be distinct. Reduced proliferation and increased apoptosis were seen in 21MT1 cells, while reduced proliferation was seen in HCC-1954 cells and increased apoptosis in JimT1 cells. Protein profiling found that tyrosine phosphorylation of candidate signaling molecules was reduced with GRB7 knock down in JimT1 cells. Immuno-blotting and immuno-precipitation experiments were performed to evaluate these effects in other cell lines. The effect of targeting these molecules in breast cancer cell growth by siRNA and inhibitors is being examined.

**Discussion** - GRB7 has essential growth promoting function in therapy resistant HER-2 positive human breast cancer cells. GRB7 knock down has pleiotropic effects on signaling in various cellular contexts. The potential of targeting GRB7 signaling in treating therapy resistant HER-2 positive breast cancer merits further study.

**Background:** Triple negative breast cancer (TNBC) presents a very aggressive behavior with a high rate of metastasis. Overexpression of HMGA1 has been reported in TNBC and has been associated with the induction of the Epithelial-Mesenchymal transition (EMT) and metastasis. Therefore, HMGA1 is considered a master regulator of tumor progression in TNBC. The objective of this work was to know which genes are directly or indirectly regulated by HMGA1 to better understand their participation in EMT and their role in aggressive TNBC.

**Methods:** We performed the silencing of the HMGA1 gene using siRNA Silencer® Select Pre-designed (s6667 HMGA1, 4390849 GAPDH, 4390843 Negative control, all from Thermo Fisher, MA, USA) in two TNBC cell lines, HCC-1395 and MDA-MB-231, and we observed the effect of this gene inhibition by microarray global expression analysis using GeneChip Human Genome U133 Plus 2.0 (Affymetrix, CA, USA), comparing the conditions of inhibition versus their own control without inhibition. After the microarray data mining, results for the HMGA1 and PRRX1 genes were validated by qPCR using the Prime Time® Primers for HMGA1 (Hs.PT.58.38699366), PRRX1 (Hs.PT.58.2820749), and GAPDH as endogenous gene (Hs.PT.39a.22214836) with SybrGreen reagent (Roche, Basel, Switzerland). The level of expression of the HMGA1 and PRRX1 proteins was analyzed by Western blot in nuclear protein extracts of each cell line before and after gene silencing. Finally, we performed an in silico analysis using the “Gene 2 promoter” tool in the Genomatix platform to search the promoters and binding proteins of the PRRX1 gene.

**Results:** The silencing of HMGA1 in a non-metastatic TNBC cell line, HCC-1395, showed deregulation of genes associated with cell proliferation and angiogenesis. Meanwhile the silencing in a TNBC-metastatic cell line, MDA-MB-231, resulted in the deregulation of genes involved in the formation and organization of the cytoskeleton, including the overexpression of PRRX1. Validation of the expression changes of HMGA1 and PRRX1 by qPCR and Western blot was performed and HMGA1 was confirmed to negatively regulate the PRRX1 gene expression. Through in silico studies, we identified several binding sites of HMGA1 to the PRRX1 promoter.

**Conclusions:** The subexpression of PRRX1 is necessary for EMT to occur. In this study, we present the interesting finding that HMGA1 regulates the subexpression of PRRX1, as supported by the experiments of transcriptional and translational expression presented in this work. To our knowledge, this is the first report describing a regulatory role of HMGA1 on PRRX1, which could explain the metastatic capacity of cancers that overexpress HMGA1.

**Key words:** Epithelial-Mesenchymal Transition, Triple Negative Breast Cancer, Mesenchymal-Epithelial Transition, Metastasis.
Title: FOXK2 aberration in breast cancer

Hong Zhang\textsuperscript{1} and Yang Yu\textsuperscript{2}. \textsuperscript{1}The University of Texas-M D Anderson Cancer Center, Houston, TX and \textsuperscript{2}Baylor College of Medicine, Houston, TX.

Body: Background: Activation of oncogenes through DNA amplification/overexpression plays important roles in cancer initiation and progression. The chromosome 17 is a frequent site of cancer-associated genetic anomalies. This cytogenetic anomaly is strongly associated with poor prognosis and is a significant predictor of relapse in breast cancer. Previous studies of breast cancer have revealed the amplification of several genomic regions on 17q. These amplifications are typically discontinuous and complex in structure, suggesting that multiple oncogenes in this chromosomal segment may be co-selected during breast carcinogenesis. By integrative analysis of public genomic datasets of breast cancers from The Cancer Genome Atlas (TCGA), we have found that FOXK2 displayed frequent genomic amplifications and correlated gene expression changes in breast cancer. FOXK2 gene is located in 17q25 and encodes a transcriptional factor with a fork head DNA binding domain, but has not yet been reported to be associated with cancer-causal genetic aberrations. Gene amplification in the 17q chromosomal region is observed frequently in breast cancers. We hypothesize that FOXK2 is an important oncogene in breast cancer and it might be a novel therapeutic target and biomarker for breast cancer.

Methods: The status of FOXK2 located at the Chromosome 17q25 was explored by mining the breast cancer TCGA datasets including 910 tumor cases and 981 normal controls. To determine whether FOXK2 amplification/overexpression is required for breast cancer cell proliferation, we assessed the effect of FOXK2 stable knockdown on proliferation and anchorage-independent growth in four cell lines with high FOXK2 expression status (MDA-MB-231, MCF-7, HCC1954 and MDA-MB-361) using lentivirus mediated shRNAs. The oncogenic activity of FOXK2 was assessed by colony formation assay. The potential interacting molecules/pathways were explored.

Results: Frequent genomic amplifications of FOXK2 were detected in breast cancers compared to normal controls in all subtypes of breast cancers classified by PAM50 by integrative analysis of public genomic datasets and its overexpression was associated with poor overall survival of breast cancer patients. FOXK2 knockdown in several breast cancer cell lines inhibited breast cancer cell proliferation and anchorage-independent growth. More importantly, overexpression of FOXK2 and oncogene RAS induced MCF10A cell colony formation, indicating that FOXK2 is an oncogene in breast cancer. Several pathways, including regulation of cell proliferation, regulation of cell division, cell adhesion and regulation of cell metabolism, were regulated by FOXK2 in breast cancer cells.

Conclusion: Our data provide compelling evidence that FOXK2 is an oncogene in breast tumorigenesis, and it might be a novel therapeutic target and a biomarker predicting poor outcome. We are assessing the incidence of FOXK2 amplification in human breast cancer specimens using immunohistochemistry and FISH on TMA tissue blocks to determine the prognostic value of FOXK2 amplification for overall prognosis and treatment resistance. We are also validating the molecular mechanism of FOXK2 in breast cancer malignancy according to the identified potential interacting molecules/pathways by analyzing the RNASeq data of a breast cancer cell line with FOXK2 knockdown.
Title: T-cell receptor beta chain variable region (TRBV) expression patterns predict response to combined trastuzumab/lapatinib treatment in the NeoALTTO/BIG-1-06 trial

Ryan Powles¹, David Redmond², Christos Sotiriou¹, Sherene Loi³, Debora Fumagalli⁴, Paolo Nuciforo⁵, Nadia Harbeck⁶, Evandro de Azambuja⁴, Severine Sarp⁷, Serena Di Cosimo⁸, Jens Huober⁹, Jose Baselga¹⁰, Martine Piccart-Gebhart⁴, Olivier Elemento², Christos Hatzis¹ and Lajos Pusztai¹. ¹Yale University, New Haven, CT; ²Weill Cornell Medical College, New York, NY; ³Peter MacCallum Cancer Center, East Melbourne, Victoria, Australia; ⁴Universite Libre de Bruxelles, Brussels, Belgium; ⁵Vall d'Hebron Institute of Oncology, Barcelona, Spain; ⁶University of Munich, Munich, Germany; ⁷Novartis Pharma AG, Basel, Switzerland; ⁸Istituto Nazionale Tumori, Milan, Italy; ⁹University of Ulm, Ulm, Germany and ¹⁰Memorial Sloan Kettering Cancer Center, New York, NY.

Body: Background: Dual anti-HER2 blockade resulted in increased pathologic complete response rate (pCR) in the 3 arm NeoALTTO trial. High immune gene expression and the absence of PIK3CA pathway mutations are predictive of pCR in all treatment arms but no markers were identified that could predict which patients require dual HER2 targeted therapy. The goal of this analysis was to examine if TRBV expression could add to the predictive function of previously identified immune markers. Patients and Methods: We analyzed RNA and Whole Exome sequencing data from 245 cancers (54% of all patients) included in the trial. The TRBV reference sequences were obtained from the International ImMunoGeneTics information system. Reads were aligned using a custom BLAST mapping pipeline and normalized by the total number of aligned reads in each sample. We calculated 3 T cell receptor metrics for each tumor including (i) total TRBV chain expression level, (ii) Shannon entropy of the normalized unique TRBV-expression frequencies which reflect TCR diversity and (iii) we also used non-negative matrix factorization (NMF) to define TRBV co-expression metagenes (TRBVMG). We evaluated correlation between these metrics and immune and proliferation gene expression signatures and genomic features of the cancer including clonal heterogeneity and mutation load. We assessed association between TRBV and pCR using multivariate logistic regression. Results: 65 distinct TRBV variants showed heterogeneous expression levels across cancers with strong co-expression patterns. Total TRBV expression correlated strongly with immune metagene expression (Spearman's ρ=0.93, P<0.001), but entropy had a weaker, inverse correlation with immune metagene expression (Spearman's ρ=−0.40, P<0.001). Associations between TRBV metrics and mutation load and clonal heterogeneity were weak. pCR correlated with higher total TRBV expression (Spearman's ρ=0.17, P<0.05). Correlation between entropy and pCR was non-significant (odds ratio (OR) for regressing entropy with pCR was <1). NMF identified 4 distinct TRBVMGs that showed substantial expression variation within immune cell rich cancers. ER-status, proliferation and immune-gene expression adjusted logistic regression analysis including a treatment-arm interaction term revealed that TRBVMG-2, characterized by high expression of TRBV4.3, TRBV6.3 and TRBV7.2 variants, was associated with higher pCR rate in patients treated with trastuzumab plus lapatinib (Interaction OR=3.23 adjusted P=0.03). In immune-rich cancers, TRBVMG-2 expression above the median was associated with higher pCR rate in the dual HER2 targeted treatment arm compared to the other arms (68% vs 21%, Fisher exact test P<0.001). Patients with immune cell rich cancers but TRBVMG-2 expression below the median had similar pCR rates in all arms (42% monotherapy vs. 28% dual therapy, P=0.46). Conclusions: TRBV expression pattern can provide predictive information beyond known immune gene expression signatures. High expression of TRBV4.3, TRBV6.3 and TRBV7.2 variants is associated with higher pCR rate with dual HER2 targeted and paclitaxel neoadjuvant therapy.
Title: Blinded molecular subtyping analysis from RNA-Seq of FFPE samples in the GeparQuinto trial reveals predictive value of VEGFA metagene for bevacizumab treatment

Body: Background:
RNA-Seq from total RNA in FFPE tissue can be more challenging due to limited capture of partially degraded RNA. Exome-capture based RNA-Seq may circumvent such problems and allow reproducible complete molecular characterization of low-quality RNA from small clinical samples.

Methods:
HER2 negative patients within the GeparQuinto trial were treated with neoadjuvant anthracycline-taxane-based chemotherapy +/- bevacizumab. Patients with bevacizumab therapy had a significantly higher pCR rate, especially within the triple negative subgroup. We performed exome-capture RNA-Seq on 5µm FFPE sections from pre-therapeutic cores of 400 HER2 negative samples from this trial. In a prospectively planned, blinded study we correlated molecular subtypes and metagenes for proliferation, stroma, MHC2, and VEGFA with clinical and histopathological data. Molecular subtypes were defined using the AIMS methods. Metagenes were calculated as mean values corresponding to previously described gene clusters after platform transfer (Rody et al. 2011 PMID 21978456, Hu et al. 2009 PMID 19291283) and then z-transformed.

Results:
296 samples with RNA-Seq data were classified as either of high (n=226) or of limited quality (n=70). For 22 samples RNA yield was insufficient and 82 did not pass initial QC. 121 (41%), 63 (21%), 34 (11.5%), 46 (15.5%), and 32 (11%) samples were defined as basal-like, HER2-enriched, luminal A, luminal B, and normal-like, respectively. Subtyping was robust with regard to gene filtering, normalization, and sample quality. ER and PR status from local IHC strongly correlated with gene expression (overall correctness 84% and 80% for ER, and 85% and 74% for PR, in samples with high and limited quality, respectively) and luminal subtypes (95% ER positive). Proliferation metagene correlated with histological grade (median -0.73, -0.39, and 0.53 in G1, G2, and G3, respectively; P<0.001) and MHC2 metagene correlated strongly with TIL counts (Rho=0.53, P<0.001). Among the high quality samples response rates (49.3% pCR overall) differed significantly by subtype, with higher pCR rates in basal-like (68.9%) and HER2-enriched (45.5%) than in luminal B (35.7%), luminal A (17.9%), and normal-like (20.0%). MHC2- (OR 1.60, 95%CI 1.21-2.12, P=0.001), proliferation- (OR 2.88, 95%CI 2.00-4.16, P<0.001), and VEGFA-metagenes (OR 1.92, 95%CI 1.41-2.60, P<0.001) were significant predictors for pCR. In a multivariate logistic regression (adjusted for bevacizumab treatment and hormone receptor status) both VEGFA metagene (OR 2.59, 95%CI 1.40-4.77, P=0.002) and the interaction between the VEGFA-metagene and bevacizumab treatment arm (P=0.023) significantly predicted pCR.

Conclusions:
Exome-capture RNA-Seq allows robust genomic characterization of clinical samples with limited FFPE material from core biopsies, and molecular subtypes and immune metagenes are predictive for pCR. The VEGFA metagene is a specific predictor for response to neoadjuvant bevacizumab treatment.
Title: Identifying clinically relevant subgroups of women with HER2-positive breast cancer: An analysis of Neo-ALTTO using the 41-gene TRAR score

Serena Di Cosimo¹, Tiziana Triulzi¹, Loris De Cecco¹, Sara Pizzamiglio¹, Evandro de Azambuja², Debora Fumagalli³, Lajos Pusztai³, Nadia Harbeck⁵, Miguel Izquierdo⁶, Lorena de la Pena⁷, Jens Huober⁸, Jose Baselga⁹, Martine Piccart², Paolo Verderio¹ and Elda Tagliaabue¹. ¹Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy; ²Institut Jules Bordet, Université Libre de Bruxelles (U.L.B.), Brussels, Belgium; ³Breast International Group (BIG), Brussels, Belgium; ⁴Yale Cancer Center, Yale School of Medicine, New Haven, CT; ⁵University of Munich (LMU), Munich, Germany; ⁶Novartis AG, Basel, Switzerland; ⁷SOLTI Breast Cancer Research Group, Barcelona, Spain; ⁸Brustzentrum, Frauenklinik, Universitätsklinikum Ulm, Ulm, Germany and ⁹Memorial Sloan Kettering Cancer Center, New York.

Body: BACKGROUND: As a neoadjuvant regimen for HER2-positive early breast cancer (BC), the use of two HER2-directed agents is more effective in producing pathological complete (pCR) responses than trastuzumab alone. Nevertheless, highly effective dual anti-HER2 combination may be unnecessary in patients who already benefit from a single agent. We previously reported that our 41-gene TRAR score is an accurate predictor of response to trastuzumab, with low scores being predictive of response to trastuzumab and favorable prognosis (Triulzi T. et al., 2015).

PATIENTS AND METHODS: Tissue specimens from HER2-positive BC patients of Neo-ALTTO trial who received neoadjuvant trastuzumab and/or lapatinib plus paclitaxel were included in this study. Analysing RNA from fresh tissue using the 41-gene signature test, the area under the ROC curve (AUC) and the corresponding 95% confidence interval was computed to evaluate the predictive ability of TRAR score with respect to pCR, the primary endpoint of Neo-ALTTO. The prognostic role of TRAR score was investigated using a Cox regression model in univariate fashion. The patterns of Event Free Survival (EFS) according to the dichotomized TRAR score were estimated using the Kaplan–Meier method.

RESULTS: The TRAR score was assessed for 226 of the 455 (49.7%) patients enrolled in the Neo-ALTTO study: 136 (60%) presented with T2 tumors, 188 (83%) with N0/1 and 128 (56.6%) with estrogen receptor negative BC. In details, basal TRAR score was available for 69, 79 and 78 patients assigned to neoadjuvant trastuzumab, lapatinib, and their combination, respectively. Overall, patients achieving a pCR showed significantly lower levels of TRAR score than those with residual disease (p <.0001). According to treatment arm, the classifier highly performed in discriminating responders (pCR) from non responders (no pCR) (trastuzumab: AUC = 0.74, 95% CI: 0.60–0.88; lapatinib: AUC = 0.76, 95% CI: 0.65–0.87; trastuzumab + lapatinib: AUC = 0.71, 95% CI: 0.59–0.83). Of note, the predictive value of the TRAR score was confirmed after adjustment for hormone receptor status. An AUC value of 0.70 (95% CI: 0.59–0.81) and 0.71 (95% CI: 0.62–0.80) was obtained in estrogen receptor positive and negative patients, respectively. We also evaluated the contribution to the predictive capability of TRAR levels and PAM50 by implementing a multivariate logistic regression model including both classifiers and clinically relevant variables. In this model the most predictive variable was TRAR. At a median follow-up of 7 years, with a total of 64 events, no statistically significant association was found between the TRAR score and EFS.

CONCLUSION: Overall, we show that our 41-gene signature is accurate in predicting patient response to neoadjuvant HER2 targeted therapy in terms of pCR. In particular, low levels of TRAR score can identify a HER2-positive breast cancer subgroup highly responsive to trastuzumab as monotherapy for whom combination with other HER2-targeted drugs does not appear justified and may be one tool used for exploring de-escalating strategies without sacrificing outcomes.
Title: Association of intrinsic subtype and immune genes with pathological complete response in the OPTIHER-HEART phase II clinical trial following neoadjuvant trastuzumab/pertuzumab-based chemotherapy in HER2-positive breast cancer

Joaquín Gavila, Mafalda Oliveira, Tomás Pascual, José Pérez, Jordi Canes, Xavier González, Laia Paré, Isabel Calvo, Eva Ciruelos, Montserrat Muñoz, Juan A Virizuela, Isabel Ruiz, Raquel Andrés, Antonia Perelló, Jerónimo Martínez, Serafín Morales, Mercedes Marín, Debora Martínez, Juan C Quero, Antonio Llombart-Cussac and Aleix Prat. 1 Fundación Instituto Valenciano de Oncología, Valencia, Spain; 2 Hospital Universitari Vall d’ Hebron, Barcelona, Spain; 3 IDIBAPS, Hospital Clinic, Barcelona, Spain; 4 SOLTI Breast Cancer Research Group, Barcelona, Spain; 5 Instituto Oncológico Baselga, Barcelona, Spain; 6 Institut Oncològic Dr. Rosell, Hospital General Cataluña, Barcelona, Spain; 7 Centro Integral Oncológico Clara Campal, Madrid, Spain; 8 Hospital 12 de Octubre, Madrid, Spain; 9 Hospital Virgen Macarena, Sevilla, Spain; 10 Hospital Universitario Sant Joan de Reus, Reus, Spain; 11 Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain; 12 Hospital Universitario Son Spases, Palma, Spain; 13 Hospital Universitario Virgen Arrixaca, Murcia, Spain; 14 Hospital Universitari Arnau Vilanova, Lleida, Spain; 15 Hospital Universitario Sagrado Corazón, Barcelona, Spain and 16 Hospital Arnau de Vilanova, Valencia, Spain.

Body: Background. In HER2-positive early breast cancer, neoadjuvant therapy based on dual HER2 blockade with trastuzumab and pertuzumab in combination with chemotherapy is associated with high rates of pCR. The OPTIHER-HEART trial examined the safety of the neoadjuvant dual blockade added to paclitaxel and liposomal doxorubicin (Gávila et al, SABCS 2016). In this analysis, we examined the intrinsic subtypes and immune genes in baseline and surgical samples from the OPTIHER-HEART trial.

Methods. OPTIHER-HEART was a multicenter single-arm phase II study of 18 weeks of neoadjuvant pertuzumab, weekly trastuzumab, liposomal doxorubicin (50 mg/m2 every 21 days) and weekly paclitaxel 80 mg/m2 in patients with stage II-IIIB HER2-positive breast cancer. pCR was defined as absence of infiltrating tumor in the breast and axilla. The expression of 55 breast cancer-related and immune genes in baseline samples and surgical specimens was measured using the nCounter platform. Intrinsic subtypes were determined by the PAM50 gene expression predictor. Univariate and multivariable logistic regression models adjusted for tumor size, ER status, age and nodal status was performed.

Results. A total of 58 of the 83 (69.8%) baseline tumor samples were available. 51.7% (n=30) were classified as HER2 enriched (HER2-E) followed by Normal-like (15.5%; n=9), Basal-like (12.0%; n=7), Luminal A (10.3%; n=6), and Luminal B (10.3%; n=6). HER2-E was the most frequent subtype in both hormone receptor (HR)-negative (50.0%) and HR-positive (52.0%) tumors. The pCR rates varied according to intrinsic subtype (p<0.001). The highest rate of pCR was observed in Basal-like (85.7%) and HER2-E (83.3%), followed by Normal-like (44.4%), Luminal A (33.3%) and Luminal B (16.6%). HER2-E tumors were associated with higher pCR rates compared to non-HER2-E tumors (83.3% vs 46.5%, unadjusted odds ratio = 5.76, 95% CI 1.71 – 19.42, P=0.004), even after adjusting for HR status, size, age and lymph node involvement (odds ratio = 13.50, 95% CI 2.51 – 72.52, P=0.002). Among the 55 genes, 14 (25.5%) were statistically significantly associated with pCR in univariate analysis (false discovery rate < 1%). Genes associated with pCR were 17q12-21 amplicon genes (e.g. GRB7 and ERBB2) and immune genes (e.g. CD8A and PD1). Genes associated with residual disease were luminal-related genes (e.g. ESR1 and PGR). Among the 14 genes, only 7 (i.e. CDH3, CD8A, PD1, EGFR, ESR1, SLC39A6, NAT1) were significantly associated with pCR beyond intrinsic subtype (HER2-E vs non-HER2-E). Finally, a total of 58 of the 80 (72.5%) surgical specimens were profiled. 77% of the samples were classified as Normal-like, followed by Luminal A (20%), Luminal B (2%) and HER2-E (2%). Normal-like was identified in a higher proportion in pCR samples (90%) compared to samples with residual disease (47%) (p<0.001).

Conclusion. HER2-E subtype and immune genes are independently associated with pCR after dual HER2 blockade and multi-agent chemotherapy. Subtyping of surgical specimens might provide additional response and outcome data and warrants further evaluation.
Title: Independent validation of the PAM50-based chemo-endocrine score (CES) in hormonal receptor positive (HR+)/HER2+ breast cancer (BC) treated with neoadjuvant (NA) anti-HER2-based therapy

Tomas Pascual¹, Maki Tanioka², M Vittoria Dieci³, Sonia Pernas⁴, Joaquín Gavila⁵, Valentina Guarnieri³, Javier Cortes⁶,⁷, Antonio Llombart⁸, Pierfranco Conte³, Mafalda Oliveira³, Laia Paré¹, Patricia Galván¹, Charles M Perou², Alexí Prat¹ and Lisa Carey⁹.
¹IDIBAPS, Hospital Clinic, Barcelona, Spain; ²University of North Carolina at Chapel Hill, Chapel Hill, NC; ³University of Padua and Veneto Institute of Oncology IOV-IRCCS, Padua, Spain; ⁴Instituto Catalán de Oncología (ICO)-Hospitalat, Barcelona, Spain; ⁵Fundación Instituto Valenciano de Oncología, Valencia, Spain; ⁶Ramon y Cajal University Hospital, Madrid, Spain; ⁷Vall d’Hebron Institute of Oncology (VHIO), Barcelona, Spain; ⁸Hospital Arnau de Vilanova, Valencia, Spain and ⁹Hospital Universitari Vall d’Hebro, Barcelona, Spain.

Body: Background. HER2+/HR+ BC is heterogeneous and subgroups with different treatment sensitivities need to be identified. We previously reported a PAM50-based CES in HR+/HER2-negative BC (Prat et al. CCR 2016). Here, we evaluated the association of CES with pathologic complete response (pCR) following anti-HER2-based therapy in HR+/HER2+ BC across 6 NA studies.

Methods. Intrinsic subtype and clinico-pathological data were obtained from 6 NA clinical studies (CHERLOB, OptiHERHEART[OHH], PAMELA, LPT109096, ICO and CALGB 40601 [CALGB is part of the Alliance for Clinical Trials in Oncology]). All patients (pts) received chemotherapy (CT) and trastuzumab, except for pts in the PAMELA study who did not receive CT. A second anti-HER2 agent (lapatinib or pertuzumab) was included in the NA of all pts in OHH and PAMELA and in one of the treatment arms in CHERLOB, LPT and C40601. CES was evaluated as a continuous variable, and categorically (CES-E[endocrine-sensitive], CES-U[uncertain] and CES-C[chemo-sensitive]) using the previously reported cut-offs. In all studies, except CHERLOB and C40601, ERBB2 mRNA levels were measured using the nCounter platform. pCR in the breast was the endpoint. We first performed statistical analyses in each dataset individually, and then in a dataset with combined patient-level data. Univariate and multivariable logistic regressions analyses were used.

Results. A total of 345 pts were included in the analysis. In the combined cohort, CES-E, CES-U and CES-C were identified in 27.5%, 23.7% and 48.6% of the pts, respectively. Table 1 summarizes the distribution and pCR rates by CES groups. In the combined cohort, CES-C was associated with higher pCR rates compared to CES-U and CES-E independent of tumor size, nodal status, anti-HER2 treatment (single vs. dual HER2 blockade), intrinsic subtype (HER2-enriched [HER2E] versus not) and study (Table 2). In the PAMELA trial (no CT), CES-C was also found associated with higher pCR rates compared to CES-E (31.6% vs. 0%). Concordant with this finding, CES-C tumors showed higher ERBB2 mRNA levels than non-CES-C (P<0.01).

Conclusion. CES shows clinical validity for predicting CT/HER2-targeting sensitivity in HER2+/HR+ BC beyond intrinsic subtype and clinicopathologic characteristics. HER2+/HR+/CES-E tumors, which represent ~20% of all HER2+ tumors, show low sensitivity to anti-HER2 regimens (with and without CT); other treatment strategies might be needed for this group.

Title: Quantitative spatial profiling of tumor associated macrophages and the PD-1/PD-L1 interaction in breast cancer

Vasiliki Pelekanou1, Veronique Neumeister1, Lajos Pusztai1 and David L Rimm1. 1Yale School of Medicine, New Haven, CT.

Body: Background: Although immunotherapy approaches are being successfully administered in some breast cancer (BC) patients (pts), biomarkers of response remain elusive. Tumor associated macrophages (TAMs) are the most prominent immune cells in breast tumors, mediating the cross-talk between tumor cells and tumor infiltrating lymphocytes (TILs). Specific biomarkers of breast TAMs’ functional status remain to be defined. CSF-1R, is a TAMs regulator and key target across cancers clinically tested, alone or combined with anti-PD-1 checkpoint inhibitors. The goals of the study were: 1) to objectively measure CSF-1R expression within all CD68+ and M2-like CD163+TAMs, as well as PD-L1/PD-1 spatial interaction and 2) to determine whether objectively quantifying these key immune mechanisms related to TAMs immunomodulation within the tumor microenvironment can predict outcome and potentially response to immunotherapy.

Methods: Tissue Microarrays (TMAs) from two Yale BC cohorts (Cohort A, all breast cases, n=320) (Cohort B, TNBC, n=132) were assessed by quantitative immunofluorescence (QIF) for CSF-1R/CD163/CD68; PD-1/PD-L1 interaction score (proportion of PD-1+ cells co-localized with PD-L1) and co-expression of the multiplexed biomarker panels. Biomarker positive cells and their co-localization were objectively measured using the AQUA method of QIF. QIF scores were compared by linear regression coefficients ($R^2$). Overall and recurrence-free survival (OS and RFS) were assessed. Our protein data were compared with transcriptome data from the METABRIC study obtained from www.cbioportal.org.

Results: CSF-1R expression was associated with expression of both CD68 and CD163 in both cohorts (A: $R^2=0.64$, B: $R^2=0.49$). CSF-1R in CD163/CD68 was higher in TNBC Cohort B (p<0.01) and in ER- cases of Cohort A (p=0.004). In Cohort A high CSF-1R expression (top 10%) in CD163+/CD68+ cells was associated with worse OS and RFS (All cases, p=0.015 and p=0.0005, respectively). After ER-status adjustment, high CSF-1R (in CD68 and CD163) was associated with worse OS and RFS only in ER- cases of Cohort A (p=0.004 and p=0.0004) and increased recurrence rate (p=0.009). High CSF-1R/CD163 (top 10%) was also associated with increased recurrence rate (p=0.004). In TNBC, high CSF-1R correlated with worse OS (p=0.01) only in CD163+ TAMs. High CSF-1R scored as a continuous variable was related with worse RFS in both CD68+ (p=0.0026, RR 1.00/2.86) and CD163+ TAMs (p=0.006, RR 1.00/2.76). However, in multivariate analysis CSF-1R was not an independent prognostic factor for OS or RFS.

PD-L1 mostly co-localized with CD68 TAMs ($R^2=0.7$). Tumor PD-L1 tended to be mutually exclusive of CSF-1R. PD-L1/PD-1 colocalization was higher in TNBC (p<0.01) and associated with better OS (p=0.01). CSF-1R in TAMs tended to be higher when PD-1/PD-L1 colocalization was low.

The trend of mutual exclusivity between CSF-1R in TAMs and PD-1/PD-L1 was confirmed by expression (mRNA) data from METABRIC study.

Discussion: This novel multiplexed method profiling key tumor-immune suppression pathways could identify BC pts likely to respond to anti-PD-1/anti-CSF-1R therapy. This method could help stratify pts for mono- or combined therapy in future clinical trials.
Title: Low levels of HER2 extracellular domain (ECD) compared to intracellular domain (ICD) in NeoALTTO may segregate benefit from lapatinib and trastuzumab in breast cancer

Body: Background: Preclinical models suggest that in some HER2 overexpressed breast cancer cases, the extracellular domain of HER2, containing the binding region for trastuzumab (T) is not present due to proteolytic cleavage. Previous measurement of HER2 ECD and ICD in HeCOG 10/05 suggested that breast cancer cases that have low levels of ECD show decreased benefit from adjuvant T therapy (Carvajal et al, 2015). These cases may be more likely to show benefit from lapatinib (L), a small molecular tyrosine kinase inhibitor. NeoALTTO, an international multi-institutional trial comparing pre-surgical treatment with L vs T vs both, showed that pCR rates were around 25-30% for L or T but increased to 50% for both. This cohort allows us to test the hypothesis that patients with low ECD may benefit more from L than T.

Methods: ECD and ICD were measured 382 cases using quantitative immunofluorescence (QIF) with domain specific antibodies (SP3, Spring biosciences for ECD and CB11, Biocare for ICD). Slides were stained and scanned, then measured using the AQUA method of QIF. All fields of view were scored and FOVs were averaged to generate a QIF score for each case. Index TMAs were used to standardize all autostainer runs and to define the QIF score cut-point that is equivalent to the clinical cut-point for the index TMA cases. Each case was then assigned to one of three groups; 1) High ECD and ICD, 2) Low ECD but High ICD, and 3) low ICD.

Results: In the lapatinib arm, both group 1 and 2 showed a pCR rate of 25% (p>0.99), but in the trastuzumab arm, Group 1 pCR rate was 34% compared to 19% for group 2 (p=0.38). In the combination arm, group 1 showed a pCR rate of 59% compared to 29% for group 2 (p=0.046). In a logistic regression model for pCR, after adjustment for treatment arm and HR status the ECD/ICD status shows a significant predictive value (p = 0.002). Although this study is not powered for event free survival (EFS), at 6 years of follow up we found that patients in group 2 on the lapatinib arm show 92% EFS compared to 69% EFS in group 1 (p=0.17). The opposite trend is seen in both trastuzumab arms where EFS for group 1 on T showed 70% vs 62% for group 2 (p=0.57) and 77% vs 71% on the T+L arm (p=0.74). In a Cox regression model for EFS after adjustment for treatment arm and HR status, the ECD/ICD status is not significant (p=0.88)

Conclusions: Cases with low levels of ECD compared to ICD appear benefit less than those with high levels of both ECD and ICD as assessed by pCR from treatments containing T. In contrast, those same patients also appear to benefit more, as assessed by EFS, on the L arm. These observations are consistent with the hypothesis that this assay could stratify benefit from L vs T based on the status of the ECD. Further assessment using this assay on the ALTTO cases is currently underway and may help confirm this observation.
2017 San Antonio Breast Cancer Symposium

Title: Analysis of biomarkers for response and resistance to the AKT inhibitor MK-2206 in the neoadjuvant I-SPY 2 trial for stage II-III high-risk breast cancer

Denise Wolf¹, Christina Yau¹, Lamorna Brown-Swigart¹, Gillian Hirst¹, Emmett Schmidt³, Steven Townson⁵, Razvan Cristescu⁵, I-SPY 2 TRIAL Investigators², Smita Asare², Don Berry³, Laura Esserman¹, Laura van 't Veer¹, Debub Tripathy⁴ and Jo Chien¹.
¹University of California, San Francisco; ²QuantumLeap Healthcare Collaborative; ³Berry Consultants, LLC; ⁴University of Texas, MD Anderson and ⁵Merck & Co., Inc..

Body: Background: The AKT inhibitor MK2206 (M) was one of the experimental agents evaluated in I-SPY 2, and graduated in the HER2+, HR-, and HR-HER2+ signatures. In I-SPY 2, all patients received at least standard chemotherapy (paclitaxel followed by doxorubicin/cyclophosphamide; T->AC). HER2- patients were randomized to receive M+T- >AC vs. T->AC. For HER2+ patients, M was administered in combination with trastuzumab (M+H+T->AC vs. H+T->AC). We hypothesize that genes in the AKT signaling axis may specifically predict response to M and tested expression levels of 10 genes: AKT1, EGFR, ERBB2, ERBB3, NRG1, IGF1R, PIK3CA, PTEN, STMN1, and MTOR. We also evaluated 9 additional genes previously shown to associate with response to M in vitro and through exploratory analyses in the metastatic setting: STARD3, TM7SF2, ALDH4A1, PRODH, SELENBP1, G3BP1, SMCR7L, TCTEXD2, and PHEX.

Methods: Data from 150 patients (M: 94 and concurrent controls: 56) were available. Pre-treatment biopsies were assayed using Agilent 44K (32627; n=119) or 32K (15746; n=31) expression arrays; and these data were combined into a single gene-level dataset after batch-adjusting using ComBat. All I-SPY 2 qualifying biomarker analyses follow a pre-specified analysis plan. We used logistic modeling to assess biomarker performance. A biomarker is considered a specific predictor of M response if it associates with response in the M arm but not the control arm, and if the biomarker x treatment interaction is significant (likelihood ratio test, p<0.05). This analysis is also performed adjusting for HR and HER2 status as covariates, and within receptor subsets, sample size permitting. Our statistics are descriptive rather than inferential and do not adjust for multiplicities of other biomarkers outside this study.

Results: Consistent with M graduation in the HER2+ signature, two candidate biomarkers on the HER2 amplicon (ERBB2, STARD3) associate with pCR in the M arm, but not in the control arm. In addition, G3BP1, a component of the RAS signaling pathway, associates with non-pCR in the M arm. However, biomarker x treatment interactions for these genes are not significant, and all three associations to response in M lose significance in a model adjusting for HR and HER2 status. Within the HER2+ subset, IGF1R is associated with non-pCR in M. Within the TN subset, higher levels of NRG1 and PIK3CA, upstream activators of AKT, associate with pCR in the M arm.

Conclusion: Following our pre-specified analysis, none of the candidate markers tested succeed as specific predictors of response to MK2206 in I-SPY 2. However, several genes in the AKT pathway associate with response to M, and in particular PIK3CA levels within the TN subset may merit further evaluation in future trials.
Title: Polyligand profiling differentiates cancer patients according to their benefit of treatment

Body: Introduction: Deconvolution of multi-nodal perturbations in cancer network architecture demands highly multiplexed profiling assays. We demonstrate the value of polyligand profiling of tumor systems states using libraries of single stranded oligodeoxynucleotides (ssODN) to distinguish between tumor tissue from breast cancer patients who did or did not derive benefit from treatment regimens containing trastuzumab.

Methods: This study included cases from women with invasive breast cancer who received chemotherapy+ trastuzumab (C+T) or trastuzumab monotherapy with available retrospective data on the time to next treatment (TTNT). A library of 2x10^{12} unique ssODN was exposed to FFPE tissues from patients who benefited (B) or not (NB) from trastuzumab-based regimens in several rounds of positive and negative selection. Two enriched libraries were screened on independent set of 42 B and 19 NB cases using a modified IHC protocol for detection of bound ssODNs. Poly-Ligand Profiles (PLP) were scored by a blinded pathologist. Two libraries, EL-NB and EL-B, showed significant p-values between groups of responders and non-responders. A Cox-PH model was fitted using either tumors’ HER2 status or PLP test results as the independent variable. Median survival time was calculated from the Kaplan-Meier estimate. A separate group of 63 cases with TTNT data from chemotherapy without trastuzumab was used as a control to distinguish prognostic from predictive performance.

Results: The PLP scores of EL-NB and EL-B were assessed by receiver operating characteristic (ROC) curves and resulted in a combined AUC value of 0.81. EL-NB and EL-B were able to effectively classify B and NB patients with either HER2-negative/equivocal (AUC = 0.73) or HER2-positive cancers (AUC = 0.84). In contrast, HER2 status alone yielded an AUC value of 0.47. The combined PLP scores for the independent set of 63 patients treated with C excluding trastuzumab resulted in an AUC value of 0.53, indicating that the assay was predictive and not simply prognostic. Kaplan-Meier curves analysis shows that PLP+ cases have 429 days median TTNT, while PLP- cases have 129 days (HR = 0.38, log-rank p = 0.001). Analysis based on HER2 status showed no significant difference in TTNT between patients that were HER2+ (280 days) or HER2-negative/equivocal (336 days, HR = 1.27, log-rank p =0.45).

Summary: Performance of the PLP assay in differentiating patients who did or did not benefit from trastuzumab therapy outperforms the standard IHC assay for HER2 status. These results represent a promising step towards the development of a CDx to identify the 50-70% of HER2+ patients who will not benefit from trastuzumab. In addition, PLP also has the potential to identify the HER2-negative/equivocal patients who may benefit from trastuzumab-containing regimens.
Title: Comprehensive gene expression biomarker analysis of CDK 4/6 and endocrine pathways from the PALOMA-2 study

Richard S Finn¹, Yuan Liu², Miguel Martin³, Hope S Rugo⁴, Veronique Dieras⁵, Seock-Ah Im⁶, Karen Gelmon⁷, Nadia Harbeck⁸, Zhou Zhu⁹, Dongrui Lu⁹, Eric Gauthier⁹, Cynthia Huang Bartlett¹⁰ and Dennis J Slamon¹. ¹Geffen School of Medicine at UCLA, Los Angeles, CA; ²Pfizer Oncology, La Jolla, CA; ³Hospital General Universitario Gregorio Marañón, Madrid, Spain; ⁴University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA; ⁵Institut Curie, and Centre Eugène Marquis, Rennes, Paris, France; ⁶Seoul National University Hospital, Seoul, Korea; ⁷British Columbia Cancer Agency, Vancouver, Canada; ⁸Brustzentrum der Universität München (LMU), Munich, Germany; ⁹Pfizer, Inc, San Francisco, CA and ¹⁰Pfizer, Inc, Collegeville, PA.

Body: Background: Palbociclib (P) is a potent, oral, highly selective, inhibitor of cyclin-dependent kinase (CDK) 4 and 6. In the Phase 3 PALOMA-2 study, P in combination with letrozole (L) demonstrated a significant improvement in progression-free survival (PFS) versus placebo (PBO) plus L. To further explore predictive markers for sensitivity and resistance to CDK4/6-based therapy or endocrine therapy (ET) alone, we performed a large gene expression analysis of baseline tumor tissues using mature PFS data with extended follow-up.

Methods: Postmenopausal women (N=666) with no prior systemic therapy for ER+/HER2- ABC were randomized 2:1 to P+L or PBO+L until disease progression, death, unacceptable toxicity, or consent withdrawal. All patients provided tumor tissues to participate in the study. 455 of 666 intent-to-treat (ITT) patients had tumor tissue appropriate for gene expression evaluation (303 [68%] P+L arm and 152 [68%] PBO+L arm). EdgeSeq Oncology Biomarker Panel (HTG Molecular Diagnostics; Tucson, AZ) was used for mRNA profiling, assessing 2534 genes involved in a variety of cancer-related pathways. Using systematic and unsupervised approaches, gene expression levels were interrogated for identification of potential genes and/or pathways associated with a treatment effect of P+L compared with PBO+L.

Results: With median follow-up of 38 months, mPFS of P+L vs L + PBO was 27.6 mos vs 14.5 mos (HR=0.563 [p<0.000001] in ITT). PFS in the biomarker-assessed group was similar. Using a supervised approach, expression of genes involved in the Cyclin D-CDK4/6-RB pathway were analyzed. This demonstrated that patients receiving P+L had a consistent benefit similar to the ITT population irrespective of various expression levels of CCND1, CCNE1/2, CDK2/4/6, RB1, and CDKN2A. These results are consistent with findings from previous IHC data (CCND1, RB, p16). Unsupervised analysis revealed that tumors with higher levels of growth factor receptors (eg. FGFR2 FDR 0.032, interaction p=0.056 and ERBB3 FDR 0.221, interaction p=0.043,) were associated with greater sensitivity to P+L vs L alone. Using parallel gene signature-based analyses, tumors with higher expression of a growth factor signature had longer PFS in the P+L arm. In addition, higher CDK4 expression was identified as a resistance marker for PBO+L arm (FDR 0.095, interaction p=0.016). Gene expression-based molecular subtyping demonstrated that both luminal A and B subtypes benefited equally from P+L vs PBO+L. Patients with lower level of tumor PD-1 expression showed more benefit from P+L (FDR 0.099, interaction p=0.021).

Conclusion: These results confirm efficacy of palbociclib + letrozole in ER+/HER2- breast cancer, and support the use of ER+ as a biomarker for sensitivity to CDK 4/6 inhibition. Expression levels (whether high or low) of genes in the Cyclin D-CDK4/6-RB pathway did not correlate with benefit from palbociclib + letrozole. These data provide evidence that the interplay between steroid hormone and peptide growth factor signaling in ER+ breast cancer drives dependence on CDK 4/6 and benefit from CDK 4/6 inhibition with palbociclib. These data can be used to guide additional therapeutic opportunities in ER+/HER2- ABC.

**2017 San Antonio Breast Cancer Symposium**

**Publication Number:** P2-09-11

**Title:** PAM50 intrinsic subtyping as a predictor of pathological complete response to neoadjuvant trastuzumab-based chemotherapy in early HER2-positive breast cancer

Sonia Pernas¹, Anna Petit¹, Fina Climent¹, Laia Pare², Javier Perez-Martin¹, Luz Ventura¹, Patricia Galvan², Catalina Falo¹, Idoia Morilla¹, Adela Fernandez-Ortega¹, Agostina Stradella¹, Tomas Pascual², Miguel Gil-Gil¹ and Aleix Prat². ¹Institut Catala d'Oncologia (ICO)-H.U.Bellvitge-Breast Unit, Hospitalet, Barcelona, Spain and ²IDIBAPs-Hospital Clinic, Barcelona, Spain.

**Body:**

**Background:** HER2-positive breast cancer (BC) is a heterogeneous disease from a clinical and biological perspective. Intrinsic subtype defined by gene expression has an important role in determining response to treatment, as seen in several neoadjuvant trials (e.g. CALGB40601, CherLOB, NeoALTTO and PAMELA). However, limited data exist in an off-trial setting. The objective of this study was to evaluate the association of intrinsic subtypes with pathological completed response (pCR) and survival outcomes of a series of HER2-positive patients (pts) homogeneously treated with trastuzumab-based primary chemotherapy (PC) in a single comprehensive cancer center.

**Methods:** Clinical-pathological data were evaluated in a series of 150 consecutive stage II-IIIC (T4d included) HER2-positive BC pts treated in ICO-Hospitalet (Spain) from August-2009 to December-2012 with weekly paclitaxel x12 followed by FEC/3w x 4 and concurrent trastuzumab for a total of 24w. HER2-positivity was considered according to ASCO-CAP 2007 guidelines. pCR was defined as ypT0/isypN0. The expression of 105 BC-related genes, including the PAM50 genes, was determined in baseline and residual formalin-fixed paraffin-embedded tumor samples using the nCounter platform. Intrinsic subtypes were determined by the research-based PAM50 gene expression predictor. Association of variables with pCR or disease-free survival (DFS) was evaluated using logistic regression analyses and cox proportional hazard models. All statistical tests were two-sided and considered significant when \( p \leq 0.05 \).

**Results:** Most pts had T2 (64%) and T4 (20%) tumors and clinically node-positive disease (77%). 53% had hormonal receptor (HR)+ disease. 84 of the 150pts (56%) achieved a pCR; HR-neg was associated with higher pCR rates (72.5% vs 42% in HR+ \( p<0.001 \)). 90 of the 150 (60%) baseline samples were evaluated. Baseline subtype distribution: HER2-enriched (HER2-E) 63%, Luminal A 11%, Basal-like 8.9%, Normal-like 8.9% and Luminal B 7.8%. Although HER2-E predominated in HR-neg tumors (74%), 53% of HR+ tumors were HER2-E. pCR rates varied according to intrinsic subtype (\( p<0.001 \)). HER2-E tumors were associated with higher pCR rates compared to non-HER2-E (68.4% vs 33.3%, \( p<0.001 \)) regardless HR-status. Five of the 8 PAM50 signatures (HER2E, ROR-S, ROR-P, Basal-like and Proliferation score) were associated with pCR, whereas Luminal A was associated with no-pCR (\( p<0.001 \)). With a median follow-up of 6.6 years, HER2-E subtype was associated with a better DFS compared to non-HER2-E (5-year DFS 92.4% vs 75.9%; HR= 0.27; 95% CI 0.08-0.91; \( p=0.034 \)). Finally, 28 of the 66 (42.4%) surgical specimens with residual disease were studied. Residual subtype distribution was: Normal-like (50.0%), Luminal A (32.1%), HER2-E (14.3%) and Luminal B (3.5%).

**Conclusions:** In this consecutive series of HER2-positive BC treated homogeneously with neoadjuvant trastuzumab-based PC, all of the main intrinsic molecular subtypes were identified with a predominance of HER2-E. HER2-E was significantly associated with pCR and survival outcome. Distribution of the intrinsic subtypes in residual disease differed from untreated tumors.
**Title:** Independent validation of the HER2-enriched subtype as a predictor of pathological complete response following trastuzumab and lapatinib without chemotherapy in early-stage HER2-positive breast cancer

Aleix Prat¹, Carmine De Angelis², Tomás Pascual¹, Carolina Gutierrez³, Tao Wang⁵, Laia Paré¹, Brent Rexer³, Javier Cortes⁴⁵, Andres Forero⁶, Antonio Llombart⁷, Antonio C Wolff⁸, Ian Krop⁹, Patricia Galván¹, Anne C Pavlick², Patricia Villagrasa¹⁰, Susan G Hilsenbeck², Rachel Schiff³, C Kent Osborne³ and Mothaffar F Rimawi². ¹IDIBAPS, Hospital Clínic, Barcelona, Spain; ²Baylor College of Medicine, Houston, TX; ³Vanderbilt University, Nashville, TN; ⁴Ramon y Cajal University Hospital, Madrid, Spain; ⁵Vall d’Hebron Institute of Oncology (VHIO), Barcelona, Spain; ⁶University of Alabama-Birmingham, Birmingham, AL; ⁷Hospital Arnau de Vilanova, Valencia, Spain; ⁸Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD; ⁹Dana Farber Cancer Institute, Boston, MA and ¹⁰SOLTI Breast Cancer Research Group, Barcelona, Spain.

**Body:**

**Background:** HER2-positive breast cancer consists of 4 intrinsic molecular subtypes (Luminal A, Luminal B, HER2-enriched [HER2-E], and Basal-like) and a Normal-like subtype, with the HER2-E subtype having the highest activation of the EGFR-HER2 pathway. Concordant with this, the HER2-E subtype was significantly associated with pathological complete response (pCR) following lapatinib and trastuzumab without chemotherapy on the PAMELA phase II neoadjuvant trial (Lancet Oncol 2017). Here, we aimed to further validate this observation in a different cohort using tumor samples from the TBCRC023 trial.

**Methods:** TBCRC023 (NCT00999804) was a randomized phase II trial combining a Simon Phase 2 design in the experimental arm with a pick-the-winner design, not powered for direct comparison. Ninety-seven women with HER2+ breast cancer measuring 2 cm or larger (median = 5 cm) were randomized in a 1:2 ratio to 12 vs. 24 weeks of lapatinib and trastuzumab. Letrozole (along with ovarian suppression if premenopausal) was added in patients whose tumors were also estrogen receptor (ER)-positive. All evaluable patients were assessed for pCR, defined as no residual invasive carcinoma in the breast. Intrinsic molecular subtypes from tumor biopsy formalin-fixed, paraffin-embedded samples taken at baseline (day 0) were determined with the nCounter-based PAM50 predictor. Gene expression PAM50 data was performed at Hospital Clinic in Barcelona blinded from clinical data. The primary outcome was the association of the HER2-E subtype (vs. non-HER2-E) with pCR. A logistic regression model adjusted for tumor size, ER status, nodal status and treatment arm was performed.

**Results:** A total of 85 of the 97 (87.6%) baseline tumor samples were available. Most patients had the HER2-E subtype (51 [60.0%]), followed by Normal-like (12 [14.1%]), Basal-like (11 [13.0%]), Luminal B (7 [8.2%]) and Luminal A (4 [4.7%]). The proportion of patients with HER2-E tumors within ER+ and ER-negative disease was 54.9% and 67.7%, respectively. At the time of surgery, 17 of 85 patients (20.0%; 95% confidence interval [CI] 0.13-0.30) had a pCR in the breast. Fourteen of 51 patients with the HER2-E subtype (27.5%; 95% CI 0.17 to 0.41) and 3 of 34 patients with non-HER2-E subtypes (8.8%; 95% CI 0.03 to 0.23) achieved a pCR at the time of surgery (adjusted odds ratio 4.33; 95% CI 1.08-17.41; P=0.039). No other clinical-pathological variable was found significantly associated with pCR in the multivariable model.

**Conclusions:** In an independent validation study performed while blinded to clinical outcomes, HER2-E subtype confirms its ability to identify patients with HER2-positive breast cancer who are likely to benefit from dual HER2 blockade therapies without chemotherapy. Further studies should be performed to prospectively validate this biomarker, alone or in combination with other biomarkers.
Body: Background: Metastatic triple negative breast cancer (mTNBC) has a poor prognosis with limited treatment options. Atezolizumab (atezo) is a humanized monoclonal antibody that inhibits the binding of PD-L1 to PD-1 and B7.1. Atezo has demonstrated promising activity in the mTNBC cohort of the phase 1 PCD4989g study. Clinical activity was previously linked to higher PD-L1 expression by IHC (ORR: 13% vs 5%) and TILs (ORR: 13% vs 7%) (Schmid et al., AACR 2017, NCT01375842). Here we characterize molecular features of tumors from atezo-treated patients and explore their potential association with clinical activity.

Methods & Results: Molecular characterization of pre-treatment tumor tissue was performed to investigate potential biological mechanisms associated with the clinical activity of atezo in mTNBC. DNA mutational analysis of tumors from 78 patients was performed with the Foundation Medicine One panel. Median tumor mutation burden (TMB) was 4.6 Mut/Mb (CI 95% 3.604 - 5.405). TMB was not associated with either TILs or immune biomarkers by IHC (PD-L1 or CD8) or with clinical activity (ORR, PFS or OS). The prevalence of loss of heterozygosity or mutations in TP53 or BRCA1/2 in this mTNBC cohort was 65%, 95%, and 10%, respectively. None of these genomic alterations were associated with clinical activity to atezo. RNA-Seq based analyses were performed in tissue from 96 patients. PAM50 profiling classified these tumors as 84% basal-like, 9% HER-2-enriched, 4% luminal A and 2% luminal B. TNBC subtyping (Burstein et al., CCR 2015) classified 42% of the tumors as basal-like (BL) immune activated (BLIA), 35% BL immune suppressed (BLIS), 17% luminal androgen receptor (LAR) and 2% mesenchymal (MES). Histopathology immune biomarkers TILs, PD-L1 and CD8 were highest in BLIA, intermediate in LAR and lowest in BLIS. ORRs by RECIST 1.1 were highest in BLIA and LAR, and lowest in BLIS and MES (17.5%, 18.8%, 0% and 0%, respectively). Although univariate analysis showed that the BLIA subgroup had significantly longer PFS and OS, multivariate analysis showed an association for both the BLIA and LAR subgroups with improved PFS and OS. High expression of pre-specified B- and T-cell RNA signatures were significantly associated with better ORR, PFS, and OS.

Conclusion: Comprehensive molecular characterization of tumors from this non-randomized phase 1 mTNBC cohort showed a low TMB. Mutations in BRCA1/2, TP53, or loss of heterozygosity did not impact atezo clinical activity. Clinical benefit from atezo was enriched in BLIA and LAR TNBC subtypes, both representing tumors with a rich tumor immune microenvironment.
Title: A predictive model of pathological response following dual HER2 blockade-only based on tumor cellularity and tumor-infiltrating lymphocytes (CelTIL) in HER2-positive breast cancer

Paolo Nuciforo¹, Esther Holgado², Antonio Llombart³, Roberta Fasani¹, Laia Paré⁴, Tomás Pascual⁴, Mafalda Oliveira⁶, Noelia Martínez², Begoña Bermejo⁴, María Vidal⁶, Sonia Pernas⁸, Rafael López³, Montserrat Muñoz⁵, Isabel Garau¹⁰, Luis Manso¹¹, Jesús Alarcón¹², Eduardo Martínez¹³, Patricia Villagrasa¹⁴, Javier Cortés² and Aleix Prat⁴,¹₄.¹

¹Vall d’Hebrón Institut d’Oncologia, Barcelona, Spain; ²Hospital Universitario Ramón y Cajal, Madrid, Spain; ³Hospital Universitari Arnau de Vilanova, Lleida, Spain; ⁴Institut d’investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; ⁵Hospital Clínic de Barcelona, Barcelona, Spain; ⁶Hospital Universitari Vall d’Hebrón, Barcelona, Spain; ⁷Hospital Clínico Universitario de Valencia, Valencia, Spain; ⁸Institut Català d’Oncologia, Hospital del Llobregat, Spain; ⁹Complejo Hospitalario Universitario de Santiago, Santiago de Compostela, Spain; ¹₀Hospital de Son Llàtzer, Palma de Mallorca, Spain; ¹¹Hospital 12 de Octubre, Madrid, Spain; ¹²Hospital Universitario Son Espases, Palma de Mallorca, Spain; ¹³Hospital Provincial Centre de Castelló, Castelló de la Plana, Spain and ¹₄SOLTI Breast Cancer Research Group, Barcelona, Spain.

Body: Background: Increased number of tumor-infiltrating lymphocytes (TILs) at baseline is associated with pathological complete response (pCR) and improved outcomes in HER2-positive early breast cancer treated with anti-HER2-based chemotherapy. In the absence of chemotherapy, the association of TILs with pCR following anti-HER2 therapy-only is currently unknown.

Methods: The PAMELA (NCT01973660) neoadjuvant trial treated 151 women with HER2-positive breast cancer with lapatinib and trastuzumab (and hormonal therapy if hormone receptor-positive) for 18 weeks. Percentage of TILs and tumor cellularity were determined at baseline (n=148) and after 2 weeks of treatment (n=134). Associations of TILs and tumor cellularity with pCR in the breast were evaluated using univariate and multivariable logistic regression models. The regression coefficients were used to derive a score based on TILs and tumor cellularity measured at week 2 (CelTIL) was derived in PAMELA and tested in week 2 samples from 65 patients with HER2+ disease recruited in the LPT109096 (NCT00524303) phase 2 neoadjuvant trial, where anti-HER2 therapy-only (trastuzumab, lapatinib or the combination) was administered for 2 weeks, followed by the addition of standard multi-agent chemotherapy for 24 weeks.

Results: In PAMELA, at baseline, TILs were significantly associated with pCR in univariate analysis but not in multivariable analysis (adjusted odds ratio [OR]=1.01, 0.98-1.03; p-value=0.620). A statistically significant increase in TILs was observed at week 2 compared to baseline (mean difference +6.9%; p-value<0.001). At week 2, TILs were significantly associated with pCR in univariate and multivariable analyses (adjusted OR=1.04, 1.01-1.06; p-value=0.009). TILs and tumor cellularity at week 2 were independently associated with pCR and a combined score (from 0 to 100) taking into account both variables was derived. CelTIL as a continuous variable was significantly associated with pCR, and patients with CelTIL-low and CelTIL-high scores (cutoff < 33.59) had a pCR rate of 0% and 33%, respectively. Independent validation of CelTIL in week 2 samples from 65 patients with HER2+ disease recruited in the LPT109096 phase 2 neoadjuvant trial will be presented at the conference.

Conclusions: A combined score of TILs and tumor cellularity at week 2 following anti-HER2 therapy-only is associated with pCR upon completion of neoadjuvant anti-HER2-based therapy.

**Title:** NTRK fusions in breast cancer: Clinical, pathologic and genomic findings

Jeffrey S Ross1,2, Jon Chung2, Julia E Elvin2, Jo-Anne Vergilio2, Shakti Ramkissoon2, James Suh2, Eric Severson2, Sugganth Daniel2, Garrett M Frampton2, David Fabrizio2, Ryan J Hartmaier2, Lee A Albacker2, Siraj M Ali2, Alexa B Schrock2, Vincent A Miller2, Philip J Stephens2 and Laurie M Gay2. 1Albany Medical College, Albany, NY and 2Foundation Medicine, Cambridge, MA.

**Body:**

**Background:** The tropomysin receptor kinase A family includes the 3 NTRK1, NTRK2 and NTRK3 genes and plays major roles in neuronal development. The recent evidence of remarkable efficacy for kinase inhibitors (TKI) targeting NTRK across a wide variety of malignancies that harbor NTRK gene fusions has stimulated great interest in determining the type of cancers driven by these therapy defining NTRK genomic alterations.

**Methods:** A consecutive series of 12,214 locally aggressive, relapsed and metastatic breast malignancies (mBM) were subjected to comprehensive genomic profiling (CGP) using DNA extracted from 40 µm of FFPE sections and adaptor ligation-based libraries to a mean coverage depth 719X for up to 315 cancer-related genes. The results were analyzed for all classes of genomic alterations (GA) including base substitutions, insertions and deletions, select fusions and rearrangements, and copy number changes. Tumor mutational burden (TMB) was determined on 1.1 Mbp of sequenced DNA. Microsatellite instability (MSI) status was calculated by a customized algorithm.

**Results:** 16 (0.13%) mBM (all female) harbored NTRK gene fusions. The median age was 51 years (range 34 to 70 years). There were 9 ductal carcinomas, 2 lobular carcinomas, 3 secretory carcinomas 1 metaplastic carcinoma and 1 angiosarcoma. Tumor stages at the time of sequencing were 12 Stage IV, 1 Stage III and 3 stage I (all 3 secretory carcinomas). In 9 cases, clinical receptor status was known: 3 (33%) were ER+/HER2- and 6 (66%) ER-/HER2- (all TNBC) with all 9 (100%) of cases HER2-. All 3 SCA were TNBC. 10 NTRK fusions involved NTRK1 featuring a variety of fusion partners (CGN, GATAD2B, LMNA, MDM4, PEAR1, and TPM3) and 6 involved NTRK3 (all ETV6 fusions). There were no NTRK2 fusions. NTRK fusion+ mBM featured a mean of 4.25 GA per sample. The most frequent non-fusion partner co-altered genes in this series of NTRK fusion+ mBM were: TP53 at 25%, IKBKE, PIK3C2B, CCND1 at 19%, and AKT, PIK3CA, MYC, CDH1, CDKN1A, PTEN, FGF3, FGF4 and FGF19 all at 13%. The median TMB for NTRK fusion+ mBM was 0.9 mutations/Mb and no cases (0%) had a TMB ≥ 10 mutations/Mb and no cases (0%) feared high microsatellite instability (MSI high). Clinical response assessment to NTRK TKI therapies in this series is ongoing.

**Conclusions:** NTRK gene fusions although extremely uncommon in breast malignancies occur across a variety of tumor types, is universally HER2 negative, more frequent in TNBC than in ER+ tumors, is associated with a moderate frequency of additional genomic alterations and a complete absence of either high TMB or high MSI. This study confirms that a CGP assay, when applied to a large cohort of near universal clinically advanced disease can identify extremely rare alterations that can lead a small number of patients to highly effective precision therapies.
Title: Tumor infiltrating lymphocytes (TILs) as a biomarker for resistance to palbociclib (Pal) in the NeoPalAna trial

Souzan Sanati1, Ruteja Barve1, Jingqin Luo1, Jeremy Hoog1, Richard Head1, Matthew Ellis2 and Cynthia Ma1. 1Washington University School of Medicine, St. Louis, MO and 2Baylor College of Medicine, Houston, TX.

Body: Background: Cyclin-dependent kinase (CDK) 4/6 inhibitors improve disease free survival for patients (pts) with advanced hormone receptor positive (HR+) and HER2 negative (HER2-) breast cancer (BC). However, there are no established biomarkers that identify sensitive versus resistant tumors. We have recently reported results from the phase II neoadjuvant NeoPalAna trial (NCT01723774) which demonstrated that Pal enhanced the anti-proliferative activity when added to anastrozole (Ana) monotherapy in HR+HER2- BC. Interestingly, a small group of pts (15%) were resistant to Pal, exhibiting persistent tumor cell proliferation (Ki67 >2.7%) on Ana plus Pal. Several studies have evaluated the prognostic and predictive importance of TILs in BC, particularly in triple negative and HER2+ subtypes. Studies evaluating TILs in HR+ BC is limited. Here we evaluated the utility of TILs in identifying Pal-resistant tumors.

Methods: Serial biopsies were collected from pts at 4 time points: baseline (BL), cycle 1 day 1 (C1D1) following 28 days of Ana monotherapy, cycle 1 day 15 (C1D15) at 2 weeks post the addition of Pal, and at surgery (Surg). TILs were evaluated using published recommendations by the TILs international working group. Agilent 4X44 whole genome gene expression arrays performed on fresh frozen biopsies at BL, C1D1, and C1D15 were analyzed for pathways and gene signatures that differentiate Pal-resistant (Pal-r) (C1D15 Ki67 >2.7%) from Ana-sensitive (Ana-s) (C1D1 Ki67 ≤2.7%) or Pal-sensitive (Pal-s) (C1D1 Ki67 >2.7% but C1D15 Ki67 ≤2.7%) tumors defined by Ki67 response. TILs at each time point were pairwise compared between response groups using Wilcoxon rank sum test and Benjamini-Hochberg adjusted two-sided p-values were reported. Change between 2 time points within a response group was evaluated by Wilcoxon signed rank test.

Results: The TILs were significantly different between Ana-s and Pal-s groups [BL p=0.03, C1D1 p=0.01, C1D15 p=.02], as well as between Ana-s and Pal-r groups [BL p=0.03, C1D1 p=0.04, C1D15 p=0.02]. Overall Pal-r samples showed the highest TILs at all time points, while Ana-s samples showed the lowest TILs. There was no significant change between time points. Elevated TILs in Pal-r group was further supported by microarray gene expression analysis which demonstrated a large group of genes associated with MHC Class-I (15+ HLA and proteasome genes) as well as immune–inflammation pathways (18+ T cell & lymphocyte markers, signaling genes) being up regulated at BL in the Pal-r group (n=5). Pal-r samples showed a similar trend in subsequent time points although the numbers of samples were small. Many genes within this immune-inflammatory group of genes were correlated with Ki67 change at C1D15 from BL, suggestive of a potential relationship with resistance.

Conclusions: Our data shows Pal resistance was consistently associated with higher TILs at BL and post treatment, which correlated with increased expression of inflammation-immune group genes. TILs may have utility to be used as a biomarker to identify Pal resistant BC. Our data is hypothesis generating and raises the possibility of immune therapy to overcome Pal resistance in BC.
**Title:** Evaluation of the oncomine comprehensive assay for the identification of actionable mutations for therapeutic stratification from the TEAM pathology cohort

Jane Bayani¹, Cheryl Crozier¹, Mary Anne Quintayo¹, Yutaka Amemiya², Xiao Zhang³, Mathieu Larivièreet, Seth Sadis¹, Jeffery M Smith⁴, Annette Hasenburg⁵, Dirk Kieback⁶, Christos Markopoulou⁷, Luc Dirix⁸, Martin Yaffe²⁹, Arun Seth²⁹, Harriet Feilotter³, Daniel Rea¹⁰ and John MS Bartlett¹,⁹

¹Ontario Institute for Cancer Research, Toronto, ON, Canada; ²Sunnybrook Health Sciences Centre, Toronto, ON, Canada; ³Queen's University, Kingston, ON, Canada; ⁴Thermo Fisher Scientific, San Francisco, CA; ⁵University of Mainz, Mainz, Germany; ⁶Helios Medical Center, Schleswig, Germany; ⁷Athens University Medical School, Athens, Greece; ⁸St. Augustinus Hospital, Antwerp, Belgium; ⁹University of Toronto, Toronto, ON, Canada and ¹⁰Cancer Research UK Clinical Trials Unit, Birmingham, United Kingdom.

**Body:** Large-scale sequencing initiatives have revealed a wealth of common and novel variants as well as copy-number aberrations, across different malignancies. This growing list of variants/aberrations can sometimes be matched to specific therapeutics. Such “actionable mutations/changes” hold promise for personalized treatment in the future, with treatments tailored to molecular abnormalities. Presently, women with hormone positive early breast cancer continue to experience improved survival on adjuvant anti-hormone therapy, but a significant number of women continue to progress. Therefore, there is a need to identify those women for whom current therapies are insufficient and to identify alternative therapeutic interventions. We explored the use of genetic profiling using a comprehensive solid tumor next generation sequencing (NGS) assay (the Oncomine Comprehensive Assay, OCA) to characterize early invasive breast cancer. The OCA is based on the Ion Torrent™ NGS platform and Ion AmpliSeq™ library preparation technology, coupled to the Oncomine™ Knowledgebase, for target selection, variant calling, and data annotations. The OCA includes 87 genes for hotspot mutation detection, 48 genes for full length sequencing and 43 genes for focal copy number assessment. The OCA provides a standardized informatics workflow and quality control (QC) parameters to process samples in a translational clinical research setting. To explore the application of the OCA to early invasive breast cancers, we performed a retrospective pilot study in a subset of cases from the TEAM trial. From the TEAM pathology samples, 420 were chosen in a case-control fashion, 413 samples were analyzed, 388 samples passed standard QC metrics, and 254 samples (65%) were found to contain 368 variants with Oncomine Knowledgebase annotations. Briefly, variants of PIK3CA were most frequent at 42.7% (157/368), followed by TP53 at 27.2% (100/368), PTEN at 5.7% (21/368), BRCA2 at 3.8% (14/368), SF3B1 (12/368), AKT1 (11/368) and PTCH1 (11/368) at 3.3%, 3.0%, 3.0%; respectively. Other variants were detected in ATM, ERBB2, RB1, FGFR2, NF1, CDKN2A, PIK3R1 and others. Amongst the 43 genes assessed for copy-number, 23 showed copy-number changes across 132 samples totalling 167 CNVs. 256 samples showed no copy-number alterations in any of the genes on the panel. ERBB2 was most frequently altered at 28.1% (47/167), followed by FGFR1 at 23.4% (39/167), CCND1 at 15.0% (25/167) and MDM2 at 10.2% (17/167). Copy-number losses were identified in TP53, RB1, PTEN, BRCA2 at 0.6% each; as well as CDKN2A at 1.8% (3/167). Analytical validation of a subset of gene variants and copy-number changes will be presented in addition to the evidence of potential future application of the Oncomine Comprehensive Assay to precision oncology goals.
Title: Multiplexed (18-Plex) measurement of protein targets in trastuzumab-treated patients using imaging mass cytometry

Body: Introduction: Recent studies have shown that the molecular heterogeneity of HER2 intracellular (ICD) and extracellular (ECD) domains, as well as overall immune infiltration, are associated with response to adjuvant trastuzumab. Traditional strategies for in situ measurement in the tumor microenvironment allow the combination of up to 6 targets, limiting our capability for in-depth interrogation of tissues. Imaging Mass Cytometry (IMC) uses metal-conjugated antibodies to provide multidimensional, objective measurement of protein targets. We used this high-throughput multiplexing platform to perform an 18-plex assessment of HER2 ICD/ECD, cytotoxic T cell infiltration and other structural and signaling proteins in a cohort of patients treated with trastuzumab.

Methods: An antibody panel for detection of 18 targets (Pancytokeratin, HER2 ICD, HER2 ECD, CD8, vimentin, cytokeratin 7, beta-catenin, HER3, MET, EGFR, ERK 1-2, MEK 1-2, PTEN, PI3K p110 alpha, Akt, mTOR, Ki67 and Histone H3) was conjugated to unique metals for detection in an IMC instrument (Fluidigm). All assays were objectively standardized and validated using quantitative immunofluoresce (QIF). Finally, the IMC technique was validated against HER2 single marker assays by QIF. We used a collection of trastuzumab-treated patients from the HeCOG 10/05 trial (n=180), and identified a case:control series using 5-year recurrence events (n=19), which were matched to controls (n=41) by age and TNM stage. Formalin-fixed, paraffin embedded tissues in tissue microarray format were ablated in the IMC attachment to the CyTOF flow cytometer for simultaneous detection of markers. Image visualization was conducted using MCD Viewer (Fluidigm). Statistical analyses were performed using a range of platforms.

Results: Patients that recurred after adjuvant treatment with trastuzumab showed a decreased fraction of HER2 ECD pixels over threshold in a compartment determined by CK and HER2 ICD compared to cases without recurrence (p=0.057). After exclusion of the lowest HER2 expressers (that would have fallen below the threshold for positive by current HER2 assays), 5-year recurrence events where associated with reduced total ECD/ICD ratio intensity in tumor (p=0.044). Patients below the median for total ECD/ICD ratio showed a trend for decreased benefit from trastuzumab (p=0.066). Levels of cytotoxic T cell infiltration, depicted by total CD8 intensity, were lower in patients with recurrences (p=0.05).

Conclusion: Objective measurement of highly multiplexed protein targets in routine, fixed breast cancer tissues shows that a decreased ratio of HER2 ECD/ICD is associated with 5-year recurrence after trastuzumab treatment. This observation is consistent with our previous work using QIF but represents the first time this has been done on identical cell content (on a single tissue section). Additionally, on the same section we found that lower levels of overall cytotoxic T cell infiltration were associated with worse outcome. Further analysis of the multiplexed data, including both correlative and distance-based analyses are underway.
**Title:** Genomic biomarker for resistance to palbociclib in the NeoPalAna trial

Jeremy W Hoog¹, Tina Treece², Lisa Blumencranz², William Audeh³, Souzan Sanati¹, Matthew J Ellis³ and Cynthia X Ma¹.
¹Washington University, St. Louis, MO; ²Agendia and ³Baylor College of Medicine.

**Body:**

**Background:** Cyclin-dependent kinase (CDK) 4/6 inhibitors are being evaluated in the adjuvant setting for patients with resected early stage hormone receptor positive (HR+) and HER2 negative (HER2-) breast cancer (BC). However, biomarkers that predict benefit from this class of agents are unknown. We have recently reported results from the phase II neoadjuvant NeoPalAna trial which demonstrated that palbociclib (Pal) enhanced the anti-proliferative activity when added upon anastrozole (Ana) monotherapy in estrogen receptor (ER) positive and HER2 negative breast cancers. Interestingly, a small group of patients was resistant to Pal, exhibiting persistent tumor cell proliferation (Ki67 >2.7%) on the combination of Ana and Pal. In this study, we evaluated the utility of a research algorithm for the 70-gene signature (70-GS) in identifying Pal resistant versus sensitive patients.

**Methods:** Serial biopsies were collected from patients at four treatment timepoints: baseline (BL), cycle 1 day 1 (C1D1) following 28 days of Ana monotherapy, cycle 1 day 15 (C1D15) at 2 weeks post the addition of Pal, and at surgery (Surg). RNA was extracted from frozen tumor biopsies at each timepoint and run on Agilent full genome microarrays (GSE93204) at Washington University. As an exploratory analysis, genes from the GPL8253 array that match the 70-GS were used to calculate a research approximation of the 70-GS index (r-GS). The distribution of the r-GS across Ki67 response groups was evaluated.

**Results:** Ki67 had previously been measured at each timepoint, and used to classify patients as being either Ana-sensitive (C1D1 Ki67 ≤2.7%), Pal-sensitive (C1D1 Ki67 >2.7%, C1D15 Ki67 ≤2.7%), or Pal-resistant (C1D15 Ki67 >2.7%). The r-GS was differentially regulated between sensitive (Ana or Pal) and Pal-resistant groups at BL (p=0.012), C1D1 (p=0.039), and C1D15 (p=0.022). The r-GS values varied widely across patients at BL, and generally became more positive (more low risk) with treatment. There was no correlation between Ki67 levels and r-GS. Furthermore, gene expression analysis was performed to elucidate the difference between Pal-sensitive vs. Pal-resistant patients, and Ana-sensitive vs. Pal-sensitive patients.

**Conclusions:** While on-treatment Ki67 indicated drug responsiveness, baseline r-GS significantly stratified patients into sensitive (Ana or Pal) versus Pal-resistant groups in the neoadjuvant setting. This preliminary finding suggests that the 70-GS may have clinical utility in identifying patients resistant to Pal for future studies. Additionally, results of the gene expression analysis may help to further develop genomic biomarkers for Pal and Ana sensitivity and resistance.
Title: Biomarker analysis of the LOTUS trial of first-line ipatasertib (IPAT) + paclitaxel (PAC) in metastatic triple-negative breast cancer (TNBC)

Matthew J Wongchenko¹, Rebecca Dent², Sung-Bae Kim³, Cristina Saura⁴, Mafalda Oliveira⁵, Jose Baselga⁶, Amy V Kapp¹, Wai Y Chan¹, Stina M Singel¹, Daniel J Maslyar¹ and Steven Gendreau¹.
¹Genentech, Inc., South San Francisco; ²National Cancer Centre, Singapore, Singapore; ³Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; ⁴Vall d’Hebron University Hospital, Vall d’Hebron Institute of Oncology, Barcelona, Spain and ⁵Memorial Sloan Kettering Cancer Center, New York.

Body: Background: The oral Akt inhibitor IPAT is being evaluated in cancers with a high prevalence of PI3K/Akt pathway activation. In the placebo-controlled randomized phase II LOTUS trial (NCT02162719), adding IPAT to PAC as first-line therapy for metastatic TNBC improved progression-free survival (PFS) in unselected patients (hazard ratio [HR]: 0.60 [95% CI: 0.37–0.98]), with a more pronounced effect in patients with PIK3CA/AKT1/PTEN-altered tumors (HR: 0.44 [95% CI: 0.20–0.99]) [Kim, Lancet Oncol in press]. An exploratory analysis was performed to understand better the potential associations between PIK3CA/AKT1/PTEN alterations and other biomarkers relevant to TNBC, as well as IPAT efficacy.

Methods: Pretreatment tumor samples (76 primary, 27 metastatic) were evaluated for genetic alterations using the FoundationOne® (Foundation Medicine) assay (n=103) and gene expression by RNA sequencing (n=73). Tumor-infiltrating lymphocytes (TILs) were quantified using the Salgado method [Salgado, Ann Oncol 2015] (n=118). Samples were classified into subtypes by gene expression based on the method developed by Lehmann and Pietenpol [Lehmann, J Clin Invest 2011].

Results: Of 42 patients (41%) with PIK3CA/AKT1/PTEN-altered tumors, 26 had an activating mutation in PIK3CA or AKT1 and 16 had an alteration in PTEN. Patients with PIK3CA- and AKT1-mutant tumors were enriched in the BL2 and LAR TNBC subtypes, whereas those with PTEN-altered tumors were enriched in the BL1 subtype. An internal analysis of the publicly available METABRIC dataset yielded similar results. PTEN alterations were also associated with reduced levels of stromal TILs compared with PIK3CA/AKT1-mutant and PIK3CA/AKT1/PTEN non-altered tumors. In an exploratory analysis of the 26 patients with PIK3CA/AKT1-mutant tumors, the effect of adding IPAT was particularly pronounced (PFS HR: 0.24 [95% CI: 0.06–0.83]; median PFS 12.9 months in the IPAT + PAC arm vs 5.0 months for placebo + PAC); interpretation of efficacy in patients with PTEN-altered tumors was limited by the size of the subgroup.

There was no enrichment of PIK3CA/AKT1/PTEN alterations in metastatic vs primary samples, nor in samples collected after (neo)adjuvant chemotherapy vs from chemotherapy-naïve patients. Additionally, there was no association between PIK3CA/AKT1/PTEN alterations and BRCA1/2 alterations. BRCA1/2 alterations were not associated with any differences in IPAT efficacy outcomes (PFS, objective response rate).

No association was observed between PIK3CA/AKT1/PTEN-altered status and gene signatures of immune cell infiltration/activation or tumor mutational burden. High (≥10%) vs low levels of stromal TILs showed a trend toward longer PFS in patients treated with placebo + PAC (HR: 0.74 [95% CI: 0.39–1.48]), but no difference was apparent in those treated with IPAT + PAC (HR: 1.14 [95% CI: 0.57–2.40]).

Conclusions: This retrospective exploratory biomarker analysis of the phase II LOTUS trial of IPAT in TNBC provides insight into the potential heterogeneity of disease biologies underlying PI3K/Akt pathway activation.
Molecular alterations and poziotinib, a pan-HER inhibitor efficacy in human epidermal growth factor receptor 2 (HER2) positive breast cancers: Combined exploratory biomarker analysis from phase II clinical trial of poziotinib for refractory HER2 positive breast cancer (BC) patients

Ji-Yeon Kim1, Eunjin Lee2, Kyunghee Park2, Hae Hyun Jung3, Woong-Yang Park2, Kyung-Hun Lee4, Joo Hyuk Sohn5, Keun Seok Lee6, Kyung Hae Jung6, Jee-Hyun Kim6, Ki Hyeong Lee6, Seock-Ah Im4 and Yeon Hee Park1. 1Samsung Medical Center, Seoul, Korea; 2Samsung Genome Institute, Seoul, Korea; 3Samsung Advanced Institute for Health Sciences and Technology, Seoul, Korea; 4Seoul National University Hospital, Seoul, Korea; 5Yonsei Cancer Center, Seoul, Korea; 6National Cancer Center Hospital, Goyang, Korea; 7Asan Medical Center, Seoul, Korea; 8Seoul National University Bundang Hospital, Soengnam, Korea and 9Chungbuk National University Hospital, Cheongju, Korea.

Body: Introduction: Poziotinib is a novel, pan-HER kinase inhibitor which showed potent anti-tumor activities through irreversible inhibition of HER family tyrosine kinases in preclinical and early clinical studies. Recent the open-label, multicenter phase II trial of poziotinib monotherapy evaluated that poziotinib is a new promising option for patients with HER2-positive metastatic BC who have failed more than two HER2 targeted therapy (NCT02418689). We evaluated genetic profiles of HER2-positive metastatic BC and investigated potential biomarkers of poziotinib for HER2-positive metastatic BC (MBC). Methods: All participants were diagnosed as HER2-positive BCs according to American Society of Clinical Oncology/College of American Pathologists HER2 guideline and provided tissue specimens that would be possible to extract DNA and RNA for next generation sequencing. We performed targeted deep sequencing with a customized 381 cancer gene panel (CancerSCAN™) and analyzed the relationship among the sequencing data, immunohistochemistry and clinical outcome. Results: From Apr 2015 to Feb 2016, 106 patients were enrolled in the trial from 7 institutes in Korea. Of 106 patients, biomarker data were available for 79 patients. TP53 was the most frequently mutated gene (70.8%) followed by PIK3CA (45.6%). HER2 single nucleotide variant (SNV) was detected in 13 BCs (16.5%) and HER3 SNV was in 9 (11.4%). The score of HER2 immunohistochemistry (IHC) was 3+ in 68 BCs and 2+ with positive in situ hybridization in 11 BCs. In copy number variant (CNV) analysis, HER2 amplification (86.1%) was most frequently observed and followed by CDK12 amplification (58.2%) and APOBEC3B deletion (30.4%). IHC score of HER2 was positively correlated to copy number (CN) of HER2 (P=0.001) but 11 breast cancer tissue did not have copy number amplification of HER2 (13.9%) (Six of HER2 IHC score 2+ and 5 of 3+). The median progression free survival (PFS) was 4.04 months (95% CI, 2.96 - 4.40) for patients who treated with poziotinib in this study. PIK3CA activating mutations were associated with short PFS compared to wild type (WT) and other SNVs (Median PFS of activating mutations vs. WT and others: 2.66 vs. 4.40 (months), P=0.009). HER2 CN amplification was positively correlated to duration of PFS (Median PFS of no amplification vs. 4 ≤ CN < 16 vs. 16 ≤ CN: 2.56 vs. 3.02 vs. 4.86 (months), P=0.032). HER2 SNVs prolonged duration of PFS without statistical significance (Median PFS of HER2 SNVs vs. WT: 4.24 vs. 3.19 (months), P=0.114), but 10 of 13 BCs with HER2 SNV (76.9%) had clinical benefit from poziotinib and 5 BCs (38.5%) had durable response more than 6 months. Conclusion: In this biomarker analysis, SNV of HER2 was frequently observed in HER2 positive MBCs and HER2 CN amplification was detected not in all. High CN amplification of HER2 derived longer PFS than those with low CN. To contrary to this, activating PIK3CA mutations shorten PFS compared to those with WT. In addition, HER2 SNVs might be a potential biomarker of poziotinib in HER2-positive MBC. Further functional study would be warranted.
Title: Use of a functional signal profiling test with high sensitivity and specificity to determine the prevalence of abnormal HER2-driven signaling activity in the HER2-negative breast cancer patient population: New patient group may benefit from HER2 therapy

Lance G Laing¹, David J Burns¹, Ian A MacNeil¹, Benjamin E Rich¹, Samantha Myhre¹, Sajjad Soltani¹ and Brian F Sullivan¹.
¹Celcuity, Minneapolis, MN.

Body: Background: Biological factors, such as HER2 signaling activity, may be important to measure in addition to expression and amplification of HER2 when identifying patients eligible for HER2 therapies. The CELx HER2 Signaling Function (CELx HSF) Test measures HER2 signaling activity in live tumor cells using a label-free impedance biosensor to identify HER2-negative breast cancer patients likely to be responsive to treatment with anti-HER2 therapies. Previous studies quantified HER2-driven signaling activity in a training set (N=34) of primary tissue samples from HER2-negative breast cancer patients and found 21% of the samples had abnormal HER2 signaling. Other studies confirmed that anti-HER2 therapies, such as trastuzumab, pertuzumab, afatinib, and neratinib, are as effective in inhibiting HER2-driven signaling activity in HER2- tumor cells as they are in HER2+ tumor cells. This study set out to confirm the prevalence of abnormal HER2 signaling amongst HER2-negative breast cancer patients in a larger sample (N=114) and to characterize the sensitivity and specificity of the CELx HSF Test.

Methods: A validation set of de-identified fresh breast tumor specimens were obtained from 114 HER2- breast cancer patients. Real time live cell response to specific HER2 agonists (NRG1b or EGF) with or without an antagonist (HER2 dimerization inhibitor) was measured using an impedance biosensor. From these responses, the net amount of HER2 participation in HER2 signaling initiated by the HER2 agonists was quantified. Samples with HER2 signaling activity levels above a previously determined cut-off value were identified as abnormal.

Results: Of the HER2- breast tumor cell samples tested, 27 of 114 patients (23.7%; 95% CI=17%-32%) had abnormal HER2 signaling activity. Little or no correlation was found between a patient's HER2 signaling activity and their estrogen receptor status or tumor grade. To compare the results obtained from the training set of 34 patients and the current set of 114 patients, the Kolmogorov-Smirnov two-sample test was applied (D=0.17, P-value 0.45) and found no significant difference between the training and validation sets. A normal mixture model was fitted to the new 114 patient data set and found that HER2- breast cancer patients fall into three distinct groups (abnormal, normal, low). Patients falling into the abnormal group had mean HER2 signaling scores 4.5 standard deviations above the mean score of the normal group. A ROC curve constructed with this data projects that both the sensitivity and specificity of the CELx HSF Test would be greater than 90%.

Conclusions: These results confirm that a clinically relevant proportion of HER2- breast cancer patients, approximately 20%, have tumors with abnormal HER2-signaling activity and may benefit from HER2 therapy. With high specificity and sensitivity, the CELx HSF test may be suitable as a companion diagnostic to identify new patients eligible to receive HER2 therapies. An interventional trial to evaluate the efficacy of trastuzumab and pertuzumab in HER2- patients selected with the CELx HSF test is underway.
Title: Diffusion-weighted MRI improves imaging prediction of response in the I-SPY 2 trial

Wen Li¹, Lisa J Wilmes¹, David C Newitt¹, Ella F Jones¹, Jessica Gibbs¹, Mimi Poon¹, Elizabeth Li¹, Savannah C Partridge², John Kornak¹, Laura J Esserman¹ and Nola M Hylton¹. ¹University of California, San Francisco, San Francisco, CA and ²University of Washington School of Medicine, Seattle, WA.

Body: Background: The I-SPY 1 TRIAL demonstrated that functional tumor volume (FTV) measured by dynamic contrast-enhanced (DCE) MRI during neoadjuvant chemotherapy (NAC) predicts both pathologic complete response (pCR) and recurrence free survival¹. In addition to DCE, the I-SPY 2 TRIAL is testing whether diffusion weighted MRI (DWI), a non-contrast method that characterizes water mobility and cellularity by measuring the apparent diffusion coefficient (ADC), acquired during the same MRI exam as DCE, can provide valuable distinct information about tumor response. We hypothesize that combining FTV and ADC can improve the predictive performance of breast MRI.

Methods: I-SPY 2 includes women with stage II or III breast cancer with tumor size $\geq 2.5$ cm. A sub-cohort of I-SPY 2 patients from 2 graduated experimental drug arms²-³ (N=115 of 263): veliparib-carboplatin (VC, N=38), neratinib (N=37) and their controls (treated with paclitaxel or paclitaxel + trastuzumab, N=40), were included in this study: 148 patients were excluded due to missing imaging data or poor DWI quality. Each patient had four MRI exams: pre-treatment (T1), early treatment (after 3 weekly cycles of experimental drugs, T2), between regimen (T3), and pre-surgery (T4). FTV and ADC were measured for the whole tumor at T1, T2, and T3. Percent change of FTV ($\Delta$FTV) and ADC ($\Delta$ADC) at T2 and T3 compared to T1 were analyzed as predictors of pCR. The predictive performance of $\Delta$FTV, $\Delta$ADC and their combination was evaluated using a logistic regression model treating pCR as the binary outcome. Odds ratios were estimated for each 10% decrease of $\Delta$FTV and 10% increase of $\Delta$ADC to reach pCR. The likelihood ratio test was used to evaluate the effect of variables in the logistic model. The statistical significance level for all testing was set at 0.05.

Results: Out of 115 patients included in this analysis, 36 (31%) reached pCR. The combined model using $\Delta$FTV+$\Delta$ADC showed statistically significant improvement over the single predictor $\Delta$FTV alone ($p=0.038$ for the period T1 to T2 and $p<0.001$ for the period T1 to T3). The odds ratio estimates represent a 27% increase in odds for each 10% increase in $\Delta$ADC after accounting for $\Delta$FTV at T2 and 38% increase at T3 (see Table 1).

Conclusion: The addition of ADC to standard FTV MRI may help refine the prediction of treatment response. Evaluation of the method by cancer subtype in a larger cohort is ongoing.

References
Body: Triple-negative breast cancer (TNBC) is one of the most aggressive subtypes of breast cancer. TNBC affects younger women and is characterized by earlier rates of relapse, higher frequency of visceral metastases, and shorter survival outcomes when compared to ER+ or HER2+ disease. Although the disease only represents ~15% of all breast cancer cases, it accounts for 25% of all breast cancer deaths – with treatment options currently limited to chemotherapy. Development of targeted therapies for TNBC is challenging due to molecular heterogeneity and lack of high-frequency “driver” alterations amenable to therapeutic intervention. Recent studies have demonstrated increased sensitivity of TNBC to the anti-proliferative effects of Bromodomain and Extra-Terminal motif inhibitor (BETi) compared to the other breast cancer subtypes. To determine mechanisms of sensitivity to BETi, we analyzed the effect of a BETi across a panel of TNBC cell line models and identified cell lines that were both sensitive and insensitive to BETi. With the intent of identifying biomarkers of sensitivity, we performed RNA-seq and precision nuclear run-on and sequencing (PRO-seq) on both sensitive and insensitive cell line models and data generated identified significant differences in key growth regulatory and apoptotic signaling pathways, including notable differences in Myc-dependent signaling. Our data suggest potential biomarkers of BETi-sensitivity that may be of value in further pre-clinical studies. Further, our results provide mechanistic rationale for combinations of BETi with select, targeted therapies in a disease that is in need of new therapeutic intervention.
Clinical and pathologic characteristics of breast cancers determined to be HER2-positive by fluorescence in-situ hybridization (FISH) using alternative chromosome 17 probes

Neelam V Desai¹, Vanda Torous¹, Cassandra Cruz¹, Stuart J Schnitt¹ and Nadine Tung¹. ¹Beth Israel Deaconess Medical Center, Boston, MA.

Body: Background:
Based on updated 2013 ASCO/CAP guideline for HER2 testing, cases with a HER2/CEP17 ratio < 2.0 but with an average HER2 copy number ≥ 4.0 and < 6.0 signals/cell are considered equivocal. In such cases, HER2 testing using alternative chromosome 17 probes was proposed as one way to resolve the equivocal FISH results. Using the alternative probe method increases the number of cancers categorized as HER2 positive but brings to question if these cancers truly represent HER2 amplified breast cancers and derive the same benefit from anti-HER2 therapies.

Methods:
Since 2013, all breast cancers at our institution that were HER2 equivocal by traditional FISH but classified as HER2 positive using the alternative probe method were assessed for clinical and pathologic features including histologic type and grade, TNM stage, HER2: alternative probe ratio, treatment, and clinical outcome.

Results:
We identified 24 invasive breast cancers considered HER2 positive by the alternative probe method: 23 (96%) were estrogen receptor-positive (ER+) and 20 (83%) were progesterone receptor-positive. Histologically, only 2 were invasive lobular carcinomas; all others were ductal or had ductal and lobular features. Most cancers (63%) had low or intermediate histologic grade: Grade 1 (n=3); Grade 2 (n=12); Grade 3 (n=9). Clinical information was available for 18 patients: 2 had metastatic disease, 1 had a local recurrence after mastectomy and 15 patients had early stage disease; 9 with node negative disease and 6 with nodal involvement. HER2 IHC was equivocal (2+) in 16 (66.7%) cases, positive (3+) in 4 (16.7%) cases, and negative (0 or 1+) in 4 (16.7%) cases. The average HER2 copy number was 4.77, the average HER2:p53 ratio was 2.61. Repeat HER2 testing on a 2nd tumor sample was performed in 8 cases: HER2-positivity was confirmed in only 2 (25%) cases and by the alternative probe only. Treatment information was available for 17 patients: 1 had T1aN0M0 lesion and did not get chemotherapy, 16 received chemotherapy and 13 received trastuzumab-based chemotherapy. Eleven patients with early stage disease received chemotherapy and trastuzumab. Of these patients, 10/11 were ER+, 7/11 were node negative and 5/11 had grade 2 tumors, yet only one tumor was assessed by oncotype recurrence score (RS = 29). Three patients received chemotherapy and trastuzumab in the neoadjuvant setting: 1 had a complete pathologic response, 1 a partial response, and 1 has not yet gone to surgery. One additional patient received neoadjuvant chemo alone and achieved a partial response.

Conclusions:
Breast cancers considered HER2+ by the alternative probe method but not by traditional FISH are almost always ER-positive and most have low or intermediate histologic grade. Repeat HER2 testing on a subsequent tumor sample did not confirm HER2-positivity in 75% of cases. Almost all patients with early stage disease received chemotherapy and trastuzumab based on the alternative probe results without molecular assessment to predict chemotherapy response. Intrinsic molecular subtyping using PAM50 analysis on these cancers is underway to determine how many are HER2-enriched by molecular assessment.
Frequency and mechanisms of elevated somatic mutation burden in metastatic breast cancer and response to immune checkpoint blockade

Erin F Cobain¹, Dan R Robinson¹, Yi-Mi Wu¹, Robert Lonigro¹, Punkaj Vats¹, Erica Rabban¹, Chandan Kumar-Sinha¹, Anne F Schott¹, Jeffrey B Smerage¹, Aki Morikawa¹, Monika L Burness¹, Catherine H Van Poznak¹, Jennifer Griggs¹, Max Wicha¹, Daniel F Hayes¹ and Arul M Chinnaiyan¹. ¹University of Michigan, Ann Arbor, MI.

Body: Background: Immune checkpoint blockade (ICB) is effective in the treatment of various malignancies. Thus far, however, results in breast cancer have been mixed. Elevated tumor mutational load, and subsequent increased likelihood of forming immunogenic neoantigens, has been correlated with response to ICB. Mutational load observed in breast cancers varies widely. However, most studies have assessed mutational load using primary tumors. Few studies have explored the frequency of high mutational load, molecular mechanisms accounting for this phenomenon, and its potential impact on response to ICB in metastatic breast cancer (MBC).

Methods: From 2011-2016, 124 patients (pts) with MBC of varying subtypes underwent research biopsy of their metastatic disease for whole genome, exome and transcriptome sequencing of tumor and matched normal sample through the Michigan Oncology Sequencing Center (Mi-OncoSeq). Those pts with elevated somatic mutation load were defined as having greater than 10 mutations per megabase of targeted sequencing and mutational signatures accounting for high mutation load were noted. Pts treated subsequently with ICB were followed to assess response.

Results: Twelve MBC pts had high mutation load (10% of cohort). Eight pts had estrogen receptor (ER) positive MBC and 4 pts had metastatic triple negative breast cancer (TNBC). In 5 cases, a clear mutational signature accounting for high mutation load was evident. Two TNBC cases harbored an APOBEC mutational signature in addition to 1 TNBC and 2 ER positive tumors displaying a microsatellite instability signature (MSI-H). Among the tumors with MSI-H signature, 1 case was associated with a pathogenic germline alteration in MLH1. Two pts were subsequently treated with ICB on a clinical trial. One pt came off study after 3 months due to progressive brain metastases and another had partial response to therapy lasting 7 months.

Conclusions: Elevated somatic mutation burden in MBC is observed in approximately 10% of pts, and is detected in both ER positive and TNBC. Since high mutation burden has been associated with increased likelihood of response to ICB, identification of this genomic feature could have important therapeutic implications for MBC pts.
Title: Integrated analysis of PTEN protein expression and PI3KCA mutations as predictors for pathological complete response in HER2-positive breast cancer

Joaquin Gavila¹, Francisco Gozalbo¹, Miguel A Climent¹, Angel L Guerrero¹, Sergio Sandiego¹, Salvador Blanch¹, Maria A Algarra¹, Virtudes Soriano¹, Vicente Guillem¹, Amparo Ruiz¹ and Jose A Lopez Guerrero¹. ¹Fundacion Instituto Valenciano de Oncologia, Valencia, Spain.

Body: Introduction: Anti-HER2 treatment has also influenced the response to neoadjuvant chemotherapy in HER2-positive breast cancer (BC) by increasing the pathologic complete response (pCR) rate. The activation of HER2 signaling causes the downstream activation of the PI3K/AKT/mTOR pathway that plays a crucial role in developing resistance to trastuzumab (T). Therefore, candidate biomarkers with a potential role in the prediction of a pCR and prognosis after anti-HER2 treatment could be selected from this pathway.

Material and Methods: We retrospectively evaluated PTEN protein expression and PI3KCA mutations in core biopsies from HER2-positive patients treated at our institution with neoadjuvant therapy based on anthracyclines, paclitaxel and T. Protein expression was assessed by immunohistochemistry and used as dichotomic variable, PTEN loss was considered if Hscore ≤ 40. The association of PTEN status, PI3KCA mutation and PI3K activation (defined as either PTEN loss and/or presence of PI3KCA) with pathological complete response (ypT0/isN0) and progression-free survival (PFS) was evaluated.

Results: In our database 86 patients with HER2-positive clinical stage II-III BC were identified. Median follow-up was 75.85 months. PTEN was available from 84 (97.7%) and PI3KCA genotype from 67 patients (77.9%). Median age was 47.34, stage III 58.8% and 50% were hormonal receptor (HR) positive. Low PTEN was described in 29.8% tumors and was statistically associated with Grade1-2 and HR positive tumors. PI3KCA mutations (exon 9 and 20) were observed in 23.9% tumors. PI3K activation was detected in 37.5% tumors. Overall, the pCR rate was 53.5%. In low PTEN tumors pCR was 12% and in PTEN-high tumors, it was 72.1% (p<.0001). pCR rate was statistically different between PIK3CA mutant and wild-type tumors (6.3% vs. 51.9%; p<.0001). PI3K activation was statistically associated with lower pCR rate (12.5 vs. 72.9%; p<.0001). In multivariable analysis adjusted for baseline parameters, HR expression (OR 4.170; 95% CI 0.975-17.829; p=0.054) and PI3K activation (OR 45.87; 95% CI 8.059-261.101; p<.0001) independently predicted pCR. In univariable analysis clinical, stage III, non-pCR and PI3K activation were correlated with worse PFS. PI3K activation was statistically associated with lower PFS at 5 years (OR 3.813; CI 95% 1.369-10.347; p=0.009) in the multivariable analysis.

Conclusions: The study showed the potential role of PIK3CA Genotype and PTEN expression in predicting pCR and prognosis after anthracycline-taxane-based chemotherapy and anti-HER2 treatment.

¹Tohoku University, 1-1, Seiryo-machi, Sendai, Miyagi, Japan; ²Graduate School of Medicine, Tohoku University; ³Tohoku University Hospital; ⁴NHO Osaka National Hospital, Osaka, Japan; ⁵Graduate School of Medicine Kyoto University, Kyoto, Japan; ⁶The Cancer Institute Hospital of JFCR, Koto-ku, Tokyo, Japan; ⁷Breast and Endocrine Surgery, Faculty of Medicine, University of Tsukuba, Tsukuba, Ibaraki, Japan; ⁸International University of Health and Welfare, Narita, Chiba, Japan; ⁹Saitama Cancer Center, Kitaadachi-gun, Saitama, Japan; ¹⁰Chiba Cancer Center, Chiba, Japan and ¹¹Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Bunkyo-ku, Tokyo, Japan.

Body: Background: HER2 (human epidermal growth factor receptor 2) testing performed by IHC (immunohistochemical) methods and FISH (fluorescence in situ hybridization) is semi-quantitative. Exact quantification of HER2 is needed to predict which patients are more or less likely to respond to anti HER2 therapy. To improve the method for cancer patients' HER2 status, we developed a novel fluorescence IHC method using new fluorescence nanoparticle. The fluorescent intensity of this new nanoparticles, termed phosphor-integrated dot (PID), was approximately 100-fold brighter than that of Quantum dots. Because of its increased brightness and analyzing technology, this PID-based fluorescent IHC(IHC-PIC) has an ability of quantifying the biomarker protein in the cancer tissue sample at single particle level. In this study, the primary objective was to investigate if pathological complete response (pCR) rate in HER2- positive breast cancer treated by trastuzumab and lapatinib containing neoadjuvant systemic therapy would depend on the level of HER2, EGFR, HER3, Ki67, ER and PgR protein quantified by this new method.

Methods: The Neo-LaTH study is a randomized phase II multicenter trial evaluating the efficacy and safety of lapatinib and trastuzumab followed by lapatinib and trastuzumab plus weekly paclitaxel with or without prolongation of anti-HER2 therapy prior to chemotherapy (18 weeks vs. 6 weeks). The primary endpoint was the comprehensive pCR rate. We evaluated the HER2, EGFR, HER3, Ki67, ER and PgR amount by nano-patho method using PID in formalin-fixed paraffin-embedded core biopsy samples taken at diagnosis retrospective analysis. Univariate and multivariate analyses were performed to determine the association between pCR and variables, including HER2, EGFR, HER3, Ki67, ER and PgR nano-patho score and clinicopathological factors including histological grade, tumor status, nodal status and HER2 FISH ratio.

Results: A total of 96 tumor samples from patients were used for the present analysis. The pCR rate was 60.4%. We obtained the images of only PID signal by the image analyses, and calculated the number of PID particles in a cell and defined it as IHC-PID score that reflects the level of HER2, EGFR, HER3, Ki67, ER and PgR protein expression in cancer cells. Univariate analysis showed that HER2 IHC-PID score(p<0.0001), ER IHC-PID score(p=0.009) and PgR IHC-PID score(p=0.019) were associated with pCR and multivariate analysis showed that HER2 IHC-PID score was significantly associated with pCR (adjusted odds ratio, 0.990 [95% CI, 0.984–0.996]; P < .0001).

Conclusion: We successfully performed the quantitative IHC-PID for HER2, EGFR, HER3, Ki67, ER and PgR. And we propose using HER2 IHC-PID score as a predictive factor for trastuzumab and lapatinib containing neoadjuvant systemic therapy. This quantitative diagnostic method would be expected to contribute to the development of a molecular therapeutic strategy.
Potential recurrence markers of locally advanced triple negative breast cancer treated by combined neoadjuvant EGFR targeting and chemotherapy, revealed by genomic analyses and assessment of tumor-infiltrating lymphocytes

Nina Radosevic-Robin¹, Emiliano Cocco², Maud Privat³, Catherine Abrial⁴, Frederique Penault-Llorca² and Maurizio Scaltriti⁵.
¹University Clermont Auvergne, INSERM U1240 "Molecular Imaging & Theranostic Strategies", Centre Jean Perrin, Clermont-Ferrand, France; ²Human Oncology and Pathogenesis Program (HOPP), Memorial Sloan Kettering Cancer Center, New York, NY; ³University Clermont Auvergne, INSERM U1240 "Molecular Imaging & Theranostic Strategies", Centre Jean Perrin, Clermont-Ferrand, France; ⁴University Clermont Auvergne, INSERM U1240 "Molecular Imaging & Theranostic Strategies", Centre Jean Perrin, Clermont-Ferrand, France and ⁵Memorial Sloan Kettering Cancer Center, New York, NY.

Body: Background: Epidermal growth factor receptor (EGFR) is expressed in ~50% of triple negative breast cancer (TNBC) and has been proposed as a therapeutic target in this disease. However, trials testing EGFR blockade in TNBC failed to show significant clinical benefit. Probable reasons for such results were patient selection based on EGFR expression and the enrollment of heavily pretreated metastatic patients. Our team has conducted two neoadjuvant trials testing the activity of the anti-EGFR antibodies panitumumab (PTB) and cetuximab (CTX) combined with chemotherapy in locally advanced TNBC. Biomarkers predictive of pathological complete response (pCR) were the level of tumor cell EGFR protein expression and tumor-infiltrating lymphocytes' (TILs) profile (PMIDs 24827135, 26649807). The PTB-treated pts had a higher pCR rate (47%) than the CTX-treated pts (24%), but also a twice higher relapse rate, after 5 years of follow-up. Here we report results of genomic and TILs studies, performed in order to reveal possible determinants of recurrences in those trials. Methods: Tumor tissues sampled before and after neoadjuvant therapy (NAT) have been analyzed by next generation sequencing (NGS) using a targeted exome panel (MSK-IMPACT) of 410 cancer-related genes. Gene expression was evaluated by Affymetrix arrays. TIL density was assessed on pre-NAT samples according to Salgado et al, 2014 (PMID 25214542). The correlation between response, recurrences, genomic and TIL findings was analyzed in a case-by-case fashion. Results: Sixteen tumors that achieved pCR (PTB: 11, CTX: 5) and 23 non-pCR tumors (PTB: 11, CTX: 12) have been analyzed. For 14 non-pCR tumors (PTB: 6, CTX: 8) data have been obtained both from the pre-NAT and the post-NAT sample. Among those tumors, 6 recurred within 2 years after surgery (PTMB: 3, CTX: 3) and assays are on-going on several others that relapsed. Several genomic aberrations that potentially played a causative role in opposing to therapy were identified. We observed multiple mutations in the PI3K pathway in several non-pCR or relapsing pts. Interestingly, in a residual tumor (RT) of a non-pCR patient we found 3 different activating mutations in PIK3CA and one in PTEN. Another example of genomic selection induced by pharmacological pressure is the emergence of a HRAS G12S mutation in a RT after CTX. Additional novel findings include in-frame mutations and deletions in ARID1B and PARP1 amplification in non-pCR pts. Most of the tumors which recurred had ≤10% TILs (9/13) and only 4/13 had ≥30%. Among the tumors with a post-NAT RT but without recurrence, 17/33 had ≤10% TILs and 16/33 ≥30%. No particular link between TIL density and mutation pattern was observed. Conclusions: This is an example of a case-by-case approach where we captured the intrinsic inter-tumor heterogeneity, which is likely responsible for the different responses to EGFR-targeting in TNBC. Genes/pathways candidate of resistance to therapy are currently being validated.
Title: A gene expression signature that predicts for trastuzumab response in HER2+ breast cancer

Abde M Abukhdeir¹, Matthew S Najor¹, Sanja B Turturro¹, Andrew R Armstrong¹, Andrew McDonald¹, Lou Fogg¹ and Melody A Cobleigh¹. ¹Rush University Medical Center, Chicago, IL.

Background: Approximately 15-20% of breast cancers overexpress HER2. These patients are eligible for trastuzumab in combination with chemotherapy. However, some patients are extreme responders to single agent trastuzumab and we wanted to identify differences in cancer gene expression that could predict response to single agent trastuzumab.

Methods: We performed paired-end RNAseq on an isogenic cellular model of trastuzumab sensitivity and resistance. We reasoned that the isogenic nature of the cellular clones used in this study would enrich for differentially-expressed genes (DEGs) that were associated with response to single-agent trastuzumab. DEGs where chosen based upon either i) large fold changes in resistant vs. sensitive clones, ii) high frequency in human HER2+ breast cancers, or iii) were found to be enriched with other DEGs in signaling pathways selected by Ingenuity Pathway Analysis (IPA). DEGs were further scrutinized based upon associations with overall survival (OS) in HER2+ human breast cancers. The resulting genes were validated using qPCR and in several independent sample sets containing gene expression profiles of human breast cancers.

Results: Discovery: RNAseq yielded 3,241 statistically-significant DEGs. We used two independent filtering pipelines to obtain 175 DEGs. Ingenuity Pathway Analysis found signaling pathways associated with eukaryotic initiation factor, lysine specific demethylase 5B, and estrogen receptor alpha to be enriched in DEGs associated with trastuzumab resistance. Of these DEGs, six genes correlated with a statistically significant change in OS in the training dataset, and were validated by qPCR in the cell lines used for the analysis. We further determined that the six-gene signature was a negative predictor of overall survival in HER2+ breast cancer patients whose cancers carried at least one DEG. Validation: Using independent cohorts from TCGA and the website KMplot.com, we validated the predictive power of the six-gene signature. Of the 47 HER2+ patients from TCGA, eight patients carried two more DEGs, while 39 carried ≤ 1 DEG. Although the numbers are small, of the 8 patients followed for four or more years, only one patient was alive as compared with 7 out of 39 patients without the signature. Similarly, Kaplan Meier analysis of gene expression data from KMplot.com revealed that only 1 out of 23 patients (4.3%) who carried high mean expression of the six-gene signature were free of distant metastases after 87 months, compared to 4 out of 43 patients (9.3%) from the cohort carrying low mean expression of the six-gene signature. In both validation cohorts, the six DEG signature was not predictive in HER2-negative breast cancers.

Discussion: Patients whose tumors lack this gene expression signature are more likely to experience a favorable response to trastuzumab therapy. This signature requires validation in a clinical cohort treated with trastuzumab monotherapy.
Title: Predictive impact of absolute lymphocyte counts for progression-free survival in HER2-positive advanced breast cancer treated with pertuzumab and trastuzumab plus eribulin or nab-paclitaxel

Kazuhiro Araki¹,², Yoshinori Ito², Ippei Fukada², Kokoro Kobayashi³, Shinji Ohno², Yoshimasa Miyagawa¹, Michiko Imamura¹, Ayako Kira¹, Yuichi Takatsu³, Chiyomi Egawa³, Hirofumi Suwa¹ and Yasuo Miyoshi¹. ¹Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; ²Breast Medical Oncology, Breast Oncology Center, The Cancer Institute of the Japanese Foundation for Cancer Research Japan, Koto, Tokyo, Japan; ³Kansai Rosai Hospital, Amagasaki, Hyogo, Japan and ⁴Hyogo Prefectural Amagasaki General Medical Center, Amagasaki, Hyogo, Japan.

Body: Background: Tumor-infiltrating lymphocytes might be a one of predictive outcome of human epidermal growth factor receptor 2 (HER2)-positive advanced breast cancer (ABC) patients (pts) who treated with trastuzumab and pertuzumab (TP) plus docetaxel. Although peripheral blood-based parameter (PBBP) is reported as a prognostic indicator of patients with early breast cancers, utility of PBBP has not been studied in HER2-positive ABC.

Objective: The aim of our study was to determine whether PBBP is significant for predictive efficacy in HER2-positive ABC treated with TP combined with eribulin (ERI) or nab-paclitaxel (Nab-PTX).

Methods: The 51 patients' data from two single arm phase II trials was included in this retrospective-prospective study; ERI + TP (n=30) or Nab-PTX + TP (n=21) registered with UMIN000012375 or UMIN000006838, respectively. We assessed the PBBP in prospectively collected data and investigated their association with progression-free survival (PFS). In consideration of PBBP, we evaluated absolute lymphocyte count (ALC), neutrophil to lymphocyte ratio (NLR) and platelet to lymphocyte ratio (PLR). The cutoff values of ALC, NLR, and PLR were set at 1000 cells/µL, 2, and 250, respectively.

Results: Median age at baseline was 58 years (range: 31-77). Median number of previous chemotherapy was 3 (range: 1-10). Pts had multiple metastases, 53% with LNs, 35% with bone, 25% with lung, 20% with liver, and 6% with brain. The objective response rate (CR+PR) and clinical benefit rate (CR+PR+ more than 6 month SD) were 37% (n=19) and 59% (n=30), respectively. The median PFS of all pts was 301 days (range: 21-1281). The PFS of pts with ALC-High was significantly better than those of ALC-low (hazard ratio (HR): 2.74, 95% confidence interval (CI): 1.28 to 5.86; p= .0097). Furthermore, improved PFS was obtained in pts with ALC greater than 1500 cells/µL compared with less than 1000 cells/uL (HR: 4.05, 95% CI: 1.60 to 11.6; p= .0029). Significant associations seem to exist irrespective of number of previous chemotherapy. Since we combined different studies for evaluating PBBP, ERI and Nab-PTX were calculated separately. Marginally significant associations between ALC and PFS were obtained both in ERI (HR: 2.18, 95% CI: 0.87 to 5.60; p=.0973) and Nab-PTX (HR: 3.26, 95% CI: 0.80 to 12.4; p=.0939). The PFS of NLR-low pts was significantly better than those of NLR-high (HR: 2.29, 95% CI: 1.01 to 5.90; p=.0477), but this statistical difference was inferior to those of ALC. There was no significant association between PLR and PFS.

Conclusions: Pre-treatment ALC-High was significantly correlated with favorable PFS of pts treated with TP irrespective of combination chemotherapy in HER2-positive ABC. Prolonged PFS of TP combination therapy might be obtained mediating through host systemic onco-immunity. These data obtained here suggest that a usefulness of ALC for selecting pts who might have clinical benefit from TP combination therapy for heavily treated HER2-positive ABC.
Title: Ki-67 index value and progesterone receptor status predict prognosis and suitable treatment in node-negative breast cancer patients with estrogen receptor positive and HER2 negative tumors

Nobuyuki Arima, Reiki Nishimura, Tomofumi Osako, Yasuyuki Nishiyama, Yasuhiro Okumura, Mamiko Fujisue and Yasuo Toyozumi. 1Kumamoto Shinto General Hospital, Kumamoto, Japan and 2Kumamoto City Hospital, Kumamoto, Japan.

Body: Background: Breast cancer is no longer a single disease with high molecular heterogeneity. Gene profiling has identified at least 4 subtypes: Luminal A, Luminal B, HER2-enriched and basal-like breast cancer. Moreover, immunohistochemistry (IHC) classification is now considered a surrogate for establishing breast cancer subtypes. In previous report Luminal A was defined as ER and PgR positive, HER2 negative, Ki-67 low and recurrence risk low based on the multi-gene-expression assay. The distinction between Luminal A-like and Luminal B-like can be made by either using a high Ki-67 value (≥20%) or a low PgR value (< 20%). In this study, patients with ER positive, HER2 negative and negative node were classified into 4 groups according to the PgR and the Ki-67 status (cutoff points: 20%) and examined retrospectively in relation to clinicopathological findings including the recurrence score (RS) and disease-free survival (DFS).

Methods: A total of 1866 invasive breast cancer patients from November 2001 to November 2016 were included in this study. The cases were classified as follows; LA as high PgR/low Ki-67 (850 cases), LB1 as high PgR/high Ki-67 (553 cases), LB2 as low PgR/high Ki-67 (226 cases), and LB3 as low PgR/low Ki-67 (237 cases). Out of all these cases, 1510 were treated with endocrine therapy alone. The median follow-up period was 78.1 months. Moreover, 23 of the cases underwent a 21-gene expression assay and the RS (< 25 and > 26) was compared with our classification.

Results: The median age was 57.4 years (range: 25 - 94). T1 tumors were more common in the LA group and rare in the LB2 group. Nuclear grade 3 and p53 overexpression were significantly correlated with LB2. Endocrine therapy alone was performed in 87.4% (LA), 77.4% (LB1), 58.8% (LB2) and 86.9% (LB3), retrospectively. There were significant differences in DFS between the LA group (5y DFS: 98%, 10 y DFS: 95.9%) and the LB2 group (5y: 89.9%, 10y: 83.6%; p<0.0001) or LB1 (5y: 94.9%, 10y: 89.5%; p<0.0001), but there was no difference with the LB3 group (5y: 98.6%, 10y: 94.7%; p=0.88). In the cases with endocrine therapy alone, LA showed a similar DFS with LB3 (p=0.25). LB2 had a significantly worse DFS in all the cases and in the cases with endocrine therapy. Chemotherapy was administered to cases with a higher nuclear grade in combination with endocrine therapy. In the LB2 group, there was no difference in DFS between the cases with endocrine therapy and in the cases with chemo-endocrine therapy. Moreover, most of the cases with LA (1/1) and LB1 (15/16) had a RS of <25, and all of the LB2 (6/6) cases had a RS of >26.

Conclusion: The patients with LA and LB3 (both: Ki-67<20%) had a favorable DFS even in the endocrine therapy alone group. However, LB1 and LB2 (both: Ki-67≥20%) had a poorer DFS. Moreover, LB2 (PgR<20% and Ki-67≥20%) was significantly correlated with a higher degree of malignancy and benefited from chemotherapy. LA and LB3 with low Ki-67 values were considered to be a part of the Luminal A group. These data suggest that PgR and the Ki-67 status are useful in predicting prognosis and deciding the treatment strategy for patients with ER-positive and HER2 negative breast cancer.
Title: Tumor-infiltrating lymphocytes and PD-L1 expression in HER2-positive breast cancer treated with neoadjuvant chemotherapy

Eriko Tokunaga¹, Katsumi Takizawa¹, Takanobu Masuda¹, Hideki Ijichi¹, Chinami Koga¹, Wakako Tajiri¹, Junko Tanaka¹, Yoshiaki Nakamura¹, Kenichi Taguchi¹ and Mayumi Ishida¹. ¹National Hospital Organization Kyushu Cancer Center, Fukuoka, Japan.

Body: Backgrounds: Neoadjuvant chemotherapy is one of the standard therapeutic strategies for HER2-positive early breast cancer. Tumor-infiltrating lymphocytes (TILs) have been shown to predict response to the neoadjuvant chemotherapy. Programmed death 1 ligand 1 (PD-L1) is a transmembrane protein, which is an immune regulatory molecule that limits antitumor immune activity. PD-L1 is expressed in a variety of cancers including breast cancer and its expression has been correlated to TIL. In this study, the relationships between TIL and PD-L1 expression and the efficacy of the neoadjuvant chemotherapy (NAC) in HER2-positive primary breast cancer were investigated. Patients and Method: Seventy-five patients with HER2-positive breast cancer at clinical stage I-IIIB, who were treated with NAC, were included in this study. Anthracycin (A) and taxane (T) (A/T) were used for 33, A and T+anti-HER2 therapy (A/T+anti-HER2) were used for 42 patients. TILs and PD-L1 was evaluated using the sections obtained by core needle biopsy before NAC. TILs were evaluated on hematoxylin and eosin (H&E)- stained sections, and reported for the stromal compartment within the borders of the invasive tumor. PD-L1 expression was analyzed by immunohistochemistry and the immunoreaction was evaluated in the tumor cells in the invasive area.

Results: Pathological complete response (pCR) was obtained in 33 patients (44%). The pCR rate was significantly higher in the patients treated with A/T+anti-HER2 than those treated with A/T alone (p=0.0080). The prognosis of the patients who achieved pCR was significantly better than that of those without pCR, in terms of recurrence-free survival (p=0.0464) and distant-metastasis-free survival (p=0.0447). TILs were < 10% in 17 (22.7%), 10-50% in 44 (58.7%) and ≥ 50% in 14 (18.7%) patients. PD-L1 was positive in 21 (28%) patients. PD-L1 expression was positively correlated with TIL (p=0.0044). High TIL was significantly associated with high pCR rate (p=0.0014); however, PD-L1 positivity itself was not associated with pCR rate. High TIL was significantly associated with high pCR rate, especially in A/T+anti-HER2 group. Intriguingly, PD-L1 expression seems to have negative impact on pCR even in the same range of TILs. Tumors with high TILs and the negative PD-L1 showed the highest pCR rate.

Conclusion: High TIL and negative PD-L1 expression in the tumor cells was significantly associated with high pCR rate, especially in the patients treated with anti-HER2 therapy.

Title: An mRNA-based method to measure PI3K activity in cancer tissue using a computational pathway model to assess FOXO transcriptional activity

Wim Verhaegh¹, Henk van Ooijen¹, Marten Hornsveld², Christa Dam¹, Astrid Eijkelenboom², Meng Dou¹, Rick Velter¹, Boudewijn Burgering² and Anja van de Stolpe¹. ¹Philips Research, Eindhoven, Netherlands and ²UMCU, Utrecht, Netherlands.

Body: Introduction
The PI3K signaling pathway is frequently active in breast cancer, and therapeutic inhibitors have been developed. However, it has proven difficult to correctly predict treatment response. We developed a method that measures functional activity of the PI3K pathway using a computational model that infers transcriptional FOXO activity (downstream of PI3K) from expression levels of its target genes. In principle, PI3K pathway activity inhibits transcriptional FOXO activity, hence inactive FOXO is indicative of active PI3K.

Method
We developed a knowledge-based computational model to infer transcriptional FOXO activity from cancer tissue mRNA expression levels, using a Bayesian network approach (Verhaegh et al., Cancer Res 2014). Model calibration was done on microarray data from HUVEC cells with inducible FOXO3.A3-ER (GSE16573).

Results
The FOXO model was biologically validated with in-house microarray data from independent breast cancer cell lines. ER positive, PIK3CAEs54K mutant MCF7 and triple negative MDA-MB-231 cells were stably transduced with a doxycycline inducible FOXO3.A3 expression vector, allowing controlled induction of FOXO3 protein activity. FOXO activity was determined to be low in untreated and 20% FBS treated MCF7 cells, and high after doxycycline, LY294002, and combination treatment. Next, we tested our FOXO model on independent MCF7, BT-20 and MDA-MB-453 cell line data treated with EGFR inhibitor erlotinib (GSE30516), showing an increase of FOXO activity upon treatment, due to reduced PI3K pathway activity (combined Wilcox rank sum test p = 7.8x10⁻⁵).

We further analyzed independent publicly available data from breast cancer patients. FOXO was generally active in healthy breast tissue. Compared to healthy breast tissue, FOXO activity was higher in normal-like and luminal A breast cancer samples (p = 1.9x10⁻⁶ and 0.025, resp.), and lower in luminal B samples (p = 4.2x10⁻⁷).

In addition to the above mechanism for regulating FOXO activity, literature suggests that FOXO can also be activated by cellular oxidative stress, which is often associated with PI3K signaling. This may be assessed using expression levels of the FOXO target gene SOD2, which is differentially expressed between the two FOXO activity modes, and whose function is to reduce oxidative stress. Public data shows an increasing percentage of elevated SOD2 levels among FOXO-active samples with increasing breast cancer aggressiveness: 7% in normal-like, 5% in luminal A, 18% in luminal B, 31% in HER2-enriched and 74% in basal like breast cancer.

Conclusion
Our computational model to measure PI3K activity using FOXO target gene mRNA levels was able to measure increased FOXO activity in multiple cancer cell lines after PI3K inhibition. FOXO activity was measured high in healthy breast tissue and in normal-like and luminal A breast cancer, and lower in luminal B, indicating PI3K activity in the latter group. In more aggressive subtypes, FOXO activity was increasingly accompanied by high SOD2 expression, suggesting oxidative stress with associated PI3K activity as the FOXO activating mechanism.

Clinical utility for improved response prediction and monitoring of PI3K pathway inhibitors is being investigated with clinical partners.
Title: Validation that a histone gene signature predicts anthracycline response in early breast cancer

Melanie Spears¹,², Elizabeth Kornaga³, Nicola Lyttle¹, Linda Liao¹, Jane Bayani¹, Mary-Anne Quintayo¹, Cindy Q Yao¹, Alister D'Costa¹, Paul C Boutros¹, Chris J Twelves⁴, Kathleen I Pritchard²,⁵, Mark N Levine⁶, Torsten O Nielsen⁷, Lois Shepherd⁸ and John MS Bartlett¹,²,⁸,⁹. ¹Ontario Institute for Cancer Research, Toronto, ON, Canada; ²University of Toronto, Toronto, ON, Canada; ³Tom Baker Cancer Centre, Calgary, AB, Canada; ⁴Leeds Institute of Cancer and Pathology and Cancer Research UK Centre, Leeds, United Kingdom; ⁵Sunnybrook Odette Cancer Centre, Toronto, ON, Canada; ⁶McMaster University and Hamilton Health Sciences, Hamilton, ON, Canada; ⁷University of British Columbia, Vancouver, BC, Canada; ⁸Canadian Clinical Trials Group, Kingston, ON, Canada and ⁹Edinburgh Cancer Research UK Centre, Edinburgh, United Kingdom.

Body: Background: The use of anthracycline-based chemotherapies has improved overall and disease free survival in breast cancer. However, anthracyclines can have significant toxicities including cardiotoxicity and leukemia. It is, therefore, imperative to identify those patients who will benefit from adjuvant anthracycline treatment and patients who could be spared unnecessary toxicities and be considered for alternative adjuvant therapy. Previous work performed by our laboratory identified a histone gene expression signature as a predictive marker of anthracycline benefit in the BR9601 clinical trial. In this study we validate the 18 histone gene signature in the MA.5 clinical trial and examine the role of the signature in individual intrinsic subtypes of breast cancer.

Methods We analysed the CCTG MA.5 clinical trial in a prospectively planned retrospective biomarker approach to validate this signature and tested the role of intrinsic subtyping as predictive markers of anthracycline benefit. RNA was extracted from patients in the MA.5 adjuvant trial evaluating the addition of epirubicin (E) to CMF and analysed using NanoString technology. Log-rank analyses validated the predictive values of the signature on distant relapse-free survival (DRFS). Cox-regression models tested independent predictive value on DRFS in the presence of treatment, age, tumour size, nodal status, HER2, ER status and grade, and treatment by marker interactions.

Results Analysis of the MA.5 clinical cohort revealed that patients whose tumour had low histone gene signature expression experienced increased DRFS (HR: 0.54, 95% CI 0.38-0.76, p=0.001) when treated with CEF compared with patients treated with CMF alone. Conversely, there was no apparent benefit of CEF vs CMF in patients with high histone gene expression signature (HR: 1.01, 95%CI 0.66-1.55, p=0.963). After multivariate analysis and adjustment for HER2, nodal status, age, grade and ER, the treatment by marker interaction for the gene signature was 0.54 (95%CI 0.31-0.94, p=0.030) for DRFS. The predictive impact of the histone signature was independent of intrinsic subtype.

Conclusion The histone gene expression signature is an independent predictor of anthracycline benefit and could be a potential candidate diagnostic assay for patients with early breast cancer.
Title: Basal biomarkers nestin and INPP4b predict gemcitabine benefit in metastatic breast cancer: Results from the phase III SBG0102 clinical trial

Karama Asleh-Aburaya¹, Stina Lyck Carstensen², Samantha Burugu¹, Dongxia Gao¹, Charlotte L Tykjær Jørgensen³, Jennifer R Won¹, Maj-Britt Jensen², Eva Balslev³, Anne-Vibeke Laenkholm³, Dorte L Nielsen⁵, Bent Ejlertsen² and Torsten O Nielsen¹.
¹Genetic Pathology Evaluation Center, University of British Columbia, Vancouver, BC, Canada; ²Danish Breast Cancer Cooperative Group, Rigshospitalet, Copenhagen, Denmark; ³Herlev and Gentofte Hospital, Herlev, Denmark; ⁴University of British Columbia, Vancouver, BC, Canada; ⁵Zealand University Hospital, Slagelse, Denmark and ⁶Herlev and Gentofte Hospital, Herlev, Denmark.

Body: Background: A growing body of evidence is suggesting that basal-like and triple negative breast cancers may be particularly sensitive to nucleoside analogues (gemcitabine, capecitabine). In a prospective-retrospective analysis of the phase III SBG0102 clinical trial randomizing metastatic breast cancer patients to gemcitabine plus docetaxel (GD) or to higher-dose single agent docetaxel (D), patients with basal-like breast cancer by PAM50 gene expression had significantly better overall survival (OS) in the gemcitabine arm. By immunohistochemistry (IHC), triple negative status was not predictive, but is a poor surrogate for the basal-like intrinsic subtype. More accurate IHC biomarkers have since become available defining basal-like breast cancers by nestin positivity or by loss of inositol polyphosphate-4-phosphate (INPP4b).

Methods: Formalin-fixed paraffin embedded blocks of primary tumor tissue corresponding to 270 of the 337 patients participated in the SBG0102 trial were used to build tissue microarrays. IHC staining and interpretation for nestin and INPP4b by pathologists (who had no access to clinical data) followed published methods. A prespecified statistical plan was executed independently by Danish Breast Cancer Group statisticians, testing the primary hypothesis that patients with basal breast cancer – defined as positive for nestin or negative for INPP4b, regardless of ER/PR/HER2 status – would have superior OS on the GD treatment arm when compared to the D treatment arm by interaction test. Secondary outcomes included time to tumor progression (TTP) and response rate. Kaplan-Meier method with log-rank test of nestin and INPP4b status was used to measure OS and TTP. Forest plots were used to visualize predictive capacities relative to IHC markers and treatment effects.

Results: Two hundred fifty two cases were evaluable for this study, among which 38 (15%) had been classified as basal-like, 45 (18%) as HER2-Enriched, 74 (29%) as luminal A and 91 (36%) as luminal B by PAM50. Among 241 cases being evaluable for both IHC nestin and INPP4b markers, positive staining of nestin or loss of INPP4b was observed in 43 (17%) of the total cases and was significantly associated with PAM50 basal-like subtype (p<0.0001). Within a median follow up of 13 years, patients assigned as IHC-basal by virtue of being “nestin+ or INPP4b-” demonstrated a significantly lower OS when compared to non-basal cases defined as “nestin- and INPP4b+” (HR=2.45, 95% CI: 1.47-4.07) (p=0.0006). The IHC-basal patients did much better on the GD vs. the D arm (HR=0.36, 95% CI: 0.19-0.68) whereas there was no such difference in outcomes for other patients (HR=0.99). The interaction test was significant (p-interaction<0.005).

Conclusions: The nestin/INPP4b IHC panel offers a practical and inexpensive technology to identify basal-like patients. In the metastatic setting, women with IHC-basal breast cancers defined using these markers have superior overall survival when randomized to gemcitabine-containing chemotherapy compared to docetaxel alone.
Title: Genomic markers but not molecular subtypes provide prognostic impact and predict anthracycline efficacy in early triple-negative breast cancer: Results from the prospective WSG PlanB trial

Body: Background: Optimal treatment, particularly use of anthracyclines in aggressive triple-negative breast cancer (TNBC), is still a controversial issue in early BC management. However, TNBC exhibits substantial molecular heterogeneity: for example, the immune phenotype seems to be associated with better outcome. An important clinical issue in early TNBC is to quantify the impact of subtypes as well as individual genes on survival and especially on anthracycline benefit.

Methods: In PlanB, patients with ER and PR<1% (local or central lab), HER2- EBC were treated by TC (6 cycles Docetaxel/Cyclophosphamide) or EC-Doc (4xEpirubicin/Cyclophosphamideà4xDocetaxel) (overall n=2449, HER2-). RNA isolation was successfully performed in n=402/449 patients with available follow-up. Gene (n=119) expression data by Nanostring\textregistered platform were entered into univariate and multivariate Cox models for disease-free survival (DFS) to identify genes (and combinations) with potential prognostic and/or predictive impact. Median follow-up was 60 months.

Results: RNA expression results were available in n=394 (203 TC vs. 191 EC-Doc): PAM-50 subtype: basal-like 82%; HER2-enriched 7%; luminal (A or B) 3.5%; normal-like 7.4%. Median age was 54; 78% were node-negative. In patients with “discordant” tumors (HR positive by local or central assessment), 76% were still basal-like, compared to 86% in “concordant” TNBC. Of 27 patients with HER2-enriched subtype, HER2 status was positive by central assessment in only five cases (18%). Within this TN cohort, 5y DFS was similar in TC (83%) and EC-Doc (79%) arms; positive nodal status and tumor size >2 cm were (unfavorable) clinical-pathological prognostic markers. Prognostic or predictive impacts of molecular subtype, risk of recurrence subgroups, or proliferation indices were not seen.

Twelve genes (incl. CD8, EGFR, GPR160, SPINT2) showed potential multivariate prognostic impact by entering the “forwards stepwise” multivariate Cox model for DFS. The upper half of patients according to the resulting “twelve-gene signature” had well over 90% 5y-DFS, whereas the lowest quartile had under 60% 5-y DFS. Several genes (incl. ERBB2, FOXC1) showed potential for a predictive impact regarding TC vs. EC-Doc by interaction analysis. Further details and perspectives for testing the robustness of these potential impacts will be presented at the meeting.

Conclusions
To our knowledge, these are the first results from a prospective, adjuvant taxane-based trial regarding molecular predictors of anthracycline efficacy and PAM-50-based prognostic factors in early TNBC. ERBB2 expression, but not HER2-enriched subtype, was predictive for A-benefit in HER2-negative BC. Molecular heterogeneity of TNBC beyond basal-like vs. non-basal-like subtype is clinically relevant and should be considered for patient stratification in ongoing trials with combination therapy. The identified prognostic gene signature should be validated in the WSG-ADAPT-TN and other TNBC trials.
Targeted sequencing in early breast cancer: Identification of novel candidate mutations predictive of anthracycline benefit

Melanie Spears¹,², Irina Kalatskaya¹, Quang M Trinh¹, Linda Liao¹, Taryne M Chong¹, Cheryl Crozier¹, Dan Dion¹, Lawerence Heisler¹, Lee Timms¹, Lincoln D Stein¹,², Kathleen I Pritchard²,³, Mark N Levine⁴, Lois Shepherd⁵, Chris J Twelves⁶ and John MS Bartlett¹,²,⁵,⁷. ¹Ontario Institute for Cancer Research, Toronto, ON, Canada; ²University of Toronto, Toronto, ON, Canada; ³Sunnybrook Odette Cancer, Toronto, ON, Canada; ⁴McMaster University and Hamilton Health Sciences, Hamilton, ON, Canada; ⁵Canadian Cancer Trials Group, Kingston, ON, Canada; ⁶Leeds Institute of Cancer and Pathology and Cancer Research UK Centre, Leeds, United Kingdom and ⁷Edinburgh Cancer Research UK Centre, Edinburgh, United Kingdom.

Body: Background The use of chemotherapies such as anthracyclines and taxanes have improved overall and disease free survival in breast cancer. For all patients, anthracyclines can have significant toxicities including cardiotoxicity and leukemia. It is therefore essential to select the subset of patients who will receive the optimal overall benefit from anthracycline therapy and to identify molecular pathways driving resistance. To fully understand the impact of mutations in the context of current breast cancer therapy, requires a comprehensive mapping of key molecular events in the context of treatment. We sequenced 101 genes, that were prioritized based on not only gene frequency, but also taking into account the importance of amino acid substitution, type of mutation and network connectivity, in 692 primary tumours to both identify driver genes and pathway cassettes and to understand their clinical significance in response to anthracycline treatment.

Methods We performed targeted sequencing in patients from the BR9601 (n=374) and CCTG MA.5 (n=703) clinical trials. The BR9601 and MA.5 clinical trials examined the effectiveness of combination chemotherapy consisting of CMF (cyclophosphamide, methotrexate and 5-fluorouracil) with or without epirubicin. DNA was extracted, samples were sequenced using AmpliSeq Technology adapted to Illumina and somatic mutations were called using a novel mutation calling pipeline (ISOWN). A priori analyses were performed using distant recurrence free survival (DRFS) as the primary endpoint.

Results: In 692 successfully analysed samples 509 (73.6%) samples exhibited at least one single nucleotide mutation (range 0-54). 94/101 genes were mutated in at least one patient. Only variants in PIK3CA, TP53, CDH1, TLE6, MLL3 and USH2A were detected in 5% or more of samples. TSC22D1, RB1 and ZNF565 were associated with increased risk of distant relapse in multivariate analyses corrected for clinic-pathological variables. No single genes were predictive of anthracycline treatment compared to CMF in multivariate analyses corrected for clinic-pathological variables. Signaling cassettes/modules were designed based on the pathway database, Reactome. Within the signaling cassettes one module was predictive of anthracycline failure. Patients with one or more mutations in this module had an increased risk of distant relapse (HR 0.52, 95% CI 0.29-0.95, p=0.034) when treated with an anthracycline containing chemotherapy regimen compared to CMF (HR 1.34 95% CI 1.05-1.72, p=0.019).

Conclusions: We successfully performed a signaling pathway-based targeted sequencing analysis within predefined signaling modules. We identified a single signaling cassette linked to anthracycline resistance in early breast cancer. However, further work to validate this study in a separate clinical trial is warranted.
Title: The impact of TP53 mutation and pathological response to neoadjuvant chemotherapy on triple negative breast cancer outcomes

Zahi Mitri¹, Chih-Hsu Lin², Kenneth R Hess³, Alastair Thompson³, Olivier Lichtarge², Rebekah Hubbard³, Chunxiao Fu³, William F Symmans³ and Stacy L Moulder-Thompson³. ¹Oregon Health and Science University, Portland, OR; ²Baylor College of Medicine, Houston, TX and ³The University of Texas MD Anderson Cancer Center, Houston, TX.

Body: Background:
Triple Negative Breast Cancer (TNBC) accounts for 15-20% of breast cancers, and has a poor prognosis compared with hormone receptor-positive or HER2-amplified disease. There is currently no targeted therapy to salvage chemotherapy resistant TNBC confirming a need for predictive biomarkers of sensitivity to therapy. This study aimed to evaluate the impact of TP53 mutations, common in TNBC, on sensitivity to therapy and patient outcomes.

Methods:
TNBC samples (pretreatment biopsies and surgical specimens, n=106) had annotated response to standardized anthracycline/taxane based neoadjuvant chemotherapy (NACT) and 3-year survival data, by which time most recurrences occur in TNBC. RNAseq was performed using Illumina HiSeq with mRNA library preparation protocol to identify TP53 mutations, which were then scored using the Evolutionary Action Score (EAS), a novel computational model shown to be successful at identifying deleterious mutations. This work was supported by an ASCO Conquer Cancer Foundation Young Investigator Award grant.

Results:
106 TNBC patients were enrolled on this study, 14 had stage I, 65 stage II, and 24 had stage III disease. 64 patient samples have been analyzed to date, of which 39 (61%) harbored a TP53 mutation, and 24 (38%) were TP53 wildtype.

Pathologic complete response (pCR) and survival
Of 47 patients who received NACT, 14 (30%) achieved a pCR, and 33 (70%) had residual disease (RD). Patients who achieved a pCR had a significantly better 3-year recurrence free survival (RFS) (100% vs 59%, p=0.011) and overall survival (OS) (100% vs 62%, p=0.01) compared to patients who had residual disease.

TP53 status and pCR
The rate of pCR was significantly higher in the TP53 mutant group (11/29, 38%) compared to TP53 wildtype (2/17, 12%) TNBC (OR = 4.6, (0.9, 24), p = 0.046). Patients with wild-type and mutant TP53 TNBC who achieved a pCR had excellent 3-year RFS and OS at 100%. Among patients with RD, TP53 wild-type TNBC exhibited a non-significant trend towards higher 3-year RFS (72% vs 49%,HR = 2.5 (0.8, 8.0) p = 0.12) and OS (79% vs 48%,HR = 2.6 (0.8, 8.4) p = 0.11) compared to TP53 mutant TNBC.

TP53 status and survival
The 3-year OS for TP53 mutant TNBC was 72%, compared to 86% for TP53 wildtype TNBC (HR = 1.5 (0.5, 4.3), p = 0.48). There was no difference in 3-year RFS between the two groups.

TP53 EAS and survival
Among 39 non-silent TP53 mutant cases, EAS ranged from 42.3 to 100 with a median score of 87.6. The 3-year OS for patients with EAS ≥66.7 was 73%, compared to 74% for patients with EAS <66.7 (HR 0.8 (0.2, 3.0), p=0.78). When separated into tertiles, the 3-year OS rates were 75%, 68%, and 77% for the lower, middle, and upper thirds respectively. The 3-year OS rates for TNBC with EAS = 0 (TP53 wildtype or silent TP53 mutation) was 87%.

Conclusion:
TP53 mutations were associated with a higher chance of achieving a pCR; NACT Patients who achieved a pCR to NACT had excellent outcomes, regardless of TP53 mutation status. In patients with RD following NACT, TP53 mutant TNBC had a trend towards worse outcomes compared to TP53 wild-type TNBC. Larger cohorts are required to further evaluate the impact of TP53 mutations and TP53 EAS on survival outcomes in TNBC.
Title: Identifying patients sensitive to anthracycline-containing therapy with quantitative proteomic and genomic profiling

Sarit Schwartz¹, Fabiola Cecchi¹, Yuan Tian¹, Christina Yau¹, Christopher Szeto¹, Matthias Rübner², Ramona Erber², Matthias W Beckmann², Arndt Hartmann², Steve Benz¹, Todd Hembrough¹ and Peter Fasching². ¹NantOmics, LLC and ²Erlangen University Hospital, Nuremberg, Germany.

Body: Background: Selecting chemotherapy based on tumor biology can improve response rates and avert toxicity. Studies of the relationship between tumor expression of TOP2A protein and response to anthracycline-based chemotherapy have yielded contradictory results. Here we used mass spectrometry (MS) to evaluate associations between tumor molecular profiles and pathological complete response (pCR) in breast cancer patients treated with neoadjuvant anthracycline-containing therapy.

Methods: Patients were selected from the ERNEST-B (Erlangen Neoadjuvant Study Breast), which is a retrospective cohort study. Archived tumor samples from anthracycline-treated breast cancer patients (n=133) were microdissected and solubilized. In each tumor sample, TOP2A and other target proteins were quantitated with a mass spectrometry assay. Molecular profiling also included RNA sequencing of the tumor and whole genome sequencing of both tumor and matched normal tissue sections. The cohort was dichotomized into high and low expressors of TOP2A using a protein level cutoff of 515 amol/ug of tumor protein. The difference in pCR (ypT0ypN0) rates between high and low expressors of TOP2A was assessed using a z-test for differences in proportion.

Results: TOP2A protein was detected in 84 of 133 (63%) tumor samples from anthracycline-treated patients (range: 178 to 3044 amol/ug). Patients whose tumor expressed TOP2A protein above the cutoff of 515 amol/ug had higher pCR rates than patients with lower TOP2A expression (35.5% vs. 12.1%; odds ratio (OR): 4.48 [95% CI: 1.53-13.28], Fisher’ exact test p = 0.004). The difference retained statistical significance in a logistic regression model adjusting for HR and HER2 status (OR: 2.23 [95% CI: 1.15-4.30], p=0.017). In a separate cohort of 19 breast cancer patients who did not receive anthracycline, there was no association between TOP2A protein expression level and pCR rate. Results from a validation cohort as well as the genomic analysis will be presented at the meeting.

Conclusions: In a retrospective analysis of anthracycline-treated breast tumors, TOP2A expression was associated with a higher rate of pCR. Targeted proteomics may predict the response of breast cancer patients to anthracycline-based therapy.
2017 San Antonio Breast Cancer Symposium

Publication Number: P2-10-07

Title: A prospective clinical utility study of the impact of the 21-gene recurrence score (RS) assay in the treatment of estrogen receptor positive (ER+), HER2 negative (HER2-), 1-3 node positive (N+) breast cancer (BC)

Julia Sun¹, Dave Fenton², Simon Baxter³, Angela Chan⁴, Sara Roberts⁵, Xiaolan Feng², Caroline Lohrisch¹, Karen Gelmon¹, Tamara Shenkier¹ and Stephen Chia¹. ¹British Columbia Cancer Agency, Vancouver, BC, Canada; ²British Columbia Cancer Agency, Victoria, BC, Canada; ³British Columbia Cancer Agency, Kelowna, BC, Canada; ⁴British Columbia Cancer Agency, Surrey, BC, Canada and ⁵British Columbia Cancer Agency, Prince George, BC, Canada.

Body: Background:
The 21-gene RS is routinely used in node negative ER+, HER2- BC to help guide chemotherapy treatment decision making. There is emerging use of the RS in limited N+ BC, though the results from the randomized clinical trial (RxPONDER) is pending. The objective of the study is to determine whether the results of the 21-gene RS will alter physician treatment decisions in ER+ HER2- limited N+ BC.

Methods:
Consenting patients (pts) with ER+, HER2-, 1-3 N+ (microscopic or macroscopic) early stage BC participated in this prospective, multi-center British Columbia Cancer Agency (BCCA) study. Treating physicians completed a questionnaire after an initial visit with the patient to document their treatment recommendation before obtaining the RS assay. At a subsequent visit, the assay result and final treatment recommendations were discussed and physicians completed a second questionnaire on the final treatment plan. The statistical assumption of the study was based upon anticipating an overall treatment decision change rate (from chemo-hormonal therapy to hormone only, or vice-versa) to be at least 30%.

Results:
Out of 84 pts enrolled, 82 went on to have RS testing. 57% of pts had T1 tumors, 40% T2 and 2% T3 tumors. The majority of pts (77%) had N1 macroscopic disease compared to 23% that had microscopic nodal involvement. 63% of cases were grade 2, followed by 23% grade 1 and 14% grade 3. 60% of RS were low (<18), 33% intermediate (18-30) and 7% were high (>30). In 53% of cases there was an altered treatment plan (49% switched from chemo-hormonal therapy to hormone only, and 4% switched from hormone only to chemo-hormonal therapy). Of the 49% that switched to hormone only, 68% had a low RS and 33% had an intermediate RS. All 4% that switched to chemo-hormonal therapy had an intermittent RS.

Conclusions:
This multi-centered Canadian study showed that in 53% of cases, treatment recommendations were changed based on the RS. This suggests that there is clinical utility for the RS in 1-3 N+, ER+, and HER2- breast cancer.
Title: A predictive test for neoadjuvant chemotherapy in breast cancer identifies a subset of triple negative patients with resistant disease and the poorest prognosis

Marcia V Fournier\textsuperscript{1}, Joan Chen\textsuperscript{2}, John Obenauer\textsuperscript{2}, Edward C Goodwin\textsuperscript{1}, Susan H Tannenbaum\textsuperscript{3} and Adam M Brufsky\textsuperscript{4}. \textsuperscript{1}Bioarray Genetics Inc., Farmington, CT; \textsuperscript{2}Rancho Biosciences LLC, San Diego, CA; \textsuperscript{3}University of Connecticut Health Center, Farmington, CT and \textsuperscript{4}University of Pittsburgh School of Medicine, Pittsburgh, PA.

Body: Prediction of pathological complete response (pCR) for neoadjuvant treatment is an area of unmet clinical need, especially for triple negative breast cancer (TNBC) as pCR is correlated with better outcomes. Predicting which patients will have residual disease (RD) provides an opportunity to improve treatment planning. We developed a test to predict which patients are likely to achieve pCR or RD to the standard of care (taxane-based) neoadjuvant chemotherapy using gene expression profiling of 325 previously identified novel biomarkers.

Three microarray datasets were used (GSE22226, GSE25055, and GSE25065) including a total of 594 stage II-III breast cancer patients of which 125 (21%) achieved pCR, and 469 (79%) RD. ER+ tumors were present in 57% of the patients and 52% were PGR+. Almost 90% of the patients were Her2-. Of 231 TNBC, 78 (33.8%) achieved pCR, while 153 (66.2%) RD. Of 303 ER+Her2-patients 26 (8.6%) achieved pCR while 277 (91.4%) RD. The cohort was divided into balanced populations with 476 patients used for training (80%) and test (20%) rounds of model development, while 118 patients were reserved as a validation set. Combining a “winnowing” process to remove genes with least predictive power, and hundreds of thousands of step-wise runs, followed by ranking genes based on conditional probabilities, we developed a 17-gene cassette (BA100) which was locked-down in the validation set with ROC (AUC) = 0.818. With a cut-off of 83% sensitivity and 68% specificity (PPV 0.4; NPV 0.94), BA100 achieved a 16% true positive rate (true pCR) and 55% true negative rate (true RD) identifying 76% of the patients who achieved pCR, and 69% of the patients with RD. In TNBC, BA100 classified 29% as true positives (TP), 36% as false positive (FP), 30% true negative (TN), and 4.8% false negative (FN). Kaplan Meier (KM) curves showed a significant difference in 5-year disease-free survival (5Y DFS) between TP and TN (p=0.00453) or FP (p=2.09E-06). However, FP had even worse outcomes than TN patients. To improve the TP rate, additional genes expressed in TNBC plus the original 325 genes were subjected to a second round of gene selection to discriminate between TP and FP, resulting in a 16-gene cassette (BA100.1). With a cut-off of 95% sensitivity and 73% specificity (PPV 0.7; NPV 0.95), applying BA100.1 reduced the FP rates from 24% to 9%, while correctly identifying 88% of RD in the validation set. KM curves showed no significant difference in 5Y DFS between 124 TNBC (53.7%) classified as TN versus 29 TNBC (12.6%) classified as FP, while a significant difference in survival rate was found between TNBC classified as TN vs TP (Cox Proportional Harzard p=8.42e-05).

Taken together, we developed a predictive test consisting of two gene cassettes that accurately identified 71% (88/104) of pCR, and 88% (417/469) of RD patients. Gene cassettes include several transcriptional repressors, PI3K signal transduction, components of telomerase, DNA repair genes, fatty acid metabolism and estrogen-independent proliferation. The test stratified TNBC with differential response to chemotherapy and survival rates so that novel approaches can be used without delay. Further validation will confirm the test utility.
Clinical correlations of serum vitamin D in patients undergoing neoadjuvant systemic therapy and survival outcomes for operable breast cancer

Marie Viala1, Akiko Chiba2, Simon Thezenas1, Laure Delmond1, Pierre-Jean Lamy1, Sarah L Mott3, Mary C Schroeder4, Alexandra Thomas2 and William Jacot1. 1Institut Régional du Cancer de Montpellier (ICM) Val d'Aurelle, Montpellier, France; 2Wake Forest University School of Medicine, Winston-Salem, NC; 3Holden Comprehensive Cancer Center, University of Iowa, Iowa City, IA and 4College of Pharmacy, University of Iowa, Iowa City, IA.

Body: Introduction: There has been increasing interest in the potential benefit of vitamin D to improve breast cancer outcomes. Pre-clinical studies suggest vitamin D enhances chemotherapy-induced cell death. We previously reported (Thomas A SABCS 2016) that low serum vitamin D levels were associated with not attaining a pathologic complete response (pCR) following breast cancer neoadjuvant chemotherapy (NAC). We report here the impact of vitamin D on survival parameters in an expanded cohort of patients.

Methods: Patients from two Iowa registries who had serum vitamin D level measured before or during NAC were included. French patients enrolled in a previous study of the impact of NAC on vitamin D and bone metabolism were also eligible for this study. Vitamin D deficiency was defined as < 20 ng/mL. pCR was defined as no residual invasive disease in breast and lymph nodes. Survival was defined from the date of diagnosis to the date of relapse (PFS) or date of death (OS).

Results: The study included 327 women. Median age was 51 years. Patients presented with HER2+, HR+/HER2- and triple negative (TN) tumors in 28.5%, 43.9% and 27.6% of the cases respectively. In this expanded cohort, vitamin D deficiency remained associated with the odds of not attaining pCR (OR 1.64; 95%CI: 1.02-2.66, p=0.04). Median follow-up was 5.33 years (range 0.5 to 9.8 years). Of these patients, there were 54 relapse and 52 deaths. In multivariate analysis, stage III disease, TN phenotype and the inability to achieve pCR were independently associated with a worse survival (Table 1).

Vitamin D deficiency was not significantly associated with survival parameters in the general population; however a trend was seen in the TN population regarding the correlation with PFS (90 patients, 5-year PFS 60.4% vs. 72.3%, p=0.18).
Conclusion: Vitamin D deficiency is associated with the inability to reach pCR in breast cancer undergoing NAC. A trend for worse survival was seen in the TN subgroup. The strong association between vitamin D deficiency and the inability to reach pCR warrant further evaluation in the TN subgroup. Prospective interventional studies are needed to elucidate if maintaining vitamin D levels during NAC, a highly modifiable variable, may be utilized to improve cancer outcomes, particularly in TN breast cancers.
Title: Oncotype Dx testing in patients with synchronous unilateral primary breast cancer

Melanie Clark¹, James Coggan¹, James Dignam², Ruta Rao¹, Lydia Usha¹, Katherine Kabaker¹ and Melody Cobleigh¹. ¹Rush University Cancer Center, Chicago, IL and ²University of Chicago, Chicago, IL.

Body: Introduction: Oncotype DX, is a commercial diagnostic test that is used to predict the likely benefit from chemotherapy in ER+, HER2-negative, node-negative breast cancer. Patients with multiple, synchronous ipsilateral primary breast cancers often have >1 tumor tested if results from the first tumor show low or intermediate recurrence scores. Whether this approach is cost effective is unknown.

Methods: We reviewed Oncotype Dx results for 907 ER+/HER2- breast cancer patients seen at Rush University Medical Center from 2/2006 to 10/2016. Thirty-nine patients (35 with the same histology) had multiple, synchronous unilateral tumor samples tested. Results were reported both on the numeric risk score associated with the test and the categorized result (low/intermediate/high) recurrence risk. For patients undergoing more than 2 tests, the first two were arbitrarily chosen for the paired analysis. Descriptive statistics were used to examine the risk score distributions and assess potential correlation between paired samples. Statistical inference methods included estimating the correlation coefficient, regression models predicting one score with another, and evaluating the paired score differences with respect to mean deviation from zero. For categorized risk score, analysis evaluating category concordance between tumors was used to assess the degree of agreement. Analyses were conducted on all patients, and a subset consisting of patients whose two tumors had the same histology, where scores may be expected to exhibit greater concordance.

Results: Categorical risk score (RS): The concordance rate for risk category was 77% (30/39 patients) and Kendall’s tau measure of association = 0.57, and was further increased to 80% (28/35 patients) and tau 0.63 for tumors with the same histology. Only one patient had tumor samples with low and high RS. A second patient had tumor samples with intermediate and high RS. Continuous RS: The correlation was 0.81 (p < 0.0001). For tumors with the same histology, correlation increased to 0.83, with regression $r^2$ (predicting second tumor RS value with first) = 0.69, indicating that the majority of variation in second score can be explained by variation in first score.

Conclusion: Oncotype Dx testing in patients with synchronous, unilateral primary breast cancers generally results in concordant results, even more so when the tumor samples are of the same histology. In our study, only 1 of the 39 patients had discordant low/high tumor pairs. Continuous scale tumor RS scores were highly correlated (> 0.8). Therefore the benefit of testing additional samples appears marginal and, with the $4,620 cost per test, may not be cost-effective.
Title: A microRNA signature associated with pathological complete response to a novel neoadjuvant therapy regimen in triple negative breast cancer

Raúl García Vázquez¹, César López Camarillo², Laurence Marchat Marchau¹, Erika Ruiz García³, Alberto Alvarado Miranda³, Héctor Maldonado Martínez³, Alma Campos Parra³, Horacio Astudillo De la Vega³, Antonio González Barrios⁵ and Sergio Rodríguez Cuevas⁶. ¹National Polytechnic Institute, México, Mexico; ²Autonomous University of Mexico City, México, Mexico; ³National Institute of Cancer, México, Mexico; ⁴National Medical Center Century XXI, México, Mexico; ⁵Regional Hospital October 1st ISSSTE, Mexico, Mexico and ⁶Breast Cancer Foundation, Mexico, Mexico.

Body: Background: Locally advanced triple negative breast cancer (laTNBC) patient’s exhibits resistance to neoadjuvant chemotherapy (NC) and poor survival. Distinct therapeutic combinations have been used to reduce high mortality. Recently, novel regimens of NC for laTNBC have achieved pathological complete response (pCR) rates of 10-50%. Evaluation of pCR during oncologic treatment is decisive to identify those patients that response or not response to NC. MicroRNAs (miRNAs) are small non-coding RNAs that represent novel and potential predictive biomarkers useful to identify the patients who will get pCR in cancer.

Methods: Thirty-five patients diagnosed with laTNBC, were invited to participate in this study and enrolled after they signed an informed consent. The 22 patients with pCR and 13 patients without pCR received the experimental NC fluorouracil, adriamycin, cyclophosphamide, cisplatin, paclitaxel (FAC--CDDP/paclitaxel). MiRNA expression profiling was evaluated for 754 miRNAs. A discovery cohort (n=10 pCR and n=8 no-pCR) and a validation cohort (n=12 pCR and n=5 no-pCR). Bioinformatics analysis revealed the affected cellular pathways in pCR group. After a median clinical follow-up of 60 months, statistical analysis was performed to identify miRNAs that could discriminate pCR from no-pCR by using FAC--CDDP/paclitaxel.

Results: MiRNAs expression profiling identified 11 miRNAs that showed significant differences between pCR and no-pCR (p<0.05 and fold change >1.5) groups. Eight miRNAs (miR-9-3p, -30a-3p, -135b, -135b*, -380-5p, -941, -652 and miR-181c*) were upregulated and three miRNAs (miR-770-5p, -584 and miR-143) were downregulated in pCR patients. The altered cellular pathways for the set of miRNAs were PI3K/AKT, FoxO, Ras and ERBB (p<0.05). Four differentially expressed miRNAs (miR-770-5p, miR-143-5p, miR-30a-3p, miR-9-3p) were confirmed in the validation phase. Expression of these miRNAs above the median level was a significant predictor of pCR to experimental NC in laTNBC patients (p<0.001).

Conclusions: These four validated miRNAs could be used as predictors of pCR in response to FAC--CDDP/Paclitaxel treatment in laTNBC patients.
Title: Effects of radiotherapy on breast cancer outcomes among stage I, low-Recurrence risk, hormone-Sensitive breast cancer: Pooled analysis of individual data from phase III trials

Jinani C Jayasekera1, Clyde Schechter2, Reshma Jagsi3, Julia White4, Judith-Anne W Chapman5, Tim Whelan6, Joseph A Sparano7, Stewart J Anderson8, Anthony Fyles9, Willi Sauerbrei10, Richard C Zellars11, Yishing Li12, Juhee Song12, Thomas Julian13, Donald Berry12, Eric J Feuer14, George Luta1 and Jeanne S Mandelblatt1. 1Lombardi Comprehensive Cancer Center, Washington, DC; 2Albert Einstein College of Medicine, Bronx, NY; 3University of Michigan, Ann Arbor, MI; 4The James, The Ohio State University Comprehensive Cancer Center, Columbus, OH; 5Canadian Cancer Trials Group, Queen’s University, Kingston, ON, Canada; 6McMaster University, ON, Canada; 7Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY; 8NRG Oncology and the University of Pittsburgh, Pittsburgh, PA; 9Princess Margaret Cancer Centre, Toronto, ON, Canada; 10Institute for Medical Biometry and Statistics, University of Freiburg, Germany; 11Indiana University, IN; 12The University of Texas MD Anderson Cancer Center, Houston, TX; 13Allegheny Breast Center, Drexel University College of Medicine and National Surgical Adjuvant Breast and Bowel Project (NSABP), Pittsburgh, PA and 14National Cancer Institute, Bethesda, MD.

Body: Purpose: Radiotherapy after breast conservation has become the standard of care. Prior meta-analyses of radiotherapy benefits pre-dated availability of gene expression profiling (GEP) to assess recurrence risk and/or did not include all relevant outcomes. This analysis utilized GEP information with individual-level data from seven clinical trials to evaluate the impact of omitting radiotherapy on recurrence and mortality.

Patients and Methods: The pooled observational data included women who had undergone breast conservation surgery for stage I, ER+ and/or PR+/HER2- cancers with clinicopathologically estimated 21-Gene Recurrence Scores (RS) of ≤18, and did not receive chemotherapy (n= 1,684). The primary endpoint was 10-year invasive or DCIS recurrence free-interval (IRFI-DCIS), including breast cancer death and was estimated using adjusted Cox models. Secondary outcomes were breast-cancer specific and all-cause survival. Covariates included for all models were age, tumor size, grade, hormonal status, type of hormonal therapy, risk score, and trial.

Results: Ten-year IRFI-DCIS was high (96.6% with radiotherapy vs. 91.6% without), for an absolute difference of 5%. Omission of radiotherapy (vs. radiotherapy) was associated with an overall adjusted hazard ratio of 2.6 (95% confidence interval 1.5-4.5) for any first event. There was only a significant increase in risk of loco-regional; not, distant recurrence, breast cancer-specific or overall survival. The effect of radiotherapy varied across subgroups, with lower first event rates for those with estimated RS of <11 (vs. 11-18), and women ages 60+ (vs. <60 years).

Conclusion: Omission of radiotherapy in hormone-sensitive patients with low recurrence risk may lead to a modest absolute increase in loco-regional recurrence, but does not appear to increase risk of distant recurrence or death.
Title: Three-year outcomes with hypofractionated (HF) versus conventionally fractionated (CF) whole breast irradiation (WBI)

Simona F Shaitelman¹, Xiudong Lei¹, Alastair Thompson¹, Pamela Schlembach¹, Isiora Arzu¹, Elizabeth S Bloom¹, Daniel J Buchholz², Gregory M Chronowski¹, Tomas Dvorak², Emily J Grade³, Karen E Hoffman¹, Patrick Kelly², George H Perkins¹, Valerie Reed¹, Shalin Shah¹, Michael C Stauder¹, Eric A Strom¹, Welela Tereffe¹, Wendy A Woodward¹, Donald Baumann¹, Diana Amaya¹, William Guerra¹, Matricia Morrison¹, Gabriel Hortobagyi¹, Kelly K Hunt¹, Thomas A Buchholz¹ and Benjamin D Smith¹.

¹The University of Texas MD Anderson Cancer Center, Houston, TX; ²Orlando Health, Orlando, FL and ³Banner Health, Gilbert, AZ.

Body: Background: Adoption of HF-WBI remains low due in part to concerns regarding its safety when used with a tumor bed boost or in patients who have received chemotherapy or have large breast size. To address this, we conducted a randomized, multicenter trial to compare CF-WBI (50Gy/25fx+10-14Gy/5-7fx) to HF-WBI (42.56Gy/16fx+10-12.5Gy/4-5fx).

Methods: From 2011 and 2014, 287 women with stage 0-II breast cancer, age ≥40 years, were randomized to CF-WBI or HF-WBI, stratified by chemotherapy and breast size. The primary outcome was the proportion of patients with adverse Breast Cancer Treatment Outcomes Scale (BCTOS) cosmetic score three years post-WBI, defined as a score of ≥2.5 (a score of 1 indicates no difference between the treated breast and contralateral breast, 2-slight difference, 3-moderate difference, 4-large difference). Secondary patient-reported outcomes included BCTOS functional status, BCTOS breast pain, Body Image Scale (BIS), and the FACT-B Trial Outcome Index (TOI). Additional secondary outcomes included photographically-assessed cosmesis scored by a 3-physician panel blinded to randomization arm using the RTOG scale, physician-assessed CTCAEv4.0, overall survival (OS), local recurrence-free survival (LRFS) and distant metastasis-free survival (DMFS). Chi-square, Fisher's exact, Wilcoxon's rank sum, logistic regression, and log-rank tests evaluated differences by treatment arm; survival was measured using the Kaplan-Meier method. All analyses were intention-to-treat.

Results: Of 287 patients enrolled, 286 received the protocol-specified radiation dose. Thirty percent received chemotherapy (73% anthracycline, 92% taxane, 22% trastuzumab), 37% had large breast size (D cup or larger), and 44% were obese (BMI≥30). All baseline characteristics were well-balanced by treatment arm (P>0.05). Median follow-up is 4.1 years. For the primary outcome, adverse BCTOS cosmetic score at 3 years was noted in 13.6% (n=15/110) of CF-WBI and 8.2% (n=8/97) of HF-WBI patients (P=0.22). There were trends for lower risk of adverse BCTOS cosmetic score with HF-WBI, compared to CF-WBI, among patients who did not receive chemotherapy (OR=0.25, 95%CI 0.06-1.03; Pinteraction=0.07) or with large breast size (OR=0.26, 95%CI 0.07-0.98; Pinteraction=0.08). There were no patient subgroups where risk of adverse BCTOS cosmetic outcome was significantly higher with HF-WBI compared to CF-WBI. For secondary outcomes, there was no difference by treatment arm for BCTOS functional status (P=0.83), BCTOS breast pain (P=0.69), BIS (P=0.45), or FACT-B TOI (P=0.79). Poor-fair cosmetic outcome at 3 years assessed by the 3-physician panel was noted in 28.8% of CF-WBI patients and 35.4% of HF-WBI patients (P=0.31). In total, 19% CF-WBI patients and 20% of HF-WBI patients had a grade 2-3 toxicity at the three-year evaluation, with no difference by treatment arm (P=0.84). Five-year OS, LRFS, and DMFS were 99%, 98%, and 99%, respectively, with no difference by treatment arm (P=0.68, 0.37, 0.62).

Conclusions: Three years after WBI followed by a tumor bed boost, outcomes with HF and CF are similar. Tumor bed boost, modern chemotherapy, and large breast size do not appear to be clinically meaningful contraindications to HF-WBI.
**Title:** Phase 0-I prospective study of proton beam radiation for locally advanced breast cancer

Rachel B Jimenez, Beow Yeap, Shea Hickey, Nicolas DePauw, Estelle Batin, Alphonse G Taghian, Hsiao-Ming Lu and Shannon M MacDonald. 1Massachusetts General Hospital, Boston, MA.

**Body:**

**Purpose/Objectives:**
The aim of this phase 0/I study was to assess the feasibility of proton beam therapy for locally advanced breast cancer (LABC) following mastectomy.

**Materials/Methods:**
Patients > age 18 with breast cancer managed with mastectomy +/- reconstruction and requiring postmastectomy radiation (RT) were eligible if: 1) breast reconstruction prevented adequate target coverage or 2) ≥ 5% of the heart received ≥ 20 Gy and/or LAD received ≥ 20 Gy by conventional planning. RT consisted of passively scattered (3D-CPT) or pencil beam scanning (PBS) RT to the chest wall and internal mammary nodes (IMN) +/- other regional lymphatics. The primary endpoint was the incidence of grade 3 radiation pneumonitis (RP) or any grade 4 toxicity within 3 months following completion of treatment. Secondary endpoints included 5 year rate of local regional control (LRC) and overall survival (OS), acute skin toxicity per CTCAE 4.0, and acute and late toxicity of breast reconstruction, including any unplanned surgical intervention due to contracture, infection, or cosmesis. In addition, patients underwent cardiac strain echocardiograms and blood-based cardiac biomarkers (MPO, pro-BNP, ultrasensitive troponin-I) prior to RT and at 4 and 8 weeks after RT to assess subclinical cardiac changes.

**Results:**
64 patients were enrolled and completed RT between 2011-2016. 23 patients received 3D-CPT through 2012 after which 41 subsequent patients received PBS. Median age was 45 years (IQR: 39-50 years). Among participants, 59 (92%) were left-sided, 2 were bilateral, and 3 were right-sided. 98.4% (n=63) received systemic chemotherapy/HER2-based therapy and of these, 56.3% (n=36) received neoadjuvant therapy. Among neoadjuvant patients, 2.8% (n=1) were clinical stage I, 67.7% (n=24) were stage II, and 30.6% (n=11) were stage III. Of 28 patients who received upfront surgery, 17.9% (n=5) were pathologic stage I, 42.9% (n=12) were stage II, and 39.3% (n=11) were stage III. 48 patients (75%) underwent immediate reconstruction. Median dose to the chest wall was 50.4GyE (range: 46.8GyE-52GyE) Median dose to the IMN was 50.4GyE (range: 45GyE-52GyE). At a median follow-up of 2.9 years among 60 living patients, LRC 3: 98% / OS 3: 92%. 1 3D-CPT patient developed grade 2 RP 4 months after RT, none developed grade 3 RP. There were no grade 4 toxicities. Acute skin toxicity was similar between modalities with 3D-CPT grade 1/2/3=4%/91%/4% versus PBS grade 1/2=15%/85% (p=0.41). Unplanned surgical re-intervention at 3 years was 17% for 3D-CPT and 28% for PBS (p=0.28).

**Conclusions:**
Proton beam RT (3D-CPT or PBS) is safe and feasible for post-mastectomy patients. Imaging and blood-based analysis of early cardiac changes in this cohort is in process, but preliminary assessment of the first 30 patients shows no decrement in cardiac strain. Randomized clinical data is needed to determine whether there are long-term clinical benefits of proton beam RT in LABC patients.
Comparing whole heart versus coronary artery dosimetry in predicting the risk of cardiac toxicity following breast radiation therapy

Sagar A Patel¹, Syed S Mahmood², Trinh Nguyen¹, Beow Y Yeap¹, Rachel B Jimenez¹, Alphonse G Taghian¹, Nandini M Meyersohn³, Tomas G Neelan¹ and Shannon M MacDonald².¹ Massachusetts General Hospital, Boston, MA; ²Massachusetts General Hospital, Boston, MA and ³Massachusetts General Hospital, Boston, MA.

Body: Purpose: Prior localization studies have implicated accelerated left anterior descending artery (LAD) atherosclerosis in the development of radiation-induced heart disease following breast radiation therapy (RT). However, whole heart dose constraints, namely mean heart dose (MHD), are most commonly utilized in RT treatment planning to predict and avoid cardiac toxicity. This study compares the relationship between MHD and LAD maximum dose (Dmax) to the onset of coronary artery disease identified on CT angiogram (CTA).

Methods: We identified 52 women with stage I-III breast cancer (36 left, 16 right) treated with adjuvant breast or chest wall 3-dimension conformal RT who subsequently underwent CTA. No cardiac substructural dose constraints were used at treatment, and coronary vessels were contoured retrospectively and reviewed by a cardiac radiologist. Dosimetry to the LAD was calculated based on the individual RT plan used for treatment. A nested case-control study of incident LAD stenosis ≥ 25% luminal involvement and coronary artery calcification (CAC) using Agatston score was conducted. Controls were matched to cases on elapsed years between RT and CTA. Odds ratios (OR) were calculated using conditional logistic regression to assess the attribution of LAD Dmax and MHD dose parameters, adjusting for Atherosclerotic Cardiovascular Disease (ASCVD) score, history of ischemic heart disease, and statin use.

Results: The median follow-up time from RT to CTA was 5.1 years (range, 2.5-18.1). LAD Dmax was more strongly associated with the onset of any CAC (Agatston score ≥1), moderate/severe CAC (Agatston score ≥101), and LAD stenosis (≥25% lumen). For any CAC, OR was 1.15 (95% CI 0.99-1.33, p=0.06) and 2.21 (95% CI 1.13-5.03, p=0.02) for MHD and LAD Dmax, respectively. For moderate/severe CAC, OR was 1.04 (95% CI 0.95-1.23, p=0.24) and 2.57 (95% CI 1.01-7.04, p=0.04) for MHD and LAD Dmax, respectively. For LAD stenosis, OR was 1.21 (95% CI 1.01-1.46, p=0.04) and 4.85 (95% CI 1.42-16.63, p=0.01) for MHD and LAD Dmax, respectively. LAD Dmax > 10 Gy was a significant threshold for increased odds of developing any CAC (OR 10.21, 95% CI 1.42-21.83, p=0.03), moderate/severe CAC (OR 5.21, 95% CI 1.16-18.36, p=0.04), and LAD stenosis (OR 6.52, 95% CI 1.39-19.67, p=0.03).

Conclusions: Compared to MHD, LAD Dmax had a stronger association with the onset of CAC and LAD stenosis identified on CTA. The LAD should be more routinely included as an avoidance structure for breast RT planning, and if confirmed on prospective analysis, a Dmax threshold of 10 Gy may serve as a useful clinical parameter to minimize late cardiac toxicity.
Title: Long-Term outcomes using electron IORT APBI for early stage breast cancer: The Verona University Hospital experience

Nunzia Luna Valentina Cernusco, Nadia Marcia, Mario de Liguoro, Maria Grazia Giri, Stefania Guariglia, Davide Lombardi, Francesca Pellini, Carlo Cavedon, Giovanni Paolo Pollini and Renzo Mazzarotto. 1Radiation Therapy Unit-Azienda Ospedaliera Universitaria Integrata di Verona, Verona, Veneto, Italy; 2Medical Physics Unit-Azienda Ospedaliera Universitaria Integrata di Verona, Verona, Veneto, Italy and 3Breast Unit-Azienda Ospedaliera Universitaria Integrata di Verona, Verona, Veneto, Italy.

Body: Purpose: Several published studies of electron intraoperative radiation therapy (IORT), when delivered as accelerated partial breast irradiation (APBI), have demonstrated that low recurrence rates of 1.5-2.5% are achieved at 5-year follow-up for ASTRO Suitable or ESTRO Good women. There has been no report on IORT APBI with longer follow-up to determine if these excellent low recurrence results persist. We evaluated our patient cohorts treated with IORT APBI, with follow-up up to 10 years, to answer the question of long-term control.

Methods and materials: From July 2006 to December 2015, 295 patients suitable for breast-conserving therapy (BCT) entered a single-arm phase II study and were treated with IOERT, as radical treatment, immediately after surgical resection using a single dose of 21 Gy to Dmax. Patient inclusion criteria were mostly ASTRO Suitable Group except for G3 grade. All patients received IOERT with a dedicated mobile linear accelerator (Mobetron, Sunnyvale, CA). A Lucite disk was placed under the gland to protect the chest wall. For each patient, the field size was selected primarily on the tumor dimension, and the applicator was chosen with a diameter that provided a 2-cm lateral margin.

Results: With a median follow-up of 60 months (1-122 months), 4 women (1.3%) experienced a true local recurrence (reappearance of the tumor in the same quadrant) diagnosed 1 year after the first treatment in 1, 3 years after in 2, and 8 years after in 1 patient. None of the patients had a new ipsilateral carcinoma (reappearance of cancer in another quadrant of the same breast). In addition, 2 women (0.67 %) developed distant metastases, 2 (0.67%) subsequently developed contralateral breast cancer, and 9 (3%) other cancers. 21 patients (7.1%) died, but only 2 (0.67%) due to breast cancer systemic progression. Patients that recurred underwent mastectomy. One woman, who developed contralateral breast cancer, was treated with IORT APBI.

Conclusion: Single-dose IOERT in early stage breast cancer can be delivered safely and with excellent results. Our long-term recurrence rates are very low and thus encourage the use of IORT in selected low risk patients even off-clinical trials.
Title: Analysis of cardiac events among node positive breast cancer (NPBC) patients treated with three-dimensional conformal radiation therapy (3D-CRT)

Julie A Bradley¹, Irina Sparks², Phillip Prior³, Carmen Bergom², Alonzo Walker², J Frank Wilson², X Allen Li² and Julia White⁴.
¹University of Florida; ²Medical College of Wisconsin; ³University of Chicago and ⁴Ohio State University.

Body: Background: Regional nodal irradiation (RNI) in addition to the chest wall and/or breast can maximize local regional control and improve overall survival, but has been associated with late cardiac morbidity. We examined NPBC patients treated with RNI using 3D-CT based radiation therapy (RT) to evaluate incidence and type of cardiac events.

Methods: Between 2000 and 2007, 156 NPBC patients were treated with RNI following lumpectomy or mastectomy using 3D-CRT. In all cases, treatment target and normal tissue volumes were delineated on treatment CT scans. The heart contour included the left ventricle and the atria. Prescription dose was typically 50Gy in 25 fractions (range 44-54 Gy) to the chest wall and/or breast PTVeval. 37% received a boost to the chest wall and 73% to the lumpectomy cavity. The mean prescription dose to the axilla and supraclavicular lymph nodes was 47.6 Gy (range 43.2 – 54 Gy) and 46.8 Gy to the IMN (range 35.3 – 50.4 Gy). The dose-volume cardiac data and incidence of cardiac events is reported.

Results: Median follow-up of surviving patients was 7 years (range, 0.3-10.6). Median patient age was 50 (range, 27-91), 52% were premenopausal, 76% estrogen receptor positive, and 18% were HER-2 positive. The IMN received > 40 Gy in 66%. Chemotherapy was used in 94% of patients, and it was anthracycline-based in 82.3%. At the time of RT, 12.5% smoked, 9% had diabetes, 33% with HTN, and 4.4% had a history of CAD.
Average mean heart dose for the cohort was 5.2 Gy (range, 0.2 - 25.3 Gy). Mean cardiac V25 was 5.4% (range, 0-20%), mean cardiac V45 was 1.7% (range, 0-13.3%), and mean maximum cardiac point dose was 45.4 Gy.
There was 1 (0.7% of cohort) right sided patient with cardiac events and 8 (5.1% of cohort) left experiencing cardiac events. A total of 18 cardiac diagnoses were experienced among the 9 patients: Coronary artery disease with or without myocardial infarction (4), congestive heart failure (6), cardiomyopathy (3), and arrhythmia (5).

Conclusions: The cardiac event rate among these NPBC patients treated with RNI and anthracycline-based chemotherapy was low, but more common in women with left-sided breast cancer compared to right. Additional analysis using 3DCRT volumes are important to validate these findings and better define the dose-volume parameters for cardiac toxicity.
Title: Evaluation of lung and heart dose in patients treated with radiation for breast cancer

Erin H Healy¹, David N Pratt¹, Dominic DiCostanzo¹, Jose G Bazan¹ and Julia White¹. ¹The Ohio State University Medical Center, Columbus, OH.

BACKGROUND: A recent systematic review of women receiving radiation therapy (RT) for breast cancer combined with modeled estimated risks of mortality from heart disease and lung cancer found that the mean heart dose (MHD) was 4.4 Gy (5.2 Gy for left-sided, 3.7Gy for right-sided) and the mean total lung dose (TLD) was 5.7 Gy. Estimated excess cardiac mortality ranged from 0.3-1.2% and lung cancer mortality ranged from 0.2-4.4% with modern RT. Using these data as a benchmark, we set to review the MHD and mean TLD for our patients receiving adjuvant breast RT in a modern era when RT planning includes meeting normal tissue constraints.

METHODS: We evaluated the MHD and mean TLD for patients with unilateral breast cancer treated with curative intent between January 2012 and May 2017 at our institution. Dosimetric data was complete for 793 patients. During this time period the MHD constraint was 4 Gy and lung V20 was 20% for breast only and 35% for regional nodal irradiation (RNI). RNI included the axillary, supraclavicular and internal mammary nodes. Patients were evaluated by laterality (right vs. left), prone vs. supine position, breast only whole breast irradiation (WBI) and RNI with intact breast or chestwall post-mastectomy. The RNI group was examined by treatment technique, intensity modulated radiation therapy (IMRT) vs. 3D conformal (3DCRT). We compared differences in the MHD and mean TLD within those groups using the Student's t-test.

RESULTS: We identified 651 patients: 481 WBI only and 170 RNI. In the RNI group, 77 (45.3%) received IMRT. Of the WBI only group, 229 (47.6%) were right-sided and 313 (65.1%) were treated prone. The mean TLD for the WBI only group was significantly lower in the prone vs. supine position (0.62 Gy vs. 3.90 Gy, p<0.0001). The prone position resulted in lower MHD for both left-sided WBI (1.17 Gy vs. 1.67 Gy, p<0.0001) and right-sided WBI (0.51 Gy vs. 0.64 Gy, p=0.1067). In patients that received RNI, the mean TLD was 8.20 Gy (SD 1.03) and the MHD was 2.67 Gy (3.25 Gy for left-sided vs. 1.83 Gy for right-sided, p=0.0001). Compared to 3DCRT, IMRT increased the MHD (2.46 Gy vs. 4.23 Gy for left-sided, p<0.0001; 0.94 Gy vs. 2.85 Gy, p<0.0001 for right-sided) and mean TLD (8.50 Gy vs. 7.95 Gy, p=0.0005).

CONCLUSIONS: In the era of RT treatment planning that incorporates normal tissue constraints, very low MHD and lower TLD are achievable in prone or supine position patients receiving WBI only for breast conserving treatment. This means lower late cardiac and lung cancer mortality risks from RT. Women that receive RNI also have acceptably low MHD but high mean TLD. Node positive breast cancer patients derive a disease free survival benefit from RNI, which must be balanced against potential late risk for lung cancer, especially in smokers. More attention should be focused on identifying lung cancer risk, smoking cessation and screening efforts in node positive breast cancer patients with indications for RNI to minimize late radiation risks.
Title: Risk factors for fibrosis after whole breast radiation therapy in lateral position : A large scale single center experience

Estelle Bronsart¹, Sylvain Dureau², Hao Ping Xu¹, Emilie Costa¹, Philip Poortmans¹, Anne Chilles¹, Frederique Berger², Anne Stilhart¹, Alain Fourquet¹ and Youlia Kirova¹. ¹Institut Curie, Paris, Ile de France, France and ²Institut Curie, Paris, Ile de France, France.

Body: Background and Purpose: We previously confirmed the efficacy and safety of our technique of whole breast radiation therapy (WBRT) in isocentric lateral decubitus (ILD) position. The purpose of this work is to evaluate the risk factors for long-term fibrosis in patients treated in ILD position.

Material and methods: We studies 832 consecutive female patients with early stage BC treated by conservative surgery followed by 3D-conformal WBRT at Institut Curie between 2005 and 2010. Fibrosis and deformation were evaluated at the end of the treatment and subsequently every 6 months during at least 5 years, using NCI CTC v3.0 scale. Different fractionation schedules were used: 66Gy in 33 fractions, 50Gy in 25 fractions, 40Gy in 15 fractions, 41.6Gy in 13 fractions and 30Gy in 5 weekly fractions.

Results: Median age is 61.5 years (range: 29 - 90); median follow up is 6.4 years (range: 1.5 - 12.4). During the follow-up, 308 patients (38.9%) had grade 1 fibrosis, and 36 patients (4.3%) only had grade 2-3 fibrosis. Among patients with grade 1 to 3 fibrosis, the median time to development of fibrosis was 1.6 years (range: 9 days – 8.3 years). In univariate and multivariate analysis, age, cup size and chemotherapy administration had no significant influence on development of breast fibrosis. The hypo fractionated schedule of 30Gy in 5 fractions significantly increased the fibrosis rate (OR=12.5; [2.7; 57.1] p=0.001). On the other hand, 40 Gy/15 fr and 41.6 Gy/13 fr had no significative influence (OR=2.2 [0.5; 11.1] p=0.32) as well as the 66 Gy/33 fr schedule (OR=3.6 [0.8; 15.4] p=0.09) compared to standard scheme of 50 Gy/25 fr. The cosmetic result was good or excellent for 84.8% of cases at the first evaluation. The 30 Gy in 5 fractions schedule significantly influenced the cosmetic result in the multivariate analysis (OR=11.2 [3.1; 43.9]; p<0.001), with increased rates of breast deformation. The risk of breast deformity was also worse for large breast size (OR=2.7 [1.3; 5.8]; p=0.02).

Conclusion: Whole breast radiation therapy in ILD position is well tolerated with good cosmesis and low rates of fibrosis, except for the 30 Gy in 5 weekly fractions schedule. Large breast size has a significantly negative influence on cosmetic results and fibrosis.
**Title:** Excellent acute toxicity outcomes with proton therapy for partial breast irradiation in early stage breast cancer: Initial results of a multi-institutional phase II trial

J Isabelle Choi¹ and Andrew L Chang¹,². ¹Scripps Proton Therapy Center, San Diego, CA and ²ProCure Oklahoma City, Oklahoma City, OK.

**Body:**

**Background and Purpose:** Partial breast irradiation (PBI) with proton therapy after lumpectomy for early stage invasive breast cancer is an area of active investigation. Advantages of this technique include a shorter treatment course and the potential for decreased morbidity versus external beam photon radiation therapy given superior sparing of the surrounding normal breast tissue. To date, multiple single-institutional studies have reported conflicting results on the acute toxicity of PBI. This prospective phase II trial investigates the feasibility, safety, and efficacy of delivering PBI with proton therapy in a multi-institutional setting.

**Methods:** Patients over the age of 50 years with ER-positive nonlobular invasive breast cancer or ductal carcinoma in situ ≤3 cm in size who had undergone lumpectomy with at least 2 mm negative surgical margins were treated with proton therapy to a dose of 40 Gy delivered over 10 daily fractions. In this initial analysis, we assess early toxicity and treatment efficacy of proton PBI. Patients were followed up at 4 weeks post-treatment and annually thereafter, along with annual mammograms. Patient-reported quality of life and physician-reported cosmesis assessments including photographs were obtained at 1 and 3 years post-treatment.

**Results:** Forty patients were enrolled, of which 38 were evaluable. At a median follow-up of 17.8 months (range 2-36 months), all patients had overall breast cosmesis that was scored “good” or “excellent”. Of 6 grade 2 acute adverse events that occurred, only 1 was radiation dermatitis, with others including lymphedema, hot flashes, and fatigue. One grade 3 acute toxicity occurred 3 weeks after radiation completion in the form of vascular disease requiring stent placement, highly unlikely to be attributable to radiation effects. Patient-reported quality of life outcomes were recorded using the standardized Breast Cancer Treatment Outcome Scale (BCTOS) scored from 1-4 (1: none; 2: mild; 3: moderate; 4: large), with endpoints receiving a score of 3 or 4 most frequently involving change in breast size, breast texture, nipple appearance, or scar tissue. Patients assigned a score of 4 for change in nipple appearance (n=2), breast shape (n=2), and scar tissue formation (n=2). To date, local, locoregional, and distant disease control are 100%, although one patient has developed a new hormone receptor-negative invasive ductal carcinoma of the contralateral breast.

**Conclusion:** Proton PBI provides excellent early cancer control with acceptable cosmetic outcomes and minimal adverse effects as per patient- and physician-reported assessments. On continued follow-up, late toxicity and cosmesis, as well as long-term disease control outcomes, will be assessed.
Title: Toxicity analysis of elderly breast cancer patients using different accelerated partial breast irradiation techniques

Daphne HM Jacobs, Corrie AM Marijnen, Gabrielle Speijer, Marieke Straver, Andreas Marinelli, Jos Merkus, Ellen MA Roelofzzen, Lida AG Zwanenburg, Ursula Fisscher, Anna L Petoukhova, Mirjam E Mast and Peter Koper.

1 Leiden University Medical Center, Leiden, Netherlands; 2 Haga Hospital, The Hague, Netherlands; 3 Haaglanden Medical Center, Leidschendam, Netherlands; 4 Haga Hospital, The Hague, Netherlands; 5 Isala Clinics, Zwolle, Netherlands and 6 Haaglanden Medical Center, Leidschendam, Netherlands.

PURPOSE: We investigated the acute toxicity of Accelerated Partial Breast Irradiation using external beam (EB-APBI) and intraoperative radiotherapy (IORT) technique.

MATERIALS AND METHODS: Women ≥60 years with unifocal breast tumors of ≤30 mm undergoing breast conserving therapy were eligible for this prospective multi-centre cohort study. After informed consent, patients were treated with IORT in one institute, EB-APBI was applied in other institutes. IORT was applied with electrons directly on the tumor bed following lumpectomy (21 Gy at 90% isodose). EB-APBI was delivered using 3D-conformal radiotherapy or IMRT in 10 daily fractions of 3.85 Gy. Acute toxicity was scored using the CTCAE v.3, initially by the treating physician and retrospectively by blinded researchers. The highest reported toxicity until 3 months after treatment was used. Patient reported symptoms were analysed using Visual Analogue Scales (VAS) for pain and fatigue (scale 0-10), and single items from the EORTC QLQ-C30 and Breast Cancer module questionnaires at different time points up till 3 months. P<0.01 was deemed significant.

RESULTS: Between January 2011 and August 2016, 622 patients were eligible, eventually 268 patients underwent IORT and 207 underwent EB-APBI. Of those, 267 (IORT) and 206 (EB-APBI) were available for toxicity analysis. Patient characteristics are shown in table 1. Although more patients experienced >grade 2 acute toxicity in the IORT group (10.4% IORT and 4.9% EB-APBI; p=0.027), grade 3 toxicity was low and did not significantly differ between groups (3.3% IORT and 1.5% EB-APBI). No grade 4 toxicity occurred. After IORT more wound infections requiring oral antibiotics (5.2% versus 1.5%) and more seroma requiring aspiration (2.2% versus 0.5%) were observed.

Results for EORTC symptoms and VAS scores are displayed in table 2. Patients treated with EB-APBI experienced significantly less fatigue direct postoperatively (EORTC p=0.003, VAS p=0.001). After 3 months, this difference dissolved, and only pain according to the VAS scale was significantly worse in the EB-APBI group (p=0.003).

EORTC: Scores of “quite a bit” and “very much” were scored positive. Percentage of patients that scored positive is shown.

CONCLUSION Even though more clinically relevant toxicity is seen in IORT treatment direct postoperatively, acute toxicity in both IORT and EB-APBI treatment is acceptable. IORT patients seem to recover more rapidly regarding fatigue than EB-APBI patients. This may be explained by the fact that IORT treatment is completed in one day.

Title: Role of postmastectomy radiotherapy after neoadjuvant chemotherapy in breast cancer patients: A study from the Japanese breast cancer registry

Minoru Miyashita¹, Naoki Niikura², Hiraku Kumamaru³, Hiroaki Miyata⁴, Takanori Ishida¹, Takayuki Kinoshita⁵, Hitoshi Tsuda⁶, Seigo Nakamura⁷ and Yutaka Tokuda². ¹Graduate School of Medicine, Tohoku University; ²Tokai University School of Medicine; ³Graduate School of Medicine, Tokyo University; ⁴Keio University; ⁵National Cancer Center Hospital; ⁶National Defense Medical College and ⁷Showa University.

Body: Background:
Postmastectomy radiotherapy (PMRT) has been shown to be beneficial in node-positive breast cancer patients. However, the role of PMRT for patients receiving modern neoadjuvant chemotherapy (NAC) are controversial. We aimed to evaluate the efficacy of radiotherapy for breast cancer patients treated with NAC and mastectomy in the Japanese Breast Cancer Registry.

Methods:
Patients who received NAC and mastectomy for cT1-4 cN0-2 M0 breast cancer were included in this analysis. We assessed locoregional recurrence (LRR), distant disease-free survival (DDFS), and overall survival (OS) using the Kaplan-Meier method and compared them between the groups with and without PMRT by nodal status after NAC; ypN0, ypN1, and ypN2-3. We also performed multivariable cox regression analysis to evaluate the association of radiotherapy and these outcomes adjusting for baseline patient and cancer characteristics.

Results:
Of the 145,530 patients registered from 2004 to 2009, we identified 3,226 patients who met our inclusion criteria with the 5-year follow-up information including 1,299 ypN0, 1,036 ypN1, and 879 ypN2-3 cases. PMRT was performed in 185 patients (14.2%) with ypN0, 265 patients (25.6%) with ypN1, and 543 patients (61.8%) with ypN2-3. There was no difference in LRR, DDFS, and OS between the groups with and without radiotherapy for ypN1 patients who received NAC (P=0.72, P=0.29, and P=0.36, respectively). For patients with ypN2-3 breast cancer, radiotherapy significantly improved LRR (P<0.001), DDFS (P=0.01), and OS (P<0.001) on univariate analysis. No difference in LRR, DDFS, and OS was observed for ypN0 patients (P=0.81, P=0.15, and P=0.05, respectively). In multivariable analysis, the use of radiotherapy was independently associated with improved LRR [hazard ratio (HR): 0.608, 95% confidence interval (CI): 0.452–0.818, P=0.001] and OS [HR: 0.685, 95% CI: 0.531–0.885, P=0.004] for ypN2-3 patients.

Effect of PMRT on locoregional recurrence by the ypN subgroups

Radiotherapy was not associated with OS among patients with ypN0 [HR: 1.325, 95% CI: 0.841–2.087, \(P=0.224\)] and ypN1 [HR: 0.880, 95% CI: 0.599–1.293, \(P=0.514\)]. There was no significant difference in DDFS with the addition of radiotherapy for all ypN subgroups.

Conclusions:
The results from this nationwide database study of breast cancer patients following modern NAC showed that PMRT did not improve survival for patients with ypN1 and ypN0. Radiotherapy might be only beneficial for ypN2-3 breast cancer patients who received NAC and mastectomy in the modern era. Randomized clinical trials are needed to optimize the use of PMRT for breast cancer patients treated with neoadjuvant chemotherapy.
Title: Prospective comparison of late toxicity and cosmetic outcome after accelerated partial breast irradiation with conformal external beam radiotherapy or single-entry multi-lumen intracavitary brachytherapy

Shane R Stecklein¹, Gildy V Babiera¹, Isabelle Bedrosian¹, Simona F Shaitelman¹, Matthew T Ballo², Welela Tereffe¹, Isidora Y Arzu¹, George H Perkins¹, Eric A Strom¹, Valerie K Reed¹, Tomas Dvorak³, Benjamin D Smith¹, Wendy A Woodward¹, Karen E Hoffman¹, Pamela J Schlembach¹, Gregory M Chronowski¹, Shalin J Shah¹, Steve M Kirsner¹, Christopher L Nelson¹, William Guerra¹, Seyyedeh S Dibaj¹ and Elizabeth S Bloom¹. ¹The University of Texas MD Anderson Cancer Center, Houston, TX; ²The University of Tennessee Health Science Center, Memphis, TN and ³UFHealth Cancer Center / Orlando Health, Orlando, FL.

Body: Purpose/Objective(s):
To prospectively compare late toxicity after accelerated partial breast irradiation (APBI) with 3D-conformal external beam radiotherapy (3D-CRT) or single-entry multi-lumen intracavitary brachytherapy.

Patients/Methods:
Two hundred eighty-one patients with pTis or pT2N0 (≤3.0 cm) breast cancer treated with segmental mastectomy were prospectively enrolled on a multi-institution observational protocol from 12/2008 – 8/2014. Patients were enrolled and treated at primary, satellite, and affiliated academic institutions. APBI was delivered using 3D-CRT or with a Contura®, MammoSite®, or SAVI® brachytherapy catheter. 3D-CRT patients were treated to 34.0 Gy (7%) or 38.5 Gy (93%) at 3.4-3.85 Gy/fx BID and brachytherapy patients were treated to 34.0 Gy at 3.4 Gy/fx BID. Per protocol, patients were clinically evaluated at 2, 6, 12, 18, and 24 months and then annually. At each clinical evaluation the radiation oncologist scored cosmetic outcome (excellent/good/fair/poor according to the Harvard Cosmesis Scale), toxicity (seroma/infection/fat necrosis/pain/telangiectasia/radiation dermatitis/hyperpigmentation/hypopigmentation/fibrosis/induration/edema/other according to CTCAE v3.0) and recurrence status.

Results:
The median age was 61 years. Of 281 patients, 211 (75%) had invasive breast cancer and 70 (25%) had in situ disease. Among patients with invasive disease, 90% were HR+/HER2-, and among patients with in situ disease, 83% were HR+. APBI was delivered with 3D-CRT in 29 (10%) patients and with single-entry multi-lumen intracavitary brachytherapy in 252 (90%) patients. Among the brachytherapy patients, APBI was delivered with the SAVI®, Contura®, and MammoSite® devices in 176 (70%), 56 (22%), and 20 (8%) patients, respectively. With a median follow-up of 49 months, rates of Grade 1 (G1) and Grade 2-3 (G2-3) toxicity are:

</table>

Mean skin dose of the maximally-irradiated 0.1 cc (D0.1cc) of skin was significantly higher in patients who developed telangiectasia (103.4% ± 16.1% compared to 96.5% ± 18.6% of prescription dose, p=0.007) and fibrosis (100.1% ± 15.5% compared to 92.8% ± 23.0% of prescription dose, p=0.02). Crude rates of fair or poor cosmetic outcome at 2-4 and 4-6 years were 6.9% and 14.8%, respectively, for 3D-CRT and 14.8% and 21.3%, respectively, for brachytherapy (p>0.05 at both
timepoints). Five-year recurrence-free survival was 96.3% with 3D-CRT and 96.1% for brachytherapy (p>0.05).

**Conclusion:**
APBI with single-entry multi-lumen intracavitary brachytherapy is associated with increased rates of grade 1 fibrosis and seroma than APBI with 3D-CRT. Higher mean skin D0.1cc is associated with increased risk of telangiectasia and fibrosis. Despite increased low-grade fibrosis, there is no significant difference in radiation oncologist-reported fair or poor cosmetic outcome out to six years, or rate of five-year ipsilateral breast recurrence.
Meta-analysis of local recurrence of invasive breast cancer after electron intraoperative radiotherapy

Jay Harness1, Chirag Shah2, Elizabeth Brooks3, Christina Via3 and Frank Vicini4. 1St. Joseph Hospital- Center for Cancer Prevention and Treatment, Orange, CA; 2Cleveland Clinic, Cleveland, OH; 3Decision Driver Analytics / Translational Technologies International, Asheville, NC and 4Michigan Healthcare Professionals/21st Century Oncology, Farmington Hills, MI.

Body: Background: Electron intraoperative radiotherapy (IORT) can be used during breast conservation surgery to treat early-stage invasive breast cancer. While IORT may be an attractive alternative to traditional post-operative radiotherapy for many patients, its effectiveness in preventing local recurrence is still being evaluated. Using data from current clinical and observational studies, we aimed to assess the impact of single-fraction electron IORT on local recurrence rates.

Methods: Studies on single-fraction electron IORT during breast conservation surgery were identified through a search of PubMed and Google Scholar, as well as secondary referencing. Local recurrence rate was the main outcome of interest. Protocols from each publication were assessed for potential sources of heterogeneity. A meta-analysis of proportions, using binomial distribution to model the within-study variability and a random effects model, was conducted to estimate a pooled local recurrence rate. In order to estimate a 5-year recurrence rate, we applied a single-sample Poisson-normal model to model the probability of events occurring during a fixed period of time (60 months).

Results: A total of 13 independent publications were identified for abstraction. The analysis demonstrated a pooled monthly local recurrence rate of 0.02% per person-month (95% CI: 0.00 – 0.06%) for the studies with < 5 years of follow-up, 0.03% per person-month (0.02 – 0.06%) for studies with ≥ 5 years of follow-up, and 0.02% per person-month (0.01 – 0.04%) overall. Based on this model, the predicted 5-year recurrence rate is 2.7%, with a 95% confidence interval of 1.9% - 3.7%.

Conclusions: According to the published literature, the rate of breast cancer local recurrence after electron IORT was 0.02% per person-month; with an adjusted 5-year recurrence rate of 2.7%. These findings support the recent guidelines from the American Society for Radiation Oncology (ASTRO) supporting the use of electron IORT in low-risk patients.

Title: IMRT use after lumpectomy in early-Stage breast cancer: Patterns of care and cost-consequences

Joshua A Roth¹, Jean McDougall², Lia Halasz³, Catherine Fedorenko¹, Qin Sun¹ and Shilpen Patel³. ¹Fred Hutchinson Cancer Research Center, Seattle, WA; ²University of New Mexico School of Medicine, Albuquerque, NM and ³University of Washington School of Medicine, Seattle, WA.

Body: BACKGROUND
The American Society for Radiation Oncology (ASTRO) issued a Choosing Wisely recommendation (CWr) against use of intensity modulated radiotherapy (IMRT) as part of breast conservation therapy in 2013, noting that “its routine use has not been demonstrated to provide significant clinical advantage”. Also, as IMRT is more expensive vs conventional radiotherapy (cRT), use in this setting may represent wasteful spending. The aims of this study were to characterize: 1) IMRT use immediately preceding the ASTRO CWr, 2) the cost-consequences of IMRT vs. cRT in the year after breast cancer diagnosis, and 3) excess annual U.S. national expenditure on IMRT in this setting.

METHODS
Surveillance Epidemiology and End Results (SEER) records for women age ≥66 years with a first primary diagnosis of Stage I/II breast cancer (2007-2012) were linked with Medicare claims (2007-2013). All cases had coverage for ≥12-months before/after diagnosis (or until death), and to be consistent with the CWr, had lumpectomy 1 month before to 6 months after diagnosis, and radiation therapy within 6 months of lumpectomy. We evaluated receipt of IMRT vs cRT within 1 year of diagnosis in 12 SEER registries. We also calculated mean direct medical expenditure in the year after diagnosis by summing all allowable charges from Medicare claims. Costs were inflated to 2017 USD. We evaluated differences in means by registry using ANOVA and compared mean costs for cases treated with IMRT vs cRT using t-test. We projected excess annual U.S. national expenditure on IMRT (vs. cRT) using the findings from aims 1 & 2 and assuming 209000 incident Stage I/II cases and that 55% receive lumpectomy.

RESULTS
Among 13037 women meeting all inclusion criteria, mean age was 74, 89.0% were white, and 19.8% received IMRT. Table 1 shows the proportions receiving IMRT by SEER registry and mean cost for cases treated with IMRT vs cRT. The proportion with IMRT varied significantly between registries (p<0.001), as did the mean cost for cases treated with IMRT (p<0.001) and cRT (p<0.001). Overall, cost for patients treated with IMRT was significantly higher vs those treated with cRT ($9644, p<0.001). Nationally, we estimated $219 million in annual excess medical expenditure on unnecessary IMRT vs. cRT.

DISCUSSION
From 2007-2013, use of IMRT in Stage I/II breast cancer was substantial (19.8%) and varied significantly across SEER registries.
Cases treated with IMRT incurred significantly higher cost ($9644) in the year following diagnosis vs. those treated with cRT. If patterns of care remain similar today, there is potentially as much as $219 million in annual U.S. national expenditure on low-value radiotherapy following lumpectomy. Our findings suggest an opportunity to improve quality in cancer care while reducing expenditure by curbing use of IMRT. Future studies should develop interventions to align practice with ASTRO CW recommendations and reduce variation in practice between regions.

Title: Adjuvant radiotherapy of early breast cancer induces a decrease in levels of TGFβ-1, MMP-9 and PDGF

Hanna Aula1,2, Tanja Skyttä1,2, Tiina Luukkaala1, Mari Hämäläinen2, Eeva Mollanen2 and Pirkko-Liisa Kellokumpu-Lehtinen1,2. 1Tampere University Hospital, Tampere, Finland and 2University of Tampere, Tampere, Finland.

Body: Purpose

Radiotherapy (RT) of early breast cancer is associated with cardiovascular morbidity. Transforming growth factor beta 1 (TGFβ-1) is a pro-fibrotic cytokine that also has a role in immunological activation and epithelial proliferation, but its clinical role remains unclear. Endoglin, matrix metalloproteinase 9 (MMP-9), platelet derived growth factor (PDGF), and oxidative stress are involved in regulation of TGFβ-1. 8-isoprostane is a biomarker of oxidative stress. The aim of our study was to evaluate the behavior of these fibrosis-associated biomarkers during adjuvant RT of early breast cancer.

Materials and methods

The study included 67 patients with early breast cancer or ductal carcinoma in situ (DCIS) receiving adjuvant RT, but no chemotherapy. The dose of RT was either 42.56 Gy in 2.66 Gy fractions or 50 Gy in 2 Gy fractions with or without boost of 10 or 16 Gy. TGFβ-1 (ng/ml), endoglin (ng/ml), PDGF (ng/ml), MMP-9 (ng/ml) and 8-isoprostane (pg/ml) were measured by enzyme-linked immunoassay (ELISA) from serum samples acquired before starting RT, 2 weeks (for 42.56 Gy) or 3 week (for 50 Gy) into RT and at the end of RT.

Results

Adjuvant RT induced significant decreases in the levels of TGFβ-1 (p=0.002), MMP-9 (p=0.017) and PDGF (p<0.001) from before RT to after RT (Table 1). Whereas, the levels of endoglin and 8-isoprostane remained stable. For the first 2 or 3 weeks of RT, TGFβ-1 remained stable and then decreased significantly by the end of RT (p=0.022). The decrease in MMP-9 was significant only from before RT to after RT (p=0.017). On the other hand, PDGF also decreased significantly during the first 2 or 3 weeks (p=0.016) and from 2-3 weeks to after RT (p=0.038). Although, endoglin remained stable throughout the whole RT, the decrease during first 2-3 weeks was significant (p=0.002).

Md median, IQR interquartile range, ¹Wilcoxon signed ranks test for change from before RT to 2-3 weeks into RT, ²Wilcoxon signed ranks test for change from 2-3 weeks into RT to after RT, ³ Wilcoxon signed ranks test for change from before RT to after RT

Conclusion

This study demonstrates the behavior of TGFβ-1, endoglin, MMP-9, PDGF and 8-isoprostane during adjuvant RT of early breast cancer. Although the role TGFβ-1 as profibrotic cytokine is widely accepted, it has not been extensively studied in radiotherapy of breast cancer. The fibrotic effects of RT take years to manifest, including increased cardiovascular morbidity. More extensive studies, with longer follow-up, are needed to determine whether the changes in TGFβ-1 and its modulators are associated with clinical, RT related, cardiovascular complications in breast cancer patients.
The safety and pathological impact of neoadjuvant radiotherapy for local advanced breast cancer undergoing mastectomy and autologous reconstruction

Caroline Baker¹,², Michael W Chao³,⁴, Sunny Jassal⁴, Derek Neoh⁴, Elaine Bevington⁴, Anthony Hyett⁴, Damien Grinsell², Su Wen Loh⁴, Natalie Zantuck⁵, David Stoney⁵, Christina Foley¹, Michael Law³, Grace Chew⁴, Vivian Yu⁵, Michael Cheng³, Mario Guerrieri³, Karen Taylor⁴, Mitchell Chipman², Margaret Cokelek³, Daryl Lim Joon⁴ and Farshad Foroudi⁴. ¹St Vincents Hospital, Melbourne, Victoria, Australia; ²Victorian Breast and Oncology Centre, Melbourne, Victoria, Australia; ³Genesis Care Cancer Centre, Melbourne, Victoria, Australia; ⁴Austin Hospital, Melbourne, Victoria, Australia; ⁵Maroondah Hospital, Melbourne, Victoria, Australia and ⁶Alfred Hospital, Melbourne, Victoria, Australia.

Body: Introduction

Delayed breast reconstructions are preferred if post mastectomy radiotherapy is indicated due to lower complication rates compared to immediate permanent implant or autologous reconstructions (AR) but cosmetic outcomes are inferior. Radiotherapy has a deleterious effect on implants and autologous tissue and often an interim tissue expander is place which has inherent pain and complications.

However, neoadjuvant radiotherapy (NART) prior to surgery allows for definitive oncological surgery to be performed with an immediate AR in a single operation and the avoidance of a temporary expander. The aim of this study is to assess the safety and downstaging impact of NART.

Methods

This is a prospective review of patients who underwent NART at GenesisCare Victoria, the Austin and the Alfred hospital. 59 LABC patients (median age 49.2 years) were divided into two groups; clinically staged and pathologically staged for reporting. There were 15 pathologically staged patients (pStage 2A-3C) and 43 clinically staged patients (cStage 2A-3B). All patients initially underwent NACT, followed by NART (median dose 50.4Gy in 28 fractions) to the breast, supraclavicular fossa and level 3 axilla with or without coverage of their Level 1 and 2 axilla, and/or internal mammary nodes. Approximately 6 weeks after completing NART, patients underwent definitive surgery and AR.

Results

All patients completed their NART with minimal toxicity and no break in treatment. 55 patients had a skin-sparing mastectomy (SSM) and 3 patients had a modified radical mastectomy. All clinically staged patients underwent an AD. ARs with a DIEP flap were performed in the majority of patients (51). The average length of hospitalisation was 6.2 days. The Miller Payne (MP) scoring index was used to record pathological responses in clinically staged patients. Overall 36 patients achieved significant downstaging of their disease, with MP scores of 5/5 for 20 and 4/5 for 16. Only 1 patient failed to achieve any downstaging with a MP score of 1/5. All 12 Her2 positive patients, 3/5 Triple negative patients and 5/26 Luminal A/B patients achieved a MP score of 5/5. All patients achieved R0 resection margins. This included 6 patients who had initial cT4 disease (cT4a X2, cT4b X1 and cT4d X3). 15 patients had initial cN2/3 disease and all successfully underwent their axillary dissections with R0 resections achieved. 10/15 had no involved axillary nodes with significant scarring seen in 6. 5/15 had residual involved nodes with significant scarring seen in 3 patients.

Post surgical toxicities were graded using Clavien-Dindo classification. 8 significant grade 3 toxicities were seen in 6 patients, with no grade 4 or 5 toxicities. No patients developed DVT or PE. No flap losses were seen.

Median follow up is 23 months. Cosmese was rated as good to excellent in all cases. 1 patient developed simultaneous loco-regional and distant recurrence with another 3 patients developing distant metastases only.

Conclusion

This review demonstrated that NART is a safe technique, which has not lead to an increase in surgical complication rates or resulted in a detriment in cosmetic outcome. NART can achieve a shorter, simpler reconstructive journey for patients.
Title: Is post mastectomy radiotherapy contributive in pN0-1mi breast cancers patients? Results of a French multi-centric cohort

Body: Aim: To assess the value of Post-mastectomy radiation therapy (PMRT) in breast cancer patients with no or minimal lymph nodes involvement.

Materials and methods: We retrospectively analyzed a French multi-centric cohort of 4283 patients treated between 1980 and 2013, by mastectomy and axillary dissection with or without PMRT. Practices were analyzed according 3 treatment periods (1980-1999, 2000-2005; 2006-2013). The value of PMRT on loco-regional recurrence, disease-free survival, breast cancer specific survival and overall survival was assessed in pN0-1mi patients, using multivariate analyses (logistic regression and Cox model). It was subsequently assessed according to the number of clinicopathologic recurrence-risk factors, generating a prognostic index (f-PMRT index), in an attempt to isolate a pN0-1mi patients subgroup deriving benefit from PMRT. We tested the accuracy of the Cambridge-PMRT (c-PMRT) index in the discrimination of patients with significantly different outcomes, as well as the value of PMRT in each c-PMRT prognostic group.

Results: PMRT was considered in more than half pN0-1mi patients of our cohort. Whereas matching pN0-1mi patients according to the number of clinicopathologic recurrence-risk factors led to isolate a higher-risk subpopulation (≥ 3 RR factors), PMRT had no significant impact on patients' outcomes, on multivariate analysis. Whereas the Cambridge-PMRT index had the potential to discriminate 3 patient populations with significantly different outcomes, its use did not help to the decision making for PMRT.

Conclusion: Despite a large cohort, we failed to isolate a subgroup of early breast cancer patients suitable for PMRT, in the absence of lymph node involvement.
Body: Purpose/Objectives: Radiation therapy is used by more than 50% of breast cancer patients, but radiation doses can be limited by normal tissue side effects. For example, breast cancer radiation therapy can improve breast cancer-specific survival, but increase cardiac deaths in those with left-sided cancers. Identifying genetic factors that can enhance tumor radiation sensitivity while decreasing normal tissue toxicities has the potential to improve the therapeutic ratio of radiation therapy – leading to more cures and less long-term toxicities. The use of animal models with differing genetic backgrounds to assess radiation toxicity, followed by genetic mapping of radiosensitivity phenotypes, has the potential to identify new targets that can predict cardiac toxicity from radiation therapy. This project examines how genetic host factors alter normal tissue toxicity risks from breast cancer radiation.

Materials/Methods: Inbred female SS rats and SS.BN3 consomic rats, that are genetically identical to SS rats except that chromosome 3 is inherited from the BN strain, have previously been shown to exhibit different vascular dynamics and breast tumor growth. For this study, adult female SS and SS.BN3 rats received image-guided whole heart radiation to a dose of 21 Gy (3 fields, AP and 2 laterals). Cardiac troponin was serially measured at 2, 6, and 12 weeks, and echocardiograms with strain analysis were performed at baseline and 3 months. The Student's t-test was used to compare values.

Results: The SS female rats exhibited enhanced cardiac toxicity compared to SS.BN3 rats, with cardiac troponin levels elevated at 12 weeks (0.32 ng/ml vs. 0.08 ng/ml for SS vs. SS.BN3, p=0.01), and moderate to severe pericardial effusions seen in 6 of 9 SS rats vs. 2 of 7 SS.BN3 rats. At 3 months post-radiation, echocardiograms revealed increased left ventricular posterior wall thickness at end diastole (LVPWd) in SS vs. SS.BN3 rats (0.25 vs. 0.20 cm, p=0.002) and increased left ventricular mass (LVM) in SS vs. SS.BN3 rats (1.54 vs. 1.28 g, p<0.001). Taken together, the SS female rats are more sensitive to cardiac irradiation than SS.BN3.

Conclusions: These results demonstrate that genetic variant on rat chromosome 3 alter the radiosensitivity to single fraction cardiac radiation therapy. Gene expression analysis and genetic mapping will be performed to identify the causative target(s). These models will also be expanded to test whether similar results are seen with fractionated cardiac radiation therapy. This project has the potential to enhance the effectiveness and toxicity profile of radiation therapy in breast cancer.
Title: Safety and efficacy of re-irradiation for locoregional breast cancer recurrences using pulsed reduced dose rate technique and concurrent capecitabine

Adam Burr¹ and Steven Howard¹. ¹University of Wisconsin, Madison, WI.

Body: Purpose: Locoregionally recurrent breast cancer presents a tremendous therapeutic challenge, but successful treatment can provide a durable cure. Re-irradiation has been performed infrequently in the recurrent setting due to concern for toxicity. Pulsed reduced dose rate radiation is a technique that can decrease the toxicity of re-irradiation by increasing normal tissue repair. Here, we update our previously published results of chest wall re-irradiation with an additional 16 patients and a focus on outcomes and long term toxicities.

Methods: Patients treated from 11/09/2000 to 04/21/2016 with pulsed reduced dose rate radiation therapy at the University of Wisconsin were identified by query of Aria radiation oncology record software. Patients were retreated to a median dose of 54 Gy (range 37.5-66 Gy) using pulsed reduced does rate technique, delivering radiation at an apparent dose rate of 0.067 Gy/min to allow for normal tissue repair. The median cumulative dose was 109.8 Gy (range 75 to 236 Gy). Eleven patients underwent comprehensive re-irradiation to the chest wall and locoregional lymphatics, while the remainder underwent re-treatment limited to the site of recurrence. Concurrent capecitabine was given to 15 patients, most frequently at 500mg BID (range 1000 mg to 1500mg daily). The Kaplan-Meier method was used for survival analysis.

Results: Thirty-three patients were identified who were treated with pulsed reduced dose rate radiation therapy for locoregionally recurrent invasive breast cancer with a median follow-up of 19.8 months (range 6.8-133.8 months). Sixteen patients were treated with curative intent and 17 patients were treated with palliative intent. Twenty-two patients had gross disease present at the time of treatment, 6 patients had microscopically positive surgical margins, and 5 patients were treated who had negative margins. The 2 year locoregional recurrence free survival was 70.5% by the Kaplan-Meier method for all patients and 81.5% for patients treated with curative intent. Two year overall survival was 43.6% for all patients and 72.2% in patients treated with curative intent. The rate of acute grade 3 skin toxicity was 21.2%. No other acute grade three toxicities occurred. A total of 9 patients (27.2%) developed late grade 3 or greater toxicities, including 4 patients who developed lymphedema, 4 patients who developed non-healing wounds, and one patient who developed both lymphedema and a non-healing wound.

Conclusion: Pulsed reduced dose rate radiation therapy with capecitabine is an effective method for treating patients with recurrent breast cancer. The moderate risk of toxicity is warranted in a subset of patients with high risk of disease recurrence or morbidity from disease progression. Further work, including prospective studies, is needed to determine the patients who who will benefit most from this technique.
Title: Tolerability and outcomes of radiation therapy for breast cancer in older women: A retrospective study in 817 patients

Kim I Cao¹, Flore Salviat², Alain Fourquet¹, Marie-Christine Falcou², Fatima Laki³, Philippe Beuzeboc⁴, Alexia Savignoni², Louis Bazire¹, Philip Poortmans¹ and Youlia M Kirova¹. ¹Institut Curie, Paris, France; ²Institut Curie, Paris, France; ³Institut Curie, Paris, France and ⁴Institut Curie, Paris, France.

Body: **Background:** Breast cancer (BC) management in older women requires an individual approach and is becoming increasingly topical given the aging population. Postoperative radiation therapy (RT) is a standard treatment of BC after breast-conserving-surgery in most patients but its relative benefit may be counteracted by potential side-effects, especially in elderly. The aim of this study was to assess acute and long-term radiation-induced toxicities and the impact of comorbidities on outcomes in the older women treated by RT for non-metastatic breast cancer.

**Materials and Methods:** Women aged ≥ 70 years at diagnosis, who received exclusive or postoperative RT for primary non-metastatic breast cancer, including carcinoma in situ, between 2003 and 2009 were retrieved from the Institut Curie registry. We calculated the Charlson Comorbidity Index (CCI) for each patient and collected the cardiovascular risk factors other than age (hypertension, dyslipidemia, smoking status). We analyzed overall survival (OS), progression free survival (PFS) and acute and late toxicities according to the CTCAE (Common Terminology Criteria for Adverse Events) v3.0.

**Results:** A total of 817 patients was included in this study. Median age at diagnosis was 76.6 years [70 – 93.3]. Most patients had HR+ (hormone-receptor positive) HER2- breast cancer (83.9 %). 517 patients (62.7%) had at least one cardiovascular risk factor. With a median follow-up of 6.7 years [0.5 - 13], OS at 5 years was 86.3% CI[95%][83.8 - 88.8], and PFS was 84.5% CI[95%][81.9 – 87.1]. OS at 5 years was statistically different according to the Charlson index: 90.2% CI[95%][87.2 – 93.3] for a CCI of 0, 84.6 % CI[95%][80.5 – 88.8] for a CCI of 1, and 78% CI[95%][70.5 – 86.2] for a CCI ≥ 2 (p < 0.001, log-rank test), respectively. Similar results were found for PFS (p < 0.001, log-rank test). 22.6% of patients had no toxicity; of those who experienced toxicity, most was limited to grade I or II. Only five cases (0.6%) of radiation – induced pneumonitis were reported after a median time of 16.4 months (grade I, n = 1; grade II, n = 2). One case (0.1%) of myocardial ischemia was described 14.5 months after RT. Women older than 80 years were less likely to have acute dermatitis (OR = 0.62; CI[95%][0.45 - 0.85]), long-term breast pain (OR = 0.31; CI[95%][0.14 - 0.62]), and long-term breast deformation (OR = 0.63; CI[95%][0.42 - 0.93]) compared to patients younger than 80 years. There was no significant association found between other cardiovascular risk factors and toxicities.

**Conclusion:** Radiation therapy for breast cancer in the older women is well-tolerated. An extended follow-up is planned in order to assess toxicities at a longer time horizon. Further studies could be envisaged to assess the quality-of-life during and after RT for breast cancer in the older patient population.
A prospective phase II study of TARGeted Intraoperative radioTherapy boost plus whole breast irradiation in breast cancer patients undergoing breast-conserving treatment

Hak Woo Lee¹, Changik Yoon¹, Sung Gwe Ahn¹, Jun Won Kim², Yoon Jin Cha³, Ik Jae Lee² and Joon Jeong¹. ¹Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea; ²Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea and ³Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea.

Body: Background: TARGIT-A trial showed that intraoperative radiotherapy (IORT) using Intrabeam® concurrent with lumpectomy within a risk-adapted approach could be considered as an option for eligible patients with early breast cancer. To introduce IORT in clinical practice for Korean breast cancer patients, safety profiles for this new technique from clinical trial with Korean are required due to ethnic (anatomical) difference. Acute toxicity is a key hurdle for patients receiving IORT, because IORT may affect wound healing and increase wound complications. We conducted a phase II study as a feasibility test of IORT at the dose of 20 Gy for the replacement of boost-EBRT in Korean women who are candidates for breast-conserving treatment.

Methods: This single-arm trial aimed to investigate acute toxicity occurred within 6 months after IORT. In 1,119 patients receiving EBRT from TARGIT-A trial, the incidence of acute toxicity within 6 months is 15%. Compared with WBRT, we aim to prove a non-inferiority of IORT with 20 Gy. A sample size of 195 achieves 80% power to detect a non-inferiority proportion (P₀) of 0.2300 using a one-sided binomial test for non-inferiority. These results assume that the actual proportion (P₁) is 0.1500. Considering a drop-out rate of 10%, the trial would need to enroll 215 patients in total. This trial is registered with ClinicalTrials.gov, number NCT02213991.

Results: From August 2014 to November 2016, 233 women with early breast cancer were screened, and 215 undergoing IORT were enrolled. In 36 women, clinically significant complications during acute period are noted. The rate of patients experiencing acute toxicity was 16.7% (95% CI, 11.8-21.7%). The actual non-inferiority margin of our trial was 21.7% under the pre-specified margin as 23.0%. In details, There are 31 with seroma collection (more than 3 times when aspiration volume is over 10cc), 2 with wound infection, and 5 with skin break down. At a median follow-up of 17.8 months, there is no local recurrence.

Conclusions: Targeted intraoperative radiotherapy using Intrabeam® is a safe procedure for Korean breast cancer patients with acceptable toxicity profile in acute period.
Title: Adjuvant radiation is associated with decreased risk of locoregional recurrence in patients with micrometastatic invasive breast cancer

Adam R Burr¹, Claire R Brickson¹ and Bethany M Anderson¹. ¹University of Wisconsin, Madison, WI.

Body: Purpose: Determining the appropriate adjuvant treatment in patients with micrometastatic disease remains a considerable challenge in the treatment of breast cancer. Recent data suggests patients with micrometastatic disease have an intermediate risk of locoregional recurrence between patients with macrometastatic disease and patients with no evidence of axillary disease. Further work is needed to tailor treatment strategies to individual patients based on tumor characteristics. Here, we reviewed the outcomes of patients with N1mic axillary disease treated at the University of Wisconsin to assess the risk of locoregional recurrence in patients with micrometastases to determine risk factors associated with increased risk of LRR.

Methods: We identified patients with pathologic T1-T3, N1mic invasive breast cancers treated at the University of Wisconsin between 01/01/2004 and 07/01/2015. The patients were identified within the UW breast cancer registry and by query of pathologic records. We utilized the Kaplan-Meier method to determine the rate of locoregional recurrence free survival and overall survival. Multivariate analysis of patient and tumor characteristics was performed using the Cox proportional hazards model using locoregional recurrence as an outcome.

Results: 154 patients were identified with micrometastatic disease with a median follow-up of 4.1 years. The 5 year locoregional recurrence free survival and overall survival for all patients was 92.6% and 88.9%, respectively. On univariate analysisl, ER negative status (HR 8.03, p<0.001), PR negative status (HR 3.18, p =0.49), Her2 amplification (HR 5.02, p=0.005), and tumor grade (HR 2.96, p=0.005) were all significantly associated with increased risk of locoregional recurrence (LRR). Radiation therapy (HR 0.174, p=0.005) was the only therapeutic variable associated with decreased risk of LRR. Lymphovascular space invasion, close or positive margins, extranodal extension, and tumor stage were not associated with risk of LRR. Additionally, the type of axillary surgery, the type of breast surgery, the use of chemotherapy, and the use of endocrine therapy were not associated with risk of LRR. On multivariate analysis, ER negative status (HR 6.39, p=0.004), Her2 amplification (HR 5.53, p=0.006), and treatment with radiation (HR 0.14, p=0.004) remained significantly associated with risk of LRR.

Conclusion: The data presented suggest that treatment with radiation is associated with decreased LRR in patients with micrometastatic disease. Patients with Her2 amplification or ER negative status are also found to be at particularly high risk of recurrence. Future work is needed to determine strategies to decrease the rates of recurrence in these high risk groups and to define subgroups of patients with micrometastatic disease for whom radiation is particularly beneficial.
Title: Effect of postmastectomy radiotherapy on breast cancer with isolated tumor cells or micrometastases in regional lymph nodes: A propensity score matched analysis using the SEER database

Wen Xia¹, Qiufan Zheng¹ and Shusen Wang¹. ¹Sun Yat-sen University Cancer Center, Guangzhou, Guangdong, China.

Body: Purpose: Postmastectomy radiotherapy (PMRT) has been strongly considered for patients with 1-3 positive axillary nodes (ALNs). The indications for PMRT are expanding to patients with negative ALNs but have multiple high-risk recurrence factors. However, for patients with isolated tumor cells (ITCs) in node or ALNs micrometastases, PMRT is equivocal. We aimed to determine the effects of PMRT on survival of patients with ITCs or ALNs micrometastases of breast cancer.

Methods: We identified patients with ITCs or ALNs micrometastases after mastectomy from the Surveillance, Epidemiology, and End Results database from 2004 to 2014. Overall survival (OS) and breast cancer-specific mortality (BCSM) were compared among patients after PMRT or not, using propensity score-matched analyses. Cox proportional hazards models and competing-risk models were performed in OS and BCSM analyses, respectively.

Results: We identified 11,622 eligible cases. PMRT was administered to 1,728 patients. Treatment was less frequent among patients who were older, patients with high-income, and patients with right-side tumor. T2 disease, more micrometastatic ALNs, grade 3 tumor, or HER2-negative disease increased the likelihood of PMRT. From the PMRT group, 1,728 (100%) were matched with 1,728 patients who did not underwent PMRT. In the matched dataset, OS at 5 years and 10 years were 88.1% and 74.2% in PMRT group, and were 87.8% and 77.3% in no PMRT group, respectively. Five-year and 10-year cumulative BCSM rate were 6.4% and 12.3% in PMRT group, and were 6.6% and 14.1% in no PMRT group, respectively. OS and BCSM were unaffected by PMRT after adjusting for multiple confounders (OS, hazard ratio, 0.92; 95% CI, 0.74 to 1.16; BCSM, subhazard ratio, 0.89; 95% CI, 0.67-1.18).

Conclusion: To the best of our knowledge, this is the largest study to date of the effect of radiotherapy on survival in breast cancer with ITCs or ALN micrometastases. In this population-based study, we do not find survival benefit of PMRT on patients with ITCs or ALN micrometastases.

Key words: Breast cancer, postmastectomy radiotherapy, isolated tumor cells, axillary nodes micrometastases, overall survival, breast cancer-specific mortality.
Title: Disparities in the application of post-mastectomy radiotherapy in Switzerland: A pooled analysis of 7 cancer registries over the 2003-2005 period

Daniel R Zwahlen¹, Silvia Ess², Michel Zimmermann¹, Andrea Bordoni³, Christine Bouchardy⁴, Harald Frick⁵, Isabelle Konzelmann⁶, Mohsen Mousavi⁷, Sabine Rohrmann⁸ and Christoph Oehler¹. ¹Kantonsspital Graubunden, Chur, Switzerland; ²Kantonsspital Sankt Gallen, Sankt Gallen, Switzerland; ³Registro Tumori del Ticino, Locarno, Switzerland; ⁴Registre Genevois des Tumeurs, Geneva, Switzerland; ⁵Krebsregister Sankt Gallen - Appenzell - FL, Sankt Gallen, Switzerland; ⁶Registre Valaisan des Tumeurs, Sion, Switzerland; ⁷Krebsregister Beider Basel, Basel, Switzerland and ⁸Krebsregister der Kantone Zurich und Zug, Zurich, Switzerland.

Body: Background: The aim of this study was to identify factors that influence the delivery of post-mastectomy radiotherapy (PMRT) in Switzerland, and to analyze the adherence to consensus guidelines.

Methods: Based on 7 regional cancer registries covering 45% of the Swiss population, we identified 1408 women which underwent mastectomy for stage I-III breast cancer between January 1, 2003 and December 31, 2005. We categorized patients according to ASCO grouping in similar fashion to other comparable studies: low-risk group (T1/T2 N0): PMRT not routinely recommended; intermediate-risk group (T1/T2 N1): PMRT controversial; high risk group (T3-T4 and/or N2-N3): PMRT recommended. We further investigated factors leading to potential overtreatment (PMRT in low-risk group) or undertreatment (absence of PMRT in high-risk group). Data analysis was performed for the entire cohort, and separately for patients <70 years and ≥ 70 years of age. Probability of receiving PMRT was assessed using multivariable logistic regression.

Results: A total of 421 patients (29.9%) received adjuvant RT after mastectomy. The rate of PMRT delivery was 67% in the high-risk group, compared to 6% and 18% in the low-risk and intermediate-risk groups, respectively.

For patients at high-risk of chest wall recurrence after mastectomy (T3-T4 or N2-N3 disease), the risk of PMRT omission was significantly associated to older age (OR 4.25 [95% CI: 2.27-7.95] for patients ≥ 70 years) and to the absence of chemotherapy (OR 4.30 [95% CI: 1.97-9.36]). In patients with T3-T4 disease, PMRT was delivered in 77% of patients < 70 years and in 42% of patients ≥ 70 years (p<0.001). In patients with N2-N3 disease, PMRT was delivered in 82% of patients < 70 years and in 51% of patients ≥70 years (p<0.001).

PMRT was delivered to 28 patients (7%) at low-risk of recurrence after mastectomy (T1-T2 N0, negative margins). It was more frequently offered to patients <40 years of age (OR 3.86 [95% CI: 1.01-14.76]), with T2 tumors (OR 3.43 [95% CI: 1.45-8.11]) and negative hormone receptor status (OR 2.60 [95% CI: 1.04-6.50]).

Positive or close surgical margins (< 1mm) were a strong indicator for PMRT (p=0.001) and chest wall boost (p<0.03).

Conclusions: After mastectomy, one third of patients (33.26%) with high-risk disease did not receive PMRT. Even if we consider only patients < 70 years, a non-trivial proportion of patients with clear indication for treatment delivery did not receive PMRT (T3-T4 disease: 23%; N2-N3 disease: 18%). Further analyses are planned to explain the apparent failure of evidence-based guidelines to impact the adoption of PMRT in women with high-risk breast cancer.
**Title:** Real-world use and outcomes of trastuzumab for HER2+ metastatic breast cancer in Australia: Analysis of the herceptin program, 2001-2015

Benjamin Daniels¹, Belinda E Kiely², Sarah J Lord²,³, Nehmat Houssami⁴ and Sallie-Anne Pearson¹. ¹Medicines Policy Research Unit, Centre for Big Data Research in Health, University of New South Wales, Sydney, NSW, Australia; ²NHMRC Clinical Trials Centre, University of Sydney, Sydney, NSW, Australia; ³School of Medicine, University of Notre Dame Australia, Sydney, NSW, Australia and ⁴Sydney School of Public Health, Sydney Medical School, University of Sydney, Sydney, NSW, Australia.

**Body: Aims**
Between December 2001 and July 2015 Australian women with HER2-positive metastatic breast cancer (MBC) accessed trastuzumab in combination with taxane chemotherapy or as monotherapy via the government funded Herceptin Program (HP); we characterise their treatment patterns and survival outcomes.

**Methods**
This retrospective, whole-of-population cohort study used linked dispensing, medical services, and death records. We stratified patients into three year-of-trastuzumab-initiation groups: 1. 2001-2002 (may include patients accessing trastuzumab in later lines); 2. 2003 - October 2006 (likely first-line treated but prior to trastuzumab availability for early breast cancer (EBC)); and 3: October 2006–June 30 2015 (most representative of contemporary practice). Patients were observed until death or censored at June 30 2016.

We estimated duration of trastuzumab therapy from the initial dispensing date for MBC until 30 days after the last dispensing. We considered a gap of ≥90 days between trastuzumab dispensings a separate course of treatment. We estimated overall survival (OS) as the time from first trastuzumab dispensing until death from any cause. We used Kaplan-Meier methods to estimate the total duration of trastuzumab therapy and OS. We used dispensing dates of cancer medicines to determine concomitant treatments and used claims for echocardiography and MUGA scans to determine the timing of cardiac monitoring.

**Results**
5,895 patients accessed trastuzumab for MBC. Median age at trastuzumab initiation was 57 years (IQR: 48 – 66). 800 patients (22%) from Group 3 also received trastuzumab for EBC. Treatment details and OS are tabulated:

Conclusions

Our real-world estimates of OS for each patient group are both similar to and shorter than those from clinical trials published during similar time periods. Group 3 median OS is 6 months shorter than the control arm of the CLEOPATRA study (34.6 v 40.8 months) while median duration of first trastuzumab course was 4 months longer (14.0 v 10.4 months), suggesting patients continue trastuzumab beyond progression. In Group 3, 25% of patients died within 15 months of starting trastuzumab, 50% survived beyond 3 years and 25% survived beyond 7 years. These estimates will be useful for clinicians discussing expected survival time with patients in routine practice. Although the cardiotoxicity of trastuzumab is well recognised, baseline cardiac assessment was not universal, even in the most recent cohort.
Title: Is breast-conserving therapy effective in women with large ductal carcinoma in situ (DCIS) lesions? A population-based analysis

Nafisha Lalani1,2,3, Lawrence Paszat1,2,3, Sharon Nofech-Mozes2,4, Rinku Sutradhar1, Sumei Gu2, Wedad Hanna2,4, Cindy Fong3, Naomi Miller4,5, Bruce Youngson1,5, Susan J Done1,5, Alan Tuck6, Martin C Chang7, Sandip Sengupta8, Prashant A Jani9, Michel Bonin10 and Eileen Rakovitch1,2,3. 1University of Toronto, Toronto, ON, Canada; 2Sunnybrook Health Sciences Centre, Toronto, ON, Canada; 3Institute of Clinical Evaluative Sciences, Toronto, ON, Canada; 4University of Toronto, Toronto, ON, Canada; 5University Health Network, Toronto, ON, Canada; 6London Health Sciences Centre, Toronto, ON, Canada; 7Mount Sinai Hospital, Toronto, ON, Canada; 8Queen's University, Kingston, ON, Canada; 9Thunder Bay Regional Health Sciences Centre & Northern Ontario School of Medicine, Thunder Bay, ON, Canada and 10Sudbury Regional Hospital, Sudbury, ON, Canada.

Body: Background: Most women diagnosed with DCIS will be treated by breast-conserving surgery (BCS) with or without radiotherapy (RT). Data on outcomes following breast-conserving therapy are predominantly based on women with small (<25mm) lesions. The paucity of data on outcomes of women with larger (>40mm) DCIS lesions leads to uncertainty of the appropriateness of breast-conserving therapy for women with larger lesions. Specifically, it is unclear if women with large tumors experience higher risks of local recurrence (LR) and invasive LR after BCS +/- RT that would preclude recommendations of breast-conserving therapy. We report the outcomes and evaluate the impact of large tumor size (>40mm) on recurrence risk in a population of women with pure DCIS treated by BCS alone or with RT.

Methods: The cohort includes all women diagnosed with DCIS in Ontario from 1994-2003 treated with BCS +/- RT; 82% had pathology review. Treatment and outcomes were ascertained through administrative databases and validated by chart review. Cox proportional hazards model was used to evaluate the impact of tumor size (≤10mm, 11-25mm, 26-39mm, ≥40mm) on the development of any LR (DCIS or invasive) and invasive LR. The 10 and 15-year LR-free survival (LRFS) and invasive LRFS rates were calculated using the Kaplan-Meier method with differences compared using the log-rank test.

Results: The cohort includes 3262 women with DCIS treated by BCS (N=1635 had RT). Median age at diagnosis was 59 years (IQR 50-68 years). Median follow-up was 13 years (IQR 8-15 years). Distribution of tumor size: 707 (22%) ≤10mm, 524 (16%) 11-25mm, 107 (3%) 26-39mm, 84 (3%) ≥40mm, unable to determine in 1840 (56%). Women with lesions ≥40mm were more likely to be ≤50 years of age at diagnosis (p=.02), have high nuclear grade (p<.001), multifocality (p<.001), and positive margins (p<.001) compared to women with smaller lesions. On multivariable analyses adjusted for age and year of diagnosis, tumor size ≥40mm was significantly associated with an increased risk of LR compared to size ≤10mm (HR=2.5, 95%CI:1.64-3.81). Other factors associated with LR were age ≤50 years (p<.001), omission of RT (p<.001), high nuclear grade (p=.002), and multifocality (p=.0008). Tumor size ≥40mm was not significantly associated with an increased risk of invasive LR (HR=1.68, 95%CI:.94-3.04). Women with tumour size ≥40mm treated with BCS alone had lower 10 and 15 year LRFS (53% and 41%) and invasive LRFS rates (78% and 75%) compared to women with smaller lesions. However, women with larger lesions treated with RT had significantly higher LRFS and invasive LRFS rates.

There was a significant interaction between tumor size ≥40mm and RT (p=.02).

**Conclusions:** Women with DCIS lesions ≥40mm treated by BCS alone experience significantly higher risks of LR and invasive LR compared to smaller lesions but this risk can be mitigated with the addition of RT.
Impact of the SSO-ASTRO consensus guidelines on invasive margins on the re-excision rate among patients undergoing breast conserving surgery (BCS)

Mariana Chavez-MacGregor, Xiudong Lei, Monica Morrow and Sharon H Giordano. 1The University of Texas MD Anderson Cancer Center, Houston, TX and 2Memorial Sloan Kettering Cancer Center, NY, NY.

Background: BCS has been historically associated with a high re-excision rate, driven in part by lack of consensus on what constitutes an adequate negative margin. The SSO-ASTRO consensus guideline on invasive margins defined a negative margin as no ink on tumor based on evidence suggesting that more widely clear margins do not further decrease the risk of recurrence, potentially reducing the need for re-excision. In a large nationwide cohort of breast cancer patients undergoing BCS for invasive breast cancer we evaluate the rates of re-excision following BCS before and after the SSO-ASTRO consensus guidelines were disseminated.

Methods: Breast cancer patients undergoing BCS for invasive breast cancer between January 2012 and December 2015 were identified among female beneficiaries in the MarketScan database. Patients receiving chemotherapy before surgery were excluded. Based upon presentation of the guideline recommendations in October 2013, the pre-guideline period was defined from January 2012 to September 2013. On-line publication of the guideline in February 2014 led to definition of the post-guideline period from March 2014 onwards. The peri-guideline period was defined as the time between the pre and post-guideline intervals. Any re-excision or mastectomy within 3 months of initial BCS was identified using ICD-9 or CPT codes. Overall re-excision rates and 95% CI were calculated; groups were compared using X² test. We used a regression model to evaluate the association between pre-peri-post guideline period and re-excision while adjusting for important covariates. Results are expressed as risk ratios (RRs) and 95% CI.

Results: A total of 38,573 patients were included (20,159 in the pre-guideline, 4,607 peri-guideline and 13,807 post-guideline). The overall re-excision rate was 23.9% (95% CI 23.4-24.3). The pre-guideline re-excision rate was 25.3% (95% CI 24.7-29.9) compared to 21.6% (95% CI 20.9-22.3) in the post-guideline period (p<0.001). The rate of mastectomy as the final surgical procedure was 20.2% in the pre-guideline period and 19.1% in the post-guideline (p=0.15). We observed significant geographic variability by state in the decrease of the re-excision rates. No change in re-excision rates was seen in Mississippi, Vermont, Georgia, Oregon, West Virginia, Arkansas, Oklahoma and Tennessee. An absolute decrease greater than 10% in the re-excision rate was observed in Indiana, Nebraska, Alabama, Maine and Nevada. In the multivariable analysis, patients undergoing BCS in the post-guideline period had a statistically significant decrease in the risk of re-excision compared to patients undergoing surgery in the pre-guideline period (RR=0.87; 95% CI 0.84-0.91; p<0.001).

Conclusions: There has been a statistically significant decrease in the re-excision rate after BCS associated with the time of the dissemination of the SSO-ASTRO consensus guideline on invasive margins. The wide geographical variation observed suggests differences in the adoption rates. Our study confirms the impact that guidelines have modifying patterns of practice, reducing the frequency of unnecessary surgical interventions.
Objective: Neoadjuvant chemotrapy (NACT) is the preferred option of treatment in locally advanced and select cases of early stage breast cancer, currently. One of the major aims is to downstage tumor status allowing more conservative surgery with the most acceptable cosmetic outcome. The presence or absence of residual invasive cancer after NACT, is one of the strong prognostic factors for risk of recurrence and the margin status is the other. Due to the excess degree of fibrosis after tumor shrinkage, to accurately predict margin status intraoperatively after NACT is a challenge for surgeon. The aim of the presented study is to evaluate the efficacy of continuous intraoperative ultrasound guided breast conserving surgery (IUG-BCS) in terms of margin status and re-excision rate. The relationship between intraoperative assessment of gross macroscopic and ultrasonographic margins and cavity shavings results, were also analyzed.

Methods: Between 2014 and 2017, IUG-BCS were performed to 194 patients after NACT. Surgeon performed continuous peroperative real-time sonographic margin assessment during resection, macroscopic evaluation, specimen US including sonographic analysis of six faces of each specimen, and shaved cavity margins for permanent pathologic assessment were the standard steps of our methodology.

Results: Of the 194 patients, 82 (42.5%) had pathologic complete response (pCR) after NAC. The sensitivity of intraoperative ultrasound localization was 100% (194/194 cases). Patients were on average 53 years old (range, 28-65). There was no difference with respect to patient characteristics including age, menopausal status, personal-family history, oral contraceptive usage, body mass index and tumor localization. Mean tumor size was 5.42 cm before NAC and 2.56 cm after NAC, for those excluding ypT0. Of the 112 patients without pCR, tumor free margins were obtained by means of IUG-BCS in 99% (665/672) of margins evaluated sonographically. Moreover, the involved margins were correctly identified by the surgeon via specimen sonography in %71.4 of the cases (5/7) which was confirmed by cavity shaving results. No frozen section analysis was performed and macroscopic evaluation of the specimen predicted nothing significant. According to permanent section analysis of the resected specimens and cavity shavings, no further intervention was required due to margin positivity. IUG-BCS with real-time specimen sonography were unable to predict involved margins in only two cases, both of them proved to be invasive lobular carcinoma without evidence of residual cancer on pathological examination of cavity shavings. Accordingly, negative margins were achieved in 100% of cases at the initial procedure verified by permanent analysis.

Conclusion: Continuous intraoperative ultrasound with specimen sonography is an invaluable and effective modality to achieve negative surgical margins after NACT. Furthermore, meticulous sonographic assessment of specimen margins together with cavity shavings from tumor bed could be a feasible method to decrease re-excision rates without frozen section analysis leading to cost-effectiveness. However, the accuracy of sonography should be questioned in case of lobular histology.
Title: Real-time, intraoperative detection of residual breast cancer in lumpectomy cavity margins using the LUM imaging system: Results of a feasibility study

Conor R Lanahan¹, Michele A Gadd¹, Michelle C Specht¹, Jorge Ferrer², Rong Tang¹, Upahvan Rai¹, Andrea L Merrill¹, Anna Biernacka¹, Elena Brachtel¹ and Barbara L Smith¹. ¹Massachusetts General Hospital, Boston, MA and ²Lumicell, Wellesley, MA.

Body: Background: Obtaining tumor-free margins is critical for local control in breast conserving surgery. Currently, 20-40% of lumpectomy patients have positive margins that require surgical re-excision. We assessed the LUM Imaging System for real-time, intraoperative detection of residual tumor in breast cancer patients. The LUM System has the particular advantage of assessing in vivo lumpectomy cavity walls rather than excised specimens, to enable more accurate excision of residual tumor.

Methods: Lumpectomy cavity walls of patients undergoing lumpectomy for invasive breast cancer or ductal carcinoma in situ (DCIS), were assessed intraoperatively using the LUM Imaging System (Lumicell Inc., Wellesley MA). LUM015, a cathepsin-activatable fluorescent agent, was given IV 4±2 hrs prior to surgery. Areas of fluorescence generated at potential sites of residual tumor in lumpectomy cavities were evaluated with a sterile hand-held device, displayed on a monitor, excised and correlated with histopathology.

Results: In vivo lumpectomy cavities were imaged with the LUM Imaging System in 60 breast cancer patients. 5 were imaged without dye. 55 received LUM015 dye preoperatively and were scanned intraoperatively. Median age was 60 years (range 44-79). Mean tumor size was 1.2cm (0.06-3.5cm) with 71% invasive cancers, 29% DCIS. The test set included 569 cavity margin surfaces assessed intraoperatively and excised. Image acquisition for each margin took approximately 1 second. The LUM Imaging System showed 100% sensitivity and 73% specificity for detection of tumor <2mm from the margin. Invasive ductal cancer (IDC), invasive lobular cancer (ILC) and areas of DCIS 1mm in size could be identified. 8 patients had positive margins on standard histopathology analysis (Table). The LUM System correctly identified all positive margins identified by standard histopathology and correctly predicted negative re-excisions in 2 of 8 patients. There were no serious adverse events. 1 patient had extravasation of LUM015 at her injection site with temporary blue skin staining but no other complication.

Conclusions: The LUM Imaging System allows real-time identification of residual tumor in the lumpectomy cavity of breast cancer patients. No sites of residual tumor were missed. Additional studies are underway to optimize this approach for reducing positive margins and second surgeries in breast cancer patients.

Title: Re-excision rates in breast conserving surgery for invasive breast cancer after neoadjuvant chemotherapy with and without the use of a radiopaque tissue transfer and X-ray system

Hans-Christian Kolberg¹, Leyla Akpolat-Basci¹, Miltiades Stephanou¹, Sarah Wetzig¹, Yüksel Cubuk², Johannes Gerharz² and Cornelia Liedtke³. ¹Marienhospital Bottrop, Klinik für Gynäkologie und Geburtshilfe, Bottrop, Germany; ²Marienhospital Bottrop, Klinik für Radiologie, Bottrop, Germany and ³Charite - Universitätsmedizin Berlin, Klinik für Gynäkologie, Berlin, Germany.

Body: Background: Published re-excision rates after breast conserving surgery for invasive breast cancer vary between 20 and 50%. In patients after neoadjuvant chemotherapy even higher re-excision rates may result from difficulties in defining the surgical target particularly in cases with excellent treatment response. Specimen radiography is reducing re-excision rates, however, defining involved margins is often difficult using standard approaches. Devices allowing horizontal and vertical examination and an exact topographic localization of the lesion in the resected tissue could reduce re-excision rates by an intraoperative detection of involved margins.

Methods: 80 patients with invasive breast cancer receiving breast conserving surgery after neoadjuvant chemotherapy and an indication for wire marking by mammography were included in this analysis. All tumors were marked with titanium clips prior to chemotherapy. In 40 patients specimen radiography was performed in a standard approach (control group), in 40 patients a tissue transfer and X-ray system based on a non-radiopaque board with radiopaque topographic markers and a stand for cranio-caudal X-rays was used (study group). A univariate analysis was carried out to evaluate the association between the use of the radiopaque tissue transfer system and the re-excision rate using a logistic regression model. Calculations were performed using the XLSTAT Biomed Software (Version 19.03, Addinsoft, NY, USA.).

Results: 19/80 patients (23.75%) required re-excision because of involved margins; among those patients, 14/40 (35%) were in the control group and 5/40 (12.5%) in the study group. The association between the use of the radiopaque tissue transfer system and the lower re-excision rate was statistically significant (p=0.023).

Conclusion: Our analysis provides a rationale for the use of a radiopaque tissue transfer system for specimen radiography in breast conserving surgery after neoadjuvant chemotherapy for invasive breast cancer in order to reduce re-excision rates. Based on these results we are planning a study including also patients receiving primary surgery.
Local recurrence of breast cancer: Salvage lumpectomy as a safe option for local treatment

Yael Sellam¹, Merav Akiva Ben David², Shira Galper², Ilanit Dromi Shahadi², Douglas Zippel², Zvi Symon² and Ilana Gelernter¹.
¹Tel Aviv University, Tel Aviv, Israel and ²Sheba Medical Center, Ramat Gan, Israel.

Body: Introduction: The best local management for breast cancer recurrence following conservative treatment for breast cancer (BC) continues to be an open question. In this study, we compared patients' outcome after salvage lumpectomy vs. patients who underwent mastectomy for ipsilateral breast tumor recurrence (IBTR).

Materials and methods: Between 1987 and 2014 we identified 121 patients with pT₀-2, N₀-3, M₀ BC who had breast conserving surgery and radiation as their primary treatment, and subsequently had IBTR (unifocal). 47 patients underwent salvage lumpectomy (SL) and 74 salvage mastectomy (SM) as the local treatment for their 1st recurrence.

Results:
Median follow-up was 14 years (2-30) from first BC diagnosis. All consecutive identified patients, 121, were included in the study. At 1st recurrence, 47 patients (39%) chose to undergo SL for their IBTR, and 74 patients (61%) opted for SM. The mean age at 1st diagnosis of BC for SL group and SM, was 52 and 47 years, respectively (p=0.006). With similar T in both groups, most patients had T1 (43%), and T2 (34%) at first diagnosis (p=0.722). The women who opted later for SM had more ALND surgery (58% vs. 33%, p=0.023) and received more neoadjuvant chemotherapy (20% vs. 4%, p=0.022) at their first BC diagnosis.

The median DFI at 1st recurrence for SL and SM group was 12 and 7 years, respectively (p=0.011). 51 local recurrences (41%) were true recurrences by location and histology. In the SL group, 78% had a documented discussion (consideration for SL vs. SM) with a surgeon/oncologist/radiation oncologist prior to surgical decision, and 70% underwent a breast MRI before final decision. Only 45% in the SM group had a discussion and 59% underwent MRI before the decision. Following surgery for their recurrence, sixteen women (34%) of SL group underwent re-irradiation (partial breast RT) and 20 (27%, p=0.04) in the SM group (chest wall scar).

For the SL and SM cohorts, 8 and 10 patients (17%, 13.5%, p=0.22) respectively, developed subsequent local recurrence as a 3rd event. The median DFI between 2nd and 3rd recurrence for SL and SM was 6.5 and 15.5 years, respectively (p=0.081). In a multivariate analysis, age at 1st diagnosis, T at 1st and 2nd recurrence, number of dissected/+ve LN, grade, type of axillary surgery as well as neo/adjuvant chemotherapy and HER2 status (both in primary and at recurrence), had no effect on 2nd recurrence occurrence for both groups; however, in MVA, undergoing SL had higher chances of having a 2nd recurrence (3rd event), p=0.020. Having re-irradiation following SL did not protect against 2nd recurrence (3rd event, p=0.42).

At a median follow-up of 14 years, 95.7% of SL patients are alive, NED, 85% are mastectomy free. 84% of patients who opted for SM are alive, NED.

Conclusions: Salvage lumpectomy following IBTR, while associated in MVA with higher second local recurrence rate than SL is not associated with inferior survival. With survival >95% at 14 years in the SL cohort, salvage lumpectomy with or without re-radiation, in a selected population (unifocal T), represents an acceptable treatment option for patients in order to delay time to mastectomy and keep the original breast without reducing BC survival. Both options should be discussed prior to any surgical decision.
Title: Rates of re-excision surgery after implementation of consensus guidelines on margins for breast-conserving surgery in stage I and II invasive breast cancer: A Nova Scotian experience

Ashley E Drohan¹ and Lucy K Helyer¹,². ¹Dalhousie University, Halifax, NS, Canada and ²IWK Health Centre, Halifax, NS, Canada.

Body: Background: In Canada, most women with early invasive breast cancer will be treated with breast-conserving surgery (BCS). The proportion of patients requiring re-excision surgery after BCS varies province to province. Until recently, there was no universally accepted definition for adequate margin width following BCS. The Society of Surgical Oncology (SSO) and American Society for Radiation Oncology (ASTRO) published consensus guidelines in 2014 to help regulate practice. The objective of this study was to determine the proportion of patients undergoing re-excision surgery before and after guideline implementation at our institution.

Methods: We performed a retrospective review of all patients with invasive breast cancer and/or ductal carcinoma in situ (DCIS) who underwent re-excision surgery between October 1, 2010- October 31, 2011 (pre-guideline) and October 1, 2014- May 30, 2016 (post-guideline). The proportion of patients requiring re-excision surgery was calculated for each time period and patient characteristics and clinical outcomes were compared.

Results: There were 188 patients identified who underwent BCS in the pre-guideline time period and 411 patients in the post-guideline time period. The proportion of patients undergoing re-excision surgery significantly decreased from 13.8 % to 7.8 % after guideline implementation (p = 0.02). Patient characteristics were similar between those who underwent re-excision before and after guideline implementation. In patients requiring re-excision surgery, histological and pathological features were similar between time periods. Margin width and indication for re-excision surgery varied between time periods. Among women who had re-excision surgery in the pre-guideline group, most (50%) had an invasive cancer margin > 1 mm. However, after guideline implementation, a frankly positive invasive cancer margin was the most common indication for re-excision surgery (65%). No significant differences in clinical outcomes were observed between patients who underwent re-excision surgery before and after guideline implementation.

Conclusion: The proportion of patients undergoing re-excision surgery after BCS has significantly decreased after SSO-ASTRO guideline implementation at our institution. This data suggests that among women with invasive breast cancer and/or DCIS, the implementation of SSO-ASTRO guidelines has led to a 43.5% decline in re-excision surgery.
Body: Introduction. In patients with advanced breast cancer, neoadjuvant chemo-therapy is performed to increase breast conserving surgery. Although MRI is known to be accurate in predicting residual cancer after treatment, if calcification remains, the issue of whether to perform surgery based on the residual tumor prediction range in mammography and MRI has not yet been solved. The objective of this study was to estimate the accuracy of residual mammographic (MMG) microcalcification and enhancing lesion in magnetic resonance imaging (MRI) in predicting residual tumor after neoadjuvant systemic treatment (NST).

Method. This is a single-center, retrospective study. We included patients with breast cancer who underwent NST and have microcalcifications in the post NST mammogram and had the surgery from January 2, 2013 to December 30, 2014. All the patients had post NST imaging exams of MMG and MRI. Final pathologic tumor size with histopathology and biomarker status was obtained after surgery. Analysis of correlation between image findings and pathology was evaluated.

Result. Of 151 patients that were included in this study, 125 patients (82.8%) had residual invasive tumor and 26 patients (17.2%) had pathologic complete response. In overall, MRI correlated better than MMG in predicting tumor size (intraclass correlation coefficient [ICC] = 0.769 vs 0.651), but for HR+/HER2- subtype, MMG had higher correlation than MRI (ICC = 0.747 vs 0.575). Specially in HR- subtype, MRI had strong correlation with pathology (ICC for HR-/HER2+ = 0.939 and TN = 0.75), while MMG tend to overestimate the tumor size (ICC for HR-/HER2+ = 0.543 and TN = 0.479).

Discussion. Overall post-NST residual microcalcifications on MMG have lower correlation with residual tumor size than MRI. In other than HR+/HER2- subtype, the extent of calcifications on pre-OP evaluation may not be accurate in evaluating the residual extent of the tumor after NST.
Title: Does breast density increase the risk of re-excision for women with breast cancer having breast conservation therapy?

Siun M Walsh¹, Sandra B Brennan², Emily Zabor³, Laura H Rosenberger¹, Michelle Stempel¹, Lizza Lebron-Zapata² and Mary L Gemignani¹. ¹Memorial Sloan Kettering Cancer Center, New York, NY; ²Memorial Sloan Kettering Cancer Center, New York, NY and ³Memorial Sloan Kettering Cancer Center, New York, NY.

Body: Background

The definition of an adequate surgical margin for breast cancer has been a hotly debated topic for over 20 years, with “no ink on tumor” now widely recognized as an adequate pathological margin for invasive carcinoma. Patients with dense breasts pose unique challenges in terms of accurate pre-operative evaluation of extent of disease and achieving adequate margins at initial surgery. The aim of this study therefore is to analyze re-excision rates and correlate with breast density and other clinical and pathological factors before and after the decision to accept 'no tumor at the inked margin” as an adequate margin.

Methods

Patients with stage I or II invasive breast cancer treated with breast conserving surgery between the 1st of June 2013 and the 31st of October 2014 were included. Patients who had surgery prior to January 1, 2014 comprise the pre-guideline group whereas those who had surgery on or after January 1, 2014 comprise the post-guideline group. Breast density was assessed by 2 independent radiologists. Inter-reader agreement was assessed using data on all study subjects and intra-reader agreement was assessed on a random sample of 121 study subjects; agreement was assessed using the kappa statistic with bootstrap confidence intervals. Logistic regression was used to model the association between breast density and re-excision, using the minimum value of breast density according to the two independent readers, within the 2 time periods. Multivariable logistic regression adjusted for patient and disease characteristics associated with re-excision on univariable analysis.

Results

The inter-reader agreement was 0.633 (95% confidence interval (CI): 0.604, 0.663) whereas the intra-reader agreement was 0.755 (95% CI: 0.663, 0.834). A total of 1205 patients were included, of whom 504 (41.8%) had surgery before the guideline change and 701 (58.2%) after. Overall 214 (17.8%) had at least one re-excision. The re-excision rate was significantly lower in the time period after the guideline change (15.1% versus 21.4%, p=0.006). There was no significant difference in tumor characteristics between the time periods. Younger age at diagnosis was the only clinicopathological factor that was significantly associated with increased breast density (p<0.001). On univariable analysis, increased breast density was associated with higher risk of re-excision (p=0.005), as was younger age, multifocality, presence of DCIS, HER2 status and extensive intraductal component (EIC). On multivariable analysis, time period, age at diagnosis, multifocality, presence of DCIS and EIC were significantly associated with re-excision, but breast density was not (OR 1.24, 95% CI 0.98-1.56, p=0.07).

Conclusions

Women who are of younger age at diagnosis are more likely to have increased breast density. Although, younger age was associated with higher rate of re-excision, we did not find breast density to be associated with a higher rate of re-excision on multivariable analysis.
Title: Does conservative surgery treatment for locally advanced breast cancer safe after neoadjuvant treatment?

Gabriela Boufelli1, Bruna Salani Mota1, Flavia Cardoso Franca1, Maira Teixeira Doria1, Jonathan Yugo Maesaka1, Marcos Desiderio Ricci1, José Roberto Morales Piato1, Fernanda Barbosa Coelho Rocha1, Aricia Helena Galvão Giribela1, Rodrigo Gonçalves1, Sergio Masili-Oku1, Max Senna Mano1, Luciano Fernandes Chala1, Bruna Maria Thompson1, Aricia Helena Galvão Giribela1, Rodrigo Gonçalves1, Sergio Masili-Oku1, Max Senna Mano1, Luciano Fernandes Chala1, Bruna Maria Thompson1, Edmund Chada Baracat1 and Jose Roberto Filassi1. 1Instituto do Câncer do Estado de São Paulo, Hospital das Clínicas, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.

Body: BACKGROUND:
The aim of this study was to assess the oncological efficacy of breast conserving surgery (BCS) after neoadjuvant chemotherapy in patients with local advanced breast cancer.

PATIENTS AND METHODS:
A retrospective cohort study was conducted with locally advanced breast cancer invasive (Stage IIb to III) treated at ICESP, an oncologic referral center between 2008 and 2016. Endpoints were disease free survival (DFS), local disease free survival (LDFS) and overall survival (OS). Multivariable analyses were performed using Cox proportional hazards models.

RESULTS:
530 patients were included, 26% (138) were stage IIB, 41.9% (222) IIIA, 29.6% (157) IIIB and 2.5% (13) IIIA. 88.8% (470) were invasive ductal carcinoma. The mean age was 51.5(23-95). 95.5% and 4.5% were submitted Neoadjuvant Chemotherapy and Hormone therapy, respectively. The BCS were performed in 24.5% (130) patients versus 75.5% (400) of mastectomies. The mean follow up was 36.4(0.16-80.2) months. There were no differences in local disease free-survival 59 (95%CI 58-61) versus 60 (95%CI 57-60); p=0.4 and overall survival 56.2 (95%CI 52-60) versus 59.3(95%CI 53-65); p= 0.24 for mastectomy and BCS. The disease free survival was lower at mastectomy group 51.4 (95%CI 49-53) versus 56,8 (95%CI 53-59); p=0.01. Logistic regression models were significant only for cancer stage both patterns, although the results were better for masses, particularly when kinetic assessments were included (LR 12.8; p = 0.005)

CONCLUSION:
In our population, the BCS does not affect the overall and local disease-free survival rates, which seems to be safe to perform in patients who desire to conserve the breast after neoadjuvant treatment.

Title: Identifying optimal candidates for three-dimensional bioabsorbable marker placement during breast cancer treatment: Incidence and predictors of postoperative complications

Benjamin C Foster¹, Theresa A Graves¹, Charu Taneja¹, Doreen L Wiggins¹, Jaroslaw T Hepel¹, David E Wazer¹ and Kara L Leonard¹. ¹Rhode Island Hospital, Providence, RI.

Body: OBJECTIVES: Radiation therapy (RT) is often an integral component of postoperative breast cancer management. Three dimensional (3D) bioabsorbable markers have been designed to assist CT-based tumor bed targeting during the RT process. There have been limited reports detailing complications following placement of such devices. This retrospective analysis attempts to identify demographic and treatment characteristics associated with complications after 3D bioabsorbable marker placement in a cohort of breast cancer patients treated at an academic medical center. METHODS: Records of 160 patients receiving a 3D bioabsorbable marker during initial breast surgery for DCIS or breast cancer were reviewed. Ten devices were removed at subsequent re-excision or mastectomy; therefore, 150 patients were ultimately evaluable. Demographic, tumor and operative/treatment characteristics were collected. Variables including body mass index (BMI), diabetes mellitus (DM), smoking, chemotherapy or RT use and excision volume (EV) were analyzed using multivariable logistic regression analysis (MVA). Endpoints included reoperation for wound complications (re-op), receipt of postoperative antibiotics (abx) and clinically palpable 3D bioabsorbable marker. RESULTS: Median follow-up was 8.2 months. Six (6/150, 4%) patients required re-op for wound complications and 5 required 3D bioabsorbable marker removal due to complications. Twenty (20/150, 13.3%) patients received abx for clinically detected postoperative wound infections. At last follow-up, 61 (61/150, 40.6%) patients noted persistent perceived fullness of the device at the lumpectomy site, and the 3D bioabsorbable marker remained palpable by the physician in 95 (95/150, 63.3%) patients. On MVA, DM and larger EV were associated with greater rates of re-op (p=0.020 and 0.012, respectively, Table 1). Mean EV was 279 cc among the re-op cohort and 85.5 cc among the no re-op cohort. DM, receipt of chemotherapy and larger EV were associated with postoperative abx prescription (p=0.005, 0.009 and 0.005, respectively, Table 2). Mean EV was 169.6 cc among those who received abx and 81.5 cc among those who did not. Larger EV was the only statistically significant predictor of a clinically palpable bioabsorbable marker during follow-up (p=0.044).

CONCLUSIONS: Rates of re-op for wound complications (4%) and postoperative infection (13.3%) were higher than expected among this cohort receiving 3D bioabsorbable markers, and were relatively high compared to historical surgical series managed without such devices. The present analysis suggests that those with larger EV, DM or receiving chemotherapy may be at greater risk for post-operative complications when a 3D bioabsorbable marker is placed. These factors should be considered when assessing candidacy for device placement.
Title: Does close margin of ductal carcinoma in situ associated with invasive breast carcinoma affect breast cancer recurrence?

Bekir Kuru¹, Savas Yuruker¹, Yurdanur Sullu¹, Bilge Gursel¹ and Necati Ozen¹. ¹Ondokuz Mayis University School of Medicine, Samsun, Turkey.

Body: Background and aims: The Society of Surgical Oncology (SSO) and the American Society for Radiation Oncology (ASTRO) consensus guidelines regarding surgical margin for patients with stage 1, 2 invasive breast cancers (IBC) associated with or without ductal carcinoma in situ (DCIS) undergoing breast conserving therapy (BCT) recommend that no ink on tumor is standard for an adequate margin and for low risk of local recurrence. However, what constitutes the adequate margin width for DCIS associated with IBC is controversial, and there are not sufficient studies on the issue. Our aim was to determine if the close surgical margin (that is, < 2 mm, but no ink on tumour) for DCIS associated with IBC leads to increased rate of local recurrence.

Material and Methods: Six hundred and twenty-eight patients with T1-2 IBC that underwent BCT and had no ink on tumour between 2009 and 2017 in our institution were included in the study. Patients who received neoadjuvant chemotherapy were excluded from the study. Age, tumour size, axillary lymph node status, resection margin status of DCIS as close than 2 mm or ≥ 2 mm, association of DCIS as present or absent, extent of extensive intraductal component (EIC) as yes or no were investigated. All patients were followed up for ipsilateral local breast recurrence.

Results: The median age was 50 (range, 29-82), and median tumor size was 25 mm (range, 5-50). Median follow up time was 46 months (range, 5-99). Of the 628 patients, 440 (70%) were found to be associated with DCIS, and 94 (15%) were associated with EIC. Of the 440 patients with DCIS, 119 (27%) had close surgical margin (<2 mm), and 321 (73%) had ≥ 2 mm surgical margin for DCIS.

Among 440 patients with DCIS associated with IBC, 3 local recurrences developed. One of the local recurrences developed in a patient who had close surgical margin for DCIS, and in other 2 patients surgical margins were ≥ 2 mm. One of 2 patients with surgical margin of ≥ 2 mm had also EIC.

Conclusions: No ink on tumour is adequate margin for DCIS associated with IBC in patients who underwent BCT and is not associated with increased ipsilateral breast cancer recurrence.
Title: ReFilx- synthetic biodegradable soft tissue fillers for breast conserving surgery in breast cancer

Wey Liang Leong¹,4,6, Soroor Sharifpoor³, Kyle Battiston⁷, Dan Charleton⁶, Mark Corrigan⁶, David R McCready¹,6, Susan J Done⁴,⁵ and J Paul Santerre²,3,7. ¹Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada; ²Institute of Biomaterials and Biomedical Engineering, University of Toronto, Toronto, ON, Canada; ³Translational Biology and Engineering Program, University of Toronto, Toronto, ON, Canada; ⁴Campbell Family Institute of Breast Cancer Research, University Health Network, Toronto, ON, Canada; ⁵Laboratory Medicine Program, University of Toronto, Toronto, ON, Canada; ⁶University of Toronto, Toronto, ON, Canada; ⁷Faculty of Dentistry, University of Toronto, Toronto, ON, Canada; ⁸Cork Breast Research Centre, Cork, Munster, Ireland and ⁹Grand River Hospital, Kitchener, ON, Canada.

Body: Introduction: Breast conserving surgery (BCS) is the most common procedure performed in breast cancers, but it can often result in breast deformities that can have negative impacts on quality of life. With better treatments, more breast cancer survivors are expected to live longer, the demand for achieving optimal cosmetic outcomes has also increased accordingly. Currently, oncoplastic techniques involving local tissue rearrangement with or without contralateral balancing procedures are used in specialized centers to achieve breast symmetry in some patients. When a breast deformity occurs, corrective options include: fat grafting, autologous flap procedures and completion mastectomy with immediate reconstruction. These techniques have long operative times, longer length of hospital stay and higher complication rates. Commercially-available synthetic implants are fabricated in pre-determined sizes and thus are not suitable to reconstruct partial breast deformities of varying size and shape. We explored the use of amino-acid based biodegradable polyurethanes as tissue fillers for BCS due to their chemical versatility, superior mechanical properties and tailored biocompatibility. Objective: To evaluate novel biodegradable polymer constructs, referred to as ReFilx, as soft tissue fillers for BCS defects. Hypothesis: Implantation of ReFilx during BCS will maintain breast shape and size and promote tissue regeneration in and around the biodegradable biomaterial, in contrast to sham controls. Methods: Two ReFilx formulations with high porosity, mechanical properties (compressive modulus=45±6 kPa and 31±9 kPa) comparable to native breast tissue and a moderate degree of swelling (202±6% and 248±6%) were selected for implantation in porcine BCS defects. Three female Yucatan Minipigs (age=4 years, weight=100-120 kg, 12 breasts per pig) received BCS to remove normal breast tissue of approximately 2 cm diameter, after which the defects were filled with ReFilx Formulation A, ReFilx Formulation B, or no filler (sham control). At 6, 12, 24, and 36 weeks post-implantation (n=3 per group), ultrasound breast examinations and mastectomies of each selected group of breasts were performed. Samples were fixed in 10% buffered formalin and stained with H&E, Masson's Trichrome and immunohistomchemistry using CD31. Results: ReFilx formulations maintained breast size and shape, with similar stiffness to native breast tissue, while sham controls collapsed over 36 weeks. The ReFilx fillers supported cell and tissue infiltration and neovascularization, as indicated by Masson's Trichrome and CD31 staining, respectively, without eliciting foreign body giant cell formation, fibrosis, or chronic inflammation, commonly associated with implanted medical devices. Conclusions: ReFilx are promising soft tissue fillers for breast volume restoration, representing a simple, versatile, permanent, and aesthetically superior solution to prevent soft tissue deformities. Title: The use of oncoplastic surgical techniques to increase successful breast conservation in invasive lobular carcinoma of the breast

Jasmine M Wong1, Merisa L Piper1, Cheryl Ewing1, Michael Alvarado1, Laura J Esserman1, Hani Sbitany1, Robert D Foster1 and Rita A Mukhtar1. 1University of California, San Francisco, San Francisco, CA.

Body: Background: Invasive lobular carcinoma (ILC) of the breast differs from invasive ductal carcinoma in its non-cohesive growth pattern. These diffuse tumors pose challenges for accurate size assessment as well as surgical resection. Patients with ILC have higher rates of positive margins and lower rates of successful breast conservation surgery. Oncoplastic surgical techniques such as oncoplastic reduction mammoplasty and lumpectomy with oncoplastic closure can allow for removal of larger areas of breast tissue than lumpectomy alone. Whether or not these techniques improve the success of breast conservation in patients with ILC is unknown.

Methods: We queried a prospectively maintained surgical database and identified 384 women treated for ILC at UCSF between 1992 and April 2017. We reviewed pathology and operative reports, and clinical outcomes data, and identified 199 women who had an initial attempt at breast conservation. Data were analyzed in Stata 14.2.

Results: Average age was 61 years (range 39-84), and 69% of patients underwent lumpectomy, 16% had lumpectomy with oncoplastic closure, and 15% had oncoplastic reduction mammoplasty. The majority of tumors were hormone receptor positive, Her2 negative, grade 2, T1 or T2, and 28% were node positive. A total of 156 women (78%) had successful breast conservation; of these, 34% had one re-excision, and 1 patient had two re-excisions. Positive margins were seen in 40% of patients overall, and were significantly lower in the lumpectomy with oncoplastic closure group and those who had shave margins taken. Among the patients who underwent lumpectomy only, obtaining shave margins was significantly associated with final negative margins (71% versus 53%, p = 0.033). Patients with oncoplastic reduction mammoplasty had significantly larger average tumor size (4.1 cm), and significantly more tissue removed (167 cm³).

Conclusions: Tailoring the surgical treatment to tumor size can increase the rate of successful breast conservation surgery for these diffuse, often non-palpable lobular cancers. For the women with the largest tumors, oncoplastic reduction mammoplasty was often recommended. This group likely represents women who were borderline candidates for breast conservation; despite this, oncoplastic reduction mammoplasty allowed 77% to ultimately have successful breast conservation. For the women with smaller tumors, removing additional tissue with shave margins and using oncoplastic techniques for closure when necessary clearly reduced positive margin rates. Surgeons should routinely obtain shave margins when performing partial mastectomy for women with ILC.
Title: Differential efficacies of DNA damaging agents in basal-like TNBC subtypes

Corena V Shaffer¹, Andrew J Robles¹, April L Risinger¹,² and Susan L Mooberry¹,². ¹University of Texas Health Science Center at San Antonio, San Antonio, TX and ²Cancer Therapy & Research Center, University of Texas Health Science Center at San Antonio, San Antonio, TX.

Body: New approaches are needed to improve long term survival for patients with metastatic triple negative breast cancer (TNBC). Women with metastatic TNBC have a worse 3-year survival compared to women with metastatic HER2+ or ER/PR+ disease.¹ Identifying the molecular vulnerabilities of TNBC subtypes could provide for optimal treatment strategies. Gene expression analyses of TNBC patient samples by Lehmann and Bauer, et al. identified 6 subtypes of TNBC.² Based on the analysis of laser dissected tumor samples, the number of tumor subtypes was reduced from 6 to 4.³ Both analyses identified two types of basal-like cancers, basal-like 1 (BL1) and basal-like 2 (BL2).²,³ The BL1 subtype is defined by the amplified expression of genes involved in cell division and DNA damage response, and RNA polymerase.² BL2 cancers express high levels of genes involved in growth factor signaling, glycolysis, and gluconeogenesis.² They show that cell lines representative of the BL1 and BL2 subtypes of TNBC are more sensitive to cisplatin than cell lines representing the other TNBC subtypes. The BL1 or BL2 categorization, however, failed to predict sensitivity to olaparib.² BL1 and BL2 representative cell lines responded differently when treated with veliparib; BL1 cells were more sensitive than BL2 cells.² We investigated the response of BL1 and BL2 cells to a variety of DNA damaging agents to determine if the BL1 or BL2 subtype was predictive of sensitivity to a particular drug. DNA damaging agents, including alkylating agents, anti-metabolites, topoisomerase inhibitors, and PARP inhibitors were tested in cells representing the BL1 and BL2 subtypes. HCC1806 cells (BL2) were found to be selectively sensitive to gemcitabine when compared to HCC1937 cells (BL1). The panel of drugs and cell lines was expanded to further understand the sensitivity of BL1 and BL2 subtypes to a variety of DNA damaging agents. Our goal is to provide preclinical evidence for the informed use of specific DNA damaging agents in the treatment of patients with BL1 or BL2 subtypes of TNBCs.

Title: Diabetes medications and risk of breast cancer in Korean females with type 2 diabetes

Jongoh Kim¹ and Min Ji Kwak². ¹Baylor College of Medicine, Houston, TX and ²The University of Texas McGovern Medical School, Houston, TX.

Body: Background: Type 2 diabetes is associated with 20-30% increased risk of breast cancer in postmenopausal women. Several diabetes medications have been linked to increased risk of malignancy. The effect of diabetes medications on the risk of breast cancer is unknown.

Methods: We used the 2011 claim data from the National Health Insurance Service in South Korea to evaluate associations between diabetes medications and breast cancer. The data was provided as a stratified sample of the nationwide health insurance claims in 2011 without links to the previous or the following years. Clinical information was collected from sequential claims per patient for the study year. Among those who had had claims for prescription of diabetes medications or diagnosis of type 2 diabetes without diagnosis of type 1 diabetes, development of breast cancer was analyzed in association with diabetes medications using multiple logistic regression. Diabetes medications were categorized as following: metformin, insulin secretagogues (including glibenclamide, gliclazide, glimepiride, glipizide, repaglinide, nateglinide, and mitiglinide), thiazolidinediones (including rosiglitazone and pioglitazone), dipeptidyl peptidase-4 (DPP4) inhibitors (including sitagliptin, saxagliptin, and vildagliptin), alpha-glucosidase inhibitors (including acarbose and voglibose), and insulin.

Result: 52,421 female subjects with type 2 diabetes aged ≥ 50 years were included in the analysis. 3,559 (6.8%) developed breast cancer. The risk of breast cancer was not significantly different by type 2 diabetes when adjusted for age (Odds Ratio [OR]1.005, 95% Confidence Interval [CI] 0.967-1.045). Metformin was used in 44.6%, insulin secretagogues in 38.7%, thiazolidinediones in 4.5%, DPP-4 inhibitors in 9.6%, alpha-glucosidase inhibitors in 10.1%, and insulin in 2.8%. When adjusted for age and one another, OR of breast cancer was 0.819 (95% CI 0.752-0.891) for metformin, 1.050 (0.966-1.141) for insulin secretagogues, 1.605 (1.392-1.850) for thiazolidinediones, 0.781 (0.680-0.897) for DPP4 inhibitors, 0.906 (0.798-1.029) for alpha-glucosidase inhibitors, and 1.729 (1.456-2.053) for insulin, respectively

OR: odds ratio, CI: confidence interval, DPP4: dipeptidyl peptidase 4

Conclusion: Metformin and DPP4 inhibitors were associated with decreased risk of breast cancer whereas thiazolidinediones and insulin were associated with increased risk of breast cancer. The cause and effect relationship could not be established because of short duration of follow up and limited availability of confounders. But our result suggests that diabetes medications may influence the risk of breast cancer. Further research is warranted to explore the effect of different diabetes medications on the development of breast cancer.
**Title:** Statin use and breast cancer survival – a Swedish nationwide study

Signe Borgquist, Per Broberg and Håkan Olsson. 1Lund University, Lund, Sweden; 2Aarhus University, Aarhus, Denmark and 3Skåne University Hospital, Lund, Sweden.

**Body:**

**Background:** A sizeable body of evidence shows that statins can cease proliferation of breast cancer and prevent breast cancer recurrence. Given the epidemiological findings from other Scandinavian populations, we hypothesized that statins may have anticancer effects and therefore reduce cancer-related mortality in a Swedish population. This study investigates the association between both pre- and post diagnostic statin use and breast cancer outcome.

**Methods:** A Swedish nation-wide retrospective cohort study of 20,559 Swedish women diagnosed with breast cancer (July 1st, 2005 through 2008). Dispensed statin medication was identified through the Swedish Prescription Registry. Breast cancer-specific death information was obtained from the national cause-of-death registry until December 31st, 2012. Cox regression models yielded hazard ratios (HR) and 95% confidence intervals (CI) regarding associations between statin use and breast cancer-specific and overall mortality.

**Results:** During follow-up, a total of 4,678 patients died, whereof 2,669 were considered breast cancer-specific deaths. Compared to non- or irregular use, regular pre-diagnostic statin use was associated with lower risk of breast cancer-specific death (HR=0.77 (95%CI 0.63-0.95), P=0.014). When evaluating diabetes patients only (N=545), this association was strengthened (HR=0.63 (95%CI 0.40-0.98), P=0.044). Post diagnostic statin use was in similarity associated with lower risk of breast cancer-related death compared to non-use (HR=0.83 (95%CI 0.75-0.93), P=0.001).

**Conclusion:** This study supports the notion that statin use is protective regarding breast cancer-specific mortality in agreement with previous Scandinavian studies, although less so with British studies. These disparities should be investigated further.
Obesity linked genetic loci are associated with decreased risk of young onset breast cancer

Jongoh Kim¹ and Min Ji Kwak². ¹Baylor College of Medicine, Houston, TX and ²The University of Texas McGovern Medical School, Houston, TX.

**BODY:**

**BACKGROUND:** Breast cancer is the most common cancer in women. The role of several genes involved in familial breast cancer is well established. However, polygenic basis of non familial breast cancer is still not known. Obesity is known to affect risk and prognosis of breast cancer. We examined the association of genetic loci linked to obesity and breast cancer.

**METHODS:** We used the genomic microarray data (Illumina Human OmniExpressExome 8) from the Two Sister Study. The Two Sisters Study recruited young onset (<age 50 years) breast cancer patients and their sisters. We tested the association of breast cancer and 32 loci linked to obesity available from the fully processed and filtered genomic data. Conditional logistic regression was used for analysis to reflect matched pairs of breast cancer patients and control sisters. The number of minor alleles in each locus was entered into the regression model.

**RESULT:** 1,458 breast cancer patients and 525 sisters as control were included in the analysis. Mean age of diagnosis of breast cancer was 44.5 years. None of the genetic loci was significantly associated with breast cancer without matching breast cancer patients and their sisters. After matching breast cancer patients and their sisters using conditional logistic regression, rs6971091 (FAM71F1), which is linked to higher risk of obesity, was significantly associated with decreased risk of breast cancer (Odds Ratio [OR] 0.682, 95% Confidence Interval [CI] 0.488-0.953). Interestingly, one locus of FTO, rs1121980, which is also linked to higher risk of obesity, became significantly associated with decreased risk of breast cancer (OR 0.381, 95% CI 0.166-0.875) when four FTO loci (rs1121980, rs8050136, rs1421085, and rs16953002) were mutually adjusted.

**CONCLUSION:** This study showed that genetic loci linked to obesity could affect the risk of breast cancer. The two loci that we identified were linked to higher risk of obesity but associated with lower risk of young onset breast cancer. This is consistent with previous studies that showed a decreased risk of breast cancer in obese premenopausal women. Limitations of this study are that we were not able to adjust known confounders including body mass index and the number of subjects was small. However, we increased the power by incorporating data structure of sister matching to find associated genetic loci. Further research is warranted to better elucidate interaction of obesity and the development of breast cancer.
Racial differences in recurrence of hormone receptor-Positive breast cancers in the Carolina breast cancer study

Katherine E Reeder-Hayes1,2, Xuezheng Sun2,3, Andrew Olshan2,3, Lisa A Carey1,2 and Melissa A Troester2,3, 1University of North Carolina; 2University of North Carolina Lineberger Comprehensive Cancer Center and 3University of North Carolina.

Racial disparities in breast cancer outcome are most pronounced among women with hormone receptor-positive, human epidermal growth factor receptor 2-negative (HR+/HER2-) disease. Several factors may contribute to this disparity, including biologic heterogeneity within the clinical HR+/HER2- subtype, and differences in access to treatment. In this study, we leverage the unique resources of the Carolina Breast Cancer Study Phase III (CBCS-III), a large prospective cohort study including tumor bio-specimens and detailed clinical annotation from black and white women with breast cancer, to examine potential contributors to racial disparities in recurrence of HR+/HER2- breast cancer.

The CBCS-III cohort includes 2,998 women recruited between 2008 and 2013 by rapid case ascertainment from 44 counties in North Carolina, stratified by age (>50 versus <50) and race (black vs white). For this analysis, we included 1,629 women with stage I-III, HR+/HER2- clinical phenotype. We performed Cox proportional hazards regression to assess the effect of race on recurrence-free survival (RFS). Model 1 was minimally adjusted for age. Model 2 additionally adjusted for clinical factors likely to vary by race and to affect recurrence risk, including stage, grade, and the receipt of adjuvant chemotherapy. Finally, for patients who had specimens available (n=935), models were fit adjusting for clinical variables as well as PAM50 Risk of Recurrence score with both proliferation index and tumor size (ROR-PT) (Model 3) or molecular subtype dichotomized as Luminal A versus other (Model 4).

With a median follow-up time of 5.5 years, 8.6% (118/1371) of whites and 14% (196/1403) among blacks had recurrence. After adjustment for age, black patients were at significantly higher risk for recurrence (HR=2.01, 95% CI 1.40-2.88), and this disparity was only partially attenuated by adjusting for baseline clinical factors (HR 1.62, 95% CI 1.11-2.36). Additional adjustment for molecular features by either ROR-PT score or molecular subtype further attenuated, but did not eliminate, the disparity in recurrence risk (HR=1.51, 95% CI 0.81,2.81 using ROR-PT and HR=1.44, 95% CI 0.77-2.69 using subtype category). Results are summarized in Table 1.

| Models of Recurrence Free Survival by Race (white = ref) |
|-----------------|-----------------|
|                 | HR              | 95% CI          |
| Model 1         | 2.01            | (1.40, 2.88)    |
| Model 2         | 1.62            | (1.11, 2.36)    |
| Model 3         | 1.51            | (0.81, 2.81)    |
| Model 4         | 1.44            | (0.77, 2.69)    |

Adjusted for: (1) age; (2)age, AJCC stage, grade, chemo; (3)ROR-PT, assay technique factor, and variables in Model 2; (4)PAM50 subtype, assay technique factor, and variables in Model 2.

In this recent population-based cohort, black women with HR+/HER2 negative disease remain twice as likely as their white counterparts to experience a recurrence within 5 years. Clinical features at disease presentation do not fully explain these outcome differences, while adjustment for biologic heterogeneity by either ROR-PT score or molecular subtype attenuates the observed disparity more than clinical features alone. There are likely residual factors not measured in this analysis, such as endocrine therapy under-use or other biologic differences, which may be targetable determinants of survival disparities. These hypotheses are being actively explored in CBCS-III.

Title: Pancreatic nutrition program (PNP): A novel weight reduction program for breast cancer survivors

Jessica Clague DeHart¹, Candice Rosen², Louise Wong², Sharla Moore², Sarah Flores², Behrouz Salehian² and Joanne Mortimer². ¹Beckman Research Institute of the City of Hope, Duarte, CA and ²City of Hope National Medical Center, Duarte, CA.

Body: BACKGROUND: Breast cancer survivors have a high prevalence of metabolic dysfunction—characterized by high glucose and weight gain. Regardless of menopausal status, overweight and obese women are at increased risk for developing breast cancer and those who are diagnosed with breast cancer experience adverse cancer-related outcomes. The underlying principle of the Pancreatic Nutrition Program (PNP) is that bio-individualized healthy food choices—eating the correct foods and food combinations for an individual's body—can minimize fluctuations in insulin by keeping blood glucose regulated (70-100 mg/dL) and this will promote sustained weight loss, improved health, and quality of life. METHODS: The primary endpoint was change in body weight at 24 weeks post-PNP. The study was powered to detect a 10% loss of weight from baseline. Secondary endpoints included change in: glucose levels, insulin resistance, body composition, body chemistry, physical fitness, biological markers, quality of life, and compliance. Postmenopausal, non-diabetic breast cancer survivors (stages I-III) within 5 years of completion of treatment who had a body mass index of 25-33 kg/m² were recruited. For the first 12 weeks, patients wore a glucometer (Abbott), which recorded glucose every 15 minutes continuously, and kept a food journal. During weekly meetings, glucometer data was reviewed with journal entries to identify food choices and combinations that would kept the subject's glucose levels between 70-100 mg/dL. At the end of the 12-weeks, the weekly meetings and glucometer were discontinued and patients were expected to maintain the PNP for an additional 12 weeks. Study endpoints were measured at baseline, 12-week and 24-week visits. RESULTS: Of the 21 patients enrolled in the study, 12 were non-Hispanic Caucasian, 5 were Hispanic, 2 were African-American, and 2 were Asian. The median age was 56 years (43-76 years). Twenty were estrogen-receptor positive, 18 progesterone-receptor positive, and 8 were HER2/neu positive. The mean body weight at baseline was 170.9 lbs (±20.4 lbs). Two patients dropped out prior to 12-weeks and 1 developed recurrent disease. Among the 18 eligible women who completed the first 12 weeks, the median weight loss at 12-weeks was 10.1 lbs (1.5-19.6 lbs). The median waist circumference lost was 2.5 inches (gain of 0.4 inches-loss of 5.5 inches). Among the women whose total cholesterol was above 200 mg/dL, 71% reduced their cholesterol below 200 mg/dL by 12-weeks. All women who had triglyceride levels above 150 mg/dL reduced their levels below 150 mg/dL by 12-weeks. Likewise, among women who were identified as being pre-diabetic based on fasting glucose or hemoglobin A1c levels, all were within normal range at 12-weeks. 6-month testing will be completed in August. Among the 15 women eligible for 6-month testing, 8 (53%) completed the testing. Of those, 7 (88%) maintained their positive results. CONCLUSIONS: Bio-individualized food choices based on glucose response combined with culturally-sensitive nutrition counseling may provide a feasible mechanism for sustainable weight loss in a population at high-risk of metabolic dysfunction. However, to increase adherence, a tapering strategy should be developed after the first 12-weeks of health counseling.
Body: Background
Metaplastic breast cancer (MBC), characterized by a mixture of epithelial, squamous or mesenchymal elements and a usually triple-negative (TN) phenotype, accounts for <1% of breast cancer diagnoses. MBC has a poor prognosis with frequent distant spread, but, paradoxically, a lower than expected rate of nodal positivity (6 to 40%). Due to its rarity there is little data on how best to evaluate and manage the axilla in women with these tumors. Thus we undertook this study to evaluate axillary management and oncologic outcomes.

Methods
With IRB approval, we identified adult patients diagnosed with MBC at our institution from 2001 to 2011 from our prospective surgical pathology database. Patient, pathology, imaging, treatment and outcome data were obtained from electronic medical record, tumor registry, pathology slide and imaging review. Median follow-up for surviving patients was 66 months. Statistical analyses were performed using JMP 10.0 software.

Results
We identified 41 MBC patients, median age 60 years (range 33-89 years), with a median tumor size of 2.7 cm; 33 (80%) were TN. 23 patients (56%) had a preoperative axillary ultrasound (AUS): 9 (39%) showed at least one suspicious axillary lymph node (LN) of whom 6 had a preoperative fine needle LN biopsy (FNA) of which 3 were positive for metastasis. 6 patients, including the 3 LN+ on FNA, had neoadjuvant chemotherapy (NAC). Operation included axillary dissection (ALND) in 14, sentinel LN biopsy (SLNB) in 23, and SLNB followed by ALND in 1, while 3 patients had no axillary surgery. 10 patients were LN+ at operation. Among 22 patients who had both an AUS and axillary surgery, AUS had a sensitivity of 100% and specificity of 78%. Patient and tumor variables in association with pathologic LN status are summarized in the table. LN positivity correlated with increasing tumor size, T stage, grade and angiolymphatic invasion. 16 patients recurred, most with distant disease (10/16, 63%), although there was a solitary axillary recurrence 8 months after a negative SLNB in one patient who did not have a preoperative AUS. Thus the accuracy of SLNB was 96% (23/24) overall, but among those without preoperative AUS, 1/7 (14%) SLNBs were falsely negative. 5-year disease-free and breast cancer-specific survival estimates were 49% and 63%.

**Conclusion**

Our study is the first to specifically address AUS and SLNB for patients with metaplastic breast cancer. AUS had 100% sensitivity and 78% specificity, while one patient without a preoperative AUS had a falsely negative SLNB. Further, AUS with FNA of suspicious LNs was useful for staging at the time of diagnosis and informing treatment. We recommend this approach for patients with MBC.
Title: Overview of the pathological results and treatment characteristics in the first 1000 patients randomized in the SERC trial: Axillary dissection versus no axillary dissection in patients with involved sentinel node

Body: Background: Three randomized trials have concluded at non inferiority of omission of complementary axillary lymph node dissection (cALND) for patients with involved sentinel node (SN). However, we can outline strong limitations of these trials to validate this attitude with a high scientific level. We designed the SERC randomized trial to compare outcomes in patients with SN involvement treated with ALND or no further axillary treatment. The aim of this study was to analyze results of the first 1000 patients included.

Patients and Methods: SERC trial is a multicenter non-inferiority phase 3 trial. Multivariate logistic regression analysis was used to identify independent factors associated with adjuvant chemotherapy administration and non-sentinel node (NSN) involvement. Results: Of the 963 patients included in the analysis set, 478 were randomized to receive cALND and 485 SLNB alone. All patient demographics and tumor characteristics were balanced between the two arms. SN ITC was present in 6.3% patients (57/903), micro metastases in 33.0% (298), macro metastases in 60.7% (548) and 289 (34.2%) were non eligible to Z0011 trial criteria.

Whole breast or chest wall irradiation was delivered in 95.9% (896/934) of patients, adjuvant chemotherapy in 69.5% (644/926), endocrine therapy in 89.6% (673/751) and the proportions were similar in the two arms. The overall rate of positive NSN was 19% (84/442) for patients with cALND. Crude rates of positive NSN according to SN status were 4.5% for ITC (1/22), 9.5% for macro metastases (13/137), 23.9% for macro metastases (61/255) and were respectively 29.36% (64/218), 9.33% (7/75) and 7.94% (10/126) when chemotherapy was administered after cALND, before cALND and for patients without chemotherapy.

Conclusion: The main objective of SERC trial is to demonstrate non inferiority of cALND omission. A strong interaction between timing of cALND and chemotherapy with positive NSN rate was observed.
Title: The loss of lymph node metastasis after neoadjuvant chemotherapy in patients with cytologically proven node-positive primary breast cancer

Maki Namura, Naoki Hayashi, Hiroko Tsunoda, Atsushi Yoshida, Junko Takei, Koyu Suzuki, Seigo Nakamura and Hideko Yamauchi. 1 St. Luke’s International Hospital and 2 Showa University, School of Medicine.

Body: Purpose: While the sensitivity to neoadjuvant chemotherapy (NAC) depends on breast cancer subtype, it has been reported that over 30% of patients with node-positive breast cancer achieved an axillary pathologic complete response (pCR) after NAC. However, axillary lymph node dissection (ALND) still remains as a standard treatment because of the difficulty of assessment of lymph node (LN) status after NAC. ALND will be omitted if axillary LN status is accurately assessed. Our purpose of this study was to predict the loss of axillary LN metastasis after NAC in primary breast cancer patients.

Patients and Methods: Among 997 consecutive patients who underwent surgery after NAC from January 2006, to December 2016, 279 patients with cytologically proven node-positive were included in this analysis. All patients were assessed using CT or PET-CT, and ultrasonography (US) before NAC. LN status after NAC was assessed by US. Patients with cT4 tumor, and supra/subclavicular and parasternal LN metastasis were excluded. Clinical LN status after NAC (ycN) was compared to pathological LN status (ypN) on surgical specimen. The association between LN status and clinicopathological factors including nuclear grade (NG), tumor size, the use of trastuzumab, and breast cancer subtypes, was assessed.

Result: Of the 279 patients with LN-positive before NAC, 166 patients (59.5%) had ER+/HER2- tumor, 51 patients (18.3%) had ER+/HER2+ tumor, 33 patients (11.8%) had ER-/HER2- tumor, and 29 patients (10.4%) had ER-/HER2+ tumor. 179 patients (64.2%) had ycN0 and 102 patients (36.6%) had ypN0. There was significant difference of rate of the loss of LN metastasis; 37 of 166 patients (22.3%) with ER+/HER2- tumor, 24 of 51 patients (47.1%) with ER+/HER2+ tumor, 19 of 33 patients (57.6%) with ER-/HER2- tumor, and 22 of 29 patients (75.9%) with ER-/HER2+ tumor, (p<0.01). The accuracy of assessment of the loss of LN metastasis by US (ycN0/ypN0) was high in 20 of 25 patients (80.0%) with ER-/HER2+ tumor and in 14 of 19 patients (73.4%) ER-/HER2- tumor compared to ER+ tumor; 21 of 39 patients (53.8%) with ER+/HER2+ tumor and 34 of 96 patients (35.4%) with ER+/HER2- tumor (p<0.01). For patients with ycN0/ypN+, the median number of residual LN metastasis was 1 in ER-/HER2+ tumor (range:1-2) and ER-/HER2- tumor (range:1-3), and 2 in ER+/HER2+ tumor (range:1-6) and ER+/HER2- tumor (range:1-14). Among patients with ER-/HER2+ tumor, there was association between the loss of LN metastasis and the use of trastuzumab (p<0.01). There was no association between the loss of LN metastasis and NG or tumor size.

Conclusion: Our results showed patients with ER-/HER2+ tumor and cytologically proven LN metastasis who received NAC with trastuzumab might have the loss of LN metastasis if assessed as ycN0 by US after NAC, whereas, the patients in ER+ tumor have a high risk to have residual LN metastasis after NAC even if assessed as ycN0. Further studies are warranted the prognostic impact of the omission of ALND for these populations.
**Title:** The axillary lymph node to primary breast tumor SUV ratio on FDG-PET/CT in FDG avid primary breast cancers: Could predict the necessity for axillary lymph node dissection

Min Kyoon Kim¹, Han Kyul Shin¹ and Hee-Chul Shin¹. ¹Chung-Ang University Hospital, Seoul, Korea.

**Body:**

**Background:** Emerging evidence has indicated that breast cancer patients with a low axillary burden do not benefit from sentinel lymph node biopsy. Thus, to specifically identify more than 3 nodes-positive patients who can proceed directly to axillary lymph node(ALN) dissection, and avoid unnecessary surgical procedures, accurate preoperative detection by radiologic assessment would be anticipated. In this study, we evaluated the usefulness of ALN to primary breast tumor SUV ratio (determined by \(^{18}\)F-FDG PET/CT) and MRI for predicting the need for ALN dissection in breast cancer surgery.

**Method:** Three hundred sixteen consecutive female patients with primary breast cancer were enrolled in this retrospective study between January 2012 and December 2016. All patients underwent preoperative \(^{18}\)F-FDG PET/CT, MRI, and surgical resection without neoadjuvant chemotherapy. The ALN to primary breast tumor SUV ratios(LN/T ratios) were calculated, and optimal cutoff values were determined by receiver operating characteristic curve analysis for predicting the presence of \(\geq 3\) ALN metastasis. The diagnostic performances of \(^{18}\)F-FDG PET/CT \(_{LN/T}\) ratio and MRI for the prediction of \(\geq 3\) ALN metastasis were determined by sensitivity, specificity, and diagnostic odds ratio(DOR). Subgroup analysis of those for FDG avid cancers were performed.

**Result:** Of the 316 patients, 36(11.4%) showed involvement of \(\geq 3\) ALNs, and 101(32%) had one or more metastatic lymph nodes. The mean SUV of the primary tumor in the 316 patients was 3.9, ranging from 0 to 26.6, while the mean SUV of the ALN was 0.81, ranging from 0 to 21.9. Axillary \(^{18}\)F-FDG uptake was positive in 75(23.7%) patients and optimal criteria of LN/T ratio for detecting the needs for ALN dissection was 0.3 determined by ROC analysis. MRI showed findings of suspicious ALN involvement in 147(46.6%) patients. The sensitivity and specificity of MRI were 0.89 and 0.56, while those of PET/CT \(_{LN/T}\) ratio were 0.69 and 0.87. In the receiver operating characteristic(ROC) analysis, the area under the curve(AUC) for MRI and PET/CT \(_{LN/T}\) ratio was 0.756 (0.682-0.829, 95% confidence interval), and 0.817(0.733-0.900, 95% confidence interval). Further analysis of the DOR for MRI showed a value of 10.37 and for PET/CT \(_{LN/T}\) ratio the DOR was 9.7. But, in a subgroup of patients with FDG-avid primary tumor(FDG above 3.9, n=108), the area under the curve was improved to 0.896 (0.817-0.975, 95% confidence interval) for PET/CT \(_{LN/T}\) ratio, while those of MRI was worsened. (0.681, 0.569- 0.793., 95% CI) DOR value of PET/CT \(_{LN/T}\) ratio for FDG avid cancers was 25.68 and their sensitivity and specificity were 0.83 and 0.84 each.

**Conclusion:** In FDG avid primary breast cancer, PET/CT \(_{LN/T}\) ratio could predict need for ALN dissection with higher accuracy than MRI. PET/CT has high potential for being used as a non-invasive imaging diagnostic technique identifying \(\geq 3\) ALNs metastases.
Title: A feasibility study of sentinel lymph node detection and analysis of safety to omit axillary lymph node dissection in clinically node-negative breast cancer patients after neoadjuvant chemotherapy

Kazuma Maeno, Kana Yamamoto, Mayu Ono, Takaaki Oba, Asumi Iesato, Koichi Ono, Tokiko Ito, Toshiharu Kanai and Ken-Ichi Ito. Shinshu University School of Medicine, Matsumoto, Nagano, Japan.

Body: Background: Concerns still remain about lower sentinel node (SN) detection and higher false-negative rates (FNR) in breast cancer patients treated with neoadjuvant chemotherapy (NAC), especially those who are clinically node-positive before NAC. It is necessary to analyze the validity of sentinel node biopsy (SNB) after NAC and evaluate whether the SN identification rate and FNR for clinically N0 (cN0) patients after NAC would be acceptable or not in order to omit axillary lymph node dissection (ALND).

Objectives and methods: We identified SN by radioisotopic methods followed by completion of ALND in cN0 patients after NAC from 2013 to 2016 as part of a clinical research study (SNB group, N=68) to analyze the accuracy of SNB, and retrospectively investigated the prognosis of patients treated with NAC from 2006 to 2012 (control group, N=92) to evaluate whether the validity of SNB would be acceptable or not.

Results: Mean patient ages in the SNB group and control group were 51.0 years and 49.5 years, respectively (p=0.17), and the distribution of intrinsic subtypes was not significantly different between the two groups. The numbers of cN1≤ before NAC in the SNB group and control group were 85.5% (57/68) and 80.4% (74/92), respectively (p=0.58), and the pathological complete response rates were 25.0% (17/68) and 19.6% (18/92), respectively (p=0.41). Lymphoscintigraphy using 99mTc-phytate acid was performed in the SNB group, and hot spots were detected at the ipsilateral axilla in 62 of 68 (91.2%) patients, in all of whom SNs could be identified by using a gamma-probe. The FNR, which indicates no metastasis in SNs and metastasis in non-SN, was 5.9% (4/68). Among these four patients, three were of the luminal type while one was triple negative. The number of patients without metastasis in both SN and non-SN, which are candidates for omission of ALND, was 26 of 68 (38.2%). They included eight of nine HER2-enriched patients and six of 13 luminal-HER2 patients. Conversely, there were no false-negative cases in these subtypes. Moreover, all SNs were identified even if there were metastases in SNs. Regarding the prognosis of the control group, the 10-year disease free survival of post-NAC N0 (ypN0) (52/92, 56.5%) and ypN1≤ (40/92, 43.5%) were 80.7% and 61.2%, respectively (p=0.08); in addition, the 10-year overall survival of yN0 and ypN1≤ were 90.4% and 72.6% (p=0.26). Thus, the prognosis of ypN1≤ was not significantly inferior to that of ypN0. If omission of ALND were performed for false negative cases, then the risk of axillary relapse would be a concern. However, these data indicate the possibility that 5.9% of FNR as shown in the SNB group would not have much influence on prognosis.

Conclusion: The accuracy of SN detection by radioisotopic methods for cN0 breast cancer after NAC was not maintained like that for -early breast cancer although it was better than the results of previous studies. However, there were no false-negative cases in HER2-enriched and luminal-HER2 subtypes, which could be potential candidates for omission of ALND. In addition, omission of ALND for false-negative patients would have less influence on the prognosis.

**Title:** Can axillary evaluation be omitted in patients preoperatively diagnosed with ductal carcinoma in situ by core needle biopsy?

Jing Si1,2, Benlong Yang1,2, Rong Guo1,2, Naisi Huang1,2, Chenlian Quan1,2, Jiajian Chen1,2 and Jiong Wu1,2,3. 1Fudan University Shanghai Cancer Center, Shanghai, China; 2Fudan University, Shanghai Medical College and 3Collaborative Innovation Center for Cancer Medicine.

**Body:**

**Background**

Patients diagnosed with ductal carcinoma in situ (DCIS) by core needle biopsy (CNB) have a great chance of upgrading invasive cancer on the final pathology. Positive axillary lymph nodes can be found in these patients. The present study sought to identify clinicopathological factors associated with upgrading and axillary lymph nodes metastasis in patients preoperatively diagnosed with DCIS by CNB.

**Materials and Methods**

This study identified 604 patients (cT1-3N0M0) with preoperative diagnosis of pure DCIS by CNB who had undergone axillary evaluation from August 2006 to December 2015 at Fudan University Shanghai Cancer Center (FUSCC). Predictors of upgrading and axillary lymph nodes metastasis were analyzed, respectively.

**Results**

Of all 604 patients, 513 (84.93%) and 91 (15.07%) patients had undergone sentinel lymph nodes biopsy (SLNB) and axillary lymph nodes dissection (ALND), respectively. Overall, 121 (20.03%) and 193 (31.95%) patients were upgraded to DCIS with microinvasion (DCISM) and IDC on final pathology, respectively. Positive axillary lymph nodes were identified in 41 (6.79%) patients, of which 35 (5.80%) patients had 1-2 positive axillary lymph nodes, 6 (0.99%) patients had 3 or more positive axillary lymph nodes. Among patients with axillary lymph nodes metastasis, 4 (9.76%), 4 (9.76%) and 33 (80.48%) patients were in DCIS, DCISM and IDC group, respectively. Predictors of upgrading included tumor size on ultrasonography ($P=0.001$), Ki-67 ($P=0.046$) and molecular subtype ($P=0.007$) in univariate analysis. In multivariate analysis, patients with larger tumor size on ultrasonography (>2cm) (OR 1.767, $P=0.001$) were more likely to be upgraded on final pathology. Also, ER+ HER2+ patients were more likely to be upgraded than ER+ HER2- patients (OR 1.659, $P=0.047$). Factors associated with axillary lymph nodes metastasis included nipple discharge ($P<0.001$), tumor size on pathology ($P=0.037$), number of lesions ($P=0.039$), axillary evaluation methods ($P=0.029$) and molecular subtype ($P=0.049$) in univariate analysis. Whereas, only nipple discharge and larger tumor size on pathology (>2cm) reached statistical significance in multivariate analysis (OR 5.959, $P<0.001$; OR 2.361, $P=0.042$).

In addition, further analysis showed upgrading on final pathology had a significant influence on axillary lymph nodes status ($P<0.001$). However, this correlation was not shown between patients with DCIS and DCISM in pairwise comparison.

**Conclusion**

The data of upgrading and axillary lymph nodes metastasis in patients with an initial diagnosis of DCIS by CNB was comparable in this cohort with published data. Despite of a 51.98% upgrading rate, the rate of axillary lymph nodes metastasis in these patients is low, which supports the omission of axillary evaluation in selected patients.
Comparison of the prognostic value of lymph node ratio versus residual lymph node status in triple negative breast cancer

Gabriel De la Cruz-Ku1, Zaida Morante2, Joseph Pinto2, Daniel Enriquez2, Eduardo Eyzaguirre1, Antonella Saavedra1, Maria Luján1, Renato Luque1, Magno Ramírez1, Jhajaira Araujo3, Hugo Fuentes2, Claudio Flores3, Mecker Moller4, Danny Yakoub4, Silvia Neciosup2 and Henry Gomez2. 1Universidad Cientifica del Sur, Lima, Peru; 2Instituto Nacional de Enfermedades Neoplasicas, Lima, Peru; 3Oncosalud - AUNA, Lima, Peru and 4Jackson Memorial Hospital, Miami, FL.

Body: Background: Triple negative breast cancer (TNBC) patients with residual disease are characterized for a bad outcome. In these patients nodal involvement after neoadjuvant chemotherapy (NAC) is one of the most important prognostic determinants. In this study we compare two prognostic variables based on nodal status, the lymph node ratio (LNR=number of positive nodes/ number of resected nodes) and residual lymph node status (ypN) in TNBC who received NAC.

Methods: We evaluated a retrospective cohort of TNBC patients with residual disease in the lymph nodes (at least 4 resected nodes) and treated with NAC between 2000-2014 at the Instituto Nacional de Enfermedades Neoplasicas (Lima-Peru). Patients were grouped in three LNR groups (≤0.20, 0.20-0.69 and ≥0.70). Survival differences were calculated by the log rank test. Prognostic factors for progression free survival (PFS) and overall survival (OS) were assessed by the Cox regression analysis.

Results: Overall, 189 were evaluated. Mean age was 48y (range: 26-73) where 53.5% were premenopausal and 16.5% had breast/ovary cancer familial background. A total of 175 pts (92.6%) had clinical T3-T4 tumors and 85.2% had nodal involvement at diagnosis. Indeed, the majority of patients had III CS (94.2%). Regarding to the LNR, 48.2% (n=91), 29.6% (n=56) and 22.2% (n=42) (22.2) had LNR ≤0.20, 0.21-0.69 and ≥0.70, respectively. Distribution of clinical differences was similar between groups, except for the clinical N stage (N2-N3: 15.4%, 46.4%, 52.3%, respectively; p<0.001). The median follow-up was 7 years. Progression risk was higher in patients with LNR ≤0.20 than 0.20-0.69 and ≥0.70 (HR=1.77, 95%CI:1.21-2.59, p=0.003 and HR=2.22, 95%CI:1.47-3.35, respectively, p<0.001). It was similar for the risk of death (HR=1.78, 95%CI: 1.17-2.70, p=0.007 and HR=2.95, 95%CI:1.91-4.56, respectively, p<0.001). LNR groups were associated to progression events (P=0.02) in contrast to ypN groups (P=0.07). In the multivariate analysis, pre-menopausal status, a higher LNR and ypT with non-complete response were prognostic factors of worse DFS. Only a higher LNR has a negative impact on OS (table 1).

Conclusion: LNR was an independent prognostic factor for TNBC in patients with residual disease with better capability than ypN to predict progression events. LNR should be considered in the risk stratification after NAC among these patients.

Title: Axillary staging after neoadjuvant chemotherapy: The comparison of surgeon performed axillary ultrasound and 18F-FDG PET/CT with pathologic status of sentinel lymph nodes in clinically node-negative breast cancer

Guldeniz Karadeniz Cakmak¹, Rabiye Uslu², Ali U Emre¹, Ozlem Elmas³, Yucel Karadere¹, Mine Buse Konuk¹, Huseyin Engin⁴ and Banu Dogan Gun⁵. ¹BEUN The School of Medicine, Zonguldak, Turkey; ²BEUN The School of Medicine, Zonguldak, Turkey; ³BEUN The School of Medicine, Zonguldak, Turkey; ⁴BEUN The School of Medicine, Zonguldak, Turkey and ⁵BEUN The School of Medicine, Zonguldak, Turkey.

Body: Objective: In the era of neoadjuvant chemotherapy (NAC), the most accurate method for axillary staging is a challenge for surgeon. Sentinel lymph node biopsy (SLNB) is the recommended choice of care for axillary staging in clinically node-negative (cN0) disease. Nevertheless, the role of preoperative axillary ultrasound (AUS) or 18F-FDG PET/CT in case of cN0 patients after NAC (ycN0) is controversial. The purpose of the presented study is to assess the correlation between surgeon performed AUS and PET/CT data with SLNB results to further determine the predictive role of AUS in pathologic staging of cN0 axilla after NAC.

Materials-Methods: A single institution, retrospective review of a prospectively maintained database was analyzed to identify ycN0 breast cancer patients with AUS and 18F-FDG PET/CT. All AUS studies were interpreted by a dedicated breast surgeon experienced in ultrasound, as “normal” according to the absence of specific characteristics shown to be commonly associated with metastatic involvement at diagnosis and at the date of operation. 18F-FDG PET/CT scans was termed as negative or positive due to the standardized uptake value (SUV). Patient, tumor and operative variables including age, body mass index (BMI), date of diagnosis and surgery, AUS, 18F-FDG PET/CT scans, SLNB results, and final pathology data were evaluated.

Results: Of the 69 patients with cN0 axilla after NAC, SNLB was found to be positive in 37 patients (53.6%). 2 (9.5%) out of 21 patients with a normal AUS and 3 (21.4%) out of 14 patients with negative PET/CT were ultimately found to be node-positive on pathologic assessment of SLNB. Intraoperative sonography accurately identified the SLN in 92.7% of cases. The sensitivity, specificity, positive and negative predictive values were 94.5%, 59.3%, 72.9% and 90.5% for surgeon-performed AUS and 91.8%, 34.4%, 61.8% and 78.6% for PET/CT scans, respectively. Overall accuracy was found to be %78.2 for AUS and 65.2.% for PET/CT. The presence of lymphovascular invasion (LVI), micrometastasis, primary tumor size, and body mass index were found to be significantly different between true and false negative AUS. None of the clinicopathological features of the primary tumor were significantly associated with FDG uptake in the axillary lesion. Micrometastatic disease, the size and number of metastatic nodes were significantly associated with FDG uptake leading to a difference between true and false negative PET/CT for axillary disease. No significant difference was noted with regard to patient age, tumor grade, histologic type, hormone receptor status, and time between AUS or PET/CT and axillary surgery.

Conclusion: Surgeon performed AUS is a beneficial tool with the potential of accurate prediction of axillary disease in up to 78% of patients after NAC. Nevertheless, the accuracy of AUS findings should be interrogated cautiously particularly for larger tumors with LVI or micrometastasis in overweight patients. Similarly, our data also imply that PET/CT had a limited value in the evaluation of axillary nodes and is not sufficient to predict axillary status particularly in case of micrometastasis after NAC.
Title: Re-evaluating the “10% rule” for sentinel lymph node biopsy with radioactive method in breast cancer; a single institutional retrospective study

Hiromi Miyamoto¹, Tomoyuki Aruga¹, Mai Onishi¹, Risa Goto¹, Naoko Iwamoto¹, Nami Idera¹, Kazumi Horiguchi¹ and Yayoi Honda¹. ¹Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Bunkyo-ku, Tokyo, Japan.

Body: Background:
When multiple radioactive sentinel lymph nodes (SLNs) are present during sentinel lymph node biopsy (SLNB), excision of those SLNs with >10% radioactive count per minute (high-CPM) of the most radioactive node (“10% rule”) has been proposed. Although this “10% rule” may avoid excessive removal of SLNs, the risk of false negative and remnant positive SLNs in the patients who have SLNs with <10% CPM (low-CPM) remain unclear. The purpose of this analysis is to determine the clinical validity of this “10% rule” for early breast cancer patients.

Method:
We reviewed the records of successful SLNBs using the radioisotope (RI) method performed between January 2001 and December 2016 in our institution. The radioactive count from each excised SLN was measured. Non-radioactive lymph nodes were excluded from this analysis. All SLNs were pathologically assessed by 2mm serial section with hematoxylin and eosin staining.

Results:
In the 3,043 patients with successful SLNB, the median number of radioactive SLNs removed was 2 (mean, 1.8; range, 1-10) and 599 patients (19.7%) had SLNs with low-CPM. The total number of radioactive SLNs was 5,472, and 875 (16.0%) out of 5,472 SLNs were low-CPM. Sixty-one (7.0%) out of these 875 SLNs with low CPM in 56 patients (1.8%) had metastatic disease by pathological assessment. The number of metastatic SLN with low-CPM was one in 51 patients and two in 5 patients. Nineteen patients (0.6%) had no metastatic lesion in SLNs with high-CPM.

Discussion and Conclusions:
If SLNB was performed by RI method alone with “10% rule”, false negative rate increased by 0.6% and underestimation increased up to 1.8%. Furthermore, 19.7% of the patients have the benefit of avoiding excessive removal of SLNs. Considering the risk and benefit, “10% rule” is a high validity method to capture metastatic SLNs even in the setting that ALND will not be performed.

Title: Can we predict the risk for non-sentinel node metastases? Results from the Swedish breast cancer registry on 23053 patients

Eva VikhePatil¹, Lars-Gunnar Arnesson¹ and Helena Fohlin². ¹University Hospital, Linkoping, Ostergotland, Sweden and ²Regional Cancer Centre, Linkoping, Ostergotland, Sweden.

Body: Introduction
Performing axillary clearance after node positive sentinel node biopsy (SNB) has been challenged. This register study aimed to predict the risk for non sentinel node metastases (non-SN) after axillary clearance in Swedish breast cancer patients. The Swedish Breast Cancer Registry has been in use since 2008 with >99% compliance. National guidelines recommended axillary clearance for macro-and micromets in SN but not for isolated tumor cells (ITC). Breast cancer screening is performed nationwide.

Methods
Registerdata for 33 314 patients, 2008 until May 2012, was evaluated. SN was performed in 23 053 patients corresponding to 69% of all patients, a stable figure since 2008. This cohort of 23053 patients is further investigated. The median age was 62 years. Breast conserving surgery (BCS) was performed in 61,5%. SN detection mode was radiocolloid and blue dye injection and often (41%) lymphoscintigraphy. Mean tumor size after BCS -16mm and in mastectomy (ME) -23 mm. BCS and ME show positive SN in 19% and 31% respectively (sign.<0.001). Number of excised nodes after axillary clearance was 13 (range 1-50). The dataset is not fully complete in all variables.

Results
Median harvested SNs was 2 (range 1-8). 5694 SN+ cases were found, distributed as14,9% macromets, 6,4% micromets and 2,0% ITC on the whole SN cohort. Screening detected cancers had metastatic SN in 18 % while clinical cases showed positivity in 28% (sign.). Altogether non-SN mets were found for 31% of SN positive patients. The risk of non-SN mets is: if 1 macromet in SN, 35% had further involved nodes. If 2 macromets in SNs, 49 % had non-SN mets and if ≥3 positive SNs the figure was 66% positive non-SN nodes (sign.<0.01). Evaluating 1299 SN micrometastatic cases gave these figures of freedom of non-SN mets: 1 micromet. node 86, 2 micromets. 77% was free and ≥3 micromets show 61,5% non-involved mets. These figures are also significant. Data on lymphovascular invasion (LVI) was available for 18754 cases and showed a significant higher risk for non-SN mets in LVI-positive tumors 43% against 27%. Tumours >20 mm and HER2 positive also show significant more non-SN mets.

Conclusion
The SN diagnostic technique works well in Sweden; 69% of patients had SN as the primary axillary procedure. SN+ was shown in 24,7%.The risk for non-SN mets is significant correlated to 2 or more involved SNs, positive LVI, tumour size >20 mm and HER2+. Is this the group for axillary surgery? We will try to get a Swedish risk score for non-SN+. A new Swedish national randomized study now investigates the need for axillary clearance in a subset of SN+ patients. Figures are collected from The Swedish Breast Cancer Registry-head K. Sandelin, Stockholm, Sweden.
Discoloration after injection of super paramagnetic iron oxide (SPIO) for sentinel node biopsy. A long term qualitative follow-up study

Madeleine Wärnberg¹, Andreas Karakatsanis¹, Shahin Abdsaleh² and Fredrik Wärnberg¹. ¹Uppsala Academic Hospital, Uppsala University, Uppsala, Sweden and ²Aleris, Uppsala University, Uppsala, Sweden.

Background

SPIO has a similar detection ratio as Technetium⁹⁹ and Patent Blue to identify sentinel nodes (SN). No allergic reactions have been observed and no nuclear medicine facilities are needed, making logistics easier. At the Academic Hospital in Uppsala, Sweden, SPIO has been used routinely for three years. After breast conserving surgery (BCS) many women developed a brownish discoloration at the injection site. The discoloration stays for a long time. To study the patient-experienced cosmetic discomfort and the natural history of the discoloration we followed our first 153 BCS women for more than two years. After modifying the technique of injection we registered the discoloration in the following 115 women.

Methods

All women injected with a retro-areolar injection of SPIO between April 2015 and October 2016 were included. The women were telephone interviewed every third month. The size of the discoloration was self-assessed and the cosmetic discomfort was classified by a scale from 0 (no discomfort) to 5 points (very discomforting). Photos were taken in selected cases after 1-2 years. Between November 2016 and April 2017, a deeper, para-tumoral injection was used and discoloration was noted 3 weeks after surgery.

Results

Ninety of 153 women (58.8%) developed a discoloration after a retro-areolar injection. The mean size was 26.1cm² (2-100cm²). The discoloration had vanished in 6.8% and 11.4% of the women after 1 and 2 years, respectively. The mean size of the discolorations was 18.2cm² (1-66cm²) and 13.6cm² (1-66cm²) after 1 and 2 years. The intensity of the color was continuously fading. The cosmetic discomfort was assessed as 2.2 points after 1 year and 1.0 after 2 years. Of 115 women with a deeper injection, 32.2% developed a discoloration with a mean size of 13.1cm² (1-36cm²), three weeks after surgery. The incidence and size of the discolorations were statistically significantly less and smaller after a deeper injection (p<0.001 and p=0.001, respectively). SNs were identified in 91% of women with a retro-areolar injection and in 93% of those with a deeper injection.

Conclusions

After an injection of SPIO, a discoloration might develop and the discoloration can stay for more than 2 years in many women. However, the color fades and the size diminish continuously and the women do not consider the discoloration a major cosmetic problem. A deeper injection reduces the incidence and the size of the discoloration with a similar detection ratio of SN. In our next study, we aim to reduce the volume of SPIO and thereby hopefully reduce the discoloration.

Title: FNAC: A predictor of final number of involved nodes at axillary clearance

Ayesha Khan¹, Nadia Hussain¹ and Tracey Irvine¹. ¹Royal Surrey County Hospital, Guildford, United Kingdom.

Body: BACKGROUND:
A vital part of pre-operative breast cancer assessment is axillary staging. Fine needle aspiration cytology (FNAC) is performed on clinically or radiologically positive axillary nodes in breast cancer. Our study looks at the sensitivity of performing FNAC in these patients and whether positive FNAC of axillary nodes can predict the final number of diseased nodes on completion axillary clearance (ANC).

METHODS:
All primary breast cancer patients undergoing FNAC between Oct 2009 to Oct 2011 were identified from electronic computer records. Data was collected on FNAC positivity, whether sentinel lymph node biopsy (SLNB) was performed, total number of nodes harvested at ANC and also the total number of diseased nodes at ANC. Patients who underwent neoadjuvant chemotherapy after a positive FNAC were analysed separately.

RESULTS:
Of the 230 patients who underwent FNAC, 130 were positive (56.5%). Of those who had a negative FNAC, 32% had a positive SLNB. We compared the ANC results of those who were FNAC positive (Group 1) with those who were FNAC negative but SLNB positive (Group 2). There was no significant difference in the mean number of harvested nodes at ANC between the two groups (mean= 17, p=0.14 on t-test). There was a significant difference in the number of diseased nodes in group 1 (mean = 7 nodes) compared with group 2 (mean = 3 nodes). In group 1, 56% of patients had 4 ≥ diseased nodes compared with 8.5% of patients in group 2. Neoadjuvant chemotherapy was given to 28 patients with a positive FNA. In this cohort, the mean number of positive nodes at axillary clearance was 2 and 10 % of patients had 4 ≥ diseased nodes on ANC. There was no significant difference in mastectomy versus breast conserving surgery rates between FNA positive and negative patients (p= 0.28 on Chi Square). The sensitivity of performing an FNAC was 81% in this study.

Key: FNAC: fine needle aspiration cytology, SLNB: Sentinel lymph node biopsy, ANC: Axillary clearance

CONCLUSION:
This study provides a predictor of the number of diseased axillary nodes in those with positive FNAC preoperatively. Over 50% of patients with a positive FNA have four or more diseased nodes compared with less than 10% in the FNAC negative but SLNB positive group. After neoadjuvant chemotherapy, FNA positive patients have a similar disease burden in the axilla as the FNAC negative but SLNB positive patients. This information can help to guide pre-operative discussions on the likely disease burden and need for adjuvant therapies such as chemotherapy and radiotherapy. Being able to predict the need for radiotherapy in particular can guide surgical decisions regarding type and timing of reconstructions to reduce the risk of surgical complications.

Title: Nomogram predicting axillary lymph node metastases to skip intraoperative analysis of sentinel lymph nodes

Jung Hyun Park¹, Young Wook Ju¹, Kyoung Eun Kim¹, Jiyoung Rhu¹, Yumi Kim¹, Eunshin Lee¹, Han-Byoel Lee¹,², Hyeong-Gon Moon¹,², Dong-Young Noh¹,² and Wonshik Han¹,². ¹Seoul National University Hospital, Seoul, Korea and ²Cancer Research Institute, Seoul National University College of Medicine, Seoul, Korea.

Body: Background: According to the American College of Surgeons Oncology Group Z0011 trial, complete axillary lymph node dissection (ALND) did not affect survival of patients with clinical T1-T2 invasive breast cancer and one to two sentinel lymph nodes (SLNs) metastases treated with lumpectomy, adjuvant systemic therapy, and radiation therapy. A significant proportion of breast cancer patients may not require ALND, in whom intraoperative analysis of SLNs can be omitted reducing operation time and cost. The aim of this study was to develop a nomogram predicting three or more axillary lymph nodes (ALNs) metastases based on preoperative imaging and clinicopathological factors.

Methods: The training set consisted of 1030 patients with clinical T1-T2 invasive breast cancer and clinically negative ALN who received surgery at Seoul National University Hospital (SNUH) between January 2010 and December 2013. Preoperative imaging techniques including ultrasonography (US), computed tomography (CT), positron emission tomography (PET), and clinicopathological features associated with three or more ALN metastases were evaluated by logistic regression analysis. A nomogram predicting three or more ALNs was developed with statistically significant factors. The validation set consisted of 781 independent patients who received surgery at SNUH between January 2014 and December 2015.

Results: Of the 1030 patients, 89 (8.6%) had three or more ALN metastases. Multivariate analysis showed that three or more ALN metastases was independently associated with tumor size (cm) by US (p<0.001), suspicious ALNs findings in US (p<0.001), chest CT (p<0.001), and PET/CT (≥ 1.4 SUV, p<0.001). Established nomogram evaluating the probability of three or more ALNs metastases includes the above four associated factors. The areas under the receiver operating characteristic (ROC) curve of the nomogram were 0.866 (95% confidence interval [CI] 0.826-0.905) for the training set and 0.867 (95% CI: 0.801-0.932) for the validation set. With cutoff point of 142, false negative ratio is 3.6%, and 8.6% of patients were candidates for intraoperative SLN analysis.

Conclusion: Patients with a strong possibility of three or more ALNs metastases can be identified using preoperative imaging methods including US, CT, and PET. The nomogram measuring this prospect may be valuable in skipping intraoperative analysis of SLNs with advantage of reduced operation time and cost.

Title: Sentinel lymph node biopsy by indocyanine green fluorescence detection in breast cancer cT1-4N0M0 patients. Frequency of false-negative results is low

Body: Breast cancer cT1-4N0M0 patients are usually need in a sentinel lymph node biopsy (SLNB). SLNB by indocyanine green (ICG) fluorescence detection is a modern technique possessing high level of lymph node detection rate, but frequency of false-negative results was not evaluated adequately.

Objective was to determine main diagnostic characteristics of the ICG fluorescence-guided SLNB in BC cT1-4N0M0 patients: node detection rate and frequency of false-negative results.

Methods: 99 patients with 100 cases of breast cancer cT1-4N0M0 (T1 – 43, T2 – 55, T3 – 1, T4 – 1) were operated, axillary part of operation consisted from the ICG fluorescence-guided SLNB and axillary lymphadenectomy of levels I–II or I–II–III. 12 patients had neoadjuvant chemotherapy and 8 – neoadjuvant hormonotherapy. Photodynamic Eye C9830 (Hamamatsu Photonics K.K) was using for emit near infrared radiation and fluorescent image registration. 2 ml 0.25% solution of ICG were injected inra- and sub-cutaneous periareolary or in a tumor projection, 2-5 minutes later it can be see fluorescent way to axillary. The procedure starting from injection of the ICG to the identification of a signal lymph node takes 15–30 minutes.

Results. Transcutaneous fluorescent lymphatic duct was visible in all 100 procedures, but not lymphatic node. Last can be found usually in a wound after Fascia superficialis and Fascia axillaris dissection. A signal lymph node was detected in 98 cases (98 %). Mean amount of sentinel lymphatic nodes = 1.9±0.1 (1-7 nodes). Mean amount of lymphatic nodes took with axillary dissection = 10.5±0.5 (5-26 nodes). In 28 (28.6%) cases of 98 were found to have metastases in signal lymph nodes. Other than signal lymph nodes had metastatic lesion only in 35.7% in signal lymph nodes N+ cases. False negative result occurred in 3 (3.1%) cases of 98, including 2 with metastases in signal lymph node finding by plan histological investigation, but not at froze section. No cases of allergic reactions or other adverse effects were diagnosed with standard subcutaneous use of indocyanine.

Conclusion. Fluorescence technique of the detection of signal lymph nodes has its own methodological issues: in most cases a signal lymph node is not visualized through the skin, it should be visualized in surgical wound using the course of lymphatic duct as guidance. Application of ICG fluorescence-guided SLNB in cN0 breast cancer patients allows high signal lymph node detection rate and low false negative rate, - 3%.

Acknowledgments. The authors thank Professor Gordon C. Wishart for the Sentinel Lymph Node Detection by ICG Fluorescence Technique teaching.
Title: How hot is enough for accurate sentinel lymph node axillary staging in breast cancer?

Moo Hyun Lee¹, Sun Hee Kang¹ and Jihyoung Cho¹. ¹Keimyung University School of Medicine, Daegu, Korea.

Body: Purpose:
Sentinel lymph node (SLN) biopsy is a well-established procedure for staging of the axilla in early-stage breast cancer and has replaced axillary lymph node dissection as the standard of care in patients with clinically lymph node–negative axilla. No consensus exists about the number of sentinel lymph nodes (SLNs) that should be removed based on radioactivity counts in breast cancer, although the “10% rule” is often used. In order to determine the frequency with which the hottest SLN 'fails' to be pathologically positive, and to determine which criteria best define the radioactive lymph node to be removed, we reviewed and analyzed our cases in which more than one SLN was detected and where there was also at least one pathologically positive node.

Methods:
We retrospectively studied 1062 breast cancer patients who underwent lymphoscintigraphy by injection of radioactive colloid and SLN biopsy between 2006 and 2015, with intraoperative determination of radioactive counts of nodes by a gamma probe.

Results:
A total of 247 patients (23.3%) had more than 1 SLN removed (mean 2.29); 53 patients (21.5%) had nodal metastases. Of the node-positive patients, the hottest SLN was positive in 90.6% (48 of 53). The lowest radioactive count of a positive SLN was 32% of that of the hottest node.

Conclusions:
In our study, most positive SLNs had the highest radioactivity and the hottest lymph node was not the pathologically positive node only in 9.4 %. Our institutional experience indicates that to obtain an acceptable false-negative rate, nodes should be removed until the 10% rule is met.
Title: Evaluation of “Systematic sonographic axillary staging” on clinically node positive breast cancer patients becoming clinically node negative after neoadjuvant chemotherapy

Tolga Ozmen¹, Mesa Lazaro¹, Alicia Vinyard¹ and Eli Avisar¹. ¹University of Miami, Miller School of Medicine, Miami, FL.

Body: Purpose
Accumulating evidence supports usage of sentinel lymph node biopsy (SLNB) for clinically node positive (cN+) breast cancer (BC) patients, who become clinically node negative (ycN-) after neoadjuvant chemotherapy (NAC). How to reassess the axilla after NAC is a challenging issue. In our institution, Systematic Sonographic Axillary Staging (SSAS) is currently being tested in this group of patients. The aim of this study is to analyze the early results of this approach.

Method
During initial presentation, systematic sonographic axillary staging is done preferentially by the surgeon. Needle biopsy is then performed of suspicious node(s). At completion of NAC, the axilla is again systematically staged sonographically, taking into account the pre-treatment disease locations. Any residual morphologically suspicious node undergoes a repeat needle biopsy. According to the evidence of residual disease, the patient is either scheduled for axillary dissection (AD) or for SLNB. We analyzed early results of SSAS on patients, who converted ycN (-) after NAC. Strictly adherence to SSAS protocol was the only inclusion criteria.

Results
A total of 25 patients were included. On repeat axillary USG after NAC, 11 patients had normal appearing and 14 patients had suspicious appearing lymph nodes (LNs). 14 patients underwent repeat biopsy; 9 patients had benign and 5 patients had malign pathology results. 20 patients underwent SLNB. Among 20 patients, 12 patients had negative SLNB and 8 patients had positive SLNB (4 patients had benign appearing LNs on repeat USG and 4 patients had benign biopsy results). 13 patients underwent AD (8 patients after positive SLNB and 5 patients directly after positive US-guided biopsy result). Among 8 patients with positive SLNB, 4 patients had macrometastatic disease (>2mm) on SLNB. In 3 of these 8 patients, no additional disease was found on AD, while 1 patient had only isolated tumor cell and 1 patient had only micrometastasis (Table 1).

* LN = lymph node

Conclusion
Systematic sonographic axillary staging is a reliable approach to cN (+) patients, who become ycN0 after NAC. This observation should be tested in a larger study.
Title: Determining the need for axillary lymph node dissection based on pre-neoadjuvant chemotherapy sentinel lymph node biopsy results

Vladimir F Semiglazov¹, Petr V Krivorotko¹, Elena K Zhiltsova¹, Garik A Dashyan¹, Konstantin U Zernov¹, Alexandr A Bessonov¹, Eketerina S Trufanova¹, Tengiz T Tabagua¹, Olga A Ivanova¹, Sergey V Kanaev¹, Sergey N Novikov¹, Pavel I Krzivickiyi¹, Zanna V Brayanceva¹, Alexander V Komayachov¹, Kirill S Nikolaev¹ and Larisa P Gigolaeva¹. ¹N.Petrov Research Institute of Oncology, St.Petersburg, Russian Federation.

Body: An open-label single institution study of sentinel lymph node biopsy prior to neoadjuvant chemotherapy is conducted in the N.N. Petrov research institute of oncology. So far 30 patients with locally advanced breast carcinoma (T2-4N0) were included. Mammography, breast US and SPECT are performed prior to hospitalization so as core biopsy with subsequent IHC staining to determine the levels of ER, PR, Ki67 and HER2. Sentinel lymph node biopsy with the use of radiocompound is performed prior to the first cycle of neoadjuvant chemotherapy. Patients receive 4 to 6 cycles with response evaluation after cycles 2, 4 and 6 (same evaluations as at the baseline). Axillary lymph node dissection is later performed along with the definitive surgery of the primary. Interim analysis showed: 3 of 30 patients with cN0 were node positive after sentinel lymph node biopsy, 27 were node-negative (sn)pN0. All patients with (sn)pN0 completed neoadjuvant chemotherapy with clinical response. No cases of upfront progression were detected. All patients (sn)pN0 underwent axillary dissection upon completion of the neoadjuvant therapy. No cases of nodal involvement were detected (ypN0). All of the patients considered node-positive after sentinel biopsy also underwent lymph node dissection after completion of the neoadjuvant therapy. 2 of them were pN1 and one was pN2.

Conclusion: sentinel lymph node biopsy in cN0 patients prior to neoadjuvant chemotherapy allows to determine a category of patients ((sn)pN0) in whom axillary dissection can be avoided, provided they remain clinically node-negative at the time of definitive surgery.
Title: Relationship of axillary total tumor load (TTL) by OSNA (one step nucleic acid amplification) in early breast cancer and clinical outcomes using strict Z0011 study criteria for axilla management

Raquel Tur1, Carlos De Grado2, María Rocío Martin1, Javier De Castro3, Elena Filipovich4, Beatriz Segovia1, Jaime Ceballos4, Juan Parrá5, Rafael Revestido1 and José E Alés-Martínez4. 1Complejo Asistencial de Ávila, Ávila, Spain; 2Complejo Asistencial de Ávila, Ávila, Spain; 3Complejo Asistencial de Ávila, Ávila, Spain; 4Complejo Asistencial de Ávila, Ávila, Spain and 5Biomedical Investigation Center (CIBER-BBN. ISCIII), Ávila, Spain.

Body: Background: The study of sentinel lymph node (SNL) assessed by OSNA provides a new variable, Total Tumoral Load (TTL). This variable is defined as the amount of CK19 mRNA copies number in all positives SLN. TTL has been showed to predict the axillary node status and has been analysed to determine its usefulness in the axillary surgical management. Based on TTL values different cut-off points have been proposed (last 25,000 copies) to establish a new tool to practice axillary lymph node dissection (ALND). We present the follow-up data of at least 5 years of breast cancer patients who underwent ALND according, strictly, to Z0011 trial criteria. We hypothesized that there will be no correlation between TTL and locoregional relapse if Z0011 are followed.

Methods: Clinicopathological and follow up data were obtained from patients with invasive breast cancer and SNL assessed by OSNA between 2011 and 2012 at Complejo Asistencial de Ávila, Spain. ALND was decided based on Z0011 study criteria independently of TTL. All patients have been followed for a minimum of 5 years.

Results: A total of 106 patients underwent SN assessed by OSNA, age range 27-85 years (mean 58.96). Of them 90% were ductal, 7.5% lobular and 2% others. By immunophenotype: Luminal A 55%, Luminal B 28%, Triple Negative 9.4%, Her2 positive 3.7% and Luminal B-Her2 positive 2.8%. TTL was equal to zero in 58 cases and greater than zero in 48 cases with a range of 280-2.700.000 copies. Only 5 cases met ALND criteria (average TTL 68.164). Average TTL in cases without ALND was 111.000. For the time being, none of them has had locoregional relapse (median follow up 65 months). 3 patients have died one metastatic disease (Negative SN), one uterine cervix cancer and one neutropenic fever.

</tbody>
</table>
Conclusions:
- Using Z0011 criteria and OSNA no locoregional recurrence has been observed so far.
- TTL did not predict risk of recurrence
- If we had based axillary management only on TTL values (i.e. higher than 25,000 copies) we would have unnecessarily increased the number of lymphadenectomies in a 22%.
This is an ongoing study that designed to increased the sample size and obtain longer follow-up data.
**Title:** Impact of prognoses on the discrepancies in histological grade of breast cancer between core needle biopsy and surgical excision specimen

Rikiya Nakamura¹, Naohito Yamamoto¹, Toshiko Miyaki¹, Ryoutarou Teranaka¹ and Makiko Itami². ¹Chiba Cancer Center, Chiba, Japan and ²Chiba Cancer Center, Japan.

**Body:** Purpose: The high reliability and utility of core needle biopsy (CNB) have been previously described. Histological grade in CNB is one of the main determinants of the need for neoadjuvant systemic therapy. Our aim in this study was to clarify the host and histopathological factors influencing the discrepancies in histological grade (HG) between CNB and surgically excision specimen (SES).

Methods: A total of 1342 operable invasive breast carcinoma biopsies were assessed and compared with surgical specimens in our hospital. Patients who required neoadjuvant chemotherapy were excluded. Histological grade (tubule formation, nuclear pleomorphism and mitotic index) was assessed between paired CNB and SET samples.

ER and PgR status were determined using immunohistochemistry(IHC). HER2 status was determined using IHC and scored from 0 to 3+. Fluorescence in-situ hybridization analysis was carried out in HER2 2+ cases. The cut off point for ER and PgR positivity was set at 1%.

Results: The clinicopathological characteristics of tumors showed in

Clinico-pathological characteristics of 1342 patients and tumors by discordance group between CNB and SES for histological grade

CNB; core needle biopsy, SES; surgical excision specimen, HH group (high grade in CNB/high grade in SES), LL group (low grade in CNB/low grade in SES), HL group (high grade in CNB/low grade in SES) and LH group (low grade in CNB/high grade in SES).

The concordance rates of HG of luminal type, HER2 type luminal HER2 type and Triple negative type in CNB and SES were 91%, 64%, 73% and 66%, respectively (p>0.001). Factors of discrepancy were T size, vessel invasion and ER/HER2 status for HG. The discrepancy factors were assessed with univariate and multivariate analysis. The underestimate and overestimate rates of HG in CNB compared to SES were 7.5% and 1.3% in ER(+)HER2(-) type, 32%, and 3.1% in HER2 type, 22% and 4.3% in
ER(+) HER2(+) type and 29% and 5.5% in Triple negative type (TN), respectively. The concordance rates of tubule formation, nuclear pleomorphism and mitotic index in CNB and SES were 81%, 97% and 93% in luminal type, 85%, 66% and 33% in HER2 type, 77%, 87% and 83% in luminal HER2 type and 82%, 67% and 73% in TN type respectively.

Conclusions: Using the largest known dataset to date of paired samples from a single institution, we evaluated the accuracy of CNB and the discrepancy factors between CNB and SES in breast cancer patients.

We conclude that CNB for histological grade assessment in patients with HER2 positive or TN breast cancer before neoadjuvant treatment should be used with caution.
2017 San Antonio Breast Cancer Symposium

Title: Concordance between immunohistochemical and gene-expression based subtyping of early breast cancer using core needle biopsies and surgical specimens - experiences from SCAN-B

Gilberto Morgan¹, Christer Larsson³, Balázs Tahin⁵, Johan Vallon-Christersson²,³, Jari Häkkinen²,³, Anna Ehinger²,³,⁴, Martin Malmberg¹, Cecilia Hegardt²,³, Åke Borg²,³, Lisa Rydén²,⁷, Lao H Saal²,³, Ingrid Hedenfalk²,³ and Niklas Loman¹,²,³. ¹Skåne University Hospital, Lund, Sweden; ²Lund University, Lund, Sweden; ³Lund University Cancer Centre, Medicon Village, Lund, Sweden; ⁴Skåne University Hospital, Lund, Sweden; ⁵Skåne University Hospital, Malmö, Sweden; ⁶Lund University, Lund, Sweden and ⁷Skåne University Hospital, Lund, Sweden.

Body: Introduction: Preoperative chemotherapy in early breast cancer increases the rate of breast preservation and provides prognostic information. Treatment decisions in these cases rely on biomarker assessments and subtyping from tissue acquired through core needle biopsies. Tumor heterogeneity and representativity are pitfalls when limited tissue is available. Biomarker expression may change considerably as a result of preoperative chemotherapy, and in a subset of cases a complete pathological response at time of surgery may even preclude any further assessment. Therefore, the reliability and reproducibility of biomarkers in base-line core biopsies are of utmost importance for patients treated with preoperative chemotherapy.

Material and Methods: In an ongoing population-based study of early breast cancer, the SCAN-B (NCT02306096), patients were identified for whom an ultra-sound guided core needle biopsy was analyzed for biomarkers during primary clinical work-up and the patient was offered primary surgery as initial treatment. Clinical biomarker profiles including immunohistochemical (IHC) determinations of ER, PgR, HER2 and Ki67 were translated to subtypes according to modified St Gallen criteria (2013) and compared with paired samples from surgical specimens. In addition, tumor specimens for biomolecule extraction and RNA sequencing were collected fresh in RNAlater.

Results: IHC data was available from 51 paired samples. The subtype distribution in core needle biopsies was DCIS in 1 case (2 %), LCIS in 1 case (2 %) Luminal A-like in 16 cases (31 %), Luminal B-like (HER2 negative) in 26 cases (51 %), Luminal B-HER2-like (HER2 positive) in 4 cases (8 %), HER2-positive (non-luminal) in 1 case (2 %) and triple negative (ductal) breast cancer in 2 cases (4 %). The subtype distribution in surgical specimens was DCIS in 0 case (0 %), LCIS in 1 case (2 %) Luminal A-like in 18 cases (35 %), Luminal B-like (HER2negative) in 23 cases (45 %), Luminal B--like (HER2 positive) in 6 cases (12 %), HER2-positive (non-luminal) in 1 case (2 %) and triple negative (ductal) breast cancer in 2 cases (4 %). Notably, 5/16 cases classified as Luminal A-like in the core needle biopsy were reclassified as Luminal B-like (HER2-negative) in the surgical specimen, whereas 9/26 cases classified as Luminal B-like (HER2-negative) in the core needle biopsy were reclassified as either Luminal A-like (7 cases) or Luminal B-like (HER2 positive) (2 cases) in the surgical specimen. In all instances, except one, transition between Luminal A-like and Luminal B-like was due to recorded Ki67 expression. One case that was classified as a DCIS in the core needle was reclassified as Luminal B-like (HER2 negative) at time of surgery.

Discussion: In this limited material, discordance between evaluations regarding Luminal A-like and Luminal B-like was considerable. Especially the misclassification of primary HER2-positive breast cancer needs further evaluation. These findings may be caused by tumor heterogeneity, and highlight the risk of both over- and under-treatment upon biomarker assessment from core needle biopsies. Data from gene expression based subtype classifications will be presented during the meeting.

Title: Detection of mutations in single tumor cells collected by fine needle aspiration in a mouse xenograft breast cancer model using MALDI-TOF

Jackie L Stilwell¹, Amy Hobeida², Ryan T Birse³, Nolan Ericson¹, Arturo B Ramirez¹, Sara Hummel³, Darryl Irwin³, Eric P Kaldjian¹ and H Kim Lyerly². ¹RareCyte, Inc, Seattle, WA; ²Duke University Medical Center, Durham, NC and ³Agena Bioscience, Inc, San Diego, CA.

Body: Background: Breast fine needle aspiration (FNA) is less invasive than a core needle biopsy and reduces the risk of infection or injury to the patient. However, less tissue is available for analysis than with biopsy. The ability to detect and analyze single atypical cells for molecular abnormalities would allow the consideration of more widely adopting FNA for diagnosis. Here we demonstrate the feasibility of this approach in a mouse xenograft model of breast cancer.

Methods: Human-into-mouse MBA-MD-231 breast cancer xenograft tumors were aspirated using a technique that approximates the clinical procedure in patients. Cells from the FNA were prepared by two methods: 1) mixing the aspirate with transfer fluid and spreading onto a Superfrost® Plus slide using RareCyte’s AccuCyte® process, and 2) spraying the aspirate directly onto a Superfrost Plus slide, then drying and fixing in ethanol. A single tumor was also disaggregated into suspension, filtered, mixed with transfer fluid and spread on to slides as in method 1 above as a control. Slides were fixed in formalin, stained on an automated immunostainer and imaged using the CyteFinder® digital fluorescence scanning microscope. Tumor cells were identified by positive nuclear, EpCAM, and cytokeratin staining, and negative CD45 staining. Tumor cells were picked from the slides and put into PCR tubes using the CytePicker® module. DNA from individual cells was amplified using the PicoPLEX® (Rubicon) whole genome amplification (WGA) kit. Quality control (QC) of the WGA reactions was performed by PCR of amplicons on eight different chromosomes. Specific gene regions surrounding 5 mutations present in MBA-MD-231 cells were amplified from the WGA products and scored for the mutations using a single PCR reaction iPLEX® Pro panel using the MassARRAY® platform (Agena Bioscience). A lung tumor panel was also run as a negative control.

Results: FNA tumor cells stained with epithelial markers similarly to cells from the disaggregated tumor control and were easily identified. Slides prepared by method 1 above spread into a uniform monolayer making it easier to pick individual cells. Cells from method 2 tended to clump making it more difficult to pick individual cells. Cells were thus picked only from method 1 slides. QC measurements of WGA products from individual cells demonstrated broad genome coverage of amplification; 10 of 14 cells exhibited 7 or more QC products out of 8. Point mutations in four genes (BRAF, KRAS, NF2, and TP53) and a deletion in one gene (CDKN2A) were measured in these cells by iPLEX® Pro chemistry on the MassARRAY® system and found in all cells picked, with all mutations identified in most cells. These mutations and the deletion were not detected in control WBCs.

Conclusions: Individual breast cancer cells were identified in FNA samples from xenograft tumors and molecularly characterized, verifying that the cells identified by positive staining were tumor cells. These results demonstrate the feasibility of detecting and verifying tumor cells in FNA samples in breast and other cancers.
Clinical utility of finding pathogenic mutations beyond BRCA1/2 in breast cancer patients

Edward D Esplin¹, Scott Michalski¹, Shan Yang¹, Heather Hampel², Joanne Jeter², Kevin Sweet², Robert Pilarski², Rachel Pearlman², Kate Shane², Pamela Brock², Judith Westman², Anu Chittenden³, Jill Stopfer³, Katherine Schneider³, Rosalba Sacca³, Samantha Stickevers³, Lindsay Kipnis³, Diane Koeller³, Shraddha Gaonkar³, Jilliane Sotelo³, Erica Vaccari³, Sarah Cochrane³, Marjan Champine⁴, Whitney Espinel⁴, Stephen E Lincoln¹ and Robert L Nussbaum¹. ¹Invitae, San Francisco, CA; ²The Ohio State University Comprehensive Cancer Center, Columbus, OH; ³Dana Farber Cancer Institute, Boston, MA and ⁴Huntsman Cancer Institute, Salt Lake City, UT.

Body: Background

The clinical utility of germline genetic testing for BRCA1 and BRCA2 has long been established. However, management recommendations for pathogenic variants in other genes, typically included in multigene panels, have only recently been included in consensus guidelines for HBOC. The clinician actions implemented for findings in these genes, and patient follow-up, are not yet well studied. We report interim results from a multi-site study of clinical actions undertaken in patients presenting with HBOC and carrying a pathogenic germline mutation in cancer risk genes other than BRCA1/2.

Methods

We retrospectively examined a cohort of patients with a personal history of HBOC who had been referred for hereditary cancer multigene testing from three major academic medical centers. For patients with pathogenic findings in a non-BRCA1/2 cancer risk gene, ordering clinicians completed a short case report form describing the clinical actions taken in response to the genetic test result, and patient follow-up. Some patients were lost to follow-up and answers of “unknown” were permitted. Genes with positive findings included CHEK2, PALB2, ATM, MUTYH, RAD51C, TP53, MSH6, RAD50, APC, BARD1, BRIP1, MSH2, NF1, NBN, PMS2, and PTEN. Case report forms were available for 77 patients as of our cut off date, and these data were de-identified and summarized for this interim report. Additional cases continue to accrue in this ongoing study.

Results

In 57% (44/77) of cases, clinicians reported that counseling and/or clinical management recommendations were changed in response to the genetic test findings. Management changes included modification of imaging surveillance (38%), considered or recommended surgical prophylaxis (12%), modified surgical plan for an existing malignancy (5%), and for one patient each: inclusion in a research trial for PARP inhibitors, modification of colonoscopy schedule, and screening for cancers other than existing malignancy. Clinicians indicated that genetic test results changed management in 48% of patients, did not change management in 29%, and had unknown impact for 23%.

Clinicians also reported that counseling and/or management for the patients' family members was changed in 67% (52/77) of cases, including family variant testing. 27% (21/77) of the patient families had cascade genetic testing, and one or more new carriers were identified in 47% (10) of the tested families. In 58% of cases, the impact of management recommendations on family members was unknown as of the case report date.

Conclusions

Pathogenic variants in non-BRCA genes are present in about 3-11% of patients with a history of HBOC. This study suggests that genetic test results in cancer genes beyond BRCA1/2 changed clinical management for a majority of patients and their family members, led to identification of new carriers, and directly impacted treatment decisions. In almost half of these patients, genetic test results impacted their health outcome, including those reported to be disease free after undergoing intervention or prophylactic surgery informed by their genetic variant. More research is needed to improve the implementation of genetic testing based management recommendations for patients and their family members.
Title: ER dependent breast cancer phenotype in BRCA 1/2 carriers

Tamar Y Peretz¹, Aviad Zick¹, Kadouri Luna¹, Albert Grinshpun¹, Amir Sonneblick¹, Beatrice Iziely¹, Tamar G Hamburger¹, Sherri Cohen¹, Avital M Granit¹, Michal Dvir¹ and Shai Rosenberg¹. ¹Hadassah-Hebrew University Medical Center, Jerusalem, Israel.

Body: Background: Hereditary breast cancer (HBC) comprises more than 10% of all breast cancers (BC). Mutations in the BRCA1/2 genes are found in approximately half of HBC patients. The majority of BRCA1 associated tumors are ER, PR and HER2 negative with basal-like expression pattern. BRCA2 associated tumors are mostly ER positive (ER+). In the present study we aim to further explore clinical and molecular characteristics of BRCA associated BC in 3 different cohorts.

Methods: Three different BC databases (DB) were evaluated: (i) Hadassah oncogenetic BC DB (n=4429); (ii) Nick-Zainal et al. BC DB (n=560), and (iii) METABRIC BC DB (n= 1980). We tested for differences in age at diagnosis between BRCA positive (BRCA+) and BRCA negative (BRCA-) patients with either ER+ or ER negative (ER-) tumors. Point mutation analysis was performed in cohorts ii & iii and mRNA differential expression (DEA) and pathway analysis were performed in cohort iii, using Ingenuity Pathway Analysis (IPA).

Results: Age (years) at diagnosis for cohorts i, ii,&iii respectively, for ER+ PT: BRCA1-44, NA, 60; for BRCA2-49, 48, 64; for BN – 53, 56, 63. For ER-: BRCA1-42, 42, 47; for BRCA2-48, 52, 49; for BN-49, 54, 56. For cohorts ii&iii, higher frequencies of TP53 and PIK3Ca mutations were found among BRCA+&BRCA-, respectively. DEA was performed between BRCA++BRCA- in ER-tumors: the major activated pathways involved cancer related processes and were highly significant (up to p=1e-7.5, FDR=1e-4.5). Surprisingly - the most significant pathway was Estrogen Mediated S-phase Entry and the most activated upstream regulator was ERBB2. Similar evaluation in ER+ showed mostly differences in immune related pathways (differences not statistically significant).

Conclusions: Younger age at presentation was observed in BRCA1 vs. BRCA2 patients. No age differences were observed between ER+&ER- PT in cohort i&ii, in cohort iii ER- BRCA+ Patients were younger than ER+ BRCA+ (similar age as ER+ BRCA-). BRCA+ show different mutational profile than BRCA-. ER+ BRCA+ and BRCA- show similar genomic characteristics. By contrast, for ER- BRCA+ differs markedly from BRCA-. This might imply that BRCA+ associated tumors consist of two genomically distinct subtypes: (i) ER-, and (ii) ER+. The results may shed light on possible somatic factors which affect the development of BC BRCA+ and carry preventive and therapeutic implications.
Title: Analysis of hereditary cancer syndromes by use of a panel of genes: More answers than questions

Nikolaos Tsoulos¹, Angela Apessos¹, Konstantinos Agiannitopoulos¹, Georgia Pepe³, Georgios Tsiaousis¹, Stavroula Kambouri¹, Dan Tudor Eniu², Andrei Ungureanu³, Eugeni Banu³, Larisa Ciule³, Alexandru Blidaru³, Angelica Chiorean³, Dana Lucia Stanculeanu³, Delia Mateescu⁷ and Georgios Nasioulas¹. ¹GeneKor M.S.A, Athens, Attiki, Greece; ²Institutul Oncologic Prof. Dr. I. Chiricuta, CLUJ, Romania; ³Amethyst Radiotherapy, Cluj-Napoca, Romania; ⁴Spitalul Sfantul Constantin, Brasov, Romania; ⁵Spitalul Clinic Judetean de Urgenta, Cluj-Napoca, Romania; ⁶Institutul Oncologic Bucuresti, Bucuresti, Romania and ⁷Regina Maria, Bucuresti, Romania.

Body: INTRODUCTION
Hereditary breast cancer is estimated to account for approximately 10% of all breast cancer cases. In addition, an estimated 15-20% of those affected by breast cancer have a positive family history. Despite the fact that BRCA1 and BRCA2 are the two most significant genes in hereditary breast cancer predisposition, twenty years of analysis has highlighted the fact, that mutations in these two highly penetrant genes, are only present in approximately 20% of high risk families. Other genes, mutations in which are associated with high risk of breast cancer, were identified because of the strong association with familial cancer syndromes, in which breast cancer is one of the defining components. Technological advances in molecular biology and especially DNA sequencing, commonly designated as “Next Generation Sequencing – NGS” have aided in the concentrated efforts to identify new genes responsible for the missing heritability, allowing the application of this knowledge in the diagnostic setting.

AIM
The aim of this study was to investigate the extent and nature of mutations in 26 genes implicated in hereditary cancer predisposition in families of Romanian descent.

MATERIALS & METHODS
In total, 297 Romanian families have been analyzed by our group in the past three years. Genomic DNA was enriched for targeted regions of 26 genes involved in hereditary predisposition to cancer (ATM, BARD1, BLM, BRCA1, BRCA2, BRIP1, CDH1, CHEK2, EPCAM only intron 8, exon 9 and 3’UTR), FAM175A, MEN1, MLH1, MRE11A, MSH2, MSH6, MUTYH, NBN, PALB2, PMS2, PTEN, RAD50, RAD51C, RAD51D, STK11, TP53, XRCC2). Sequencing was carried out using the Illumina NGS technology. Reads were aligned to the reference sequence (GRCh38), and sequence changes were identified and interpreted in the context of a single clinically relevant transcript. The presence of large genomic rearrangements was investigated by use of MLPA. All clinically significant observations were confirmed by orthogonal technologies.

RESULTS
In total, a pathogenic mutation was identified in 79 of the 297 families (26.6%) analyzed. Clinically significant mutations were identified in 17 of the genes included in the panel. The most commonly mutated genes in the Romanian population were BRCA1 and BRCA2, accounting for 50% of the mutations identified, followed by PALB2 (12%), CHEK2 (9.4%) and ATM, NBN and RAD50 which accounted for 3.5% of the mutations each. Of note is that 7 of the 79 affected families (8.8%) carried clinically significant mutations in two different genes.

CONCLUSIONS
Our results support the clinical significance of analysis of a panel of genes involved in hereditary cancer predisposition. In this series of patients, analysis of this panel allowed for the identification of 14% additional pathogenic variants. This is especially true in those cases where more than one pathogenic variant was identified.
Title: BRCA1/2 polymorphisms in Chinese breast cancer patients: Database from a national multi-center large-scale study

Zefei Jiang1, Fengrui Xu1, Peifen Fu2, Zhimin Fan3, Feng Jin4, Hong Liu5, Xiaojia Wang6, Haiqing Zhang7, Haibo Wang8 and Jianguo Zhang9. 1 Affiliated Hospital of Academy of Military Medical Sciences; 2 The First Affiliated Hospital of Zhejiang University; 3 The First Affiliated Hospital of Jilin University; 4 The First Affiliated Hospital of China Medical University; 5 Tianjin Medical University Cancer Institute and Hospital; 6 Zhejiang Cancer Hospital; 7 Dalian Central Hospital; 8 Affiliated Hospital of Qingdao University and 9 Second Affiliated Hospital of Harbin Medical University.

Body: Background: To determine the characteristics of BRCA1/2 germline mutations and establish the BRCA1/2 mutations database of China, we launched a national multi-center study and detected the characteristics of BRCA1/2 germline mutations in a large cohort of Chinese people with breast cancer.

Methods: A total of 1725 Chinese women from 39 centers with breast cancer were enrolled in this study. Genomic DNA was extracted from the patient's saliva and be sequenced by next-generation sequencing for BRCA1/2 mutations.

Results: In total, 149 patients (9.21%) carried a BRCA1 or BRCA2 mutation (113 in BRCA1 and 117 in BRCA2) in this cohort and the mutation types is shown in table 1.

Title: Association between BRCA1 and BRCA2 mutations and survival in breast cancer patients according to molecular subtype

Olivier Tredan¹, Solene De Talhouet¹, Julien Peron², Alex Friedlaender³, Aurelie Vuilleumier³, Valeria Viassolo³, Aurelie Ayme³, Pierre O Chappuis³, Adrien Buisson², Valerie Bonadona¹, Alexandre Bodmer³ and S Intidhar Labidi-Galy³. ¹Centre Léon Bérard, Geneva, Switzerland; ²Hospices Civils de Lyon, Lyon, France and ³Geneva University Hospitals, Geneva, Switzerland.

Body: Background:
Germline mutations in BRCA1/BRCA2 genes increase the risk of breast and ovarian cancers. In ovarian cancer patients (pts) treated with platinum, BRCA1, and especially BRCA2, carriers have better survival than non-carriers. In breast cancer pts, BRCA1 carriers have higher response rate to neoadjuvant chemotherapy, however the benefit on survival remains unclear.

Patients and Methods:
A cohort study was conducted in France and Switzerland and consisted in 860 pts diagnosed with early breast cancer who underwent genetic screening for BRCA1/BRCA2 germline mutations and who received neo(adjuvant) chemotherapy. Disease-free survival (DFS) and Breast-cancer specific survival (BCSS) were analyzed according to BRCA1/BRCA2 mutations and breast cancer subtype (triple negative breast cancers (TNBC) vs non-TNBC).

Results:
One hundred and forty-three pts carried BRCA1 mutation; 88 had BRCA2 mutation; and 629 were non-carriers. Median age at diagnosis was 39 years; median follow-up was 4.8 years. Two hundred and fifty-three pts had TNBC (94 BRCA1, 14 BRCA2 and 145 non-carriers), and 607 had non-TNBC (49 BRCA1, 74 BRCA2 and 484 non-carriers). Among TNBC pts, BRCA2 mutations were associated with higher 5-years DFS (100% vs 71% for non-carriers and 80% for BRCA1 carriers; log-rank p=0.040), and BCSS (100% vs 78% for non-carriers and 92% for BRCA1 carriers; log-rank p=0.011). BRCA1 mutations were associated with higher 5-years DFS compared to non-carriers, but the association did not reach statistical significance (HR adjusted on nodal status=0.64; 95%CI 0.36-1.16, Wald test p=0.14). BRCA1 mutations were associated with an improved 5-years BCSS compared to non-carriers (HR adjusted on nodal status=0.38; 95%CI 0.16-0.87, Wald test p=0.022). In non-TNBC patients, BRCA1 or BRCA2 mutations were not associated with higher 5-years DFS (79% for BRCA1, 79% for BRCA2 carriers, and 80% for non-carriers; log-rank p=0.88) nor BCSS (94%, 92%, and 94% respectively; log-rank p=0.79).

Conclusions:
Among pts with TNBC, having BRCA germline mutation was associated with improved survival. In our cohort of TNBC pts, BRCA2 carriers did not present breast cancer relapse.

Title: Telomerase polymorphism and breast cancer

Miriam M Alvares¹, Katherine S Rodrigues², João N Matos² and Diego M Oliveira². ¹Centro de Cancer de Brasília - CETTRO, Brasília, Distrito Federal, Brazil and ²Hospital Universitário de Brasília - HUB, Brasília, Distrito Federal, Brazil.

Body: Introduction:
Telomerase is an enzyme responsible for telomere maintenance in almost all human cancer cells, but generally not expressed in somatic ones. The minimum essential components of telomerase are the catalytic subunit, telomerase reverse transcriptase (TERT), and a non-coding RNA (TERC); TERT reverse transcribes telomere DNA using TERC as the template (1). Given the fundamental role of TERT in oncogenesis, polymorphisms of genes related to telomerase may influence the expression levels of this enzyme, influencing the host's susceptibility to tumor progression and metastasis [2,3]. Some studies have linked these polymorphisms with susceptibility and/or survival of patients with breast cancer [2,4,5,6]. In this work, we analyzed a region in the second intron of the gene TERT, located in chromosome 5p15.33, by sequencing, in order to find mutations associated with clinical aspects. The DNA of 65 patients with breast cancer were evaluated.

Methodology:
The population consisted of breast cancer patients who accepted to participate in the study, attended from March 2015 to September 2016 at a public hospital (HUB) and a private center for cancer treatment (Cettro®), both in Brasilia city – Brazil. Standard DNA extraction from blood samples was performed by dehydration and precipitation with saturated NaCl solution. The concentration and purity of the DNA were determined by spectrophotometry using the NanoDrop One equipment® (Themo Scientific, Madison, USA). The region of interest was amplified by conventional PCR. The primer sequences were: F: 5'-ATG CGA CAG TTC GTG GCT CA-3' and R: 5'-ATC CCC TGG CAC TGG ACG TA-3'. The sequencing was performed in the AB 3500 Genetic Analyzer® (Applied Biosystems). Data were analyzed by using software Chromas Lite ® (2.01, Technelysium Pty Ltd.) and the BLAST (NCBI - http://blast.ncbi.nlm.nih.gov/Blast.cgi). GraphPad Prism software version 7.02 was used for statistical analyzes.

Results and Conclusion:
A total of 65 patients were selected for DNA analysis. We identified a recurrent mutation (C>T) among them. The allelic frequencies were 0.79 for C and 0.21 for T. Only three patients had genotype TT, but 21 were heterozygous (CT). This polymorphism was significantly associated with tumor grade, the presence of T allele were implicated in more aggressive (grade 3) tumors (p=0.028, chi-square test). Those patients with genotype CT were at greater risk than others with CC genotype of having high grade (3) breast tumors (odds ratio = 6.13, 95% confidence interval 1.46, 25.74; relative risk 1.9, 95% confidence interval 1.02, 3.59).
Body: Introduction
The management of breast cancer (BC) patients who undergo mastectomy in the setting of 1-3 positive lymph nodes has been controversial. This retrospective Translational Breast Cancer Research Consortium study evaluated the molecular aberrations associated with locoregional recurrence (LRR) or distant metastasis (DM) compared to controls in an effort to identify molecular predictors associated with recurrence.

Methods/Materials
We identified 115 HER2 negative, therapy naïve, T 1-3 and N 0-1 BC patients treated with mastectomy and no post mastectomy radiation therapy from 1997 to present with available FFPE tissue blocks. The cohort included 32 patients with LRR, 34 with DM, and 49 controls (without recurrence) who were matched for stage, grade, hormone receptor status, age ≤ or > 50, chemotherapy receipt, and margin status. Matched primary and recurrent LRR samples were available for 3 patients. Hybrid capture next generation sequencing (NGS) of 142 cancer related genes and RNAseq were performed to identify DNA/RNA alterations associated with LRR or DM. The frequency of common alterations on NGS was compared with Fisher's exact test. Expression of each gene from mRNA-Seq was treated as an explanatory variable. Immunohistochemistry (IHC) was performed for PTEN, Ki-67 and cleaved caspase 3 (CC3). PTEN loss and percentage of Ki-67 and CC3 positive cells were compared between groups with Fisher's exact test and nonparametric methods, respectively.

Results
RNAseq was performed on 115 patients; there was no difference in RNA expression levels between the groups. DNA analysis was performed on 57 patients (17 LRR, 15 DM and 25 controls), NF1 mutation rate was significantly elevated in both the LRR (24%) and DM (27%) samples compared to controls 0%; (p=0.0070). The mitogen activated protein kinase (MAPK) pathway was significantly mutated in both LRR (47%) and DM (40%) samples compared to the controls 0%; (p<0.0001). There was no significant difference in the rate of alterations of the PI3K/Akt/mTOR pathway among the three groups. Of three patients with matched primary vs LRR samples, one had concordant mutations. The second patient had additional mutations in the LRR, including gain of a NF1 mutation. The third patient had complete discordance of mutations identified in primary and LRR and had gain of HER2 amplification, suggestive of a new primary. There was no significant association between the groups and the loss of PTEN expression or CC3 expression. There was a significant difference between Ki 67 positive cells in patients with LRR (mean 29%), DM (mean 26%) versus controls (mean 14%, p= 0.0011). HR+ patients were significantly more likely to have a positive PTEN, lower Ki-67 and lower CC3 expression, p=0.0004, p<0.0001, and p<0.0001 respectively.

Conclusions
In this matched cohort analysis, mutations in the MAPK pathway, specifically NF1, were associated with both LRR and DM, suggesting that alterations in this pathway are associated with a more aggressive tumor phenotype. However, there were no molecular features that discriminated between those likely to recur locally alone versus distantly. Further study is needed to validate these findings, and to determine whether targeting alterations in this pathway could decrease the risk of recurrence.
Body: Background: Despite a growing understanding of the somatic landscape of breast tumors from BRCA1 and BRCA2 mutation carriers, less is known about breast tumors from carriers of germline mutations in other homologous recombination and DNA repair pathway genes such as ATM, CHEK2, and PALB2.

Methods: We identified 44 clinically annotated breast cancer cases that included carriers of germline mutations in BRCA1 (n=9), BRCA2 (n=9), ATM (n=5), CHEK2 (n=7), and PALB2 (n=6) from the Hereditary Cancer Risk Program at BUMC. Sporadic breast cancers cases (n=8) were also collected. Genomic DNA and RNA were extracted from macro-dissected FFPE tumor sections, adjacent normal FFPE tissue, along with constitutional genomic DNA from blood. Expanded whole exome sequencing (WES) was performed on normal/tumor pairs and RNA-seq from tumors for each case. Bioinformatics analysis was performed using industry standard methods for somatic characterization.

Results: All germline mutations were confirmed by WES. Somatic mutational analysis and copy number profiling from WES revealed the greatest similarities among BRCA1 and CHEK2 carriers. As expected, TP53 mutations were found in 8 of 9 BRCA1 carriers as all were triple negative subtype. We also detected somatic TP53 mutations in tumors from 4 of 7 CHEK2 carriers. Somatic TP53 mutations were found in only 1 of 7 BRCA2 tumors and 1 of 4 PALB2 tumors tested. Furthermore, BRCA1 and CHEK2 tumors showed trends of having higher mutation burden. Analysis of copy number BRCAness demonstrated stronger similarities between BRCA1, ATM, CHEK2, and PALB2 tumors. BRCA2 tumors were unique with fewer events and characterized by specific amplifications including 11q23 (CCND1) and 17q23 (BRIP1). Hierarchical clustering of RNA-seq data revealed strong clustering of BRCA1 tumors compared to all other tumors, predominantly attributed to breast cancer subtype. Furthermore, pathway analysis of genes that distinguish BRCA1 mutation positive versus non-BRCA mutated tumors showed strong correlation to pro-inflammatory and immune pathway signatures.

Conclusions: Molecular analysis of 44 breast cancers from individuals with inherited predisposition to breast cancer via BRCA1, BRCA2, ATM, CHEK2, and PALB2 germline mutations demonstrated strongest somatic similarities between BRCA1 and CHEK2 tumors although all BRCA1 were TNBC and all CHEK2 tumors were ER positive. Marked differential gene expression differences in RNA expression patterns were observed in BRCA1 mutation carriers compared with all other groups analyzed. Our study is among the first to interrogate the profile of non-BRCA mutated hereditary breast cancers.
Body: Background The human epidermal growth factor receptor 2 (ERBB2) can be altered by somatic mutations (with/without ERBB2 amplification) that likely drive tumorigenesis. Here, we present the first study that thoroughly investigates the behavior of patients with ERBB2 mutated tumors in a large unselected cohort of metastatic breast cancer (MBC) patients.

Patients and Methods We included retrospectively all MBC patients with sufficient tumor material available, independent of hormone receptor or ERBB2 amplification status, diagnosed between 2000 and 2015 at the Multidisciplinary Breast Center of University Hospitals Leuven. Genomic DNA extracted from primary breast tumors was subjected to deep targeted re-sequencing using an assay covering 5 exons (exons 8, 17, 19, 20 and 21) known to accumulate ERBB2 hotspot mutations. Clinical characteristics, treatment response and outcomes (excluding bilateral BC) were compared between patients with and without ERBB2 mutations.

Results We established and validated a research use only next-generation sequencing assay across five exons of ERBB2. Somatic ERBB2 mutations with an allelic frequency of ≥5% in at least one independent analysis, were observed in 1.8% (13/721) of MBC patients. MBC patients with ERBB2 mutant primary tumors appear to have similar patient and tumor characteristics (TNM stage, grade, and receptor and HER2 status) compared to non-mutant patients and ERBB2 mutations occur in all molecular subtypes (7 ER+/HER2-, 4 HER2+, 2 triple negative). However, we see a small trend towards enrichment in the invasive lobular carcinomas (ILC) in the ERBB2 mutant patients vs. the non-mutant patients (4/13 (31%) vs. 97/695 (14%), p=0.086). ER+ patients with an ERBB2 mutant tumor who received first line aromatase inhibitor (AI) (n=3) had a worse median time to progression (TTP) compared to non-mutant patients (n=156) (TTP 103 vs. 311 days, p=0.04), AI use in any line had also a worse TTP (n=8 vs. 376; TTP 74 vs. 213 days, p=0.006). TTP was not significantly different for other standard therapies, but numbers were small. Median distant disease free survival (DDFS) defined as time from primary diagnosis to first metastasis, was slightly shorter for ERBB2 mutant tumors (n=9 vs 514; DDFS 1.4 vs. 2.9 years, p=0.066). However, in ER+/HER2- ERBB2 mutant tumors, median DDFS was significantly shorter in non-mutant patients (n=5 vs. 328; DDFS 0.8 vs. 4.0 years, p=0.02). Median overall survival (OS) after diagnosis of MBC was numerically lower for mutant patients in all subtypes vs. non-mutant patients (n=11 vs. 669; OS 1.1 vs. 2.3 years, p=0.457), and in ER+/HER2- disease (n=6 vs. 431; OS 1.0 vs. 2.9 years, p=0.07).

Conclusion In our large MBC cohort, patients with ERBB2 mutant tumors appear to have similar tumor and patient characteristics as ERBB2 non-mutant tumors. ERBB2 mutations do not seem to occur more or less often in specific breast cancer subtypes except for a slight increase for ILC. In ER+/HER2- MBC, patients with ERBB2 mutant tumors appear to be adversely prognostic; having a shorter DDFS after early breast cancer treatment, and in metastatic disease, they respond worse on AI and have a trend for worse OS compared to non-mutant cases.
Title: Germline and somatic mutation status in tissues from BRCA1/2 carriers

Vassiliki Kotoula1, Efterpi Demiri1, Florentia Fostira1, Eleni Vrettou1, Kyriaki Papadopoulou1, Ioannis Tikas1, Konstantinos Papazisis1, Thomas Zaramboukas1, Anthoula Asimaki-Vlachopoulou1, Spyros Miliaras1, Elena Fountzilas1, Ananias Ananiadis1, Sofia Chrisafi1, Christos Poulios1, Ioannis Natsiopoulos1, Aris Tsiftsoglou1 and George Fountzilas1. 1Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece.

Body: Background – aim: In carriers of BRCA1/2 pathogenic mutations (mut), it is expected that the germline mut is present in all tissues, particularly in normal; the somatic mut status in normal tissues from these patients is usually not addressed. We investigated the mut status in normal and tumor tissues in a real-life cohort of BRCA1/2 carriers who underwent prophylactic surgery.

Methods: All 53 women had known BRCA1/2 germline mut that had been assessed independently; 42 had previous cancer manifestation (PCM); all had prophylactic mastectomy; 22 had prophylactic hystero-salpingo-oophorectomy. By using a 60-gene NGS panel, we examined the mut status of 231 samples, 39 peripheral blood and 192 paraffin tissues (FFPE: 46 tumors, out of which 43 breast; 97 normal breast [NB]; 49 normal ovary and salpinx [NGYN]). Germline mut status was interrogated in tissues with the above panel, Sanger sequencing and a multiplex PCR protocol for large exonic deletions, along with extensive FFPE DNA quality control (QC) to exclude false negatives.

Results: Eight patients carried germline BRCA2 and 45 BRCA1 mut (29 in the BRCT-domain; 31 substitutions/indels). We identified somatic mut in 85% of the tumors and in 64% of the normal samples; mut were found significantly more often (p=0.003) and in higher numbers (p<0.001) in NGYN than in NB. In NB and NGYN, top 3 genes with somatic mut were BRCA2 (28%), BRCA1 (17%), TP53 (7%). In tumors, somatic mut were most frequent in TP53 (49%; p<0.001) and BRCA1 (38%; p=0.039). Among all tissue types, the 5 tumors post-neoadjuvant treatment had the highest and NB the lowest mut load (p=0.001). In NB and NGYN, mut load was not affected by PCM or BRCA1 mut domain but it was higher in BRCA1 vs. BRCA2 carriers (p=0.027) and in those with BRCA1 substitutions/indels vs. exon deleting and skipping mut (p<0.001). In tumors, germline BRCA1 substitutions/indels were associated with higher mut load (p=0.014). We validated germline mut status in all blood samples and in 111 tissue samples that passed FFPE DNA QC from 40 patients. The germline mut was not found in 14 samples (4 breast tumors; 3 NB; 7 NGYN) from 10 (25%) patients, all BRCA1 carriers, 9 with germline mut in the BRCT-domain. The only non-BRCT domain germline mut that was lost in one breast tumor, p.V1234fs, was replaced by the R1751* (validated), again in the BRCT domain. In normal tissues, those with lost germline mut had significantly less somatic mut compared to those with preserved germline mut (p<0.001).

Conclusions: In BRCA1/2 carriers, somatic mut in BRCA genes and TP53 are present in normal breast and GYN tissues, more frequently in the latter, and seem associated with the mutated gene and with the type of mut in the germline. The mut status of normal breast tissue does not seem to be affected by neoadjuvant chemotherapy for breast cancer. The observed BRCA1 germline mut loss, particularly in normal tissues, may be approached as a negative selection for the inherited mut; similarly to the described germline mut reversion after chemotherapy, tissues may react to deleterious effects of haploinsufficiency, which needs functional validation.
Title: Outliers—extreme long-term survivors with metastatic breast cancer

Ifna H Ejebe¹, Ryan A Denu², Colin Longhurst³, Jordan D Bauman¹, Stephanie MacGregor⁴, Kristy Lee⁵ and Mark E Burkard⁶.
¹School of Medicine and Public Health, University of Wisconsin--Madison, Madison, WI; ²University of Wisconsin--Madison, Madison, WI; ³University of Wisconsin--Madison, Madison, WI; ⁴University of Wisconsin--Madison, Madison, WI and ⁵University of Wisconsin--Madison, Madison, WI.

Body: Breast cancer has an extremely heterogeneous clinical course, but the specific causes for this diversity are largely unknown. Understanding the basis for extreme long-term survival with incurable cancer can be of value for prognosis or possible interventions if they arise from modifiable factors.

Methods: We identified patients at our institution with persistent and distant metastases who are alive greater than 5 years from initial diagnosis, and evaluated the clinical characteristics of this population. Additionally we evaluated the published METABRIC cohort of patients who died of cancer to compare patients with greater than median survival (late) to those who died with less than median survival (early). In doing so, we evaluated the non-exclusive alternative hypotheses that long-survival is dictated by cancer genomes versus by host immunity. To do this, we grouped somatic mutations into 11 common pathways and compared the likelihood of being present in the tumors causing early versus late death, when stratified for hormone receptor [HR] status. To evaluate the effect of immune infiltration, we used gene expression profiles using the CIBERSORT algorithm (Nat Methods 12:453, 2015).

Results: We identified 53 individuals who are alive with metastatic breast cancer greater than 5 years from the original diagnosis. The four longest-term survivors were diagnosed with breast cancer in 1978, 1978, 1979, and 1980 and developed metastasis in 1982, 2007, 1996, and 2000 respectively. The median time to metastasis was 4.5 years. Of these, 80% had ER and/or PR-positive breast cancer, 9% triple negative and 18% had HER2+ disease. The longest-term survivors tend to have well-differentiated histology. Analysis of the METABRIC data, demonstrated, as expected, that long survival correlates with hormone-receptor-positive disease. Among 647 subjects who died of cancer, 192 were HR-negative (median survival 36 mo.) and 455 were HR-positive (median survival 76 mo.). Among HR-positive there were no statistical differences in genome profiles between long-versus-short survivors. By contrast, among HR-negative tumors, mutations PI3K-pathway genes and microenvironment maintenance were associated with longer survival (p=0.041 and p=0.047, respectively). CIBERSORT was used to provide quantitative estimates of infiltrating tumor cells, allowing patient groups to be divided by quartiles. However, no significant differences were found in survival among quartiles in T-cell infiltration, in T-cell subsets (activated CD4 memory, CD8, and Tregs) or in monocyte/macrophage subsets.

Conclusions: Some patients live for extended periods of time with metastatic breast cancer. Long-term survival of breast cancer can be explained, in part, by the cell-autonomous features of the tumor, including HR status and genes involved in PI3K signaling and microenvironment maintenance, but no major differences were found in immune infiltrates. Although these data are representative of longer-than-median survivors, extreme long-term survivors may have additional unique features in genomic and immune characteristics.
Title: Genomic analysis of cancers arising in breasts with different mammographic density

Kylie L Gorringe¹, Siobhan Hughes¹, Carolyn Nickson², Lisa Devereux¹, Vicki Pridmore³, Simone M Rowley¹, David J Byrne¹, Dane Cheasley¹, Anne M Kavanagh², G Bruce Mann⁴, Stephen B Fox¹ and Ian G Campbell¹. ¹Peter MacCallum Cancer Centre, Melbourne, VIC, Australia; ²The University of Melbourne, Melbourne, VIC, Australia; ³BreastScreen Victoria, Melbourne, VIC, Australia; ⁴The Royal Women's Hospital, Melbourne, VIC, Australia.

Body: Background: High mammographic density (MD) is a known risk factor for breast cancer, but it is currently unknown whether this altered microenvironment leads to the development of genomically different tumours.

Method: We used lifepool, an Australian prospective population-based cohort of over 53,000 women currently in a mammographic screening program, to identify >1000 cases of breast carcinoma (in situ and invasive breast cancer) for analysis. Pathology reports, detection modality (screen-detected/interval), MD data (AutoDensity, Nickson et al., 2013 DOI:10.1186/bcr3474), germline DNA and tumor tissue were available for a subset of cases. Tumours were classified into quintiles, depending on the relative MD ranking of the most recent normal mammogram. Tumour DNA was analysed using Affymetrix OncoScan MIP arrays or using a targeted Agilent SureSelect and Illumina sequencing panel of 105 genes relevant to breast cancer. Copy number and mutation data were compared between tumours from the highest (high-MD) and lowest (low-MD) quintiles of MD.

Results: Preliminary analysis found no significant differences in clinico-pathological features between tumours from breasts with high-MD (n=38) and low-MD (n=35). Genomic analysis of 8 high-MD tumours and 8 low-MD tumours identified chromosome 15 loss as being significantly enriched in low-MD tumours. Only Low-MD tumours to date contained TP53 mutation (3/8). Data will be presented from at least an additional 9 low-MD and 15 high-MD tumours currently undergoing genomic assays.

Conclusion: When complete, our data will be the first to evaluate the somatic genetic events in tumours arising in low-MD and high-MD breasts. Although our cohort to date is small, it may be possible that tumours from extremes of MD have different genomic characteristics.
Title: Novel genetic features associated with 8p11-p12 amplification in breast carcinoma

Toshima Z Parris¹, Jana Biermann¹, Hanna Engqvist¹, Elisabeth Werner Rönnerman¹,⁵, Katarina Truvé⁶, Szilárd Nemes⁴, Eva Forssell-Aronsson⁶, Giovanni Solinas⁶, Anikó Kovács², Per Karlsson¹ and Khalil Helou¹. ¹Institute of Clinical Sciences, Sahlgrenska Cancer Center, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden; ²Sahlgrenska University Hospital, Gothenburg, Sweden; ³Bioinformatics Core Facility, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden; ⁴Swedish Hip Arthroplasty Register, Gothenburg, Sweden; ⁵Institute of Clinical Sciences, Sahlgrenska Cancer Center, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden and ⁶The Wallenberg Laboratory, University of Gothenburg, Gothenburg, Sweden.

Body: Background: Genome instability contributes to the neoplastic phenotype by promoting gene loss and duplications, which in turn can have a detrimental effect on patient outcome by inactivating tumor suppressor genes or hyperactivating oncogenes. In breast carcinoma, DNA amplification of the 8p11-p12 genomic region has been associated with tumor progression and poor prognosis. The aim of this study was to characterize recurrent genetic features (other than DNA amplification) associated with 8p11-p12 amplification in breast carcinoma.

Methods: DNA copy number profiling data for 229 primary invasive breast carcinomas (corresponding to 185 patients diagnosed in Western Sweden between 1988 and 1999) were evaluated to identify 8p11-p12 amplified cases. Illumina paired-end whole transcriptome sequencing (RNA-seq) and whole-genome SNP genotyping were subsequently performed on 23 breast carcinomas harboring high-level regional 8p11-p12 amplification to characterize recurrent genetic variants (SNPs and indels), expressed gene fusions, gene expression profiles and allelic imbalances. The 23 samples were stratified into the molecular subtypes, resulting in 16 Luminal B/HER2-, two Luminal B/HER2+, four HER2/ER-, and one Basal-like sample. The Cancer Genome Atlas (TCGA) RNA-seq data for 10 primary breast carcinomas lacking the 8p11-p12 amplicon (SNP segmented mean < 0.4) were used as controls. Gene fusions were validated using dual-color fluorescence in situ hybridization (FISH) with co-hybridized biotin-16-dUTP and dioxigenin-11-dUTP labeled bacterial artificial chromosome (BAC) probes.

Results: Here, we report that despite the high number of gene fusions (133±31 (±SEM)) and exonic variants (411±16) identified per tumor, few gene fusions (n=46) and exonic variants (n=11) spanned the 8p11-p12 genomic region. Gene fusions predominantly contained at least one fusion partner spanning non-coding RNAs (ncRNAs; 86%), in particular MALAT1, which is induced by estrogen and of prognostic value in breast cancer. The majority of fusion breakpoints were associated with DNA copy number gains and losses, as well as, extensive intratumoral heterogeneity for specific fusion events. Intriguingly, novel 8p11-p12 amplification-specific genetic variants (HIST1H1E frameshift insertion, UQCRHL nonsynonymous SNV, MTUS1 frameshift insertion, NPIPA5 frameshift deletion) were identified that also resulted in mutation-dependent changes in gene expression levels.

Conclusions: Taken together, these findings have provided further insight into the genetic landscape of 8p11-p12 amplified breast carcinomas, including novel gene fusions and genetic variants. However, further studies are required to develop effective strategies to target 8p11-p12 amplification in breast carcinoma.

Title: Genomic analysis of breast papillomas

Kenneth J Elder1, Tanjina Kader2,3, Pru Hill4, Ken Opeskin4, David L Goode3,5, Jia-Min Pang6,7, Stephen B Fox6, Gregory B Mann1, Ian G Campbell1,2,7 and Kylie L Gorringe1,2,7. 1The Breast Service, The Royal Women’s Hospital; 2Cancer Genetics Laboratory, Peter MacCallum Cancer Centre; 3University of Melbourne; 4St Vincent’s Hospital; 5Bioinformatics and Cancer Genomics Laboratory, Peter MacCallum Cancer Centre; 6Peter MacCallum Cancer Centre and 7University of Melbourne.

Body: Background: Papillomas are often found co-existing with breast carcinoma yet they are not considered to be a true precursor of the disease. Previous studies have shown that some cases may carry copy number alterations (CNA) or mutations in AKT1/PIK3CA (Troxell et al., 2010, Modern Pathology 23: 27-37) suggesting this lesion may have malignant potential. To date, a detailed study of both pure papillomas (not associated with cancer) and those seen in the same breast as a carcinoma has not been undertaken. Therefore, we set out to investigate the molecular changes associated with this lesion and whether papillomas can be clonally related to synchronous breast carcinoma.

Method: Papilloma cases were identified from a hospital database and independently reviewed by consultant pathologists followed by micro-dissection of formalin-fixed paraffin-embedded tumour tissue and DNA extraction. For CNA detection either Affymetrix Molecular inversion Probe (MIP) 330K arrays were used or low-coverage whole genome sequencing using 5-10 ng of DNA (Kader et al., 2016, Genome Medicine 8: 121) where there was insufficient DNA for MIP arrays. We applied either of these 2 methods to 24 cases of pure papilloma as well as 20 papilloma with synchronous ductal carcinoma in situ (DCIS) and/or invasive ductal carcinoma (IDC). Additionally, targeted exon sequencing of breast cancer driver genes was performed for a subset of cases.

Results: Among the pure papillomas 31% (5/16) showed CN change with, the most frequent change being 16q loss (2/16). Of the papillomas synchronous with DCIS/IDC analysed to date, 2/5 were shown to be clonal with the co-existing carcinoma. Final CNA analysis will be presented for 24 pure papilloma cases and 20 synchronous cases. Targeted sequencing revealed that all for pure papillomas analysed to date harboured somatic mutations in PIK3CA (3/4 cases) and PIK3R1 (1/4,) suggesting that most papillomas are driven by alterations in the PI3-kinase/AKT pathway. The final sequencing data to be presented will include an additional 5 pure papillomas and 10 synchronous cases.

Conclusion: Our observation that 40% of papillomas are clonal to breast carcinoma suggests that DCIS or IDC can arise from a common ancestor as co-existing papillomas, however, most papillomas co-existing with carcinoma are likely to be independent in our cohort.

Title: Integrated analysis of genetic variations in Chinese breast cancer from a single institution

Ning Liao¹, Guo-Chun Zhang¹, Yulei Wang¹, Li Cao¹, Kai Li¹, Chong-Yang Ren¹, Ling-Zhu Wen¹, Yumei Shi¹, Wenzhen Zhu¹ and Xiaoqing Chen¹. ¹Cancer Center, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China.

Body: To investigate the characteristics of somatic mutation or copy number variations in Chinese breast cancer, tumor tissues from 105 patients diagnosed at age from 26 to 81 (median age 48) were assessed by next-generation sequencing technology using a customized panel, including 33 genes of putative tumor suppressors or oncogenes. At least one genetic alteration (including mutations, copy number variations and fusion genes) was observed in 99/105 (94%) samples. Similar to the previous report in TCGA dataset, TP53 (49%) and PIK3CA (43%) were the most frequently mutated genes, which occurred in a significant mutual exclusive manner (p<0.05). Three genes including MYC copy number amplification (35%), FGFR1 (19%) and GATA3 mutation (16%) were altered at the frequency of >10% in our dataset, in which the occurrence of MYC amplification was higher than the TCGA cohort (22%, p<0.05). Importantly, we identified four fusion genes of FGFR1 including one previously reported (TACC1-FGFR1) and three novel fusion ones (MIR1268A-FGFR1, LZTS1-AS1-FGFR1, and LINC01605-FGFR1). Unlike the high prevalence of CCND1 amplification (17%) and CDH1 mutations (13%) in TCGA dataset, genetic variations of CCND1 and CDH1 in our study occurred at a low frequency with 2% and 4%, respectively (p<0.05). In addition, we also identified three novel ESR1 mutations (ESR1 G74R, D230H and M250T) in the untreated patients with early breast cancer. Furthermore, nonnegative matrix factorization (NMF) clustering of genetic variations revealed five distinct molecular classes in our dataset. NMF class I was characterized by a high rate of HR+/ERBB2- tumors (80%) and genetic alterations of FGFR1 (100%). A gain of ERBB2 gene was observed in 93% of NMF class II along with TOP2A amplification in 57% of HR+/ERBB2+ tumors. NMF class III was characterized by a high rate of HR+/ERBB2- (95%) and GATA3 mutations (75%) without TP53 mutation. The characteristics of NMF class IV were the high rate of PIK3CA mutations (95%) and HR+/ERBB2- tumors (75%) along with low rate of TP53 mutations. More HR-/ERBB2- tumors (39%) were observed in NMF class V with a high rate of MYC amplification (82%) and TP53 mutation (89%). Further analysis in the TCGA cohort revealed the patients in NMF class V had the shorter survival time than other clusters. Collectively, we identified several novel genetic variations and generated a preliminary profile of somatic genetic aberrations that could classify Chinese breast cancer in this study, and may represent novel therapeutic targets for molecular subsets of breast cancer.

Title: Analysis of somatic transposable element insertions in a breast cancer genome

Robin Paul¹, Jeffrey P Solzak¹, Yu-Hsiang Chen¹, Bradley A Hancock¹ and Milan Radovich¹. ¹Indiana University, Indianapolis, IN.

Body: Introduction: More than 50% of the human genome consists of transposable elements (TE). However most TEs are inactive and remain relatively stable among different human populations. However, some classes of retrotransposons consisting of Alu, SVA, ERV and L1s are active and believe to be involved in cancer. Commonly used bioinformatics pipelines of whole genome sequencing (WGS) data do not currently analyze for somatic TE insertions, and maybe missing an important class of somatic mutations. As a proof-of-concept, we analyzed the HCC1143 triple-negative breast cancer cell line along with a matched normal control to analyze for the presence of somatic TEs.

Methods: WGS data of the HCC1143 cell line along with the matched lymphoblastoid control cell line, HCC1143BL, were downloaded from the NCI GDC Commons. We used discordant read-pair (only one paired-end read matches to the reference genome) and split-read (part of a read matches to the reference) analysis to detect novel somatic TE insertion sites in genes known to play important roles in cancer proliferation.

Results: Most TE insertions are heterogenous in nature such that they insert only in a small subset of the cells. Therefore by comparing the number of split reads and discordant reads to the total number of reads the heterogeneity of the insertion can be inferred. The discordant and split read analysis revealed about 30 high confidence hits. A subset of the high confidence hits were validated experimentally using PCR amplification and gel electrophoresis. About 85% of the hits were successfully validated. A subset of the validated hits known to be relevant to breast cancer have been shown in Table 1.

Discussion: Using the approach described above, we were able to detect somatic TEs within several genes known to be involved in cancer. PBRM1, a gene involved in chromatin remodeling, was found to have several exons replaced with a TE insert. Other genes such as CSMD1 is a known tumor suppressor gene, and TMEM181 which is involved in tamoxifen response. These results suggest that TE insertions may be involved in cancer biology. Therefore, TE insert prediction can serve as useful biomarkers for early detection and have precision medicine implications in the treatment of breast cancer. Analyses in additional breast cancer patient genomes is currently underway.
Title: Implications of somatic TP53 and PIK3CA mutations in patients with metastatic breast cancer who underwent germline BRCA testing

Clinton Yam¹, Angelica Gutierrez Barrera¹, Davis Huang¹, Xinyi Lin², Jennifer K Litton¹ and Banu Arun¹. ¹The University of Texas MD Anderson Cancer Center, Houston, TX and ²Duke-NUS Medical School, Singapore, Singapore.

Body: Background: TP53 and PIK3CA are the most frequently mutated genes in breast cancer. However, there is limited data evaluating the impact of somatic mutations in TP53 and/or PIK3CA patients (pts) with metastatic breast cancer (MBC) who have undergone germline testing for BRCA mutations. Here, we report the frequency of somatic TP53 and PIK3CA mutations in MBC pts who previously underwent germline BRCA (gBRCA) testing and evaluate their impact on long-term outcomes.

Methods: We identified pts with MBC from our prospectively maintained high risk genetics database who underwent gBRCA testing and had somatic mutation testing performed for TP53 and/or PIK3CA through hotspot sequencing of single genes or as part of a next generation sequencing panel. Univariable logistic regression was used to evaluate associations between clinicopathological characteristics, including gBRCA status, and the presence of somatic TP53 and PIK3CA mutations. Overall survival (OS) was defined as the time from diagnosis to death from any cause. Multivariable cox regression analysis was used to identify independent predictors of OS.

Results: 104 pts met all inclusion criteria. Somatic mutations in TP53 and PIK3CA were found in 46% (39/84) and 23% (24/104) of tested pts, respectively. Associations between clinicopathological characteristics and somatic TP53 and PIK3CA mutation status are summarized in Table 1. Pts with hormone receptor positive (HR+) disease were less likely to have TP53 mutations (odds ratio [OR]: 0.28, 95% confidence interval [CI]: 0.11-0.70, p=0.007) but more likely to harbor PIK3CA mutations (OR: 3.27, 95% CI: 1.11-9.62, p=0.031). There were no significant associations between gBRCA mutation status and somatic TP53 or PIK3CA mutations. On multivariable analysis, somatic TP53 mutations (adjusted hazard ratio [aHR]: 1.98, 95% CI: 1.10-3.58, p=0.023) and de novo metastatic disease (aHR=2.88, 95% CI: 1.26-6.58, p=0.012) independently predicted poorer OS, while HR+ disease (aHR: 0.40, 95% CI: 0.21-0.74, p=0.004) and HER2+ disease (aHR: 0.33, 95% CI: 0.13-0.83, p=0.019) were significantly associated with improved OS. PIK3CA mutations (aHR: 1.20, 95% CI: 0.59-2.44, p=0.62) and gBRCA mutations (aHR: 0.78, 95% CI: 0.33-1.83, p=0.57) did not significantly impact OS in this study.

Conclusion: In this study, somatic TP53 mutations independently predicted worse OS in pts with MBC after adjusting for significant covariates, including gBRCA mutation status. These findings should be validated in a larger cohort of pts.

Title: Immune and transcriptional signatures of dendritic cell (DC) vaccination combined with chemotherapy in locally advanced, triple-negative breast cancer (TNBC) patients

A Karolina Palucka¹, Lee K Roberts², Sandra M Zurawski², Jessica Tarnowski², Jacob Turner², Xuan Wang², Derek Blankenship², Jennifer L Smith³, Maren K Levin², Jennifer P Finholt², Susan B Burkeholder², Roxana Timis², Luz Stella Muniz², Tuoc Dao³, Michael Grant³, Jacques Banchereau¹, Gerard Zurawski², Virginia Pascual⁴ and Joyce A O’Shaughnessy³.

¹The Jackson Laboratory for Genomic Medicine, Farmington, CT; ²Baylor Scott & White Research Institute, Dallas, TX; ³Baylor University Medical Center, Texas Oncology, US Oncology, Dallas, TX and ⁴Weill Cornell Medicine, Cornell University, New York, NY.

BACKGROUND: Women with TNBC who do not achieve a pathologic complete response (pCR) with preoperative (preop) chemotherapy have a high risk of recurrence and death from BC. Immunotherapy is an attractive strategy as human BCs can be immunogenic, and enhancing the immune effector function may augment the cytotoxic effects of standard therapies.

CLINICAL TRIAL: Following IRB-approved informed consent, 10 pts with locally advanced TNBC received preop dose-dense doxorubicin/cyclophosphamide (AC) followed by paclitaxel and carboplatin (TCb) chemotherapy, combined with antigen-loaded (TNBC antigens: Cyclin B1, WT1, and control viral antigens: CEF) autologous monocyte-derived DC vaccinations administered intratumorally and subcutaneously. DCs were generated with GM-CSF and type I interferon, loaded with antigen in the form of long peptides and activated with innate ligands (LPS and Clo75) and CD40 ligand. Vaccines were given at 4 time points prior to definitive surgery, and 3 times post-surgery, pre- and post-radiation therapy (RT). Safety was the primary study endpoint, and pCR rate in breast and axilla was a secondary endpoint. Correlative studies included assessment of immune response via ELISpot and transcriptional profiling of blood samples collected over time.

RESULTS: All pts received the 4 vaccines during preop chemotherapy, and 7/10 received all 7 vaccines. At the time of definitive surgery, 4 pts achieved a pCR, 3 pts had macroscopic residual disease in the breast and axillary lymph nodes, and 3 pts had residual cancer burden scores of 1. As of June 1, 2017, all pts have been in follow-up for at least 1 year s/p completion of all vaccines, and 7/10 patients have no evidence of disease.

To assess immune signatures with IFN-γ-ELISpot, PBMCs from baseline (BL) and several time points during vaccine treatment were cultured with control peptides or with peptide libraries covering vaccine antigens. Using a linear mixed model to account for repeated and missing observations we found statistically significant (α = 0.05) increases in Cyclin B1, WT1, and CEF ELISpots in at least 1 time point post-DC vaccination and in follow-up. Compared to BL, Cyclin B1 and WT1 increased at 3 day pre-RT in 8/10 and 7/10 pts, respectively. To assess transcriptional signatures, a linear mixed model was utilized to determine statistically significant differences in fold-change over time compared to the BL and healthy controls. Modular analysis of differentially expressed transcripts at BL revealed downregulation of transcripts related to the monocyte lineage in 7/10 pts. Longitudinal analysis revealed profound transcriptional changes during AC with downregulation of lymphocyte modules and upregulation of innate and inflammation modules. While the latter ones have normalized during TCb and follow-up, T cell module remained substantially downregulated throughout treatment and follow-up.

CONCLUSIONS: Combination of preop chemotherapy and intratumoral and subcutaneous autologous DC vaccination is safe in locally advanced TNBC pts and is linked with profound changes in immune transcription signatures and with expansion of antigen-specific immune responses that can be detected in IFN-γ ELISpot.

Title: Immune profiling of paired primary and recurrent triple negative breast cancer

Ting-Fang He¹, Susan Yost¹, Daniel Schmolze¹, Roger Wang¹, Anthony Rosario¹, Travis Tu¹, Peiguo Chu¹, Peter Lee¹ and Yuan Yuan¹. ¹City of Hope Comprehensive Cancer Center and Beckman Research Institute, Duarte, CA.

Body: Background: Triple negative breast cancer (TNBC) is a heterogeneous disease with several molecular subtypes: basal-like1 (BL-1), basal-like 2 (BL-2), mesenchymal (M), and luminal androgen receptor (LAR). Molecular evolution of TNBC through chemotherapy selection pressure is well recognized but poorly understood. In addition, approximately 20% of TNBCs respond to PD-1 or PD-L1 inhibitors. It has been observed that heavily pre-treated patients may not respond well to immunotherapy. This study was carried out to perform immune profiling of paired primary and recurrent TNBC. Here we report the result of the first 10 paired tissue pilot analysis.

Methods: Twenty specimens were identified through an IRB-approved protocol via the City of Hope Biospecimen Repository (2002-2015). Two brain and one bone metastasis specimens were not included due to technical difficulty. Formalin-fixed paraffin embedded (FFPE) sample blocks were cut into 5-mm thick slides and labeled with the following antibodies: CD4, CD8, CD3, FOXP3, CD20, CD33, Pan-CK, and PD-1 using the multiplex IHC opal method. Image acquisition and cell counting were carried out using PerkinElmer Vectra automated quantitative pathology imaging system and inForm software analysis (PerkinElmer, Waltham, MA). mRNA expression profiling was performed using Affymetrix Human Genechip 2.0. Raw data were normalized and processed using Expression Console. Using Vanderbilt TNBC sub-classification tool, we have sub-classified the 20 primary and recurrent TNBC specimens. Tumor mutation burden (TMB) was generated through FoundationOne® platform.

Result: A total of 17 samples were analyzed (M, 5; LAR, 3; BL-1, 4; BL-2, 5). M-subtype had a significantly lower tumor-infiltrating CD3+ T cells (p=0.005), CD8+ T cells (p=0.024), CD4+ T cells (p=0.065) and CD4+FOXP3+ Treg cells (p=0.054), irrespective of the site of metastasis. CD20+ B cells were particularly enriched in BL-1 subtype (p=0.0013, 23.5% of 17 samples). Of 17 samples, 8 had TMB. Seven had low TMB (<10 mut/Mb) and one had intermediate TMB (11 mut/Mb, LAR subtype). The tumor with intermediate TMB had the highest quantity of tumor-infiltrating CD3+ T cells, CD8+ T cells, CD8+PD1+ T cells, and CD4+FOXP3+PD1+ Treg cells compared to the 7 tumors with low TMB. Compared with recurrent tumors, primary tumors had a significantly higher percentage of tumor-infiltrating T cells (TIL). To validate multiplexed IHC results, these samples were evaluated by a licensed pathologist at City of Hope using the International TILs Working Group 2014 guidelines, and there was a good correlation between percent of TILs and CD3+ T cells by IHC approach.

Conclusion: To our knowledge, this is the first study linking tumor immune cell profiles with the TNBC 4 subtypes. Distinctive immune cell patterns were observed among 4 TNBC subtypes. M subtype had significantly lower TILs, which may indicate poor response to checkpoint inhibitors. Further analysis of a total of 50 paired TNBCs is currently underway.

Title: Metaplastic breast cancers: Genomic profile, mutational burden and TILs

Jessica Taft¹, James Suh², Baljit Singh¹, Carsten Denkert³, Andrea B Troxel¹, Jeffrey S Ross²,⁴ and Sylvia Adams¹. ¹NYU Langone Medical Center, New York, NY; ²Foundation Medicine, Inc, Cambridge, MA; ³Charite Comprehensive Cancer Center, Berlin, Germany and ⁴Albany Medical College, Albany, NY.

Body: Background: Metaplastic breast cancers (MPBC) are rare, typically triple negative aggressive tumors composed of both, adenocarcinoma and metaplastic elements. Recent evidence that TNBC and MPBC can respond vigorously to immune checkpoint inhibitor therapy (Adams et al, ASCO 2017 and npj Breast Cancer 2017) has prompted the following comprehensive genomic profiling (CGP) and histopathologic assessment of tumor infiltrating lymphocytes (TIL) designed to uncover potential biomarkers of immunotherapy response for MPBC, including mutational burden, Microsatellite Instability (MSI) status and gene amplification of 9p21.4 (or CD274, which includes the PD-L1 locus).

Methods: 12,214 locally aggressive, relapsed and metastatic breast malignancies (mBM) were subjected to CGP using DNA extracted from 40 µm of FFPE sections and adaptor ligation-based libraries to a mean coverage depth >650X for up to 315 cancer-related genes. The results were analyzed for all classes of genomic alterations (GA) including base substitutions, insertions and deletions, select rearrangements, and copy number changes. Tumor mutational burden (TMB) was determined on 1.1 Mbp of sequenced DNA. MSI status was determined by an algorithm based on the sequencing results. TIL were assessed on archived H&E tumor sections and enumerated per guidelines established by the TIL Working Group (Salgado, Ann Oncol 2015) in a subset of MPBC with the highest TMB and compared with low TMB cases.

Results: 165 of mBM cases were MPBC (1.4%) and are included in this study. All patients were female with a median age of 60 (range 24-86). 165 of the MPBC cases (100%) harbored a wide variety of GA involving more than 100 individual genes. The most common GA were identified in TP53 (65%), followed by PIK3CA (37%). No cases of MSI hi status (0/103) and only one case with amplification of 9p21.4 (1/165, 0.6%) were observed. Most MPBC had a low mutational burden, with a median TMB of 2.7 mutations/Mb (range 0-39.6). Only 11/165 tumors (6.7%) were found to have a TMB over 10 mutations/Mb, including 3 cases (1.8%) with TMB >20. Tumor sections were available for TIL review from 9/11 cases with highest TMB, as well as 11 control cases with lowest TMB. TIL were more frequently observed in high versus low TMB MPBC, with median TIL percentage of 40 and 20 (range 10-80 and range 10-60), respectively, although this difference was not statistically significant (Wilcoxon rank-sum test, p=0.15).

Conclusions: Genomic profiling in the largest cohort of MPBC reported to date confirms that MPBC is enriched for TP53 and PIK3CA mutations and many tumors harbor targetable GA. The frequently observed tumoral PD-L1 expression in MPBC is not based on gene amplification as amplification of 9p21.4 is rare. Most tumors had a low mutation burden, and no significant association of TIL with TMB was observed, suggesting additional processes underlying MPBC immunogenicity.
Title: An IL-15 superagonist enhances antibody-dependent cell-mediated cytotoxicity against breast cancer cells regardless of FCGR3A (CD16) genotype and rescues NK cell from TGF-β1-induced immunosuppression

Rika Fujii1, Hing C Wong2, Jeffrey Schlom1 and James W Hodge1. 1Laboratory of Tumor Immunology and Biology, National Cancer Institute, NIH, Bethesda, MD and 2Altor BioScience Corporation, Miramar, FL.

Body: It has been reported that the Natural killer (NK) cell with FCGR3A (CD16a) V genotype is associated with enhanced clinical response to IgG1 monoclonal Ab (mAb) therapy such as trastuzumab, rituximab and cetuximab (1,2), suggesting a role of antibody-dependent cell-mediated cytotoxicity (ADCC) induced by NK cells. NK cells express three types of polymorphism of CD16; FcγRIIIa-158 VV, VF, FF, which are derived from the genotype of FCGR3A. It is a clinical challenge to improve the outcome in patients with FCGR3A 158FF genotype whose NK cells have lower affinity to mAb and mediate poor ADCC activity. The IL-15 superagonist/IL-15Rα-Fc fusion complex (ALT-803) activates the IL-15 receptor on CD8 T cells and NK cells, inducing their expansion, cytotoxity, and ADCC against B cell lymphoma (3, 4, 5).

Here, we examined the effect of ALT803 on NK cell-mediated ADCC activity by the the anti-HER2 IgG1 mAb trastuzumab in HER2+ cell lines (SKBR3, BT474, MDA-MB-453). In addition, we used the anti-epidermal growth factor receptor(EGFR) IgG1 mAb cetuximab in EGFR positive TNBC cell lines (MDA-MB-231, SUM149, BT549). Finally, we examined the anti-PD-L1 IgG1 mAb avelumab was used for PD-L1 positive breast cancer cell lines (MDA-MB-231, BT549). Trastuzumab, cetuximab, and avelumab all significantly increased NK cell-induced lysis via ADCC. ALT803 significantly further increased both NK induced lysis and ADCC activity in all the cell lines. There was a significant positive correlation for the mean of ADCC lysis induced by NK cells from three FF (21%), three VF (33%), three VV (45%) donors. ALT803 significantly increased the mean of ADCC lysis by NK cells from all donors of each genotype to the same extent. ALT803 increased the expression of NK cell-activating receptors and cytotoxic granules regardless of the genotype of NK cell FCGR3A in terms VV, VF, or FF.

We further examined the potential of ALT803 for NK cell-cytotoxicity suppressed by TGF-β1 which is one of the main barriers to immunity in the tumor microenvironement (TME). NK cells treated with TGF-β1 showed lower expression of activating receptors and cytotoxic granules, culminating in decreased lysis of MDA-MB231. ALT803 inhibited TGF-β1 from down-regulating the expression of NK cell-activating receptors and cytotoxic granules, and from suppressing the cytotoxicity of NK cells to MDA-MB231.

In conclusion, the IL-15 superagonist ALT803 can potentially increase the clinical benefit of ADCC-based mAb therapy for breast cancer patients, regardless of the genotype of FCGR3A. Moreover, ALT803 prevented NK cell-cytotoxicity from TGF-β1-induced suppression, providing a rationale for ALT803 therapy to overcome TME-mediated immunosuppression.

Title: Class IIa HDAC inhibition promotes an anti-tumor macrophage phenotype that induces breast tumor regression and inhibits metastasis

Jennifer L Guerriero1, Alaba Sotayo1, Holly E Ponichtera1, Jessica A Castrillon1, Alexandra L Pourzia1, Sara Schad1, Shawn F Johnson1, Ruben D Carrasco2, Suzan Lazo1, Roderick T Bronson3, Scott P Davis4, Mercedes Lobera4, Michael A Nolan4 and Anthony Letai1. 1Dana-Farber Cancer Institute, Boston, MA; 2Brigham and Women's Hospital, Boston, MA; 3Harvard Medical School, Boston, MA and 4GlaxoSmithKline, Cambridge, MA.

Body: While tumor-associated macrophages (TAMs) often have net pro-tumor effects, their embedded location and their untapped potential provide impetus to the discovery of strategies to turn them against tumors. We recently reported that a first in class selective class IIa HDAC inhibitor (TMP195) influenced human monocyte responses to colony stimulating factors CSF-1 and CSF-2 in vitro. Here, we utilize a macrophage-dependent autochthonous mouse model of breast cancer to demonstrate that in vivo TMP195 treatment alters the tumor microenvironment and reduces tumor burden and pulmonary metastases through macrophage modulation. TMP195 induces recruitment and differentiation of highly phagocytic and stimulatory macrophages within tumors. Furthermore, combining TMP195 with chemotherapy regimens or T-cell checkpoint blockade in this model significantly enhances the durability of tumor reduction. These data introduce class IIa HDAC inhibition as a novel means to harness the anti-tumor potential of macrophages to enhance cancer therapy.
Title: Prognostic value of the neutrophil-to-lymphocyte ratio (NLR) and its relation to stromal tumor infiltrating lymphocytes (sTILs) in triple negative breast cancer (TNBC)

Roberto A Leon-Ferre¹, Mei-Yin Polley¹, Heshan Liu¹, Judith Gilbert¹, Victoria Cafourek¹, David Hillman¹, Vivian Negron¹, Judy C Boughey¹, Minetta C Liu¹, James N Ingle¹, Krishna Kalari¹, Fergus J Couch¹, Daniel W Visscher¹ and Matthew P Goetz¹. ¹Mayo Clinic, Rochester, MN.

Body: Background: While TNBC remains the most aggressive type of breast cancer (BC), substantial heterogeneity in biology and outcomes exists among TNBC subtypes. Historically, risk stratification of TNBC has been based on anatomic factors such as tumor size, nodal involvement and presence of distant metastases. However, these features alone fail to accurately predict outcomes. Tumor immune infiltration (sTILs) and distribution of immune cell subsets in the peripheral blood (NLR) have emerged as variables reported to be associated with outcomes in TNBC. We sought to evaluate whether NLR and sTILs provided independent prognostic information in TNBC.

Methods: From a cohort of 9,982 women who underwent BC surgery at Mayo Clinic, Rochester, MN between Jan 1985 and Dec 2012, we identified 605 centrally-confirmed TNBC tumors. Patients (pts) with prior BC, bilateral BC, non-invasive disease, stage IV, neoadjuvant therapy, endocrine therapy, or adenoid cystic histology were excluded. For eligible tumors, clinical and pathologic variables were evaluated, including peripheral blood NLR and central assessment of sTILs per the 2014 International TILs Working Group recommendations. We calculated the Pearson correlation coefficient (PCC) between NLR and sTILs and constructed Cox Proportional Hazards Models to evaluate their association with invasive-disease free (IDFS) and overall survival (OS). NLR and sTILs were both analyzed as continuous variables.

Results: Most pts had T1-2 (95%) and N0-1 disease (86%). Median OS follow-up was 10.6yrs. Median IDFS was 12yrs (95%CI 10.2-16.7) and median OS was 18.8yrs (95%CI 15.6-20.8). NLR and sTILs were available in 408 and 599 pts, respectively. The median NLR and sTIL content were 2.29 (0.14-10.50) and 20% (0-90%), respectively. NLR and sTILs were poorly correlated (PCC 0.0237). On univariate analysis (UVA), a higher NLR was associated with worse IDFS (HR 1.13; 95%CI 1.02-1.26, p=0.02) and OS (HR 1.17; 95%CI 1.04-1.31, p=0.01). Each 1% increment in sTILs was associated with improved IDFS (HR 0.99; 95%CI 0.98-0.99, p=0.001) and OS (HR 0.99, 95%CI 0.98-1.00, p<0.001). Among pts with high sTILs (≥20%), a higher NLR remained significantly associated with worse IDFS (HR 1.21; 95%CI 1.05-1.38, p=0.007) and OS (HR 1.25; 95%CI 1.09-1.44, p=0.001). In contrast, among pts with low sTILs (<20%), NLR was not associated with IDFS (HR 1.07; 95%CI 0.89-1.28, p=0.49) or OS (HR 1.07; 95%CI 0.88-1.30, p=0.49). The interaction test between NLR and sTILs did not reach statistical significance. A multivariate analysis (MVA; including age, menopausal status, histologic subtype, grade, tumor size, nodal stage, Ki-67, NLR, sTILs, adjuvant chemotherapy, type of surgery and adjuvant radiation) showed that sTILs remained independently associated with IDFS (HR 0.99, 95%CI 0.97-1.0, p=0.019) and OS (HR 0.99, 95% CI 0.97-1.0, p=0.044), whereas NLR did not.

Conclusions: A lower NLR and a higher sTIL content were each associated with improved IDFS and OS among pts with nonmetastatic TNBC on UVA. However, when evaluated on a MVA, only sTILs remained independently associated with IDFS and OS. Our data suggest that the effect of sTILs on outcomes may not be modified by the NLR.
Title: Improving CAR T cell function by reversing the immunosuppressive tumor environment of breast cancer

Body: Adoptive transfer of T cells redirected to tumor-associated antigens (TAAs) by expression of chimeric antigen receptors (CARs) can produce tumor responses, even in patients with resistant malignancies. To target breast cancer, we generated T cells expressing a CAR directed to the TAA mucin-1 (MUC1). T cells expressing this CAR (86±1.9%, n=5) specifically killed MUC1-expressing cells (MDA-MB-468 – 45.9±7.3%, MCF-7 – 36.8±3.6%) but not MUC1(-) 293T cells (3.7±1.6% specific lysis, 20:1 E:T, n=3). Although these CAR T cells had potent anti-tumor activity against breast cancer cells, when exposed to the Th2-polarizing cytokine IL4 ([which is upregulated in tumor samples (Oncomine, p<0.05)] we observed a dramatic reduction in their cytolytic potential [IL2 - 45.9±7.3% vs IL4 - 11.3±3.7% specific lysis, 20:1 E:T ratio, n=4]. Thus, to protect our CAR.MUC1 T cells from the negative influences of IL4, we generated an inverted cytokine receptor (ICR) in which the IL4 receptor exodomain was fused to the IL7 receptor endodomain (4/7 ICR). Transgenic expression of this molecule in CAR.MUC1 T cells (55±4.8% double positive cells, n=5), restored the cytolytic function of CAR T cells (30.9±8.1% specific lysis, 20:1 E:T, n=3). Next, to determine the long term effects of this modification we co-cultured transgenic T cells with MUC1+ tumor cells and measured tumor and T cells numbers. In the presence of IL4, only double positive (CAR.MUC1-4/7) T cells expanded and eliminated the tumors in vitro and in vivo. However, upon tumor elimination, transgenic T cells rapidly contracted, demonstrating the antigen- and cytokine-dependence of the product. In conclusion, CAR.MUC1-4/7 T cells can effectively target breast cancer cells and retain their cytotoxic function even in the IL4-rich tumor microenvironment.
Title: Lymphoid and myeloid cell characterization of inflammatory breast cancer tumor microenvironment and correlation to pathological complete response

Sangeetha M Reddy¹, Alexandre Reuben¹, Hong Jiang¹, Jason Roszik¹, Michael T Tetzlaff¹, James Reuben¹,², Linghua Wang¹, Takahiro Tsujikawa³,², Souptik Barua¹, Arvind Rao¹, Lily Villareal¹, Anita Wood¹, Wendy Woodward¹,², Naoto T Ueno¹,², Savitri Krishnamurthy¹,², Jennifer A Wargo¹ and Elizabeth A Mittendorf¹,². ¹The University of Texas MD Anderson Cancer Center, Houston, TX; ²Morgan Welch Inflammatory Breast Cancer Research Program and Clinic, Houston, TX; ³Oregon Health and Sciences University, Portland, OR and ⁴Kyoto Prefectural University of Medicine, Kyoto, Japan.

Background: Inflammatory breast cancer (IBC) is an aggressive form of breast cancer with poor response rates to current chemotherapy regimens. With recent successes of immune targeted therapies in other solid tumors and a growing understanding of how the immune tumor microenvironment (TME) affects non-IBC outcomes, we sought to characterize the immune TME in IBC to identify biomarkers of treatment response and potential targets for drug development.

Methods: Pre-treatment core biopsy samples were identified from the MD Anderson Cancer Center IBC tissue bank from patients with stage III and de novo stage IV (with T4d) disease who received neoadjuvant chemotherapy (NAC) with intent to take to mastectomy. Lymphocytes were characterized by stromal tumor infiltrating lymphocyte (sTIL) quantification, CD8 T cell quantification, and T cell receptor sequencing. PD-L1 expression was assessed using DAKO 22C3 clone on tumor and immune cells. Myeloid cells were characterized using a multiplex immunohistochemistry approach, using CD68 and CD163 for macrophage markers, tryptase for mast cell marker, HLA-DR for class II antigen presentation marker, and cytokeratin as tumor marker. Spatial analyses were performed by determining probabilities of finding cell 1 of interest within 20 uM of cell 2 of interest and computing area under the curve for statistical comparison.

Results: 91 patients with stage III (N=62) or de novo stage IV (n=29) disease were identified. Breast cancer subtype included 25 triple negative, 34 HER2+ and 32 HER2-HR+. 86 patients received a mastectomy, of whom 33 (38.4%) patients experienced a pathologic complete response (pCR). sTIL was higher in stage III tumors (11.9 vs 4.8%, p<0.001) and in those having a pCR (13.8 vs 7.3%, p=0.019). CD8 T cell density (available in 48 cases) similarly was higher in stage III patients (360.3 vs 178.8 counts/mm², p=0.040) and pCR cases (452.3 vs 219.2 counts/mm², p=0.080) but also higher in HER2+ disease (560.9 for HER2+ vs 239.9 counts/mm², p=0.008 for TNBC and 153.6 counts/mm², p=0.005 for HER2-HR+). T cell clonality (available in 32 cases) ranged from 0.004 to 0.242 but showed no correlation to tumor characteristics or response. PD-L1 complete tumor membranous expression was seen in only 1 of 47 cases, whereas PD-L1 positivity on immune cells was seen on 36.2% of cases; neither correlated to response. Myeloid cell assessment (available in 25 cases) showed higher mast cell infiltration in non-pCR cases (63.8 vs 26.8 counts/mm², p=0.008) and spatial analysis (performed on 10 cases) identified that closer proximity of mast cells to CD8 T cells correlates with response (AUC 6.0 vs 2.2, p=0.017), suggesting a possible immunosuppressive mechanism. HLA-DR analysis demonstrated no difference by response as a single stain marker, but co-localization of HLA-DR with cell type shows higher HLA-DR expression on tumor cells in non-responders (14.6 vs 1.6%, p=0.031).

Conclusions: Higher TIL and CD8 T cell density are correlated with improved responses to NAC in IBC. Mast cell infiltration and HLA-DR expression on tumor cells are inversely correlated to response and suggest possible mechanisms of resistance. Mast cells could present potential therapeutic target in IBC.
Title: Prognostic factors for therapeutic personalized peptide vaccines in patients with metastatic recurrent breast cancer

Uhi Toh1, Shuko Saku1, Nobutaka Iwakuma1, Yuko Takao1, Mina Okabe1, Momoko Akashi1, Akira Yamada2, Shigeki Shichijo3, Kyogo Itoh3 and Yoshito Akagi1. 1Kurume University School of Medicine, Kurume, Japan; 2Kurume University Research Center for Innovative Cancer Therapy, Kurume, Fukuoka, Japan and 3Kurume University Cancer Vaccine Center, Kurume, Fukuoka, Japan.

Body: Background: We have previously reported the prognostic role of humoral antigen spreading response against prostate-related antigen (PRA) for metastatic recurrent breast cancer (mrBC) patients who received personalized peptide vaccine (PPV) therapy (Toh U, SABCS 2015). The prognostic effect was additionally evaluated by the clinical relevant factors including intrinsic subtype, the regimens of combined chemo-hormonal therapies in present study.

Methods: We analyzed serum IgG responses to all of the peptide candidates included PRAs (PSA, PAP and PMSA) after PPV therapy by the Luminex system using peripheral blood samples from 77 vaccinated mrBC patients. The clinical factors and relevant events were statistically evaluated.

Results: After 6 and 12 cycles of PPV therapy, the serum IgG of anti-PSA, anti-PAP, and/or anti-PMSA increased significantly in 31 patients (PRA response group), and the median progression free survival (PFS) and median overall survival (OS) were 8.1 and 14.3 months, but were 5.1 and 10.8 months, respectively, in the remaining 46 patients with no anti-PRA IgG response (PRA non-response Group). The anti-PRA IgG level was marginally correlated with PFS (p=0.059) and OS (p=0.082) between these two groups, which was a significant prognostic factor for PFS (Log-rank: 0.009) in estrogen-positive cancer patients (ER+). The statistical analyses showed that the clinical outcome was in favor of > 60 year-old patients, those with longer PPV therapies (>3 months), and those who received combined standard hormonal therapies or bisphosphonate/anti-RANKL therapy.

Conclusions: This study indicated a clinical significance between the pre-and post- PPV therapy measurement of serum anti-PRA IgG in patients with mrBC, which may be a useful prognostic marker for monitoring peptide vaccine treatment outcomes, particularly for patients ≥ 60 years with ER+ breast cancer. These results also suggest that the immunotherapeutic peptide vaccine could be efficiently combined with hormonal therapy, anti-HER2 therapy, and bisphosphonate/anti-RANKL therapy in mrBC patients.
Impact of neoadjuvant systemic therapy on sTIL in breast cancer

Avan Armaghani1, Ruth Asirvatham1, Lazarus Mramba1 and Karen Daily1. 1University of Florida, Gainesville, FL.

Body: Background
Multiple studies have shown a correlation between the presence of stromal tumor infiltrating lymphocytes (sTIL) and breast cancer outcomes. Higher sTIL are associated with higher rates of pCR, DFS, and OS. These findings have been primarily observed in TNBC and in HER2+ rather than in HR+, which overall has lower sTIL. Despite this growing body of prognostic evidence, there is little data comparing sTIL at diagnosis to sTIL after neoadjuvant systemic treatment. Understanding the impact of treatment on sTIL may lead to novel techniques to increase host immune response in the tumor microenvironment. The objective of this study was to correlate sTIL in paired samples before and after standard neoadjuvant systemic therapy, and then to identify the direction and magnitude of change in sTIL along with any associated features.

Methods
Institutional pathology database was queried for invasive breast carcinoma with “yp” in staging designation. From July 2013 to September 2016, there were 122 cases identified. When cases were excluded due to unavailable biopsy slides, there were 61 cases remaining. Needle biopsy and final surgical specimens were evaluated using International TIL Working Group 2014 guidelines and reported as a whole number percentage. In specimens with pCR, where there are no applicable guidelines, sTIL were determined by estimating the lymphoplasmacytic infiltrate in the tumor bed. Additional information gathered from the electronic medical record included patient age, clinical TNM stage, breast cancer subtype (HR+, HER2+, TNBC), neoadjuvant systemic therapy regimen (anthracycline, nonanthracycline, Trastuzumab-containing, endocrine), and response to treatment (pCR, residual invasive disease). A negative binomial generalized linear mixed model was used for analysis.

Results
Overall the sTIL declined from biopsy to surgery by about 36% ($\beta = -0.448, S.E. = 0.223, pvalue = 0.045$). However, there were 19/61 patients who had an increase in sTIL with neoadjuvant systemic therapy. For this group, the mean biopsy sTIL was 9.7% while the mean surgery sTIL was 28.7%, significantly higher than the mean biopsy ($p-value < 0.001$). This group was not associated with age, stage, breast cancer subtype, or regimen. We examined our results in the 37/61 patients who did not achieve pCR. In all breast cancer subtypes, this group had an increase from biopsy to surgery in sTIL, with no significant difference between treatment regimens. Increasing age was significantly associated with lower sTIL in both biopsy and surgery specimens ($p-value = 0.033$). For every decade increase in age, sTIL decreased by about 37%.

Discussion
Overall the sTIL declined from biopsy to surgery. In the group of patients with an increase in sTIL, there was no significant correlation with systemic treatment regimen. There was a nonsignificant trend towards increasing sTIL and residual disease at surgery. We hypothesize that the host immune response declined after tumor eradication in pCR and remained active when residual disease was present. Increasing age was significantly associated with lower sTIL. Further work to identify additional factors associated with sTIL is needed to guide efforts to alter the immune response for improved breast cancer outcomes.
Body: Background: African American women have worse prognosis and poor survival rates due to lack of Androgen Receptor expression. These subtypes, the Quadruple Negative Breast Cancers (QNBC), currently have no treatments. Previously, we found that AA TNBC have 28% more chance of being QNBC and have 25% higher rate of progression vs the Caucasian Americans (CA). Also, these QNBC patients have a unique immune and basal signature. Here, we explore individual genes and their correlation to race and immune therapies.

Methods: We analyzed AR mRNA expression in 925 tumors from CA or AA women from The Cancer Genome Atlas and independently validated AR protein levels by immunohistochemistry in 197 primary tumors. Samples were dichotomized as AR positive or negative using mean gene expression cutoff. Gene expression comparisons among groups were determined using standard t-tests, ANOVA, and odds ratios with a significance threshold alpha of 0.05. Therapy targets were selected from the list of significantly differentiated genes. Boxplots and heatmaps were made using R packages. Cumulative Incidence plots for time to progression were constructed using XLStats and Grays test for significance.

Results: QNBC CA have higher expression of PDCD4 (p <.001), CD46 (p <.001), CD3EAP (p =.04) and CD84 (p =.07) compared to QNBC AA. CD47 (p =.63) and PD1 (p =.96) express no significant differences in race. QNBC AA show higher expression of NFKB (p <.001), CCL2 (p <.001), and IL12 (p <.001) compared to QNBC CAs. Interestingly, QNBCs with high expressions of CD47 (p =.04) have poor prognosis. Thus, QNBC patients with low expression of CD46 (p =.025), PDCD4 (p < .001), and CD3EAP (p < .001) have poor prognosis and overall survival.

Conclusions: Current immune targeted therapies like CD47 and PD1 looks favorable for treatment in some QNBC patients. Race appears to effect other major therapy target gene expressions in the QNBC immune basal signature as well. This may imply that QNBC AA and CA have different immune response which may explain racial progression differences. Assessment of immune markers may contribute to more accurate prognosis.
Title: VISTA expression on tumor-infiltrating lymphocytes in breast cancer: Clinical correlates and association with PD-1

Samantha Burugu\textsuperscript{1,2}, Dongxia Gao\textsuperscript{2} and Torsten O Nielsen\textsuperscript{1,2}. \textsuperscript{1}Department of Pathology and Laboratory Medicine, Vancouver, BC, Canada and \textsuperscript{2}Genetic Pathology Evaluation Centre, Vancouver, BC, Canada.

Body: Background: The V-domain containing Ig Suppressor of T Cell Activation (VISTA) is a recently discovered immune checkpoint receptor with homology to PD-1. VISTA expression on tumor-infiltrating lymphocytes (TILs) blocks their proliferation and effector functions. Recent pre-clinical data in cancer mouse models treated with anti-VISTA and anti-PD-L1 combinations showed promising results and non-redundant functions of VISTA and PD-L1 blockade. However, the expression and prognostic value of VISTA+ TILs in primary breast tumors has not been investigated in detail. Here we assess expression, prognostic value, and associations of VISTA+TILs with other immune checkpoint markers (PD-1/PD-L1, LAG-3, and IDO-1) and with H&E TIL counts.

Methods: A tissue microarray consisting of breast carcinoma primary excision specimens (n=330) from the University of British Columbia hospital, linked to detailed clinicopathological data and outcomes, was used in this study. Patients from this cohort did not receive neoadjuvant treatment. A VISTA antibody (Clone D1L2G) was applied on a 4µm section of the tissue microarray by immunohistochemistry using a Ventana automated stainer. VISTA+TILs in direct contact with tumor nest were scored and reported as absolute count per 0.6mm core. Positive cases were defined as cases with VISTA+TILs ≥ 1. All descriptive and survival analyses were conducted using SPSS software.

Results: VISTA+TILs were present in 30% of cases and were significantly (p<0.05) associated with younger age (<50 years old), larger tumors (>2cm), hormone receptor negativity (ER/PR) and high Ki67 proliferation index (≥ 13.25%). Almost half (48%) of basal-like breast cancers were positive for VISTA expressing TILs. No significant prognostic associations were observed in this cohort. Among the immune checkpoint receptors analyzed, VISTA+TILs were highly associated with PD-1+ TILs: 79% of cases positive for PD-1+TILs were also infiltrated by VISTA+TILs. Interestingly, we found that VISTA+TILs and PD-1+TILs were enriched in cases with otherwise low levels (<10%) of H&E TILs.

Conclusions: Our study identifies the presence of VISTA+TILs in breast cancer patients and its strong association with PD-1+TILs. These results suggest that VISTA blockade could be a good candidate for combination therapy with other immune checkpoint inhibitors, a concept being tested in early phase clinical trials. Validation of these findings in a larger independent cohort powered for multivariate analysis is currently ongoing.
Title: The neo-epitope landscape of breast cancer: Implications for immunotherapy

Pooja Narang1, Meixuan Chen2, Amit A Sharma2, Karen S Anderson1,2 and Melissa A Wilson Sayres1,3. 1School of Life Sciences, Arizona State University, Tempe, AZ; 2Center for Personalized Diagnostics, The Biodesign Institute, Arizona State University, Tempe, AZ and 3Center for Evolution and Medicine, The Biodesign Institute, Arizona State University, Tempe, AZ.

Body: Introduction: Immune checkpoint blockade is an effective immunotherapy for multiple cancers, including a subset of TNBCs. The clinical response to checkpoint blockade correlates with high tumor mutational burden. Cancer-induced mutations are predicted to generate new HLA-binding epitopes (neo-epitopes), which are potential targets of T cells. To determine the neo-epitope load in breast cancer, we developed a rapid bioinformatics pipeline and filtering strategy, EpitopeHunter, to identify and prioritize clinically relevant neo-epitopes from the landscape of somatic mutations. Here, we determined the specificity and frequency of neo-epitopes from the TCGA dataset of invasive breast cancers.

Methods: We analyzed 842 tumor and normal breast cancer exome sequencing from the TCGA dataset. Subgroup analysis was performed based on the IHC status of ER, PR and HER2: (i) TNBC (n=98); (ii) ER and/or PR(+), Her2(-) (n=604); and (iii) ER and PR(+/-), Her-2(+) (n=140). Cancer specific mutations were called uniformly for the aligned tumor and normal pairs using VarScan2. For each annotated non-synonymous mutation, we generated all possible neo-epitopes (up to 11-mers) including the mutant amino acid. HLA typing of A, B and C MHC class I genes of each patient was determined using the POLYSOLVER algorithm. We selected high affinity binding epitopes using the IEDB prediction algorithm based on the known epitopes to identify likely binding of each neo-epitope within the suite of patient-specific HLA alleles (IEDB score < 500). We then filtered the epitopes based on tumor transcript abundance using RNAseq expression for 837/842 patients. An expression value of FPKM > 2 was used as a cut-off for the expressed neo-epitopes.

Results: Total mutational burden was highest for TNBC (median=53, range: 2-1162); followed by ER and PR(+/-), Her-2(+) (median=40, range: 6-4983); and lowest for ER and/or PR (+), Her-2(-) (median=30, range: 0-5515). About 15% of the nonsynonymous mutations led to the generation of neo-epitopes. The neo-epitope load (high affinity neo-epitopes with IEDB score <500) is highly correlated with the mutational burden (R^2= 0.8-0.9). Number of patients with at least one neo-epitope expressed in each category was: TNBC (n= 79/97, 81%); ER and/or PR(+), Her2(-) (n=478/600, 79%); and ER and PR(+/-), Her-2(+) (n=115/140, 82%). Overall, 672/837 patients have at least one predicted high affinity neo-epitope expressed, with an average of 14.7 (1-525) neo-epitopes expressed per patient.

Conclusions: We have developed a rapid bioinformatics pipeline, EpitopeHunter, for the identification of neo-epitopes from tumor sequencing data. Eighty percent of breast cancer patients have at least one expressed neo-epitope, which may serve as candidates for targeted immunotherapy.

Title: Expression of the tumor associated carbohydrate antigen Tn and immune effectors in invasive breast cancer

Benjamin Verret¹, Caroline Rossoni¹, Doris Lebeherec¹, Stefan Michiels¹, Eduardo Castanon-Alvarez¹, Claude Leclerc², Suzette Delaloge¹, Cecile Artaud² and Magali Lacroix-Tikri¹. ¹Gustave Roussy, Villejuif, France and ²Institut Pasteur, Paris, France.

Body: Background:
Glycosylation is a post-translational modification generating complex carbohydrate O-glycans. Tn antigen, a N-acetyl-galactosamine-α-O-Ser/Thr residue that is the core glycosylated component of complex mucin-type O-glycans, is expressed in breast cancers. Tn has been associated with invasion, survival and decreased T-cell mediated immune response in several types of cancer including breast cancer. There is therefore a potential rationale to combine Tn vaccine with checkpoint blockers such as PD-1/PDL-1 inhibitors. Little is known regarding the link between the respective expression of Tn antigen, PDL-1, and TILs, in breast cancer. Our study aimed at characterizing Tn expression in a series of invasive breast cancers, and its correlation with immune response.

Methods
Tn expression was analyzed by immunohistochemistry performed on a tissue microarray of 1864 invasive breast cancer samples (1850 patients for statistical analyses), consisting of 189 (10%) TNBC, 1601 (86%) ER and/or PR positive à checker tumors and 191 (10%) HER-2 positive tumors treated at our institution between 2005 and 2013. Among these cases, 50 luminal B tumors and 50 TNBC were selected for full section and immune analysis, i.e. to study the pattern of Tn expression across whole tumor section and the link between Tn expression and the level of CD3+ and CD8+ infiltrates, and PDL-1 expression. The level of Tn expression was assessed using H-score, combining the percentage of stained cells with staining intensity.

Results:
In the 100 initial samples, Tn expression was observed in 95%, with a H-Score>10 in 85% of the cases, and with homogeneous staining across the whole tumor section in 86% of the cases. Tn expression was increased in Luminal B subtype as compared to TNBC, with a mean H-Score of 100.9 vs 55, respectively (p <0.0001). The CD3+ infiltrate was more important in TNBC as compared to luminal B tumors (mean stromal CD3+: 34.3% vs 21.2%, p=0.0052). No significant difference was found for the CD8+ infiltrate. PDL-1 expression in stromal cells (≥1%) was observed in 43% of the cases, and increased in TBNC as compared to Luminal B (mean of 7.3% vs 2.2% of cells respectively, p=0.0252). In both tumor subtypes, we observed a positive correlation between the CD3/CD8 infiltrates and PDL-1 expression in stroma cells (p<0.0001), but not with Tn expression. In the TMA cohort, Tn expression was observed in 1723 (92%) tumors with a mean H-Score of 82.75. Similarly, to the results obtained in full section, Tn expression was less intense in TNBC as compared to other subtypes (mean H-Score of 62 vs 85, p<0.001). Tn expression was lower in histological grade I as compared to grade II/III tumors (64,69 for grade I, 88,84 for grade II and 88.99 for grade III, p<0.0001), and significantly higher in HER2 positive tumors versus others (mean H score 62,06 for HER2-/RE-, 119,05 for HER2+ and 80,25 for HER2-/RE+, p<0.0001).

Conclusion:
Our study shows a lower level of expression of Tn antigen in TNBC as compared to luminal tumors. We could not identify any correlation between Tn antigen expression and immune status of the tumor as defined by CD3+, CD8+ and PDL-1+ infiltrate in tumor stroma. The role of Tn antigen in the HER2-positive subgroup requires further investigation.
Title: PD-1 expression and its correlation with tumour infiltrating lymphocytes and Ki67 in patients with breast cancer

Hanne Vos¹, Kathleen Lambein¹, Giuseppe Floris², Ines Nevelsteen¹ and Ann Smeets¹. ¹University Hospitals Leuven, Leuven, Belgium and ²University Hospitals Leuven and Translational Cell & Tissue Research, KU Leuven, Leuven, Belgium.

Body: Introduction: Immunotherapy targeting the programmed death-1 (PD-1) checkpoint has resulted in good outcomes in patients with melanoma, non-small cell lung cancer and head and neck cancer. Recent data have showed that patients with ER/PR negative breast cancer might benefit from immunotherapy as well. We investigated PD-1 expression on tumour infiltrating lymphocytes (TILs), the presence of TILs and Ki67. Furthermore, the association of PD-1, TILs and Ki67 with time to metastasis was statistically determined.

Methods: Resection specimens of 284 patients with an ER/PR negative invasive ductal adenocarcinoma of at least 2 cm were analysed. Haematoxylin-eosin staining was performed to determine the percentage of TILs. Subsequently these percentages were divided into three groups: less than 10%, 10%-30% and more than 30% which matches with respectively 30%, 50% and 20% of the patients. PD-1 expression on the TILs of 116 patients and Ki67 expression of 185 patients were assessed using immunohistochemistry.

Results: An increase in the fraction of TILs was significantly associated with a lower risk of metastasis (hazard ratio [HR] = 0.7, 95% CI = 0.6-0.9). PD-1 expression on TILs was observed in 97% of the patients. Three patients had no expression of PD-1, this lack of PD-1 expression significantly increased the risk of metastasis (HR = 5.541, 95% CI = 1.2-25.0). No association could be noted between PD-1 expression and the amount of TILs or Ki67 (p-values of respectively 0.272 and 0.637). Similarly, no association could be noted between Ki67 and the amount of TILs (p-value = 0.1954).

Conclusion: PD-1 was expressed on TILs in patients with breast cancer. Surprisingly, no correlation was found between PD-1 expression and TILs or Ki67. However, an increased amount of TILs was significantly associated with a lower risk of metastasis.
Title: A mathematical model for predicting immune response in a trastuzumab treated HER2+ breast cancer animal model: Preliminary efforts

Angela M Jarrett1, Thomas E Yankeelov1, Lauren I Ehrlich1, Wesley Godfrey1 and Anna G Sorace1. 1University of Texas at Austin, Austin, TX.

Body: Introduction: Trastuzumab is a targeted antibody to the human epidermal growth factor receptor 2 (HER2) that induces cell cycle arrest and is used in the treatment of HER2+ positive breast cancer. We have recently presented in vivo evidence in a murine model that trastuzumab also improves vascular delivery of subsequent cytotoxic therapies. The mechanism by which trastuzumab and the immune system interact to regulate tumor-associated angiogenesis is not well characterized. Therefore, we offer a preliminary report on a mathematical framework to systematically investigate the potential interactions among the immune response, tumor cells, vasculature, and other environmental factors based on experimental data for the BT474 murine model of HER2+ breast cancer.

Experimental: BT474 breast cancer cells were implanted subcutaneously into athymic nude mice. After tumors reached 250 mm^3, mice were treated with trastuzumab or saline, tumor volumes were recorded, and tumors were extracted at various times over seven days. Immunohistochemistry for treated and control tumors were evaluated for 0, 1, 3, 4, and 7 days post trastuzumab treatment. Histology data includes: percent hypoxia (pimonidazole), percent necrosis, and vascular maturation index (VMI, ratio of alpha-smooth muscle actin to total vessel counts as stained with CD31). Ongoing studies are quantifying immune cell infiltration through immunofluorescent imaging of F4/80 and CD11c expression.

Modeling: We developed a system of five coupled, ordinary differential equations that accounts for the temporal variation in tumor growth, vasculature, hypoxia, necrosis, and immune response. The general immune response component corresponds to the mouse's pro-inflammatory responses, as T cell driven responses are absent in this murine model. Uncertainty analysis was performed to verify plausible overlap between the model's predictions and the experimental data—where local and global samplings of all parameters were used to generate potential model results to be compared to the data for both control and treated mouse sets. Sensitivity analysis was performed using Sobol' Indices to determine the driving parameters of the system to identify target parameters for experimental estimation. The model parameters were calibrated using mean and standard deviations for the available data (tumor volume, VMI, percentage of hypoxia, and percentage of necrosis) for each experimental time point to predict the differences of the immune component between the treated and control tumors.

Results and Discussion: The model is well behaved and can be calibrated with the available data. The model predicts distinct differences for the immune response between the control and treated groups—showing increasing versus decreasing immune component values over time for treated versus control results, respectively. Preliminary results from the immunofluorescent imaging data support the immunological predictions of the model; in particular, the amount of immune infiltration (i.e., more immune cells) in necrotic areas is greater in the treated than the untreated tumors (p<0.025).

Title: The numbers of Foxp3 positive cells in simultaneous bilateral breast cancer

Risa Goto¹², Yuko Hirota³, Tomoyuki Aruga¹, Shinnichiro Horiguchi¹, Sakiko Tazawa³, Seigo Nakamura² and Masafumi Takimoto².
¹Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Bunkyoku, Tokyo, Japan; ²Showa University, Shinagawaku, Tokyo, Japan and ³Showa University Koto Toyosu Hospital, Kotoku, Tokyo, Japan.

Body: Background
Evasion of the immune system is one of the hallmarks of malignant tumors, and recently blocking of such evasion has been used in clinical practice for the treatment of some types of cancers. Recruitment of regulatory T cells (Tregs), which express the specific marker Foxp3, is an established mechanism of escaping from the immune system. In breast cancer, it has been reported that the number of Tregs differs widely among breast cancer subtypes, and that patients who have many Tregs around the tumor tend to have a poor prognosis. However, the factors that are important for the recruitment of Tregs are not well known. Thus, factors that depend on the host (e.g., age or comorbidity), on the tumor (e.g., subtype, grade, or stage), or on measurement error might be the cause of the observed differences in the number of Tregs. In this study, we investigated the numbers of Tregs in simultaneous bilateral breast cancer patients in order to determine the factors that influence the recruitment of Tregs, while excluding differences in individuals as much as possible.

Material and methods
Patients who had breast cancer in both breasts and who underwent simultaneous surgery between January 2005 and September 2015 at two institutions were enrolled in this study. Patients who underwent primary systemic therapy who were diagnosed with ductal carcinoma in situ, or who were stage IV were excluded. The average numbers of Foxp3-positive (Foxp3+cells) were determined from scores of five high-power fields (HPFs). The association between the difference in Foxp3+ cell number between each breast in a single individual and clinicopathological features was examined.

Results
Seventy patients were included in this study. Their ages ranged from 39-85 (median 54) years old. Ninety five percent of the tumors were invasive ductal carcinoma non-special type. Eighty eight (62.9%), 43 (30.7%), and 9 (6.4%) of the tumors were T1, T2, and ≥T3, respectively, and 102 (72.9%) of the tumors were node-negative. Regarding nuclear grade (NG), 104 (74.3%), 21 (22.1%), and 7 (5%) of the tumors were NG1, 2, and 3, respectively. As for subtype, 124 (88.6%), 9 (6.4%), and 7 (5%) were ER-positive and HER2-negative(ER+/HER2-), ER-positive or negative and HER2-negative(ER±/HER2+), and ER-negative and HER2-negative(ER-/HER2-), respectively. The numbers of Foxp3+ cells ranged from 0 to 39.8 (median 3.3)/HPF, and difference in Foxp3+ cell number between each breast in a single individual ranged from 0 to 34 (median 3.9)/HPF.

Differences in tumor size and node status in individuals did not impact on the number of Foxp3+ cells. However, the number of Foxp3+ cells in tumors that were NG3 (P=0.00098) or ER±/HER2+ or ER-/HER2- type (P=0.00586) were statistically significantly increased compared with tumors that were NG1/2 or ER+/HER2- type in the same host.

Furthermore, the difference of Foxp3+ cells between each tumor in a single individual were quite small regarding tumor size and node status in 53 patients who had similar NG and subtype tumors in both breasts.

Conclusions
The number of Foxp3+ cells showed no relationship with tumor size, or lymph node status in simultaneous bilateral breast cancer patients. High NG, ER±/HER2+ or ER-/HER2- type of the tumor were involved with enhancement of the recruitment of Tregs.

Title: The complex landscape of breast cancer immune evasion and its implications to personalized and combined immunotherapy

Mayassa J Bou-Dargham¹, Yuhang Liu², Qing-Xiang Amy Sang¹ and Jinfeng Zhang². ¹Florida State University, Tallahassee, FL and ²Florida State University, Tallahassee, FL.

Body: Cancer immunotherapy activates the patient’s immune system to recognize and kill cancer cells. The efficacy of immunotherapy in human breast cancer (BRCA) is hindered by the poor understanding of the immune system’s anti-tumor response and tumor evasive mechanisms, and the lack of optimized treatment regimens for each BRCA patient. There are 6 known evasion mechanisms (M) by which tumors can escape immune surveillance. M1: immunosuppression via interleukin 10 (IL-10) and tumor growth factor beta (TGF-β); M2: induction of tolerance by cytotoxic T-lymphocyte associated protein 4 (CTLA-4), programmed cell death protein 1 (PD-1) and its ligands (PD-L1/PD-L2), and interferon gamma (IFN-γ); M3: apoptosis resistance via the expression of anti-apoptotic molecules, namely baculoviral IAP repeat-containing protein 3 (BIRC3), TNF receptor associated factor 1 (TRAF1), and TNF alpha induced protein 3 (TNFAIP3); M4: counterattack via decoy death receptors; M5: impaired antigen presentation by decreasing beta 2 microglobulin (B2M) and human leukocyte antigens A and B expression (HLA-A and HLA-B); and M6: ignorance caused by the absence of a danger signal or an antigen. Yet, which mechanisms or combination of mechanisms BRCA tumors utilize is unknown. Moreover, the currently used biomarkers for the choice of immunotherapy are not ideal, as for example, not all PD-L1⁺ patients respond to anti-PD-L1 treatment, and certain PD-L1⁻ patients respond. Thus, there is a need for more precise biomarkers. Using the sequential biclustering method on the RNA-sequenced data of BRCA from The Cancer Genome Atlas (TCGA), eighty-one percent of BRCA patients were grouped into 7 different clusters (CL) of immune evasion subtypes. We found that the majority of breast cancer tumors utilize multiple immune evasion mechanisms. Tumors may use from 1 up to 4 combinatorial mechanisms simultaneously. We also identified classifier genes that would help sort patients based on their evasion mechanisms, and guide the choice of immunotherapy. This is especially important since the immune evasion molecules may not be the ideal biomarkers for the best choice of immunotherapy. Moreover, we showed that triple negative breast cancer (TNBC) patients were significantly associated with CL2 (M5).
Title: Regorafenib induces immunogenic cell death via p-stat3 inhibition in triple negative breast cancer cells

Chun-Yu Liu1, Ka-Yi Lau1, Tzu-Ting Huang1, Ji-Lin Chen1, Pei-Yi Chu2, Chun-Teng Huang3, Wan-Lun Wang1 and Ling-Ming Tseng1. 1Taipei Veterans General Hospital, Taipei, Taiwan; 2Show Chwan Memorial Hospital, Taiwan and 3Yang-Ming Branch of Taipei City Hospital, Taiwan.

Body: Background
Metastatic triple-negative breast cancer (TNBC), despite being chemo-sensitive, remains poor prognostic. Rising data have suggested some anti-cancer agents exert immunostimulatory activities through inducing immunogenic cell death (ICD). ICD can be detected by presence of damage-associated molecular patterns (DAMPs) such as cell surface exposure of calreticulin (CRT), secretion of ATP, and increase in high-mobility group box protein B1 (HMGB1) release from dying tumor cells. Signal transducer and activator of transcription 3 (STAT3) activity is activated in TNBC and regorafenib has been shown to suppress p-STAT3 signal. We tested whether regorafenib induces ICD in TNBC.

Methods
Mice TNBC cell line 4T1 cells were treated with regorafenib and cell survival was examined by MTT assay and flow cytometric analysis. DAMPs were examined by western blot analysis, immunofluorescence microscopy and luminescent assay. The correlation between regorafenib-mediated ICD and STAT3 inhibition were validated in ectopic STAT3 transfected 4T1 cells. Moreover, we investigated the combination strategies of regorafenib with immune checkpoint blockade in syngeneic 4T1 tumor bearing mice (TNBC animal model) with treatment of regorafenib or mPD1 treatment alone/ combination of mPD1 and regorafenib.

Results
The results demonstrated that regorafenib reduced cell survival and induced cell apoptosis in a dose-dependent pattern in 4T1 cell line. Regorafenib induced ICD, as evidenced by it triggered the release of HMGB1 and ATP, as well as the exposure of CRT on the cell surface. Moreover, regorafenib-induced ICD was attenuated by ectopic expression of STAT3 (thus increased phosphorylation of STAT3) in STAT3-overexpressed 4T1 cells. Last but not the least, we observed 4T1 tumor bearing mice with treatment of regorafenib alone, or anti-PD1 monoclonal antibody (mAb) alone, or in combination of regorafenib and anti–PD1 mAb resulted in reduced size of primary tumors, increased survival and fewer lung metastases. Flow cytometric analysis revealed regorafenib treatment increased activated CD8+ T cells, increased antigen-presenting dendritic cells, and suppressed regulatory T cells (Tregs) in mice spleen.

Conclusions
Regorafenib induced ICD in 4T1 cells via the inhibition of p-STAT3. Regorafenib also promoted CD8+ T cells activation and antigen presenting ability of dendritic cells, and suppressed Tregs. Our study demonstrated regorafenib as an ICD-inducer and immunomodulator and its potential combination with immune checkpoint blockade in TNBC.
Title: A study on amount, localization and immune phenotype of tumor-infiltrating lymphocytes in different subtypes of breast cancer

Savelina L Popovska¹, Polina D Dimitrova¹ and Tereza B Dineva¹. ¹Medical University, Pleven, Bulgaria.

Body: Objective: The aim of the study was to investigate the localization, amount and type of lymphocytic infiltrate, found in different molecular subtypes of breast cancer (BC).

Methods: Retrospectively, 100 cases of invasive BC were analyzed and immunohistochemically (IHC) stratified in four subtypes (Luminal A and Luminal B-like, HER2-positive, and triple negative (TN). The percentage of stromal areas occupied by tumor-infiltrating lymphocytes (TILs) was assessed for H&E slides. The samples were IHC-stained for CD3, CD4, CD8, CD20 and FoxP3. The immunophenotyped lymphocytes - intratumoural and stromal, were separately counted, semi-quantitatively graded and further analyzed.

Results: A total of 10% of all tumors were lymphocyte-predominant BC. Intratumoral and stromal TILs were predominantly CD3+T-lymphocytes. High counts of all subtypes TILs - intratumoral and stromal, were most common for TNBC and HER2-positive BC.

In TNBC, the intratumoral CD3+TILs are significantly related to CD8+ (p=0.002) and FoxP3+ phenotype (p=0.010). In HER2 BC, the intratumoral and stromal CD3+ TILs were significantly related to FoxP3+ phenotype (p = 0.035 and p= 0.011, respectively).

Conclusion: CD3+T-cell mediated immunity, especially the one related to CD8+ and FoxP3+ lymphocytes was the leading one in antitumor response in BC, and high count of intratumoral and stromal lymphocytes predominated in TN and HER2-positive BC.

Key words: Breast cancer, tumor-infiltrating lymphocytes, CD3, CD4, CD8, CD20, FoxP3.
Title: An integrative approach to the discovery of triple-negative breast cancer markers derived from extracellular vesicles

Botond Igyártó¹, Ritin Sharma¹, Krystine Garcia¹, Victoria David-Dirgo¹, Khyati Pathak¹, Mitchell Kroll², Panieh Terraf³, Kendall Van Keuren-Jensen³ and Patrick Pirrotte¹. ¹Collaborative Center for Translational Mass Spectrometry, Translational Genomics Research Institute, Phoenix, AZ; ²Baylor Institute for Immunology Research, Dallas, TX and ³Center for Noninvasive Diagnostics, Translational Genomics Research Institute, Phoenix, AZ.

Body: Triple-negative breast cancer (TNBC) is an aggressive subtype accounting for nearly 20% of all breast cancer (BC) cases with disproportionally poor prognosis. Treatment options are limited by the lack of expression of common BC receptors targeted by FDA-approved small molecule inhibitors, resulting in an unmet need for efficient and cost effective treatments. Immunotherapies are emerging as a powerful alternative to standard chemo- and radiation therapy. Our objectives are to generate vaccines targeting TNBC and to identify circulating biomarkers capable of monitoring their therapeutic efficacy in a human transgenic mouse model (C57BL/6) compatible with EO771.LMB, a murine cell line of TNBC with a reported basal-like phenotype.

Our current study characterized the cancer-related proteomic and metabolic signatures derived from extracellular vesicles isolated from EO771.LMB. It has been shown that extracellular vesicles (EV) shed by tumors carry complex cargos comprised of proteins, metabolites and nucleic acids and may exhibit cancer-specific signatures with a potential as prognostic markers or predictors of therapy response. EVs released by TNBC tumors into circulation might provide non-invasive and highly actionable insight into the tumor biology of this aggressive cancer.

To further our understanding of cancer-specific EV proteomes, we used mass-spectrometry based proteomics and identified a total of 2265 unique proteins from EVs isolated from conditioned media from EO771.LMB. Our survey across the EV proteome, the expression proteome (5096) and phosphoproteome (2728) identified 6461 unique proteins overall. Within EV sub-fractions, microvesicles and apoptotic bodies were characterized by proteomic cargos different from exosomes. Over 90% of proteins identified in EVs shed by cultured EO771.LMB mapped with proteins curated in ExoCarta. Of interest, exploration of the EV proteome identified 47 GPI-anchored surface proteins. These candidate membrane proteins included Glypican-1 and CD109, previously reported as highly specific to cancer, as well as potential TNBC-specific markers. Our multipronged strategy for deep proteomic profiling of EO771.LMB enhanced identification by ~25% compared to global whole cell proteomics alone. We also identified ~3150 metabolites corresponding to lysophosphatidyl choline (35%), fatty-acids, -esters, -amides, -alcohols (30%), glycerophospholipids and sphingolipids (16%), sugar (1%), amino acids and biogenic amines (4%), organic acids and derivatives, cyclic alcohols, aromatic compounds and steroids (13%). Of these, 1450 metabolites were shared between cell line and EVs. A proteogenomic approach expanded identification to onco-proteoforms and tumor-specific peptides not represented in canonical databases. Custom, cell-specific protein databases derived from whole transcriptome sequencing of EO771.LMB elucidated novel protein variants and mutations. Pan-cancer markers vs. TNBC-specific markers will be verified in other murine cell lines, across multiple cancer types and fibroblast controls. Optimal membrane markers for downstream immune-affinity purification from plasma will be proposed, and their ability to diagnose disease or monitor tumor load during treatment will be discussed.
Anti-uPAR antibody drug conjugates for targeted therapy of triple-negative breast cancer

Efrat Harel¹, Jesse McFarland³, Gregory Bleck³, Susie Brain⁴, Penelope Drake³, David Rabuka³, Laura Vantveer⁴ and Charles Craik¹.¹University of California, San Francisco, CA; ²Laboratory Medicine, Helen Diller Family Comprehensive Cancer Center, San Francisco, CA; ³Catalent Biologics, Emeryville, CA and ⁴Breast Science Advocacy Core, University of California, San Francisco, CA.

Body: Background: Triple negative Breast Cancer (TNBC) is a highly aggressive BC subtype, with an increased likelihood of distant recurrence and of death compared with other types of BC. Patients diagnosed with TNBC lack the estrogen and progesterone receptors, the human epidermal growth factor 2 receptor and do not respond well to current therapies. One hallmark of TNBC is increased uPAR expression. As uPAR was observed in BC and its metastasis but not in normal tissue, anti-uPAR Abs can serve as a targeted therapy for TNBC. The Craik lab used recombinant phage display technology to identify anti-human-uPAR Abs. Two of those human antibodies, 2G10 and 3C6, were tested in in vitro and in vivo TNBC models and demonstrated therapeutic potential. In the mouse model of TNBC the “naked” Abs targeting two distinct subdomains of the receptor slowed or blocked tumor growth. Moving forward in validating the antibodies as a therapeutic for aggressive breast cancer, we have chosen to develop them as a ‘weaponized antibody’ therapy in the form of antibody-drug conjugates (ADCs). Excellent proof of concept for the therapeutic potential of anti uPAR ADC was achieved with anti uPAR (2G10) conjugated to the therapeutic radioisotope 177Lu. With the current limitations of radiotherapy we conjugated 2G10 and 3C6 to make ADCs with a known cytotoxic agent that is available for the treatment of cancer.

Hypothesis: We hypothesize that human anti uPAR mAbs, when coupled to a cytotoxic drug will demonstrate cancer-selective cell killing in mouse xenograft models of TNBC, and are safe with a large therapeutic window, thereby validating uPAR as a therapeutic target for TNBC and anti-uPAR antibodies as a potential therapeutic.

Study design: We tested the ability of the ADCs to target the urokinase receptor that is over-expressed in breast cancer, for therapy. Six- SMART TAG (CATALENT) based anti uPAR (2G10 and 3C6) ADCs have been assembled and characterized. The 6 ADCs with cleavable and non-cleavable linkers, 3 different toxins (alkylation agent and antimotic agents) and drug antibody ratio (DAR) of~2 were produced in reagent quantities. The ADCs were tested in vitro in head-to-head comparisons between the ADC form and unconjugated mAb for their cell killing ability using cell culture assays. Further characterization was performed in vivo TNBC models.

Results: The anti uPAR ADCs were able to recognize uPAR in TNBC cell lines. The ADC 3C6 AzaHIPS-4AP-MMAE exhibited the greatest therapeutic effect in vitro in TNBC cell lines and showed significant slowing or blocking tumor growth in a mouse model of TNBC.

Conclusions: Our results indicate the therapeutic potential of anti-uPAR ADC for TNBC.

Acknowledgments: This work was supported by the Target Validation Initiative grant from the UCSF Helen Diller Family Comprehensive Cancer Center and a grant from Susan G. Komen (PDF15330246) made possible through fundings from American Airlines.
**Body: Introduction:** Secreted frizzled related protein-2 (SFRP2) is overexpressed in breast tumor endothelium and epithelium, and stimulates angiogenesis via the calcineurin/NFAT pathway. We hypothesized that a humanized SFRP2 monoclonal antibody (mAb) would inhibit tumor growth.

**Methods:** Humanization of SFRP2 mAb. V region genes encoding the murine SFRP2 mAb were cloned and used to construct chimeric antibodies comprising the murine V regions combined with human IgG1 heavy chain constant regions and κ light chain constant regions, were expressed in HEK293 cells, purified and tested for binding to SFRP2 in a competition ELISA assay. The antibodies were purified from cell culture. Immunogenicity testing of hSFRP2 mAb. The lead fully humanized and chimeric anti-SFRP2 antibodies were tested against a cohort of 22 healthy donors using EpiScreen™ time course T cell assay in order to determine the relative risk of immunogenicity. Endothelial tube formation assay: Cells were plated in Matrigel alone, with SFRP2 30nM, IgG1 control + SFRP2 30nM, or SFRP2 30nM + a dose range of hSFRP2 mAb from 0.1-10 uM. Tubes were quantified after 4 hours. Determination of maximum allowable dose of hSFRP2 mAb in mice. 1 x 10^6 SVR angiosarcoma cells were injected s.c. into nude mice. Mice were treated with 1, 2, 4, 10 and 20 mg/kg iv of hSFRP2 mAb q 3 days for 3 weeks. The livers and kidneys were resected, and paraffin embedded sections were stained with hematoxylin and eosin. Next we injected 5 x 10^6 hS578t triple negative breast cancer into the mammary fat pad on female nude mice, and treatment was started when tumors reached apx 100 mm^3 after 37 days. Control mice received IgG1 control (4 mg/kg) iv q3 days, and treated mice received hSFRP2 mAb 4 mg/kg iv q3 days for 5 weeks.

**Results:** Immunogenicity testing. The hSFRP2 mAb induced no positive responses using SI ≥ 2.0, p < 0.05 threshold in any of the donors in the proliferation assay, whereas the chimeric anti-SFRP2 antibody induced positive T cell proliferation responses in 23% of donors. Endothelial tube formation in vitro. The hSFRP2 mAb inhibited SFRP2 induced endothelial tube formation in a dose dependent manner with an IC50 of 2.7 µM. Inhibition of tumor growth in vivo. Angiosarcoma: There was no weight loss or lethargy in any of the mice after 3 weeks of treatment at any of the doses, including the 20 mg/kg dose. Control and group 20 mg/kg livers and kidneys showed no abnormalities detected in any of these organs. We tested efficacy of the hSFRP2 mAb at a dose of 4 mg/kg, using 10 mice per group. This shows a statistically significant reduction in tumor volume by 40% in the hSFRP2 mAb compared to control (p=0.04). For hs578t breast tumors here was a 57% reduction in tumor volume in hSFRP2 mAb compared to control (793 mm^3 ±72 vs. 341 mm^3 ± 25, n=10, p<0.0001).

**Conclusion:** We have generated a novel humanized SFRP2 mAb that lacks immunogenicity and inhibits triple negative breast cancer and angiosarcoma in vivo as a single agent without toxicity.
Title: Tackling bone metastatic breast cancer growth with novel bone-seeking matrix metalloproteinase-2 inhibitors

Marilena Tauro¹, Antonio Laghezza², Paolo Tortorella², Hatem H Soliman¹ and Conor C Lynch¹. ¹H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL and ²University of Bari "A. Moro", Bari, Italy.

Body: Background. Despite medical advances, currently there is no treatment for breast to bone metastasis. The progression of bone metastatic breast cancer is critically dependent on interactions with the surrounding microenvironment. Therefore, identifying the underpinning molecular mechanisms is vital for the development of new therapies.

Rationale. Gene expression analysis and validation in human and murine specimens of bone metastases revealed matrix metalloproteinases, such as MMP-2, are highly expressed in the bone metastatic microenvironment. Genetic ablation of MMP-2 demonstrated the importance of this MMP in driving the growth of the osteolytic bone metastatic breast cancer by regulating the bioavailability of transforming growth factor β (TGFβ). These data support the rationale for the development of a highly specific MMP-2 inhibitor for the eradication of active bone metastatic breast cancer.

Methods. We utilized a novel chemical approach to synthesize bone seeking MMP inhibitors (BMMPIs) on a bisphosphonic backbone, with specificity for MMP-2 in the nanomolar range (IC₅₀=140 nM). In vitro, we tested the effect of BMMPIs at varying doses (1nM-100µM) on the viability of the major cellular components of the cancer-bone microenvironment, namely breast cancer cells (PyMT, 4T1), osteoblasts (MC3T3) and osteoclasts (primary monocytes and RAW 264.7). In vivo, mice were intratibially inoculated with either luciferase expressing 4T1 or PyMT (1x10⁵) cells. Mice (n=10/group) then received vehicle, zoledronate (1 mg/kg) or BMMPIs (1 mg/kg). Tumor growth was determined via luminescence quantitation. Cancer induced bone disease was measured ex vivo by µCT, Xray and histomorphometry. MMP activity in vivo and ex vivo was determined via specific activatable MMP probes. Pharmacokinetic and pharmacodynamic studies were performed. Plasma and bone marrow supernatants were collected from PyMT-R221A tumor bearing mice treated with ML115 (5mg/Kg) at 0.25, 0.5, 1, 2, 4, 8, 24 hours and three weeks (n=3 mice/time point). Currently, we are investigating the BMMPIs ability to impact the metastatic process through an in vivo model of intracardiac inoculation.

Results. BMMPIs significantly impacted the viability of breast cancer cells and osteoclasts in vitro (p<0.05) compared to control. In vivo, BMMPIs significantly reduced the growth of bone metastatic breast cancer compared to control and the standard of care bisphosphonate, zoledronate. MMP activity was also lower in the BMMPI treated groups (using tumor burden to normalize values). µCT/Xray/Histomorphometry analysis also illustrated the significant beneficial effects of the BMMPIs in reducing the size of osteolytic lesions (up to 80% by µCT; p<0.05). ML115 is rapidly cleared from the plasma and accumulates selectively in the bone marrow microenvironment over time.

Conclusions. MMP-2 specific BMMPIs prevent bone metastatic breast cancer growth by impacting cancer cell viability and cancer induced osteolysis. Given that bisphosphonates are well tolerated in the clinical setting, we predict that BMMPIs could be translated to the clinical setting for the treatment and eradication of bone metastatic breast cancer.
Title: Dual p38/NLK kinase inhibitor as potential novel therapeutic agent for tamoxifen-resistant luminal breast cancer

Xian Wang¹,², Xixi Cao³, Jamunarani Veeraraghavan³, Lanfang Qin³, Jin-Ah Kim³, Ying Tan³, Susan G Hilsenbeck³, Rachel Schiff³ and Xiaosong Wang¹,². ¹University of Pittsburgh Cancer Institute, Pittsburgh, PA; ²University of Pittsburgh, Pittsburgh, PA and ³Lester & Sue Smith Breast Center, Baylor College of Medicine, Houston, TX.

Body: Background: Tamoxifen is the most commonly used endocrine agent for estrogen receptor (ER) positive breast cancer (also known as luminal breast cancer). However, approximately half of the patients develop resistance after initial response to tamoxifen. To date, no effective targeted therapy exists to overcome it. We previously identified the role of nemo-like kinase (NLK), a serine-threonine kinase that functions in stress response and neurite outgrowth, in breast endocrine resistance. In addition, activation of p38 MAPK has been reported to modulate ER signaling and promote endocrine resistance. We identified a highly selective dual p38 and NLK kinase inhibitor (PNKI) through analysis of public kinase profiling datasets, and evaluated its therapeutic effect in endocrine-resistant breast cancers using in vitro and in preclinical mouse models. Experimental design and methods: To determine the in vitro therapeutic window of PNKI, we treated an acquired tamoxifen-resistant cell line (MCF7-TamR) and a benign breast epithelial cell line (MCF10A) with gradually increasing doses of PNKI. To determine the effect of PNKI on tamoxifen-resistant breast cancer cells, we treated primary tamoxifen-resistant breast cancer cell line BT483, and MDA-MB415, together with acquired tamoxifen-resistant line MCF7 TamR, T47D TamR, and ZR-75-B TamR, with 0.5 uM PNKI in the presence of different doses of Tamoxifen. To evaluate the therapeutic effect of PNKI in a T47D-derived xenograft tumor model with acquired tamoxifen resistance, we administered PNKI alone or in combination with Fulvestrant, the second-line endocrine therapy agent, or with Everolimus, the mTOR inhibitor that could improve patient outcomes in several clinical trials. Mice bearing xenografts were randomized into six treatment groups (Vehicle, PNKI, Fulvestrant, Fulvestrant+PNKI, Everolimus, Everolimus+PNKI). Tumor growth was tracked closely. The tumors harvested two weeks after treatments started were profiled with Reverse Phase Protein Array (RPPA) to assess the early signaling changes after treatments. The therapeutic effect of PNKI were also evaluated in a patient-derived xenograft (PDX) model of de novo endocrine resistant breast cancer. Mice bearing the PDX tumors were randomized to four treatment groups (Vehicle, PNKI, Everolimus, Everolimus+PNKI) and tumor growth curve was measured timely. Results: PNKI showed an in vitro therapeutic window at 0.1-1µM for MCF7-TamR cells. Breast cancer cell lines with either de novo or acquired Tamoxifen resistance became more sensitive to tamoxifen when treated with 0.5uM PNKI. The concomitant treatment of PNKI and Everolimus results in significant decreased tumor burden and prolonged progression free survival in the both T47D-TamR xenograft tumors and re-transplanted de novo endocrine-resistant PDX tumors compared to other treatments. RPPA data of T47D-TamR tumors harvested following 2-week treatments revealed that several key survival signaling in breast cancer are repressed only when PNKI are combined with Everolimus. Conclusion: The dual p38 and NLK inhibitor (PNKI) exhibited potential therapeutic value as adjuvant agent to the mTOR inhibitor everolimus for acquired or de novo tamoxifen-resistant luminal breast cancers.
Title: Bcl-2 functional converters inhibit tumor growth and metastatic potential in zebrafish xenografts

John Gamble¹, Martin Pearce¹, Prasad Kopparapu¹, Hyo Sang Jang¹, Robert Tanguay¹, Julie Greenwood¹ and Siva Kolluri¹. ¹Oregon State University, Corvallis, OR.

Body: While potential therapies might have pronounced success in the simplified settings in cell culture medium, many drugs fail or underperform when cancer cells are encased in a complex 3D microenvironment. Although, rat and mouse models will continue to be the gold standard for in vivo data in drug discovery, zebrafish xenograft models have emerged as a powerful model that can quickly and efficiently deliver in vivo drug efficacy data before commitment to expensive and time consuming rodent models. We have discovered several compounds that work as B-cell lymphoma 2 (Bcl-2) functional converters and activate Bcl-2 into a killer instead of its native anti-apoptotic role. In this study, we use a zebrafish xenograft model to evaluate the ability of these compounds to inhibit xenograft tumor growth of Bcl-2 expressing cancer cells, including triple negative breast cancers. Live fluorescent imaging of cancer cells within zebrafish embryos revealed a decrease in cancer cell growth while under treatment of compounds. Furthermore, the agents that converted Bcl-2 into pro-apoptotic protein also inhibited the metastatic potential of the cancer cells. Therefore, this study demonstrates zebrafish xenograft techniques that can be used to quickly and efficiently obtain in vivo drug discovery data. Moreover, we report novel Bcl-2 functional converter compounds that can effectively reduce xenograft tumor growth and its ability to invade tissue in a living 3D environment and establish the role of Bcl-2 in cancer progression.
**Title:** Sensitivity of triple negative breast cancer cell lines to PCM-075, a highly selective polo-like kinase 1 inhibitor

Peter J P Croucher¹, Aleksandra Franovic¹, Dario Ballinari², Fabio Gasparri², Laura Giorgini², Penn Whitley¹, Barbara Valsasina² and Mark G Erlander¹. ¹Trovagene, Inc., San Diego, CA and ²Nerviano Medical Sciences, S.R.L., Nerviano MI, MI, Italy.

**Body:**

**Background:** The clinical adoption of targeted agents has vastly improved outcomes for subsets of breast cancer patients. Triple negative breast cancer (TNBC), however, remains a significant challenge due to its aggressive nature and lack of therapeutic options beyond chemotherapy. Polo-like kinases (PLKs), a family of serine-threonine kinases, regulate various cellular processes including mitosis, DNA replication, and stress response. Therapeutic targeting of PLK1 is of particular interest as it is over-expressed in many malignancies, including TNBC, and is required for progression through the G2/M phase of the cell cycle. PCM-075 is an orally-available, highly selective PLK1 inhibitor currently under clinical investigation. Our aim was to evaluate the activity of PCM-075, and related PLK inhibitors, in breast cancer cell lines.

**Methods:** We examined the activity of six PLK inhibitors (PCM-075, GSK461364, GW-843682X, BRD-K70511574, BI-2536, and Rigosertib) as measured by IC_{50} values across 40 publicly-available (Cancer Cell Line Encyclopedia, Broad Institute, Harvard, MA) breast cancer cell lines. PLK inhibitors were selected based on the availability of both IC_{50} and gene expression data for shared cell lines (Cancer Therapeutic Response Portal, Broad Institute). Statistically significant rank correlations between IC_{50} and normalized expression values for 18,541 genes were computed for each compound and across compounds by combining P-values. The relative expression status of the ERBB2, ESR1, and PGR genes was similarly assessed for each cell line.

**Results:** Hierarchical clustering based on the set of nominally significantly correlated genes (n = 350) revealed two clusters, suggesting that sensitivity to PLK inhibitors is determined by ESR1 status with positive (ER+) cell lines being insensitive. Further refinement of the cell line status according to ERBB2, ESR1, and PGR expression confirmed that ER- cell lines are the most sensitive to PLK inhibition. Among cell lines for which PCM-075 IC_{50} data was available, of 5 ER-/Her2+ cell lines, 2 were sensitive and 3 were insensitive. Of 17 TNBC cell lines, 14 (82%) were sensitive i.e. IC_{50} < 100 nM (PCM-075: Median ER+ IC_{50} = 1.000 mM; Median TNBC IC_{50} = 0.049 mM; P = 0.005). PCM-075 and GSK461364 exhibited similar sensitivity profiles and combining these data enhanced the distinction between ER+ and TNBC cell lines (PCM-075 and GSK461364: Median ER+ IC_{50} = 4.250 mM; Median TNBC IC_{50} = 0.049 mM; P = 0.0004). This was not the case for the remaining compounds combined (Median ER+ IC_{50} = 1.000 mM; Median TNBC IC_{50} = 0.409 mM; P = 0.018).

**Conclusions:** Examination of cell line response data across breast cancer cell lines indicates that ER- and specifically TNBC cell lines are exquisitely sensitive to PLK inhibition. Insufficient data was available to understand the relevance of Her2 status to this observation. Interestingly, the observed differential activity was pronounced for more selective PLK1 inhibitors. These findings suggest that this drug class may represent a viable therapeutic option and support further studies to assess the efficacy of PCM-075 in TNBC.
Human endogenous retrovirus TROJAN promotes triple negative breast cancer progression and represents a potential therapeutic target

Xi Jin, Xiao-En Xu, Yi-Zhou Jiang and Zhi-Min Shao. Fudan University Shanghai Cancer Center, Shanghai, China.

Body: Human endogenous retroviruses (HERVs) play pivotal roles in the development of breast cancer. However, the detailed mechanisms of noncoding HERVs remain elusive. We used RNA-Seq to analyze the transcription level of each HERV loci across the genome in eight pairs of triple negative breast cancer (TNBC) and normal breast tissues. We identified one LTR70, which we dubbed TROJAN, was a TNBC related HERV. We also found that HERVs could not be researched as families because each members from the same family had different expression patterns in TNBC. TROJAN promoted proliferation and invasion in TNBC cells and indicated poor outcomes in patients. Here, we confirmed that TROJAN regulated the progression of TNBC through multiple mechanisms, with ZMYND8, a metastasis-repressing factor, being one of the targets of TROJAN. TROJAN could bind to ZMYND8, promoting its degradation through ubiquitin-proteosome system, and downregulated the transcription level of EGFR, thus stimulating the metastasis of TNBC. The association of TROJAN, ZMYND8, and EGFR was subsequently confirmed in clinical samples. Furthermore, our study verified that the therapeutic delivery of antisense oligonucleotides targeting TROJAN significantly suppressed metastasis of TNBC in vivo. In conclusion, TROJAN promotes the progression of breast cancer and serves as a potential therapeutic target in TNBC.
Title: The BET bromodomain inhibitors ZEN-3694 and ZEN-3309 targets several mechanisms of resistance to endocrine therapies in preclinical models of ER+ breast cancers

Olesya A Kharenko1, Reena G Patel1, Ravi Jahagirdar1, Sarah Attwell1, Cyrus Calosing1, Laura Tsujikawa1, Eric Campeau1, Sanjay Lakhotia2 and Henrik C Hansen1. 1Zenith Epigenetics, Calgary, AB, Canada and 2Zenith Epigenetics, San Francisco, CA.

Body: More than 200,000 women are diagnosed with breast cancer every year in the United States. About 80% of these cases are estrogen receptor positive (ER+), which is characterized by the up-regulation of ER signaling and downstream activation of cyclin-dependent kinases CDK4/6 and cyclin D1 (CCND1). Current lines of therapies include either endocrine therapies or CDK4/6 inhibitors, which have resulted in great improvement in the treatment of ER+ breast cancer. As expected, resistance to these therapies occurs over time and the development of additional therapeutic strategies is needed. Recently, the bromodomain and extra terminal (BET) proteins BRD3 and BRD4 were shown to be involved in the transcription of ER, and BET inhibitor (BETi) treatment can suppress ER-mediated signaling, offering a potential strategy to overcome endocrine resistance by further shutting down ER signaling regardless of ESR1 mutation status. However, it is still unclear if BRD3/4 are involved in the mechanisms of resistance to endocrine therapies, and whether BETi can potently inhibit the proliferation of ER+ breast cancer cells that are resistant to CDK4/6 inhibitors.

ZEN-3694 is an orally bioavailable small molecule bromodomain BET inhibitor currently undergoing clinical development in metastatic castration-resistant prostate cancer (mCRPC). ZEN-3694 showed efficacy in a panel of ER+ breast cancer cell lines and synergized with both tamoxifen and fulvestrant to inhibit proliferation and induce apoptosis. ZEN-3694 also showed activity in several models of resistance to ER+ breast cancer therapies, including tamoxifen, fulvestrant, estrogen-deprivation, as well as with CDK4/6 inhibitors. Analysis of the major pathways that were up-regulated upon acquisition of resistance to endocrine therapies and down-regulated by ZEN-3694 revealed several key players previously involved in developing resistance to endocrine therapies in breast cancer patients, including: inflammatory cytokines (IL-6, IL-1A, IL-1B), inducers and regulators of epithelial-mesenchymal transition (EMT) (Slug and ZEB-1), cancer stem cell marker (CD44), and angiogenesis regulators (VEGFA, VEGFC). Therefore, several of the transcriptional programs linked to the acquisition of resistance to endocrine therapies are regulated by BET proteins and inhibited by ZEN-3694.

Together, these results suggest that BET inhibitors have the potential to be a novel therapeutic strategy to treat ER+ breast cancer patients developing resistance to endocrine therapies as well as CDK4/6 inhibitors.

Title: Imipridone compounds inhibit breast cancer mTORC1 signaling through integrated stress response-mediated upregulation of endogenous mTORC1 inhibitor sestrin2

Marie D Ralff1,2, C Leah B Kline2 and Wafik S El-Deiry2. 1Lewis Katz School of Medicine, Temple University, Philadelphia, PA and 2Fox Chase Cancer Center, Philadelphia, PA.

Body: Breast cancer is a major cause of cancer-related death and there is a need for novel therapies with increased efficacy and decreased toxicity. The small molecule ONC201 was initially identified as a TRAIL pathway inducer. The compound has entered early phase clinical trials and is being tested in a range of solid tumors and hematological malignancies. Our previously published data demonstrate that ONC201 has potent anti-proliferative and pro-apoptotic effects in a broad range of breast cancer subtypes through TRAIL-dependent and TRAIL-independent mechanisms. Analogs of ONC201 with a shared pharmacophore have been developed and form the novel “imipridone” class. When compared with ONC201, imipridones ONC206, ONC212, and ONC213 showed increased potency of anti-proliferative or pro-apoptotic effects in breast cancer cells. We were interested in further defining the previously unstudied anti-proliferative effects of the imipridone compounds. Single agent efficacy of potent imipridone ONC212 in a xenograft model of TNBC was observed in the absence of apoptosis induction. This indicates that the anti-proliferative actions of the compound are sufficient for an in vivo anti-tumor effect. Our lab has previously shown that ONC201 activates an ATF4-dependent integrated stress response (ISR), essential for apoptosis induction in colon cancer cells. In contrast, in breast cancer cells, although ATF4 knockdown did not block cell death induced by ONC201 it did partially abrogate the anti-proliferative effects of the compound. The mammalian target of rapamycin complex 1 (mTORC1) is a well-known regulator of cellular growth and proliferation. mTORC1 signaling is inactivated in breast cancer cells following treatment with ONC201 and its analogs ONC212 and ONC213, regardless of whether the cells undergo apoptosis. Knockdown of ATF4 abrogated ONC201-mediated inhibition of p70 S6 kinase and ribosomal protein S6 phosphorylation, linking ISR induction to mTORC1 inhibition. We hypothesized that sestrin2, an endogenous mTORC1 inhibitor known to be upregulated following cellular stress, might represent a link between induction of ATF4 and inhibition of mTORC1. Treatment with ONC201 and its analogs ONC212 and ONC213 in multiple breast cancer cell lines resulted in sestrin2 upregulation. This was blocked by ATF4 knockdown. Furthermore, knockdown of sestrin2 abrogated the effects of ONC201 on mTORC1 signaling in breast cancers from multiple molecular subtypes. Previous mechanistic studies have focused exclusively on the relevance of ATF4 in the pro-apoptotic effects of ONC201. The novel findings described here help to elucidate the mechanism behind the potent and understudied anti-proliferative effects of the imipridones. Our findings also strengthen the preclinical rationale for testing of imipridone compounds against breast cancers regardless of molecular subtype.
**Title:** Discovery of novel oridonin-derivatives for the treatment of metastatic breast cancer

Dengfeng Li¹, Ziwei Zhang², Ye Ding³, Zhi Zheng⁴, Jiabin Dong⁵, Hyejin Kim⁶, Jimin Xu⁷, Haiying Chen⁸, Jia Zhou⁹ and Qiang Shen¹⁰. ¹The University of Texas, M.D. Anderson Cancer Center, Houston, TX; ²The University of Texas, M.D. Anderson Cancer Center, Houston, TX; ³University of Texas Medical Branch, Galveston, Houston, TX; ⁴The University of Texas, M.D. Anderson Cancer Center, Houston, TX; ⁵The University of Texas, M.D. Anderson Cancer Center, Houston, TX; ⁶The University of Texas, M.D. Anderson Cancer Center, Houston, TX; ⁷University of Texas Medical Branch, Galveston, Houston, TX; ⁸University of Texas Medical Branch, Galveston, Houston, TX; ⁹University of Texas Medical Branch, Galveston, Houston, TX and ¹⁰The University of Texas, M.D. Anderson Cancer Center, Houston, TX.

**Body:** Metastasis to other organs is the major cause of death from breast cancer. The 5-year survival rate is approximately 99% for localized breast cancer, but sharply drops to approximately 26% for patients with distant metastasis. However, there are currently no effective, targeted therapies available for treating metastatic breast cancer. Oridonin, a complex *ent*-kaurene diterpenoid isolated from Chinese traditional herb *Rabdosia rubescens*, has demonstrated great potential in the treatment of various human cancers. However, relatively low aqueous solubility and bioavailability limited its development into clinical applications. Herein, a number of novel nitrogen-enriched heterocyclic oridonin derivatives and dienone analogs such as YD0514, CYD0618, and CYD0686 have been generated from oridonin. These derivative analogs showed improved anti-proliferation effects against breast cancer cells, compared to oridonin. YD0514, CYD0618, and CYD0686 also displayed significant suppression of migration and invasion in MDA-MB-231 cell, a highly metastatic triple-negative breast cancer cell line. Furthermore, YD0514, CYD0618 and CYD0686 also inhibited the endothelial adhesion of GI101 and its derived, highly metastatic sublines, to the endothelium. We next found that YD0514, CYD0618, and CYD0686 can significantly inhibit the expression and phosphorylation of FAK and block the expression of integrin family members in those highly metastatic breast cancer cell lines. Further pathway analysis demonstrated that YD0514, CYD0618, and CYD0686 inhibited cellular motility potentially by decreasing RHOA/ROCK signaling pathway. Our findings suggest that novel oridonin-derivatives, YD0514, CYD0618, and CYD0686 have the great potential to be developed as effective therapeutics for the treatment of metastatic breast cancer. This work was supported by Grants P50 CA097007, and P30DA028821 (JZ) from the NIH, CPRIT (JZ), John Sealy Memorial Endowment Fund (JZ), DFI Grants from MD Anderson Cancer Center (QS), and Holden Family Research Grant in BC Prevention (QS).
The impact of the Chinese medicine ShenLingLan on triple negative breast cancer, the metabolic and signalling pathways and clinical implications

Wen G Jiang¹, Sioned Owen¹, Fiona Ruge¹, Yong Gao², Hongtao Wang², Cong Wei², Yiling Wu² and Eleri Davies³. ¹Cardiff University School of Medicine, Cardiff, Wales, United Kingdom; ²Yiling Pharmaceuticals, Shijiazhuang, Hebei Province, China and ³Breast Cancer Centre, University Llandough Hospital, Cardiff, Wales, United Kingdom.

Body: Background. Triple negative breast cancer (TNBC) is a challenging both in the choice of therapies and clinical outcomes. In the present study, we investigated the potential prospect of a Chinese medicine formation, ShenLingLan, shown to have benefit to patients with cancer and able to influence the biological behaviour of cancer cells, on breast cancer cells in particular the differential response from TNBC and non-TNBC cells and, on the discovery that TNBC cells were particularly sensitive to the medicine, we went on to determine the signalling and mechanism of action.

Methods. A panel of three TNBC (MDA MB-231, BT20 and BT549) and a panel of three non-TNBC (MCF-7, ZR 75-1 and T47D) cells were used. A soluble extract from ShenLingLan, designated as SLDM, was utilised during this study. The proliferation, cellular migration and adhesiveness were tested using conventional and biophysical methods. Signalling profiling was conducted using a protein kinase array platform (Kinexus™). Metabolic profiling was conducted using the Seahorse platform. Expression of insulin receptor (IR) and insulin-like growth factor receptor (IGFR) gene transcripts (quantitative transcript analysis) and proteins (IHC) were conducted using a fresh breast cancer cohort and tissue array, respectively.

Results. SLDM had little effects on the growth of breast cancer cells. However, it had profound inhibitory effects on the migration of both TNBC and non-TNBC cells in a concentration dependent manner. Interestingly, TNBC cells were 5-20 times more sensitive than the non-TNBC cells in their migration and cell adhesion responses to SLDM. The protein array platform further revealed that, of the wide range of protein kinases, IR and IGFR1 were the most affected in that SLDM resulted in 25-50% reduction in the phosphorylation of IR and IR substrate in TNBC cells. SLDM also caused a contrasting response in IGFR1 phosphorylation in TNBC and non-TNBC cells. Metabolically, TNBC and non-TNBC cells responded to SLDM in very different fashions. For example, in TNBC cells SLDM resulted in a significant decrease in glycolytic activities, in particular that driven by insulin (30.2±12.2 pmol/min in control, 47.7±10 pmol/min with insulin and 35.4±4.2 pmol/min with insulin/SLDM, p=0.01). There is evidence that the mitochondria oxygen consumption (OCR) was also affected by SLDM in TNBC cells (p=0.01). These changes induced by SLDM were in clear contrast to non-TNBC cells which did not respond with significant reduction. Both TNBC and non-TNBC breast cancer tissues have higher IR staining than normal mammary tissues (p<0.001). TNBC tumours also demonstrated significantly more positive IR staining than the non-TNBC tumours (p=0.04).

Conclusion. ShenLingLan has a profound inhibitory effect on the migration and cell-matrix adhesion of TNBC cells, with marked effect on the metabolics of these cells. This effect connects with reduction of the IR and IGFR activation, mainly through the reduction in glycolysis. Together with the clinical implication of IR and IGFR in breast cancer, ShenLingLan has an important role in the treatment of breast cancer with an emphasis in TNBCs.
Title: IRS1 expression is required for estrogen stimulated growth in breast cancer cells

Xihong Zhang¹, Sidhant Varma¹ and Douglas Yee¹. ¹Masonic Cancer Center, University of Minnesota, Minneapolis, MN.

Body: Insulin receptor substrate (IRS) proteins are adaptor proteins phosphorylated by activated type I insulin-like growth factor receptor (IGF-1R) and insulin receptor (IR). In addition to their roles in normal cell physiology, we have shown IRS expression is required for breast cancer cell growth and motility. IRS1 plays a more important role in mitogenesis and survival while IRS2 in cancer cell metastasis. Moreover, this family of adaptor proteins is also involved in the signal transduction of many other transmembrane receptors. Thus, IRS proteins could be potential cancer therapeutic targets. We have previously shown that reduced IRS1 impairs IGF and insulin stimulated cancer cell growth and tumorigenicity even when signaling is not affected due to possible compensation of IRS2 and other adaptor proteins. To further study the role of IRS-1 function in breast cancer, we created doxycycline inducible IRS-1 shRNA cells. We also found that IRS1 knockdown significantly reduced estradiol stimulated growth. To investigate if reduced IRS1 regulated E2 stimulated binding of ERα ChIP assay was performed using the pS2 promoter. Compared to parental MCF-7L cells, inducible IRS1 knock down clone 3G5 demonstrated significantly reduced promoter binding. Degradation of IRS-1 with a pharmacologic antagonist (NT-157) also diminished ERα binding to pS2 promoter. Further qRT-PCR analysis for mRNA levels of estrogen regulated genes, such as PGR, TFF1, etc. showed those genes were significantly down regulated. To evaluate effects of IRS-1 levels on estrogen stimulated growth, we evaluated 3G5-B12 (a subclone of 3G5) cell growth in a xenograft model. 3G5-B12 cells have similar levels of IGFIR and ERα expression compared to their parent cells. Estrogen dependent xenograft growth was similar to those of parent MCF-7L cells. After doxycycline was administered in the diet, 3G5-B12 tumor growth was significantly inhibited compared to those fed with normal mouse diet, and this inhibition was prolonged at least 2 and a half months. Parental MCF-7L tumor growth was not affected by the doxycycline diet. Doxycycline inducible IRS1 knock down significantly prolonged the time before tumors reached 1000mm³ compared with those tumors on a normal diet. In conclusion, IRS-1 is required for optimal estrogen receptor function as measured by promoter binding and xenograft growth. Our data suggested suppression of IRS-1 function may target several growth pathways in breast cancer cells and represents a new drug target.
Title: Inhibition of sushi domain containing 2 (SUSD2) cleavage prevents surface presentation of galectin-1 on breast cancer cells

Mitch E Patrick and Kristi A Egland. Sanford Research, Sioux Falls, SD.

Body: Routinely used therapies are not adequate to treat the heterogeneity of breast cancer (BCa), and consequently, more therapeutic targets are desperately needed. Sushi Domain Containing 2 (SUSD2) is a type I transmembrane protein composed of functional domains inherent to adhesion molecules. SUSD2 is highly expressed in BCa but has minimal expression in other normal tissues. Using an in vivo syngeneic mouse model, the Egland lab demonstrated that mice with Susd2-expressing tumors showed increased tumor growth and decreased survival compared to vector controls. Interestingly, Susd2-expressing tumors contained 50% fewer infiltrating CD4 T cells when compared to vector control tumors. In vitro co-culture assays of MDA-MB-231 and Jurkat cells showed that MDA-MB-231-SUSD2 cells increased T cell death compared to MDA-MB-231-vector cells. Our preliminary experiments suggest that SUSD2 acts through the protein Galectin-1 (Gal-1) to achieve T cell killing. Gal-1 has been implicated as a major contributor to cancer immune evasion and angiogenesis. When Gal-1 is targeted by an inhibitory molecule, cancer progression is reduced. Surface presentation of Gal-1 by cancer cells was shown to be required for T cell killing. We have previously shown that localization of Gal-1 on the surface of cells is dependent on the presence of SUSD2; therefore, disrupting the SUSD2-Gal-1 interaction offers a potential new therapeutic strategy for BCa. Western immunoblot analysis using an anti-SUSD2 antibody against the C-terminus showed that SUSD2 runs as two bands, a 110kDa full-length band and a 60kDa fragment, suggesting that SUSD2 is cleaved. When antibodies against both the C-terminus and N-terminus of SUSD2 were used, three bands were observed: a full-length 110kDa band and fragment bands of 60kDa and 50kDa. The cleavage site and significance of this cleavage with respect to SUSD2 and Gal-1 interactions previously has not been investigated. Edman degradation was used to sequence the C-terminal SUSD2 fragment and determined that the cleavage site is within the Von Willebrand type D domain, between the aspartic acid and proline of the GDPH sequence. Deletion of the GDPH sequence showed a complete inhibition of SUSD2 cleavage. Furthermore, non-cleaved SUSD2 was unable to localize to the plasma membrane indicating that SUSD2 cleavage is important for cell surface presentation. Consistently, Gal-1 was not localized to the cell surface in MDA-MB-231 cells expressing the non-cleavable SUSD2 mutant. Our results indicate that SUSD2 cleavage is a processing step required for Gal-1 surface localization and inhibiting SUSD2 processing may be a viable targeting strategy. We are treating SUSD2-expressing BCa cells with protease inhibitors to identify the protease responsible for SUSD2 cleavage. The identification of this protease would provide a potential target for decreasing BCa tumorigenesis and increasing survival of BCa patients.
Body: Under physiological conditions low voltage-activated calcium channels (LVA, also called T-type channels) occur mostly in the brain, peripheral nervous system, smooth muscles, and pacemaker of the heart. However, LVA are often aberrantly expressed in various cancers and their overexpression is inversely correlated with outcomes. Active LVA contribute to proliferation, progression and resistance to therapy in several human cancers, including breast cancer (BC). The molecular mechanism of this activity is still not fully understood, and there is a lack of pre-clinical studies that target LVA in animal models of BC. Data from the Cancer Genome Atlas (TCGA) show a positive correlation between HER2 gene amplification and LVA channel overexpression, particularly of Cav3.1 (CACNA1G) subunit. The goal of this study is to identify functional links between HER2 receptor signaling and LVA channels, and validate LVA Ca\textsuperscript{2+} channels as a potential target for BC therapy. Inhibition of LVA, by small molecule antagonist mibefradil (MIB) or shRNA, significantly decreased the activity of PI3K/mTOR/AKT pathway in HER2-positive BC cell lines, blocked cell cycle progression, and at higher concentrations induced apoptotic cell death. Furthermore, LVA antagonist, mibefradil, sensitized cells to trastuzumab, lapatinib and paclitaxel, commonly used standard treatments for HER2-positive BC. To test the effects of LVA inhibition in vivo, the MMTV-PyMT mouse model of BC was used. In this model several features of HER2-positive BC are recapitulated, such as activation of PI3K/AKT/mTOR pathway, overexpression of HER2, BIRC5 and cyclin D1, and low expression of ER\textalpha, PGR and FOXA1. In PyMT animals palpable tumors can be detected at the age of 10-12 weeks, and 100% of animals will develop high tumor burden, including lung metastases, at the age of 15-20 weeks. Expression of CACNA1G subunit was detected in breast epithelial cells of 7 week old mice, and throughout the adult life, in both wild-type and PyMT animals, but CACNA1G was not expressed in lung or skeletal muscles. In in vitro experiments, cell lines derived from PyMT tumors were sensitive to MIB. In in vivo experiment, 5 to 7 weeks-old PyMT mice were fed either control or MIB-containing diet ad lib. Analysis of mouse serum revealed stable MIB concentration of \~1500 ng/mL achieved within one week of treatment. In MIB-fed animals tumor appearance was delayed by 2 weeks, and the tumors were smaller as compared to control, thus suggesting a supporting role for LVA channels in breast tumor development and progression. Together, our observations provide new insights into the role of Ca\textsuperscript{2+} channels in HER2 driven BC and posit a future use of LVA channel antagonists for the treatment HER2-positive breast tumors.
Purpose: Breast tumors classified as ‘triple negative’ (TNBC) lack defining markers ER/PR/HER2 and do not have clinically-approved targeted therapy. This heterogeneous classification of breast cancers, while immediately responsive to standard chemotherapy, commonly develop resistance and have a poor five-year survival rate. As such, the identification of new therapeutic targets are warranted. As part of our drug discovery platform, we have identified EphA2, as a synthetic-lethal gene that enhances the therapeutic action of FDA-approved, anti-inflammatory compounds. Thus we sought to ascertain the relevance of EphA2-targeted therapy in TNBC, through the evaluation of the marker in preclinical and clinical specimens.

Methods: Sixty-one human and murine breast cancer cell lines or patient-derived xenografts were collated. Protein lysates were created from cells in vitro or from respective tumors established from cells implanted into NSG mice. Forty-nine tumors established (minimum 500mm$^3$) and were surgically removed, fixed in formalin and paraffin embedded. A TMA was constructed with tumor specimens represented twice on the array and reflected all molecular subtypes including; ER-positive (n=5), PR-positive (n=3), HER2-positive (n=9) and TNBC (n=31). Immunostaining for EphA2 was performed with the rabbit monoclonal antibody EphA2 (D4A2) XP (Cell Signaling, #6997) using manufacturer's instructions. Immunostaining was evaluated using the H-score method (score between 0-300), with positive staining for EphA2 reflecting a score of 100 or greater. Analysis of breast cancer lysates by western blot was analyzed by absolute and relative quantitation methods; gene expression data was assessed through Oncomine or using the BreastMark algorithm (http://glados.ucd.ie/BreastMark/). This algorithm integrates gene expression and survival data from 26 datasets on 12 different microarray platforms corresponding to ~17,000 genes in up to 4,738 samples.

Results: In an integrated gene expression platform (BreastMark), we observed that elevated EphA2 expression was associated with poor prognosis in a cohort of TNBC patient tumor samples. Western blot analysis of EphA2 protein on breast cancer cell lines, identified a greater percentage of TNBC cells expressing EphA2 compared to non-TNBC cell lines. EphA2 immunostaining was observed in the majority of tumor tissues. When present on cancer cells, EphA2 localized to the cell surface; while displaying ubiquitous localization within stromal populations. Cell surface expression of EphA2 on cancer cells was largely restricted to TNBC tumors (11/31 tumors, 35.5%) compared to other molecular subtypes (1/13 non-TNBC tumors, 7.7%; p = 0.0294). Expression of EphA2 in stromal cell populations was similar between groups (TNBC = 22/31, non-TNBC = 11/13; p = 0.1711).

Conclusions: Our analysis determined that EphA2 was specifically expressed on cancer cells derived from tumors with a ‘triple-negative’ molecular subtype. Collectively our data suggests that EphA2 is an emerging target in TNBC and that therapies directed against EphA2 may provide a significant benefit for a majority of patients that express this marker.
Potential of breast tumour kinase (Brk) as a therapeutic target: Brk modulates drug responses in breast cancer cell lines

Haroon Hussain¹ and Amanda Harvey¹. ¹Institute of Environment Health and Societies, London, Uxbridge, United Kingdom.

**Body: Background:** Breast tumour kinase (Brk/PTK6) is over-expressed in up to 86% of all breast cancers and has shown to be involved in the processes regulating tumour development and progression. A few Brk inhibitors are in development and our studies indicate potential for a Brk inhibitor to be used in combination with current breast cancer therapies. Furthermore the effect of common breast cancer therapies and Brk inhibition on the expression of \( ptk6 \) as well as its alternatively spliced isoform (ALT-PTK6) have not been previously been shown. Using qPCR we have determined gene expression of both genes before and after treatment.

**Methods:** Breast cancer cell lines T47D, GI101, BT474, SKBR3, MDA-MB 231, and MDA-MB 436 were treated with Brk inhibitor, Compound 4f (Mahmoud et al, 2012) and common breast cancer therapies (Taxol, Doxorubicin, Lapatinib and Tamoxifen) at concentrations ranging from 0µM to 10µM. Western blotting was carried out to determine levels of Brk and activation of Brk substrate; STAT3 after treatment with Brk inhibitor. RNA was extracted using Qiagen Mini RNase prep kit, cDNA synthesized using Invitrogen Superscript II Reverse Transcriptase and qPCR carried out using primers specific for PTK6 or primers that recognized both transcripts (PTK6 and ALT-PTK6) for total expression.

**Results:** In all cell lines tested there was a moderate reduction in cell proliferation following treatment with the Brk inhibitor (4f). However a greater effect was observed in combination therapy. Triple negative breast cancer cell lines MDA-MB 231 and MDA-MB 436 were treated with Compound 4f and Taxol or Doxorubicin (n=3) resulting in modest but statistically significant reduction in cell numbers. Cell responses to Taxol in both cell lines were significantly greater in the presence of 4f over a range of doses (\( P < 0.05 \) and \( P < 0.007 \)). Responses to Doxorubicin were also significantly improved in the presence of 4f (\( P < 0.03 \) for MDA-MB-231 and \( P = 0.03 \) for MDA-MB-436). Co-treatment of HER2 positive breast cancer cell lines BT474 and Sk-Br-3 with Lapatinib and 4f showed significant increase in responses over a range of doses between 0.31 and 5µM (n=3, \( P < 0.05 \) for BT474 and \( P \) between 0.03 and 0.0004 for Sk-Br-3). In comparison to untreated cells, there was statistically significant reduction in \( ptk6 \) and Total gene expression observed at various time points within multiple breast cancer cell lines in response to Compound 4f treatment. Significant differences between untreated and treated cells for T47D cell line were at 8 hours post treatment (\( p = 0.02 \)), 2 and 4 hours post treatment in GI101 cell line (\( p=0.04 \) and \( p=0.02 \) respectively), 8 and 24 hours post treatment in Sk-Br-3 (\( p=0.001 \) and \( p=0.017 \) respectively) and 8 hours post treatment in MDA-MB 231 cell lines (\( p=0.03 \)).

**Conclusion:** Inhibition of Brk led to a decrease in \( ptk6 \) gene expression. Expression ratios of \( ptk6 \) and the short isoform ALT-PTK6 were determined and a reduction of \( ptk6 \) gene correlated with elevation of ALT-PTK6 and vice versa. Inhibition of Brk also indicated an increase in breast cancer cell sensitivity to current breast cancer therapies. Our studies thus indicate potential for inhibition of Brk kinase activity in combination with current breast cancer treatments.
Title: TRIM44 is a possible poor prognostic factor for breast cancer patients and positively regulates NF-κB signaling pathway

Hidetaka Kawabata1,2,3,4, Kotaro Azuma1, Kazuhiro Ikeda4, Ikuko Sugitani2,3, Keiichi Kinowaki4, Takeshi Fujii4, Akihiko Osaki3, Toshiaki Saeki3, Kuniko Horie-Inoue2 and Satoshi Inoue1,2. 1Tokyo Metropolitan Institute of Gerontology, Tokyo, Itabashi-ku, Japan; 2Research Center for Genomic Medicine, Saitama Medical University, Hidaka, Saitama, Japan; 3Saitama Medical University International Medical Center, Hidaka, Saitama, Japan and 4Toranomon Hospital, Minato-ku, Tokyo, Japan.

Body: [Background]
Many of the tripartite motif (TRIM) proteins, like Efp/TRIM25 which was identified by our group previously (Nature 417, 871-875, 2002), function as E3 ubiquitin ligases, and are thought to be involved in various physiological and pathological processes such as immunity and oncogenesis. In regard to tripartite motif containing 44 (TRIM44), which is an atypical TRIM family protein lacking RING finger domain, some evidences suggest that it is implicated in the progression of several human malignancies. But its pathophysiological significance in breast cancer remains unknown.

[Methods]
In the present study, immunohistochemical analysis using anti-TRIM44 antibody was performed in clinical breast cancer tissues from 129 patients with the approval of institutional ethical committees (approval number: 845). We then explored the pathophysiological role of TRIM44 in breast cancer by modulating TRIM44 expression in MCF-7 and MDA-MB-231 breast cancer cells.

[Results]
TRIM44 strong immunoreactivity was significantly associated with nuclear grade, distant disease-free survival and overall survival of the breast cancer patients. With multivariate analysis it was shown that the TRIM44 status was an independent prognostic factor for distant disease-free survival and overall survival. The proliferation of MCF-7 and MDA-MB-231 cells was significantly decreased by siRNA-mediated TRIM44 knockdown. TRIM44 knockdown also suppressed migration of MDA-MB-231 cells. Microarray analysis and qRT-PCR revealed that TRIM44 knockdown upregulated CDK19 (Cyclin Dependent Kinase 19), which is reported to be a tumor suppressor gene, whereas downregulated MMP1 (Matrix Metallopeptidase 1) in MDA-MB-231 cells. Notably, TRIM44 knockdown impaired nuclear factor-kappa B (NF-κB)-mediated transcriptional activity stimulated by tumor necrosis factor α (TNFα). Moreover, TRIM44 knockdown substantially attenuated the TNFα-dependent phosphorylation of p65 subunit of NF-κB and IκBα in both MCF-7 and MDA-MB-231 cells.

[Discussion]
Our clinical study showed that prognosis of breast cancer patients is correlated with the immunoreactivity detected by anti-TRIM44 antibody. This result suggested that expression of TRIM44 protein could be used as a potential biomarker of breast cancer. We demonstrated that NF-κB signaling pathway is modulated by TRIM44. Since NF-κB augmentation is shown to be related to aggressive character of breast cancer, stimulation of NF-κB signaling with TRIM44 might be underlying mechanism of poor prognosis. Our in vitro study showed TRIM44 knockdown caused attenuated proliferation and migration of breast cancer cells, raising the possibility of TRIM44 as a potential therapeutic target for breast cancer. These findings provide new clues to develop alternative effective strategies for breast cancer management.
Title: The pan-HER inhibitor, neratinib and wingless-type MMTVs (Wnt)/Wnt regulators in human breast cancer; a biological and clinical perspective

Sioned Owen¹, Fiona Ruge¹, Alshad S Lalani², Francesca Avogadri-Connors², Richard P Bryce², Eleri Davies³ and Wen G Jiang¹.
¹Cardiff University School of Medicine, Cardiff, Wales, United Kingdom; ²Puma Biotechnology, Inc., Los Angeles, CA and ³Breast Cancer Centre, University Llandough Hospital, Cardiff, Wales, United Kingdom.

Body: Background. Neratinib is an orally available tyrosine kinase inhibitor that irreversibly binds and inhibits EGFR, HER2 and HER4 receptor tyrosine kinases. Neratinib has been shown to have clinical activity in HER2-amplified or overexpressed breast cancers and those with HER2 mutations. However, there are indications that it may also work on other subtypes that are not strongly positive for the receptors. The present study first screened the effects of neratinib on a range of kinase targets and identified that the Wnt signalling components are key factors that allow neratinib to interact and targets. These targets were also validated in a cohort of human breast cancer.

Methods. Human breast cancer cohorts (n=124) were tested for the transcript expression of HER family including EGFR, HER2, HER3 and HER4 and a number of Wnt family members and the Wnt signalling regulators, ie. GSK3, Axin-1, Axin-2 and β-catenin. The expression patterns were analysed against the clinicopathological and survival status of the patients. Neratinib was tested on a panel of breast cancer cell lines including triple negative cells for the effects on cytotoxicity, cell growth, matrix adhesiveness and cellular migration. Signalling kinase pathways were screened using an antibody based kinase array. The effect of neratinib on multiple protein kinases was tested on the cell models, together with other kinase inhibitors.

Results. Neratinib had an inhibitory effect on the cellular migration and cell-matrix adhesiveness of breast cancers at non-toxic concentrations, an effect more profound with MCF-7 and T47D cell lines than with BT20 and MDA MB-231 which are negative for the ER/EGFR/HER2 receptors. Of the multiple kinase inhibitors tested, neratinib was found to exert inhibition on cell function in synergy with the Wnt/β-catenin inhibitor (FK535) and GSK3 inhibitor (TWS119). The expression of the HER and Wnt family members, Wnt Inhibitory Factor-1 and Wnt regulators varied in mammary and breast cancer tissues and in their correlation with the clinicopathological factors. Of the aberrantly expressed receptors, Wnts and Wnt regulators, HER-2 and 4 were found to significantly correlate with Wnt10b (p<0.05), EGFR/HER1 was found significantly correlated with GSK3 (p<0.05) and HER-3 with Wnt5a (p<0.03). Furthermore, we identified that the integrated expression pattern of five of these factors, namely EGFR, HER2, HER4, Wnt5 and Wnt Inhibitory Factor-1 formed an expression signature that were significantly linked to the overall survival (survival time 148±3.7 vs 113.7 ±7.5 months for favourable and non-favourable pattern, respectively, p=0.002) and disease free survival (p=0.004) of the patients (median follow-up 120 months)

Conclusion. Neratinib, at non-toxic concentration levels, is a profound inhibitor of the migration and matrix adhesion of breast cancer cells, cell functions linked to the aggressiveness and metastasis of breast cancer cells. Its synergistic effects with the Wnt and GSK3 inhibitor, together with the prognostic value of the HER family/Wnt, indicate that the Wnt pathway together with the HER family forms a new molecular indicator and target when considering neratinib in the treatment patients with breast cancer.
Title: Temozolomide as a targeted therapy strategy for triple negative breast cancer

Elizabeth N Kornaga¹, Kathy Gratton², Qiao Shi², Ailian Yang², Nancy A Nixon¹,², Gloria Roldan Urgoiti¹,² and Don G Morris¹,².
¹Alberta Health Services, Calgary, AB, Canada and ²University of Calgary, Calgary, AB, Canada.

Body: BACKGROUND:
Approximately 15% of newly diagnosed breast cancers are classified as triple negative (TNBC). TNBCs are considered more aggressive and have a worse prognosis as no targeted therapies are currently available. These tumors are routinely treated with chemotherapy agents with only modest proven efficacy.

Temozolomide (TMZ) is an oral chemotherapy agent commonly used for the treatment of brain tumors and melanoma. TMZ is an alkylating agent, and its therapeutic benefit depends on its ability to alkylate/methylate DNA, most commonly at the N-7 or O-6 positions of guanine residues. This process leads to DNA damage and subsequently triggers cell death. Cells that express the enzyme O⁶-Methylguanine-DNA Methyltransferase (MGMT) are able to repair damage caused by TMZ. Tumors that lack expression of MGMT, owing to methylation of the gene promoter, demonstrate a better response to TMZ treatment as a result of synthetic lethality.

It was first reported in 2012 that TNBCs were more likely to be MGMT methylated, which was confirmed by another group that reported up to 64% of wild-type BRCA1 TNBC exhibited MGMT gene methylation. In 2013 it was found that basal-like breast cancers were more likely to be MGMT methylated and linked to larger tumor size. Together these findings suggest that a sub-population of TNBCs lack MGMT expression, due to promoter methylation.

Currently, TMZ is not a treatment option for breast cancers given the modest efficacy of TMZ noted in breast cancer clinical trials; however, most of these trials have focused on using this agent to either treat or prevent brain metastases, due to TMZ's ability to cross the blood-brain barrier. Importantly, none of these trials investigated MGMT expression or specifically TNBC populations.

We hypothesize that TMZ may be a viable and efficacious treatment option for TNBCs that lack MGMT expression, due to promoter methylation.

METHODS:
We analyzed 12 archival specimens and 4 TNBC cell lines (HTB132, HTB26, HTB126 and HCC1806) for MGMT expression using a qRT-PCR clinical assay available from Calgary Laboratory Services. Additionally, we also looked at MGMT protein expression in the cell lines using Western Blot analysis to confirm the qRT-PCR results. Finally, we performed an in vitro assay with TNBC cell lines to determine cytotoxicity of TMZ.

RESULTS:
Analysis of the archival specimens found that 33% of samples analyzed had MGMT promoter methylation by qRT-PCR. Additionally, we found that HTB26 and HTB126 cell lines showed MGMT promoter methylation by qRT-PCR analysis. Western Blot analysis confirmed lack of MGMT expression in these two cell lines, and also identified another cell line (HCC1806) lacking MGMT protein that was classified as unmethylated by the qRT-PCR clinical assay. Moreover, our in vitro assay found that two cell lines (HTB26 and HCC1806) showed a noticeable response to treatment with TMZ. Interestingly, HTB126 did not show response to TMZ, suggesting that there may be another putative resistance pathway.

CONCLUSIONS:
Preliminary findings suggest that TMZ may be a viable targeted treatment option for TNBCs. Currently, we are investigating drug response using in vivo mouse models, as well as investigating synergistic combination therapy options.
**Title:** ERRβ copy number and expression in triple negative breast cancer

Aileen I Fernandez¹, Garrett Graham¹, Balázs Győrffy², Luciane Cavalli¹, Akanksha Mahajan¹ and Rebecca B Riggins¹.
¹Georgetown University, Washington, DC and ²MTA TTK Lendület Cancer Biomarker Research Group, Semmelweis University, Budapest, Hungary.

**Body:**

**Introduction:** Triple negative breast cancer (TNBC) is a highly aggressive form of breast cancer prevalent in African-American (AA) women defined as estrogen receptor- (ER), progesterone receptor- (PR), and human epidermal growth factor receptor 2- (HER2) negative. Because ER- and HER2-targeted therapies are ineffective in TNBC, systemic chemotherapy is the standard of care and there is a tremendous need for new effective therapies with less toxicity. Steroid hormone receptors are highly druggable targets, and orphan nuclear receptors, members of the nuclear receptor superfamily, are emerging as targets for cancer therapy. In fact, we have previously shown that treatment of TNBC cells with a small molecule agonist ligand (DY131) for estrogen related receptor beta (ERRβ), has growth inhibitory and anti-mitotic activity. We have also shown that increased mRNA expression of ERRβ, correlates with better recurrence- and distant metastasis-free survival in TNBC/basal-like breast cancer. The goal of our current work is to comprehensively characterize ERRβ copy number and mRNA status in TNBC and determine its association with patients’ prognosis.

**Methods:** ESRRB copy number was determined in 106 primary breast tumors (TNBC n=56, nonTNBC n=50) by array-CGH, using the Agilent SurePrint G3 Human CGH platform. ESRRB mRNA data and its association with overall survival was determined in systemically untreated patients from METABRIC using Illumina gene expression array data (probe ID ILMN_1707398).

**Results:**

**Copy number alterations (CNAs).** Copy number losses at the ESRRB locus (14q24.3) were observed in 10/56 (17.8%) of TNBC vs. 10/50 (20%) of nonTNBC, while copy number gains were detected in 43/56 (76.8%) of TNBC vs. 29/50 (58%) of nonTNBC (c² *p=0.036). Interestingly, in both TNBC and non-TNBC, ESRRB loss was seen with markedly higher frequency in AA patients when compared to Caucasian (CA) patients (c² *p=0.012 for TNBC, p=0.052 for non-TNBC).

**mRNA expression.** Among patients not treated with systemic chemotheraphy in the METABRIC dataset, low ESRRB mRNA was significantly associated with shorter overall survival in TNBC, but not ER+ or HER2+ patients (TNBC hazard ratio 0.24, 95% confidence interval 0.07-0.85, *p=0.016). Low ESRRB also correlated with reduced overall survival in TP53 mutant (but not wild type) tumors (hazard ratio 0.28, 95% confidence interval 0.1-0.82, *p=0.013).

**Conclusions:** ESRRB presents significantly high levels of copy number losses in TNBC when compared to non-TNBC tumors. In breast tumors from AA women, both the TNBC and non-TNBC subtypes are significantly more likely to have reduced ESRRB copy number vs. CA women. Low ESRRB mRNA expression predicts for poor overall survival in TNBC and TP53 mutant tumors. These data advocate that ERRβ expression has prognostic value in breast cancer, particularly TNBC. Future goals include immunohistochemistry staining, and analysis, of a tissue microarray consisting of 150 primary breast tumors (50 TNBC, 50 ER+, 50 HER2+); as well as ERRβ overexpression and knock-down studies in TNBC cell lines to define the role it plays in TNBC.
Title: Modulation of FASN under obese conditions

Tommy Pham1, Ali Oberman1, Irene Kim1, Gabby Lee1, Duan Quach1, Gloria Galván1, Christopher Jolly1, David Cavazos2, Andrew Brenner2 and Linda deGraffenried1. 1The University of Texas at Austin, Austin, TX and 2The UT Health Science Center at San Antonio, San Antonio, TX.

Body: Introduction: Obesity is known to be associated with a worse breast cancer prognosis, in part through altering metabolism in cells of the tumor microenvironment. In particular, changes in metabolism associated with fatty acid utilization have been noted in not only breast cancer, but also several other cancer types. This includes changes to both expression and activity of the Fatty Acid Synthase enzyme (FASN), which is responsible for production of long chain fatty acids, including palmitate. These changes in long chain fatty acid production can modulate tumor behavior through modulation of energy utilization such as beta-oxidation, as well as plasma membrane modulation with phospholipids. Our previous studies have demonstrated that exposure to obese conditions induces significant changes in breast cancer cell proliferation. Additionally, obesity modulates activity of other cells within the tumor microenvironment, including adipocytes, which might influence the cancer cell itself. We hypothesize one particular mechanism that supports these changes is obesity-induced upregulation of FASN and that FASN may be a viable target to limit obesity-induced progression.

Methods and Results: FASN has been shown to promote cancer cell proliferation through generating fatty acid precursors required for cell proliferation, altering membrane fluidity, and activating oncogenic signaling pathways. To determine if modulation of FASN is an important mechanism by which obesity promotes disease progression, MCF-7 breast cancer cells and human pre-adipocyte cells (ASC) were exposed to 2% sera from obese postmenopausal women and 2% sera from non-obese (control) women. Preliminary quantitative PCR results demonstrated that exposure to the obese sera resulted in increased expression of FASN in both the cancer cells as well as the ASC. Current studies are on-going to determine if 1) FASN up-regulation results in increased long-chain and free fatty acid production in both the cancer and adipocyte cells, 2) whether changes in long chain and free fatty acid production results in altered metabolism and plasma membrane status and 3) whether targeting FASN with a new generation of FASN inhibitors currently being investigated in the clinic can modulate obesity-induced disease progression.

Conclusions: Our findings indicate that obesity promotes upregulation of FASN in several cells within the tumor microenvironment, including adipocytes and the cancer cell itself. We have also found that using a FASN inhibitor is effective in limiting cancer cell viability and proliferation. Our on-going studies will confirm if this is an important mechanism by which obesity promotes disease progression. Since FASN inhibitors are currently being investigated in the clinic, the results of these studies will provide a better understanding of how obesity alters the biology of the disease, and may identify a novel target for improving patient outcomes.
Body: Background: Invasive lobular carcinomas (ILC) account for around 15% of all oestrogen receptor (ER) positive invasive breast cancers. The EndoPredict assay (EPclin) is a multigene classifier to predict the likelihood of distant recurrence in ER-positive, HER2-negative breast cancer patients treated with adjuvant endocrine therapy and has been validated in several retrospective translational studies. However, these validation studies did not include an analysis of the histological subtypes. Here, we investigate the role of EPclin for the prediction of distant recurrence in women with ILC and compare the prognostication to those with invasive ductal carcinoma (IDC) in TransATAC.

Methods: Data on EPclin and histological type of tumour were available for 928 postmenopausal women with ER-positive, HER2-negative disease treated with 5 years of tamoxifen or anastrozole. The primary endpoint was distant recurrence and the primary objective was to assess the prognostic value of EPclin for the prediction of distant recurrence in women with invasive lobular carcinoma. Kaplan–Meier and Cox regression analyses were used to determine distant recurrence risk for 0-10 years of follow-up. Likelihood ratio tests were used to assess the prognostic information provided by EPclin. Hazard Ratios (HR) are for a change in 1 Standard Deviation.

Results: 141 (15.2%) had ILC, 710 (76.5%) IDC, and the remaining 77 (8.3%) were of different histological type. EPclin provided highly significant prognostic value for distant recurrence in women with ILC (HR=3.33 (2.33-4.77), P<0.001; LR-χ²=38.4). For those with IDC, EPclin was highly prognostic for distant recurrence over 10 years of follow-up (HR=2.41 (2.04-2.84), P<0.001; LR-χ²=95.5). EPclin was more prognostic in IDC than ILC, and a significant interaction between EPclin and tumour type (ILC/IDC) was observed (P-interaction=0.038). 89 (63.1%) women with ILC were categorised into the low EPclin risk group and 52 (36.9%) into the high risk group. A highly significant separation between EPclin low and high risk groups was observed for ILC (10-year distant recurrence risk low: 6.2% (2.6-14.2) vs. high: 36.6% (24.2-52.1); HR=7.36 (2.71-20.01)). For women with IDC, 406 (57.2%) were categorised into the low risk group by EPclin and 304 (42.8%) were deemed high risk, with significant separation between risk groups (10-year distant recurrence risk low: 6.2% (4.1-9.3) vs. high: 28.5% (23.5-34.3); HR=5.59 (3.48-8.98)). We did not observe any differential efficacy of treatment between histological subtype and EPclin risk group.

Conclusions: This is the first analysis to focus on the role of EPclin for the prognostic assessment of women with ILC. Although numbers of women with ILC in TransATAC were small, EPclin provided highly significant prognostic information and risk stratification for this subgroup of women. 10-year distant recurrence risk in the EPclin low risk groups were similar between ILC and IDC, suggesting that chemotherapy is not indicated, irrespective of tumour type. Our results show that EPclin is informative in women with ILC.
Title: Validation of the online prediction tool PREDICT v. 2.0: A large population-based study in the Netherlands

Marissa C van Maaren1,2, Corneliene D van Steekbeek1,2, Paul DP Pharoah3, Annemieke Witteveen2, Gabe S Sonke4, Luc JA Strobbe5, Philip MP Poortmans6 and Sabine Siesling1,2. 1Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, Netherlands; 2MIRA Institute for Biomedical Technology and Technical Medicine, University of Twente, Enschede, Netherlands; 3University of Cambridge, Cambridge, United Kingdom; 4Netherlands Cancer Institute, Amsterdam, Netherlands; 5Canisius Wilhelmina Hospital, Nijmegen, Netherlands and 6Institut Curie, Paris, France.

Body: Background
This study aimed to validate the online prediction tool PREDICT version 2.0 on a large population-based cohort in the Netherlands. Separate analyses were performed to study its validity in specific prognostic subgroups.

Methods
All women diagnosed with non-metastasised primary invasive breast cancer in 2005, who received surgery as part of their treatment, were selected from the nationwide Netherlands Cancer Registry (NCR). The predicted 5-year and 10-year overall survival (OS) from PREDICT were compared with the observed OS from the NCR, for the overall cohort (separated by ER- and ER+ patients) and for predefined subgroups based on age, T stage, N stage, presence of micrometastases, grade, HER2 status, type of surgery, use and type of adjuvant systemic therapy and generation chemotherapy. Our a priori assumption was that PREDICT accurately predicted OS whenever the differences between predicted and observed outcomes were within a range of 5%, since a difference of 5% or more was considered as clinically relevant. The discriminatory accuracy and goodness-of-fit were determined using the area under the receiver operating characteristic curve (AUC) and the Chi2-test, respectively.

Results
Our study population consisted of 8,834 patients. Discriminatory accuracy for 5-year OS was good with an AUC of 0.80. For ER- and ER+ patients, the AUCs were 0.75 and 0.79, respectively. Predicted 5-year OS differed from observed by -1.4% (p=0.14) in the entire cohort, by -4.9% (p=0.02) in ER- patients and -0.7% (p=0.53) in ER+ patients. In all predefined subgroups no statistically significant differences between predicted and observed events were observed.

Discriminatory accuracy for 10-year OS was good with an AUC of 0.78 for the overall cohort, 0.76 for ER- patients and 0.78 for ER+ patients. Predicted 10-year OS differed from observed by -1.0% (p=0.27) in the entire cohort, by -5.3 (p=0.01) in ER- patients and -0.1% (p=0.92) in ER+ patients. Ten-year OS was overestimated in patients ≥75 years (6.3%, p=0.00), and underestimated in T3 stage (-13.%, p=0.00) and in patients treated with both endocrine therapy and chemotherapy (-6.6%, p=0.02).

Conclusion
PREDICT accurately predicts 5-year OS in the entire Dutch validation population, and in all predefined subgroups. However, 10-year OS was overestimated for patients ≥75 years, and underestimated for T3 stage and patients treated with both endocrine therapy and chemotherapy. Given PREDICT’s intentions to guide treatment decision-making, PREDICT may serve as a reliable prediction tool for the Dutch breast cancer population, but especially in patients ≥75 years, 10-year OS predictions should be interpreted with care.
Title: Validation of a nomogram for predicting recurrence among women with ductal carcinoma in situ and breast conserving surgery in an integrated health care system

Michael C Leo¹, Melanie Francisco¹, Charisma Jenkins¹ and Sheila Weinmann¹. ¹Kaiser Permanente Center for Health Research, Portland, OR.

Body: Current management of ductal carcinoma in situ (DCIS) most often entails removing the lesion by breast-conserving surgery. Quantifying the risk of a patient's ipsilateral breast event (IBE) recurrence, either invasive cancer or DCIS, after breast conserving surgery remains a clinical concern. The aim of this study was to validate the Memorial Sloan-Kettering Cancer Center (MSKCC) nomogram to predict IBE recurrence in patients from our institution.

Patients and Methods
We retrospectively identified 608 patients in the Kaiser Permanente Northwest integrated healthcare system with a diagnosis of DCIS who had undergone local excision from 1990 through 2007. We assessed the performance of the MSKCC nomogram for predicting IBE recurrence using measures of discrimination (how well risk scores separate those with and without the event) and calibration (agreement between predicted and observed risk). We calculated Harrell's C and R² to provide estimates of discrimination. We calculated the calibration slope by performing a Cox regression using the prognostic index (PI; predicted log relative hazard based on the original Cox coefficients), with a slope not significantly different from 1 indicating no difference in discrimination from the development sample. We also examined discrimination by comparing the KM curves of 4 risk groups and in a Cox regression as a predictor, which were created using Cox's method (4 groups using the 16th, 50th, & 84th percentiles), as no risk groups were defined in the MSKCC development study. We examined whether there was model misfit by testing each predictor in a Cox regression with an offset of the PI. Finally, we assessed calibration by plotting the observed rates and associated 95% CIs against the predicted probabilities for groups based on 4 risk groups and octiles.

Results
The median follow-up time for the KPNW cohort was 125 months. The 10-year IBE recurrence rate was 9.5%, 95% CI [7.0%, 13.0%). Harrell's C was .70, which is comparable to what has been found in other validation studies. The PI accounted for 22% of variation in time (R² = .22, 95% CI [.08, .38]). The test of the calibration slope provided no support that discrimination in this sample differs from the development study (LR χ²(1)=0.21, p=.65). An examination of the Kaplan-Meier curves among the risk groups showed good separation of the high risk group compared to the others, but little separation between the lowest two risk groups. None of the predictors demonstrated evidence for differential weighting from the MSKCC coefficients (p values ranged from .08 to .97). Calibration was good for the lowest, low, and moderate risk groups, but there was underprediction in the high risk group. When examining calibration using octiles, we found a similar pattern to that of other validation studies in which the highest octile had the furthest departure from perfect agreement.

Conclusion
The MSKCC nomogram for predicting IBE recurrence in patients with DCIS who were treated with local excision have some utility, and our results are consistent with other validation efforts. However, there is much potential to further increase the prediction of recurrence beyond what is possible with the MSKCC nomogram.
Title: Prognostic value of OncoMasTR: A novel multigene signature based on master transcriptional regulators

Stephen Barron¹, Karin Jirström², Helena Jernström², Christian Ingvar², Bruce Moran¹,³, Chan-Ju Angel Wang¹, Tony Loughman¹, Bozena Fender¹, Peter Dynoodt¹, Cesar Lopez-Ruiz¹, Niamh Russell³ and William M Gallagher¹,³.¹ OncoMark Ltd, Dublin, Ireland; ² Lund University and Skåne University Hospital, Lund, Sweden and ³ School of Biomolecular and Biomedical Science, Conway Institute, University College Dublin, Dublin, Ireland.

Body: Background
Multigene prognostic signatures (MGPS) enable identification of candidate patients for treatment de-escalation in early stage breast cancer (BC). Here we present OncoMasTR, a MGPS for classifying the risk of distant metastasis (DM) in ER-positive, HER2-negative BC patients with up to 3 involved lymph nodes (LNs). OncoMasTR was discovered via a novel transcriptional network analysis methodology that identified genes that regulate previously identified prognostic biomarkers. These upstream genes, termed master transcriptional regulators (MTRs), were shown to provide improved prognostic performance compared with downstream genes. OncoMasTR has been mechanistically verified by RT-qPCR, immunohistochemistry and chromatin immunoprecipitation. OncoMasTR has been further trained to include clinicopathological information (CPI) to maximise its prognostic performance.

Methods
Two independent sample sets: 225 patients from Malmö University Hospital and 100 patients from Skåne University Hospital were used for training, cross-validation and refinement of OncoMasTR. RNA extracted from 225 archived tissues was analysed by RT-qPCR to measure the expression levels of the MTRs. Statistical models of all possible combinations of MTRs were trained and cross-validated (1,000 times x 2-fold) using the first set of 225 samples. Statistical models with the best cross-validated performance were further evaluated on RT-qPCR data from the second independent set of 100 samples. Robustness of the data was verified by assessing the reproducibility of OncoMasTR across 6 days, using 6 unique kit lots, conducted by 4 operators on 3 RT-qPCR instruments.

Results
In the first training set of 225 patients, OncoMasTR classified up to 72% of LN0 patients and 58% of LN0-3 patients as low risk, with ≤5.0% DM within each group. When incorporating CPI, its prognostic performance further improved to a c (concordance) index > 0.8. Results showed that the OncoMasTR molecular score and CPI add statistically significant prognostic value to each other. In the independent verification set, all patients with DM were correctly classified as high risk (p<0.01). In relation to reproducibility, the OncoMasTR test displayed robust performance; the molecular score coefficient of variation was 2.6% across days, kit lots, operators and instruments. Individual MTR assays demonstrated linearity over >2000-fold RNA input range and PCR efficiencies ranged from 92% to 101%.

Conclusions
OncoMasTR development and verification results show analytical robustness and clinically accurate risk stratification. Furthermore, OncoMasTR's binary classification of risk avoids an ambiguous intermediate risk classification and has potential to provide clinicians with useful, actionable information to support treatment decisions. The OncoMasTR test is now ready for large-scale clinical validation.
Margins in breast conserving surgery after neoadjuvant therapy

Jungeun Choi¹, Mehra Golshan¹, Jiani Hu², Haley Cecile Gagnon², Stephen Densantis², Bill Barry² and Tari King¹. ¹Brigham and Women’s Hospital/Dana Farber Cancer Institute, Boston, MA and ²Dana Farber Cancer Institute, Boston, MA.

Background: The margin consensus guideline for patients undergoing primary breast conserving surgery (BCS) and whole breast radiotherapy defines a negative margin as no tumor on ink and concludes that wider margins do not improve local recurrence (LR) rates. There are few studies examining BCS margin width after neoadjuvant chemotherapy (NAC). We sought to determine the impact of margin width on LR and survival rates after NAC and BCS. Methods: Institutional database were reviewed to identify patients with stage I-III breast cancer treated with NAC and BCS from 2002-2014. Patients with inflammatory breast cancer were excluded. Chart review was performed to collect detailed patient and treatment factors. Margins widths were collected as reported and grouped as: positive (ink on tumor), close (<2mm), and negative (>2mm), for the purposes of this analysis. Cox regression was used to determine the relationship between margin width and local recurrence, disease free survival (DFS) and overall survival (OS). Result: 395 patients underwent NAC followed by BCS during the study period. The result was same as below.

*pCR was defined as no invasive or in situ disease in breast and no tumor in axillary node

Median patient age was 51 yrs (range 22-79); median tumor size at presentation was 3.0 cm (range 0.6-11.0) and 188 (47.6%) patients (pts) presented with clinically node positive disease. Breast cancer subtypes included 148 (37.5%) pts with HR-/Her2-, 48 (12.2%) pts with HR-/Her2+, 124 (31.4%) pts with HR+/Her2- and 72 (18.2%) pts with HR+/Her2+, disease. Among all patients
the pCR rate, defined as no invasive or in situ disease, in the breast was 27.3% (108/395) and the pCR rate in the breast and axillary nodes was 24.6% (97/395). Final margin status included 8 (2.0%) pts with positive margins, 99 (25.1%) with close <2mm and 180 (45.6%) with negative (>2mm) margins. Among the patients with "positive margins"; all were noted to be posterior or anterior and the surgeon noted that reexcision was not possible. At a median follow-up of 53.0 months the LR rate was 2.8% and DFS was 87.4%. On cox regression, HR positive subtype (p=0.048), pCR (p=0.035), and pathologic negative node (p<0.001) were correlated with favorable DFS and pathologic negative node (p<0.001) was correlated with favorable OS. There was no difference in LR rate, DFS or OS between 'close/positive margin' and '>2mm margin groups. **Conclusion:** In this cohort of patients treated with NAC followed by BCS, LR rates were very low and there was no difference in DFS between patients with margins < 2mm or > 2mm. Further studies are needed to confirm the effect of margin width in the NAC setting.
**Title:** Prognostic associations of plasma hepcidin in early breast cancer (BC)

Katarzyna J Jerzak1, Ana Elisa Lohmann2, Marguerite Ennis2, Elizabeta Nemeth3, Tomas Ganz3 and Pamela J Goodwin2.
1Sunnybrook Odette Cancer Centre, Toronto, ON, Canada; 2Mount Sinai Hospital, Toronto, ON, Canada and 3University of California, Los Angeles, Los Angeles, CA.

**Body:** Background: Intra-tumor RNA expression of hepcidin has been linked to adverse metastasis-free survival in women with early BC, but the prognostic implications of this inflammatory marker and iron-regulating peptide are unknown.

**Methods:** Using an ELISA assay, we measured plasma hepcidin in the banked blood of 518 women who were recruited from 1989-1996 for a prospective cohort study regarding diet and lifestyle factors in BC. Blood had been obtained 4-12 weeks post-operatively and prior to treatment with radiation, chemotherapy or hormonal therapy. Women ages 18 to 75 with T1-3, N0-1, M0 BC who underwent surgery and axillary dissection were included; those with metabolic disorders were excluded. Tumor size, grade and ER/PR expression were abstracted from pathology reports; HER2 status was unknown. Median follow-up was 12.1 years (range, 0.2 to 17 years).

Univariable Cox regression models were used to determine the association between hepcidin and i) time to distant BC recurrence (primary outcome), and ii) time to death due to any cause. Multivariable Cox proportional hazards models were adjusted for age (continuous), T stage (T2, T3, Tx vs T1), tumor grade (3 vs 2 or 1), N stage (node positive vs negative), ER/PR expression (both ER and PR negative vs either positive) a-priori. Associations between hepcidin and CRP, IL6, insulin, cholesterol, glucose, vitamin D, total iron, transferrin, and soluble transferrin receptor; sTfR were explored (Pearson's coefficients).

**Results:** Hepcidin ranged from 4.70-190.70 ng/L (median 16.25; IQR 16.40 ng/L). To ensure normal distribution, a transformed \[-1/sqrt (x)\] hepcidin variable was used for prognostic analyses. Average age was 50.3±9.7 years. 16% were obese [body mass index (BMI) >30kg/m^2], 30% (n=156) were node positive, 35% (n=181) had grade 3 tumors and 71% (n=370) had ER and/or PR positive tumors. 77% underwent a lumpectomy, 73% (n=380) received adjuvant radiotherapy and 39% (n=203) received adjuvant chemotherapy.

Plasma hepcidin was not univariably associated with either time to distant BC recurrence (HR for 75th percentile versus 25th 1.20; 95%CI 0.79-1.32) or time to death due to any cause (HR 1.23; 95%CI 0.95-1.59) in the overall cohort; multivariable results were similar. In pre-planned analyses, the prognostic association of hepcidin differed by BMI (≤30 vs >30 kg/m^2; interaction p-values <0.05): among obese women, higher hepcidin was significantly associated with a shorter time to distant BC recurrence in both univariable (HR 1.81; 95%CI 1.06–3.10) and multivariable (HR 1.84; 95%CI 1.04–3.25) models. Higher hepcidin was associated with shorter time to death due to any cause in a univariable model (HR 1.91; 95%CI 1.13–3.22) but not in a multivariable analysis. There was a moderate association between hepcidin and total iron (r=0.35), transferrin (r=0.43) and sTfR (r=-0.39); associations with IL6, CRP and metabolic factors were very weak (r<0.2).

**Conclusion:** Higher plasma hepcidin was independently associated with a shorter time to distant BC recurrence in obese women but not in the overall cohort. Further investigation of hepcidin and mechanisms linking it to adverse BC outcomes is warranted.

**Title:** Impact of gene-expression profiling in patients with early breast cancer when applied outside the guideline directed indication area

Kay Schreuder¹², Anne Kuijer³, Emiel JTh Rutgers⁴, Carolien H Smorenburg⁴, Thijs Van Dalen⁵ and Sabine Siesling¹².

¹Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, Netherlands; ²University of Twente, Enschede, Netherlands; ³Diakonessenhuis Utrecht, Utrecht and ⁴Antoni van Leeuwenhoek Hospital – Netherlands Cancer Institute, Amsterdam, Netherlands.

**Body: Purpose**

In Dutch guidelines gene expression profiles (GEP) are indicated in estrogen receptor positive early breast cancer patients in whom benefit of chemotherapy (CT) is controversial based on traditional prognostic factors alone. Aim of the current study is to assess the use and impact of GEP on administration of adjuvant CT in breast cancer patients who have according to national guidelines a clear indication to either use or withhold adjuvant chemotherapy (clinical high or low risk).

**Methods**

Clinical low- and high risk patients, according to Dutch breast cancer guidelines, diagnosed between 2011-2014 were selected from the Netherlands Cancer Registry (NCR). Influence of GEP use and GEP test result on CT administration was assessed with logistic regression.

**Results**

Overall, 26,425 patients were identified; 4.8% of patients with clinical low-risk (444/ 9,354), 7.5% of the patients with a clinical high-risk (1,281/ 17,071) received a GEP. GEP use was associated with a significantly increased odds of CT administration in clinical low-risk patients (OR=2.12 95%CI: 1.44-3.11). In clinical high-risk patients GEP use was associated with a decreased frequency of CT administration (OR=0.55, 95%CI: 0.48-0.63). Adherence to the GEP result was higher in clinical high-risk patients with a discordant GEP result as compared to clinical low-risk patients with a discordant GEP result: 71.7% vs. 52.2%, respectively.

**Conclusion**

GEP is frequently used outside the indicated area and significantly influenced the administration of adjuvant CT, although adherence to the test-result was limited.
Title: Development and validation of a broad-based second generation multi marker “Morphometric IHC” test for optimal treatment planning of stage 1 and 2 breast cancer patients in low resource settings

Somashekhar SP\textsuperscript{1}, Manjiri M Bakre\textsuperscript{2}, Charusheila Ramkumar\textsuperscript{2}, Chetana Basavaraj\textsuperscript{2}, Arunkumar Attuluri\textsuperscript{2}, Lekshmi Madhav\textsuperscript{2}, Chandra Prakash\textsuperscript{2}, Nirupama Naidu\textsuperscript{2} and Sukriti Malpani\textsuperscript{2}. \textsuperscript{1}Manipal Comprehensive Cancer Center, Manipal Hospital, Bangalore, Karnataka, India and \textsuperscript{2}OncoStem Diagnostics Pvt Ltd., Bangalore, Karnataka, India.

Body: Aims:
Assessment of 'risk of recurrence' in ER+ breast cancer patients based on clinical parameters and existing hormone receptor signaling pathway and/or proliferation based biomarkers is insufficient, leading to treatment of majority of patients with chemotherapy. First generation risk identification tests like OncotypeDx and Mammaprint are not impactful in India and SE Asia as are largely prognostic with limited chemotherapy-predictivity and are prohibitively expensive. A cost-effective 'predictive' test which will accurately estimate the 'risk of recurrence' for a 'broader' (node - & +) set of breast cancer patients in low resource settings is urgently required.

Materials and Methods:
Using a retrospective training cohort of 300 node– and node+ patients, we developed 'CanAssist-Breast'- a Morphometric Immunohistochemistry based test comprising 5 biomarkers plus three clinical parameters (Tumor size, grade and node status) to arrive at 'CanAssist-Breast Score'. The risk stratification model was developed using cutting edge support vector based machine learning technology. CanAssist-Breast Score stratifies patients into an all actionable 'low or high' risk for recurrence, with no intermediate zone. CanAssist-Breast biomarkers include cancer stem cell markers, Cadherins, and ATP transporter proteins - all critical players in the various steps of chemotherapy resistance leading to metastasis.

Results:
We validated CanAssist-Breast in accordance with EGAPP recommendations which require that prognostic tests be validated both analytically and clinically prior to being utilized in patients. Analytical validation experiments were performed to assess 'variation' in the outcome prediction due to critical IHC variables. We tested inter-pathologists, sample, operator and laboratory site variation and found high concordance in the outcome predictions across all variables, confirming the robustness and reproducibility of the test.

Extended clinical validation on 1000+ pre and post-menopausal cases shows NPV of 95%. The majority of patients in 'low risk' had Stage 2, Grade 2/3 disease over Stage 1, Grade 1 disease, demonstrating that CanAssist-Breast reclassifies patients who would be considered high risk clinically.

In a head-to-head pilot study of 100 patients with Oncotype Dx, CanAssist-Breast test had about 80% concordance with Oncotype in the 'low risk' category. Importantly, CanAssist-Breast correctly stratified few recurred cases as 'high risk' which were called 'low risk' by Oncotype Dx and thus were not treated with chemotherapy.

Conclusion:
In conclusion, we have developed a robust, accurate and low-cost prognostic test to predict risk of recurrence and enable optimal treatment planning in patients with early stage Breast Cancer.

Title: The prognostic impact of retinoic acid-induced 2 (RAI2) expression in ERα-positive breast cancer patients

Sayaka Nishikawa1, Naoto Kondo1, Yumi Endo1, Yukari Hato1, Tomoka Hisada1, Mayumi Nishimoto1, Yu Dong1, Katsuhiro Okuda2, Hiroyuki Kato3, Satoru Takahashi3, Ryoichi Nakanishi2 and Tatsuya Toyama1. 1Nagoya City University Graduate School of Medical Sciences, Nagoya, Aichi, Japan; 2Immunology and Surgery, Nagoya City University Graduate School of Medical Sciences, Nagoya, Aichi, Japan and 3Nagoya City University Graduate School of Medical Sciences, Nagoya, Aichi, Japan.

Body: Background: Breast cancer cells disseminate to the bone marrow and form bone metastases in a large majority of late-stage patients. Retinoic Acid-Induced 2 (RAI2) was reported as a putative suppressor of early hematogenous dissemination of tumor cells to the bone marrow in breast cancer, particularly in estrogen receptor α (ERα)-positive breast cancer. Here, we investigated mRNA expression of RAI-2 in breast cancer patients during long-term follow-up.

Materials and methods: A total of 451 invasive breast cancer tissues was available for analysis of RAI2 mRNA using a TaqMan PCR system. We also sought correlations between clinicopathological factors and levels of RAI2 expression in these samples. The expression of markers associated with tumor-initiating capacity, such as SNAI1, SNAI2 and VIM was also analyzed. The median follow-up period was 9.0 years. Survival curves were analyzed using the Kaplan-Meier method. Cox proportional hazards regression analysis was used for univariate and multivariate analyses of prognostic values.

Results: We found positive correlations between low expression of RAI2 mRNA and shorter disease-free survival and overall survival in breast cancer patients (P=0.003, P<0.0001, respectively), which was limited to ERα-positive patients (P=0.04, P=0.0009, respectively), and not seen in ERα-negative patients (P=0.52, P=0.27, respectively). Low RAI2 mRNA levels were positively correlated with high grade, ERα-negativity and PgR negativity. Multivariate analysis indicated that low level RAI2 mRNA expression was an independent factor for survival both overall in breast cancer and in ERα-positive breast cancer patients

Conclusion: We show that low expression of RAI2 is an independent factor predictive of a poor prognosis in ERα-positive breast cancer patients. RAI2 could be a promising candidate biomarker and therapeutic target in ERα-positive breast cancer to prevent dissemination to the bone marrow.
Prognostic relevance of neutrophil-to-lymphocyte ratio (NLR) in young women with breast cancer (BC)

Katarzyna J Jerzak¹, Siqi Zhu¹, Sharon Nofech-Mozes¹, Gregory Pond² and Ellen Warner¹. ¹Sunnybrook Odette Cancer Centre, Toronto, ON, Canada and ²McMaster University, Hamilton, ON, Canada.

Body: Background: Many studies suggest that a high NLR prior to systemic treatment is an adverse prognostic marker for BC but its role in women ≤ age 40 in general, and in those with pregnancy associated BC (PABC) in particular is unknown. We investigated whether the NLR is independently prognostic for recurrence-free survival (RFS) in a prospective database of young BC patients.

Methods: A prospective database of women ≤40 years of age diagnosed with BC from 02-2008 to 01-2015 was analyzed. Data regarding age, stage at diagnosis, pathology, treatment and clinical outcomes were available; the NLR was abstracted from the patients’ medical record retrospectively with all values obtained post-diagnosis and prior to systemic therapy. The Kaplan-Meier method was used to estimate time-to-event outcomes, with a primary outcome of RFS. Insufficient events had occurred to analyze overall survival. Univariable Cox proportional hazards regression models were used to evaluate factors that were potentially prognostic for RFS; a subsequent multivariable Cox proportional hazards model adjusted for nodal involvement, PABC status and tumor size. All tests were two-sided and statistical significance was defined as a p-value ≤0.05.

Results: Of 233 women in the database, 208 had a NLR and outcomes available for analysis. The mean age of patients was 35.1 and 24% (n=66/233) had PABC (BC diagnosed during pregnancy or ≤ 24 months postpartum); the median size of their tumors was 2.8 cm (range 0.1 cm – 19.0 cm) and 48% (n=102/211) were node positive. The majority of women had hormone receptor positive (92%; n=206/223) and HER2 negative 75% (n=160/212) disease, 50% (n=112/223) were treated with breast conserving surgery, 61% (n=142/233) received adjuvant radiotherapy and 83% (n=184/223) received adjuvant chemotherapy. With a median follow-up of 41 months, 16 patients (7%) experienced a local recurrence and 25 (11%) had distant recurrent disease. A higher NLR was prognostic for an adverse RFS in both uni- and multi-variable models (Table). The neutrophil count, individually, was also prognostic for adverse RFS but the lymphocyte count was not. The findings for patients with PABC and non-PABC were similar (interaction tests >0.05).

Conclusions: A higher NLR is prognostic for adverse RFS in our cohort of women ≤40 years of age with BC, including those with PABC. In our study, a higher neutrophil count drives the prognostic effects of NLR, suggesting an inflammatory state. If our results are confirmed in larger data sets, these findings may warrant the investigation of anti-inflammatory agents in the treatment of young women with BC. As BC in this age group has a worse prognosis than BC in older women, the potential benefit of anti-inflammatory agents may be easier to observe in this population.
Title: Serum thymidine kinase activity is an independent prognostic factor for progression-free and overall survival in women with metastatic breast cancer

Anna-Maria Larsson¹,², Sara Jansson¹, Pär-Ola Bendahl¹, Sara Baker¹, Mattias Bergqvist³, Kristina Aaltonen¹ and Lisa Rydén⁴,⁵. ¹Lund University, Lund, Sweden; ²Skåne University Hospital, Lund, Sweden; ³Biovica International AB, Uppsala, Sweden; ⁴Lund University, Lund, Sweden and ⁵Skåne University Hospital, Malmö, Sweden.

Body: Introduction:
Although prognosis and treatment of metastatic breast cancer (MBC) have improved over the last years, there is still an unmet clinical need for more precise prognostic and treatment monitoring tools. Liquid-based markers are preferred since they reflect real-time tumor progression and are not dependent on repeated invasive tissue biopsies. Thymidine kinase 1 (TK1) is an enzyme involved in nucleotide metabolism and has a fundamental role in the DNA synthesis. It can be used as a marker of cell proliferation rate and the TK1 activity has demonstrated correlations to prognosis and usefulness for treatment monitoring in different malignancies. The aim of this study was to determine serum TK1 activity (sTK1) levels measured with the DiviTum assay (Biovica, Sweden), in women with MBC scheduled for 1st line systemic therapy and to evaluate its potential for prediction of outcome and treatment monitoring.

Methods:
142 women with MBC scheduled for 1st line systemic treatment and included in a prospective monitoring trial (CTC-MBC, NCT01322893) were evaluated for sTK1 at baseline (BL) and during treatment at 1, 3 and 6 months. 132 patients had at least one follow-up sample. sTK1 activity levels were measured and correlations to important clinicopathological variables and prognosis (PFS and OS) at BL and during treatment were evaluated.

Results:
The median sTK1 level at BL was 391 u/L (range 10-35520 u/L). When comparing patients with high (above median) versus low (below median) sTK1 levels at BL, high sTK1 levels were found to be associated to worse performance status (p=0.001) and high number of metastatic sites (p=0.03). There was also a statistically significant association between high sTK1 levels and high Ki67 expression in biopsies from metastatic lesions (p=0.038). In univariable analyses high sTK1 levels correlated to worse PFS and OS (HR_{PFS-BL} 2.32, p<0.001; HR_{OS-BL} 2.54, p<0.001) at BL. In multivariable analysis adjusted for clinically used prognostic factors, sTK1 was an independent prognostic factor for PFS and OS (HR_{PFS-BL} 2.4, p<0.001; HR_{OS-BL} 2.0, p=0.01). During treatment, sTK1 was significantly associated with OS from each of the four time points and onwards (BL, 1, 3, 6 months) (HR_{OS-1m} 1.93, p=0.01; HR_{OS-3m} 2.35, p=0.02; HR_{OS-6m} 2.78, p=0.002) in univariable analysis. High sTK1 levels were also associated with impaired PFS (HR_{PFS-1m} 1.48, p=0.06; HR_{PFS-3m} 1.52, p=0.07; HR_{PFS-6m} 2.03, p=0.009) and these associations were significant at BL and 6 months.

Discussion:
sTK1 activity level is an independent prognostic factor for PFS and OS in patients with MBC scheduled for 1st line systemic therapy. During treatment, sTK1 is prognostic for OS evaluated from all time-points up to 6 months. The sTK1 effects observed for PFS are slightly weaker, but still propose potential usefulness for treatment monitoring. Further, sTK1 levels correlate to Ki67 expression in metastatic lesions suggesting that it can be useful as a liquid-based real-time proliferation marker. In conclusion, these results are clinically relevant for prognostication and treatment monitoring in patients with MBC. Future studies of sTK1 are justified to further elucidate in what settings this marker is most useful.
Title: Prediction of distant recurrence in low risk early breast cancer by RT-qPCR based subtyping using MammaTyper®

Mark Laible¹, Kerstin Hartmann¹, Claudia Gürtler¹, Tobias Anzeneder², Stephan Weber³, Thomas Keller³ and Ugur Sahin¹. ¹BioNTech Diagnostics GmbH, Mainz, Germany; ²PATH Biobank, München, Germany and ³ACOMED Statistik, Leipzig, Germany.

Body: Background:
Estrogen receptor (ER/ESR1), progesterone receptor (PR/PGR) and epidermal growth factor receptor 2 (HER2/ERBB2) are routinely assessed by immunohistochemistry (IHC) during workup of breast cancer samples. The routine use of Ki67 (MKI67) IHC assessment in the context of breast cancer subtyping, however, remains controversial, due to poor reproducibility and lack of standardization.

The MammaTyper® test is an in-vitro diagnostic (IVD) test which measures the expression status of the four breast cancer biomarkers ERBB2, ESR1, PGR and MKI67 on the mRNA level via reverse transcription-quantitative PCR (RT-qPCR) and has demonstrated a high degree of reproducibility in the assessment of the four markers.

In this retrospective analysis we assessed the prognostic power of molecular subtyping by MammaTyper® in archived samples from low risk early breast cancers treated with adjuvant endocrine therapy only.

Methods:
ER+/HER2- (according to initial diagnosis) FFPE breast cancer samples from patients treated with adjuvant endocrine therapy only were obtained from 6 different centers. Tumor cellularity was assessed by H&E staining and RNA was extracted from samples with a tumor cell content of ≥20% using a bead-based RNA purification kit (RNXtract®). Total RNA was then used as input for MammaTyper® RT-qPCR. Expression values were classified as positive or negative for each marker based on predefined cutoff values. Tumor subtypes were assigned to each sample based on the combination of binary (pos/neg) single marker expression status according the St Gallen surrogate subtype definition. Distant disease free survival of Luminal A-like samples vs. samples with other subtypes was assessed by Kaplan Meier analysis and Cox regression using SAS version 9.4.

Results:
The final analysis included 319 samples with sufficient tumor cellularity and RNA content for reliable analysis. The rate of distant recurrence in the analyzed set was 8.5%. Median follow up was 7.8 years. The MammaTyper® test called 60% (192) of samples as Luminal A-like (4.7% (9) distant events), 37% (119) as Luminal B-like (HER2 negative) (13.4% (16) distant events), 1.3% (4) as Triple negative (ductal) (25% (1) distant events), 0.6% (2) as “not defined according to St Gallen” (ESR1-/PGR+) (50% (1) distant events) and 0.6% (2) as Luminal B-like (HER2 positive) (no distant events).

When comparing Luminal A-like samples with the samples of the other subtypes in survival analysis, Luminal A-like samples had a significantly better distant disease free survival when assessing samples from patients with pN0 status (278) (p=0.0177, HR=0.344 (95% CI 0.137-0.866), pN1 status (0-3 affected nodes) (314) (p=0.0153, HR=0.374 (95% CI 0.163-0.855) as well as for all samples (p=0.0032, HR=0.319 (95% CI 0.143-0.711).

Conclusion:
Determination of HER2, ER, PR and Ki67 mRNA levels allows molecular subtyping according to the St Gallen surrogate subtype definition. Low risk of distant recurrence could be confirmed for the MammaTyper® Luminal A-like samples suggesting that for this patient group endocrine treatment alone may be sufficient. The high degree of standardization of mRNA measurement may drive the use of the Ki67/MKI67 biomarker in routine breast cancer pathology.
Body: Background: Breast cancer is the most frequent neoplasm in women worldwide and in Mexico, being also the leading cause of cancer death in women. In Mexico, a higher proportion of this tumor subtype (23.1%) has been reported. Patients with TNBC are characterized by aggressive clinical histories and presentation at an early age (in the premenopausal stage), in addition to an increased risk of recurrence and death. However, the main reason for the unfavorable prognosis of these patients lies in the heterogeneity of the disease, as well as the absence of well defined molecular targets that could support the bases of targeted therapy. The heterogeneity in TNBC has been characterized through the knowledge of the biological nature of specific entities within this disease. In 2011 Lehmann et al reported for the first time that TNBC was classified into 6 subgroups. The 6 well-defined subtypes are basal type 1 (BL1), basal type 2 (BL2), immunomodulator (IM), mesenchymal type (M), mesenchymal stem like (MSL), luminal androgen receptor (LAR). In this way the molecular subgroups are sufficiently defined genomically and only little is known clinically of these tumor entities. Therefore, we consider that an important advance for the knowledge of subgroups of TNBC would be the clinico-pathological characterization of these tumors.

Method: To begin with the description of each tumor group, 69 patients were recruited with corroborated diagnosis of TNBC, where all patients had inclusion criteria of 0% positivity to estrogen, progesterone and HER2. To classify our patients we used genomic analysis using the Human Gene 2.0 microarray platform of affymetrix and subsequently 70 samples (a duplicate patient) underwent bioinformatic analysis with the TNBCtype tool developed by Vanderbilt University for access as Web application, whose classification algorithm is based on 3,247 expression profiles of 21 different breast cancer studies from which 6 subgroups of TNBC are identified. We excluded 3 samples because the algorithm indicated that they did not have a TN molecular profile. The remaining 67 samples were analyzed.

Results: The TNBCtype tool classified 67 samples per subtype within the triple-negative type: 10 basal-like (BL1), 11 basal-like (BL2), 16 immunomodulatory, 6 luminal with androgen receptor (LAR), 12 Mesenchymal and 1 mesenchymal stem like. with a significant high of confidence.

Once the patients were classified, overall survival and progression free survival studies were performed per molecular subgroup, as well as univariate and multivariate analyzes with the following variables; Clinical variables: Clinical status, Ki67, CEA (ng / ml), CA 15-3 (U / ml), Neo-adjuvant, Adjuvant, Radiotherapy, Recurrence, Lung metastasis, Liver metastasis and Bone metastasis; Pathologic variables: Histological type, Scarff-Bloom-Richardson grading (SBR), Histological grade, Vascular invasion, EGFR, CK 5/6, ACTIN, RA, P63, CK17 and CK14. Some significant differences were found between groups.

Conclusion: The results obtained so far are the basis for the discrimination of tumor groups with better prognosis versus poor prognosis in triple negative breast cancer.
Title: ER, PR and HER2 biomarkers in UK and Irish clinical breast cancer testing: analysis of results from >168,000 patients

Andrew Dodson¹, Suzanne Parry², Merdol Ibrahim², John Bartlett³, Mitch Dowsett¹ and Keith Miller². ¹Institute for Cancer Research, London, United Kingdom; ²UK NEQAS ICC & ISH, London, United Kingdom and ³ntario Centre for Cancer Research, Toronto, ON, Canada.

Body: AIMS
To describe and analyse >168,000 sets of results from clinical breast biomarker testing carried-out between 2009 and 2016 in the UK and Republic of Ireland, focussing on biological relationships. To present robust confirmatory evidence on known associations and provide new data on previously undescribed or unconfirmed ones.

BACKGROUND
Between Jan-2009 and Jan-2016 the UK National External Quality Assessment Scheme for Immunocytochemistry and In-situ Hybridisation (UK NEQAS ICC&ISH) collected results on clinical breast cancer testing, comprehensively for human epidermal growth factor receptor-2 (HER2) and optionally for estrogen receptor (ER) and progesterone receptor (PR), from most UK and Irish testing centres. Primary objectives were to assess and, where indicated achieve improvements in testing quality. The size and scope of the data-set is unparalleled in the literature and represent a significant reference resource for the breast cancer community.

METHODS
UK NEQAS ICC&ISH created and curated an on-line data-entry system allowing centres to systematically collect their own HER2, ER and PR results from clinical testing; for HER2, immunohistochemical (IHC) and in-situ hybridisation (ISH) data were collected; for ER and PR, IHC results could be entered according to local practise format. Tools and guidance were provided enabling centres to analyse their data for local audit and quality assurance. Clinicopathologic data was also collected, including: patient age at diagnosis, histological tumor type, tumor grade, site/stage (primary, recurrence, metastasis) and sample type (core, excision).

RESULTS
Data are present on 168,793 patients. 173 centres contributed ≥100 entries (96% of total). Median age was 62 years (IQR: 51-72). Tumor type was stated in 42%: 76% were invasive ductal, and 13% invasive lobular carcinoma. Grade was stated in 56%: 15% were Grade 1, 55% Grade 2 and 30% Grade 3. Site/stage was stated in 56%: 92% were primary, 2% recurrent and 6% metastatic. Sample type was stated in 70%: 75% were cores and 25%, excision.

Receptor statuses were available as follows; HER2 (100%): 87% negative, 13% positive; ER (45%): 15% negative, 85% positive; PR (31%): 29% negative, 71% positive.

HER2 data were available as follows; category by IHC: 91%; amplification status by ISH: 15%; HER2 gene/chromosome 17 (CEP17) ratio: 15% (86% of which were IHC 2+); HER2 gene copy number: 7%; CEP17 copy number: 7%.

HER2-positive rate was 24% in ER-negative and 11% in ER-positive cases. HER2-positive status was negatively associated with increasing ER positivity (rho -0.22, P<0.001). 71% of HER2-positive cases were ER-positive and 29% were ER-negative. The HER2 2+ rate was 14% in ER-negative and 21% in ER-positive cases. Considering only IHC 2+ cases, median HER2 copy number was 5.4 in ER-negative and 4.4 in ER-positive disease.

Comprehensive description of significant associations for all parameters will be presented.

CONCLUSION
The unique size and scope of this data-set has allowed confirmation of known associations for HER2, ER and PR with clinicopathologic and biological characteristics in breast cancer to very high confidence levels, and has uncovered previously undescribed relationships in both ER-positive and ER-negative disease.
Title: Vitamin D and breast cancer risk by pathologic subtypes in Spain (MCC-Spain)

Marina Pollán1,2, Virginia Lope1,2, Adela Castelló1,2, Antonio Mena-Bravo6, Pilar Amiano2,4, Nuria Aragonés1,2, Tania Fernández-Villa2,5, Marcela Guevara2,6, Trinidad Dierssen2,7, Guillermo Fernández-Tardón2,8, Gemma Castaño-Vinyals2,9, Rafael Marcos-Grajera2,10, Victor Moreno2,11, Dolores Salas-Trejo12, Marian Díaz-Santos13, Manolos Kogevinas2,9, Beatriz Pérez-Gómez1,2 and Feliciano Priego-Capote3. 1National Center for Epidemiology; Carlos III Institute of Health, Madrid, Spain; 2Consortium for Biomedical Research in Epidemiology & Public Health (CIBERESP), Madrid, Spain; 3University of Córdoba, Córdoba, Spain; 4Public Health Division of Gipuzkoa, BioDonostia Research Institute, Sam Sebastian, Guipuzcoa, Spain; 5University of León, Institute of Biomedicine (IBIOMED), León, Spain; 6Instituto de Salud Pública de Navarra, IdiSNA, Pamplona, Navarra, Spain; 7University of Cantabria—IDIVAL, Santander, Cantabria, Spain; 8IUOPA University of Oviedo, Oviedo, Asturias, Spain; 9ISGlobal, Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain; 10Epidemiology Unit & Girona Cancer Registry, Oncology Coordination Plan, Autonomous Government of Catalonia, Girona, Spain; 11IDIBELL-Catalan Institute of Oncology, L’Hospitalet de Llobregat, Barcelona, Spain and 12Consellería de Sanidad Universal y Salud Pública, Generalitat Valenciana, Fundación para el Fomento de la Investigación Sanitaria y Biomédica de la Comunidad Valenciana (FISABIO), Valencia, Spain.

Body: Introduction: Vitamin D (VD) is involved in proliferation, apoptosis, differentiation, invasion and metastasis. Epidemiological studies show a clear protective effect of VD for colorectal cancer, while the evidence for breast cancer (BC) is less conclusive. Up to 50% of the population worldwide may have insufficient levels of 25-OH-vitamin D (25OHVD), the biomarker reflecting VD status. Our goal was to study the association between serum 25OHVD and BC risk by pathologic subtype in a subsample of BC cases/controls from a large case-control study in Spain.

Methods: MCC-Spain is a population-based multicase-control study on environmental and genetic factors (http://www.mccspain.org/). Here, we selected 558 BC cases who donated blood samples before starting chemotherapy, radiotherapy or hormonotherapy and 558 controls were frequently matched -by region, age and body mass index (BMI). 25OHVD was estimated by chromatograph-mass spectrometer in a sample of 200 µL serum. The effect (OR) of 25OHVD was estimated from mixed logistic regression models (random term = region), adjusted for age, BMI, menopausal status, reproductive factors, family history of BC, previous biopsies, hypercholesterolemia, reproductive factors, family history of BC, previous biopsies, hypercholesterolemia, hormonal treatment, skin color, tobacco, physical activity and season of sampling. We used multinomial models -with the same co-factors- to estimate the association according to BC pathologic subtypes: a) luminal: ER+ or PR+ with HER2-, b) HER2+, and c) triple negative (TN): ER-, PR- and HER2-.

Results: 25OHVD levels were available in 546 cases and 558 controls. Mean 25OHVD was 48.2 nmol/L in controls and 43.6 in cases (P<0.01). Overall, BC risk decreased with increasing 25OHVD levels (OR per 10 nmol/L=0.88; P<0.001), with no differences in pre- and postmenopausal women. While similar ORs were found for luminal and HER2+ tumors (OR per 10 nmol/L= 0.89 and 0.88 respectively), a stronger effect was observed for TN (OR=0.64, P-heterogeneity: 0.039). No differences were observed according to TNM stage (P-heterogeneity=0.706). Among BC cases, similar 25OHVD levels were observed in cases sampled in weeks 1&2 and weeks 3&4 after diagnosis, but 25OHVD level was lower among cases sampled > 1 month after diagnosis. A sensitivity analysis including only BC cases sampled in the first month showed a slightly lower effect (OR per 10 nmol/L=0.92; P=0.034), similar to the effect reported in meta-analyses of cohort studies. This analysis confirmed the stronger association found for TN tumors (OR= 0.53, P=0.001; P-heterogeneity=0.012). Finally the dose-response analysis showed a downward (protective) effect up to concentrations around 90 nmol/L, from which the risk increased. However, only 3% of women had levels over 90 nmol/L.

Conclusions: To our knowledge, this is the 1st study providing information on the effect of VD by BC subtypes. Our results show a clear protective effect, particularly against TN tumors.

Title: Risk stratification using clinical risk factors and genetic variants in a personalized screening trial

Yiwey Shieh\(^1\), Elad Ziv\(^1\), Martin Eklund\(^2\), Leah Sabacan\(^1\), Roxanna Firouzan\(^1\), Lisa Madlensky\(^3\), Hoda Anton-Culver\(^4\), Alexander Borowsky\(^5\), Andrea LaCroix\(^3\), Arash Naeim\(^6\), Barbara Parker\(^3\), Laura van't Veer\(^1\), Laura Esserman\(^1\), Jeffrey Tice\(^1\) and WISDOM Study and Athena Network Investigators\(^7\). \(^1\)University of California San Francisco, San Francisco, CA; \(^2\)Karolinska Institutet, Stockholm, Sweden; \(^3\)University of California San Diego, San Diego, CA; \(^4\)University of California Irvine, Irvine, CA; \(^5\)University of California Davis, Sacramento, CA; \(^6\)University of California Los Angeles, Los Angeles, CA and \(^7\)WISDOM Study and Athena Network Investigators.

Body: Introduction: Tailoring breast cancer screening according to individual risk may represent an improvement over the current practice of age-based screening. WISDOM (Women Informed to Screen Depending on Measures of Risk) is an ongoing randomized trial comparing the safety, efficacy, cost, and patient acceptability of personalized versus annual screening. Women in the personalized arm receive screening recommendations based on sequencing of 9 genes associated with hereditary breast cancer and a 5-year risk estimate from the Breast Cancer Surveillance Consortium (BCSC) risk model modified by a polygenic risk score (PRS) comprised of 75 single nucleotide polymorphisms. WISDOM represents the first-ever use of a PRS to prospectively modify risk estimates and allows comparison of risk model performance in a population-based setting. Thus, we evaluated the risk estimates generated by: 1) the Breast Cancer Risk Assessment Tool (BCRAT) based on the Gail model, 2) the BCSC model, and 3) the BCSC model modified by the PRS (BCSC-PRS).

Methods: We analyzed participants in the personalized screening arm of the WISDOM Study (NCT02620852). The trial opened in October 2016 and is enrolling participants aged 40-74 years. Participants’ self-reported demographic and risk factor information were collected through an online portal. Genotyping of participants in the personalized arm was done using a custom panel from Color Genomics. 5-year risk estimates were generated using the BCRAT (2011 version), BCSC, and BCSC-PRS models. In the latter, the PRS was used as a Bayesian likelihood ratio to modify the BCSC 5-year risk estimate. We compared the distributions of BCRAT, BCSC, and BCSC-PRS risk estimates around a low-risk (<1%) and moderately high-risk (≥3%) threshold using a paired statistical test (McNemar).

Results: To date, WISDOM has enrolled 2,065 participants, of whom 1,157 are in the personalized arm and 830 have completed risk assessment. The median age was 57 years (interquartile range, IQR 49-64). 83% were Caucasian, 2% African-American, and 7% Asian. 8% self-reported as Hispanic. The median 5-year risk was 1.7% (IQR 1.1-2.3%) using the BCRAT, 1.6% (IQR 1.1-2.3%) using the BCSC model, and 1.5% (IQR 0.9-2.7%) using the BCSC-PRS model. The BCSC-PRS model classified more women into the low (<1%) and moderately high-risk (≥3%) risk categories compared with the BCRAT (p < 0.001) and BCSC model (p < 0.001), Table.

Discussion: Adding a PRS to the BCSC model categorized significantly more women below the low-risk threshold and above the moderately high-risk threshold compared with the BCSC model and BCRAT. Furthermore, the BCSC and BCRAT generated similar distributions of risk estimates. Follow-up with incident breast cancer data is needed to determine whether the reclassification provided by the PRS improves risk stratification and clinical outcomes. However, our preliminary findings suggest that incorporating genetic variants into a validated clinical model is feasible and could enhance risk prediction.
Title: A comprehensive tool for measuring mammographic density changes over time

Mikael Eriksson¹, Jingmei Li¹, Karin Leifland², Kamila Czene¹ and Per Hall¹. ¹Karolinska Institutet, Stockholm, Sweden and ²South General Hospital, Stockholm, Sweden.

Body: Background. Mammographic density is a marker of breast cancer risk and diagnostics accuracy. A change in mammographic density over time is potentially a stronger predictor of breast cancer and a strong proxy for response to endocrine treatment. We developed the STRATUS software to enable automated measurements of density changes over time in research studies and clinical follow-up.

Method. Raw and processed images from the same mammogram were sampled from ~40,000 healthy women. Mammographic density was measured on raw images, using FDA approved software (iCAD), and used as a template for machine learning of STRATUS to measure density on processed images. A similar two-step design was used to train density measures in analogue images. Relative risks of density were estimated in three case-control studies. An alignment protocol was developed on 11,409 women to reduce non-biological variability in density change. The protocol was evaluated in 15,256 women having two regular mammography screens. Difference and variance of density were compared before and after image alignment.

Results. The relative risk of percent mammographic density was 1.6 (95% confidence interval CI 1.3-1.8) per standard deviation. The discrimination was AUC 0.62 (CI 0.60-0.64). Type of image did not influence the risk associations. Alignment decreased the non-biological variability in density change from SD 2.4 to SD 1.8 cm², p<0.001.

Conclusion. STRATUS density measures showed same risk estimates regardless of type of image used. The alignment protocol identified a true density change over time. STRATUS has the potential to become a useful tool for research and clinical follow up.
Body: **Introduction:** The 21-gene recurrence score (RS) assay categorizes hormone receptor positive, node negative breast cancers (BC) into 3 risk groups for recurrence. We previously showed that the AAMC Model, using only standard pathology data, accurately does the same. This study compares the recurrence rate of the AAMC Model's risk groups to RS-based risk groups. A 2-step approach then is used, in which the AAMC model is applied first, and the RS assay is used only for AAMC intermediate risk cases. AAMC intermediate cases were reclassified by RS into low or high risk groups.

**Methods:** From a prospective registry of newly diagnosed BC, we selected invasive, hormone receptor positive, HER2 negative, lymph node negative cases from 2005 to 2015 tested with RS assay. Five-year Kaplan-Meier distant recurrence rates were calculated for each risk category.

**Results:** 1268 cases were included. Five-year recurrence rates were similar between the AAMC Model's low risk group and RS<18 low risk group, as well as between the AAMC Model's high risk group and the RS>30 high risk group. Applying the RS assay to the 715 cases in the AAMC Model's intermediate group resulted in re-classifying 417 (58%) as low risk and 41 (6%) as high risk. Using RS alone, 33% of cases were intermediate risk (n=424), whereas in the 2-step approach 20% were intermediate risk (n=257). For the 2-step approach, the 5-year distant recurrence rate was 3.3% for the low risk group (n=740) and 24.4% for the high risk group (n=271).

**Conclusions:** Five-year recurrence rates in the AAMC Model's low and high risk groups were similar to those in RS-based risk groups. The 2-step approach, with RS used only for AAMC intermediate cases, resulted in larger low and high risk groups with equivalent prognostic accuracy, compared to use of the RS assay alone. The 2-step approach reliably identifies a large number of patients unlikely to benefit from 21 gene assay and provides substantial cost savings.

### Kaplan-Meier Calculated 5-year Distant Recurrences Rates for 4 Models: 1268 Patients

Title: Predicting cardiovascular versus cancer mortality in a cohort of breast cancer survivors

Nicole M Leoce¹, Mary Beth Terry¹, Zhezhen Jin¹, Lawrence H Kushi², Janise M Roh² and Cecile A Laurent². ¹Columbia University, New York, NY and ²Kaiser Permanente Northern California, Oakland, CA.

Body: Background: Given improved survival after breast cancer diagnosis for women with non-metastatic disease, many will likely survive their disease and ultimately die from causes other than breast cancer, the most frequent being cardiovascular disease. There are numerous risk prediction models, such as the Framingham risk score, to identify persons who are at high risk for a cardiovascular event or death. However, these models have been developed for use in the general population and have not been validated in any cohorts of cancer survivors, who are at increased risk for competing causes of death. We evaluated commonly used risk models for cardiovascular events on a contemporary cohort of breast cancer survivors, and developed a new risk model to simultaneously predict the likelihood of death from breast cancer or cardiovascular disease (CVD).

Methods: We included all women diagnosed with stage I-III breast cancer between January 1, 2000 and December 31, 2010 in Kaiser Permanente Northern California (KPNC) with follow-up through April 30, 2015. Specifically, we extracted from KPNC clinical and other databases: breast cancer characteristics, cardiovascular risk factors (cholesterol, blood pressure (BP), diabetes, BP lowering medication, smoking status), cardiovascular events, and cause of death. We assessed discrimination for the Framingham, CORE and SCOREOP cardiovascular risk models using the area under the receiver operating characteristic curve (AUC), and calibration by comparing the observed to the expected events. We used a multi-state model based on Cox cause specific hazards (CSH) to jointly model the risk of cardiovascular death and breast cancer death, while accounting for all other causes.

Results: In this population of 20,462 KPNC breast cancer survivors with a median follow-up of 7.5 years, there were 695 cardiovascular and 842 breast cancer deaths. The existing cardiovascular risk models discriminated adequately (AUCs ranging 0.64 – 0.78), though models predicting cardiovascular mortality tended to over-predict, while those predicting non-fatal events tended to under-predict. Models developed to predict in a shorter time frame (<5 years), performed slightly better (E/O ratios of 1.08 and 1.18 for Framingham predicting events in the next 2 and 4 years, respectively). In our multi-state model, many of the traditional cardiovascular risk factors were no longer statistically significant (diabetes, BP) in predicting cardiovascular mortality, while the breast cancer characteristics (grade, tumor size, nodal involvement), as well as a prior history of CVD, were most useful in predicting cause of death. The model performed well, with AUCs of 0.85 (95% CI 0.83, 0.86) for 5-year risk of cardiovascular death and 0.85 (95% CI 0.84, 0.87) for breast cancer death.

Conclusion: If replicated in an independent cohort, our model suggests that breast cancer characteristics can help predict overall mortality as well as cardiovascular death. Given the risk of cardiovascular death in the population of breast cancer survivors, joint modeling of breast and cardiovascular mortality is warranted.
Title: Breast cancer risk assessment in a multiethnic patient population

Hannah Lui Park\textsuperscript{1}, Alyssa Columbus\textsuperscript{1}, Athena Breast Health Network Investigators and Advocate Partners\textsuperscript{2}, Richard Kelly\textsuperscript{1}, Andrea Alvarez\textsuperscript{1}, Deborah Goodman\textsuperscript{1}, Kathryn Larsen\textsuperscript{1}, Argyrios Ziogas\textsuperscript{1} and Hoda Anton-Culver\textsuperscript{1}. \textsuperscript{1}University of California, Irvine, Irvine, CA and \textsuperscript{2}University of California, San Francisco, San Francisco, CA.

Body: The United States Preventive Services Task Force recommends that women who are at increased risk for breast cancer and at low risk for adverse medication effects should be offered risk-reducing medications, such as tamoxifen or raloxifene, by their clinicians. In addition, the National Comprehensive Cancer Network recommends risk counseling for women with a 5-year risk of $\geq 1.7\%$ as calculated by the NCI-developed Breast Cancer Risk Assessment Tool (BCRAT, based on the Gail model) or other risk model. Thus, breast cancer risk assessment is important for the identification of women at "high risk" who should be offered risk counseling and potentially intervention. The Athena Breast Health Network, which has served $>120,000$ breast screening patients across California and the midwest, has integrated breast cancer risk assessment into its clinical breast screening programs. The goal of our study was to characterize breast cancer risk for $>10,000$ mammography patients in the University of California Irvine Athena Breast Health Network, overall and by race/ethnicity, using several different risk models, including the BCRAT, BCSC, and IBIS models. Our cohort was comprised of 47\% non-Hispanic White, 13\% non-Hispanic Asian, 38\% Hispanic, and 2\% women of other race/ethnicities. Using data collected from electronic medical records and self-completed questionnaires, we determined that, as expected, non-Hispanic White and Asian women had higher breast cancer risk scores than Hispanic women for all risk models (5-year risks = 1.51-1.68\% and 1.22-1.40\% vs. 0.95-1.05\%, respectively). In addition, when women were categorized as "increased risk" according to a given risk model if their 5-year risk score was $\geq 1.7\%$, the percentages of women at "increased risk" were higher in White women (26.5–42.2\%) than in Asian (15.8–28.6\%) and Hispanic (6.2–10.7\%) women. However, the correlations between risk models were low to moderate in our cohort, overall (Pearson's $r = 0.47-0.62$) and especially for Asian women (Pearson's $r = 0.29-0.49$). Our results indicate that using only one risk model in a clinical breast cancer risk assessment program to identify "high risk" women would miss a significant proportion of women who would have been considered "high risk" according to another risk model. Conversely, some women who are identified as "high risk" according to one model may not need risk counseling and intervention since they are not considered "high risk" according to two other models. As our cohort expands and incident breast cancers occur, we will be able to determine which risk model or combination of risk models will have the highest discriminatory accuracy for predicting breast cancer risk in women of different race/ethnicities, which will enable our risk assessment programs to have a more targeted approach to risk counseling and intervention.
Title: Overeating and breast cancer risk by pathologic subtypes: EpiGEICAM study

Body: Introduction: It has been reported that overeating may be the greatest avoidable cause of cancer in nonsmokers and obesity increases postmenopausal breast cancer (BC) risk. Calorie restriction reduces BC incidence in experimental animals, but the evidence in humans is more limited. This study analyzes the association between female BC risk and excessive or restricted calorie consumption in Spain.

Methods: EpiGEICAM is a multicenter case-control study including 1017 matched pairs (age & town) of incident BC cases and healthy controls in 14 regions in Spain. Participants filled a structured questionnaire. Average calorie intake (cals) during the 5 years previous to diagnosis (cases) or interview (controls) was estimated using a validated 117-item semiquantitative food-frequency questionnaire. Expected calorie intake (cals_exp) was calculated from a linear regression model taking into account the basal metabolic rate (Sabounchi’s meta-regression) and the amount of physical activity performed by each woman (5 categories). For each woman the prediction interval (99%) of cals_exp was used to consider her calorie intake as “normal” (NCI) (cals inside this interval –the reference group-), “excessive” (ECI) (cals>upper limit of the interval) or “restricted” (RCI) (cals<lower limit of the interval). The association of ECI and RCI with BC, overall and by pathologic subtype (luminal (ER+ and/or PR+ with HER2-), HER2+ and triple negative), was evaluated using conditional and multinomial logistic regression models, adjusted for age and region (multinomial models), education, body mass index (BMI), smoking, age at menarche & at first birth, menopausal status, previous history of benign breast disease, family history of BC, hormonal replacement therapy (HRT), physical activity and two scores reflecting the participant’s adherence to Mediterranean and Western dietary patterns.

Results: After excluding participants with extreme calorie intake, 973 case-control pairs were considered. Average number of calories was higher in BC cases (1990 kcals) than controls (1897 kcals) \(P=0.001\). Women with RCI (cals<80% of the predicted limit) had lower BC risk (OR=0.52, \(P=0.001\), being this effect more marked in premenopausal women (OR=0.36; \(P=0.001\). On the contrary, women with ECI (cals>40% of the predicted limit) showed increased BC risk (OR=1.92; \(P=0.001\) being this effect stronger in postmenopausal women (OR=2.61; \(P=0.001\). By pathologic subtypes, no statistically significant differences were observed, but ECI (over 40%) was strongly associated with HER2+ tumors (OR=2.05, \(P=0.021\). No differences in the effect of ECI or RCI were observed by levels of BMI, tobacco or HRT.

Conclusion: After taking BMI into account, excessive energy intake increases BC risk, while relative caloric restriction seems to have a protective effect. Moderate calorie restriction, in combination with regular physical activity, could be a good strategy for BC prevention.

Title: Assessing utility of breast cancer risk assessment tool in comparison to Tyrer-Cuzick model for determination of breast cancer risk and implications for chemoprevention

Holly J Pederson¹, Courtney Yanda¹, Michele Kline¹, Marcellia Stephens¹, Shazia T Goraya¹, Stephen R Grobmyer¹ and Michael W Kattan¹. ¹Cleveland Clinic, Cleveland, OH.

Body: Background
Despite findings that the Tyrer-Cuzick (IBIS Breast Cancer Risk Evaluation Tool or TC) model is more predictive of breast cancer risk than the Gail model (NCI maintained Breast Cancer Risk Assessment Tool or BCRAT), BCRAT is commonly clinically used as per the United States Preventive Services Task Force (USPSTF), with a 5-year risk for breast cancer (BC) of greater than 3% on BCRAT, the benefits of preventive medication likely outweigh the risks. We aimed to compare the models, 1: to see if a 10 year risk estimate per the TC model reliably correlated with the 3% 5 year risk per BCRAT, and 2: to analyze the subset of patients with atypical hyperplasia (AH) and lobular carcinoma in situ (LCIS) who are known both to be at high risk for breast cancer and to benefit from chemoprevention. Our hypothesis is that BCRAT has limited utility in risk estimation, and the most comprehensive model for risk estimation and clinical decision making is TC.

Methods
200 women ages 35-64 women followed in benign breast clinic were included. Risk estimations were run using BCRAT, TC version 7 (v7) and TC version 8 (v8). A Pearson's Correlation test was conducted to investigate the relationship between the TC models and the BCRAT model. A p-value < 0.05 was considered statistically significant.

Results
Analysis showed a positive moderate-strength relationship between the TC v7 10-year risk and the 5-year BCRAT risk for this population (R = 0.468, P<0.001) and a positive moderate-strength relationship between the TC v8 10-year risk and the 5-year BCRAT risk (R = 0.550, P<0.001). A TC v7 risk of 8.09% (95% confidence interval (CI): 7.42-8.75) and a TC v8 risk of 8.54% (95% CI: 7.85-9.24) corresponded to a BCRAT risk of 3%. However, much error was present when assessing consistency and correlation between the models.

A total of 36 patients were diagnosed with AH, 2 patients were diagnosed with LCIS and 7 patients were diagnosed with both AH and LCIS. 11 patients who had AH had an estimated 5-year risk per the BCRAT model of <3%. Two of these patients were pre-menopausal and African American and one was pre-menopausal and Hispanic. Of the remaining 8 patients, all were under the age of 60.

Of the 30 patients who had a BCRAT 5-year estimated risk of BC of >3% but no AH or LCIS, 12 had two first degree relatives with breast cancer and 16 had a first-degree relative with BC and at least two benign breast biopsies.

Conclusion
BCRAT is limited and caution is warranted with its use in assessing risk and for counseling around chemoprevention benefit. There is not reliable correlation between the 5 year BCRAT risk estimate and the 10 year TC risk estimate. Chemoprevention should be discussed for patients with AH, LCIS or 2+ first degree relatives with breast cancer. Further, BCRAT may underestimate risk in minority populations and others with AH. For a limited group of patients with moderate risk, dual modeling may be clinically useful in making chemopreventive recommendations.
Body: Introduction: Although breast cancer (BC) is the most frequent tumor in women worldwide, well-established risk factors account for 40%-50% of cases. The influence of environmental factors is not well known. Our objective was to assess the association between residential proximity to industrial facilities included in the European Pollutant Release and Transfer Register and risk of BC, according to different categories of industrial groups and specific pollutants released, in the context of a multicentric population-based case-control study carried out in Spain (MCC-Spain).

Methods: MCC-Spain is a frequency matched, multicase-control study that evaluates environmental and genetic factors associated with the risk of BC and other tumors in 12 regions in Spain (http://www.mccspain.org/). Given the study design, the present work was restricted to small administrative divisions including both BC cases and controls. A total of 452 BC cases and 1511 controls from the original set were included. Using GIS methods, distances were computed from the respective subject’s residences to the 116 industries located in the study areas. We used logistic regression to estimate odds ratios (ORs) and 95% confidence intervals (95%CIs) for categories of distance (from 1 km to 3 km) to industrial facilities, adjusting for age, family history of breast cancer, age at menarche, educational level, body mass index one year before the interview, age at first birth, menopausal status, and previous biopsies.

Results: Excess risk (OR; 95%CI) of breast cancer was detected near industries as a whole (1.30; 1.00-1.69 at 3 km), particularly organic chemical industry (2.12; 1.20-3.76 at 2.5 km), food and beverage sector (1.87; 1.26-2.78 at 3 km), ceramic (4.71; 1.62-13.66 at 1.5 km), surface treatment using organic solvents (2.00; 1.23-3.24 at 3 km), and surface treatment of metals and plastic (1.51; 1.06-2.14 at 3 km). By pollutants, the excess risk (OR; 95%CI) was found in women close to industries releasing pesticides (2.09; 1.14-3.82 at 2 km), and dichloromethane (2.09; 1.28-3.40 at 3 km).

Conclusions: Our results suggest a possible increased risk of BC in women living near certain industrial facilities. These findings support the need for more detailed exposure assessment of certain toxics released by these industries.

A genetically underserved community

Robin L Sanders and Michelle Wilson. Baylor Scott and White Hillcrest, Waco, TX.

Body: It is estimated 5-10% of breast cancer can be attributed to a hereditary predisposition. By knowing a woman’s risk for breast cancer, risk reduction strategies can be discussed. Waco, Texas is an underserved community with the nearest geneticists and genetic counselors 35 miles away. This is a multidisciplinary approach to developing a breast cancer risk assessment and genetic carrier screening program in Waco, Texas.

Program Development The initial pilot was designed as a two-week trial to see what the prevalence of at risk women for breast cancer is in our community. The Breast Center distributed a cancer history questionnaire to all of their patients. The women were scored on the Tyrer-Cuzik Breast Cancer Lifetime Risk Assessment Model and surveyed for family and personal history of cancer. Total patients screened in the Breast Center 619. Of these 63.8% had a personal or family history of cancer and 21.8% meet NCCN 2015 criteria for genetic testing. It was projected a 5.3% mutation carrier status in our population and a 14% high risk breast cancer population (>20% lifetime risk of breast cancer).

Methods As a quality initiative, the Breast Center distributed the screening questionnaire and Tyrer-Cuzik score for each woman. Each questionnaire is assessed by a NP for genetic evaluation per NCCN guidelines Genetic/Familial High-Risk Assessment: Breast and Ovarian v1.2016 and NCCN Genetic/Familial High-Risk Assessment; and Colorectal v.1.2016. Allowing for insurance coverage differences, if the patient meets the above criteria, the patient is offered an appointment with informed consent, and genetic counseling services provided by the NP allowing for testing same day as consultation. This program is ongoing, the results listed began January 4, 2016 and ended December 30, 2016. Total patients seen in Breast Center 11,196. Total patients screened for family history 9,726. Patients with family or personal history was 51%, of that 24% met NCCN genetic testing criteria. Patients tested 316, with 5.7% identified genetic mutations

Women with a >20% lifetime risk of breast cancer 14%.

Conclusion The first year of the program, demonstrated our patient population has a 5.7% prevalence of mutation detection. In addition, a 7.2% high risk breast cancer prevalence was identified. It is imperative to bring awareness to underserved communities to reduce the risk of cancer. This program was developed to improve access to genetic services and identify high risk individuals in our community. The detection rate for our population in this small pilot was 5.7% which is comparable to expected. This pilot program identifies an important role for interdisciplinary approach to genetic services.
Title: Tamoxifen and contralateral breast cancer (CBC) risk for BRCA1 and BRCA2 mutation carriers: An updated analysis of data from the Kathleen Cuningham Foundation consortium for research into familial breast cancer, the International BRCA1 and BRCA2 Carrier cohort study and the breast cancer family registry

Body: Background: Findings from an analysis published in 2013, using combined retrospective and prospective data pooled from 3 cohort studies, were consistent with tamoxifen use after 1st breast cancer (BC) being associated with reduced CBC risk for both BRCA1 and BRCA2 mutation carriers, although the analysis of prospective data alone (based on 100 incident CBCs) gave inconclusive results. The association did not differ by estrogen receptor (ER) status of the 1st BC, suggesting that tamoxifen may be a useful secondary BC prevention agent for mutation carriers regardless of the ER status of their 1st BC. The aim of this updated analysis was to assess these associations after incorporating data from an additional 1,279 mutation carriers and with further follow-up providing 153 additional prospective CBC events. Methods: Eligible women were BRCA1 and BRCA2 mutation carriers diagnosed with unilateral BC since 1970 and with no other invasive cancer or tamoxifen use before their 1st BC. They were followed up from their 1st BC (or, for the prospective analysis, from the later of recruitment and 1st BC diagnosis) to the development of CBC or censoring (at contralateral mastectomy, death or loss to follow-up). Hazard ratios (HRs) for CBC associated with tamoxifen use were estimated using Cox regression, adjusting for year and age of diagnosis, country and bilateral oophorectomy; analyses were also stratified by ER status of the 1st BC. Results: This 2017 analysis includes 3,743 mutation carriers (BRCA1 2,343; BRCA2 1,400) with 21,436 person years of follow-up. Compared with the 2013 analysis, the strengths of the inverse associations were attenuated after including the additional data.

*Combined = retrospective and prospective, N=number, BRCA1 & BRCA2=mutation carriers, Tam 1st BC= Tamoxifen for 1st Breast Cancer

In this updated prospective analysis, the inverse association between tamoxifen use for 1\textsuperscript{st} BC and CBC risk was most apparent for women with ER positive 1\textsuperscript{st} BC, especially for BRCA2 mutation carriers: BRCA1 ER positive HR=0.45 (95% CI 0.17-1.22, p=0.12), BRCA1 ER negative HR= 0.87 (95% CI 0.45-1.67, p=0.67), BRCA2 ER positive HR=0.33 (95% CI 0.15-0.74, p<0.007), BRCA2 ER negative HR=1.12 (95% CI 0.27-4.70, p=0.88).

**Conclusions:** Tamoxifen use for 1\textsuperscript{st} BC might reduce CBC risk for mutation carriers, but predominantly for those with an ER positive 1\textsuperscript{st} BC. These data do not support use of tamoxifen to prevent CBC for mutation carriers with ER negative BC.
**Title:** Presence of atypia in ductal lavage and risk of subsequent breast cancer in a prospective study

Andrea De Censi, Massimiliano Cazzaniga, Sara Gandini, Chiara Casadio, Laura Chiapparini, Aliana Guerrieri-Gonzaga, Debora Macis, Paolo Veronesi and Bernardo Bonanni. 1Ospedali Galliera, Genova, Italy; 2Queen Mary University, London, United Kingdom and 3IEO-Istituto Europeo di Oncologia, Milano, Italy.

**Body:** Background: Atypical hyperplasia is considered a nearly obligate precursor of breast cancer and is associated with a higher risk of developing breast cancer (BC). Attempts to improve early detection of breast cancer and to provide individualized breast cancer risk assessment would greatly benefit from sampling cellular material from the target tissue. Ductal lavage (DL) is a minimally invasive technique which provides adequate material to detect atypical cells in mammary ducts. However, long term data of the association between atypia from ductal lavage and BC risk are lacking. We studied the prevalence of atypia in DL in different risk categories and its ability to predict BC development in women at risk. Methods: From March 2000 to July 2012 we performed DL in a consecutive series of 348 women with median age of 45 years (range 19-74) at increased BC risk based on the following characteristics: 5 yrs Gail model > 1.66% or > 10% probability of BRCA mutation (n = 155), history of contralateral BC (CBC, n = 161), presence of a BRCA pathogenic variant (n = 32). We analyzed the presence of atypical cells in the baseline specimen of ductal lavage and in repeated lavage and observed their evolution during follow-up. Results: The procedure was safe and well tolerated in most women, with pain and discomfort preventing the procedure in 5.4% of subjects. Overall, 126 (36%) women had atypia at baseline, with a prevalence of 32%, 39%, and 41% in the Gail, CBC and BRCA groups, respectively (p = 0.38). The overall prevalence of atypia considering all visits was 44% (range 36-51). After a median follow up of 6 years, cumulative BC events were 8% in women without atypia versus 14% in those with atypia (log-rank p = 0.08). In the highest risk groups (CBC and BRCA pathogenic variants), the number of BC events was 16 (21%) in women with atypia versus 11 (10%) in women without atypia (p = 0.02 after adjustment for age). Conclusions: Our findings suggest that cytologic atypia in the fluid obtained by DL predicts subsequent BC in women at increased risk, providing individual risk assessment. The reversal of atypia in DL should be evaluated as a surrogate biomarker of BC therapeutic prevention. **2017 San Antonio Breast Cancer Symposium**

**Publication Number:** P3-10-03

**Title:** Effects of guideline-concordant treatment on ED visits, hospitalizations, and cost in metastatic breast cancer

Gabrielle B Rocque¹, Courtney P Williams¹, Bradford E Jackson², Karina L Halilova¹, Stacey A Adewakun¹, Maria Pisu¹, Andres Forero¹ and Smita Bhatia¹. ¹University of Alabama at Birmingham, Birmingham, AL and ²JPS Health Network, Fort Worth, TX.

**Body:**

**Purpose:** The National Comprehensive Cancer Network (NCCN) developed treatment guidelines that have directed care of patients with cancer for over 20 years. Receipt of treatment according to these guidelines is increasingly recognized as a marker of high quality care. A knowledge gap exists regarding concordance of treatment regimens for metastatic breast cancer with NCCN guidelines, as well as the potential impact of this concordance (or lack thereof) on resource utilization and costs – an issue that assumes significance in the new era of value-based healthcare.

**Methods:** From 2007-2013, women with de novo (n=988) or recurrent, treated metastatic breast cancer (n=5,651) were evaluated for concordance of first-line systemic therapy with NCCN guidelines within the SEER–Medicare linked database. Types of non-concordant treatments were reviewed and categorized. Outcomes include monthly rates of ED visits, monthly rates of hospital admissions, total overall and Medicare costs, and mortality. Specific (hospitalizations, antineoplastic agents, growth factor) and total costs to Medicare (excluding home health, hospice, skilled nursing facility) were calculated from initiation of treatment until death or available follow-up and examined by concordance status. Part D costs were excluded because costs are shared by Medicare, other payers, and patients. Cox regression was used to evaluate mortality risk. Student's t-tests, generalized linear models, and generalized mixed effects models were utilized to evaluate the relationship between concordance status and outcomes.

**Results:** We previously reported the prevalence of non-concordant first-line systemic therapy for de novo metastatic breast cancer (19%) and recurrent metastatic breast cancer (18%). The adjusted risk of mortality was comparable by concordance status. In the current analysis, non-concordant treatments were associated with a 9% increased rate of ED visits and a 7% increased rate of hospitalizations (p<.01). Total Medicare cost for patients receiving concordant and non-concordant treatments was $79,372 and $109,471, respectively (p<.001). Significant cost differences were found when comparing patients receiving concordant and non-concordant treatments by antineoplastic agents ($14,256 vs $24,817, p<.001) and growth factor ($1,754 vs $3,414, p<.001). A trend toward lower cost attributed to hospitalizations was observed for patients receiving concordant treatment compared to those receiving non-concordant treatment ($28,113 vs $34,134, p=.06). Overall, hospitalizations, antineoplastic agents, and growth factor accounted for 56% of total Medicare costs. Average monthly Medicare costs were higher for non-concordant patients by $1,761 (p<.01).

**Conclusions:** While not associated with increased overall mortality, non-concordant treatment is associated with higher health care utilization rates and cost. Increased costs attributed to non-concordant care were largely driven by antineoplastic agents and growth factor use. These findings may have policy implications for payment reform initiative, in particular pathway programs which aim to reduce variability in care and spending on medications.
Title: Obesity and adipose inflammation in men with breast cancer

Samantha Williams¹, Julia C Parrish², Xi K Zhou³, Hanhan Wang³, Anneloor Dierickx⁴, Ayca Gucalp¹, Andrew J Dannenberg³ and Neil M Iyengar¹. ¹Memorial Sloan Kettering Cancer Center, New York, NY; ²University of Washington School of Medicine, Anchorage, AK; ³Weill Cornell Medicine, New York, NY and ⁴University of Ghent, Ghent, Belgium.

Body: Background: Elevated body mass index (BMI) is associated with increased risk of hormone receptor (HR)-positive breast cancer in postmenopausal women and worsened outcomes after breast cancer diagnosis. These observations may be partly attributable to adipose inflammation, which is prevalent in the breasts of obese women and is associated with worsened breast cancer survival. In men, some studies have reported obesity to be a risk factor for breast cancer, however the biologic links are not well characterized. Whether adipose inflammation occurs in male breast tissue has not been previously reported. Here we examined the relationships among pre-diagnosis BMI, adipose inflammation, and breast cancer features in men.

Methods: Males diagnosed with stage 0 – III breast cancer who underwent mastectomy at Memorial Sloan Kettering (MSK) between August 1991 – November 2011 were included in this retrospective cohort study. Pre-operative BMI was categorized as normal or underweight (<25), overweight (25 – 29.9), obese (≥30), or morbidly obese (≥40 or ≥35 + co-morbidity). Archived breast tissue was subjected to CD68 immunohistochemistry to detect adipose inflammation, defined by the presence of dead or dying adipocytes surrounded by macrophages – known as crown-like structures of the breast (CLS-B). Clinicopathologic associations with BMI and CLS-B were analyzed by logistic regression and Fisher's exact test.

Results: A total of 141 men were included; median age 63 (range 23 – 96). By BMI category, 25 were normal or underweight, 65 overweight, and 51 obese – of which 19 were morbidly obese. Only 11 men had known BRCA1/2 mutations. Median age at diagnosis was 69 in normal/underweight men versus 63 in obese men and 51 in morbidly obese men (P≤0.05). Among those with invasive tumors, average tumor size was 1.50 cm (± 0.84) in normal/underweight men versus 2.04 (±0.81) in morbidly obese men (P≤0.05). Archived breast tissue was available from 92 (65%) men. Breast adipose inflammation was present in 55 (60%) men, and average BMI was 31 (±8) versus 28 (±5) in men with versus without inflammation, respectively (P=0.07).

Conclusions: Obesity is associated with early onset breast cancer in men. Morbidly obese men were diagnosed with breast cancer at an even younger age and had larger tumors than normal weight individuals. These findings support further studies to investigate mechanisms, such as adipose inflammation, through which obesity may promote breast cancer in men.
Title: Normal breast biopsies reveal an "active" transcriptome associating with higher breast cancer risk (Gail) scores and increased IGF-1 growth factor expression

Christopher Benz¹, Christina Yau¹, Stephen Benz², Gregor Krings³ and Mark Powell⁴. ¹Buck Institute for Research on Aging, Novato, CA; ²NantOmics LLC, Culver City, CA; ³University of California, San Francisco, San Francisco, CA and ⁴Zero Breast Cancer, San Rafael, CA.

Background: Recent studies have identified at least two different transcriptional subtypes of benign human breast tissue (Haakensen et al., 2011), including an “active” subtype associated with increased risk of later life mortality from breast cancer (Troester et al., 2016). However, previous studies used "normal" breast samples from cosmetic surgery, biopsies from abnormal mammograms, or cancer-adjacent tissue. The present study evaluates normal breast transcriptome phenotypes from healthy women who donated for this study purpose only.

Methods: 200 formalin-fixed paraffin-embedded (FFPE) breast tissue biopsy samples were analyzed from healthy, parous non-Hispanic white women ranging in age from 27–66 (median = 45) with no prior history of breast cancer (<16% had prior breast biopsies), who donated to the Komen Tissue Bank (KTB) and provided questionnaire data enabling calculation of breast cancer risk (Gail) scores. Extractable RNA from FFPE sections sufficient for RNA sequencing (~100ng) was obtained from 145/200 donor samples; digitized H&E analysis confirmed normal breast histology. Transcript levels were quantified using RSEM and normalized; 2558 genes were used for unsupervised hierarchical clustering to identify “active” vs. “inactive” normal transcriptome subtypes as previously described (Roman-Perez et al., 2012), and these subtypes were compared for risk scores and IGF1R and IGF-1 gene expression levels and their respective signatures (Creighton et al., 2008; Mu et al., 2012).

Results: As expected, the normal histologic composition of these KTB samples varied considerably with mean % adipose area twice that of fibrous area, and epithelial content averaging <5%. Unsupervised gene expression analysis produced two primary clusters, with 31% of donor samples showing the “active” transcriptome phenotype. These “active” breast samples came from women with significantly higher Gail scores (Wilcoxon rank sum p=0.007) and showed significantly different expression levels in 12 of 17 IGF-1/IGF1R pathway genes (FDR-corrected p values) including higher IGF-1, IGF-2, IRS1, IRS2, IGF2R, IGFBP3, IGFBP5, IGFBP6, and IGF2BP3 levels, and lower IGF1R, IGFBP2, and IGFBP3 transcript levels. A multigene signature associated with IGF-1 induction was consistent with the 2-fold significant increase in mean IGF-1 mRNA levels seen in this “active” subset; likewise, an independent multigene signature associated with IGF1R activation was consistent with the 0.84-fold significant reduction in mean IGF1R mRNA levels observed in this same subset.

Conclusion: Over 30% of healthy adult women with histologically normal breast tissue carry an "active" breast transcriptome phenotype previously linked to co-existent breast cancer and now shown to be associated with increased future risk of developing breast cancer assessed by Gail score. This “active” transcriptome phenotype is characterized by increased endogenous IGF-1 activity, a known breast cancer promoting growth factor, along with an inverse reduction in IGF1R expression and activity as previously seen in some breast cancers. Further morphologic and molecular characterization of this risk-associated subset of normal breast tissues is underway.
Title: What is the latest evidence on diet, nutrition, physical activity and cancer – key findings from the WCRF/AICR continuous update project

Inger Thune¹,², Kate Allen³, Rachel L Thompson³, Martin J Wiseman³, Panagiota Mitrou³ and Deirdre McGinley-Gieser⁴. ¹Oslo University Hospital, Oslo, Norway; ²University of Tromsø, Tromsø, Norway; ³World Cancer Research Fund International, London, United Kingdom and ⁴American Institute for Cancer Research, Arlington, VA.

Body: Introduction:
Since 1997, World Cancer Research Fund (WCRF) International and the American Institute for Cancer Research (AICR) have been at the forefront of synthesizing and interpreting the accumulated scientific literature on the link between diet, nutrition, physical activity and cancer, and deriving evidence-based Cancer Prevention Recommendations. The 2007 WCRF/AICR 2nd Expert Report, using a robust method and systematic literature reviews, was a landmark in the analysis of evidence linking diet, body weight and physical activity to cancer and led to the establishment of the Continuous Update Project (CUP). New findings from the CUP systematic review have been released for 12 cancers, and updated findings for breast cancer have just been released. The 2018 WCRF/AICR 3rd Expert Report, to be published in 2018, will include a new review of the WCRF/AICR Cancer Prevention Recommendations.

Methods:
The review was conducted as part of the Continuous Update Project (CUP).
The research team at Imperial College London searched PubMed for relevant prospective studies up to April 30, 2015. Dose-response meta-analyses were conducted and summary relative risks (RR) were calculated using a random effects model. Analyses comparing the highest versus the lower categories were also conducted. An international panel of experts (CUP Panel) reviewed the evidence and drew conclusions.

Results:
The updated Breast Cancer Report included 119 studies from around the world, comprising more than 12 million women and over 260,000 cases of breast cancer.
The latest evidence suggests that vigorous physical exercise reduces your risk of breast cancer before menopause by 17%. In addition, the report reconfirms the link between physical activity and decreased risk of breast cancer after menopause. Taking at least 30 minutes of moderate physical activity, such as brisk walking, or 15 minutes of vigorous physical activity each day can reduce your risk of breast cancer after menopause by 10%. Greater body fatness and weight gain as an adult does increase the risk of breast cancer after menopause. However, in contrast we observed greater body fatness in young adulthood may reduce breast cancer risk both before and after menopause.
The report found strong evidence that drinking just the equivalent of a small glass of wine or half a pint of beer a day (about 10g alcohol content), could increase your pre-menopausal breast cancer risk by 5% and your post-menopausal breast cancer risk by 9%.

Conclusions:
Recent evidence has resulted in new findings and changes to the CUP Panel's conclusions from the 2010 Breast Cancer Report with regard to physical activity and body fatness at different life periods. In addition, new evidence confirmed their judgements on alcohol.
The CUP provides a unique resource synthesizing epidemiological and other evidence on diet, nutrition, physical activity and cancer, to facilitate related research, and underpin advice to the public and policy-makers.
Evidence is accumulating that the degree of adherence to WCRF/AICR recommendations is associated with lower mortality of cancer overall, of specific cancers and of all-cause mortality.
Title: Uptake of risk reducing measures in healthy BRCA 1-2 mutation carriers from Northern Italy: Outcomes of 9 years of close-surveillance. Experience of the hereditary cancer clinic in the region of Veneto, Italy

Antonella Rastelli1,2, Fabio Azzolin1, Silvia Tognazzo1, Elisa Alducci1 and Stefania Zovato1. 1IOV (Istituto Oncologico Veneto), Padova, Italy and 2Washington University School of Medicine, Saint Louis, MO.

Body: Background: There are several options for cancer reduction in women with a BRCA 1-2 mutation, including prophylactic surgery, chemo-prevention and close surveillance. Each of these measures offers varying levels of effectiveness with prophylactic mastectomy (PM) and oophorectomy (PO) providing the greatest risk reduction for the development of breast and ovarian cancer. The uptake of preventive procedures, however, differs according to country, not only in relation to access to care, but also cultural preferences. Here we present data on the experience of the Hereditary Cancer Center at the Istituto Oncologico Veneto, which is one of the few centers in Northern Italy to offer not only genetic testing, but also long-term follow-up to healthy carriers of the BRCA 1-2 genes. Methods: 106 healthy women were identified within a cohort of BRCA positive individuals followed since 2008. Upon learning of their BRCA mutation carrier status, they all agreed to enroll in a long-term protocol of close-surveillance. All women were also informed about risk-reducing surgery such as PO and PM. Results: The age in this sample ranged between 20 and 77 years with a median of 41.5. The average follow-up time was 4.3 +/-2.4 years. We observed that PO was more commonly accepted (41% 44/106) than PM (11% 12/106). The mean age at the time of PO was 47.3. In the PM group, half of the women decided to undergo such procedure only after being diagnosed with breast cancer. The mean age at the time of PM in the healthy subjects was 41.8 years. Over the follow-up period, 9.4% of the patients (10/106) developed BRCA related malignancies, of which 9 breast and 1 ovarian cancer. Of the 9 breast events, 2 were diagnosed at stage 0, 2 at stage I, 3 at stage II, and 2 at stage III. All cancer cells were aggressive (grade 3). Of the 2 stage III breast tumors, 1 was diagnosed on the very 1st breast MRI screening, and the other after an interval of 3 years due to the patient being pregnant and then breastfeeding. The 3 cases of stage II breast cancer, despite being 1 cm or less in size, already had node involvement. Both stage III breast tumors were triple negative in BRCA 1 carriers. The other breast cancers were ER+ and none was Her2+. Of the ER+ breast events 4 occurred in BRCA2 and 2 in BRCA1 carriers. Except for the 2 Stage 0 tumors, which arose in women who had a previous oophorectomy, all the other breast malignancies developed in carriers who still had their ovaries and were premenopausal. The one serous ovarian cancer was diagnosed at Stage II in a 77 years-old BRCA1+ woman. Conclusions: In this sample of healthy northern Italian women carriers of BRCA mutations, close to 10% developed a tumor within 5 years of follow-up with an aggressive cell phenotype. The more accepted method of risk-reduction in this group of women was PO as compared to PM. A protocol of close-surveillance allows for an early stage diagnosis in about half of the women who develop a breast tumor.
Title: Breast cancer in octogenarians: Presentation and treatment affect mortality

Jason P Wilson¹, Vijayakrishna Gadiyaram¹ and Peter W Blumencranz¹. ¹Morton Plant Mease Hospitals, Clearwater, FL.

Body: Background: Breast cancer incidence increases in age. Unfortunately, elderly patients are often under-treated and under-diagnosed affecting their overall survival with limited availability of clinical trial data.

Patients and Methods: We used data from our cancer registry and our state cancer registry to evaluate cases of breast cancer diagnosed between the years 2005 and 2010 with follow up data available to date to examine the method of diagnosis (mammogram vs. palpable abnormality), age at diagnosis, stage at diagnosis, type of surgery, receptor status, treatment received, and survival. We then were able to use our state database which contained data regarding causality of death. Based on the data available we were able to evaluate the impact of the method of diagnosis and treatment on patient mortality.

Results: A total of 495 octogenarian breast cancer patients were diagnosed between 2005 and 2010. The median age at diagnosis was 85 with a range of 81-102. Out of the 495 patients 55% were diagnosed with a mammogram and 41% by palpable abnormality. The patients who presented with a palpable mass were more likely to die of breast cancer (26%) than the patients who presented with a screening abnormality (9%). The patients with a screening abnormality also had a longer survival (30.0 months) among patients who died from breast cancer as opposed to those who presented with a palpable abnormality who died from breast cancer (16.7 months). While the number of patients dying from other causes was similar (65% screened vs. palpable) the patients with palpable findings had a shorter survival (30.5 months) compared to those detected by screening (48.9 months).

Table 1: Comparison of outcomes between screen detected and physical exam detected breast cancer patients

</tr>
</tbody>
</table>

There was an improvement in survival among patients who presented with a palpable mass and were treated with endocrine therapy (17.3 vs 11%). This improvement did not extend to the screened population (24.3% vs 29%), although the patients who died from breast cancer had an overall longer survival (35.4 months vs 27.3 months). There was also an improvement in survival among patients who received radiation therapy in both the screened (33% vs. 22%) and palpable (22.5% vs 11.1%) groups. Only 6% of patients in the entire study received chemotherapy.

</tr>
</tbody>
</table>

Conclusion: Our data support continued use of screening mammography in patients who are at good surgical risk into their 80's. The patients who were diagnosed with symptoms fared worse than the patients who had their cancer discovered on routine
imaging. There was an improvement in patients who were treated with adjuvant endocrine and radiation therapy although the rationale behind providing or excluding treatment cannot be discerned from this retrospective registry study.
Title: The association age-related parity and HER2 over-expression in breast cancer

Soo Youn Bae¹, Jiyoung Kim², Ji Young You¹, Seung Pil Jung¹ and Jeong Won Bae¹. ¹Korea University Anam Hospital, Seoul, Korea and ²Jeju National University of Hospital, JeJu, Korea.

Body: Backgrounds

Reproductive factors, such as age at menarche, parity, age at first birth, and breast feeding, are known to be associated with risk of breast cancer. Recent studies show the association between the reproductive factors and the molecular subtypes of breast cancer, especially in luminal-like subtypes. Nulliparity is known a risk factor of breast cancer, multiparity is considered a protective factor. However, pregnancy associated breast cancers show the high expression of HER2, Therefore, we hypothesized the number of birth (multiparity) is correlated with the over-expression of HER2.

Methods

We reviewed the database of 2,594 breast cancer patients were over 20 years of age, diagnosed between January 2000 and April 2017 at Korea University of Anam Hospital, Seoul, Korea. According the number of birth, nulliparous (the number of birth = 0; 271 patients), primiparous (the number of birth = 1; 420 patients) and multiparous (the number of birth ≥2; 1,903 patients) groups were classified.

Results

The median age (range) of nulliparous, primiparous and multiparous groups was 43 (22-77), 48 (27-87) and 51 (26-86) years (P<0.001). In univariate analysis, the number of birth was associated with the expression of ER and HER2, nulliparous patients showed higher ER positivity (P=0.013) and multiparous patients showed higher HER2 overexpression (P=0.048). There was no association with PR and Ki-67 level. In logistic regression with age, the parity was negative correlation with ER positivity (OR 0.83, 95% CI 0.72-0.95, P=0.010) and positive correlation with HER2 overexpression (OR 1.18, 95% CI 1.02-1.36, P=0.021) and multiparity was higher HER2 overexpression (OR 1.72, 95% CI 1.12-2.63, P=0.013), there was no difference in HER2 overexpression between nulliparous and primiparous patients.

Conclusion

Parity was associated with ER and HER2 expression, multiparous patients were associated with ER negativity and HER2 overexpression, especially in premenopausal women. This suggests that pregnancy could affect risk of breast cancer, especially in HER2 positive breast cancer subtype (ER- HER2+ tumors), before menopause. We need further investigation and evaluation.
Title: Triple negative breast cancer in young Peruvian patients: 15-years' experience in a public hospital

Zaida Morante¹, Gabriel De la Cruz-Ku³, Joseph Pinto², Jhajaira Araujo¹, Eduardo Eyzaguirre³, Antonella Saavedra³, Maria Lujan³, Daniel Enriquez¹, Magno Ramirez³, Hugo Fuentes¹, Silvia Neciosup¹ and Henry Gomez¹. ¹Instituto Nacional de Enfermedades Neoplasicas, Lima, Peru; ²Oncosalud, Lima, Peru and ³Universidad Cientifica del Sur, Lima, Peru.

Body: Background: The incidence of breast cancer (BC) is low in young women and is characterized by a high prevalence of triple-negative tumors, representing a group of high risk. In this work, we describe the clinicopathological and epidemiological features of triple-negative breast cancer (TNBC) in patients aged ≤35 years.

Methods: We reviewed information of TNBC patients diagnosed at ≤35 years old and treated at the Instituto Nacional de Enfermedades Neoplasicas (between 2000 and 2014). The Cox proportional hazard model was used to identify prognostics factors for DFS and OS.

Results: In total, of 243 out 2007 cases (12.11%) were very young TNBC patients. The median follow-up was 9 years. The median age was 32 years (range: 19-35); 14.8% had obesity. A total of 40 (16.5%) patients had a family history of breast-ovary cancer (FHBOC). Regarding to the clinical-pathological characteristics, 59.4% presented T-Stages 3/4; 65.2% had nodal involvement and 7 patients (2.9%) had bilateral BC. Most of patients were diagnosed at Clinical Stage (CS) III (50.8%). The most common histological subtype the was ductal invasive carcinoma (92.1%), followed by medullar (4.5%) and lobulllar (1.7%). A high histological grade was frequent (84.7%), while 71 cases (49%) were diagnosed with vascular permeation and 55 (48.2%) with macrometastasis in lymph nodes. The majority of patients underwent mastectomy (60.2%) compared to lumpectomy (39.8%). Locoregional relapse and distant metastasis were reported in 30.9% and 49.4% of cases, respectively. The most frequent sites of metastases were lung (14.8%) and brain (11.5%). In the multivariate analysis, only N3 stage was associated with a poor outcome in terms of (N0 vs N3, HR=7.89, 95%CI:2.76-22.56, p<0.001). Variables associated with the risk of death were N stage (P<0.001 for N0 vs N3), neoadjuvant chemotherapy (P<0.027), adjuvant chemotherapy (P<0.001), and radiotherapy (P=0.008).

Conclusions: TNBC in very young Peruvian women was characterized by advanced stage at diagnosis. In these patients, nodal involvement was the most important prognostic factor for DFS. It presents distinctive characteristics and poorer outcomes in terms of DFS and OS.

Title: Breast cancer risk assessment and evaluation of risk-based screening practices by primary care providers: A single institution experience

Henry P Igid1, J Drew Payne1, Anita Sultan1, Sean Y Kow1, Keeley L Hobart1, Teri Nichole Payne1 and Catherine Jones1. 'Texas Tech University Health Sciences Center, Lubbock, TX.

Body: Background: Risk reduction intervention for primary prevention of breast cancer (BC) with tamoxifen, raloxifene, exemestane, and anastrazole has been well studied in high risk women. Despite this established risk reduction strategy, chemoprevention (CP) remains underutilized. In this retrospective chart review, we describe the utilization of BC risk assessment, prevention awareness, and adherence to BC screening recommendations among primary care providers in Internal Medicine (IM), Family Medicine (FM), and Obstetrics and Gynecology (OB) in our institution.

Methods: A total of 1220 electronic charts of women aged ≥35 and ≤78 who came for preventive visits in 2014 (n=1076, OB; n=59, IM; n=80, FM) were reviewed. Charts were evaluated for pertinent histories related to BC risk assessment. Gail scores were calculated for all patients based on available histories with conservative estimates in those with incomplete data recorded. Screening compliance with annual or biennial mammography was recorded.

Results: The percentage of patients having adequate histories in the chart to allow calculation of Gail score was 56.9% in OB, 9.4% in FM, and 1.7% in IM, χ²(2)=131.08, p<0.001. Age at menarche was not documented in 29.5% of OB patients, 56.5% of FM patients, and 94.5% of IM patients, χ²(2)=123.78, p<0.001. Age at first live birth or parity was not documented in 17.8%, 85.9%, and 97.7% of OB, FM, and IM patients respectively, χ²(2)=286.89, p<0.001. Calculation of the Gail score yielded a total of 149 patients (12.2%) who are considered high-risk and potentially eligible for CP. No patients were offered CP as part of their care. IM physicians had significantly higher adherence to BC screening recommendations by NCCN, ACS, and USPSTF (55.36%-81%) compared with OB (45.74%-68.3%), and FM physicians (45.88%-68.6%), (p<0.001). No patients had documented risk-based BC screening even among those found to be high-risk.

**Conclusions**: BC risk assessment, risk-based screening, and use of BC chemoprevention is not adequately practiced by primary care providers. Primary care providers' adherence to BC screening recommendations was closest to USPSTF guidelines (68.3% to 81.1%) and did not follow risk-based screening recommendations. Rates of adherence to chemoprevention and mammogram screening recommendations approximated national data.

Title: Bilateral breast cancer in China: A 10-year single-center retrospective study

Huiping Li1, Hanfang Jiang1, Ruyan Zhang1, Bin Shao1, Ying Yan1, Ran Ran1 and Lijun Di1. 1Peking University Cancer Hospital & Institute, Beijing, China.

Body: BACKGROUND: Women with unilateral breast cancer are at increased risk for developing contralateral disease. The objective of the single-center retrospective study was to evaluate the incidence of bilateral breast cancer (BBC) and to analyze the clinicopathological characteristics for BBC in China.

METHODS: We retrospectively reviewed the electronic medical records of 3924 female patients with breast cancer consecutively treated at the department of Breast Oncology in the Peking University Cancer Hospital between 2006 and 2016. BBC was categorized as synchronous (within 6 months) or metachronous bilateral breast cancer (after 6 months of a first tumor). Patients with BBC were identified according to the criteria described by Chaudary et al. Patients with stage IV first breast cancer, and those who were found to have distant metastases between the first and second primary breast cancer were excluded. Analyses of demographic, clinicopathologic, and treatment characteristics were done between sBBC and mBBC.

RESULTS: The incidence of BBC in our population was 3.2% (127 of 3924). Of those, 2.5% (99 of 3924) were metachronous bilateral breast cancer (mBBC), and 0.71% (28 of 3924) were synchronous bilateral breast cancer (sBBC). The overall median age of the patients at first diagnosis was 45 years (range, 27-81 years). The age of onset of the first mBBC was significantly younger than that of sBBC (p = 0.027). In mBBC subgroups, the median time interval between first and second tumors was 68 months (range, 7-342 months), and 80.8% of the second tumor were diagnosed within 10 years of the diagnosis of the first tumor. A positive family history of breast cancer was found in 25% of sBBC and 9.1% of mBBC (p = 0.025). In ER-negative first tumor of mBBC, 56.1% of the second tumor were ER-positive. Mastectomy was the commonest surgery performed in these patients.

CONCLUSIONS: Our results confirmed the necessity of screening contralateral breast at the diagnosis of unilateral breast cancer and following-up for Chinese patients with breast cancer.
Body: Background: Despite available treatment for early-stage breast cancer (BC), 15%-25% of patients with early-stage human epidermal growth factor receptor 2–positive (HER2+) BC eventually experience recurrence after initial treatment. The prognosis for women with HER2+ disease recurrence is poor. Most recurrences involve incurable metastatic disease. In the US, the total cost to society attributable to metastatic BC of any subtype was $12.2 billion accrued over 5 years, or $2.4 billion per year ($98,571 per patient-year). Treatment-related cost, 57% of total costs, was the largest contribution, with over $1.0 billion per year. The purpose of this study was to assess the clinical and economic burden of recurrence in patients with early-stage HER2+ BC.

Methods: We conducted two systematic literature reviews (SLRs) and one targeted literature review (TLR) in PubMed, Embase, and Cochrane databases. The SLRs (no publication date limit; clinical SLR conducted on November 8, 2016; economic SLR conducted on October 25, 2016) searched for randomized clinical trials of neratinib and other treatments and economic data (models, utility, resource use, and cost), and the TLR (publications published from January 2006 to September 2016) searched for burden-of-illness studies in early-stage HER2+ BC.

Results: A total of 4,708 abstracts (2,649 clinical SLR; 969 economic SLR; 1,090 TLR) were identified from all searches, and full-text review was conducted for 796 articles (507 clinical SLR; 151 economic SLR; 138 TLR). Of these, 159 (72 clinical SLR; 33 economic SLR; 54 TLR) followed protocol-specified criteria for inclusion. Based on clinical trials in the neoadjuvant and/or adjuvant setting, disease-free survival rates at 4 years ranged from 78% to 90%. HER2-targeting adjuvant regimens such as lapatinib added to trastuzumab and extending trastuzumab to 2 years have been unsuccessful in reducing the risk of recurrence. Women who had a recurrence, regardless of HER2 status, reported significantly poorer functioning on various quality of life (QoL) domains compared with women who remained disease free. All patients with early-stage BC, regardless of HER2 status, diagnosed with their first recurrence experienced cancer-related distress and no improvement in QoL (physical health and functioning) after 1 year. In the US, the total expected per-patient costs for all BC, regardless of HER2 status, over 10 years was $53,454 with metastatic recurrence, $61,601 with locoregional recurrence, and $61,188 with contralateral recurrence as compared with $42,005 (background costs) with no recurrence (2004 US $). The overall cost of recurrence in women with HER2+ BC in the US was estimated to be $240 million to $1.7 billion over the lifetimes of each 1-year cohort of 7,298 patients (2008 US $).

Conclusions: These results identified few studies on patients with early-stage HER2+ BC and suggest that future studies are warranted. Recurrence in women with HER2+ BC is associated with decreased QoL and high costs. After adjuvant therapy, there is still risk of recurrence, thus the clinical and economic burden remains. There is an unmet medical need in early-stage HER2+ BC, and new therapies are needed to reduce the risk of recurrence.

**Title:** Stellate cells and mesenchymal stem cells in benign mammary stroma are associated with risk factors for breast cancer

Håkan L Olsson¹², Bjorn L Isfoss¹, Bo Holmqvist¹ and Helena Jernstrom². ¹Clinical Sciences, Lund University, Lund, Sweden and ²Clinical Sciences, Lund University, Lund, Sweden.

**Body:**

**Background:** It is not known whether stromal cells in benign breast tissue can mediate risk of breast cancer. We recently described aldehyde dehydrogenase 1 A1 (ALDH1) positive (+) cells in morphologically normal breast stroma of premenopausal women, and the data indicated that their distribution is associated with clinical risk factors for breast cancer. The aim of the present study was to define the identities of these cells using histological and immunohistological methods, and to investigate associations between those cells and hormonal and genetic risk factors in pre- and postmenopausal women.

**Methods:** Stroma of morphologically normal tissue was analyzed in samples from 101 well-characterized women whose breasts had been operated. Morphology and immunolabeling were applied to determine cell identities based on the putative stem cell markers ALDH1 and stage-specific embryonic antigen-3 (SSEA3), and immunophenotypes indicating mast cells or stellate cells. The results were compared with the patients' risk factors using regression analysis (two-tailed).

**Results:** ALDH1+ round/oval cells were associated with low parity in BRCA1/2 carriers ($p = 0.022$), while in non-BRCA1/2-carriers they were negatively associated with nulliparity ($p = 0.057$). In premenopausal women ALDH1+ round/oval cells were associated with family history ($p = 0.058$). SSEA3+ round/oval cells were morphologically and immunohistologically consistent with multilineage stress-enduring (Muse) cells, and these cells were independently associated with the breast cancer risk factors low parity ($p = 0.015$), family history ($p = 0.021$), and hormone use after menopause ($p = 0.032$). ALDH1+ spindle-shaped/polygonal cells were immunohistologically consistent with stellate cells, and were negatively associated with family history of breast cancer ($p = 0.001$).

**Conclusion:** This study identified novel stromal cell types in benign breast tissue that have a potential for stratifying women for breast cancer risk.

Title: Competing mortality risks: Cardiovascular risk versus risk of metastatic disease in breast cancer patients receiving adjuvant therapy

Lisa Prior1, Hannah Featherstone1, Killian Nugent1, Marvin Lim1 and Catherine Kelly1. 1Mater Misericordiae University Hospital, Dublin, Ireland.

Body: Background
Breast cancer is the most commonly diagnosed cancer in women in Ireland. The 5 year net survival is over 80%. Most women diagnosed with breast cancer do not die from the disease and instead cardiovascular disease (CVD) remains the most frequent cause of death. Many breast cancer patients are older and have established CVD risk factors. They are at further risk of a cardiovascular (CV) event due to exposure to anthracyclines, HER2 targeted agents, endocrine therapy and radiotherapy. In this study, we aimed to compare the 10 year risk of breast cancer mortality versus that of a CV event or death in an oncology day ward population at our centre through the use of online prognostic risk calculators. Furthermore, we sought to investigate the predicted outcome of lifestyle changes on their overall CV risk and level of interest in addressing these risk factors.

Methods
This was a cross cohort study of all breast cancer patients attending for adjuvant chemotherapy at our institution from September 2015 to September 2016. To calculate patients’ 10 year CVD risk, we used the JBS3 online calculator. Using this calculator we could also predict patient’s lifetime CV risk. To calculate patients’ 10 year mortality risk from breast cancer we used NHS predict! These calculators incorporate several variables which we identified from chart review, the use of questionnaires and the performance of a serum lipid test.

Results
101 subjects were identified. All patients (pts) completed questionnaires. Eighteen pts were excluded from CV risk analysis due to lack of lipid profile. Of 83 pts, 83% (n=69) were >50 years of age and 17% (n=14) pts were <50 years of age. The median age in the >50 age group (grp) was 59 and 42 in the <50 age grp. The median BMI in the >50 and <50 grp was 29.2 and 26.4 respectively. Forty-two percent (n=29) of pts in the >50 grp were smokers/ex smokers and 49% (n=7) were in the <50 grp. Twenty-nine percent (n=20) in the >50 grp were on statins and 25% (n=17) were on antihypertensives. Fifty-two percent (n=36) of pts in the >50 grp and 66% (n=10) received anthracyclines. Fifty percent in both grps received left sided radiotherapy. Ninety five percent (n=63) were on endocrine therapy in the >50 grp and 93% (n=13) in the <50 grp. Forty-one percent in the >50 grp (n=28) and 29% (n=4) of patients in the <50 grp received Trastuzumab. In the >50 grp, 13% (n=9) were found to have a high 10 year cardiovascular risk (>20% risk of CV event) and 28% were found to be at moderate risk (n=19). Ten percent of patients were found to have a CV risk that exceeded their breast cancer mortality risk (n=7). Even though the 10 year CV risk was low in patients <50, their median lifetime risk was calculated at 52%. Eighty seven percent of pts were interested in receiving advice on reducing their cardiovascular risk. The predicted median 10 year cardiovascular risk of age>50 patients in the high risk group post CV risk modification was 8.8% (+/-5.6) versus 28% (+/-8) at baseline.

Conclusion
This patient population has significant CV risk factors at baseline. Benefits predicted with CV risk intervention model and significant patient interest indicates that formalised CV risk prevention strategy is needed.
Body: Background/Objective: Biomarkers such as estrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor 2 (HER2neu) are associated with the survival and recurrence of invasive breast cancer (IBC). Presence of these markers often helps to dictate treatment plans. The purpose of this study is to identify the predictors of overall survival (OS) and disease-free survival (DFS) for women diagnosed with IBC. In this study, we compared OS and DFS in the following five categories based on biomarker expression: triple-negative (TN), triple-positive (TP), HER2neu-positive, Luminal A (LA) and Luminal B (LB).

Method: We retrospectively examined 6,231 records of women diagnosed with IBC from 2006 through 2015 within the Aurora Health Care system. The majority of the women were white (90.8%) and non-Hispanic (97.4%). The women in this study were categorized in the age groups: 20-39 (4.9%), 40-59 (42.8%), 50-69 (40.7%) and 70+ years (11.6%). We used descriptive statistics for all category and numeric variables. Kaplan-Meier curve was used to compare OS and DFS in the five categories. Cox proportional hazards regression was used to identify the significant predictors of OS and DFS. We used alpha of 0.05 for all statistical tests and all statistical analysis was done using SAS 9.4.

Results: OS was 86.39% and the DFS rate was 84.43%. In multivariate analysis significant predictors of OS included age (HR=1.94 for 60-69 vs 20-39 p=0.001 and HR=5.3 for 70+ vs 20-39 p<0.001), race (HR=0.57, p=0.043 for white vs other), ethnicity (HR=0.34, p=0.032), HER2neu expression (HR=0.58, p <0.001), size of the tumor (HR=1.001 p=0.011), grade differentiation (HR=0.62 p < 0.001) and cancer stages (HR of 1.17, 4.8, 15.2 for II, III and IV vs I, p<0.001). Furthermore treatments such as surgery (HR=0.64, p< 0.001), chemotherapy (HR=0.63, p <0.001) and hormonal therapy (HR=0.48, p <0.001) showed significantly improved OS in the patients. Similarly significant predictors of DFS included, age (HR=1.8, p <0.001 for 70+ vs 20-39); PR (HR=0.70, p=0.003), HER2neu (HR=0.60, p <0.001) tumor size (HR=1.001, p=0.002), cancer stage (HR=2.7, 9.2, 25.5 for II, III, IV vs I, p<0.001); differentiation of the tumor (HR=0.75, p=0.002, moderate differentiation; well differentiated, HR=0.50, p <0.001). Moreover, the treatments such as surgery (HR=0.42, p <001) radiation, chemotherapy and hormonal therapy (HR=0.58, 0.62, 0.51 p <0.001) significantly increased DFS. Furthermore OS was better for women diagnosed with TP, LA, HER2, LB types compared to women with TN (p<0.001). Similarly the probability for DFS was higher for TP also was higher compared to the probabilities all the other categories (LA, LB, HER2 and TN p <0.05). LA had better DFS then LB, HER2 and TN. LB and HER2 had better DFS than TN (p<0.05).

Conclusion: This large study suggests that treatment based on biomarker expression (ER, PR and HER2/Neu) has improved OS and DFS for women with IBC. Increase in tumor size, cancer stage and poor differentiation of the tumor had adverse effect on both OS and DFS. Treatment modalities such as surgery, radiation, chemotherapy and hormonal therapies significantly improved both OS and DFS.
Title: Factors associated with mammographic density in Japanese women

Ken Uchida¹, Hitoshi Ohashi¹, Nogi Hiroko² and Rei Mimoto². ¹Shinjuku Medical Center, Shinjuku-ku, Tokyo, Japan and ²The Jikei University School of Medicine, Minato-ku, Tokyo, Japan.

Body: Background: Increased mammographic breast density decreases the sensitivity and the specificity of mammography screening and is associated with a significant risk factor for breast cancer. No studies were identified that examined the impact of supplemental screening on breast cancer recurrence rates or mortality for women with dense breasts. The aim of this study is to examine factors associating with breast density in Japanese women.

Data sources and methods: We used mammography check-up participants (n=5159, women aged 40 years or older) between Apr 2014 and Mar 2017 as our baseline data. Using a self-administered questionnaire, data of life style were collected. Logistic regression was used to estimate the odds of having dense breasts by age, body mass index (BMI), alcohol consumption, smoking, parity, menopausal status, dysmenorrhea, hormone replacement therapy (HRT), family history of breast cancer, physical exercise, fried foods intake, brightly colored vegetables intake, coffee intake, tea intake and bone mineral density. Breast densities were divided into four categories based on BI-RADS classification. BI-RADS 3 and 4 were defined as dense breast. All statistical tests were two-sided.

Results: Dense breast accounted for 62.3% of mammography screening participants. Dense breast at an early age was more frequent as 78.0% in the 40's. Alcohol intake (20 g or more a day, OR=1.62, 0.026) in post-menopausal women showed statistically significant positive interaction with dense breast. Weak positive interaction was seen in bone mineral density>80% (OR=0.63, 0.086, n=775). On the other, age (OR=0.97, <0.001), BMI (OR=0.78, <0.001), number of live birth (one; OR=0.77, <0.030, two or more; OR=0.37, <0.001) and post-menopause (OR=0.60, <0.001) showed statistically significant negative interactions with dense breast.

Conclusion: Dense breast accounted for 62.3% of all participants. Dense breast was more frequent at early age as 78.0% in their 40's. Alcohol consumption and bone mineral density in post-menopausal women were positive interaction with mammographic breast density. On the contrary, age, BMI, number of live birth and post-menopause were negative interaction with mammographic breast density.
Title: Treatment patterns for young women with HR+/HER2- metastatic breast cancer in the United States in the era of CDK 4/6 inhibitors

Harold J Burstein1, Erica L Mayer1, Angela DeMichele2, James Harnett3, Jack Mardekian3, Lynn McRoy3, Cynthia Huang Bartlett3, Maria Koehler3 and Mothaffar Fahed Rimawi4. 1Dana Farber Cancer Institute, Brigm and Women’s Hospital, Harvard Medical School, Boston, MA; 2Perelman School of Medicine University of Pennsylvania, Philadelphia, PA; 3Pfizer, Inc, New York, NY and 4Dan L Duncan Cancer Center at Baylor College of Medicine, Houston, TX.

Body: Background: NCCN guidelines recommend that premenopausal women with HR+/HER2- metastatic breast cancer (MBC) be rendered postmenopausal and then treated accordingly. After its approval in February 2015, the CDK4/6 inhibitor palbociclib (P), in combination with endocrine therapy (ET), has become a standard of care in the first-line or pretreated settings for women with HR+/HER2- MBC. Specialty pharmacy prescription data indicate that 12% of all women with HR+/HER2- MBC treated with P in the United States are younger than 50 years of age. We assessed the real world treatment patterns and outcomes before and after approval of P in women with HR+/HER2- MBC. We further sought to assess the impact of the NCCN guidelines for premenopausal women on treatment patterns and outcomes.

Methods: This retrospective cohort study utilized electronic health record (EHR) data from Flatiron Health (Fl) from 1/2012 through 4/2017 to evaluate patient characteristics and first-line ET treatment patterns among women with HR+/HER2- MBC prior to and after P approval. Menopausal status was defined by age (< 50 vs >50 yrs). Additional datasets of > 13,000 pts with MBC in the Truven Health MarketScan and Optum Clininformatics claims and Humedica EHR databases will be included to represent a more comprehensive dataset and evaluate clinical outcomes.

Results and Discussion: Initial results include 4,537 pts in the Fl database who initiated a first-line ET regimen. Overall, 30% of pts < 50 yrs used P compared to 29% of women age >50. Treatment patterns for initial endocrine therapy are shown in the table.

</tbody>
</table>

Decreased use of tamoxifen as 1st line ET was observed in pts < 50 yrs over the observed time. 47% of young pts initiated endocrine based treatment with AI monotherapy in the pre-P era, consistent with the NCCN guidelines. About 26% (pre-P) and 34% (post-P) of pts ≤50 yrs initiated first ET with ovarian suppression in the analyzed treatment eras. The concurrent use of LHRH increased 8%.

Conclusions: The treatment paradigm for women with HR+/HER2- MBC has evolved over the last >5 years. Consistent with NCCN guidelines, more young pts are receiving ovarian suppression as part of initial therapy, and pts regardless of age are receiving treatment with P. There has been a related decrease in use of tamoxifen for younger pts and overall. These data illustrate rapid incorporation of palbociclib into standard care for US pts with HR+/HER2- MBC. Further treatment patterns and
therapy outcome data for these groups reflecting real world use ET regimens of over 17,000 pts in the combined cohort, will be reported.
Title: A randomized phase II trial of toremifene (120 mg) versus fulvestrant (500 mg) after prior non-steroidal aromatase inhibitor in postmenopausal women with hormone receptor-positive metastatic breast cancer (Hi-FAIR fx study)

Reiki Nishimura, Yutaka Yamamoto, Kazutaka Narui, Yuko Kijima, Yasuo Hozumi, Masahiko Ikeda, Shintaro Takao, Shoichiro Ohtani and Hirotaka Iwase. 1Kumamoto Shinto General Hospital, Kumamoto, Japan; 2Graduate School of Medical Sciences, Kumamoto University, Kumamoto, Japan; 3Yokohama City University, Yokohama, Japan; 4Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, Japan; 5Ibaraki Clinical Education and Training Center, Faculty of Medicine, Tsukuba University/Ibaraki Prefectural Central Hospital, Kasama, Japan; 6Fukuyama City Hospital, Fukuyama, Japan; 7Hyogo Cancer Center, Akashi, Japan and 8Hiroshima City Hiroshima Citizens Hospital, Hiroshima, Japan.

Body: Background: After the failure of a non-steroidal aromatase inhibitor (nsAI) for postmenopausal patients with advanced/metastatic breast cancer (BC), it is unclear which of the various kinds of endocrine monotherapy is the most appropriate. In a previous report it was found that toremifene 120 mg (TOR 120), a selective estrogen receptor modulator (SERM), was superior to steroidal AI in terms of progression-free survival after ns-AI in the Hi-FAIR ex trial. A phase II randomized trial of TOR 120 versus fulvestrant 500 mg (FUL 500), a selective estrogen receptor down regulator (SERD), was also conducted to select the most promising endocrine monotherapy after ns-AI in advanced/metastatic BC (Study registry number: UMIN000010087).

Patients and Methods: Postmenopausal women (n=106) with advanced/metastatic hormone-receptor positive BC from October 2011 to September 2014 were enrolled in this study. Fifty-three of the patients were randomly assigned to the TOR 120 (120 mg daily p.) group and 53 of the patients were randomly assigned to the FUL 500 group. In the FUL 500 group they were administered 500 mg of fulvestrant intramuscularly (im) on day 0, then 500 mg im on days 14 and 28 and every 28 days thereafter. If treatment failure occurred in either of the randomly assigned groups the patients were then removed and treated accordingly. A full analysis set was targeted for all cases that received the protocol treatment even once (TOR 120 (n=53) and FUL 500 (n=52)). The primary end point was the clinical benefit rate (CBR). The secondary end points were the objective response rate (ORR), progression-free survival (PFS), time to chemotherapy (TTCT), overall survival (OS), toxicity, and CBR, ORR and PFS after crossover of non-assigned treatment.

Results: A median follow up period of 30 months revealed that the CBR of FUL 500 (57.7%) tended to be superior to the CBR of TOR 120 (45.3%), the odds ratio (OR) was 1.70 (95% CI 0.74–3.62), and the median PFS was 7.8 months in the FUL 500 group and 5.8 months in the TOR 120 group. Moreover the hazard ratio (HR) was 0.79 (95% CI 0.52–1.21). However, there was no difference between the two groups in terms of ORR (17.7% and 15.1%, respectively), TTCT (13.3 months vs. 17.7 months, HR = 0.94 (95%CI 0.57 – 1.53)), and OS (33.4 months vs. not reached HR 1.29; 95% CI 0.80–2.09). At the cross-over phase, 33 and 24 patients after failure of assigned treatment were treated with FUL 500 and TOR 120, respectively. The CBR and PFS of FUL 500 after TOR 120 was better than that of TOR 120 after FUL 500 (CBR; 42.4% vs. 20.8%, OR = 0.33, 95%CI 0.09 – 1.11, median PFS; 6.2 months vs. 3.4 months; HR = 1.95, 95%CI 1.08–3.51). No difference between the two groups was observed in PFS from randomization to the end of the crossover phase. Moreover, there were few severe adverse events in either of the two groups.

Conclusions: FUL 500 used as a subsequent endocrine therapy for advanced/metastatic BC patients who failed ns-AI could potentially be more effective than TOR 120. However, the efficacy of SERM after failure of FUL 500 may be limited.
Title: The impact of dose delays and reductions on toxicity and progression free survival (PFS) in patients receiving palbociclib

Katherine K Clifton, Jaime Kimmel, Min Yi, Barnett Chad, Jennifer Litton, Tripathy Debu and Karuturi Meghan. MD Anderson Cancer Center, Houston, TX.

Body: Background: Despite the high rates of neutropenia observed in the PALOMA studies, the incidence of neutropenic fevers remained low. The safety analysis from the PALOMA-3 trial showed no difference in PFS among pts who had dose reductions or delays secondary to neutropenia. We conducted a retrospective study to analyze the impact of dose delays and reductions on toxicity and progression free survival (PFS) in pts receiving palbociclib as standard of care.

Methods: Pts with metastatic ER positive breast cancer receiving palbociclib in any line of therapy were identified from a cohort at MD Anderson Cancer Center. Clinical, demographic, baseline labs, comorbidities and recurrence data were collected. Dose delays, dose reductions, and toxicities were recorded up to the first 6 cycles of palbociclib. Early dose delays and reductions were defined as events occurring during the first 2 cycles of palbociclib while late events were defined as cycles 3-6. Data was analyzed using Fischer’s exact test for categorized variables and T test/Wilcoxon rank-sum test for continuous variables. PFS was analyzed using the Kaplan Meier method and Cox model was used to analyze factors associated with PFS.

Results: 344 pts who met eligibility criteria were included in the analysis. Pts receiving palbociclib on clinical trial were excluded. 109 (31.6%) pts received dose reductions and 153 (44.4%) experienced dose delays. The rate of neutropenic fever was low, occurring in 2.3% of all pts. There was a significant association between pts experiencing dose reductions and Hispanic race, baseline ANC, history of adjuvant endocrine therapy, adjuvant radiation therapy (XRT), and heart disease. History of adjuvant XRT, baseline ANC, and heart disease were associated with dose delays. Toxicities, including neutropenic fever, infections requiring antibiotics, and hospitalizations, were associated with dose reductions and dose delays. Median PFS for the cohort was 263.5 days. There was no significant association between early dose reductions or delays with PFS. Pts experiencing late dose delays (hazard ratio [HR], 0.4, P=0.0001) and reductions (HR, 0.4, P=0.0005) had a significantly longer PFS. Median PFS for pts without late dose delays was 228 days compared to 313.5 days for pts with late dose delays. Median PFS for pts without late dose reductions was 246 days compared to 305.5 days for pts with late dose reductions. In the multivariable analysis, liver metastasis, metastatic line, and higher tumor grade were associated with worse PFS. Pts receiving palbociclib and fulvestrant were found to have worse PFS than pts receiving palbociclib and letrozole.

Conclusions: Similar to the PALOMA trials, this study found that while the rate of toxicities such as neutropenic fever were low, dose reductions and delays were common. In pts receiving palbociclib as standard of care, pts with late dose reductions and delays had a longer PFS than those without dose reductions and delays. It is reassuring that the PFS was not negatively affected in pts with dose reductions and delays. As use of palbociclib as standard of care becomes more common, further larger retrospective studies are warranted to examine the impact of dose delays and reductions.
Title: Phase I/II trial of palbociclib in combination with bicalutamide for the treatment of androgen receptor (AR)+ metastatic breast cancer (MBC)

Ayca Gucalp¹, Marcia Edelweiss¹, Sujata Patil¹, Mrinal M Gounder¹, Kimberly N Feigin¹, Adriana Corben², Artavazd Arumov¹ and Tiffany A Traina¹. ¹Memorial Sloan Kettering Cancer Center and ²Icahn School of Medicine at Mount Sinai.

Body: Background: The androgen-signaling pathway plays a role in breast cancer (BC) pathogenesis and emerging evidence suggests the androgen receptor (AR) is a therapeutic target. TBCRC011 established safety and efficacy of inhibiting AR with bicalutamide (B) in patients (pts) with androgen AR+/ER/PgR- metastatic BC (MBC). Treatment with B at 150 mg oral daily demonstrated a clinical benefit rate (CBR) of 19% in this population. The rationale for combining palbociclib (P) with AR blockade stems from prior work in ER+ MBC. P is an oral, selective inhibitor of CDK4/6 activity which significantly improved median progression-free survival (PFS) in combination with letrozole compared to letrozole monotherapy for the treatment of postmenopausal pts with ER+ MBC in the first-line setting. Consistent with preclinical data, P has been shown to reduce growth of AR+ ER/PgR- MDA-MB-453 breast cancer cells via reduced Rb phosphorylation. It has been shown that AR+ TNBC expresses a luminal profile and has intact Rb protein, the target of palbociclib activity. Therefore, we hypothesize that P will increase the efficacy of B in pts with metastatic AR+ TNBC. NCT02605486.

Methods: Pts with AR+ (IHC ≥ 1%)/ER any/HER2(-) MBC on central review at MSK were eligible if met following criteria: ECOG ≤ 2, postmenopausal, no limit to prior regimens. Pts with ER+ BC must have had 1 prior endocrine therapy. Treatment: B orally daily and P orally daily 3 weeks on 1 week off. DLT period = 28 days. Pts are evaluated for toxicity every 2-4 weeks and for response every 8 weeks. Phase I standard 3+3 design with 3 dose escalations. The primary objective of the phase I portion of the study is to determine the recommended phase II dose of P in combination with B. Plasma for pharmacokinetics (PK) was collected throughout the study.

Results: As of 5/11/17, 15 pts with AR+ MBC were enrolled to the phase I portion. Target accrual has been met for the phase I and has since closed. No DLTs were reported in any of the dose escalation cohorts. The maximum tolerated dose was determined to be B 150 mg daily and P 125 mg daily for 21 days in a 28 day cycle. Treatment has been well tolerated with no related Grade 4 or 5 adverse events (AEs). The most common grade 3 significant AEs were hematologic including neutropenia n=5, leukopenia n= 4, and lymphocytopenia n=3 and thought to be related to P. One Grade 4 hypercalcemia led to hospitalization and was deemed related to disease progression. Median time on study was 8 weeks (2-47 weeks). One patient from the phase I remains on study. PK analysis is ongoing and will be presented, including drug-drug interaction data.

Conclusions: The combination of B+P has been well tolerated with no unexpected toxicity observed. Updated safety, response, and PK data will be presented. Enrollment on phase II is ongoing.
Title: Everolimus-exemestane (EE) vs palbociclib-fulvestrant (PF) or abemaciclib-fulvestrant (AF) or everolimus-fulvestrant (EF) in the treatment of metastatic HR+, HER2- metastatic breast cancer and prior aromatase inhibitors treatment. An indirect comparison with network meta-analysis

Lorenzo Gianni, Valentina Arcangeli, Caterina Gianni, Lucia Stocchi, Lorenzo Menghini, Domenico Samorani, Claudio Ridolfi, Tamburini Emiliano and Davide Tassinari. 1Infermi Hospital, AUSL Romagna, Rimini, RN, Italy; 2Servizio di Diagnostica Senologica e Prevenzione, Infermi Hospital, AUSL Romagna, Rimini, RN, Italy and 3UO General Surgery, Franchini Hospital, AUSL Romagna, Santarcangelo di Romagna, RN, Italy.

Body: Background. Treatment options for patients with hormone receptor positive metastatic breast cancer (MBC) and prior treatment with aromatase inhibitors (AIs) include EE or PF. To date no direct comparison has been presented between EE and Fulvestrant plus Cyclin-dependent Kinase 4/6 (CDK4/6) inhibitors in this setting. The objective of this study was to compare the efficacy of EE to PF or AF or EF in the treatment of metastatic HR+, HER2- breast cancer pre-treated with AIs.

Methods. An indirect comparison with a network meta-analysis comparing EE with PF or AF or EF in the treatment of metastatic HR+, HER2- breast cancer pre-treated with AIs was performed. The Progression-Free-Survival (PFS) was the primary end point of all our indirect comparisons. Efficacy data were expressed as Hazard Ratio (HR) and 95% Confidence Interval (95CI), assuming an α-error of 5% as index of statistical significance.

Results. All the data of the BOLERO-2 trial, the Bachelot et al network meta-analysis (Breast Cancer Treat Rep 2014), the Paloma-3, the Monarch-2, and the prECOG trials were analyzed and indirectly compared in a network meta-analysis. 6 orders of comparison were performed: AF vs PL, PF vs EE, AF vs EE, EF vs AF, EF vs PF and EF vs EE. The pooled HR and 95%CI are reported in table1.

Table 1: difference in PFS between comparators

</tbody>
</table>

Conclusions. Till today EE and PF represent active and approved treatments for patients with metastatic HR+, HER2- breast cancer treated with AIs. The results of Monarch-2 study with AF vs Fulvestrant and prECOG study with FE vs Fulvestrant were recently presented and were included in this metaanalysis, while the results of Ribociclib and Fulvestrant vs Fulvestrant (Monaleesa-3 study) are not currently available.

These studies generally show that combination of hormone therapies with Everolimus or CDK4/6 inhibitors are better than hormone-therapy alone, however no direct comparisons between these treatment combinations exist in literature. The results of our indirect treatment comparisons suggests that EE is similar and, in some cases, it may be even better than other treatment options. The optimal treatment strategy and sequence for patient with MBC and prior treatment with AIs should be evaluated in clinical trials. Meanwhile these data could be considered together with safety and the economic profile to help physicians in daily clinical practice.
Title: A phase 1 study of KHK2375 (entinostat) as monotherapy and in combination with exemestane in Japanese patients with hormone receptor-positive, HER2-negative, advanced or recurrent breast cancer

Akihiko Shimomura¹, Norikazu Masuda², Kenji Tamura¹, Hiroyuki Yasojima², Masataka Sawaki², Yozo Nishimura⁴, Shigehira Saji⁵ and Hiroji Iwata³. ¹National Cancer Center Hospital, Tokyo, Japan; ²National Hospital Organization Osaka National Hospital, Osaka, Japan; ³Aichi Cancer Center Hospital, Nagoya, Japan; ⁴Kyowa Hakko Kirin Co., Ltd., Tokyo, Japan and ⁵Fukushima Medical University, Fukushima, Japan.

Body: Background: Patients (pts) with hormone receptor-positive (HR+) and non-life threatening advanced or metastatic breast cancer (BC) are usually treated with sequential endocrine therapies. Endocrine therapies are continued until tumor cells acquire resistance to them, following which pts are switched to cytotoxic chemotherapy. Entinostat (ENT) is an oral inhibitor of class I histone deacetylases (HDACs) and is expected to be used for endocrine therapy-resistant pts. The efficacy of ENT in combination with an aromatase inhibitor (AI) for HR+ BC was demonstrated in a previous randomized phase 2 study. Because of the lack of data on safety and pharmacokinetics (PK) in Japanese HR+ BC pts, we performed this dose escalation phase 1 study to investigate the safety of ENT monotherapy and combination therapy with exemestane (EXE) in postmenopausal women with advanced or recurrent HR+ BC. Secondary objectives were to assess PK and efficacy.

Methods: This study was based on a 3+3 dose escalation design. Postmenopausal women with advanced or recurrent HR+ HER2- BC previously treated with nonsteroidal AIs and with ECOG PS 0-1 were enrolled. The dose limiting toxicities (DLT) of ENT monotherapy (3 mg/qw, 5 mg/qw, or 10 mg/q2w) in Cohort 1-3 and those of ENT (5 mg/qw or 3 mg/qw) in combination with EXE 25 mg/qd in Cohort 4-5 were assessed for 7 and 28 days, respectively. Pts continued ENT (3 mg or 5 mg) in combination with EXE even after the DLT observation period until disease progression or discontinuation for other reasons. Adverse events (AEs) were graded per NCI-CTCAE version 4.03. Tumor response was evaluated by RECIST version 1.1 every 8 weeks. ENT concentration was measured intensively. Samples of peripheral blood mononuclear cells (PBMC) were collected to measure protein lysine hyperacetylation and for immune subset analysis. Optional tumor biopsies for biomarker assessment were collected before and during treatment.

Results: Twelve pts were enrolled and three each were assigned to Cohort 1-4 between Nov 2015 and Sept 2016. Neither DLT nor grade 3-5 AE occurred. As no DLT occurred in Cohort 4, Cohort 5 was omitted as originally planned. The drug-related AEs observed in ≥2 pts during the DLT observation period were grade 1-2 hypophosphatemia (1 pt each in Cohort 2, 3, and 4), grade 1 nausea (1 pt in Cohort 3 and 2 pts in Cohort 4), and grade 1-2 platelet count decreased (2 pts in Cohort 4). AUC₀-₁₆₈ increased in a dose proportional manner. As of May 2017, 4 pts continue to receive study treatment, including one treated for more than 18 months. Biomarker data including protein lysine hyperacetylation and immune subset in PBMC and results of paired biopsy samples will be reported.

Conclusions: This study showed the tolerability of the combination therapy of ENT 5 mg with EXE 25 mg in Japanese pts. There were no new safety concerns as compared to those reported previously. Following this result, a randomized phase 2 study for Japanese pts is planned.

Clinical trial information: NCT02623751.

**Body:**

**Background**

For breast cancer patients with metastases which are not life threatening national and international guidelines recommend the exhaustion of all antihormonal therapeutic options before recommending chemotherapy. In Germany up to now only everolimus was an additional option to overcome endocrine resistance. CDK4/6 inhibitors recently became available in Germany (Nov 2011). Aim of this analysis was the identification of predictors for a decision against an antihormonal treatment.

**Methods**

The PRAEGNANT metastatic breast cancer registry (NCT02338167) is a prospective registry for metastatic breast cancer patients. Besides biomarker research the description of real-world treatment data was one of the main study aims. This analysis was restricted to first line metastatic patients who were hormone receptor (HR) positive and HER2 negative. First, predictors were identified with a multiple logistic regression model. Then patients, who received chemo or not, were compared with regard to overall survival using Cox regression analysis with the predictors for chemotherapy from above and additionally chemo status (yes/no).

**Results**

A total of 389 HR-positive and HER2-negative patients with detailed treatment information were included during the 1st line therapy into PRAEGNANT. Of those 173 (44.5%) received a chemotherapy, 190 an antihormone therapy (AHT) (48.8%), and 26 (6.7%) everolimus+AHT. In the multiple logistic regression model, older patients, lower graded tumors, bone only disease and previous adjuvant chemotherapy were associated with a lower rate of first line chemotherapies. BMI and number of concomitant diseases had an influence with patients having a G1, G2 and G3 tumor receiving 1st line chemo in 28.0%, 38.4% and 63.2% of the cases respectively. Patients who received chemo seemed to have a worse overall survival than patients who did not receive chemo (adjusted HR 1.58; 95% CI, 0.89 to 2.18). However, this result was not significant (p = 0.12). Overall survival was primarily influenced by ECOG and location of metastasis.

**Conclusion**

The usage of chemotherapy can be predicted with age, metastasis pattern, grading and previous use of chemotherapy. However, we could not show that patients benefited from chemotherapy. On contrary, there was a tendency that patients treated with...
chemotherapy had poorer overall survival. Further studies with larger sample sizes are needed to confirm this claim.
Population characteristics and utilization patterns of patients treated with palbociclib over 2 years of post-approval

Background: Palbociclib (PAL) was the first-in-class cyclin dependent kinase (CDK) 4/6 inhibitor approved in the United States (US) in combination with an aromatase inhibitor [AI] or fulvestrant for the treatment of HR+/HER2- advanced/metastatic breast cancer (ABC/MBC) as initial or later-line endocrine therapy (ET). Over 60,000 patients have been treated in the US with PAL since its approval (02/2015). We described population characteristics and utilization patterns in patients who initiated treatment with PAL, using a real-world oncology electronic health record (EHR) database.

Methods: This was a retrospective observational study using de-identified Flatiron (FI) EHR data. As of study cutoff, the FI provider network comprises over 265 community cancer clinics and 3 academic cancer centers across 2500 clinicians and more than 1.5 million active cancer patients throughout the 50 states in the US. Adult MBC patients with a record of initiation with PAL on or after 02/03/2015 (drug approval) and prior to 03/31/2017 (study cutoff) were identified. The line of therapy (LOT) in the metastatic setting was assigned by evaluating systemic treatments (including chemotherapy) pre-and post-PAL initiation. The combination ET was defined as having a record of an ET within 28 days of the recorded order of PAL.

Results: Overall, 1871 patients were identified as having initiated PAL: 1841 (98.4%) are females and 30 (1.6%) are males. Of those females, 1057 (57.4%) received PAL with an AI and 752 (40.8%) received PAL with FUL. Mean follow-up from PAL initiation was 10.2 mos (SD: 6.7) and 36.8% were followed up for >12 mos. Mean age was 64.5 yrs (12.2% ≤50 yrs, 53.1% ≥65 yrs and 21.9% ≥75 yrs). Confirmed HR+/HER2- was observed in 85.1% of patients. Of patients with available ECOG-performance score (PS) at PAL initiation (n=1062), 82.1% had score 0/1, 14.6% had score 2, and 3.3% had score 3/4. Of patients with a known PAL starting dose (n=765), 90.6% initiated at 125mg, 6.7% at 100mg and 2.7% at 75mg. Among patients who initiated PAL with an AI, 45.7% initiated at LOT1, 23.8% at LOT2, 30.6% at LOT3+. Among patients who initiated PAL with FUL, 22.3% initiated at LOT1, 32.5% at LOT2, 45.2% at LOT3+. Among all patients who initiated PAL at LOT1 (regardless of combination partner; n=726), 65.7% used PAL with an AI. A total of 26.3% of patients received chemotherapy before PAL initiation among all females in the metastatic setting, and the most frequent ET regimen following PAL treatment is FUL alone (15.6%).

Conclusions: This study described the palbociclib population and utilization over 2+ years post-approval. Patients who initiated PAL represent the spectrum of those with HR+/HER2- MBC, including both females and males (1.6% of all PAL users). Among female patients, 12.2% were ≤50 yrs of age and 21.9% ≥75 yrs, and 17.9% had ECOG score ≥2 at initiation of PAL. Among all females treated with PAL in combination with an AI, more than 45% of patients initiated the regimen at the first line in the metastatic setting. Results with additional follow-up for the same cohort and data on real-world clinical outcomes (provided data become available) will be presented at the conference.
Title: 0.005% estriol vaginal gel in hormone receptor-positive postmenopausal women with early stage breast cancer in treatment with aromatase inhibitors (AIs) in the adjuvant setting. A phase II prospective, randomized, double-blind placebo-controlled study - “the Blissafe study”

Pedro Sánchez-Rovira¹, Angelica Lindén Hirschberg², Miguel Gil-Gil³, Silvia Antolín-Novoa⁴, Laura García-Estévez⁵, Begoña Bermejo de las Heras⁶, Jesús Presa-Lorite¹, Isabel Sánchez-Vigil de la Villa⁶, Javier Suárez-Almarza⁶ and Concepción Nieto-Magro⁶.¹ Complejo Hospitalario de Jaén, Jaén, Spain; ²Karolinska University Hospital, Stockholm, Sweden; ³Institut Català D’ Oncologia (I.C.O.), Barcelona, Spain; ⁴Complejo Hospitalario Universitario A Coruña, La Coruña, Spain; ⁵Hospital HM Universitario Sanchinarro, Madrid, Spain; ⁶Hospital Clínico Universitario de Valencia, Valencia, Spain; ⁷GEICAM - Spanish Breast Cancer Group, Madrid, Spain and ⁸ITF Research Pharma S.L.U, Madrid, Spain.

Body: BACKGROUND: 0.005% Estriol vaginal gel is a new formulation for the local treatment of postmenopausal vaginal atrophy which delivers an ultra-low dose of estriol (50mcg) per application. A study is proposed with the hypothesis that 0.005% Estriol vaginal gel is an efficacious and safe option to treat moderate to severe symptoms of vaginal atrophy caused by AIs without producing significant decline in gonadotropins or increase in systemic estrogens.

METHODS: 70 women with breast cancer receiving AIs and suffering from moderate to severe symptoms of vaginal atrophy were randomized to receive 1g of estriol gel or placebo gel (4:1) daily for 3 weeks and twice weekly up to 12 weeks. Preliminary data from an initial phase comprising 10 women treated for 3 weeks suggested that 0.005% Estriol vaginal gel did not have an influence on hypophyseal axis or estrogens. In the second study phase planned in 60 women, vaginal dryness and other symptoms and signs were analyzed with a 4-point severity scale (none, mild, moderate, severe) at baseline and at weeks 3 and 12. Estriol (E3), estradiol (E2) and estrone (E1) were analyzed by ultrasensitive LC-MS/MS assay (LOQ: 1pg/ml, 3pg/ml and 5pg/ml for E3, E2 and E1, respectively) at baseline and at weeks 1, 3, 8 and 12. FSH and LH were determined by Chemiluminiscency at the same timepoints and also at screening. Changes in vaginal parameters and hormonal levels were assessed. Adverse events were collected.

RESULTS: 61 women aged 59.2 (7.1) from 5 sites in Spain and Karolinska University Hospital in Sweden comprised the ITT analysis. At baseline, all women but one were treated with anastrozole or letrozole. One-third complained from moderate and two-thirds from severe vaginal dryness. 50 received estriol and 11 placebo. Women that received estriol slightly increased E3 levels [median (Q25-Q75)] to 3.9 (0.5-12.1), 1.9 (0.5-6.8), 0.5 (0.5-6.0) and 0.5 (0.5-7.3) pg/ml at w1, w3, w8 and w12 respectively. In these women E2 and E1 remained below LOQ in all samples but one at w12. Variation of FSH between baseline and w12 was not different from the variation of FSH before treatment (p=0.11 Wilcoxon), while small oscillations were observed between baseline and w1 and baseline and w3 as compared to FSH variation before treatment (p<0.05 Friedman, Dunn’s correction). A clinical superiority was observed at the end of treatment in women that received estriol in the improvement of their vaginal dryness, vaginal maturation value and score of vaginal signs vs those that received placebo ( p<0.01, p=0.01, p<0.01, respectively, Mann-Whitney-Wilcoxon). One serious adverse event emerged before the patient initiated treatment.

CONCLUSIONS: These data confirm the efficacy of 0.005% Estriol vaginal gel in women with breast cancer suffering from bothersome vaginal symptoms, with a transitory negligible absorption of estriol in initial weeks and a non-significant variation of FSH after 12 weeks of treatment. These findings provide confidence for the safe use of 0.005% Estriol vaginal gel in women with breast cancer with an indication for vaginal symptoms improvement.
Predictors of adherence to adjuvant endocrine therapy (ET) for early breast cancer (BC) in a prospective clinic-based cohort

Karen L Smith¹, Sri LH Yeruva², Amanda Blackford¹, Chiung-Yu Huang¹, Kelly E Westbrook³, Brennen A Harding¹, Ar’Lena Smith¹, John Fetting¹, Antonio C Wolff¹, Danijela Jelovac¹, Robert S Miller⁴, Roisin Connolly¹, Deborah Armstrong¹, Raquel Nunes¹, Kala Visvanathan¹ and Vered Stearns¹.

¹Johns Hopkins University School of Medicine, Baltimore, MD; ²Howard University School of Medicine, Washington, DC; ³Duke University Medical Center, Durham, NC and ⁴American Society of Clinical Oncology, Alexandria, VA.

Body: Background: Adjuvant ET is associated with improved survival in women with hormone receptor-positive early BC. Nonetheless, more than a quarter of women are non-adherent or discontinue therapy early. We aimed to identify whether baseline characteristics and changes in weight and patient-reported outcomes (PRO) early during the course of ET are associated with medication adherence behavior (MAB) in a prospective cohort.

Methods: We enrolled women initiating or switching adjuvant ET for stage 0-III BC in a prospective clinic-based cohort. Participants completed PRO questionnaires at baseline, and 3, 6, and 12 months (mo) after initiating ET. PRO questionnaires included FACT-ES, the NIH PROMIS measures for pain interference, fatigue, depression, anxiety, physical function, and sleep disturbance, and the MOS Sexual Functioning Scale. MAB was assessed by the Medication Adherence Questionnaire (MAQ). MAB was defined as high (MAQ score=0), or medium/low (MAQ score>0). Questionnaires were administered through the PatientViewpoint web-based interface. We tested changes in mean PRO scores from baseline to follow-up time points with paired t-tests. We explored associations between baseline characteristics, and changes in weight and PRO at 6 mo with MAB at 12 mo using Fisher's exact test, Wilcoxon rank sum tests and t-tests. P-values <0.05 were considered significant.

Results: From March 2012 to December 2016, 336 women enrolled in the cohort. Mean age was 60 (range 26-90), 84% were Caucasian, and 67% were post-menopausal. Overall, 57% received an aromatase inhibitor, 43% received tamoxifen, and 28% received prior taxane chemotherapy. Median follow-up was 12 mo. At baseline, 61% were overweight/obese, and 21% gained >5% of baseline weight by 12 mo. Mean baseline and follow-up scores at 3, 6 and 12 mo were within 1 standard deviation of reference population means for all PRO measures. Compared to baseline, endocrine symptoms were increased at 3, 6 and 12 mo (p<0.05), while sexual function and depression did not differ between baseline and any follow-up time point (p>0.05). At 6 mo, anxiety was reduced, physical function was improved and pain impact was reduced compared to baseline (p<0.05). MAB was high for 71% of participants at 12 mo. Preliminary data demonstrate that, compared to those with high MAB at 12 mo, women with medium/low MAB at 12 mo took fewer concomitant medications at baseline, and had more improvement in anxiety and sexual function at 6 mo. MAB at 12 mo did not differ according to race, type of ET, baseline weight or PRO measures, or 6 mo change in weight or other PRO measures.

Conclusions: Early changes in anxiety and sexual function during the course of adjuvant ET and the number of baseline concomitant medications may separate women with subsequent high versus medium/low MAB risk. Weight loss interventions and symptom management are needed for women receiving adjuvant ET during the first year of treatment. Our data will be used to create a model to predict MAB for validation studies and as the basis to devise interventions to improve adherence to adjuvant ET.

Title: Impact of genetic polymorphisms on plasma levels of tamoxifen and its metabolites and toxicity: 6-months results of the adjuvant breast cancer longitudinal PHACS study (NCT01127295)

Melanie White-Koning1, Cécile Arellano1, Valérie Le Morvan2, Alexandre Evrard3, Alicja Puzskiel1,6, Christelle Vachoux1, Jérôme Dauba4, Philippe Houyau4, Muriel Poublanc6, Jacques Robert4, Jean-Christophe Boyer3, Henri Roché6, Fabienne Thomas1,6 and Etienne Chatelut1,6. 1CRCT, Inserm, Université de Toulouse, UPS, Toulouse, Cedex 1, France; 2Institut Bergonié, Bordeaux, France; 3CHU Carrémeau, Nîmes, France; 4CH Mont-de-Marsan, Mont-de-Marsan, France; 5Clinique Claude Bernard, Albi, France and 6Institut Claudius Regaud, IUCT-Oncopele, Toulouse, Cedex 9, France.

Body: Supported by a PHRC grant (#09-18-005)

Background: The role of CYP2D6 genetic polymorphisms and plasma levels of active metabolites of tamoxifen (TAM) on clinical response and occurrence of side effects remains controversial. We conducted a prospective, adjuvant, multicentre, 3-year follow-up study of breast cancer patients in order to evaluate the relationships between pharmacogenetics, pharmacokinetics and toxicity of TAM and its metabolites (n=879) or aromatase inhibitors (AI, n=1098). The present report focuses on the evaluation at 6 months after inclusion of 864 patients treated with 20 mg/day TAM. The clinical results and the AI PG/PK analyses are described elsewhere (abstracts #851544 and #851525).

Methods: Residual plasma concentrations for tamoxifen and its 6 major metabolites (endoxifen ENDO, 4-hydroxy-tamoxifen 4-OH-TAM, N-desmethyl TAM, TAM-N-oxyde, 4'-OH-TAM and Z'ENDO) at 6 months after start of treatment were measured by UPLC-MS/MS in 789 patients. Nine patients with TAM concentrations below the limit of quantification were excluded for non-compliance. SNP genotyping of 95 selected SNPs was performed on the Biomark (Fluidigm) in a microfluidic multiplex 96 dynamic array chip with Taqman assays and was available for 857 patients. Patients were classified according to their CYP2D6 metaboliser status (MS) (PM, IM, EM and UM) based on presence of functional, decreased function or no functional alleles (*4, *6, *7, *9, *10, *17, *41) and number of CYP2D6 copies (*5 or duplication). Metabolic ratios (MR) were calculated for TAM/4-OH-TAM, TAM/N-desmethyl tamoxifen (NDT), NDT/ENDO and 4-OH-TAM/ENDO. Anti-estrogenic activity score (AAS) was calculated according to a recently proposed algorithm (De Vries Schultink et al., Breast Cancer Res Treat. 2017). Toxicity was measured as a binary outcome (first occurrence or worsening of hot flushes, fatigue, depression, pain, arthralgia, vaginal dryness). All genetic associations were adjusted for multiple testing.

Results: ENDO concentration and AAS increased significantly with CYP2D6 MS (p<0.001). The presence of a CYP3A4*22 allele was significantly associated with endoxifen concentrations; this association remained significant after adjusting for CYP2D6 MS. TAM/4-OH-TAM MR was significantly influenced by the presence of CYP3A4*22, CYP2C19*2 and *17, and CYP2D6 status. The percentage of patients having an AAS>=1798 (i.e., threshold previously associated with recurrence-free survival RFS by De Vries et al. 2017) was 6%, 50%, 84% and 91% of patients respectively classified as PM, IM, EM and UM. Side effects were not significantly associated with higher levels of TAM metabolites concentrations. After correction for multiple testing, SNPs or CYP2D6 MS were not significantly associated with occurrence or worsening of adverse events, premature treatment discontinuations or switch due to toxicity within the first 6 months.

Conclusions: In this large prospective study, we quantified the impact of PG on TAM PK and AAS, previously shown to predict RFS. Although the toxicity observed after 6 months of TAM does not seem correlated with PK or PG, these relationships need to be re-evaluated during the 3-year follow-up.
Title: Efficacy of extended adjuvant aromatase inhibitors in subgroups of women with early breast cancer

Hadar Goldvaser¹, Ibrahim Algorashi¹, Domen Ribnikar¹, Habeeb Majeed¹, Alberto Ocana², Bostjan Seruga³, Arnoud J Templeton⁴ and Eitan Amir¹. ¹Princess Margaret Cancer Centre, Toronto, ON, Canada; ²Translational Research Unit, Centro Regional de Investigaciones Biomedicas Universidad de Castilla La Mancha, Albacete University Hospital, Albacete, Spain; ³Institute of Oncology Ljubljana, Ljubljana, Slovenia and ⁴St. Claraspital, Faculty of Medicine, University of Basel, Basel, Swaziland.

Body: Background: Randomized trials (RCTs) have reported improvements in breast cancer outcomes from extending treatment with aromatase inhibitors (AIs) beyond the initial 5 years after diagnosis. It is uncertain whether this effect is consistent in different subgroups.

Methods: We identified RCTs that compared extended AIs to placebo or no treatment using a systematic search of MEDLINE. The search was supplemented by a review of abstracts from the American Society of Clinical Oncology and San Antonio Breast Cancer Symposium meetings between 2013 and 2016. Hazard ratios (HRs) and 95% confidence intervals (CI) for disease-free survival (DFS) were extracted or estimated from forest plots and included in a meta-analysis using generic inverse variance and random effects modelling. Pre-specified subgroups included age (<60 ± 5 years vs. ≥60 ± 5 years), tumor size (≤2 cm vs. >2 cm), nodal status (positive vs. negative), hormone receptor status (estrogen [ER] and progesterone receptor [PR] positive vs. ER or PR positive) and administration of adjuvant chemotherapy (yes vs. no).

Results: Seven trials comprising 16,349 patients were analyzed. Studies designs and prior endocrine therapy are shown in Table 1.

</tbody>
</table>

The pooled effect of prolonged treatment with AIs in different subgroups is shown in the Table 2.

Table 2: Intra-subgroup comparison of longer AIs treatment effect by subgroups

| Subgroup A | Subgroup B | HR (95% CI) Subgroup A | HR (95% CI) Subgroup B | P for difference |
|------------|------------|------------------------|------------------------|----------------|---|
| Age <60 ± 5 | Age ≥60 ± 5 | 0.83 (0.70-0.99) | 0.85 (0.74-0.97) | 0.64 |
| T >2 cm | T ≤2 cm | 0.77 (0.55-1.06) | 0.88 (0.68-1.13) | 0.44 |
Overall, the effect of prolonged AIs was similar in all subgroups. However, non-significantly greater effect sizes were seen in patient with larger tumors, nodal involvement, presence of both ER and PR expression and those treated with adjuvant chemotherapy.

Conclusions: Extended treatment with adjuvant AIs is associated with similar relative improvements in DFS in all subgroups analyzed. The greater effect size seen in node positive and large tumor subgroups and the higher baseline risk of recurrence will likely translate to a higher absolute benefit from extended AIs in these groups.
Serum levels of the active tamoxifen metabolite Z-4OHtam is predictive of long-term survival in luminal B subtype of breast cancer patients

Body: Background

Tamoxifen (tam) is the main adjuvant endocrine treatment option in premenopausal breast cancer (BC) patients comprising luminal-like tumors. However, a significant proportion of tam-users will experience a relapse within 15 years of primary surgery. We postulate that some patients do not achieve the full clinical benefit of tam due to inter-individual differences in the metabolism of the drug and that the clinical relevance of this may be different between molecular subtypes of BC. Here, we have compared the prognostic value of threshold levels of active tam metabolites in PAM50 luminal (lum) A and B molecular subtypes.

Material and Methods

A number of 64 lum-like BC patients who were relapse-free 3 years after surgery, were retrospectively analyzed in the observational Oslo1 study. All patients received 20 mg tamoxifen daily for 5 years. Serum was obtained at the time of the 3 years follow-up. A sensitive and accurate LC-MS/MS method was developed and validated for the detection and quantification of tam and 9 metabolites in human serum. The median follow-up time from serum sampling to BC death or last follow-up was 13.9 years (0.6-16.5). Recurrence score and molecular subtype of the patients were determined on FFPE-tumor samples using the PAM50 classification algorithm.

Results

A linear trend was identified for the correlation between active metabolite Z-4OHtam and BCSS (p=0.021, HR=0.64, CI95=0.43–0.93). There was no linear association between the remaining metabolites and BC outcome. We further explored the possible association between survival and concentration thresholds for the active metabolites Z-4OHtam and Z-endoxifen and identified supervised cut off values representing low concentrations for Z-4OHtam (≤3.26 nM) and Z-endoxifen (≤9.00 nM). BC patients with low Z-4OHtam had a BCSS of 33.3% compared to 82.8% in patients with Z-4OHtam >3.26 nM (p<0.001, logrank; HR=6.83, CI 95=2.09-22.36). Lum status (A vs B; HR=5.50, CI95= 1.66-18.25) and Z-4OHtam concentration status (high vs low; HR=6.05, CI95=1.74-21.06) were the only factors left in the final multivariable model. A log-linear relationship between the ROR score and BCSS (p=0.002, HR=1.09, CI95=1.03–1.15) was identified after adjustment of clinically relevant variables and lum status was highly prognostic, (Lum A vs B; p=0.001, HR=5.2, CI=1.72-15.46). Therefore, we wanted to compare the prognostic value of the Z-4OHtam threshold in patients subgroups stratified by lum status. Low concentrations of Z-4OHtam were associated with poorer survival for patients in the lum B group only (HR=4.94, CI 95=1.16-21-02). For the lum A patients no significant association was found.

Discussion

Low levels (≤ 3.26 nM) of the active tam metabolite Z-4OHtam was associated with a poorer long-term outcome in tam-treated BC patients. However, when grouping patients according to the PAM50-based molecular subtype, this was only significant in patients belonging to the lum B subtype. Our results suggest that higher levels of active tam metabolites and thus better ER blockage are more important in the more aggressive lum B subtype.

**Title:** Fertility concerns and their impact on hormonal therapy decisions in young breast cancer survivors

Philip D Poorvu¹, Kathryn J Ruddy¹, Shari I Gelber¹, Rulla M Tamimi², Jeffrey Peppercomb³, Lidia Schapira⁴, Virginia F Borges⁵, Steven E Come⁶, Ann H Partridge¹ and Shoshana M Rosenberg¹. ¹Dana-Farber Cancer Institute, Boston, MA; ²Brigham and Women’s Hospital, Boston, MA; ³Massachusetts General Hospital, Boston, MA; ⁴Stanford University, Stanford, CA; ⁵University of Colorado Cancer Center, Aurora, CO, United Arab Emirates and ⁶Beth Israel Deaconess Medical Center, Boston, MA.

**Body:**

**Background:** Fertility is a critical issue for young breast cancer (BC) survivors and can be diminished by adjuvant chemotherapy or by age-related decline in ovarian reserve over time. Little is known about how fertility concerns affect decision-making and persistence with endocrine therapy (ET) given the standard 5-10 year duration of therapy during which pregnancy is contraindicated.

**Methods:** As part of a multi-center, prospective cohort study enrolling women with newly diagnosed (dx) BC at age ≤40 years between 2006-2016, we identified participants with HR+, Stage I-III BC, without documented recurrence and with at least 3 years of follow-up. Participants completed serial surveys that include questions about socio-demographics, fertility issues and outcomes, treatment, and decision-making. ET use and pregnancy outcomes were evaluated up to 5 years post-dx (mean follow-up: 4.4 years). We used t-tests and chi-square tests to evaluate differences between women who indicated at least once in the first 2 years following diagnosis that fertility concerns affected their ET decisions and those who did not, and multi-variable logistic regression to identify factors independently associated (p≤0.05) with indicating ET decisions were affected by fertility concerns.

**Results:** Among 479 women included in this analysis, 33% (156/479) indicated that fertility concerns affected their decision regarding hormonal therapy – by choosing to defer treatment, stop early, or indicating that they may stop early or interrupt at a future time. Among these women, 44% (67/156) did not initiate or stopped ET (at least temporarily) vs. 21% (68/323) among women who did not indicate that fertility concerns affected their decision (p<0.0001). Among the 67 women with fertility concerns who did not initiate/discontinued ET, 29 (43%) subsequently reported a pregnancy within 5 years of dx. Women who were younger at dx, not partnered, nulliparous, and those who had a pre-treatment discussion about fertility with a provider were more likely to indicate that fertility concerns affected their ET decision (Table). In multi-variable analyses, only no or low parity remained significant: no children at diagnosis vs. ≥2 OR 9.86, 95% CI: 5.19-18.75, 1 child at diagnosis vs. ≥2: OR 6.28, 95% CI: 3.18-12.39.

**Conclusion:** Concern about fertility is a contributor to ET decisions among a significant number of young women with HR+ BC. Ongoing research, including the POSITIVE trial (NCT 02308085), an international study that is exploring the safety and feasibility of interrupting ET for pregnancy after HR+ BC, will provide much needed evidence that will help inform and guide both patients and providers as they make fertility and treatment decisions.

Title: Pharmacogenetic determinants of aromatase inhibitors pharmacokinetics and side effects: 6-month results of the adjuvant breast cancer longitudinal PHACS study (NCT01127295)

Fabienne Thomas1,2, Pierre Marquet3, Frédéric Pinguet4, Melanie White-Koning2, Jacques Robert5, Naïma Tafzi3, Isabelle Solassol4, Raymond Despax6, Nadia Levasseur7, Stephen Ellis8, Angélique Massoubre1, Litaty Mbatchi9, Valérie Le Morvan5, Henri Roché1, Étienne Chatelut1,2 and Alexandre Evrard9. 1Institut Claudius Regaud, IUCT-O, Toulouse, France; 2CRCT, Inserm, Univ Toulouse, Toulouse, France; 3CHU Limoges, Limoges, France; 4ICRM, Montpellier, France; 5Institut Bergonié, Bordeaux, France; 6Clinique Pasteur, Toulouse, France; 7CH Cahors, Cahors, France; 8Centre Catalan d’Oncologie, Perpignan, France and 9CHU Carémeaux, Nîmes, France.

Body: Supported by a PHRC grant (#09-18-005)

Background: Recent literature has suggested that germline genetic variants of drug-metabolizing enzymes or CYP19A1 (coding for aromatase) may be involved in the systemic aromatase inhibitors (AI) concentrations or the occurrence of side effects (Hertz et al. Pharmacogenomics 2017). A prospective multicentre 3-year follow-up study was carried out to investigate the relationships between pharmacogenetics (PG), pharmacokinetics (PK) and toxicity in breast cancer patients treated with adjuvant AI (n=1098) or tamoxifen (n=879). The clinical results and the tamoxifen PG/PK analyses are described elsewhere (abstracts #851544 and #850248).

Methods: SNP genotyping of 95 SNPs was performed on the Biomark (Fluidigm) with Taqman assays and was available for 373, 515 and 151 patients treated with anastrozole (ANA), letrozole (LETRO) and exemestane (EXE) respectively. CYP2A6 metaboliser status (MS) (poor, intermediate or normal) was determined based on alleles function (*1, *9, *2) and number of CYP2A6 copies. Trough plasma concentrations of each drug were determined 6 months after the start of the study by UPLC-MS/MS and were available for 342, 463 and 130 patients of the ANA, LETRO and EXE arms. Patients with AI concentrations below the limit of quantification were excluded for non-compliance (9 patients for ANA, 8 patients for LETRO and 7 patients for EXE). Toxicity was measured as a binary outcome (occurrence or worsening of hot flushes, fatigue, pain, arthralgia, vaginal dryness). All genetic associations were adjusted for multiple testing.

Results: ANA concentration was significantly higher in patients experiencing pain (p=0.025) and was associated with rs28365063 (UGT2B7 g.372A>G).

LETRO concentrations were strongly associated with CYP2A6 metabolizer status (p=0.0001) but did not differ in patients with or without toxicity.

In the EXE arm, patients with hot flushes or arthralgia had a significantly lower level of exemestane (p= 0.0002 and p=0.023 respectively) but since the metabolism of EXE leads to active 17-hydroxexemestane, we can hypothesize that the lower EXE concentration is an indirect reflection of the metabolite formation. A SNP (rs2307424) in NR1I3 gene (coding for the constitutive androstane receptor CAR) was associated with EXE concentrations. CAR has been shown to regulate CYP2B6, which is involved in the formation of 6-hydroxy-methyl-exemestane (inactive metabolite).

Regarding the relationships between PG and toxicity, in the ANA arm, 3 SNPs of CYP19A1 gene tended to be associated with hot flushes worsening (rs934635) and arthralgia (rs10046 and rs2304463) but did not remain significant after multiple tests correction. In the EXE arm, several SNPs in NR1I3 gene were associated with EXE concentrations. CAR has been shown to regulate CYP2B6, which is involved in the formation of 6-hydroxy-methyl-exemestane (inactive metabolite).

Conclusions: Our study confirms the predominant role of CYP2A6 in LETRO PK. To our knowledge, this is the first study to report on the role of UGT2B7 rs28365063 in ANA and NR1I3 in EXE PK and side effects. These relationships need to be re-evaluated with the drug concentrations obtained during the 3-year follow-up.

Title: Evaluation of treatment compliance during extended endocrine therapy; secondary analysis of the IDEAL trial

Erik J Blok\textsuperscript{1,2}, Judith R Kroep\textsuperscript{2}, Elma Meershoek-Klein Kranenbarg\textsuperscript{1}, Marjolijn Duijm-de Carpentier\textsuperscript{1}, Johan WR Nortier\textsuperscript{2}, Emiel JTh Rutgers\textsuperscript{3} and Cornelis JH van de Velde\textsuperscript{1}. \textsuperscript{1}Leiden University Medical Center, Leiden, Netherlands; \textsuperscript{2}Leiden University Medical Center, Leiden, Netherlands and \textsuperscript{3}Netherlands Cancer Institute, Amsterdam, Netherlands.

Body: In the first clinical trial reports about extended endocrine therapy in early breast cancer, treatment compliance appeared as a major concern. Earlier, it was shown in the IDEAL trial that approximately 35% of all patients stopped therapy before the allocated time. This additional study was conducted to evaluate the factors contributing to early treatment discontinuation.

Methods: In the IDEAL trial, a total of 1824 patients were randomized between either 2.5 or 5 years of extended letrozole, after 5 years of any adjuvant endocrine therapy. Only eligible patients who started therapy were included in the analysis. Adverse events were collected until 30 days after last treatment dose Reasons for ending therapy were collected prospectively at the time of treatment discontinuation.

Results: The majority of early treatment discontinuation was caused by adverse events (AEs) (n=372, 20.4% of all patients, 58% of all early treatment discontinuations). The most frequently reported AEs associated to treatment discontinuation were arthralgia (n=71, 9.9% of AEs associated treatment discontinuation), fatigue (n=48, 6.7%), depression (n=47, 6.5%), hot flashes (n=47, 6.5%) and alopecia (n=39, 5.4%). Of all AEs associated to early discontinuation, 86% was grade 1 or 2 (table 1). All grade 5 events were not associated to therapy.

</table>

Furthermore, the influence of previous type of adjuvant endocrine therapy was evaluated. Of all patients initially treated with 5 years of tamoxifen, 29% stopped due to an AE. In contrast, patients who were treated with aromatase inhibitors during the first 5 years, either with monotherapy or after 2-3 years of tamoxifen, stopped due to AEs in 22% and 18% respectively (Pearson Chi-square p-value 0.001). The average number of AEs per patient per previous treatment group was 2.27 for tamoxifen monotherapy, 2.03 for AI monotherapy and 1.73 in the sequential group. Corrected for the number of AEs in each group, patients pre-treated with 5 years of tamoxifen had a chance of treatment discontinuation of 12.7% per AE, compared to 10.8% and 10.4% for AI monotherapy and sequential therapy respectively. Additionally, of patients that completed regular adjuvant therapy between 1 and 2 years before randomization, 34% stopped due to adverse events. In contrast, of patients that completed therapy within 6 months before randomization stopped in 19% of all cases (Pearson Chi-square p-value <0.001).

Conclusion: We have shown that adverse events are an important factor in early treatment discontinuation. Furthermore, the relation between adverse events and early discontinuation is influenced by the type of earlier therapy, with the highest rate of discontinuation for AI-naïve patients. This suggests that after 5 years of tamoxifen, patients are more inclined to stop therapy when encountering new AI-related adverse events compared to patients who were pre-treated with an AI.

Title: CYP2D6*10 genotype was associated with worse outcome of premenopausal breast cancer patients receiving adjuvant tamoxifen but not toremifene: A single institution experience

Bo Lan1, Fei Ma1, Ying Fan1, Xiaoyu Zhai1 and Binghe Xu1. 1National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China.

Body: Background: Tamoxifen (TAM), a selective estrogen receptor modulator (SERM), is the most widely used adjuvant endocrine therapy for premenopausal breast cancer patients. Cytochrome P-450 (CYP450) enzyme, CYP2D6, is involved in the conversion of tamoxifen to endoxifen which is one of the main active metabolites of tamoxifen in vivo. Variants of CYP2D6 gene may result in a decreased enzyme activity and lead to poor prognosis of the patients. Different from caucasians, the most common polymorphism among Chinese women is allelic variant *10, which generates a 188 C to T transition, resulting in a lower activity of the enzyme. Based on some retrospective studies, tamoxifen-treated patients with the CYP2D6*10 T/T genotype have a worse clinical outcome. Toremifene (TOR), another kind of SERM is not metabolized by CYP2D6 enzyme thus may not be influenced by its polymorphism. We conducted this study to validate the association between CYP2D6*10 genotype and the outcomes of patients receiving TAM and TOR respectively.

Methods: A total of 276 patients with primary early-stage ER-positive breast cancer received adjuvant tamoxifen (n=169) or toremifene (n=107) therapy at National Cancer Center from 2004-2012 were analyzed. All patients had received 5-year endocrine therapy after completion of surgery. TaqMan SNP genotyping assays was performed on CYP2D6*10 from blood samples. The association of CYP2D6 *10 genotype with disease free survival (DFS) and clinicopathological characteristics was analyzed in patients receiving tamoxifen and toremifene.

Results: 32.6% (90 of 276) of the patients were homozygous for wild-type C/C genotype, 47.1% (130 of 276) were heterozygous for C/T genotype, and 20.3% (56 of 276) were homozygous for variant T/T genotype. The frequency of CYP2D6 *10 allele in our study was 43.8%. The 5-year DFS rate for tamoxifen and toremifene treatment group were 81.6% and 83.2% respectively. There was no significant difference of DFS between the two groups (P=0.274). Among 169 patients in tamoxifen group, 5-year DFS rate was considerably lower in patients with homozygous variant T/T genotype than those with wild-type C/C or C/T genotype (73.4% versus 83.2%, P=0.004). And the T/T genotype was found to be a significant prognostic marker for DFS in multivariate analysis (hazard ratio = 4.7; P<0.001) after adjusting for patient’s characteristics mentioned above. For the toremifene group, there was no difference of DFS between T/T genotype and the others (P=0.332). For all the 56 homozygous variant T/T genotype patients, patients receiving toremifene treatment had a much higher 5-year DFS rate than those receiving tamoxifen but unfortunately it was not statistically significant (90.0% versus 73.4%, P=0.192).

Conclusions: About one fifth of Chinese breast cancer patients had homozygous T/T genotype which might get less benefit from TAM adjuvant treatment. Toremifene may be a better option for this kind of patients. Further large-scale prospective clinical studies are warranted to validate this concept.
First 6-month report of the longitudinal PHACS study (Pharmacology and Hormonotherapy (HT) for Adjuvant breast Cancer (BC) Study, NCT01127295)

Institut Claudius Regaud, IUCT-Oncopole, Toulouse, Cedex 9, France, Metropolitan; CHU Limoges, Limoges, France, Metropolitan; Institut Bergonié, Bordeaux, France, Metropolitan; Institut de Cancérologie de Montpellier, Montpellier, France, Metropolitan; Clinique St Jean du Languedoc, Toulouse, France, Metropolitan; Centre Hospitalier, Brive, France, Metropolitan; Polyclinic Bordeaux Nord Aquitaine, Bordeaux, France, Metropolitan; Clinique Pasteur, Toulouse, France, Metropolitan; CHU Carémeau, Nîmes, France, Metropolitan; Clinique Tivoli, Bordeaux, France, Metropolitan; Centre de Recherche en Cancérologie de Toulouse, INSERM, Toulouse, France, Metropolitan.

Body: Background: BC is a hormone-dependent disease for 75% of pts. HT is used in both adjuvant and metastatic settings for hormone-receptor (HR) positive tumors. In adjuvant situation, a 5-year HT period at least is recommended. Side-effects (SE) frequently alter quality of life and compliance, reducing the well-known benefits in risks of relapses and specific deaths. Underlying mechanisms are well understood for estrogen deprivation-induced events such as hot flashes, but little is known on arthralgia under aromatase inhibitors (AI). So, pharmacogenomics (PG), pharmacokinetics (PK), potential medications interactions are of value to explain individual drugs exposures, possible related side-effects and compliance to treatment.

Methods: We performed a prospective, multicenter, longitudinal study registering early clinical outcomes and SE during the first 3 years of adjuvant HT with tamoxifen (T) or AI. All tumors expressed at least one HR (>10%). The choice of HT molecule and one-drug or sequential treatment were left to the investigator. Pts were followed every 6 months with clinical examination by the referent oncologist and PK sampling each time. Biologic research consisted in PG investigations of different genes involved in the PK and pharmacodynamics of T and AI (95 SNPs) at baseline. SE, concurrent medications and compliance were registered by both the pts on a diary card and the physician. Evaluation was done only on new occurrence or increased grade of symptoms.

Results: This first report focuses on characteristics of the population and the results after the 6 first months of treatment. Between June 2010 and October 2014, 23 centers recruited 2000 pts. 23 were excluded leaving 1977 fully evaluable women; 879 (44%) started with T, 1098 (55%) with AI (554 letrozole (L), 390 anastrozole (A), 154 exemestane (E)). 56% of them had previously received chemotherapy, 96% radiotherapy and 8% trastuzumab. Main characteristics were well balanced between the 2 classes of drugs; T was given mainly for pre- or perimenopausal pts. Most frequent co-morbidities were hypertension (8% T, 31% AI) and dyslipidemia or diabetes (T 11%, AI 26%). To note, almost 30% of pts described arthralgias at entrance and 37% had hot flashes. At 6 months, 122 pts (6%; 43 T, 79 AI) had stopped treatment mainly for toxicity (11 T; 12 AI), progression or death (7 T; 4 IA), personal reasons (15 T; 37AI); 4 asked for changing T and 52 AI (equally for the 3 drugs). All these events were significantly more frequent for AI pts (p=0.042) and with E within the AI class (p<0.001). Main changes in onset or increased intensity of symptoms concerned hot flashes with all drugs (30%), asthenia (20%), insomnia (20%), weight gain (17%), arthralgias (15% for T, 30% for AI), thrombotic events (24 of which 11 with T). 3 grade3 SAE HT-related were reported.

Conclusions: These preliminary data on the first 6-months exposure to HT on adjuvant setting in the real-life confirm early rates of withdraws and toxicities. Longer follow-up and subsequent PK analysis should help to understand persistent side-effects and reasons for non-compliance to adjuvant HT.
Title: Disparities in adjuvant hormone adherence in breast cancer patients within a universal healthcare model

Zachary W Veitch1, Omar F Khan1, Derek Tilley2, Xanthoula Kostaras2, Karen King3, Sasha Lupichuk1 and Patricia Tang1. 1Tom Baker Cancer Centre - University of Calgary, Calgary, AB, Canada; 2Alberta Health Services - Cancer Control, Edmonton, AB, Canada and 3Cross Cancer Institute - University of Alberta, Edmonton, AB, Canada.

Body: Background: Patient adherence to adjuvant hormonal therapy for breast cancer (BC) is correlated with improved survival. Recent publications have demonstrated ethnic disparities in adjuvant hormone adherence (AHA) for privatized healthcare models. Objective: To identify disparities in AHA for BC patients within a universal healthcare system in Alberta, Canada. Methods: Patients diagnosed from 2007-2014 with stage I-III, ER+/HER2- BC receiving adjuvant FEC or DC chemotherapy and at least one month of adjuvant hormonal therapy in Alberta, Canada were retrospectively assessed. Hormone monotherapy (tamoxifen, AI), switch strategies (tam to AI), and treatment duration were collected. Compliance was assessed with central pharmacy data. Patient ethnicity was identified using patient first/last and parental last name via Onolytics® ethnographic software. Ethnicity was further verified using a centrally collected place of birth. Age, AJCC stage, psychiatric diagnoses (mood, bipolar), and comorbidity were collected. Log rank and Chi squared were used to assess difference between adjuvant hormonal therapy for variables at 1, 2, and 5 years. Log rank p-values at 2 years are reported. Results: A total of 2,399 ER+ patients were included for analysis. AHA was non-significant for ethnicity (p=0.797), comorbidity (p=0.623), psychiatric disorders (p=0.145), or elderly cohorts (p= 0.814). AHA was highest for planned hormonal switch strategies (p=0.004) compared to monotherapy.

**Conclusion:** AHA is not dependent on ethnicity, age, comorbidity, or psychiatric diagnosis in a universal healthcare model. Conversely, higher rates of AHA are seen with planned switch strategy compared to monotherapy, contradictory to the BIG I-98 trial. Patients with higher stage, and thus higher risk of BC recurrence have increased adherence compared to their low risk counterparts. Reinforcement of AHA for low/moderate risk BC patients, in addition to tamoxifen to AI switch strategies may improve overall adherence.
**Title:** Serum estrogen-levels in women 48-56yrs with hormone receptor-positive breast cancer. Cross-Sectional study using an ultra-sensitive LC-MS/MS-method

Maxime Van Houdt¹, Patrick Neven¹, Lintermans Anneleen¹, Jans Ivo¹, Vanderschueren Dirk¹, Billen Jaak¹, Laenen Annouschka¹ and Wildiers Hans¹. ¹University Hospitals of Leuven, Leuven, Belgium.

**Background and Purpose:** Randomized clinical trials in early stage hormone receptor positive breast cancer (HR+BC), have shown that total estrogen suppression (TES) for 5 yrs or after 2-3 yrs of tamoxifen treatment improved outcome over 5 yrs of TAM monotherapy. This relative improvement is in absolute figures most visible in patients with a high relapse risk. To achieve TES, women need to be (rendered) menopausal and treated with an oral aromatase inhibitor (AI). We measured serum estrogens in women of peri-menopausal age with HR+BC starting or on anti-hormonal agents.

**Methods:** Serum estradiol (E2) and estrone (E1) were quantified using a sensitive liquid chromatography-tandem mass spectrometry method (LC-MS/MS; Pauwels et al. JCO 2013) in women 48-56 yrs old with HR+BC starting or on anti-hormonal therapy in a cross sectional observational monocentric study. We report the frequency that (and explore why) AI-users had estrogens above the lower limit of quantification (LLOQ). We measured estrogen levels in TAM users with > 3 months' amenorrhea by previous use of (neo)adjuvant chemotherapy. Finally, we studied the frequency of both estrogens or either alone were < LLOQ in non-users. Statistics are descriptive; biomarkers for estrogen levels were analyzed using linear mixed models.

**Results:** Estrogen levels were assessed in 566 samples from 401 women; 96 (126 samples) were on AI, 128 (182 samples) on TAM and 217 (258 samples) non-users. Some patients had more than one blood sample in different groups. 13.5% of AI users were above LLOQ for E2 and E1; 7.5% for E1 alone. Some were due to ovarian reactivation. An important proportion (18%) of 83 non-hysterectomized TAM users with amenorrhea had E2 levels >40ng/L; 9.1% and 28.2% respectively in patients who had and didn't have (neo)adjuvant chemotherapy. None of non-users were below LLOQ for E1, while 20.7% were below LLOQ for E2.

**Conclusions:** TES is not always achieved in AI-users; reasons why were multiple. Amenorrhea is no guarantee for TES in TAM users, as a significant proportion had high E2 levels even when previously exposed to (neo)adjuvant chemotherapy. Using LC-MS/MS, undetectable levels for E1 better reflect TES than below LLOQ for E2.
**Body: Background:** Atypical hyperplasia of the breast is a high-risk benign lesion that is found in approximately 10% of benign breast biopsies[1] and confers a risk for future breast cancer[2]. The American Society of Clinical Oncology guideline states that pharmacologic risk reduction with the use of a selective estrogen receptor modulator or an aromatase inhibitor should be discussed with women with a 5-year projected absolute risk of breast cancer of 1.7% or higher[3]. The NCCN guideline for risk reduction recommends consideration of risk-reduction interventions, including the use of pharmacologic agents in women with a 5-year risk of 1.7% or higher and a life expectancy of 10 years or longer [4]. The majority of women with atypical hyperplasia meet this risk criterion with their cumulative risk of approximately 1% per year.

**Method:** We retrospectively reviewed excisional biopsy pathology reports between January 2016 and June 2016 with the diagnosis of atypical ductal or lobular hyperplasia to identify patients with pure atypical hyperplasia. Medical records of these patients were then reviewed to identify the percentage of patients referred to a medical oncologist for chemoprevention discussion and the percentage of patients who received chemoprevention following excisional biopsy.

**Results:** Two hundred seventy six patients with the diagnosis of atypical ductal or lobular hyperplasia were identified. Two hundred and sixteen patients were excluded from the analysis due to the presence of other histologies such as carcinoma in situ and invasive carcinoma. Medical records of the remaining sixty patients with pure atypical hyperplasia were reviewed. Eighteen patients’ charts were unavailable for review. All of the remaining forty two patients had a 5-year breast cancer risk of 1.7% or higher. Five of these patients (8.3%) were referred to a medical oncologist for chemoprevention discussion. Two of these five patients (2.3%) received chemoprevention with tamoxifen. For patients who were not referred to medical oncologist, there was one documented discussion of chemoprevention with patient by her surgical oncologist. One patient underwent prophylactic bilateral mastectomies, and therefore, chemoprevention was not recommended.

**Conclusion:** Multidisciplinary strategies need to be implemented to bridge the gap between guidelines and clinical practices which may lead to improved patient outcomes.

Asahikawa-Kosei General Hospital, Asahikawa, Japan; ¹³Tohoku University Graduate School of Medicine, Sendai, Japan and ¹⁴Chuo University, Tokyo, Japan.

**Body:**

**Background:** Whether adjuvant chemotherapy is required for patients (pts) with intermediate-risk endocrine-responsive postmenopausal breast cancer (BC) remains unknown. Sufficient data have not been available about the long-term prognosis of patients with neoadjuvant endocrine therapy (ET). NEOS is a randomized phase III study that assessed the long-term prognosis of estrogen receptor positive (ER+) primary breast cancer (PBC) pts who received neoadjuvant ET with/without adjuvant chemotherapy.

**Methods:** Postmenopausal BC pts with ER+/-HER2 negative, T1c-2, clinically node negative, under 76 years old were enrolled at primary registration. Pts were treated by letrozole (LET) in weeks 24-28 after primary enrollment. Pts experienced progression (PD) during neoadjuvant phase were excluded at randomization and received any systemic therapy driven by investigators before or after surgery. The long-term prognosis was followed in all registered pts including PD pts. Response to neoadjuvant ET was evaluated as complete response (CR), partial response (PR) or stable disease (SD) using calipers, ultrasound and MRI (or CT) at the baseline and end of treatment before surgery. Pts who met eligibility criteria were randomized 1:1 to LET for 4.5-5 years after chemotherapy or LET alone for 4.5-5 years without chemotherapy after surgery. Pts excluded at second registration were treated any systemic therapies driven by investigators. The primary endpoint was disease-free survival (DFS) and secondary endpoints included overall survival (OS), clinical response rate in neoadjuvant phase, pathological response, and breast-conserving surgery rate. The randomization code have been blinded to the investigators.

**Results:** Between May 2008 and June 2013, 904 patients were enrolled at primary registration from 100 institutions in Japan (median follow-up: 4.0 years) and 24 pts were withdrawn during neoadjuvant phase. The median age was 63 years, T1c:37%, T2:63%, and PgR+:78%. Clinical response rates (CR, PR, SD and PD) were 2% (16pts), 48% (421pts), 45% (400pts) and 5% (43pts), respectively and, in each response category, 0% (0/16), 5.5% (23/421), 7.8% (31/400), and 20.9% (9/43) experienced DFS events. DFS in PD pts to neoadjuvant ET were statistically significantly worse than CR, PR, SD and PT (p<0.0001, hazard ratio 4.7 (95% CI:2.3-9.5). The prognosis after surgery in 669 randomized pts was good regardless with/without chemotherapy, forty four pts (6.6%) experienced DFS events after surgery. The predictive markers of PD for neoadjuvant ET were yet unclear among evaluated clinical factors.

**Conclusion:** This is the first report of DFS in the largest neoadjuvant ET trial (NEOS). The DFS of postmenopausal, ER+/HER2-, PBC pts excluding PD pts to neoadjuvant ET is highly good regardless with/without chemotherapy. Neoadjuvant ET with utilization of PD response as a prognostic marker can be considered as a standard treatment option for these patients. Clinical trial information: UMIN000001090.

Title: Change in oncotype DX variables and Ki67 response and outcome in women with ER positive early breast cancer treated with neo-adjuvant anastrozole and fulvestrant

Qamar J Khan¹, Carol J Fabian¹, Bruce F Kimler¹, Anne P O'Dea¹, Joshua Mamen¹, Amanda Amin¹, Jamie Wagner¹, Michelle Springer¹, Stella Baccaray¹ and Priyanka Sharma¹. ¹The University of Kansas Medical Center, Kansas City, KS.

Body: Neo-adjuvant endocrine therapy (NAET) provides opportunity for on-treatment assessment of endocrine responsiveness and need for adjuvant chemotherapy (C) in ER+/HER2 negative breast cancer (BC). We investigated Ki67-IHC response to NAET, the 21-gene Recurrence Score (RS; Oncotype DX), and Postoperative Endocrine Prognostic Index (PEPI) as predictors of response and recurrence in a neoadjuvant trial of fulvestrant (F) + anastrozole (A). The combination had been shown to improve survival compared to A alone in ER+ metastatic breast cancer.

Design: Single arm phase II trial of postmenopausal women with clinical stage II/III ER+/HER2 negative BC and RS ≤25. Following initial biopsy (CNB) women received NAET for 4 months: A 1mg (PO) daily continuously from day 1 until surgery + F 500mg IM on day 1, 14 and 28 of cycle 1, and on the last day of 3 subsequent 28 day cycles (total 6 doses of F) followed by surgery. Ki67-IHC and RS (weighted heavily by gene expression of ESR1, HER-2, Ki67, and PR) were assessed at baseline and at surgical resection (3-4 weeks after last F). Chemotherapy was allowed at physician discretion and recommended for PEPI>0. All patients received adjuvant A.

Results: 51 patients were screened and RS was performed on initial CNB with a success rate of 96%. 7 were not eligible due to RS>25. 42 patients were enrolled. 18 (49%) had PEPI score of 0 at surgery. Median RS was 12 at baseline and 17 at surgery for the 36 patients with evaluable tissue at both time points. 28/36 (78%) patients had numeric increase in RS at surgery and 5/36 had RS > 25 at surgery. Increase in RS is likely driven by decrease in ESR1 gene expression (p=0.063). Median RS at surgery but not at baseline was associated with PEPI score of 0 (p=0.02). Ki67 gene expression at surgery was lower in patients with PEPI 0 (p=.003) whereas ESR1 expression was higher (p=.024). Median Ki67-IHC was 5% (mean 7.6%) at baseline and 1% (mean 2.8%) at surgery for the 37 patients with evaluable tissue at both time points. 35 of these 37 (94%) had decrease in Ki67-IHC from baseline to surgery; only 2/37 had an increase in Ki67-IHC at surgery. 22% of women received adjuvant chemotherapy. At median follow up of 61 months, only 3/42 patients have had a recurrence: the two patients with an increase in Ki67-IHC from baseline to surgery had a recurrence; plus a third who was taken off trial during therapy due to clinical progression and received C prior to surgery.

Conclusions: 4 months of neo-adjuvant anastrozole + fulvestrant results in decrease in Ki67-IHC in 94% of women with stage II/III ER+ HER2 negative breast cancer. No patients with decrease in Ki67-IHC at surgery have had a breast cancer recurrence. The majority of patients treated with this regimen do not need chemotherapy. A small number of patients with on-therapy increase in Ki67-IHC are at high risk of recurrence. Oncotype DX RS and expression of some of the component genes (ESR1 and Ki67) change with NAET. Expression of ESR1 and Ki67 genes at surgery after NAET is associated with PEPI score of 0 and should be explored as potential response biomarkers in NAET trials.
Title: Long-term outcome of neoadjuvant endocrine therapy followed by breast conserving surgery

JD Yau\textsuperscript{1}, Arran K Turnbull\textsuperscript{1}, Lorna Renshaw\textsuperscript{2}, Jane Keys\textsuperscript{2}, Alexander Leeper\textsuperscript{2}, Jeremy S Thomas\textsuperscript{3} and J Michael Dixon\textsuperscript{2}. \textsuperscript{1}Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, United Kingdom; \textsuperscript{2}Edinburgh Breast Unit, Western General Hospital, Edinburgh, United Kingdom and \textsuperscript{3}Western General Hospital, Edinburgh, United Kingdom.

Body: Background: Neoadjuvant therapy (NET) in women with large or locally advanced estrogen receptor (ER)-rich breast cancers (BC) allows the option of breast-conserving surgery (BCS) + radiotherapy (RT). The aim was to study the long term safety of this strategy.

Methods: 280 postmenopausal women (median age 77, range 50-95, table 1) with ER-rich BC had BCS after NET (median duration 4.8 mths, range 1.7-42.8 mths). 221 (79%) received only letrozole. 59 (21%) began on letrozole and were switched to anastrozole, exemestane or tamoxifen due to adverse events or lack of clinical response. 200 patients (71%) had adjuvant RT (RTgroup) and 25 (9%), adjuvant chemotherapy. Median follow-up = 5.5 years.

Results:
254 patients had NET response data. 74% had a clinical response. NET response was higher for grade 1 (84%) than for 2 (73%) or 3 (72%) cancers. Actuarial local recurrence rates (LRR) were 8% (95%CI±0.04) and 12% (95%CI±0.06) at 5 & 10 years. Actuarial overall BC...
Recurrence rates were 14% (95% CI ± 0.04) and 27% (95% CI ± 0.12) at 5 & 10 years, with BCS death rates of 7% (95% CI ± 0.04) and 14% (95% CI ± 0.10) at 5 & 10 years, showing only half with recurrence died from BC. Crude all-cause mortality but not BC-specific survival (BCSS) favoured those who had adjuvant RT (P < 0.001) or chemotherapy (P = 0.006). The 15-year rate was 50.9%, while BCS death rate was only 7.3%.

Positive nodes were associated with worse overall recurrence free survival (RFS) (P = 0.007) but not local RFS or BCSS. Tumour size was not associated with RFS or BCSS. Tumour grade was not associated with RFS but grade 3 patients had a lower BCSS (P = 0.002) compared to patients grade 1/2 cancers. RT was associated with improved LRR (P < 0.0001) and overall RR (P = 0.038): 5 & 10 year in RT group were 5% (95% CI ± 0.04) + 7% (95% CI ± 0.04) vs 9% (95% CI ± 0.12) + 31% (95% CI ± 0.24) in no-RT group. The 5 & 10 year ORR in the RT group was 14% (95% CI ± 0.06) and 39% (95% CI ± 0.16) vs 28% (95% CI ± 0.16) + 38% (95% CI ± 0.24) in the no-RT group. Although differences were not significant, BCSS was higher in the no-RT group: 5 & 10 yearly BCSS rates were 10% (95% CI ± 0.04) and 20% (95% CI ± 0.12) vs 6% (95% CI ± 0.08) + 12% (95% CI ± 0.14) in RT group.

16/67 patients with T3/4 cancers with no RT had lower overall RFS (P = 0.018) but no difference in local RFS. 13/98 patients with node +ve disease with no RT had lower LRR (P = 0.002) and overall RR (P = 0.024). 54/169 node -ve patients with no RT had lower LRR (P = 0.019) but similar overall RR. 50/183 patients with grade 1/2 cancers had no RT and had lower LRR (P < 0.0001) and overall RR (P = 0.049). BCSS was not associated with RT use in subgroups related to tumour size, node status or grade.

Discussion:
• Response to NET is not worse in ER rich grade 3 or node positive cancers.
• After NET, BCS and RT provides excellent LRR.
• BCSS rates were low; most died of other causes.
• NET followed by BCS and RT is safe even for grade 3 and node positive cancers.
• BCS alone provides adequate disease control for majority with significant co-morbidities.

Title: Tailored neoadjuvant endocrine and chemo-endocrine therapy for postmenopausal patients with estrogen receptor-positive human epidermal growth factor receptor 2-negative primary breast cancer

Norikazu Masuda, Nobuaki Sato, Takashi Morimoto, Takayuki Ueno, Chizuko Kanbayashi, Koji Kaneko, Hiroyuki Yasojima, Shigehira Saji, Hironobu Sasano, Satoshi Morita, Shinji Ohno and Masakazu Toi. 1National Hospital Organization Osaka National Hospital, Osaka, Japan; 2Niigata Cancer Center, Niigata, Japan; 3Yao Municipal Hospital, Yao, Osaka, Japan; 4School of Medicine, Kyorin University, Mitaka, Tokyo, Japan; 5Fukushima Medical University, Fukushima, Japan; 6Tohoku University, Sendai, Miyagi, Japan; 7Kyoto University Graduate School of Medicine, Kyoto, Japan; 8Breast Oncology Center, Cancer Institute Hospital, Ariake, Tokyo, Japan and 9Graduate School of Medicine, Kyoto, Japan.

Body: Aims We investigated the efficacy and safety of initial neoadjuvant endocrine therapy with exemestane (EXE) alone followed by subsequent tailored treatment with EXE alone for responders or EXE plus oral metronomic cyclophosphamide (CPA) for non-responders.

Methods In this multicenter open-label phase II study, we enrolled postmenopausal patients with primary invasive estrogen receptor (ER)-positive, HER2-negative, stage I–IIIA (T1c–T3 N0–2 M0) breast cancer and Ki67 index ≤ 30%. Patients first received EXE 25mg/day for 12 weeks. Based on clinical response and change in Ki67 index in response to the initial therapy, patients who achieved complete response (CR), partial response (PR) with Ki67 index ≤5% after treatment, or stable disease (SD) with Ki67 index ≤5% both before and after treatment were defined as responders. Non-responders were defined as patients with PR and Ki67 index >5% after treatment, or SD and Ki67 index >5% before or after treatment. For the subsequent 24 weeks, responders continued the EXE monotherapy (continued EXE group), whereas non-responders switched to combination therapy with EXE plus CPA 50mg/day (EXE+CPA group). The primary endpoint was clinical response (CR and PR) at weeks 24 and 36.

Results A total of 59 patients (median age 69 years, range 53–86 years) were enrolled between January 2011 and July 2015. After exclusion of 3 (2 with progressive disease, 1 with an adverse event, AE) who discontinued treatment in the initial 12-week EXE monotherapy period, 56 remained enrolled to receive subsequent treatment. After 8–12 weeks of the initial EXE monotherapy, 14 patients were classified as responders (9 with PR and Ki67 index ≤5% after treatment; 5 with SD and Ki67 index ≤5% before and after treatment), whereas 42 were classified as non-responders (3 with PR and Ki67 index >5% after treatment; 39 with SD and Ki67 index >5% before or after treatment). Clinical response rates at weeks 24 and 36 were 85% (12/14, 95%CI 57.2–98.2%) and 76% (10/13, 95%CI 46.2–95.0%), respectively, in the continued EXE group, and 56% (23/41, 95%CI 39.7–71.5%) and 76% (30/39, 95%CI 60.7–88.9%), respectively, in the EXE+CPA group. At week 36, no significant difference was found in median Ki67 index between the continued EXE and EXE+CPA groups (3.5% and 4.0%, respectively). The proportion of patients with preoperative endocrine prognostic index (PEPI) 0 was also similar between the continued EXE and EXE+CPA groups (21.4% and 23.8%, respectively). The breast-conserving surgery rate was 71.4% and 69.0%, respectively. Grade 3 AEs were elevated liver enzymes (1 patient) in the continued EXE group, and gastritis, hypertriglyceridemia, and bone mineral density loss (1 patient each) in the EXE+CPA group.

Conclusion Switching from EXE monotherapy to EXE+CPA combination therapy based on clinical response and biological response (change in Ki67 index) to initial therapy improved subsequent clinical response in non-responders. Favorable clinical response to EXE alone was maintained in responders. Tailored neoadjuvant endocrine and chemo-endocrine therapy was shown to be effective in postmenopausal ER-positive breast cancer patients. (JBCRG-11CPA; UMIN000004751)
Title: Effects of adding budesonide or colestipol to loperamide prophylaxis on neratinib-associated diarrhea in patients with HER2+ early-stage breast cancer: The CONTROL trial

Body: Background: Neratinib is an irreversible pan-HER tyrosine kinase inhibitor. Results from the randomized, placebo-controlled, Phase III ExteNET study demonstrated that neratinib significantly improves 24-month iDFS in patients (pts) with trastuzumab-treated early-stage HER2+ breast cancer (HR 0.67; 95% CI 0.50–0.91; p=0.009) [Chan et al. Lancet Oncol 2016]. In ExteNET, loperamide prophylaxis was not mandated, and diarrhea was the most commonly observed toxicity (grade 3, 39.8%). To reduce neratinib-associated diarrhea, high-dose loperamide prophylaxis given with the first 1–2 cycles of neratinib has been incorporated into all neratinib clinical trials; available data suggest that loperamide prophylaxis reduces the incidence and median cumulative duration of higher-grade neratinib-related diarrhea. CONTROL is an international, open-label, sequential cohort, phase II study investigating the effects of prophylaxis with loperamide ± the long-acting corticosteroid budesonide or bile acid sequestrant colestipol on neratinib-associated diarrhea. We present updated data from this study.

Methods: Pts with stage 1–3c HER2+ breast cancer who completed trastuzumab-based adjuvant therapy within 1 year were eligible. All pts received oral neratinib 240 mg once daily for 1 year + oral loperamide prophylaxis for 1 or 2 cycles (1 cycle = 28 days) ± budesonide or colestipol for the first cycle (see table). Adverse events were graded according to NCI-CTCAE (v4.0). Primary endpoint: incidence of grade ≥3 diarrhea.

1. Oral loperamide 4 mg, then 2 mg q4h d1-3, then 2 mg q6-8h d4-56 (original); 2. Oral loperamide 4 mg, then 4 mg tid d1-14, then 4 mg bid d15-56 (modified); 3. Oral budesonide 9 mg qd d1-28; 4. Oral colestipol 2 g qd d1-28; 5. Chan et al. *Lancet Oncol* 2016; 6. Original,\(^1\) n=28; modified,\(^2\) n=109; 7. Grade 4 events: CONTROL, n=0; ExteNET, n=1; 8. Treatment ongoing in all CONTROL cohorts. CONTROL data cut-off: Apr 2017.

**Conclusions:** A structured loperamide prophylactic regimen for 1 or 2 cycles reduces the incidence, severity and duration of neratinib-associated diarrhea compared with events observed in the ExteNET trial. Adding budesonide or colestipol appears to further diminish the duration and number of episodes of diarrhea and improves neratinib tolerability. Final analysis of the CONTROL study will be performed when all pts have completed 12 months of neratinib therapy. Updated data will be available at the meeting.

**Title:** Incidence of venous thromboembolism in patients with hormone receptor-positive HER2-negative metastatic breast cancer treated with CDK 4/6 inhibitors: A systematic review and meta-analysis of randomized controlled trials

Kyaw Z Thein¹, Myo H Zaw², Aung M Tun², Catherine Jones¹, Saba Radhi¹, Fred Hardwicke¹ and Thein H Oo². ¹Texas Tech University Health Sciences Center, Lubbock, TX; ²The Brooklyn Hospital Center, New York, NY and ³The University of Texas MD Anderson Cancer Center, Houston, TX.

**Body: Background:**

The cyclin dependent kinases (CDK) along with their partners, the cyclins, have a crucial role in regulation of the cell cycle. Several CDK-targeted agents have been employed in hormone receptor positive metastatic breast cancer (MBC) with noteworthy safety concerns. Nevertheless, the impact of this agent on risk of venous thromboembolism (VTE) remains uncertain. We performed a systematic review and meta-analysis of randomized controlled trials (RCT) to determine the risk of VTE among patients with hormone receptor-positive HER2-negative MBC treated with CDK 4/6 inhibitors.

**Methods:**

We systematically conducted a comprehensive literature search using MEDLINE, EMBASE databases and meeting abstracts through June 2017. Trials that mention deep vein thrombosis and pulmonary embolism as adverse effects were incorporated in the analysis. The primary meta-analytic approach was a fixed effects model using the Mantel-Haenszel (MH) method. It was used to calculate the estimated pooled risk ratio (RR), and risk difference (RD) with 95% confidence interval (CI). Pooled VTE rates were estimated as follows: we multiplied the median follow-up duration by the sample size. Crude study-specific VTE rates were then calculated by dividing the number of incident VTE cases by the total number of person-months follow-up.

**Results:**

A total of 2671 patients with hormone receptor-positive HER2-negative MBC from four phase 3 studies and one phase 2 study were eligible for analysis. The study arm used palbociclib-letrozole, palbociclib-fulvestrant, ribociclib-letrozole and abemaciclib-fulvestrant while the control arm utilized placebo in combination with letrozole or fulvestrant. The $I^2$ statistic for heterogeneity was 13.6, and the heterogeneity $X^2$ (Cochran’s Q) was 4.6 ($P=0.3$), suggesting homogeneity of results among the randomized trials. The VTE incidence was 24 (1.46%) in CDK 4/6 group vs 4 (0.39%) in control group. The pooled RR for VTE was 2.736 (95% CI: 1.115 – 6.714, $P = 0.028$) and the absolute RD was 0.010 (95% CI: 0.002 – 0.018, $P = 0.010$) according to the fixed effects model. By the random effects model, the pooled RR was 2.411 (95% CI: 0.809 – 7.181, $P = 0.114$) and RD was 0.009 (95% CI: 0.0 – 0.019, $P = 0.048$). Over median follow up of 36 months, the RR for VTE was 3.792 (95% CI: 1.838 – 7.822, $P < 0.0001$) and RD was 0.024 (95% CI: 0.014 – 0.034, $P < 0.0001$) with the fixed effects model. By the random effects model, the pooled RR for VTE was 4.248 (95% CI: 0.952- 18.959, $P = 0.058$) and RD was 0.026 (95% CI: 0.004 – 0.021, $P < 0.0001$). The pooled rate of VTE among CDK 4/6 group was 2.99 per person years compared to 0.50 per person years among control arm.

**Conclusion:**

Approximately 1% of patients on letrozole or fulvestrant alone developed VTE in previous studies. Our meta-analysis demonstrated that the addition of CDK 4/6 inhibitors to letrozole or fulvestrant, contribute to higher incidence of VTE. More randomized trials are required to determine the actual relation and definitive incidence of VTE, a major cause of morbidity and mortality among these patients.

Title: PRESAGE : Prospective multicenter feasibility study of fertility preservation before neoadjuvant or adjuvant chemotherapy for breast cancer: Preliminary results

Virginie Bordes¹, Camille Frick¹, Florence Leperlier², Aliette Dezellus¹, Pascaline De Blay³, Fabienne Maigne³, Baptiste Sauterey⁴, Paule Augereau⁴, Claudia Lefeuvre-Plesse⁵, Mario Campone¹ and Sophie Mirallie². ¹ICO René Gauducheau, Nantes, France; ²CHU, Nantes, France; ³CHD Vendée, La Roche Sur Yon, France; ⁴ICO Paul Papin, Angers, France and ⁵Centre Eugene Marquis, Rennes, France.

Body: Background: Breast cancer is the most frequent form of cancer for young women. For these patients, breast cancer is generally more aggressive and chemotherapy is more often needed. Chemotherapy is commonly associated with amenorrhea and a decrease of ovarian reserve depending on the patient's age, agents and dose. There are no guidelines to prevent subfertility for young women on cytotoxic treatments. Embryo, oocyte and ovarian tissue cryopreservation are the three options to preserve fertility. Embryo and oocyte cryopreservation require controlled ovarian stimulation (COS). The use of COS is associated with an increase of estradiol levels. It led to develop protocols using Tamoxifene or Letrozole combined with FSH to protect patients of the potential deleterious effects of the COS. We are currently conducting a study: PRESAGE, the first French prospective multicenter feasibility study of fertility preservation by COS combined with Tamoxifene and oocyte +/- embryo cryopreservation before neoadjuvant (NAC) or adjuvant (AC) chemotherapy for breast cancer.

Material and method: Prospective multicenter study for patients of less than 40 years, with a breast cancer for whom a treatment of NAC or AC is indicated and who wish to preserve their fertility. The main objective: To evaluate the feasibility of a COS associating Tamoxifène with FSH followed by an oocyte more and less embryo cryopreservation. The secondary objectives: evaluation of the average deadline prior to the beginning of the chemotherapy, the impact of the type of COS (depending on the phase of the menstrual cycle, conventional-start or random-start COS protocol) on the number and the quality of oocytes harvested. Statistical analysis was performed using BiostaTGV software.

Results: The 50 first patients were included between February 2014 and May 2016. Mean age of the patients was 31 years, half of it was nulliparous (25/50) and 20 % (10/50) were single. They presented mainly SBR II (23/50, 46 %) or III (25/50, 50 %) lesions, ER + (34/50, 68 %). 13 patients benefited from a NAC and 37 of an AC. In the NAC group, the time between the first oncologist's consultation and the fertility specialist's consultation was 3,5 +/- 3,9 days and the time between the first oncologist's consultation and the beginning of the chemotherapy was 24,5 +/- 6 days. The success rate of the COS procedure was 88 % (44/50) with no significant difference between the groups according to the type of COS (conventional-start vs. random-start p = 0.61) but there was a significant difference according to the type of chemotherapy (AC vs. NAC p= 0.03). In the 44 patients who had oocyte retrieval, the number of oocytes was 11,6 +/- 6,3 and an IVF was performed with 11,3% of patients (5/44) with 5,4 +/- 4,6 embryos obtained. We have found no impact of the type of chemotherapy or the type of COS on the number of oocytes or embryos preserved.

Conclusion: with an 88% success rate, our study suggests that COS with Tamoxifene and FSH is feasible before adjuvant or neoadjuvant chemotherapy with less success in this context but without any impact on the number of oocytes collected. We hope that these preliminary results will be confirmed at the end of the study.

Title: Hepatic pseudocirrhosis in breast cancer – analyses of clinical and prognostic factors

Dharmesh Gopalakrishnan1 and Jame Abraham2. 1Cleveland Clinic Foundation, Cleveland, OH and 2Taussig Cancer Institute, Cleveland Clinic Foundation, Cleveland, OH.

Body: Background
Hepatic pseudocirrhosis (HP) is a rare entity characterized by radiological changes in the liver resembling cirrhosis (lobular contour, nodularity, capsular retraction, and atrophy), reported most frequently in patients (pts) with treated metastatic breast cancer (BC). Cases in literature have been associated with poorer prognosis than true cirrhosis with fatal outcome nearly always in a few months. Little is known about factors which predispose to HP or influence its prognosis.

Methods
In this retrospective observational study, we reviewed abdominal radiology reports (CT, MRI, and ultrasound scans) of all our pts with BC diagnosed between 01/01/07 and 12/31/16, to identify those with HP. Cirrhosis on baseline imaging, pre-existing chronic liver disease, hepatitis B/C, and heavy alcohol use were exclusion criteria. Routine descriptive statistical measures were employed. Multiple regression was used to analyze factors affecting survival. p <0.05 was considered significant.

Results
We identified 86 pts with HP who satisfied inclusion/exclusion criteria. All were females, 89.5% were Caucasian. 83.7% of primary tumors were ER+, 58.1% were PR+ and 17.4% were HER2+. 25.6% had an invasive lobular component. The vast majority had distant metastases (mets) (97.7%) and liver mets (94.2%) at the time of diagnosis of HP, though 52.3% had stage I/II BC on initial presentation. Median size of the largest liver met was 30.0 mm and 87.2% pts had >10 liver mets. Most pts were heavily pre-treated before the manifestation of HP – 84.9% had received hormonal therapy (median cumulative duration of 35 months each of tamoxifen and aromatase inhibitors), 18.6% got anti-HER2 therapy (median duration of 15 months), and 96.5% received chemotherapy (81.4% had received ≥2 lines of chemotherapy). Median interval from diagnosis of BC to detection of HP was 6.3 years (IQR 2.9-9.6). 36% had ≥1 signs of portal hypertension (splenomegaly 15.1%, esophageal/gastric varices 18.6%, variceal bleeding 9.3% and ascites with high albumin gradient 34.9%), while 48.8% had ≥1 signs of hepatocellular failure (jaundice 47.7%, coagulopathy 30.2%, hepatic encephalopathy 14.0%). Detection of HP often led to changes in BC therapy – chemotherapy was changed in 46.5% pts, stopped in 24.4%, hormonal therapy was changed in 18.6%, stopped in 15.1%, and hospice care was initiated in 19.8% pts. Status of BC and liver mets at initial detection of HP were variable – 53.5% had disease progression while 45.3% had continued response; 40.7% had enlarging, 23.4% had stable and 30.9% had shrinking liver mets. Median survival after detection was HP was 3.6 months (1.1-11.5). Death was due to BC-progression in 83.4% pts and HP-related complications (GI bleeding, hepatic failure) contributed in 28.6% pts. Using multiple regression, lower albumin level and a higher number of metastatic sites at initial detection of HP were found to be independently associated with shorter post-HP survival (R² 16.6%, F(2,74) 7.37, p=0.001).

Conclusions
We report the largest series, till date, of BC patients with HP, an entity which can be complicated by portal hypertension and hepatocellular failure, and with marked impact on BC survival and management. Studies are needed to identify risk factors and management strategies.
Title: Safety of granulocyte colony-stimulating factors and their biosimilars: A meta-analysis of randomized clinical trials in breast cancer patients receiving cytotoxic chemotherapy

Andriy Krendyuk1, Edoardo Botter2,3 and Giuseppe Curigliano4. 1Hexal AG, Holzkirchen, Germany; 2Women and Children's Division, Norwegian National Advisory Unit on Women's Health, Oslo University Hospital, Oslo, Norway; 3Cancer Registry of Norway, Oslo, Norway and 4European Institute of Oncology, Division of Experimental Therapeutics, Oslo, Norway.

Body: Background: Neutropenia is a common adverse event reported in cancer patients undergoing cytotoxic chemotherapy. Granulocyte colony-stimulating factors (G-CSFs) such as filgrastim and pegfilgrastim are widely used to prevent neutropenia. Several biosimilars of G-CSF are now available. Biosimilar development involves a series of comparisons between the proposed biosimilar and reference performed in a step-wise fashion to eliminate any concerns regarding the similarity of the medicines. Randomized clinical trials (RCTs) are then performed to confirm that the reference product and its biosimilar provide the same clinical efficacy and safety. Patients with breast cancer (BC) are the most sensitive population in which to confirm similarity of G-CSF biosimilars, however there are some differences between clinical studies. The aim of this meta-analysis was to compare the safety profiles of approved or proposed G-CSF biosimilars (filgrastim or pegfilgrastim) with reference G-CSF in patients with BC.

Methods: A Medline literature search up to March 2017 identified randomized clinical trials (RCTs) comparing biosimilar G-CSF to reference in BC patients. Safety analyses included calculation of risk ratios for bone pain events, myalgia events and serious adverse events. Random effect models were fitted to obtain the pooled estimates of the risk ratio for the outcomes and their corresponding 95% confidence intervals (CIs).

Results: Eight eligible RCTs were included in this meta-analysis. Risk ratios for bone pain events (risk ratio 1.01 [95% CI -0.76, 1.34]; Table), myalgia events (risk ratio 0.94 [95% CI 0.63, 1.40]) and serious adverse events (risk ratio 1.01 [95% CI 0.76, 1.34]) showed no significant differences between reference and biosimilar G-CSF.

Conclusions: This meta-analysis showed no differences in the safety profile of biosimilar and reference G-CSF in breast cancer patients.
The prevention and management of chemotherapy-induced peripheral neuropathy in breast cancer patients: A systematic review

Kate E Roberts¹,², Sophie Feng¹,², India Adsett³, Kirsty Rickett² and Natasha Woodward¹,². ¹Mater Adults Hospital, Brisbane, Queensland, Australia; ²University of Queensland, Brisbane, Queensland, Australia and ³Griffith University, Southport, Queensland, Australia.

Body: Background: Chemotherapy induced peripheral neuropathy (CIPN) remains a common treatment related adverse event for breast cancer (BC) patients. CIPN interferes with the ability to complete chemotherapy & therefore potentially compromises survival outcomes. CIPN can worsen health-related quality of life and also add to the ongoing morbidity experienced by BC survivors. Previously, systematic reviews & ASCO guidelines have examined CIPN across many cancer types & different chemotherapies, which may lead to the introduction of confounding factors not relevant to BC patients. A recent prospective cohort also identified other specific lifestyle factors associated with CIPN in BC patients (1). From our search, a systematic review specifically looking at CIPN in BC patients has not previously been undertaken.

Methods: We conducted a systematic search in PubMed, EMBASE, CINAHL and CENTRAL. Clinical trials and observational studies for all potential pharmacological and non-pharmacological interventions were included. Risk of bias for full-text papers was assessed using the Cochrane Risk of Bias Assessment or the modified Newcastle Ottawa score.

Results: Of 706 records being identified, 601 unique citations were screened with 21 full text papers retrieved for assessment, and 16 studies included in the qualitative assessment. We identified 10 randomised controlled trials (RCTs), one observational cohort study, and five controlled before-and-after studies (CBA). Pharmacological interventions which were investigated included calcium/magnesium infusion, glutamine, amifostine, goshajinkigan, omega 3 fatty acids, acetyl-L-carnitine, pregabalin, alpha-lipoic acid and minocycline. Non-pharmacological interventions included body mass index & lifestyle factors, electroacupuncture, exercise, limb hypothermia, carbon dioxide limb bathing and limb compression therapy. All trials identified were investigating primary prevention of CIPN in the setting of taxane chemotherapy. Improvements in the incidence of CIPN were reported with omega 3 fatty acids, glutamine and alpha-lipoic acid, but only one of these studies is a published RCT. In two of the studies, the benefit was identified only on physical examination, but no significant benefit with nerve conduction (NCS) testing. On subgroup analysis of trials investigating exercise, there was a benefit in the use of high intensity exercise versus low intensity exercise, particularly in patients <50 years old within a healthy weight range. Mixed results were seen with goshajinkigan. An increase in CIPN was seen with antioxidant use, electroacupuncture and acetyl L carnitine. Majority of the RCTs were associated with a high overall risk of bias.

Conclusions: There has been a paucity of research on CIPN in BC patients. There were no interventions identified in this systematic review which show a clear clinical benefit in the prevention of CIPN in BC patients. BC patients may have specific lifestyle and hormonal factors which influence CIPN and this should prompt ongoing specific patient focussed research within this subgroup with large, blinded, randomised controlled trials.

Early detection of chemotherapy-induced cardiotoxicity in breast cancer patients

Carmen Salvador-Coloma¹,³, Amparo Hernández¹, Sandra Tejedor¹, Vicente Miró², Laura Palomar², Antonio Salvador², Pilar Sepúlveda¹ and Ana Santaballa³. ¹Instituto de Investigación Sanitaria La Fe, Valencia, Spain; ²Servicio de Cardiología. Hospital Universitario y Politécnico La Fe, Valencia, Spain and ³Servicio de Oncología Médica. Hospital Universitario y Politécnico La Fe, Valencia, Spain.

**Body: BACKGROUND**

The incidence of cardiotoxicity in patients receiving treatment for breast cancer is unknown. There is not enough evidence about early detection and appropriate management of cardiotoxicity. The aim of this study is to identify early markers of risk of cardiac toxicity.

**MATERIAL AND METHOD**

Prospective study was conducted between 2014 and 2017 based on a cohort of 97 patients diagnosed with breast cancer treated with chemotherapy. Analytical biomarkers (natriuretic peptide, ultra-sensitive T troponin), echocardiogram parameters (left ventricular ejection fraction (LVEF) and global longitudinal strain (GLS)) and electrocardiogram were performed. Analytical biomarkers were measured each chemotherapy cycle and cardiology test were performed before starting chemotherapy, 3 months afterwards, and then every six months during 5 years. Cardiotoxicity was defined as a reduction in basal LVEF >10% with LVEF<55% in asymptomatic patients or >5% with LVEF<55% in symptomatic patients.

**RESULTS**

Patients characteristics are shown in table 1

. All patients had the basal LVEF in normal range. Median follow-up was 26.5 months (13.5-39.6 months). A total of 10.3% had cardiotoxicity with reduction in basal LVEF >10% with LVEF<55% being asymptomatic and 2.1% were symptomatic. Five of these patients were treated with heart failure therapy: 5 with ACE (angiotensin converting enzyme) inhibitors and 3 with beta- blockers. Two of those (40%) who received specific treatment recovered basal LVEF-levels, 2 maintained LVEF dysfunction, and 1 died during follow-up due to tumor-related causes. In 83.3% of patients, cardiotoxicity occurred within the first year of follow-up. In 50 patients SLG was calculated, in 30% it was lower than -12% in some measurement phase. In 5 cases the LVEF fell below 55% and the LRP decreased by 12% coincided. The others patients, although they did not develop cardiotoxicity according to the established criteria, a decrease of the LVEF is observed during the treatment and in the first control, between 3-7%, which subsequently tends to recover spontaneously.

miRNA 21-5p, miRNA-133b, miRNA 210-3p, miRNA 423-5p, and miRNA-663b were analyzed. A model has been evaluated where a correlation between the levels of miRNA-133b, miRNA-21-5p and miRNA-210-3p and the decrease of LVEF in relation to
treatment was observed.

CONCLUSIONS
Control by echocardiography and serum markers allowed us to detect early cardiotoxicity events and provide us an opportunity to start heart failure therapy on time with the aim of improving the control and evolution of it. Levels of miR-133b, miR-21-5p and miR-210 may alert for a risk of cardiotoxicity and can help to make decisions about treatments.

Title: The impact of a structured surveillance protocol using bioimpedance spectroscopy (BIS) on preventing breast cancer related lymphedema (BCRL) in high-Risk patients

Pat Whitworth¹, Andrea Cooper¹, Chirag Shah² and Frank Vicini³. ¹Nashville Breast Center, Nashville, TN; ²Cleveland Clinic, Cleveland, OH and ³Michigan Healthcare Professionals, Farmington Hills, MI.

Body: Background: We evaluated the impact of structured surveillance using bioimpedance spectroscopy (BIS) to prevent clinical BCRL in a group of high-risk (axillary lymph node dissection) patients.

Methods: From April 2010 through November 2016, 93 patients who were treated with axillary lymph node dissection (ALND) were prospectively monitored with BIS using L-Dex (Impedimed). Patients received a pre-operative baseline L-Dex measurement followed by post-operative assessments at regular intervals. An elevated L-Dex score was defined as an increase of ≥10 points above baseline (considered subclinical BCRL). Intervention consisted of applying an over the counter (OTC) sleeve for 4 weeks followed by re-evaluation. The need for complete decongestive physiotherapy (CDP) represented a surrogate for the development of clinically significant, chronic BCRL.

Results: Median follow-up was 24 months (range: 0.3-206.4 months). The median number of nodes removed was 19 (range: 5-41) and the median number of positive nodes was 3. Median age was 53 years old. Eighty percent of patients underwent mastectomy and the remainder breast conserving therapy. 55% of patients received taxane based chemotherapy, 24% received some form of axillary RT (15% high tangents and 9% comprehensive regional nodal RT) and 74% had an elevated body mass index (BMI, > 25). Overall, 75% of these patients had at least one additional high-risk feature, 48% had at least two, and 6% had 3 (either taxane chemotherapy, axillary RT or elevated BMI). Thirty-three patients (35.4%) developed an elevated L-Dex score at some point during follow up. Overall, 10 patients (11%) required CDP at any point after treatment.

Conclusions: The results of this analysis support previously published data on the efficacy of prospective BCRL surveillance and early intervention using BIS. Of the 93 high-risk patients prospectively followed and managed in this structured BCRL protocol, 11% required CDP. These results compare favorably to all contemporary studies reporting BCRL rates in high-risk patients.
Title: Low rates of chronic breast cancer related lymphedema (BCRL) in a cohort of high-Risk patients undergoing prospective surveillance with bioimpedance spectroscopy (BIS)

David Kaufman¹, Chirag Shah² and Frank Vicini³. ¹Breast Cancer Specialists, Bethpage, NY; ²Cleveland Clinic, Cleveland, OH and ³Michigan Healthcare Professionals, Farmington Hills, MI.

Body: Background: We report outcomes using prospective BIS surveillance in a high-risk cohort of patients who all underwent axillary lymph node dissection (ALND).

Methods: From 8/2010 through 12/2016, 206 consecutive patients were evaluated with BIS as part of a prospective surveillance program. 30 underwent ALND and constitute the study population. The program included pre-operative BIS measurement as well as post-operative assessments at regular intervals. Patients with L-Dex readings increasing by more than 10 from baseline were considered to have subclinical BCRL and treated with an over-the-counter (OTC) compression sleeve for 4 weeks. For the purpose of this analysis, additional high-risk features were defined as receipt of axillary radiation, a high body mass index (BMI) or the use of taxane based chemotherapy. Chronic BCRL was defined as the need for complex decongestive physiotherapy (CDP).

Results: Median follow-up was 36 months (range: 4.8-122.1 months). The median number of nodes removed was 18 (range: 5-32) and the median number of positive nodes was two. The median age for the cohort was 57.5 years old with 70% of patients undergoing mastectomy and the remainder breast conserving therapy. With respect to additional high-risk features, 77% also received taxane-based chemotherapy, 62% axillary irradiation, and 48% had an elevated BMI. Overall, 86% of patients had at least one additional high-risk feature, 70% at least two, and 23% had all three additional high-risk features. Seven patients (23%) had an elevated L-Dex score at some point during follow-up and underwent intervention with an OTC sleeve for 4 weeks. To date, no patients have required CDP at any time.

Conclusions: Prospective surveillance with BIS in a high-risk cohort of patients all undergoing ALND (plus additional high-risk features) led to no patients requiring CDP. These excellent findings are consistent with growing data supporting the use of BIS in prospective BCRL surveillance programs.
Title: Proposed biosimilar pegfilgrastim LA-EP2006 shows similarity in pharmacokinetics and pharmacodynamics to reference pegfilgrastim in healthy subjects

Roumen Nakov¹, Sreekanth Gattu¹, Jessie Wang², Maria Velinova³ and Andrej Skerjanec⁴. ¹Hexal AG, Holzkirchen, Germany; ²Sandoz Inc., Princeton, NJ; ³PRA Health Sciences, Gronigen, Netherlands and ⁴Sandoz AG, Basel, Switzerland.

Body: Background: Granulocyte colony-stimulating factors such as filgrastim and its long-acting version pegfilgrastim are widely used to prevent neutropenia in patients receiving chemotherapy. LA-EP2006 is a proposed biosimilar pegfilgrastim that has been compared with reference pegfilgrastim and shown to have no clinically meaningful differences regarding efficacy and safety in breast cancer patients receiving myelosuppressive chemotherapy.¹,²

Methods: This single-dose, randomized, double-blind, two-way crossover study evaluated the pharmacokinetics (PK), pharmacodynamics (PD), immunogenicity and safety of LA-EP2006 and reference pegfilgrastim (Neulasta®, Amgen) in healthy male and female subjects. Subjects were randomized to receive a single 6 mg subcutaneous (sc) injection of LA-EP2006 or reference on Day 1. After dosing, subjects underwent a 4-week assessment period followed by a 4-week washout period before crossing over to receive the other pegfilgrastim and were assessed for a further 4 weeks. The primary objective was to determine PK similarity of LA-EP2006 and reference pegfilgrastim \( (AUC_{0→∞}, AUC_{0→\text{last}} \text{ and } C_{\text{max}}) \), and then PD similarity (absolute neutrophil count [ANC] response in terms of AUEC \( 0→\text{last} \) and \( E_{\text{max}} \)). Secondary objectives included safety and immunogenicity.

Results: A total of 92 subjects were randomized to receive LA-EP2006 then reference (LA-EP2006/reference), and 93 subjects were randomized to receive reference then LA-EP2006 (reference/LA-EP2006) with one subject enrolled but not receiving study medication. A total of 169 subjects were included in the PK and PD analyses. Demographics and baseline characteristics were similar between groups in both treatment periods. PK similarity was shown since the 90% confidence interval (CI) for the geometric mean ratio of LA-EP2006 vs. reference was within the predefined similarity range 0.8–1.25. PD similarity was shown since the 95% CI for the ratio of LA-EP2006 vs. reference was within the predefined similarity range 0.8–1.25 (Table). Secondary endpoints and safety were similar between groups. No neutralising antibodies were detected.

PK and PD parameters for the comparison between LA-EP2006 and reference pegfilgrastim (N=169)*.

Title: Comparative effectiveness of antiemetic regimens for highly emetogenic chemotherapy-induced nausea and vomiting: A systematic review and network meta-analysis

Takamichi Yokoe1, Tetsu Hayashida1, Aiko Nagayama1, Tomoko Seki1, Maiko Takahashi1, Toshimi Takano2, Takayuki Abe3 and Yuko Kitagawa1. 1Keio University School of Medicine, 35 Shinanomachi, Shinjyuku, Tokyo, Japan; 2Toranomon Hospital, 2-2-2 Toranomon, Minatoku, Tokyo, Japan and 3Keio University School of Medicine, Clinical and Translational Research Center, 35 Shinanomachi, Shinjyuku, Tokyo, Japan.

Body: Background
The optimal choice of antiemetic therapy for chemotherapy-induced nausea and vomiting (CINV) needs to be clarified. This study assessed the efficacy and safety of antiemetic regimens for highly emetogenic chemotherapy (HEC).

Methods
Randomized trials that compared different antiemetic regimens were included from MEDLINE. Quality was assessed using the Cochrane risk-of-bias tool. We followed Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) guidelines. Data were pooled using random-effects models. We conducted indirect comparisons using network meta-analysis of a Bayesian model. The main outcomes were the odds ratio (OR) for overall complete response (CR [i.e., no emesis and no rescue]). Safety was assessed from the trial description. All statistical tests were two-sided.

Findings
We systematically reviewed 24 randomized control trials (12,104 participants), which compared 12 different antiemetic regimens. Palonosetron (PAL) 0·75 mg (PAL0·75) + dexamethasone (Dex); aprepitant (APR) + a serotonin-3 receptor antagonist (5HT3) + Dex; and APR + PAL (0·25 mg or 0·50 mg) + Dex were more favorable than the reference regimen (OR, 1·51; 95% credibility interval [95%CrI], 1·18-1·91; OR, 1·78; 95%CrI, 1·58-2·05; and OR, 2·28; 95%CrI, 1·66-3·18, respectively). The oral combination of netupitant and palonosetron (NEPA) was more effective than conventional regimens (OR, 2·39; CrI, 1·73-3·30). Olanzapine (OLZ)-containing regimens were apparently the most effective: the ORs of OLZ + 5HT3 + Dex, OLZ + PAL + Dex, and OLZ + APR + 5HT3 + Dex were 2·78, 2·58, and 4·98, respectively.

Interpretation
The regimens of PAL0·75 + Dex, APR + 5HT3 + Dex, and APR + PAL + Dex were more favorable in conventional regimens (i.e., regimens without NEPA or OLZ), which support the NCCN guideline strategy. NEPA could be a better choice than conventional regimens. OLZ-containing regimens could be an optimal choice; thus, more trials need to be accumulated.
Title: The effect of participation in RCT on outcomes in patients with early breast cancer compared to the general breast cancer population

Meghan B Brennan¹, Dorothy Wiley², Daidong Wang¹, Xiaoyan Wang¹ and Peter Fasching³. ¹UCLA-School of Medicine, Los Angeles, CA; ²UCLA-School of Nursing, Los Angeles, CA and ³University Hospital Erlangen-Fridrich-Alexander-University Erlangen-EMN, Erlangen, Germany.

Body: Background: Breast cancer trial enrollment, while slightly higher than some other histologies, still remains low, at less than 4%. Research suggests lack of clinical trial participation is due to poor patient and clinician commitment and interest. Increasing incentive for trial participation may enhance engagement of patients and healthcare providers leading to increased patient enrollment. One incentive would be to understand benefits of trial participation with regards to better survival and outcomes. The purpose of this study is to determine differences in survival, overall and breast cancer specific, and surgical management, for women who participate in early breast cancer randomized clinical trials (RCT) compared to the general breast cancer population who received similar standard therapy outside of a RCT.

Methods: Patients included in this retrospective analysis were from one of three (3) international, randomize, adjuvant breast cancer trials (RCT-participants) and women with breast cancer from the general U.S. population, from Surveillance Epidemiology and End Results Program (SEER-13), the controls. Women diagnosed between 1997-2004 with invasive breast cancer, tumor (T) size 1-3, lymph node (LN) positive (LN1/2), hormone receptor positive or negative, HER2 positive or negative, treated with surgery, adjuvant radiation, and chemotherapy were included in the analysis. In this study, propensity score analysis (PSA) was done to provide weight to each data point for each variable in order to more closely represent similar populations. PSA, considered superior to a standard Cox multivariate analysis as it attempts to reduce the bias due to confounding or correlated predictive variables. Subsequently, the propensity score was applied to a Cox proportional hazards model to determine hazard ratios (HR), with a Wald 95% confidence interval (CI), of trial participation on survival. Similarly, PSA was done for surgical outcomes. A multivariate logistic regression was performed to calculate the odds ratios, with a Wald 95% CI, to determine if RCT participation compared to the SEER-13 control had an impact on surgical outcomes, mastectomy versus breast conserving surgery (BCS).

Results: The total sample size was 9255 patients, 1795 RCT-participants and 7460 SEER-13 controls. After controlling for all other significant predictors of survival, RCT participation significantly reduced risk of breast cancer related death at 5-years by more than 25% and 18% at 10 years [HR: 0.75 (95% CI: 0.64-0.87); p=0.00020; and HR: 0.83 (95% CI: 0.74-0.93); p=0.00165, respectively]. Additionally, we demonstrated a significant reduction in risk of all-cause mortality for RCT-participants, at both 5-years and 10-years [HR: 0.83 (95% CI: 0.72--0.95); p=0.009; and HR: 0.79 (95% CI: 0.71-0.87); p<0.00001, respectively]. Additionally, RCT-participants were significantly less likely to undergo invasive surgical management (mastectomy) compared to SEER-13 controls [OR: 0.78 (95% CI: 0.66-0.92;) p=0.03].

Conclusion: RCT-participants have a reduced risk of death at 5 years and 10 years compared to the general breast cancer population. Additionally, RCT-participants are less likely to undergo mastectomy than the SEER-13 controls.
Treat ER+ight Canadian prospective observational study in HR+ advanced breast cancer: 2nd interim analysis

Susan Dent¹, Nadia Califaretti², Catherine Doyle³, Cristiano Ferrario⁴, Edmond Chouinard⁵, Swati Kulkarni⁶, Josee-Anne Roy⁷, Sabrina R Perri⁸ and Stephen Chia⁹. ¹Ottawa Hospital Cancer Center, Ottawa, ON, Canada; ²Grand River Regional Cancer Center, Kitchener, ON, Canada; ³Deschênes-Fabia Breast Cancer Center, Quebec City, QC, Canada; ⁴Segal Cancer Center - Jewish General Hospital, Montreal, QC, Canada; ⁵Cambridge Memorial Hospital, Cambridge, ON; ⁶Windsor Regional Cancer Center, Windsor, ON, Canada; ⁷Hopital Sacré-Coeur de Montreal, Montreal, QC, Canada; ⁸Novartis Pharmaceuticals Canada Inc., Dorval, QC, Canada and ⁹BC Cancer Agency - Vancouver Cancer Center, Vancouver, BC, Canada.

Body: Treat ER+ight is the 1st prospective observational study in Canadian postmenopausal women with HR+ HER2– advanced breast cancer currently receiving endocrine therapy (ET) alone or in combination with targeted therapy (TT) (NCT02753686).

Methods: This pre-planned interim analysis describes baseline characteristics, treatment sequence, monitoring patterns, patient-reported quality-of-life (QoL) and resource utilization of patients enrolled in ET and ET+TT cohorts within the 1st 3 months of therapy. At data cut-off (13Mar‘17), 100 patients were enrolled from 24 sites since Mar‘16.

Enrollment therapy (%): everolimus+exemestane (35), fulvestrant (15), palbociclib + letrozole (15), tamoxifen (14), exemestane (7), palbociclib+fulvestrant (7), letrozole (4) and palbociclib+exemestane (1). Follow-up visits with physician after therapy initiation ET, ET+TT (%): week 2 (5, 47), month 1 (71, 67), month 3 (43, 31). Numerical differences were observed in EORTC QLQ C30 and BR23 global health status/QoL, functional and symptom scale scores between ET and ET+TT cohorts. Mean changes in
transformed scores from baseline to month 3 were generally similar between cohorts however 'therapy side effects' symptom item worsened in ET+TT cohort (P = 0.031, Wilcoxon rank sum). Resource utilization in between scheduled visits during 1st 3 months of therapy was similar between cohorts for physician/radiology, hospitalizations and ER visits however patient calls to supportive care nurse was increased in ET+TT cohort (P = 0.008, Fisher’s exact). Treatment discontinuation rate (20%) was similar between cohorts with progression as predominant reason for initiating next therapy. Chemotherapy (CT) was the most frequent subsequent therapy and represented 1st line metastatic CT for majority of patients.

Conclusions:
ET+TT patients were younger, had better ECOG, more visceral disease and 60% received everolimus+exemestane with <10% receiving prior CDK4/6 therapy. Half of patients in ET+TT cohort returned for a follow-up visit with oncologist within 2 weeks of therapy initiation (compared to minority in ET cohort) and called the supportive care nurse in between scheduled visits. Patient-reported Qol within 1st 3 months of therapy was generally similar between cohorts. Therapy-related AEs impacted the patient-reported experience in ET+TT cohort however AEs did not lead to therapy discontinuation in over 85% of cases. These results highlight the importance of: (1) proactive AE patient education/management upon ET+TT initiation and at subsequent follow-up visits, (2) week 2 visit and (3) additional nursing telephone support in between visits.

Title: Clinical benefit, toxicity, and cost of metastatic breast cancer drug therapies: Visualizing randomized and non-randomized evidence

John Silberholz¹, Linda Vahdat² and Dimitris Bertsimas³. ¹University of Michigan, Ann Arbor, MI; ²Weill Cornell Medicine, New York, NY and ³Massachusetts Institute of Technology, Cambridge, MA.

Body: Background: Given the rapidly expanding size of the clinical trial literature for metastatic breast cancer (MBC) clinical trials, oncologists need tools that enable them to efficiently review the settings and results of previous studies.

Methods: We searched the Cochrane Central Register of Controlled Trials and PubMed to identify clinical trials testing MBC drug therapies. Key eligibility criteria included >90% of patients enrolled in trial having MBC, therapeutic clinical trials, and Phase II or III studies with at least 10 patients at a dosage level. From each study, we extracted information about clinical benefit and toxicity of drug therapies, and we further estimated the costs of all drug therapies. We built a web-based visualization tool that presents the results of all studies testing a given drug combination, stratified based on patients’ receptor statuses and prior exposure to therapy. The tool presents both aggregate and study-level results, and reports both unadjusted study results and standardized results based on key patient characteristics in the study populations.

Results: We included 1,783 studies containing 2,549 treatment arms and 170,515 patients in the visualization tool. The tool reports information on 77 HER-2-directed therapies, 101 hormonal therapies, and 675 undirected therapies. The visualization tool has been made publicly accessible for patients and doctors to access at http://cancertrials.info.

Discussion: We believe this tool will make literature reviews significantly more efficient for oncologists, enabling them to better leverage insights from the clinical trial literature when making treatment decisions.
**Title:** Signalling pathways targeted by the YangZheng Xiaoji extract and the therapeutic implications in human breast cancer

Wen G Jiang¹, Lin Ye¹, Sioned Owen¹, Fiona Ruge¹, Tracey A Martin¹, Andrew J Sanders¹, Gong Gao², Cong Wei², Yiling Wu² and Eleri Davies³. ¹Cardiff University School of Medicine, Cardiff, Wales, United Kingdom; ²Yiling Pharmaceuticals, Cardiff, Hebei Province, China and ³Breast Cancer Centre, University Llandough Hospital, Cardiff, Wales, United Kingdom.

**Body:** Background. Yangzheng Xiaoji is a formulation of Chinese medicine and has been used in the treatment of solid cancer as an adjuvant to chemotherapy by reducing the side effects to the patient. There has been evidence to show that the medicine has a direct biological role in cancer cells. In the present study, we sought to investigate the potential effects of the medicine on breast cancer cells and in particular aimed to identify the key targets and molecular pathways contributing to the anti-cancer effect of the medicine.

Methods. Human breast cancer cell lines (BT549, BT20, MDA MB-231, MCF-7 and ZR 75-1) with varying invasiveness and receptor status were used. The soluble extract of Yangzheng Xiaoji, namely DME25 was used in the study. The effects of DME25 on the growth, toxicity and cellular migration were assessed. Signalling kinase changes were screened using kinase antibody array based array technologies. Kinases were also validated using phosphorylation based protein blotting.

Results. Of the five breast cancer cell lines tested, Yangzheng Xiaoji extract DME25 showed little cytotoxicity over a broad range of concentrations. However, DME25 were able to markedly reduce the migration of the panel of breast cancer tested, without being toxic. Triple negative cells responded in a similar fashion with other cells. It was also noted that the adhesion of these cells were also inhibited by DME25. Using a protein kinase array, it was shown that a number of kinase complexes were inhibited by the medicine, notable ones including EGFR family kinases (reduced by 35%), Janus protein kinases (JAK) (by 57%), and Ras-related C3 botulinum toxin substrate (Rac1 or CDC42 GTPase) (by 49%) and Ribosomal protein S6 kinases (RSKs) (by 52%). Given the clinical significance of RSKs in human breast cancer, we further evaluated the role of RSK and RSK inhibitors in DME mediated cell functions and have demonstrated that both in triple negative breast cancer cells and receptor positive breast cancer cell lines, DME25 was able to synergistically enhance the effect of RSK2 inhibitor, SL1010-1, on the both the cellular migration and cell growth.

Conclusion. Yangzheng Xiaoji has a broad and direct effect on the migration of breast cancer, an effect unrelated to hormone receptor status and independent of cytotoxicity. The medicine appears to target kinase pathway, particularly for the RSK kinases, suggesting an important clinical implication in the treatment of breast cancer.
Title: Early breast cancer in the elderly: characteristics, therapy, and long-term outcome

Omer Gal¹, Yael Ishai¹, Aaron Sulkes¹,³, Tzipora Shochat² and Rinat Yerushalmi¹,³. ¹Davidoff Cancer Center, Rabin Medical Center - Beilinson Hospital, Petach Tikva, Israel; ²Statistical Consulting Unit, Rabin Medical Center - Beilinson Hospital, Petach Tikva, Israel and ³Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel.

Body: Objective: The number of older adults diagnosed with breast cancer is increasing. However, data on breast cancer characteristics, treatment, and survival in elderly women are sparse.

Methods: The database of a tertiary cancer center was searched for all women aged ≥65 years who were diagnosed with early breast cancer in 2004-2007. Patients were divided into two age groups: 65-75 years and >75 years. Data on tumor, treatment and outcome parameters were compared.

Results: The cohort included 390 patients. The older group underwent more mastectomies but less axillary surgery or adjuvant systemic therapy. Median overall survival (OS) was 9.5 years in the older group and not reached in the younger group; the 8 year disease-free survival rates were 85% and 88%, respectively (p=0.27). Both age and tumor subtype had an effect on OS and recurrence rates (p<0.001 for OS; p=0.16 for recurrence). The worst outcome was noted in women aged >75 years with triple-negative (TN) disease.

Conclusion: Treatment approach was different between both age groups, despite similar tumor characteristics. TN subtype presented as the most aggressive disease in both age groups. Physicians should be alert to these findings and select treatment on a case-by-case basis.
Title: Using the new pan-cancer clinical data resource (TCGA-CDR) to identify breast cancer genomic correlates associating with different survival outcome endpoints

Jianfang Liu¹, Tara Lichtenberg², Katherine A Hoadley³, Andrew Cherniack⁴, Laila Poisson⁵, Albert J Kovatich⁶, Christopher Benz⁷, Vesteinn Thorsson⁸, TCGA PanCanAtlas Research Network, Craig D Shriver⁹ and Hai Hu¹.¹ Chan Soon-Shiong Institute of Molecular Medicine at Windber, Windber, PA; ²Nationwide Children's Hospital, Columbus, OH; ³University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁴The Eli and Edythe L. Broad Institute of MIT and Harvard, Cambridge, MA; ⁵Henry Ford Health System, Detroit, MI; ⁶Clinical Breast Care Project, Murtha Cancer Center, Uniformed Services University / Walter Reed National Military Medical Center, Bethesda, MD; ⁷Buck Institute for Research on Aging, Novato, CA; ⁸Institute for Systems Biology, Seattle, WA and ⁹Murtha Cancer Center, Uniformed Services University / Walter Reed National Military Medical Center, Bethesda, MD.

Body: Introduction

The Cancer Genome Atlas (TCGA) generated abundant high quality molecular data, however its relatively short-term patient follow-up limited its immediate clinical utility. We led a PanCanAtlas effort to systematically collate, integrate, and quality check the large body of acquired clinicopathologic data, generated 4 primary clinical outcome endpoints for each case, and created a new Pan-Cancer Clinical Data Resource (TCGA-CDR) for public use. We report here on the utility and validity of this TCGA-CDR in relating breast cancer (BC) genomic information to survival endpoints.

Methods

Clinicopathologic data from all data files were integrated and processed. Overall survival (OS), disease-specific survival (DSS, an approximation), progression-free interval (PFI), and disease-free interval (DFI) were derived. Tests of the adequacy of the follow-up intervals for each endpoint were performed, and quality evaluation of these endpoints was established by their comparison with different clinical features. As a case study we compared each survival endpoint for significant association (FDR <0.2) with chromosomal aneuploidy.

Results

The 4 endpoints were derived for 1097 TCGA BC cases having a median follow-up time of 27.7 months. Median times to events/censorship for OS, DSS, PFI, and DFI were 41.8/25.0, 32.6/26.0, 26.0/25.0, and 25.4/25.0 months respectively. PFI and DFI passed tests for adequate follow-up times; OS and DSS partially passed the same tests signaling some caution with their use in genomic associations.

Using the endpoints, outcomes of patients with ER+ and ER- tumors were compared, along with those of patients with low (I&II) and high (III&IV) stage breast tumors. Univariate analyses suggested patients with ER+ tumors had significantly better survival than patients with ER- tumors when using PFI (p=0.005), DFI (p=0.001), and DSS (p=0.009), with OS not reaching significance (p=0.09). Patients with low stage tumors showed significantly better outcomes than patients with high stage tumors for each endpoint (p<0.001). The 4 endpoints were also evaluated for their significant associations with chromosomal arm aneuploidy. Adjusted for patient age and AJCC stage, tumors with a loss of 8q and 8p (p=0.019, FDR=0.37) had worse PFI; and those with loss of 8q, 20q, and 8p had worse DFI. Tumors with gain of 11q or loss of 14, 7q, 12q, 18q, 20q, 3p, 7p, 8p, 18p, and 20p had worse OS. In contrast, tumors with loss of 16q had better DSS, while those with loss of 3q, 12q, 17q, 18q, 19q, 20q, 3p, 8p, 12p, 18p, 19p, and 20p had worse DSS. The finding that 8p loss associated with worse survival for all 4 endpoints, while 18p loss associated with worse OS and DSS, agrees with literature reports.

Conclusion

These findings confirm that PFI and DFI, as extracted from the TCGA-CDR, are valid and appropriate BC survival endpoints, while OS and DSS may be recommended with some caution when employing TCGA data to evaluate new relationships between breast cancer genomic abnormalities and clinical outcomes.

Title: Geographic variation in adverse event reporting patterns in breast cancer clinical trials

Valeria González1, Andrés Machado1, Helena Fung2, Gonzalo Spera1, Carlos Meyer1, Pablo Millán1, John R Mackey3 and Rodrigo Fresco1. 1Translational Research in Oncology (TRIO), Montevideo, Uruguay; 2Translational Research in Oncology (TRIO), Edmonton, AB, Canada and 3University of Alberta, Edmonton, AB, Canada.

Body: Introduction: Adverse event (AE) reporting in clinical trials (CT) informs the safety of investigational products. Once approved, safety information in the monograph and prescribing information mainly derive from CT data. Some studies have shown geographic variations in the AE reporting patterns in multinational CT; none of them assessed this variation in cancer CT. We conducted a study to analyze the geographic AE reporting patterns in two breast cancer (BC) CT conducted by Translational Research in Oncology (TRIO).

Objective: To perform a quantitative and qualitative comparison of non-serious AE (NSAE) and serious AE (SAE) reporting patterns between several geographic regions, in breast cancer CT conducted by TRIO.

Methodology: We retrospectively analyzed aggregated NSAE/SAE data (as reported by investigators) from all patients randomized in two completed phase 3, multinational CT of anticancer therapies in advanced BC. Participating countries were grouped in 7 regions according to their geographic location (East Asia, Eastern Europe, Latin America and Caribbean, Middle East and Africa, Non-Eastern Europe, North America, Oceania). Regions were kept masked and numbered from 1 thru 7. AE data were extracted from the clinical data bases. For each region we calculated the mean number of NSAE and SAE per patient (pt), the mean number of NSAE and SAE per cycle/per pt, and the percentage (%) of pt experiencing selected AE (fatigue, febrile neutropenia and emesis). Comparisons between regions were done using unequal variance t-test and Fisher’s exact test.

Results: 1,863 patients from 35 countries and 310 sites were included. Mean number of pt per region was 331. We found significant variation in the number of NSAE/SAE reported across several regions. Two regions (1 and 6) reported the highest mean number of AE while region 4 the lowest rates. The mean number of NSAE reported in region 4 is approximately 3-fold lower than regions 1 and 6 (mean NSAE 22.8 [region 1] vs. 7.9 [region 4]; p <.0001; mean NSAE cycle/pt 9.7 [region 1] vs. 3.2 [region 4]; p <.0001). Region 4 reported 8-fold lower rates of SAE than region 1 (mean number SAE 0.1 vs. 0.8, p<.0001) (Table 1). % of pt experiencing AE fatigue, febrile neutropenia and nausea/vomiting also varied significantly across regions, especially between regions 1 and 4 (Table 2).

<table>
<thead>

Conclusion: NSAE and SAE reporting patterns vary markedly by geographic region and one region appears to systematically under report both NSAE and SAE. These data warrant confirmation, and if confirmed, may provide an important caveat on the interpretation of reported study safety data.
Title: Influence of non-measurable disease on progression-free survival in patients with metastatic breast cancer

Hadar Goldvaser¹, Domen Ribnikar¹, Rouhi Fazelzad¹, Bostjan Seruga², Arnoud J Templeton³, Alberto Ocana⁴ and Eitan Amir⁴.
¹Princess Margaret Cancer Centre, Toronto, ON, Canada; ²Institute of Oncology Ljubljana, Slovenia, Ljubljana, Slovenia; ³St. Claraspital Basel and Faculty of Medicine, University of Basel, Basel, Switzerland and ⁴5Research Unit. Albacete University Hospital, Albacete, Spain.

Body: Background:
Progression free-survival (PFS) is the dominant endpoint in phase 3 randomized controlled trials (RCTs) in women with metastatic breast cancer (MBC), and requires the ability to measure target lesions. It is unknown whether treatment effect on PFS is consistent among patients with measurable and non-measurable disease.

Methods:
We searched MEDLINE, EMBASE and COCHRANE for phase 3 RCTs in MBC that reported outcomes in subgroups with non-measurable (or bone only disease, if not reported explicitly) and measurable disease. Data were extracted and a single hazard ratio (HR) and 95% confidence intervals (CI) were computed to compare the individual trial treatment effect in non-measurable versus measurable disease. Data were then pooled in a meta-analysis. We repeated the analysis comparing bone only to non-bone only disease and performed subgroup analyses based on drug mechanism of action.

Results:
Of 82 RCTs that enrolled patients with non-measurable disease, 16 trials comprising 8516 patients were eligible for analysis. All included RCTs used PFS or time to progression as primary endpoints. There was no difference in pooled treatment effect between patients with non-measurable and measurable disease (HR 1.01, 95% CI 0.89-1.15, p=0.82). However, compared to non-bone only disease, a significantly greater effect on PFS was seen in those with bone only disease (HR 0.82, 95% CI 0.70-0.98, p=0.03). Subgroups analyses according to drug mechanism are shown in Table 1

CI- confidence interval, HR- hazard ratio

. Compared to patients with measurable disease, there was a greater effect on PFS in those with non-measurable disease in RCTs of signal transduction inhibitors and endocrine therapy (HR 0.74, 95% CI 0.59-0.94, p=0.01). There was a lesser effect on PFS in patients with non-measurable disease in RCTs of antiangiogenic drugs (HR 1.34, 95% CI 1.05-1.71, p=0.02). Comparable effect on PFS was shown in RCTs evaluating endocrine therapy and chemotherapy.

Conclusions:
There is variability in treatment effect on PFS in patients with measurable and non-measurable disease. There is greater effect on PFS in RCTs of endocrine therapy and signal transduction inhibitors and in patients with bone only disease. Standardization of PFS determination in patients with non-measurable and bone only disease is warranted.
**Title:** Concordance of real world progression free survival (PFS) on endocrine therapy as first line treatment for metastatic breast cancer using electronic health record with proper quality control versus conventional PFS from a phase 3 trial

Cynthia Huang Bartlett¹, Jack Mardekian¹, Matthew Cotter¹, Xin Huang¹, Zhe Zhang¹, Christina M Parrinello², Amy P Abernethy² and Maria Koehler¹. ¹Pfizer, New York, NY and ²Flatiron Health, New York, NY.

**Body:**

**Background:** There is growing interest to assess treatment effect with clinical endpoints that are reflective of real world clinical practice based on data systemically collected from the electronic health record (EHR). This study compared real world PFS (rwPFS) among a cohort of female patients (pts) treated with letrozole (LET) monotherapy as first-line therapy for metastatic breast cancer (MBC) in routine clinical practice to PFS using RECIST criteria from the LET alone cohort in a randomized clinical trial (PALOMA-2).

**Methods:** For rwPFS, assessments were based on clinician notes, radiological reports, and pathological reports available in the EHR. Data were extracted from the EHR using technology-enabled abstraction; relevant documents were presented to trained human experts and data were entered into an electronic interface mimicking a case report form, with centralized management and quality controls. The patient cohort was derived from a large, longitudinal, demographically and geographically diverse EHR database of pts receiving cancer care at U.S. community-based and academic clinics (Flatiron Health); pts were all females who began treatment with LET for MBC as first-line treatment between January 1, 2011 and September 30, 2015. PFS in the clinical trial used a conventional definition based on RECIST; data were from the Pfizer clinical study PALOMA-2 database; 222 post-menopausal women in the LET alone arm met pre-specified inclusion/exclusion criteria and assessment intervals with enhanced data collection as previously detailed (Finn, NEJM 2016). All data were de-identified. Propensity score matching using a nearest neighbor algorithm with caliper=0.10 (maximum difference in propensity scores for a match) was performed to assess the consistency between the two approaches to PFS assessment. Kaplan-Meier estimates of median rwPFS/PFS are reported.

**Results:** 107 pts met eligibility criteria from the EHR subset. Pts were younger and had less extensive disease in the PALOMA 2 cohort: The mean age was 60.6 vs 68.6 years and the proportion stage IV at diagnosis was 32.4% versus 39.3% in the LET alone cohort in PALOMA-2 compared to the EHR cohort, respectively. Propensity matching with caliper=0.10 based on age, stage at diagnosis and # of disease sites identified 79 pts from each cohort.

**Summary of Progression-Free Survival in Matched Data Using Propensity Score Matching Method (Kaplan-Meier estimates)**

</tbody>
</table>

**Conclusion:** This analysis showed concordance between rwPFS and RECIST-based PFS for LET-treated MBC matched pts using a caliper=0.10 in the first line setting. Clinically meaningful information on treatment effect could be derived from a rwPFS assessment based on EHR data abstraction that incorporates proper quality controls.
Impact: These data increase confidence in the use of rwPFS as a primary outcome in real-world studies.
Title: Adiposity at age 10 and mammographic density among premenopausal women

Aliya Alimujiang1, Kellie R Imm1, Catherine M Appleton7, Graham A Colditz1, Catherine S Berkey3 and Adetunji T Toriola1.
1Washington University School of Medicine and Siteman Cancer Center, St Louis, MO; 2Washington University School of Medicine, St Louis, MO and 3Brigham & Women’s Hospital and Harvard Medical School, Boston, MA.

Body: Background: Higher mammographic breast density is a strong risk factor for breast cancer. Early-life factors may influence breast development and subsequent breast density in adulthood. Although childhood adiposity is inversely associated with breast cancer risk, the association of childhood adiposity with mammographic breast density in premenopausal women has not been adequately studied. This knowledge could provide insight into pathways linking mammographic density and breast cancer risk. We investigated the associations between adiposity at age 10 and mammographic density.

Methods: We collected data from 370 premenopausal women during their routine screening mammograms at Washington University in St. Louis, MO from December 2015 to October 2016. Body size at age 10 was self-reported using the Stunkard 9-figure Somatotype pictogram. For these analyses, the Stunkard pictogram was collapsed into 4 groups: (i) body size 1 or 2, (ii) body size 3 or 4, (iii) body size 5, (iv) body size 6 or higher. Body mass index (BMI) at age 10 was imputed using BMI and Stunkard data from the Growing Up Today Study. Trained personnel collected women’s height and weight, which were used to calculate current BMI. We used the Volpara software to evaluate the following volumetric mammographic density measures: volumetric percent density (VPD), dense volume (DV) and non-dense volume (NDV). Age-adjusted Pearson correlations and multivariable linear regression models (adjusted for age, age at each given birth, family history, race, education, oral contraceptive use, and breast feeding history) were used to evaluate the associations between adiposity at age 10 and volumetric mammographic density measures.

Results: The mean age at the time of screening mammogram was 47.1 years. The majority of the women (43.8%) reported having body size 1 or 2, followed by body size 3 or 4 (34.9%), body size 5 (13.8%) and body size 6 (7.6%) at age 10. We observed a negative correlation between BMI at age 10 ($r = -0.28$, p-value <0.001) and VPD, and a positive correlation between BMI at age 10 ($r = 0.27$, p-value <0.001) and NDV. In multivariable regression models, adiposity at age 10 was significantly inversely associated with VPD, and positively associated with NDV. A 1 kg/m$^2$ increase in BMI at age 10 was associated with a 6.3% decrease in VPD (p-value <0.001), and a 6.7% increase in NDV (p-value <0.001). Compared to women whose body sizes were 1 and 2 at age 10, women with body size 3 or 4 had a 17.6% decrease in VPD, and a 28.5% increase in NDV; women with body size 5 had a 32.3% decrease in VPD, and a 58.1% increase in NDV, and women with body sizes ≥6 had a 46.6% decrease in VPD, and a 75.1% increase in NDV (all p-values <0.05). The associations of body size at age 10 and VPD were attenuated, but still statistically significant when we adjusted for current BMI. No statistically significant associations were found between adiposity at age 10 and DV.

Conclusions: Our findings of an inverse association between adiposity at age 10 and percent density suggest that adiposity at age 10 could impact breast cancer development via its effect on mammographic density. Mechanistic studies to understand how childhood adiposity reduces mammographic density and breast cancer development in premenopausal women are needed.
Title: Choosing wisely: Radiographic surveillance after breast conservation therapy in HER2+ breast cancer

Ashlyn Everett¹, Audrey S Wallace¹, Jennifer F De Los Santos¹, Gabrielle B Rocgue¹, Catherine S Parker¹ and Kimberly S Keene¹. ¹University of Alabama Birmingham.

Body: Purpose/Objective(s): ASTRO Choosing Wisely campaign recommends no more than annual mammography after breast conservation therapy (BCT). HER2+ disease portends increased risk of locoregional recurrence in comparison to Luminal A disease. Our previous institutional practice included surveillance imaging every 6 months for the first 2-3 years after BCT. The purpose of this study is to evaluate surveillance imaging intervals as a means of detecting early locoregional recurrence at one institution.

Materials/Methods: Women with HER2+ locoregionally confined invasive breast cancer treated with lumpectomy and radiation as part of breast conservation therapy at one institution were retrospectively identified after IRB approval. Patient demographics, treatment, surveillance, and outcomes data were captured. BRCA+ patients or those without available surveillance follow-up at our institution were excluded. Surveillance period started after the last fraction of radiation was completed.

Results: In 86 women treated from 2008-2016, median age at diagnosis was 57, and 69% were Caucasian. Most patients were treated for Stage I-II invasive ductal carcinoma. All but one were treated with chemotherapy, with similar distribution between adjuvant and neoadjuvant regimens. Receptor status was as follows: ER+ 66%, PR+ 59%, ER+/PR+/HER2+ in 58%, ER-/PR-/HER2+ in 33%. Mammography +/- ultrasound was utilized, with infrequent use of magnetic resonance imaging. Median time from end of radiation to first surveillance imaging was 4 months. All women had 1 post-BCT imaging, with 2nd, 3rd, and 4th available in 91%, 85%, 73% respectively. Interval frequency between first 4 images was 6 months. No patients had expired at the time of analysis. Recurrence were identified in 2 women: 1 identified clinically after negative mammography, and 1 identified on mammography at 27 months.

Conclusion: While overall events are small, discordant biannual mammography did not identify locoregional recurrences in this biologically higher risk group in the first two years post-treatment. This data supports current guideline recommendations limiting surveillance breast imaging in patients undergoing breast conservation to an annual frequency.
Recall rates during breast cancer surveillance in high-risk women with dynamic contrast-enhanced magnetic resonance imaging every 6 months: Results from a single institution study

Kristen D Whitaker¹, Hiroyuki Abe¹, Deepa Sheth¹, Dezheng Huo¹, Toshio F Yoshimatsu¹, Marion Verp¹, Yonglan Zheng¹, Greg Karczmar¹, Rodrigo Guindalini¹ and Olufunmilayo I Olopade¹. ¹University of Chicago, Chicago, IL.

Purpose: To compare recall rates and biopsy rates in high-risk women undergoing semi-annual dynamic contrast-enhanced magnetic resonance imaging compared to recommended annual DCE-MRI.

Background: In high-risk women with BRCA1/BRCA2 mutations and/or a personal or family history of breast cancer, annual breast MRI has shown improved sensitivity and cancer detection compared to mammography and is recommended annually in addition to mammogram. The routine use of breast MRI screening in this patient population is not widespread due to concerns for higher recall rates and false positive biopsy results, which often contribute to higher healthcare costs and increased stress. Breast MRI screening acceptability is dependent on sensitivity and recall rates. The acceptable recall rate for breast MRI is generally considered to be between 6-12% based off the results from studies that used annual DCE-MRI screening.

Methods: Between 2004 and 2016, a prospective cohort of high-risk women underwent semi-annual DCE-MRI and annual mammography. For subjects with BI-RADS score of 4 or 5 on DCE-MRI, biopsy was recommended. For subjects with BI-RADS score of 0 on DCE-MRI and/or BI-RADS scores of 0,4, or 5 on MG, further investigation by imaging was recommended and biopsy was performed if clinically appropriate. Tests with BI-RADS scores of 3 were discussed case-by-case. Recall was defined as women being recommended for further imaging (i.e. US and/or MG) in order to provide additional information. Women that are recalled may go on to have a subsequent biopsy based on the findings.

Results: 295 women were recruited to the study; 44% of the study participants had mutations in BRCA1 or BRCA2. 2111 DCE-MRI screening tests and 1225 mammography were performed. The sensitivity and specificity was 93.7% and 96.6% respectively for DCE-MRI and 50% and 97.7% respectively for mammogram. The positive predictive value was 17% for MRI and 22% for mammography. Eighty-nine women had 106 recalls. 74 due to DCE-MRI imaging alone, 18 due to mammography alone, and 14 due to both image modalities. The recall rate was 4.2% for DCE-MRI and 2.6% for mammography. In total, 56 biopsies were performed. 3 DCIS and 13 invasive breast cancers were diagnosed. On average, 5.9 women would have to be recalled on DCE-MRI with 3.3 biopsies to diagnose one cancer case. 4 women would have to be recalled on mammography with 2.1 biopsies to diagnose one cancer.

Conclusion: Semi-annual DCE-MRI screening in high-risk women demonstrated high sensitivity without substantially increasing recall rates or biopsy rates to an unacceptable value. Our single institution DCE MRI protocol achieved recall rates lower than those considered acceptable for annual MRI or mammography. This study demonstrates that with radiology reader expertise, careful clinical decision making, and improved MRI technology, it is possible to achieve recall rates lower than those achieved with annual mammography or MRI even when DCE-MRI screening exams occur more frequently than those currently recommended by guidelines. Additional data including QOL and cost effectiveness analysis will be presented.

Title: Contrast-enhanced MRI does not accurately predict pathologic complete response (pCR) after neoadjuvant chemotherapy in early or locally advanced breast cancer

Simon P Gampenrieder¹, Andreas Peer¹, Christian Weismann², Matthias Meissnitzer², Gabriel Rinnerthaler¹, Johanna Webhofer¹, Theresa Westphi¹, Marina Popovscaia³, Thomas Meissnitzer², Roland Reitsamer¹, Cornelia Hauser-Kronberger⁵, Heike Egger², Klaus Hergan², Brigitte Mlineritsch¹ and Richard Greil¹. ¹Paracelsus Medical University Salzburg, Salzburg, Austria; ²Paracelsus Medical University Salzburg, Salzburg, Austria; ³Medical University of Innsbruck, Innsbruck, Austria; ⁴Paracelsus Medical University Salzburg, Salzburg, Austria and ⁵Paracelsus Medical University Salzburg, Salzburg, Austria.

Body: Background: Patients with early or locally advanced breast cancer achieving a pathologic complete response (pCR) after neoadjuvant chemotherapy have a lower risk for recurrence or death compared to patients with residual invasive cancer. In the future, breast surgery might be avoided in patients in whom the presence of residual tumor after neoadjuvant therapy can be ruled out with very high confidence. Magnetic resonance imaging (MRI) has been shown to be the most accurate radiologic tool in breast cancer diagnostics and follow-up care. Therefore, we investigated the diagnostic accuracy of contrast-enhanced MRI to predict a pathological complete remission after neoadjuvant chemotherapy.

Methods: This retrospective study included all non-metastatic breast cancer patients treated with neoadjuvant chemotherapy followed by a contrast-enhanced MRI and breast cancer surgery at our institution between 09/2006 and 05/2016. Three specialized breast radiologists, blinded to the clinical and pathological data, reevaluated all preoperative MRI scans and recorded the presence or absence of contrast enhancement as indicator for residual cancer. pCR was defined as no invasive tumor in breast and axilla (ypT0/is N0), however 3 alternative definitions were investigated as well (ypT0 N0, ypT0/is and ypT). Cross tables were used to calculate sensitivity, specificity, pCR-predictive value (PPV), non-pCR-predictive value (NPV) and accuracy. P-values reflecting PPV and NPV differences between various patient subgroups were calculated with Fisher's exact test. The Kaplan-Meier method was used for estimates of distant-recurrence-free survival (DRFS) and overall survival (OS).

Results: In total, 246 patients fulfilled the inclusion criteria and were evaluated. Overall pCR and radiologic complete remission (rCR) rate were 29% and 45%, respectively. Only 48% of rCR corresponded to a pCR (PPV). Conversely, in 87% of cases, residual tumor in the MRI was pathologically confirmed (NPV). The sensitivity to detect a pCR was 75%, while specificity and accuracy were 67% and 69%, respectively. The diagnostic performance of MRI to predict treatment response varied between different histologic and molecular tumor subtypes, however there were little differences between the 4 pCR definitions. The PPV was significantly lower in the hormone-receptor(HR)-positive subgroup compared with the HR-negative subgroup (33% vs. 61%; P = 0.004), especially in luminal-A-like (7%) and lobular carcinomas (0%), respectively. Despite the low concordance (Kohens kappa -0.1), the prognostic value for distant recurrence-free survival was similar between rCR (HR 0.29) and pCR (HR 0.27), respectively. The median pathologic tumor size of residual disease in false-positive cases (rCR but no pCR) was 0.7 cm (SD 0.98 cm).

Conclusion: Contrast-enhanced MRI does not accurately predict pCR after neoadjuvant chemotherapy in early or locally advanced breast cancer, especially in HR-positive tumors. However, in case of false rCR the dimension of residual disease is generally small. Since residual tumor tissue can be detected with high precision, preoperative breast MRI is still of value for operation planning.

Title: Pre-neoadjuvant therapy MRI phenotype can predict response to neoadjuvant endocrine therapy

Talal Hilal¹, Matthew Covington¹, Barbara Pockaj¹, Donald Northfelt¹, Teresa Wu¹, Christine Zwart¹, Jing Li¹ and Bhavika K Patel¹.

¹Mayo Clinic, Phoenix, AZ.

Body: OBJECTIVE: Neoadjuvant endocrine therapy (NET) is increasingly used for the treatment of low and intermediate grade, hormone receptor positive, HER2 negative breast cancer. Several MRI phenotypes that may predict response to neoadjuvant chemotherapy (NAC) have been identified, but little data exists for phenotypes associated with response to NET. This study analyzed imaging phenotypes for all patients treated with NET with the aim to identify specific features that can be predictive of response to therapy.

MATERIALS AND METHODS: The study was retrospective and included 21 patients with clinical stage I, II, and III breast cancer. The tumors were grade 1 or 2, estrogen receptor (ER) positive in >20% of cells, and HER2 non-amplified. MRI examinations were performed in all women before NET. MRI interpretation included mass shape, non-mass enhancement (NME) pattern, background parenchymal enhancement, and MRI phenotype (I well-defined unilocentric mass; II well defined multilobulated mass; III area enhancement with nodularity; IV area enhancement without nodularity; V septal spreading). Type of neoadjuvant endocrine therapy included: tamoxifen alone, an aromatase inhibitor (AI) alone, AI + ovarian suppression, and AI + a non-chemotherapeutic agent. Patients received NET for a total duration ranging between 3 - 6 months, with one patient receiving therapy for 18 months. Clinically meaningful response was defined as stable or decreased tumor size by clinical exam and confirmed at resection by comparing final pathologic T stage with clinical T stage.

RESULTS: Twenty-one patients were identified. Median age was 62 (range 36-84) years. Most were post-menopausal 17 (81%). Pre-neoadjuvant median tumor size on MRI was 3.9 (range 1.0-7.5) cm and comprised T1 3 (14.3%), T2 8 (38.1%), T3/4 10 (47.6%). Pre-treatment N stage was N0 14 (66.7%), N1 7 (33.3%) and pre-NET stage was I in 3 (14.3%), II in 8 (38.1%), and III in 10 (47.6%) patients. The majority 17 (81%) had some tumor reduction, and 4 (19%) had no response. No one achieved a complete response. Of the 17 responders, 7 (41%) had a good response defined as >25% decrease in tumor size. Median tumor size after NET was 3.1 (range 0.6-11) cm and the distribution of T stage was T1 7 (33.3%), T2 9 (42.9%), and T3/4 5 (23.8%). Eleven of 12 (92%) patients with well-defined phenotypes had a response as compared to 6 of 9 (67%) patients with non-well defined phenotypes. Phenotype was not predictive of a good response to therapy, 4 were in the well-defined phenotype and 3 were in the non-well defined phenotype groups. All 4 non-responders had moderate or marked background enhancement as compared to 5 of 17 responders (p = 0.02).

CONCLUSION: A well-defined pre-treatment MRI phenotype was significantly predictive of a positive response to NET, while a non-well-defined MRI phenotype and higher degree of background enhancement was significantly predictive of negative response to NET. This warrants further prospective evaluation, especially in association with Ki-67 levels. If validated, pre-treatment MRI phenotype can be applied in the clinical decision to either initiate NET or referral for upfront surgical resection.

Title: Quantitative MRI features analysis for differentiation of triple negative and HER2 positive subtypes of breast cancer

Gaiane M Rauch1, Heng Li1, Hongtu Zhu1, Beatriz E Adrada1, Lumarie Santiago1, Rosalind P Candelaria1, Hao Wang1, Jessica Leung1, Alastair Thompson1, Jennifer Litton1, Yun Wu1, Bora Lim1, Stacy Moulder1, Elizabeth A Mittendorf1 and Wei Yang1.

1The University of Texas MD Anderson Cancer Center, Houston, TX.

Body: Objective: The aim of this study was to evaluate ability of quantitative analysis of MRI features to distinguish triple negative (TN) and HER2 positive (HER2+) subtypes of breast cancer, which have different biological characteristics, exhibiting different growth patterns and response to treatment.

Materials and Method: Breast cancer patients, who had MRI exam of the breast in our institution at the time of staging for breast carcinoma and who subsequently had surgery (segmentectomy or mastectomy) from January 1, 2008 through December 31, 2015 were identified. All lesions were evaluated by radiologists in accordance with the BI-RADS lexicon. The patient's age, breast cancer histology, multifocality/multicentricity (MF/MC), lesion size, axillary lymphadenopathy (LAN), MRI morphologic and enhancement characteristics were documented. Quantitative MRI feature analysis was performed using shape, texture, and histogram based features. Machine-learning-based (Xgboost) models were used to predict subtypes, and Leave-one-out cross-validation (LOOCV) was used to avoid model overfitting. Statistical significance was determined using the Student's t-test.

Results: Total of 105 patients, 51 patients with TN and 54 patients with HER2+ breast cancer were included in analysis. Mean age for TN was 50 (range 29-79) years old and for HER2+ was 49 (range 25-70) years old. Axillary LAN and MF/MC disease was seen more commonly in HER2+ patients when compared to TN patients, but didn't reach statistical significance (13 vs 7, p=0.9; and 31 vs 20, p=0.06, respectively).

Mass rim enhancement was associated with TN subtype and irregular mass enhancement was associated with HER2+ subtype of breast cancer (p<0.05). Quantitative analysis showed that six out of the top 10 ranked MRI features: surface to volume ratio, difference variance, difference entropy, inverse difference moment, 75 percentile in histogram and sum average, were significantly different between these 2 subtypes with p<0.05. When the significant features were incorporated to distinguish TN and HER+ subtypes, use of the top 2 features achieved the best accuracy on LOOCV of 0.69.

Conclusion: The quantitative MRI features show promise in distinguishing TN and HER2+ breast cancer subtypes reflecting their underlying biological characteristics and may be used as predictive quantitative biological markers. Further studies in a larger cohort evaluating associations with treatment response are underway.

Title: Diagnostic value of breast MRI in evaluating total extent of disease when non-calcified DCIS is present in stereotactic core biopsy samples

Deepa Sheth¹, Jean Bao¹, Hiroyuki Abe¹ and Nora Jaskowiak¹. ¹University of Chicago Medicine, Chicago, IL.

Body:

PURPOSE
To compare the extent of disease as seen on mammography, breast MRI and final surgical pathology in all patients with non-calcified DCIS identified on stereotactic core biopsy. Can MRI provide useful diagnostic information to the surgeon when mammographically occult DCIS is present.

METHOD AND MATERIALS
All patients with stereotactic core biopsies performed at the University of Chicago from 2010 to 2017 were retrospectively reviewed. Patients with pathology demonstrating DCIS in non-calcified cores on stereotactic biopsy were further selected based on whether they had a subsequent breast MRI and definitive surgical treatment. A total of 76 patients met these criteria. All patients undergoing stereotactic core biopsy had at least six 9-gauge cores removed, all of which were radiographed and separated based on whether calcifications were present or absent. Select patients with documented DCIS in the non-calcified cores had a MRI. All patients with MRI underwent a routine diagnostic protocol consisting of one pre- and five post-contrast bilateral, fat suppressed T1 sequences along with a non-fat suppressed T2 sequence. Final surgical treatment was subsequently determined and performed by the breast surgeon.

RESULTS
76 women met all criteria for this study. In 16/76 (21%) of the cases, MRI revealed greater extent of disease than was detected via mammography, and led to change in management in half of those cases (8/76 - 11%). In all 16 of these cases, final surgical pathology confirmed the MRI-detected extent of disease. In 52/76 (68%) of the cases, MRI confirmed the extent of disease detected on mammography and final surgical pathology. In 8/76 (11%) of the cases, MRI showed little to no abnormal enhancement at site of mammographically detected calcifications, even though final surgical pathology confirmed presence of residual disease.

CONCLUSION
The presence of non-calcified DCIS in stereotactic core biopsy samples raises the suspicion for the presence of mammographically occult disease. Breast MRI performed in this setting shows that in majority (82% -68/76) of the cases, MRI can either confirm or even advantageously reveal greater extent of disease than was initially detected on mammography. Furthermore, there can be a change in management due to the breast MRI findings.

CLINICAL RELEVANCE/APPLICATION
Breast MRI can be a useful diagnostic tool for the surgeon when non-calcified DCIS is present in stereotactic core biopsy samples.
Title: Intratumoral and peritumoral MRI signatures of HER2-enriched subtype also predict pathological response to neoadjuvant chemotherapy in HER2+ breast cancers

Nathaniel Braman¹, Prateek Prasanna¹, Salendra Singh², Niha Beig¹, Hannah Gilmore², Maryam Etesami², David Bates¹, Katie Gallagher¹, B Nicolas Bloch¹, George Somlo⁵, William Sikov⁶, Lyndsay Harris³, Donna Plecha², Vinay Varadan² and Anant Madabhushi¹. ¹Case Western Reserve University, Cleveland, OH; ²Case Comprehensive Cancer Center, Cleveland, OH; ³National Institutes of Health; ⁴Boston Medical Center, Boston, MA; ⁵City of Hope Beckman Research Institute and Medical Center, Duarte, CA and ⁶Brown University, Providence, RI.

Body: Background: Applying the PAM50 classifier to targeted RNA-Sequencing data allows HER2+ tumors to be sub-categorized into intrinsic breast cancer subtypes. HER2+ breast cancers belonging to the HER2-enriched [HER2-E] subtype exhibit the highest rate of response to neoadjuvant therapy with combination of HER2-blockade and chemotherapy, as well as dual-HER2 blockade alone. A non-invasive predictor of PAM50 subtype from clinical dynamic contrast-enhanced MRI [DCE-MRI] could provide valuable clinical guidance in the treatment of HER2+ breast cancer. In this work, we identify a set of computer-extracted heterogeneity features computed within the lesion and its surrounding peritumoral region capable of distinguishing HER2-E from other HER2+ breast cancers [Non-HER2-E]. We then demonstrate that this imaging signature of HER2-E is also predictive of pathological complete response [pCR] in an independent HER2+ testing set, consistent with the HER2-E subtype’s elevated response to HER2-targeted therapy.

Methods: The training set consisted of 42 HER2+ patients with both 1.5 or 3 T DCE-MRI and targeted RNA sequencing collected prior to neoadjuvant treatment from a multicenter trial [BrUOG 211B, n=35] and The Cancer Genome Atlas-Breast Cancer project [TCGA-BRCA, n=7]. Intrinsic subtypes were assigned by unsupervised hierarchical clustering of the PAM50 gene set. 19 patients were determined to belong to the HER2-E subtype, while the remaining 23 represented non-HER2-E subtypes [19 HER2-Luminal, 4 HER2-basal]. Lesion boundaries were annotated by an expertly trained radiologist and expanded to 5 annular peritumoral regions in 3 mm increments out to a maximum radius of 15 mm. Computer-extracted heterogeneity features were computed voxelwise within intratumoral and peritumoral regions by first order statistics. A top HER2-E-associated feature from each region was identified by Wilcoxon feature selection and used to train a diagonal linear discriminant analysis [DLDA] classifier to predict HER2-E in a 3-fold cross-validation setting. This classifier was then applied to pCR prediction from DCE-MRI in a testing set of 28 HER2+ patients with available post neoadjuvant chemotherapy surgical specimens at one institution. 16 patients achieved pCR (ypT0/is), while the remainder had partial or no response (non-pCR).

Results: A combination of heterogeneity features within the intratumoral region and annular peritumoral regions out to 12 mm from the tumor yielded optimal results within the training set, with an average HER2-E prediction AUC of .77 +/- .03. When applied to response prediction in an independent testing set, this HER2-E classifier was predictive of pCR (AUC = .72).

Conclusions: Computer-extracted heterogeneity features calculated within the tumor and the surrounding peritumoral environment on DCE-MRI were able to distinguish the HER2-E PAM50 intrinsic subtype from other HER2+ breast cancers. HER2-E was characterized by elevated expression of intratumoral and peritumoral heterogeneity features, indicating a more disordered imaging phenotype within and around the tumor. Additional independent validation of these findings is needed.
Title: Radiogenomic analysis of HER2+ breast cancer reveals MRI features correlated with genomic immune index are predictive of neoadjuvant chemotherapy response

Nathaniel Braman1, Prateek Prasanna1, Salendra Singh2, Niha Beig1, Hannah Gilmore2, Maryam Etesami2, David Bates4, Katie Gallagher4, B Nicolas Bloch4, George Somlo5, William Sikov6, Lyndsay Harris3, Donna Plecha2, Vinay Varadan2 and Anant Madabhushi1. 1Case Western Reserve University, Cleveland, OH; 2Case Comprehensive Cancer Center, Cleveland, OH; 3National Institutes of Health; 4Boston Medical Center, Boston, MA; 6City of Hope Beckman Research Institute and Medical Center, Duarte, CA and 6Brown University, Providence, RI.

Body: Background: It has been previously shown that computer-extracted heterogeneity features calculated within the peritumoral region of a breast cancer from baseline dynamic contrast-enhanced MRI [DCE-MRI] can predict treatment outcome. This approach may due to microenvironmental signatures of elevated immune response, a predictor of favorable response to neoadjuvant chemotherapy [NAC] in HER2+ breast cancer. We assessed the correlation between peritumoral radiomic features and a tissue-derived genomic immune index [II] in HER2+ breast cancer and whether these immune-correlated imaging features are predictive of pathologic response.

Methods: 33 HER2+ patients with both 1.5 or 3 T DCE-MRI imaging and targeted RNA sequencing of biopsy samples collected prior to NAC from a multicenter trial [BrUOG 211B, n=26] and The Cancer Genome Atlas-Breast Cancer project [TCGA-BRCA, n=7] were retrospectively analyzed. II was derived from expression of a 140-gene immune signature using the ESTIMATE algorithm. An attending breast radiologist annotated lesion boundaries on the DCE-MRI phase of peak contrast enhancement. Beyond this intratumoral region, 5 annular peritumoral regions in 3 mm increments out to a maximum radius of 15 mm were analyzed. Computer-extracted heterogeneity descriptors computed within the intratumoral and peritumoral regions were summarized by first order statistics. Redundancy was reduced by eliminating correlated imaging features (R^2>.6). From the remaining features, the 5 features that were collectively best correlated with II were selected by feed forward, leave-one-out multilinear regression. The regression model was applied to an independent test set of 28 HER2+ patients with post NAC surgical specimens. The estimated II was assessed for its ability to differentiate patients who achieved a pathologic complete response in the breast [pCR, ypT0/is] (n=16) and those who did not (n=12) by 2-sided Wilcoxon rank sum test of median and area under the receiver operating characteristic curve (AUC).

Results: The set of top features that significantly correlated (p<.05) with II were entirely within the 3-6 mm and 6-9 mm peritumoral regions. These features characterized uneven patterns of enhancement and heterogeneity of intensity values. Within the testing set, predicted II was significantly higher among responders (pCR: 12.8 +/- .3, non-pCR: 12.5 +/- .3, p<.05) and distinguished the two with an AUC of .73.

Conclusions: From a set of quantitative features characterizing heterogeneity within the peritumoral region on DCE-MRI, we identified peritumoral imaging features correlated with a genomic index of immune response in HER2+ breast cancer and were predictive of pathologic response in an independent testing set. Our findings suggest that the predictive capability of peritumoral radiomics may be tied to a patient's immune response to the cancer. In addition to providing insight to the biological basis of peritumoral radiomics, imaging signatures of immune response themselves possess clinical value as a potential means for the non-invasive prediction of HER2+ cancer biology and treatment outcome. Additional independent validation is needed on a larger test set to confirm our preliminary findings.

Title: Repeatability and reproducibility of quantitative breast MRI in community imaging centers: Preliminary results

Anna G Sorace¹, Jack Virostko¹, Chengyue Wu¹, Angela M Jarrett¹, Stephanie L Barnes¹, Jeffrey Luci¹, Debra A Patt², Boone Goodgame¹, Sarah Avery³ and Thomas E Yankeelov¹. ¹University of Texas at Austin, Austin, TX; ²Texas Oncology, Austin, TX and ³Austin Radiological Association, Austin, TX.

Body: Introduction: The primary purpose of this study is to evaluate the repeatability and reproducibility of quantitative breast MRI across community imaging centers with the ultimate goal of using these techniques to predict breast cancer response early in the course of neoadjuvant therapy (NAT). Dynamic contrast-enhanced MRI (DCE-MRI), diffusion-weighted MRI (DW-MRI), and magnetization transfer MRI (MT-MRI) performed early in the course of breast NAT has the potential to predict eventual response prior to changes in tumor size. This enables tailoring of treatment plans and the opportunity to substitute ineffective therapies with alternative approaches. We present preliminary results on the reproducibility and repeatability of $T_1$, apparent diffusion coefficient (ADC), and magnetization transfer ratio (MTR) measurements in normal breast fibroglandular tissue (FGT) in the community setting.

Experimental Design: MRI was performed at two community imaging centers and one academic research facility using 3T Siemens Skyra scanners equipped with 8- or 16-channel breast coils. To assess repeatability of the imaging techniques, normal subjects (N=10, ages 22-62) were scanned twice, separated by subject repositioning. To assess reproducibility across sites, normal subjects (N=3) were scanned at three imaging centers. To assess quantitative $T_1$ measurements, subjects were scanned using a spoiled gradient echo (SPGE) sequence and variable flip angles (2, 4, 6, ..., 20) with TR/TE = 7.9/2.71 ms and corrected for $B_1$ inhomogeneity. To assess the ADC, subjects were scanned using an echo-planar monopolar spin echo sequence with the following parameters: TR/TE = 3000/52 ms and $b$-values = 0, 200, 800 s/mm². MT-MRI was acquired using two gradient echo sequences with TR/TE = 48.0/6.40 ms, one with the inclusion of a 1500 Hz off-resonance saturation pulse. FGT was segmented using k-means clustering. Women undergoing NAT for breast cancer are being recruited and scanned with DCE-MRI, DW-MRI, and MT-MRI at baseline (prior to beginning therapy) and three early time points during the course of NAT to evaluate early prediction of response to therapy.

Results: Reproducibility scans of normal breast FGT yielded an average difference of 8.4% in $T_1$ measurement, 7.0% in ADC measurement, and 12.7% in MTR measurement between sites. Repeatability scans of the same subject’s FGT showed an average percent difference of 6.7% in $T_1$ measurement, 4.5% in ADC measurement, and 11.6% in MTR measurement between the two scans. A multi-site trial performing quantitative DCE-MRI, DW-MRI, and MT-MRI in patients undergoing breast NAT in the community setting (N=16 at the time of submission) has been ongoing to predict response to NAT using quantitative MRI.

Conclusion: Quantitative DCE-, DW-, and MT-MRI of the breast is both repeatable and reproducible across MRI scanners in community imaging centers. A quantitative breast MRI protocol can be deployed at community imaging centers for breast cancer patients. These results and ongoing work highlight the feasibility of future clinical dissemination of quantitative MRI for predicting early response to NAT, therefore expanding these novel techniques to a widespread patient population.

We acknowledge the support of CPRIT RR160005.
Body: Objective: To assess the association of MRI BPE and pathological response in women diagnosed with stage II/III breast cancer submitted to NAC. Methods: This observational and cross-sectional retrospective study was performed in consecutive women who underwent NAC and had MRI exams before and after chemotherapy. The MRI was done before and after 2 weeks of completing NAC. BPE was classified according to ACR-BIRADS 5th edition. The type of BPE before NAC, its changes and the relationship to total pathologic complete response (TpCR) were evaluated. Data were paired with patient age, size on MRI before and after NAC, features of clinical response according to the RECIST criteria, tumor grade and immunohistochemical (IHC) subtypes. MRI assessment included amount of fibroglandular tissue, symmetry of BPE and measurement of tumor at the longest diameter. All images were blinded reviewed by a radiologist. We used for the changes of the BPE the Bowker symmetry test or the McNemar test and to analyze the factors related to the clinical and pathologic responses, logistic regression analysis. The level of significance adopted was 5% (p<0.05). Results: We studied 71 women between 2009 and 2016. The medium age was 37 years old. BPE was symmetrical in 68 women (95.8%). Moderate and marked BPE was present in 28 (39.4%) of the affected breasts and in 25 (34.2%) of the contralateral breasts. After NAC all BPE were symmetrical and just 3% of them were moderate or marked. Regarding the IHC subtype, 40 women (56.3%) were triple negative or HER2 positive, and these women had a higher frequency of TpCR (55% for each, compared to 12.9% in patients with luminal subtypes). We found to be independently associated with pCR: the reduction of BPE (in the affected or contralateral breast) and the molecular subtypes triple negative and HER2 positive.

* OR (Odds Ratio) = Risk ratio to pCR; (n=26 pCR, n=7 DpCR, n=31 PR e n=7 ED, where Total pCR is pathological complete response (without invasive and DCIS in the breast and axilla) DpCR is pathological response with just DCIS, PR is partial response and ED is stable disease – we haven't progression disease). CI 95% OR = Confidence interval of 95% to risk ratio. Ref.: reference level. Proportional risk models.

**Conclusion:** BPE reduction was significantly associated with TpCR. Nevertheless, patterns of BPE pre-NAC have no association with pathological response.
Title: Breast cancer surveillance in high-risk women with dynamic contrast-enhanced magnetic resonance imaging every 6 months: Results from a single institution study

Kristen Whitaker1, Rodrigo Guindalini, Hiroyuki Abe1, Deepa Sheeth1, Dezheng Huo1, Susan Hong1, Jane Churpek1, Marion Verp1, Elias Obeid1, Yonglan Zheng1, Andrea Amico1, Toshio Yoshimatsu1 and Olufunmilayo Olopade1. 1The University of Chicago Medicine, Chicago, IL.

Body: Purpose: To develop a novel approach for early detection of breast cancer and examine molecular features of screen detected cancers in prospectively ascertained high-risk women undergoing semi-annual dynamic contrast-enhanced breast magnetic resonance imaging (DCE-MRI) for women at high genetic risk.

Background: Women with a personal or family history of breast cancer and genetic mutation carriers of BRCA1 and BRCA2 have a higher than normal risk of breast cancer. An intensified screening surveillance regimen is an early detection strategy in high-risk women. The American Cancer Society recommends annual DCE-MRI in addition to annual mammogram based off several pivotal screening studies that demonstrated improved sensitivity and cancer detection rates and decreased interval cancer rates with the addition of annual DCE-MRI. Questions remain regarding the optimal screening modality and interval regimen in these high-risk women.

Methods: Between 2004 and 2016, we assembled a prospective cohort of high-risk women undergoing semi-annual DCE-MRI and annual mammography. To be eligible, women had a lifetime breast cancer risk >20% and/or tested positive for a pathogenic mutation using a cancer gene panel including BRCA1, BRCA2, CDH1, PALB2, CHEK2 and other cancer susceptibility genes in the DNA repair pathway. Somatic mutation events in screen-detected tumors were investigated using UW-OncoPlex cancer gene panel using DNA extracted from FFPE shavings.

Results: 295 women were recruited to the study; 44% of the study participants had pathogenic mutations in BRCA1 or BRCA2 genes. At a median follow-up of 3.3 years (range 0-12 years), 3 DCIS and 13 early stage invasive breast cancers were detected, of which 14 occurred in subjects with identifiable pathogenic mutations (11 BRCA1, 2 BRCA2, 1 CDH1). The incidence rate is 1.3% in all subjects, but 3.5 % per year in BRCA1 carriers. DCE-MRI identified all 13 invasive cancers at a mean size of 0.61 cm (range 0.1-1.0 cm); none had lymph node metastasis. No interval cancers occurred. In addition, 7 of the breast cancers were detected on DCE-MRI imaging obtained at the 6 months screening interval; they would be interval cancers if only annual screening were implemented. There was very little DNA for somatic mutation testing in the majority of cases. However, as expected, there was heterogeneity in the spectrum of mutations but the most commonly somatically mutated gene in the early cancers was TP53.

Conclusions: DCE-MRI every 6 months performed well for early detection of invasive breast cancer in high-risk women, accomplishing the ultimate goal of breast cancer screening—detecting node-negative, invasive tumors less than 1 cm. Semi-annual DCE-MRI performed especially well in BRCA1 mutation carriers at risk for the most aggressive subtype of breast cancer. Further interventional studies evaluating this novel screening approach are warranted to personalize breast cancer risk assessment and prevention.

Title: Accuracy of breast magnetic resonance imaging has limited value to reduce the margin-positive rate: A study in relation to the molecular subtypes

Soong June Bae¹, Sung Gwe Ahn¹, Changik Yoon¹, Yoon Jin Cha² and Joon Jeong¹. ¹Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea and ²Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea.

Body: Background: Newly released guideline standardizing a negative margin after breast-conservative surgery (BCS) as “no ink on tumor” by SSO-ASTRO stressed the importance of estimation tumor extent with comprehensive breast imaging studies. To evaluate clinical value of breast magnetic resonance imaging (MRI) in patients with BCS, we compared the degree of correlation between MRI-pathology and ultrasonography (US)-pathology according to subtypes. In addition, we investigated the margin-positive rates and secondary operation rates for margin clearance.

Methods: We identified patients with invasive breast cancer who had preoperative breast MRI and ultrasound between 2011 and 2016. We excluded patients having large tumor more than 5cm or multiple tumors or undergoing mastectomy. Patients were classified into 4 subtypes based on the immunohistochemistry; luminal A, luminal B/HER2, HER2, triple-negative breast cancer (TNBC). Lin’s concordance correlation coefficient was used to measure the agreement between the MRI or US and tumor extent. Tumor extent was defined as pathologic tumor size including in situ carcinoma. Margin-positivity was assessed based on intraoperative frozen examination.

Results: A total 516 patients with single tumor undergoing BCS were included. Means of tumor size were 1.99 ± 0.91 cm by pathologic examination, 1.91 ± 1.01 cm by MRI, and 1.76 ± 0.92 cm by US, respectively. The correlation coefficient of MRI-pathology was significantly higher than that of US-pathology (r=0.6975 vs. 0.6211, P=0.001). A superiority of MRI than US in measuring pathologic extent was only observed in TNBC (r=0.8089 vs. 0.6014, P<0.001), whereas the agreement between the MRI or US and tumor extents was low in the HER2 (MRI: 0.3509, US: 0.3165). Also, the margin-positive rate was higher in HER2 (luminal A, 11.6%; luminal B/HER2, 17.5%; HER2, 29.6%; TNBC, 17.8%; P=0.0382). In the post-hoc test, the HER2 was more likely to have positive margin compared to Luminal A (P=0.0039). There is no significant difference in secondary operation as margin clearance according to the subtypes (P>0.999).

Conclusions: Given a superiority of MRI to US in preoperative assessment, MRI-guided BCS did not reduce the margin-positive rate in TNBC. In the HER2, size correlation of MRI-pathology was very low, and the margin-positive rate was high. Collectively, our findings suggest that accuracy of MRI has limited value to reduce the margin-positive rate.
Title: Predicting surgical upgrade of breast lesions detected by MRI-guided biopsy

Angela Chen¹ and Rachel Brem¹. ¹George Washington University, Washington DC.

Body: Background:
Patients who have suspicious breast lesions identified with MRI without mammographic- or ultrasound-correlated biopsy require MRI-guided biopsy. However, MRI-guided biopsy may underestimate the pathology due to intrinsic heterogeneity, in which subsequent surgical excision may reveal an upgrade. The reported upgrade rate is variable across studies, subclasses of lesion, and needle gauge, and no associative factors have been identified. This study investigated demographic and histologic characteristics of lesions that underwent MRI-guided biopsy to determine possible factors for predicting later upgrade at surgery.

Methods:
All MRI-guided vacuum biopsies performed between 2012 and 2017 at GWU Breast Imaging Center were reviewed. Surgical excision was performed for high risk lesions and imaging discordance in benign lesions. Variables investigated include patient age, menopausal status, personal/family history of breast cancer and breast pathology. T-test and Pearson's chi-squared test were used to determine statistical significance (alpha=0.05).

Results:
Of 379 lesions from 295 patients that underwent MRI-guided biopsy, 117 lesions from 96 patients underwent subsequent surgical excision. Pathology of the 117 lesions included benign (14/117; 12%), ALH (17/117; 15%), LCIS (10/117; 9%), ADH (10/117; 9%), papilloma (25/117; 21%), radial scar (12/117; 10%), DCIS (13/117; 11%), invasive cancer (10/117; 9%), and others (6/117; 5%). 14 of 117 lesions (12%) were upgraded at surgery: 5 upgraded from benign to high-risk, 1 upgraded from benign to DCIS, 4 upgraded from high risk to DCIS, 1 upgraded from high risk to invasive cancer and 3 upgraded from DCIS to invasive cancer. All 14 patient with upgrades (100%) had a personal history of breast cancer. No association was found with age, menopausal status, breast pathology, or family history.

Conclusions:
Our study demonstrated a surgical upgrade rate of 12%. All upgrades occurred in women with a personal history. We suggest that patients with a personal history of breast cancer pose a higher risk of surgical upgrade at excision.
**Title:** Can background parenchymal enhancement (BPE) predict the chance of multicentric/bilateral breast cancer on staging breast MRI?

Ana Paula A Benveniste¹, Lilian O Ebuoma¹, Arti Jonna¹, Kenny Sam¹, Frederich J Severs Jr.¹, Ashley Roark¹, Karla A Sepulveda¹, Ortiz-Perez Tamara¹ and Emily E Sedgwick¹. ¹Baylor College of Medicine, Houston, TX.

**Body:** Purpose: Can background parenchymal enhancement (BPE) predict the chance of multicentric/bilateral breast cancer on staging Breast MRI?

Materials and Methods: Retrospective review of women diagnosed with breast cancer who underwent a breast MRI for staging of disease was performed at a single institution from October 2012 to September 2015.

Results: Breast MRI for staging was done for 435 patients diagnosed with breast cancer. Ages ranging from 24 to 86 years old (median, 52 years); sizes ranging from 0.5 to 13.5 cm (mean, 3.5 cm). 29 patients (7%) had biopsy-proven second tumors in the same breast but different quadrant as the primary tumor or in the contralateral breast. From the 435 patients, 304 had minimal/mild BPE and 103 had moderate/marked BPE (28 missing). Of the patients with an invasive primary cancer and a second tumor in the same breast but different quadrant as the primary tumor or in the contralateral breast, 12 of 29 patients had discordance in subtypes between the primary and secondary tumors (41%) and 17 of 29 had concordance in the subtypes between the primary and secondary tumors (59%). 6.3% (19 out 304) of patients with minimal/mild BPE had multicentric/bilateral disease and 9.7% (10 out 103) of patients with moderate/marked BPE had multicentric/bilateral breast cancer.

Conclusion: 435 patients with recent diagnosis of breast cancer who underwent staging breast MRI for diagnosis of additional sites of disease, 7% was diagnosed with an additional site of cancer. From these group of patients, approximately 6% had other site of disease among patients who had minimal/mild BPE in the breast MRI versus 10% of patients with moderate/marked BPE. BPE may play a role in the setting of multicentric/bilateral breast cancer.
Title: Causes of endocrine therapy resistance: An in-depth genomic analysis of resistant multidrug ER+ breast cancers

J Michael Dixon², Arran K Turnbull³, Maki Tanioka³, Amy Wheless³, Amy Garrett³, Carlos Martinez-Perez¹, Joel Parker³, Xiaping He³, Andrew H Sims¹, Jeremy S Thomas⁴, Lisa A Carey³ and Charles M Perou³. ¹Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, United Kingdom; ²Edinburgh Breast Unit, Western General Hospital, Edinburgh, United Kingdom; ³Lineberger Comprehensive Cancer Cente, University of North Carolina, Chapel Hill, NC and ⁴Western General Hospital, Edinburgh, United Kingdom.

Body: Background: 70% of all breast cancers (BCs) are ER+. Not all ER+ cancers respond to endocrine therapy (ET) and many eventually develop resistance. The aim was to perform in-depth genomic analysis of both primary resistant BCs, that do not respond to ET, and cancers which progress (>40% increase in size) after an initial response as they acquire resistance (AQR) to ET.

Methods: A unique series of 48 post-menopausal women with ER+ BC received neoadjuvant ET using letrozole (L) or anastrozole (A) (mean treatment duration 17 months, range 3-67). 13/48 received up to 4 lines of ET. 12/48 responded to A or L, 16/48 had primary resistance and 20/48 had AQR.

Of 20 with AQR, 13 had 2nd line ET with A or tamoxifen (T). 6 had 3rd line ET with exemestane (E) and 1 had 4th line megestrol acetate (MA). Serial RNA & DNA from 3-5 cancer samples/patient (226 samples) had Ribo0-RNAseq, DNA exome sequencing and somatic mutation detection using UNCeqR. We have data so far on 29 patients: 5 responders, 4 with primary resistance and 20 AQR, the full cohort will be complete shortly.

Results:
ESR1 Mutations (ESRM): 1/5 responders had an ESRM (E380Q) at diagnosis. This clone disappeared with response to L. 5/20 patients with AQR (25%) had clonal expansion of an ESRM during 1st line ET (L:4, A:1). 4 had a chr6:152419926[lowbar]A:G (D538G) ESRM and 1 had a novel ESRM. Of the 5 with ESRM acquired during 1st line ET, the mutant allele fraction (MAF) increased further in the 4 who had 2nd ET (3:T, 1:E) and increased further for the 2 who had 3rd line E.

ESR1 Amplification (ESRA): 5 patients developed ESRA. 3/5 developed ESRA on 2nd or 3rd line E that was not present on AQR to 1st line L or A and 2nd line T. The other 2 developed ESRA on L. 2/5 with ESRA had concomitant CYP19A1 amplification. One patient with ESRA that developed on 3rd line E subsequently responded to MA. No patients with primary resistance to 1st line ET had an ESRM or ESRA.

PIK3CA mutations (PIK3M): 5/20 with AQR had PIK3M (25%). 3/7 had PIK3M at diagnosis and in 3 MAF increased between 1st and 2nd line ET. 2/7 developed PIK3M when resistant to 2nd line ET, 1 of the 2 had ESRA. 2 patients responsive to L had PIK3M at diagnosis and MAF decreased with therapy.

Other Mutations: Unique mutations with limited commonality developed and new clones expanded in the remaining cancers during primary and acquired resistance. Clonality analysis of AQR samples to different ETs showed proliferation of specific clones, characterised by novel sets of mutations, which typically became the dominant clone at the time of resistance to a particular agent.

Summary: 13/20 with acquired resistance had ESRM, ESRA, or PIK3M in resistant tumours: 1 had all 3, 2 ESRM + ESRA, 1 ERSA + PIK3CA, 4 ESRM only, 2 ESRA only and 3 had PIK3M only.

Conclusions:
- Endocrine resistance is complex
- ESRM or ESRA is uncommon at diagnosis and does not explain primary ET resistance
- ESRM (in particular the D538G mutation) occurs in one-third of patients with acquired resistance. 2nd line ET results in clonal selection and expansion of ESRM cells. Assessing recurrences for ESRM by in situ detection has clinical utility
- ESRA is only seen in heavily ET-pre-treated tumours, with its significance being unknown.
Title: Characterizing and targeting chemoresistant subclones in patient-derived xenograft models of triple negative breast cancer

Gloria V Echeverria¹, Sahil Seth², Zhongqi Ge¹, Yuting Sun², Emilia DiFrancesco², Rosanna Lau⁴, Joe Marszalek², Stacy Moulder³, Fraser Symmans¹, Timothy P Heffernan², Jeffrey T Chang⁵ and Helen Piwnica-Worms¹. ¹The University of Texas M.D. Anderson Cancer Center, Houston, TX; ²Institute for Applied Cancer Science, The University of Texas M.D. Anderson Cancer Center, Houston, TX; ³The University of Texas M.D. Anderson Cancer Center, Houston, TX; ⁴The University of Texas M.D. Anderson Cancer Center, Houston, TX and ⁵The University of Texas Health Science Center, Houston, TX.

Body: Fifty percent of all triple negative breast cancer (TNBC) patients harbor significant residual tumor burden following treatment with standard neoadjuvant chemotherapy (NACT), resulting in poor prognosis. Recent studies in TNBC have revealed extensive intra-tumoral heterogeneity at the time of diagnosis and throughout disease progression, but the relative contributions of these heterogeneous populations of tumor cells to chemoresistance are not well understood.

The primary tumor, dermal metastasis, and germline reference were obtained from a patient with untreated metastatic TNBC. Tumor cells were engrafted into the humanized mammary fat pads of NOD/SCID mice to establish PDX models of the primary (PIM001-P) and metastatic (PIM001-M) tumors. RNA sequencing and whole-exome sequencing (WES), performed on the patient's primary and metastatic tumors and the first- and third- passage PDX models revealed transcriptomic profiles and subclonal heterogeneity of the patient's tumors were recapitulated in the PDX models.

Treatment of mice engrafted with PIM001-P tumors with NACT (Adriamycin plus cyclophosphamide, AC) resulted in partial response, the magnitude of which was diminished in mice bearing PIM001-M tumors. Tumor subclones were tracked during chemotherapy treatment in mice engrafted with PIM001-P tumors using lentiviral non-targeting DNA barcodes. Residual tumors maintained the clonal architecture of untreated tumors, and deep WES revealed stable maintenance of somatic mutant allele frequencies throughout treatment. Therefore, selection of pre-existing resistant clones did not lead to AC resistance in this model. Interestingly, only 25% of residual tumor clones contributed to primary relapse once treatment was halted, suggesting only a subpopulation of tumor cells was able to reconstitute the tumor.

RNA sequencing and reverse phase protein array revealed that while vehicle-treated and regrown tumors were highly similar, residual tumors harbored a unique profile characterized by numerous significant alterations in RNA and protein levels. Together, these results suggest that residual tumors enter into a transient drug-resistant state that is reversible. Residual tumors were enriched for alterations in pathways such as metabolism, extracellular matrix remodeling, and cell-cell communication.

Pharmacologic targeting of the residual tumor state with an inhibitor of mitochondrial oxidative phosphorylation led to significant inhibition of tumor regrowth following AC treatment. Additional vulnerabilities identified in residual tumors are being targeted therapeutically with the goal of eradicating residual tumor cells.
Title: Breast tumors escape endocrine therapy by the coordinated activities of HER2/3 and FOXA1

Antoni Hurtado1, Shxiong Wang1, Siv Gilfillan1, Jens Henrik Norum1, Helga Bergholtz1, Sachin Kumar Singh1, Anne Marthe Fosdahl1, Silje Nord1, Olav Engebraten1, Ole Christian Lingjaerde1, Meritxell Bellet2 and Therese Sørlie1. 1University of Oslo, Oslo, Norway and 2Vall d’Hebron Institute of Oncology, Barcelona, Spain.

Body: Hormone therapy reduces tumor growth of Estrogen Receptor (ER) positive breast cancer patients. However, relapse to these therapies occurs in a substantial number of patients. Hormone therapy is sequentially used in the treatment of resistant patients. Nevertheless, the results of these therapies are globally poor, with median Progression Free Survival of only 2.8 to 4.5 months (Turner, N Engl J Med 2015). The choice of these treatments is based on the premise that ER is still the main driving force of proliferation in these tumors. We have now analyzed the expression of HER2 in low-grade HER2 negative tumors from patients with who initially responded to hormone therapy but eventually relapsed and compared those to metastases from the same patients once have relapsed. Our results reveal that metastases have increased HER2 expression compared to primary tumor biopsies of the same patient, which suggested the cross talk between HER2 and ER might be the driving force of tumor growth for metastases. Importantly, the signaling of HER2 is complex and its activation is usually dependent of dimerization with other receptor tyrosine kinases in cell membrane such as EGFR or HER3. Our study reveals that EGFR or HER3 use different mechanisms to control the function of ER and the transcription factor FOXA1. Our data confirms that ER and FOXA1 mediate the EGFR signaling in hormone resistant tumors as previously described (Shou, JNCI 2004). By contrast, HER3 confers insensitivity to anti-ER drugs by driving proliferation in an ER independent manner but still dependent of FOXA1. Now, we prove that in response to HER2/3 signaling, FOXA1 controls the transcription of genes associated with poor prognosis and metastases by binding to chromatin regions poorly enriched of ER binding. By doing so, FOXA1 leads to an ER-independent growth and therefore confers insensitive to anti-ER drugs. The role of FOXA1 contribution to breast cancer progression independently of ER is unforeseen, since we previously reported that the ER chromatin interactions are mediated by FOXA1 (Hurtado, Nat Genetics 2011). Now, our study reveals that FOXA1 is acetylated by the acetyltransferase EP300 and that such post-translational modification retains FOXA1 at ER chromatin regions. By contrast, HER2/3 signaling hinders FOXA1 acetylation and facilitates the binding of FOXA1 to chromatin regions poorly enriched of non-ER sites. Moreover, the expression of FOXA1 mutant defective for acetylation mimics the HER2/3 effect and also confers insensitivity to hormone therapy. Altogether, our study supports that ER/EP300 limits the binding of FOXA1 and the ER independent function. By contrast, in hormone resistant tumors with enhanced HER2/3 signaling, FOXA1 becomes less acetylated and now can binds without restrictions to chromatin regions poorly enriched of ER sites. As a consequence, the tumor gains the ability to grow independently of ER and therefore becomes insensitive to anti-ER therapies. Our study provide insight into tumor heterogeneity, revealing mechanistic insight into what tumors should be targeted with specific HER-targeted therapies and defining whether ER is still functional and still valid as a single drug target.
Targeting the mevalonate pathway in HER2-positive breast cancer to overcome resistance to anti-HER2 therapy

Vidyalakshmi Sethunath1, Huizhong Hu1, Carmine De Angelis1, Jamunarani Veeraraghavan1, Lanfang Qin1, Motthaffar F Rimawi1, Kent C Osborne1 and Rachel Schiff1. 1Baylor College of Medicine, Houston, TX.

Body: Background: Despite the advent of HER2-targeted therapies for HER2+ breast cancer (BC), including the monoclonal antibody trastuzumab (T) either alone or in combinations, resistance still poses a major clinical challenge. Using our broad panel of HER2+ cell lines made resistant (R) to T alone (TR), and to lapatinib plus T (LTR), we observed that in resistant models where HER2 remains inhibited, especially the LTR derivative, the mevalonate (MVA) pathway is activated and provides an alternative proliferative signal, including the activation of mTOR, to drive resistance. While these resistant cell models were hypersensitive to the widely-used cholesterol-lowering statins, the role of other MVA pathway inhibitors such as zoledronic acid (ZA), which is in clinical use to treat bone metastasis, in overcoming resistance to HER2-targeted therapy has not been explored. Based on recent reports and our preliminary data using reverse phase protein array (RPPA) analysis, the YAP/TAZ transcription factor (TF) emerged as a potential mediator of MVA pathway signaling to mTOR. Here, we investigated the therapeutic efficacy of additional MVA pathway inhibitors and the role of YAP/TAZ in mediating resistance to HER2-targeted therapy.

Methods: HER2+ SKBR3 and AU565 BC cells and their LTR derivatives were used. Changes in cell growth upon genetic and pharmacologic inhibition of the MVA pathway were quantified by methylene blue staining. Luciferase reporter assays and western blots (WB) measured changes in total and phosphorylated (S127 and S381/inactive) YAP protein levels to examine activity of the YAP/TAZ TF complex. To validate the function of YAP/TAZ in resistance, we performed YAP/TAZ knockdown (siRNA), overexpression of dominant-active YAP constructs (S381A, S381/127A), and qRT-PCR assessment of YAP/TAZ target gene expression.

Results: ZA, like simvastatin (Sim), selectively inhibited the growth of resistant cells in a dose-dependent manner. This inhibition was rescued by geranyl geranyl pyrophosphate (GGPP), a downstream metabolite, but not by MVA, an upstream metabolite, indicating the on-target effect of ZA. Further, ZA and Sim combination showed a synergistic growth-inhibitory effect in R but not in parental (P) cells. YAP/TAZ luciferase reporter assays and phosphorylated YAP and total TAZ levels by WB, confirmed the increased activity of YAP/TAZ in R models, which was selectively inhibited by Sim or ZA and was rescued by the corresponding downstream metabolites. YAP/TAZ knockdown selectively inhibited resistant cell growth and mTOR signaling in R vs. P cells, and dominant-active YAP/TAZ rescued the mTOR inhibition by Sim. YAP/TAZ inhibition by siRNA or by Sim significantly decreased the expression of YAP/TAZ target gene survivin in R vs. P cells, and the Sim inhibition was rescued by MVA.

Conclusions: The MVA pathway plays a critical role in mediating resistance to anti-HER2 therapy, which was overcome by Sim and ZA either alone or in combination. Given the synergistic effect of Sim and ZA, their combination may offer a therapeutic strategy to overcome HER2-targeted therapy resistance. Our results also reveal the role of YAP/TAZ in MVA pathway-mediated HER2-targeted therapy resistance, which could suggest new biomarkers and therapeutic targets.
Title: AP-1 as a potential mediator of resistance to the cyclin-dependent kinase (CDK) 4/6-inhibitor palbociclib in ER-positive endocrine-resistant breast cancer

Body: Background: The CDK4/6-inhibitor palbociclib (Palbo) in combination with endocrine therapy (ET) substantially improves progression-free survival compared to ET alone. However, almost all initial responders eventually develop resistance and relapse. Delineating the early adaptive signaling and the mechanisms underlying resistance to CDK4/6 inhibition is therefore crucial to identify new biomarkers and therapeutic targets to enhance the efficacy of Palbo and improve patient outcome.

Materials and Methods: MCF7 parental (P) cells and derivative lines made resistant (R) to tamoxifen (TamR), estrogen deprivation (EDR), or fulvestrant (FulR) were used. The MCF7P line and its endocrine-R (EndoR) derivatives were exposed to increasing concentrations of Palbo to generate acquired Palbo-R (PDR) models. The proteomic/signaling profiles of P and EndoR cells upon short-term Palbo treatment and as PDR develops were determined using reverse-phase protein arrays (RPPA). Transcriptional activity of the activator protein-1 (AP-1) transcription factor (TF) was measured by luciferase reporter assay. Global AP-1 blockade was achieved using a pINDUCER system to express doxycycline (Dox)-inducible dominant-negative (DN) c-Jun that lacks the transcriptional activation domain. Cell growth and colony formation were assessed using methylene blue staining and clonogenic assays, respectively. Levels of phosphorylated (p)-RB and CDK2 were assessed by Western Blot.

Results: In P and all EndoR cell models, Palbo inhibited cell growth and colony formation in a dose-dependent manner, though the inhibitory effect was greater in the EndoR cells compared to P cells [IC50 value of P cells >3 times that of EndoR lines (p<0.001); clonogenic % inhibition at 100nM = 54 in P and >85 in EndoR lines (p<0.001)]. Across the P and all EndoR models, short-term Palbo treatment resulted in increased levels of several membrane and intracellular signaling molecules, TFs, and enzymes. Among these, the AP-1 TF components c-Jun and p-c-Jun showed the highest increase across all models, with the utmost change observed in the TamR model (Fold-change = 4.4, 4.0 for total and p-c-Jun, respectively). Since we also observed that acquired resistance to Palbo in the TamR model was associated with higher AP-1 transcriptional activity and increased total and p-c-Fos levels, we assessed the efficacy of combining Palbo with AP-1 blockade in the TamR model. In two independent TamR clones ectopically expressing inducible DN-c-Jun, AP-1 blockade (+Dox) in combination with Palbo was highly effective in inhibiting cell growth and reducing p-RB and CDK2 levels compared to single agent treatments. In addition, in both the TamR/DN-c-Jun-expressing clones, the combination of Palbo, AP-1 blockade, and fulvestrant resulted in cell death and a significantly greater cell growth inhibition compared to any dual or mono treatments.

Conclusion: Our results suggest activation of AP-1 as a potential mechanism of resistance to Palbo in ER+ EndoR models. Transcriptomic profiling of the Palbo-sensitive and R cells, currently underway, will provide an in-depth understanding of the role of AP-1 as well as other key targets and associated molecular mechanisms in Palbo resistance.
Title: PRKCQ promotes chemotherapy resistance by regulating levels of Bim

Hanna Y Irie¹, Jessica H Byerly¹, Koichi Ito¹ and Elisa R Port². ¹Icahn School of Medicine at Mount Sinai, New York, NY and ²Mount Sinai Hospital, New York, NY.

Body: Background/Rationale: Genomic heterogeneity and lack of targeted therapies pose significant challenges for the treatment of triple negative breast cancer (TNBC), particularly those that are resistant to standard of care chemotherapy treatments. We identified PRKCQ as a driver of epithelial-mesenchymal transition (EMT) that promotes anoikis resistance, invasion and metastatic lung colonization of TNBC cells. PRKCQ also promotes resistance to the apoptosis-inducing effects of chemotherapies standardly used to treat patients with TNBC. Downregulation of PRKCQ enhances apoptosis of chemotherapy-treated TNBC cells. Our study aims to determine the mechanism for chemotherapy sensitivity regulation by PRKCQ and to determine whether PRKCQ is associated with relative chemotherapy resistance in patient triple negative tumors.

Methods: Using models of both gain- and loss-of function of PRKCQ, we performed a comprehensive analysis of the expression status of Bcl2 family members, which are directly responsible for chemotherapy-induced apoptosis. We validated the critical, causal contribution of affected Bcl2 proteins to apoptosis regulation by PRKCQ in TNBC cells. PRKCQ kinase activity-dependent regulation of chemotherapy sensitivity was evaluated using PRKCQ small molecule inhibitors. Finally, an immunohistochemistry-compatible PRKCQ antibody was optimized and is being used to interrogate the expression of PRKCQ in patient triple negative tumor biopsies obtained prior to neoadjuvant chemotherapy treatment.

Results: PRKCQ specifically regulates the expression of Bim, a pro-apoptotic member of the Bcl2 family; overexpression of PRKCQ suppresses Bim transcript and protein levels, whereas PRKCQ downregulation in TNBC cells increases these levels. The kinase activity of PRKCQ is important for Bim regulation, as overexpression of kinase-dead PRKCQ fails to suppress Bim and treatment with a PRKCQ inhibitor phenocopies the effects of PRKCQ shRNA treatment on Bim levels. Basal levels of Bim have been reported to be a critical set point for sensitivity of cancer cells to chemotherapy and targeted therapies. Here, modulation of Bim levels is sufficient to alter chemotherapy sensitivity of TNBC cells. PRKCQ-dependent suppression of Bim is dependent on Erk/MAPK activity. Ongoing work will determine association between PRKCQ expression with chemotherapy sensitivity of patient TNBC.

Conclusions: PRKCQ is a critical regulator of chemotherapy sensitivity via its ability to modulate Bim, a pro-apoptotic Bcl2 family member. The kinase dependency of this regulation highlights the promises of PRKCQ small molecule inhibitors as a potential therapeutic strategy to enhance the anti-tumor effects of chemotherapy treatment for patients with TNBC.

Title: Combined genome-scale CRISPR-Cas9 knockout screening with transcriptome sequencing to identify paclitaxel related drivers in triple negative breast cancer

Bi Lian, Hu Xin and Shao Zhimin. ¹Fudan University Shanghai Cancer Center, China and ²Shanghai Medical College, Fudan University, China.

Body: Background. Triple negative breast cancer (TNBC) is an aggressive subtype of breast cancers, for which the only standard therapeutics is chemotherapy containing Taxol. However, quite a number of TNBC patients cannot get the expected drug response after paclitaxel treatment and the resistant mechanism has not been clear yet. Other than the traditional “genotype-to-phenotype” means, the high-throughput functional screening, such as CRISPR-CAS9 library, selects genes with the phenotype of interest. Here, we combine the novel screening model with the drug-resistant genotype to explore the decisive role in paclitaxel effect.

Methods. Breast cancer cell line MDA-MB-231(231WT) was treated by paclitaxel from 1ug/ml to 5ug/ml to establish a paclitaxel-resistant cell type (231PTX) for transcriptome sequencing. Genome-scale CRISPR-Cas9 sgRNA library was made into lentivirus to affect MDA-MB-231 cells expressed Cas9 protein (231cas9). Then 231cas9-sgRNA was treated by low dose of paclitaxel for 14 days and was read by next generation sequencing. RNA sequencing data was processed to TPM values and sgRNA data to gene ranking and p value. The threshold of “231PTX TPM/231WT TPM” was above 2 or below 1/2 and the gene p value was smaller than 0.05. Biological technology applied in this study includes western blot (WB), immunofluorescence (IF), real time PCR and cell proliferation assay. In vivo, 20 balb/c mouse were injected MDA-MB-231 in situ for tumor formation and were treated with paclitaxel/normal saline for six times.

Results. Crosstalk between these two sequencing data had result of 124 genes related to paclitaxel resistance (fold change> 2 and p value<0.05 compared Day 14 treated group to Day 14 untreated group) and 18 genes related to paclitaxel sensitivity (fold change< 1/2 and p value<0.05 compared Day 14 untreated group to Day 14 treated group). Considering clinical prognosis and gene information, six paclitaxel resistant candidates and four paclitaxel sensitive candidates were chosen for further research. Eight (STRA6, BIRC3, MTUS1, HDAC9, ADAM28, S1PR5, TNNC1, ZKSCAN7) of ten candidates displayed consistent phenotypes with sequencing results including mRNA expression and the cellular proliferation in paclitaxel treatment. HDAC9 is a histone deacetylation gene that is likely to be a paclitaxel resistant gene. Knockout HDAC9 (231H9 KO) contributed to nearly 2-fold decrease IC50 value (1.7nM versus 3.7nM, p value<0.01). Confocal microscopy observed the formation of multiple spindle foci in the paclitaxel treated 231H9 KO cells. After treatment with paclitaxel, the mark of polymerized tubulin, acetylation tubulin and the mark of cell cycle G2/M, cyclin B1 were notably increased when HDAC9 knockout in both MD-MB1-231 and BT-100 cell lines. In vivo assays found that HDAC9 knockout induced the declined tumorigenesis and more sensitive breast tumors to paclitaxel.

Conclusions. Combined Genome-scale CRISPR-Cas9 knockout screening with transcriptome sequencing is efficient to investigate potent drug targets. In vitro assays suggest that HDAC9 is conductive to paclitaxel resistance in TNBC cells. In vivo results imply inhibition HDAC9 may beneficial to paclitaxel therapeutic response.

Title: Chromosomal instability predicts taxane sensitivity in breast cancer

Karla Esbona¹, Ning Jin¹, Kayla L Correia-Staudt², Angela M Lager³, Tracy Heidke³, Jennifer Laffin³, Beth A Weaver⁴ and Mark E Burkard¹. ¹University of Wisconsin--Madison, Madison, WI; ²School of Medicine and Public Health, University of Wisconsin--Madison, Madison, WI; ³University of Wisconsin--Madison, Madison, WI and ⁴University of Wisconsin--Madison, Madison, WI.

Body: Taxanes remain among the most effective agents for the treatment of breast cancer. However, ~50% of patients who receive this therapy do not have a clinical response. Previously, we identified the mechanistic effects of taxane therapy by sampling primary human breast tumors 20 hours after infusion (Sci Trans Med 26:229ra43, 2014). We determined that paclitaxel caused cells to transit mitosis on multipolar spindles, resulting in increased chromosome gains and losses. Preclinical models suggest that tumors have enhanced sensitivity if they have baseline chromosome gains/losses, known as chromosome instability (CIN). The aim of this study was to compare CIN against other predictive biomarkers in a retrospective cohort of advanced breast cancer patients who receive single-agent taxane therapy.

Methods: We identified 36 subjects with metastatic breast cancer and measurable disease who received taxane therapy and had available archived tissue. Responses were determined by RECIST 1.1 criteria. We evaluated chromosome number on a cell-by-cell basis using 6 centromeric FISH probes. Additionally we measured rates of proliferation by phospho-histone H3 (p-HH3) and Ki67, previously reported biomarkers, β-tubulin III, P-gp1 and MAD1 by quantitative immunofluorescence. CIN was estimated as the fraction of cells with non-modal chromosome numbers across chromosomes 3, 4, 7, 9, 10, and 17.

Results: Of the 36 subjects, 19 had ER/PR+HER2- disease (53%), 9 had HER2-positive disease (25%), and 8 TNBC (22%). Single-agent chemotherapy was used for all including paclitaxel in 16, nab-paclitaxel in 17, and docetaxel in 3 (HER2+ patients received concurrent trastuzumab). RECIST responses ranged from disease progression (8%, n=3), stable disease (50%, n=18), and partial response (42%, n=15). No complete responses were observed. Time on therapy ranged from 1.4 months to 28 months. No statistically significant correlations were found between tumor type or prior chemotherapy and response to taxanes. Archived metastatic samples were available for 21 subjects. Analysis showed large variations in Ki67, pHH3, β-tubulin III, P-gp1, MAD1, and CIN amongst samples. The strongest correlation was found between tumor response and high levels of CIN, with a Spearman’s correlation coefficient of 0.38 (p=0.04). Surprisingly, there was an inverse correlation between Ki67 and taxane response, although this did not reach statistical significance.

H = H-score; CIN is estimated as % of cells with non-modal chromosomes

Conclusions: Chromosomal instability is a promising biomarker for predicting sensitivity to taxane therapies. Additional studies will be necessary to validate CIN as a biomarker and to determine whether 6-chromosome FISH can be supplanted by low-pass single-cell DNA sequencing.
Title: Clinical observation of lapatinib versus continued use of trastuzumab for trastuzumab-resistant HER2-positive advanced breast cancer

Yongmei Yin¹, Wei Li¹, Xiang Huang¹, Jian Wang², Ziyi Fu² and Jun Li¹. ¹The First Affiliated Hospital of Nanjing Medical University, Nanjing, Jiangsu, China and ²Nanjing Medical University, Nanjing, Jiangsu, China.

Body: Objective: To compare the efficacy, adverse effects and survival of lapatinib versus continued use of trastuzumab for trastuzumab-resistant human epidermal growth factor receptor 2 (HER2)-positive advanced breast cancer.

Methods: Patients who began the regimen of lapatinib plus capecitabine (LC or LX) or trastuzumab beyond progression (TBP) between May 2013 and October 2016 were selected from the First Affiliated Hospital of Nanjing Medical University. All of their clinical data were recorded, including age, performance status, hormone receptor status, metastatic site, primary or acquired trastuzumab resistance, previous treatment and so on. They were followed up until death or April 30, 2017. The primary end point was progression-free survival (PFS). The efficacy and safety of the two regimens were evaluated according to Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1 and Common Terminology Criteria for Adverse Events (CTCAE) version 4.0, respectively. Data were analyzed by SPSS version 19.0.

Results: In total, 95 patients were identified, including 40 treated with LX and 55 with TBP. Median follow-up time was 16.0 months. There was no difference in objective response rate (ORR) and disease control rate (DCR) between the two groups. By the end of follow-up, median PFS was 6.3 months with LX and 7.1 months with TBP (P=0.676). In patients with primary trastuzumab resistance, longer PFS was observed in LX group compared with TBP group [median PFS: 8.0 months vs. 5.3 months, hazard ratio (HR)=0.416, 95% confidence interval (CI): 0.177-0.981, P=0.038]. The incident rate of new brain metastases during treatment was 2.5% in LX group and 10.9% in TBP group, respectively (P=0.233). Both regimens showed similar outcomes in baseline brain metastases. Grade 3-4 adverse effects included diarrhea 7.5%(3/40) and hand-foot syndrome 12.5%(5/40) in LX group, along with leukopenia 18.2%(10/55), thrombocytopenia 9.1%(5/55) and nausea/vomiting 3.6%(2/55) in TBP group.

Conclusion: LX and TBP were similarly effective for patients with HER2-positive breast cancer progressing on prior trastuzumab-containing therapy. Both were well tolerated in general. Lapatinib tended to reduce the risk of disease progression in patients resistant to trastuzumab primarily. LX or TBP after local treatment appeared to show no difference in treating patients with brain metastases.

Title: Effects of PI3K inhibitors on endocrine-resistant cell lines and differences in the characteristics of ER positive breast cancer cells after acquired resistance to the inhibitors

Emi Tokuda¹,², Takayuki Komatsu¹, Shunta Sasaki¹, Kouki Tsuboi¹, Misato Nakamura¹, Masafumi Iida¹, Toshifumi Niwa¹, Mitsue Saito² and Shin-Ichi Hayashi¹. ¹Tohoku University Graduate School of Medicine, Sendai, Japan and ²Juntendo University Hospital, Tokyo, Japan.

Body: Background

Mutations in phosphatidylinositol 3-kinase (PI3K), which encodes the catalytic subunit of PI3Kα, is one of the most frequent genomic alterations and is found in about 40% of estrogen receptor (ER)-positive, HER2 negative breast cancers. PIK3CA mutations promote the growth and proliferation of cancers via activation of the PI3K/mammalian target of rapamycin pathway and can mediate resistance to endocrine therapies in breast cancer. Although several clinical trials for PI3K inhibitors (PI3Kis) in ER-positive metastatic breast cancers are ongoing, the effects of PI3Kis on endocrine-resistant breast cancers with various characteristics and definitive biomarkers of PI3Kis are unclear. Using endocrine-resistant cells established in our laboratory, we evaluated the efficacy of PI3Ki in these cell lines and identified the characteristics associated with acquired resistance to PI3Kis in endocrine-resistant cells.

Results

Long-term estrogen deprivation-resistant (EDR) cell lines and fulvestrant-resistant cell lines (MFR and TFR) were established from MCF-7 and T-47D cells in our previous studies. These cell lines showed different ER expression levels, including high expression (EDR-1), low expression (EDR-2, -3), or no expression (MFR, TFR); all of these cell lines had the same PIK3CA mutations as the parental cell lines. The pan-class1 PI3Ki buparlisib (BKM120) and α-specific PI3K inhibitor alpelisib (BYL719) inhibited the proliferation of endocrine-resistant cell lines when compared with their parental cells. Among endocrine-resistant cells, MFR cells were dramatically inhibited by PI3Kis. Colony formation assays indicated that MFR cells were more sensitive to PI3Kis than other cells lines. Next, we established PI3Ki- and everolimus-resistant cell lines from EDR-1, EDR-2, and MFR cells using BKM120, BYL719, and everolimus. Analysis of the time required to generate resistant cells showed that MFR cells required twice as long to acquire resistance compared with EDR cells. Furthermore, the time required to acquire resistance to BYL719 was shorter than that for BKM120. BYL719-resistant (BYL-R) cells were effectively inhibited by BKM120 to a degree similar to that of parental cells; however, BYL-R cells lost sensitivity to BYL719 and everolimus. Evelolimus-resistant (EVE-R) cells were also the same. In contrast, BKM120-resistant (BKM-R) cells showed less sensitivity to BKM120, BYL719, and everolimus. In other words, the pan-PI3Ki BKM120 was able to inhibit the growth of BYL-R and EVE-R cells, whereas BYL719 and everolimus were not able to inhibit BKM-R cells sufficiently. In addition, there were no changes in ER expression in EDR-1, EDR-2, and MFR cells exposed to PI3Kis for 1 h. Interestingly, ER expression on EDR-2 cells with acquired resistance to PI3Kis was increased compared with that in parental cells.

Conclusion

Our findings showed that PI3Kis exhibited remarkable efficacy in all types of EDR cells, particularly in fulvestrant-resistant cell lines. In PI3Ki- and everolimus-resistant cell lines, BKM120 and BYL719 showed different effects, and BYL719 and everolimus may exhibit cross-resistance. Furthermore, PI3Kis were likely to change the expression of ER.
Body: The majority of breast cancer-specific deaths occur in women with recurrent, ERα (+), metastatic tumors that are initially responsive to endocrine therapy yet become endocrine-resistant. There is a critical need for novel therapeutic approaches to re-sensitize recurrent ERα (+) tumors to endocrine therapies. The objective of this study was to elucidate mechanisms of improved effectiveness of combined targeting of ERα and XPO1, a nuclear transport protein in overcoming endocrine resistance. Using Cignal Finder pathway profiling, Seahorse metabolic profiling and GC/MS whole metabolite profiling, we found that combination of 4-OH-Tamoxifen (4-OH-Tam) and Selinexor (SXR), a highly selective XPO1 inhibitor that is currently in clinical trials for leukemia and prostate cancer, inhibited Akt phosphorylation by changing the phosphorylation status and localization of the kinase. Since we observed dramatic changes in Akt activity, we hypothesized that metabolic pathways and consequently metabolic profile of breast cancer cells would change in the presence of 4-OH-Tam and SXR. These cells were more dependent on mitochondria for energy production. Their glucose and fatty acid dependency decreased in the presence of SXR and cells were more dependent on glutamine as the mitochondrial fuel source. We demonstrated that combined targeting of XPO1 and ERα rewires metabolic pathways and induce autophagy. Remodeling metabolic pathways to regenerate new vulnerabilities in endocrine-resistant tumors is novel, and given the need for better strategies for improving therapy response of relapsed ERα (+) tumors, our findings show great promise for combined targeting of ERα and XPO1 in the clinic to reduce cancer recurrences.

**Title:** OTULIN promotes resistance and metastasis upon chemotherapy in TNBC by activating Wnt/β-catenin signaling

Zhaohui Wu¹, Wei Wang¹, Bo Zhang¹, Jingyan Xue², Yayun Chi² and Jiong Wu². ¹The University of Tennessee Health Science Center, Memphis, TN and ²Fudan University Shanghai Cancer Center, Shanghai, China.

**Body:** Triple-negative breast cancer (TNBC) or Basal-like breast cancer is characterized by worse prognosis than other breast cancer subtypes due to the rapid-arising therapeutic resistance accompanied by aggressive metastasis. The therapy-resistant tumor cells, including cancer stem-like cells (CSCs) with intrinsic resistance or tumor cells acquired resistance during treatments, could repopulate the primary tumors and serve as seeds for recurrent metastatic lesions. However, the molecular events orchestrating the innate and acquired therapeutic resistance are not completely understood. We found a recently identified linear ubiquitin-specific deubiquitinase OTULIN is overexpressed in breast tumors, especially in the basal-like subtype, compared with normal breast tissues. Moreover, OTULIN overexpression significantly increased TNBC cells resistance to chemotherapy and is associated with shorter RFS in breast cancer patients. Mechanistically, we found genotoxic treatments activate OTULIN, which promotes epithelial-to-mesenchymal transition (EMT) in TNBC cells through increased activity of Wnt/β-Catenin signaling. OTULIN overexpression significantly increased TNBC cells resistance to chemodrugs while inhibiting Wnt/β-Catenin sensitized TNBC xenografts to Doxorubicin treatment in vivo. Our findings suggest that OTULIN-mediated Wnt/β-Catenin activation may increase TNBC therapeutic resistance and aggressiveness by promoting EMT. Targeting OTULIN and the chemotherapy-induced Wnt/β-Catenin activation may serves as promising strategy to mitigate drug resistance and reduce metastasis in TNBC patients receiving chemotherapy.
Title: Targeting Src kinase blocks development of afatinib resistance in HER2-positive breast cancer

Neil Conlon¹, Alexandra Canonici¹, Clare Morgan², Mattia Cremona², Bryan T Hennessey², Alex Eustace², Neil O'Brien³, Dennis Slamon³, John Crown⁴ and Norma O'Donovan¹. ¹National Institute for Cellular Biotechnology, Dublin City University, Dublin, Ireland; ²Royal College of Surgeons in Ireland, Dublin, Ireland; ³University of California Los Angeles, Los Angeles and ⁴St. Vincent's University Hospital, Dublin, Ireland.

Body: Background: Afatinib is an irreversible pan-HER inhibitor approved for non-small cell lung cancer. We have previously shown that afatinib inhibits growth of HER2-positive breast cancer cells and enhances response to trastuzumab. However, we have also shown that long-term exposure to tyrosine kinase inhibitors leads to the development of acquired resistance. To determine if acquired afatinib resistance develops in HER2-positive breast cancer cells, we exposed a HER2-positive breast cancer cell line to afatinib for 6 months and investigated alterations in the cells following long-term exposure.

Methods: SKBR3 cells were treated with 150 nM afatinib twice-weekly for 6 months. Growth response to drug inhibitors was assessed by acid phosphatase assay. Drug sensitivity was examined in four HER2-positive cell lines (SKBR3, EFM192A, BT474 and HCC1954) and three acquired trastuzumab resistant cell lines (SKBR3-T, BT474-T and EFM192A-T). Reverse phase protein array (RPPA) was used to determine alterations in key signaling pathways. Src, p-Src, EGFR, p-EGFR, ERK1/2, p-ERK 1/2 levels were examined by Western blotting. To examine the prevention of the development of afatinib resistance, cells were treated twice weekly with afatinib, dasatinib, or the combination and stained with crystal violet when confluent.

Results: Following 6 months of afatinib treatment, the SKBR3-A cells were more resistant to afatinib compared to parental cells (IC₅₀ SKBR3-A 284 ± 28.2 nM vs SKBR3-Par 10.9 ± 3.4 nM). Furthermore, the resistant cells were cross-resistant to lapatinib, neratinib and trastuzumab. RPPA interrogation of the SKBR3-A cells showed alterations in several pathways, including significantly increased levels of p-Src (Y416). SKBR3-A cells were more sensitive to Src inhibition with dasatinib compared to SKBR3-Par cells and the combination of afatinib and dasatinib was highly synergistic in SKBR3-A cells (CI value = 0.09 ± 0.06). The combination of afatinib and dasatinib was also synergistic in the trastuzumab resistant SKBR3-T cells (Table). Afatinib and dasatinib inhibited EGFR and Src activation and ERK 1/2 signalling in SKBR3-A cells.

Short-term resistance assays showed that the addition of dasatinib to afatinib blocks the emergence of resistant cells in three of four HER2 positive cell lines tested and two of the three acquired trastuzumab resistant cell lines tested.

Conclusion: HER2-positive breast cancer cells that are highly sensitive to afatinib can develop acquired resistance to afatinib within six months. Src is a potential target to prevent the development of afatinib resistance and thus combined treatment with afatinib and dasatinib may be beneficial in patients with HER2-positive breast cancer.

Title: Cyclin E affects Smad3 pathway in trastuzumab resistant HER2+ breast cancer

Joseph T Decker¹, Lei Wan¹, Lonnie D Shea¹ and Jacqueline S Jeruss¹. ¹University of Michigan.

Body: Introduction and Objective: HER2 amplification is found in approximately 20% of patients with breast cancer and is associated with poor prognosis. Trastuzumab, a humanized anit-HER2 antibody, has been shown to improve patient outcomes, but clinical efficacy for this treatment is limited by the high rate of drug resistance. Cyclin E overexpression and cyclin-dependent kinase 2 (CDK2) activation correlate with trastuzumab resistance, and the underlying mechanisms of this correlation are an area of active study. In this work, we examined the contribution of cyclin E/CDK2-mediated Smad3 noncanonical phosphorylation to trastuzumab resistance in HER2+ breast cancer.

Methods: Trastuzumab resistant BT474R2 cells were developed by culturing BT474 cells in trastuzumab-supplemented media for 18 months. These cells were then inoculated into immunodeficient mice and treated with trastuzumab twice weekly. BT474 and BT474R2 cells were used to study cell proliferation, phosphorylation in the Smad3 linker region and transcription factor activities with a living cell array.

Results: Inhibition of cyclin E activity with CDK2 inhibitor therapy (CDK2i, 600 nM) significantly decreased BT474R2 cell proliferation. CDK2i treatment led to decreased phosphorylation at T179 (p<0.01), S204 (p<0.01) and S213 (p<0.05) in the Smad linker region. Further, CDK2i increased expression of p15 (p<0.05) and decreased expression of c-myc (p<0.05) in comparison with trastuzumab treatment. Transduction of BT474R2 cells with a 5M Smad3 construct containing inhibitory mutations in 5 CDK2 phosphorylation sites resulted in decreased cell proliferation. In a transfected cell array using BT474 and BT474R2 cells, activities of cell proliferation and metastasis-associated transcription factors were significantly different between the trastuzumab sensitive and resistant cells.

Conclusions: Taken together, overexpression of cyclin E leads to Smad3 noncanonical phosphorylation and results in trastuzumab resistance in HER2+ breast cancer. CDK2i treatment may be a promising therapeutic strategy for patients with trastuzumab resistance.
Title: Loss of mismatch repair predicts resistance to endocrine therapy and sensitivity to CDK4/6 inhibitors in ER+ breast cancer

Svasti Haricharan1, Nindo Punturi1, Purba Singh1, Kimberly R Holloway1, Meenakshi Anurag1, Jacob Schmelz1, Cheryl Schmidt1, Jonathan T Lei1, Vera Suman2, Kelly Hunt2, John A Olson Jr4, Jeremy Hoog5, Shunqiang Li5, Shixia Huang1, Dean P Edwards1, Shyam M Kavuri1, Matthew N Bainbridge6, Cynthia X Ma5 and Matthew J Ellis1. 1Baylor College of Medicine; 2UT MD Anderson Cancer Center; 3Mayo Clinic; 4University of Maryland School of Medicine; 5Washington University School of Medicine and 6Rady's Children's Hospital.

Body: Estrogen receptor positive (ER+) breast cancer is treated with endocrine therapy but intrinsic resistance occurs in ~1/3 of patients and acquired resistance in ~1/5 of the remainder. While many resistance mechanisms have been explored, clinical trials testing associated therapeutics have had mixed outcomes. Understanding mechanisms of resistance and finding therapeutic strategies to target them, therefore, remain important challenges.

In this study we discover an intriguing link between mismatch repair (MMR) deficiency, specifically of the MutL complex (MLH1/3, PMS1/2), and endocrine therapy resistance in ER+ disease. We find a direct role for MutL loss in inducing endocrine therapy resistance in vitro and in vivo by knocking down multiple MutL genes using CRISPR and stable shRNA approaches validated using standard rescue experiments. We identify the underlying mechanism: MutL deficiency in ER+ breast cancer abrogates Chk2-mediated feedback inhibition of CDK4/6 that appears necessary for endocrine therapy responsiveness. Consequently, pharmacological targeting of CDK4/6 in vitro and in vivo significantly inhibits growth of endocrine therapy resistant MutL-deficient ER+ breast cancer cells. These results are corroborated by data from a neoadjuvant clinical trial demonstrating that cell cycle regulation of MutL-mutant tumors is estrogen-independent but CDK4/6 dependent.

The results of this study provide important biological and clinically relevant insights. 1) a novel role for MMR in endocrine therapy resistance 2) A mechanism underlying the effectiveness of CDK4/6 inhibitors in some de novo endocrine therapy resistant tumors. While there are currently no biomarkers to guide the use of CDK4/6 inhibitors for ER+ breast cancer, markers of MMR dysregulation could identify patients in whom CDK4/6 inhibition may, most effectively, prevent disease recurrence.
Characterising the effects of neoadjuvant endocrine therapy on primary cancers and nodal metastasis

J Michael Dixon¹, Arran K Turnbull², Maki Tanioka⁴, Joel Parker⁴, Xiaping He⁴, Anu Fernando⁴, Lorna Renshaw¹, Jane Keys¹, Jeremy S Thomas³, Andrew H Sims², Lisa A Carey⁴ and Charles M Perou⁴. ¹Edinburgh Breast Unit, Western General Hospital, Edinburgh, United Kingdom; ²Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, United Kingdom; ³Western General Hospital, Edinburgh, United Kingdom and ⁴Lineberger Comprehensive Cancer Center, Chapel Hill, NC.

Background: Approximately 40% of ER+ breast cancer present with nodal metastasis. To date, there has been no comparison of the molecular response of primary cancers and metastases to ET. Recent evidence suggests that nodal metastases have different clones and subclones compared to the primary tumour. The aim of this study is to characterise the molecular response of primaries and nodal metastases to ET.

Methods: A unique set of 7 post-menopausal women with ER-positive breast cancer had biopsies taken from the primary tumour and a positive lymph node at diagnosis and at surgery following 3-12 months of neoadjuvant letrozole. 14-day and 3-6 month on-treatment biopsies from the primary tumour and involved nodes were also taken from the same patients, giving a total of 75 samples. Lymph node FFPE blocks were stained for cytokeratin and macro-dissected to enrich for tumour tissue. RNA and DNA were extracted and Ribo0-RNAseq, DNA exome sequencing and somatic mutation detection using UNCeqR performed. Whole-transcriptome AmpliSeq targeted-sequencing has been analysed for 4 patients.

Results: Multi-dimensional scaling and hierarchical clustering analysis based on all transcripts and the 500 most variably expressed genes revealed that primaries and nodal metastases are strongly associated at diagnosis but some nodes diverge during ET treatment. Analysis of estrogen-responsive proliferation-associated genes (n=60) in nodal metastasis revealed a reduction in expression of the majority of genes with ET. However, the expression levels of some remained high in the on-treatment node samples in all 4 patients analysed compared with the matched primary tumour on treatment. In particular, expression of genes involved in DNA replication and regulation of cell cycle including MCM6 and RRM2 (DNA replication), ASPM and CEP55 (mitosis) and CDKN3 (regulation of cell cycle) persisted at high levels in nodal metastases, but reduced in the primary cancers. Similarly, primary tumours had increased levels of ECM remodeling genes (n=60) as treatment continued, while levels in the nodal metastasis were heterogeneous on-treatment. Full genome sequencing results will be available by December 2017.

Discussion
- This is the first study to investigate genomic and transcriptomic changes with ET in both primary cancers and nodal metastases.
- On-treatment changes in nodal disease are heterogeneous between patients and within the same patient.
- Nodal metastases do respond to ET with reduced levels of proliferation-associated genes.
- Some proliferation-associated genes appear to maintain higher expression in nodal disease.
- Patterns of gene expression observed in some nodal metastases are consistent with profiles previously described by us for ET resistance and recurrent disease.
- Nodal metastases may accumulate mutations during treatment with ET and on-going analysis will clarify this.
Title: Hyperactive FOXA1 activates super-enhancer-engaged HIF2α/EPAS1 to promote endocrine-resistant metastatic ER-positive breast cancer

Xiaoyong Fu\(^1\,^2\,^3\), Resel Pereira\(^1\,^2\), Carmine De Angelis\(^1\,^2\,^4\), Jamunarani Veeraraghavan\(^1\,^2\,^4\), Martin J Shea\(^1\,^2\,^4\), Sarmistha Nanda\(^1\,^2\,^4\), Qin Feng\(^3\), Rinath Jeselsohn\(^5\), Bert W O'Malley\(^2\,^3\), Myles Brown\(^5\), C Kent Osborne\(^1\,^2\,^3\,^4\) and Rachel Schiff\(^1\,^2\,^3\,^4\).

Duncan Comprehensive Cancer Center, Baylor College of Medicine, Houston, TX; 3 Baylor College of Medicine, Houston, TX; 4 Baylor College of Medicine, Houston, TX and 5 Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA.

Body: Background: We have recently reported that acquired endocrine resistance (Endo-R) in multiple ER+ breast cancer (BC) Endo-R cell models is driven by high levels of FOXA1 (High-FOXA1), via gene amplification and/or overexpression (OE), leading to coordinated reprogramming of the FOXA1 genomic binding (cistrome) and transcriptome. Forced FOXA1 OE in parental (P) cells induced similar transcriptional reprogramming leading to Endo-R and metastasis. Recent clinical data showing enrichment of FOXA1 amplification in ER+ metastases further support the clinical importance of our findings. However, the molecular components and the mechanism of High-FOXA1-induced transcriptional reprogramming in Endo-R and metastasis are unknown.

Methods: High-FOXA1-containing MCF7 tamoxifen-resistant (TamR) and P/FOXA1-OE cells were used in this study. An integrative multi-OMICS approach was employed to analyze transcriptome (RNA-seq), FOXA1 cistrome, and histone H3K27 acetylation (ac) (ChIP-seq). Intersection of High-FOXA1-induced transcriptome and distinct FOXA1 cistrome-predicted genes defined a High-FOXA1 core gene signature (CGS). Gene Set Enrichment Analysis (GSEA) and Gene Ontology (GO) were used for functional annotation. Cell growth and migration/invasion were measured by a bright-field automated cell counter and Transwell insert system. Altered gene expression was measured by RT-qPCR. High-FOXA1 signaling inhibition included gene knockdown (siRNA) or pharmacologic blockage (the EPAS1 inhibitor PT2385). The predictive role of EPAS1 and the associated gene signature were analyzed using publicly available BC datasets.

Results: FOXA1 OE reprogrammed the FOXA1 cistrome in P cells to resemble that of the TamR cells. The FOXA1 cistrome was significantly correlated with the deposition of H3K27ac in TamR vs. P cells (P<2.2e-16). Similarly, the differentially expressed genes in TamR vs. P cells were enriched for FOXA1 binding at enhancers demarcated by H3K27ac (P=8e-125). The FOXA1-CGS was linked to multiple metastasis-related GO terms including “hypoxia response”, enriched for the cancer secretome gene set (P=4.1e-16), and highly represented in the Endo-R transcriptome across our multiple cell models (MCF7, 600MPE, and CAMA1) (P<0.01). Integrative analysis of H3K27ac-defined super-enhancers (SEs) and altered cistrome/transcriptome upon High-FOXA1 nominated EPAS1, a hypoxia-inducible transcription factor (TF), as a top candidate of SE-activated TFs amplifying High-FOXA1 signaling. EPAS1 blockade markedly repressed the secretome genes (e.g., IL8 and S100P) and cell migration and invasion in TamR cells. Primary ER+ tumors (TCGA) with high EPAS1 are enriched for a cancer secretome gene set (P=3e-4). High EPAS1 predicts poor distant metastasis-free survival in ER+ BC treated with endocrine therapy (P=0.34).
